**Parameters**

- **axis** [{0 or ‘index’}, default 0] Axis to direct sorting. The value ‘index’ is accepted for compatibility with DataFrame.sort_values.
- **ascending** [bool or list of bools, default True] If True, sort values in ascending order, otherwise descending.
- **inplace** [bool, default False] If True, perform operation in-place.
- **kind** [{‘quicksort’, ‘mergesort’, ‘heapsort’, ‘stable’}, default ‘quicksort’] Choice of sorting algorithm. See also numpy.sort() for more information. ‘mergesort’ and ‘stable’ are the only stable algorithms.
**na_position** [‘first’ or ‘last’], default ‘last’: Argument ‘first’ puts NaNs at the beginning, ‘last’ puts NaNs at the end.

**ignore_index** [bool, default False]: If True, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

**key** [callable, optional]: If not None, apply the key function to the series values before sorting. This is similar to the `key` argument in the builtin `sorted()` function, with the notable difference that this `key` function should be vectorized. It should expect a `Series` and return an array-like.

New in version 1.1.0.

**Returns**

Series or None: Series ordered by values or None if `inplace=True`.

**See also:**

* `Series.sort_index`: Sort by the Series indices.
* `DataFrame.sort_values`: Sort DataFrame by the values along either axis.
* `DataFrame.sort_index`: Sort DataFrame by indices.

**Examples**

```python
>>> s = pd.Series([np.nan, 1, 3, 10, 5])
>>> s
0   NaN
1   1.0
2   3.0
3  10.0
4   5.0
dtype: float64

Sort values ascending order (default behaviour)

```python
>>> s.sort_values(ascending=True)
1   1.0
2   3.0
4   5.0
3  10.0
0   NaN
dtype: float64
```

Sort values descending order

```python
>>> s.sort_values(ascending=False)
3  10.0
4   5.0
2   3.0
1   1.0
0   NaN
dtype: float64
```

Sort values inplace
>>> s.sort_values(ascending=False, inplace=True)
3  10.0
4  5.0
2  3.0
1  1.0
0  NaN
dtype: float64

Sort values putting NAs first

>>> s.sort_values(na_position='first')
0  NaN
1  1.0
2  3.0
4  5.0
3  10.0
dtype: float64

Sort a series of strings

>>> s = pd.Series(['z', 'b', 'd', 'a', 'c'])
>>> s
0 z
1 b
2 d
3 a
4 c
dtype: object

>>> s.sort_values()
3  a
1  b
4  c
2  d
0  z
dtype: object

Sort using a key function. Your key function will be given the Series of values and should return an array-like.

>>> s = pd.Series(['a', 'B', 'c', 'D', 'e'])
>>> s.sort_values()
1  B
3  D
0  a
2  c
4  e
dtype: object

>>> s.sort_values(key=lambda x: x.str.lower())
0  a
1  B
2  c
3  D
4  e
dtype: object

NumPy ufuncs work well here. For example, we can sort by the \( \sin \) of the value
```python
>>> s = pd.Series([-4, -2, 0, 2, 4])
>>> s.sort_values(key=np.sin)
1   -2
4    4
2    0
0   -4
3    2
dtype: int64
```

More complicated user-defined functions can be used, as long as they expect a Series and return an array-like

```python
>>> s.sort_values(key=lambda x: (np.tan(x.cumsum())))
0   -4
3    2
4    4
1   -2
2    0
dtype: int64
```

### pandas.Series.sparse

`Series.sparse()`

Accessor for SparseSparse from other sparse matrix data types.

### pandas.Series.squeeze

`Series.squeeze(axis=None)`

Squeeze 1 dimensional axis objects into scalars.

Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.

This method is most useful when you don’t know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call `squeeze` to ensure you have a Series.

**Parameters**

- `axis` `[[0 or ‘index’, 1 or ‘columns’, None], default None]` A specific axis to squeeze.

  By default, all length-1 axes are squeezed.

**Returns**

- `DataFrame, Series, or scalar` The projection after squeezing `axis` or all the axes.

See also:

- `Series.iloc` Integer-location based indexing for selecting scalars.
- `DataFrame.iloc` Integer-location based indexing for selecting Series.
- `Series.to_frame` Inverse of DataFrame.squeeze for a single-column DataFrame.
Examples

```python
>>> primes = pd.Series([2, 3, 5, 7])
```

Slicing might produce a Series with a single value:

```python
>>> even_primes = primes[primes % 2 == 0]
>>> even_primes
0  2
dtype: int64

>>> even_primes.squeeze()
2
```

Squeezing objects with more than one value in every axis does nothing:

```python
>>> odd_primes = primes[primes % 2 == 1]
>>> odd_primes
1  3
   2  5
   3  7
dtype: int64

>>> odd_primes.squeeze()
1  3
   2  5
   3  7
dtype: int64
```

Squeezing is even more effective when used with DataFrames.

```python
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```python
>>> df_a = df[['a']]
```

So the columns can be squeezed down, resulting in a Series:

```python
>>> df_a.squeeze('columns')
0  1
   1  3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```python
>>> df_0a = df.loc[df.index < 1, ['a']]
>>> df_0a
(continues on next page)```
Squeezing the rows produces a single scalar Series:

```python
>>> df_0a.squeeze('rows')
a    1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```python
>>> df_0a.squeeze()
1
```

### pandas.Series.std

`Series.std(axes=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)`

Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

**Parameters**

- `axis` ([index (0)])
- `skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- `level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- `ddof` [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- `numeric_only` [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

scalar or Series (if level specified)

**Notes**

To have the same behaviour as `numpy.std`, use `ddof=0` (instead of the default `ddof=1`)
**pandas.Series.str**

Series.`str()`
Vectorized string functions for Series and Index.
NAs stay NA unless handled otherwise by a particular method. Patterned after Python’s string methods, with some inspiration from R’s stringr package.

**Examples**

```python
>>> s = pd.Series(['A_Str_Series'])
>>> s
0  A_Str_Series
dtype: object

>>> s.str.split('_')
0  [A, Str, Series]
dtype: object

>>> s.str.replace('_', '')
0  AStrSeries

dtype: object
```

**pandas.Series.sub**

Series.`sub`(other, level=None, fill_value=None, axis=0)
Return Subtraction of series and other, element-wise (binary operator `sub`).
Equivalent to `series - other`, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

Series The result of the operation.

**See also:**

- `Series.rsub` Reverse of the Subtraction operator, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.subtract(b, fill_value=0)
a 0.0
b 1.0
c 1.0
d -1.0
e NaN
dtype: float64
```

**pandas.Series.subtract**

Series.subtract (other, level=None, fill_value=None, axis=0)
Return Subtraction of series and other, element-wise (binary operator sub).

Equivalent to series - other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

- **Series** The result of the operation.

See also:

- **Series.rsub** Reverse of the Subtraction operator, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64

>>> a.subtract(b, fill_value=0)
a 0.0
b 1.0
c 1.0
d -1.0
e NaN
dtype: float64
```

**pandas.Series.sum**

Series.sum(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)
Return the sum of the values over the requested axis.

This is equivalent to the method numpy.sum.

**Parameters**

- **axis** ([index (0)]) Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **min_count** [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.
- **kwargs** Additional keyword arguments to be passed to the function.

**Returns**

- scalar or Series (if level specified)

**See also:**

- **Series.sum** Return the sum.
- **Series.min** Return the minimum.
Series.max  Return the maximum.
Series.idxmin  Return the index of the minimum.
Series.idxmax  Return the index of the maximum.
DataFrame.sum  Return the sum over the requested axis.
DataFrame.min  Return the minimum over the requested axis.
DataFrame.max  Return the maximum over the requested axis.
DataFrame.idxmin  Return the index of the minimum over the requested axis.
DataFrame.idxmax  Return the index of the maximum over the requested axis.

Examples

```python
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider'],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
       warm  dog  4
           falcon  2
       cold  fish  0
           spider  8
Name: legs, dtype: int64

>>> s.sum()
14

By default, the sum of an empty or all-NA Series is 0.

```python
>>> pd.Series([], dtype="float64").sum()  # min_count=0 is the default
0.0
```

This can be controlled with the min_count parameter. For example, if you’d like the sum of an empty series to be NaN, pass min_count=1.

```python
>>> pd.Series([], dtype="float64").sum(min_count=1)
nan
```

Thanks to the skipna parameter, min_count handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).sum()
0.0

>>> pd.Series([np.nan]).sum(min_count=1)
nan
```
**pandas.Series.swapaxes**

Series.swapaxes (axis1, axis2, copy=True)

Interchange axes and swap values axes appropriately.

Returns

y [same as input]

**pandas.Series.swaplevel**

Series.swaplevel (i=-2, j=-1, copy=True)

Swap levels i and j in a MultiIndex.

Default is to swap the two innermost levels of the index.

Parameters

i, j [int or str] Levels of the indices to be swapped. Can pass level name as string.

copy [bool, default True] Whether to copy underlying data.

Returns

Series Series with levels swapped in MultiIndex.

Examples

```python
>>> s = pd.Series(
...     ["A", "B", "A", "C"],
...     index=[
...         ["Final exam", "Final exam", "Coursework", "Coursework"],
...         ["History", "Geography", "History", "Geography"],
...         ["January", "February", "March", "April"],
...     ],
... )
>>> s
Final exam History January A
Geography February B
Coursework History March A
Geography April C
dtype: object
```

In the following example, we will swap the levels of the indices. Here, we will swap the levels column-wise, but levels can be swapped row-wise in a similar manner. Note that column-wise is the default behaviour. By not supplying any arguments for i and j, we swap the last and second to last indices.

```python
>>> s.swaplevel()
Final exam January History A
February Geography B
Coursework March History A
April Geography C
dtype: object
```

By supplying one argument, we can choose which index to swap the last index with. We can for example swap the first index with the last one as follows.
We can also define explicitly which indices we want to swap by supplying values for both i and j. Here, we for example swap the first and second indices.

```python
>>> s.swaplevel(0, 1)
History  Final exam  January  A
Geography Final exam  February B
History  Coursework March  A
Geography Coursework  April  C
dtype: object
```

### pandas.Series.tail

**Series**.tail(n=5)

Return the last n rows.

This function returns last n rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

For negative values of n, this function returns all rows except the first n rows, equivalent to `df[n:]`.

**Parameters**

- n [int, default 5] Number of rows to select.

**Returns**

- type of caller The last n rows of the caller object.

**See also:**

- `DataFrame.head` The first n rows of the caller object.

**Examples**

```python
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
... 'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
    animal
0  alligator
1       bee
2   falcon
3      lion
4   monkey
5   parrot
6     shark
7    whale
8     zebra
```

Viewing the last 5 lines
Viewing the last $n$ lines (three in this case)

```python
>>> df.tail()
   animal
 0   monkey
 1   parrot
 2   shark
 3   whale
 4   zebra
```

For negative values of $n$

```python
>>> df.tail(3)
   animal
 0   monkey
 1   parrot
 2   shark
 3   whale
 4   zebra
```

```
>> df.tail(-3)
   animal
 0   lion
 1   monkey
 2   parrot
 3   shark
 4   whale
 5   zebra
```

**pandas.Series.take**

Series.take(indices, axis=0, is_copy=None, **kwargs)

Return the elements in the given positional indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

**Parameters**

- **indices** [array-like] An array of ints indicating which positions to take.
- **axis** [[0 or ‘index’, 1 or ‘columns’, None], default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.
- **is_copy** [bool] Before pandas 1.0, is_copy=False can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, take always returns a copy, and the keyword is therefore deprecated.

Deprecation since version 1.0.0.

- **kwargs** For compatibility with numpy.take(). Has no effect on the output.

**Returns**

- **taken** [same type as caller] An array-like containing the elements taken from the object.

**See also:**

- **DataFrame.loc** Select a subset of a DataFrame by labels.
- **DataFrame.iloc** Select a subset of a DataFrame by positions.
**numpy.take**  Take elements from an array along an axis.

### Examples

```python
def = pd.DataFrame([('falcon', 'bird', 389.0),
    ('parrot', 'bird', 24.0),
    ('lion', 'mammal', 80.5),
    ('monkey', 'mammal', np.nan)],
    columns=['name', 'class', 'max_speed'],
    index=[0, 2, 3, 1])
def

# Take elements at positions 0 and 3 along the axis 0 (default).
# Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's
# because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.
>>> df.take([0, 3])

# Take elements at indices 1 and 2 along the axis 1 (column selection).
>>> df.take([1, 2], axis=1)

# We may take elements using negative integers for positive indices, starting from the end of the object, just
# like with Python lists.
>>> df.take([-1, -2])
```

**pandas.Series.to_clipboard**

```
Series.to_clipboard(excel=True, sep=None, **kwargs)
Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

**Parameters**

- **excel** [bool, default True] Produce output in a csv format for easy pasting into excel.
  - True, use the provided separator for csv pasting.
False, write a string representation of the object to the clipboard.

**kwargs These parameters will be passed to DataFrame.to_csv.

See also:

- **DataFrame.to_csv** Write a DataFrame to a comma-separated values (csv) file.
- **read_clipboard** Read text from clipboard and pass to read_table.

**Notes**

Requirements for your platform.

- **Linux**: xclip, or xsel (with PyQt4 modules)
- **Windows**: none
- **OS X**: none

**Examples**

Copy the contents of a DataFrame to the clipboard.

```python
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
```

```python
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the index by passing the keyword `index` and setting it to false.

```python
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 0,1,2,3
... # 1,4,5,6
```
Changed in version 1.2.0: Support for binary file objects was introduced.

**sep** [str, default ‘,’] String of length 1. Field delimiter for the output file.

**na_rep** [str, default ‘’] Missing data representation.

**float_format** [str, default None] Format string for floating point numbers.

**columns** [sequence, optional] Columns to write.

**header** [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

**index** [bool, default True] Write row names (index).

**index_label** [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and header and index are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use index_label=False for easier importing in R.

**mode** [str] Python write mode, default ‘w’.

**encoding** [str, optional] A string representing the encoding to use in the output file, defaults to ‘utf-8’. encoding is not supported if path_or_buf is a non-binary file object.

**compression** [str or dict, default ‘infer’] If str, represents compression mode. If dict, value at ‘method’ is the compression mode. Compression mode may be any of the following possible values: {‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}. If compression mode is ‘infer’ and path_or_buf is path-like, then detect compression mode from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’ or ‘.xz’. (otherwise no compression). If dict given and mode is one of {‘zip’, ‘gzip’, ‘bz2’}, or inferred as one of the above, other entries passed as additional compression options.

   Changed in version 1.0.0: May now be a dict with key ‘method’ as compression mode and other entries as additional compression options if compression mode is ‘zip’.

   Changed in version 1.1.0: Passing compression options as keys in dict is supported for compression modes ‘gzip’ and ‘bz2’ as well as ‘zip’.

   Changed in version 1.2.0: Compression is supported for binary file objects.

   Changed in version 1.2.0: Previous versions forwarded dict entries for ‘gzip’ to gzip.open instead of gzip.GzipFile which prevented setting mtime.

**quoting** [optional constant from csv module] Defaults to csv.QUOTE_MINIMAL. If you have set a float_format then floats are converted to strings and thus csv.QUOTE_NONNUMERIC will treat them as non-numeric.

**quotechar** [str, default ‘”’] String of length 1. Character used to quote fields.

**line_terminator** [str, optional] The newline character or character sequence to use in the output file. Defaults to os.linesep, which depends on the OS in which this method is called (‘\n’ for linux, ‘\r\n’ for Windows, i.e.).

**chunksize** [int or None] Rows to write at a time.

**date_format** [str, default None] Format string for datetime objects.

**doublequote** [bool, default True] Control quoting of quotechar inside a field.

**escapechar** [str, default None] String of length 1. Character used to escape sep and quotechar when appropriate.
decimal [str, default ‘.’] Character recognized as decimal separator. E.g. use ‘,’ for European data.

ersrors [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for open() for a full list of options.

New in version 1.1.0.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

Returns

None or str If path_or_buf is None, returns the resulting csv format as a string. Otherwise returns None.

See also:

read_csv Load a CSV file into a DataFrame.
to_excel Write DataFrame to an Excel file.

Examples

```python
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                    'mask': ['red', 'purple'],
...                    'weapon': ['sai', 'bo staff']})

>>> df.to_csv(index=False)
'name,mask,weapon
Raphael,red,sai
Donatello,purple,bo staff'

Create ‘out.zip’ containing ‘out.csv’

```python
>>> compression_opts = dict(method='zip',
...                           archive_name='out.csv')

>>> df.to_csv('out.zip', index=False, compression=compression_opts)
```

pandas.Series.to_dict

Series.to_dict (into=<class 'dict'>)

Convert Series to {label -> value} dict or dict-like object.

Parameters

into [class, default dict] The collections.abc.Mapping subclass to use as the return object. Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

Returns

collections.abc.Mapping Key-value representation of Series.
Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_dict()
{0: 1, 1: 2, 2: 3, 3: 4}
>>> from collections import OrderedDict, defaultdict
>>> s.to_dict(OrderedDict)
OrderedDict([(0, 1), (1, 2), (2, 3), (3, 4)])
>>> dd = defaultdict(list)
>>> s.to_dict(dd)
defaultdict(<class 'list'>, {0: 1, 1: 2, 2: 3, 3: 4})
```

pandas.Series.to_excel

Series.to_excel(excel_writer, sheet_name='Sheet1', na_rep='', float_format=None, columns=None, header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf', verbose=True, freeze_panes=None, storage_options=None)

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an ExcelWriter object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique sheet_name. With all data written to the file it is necessary to save the changes. Note that creating an ExcelWriter object with a file name that already exists will result in the contents of the existing file being erased.

Parameters

- excel_writer [path-like, file-like, or ExcelWriter object] File path or existing ExcelWriter.
- sheet_name [str, default 'Sheet1'] Name of sheet which will contain DataFrame.
- na_rep [str, default ''] Missing data representation.
- float_format [str, optional] Format string for floating point numbers. For example float_format="%.2f" will format 0.1234 to 0.12.
- columns [sequence or list of str, optional] Columns to write.
- header [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.
- index [bool, default True] Write row names (index).
- index_label [str or sequence, optional] Column label for index column(s) if desired. If not specified, and header and index are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- startrow [int, default 0] Upper left cell row to dump data frame.
- startcol [int, default 0] Upper left cell column to dump data frame.
- engine [str, optional] Write engine to use, 'openpyxl' or 'xlsxwriter'. You can also set this via the options io.excel.xlsx.writer, io.excel.xls.writer, and io.excel.xlsxwriter.

Deprecated since version 1.2.0: As the xlwt package is no longer maintained, the xlwt engine will be removed in a future version of pandas.
**merge_cells** [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.

**encoding** [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.

**inf_rep** [str, default ‘inf’] Representation for infinity (there is no native representation for infinity in Excel).

**verbose** [bool, default True] Display more information in the error logs.

**freeze_panes** [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

See also:

**to_csv** Write DataFrame to a comma-separated values (csv) file.

**ExcelWriter** Class for writing DataFrame objects into excel sheets.

**read_excel** Read an Excel file into a pandas DataFrame.

**read_csv** Read a comma-separated values (csv) file into DataFrame.

**Notes**

For compatibility with to_csv(), to_excel serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible to write further data without rewriting the whole workbook.

**Examples**

Create, write to and save a workbook:

```python
gf1 = pd.DataFrame([[‘a’, ‘b’], [‘c’, ‘d’]],
                  index=[‘row 1’, ‘row 2’],
                  columns=[‘col 1’, ‘col 2’])
gf1.to_excel(“output.xlsx”)
```

To specify the sheet name:

```python
gf1.to_excel(“output.xlsx”,
       sheet_name=’Sheet_name_1’)
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:
>> df2 = df1.copy()

>> with pd.ExcelWriter('output.xlsx') as writer:
...    df1.to_excel(writer, sheet_name='Sheet_name_1')
...    df2.to_excel(writer, sheet_name='Sheet_name_2')

ExcelWriter can also be used to append to an existing Excel file:

>> with pd.ExcelWriter('output.xlsx', mode='a') as writer:
...    df.to_excel(writer, sheet_name='Sheet_name_3')

To set the library that is used to write the Excel file, you can pass the `engine` keyword (the default engine is automatically chosen depending on the file extension):

>> df1.to_excel('output1.xlsx', engine='xlsxwriter')

### pandas.Series.to_frame

Series.to_frame (name=None)

Convert Series to DataFrame.

**Parameters**

- **name** [object, default None] The passed name should substitute for the series name (if it has one).

**Returns**

- **DataFrame** DataFrame representation of Series.

**Examples**

```python
>>> s = pd.Series(['a', 'b', 'c'],
...               name='vals')
>>> s.to_frame()
   vals
0  a
1  b
2  c
```

### pandas.Series.to_hdf

Series.to_hdf (path_or_buf, key, mode='a', complevel=None, complib=None, append=False, format=None, index=True, min_itemsize=None, nan_rep=None, dropna=None, data_columns=None, errors='strict', encoding='UTF-8')

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different key.
Warning: One can store a subclass of DataFrame or Series to HDF5, but the type of the subclass is lost upon storing.

For more information see the user guide.

Parameters

path_or_buf [str or pandas.HDFStore] File path or HDFStore object.

key [str] Identifier for the group in the store.

mode [{‘a’, ‘w’, ‘r+’}, default ‘a’] Mode to open file:

- ‘w’: write, a new file is created (an existing file with the same name would be deleted).
- ‘a’: append, an existing file is opened for reading and writing, and if the file does not exist it is created.
- ‘r+’: similar to ‘a’, but the file must already exist.

complevel [{0-9}, optional] Specifies a compression level for data. A value of 0 disables compression.

append [bool, default False] For Table formats, append the input data to the existing.

format [{‘fixed’, ‘table’, None}, default ‘fixed’] Possible values:

- ‘table’: Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
- If None, pd.get_option(‘io.hdf.default_format’) is checked, followed by fallback to “fixed”

errors [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for open() for a full list of options.

encoding [str, default “UTF-8”]

min_itemsize [dict or int, optional] Map column names to minimum string sizes for columns.

data_columns [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See Query via data columns. Applicable only to format=’table’.

See also:

read_hdf Read from HDF file.
**DataFrame.to_parquet** Write a DataFrame to the binary parquet format.

**DataFrame.to_sql** Write to a SQL table.

**DataFrame.to_feather** Write out feather-format for DataFrames.

**DataFrame.to_csv** Write out to a csv file.

### Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
                    index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')

We can add another object to the same file:

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```python
>>> pd.read_hdf('data.h5', 'df')
A   B
a  1   4
b  2   5
c  3   6

>>> pd.read_hdf('data.h5', 's')
0   1
1   2
2   3
3   4
dtype: int64
```

Deleting file with data:

```python
>>> import os
>>> os.remove('data.h5')
```

**pandas.Series.to_json**

Series.to_json(path_or_buf=None, orient=None, date_format=None, doubleprecision=10,
force_ascii=True, date_unit='ms', default_handler=None, lines=False, compression='infer',
index=True, indent=None, storage_options=None)

Convert the object to a JSON string.

Note NaN’s and None will be converted to null and datetime objects will be converted to UNIX timestamps.

**Parameters**

- **path_or_buf** [str or file handle, optional] File path or object. If not specified, the result is returned as a string.
- **orient** [str] Indication of expected JSON string format.
  - Series:
    - default is ‘index’
allowed values are: {‘split’, ‘records’, ‘index’, ‘table’}.

• DataFrame:
  – default is ‘columns’
  – allowed values are: {‘split’, ‘records’, ‘index’, ‘columns’, ‘values’, ‘table’}.

• The format of the JSON string:
  – ‘split’ : dict like {‘index’ -> [index], ‘columns’ -> [columns], ‘data’ -> [values]}
  – ‘records’ : list like [{column -> value}, . . . , {column -> value}]
  – ‘index’ : dict like {index -> {column -> value}}
  – ‘columns’ : dict like {column -> {index -> value}}
  – ‘values’ : just the values array
  – ‘table’ : dict like {‘schema’: {schema}, ‘data’: {data}}

Describing the data, where data component is like orient='records'.

date_format [{None, ‘epoch’, ‘iso’}] Type of date conversion. ‘epoch’ = epoch milliseconds, ‘iso’ = ISO8601. The default depends on the orient. For orient='table', the default is ‘iso’. For all other orients, the default is ‘epoch’.

double_precision [int, default 10] The number of decimal places to use when encoding floating point values.

force_ascii [bool, default True] Force encoded string to be ASCII.

date_unit [str, default ‘ms’ (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’, ‘ns’ for second, millisecond, microsecond, and nanosecond respectively.

default_handler [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

lines [bool, default False] If ‘orient’ is ‘records’ write out line-delimited json format. Will throw ValueError if incorrect ‘orient’ since others are not list-like.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

index [bool, default True] Whether to include the index values in the JSON string. Not including the index (index=False) is only supported when orient is ‘split’ or ‘table’.

indent [int, optional] Length of whitespace used to indent each record. New in version 1.0.0.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.
New in version 1.2.0.

Returns

None or str If path_or_buf is None, returns the resulting json format as a string. Otherwise returns None.

See also:

read_json Convert a JSON string to pandas object.

Notes

The behavior of indent=0 varies from the stdlib, which does not indent the output but does insert newlines. Currently, indent=0 and the default indent=None are equivalent in pandas, though this may change in a future release.

orient='table' contains a 'pandas_version' field under 'schema'. This stores the version of pandas used in the latest revision of the schema.

Examples

```python
>>> import json
>>> df = pd.DataFrame(
...     [["a", "b"], ["c", "d"],
...      index=["row 1", "row 2"],
...      columns=["col 1", "col 2"],
...     )

>>> result = df.to_json(orient="split")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "columns": [
        "col 1",
        "col 2"
    ],
    "index": [
        "row 1",
        "row 2"
    ],
    "data": [
        [
            "a",
            "b"
        ],
        [
            "c",
            "d"
        ]
    ]
}
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.
Encoding/decoding a Dataframe using 'index' formatted JSON:

```python
>>> result = df.to_json(orient="index")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "row 1": {
        "col 1": "a",
        "col 2": "b"
    },
    "row 2": {
        "col 1": "c",
        "col 2": "d"
    }
}
```

Encoding/decoding a Dataframe using 'columns' formatted JSON:

```python
>>> result = df.to_json(orient="columns")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "col 1": {
        "row 1": "a",
        "row 2": "c"
    },
    "col 2": {
        "row 1": "b",
        "row 2": "d"
    }
}
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```python
>>> result = df.to_json(orient="values")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[
    ["a", "b"],
    ["c", "d"],
]
```
Encoding with Table Schema:

```python
>>> result = df.to_json(orient="table")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "schema": {
        "fields": [
            {
                "name": "index",
                "type": "string"
            },
            {
                "name": "col 1",
                "type": "string"
            },
            {
                "name": "col 2",
                "type": "string"
            }
        ],
        "primaryKey": [
            "index"
        ],
        "pandas_version": "0.20.0"
    },
    "data": [
        {
            "index": "row 1",
            "col 1": "a",
            "col 2": "b"
        },
        {
            "index": "row 2",
            "col 1": "c",
            "col 2": "d"
        }
    ]
}
```

**pandas.Series.to_latex**

`Series.to_latex(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, bold_rows=False, column_format=None, longtable=None, escape=None, encoding=None, decimal='.', multicolumn=None, multicolumn_format=None, multirow=None, caption=None, label=None, position=None)`

Render object to a LaTeX tabular, longtable, or nested table/tabular.

Requires `\usepackage{booktabs}`. The output can be copy/pasted into a main LaTeX document or
read from an external file with \input{table.tex}.

Changed in version 1.0.0: Added caption and label arguments.

Changed in version 1.2.0: Added position argument, changed meaning of caption argument.

Parameters

- **buf** [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

- **columns** [list of label, optional] The subset of columns to write. Writes all columns by default.

- **col_space** [int, optional] The minimum width of each column.

- **header** [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

- **index** [bool, default True] Write row names (index).

- **na_rep** [str, default ‘NaN’] Missing data representation.

- **formatters** [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.

- **float_format** [one-parameter function or str, optional, default None] Formatter for floating point numbers. For example float_format="%.2f" and float_format="{:0.2f}".format will both result in 0.1234 being formatted as 0.12.

- **sparsify** [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.

- **index_names** [bool, default True] Prints the names of the indexes.

- **bold_rows** [bool, default False] Make the row labels bold in the output.

- **column_format** [str, optional] The columns format as specified in LaTeX table format e.g. ‘rc’l for 3 columns. By default, ‘l’ will be used for all columns except columns of numbers, which default to ‘r’.

- **longtable** [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a usepackage{longtable} to your LaTeX preamble.

- **escape** [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.

- **encoding** [str, optional] A string representing the encoding to use in the output file, defaults to ‘utf-8’.

- **decimal** [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

- **multicolumn** [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.

- **multicolumn_format** [str, default ‘l’] The alignment for multicolumns, similar to column_format The default will be read from the config module.

- **multirow** [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a usepackage{multirow} to your LaTeX preamble. Will print centered
labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

**caption** [str or tuple, optional] Tuple (full_caption, short_caption), which results in `\caption[short_caption]{full_caption}`; if a single string is passed, no short caption will be set.

New in version 1.0.0.

Changed in version 1.2.0: Optionally allow caption to be a tuple (full_caption, short_caption).

**label** [str, optional] The LaTeX label to be placed inside `\label{}` in the output. This is used with `\ref{}` in the main .tex file.

New in version 1.0.0.

**position** [str, optional] The LaTeX positional argument for tables, to be placed after `\begin{}` in the output.

New in version 1.2.0.

**Returns**

- **str or None** If buf is None, returns the result as a string. Otherwise returns None.

**See also:**

`DataFrame.to_string` Render a DataFrame to a console-friendly tabular output.

`DataFrame.to_html` Render a DataFrame as an HTML table.

**Examples**

```python
>>> df = pd.DataFrame(dict(name=['Raphael', 'Donatello'],
...                      mask=['red', 'purple'],
...                      weapon=['sai', 'bo staff']))
>>> print(df.to_latex(index=False))
\begin{tabular}{lll}
<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>mask</td>
<td>weapon</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Raphael</td>
<td>red</td>
<td>sai</td>
</tr>
<tr>
<td>Donatello</td>
<td>purple</td>
<td>bo staff</td>
</tr>
</tbody>
</table>
\end{tabular}
```

**pandas.Series.to_list**

`Series.to_list()`

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

**Returns**

- list

**See also:**
numpy.ndarray.tolist  Return the array as an a.ndim-levels deep nested list of Python scalars.

pandas.Series.to_markdown

Series.to_markdown (buf=None, mode='wt', index=True, storage_options=None, **kwargs)
Print Series in Markdown-friendly format.
New in version 1.0.0.

Parameters

buf  [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the
output is returned as a string.

mode  [str, optional] Mode in which file is opened, “wt” by default.

index  [bool, optional, default True] Add index (row) labels.
New in version 1.1.0.

storage_options  [dict, optional] Extra options that make sense for a particular storage
connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-
value pairs are forwarded to urllib as header options. For other URLs (e.g.
starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec.
Please see fsspec and urllib for more details.
New in version 1.2.0.

**kwargs  These parameters will be passed to tabulate.

Returns

str  Series in Markdown-friendly format.

Notes

Requires the tabulate package.

Examples

```python
>>> s = pd.Series(['elk', 'pig', 'dog', 'quetzal'], name='animal')
>>> print(s.to_markdown())
<table>
<thead>
<tr>
<th align="right"></th>
<th align="left">animal</th>
</tr>
</thead>
<tbody>
<tr>
<td align="right">0</td>
<td align="left">elk</td>
</tr>
<tr>
<td align="right">1</td>
<td align="left">pig</td>
</tr>
<tr>
<td align="right">2</td>
<td align="left">dog</td>
</tr>
<tr>
<td align="right">3</td>
<td align="left">quetzal</td>
</tr>
</tbody>
</table>
```

Output markdown with a tabulate option.

```python
>>> print(s.to_markdown(tablefmt="grid"))
+----+----------+
|    | animal    |
+----+----------+
| 0  | elk      |
+----+----------+
```

(continues on next page)
pandas.Series.to_numpy

Series.to_numpy (dtype=None, copy=False, na_value=<no_default>, **kwargs)

A NumPy ndarray representing the values in this Series or Index.

Parameters

dtype [str or numpy.dtype, optional] The dtype to pass to numpy.asarray().
copy [bool, default False] Whether to ensure that the returned value is not a view on
another array. Note that copy=False does not ensure that to_numpy() is
no-copy. Rather, copy=True ensure that a copy is made, even if not strictly
necessary.

na_value [Any, optional] The value to use for missing values. The default value de-
dpends on dtype and the type of the array.

New in version 1.0.0.

**kwargs Additional keywords passed through to the to_numpy method of the un-
derlying array (for extension arrays).

New in version 1.0.0.

Returns

numpy.ndarray

See also:

Series.array Get the actual data stored within.
Index.array Get the actual data stored within.

DataFrame.to_numpy Similar method for DataFrame.

Notes

The returned array will be the same up to equality (values equal in self will be equal in the returned array;
likewise for values that are not equal). When self contains an ExtensionArray, the dtype may be different.
For example, for a category-dtype Series, to_numpy() will return a NumPy array and the categorical
dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming
copy=False). Modifying the result in place will modify the data stored in the Series or Index (not that we
recommend doing that).

For extension types, to_numpy() may require copying data and coercing the result to a NumPy type
(possibly object), which may be expensive. When you need a no-copy reference to the underlying data,
Series.array should be used instead.
This table lays out the different dtypes and default return types of `to_numpy()` for various dtypes within pandas.

<table>
<thead>
<tr>
<th>dtype</th>
<th>array type</th>
</tr>
</thead>
<tbody>
<tr>
<td>category[T]</td>
<td>ndarray[T] (same dtype as input)</td>
</tr>
<tr>
<td>period</td>
<td>ndarray[object] (Periods)</td>
</tr>
<tr>
<td>interval</td>
<td>ndarray[object] (Intervals)</td>
</tr>
<tr>
<td>IntegerNA</td>
<td>ndarray[object]</td>
</tr>
<tr>
<td>datetime64[ns]</td>
<td>datetime64[ns]</td>
</tr>
<tr>
<td>datetime64[ns, tz]</td>
<td>ndarray[object] (Timestamps)</td>
</tr>
</tbody>
</table>

**Examples**

```python
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.to_numpy()
array(['a', 'b', 'a'], dtype=object)
```

Specify the dtype to control how datetime-aware data is represented. Use `dtype=object` to return an ndarray of pandas `Timestamp` objects, each with the correct tz.

```python
>>> ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> ser.to_numpy(dtype=object)
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET'),
      Timestamp('2000-01-02 00:00:00+0100', tz='CET')],
      dtype=object)
```

Or `dtype='datetime64[ns]'` to return an ndarray of native datetime64 values. The values are converted to UTC and the timezone info is dropped.

```python
>>> ser.to_numpy(dtype="datetime64[ns]"
... array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00...'],
      dtype='datetime64[ns]')
```

**pandas.Series.to_period**

`Series.to_period(freq=None, copy=True)`

Convert Series from DatetimeIndex to PeriodIndex.

**Parameters**

- `freq` [str, default None] Frequency associated with the PeriodIndex.
- `copy` [bool, default True] Whether or not to return a copy.

**Returns**

- `Series` Series with index converted to PeriodIndex.
pandas.Series.to_pickle

Series.to_pickle(path, compression='infer', protocol=5, storage_options=None)

Pickle (serialize) object to file.

Parameters

path [str] File path where the pickled object will be stored.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] A string representing the compression to use in the output file. By default, infers from the file extension in specified path. Compression mode may be any of the following possible values: {‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}. If compression mode is ‘infer’ and path_or_buf is path-like, then detect compression mode from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’ or ‘.xz’. (otherwise no compression). If dict given and mode is ‘zip’ or inferred as ‘zip’, other entries passed as additional compression options.

protocol [int] Int which indicates which protocol should be used by the pickler, default HIGHEST_PROTOCOL (see [1] paragraph 12.1.2). The possible values are 0, 1, 2, 3, 4, 5. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST_PROTOCOL.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

See also:

read_pickle Load pickled pandas object (or any object) from file.

DataFrame.to_hdf Write DataFrame to an HDF5 file.

DataFrame.to_sql Write DataFrame to a SQL database.

DataFrame.to_parquet Write a DataFrame to the binary parquet format.

Examples

```python
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> original_df.to_pickle("./dummy.pkl")

>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0    0    5
1    1    6
```
>>> import os
>>> os.remove("./dummy.pkl")

pandas.Series.to_sql

Series.to_sql(name, con, schema=None, if_exists='fail', index=True, index_label=None, chunksize=None, dtype=None, method=None)

Write records stored in a DataFrame to a SQL database.
Databases supported by SQLAlchemy [1] are supported. Tables can be newly created, appended to, or overwritten.

Parameters

- **name** [str] Name of SQL table.
- **con** [sqlalchemy.engine.(Engine or Connection) or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable See [here](#).
- **schema** [str, optional] Specify the schema (if database flavor supports this). If None, use default schema.
- **if_exists** [{'fail', 'replace', 'append'}, default 'fail'] How to behave if the table already exists.
  - fail: Raise a ValueError.
  - replace: Drop the table before inserting new values.
  - append: Insert new values to the existing table.
- **index** [bool, default True] Write DataFrame index as a column. Uses index_label as the column name in the table.
- **index_label** [str or sequence, default None] Column label for index column(s). If None is given (default) and index is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- **chunksize** [int, optional] Specify the number of rows in each batch to be written at a time. By default, all rows will be written at once.
- **dtype** [dict or scalar, optional] Specifying the datatype for columns. If a dictionary is used, the keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode. If a scalar is provided, it will be applied to all columns.
- **method** [{None, 'multi', callable}, optional] Controls the SQL insertion clause used:
  - None : Uses standard SQL INSERT clause (one per row).
  - 'multi': Pass multiple values in a single INSERT clause.
  - callable with signature (pd_table, conn, keys, data_iter).
Details and a sample callable implementation can be found in the section `insert method`.

**Raises**

`ValueError` When the table already exists and `if_exists` is ‘fail’ (the default).

**See also:**

`read_sql` Read a DataFrame from a table.

**Notes**

Timezone aware datetime columns will be written as `Timestamp with timezone` type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

**References**

[1], [2]

**Examples**

Create an in-memory SQLite database.

```python
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```python
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
   name
0  User 1
1  User 2
2  User 3
```

```python
>>> df.to_sql('users', con=engine)
```

```python
>>> engine.execute("SELECT * FROM users").fetchall()
```

```python
[[0, 'User 1'], (1, 'User 2'), (2, 'User 3')]
```

An sqlalchemy.engine.Connection can also be passed to `con`:

```python
>>> with engine.begin() as connection:
...     df1 = pd.DataFrame({'name' : ['User 4', 'User 5']})
...     df1.to_sql('users', con=connection, if_exists='append')
```

This is allowed to support operations that require that the same DBAPI connection is used for the entire operation.

```python
>>> df2 = pd.DataFrame({'name' : ['User 6', 'User 7']})
>>> df2.to_sql('users', con=engine, if_exists='append')
>>> engine.execute("SELECT * FROM users").fetchall()
```

```python
[[0, 'User 1'], (1, 'User 2'), (2, 'User 3'),
```

(continues on next page)
Overwrite the table with just `df2`.

```python
>>> df2.to_sql('users', con=engine, if_exists='replace', ...    index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 6'), (1, 'User 7')]  
```

Specify the `dtype` (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```python
>>> df = pd.DataFrame({"A": [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0

>>> from sqlalchemy.types import Integer

>>> df.to_sql('integers', con=engine, index=False, ...    dtype="A": Integer())
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

### pandas.Series.to_string

`Series.to_string(buf=None, na_rep='NaN', float_format=None, header=True, index=True, length=False, dtype=False, name=False, max_rows=None, min_rows=None)`

Render a string representation of the Series.

**Parameters**

- **buf** [StringIO-like, optional] Buffer to write to.
- **na_rep** [str, optional] String representation of NaN to use, default ‘NaN’.
- **float_format** [one-parameter function, optional] Formatter function to apply to columns’ elements if they are floats, default None.
- **header** [bool, default True] Add the Series header (index name).
- **index** [bool, optional] Add index (row) labels, default True.
- **length** [bool, default False] Add the Series length.
- **dtype** [bool, default False] Add the Series dtype.
- **name** [bool, default False] Add the Series name if not None.
- **max_rows** [int, optional] Maximum number of rows to show before truncating. If None, show all.
- **min_rows** [int, optional] The number of rows to display in a truncated repr (when number of rows is above max_rows).
pandas: powerful Python data analysis toolkit, Release 1.3.2

Returns

str or None  String representation of Series if buf=None, otherwise None.

pandas.Series.to_timestamp

Series.to_timestamp (freq=None, how='start', copy=True)
    Cast to DatetimeIndex of Timestamps, at beginning of period.

Parameters

freq [str, default frequency of PeriodIndex] Desired frequency.

how [[‘s’, ‘e’, ‘start’, ‘end’]] Convention for converting period to timestamp; start of period vs. end.

Returns

Series with DatetimeIndex

pandas.Series.to_xarray

Series.to_xarray()
    Return an xarray object from the pandas object.

Returns

xarray.DataArray or xarray.Dataset  Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

See also:

DataFrame.to_hdf  Write DataFrame to an HDF5 file.
DataFrame.to_parquet  Write a DataFrame to the binary parquet format.

Notes

See the xarray docs

Examples

```python
>>> df = pd.DataFrame([{'falcon': 'bird', 389.0, 2},
                    {'parrot': 'bird', 24.0, 2},
                    {'lion': 'mammal', 80.5, 4},
                    {'monkey': 'mammal', np.nan, 4}],
                   columns=['name', 'class', 'max_speed',
                             'num_legs'])
>>> df
   name  class  max_speed  num_legs
0  falcon   bird      389.0        2
1  parrot   bird       24.0        2
2    lion  mammal      80.5        4
3  monkey  mammal        NaN        4
```
```python
>>> df.to_xarray()
<xarray.Dataset>
Dimensions:   (index: 4)
Coordinates:
  * index (index) int64 0 1 2 3
Data variables:
  name (index) object 'falcon' 'parrot' 'lion' 'monkey'
  class (index) object 'bird' 'bird' 'mammal' 'mammal'
  max_speed (index) float64 389.0 24.0 80.5 nan
  num_legs (index) int64 2 2 4 4

>>> df['max_speed'].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389. , 24. , 80.5, nan])
Coordinates:
  * index (index) int64 0 1 2 3

>>> dates = pd.to_datetime(['2018-01-01', '2018-01-01', ...
                           '2018-01-02', '2018-01-02'])
>>> df_multiindex = pd.DataFrame({'date': dates,
                                ...
                                'animal': ['falcon', 'parrot',
                                           'falcon', 'parrot'],
                                ...
                                'speed': [350, 18, 361, 15]})
>>> df_multiindex = df_multiindex.set_index(['date', 'animal'])

>>> df_multiindex
 date animal  speed
2018-01-01 falcon 350
   parrot 18
2018-01-02 falcon 361
   parrot 15

>>> df_multiindex.to_xarray()
<xarray.Dataset>
Dimensions:   (animal: 2, date: 2)
Coordinates:
  * date (date) datetime64[ns] 2018-01-01 2018-01-02
  * animal (animal) object 'falcon' 'parrot'
Data variables:
  speed (date, animal) int64 350 18 361 15

pandas.Series.tolist

Series.tolist()

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:
**numpy.ndarray.tolist**  Return the array as an a.ndim-levels deep nested list of Python scalars.

**pandas.Series.transform**

```python
Series.transform(func, axis=0, *args, **kwargs)
```

Call `func` on self producing a Series with transformed values.

Produced Series will have same axis length as self.

**Parameters**

- `func` [function, str, list-like or dict-like] Function to use for transforming the data. If a function, must either work when passed a Series or when passed to `Series.apply`. If `func` is both list-like and dict-like, dict-like behavior takes precedence.

  Accepted combinations are:
  - function
  - string function name
  - list-like of functions and/or function names, e.g. `[np.exp, 'sqrt']`
  - dict-like of axis labels -> functions, function names or list-like of such.

- `axis` [{0 or 'index'}] Parameter needed for compatibility with DataFrame.

- `*args` Positional arguments to pass to `func`.

- `**kwargs` Keyword arguments to pass to `func`.

**Returns**

- `Series` A Series that must have the same length as self.

**Raises**

- `ValueError` [If the returned Series has a different length than self.]

**See also:**

- `Series.agg` Only perform aggregating type operations.

- `Series.apply` Invoke function on a Series.

**Notes**

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

**Examples**

```python
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
   A  B
0  0  1
1  1  2
2  2  3
>>> df.transform(lambda x: x + 1)
   A  B
0  1  2
1  2  3
2  3  4
```
Even though the resulting Series must have the same length as the input Series, it is possible to provide several input functions:

```python
>>> s = pd.Series(range(3))
>>> s
0    0
1    1
2    2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
sqrt  exp
0 0.000000  1.000000
1 1.000000  2.718282
2 1.414214  7.389056
```

You can call `transform` on a GroupBy object:

```python
>>> df = pd.DataFrame({
...     "Date": ["2015-05-08", "2015-05-07", "2015-05-06", "2015-05-05", 
...     "Data": [5, 8, 6, 1, 50, 100, 60, 120],
...     "c": [1, 1, 1, 2, 2, 2, 2],
...     "type": ["m", "n", "o", "m", "m", "n", "n"]
... })
>>> df
date  data  c  type
0  2015-05-08  5  1  m
1  2015-05-07  8  1  n
2  2015-05-06  6  2  o
3  2015-05-05  1  1  m
4  2015-05-08  50  2  m
5  2015-05-07  100  2  m
6  2015-05-06  60  2  n
7  2015-05-05  120  2  n
```

(continues on next page)
```python
>>> df['size'] = df.groupby('c')['type'].transform(len)
>>> df
   c type size
0  1  m   3
1  1  n   3
2  1  o   3
3  2  m   4
4  2  m   4
5  2  n   4
6  2  n   4
```

**pandas.Series.transpose**

```python
Series.transpose(*args, **kwargs)
```

Return the transpose, which is by definition self.

**Returns**

%(klass)s

**pandas.Series.truediv**

```python
Series.truediv(other, level=None, fill_value=None, axis=0)
```

Return Floating division of series and other, element-wise (binary operator truediv).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

- **Series** The result of the operation.

**See also:**

- **Series.rtruediv** Reverse of the Floating division operator, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
d    0.0
e    NaN
dtype: float64
```

`pandas.Series.truncate`

`Series.truncate` *(before=None, after=None, axis=None, copy=True)*

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

**Parameters**

- `before` [date, str, int] Truncate all rows before this index value.
- `after` [date, str, int] Truncate all rows after this index value.
- `axis` [{0 or 'index', 1 or 'columns'}, optional] Axis to truncate. Truncates the index (rows) by default.
- `copy` [bool, default is True.] Return a copy of the truncated section.

**Returns**

- `type of caller` The truncated Series or DataFrame.

See also:

- `DataFrame.loc` Select a subset of a DataFrame by label.
- `DataFrame.iloc` Select a subset of a DataFrame by position.
Notes

If the index being truncated contains only datetime values, `before` and `after` may be specified as strings instead of Timestamps.

Examples

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
...                    'B': ['f', 'g', 'h', 'i', 'j'],
...                    'C': ['k', 'l', 'm', 'n', 'o']},
...                   index=[1, 2, 3, 4, 5])
>>> df
    A  B  C
  1  a  f  k
  2  b  g  l
  3  c  h  m
  4  d  i  n
  5  e  j  o

>>> df.truncate(before=2, after=4)
    A  B  C
  2  b  g  l
  3  c  h  m
  4  d  i  n

The columns of a DataFrame can be truncated.

```python
>>> df.truncate(before="A", after="B", axis="columns")
    A  B
  1  a  f
  2  b  g
  3  c  h
  4  d  i
  5  e  j
```  

For Series, only rows can be truncated.

```python
>>> df['A'].truncate(before=2, after=4)
    2  b
    3  c
    4  d
Name: A, dtype: object
```

The index values in `truncate` can be datetimes or string dates.

```python
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
      A
2016-01-31 23:59:56  1
2016-01-31 23:59:57  1
2016-01-31 23:59:58  1
2016-01-31 23:59:59  1
2016-02-01 00:00:00  1
```
Because the index is a DatetimeIndex containing only dates, we can specify before and after as strings. They will be coerced to Timestamps before truncation.

Note that truncate assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
    A
2016-01-10 23:59:55  1
2016-01-10 23:59:56  1
2016-01-10 23:59:57  1
2016-01-10 23:59:58  1
2016-01-10 23:59:59  1
```

**pandas.Series.tshift**

Series.tshift (periods=1, freq=None, axis=0)
Shift the time index, using the index’s frequency if available.

Depreciated since version 1.1.0: Use shift instead.

**Parameters**

- **periods** [int] Number of periods to move, can be positive or negative.
- **freq** [DateOffset, timedelta, or str, default None] Increment to use from the tseries module or time rule expressed as a string (e.g. ‘EOM’).
- **axis** [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Corresponds to the axis that contains the Index.

**Returns**

- **shifted** [Series/DataFrame]
Notes

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown.

`pandas.Series.tz_convert`

`Series.tz_convert(tz, axis=0, level=None, copy=True)`  
Convert tz-aware axis to target time zone.

**Parameters**

- `tz` [str or tzinfo object]  
- `axis` [the axis to convert]  
- `level` [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None.  
- `copy` [bool, default True] Also make a copy of the underlying data.

**Returns**

- `{klass}` Object with time zone converted axis.

**Raises**

- `TypeError` If the axis is tz-naive.

`pandas.Series.tz_localize`

`Series.tz_localize(tz, axis=0, level=None, copy=True, ambiguous='raise', nonexistent='raise')`  
Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use `Series.dt.tz_localize()`.

**Parameters**

- `tz` [str or tzinfo]  
- `axis` [the axis to localize]  
- `level` [int, str, default None] If axis ia a MultiIndex, localize a specific level. Otherwise must be None.  
- `copy` [bool, default True] Also make a copy of the underlying data.  
- `ambiguous` ['infer', bool-ndarray, ‘NaT’, default ‘raise’] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the ambiguous parameter dictates how ambiguous times should be handled.
  
  - ‘infer’ will attempt to infer fall dst-transition hours based on order  
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)  
  - ‘NaT’ will return NaT where there are ambiguous times  
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.
nonexistent [str, default 'raise'] A nonexistent time does not exist in a particular time-zone where clocks moved forward due to DST. Valid values are:

- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

Series or DataFrame Same type as the input.

Raises

TypeError If the TimeSeries is tz-aware and tz is not None.

Examples

Localize local times:

>>> s = pd.Series([1],
...                     index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00 1
dtype: int64

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

>>> s = pd.Series(range(7),
...                     index=pd.DatetimeIndex(['2018-10-28 01:30:00',
...                     '2018-10-28 02:00:00',
...                     '2018-10-28 02:30:00',
...                     '2018-10-28 02:00:00',
...                     '2018-10-28 02:30:00',
...                     '2018-10-28 03:00:00',
...                     '2018-10-28 03:30:00']))
>>> s.tz_localize('CET', ambiguous='infer')
2018-10-28 01:30:00+02:00 0
2018-10-28 02:00:00+02:00 1
2018-10-28 02:30:00+02:00 2
2018-10-28 02:00:00+01:00 3
2018-10-28 02:30:00+01:00 4
2018-10-28 03:00:00+01:00 5
2018-10-28 03:30:00+01:00 6
dtype: int64

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly

>>> s = pd.Series(range(3),
...                     index=pd.DatetimeIndex(['2018-10-28 01:20:00',
...                     '2018-10-28 02:36:00',
...                     '2018-10-28 03:46:00']))
If the DST transition causes nonexistent times, you can shift these dates forward or backward with a timedelta object or 'shift_forward' or 'shift_backward'.

```python
>>> s = pd.Series(range(2),
                 index=pd.DatetimeIndex(['2015-03-29 02:30:00',
                                         '2015-03-29 03:30:00']))
```

```python
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
2015-03-29 03:00:00+02:00 0
2015-03-29 03:30:00+02:00 1
dtype: int64
```

```python
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
2015-03-29 01:59:59.999999999+01:00 0
2015-03-29 03:30:00+02:00 1
dtype: int64
```

```python
>>> s.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
2015-03-29 03:30:00+02:00 0
2015-03-29 03:30:00+02:00 1
dtype: int64
```

### pandas.Series.unique

**Series.unique()**

Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

**Returns**

- `ndarray` or `ExtensionArray` The unique values returned as a NumPy array. See Notes.

**See also:**

- `unique` Top-level unique method for any 1-d array-like object.
- `Index.unique` Return Index with unique values from an Index object.

**Notes**

Returns the unique values as a NumPy array. In case of an extension-array backed Series, a new `ExtensionArray` of that type with just the unique values is returned. This includes:

- Categorical
- Period
- Datetime with Timezone
- Interval
- Sparse
• IntegerNA

See Examples section.

Examples

```python
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])

>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')

>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern') for _ in range(3)]).unique()
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]

An Categorical will return categories in the order of appearance and with the same dtype.

```python
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
['b', 'a', 'c']
Categories (3, object): ['a', 'b', 'c']

```python
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'), ordered=True)).unique()
['b', 'a', 'c']
Categories (3, object): ['a' < 'b' < 'c']
```

pandas.Series.unstack

Series.unstack(level=-1, fill_value=None)

Unstack, also known as pivot, Series with MultiIndex to produce DataFrame.

Parameters

- **level** [int, str, or list of these, default last level] Level(s) to unstack, can pass level name.
- **fill_value** [scalar value, default None] Value to use when replacing NaN values.

Returns

DataFrame Unstacked Series.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4], index=pd.MultiIndex.from_product([['one', 'two'], ['a', 'b']]))

>>> s
one  a  1
   b  2
two  a  3
   b  4
dtype: int64
```

3.3. Series
>>> s.unstack(level=-1)
a    b
one  1  2
two  3  4

>>> s.unstack(level=0)
one  two
   a  1  3
   b  2  4

pandas.Series.update

Series.update(other)
Modify Series in place using values from passed Series.
Uses non-NA values from passed Series to make updates. Aligns on index.

Parameters

other [Series, or object coercible into Series]

Examples

>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6]))
>>> s
0  4
  1  5
  2  6
dtype: int64

>>> s = pd.Series(['a', 'b', 'c'])
>>> s.update(pd.Series(['d', 'e'], index=[0, 2]))
>>> s
0  d
  1  b
  2  e
dtype: object

>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6, 7, 8]))
>>> s
0  4
  1  5
  2  6
dtype: int64

If other contains NaNs the corresponding values are not updated in the original Series.

>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, np.nan, 6]))
>>> s
0  4
  1  2
(continues on next page)
other can also be a non-Series object type that is coercible into a Series

```python
>>> s = pd.Series([1, 2, 3])
>>> s.update([4, np.nan, 6])
>>> s
0 4
1 2
2 6
dtype: int64
```

```python
>>> s = pd.Series([1, 2, 3])
>>> s.update({1: 9})
>>> s
0 1
1 9
2 3
dtype: int64
```

**pandas.Series.value_counts**

Series.value_counts(normalize=False, sort=True, ascending=False, bins=None, dropna=True)

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

**Parameters**

- normalize [bool, default False] If True then the object returned will contain the relative frequencies of the unique values.
- sort [bool, default True] Sort by frequencies.
- ascending [bool, default False] Sort in ascending order.
- bins [int, optional] Rather than count values, group them into half-open bins, a convenience for `pd.cut`, only works with numeric data.
- dropna [bool, default True] Don’t include counts of NaN.

**Returns**

Series

**See also:**

- `Series.count` Number of non-NA elements in a Series.
- `DataFrame.count` Number of non-NA elements in a DataFrame.
- `DataFrame.value_counts` Equivalent method on DataFrames.
Examples

```python
>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0   2
1.0   1
2.0   1
4.0   1
dtype: int64
```

With `normalize` set to `True`, returns the relative frequency by dividing all values by the sum of values.

```python
>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0 0.4
1.0 0.2
2.0 0.2
4.0 0.2
dtype: float64
```

**bins**

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.

```python
>>> s.value_counts(bins=3)
(0.996, 2.0] 2
(2.0, 3.0] 2
(3.0, 4.0] 1
dtype: int64
```

**dropna**

With `dropna` set to `False` we can also see NaN index values.

```python
>>> s.value_counts(dropna=False)
3.0   2
1.0   1
2.0   1
4.0   1
NaN   1
dtype: int64
```

**pandas.Series.var**

`Series.var(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)`

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument.

**Parameters**

- **axis** ([{index (0)}])
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - \) ddof, where \( N \) represents the number of elements.

**numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

scalar or Series (if level specified)

**Notes**

To have the same behaviour as numpy.std, use \( ddof=0 \) (instead of the default \( ddof=1 \))

**pandas.Series.view**

```
Series.view(dtype=None)
```

Create a new view of the Series.

This function will return a new Series with a view of the same underlying values in memory, optionally reinterpreted with a new data type. The new data type must preserve the same size in bytes as to not cause index misalignment.

**Parameters**

dtype [data type] Data type object or one of their string representations.

**Returns**

Series A new Series object as a view of the same data in memory.

**See also:**

**numpy.ndarray.view** Equivalent numpy function to create a new view of the same data in memory.

**Notes**

Series are instantiated with \( dtype=float64 \) by default. While numpy.ndarray.view() will return a view with the same data type as the original array, Series.view() (without specified dtype) will try using float64 and may fail if the original data type size in bytes is not the same.

**Examples**

```
>>> s = pd.Series([-2, -1, 0, 1, 2], dtype='int8')
>>> s
0 -2
1 -1
2  0
3  1
4  2
dtype: int8
```

The 8 bit signed integer representation of \(-1\) is \texttt{0b11111111}, but the same bytes represent 255 if read as an 8 bit unsigned integer.
The views share the same underlying values:

```
>>> us[0] = 128
>>> s
  0  -128
  1   -1
  2    0
  3    1
  4    2
dtype: int8
```

### pandas.Series.where

**Series.where**

```
Series.where(cond, other=nan, inplace=False, axis=None, level=None, errors='raise',
try_cast=<no_default>)
```

Replace values where the condition is False.

**Parameters**

- **cond** [bool Series/DataFrame, array-like, or callable] Where `cond` is True, keep the original value. Where False, replace with corresponding value from `other`. If `cond` is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

- **other** [scalar, Series/DataFrame, or callable] Entries where `cond` is False are replaced with corresponding value from `other`. If other is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

- **inplace** [bool, default False] Whether to perform the operation in place on the data.

- **axis** [int, default None] Alignment axis if needed.

- **level** [int, default None] Alignment level if needed.

- **errors** [str, {'raise', 'ignore'}, default ‘raise’] Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.
  - ‘raise’: allow exceptions to be raised.
  - ‘ignore’: suppress exceptions. On error return original object.

- **try_cast** [bool, default None] Try to cast the result back to the input type (if possible).
  - Deprecated since version 1.3.0: Manually cast back if necessary.

**Returns**

- Same type as caller or None if `inplace=True`.

**See also:**
DataFrame.mask()  Return an object of same shape as self.

Notes

The where method is an application of the if-then idiom. For each element in the calling DataFrame, if cond is True the element is used; otherwise the corresponding element from the DataFrame other is used.

The signature for DataFrame.where() differs from numpy.where(). Roughly df1.where(m, df2) is equivalent to np.where(m, df1, df2).

For further details and examples see the where documentation in indexing.

Examples

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1     1.0
2     2.0
3     3.0
4     4.0
dtype: float64
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
>>> s.mask(s > 1, 10)
0    0
1     1
2    10
3    10
4    10
```

```
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
```

```
>>> m = df % 3 == 0
```

(continues on next page)
pandas.Series.xs

Series.xs (key, axis=0, level=None, drop_level=True)

Return cross-section from the Series/DataFrame.

This method takes a key argument to select data at a particular level of a MultiIndex.

**Parameters**

- **key** [label or tuple of label] Label contained in the index, or partially in a MultiIndex.
- **axis** [[0 or ‘index’, 1 or ‘columns’], default 0] Axis to retrieve cross-section on.
- **level** [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.
- **drop_level** [bool, default True] If False, returns object with same levels as self.

**Returns**

Series or DataFrame Cross-section from the original Series or DataFrame corresponding to the selected index levels.

**See also:**

- **DataFrame.loc** Access a group of rows and columns by label(s) or a boolean array.
- **DataFrame.iloc** Purely integer-location based indexing for selection by position.
Notes

xs cannot be used to set values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of xs functionality, see MultiIndex Slicers.

Examples

```python
>>> d = {'num_legs': [4, 4, 2, 2], ...
...     'num_wings': [0, 0, 2, 2], ...
...     'class': ['mammal', 'mammal', 'mammal', 'bird'], ...
...     'animal': ['cat', 'dog', 'bat', 'penguin'], ...
...     'locomotion': ['walks', 'walks', 'flies', 'walks']}
>>> df = pd.DataFrame(data=d)
>>> df = df.set_index(['class', 'animal', 'locomotion'])

num_legs  num_wings
class animal locomotion
  mammal  cat  walks 4 0
  mammal  dog  walks 4 0
  mammal  bat  flies 2 2
  bird    penguin  walks 2 2

Get values at specified index

```python
>>> df.xs('mammal')

num_legs  num_wings
animal locomotion
  cat  walks 4 0
  dog  walks 4 0
  bat  flies 2 2
```

Get values at several indexes

```python
>>> df.xs(('mammal', 'dog'))

locomotion
  walks 4 0
```

Get values at specified index and level

```python
>>> df.xs('cat', level=1)

class locomotion
  mammal  walks 4 0
```

Get values at several indexes and levels

```python
>>> df.xs(('bird', 'walks'), ...
...     level=[0, 'locomotion'])

num_legs  num_wings
animal
  penguin 2 2
```

Get values at specified column and axis
3.3.2 Attributes

<td>Get the properties associated with this pandas object.</td>
</tr>
<tr>
<td>Series.set_flags</td>
<td>Return a new object with updated flags.</td>
</tr>
</tbody>
</table>

**pandas.Series.empty**

**property** Series.empty

Indicator whether DataFrame is empty.

- True if DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

**Returns**

- bool: If DataFrame is empty, return True, if not return False.

**See also:**

- **Series.dropna**: Return series without null values.
- **DataFrame.dropna**: Return DataFrame with labels on given axis omitted where (all or any) data are missing.
Notes

If DataFrame contains only NaNs, it is still not considered empty. See the example below.

Examples

An example of an actual empty DataFrame. Notice the index is empty:

```python
>>> df_empty = pd.DataFrame({'A' : []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []
>>> df_empty.empty
True
```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```python
>>> df = pd.DataFrame({'A' : [np.nan]})
>>> df
   A
0  NaN
>>> df.empty
False
>>> df.dropna().empty
True
```

3.3.3 Conversion

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.astype(dtype[, copy, errors])</td>
<td>Cast a pandas object to a specified dtype dtype.</td>
</tr>

</tr>
<tr>
<td>Series.to_period([freq, copy])</td>
<td>Convert Series from DatetimeIndex to PeriodIndex.</td>
</tr>
<tr>
<td>Series.to_timestamp([freq, how, copy])</td>
<td>Cast to DatetimeIndex of Timestamps, at beginning of period.</td>
</tr>
<tr>
<td>Series.to_list()</td>
<td>Return a list of the values.</td>
</tr>
<tr>
<td>Series.<strong>array</strong>(dtype)</td>
<td>Return the values as a NumPy array.</td>
</tr>
</tbody>
</table>
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.Series.__array__

Series.__array__(dtype=None)
Return the values as a NumPy array.

Users should not call this directly. Rather, it is invoked by `numpy.array()` and `numpy.asarray()`.

Parameters

dtype [str or numpy.dtype, optional] The dtype to use for the resulting NumPy array. By default, the dtype is inferred from the data.

Returns

numpy.ndarray The values in the series converted to a `numpy.ndarray` with the specified dtype.

See also:

array Create a new array from data.
Series.array Zero-copy view to the array backing the Series.
Series.to_numpy Series method for similar behavior.

Examples

```python
>>> ser = pd.Series([1, 2, 3])
>>> np.asarray(ser)
array([1, 2, 3])
```

For timezone-aware data, the timezones may be retained with `dtype='object'

```python
>>> tzser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> np.asarray(tzser, dtype="object")
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET'),
      Timestamp('2000-01-02 00:00:00+0100', tz='CET')],
      dtype=object)
```

Or the values may be localized to UTC and the tzinfo discarded with `dtype='datetime64[ns]'`

```python
>>> np.asarray(tzser, dtype="datetime64[ns]")
array(['1999-12-31T23:00:00.000000000', '2000-01-01T00:00:00.000000000', ...
      '2000-01-02T00:00:00.000000000'],
      dtype='datetime64[ns]')
```

3.3.4 Indexing, iteration

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.get(key[, default])</td>
<td>Get item from object for given key (ex: DataFrame column).</td>
</tr>
<tr>
<td>Series.at</td>
<td>Access a single value for a row/column label pair.</td>
</tr>
<tr>
<td>Series.iat</td>
<td>Access a single value for a row/column pair by integer position.</td>
</tr>
<tr>
<td>Series.loc</td>
<td>Access a group of rows and columns by label(s) or a boolean array.</td>
</tr>
<tr>
<td>Series.iloc</td>
<td>Purely integer-location based indexing for selection by position.</td>
</tr>
<tr>
<td>Series.<strong>iter</strong>()</td>
<td>Return an iterator of the values.</td>
</tr>
</tbody>
</table>

Table 37 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.items()</code></td>
<td>Lazily iterate over (index, value) tuples.</td>
</tr>
<tr>
<td><code>Series.iteritems()</code></td>
<td>Lazily iterate over (index, value) tuples.</td>
</tr>
<tr>
<td><code>Series.keys()</code></td>
<td>Return alias for index.</td>
</tr>
<tr>
<td><code>Series.pop(item)</code></td>
<td>Return item and drops from series.</td>
</tr>
<tr>
<td><code>Series.item()</code></td>
<td>Return the first element of the underlying data as a Python scalar.</td>
</tr>
<tr>
<td><code>Series.xs(key[, axis, level, drop_level])</code></td>
<td>Return cross-section from the Series/DataFrame.</td>
</tr>
</tbody>
</table>

**pandas.Series.__iter__**

Series.__iter__()  
Return an iterator of the values.  
These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period).  
**Returns**  

iterator

For more information on .at, .iat, .loc, and .iloc, see the indexing documentation.

### 3.3.5 Binary operator functions

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.add(other[, level, fill_value, axis])</code></td>
<td>Return Addition of series and other, element-wise (binary operator add).</td>
</tr>
<tr>
<td><code>Series.sub(other[, level, fill_value, axis])</code></td>
<td>Return Subtraction of series and other, element-wise (binary operator sub).</td>
</tr>
<tr>
<td><code>Series.mul(other[, level, fill_value, axis])</code></td>
<td>Return Multiplication of series and other, element-wise (binary operator mul).</td>
</tr>
<tr>
<td><code>Series.div(other[, level, fill_value, axis])</code></td>
<td>Return Floating division of series and other, element-wise (binary operator truediv).</td>
</tr>
<tr>
<td><code>Series.truediv(other[, level, fill_value, axis])</code></td>
<td>Return Floating division of series and other, element-wise (binary operator truediv).</td>
</tr>
<tr>
<td><code>Series.floordiv(other[, level, fill_value, axis])</code></td>
<td>Return Integer division of series and other, element-wise (binary operator floordiv).</td>
</tr>
<tr>
<td><code>Series.mod(other[, level, fill_value, axis])</code></td>
<td>Return Modulo of series and other, element-wise (binary operator mod).</td>
</tr>
<tr>
<td><code>Series.pow(other[, level, fill_value, axis])</code></td>
<td>Return Exponential power of series and other, element-wise (binary operator pow).</td>
</tr>
<tr>
<td><code>Series.radd(other[, level, fill_value, axis])</code></td>
<td>Return Addition of series and other, element-wise (binary operator radd).</td>
</tr>
<tr>
<td><code>Series.rsub(other[, level, fill_value, axis])</code></td>
<td>Return Subtraction of series and other, element-wise (binary operator rsub).</td>
</tr>
<tr>
<td><code>Series.rmul(other[, level, fill_value, axis])</code></td>
<td>Return Multiplication of series and other, element-wise (binary operator rmul).</td>
</tr>
<tr>
<td><code>Series.rdiv(other[, level, fill_value, axis])</code></td>
<td>Return Floating division of series and other, element-wise (binary operator rtruediv).</td>
</tr>
<tr>
<td><code>Series.rtruediv(other[, level, fill_value, axis])</code></td>
<td>Return Floating division of series and other, element-wise (binary operator rtruediv).</td>
</tr>
</tbody>
</table>
**Table 38 – continued from previous page**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.rfloordiv(other[, level, fill_value, ...])</code></td>
<td>Return Integer division of series and other, element-wise (binary operator <code>rfloordiv</code>).</td>
</tr>
<tr>
<td><code>Series.rmod(other[, level, fill_value, axis])</code></td>
<td>Return Modulo of series and other, element-wise (binary operator <code>rmod</code>).</td>
</tr>
<tr>
<td><code>Series.rpow(other[, level, fill_value, axis])</code></td>
<td>Return Exponential power of series and other, element-wise (binary operator <code>rpow</code>).</td>
</tr>
<tr>
<td><code>Series.combine(other, func[, fill_value])</code></td>
<td>Combine the Series with a Series or scalar according to <code>func</code>.</td>
</tr>
<tr>
<td><code>Series.combine_first(other)</code></td>
<td>Update null elements with value in the same location in ‘other’.</td>
</tr>
<tr>
<td><code>Series.round([decimals])</code></td>
<td>Round each value in a Series to the given number of decimals.</td>
</tr>
<tr>
<td><code>Series.lt(other[, level, fill_value, axis])</code></td>
<td>Return Less than of series and other, element-wise (binary operator <code>lt</code>).</td>
</tr>
<tr>
<td><code>Series.gt(other[, level, fill_value, axis])</code></td>
<td>Return Greater than of series and other, element-wise (binary operator <code>gt</code>).</td>
</tr>
<tr>
<td><code>Series.le(other[, level, fill_value, axis])</code></td>
<td>Return Less than or equal to of series and other, element-wise (binary operator <code>le</code>).</td>
</tr>
<tr>
<td><code>Series.ge(other[, level, fill_value, axis])</code></td>
<td>Return Greater than or equal to of series and other, element-wise (binary operator <code>ge</code>).</td>
</tr>
<tr>
<td><code>Series.ne(other[, level, fill_value, axis])</code></td>
<td>Return Not equal to of series and other, element-wise (binary operator <code>ne</code>).</td>
</tr>
<tr>
<td><code>Series.eq(other[, level, fill_value, axis])</code></td>
<td>Return Equal to of series and other, element-wise (binary operator <code>eq</code>).</td>
</tr>
<tr>
<td><code>Series.product([axis, skipna, level, ...])</code></td>
<td>Return the product of the values over the requested axis.</td>
</tr>
<tr>
<td><code>Series.dot(other)</code></td>
<td>Compute the dot product between the Series and the columns of other.</td>
</tr>
</tbody>
</table>

### 3.3.6 Function application, GroupBy & window

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.apply(func[, convert_dtype, args])</code></td>
<td>Invoke function on values of Series.</td>
</tr>
<tr>
<td><code>Series.agg([func, axis])</code></td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td><code>Series.aggregate([func, axis])</code></td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td><code>Series.transform(func[, axis])</code></td>
<td>Call <code>func</code> on self producing a Series with transformed values.</td>
</tr>
<tr>
<td><code>Series.map(arg[, na_action])</code></td>
<td>Map values of Series according to input correspondence.</td>
</tr>
<tr>
<td><code>Series.groupby([by, axis, level, as_index, ...])</code></td>
<td>Group Series using a mapper or by a Series of columns.</td>
</tr>
<tr>
<td><code>Series.rolling(window[, min_periods, ...])</code></td>
<td>Provide rolling window calculations.</td>
</tr>
<tr>
<td><code>Series.expanding([min_periods, center, ...])</code></td>
<td>Provide expanding transformations.</td>
</tr>
<tr>
<td><code>Series.ewm([com, span, halflife, alpha, ...])</code></td>
<td>Provide exponential weighted (EW) functions.</td>
</tr>
<tr>
<td><code>Series.pipe(func, *args, **kwargs)</code></td>
<td>Apply <code>func(self, *args, **kwargs)</code>.</td>
</tr>
</tbody>
</table>
### 3.3.7 Computations / descriptive stats

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.abs()</code></td>
<td>Return a Series/DataFrame with absolute numeric value of each element.</td>
</tr>
<tr>
<td><code>Series.all([axis, bool_only, skipna, level])</code></td>
<td>Return whether all elements are True, potentially over an axis.</td>
</tr>
<tr>
<td><code>Series.any([axis, bool_only, skipna, level])</code></td>
<td>Return whether any element is True, potentially over an axis.</td>
</tr>
<tr>
<td><code>Series.autocorr([lag])</code></td>
<td>Compute the lag-N autocorrelation.</td>
</tr>
<tr>
<td><code>Series.between(left, right[, inclusive])</code></td>
<td>Return boolean Series equivalent to left &lt;= series &lt;= right.</td>
</tr>
<tr>
<td><code>Series.clip([lower, upper, axis, inplace])</code></td>
<td>Trim values at input threshold(s).</td>
</tr>
<tr>
<td><code>Series.corr(other[, method, min_periods])</code></td>
<td>Compute correlation with other Series, excluding missing values.</td>
</tr>
<tr>
<td><code>Series.count([level])</code></td>
<td>Return number of non-NA/null observations in the Series.</td>
</tr>
<tr>
<td><code>Series.cov(other[, min_periods, ddof])</code></td>
<td>Compute covariance with Series, excluding missing values.</td>
</tr>
<tr>
<td><code>Series.cummax([axis, skipna])</code></td>
<td>Return cumulative maximum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>Series.cummin([axis, skipna])</code></td>
<td>Return cumulative minimum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>Series.cumprod([axis, skipna])</code></td>
<td>Return cumulative product over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>Series.cumsum([axis, skipna])</code></td>
<td>Return cumulative sum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>Series.describe([percentiles, include,...])</code></td>
<td>Generate descriptive statistics.</td>
</tr>
<tr>
<td><code>Series.diff([periods])</code></td>
<td>First discrete difference of element.</td>
</tr>
<tr>
<td><code>Series.factorize([sort, na_sentinel])</code></td>
<td>Encode the object as an enumerated type or categorical variable.</td>
</tr>
<tr>
<td><code>Series.kurt([axis, skipna, level, numeric_only])</code></td>
<td>Return unbiased kurtosis over requested axis.</td>
</tr>
<tr>
<td><code>Series.mad([axis, skipna, level])</code></td>
<td>Return the mean absolute deviation of the values over the requested axis.</td>
</tr>
<tr>
<td><code>Series.max([axis, skipna, level, numeric_only])</code></td>
<td>Return the maximum of the values over the requested axis.</td>
</tr>
<tr>
<td><code>Series.mean([axis, skipna, level, numeric_only])</code></td>
<td>Return the mean of the values over the requested axis.</td>
</tr>
<tr>
<td><code>Series.median([axis, skipna, level,...])</code></td>
<td>Return the median of the values over the requested axis.</td>
</tr>
<tr>
<td><code>Series.min([axis, skipna, level, numeric_only])</code></td>
<td>Return the minimum of the values over the requested axis.</td>
</tr>
<tr>
<td><code>Series.mode([dropna])</code></td>
<td>Return the mode(s) of the Series.</td>
</tr>
<tr>
<td><code>Series.nlargest([n, keep])</code></td>
<td>Return the largest n elements.</td>
</tr>
<tr>
<td><code>Series.nsmallest([n, keep])</code></td>
<td>Return the smallest n elements.</td>
</tr>
<tr>
<td><code>Series.pct_change([periods, fill_method,...])</code></td>
<td>Percentage change between the current and a prior element.</td>
</tr>
<tr>
<td><code>Series.prod([axis, skipna, level,...])</code></td>
<td>Return the product of the values over the requested axis.</td>
</tr>
<tr>
<td><code>Series.quantile([q, interpolation])</code></td>
<td>Return value at the given quantile.</td>
</tr>
<tr>
<td><code>Series.rank([axis, method, numeric_only,...])</code></td>
<td>Compute numerical data ranks (1 through n) along axis.</td>
</tr>
<tr>
<td><code>Series.sem([axis, skipna, level, ddof,...])</code></td>
<td>Return unbiased standard error of the mean over requested axis.</td>
</tr>
<tr>
<td><code>Series.skew([axis, skipna, level, numeric_only])</code></td>
<td>Return unbiased skew over requested axis.</td>
</tr>
<tr>
<td><code>Series.std([axis, skipna, level, ddof,...])</code></td>
<td>Return sample standard deviation over requested axis.</td>
</tr>
<tr>
<td><code>Series.sum([axis, skipna, level,...])</code></td>
<td>Return the sum of the values over the requested axis.</td>
</tr>
</tbody>
</table>

Table 40 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.var([axis, skipna, level, ddof, ...])</code></td>
<td>Return unbiased variance over requested axis.</td>
</tr>
<tr>
<td><code>Series.kurtosis([axis, skipna, level, ...])</code></td>
<td>Return unbiased kurtosis over requested axis.</td>
</tr>
<tr>
<td><code>Series.unique()</code></td>
<td>Return unique values of Series object.</td>
</tr>
<tr>
<td><code>Series.nunique([dropna])</code></td>
<td>Return number of unique elements in the object.</td>
</tr>
<tr>
<td><code>Series.is_unique</code></td>
<td>Return boolean if values in the object are unique.</td>
</tr>
<tr>
<td><code>Series.is_monotonic</code></td>
<td>Return boolean if values in the object are monotonic_increasing.</td>
</tr>
<tr>
<td><code>Series.is_monotonic_increasing</code></td>
<td>Alias for is_monotonic.</td>
</tr>
<tr>
<td><code>Series.is_monotonic_decreasing</code></td>
<td>Return boolean if values in the object are monotonic_decreasing.</td>
</tr>
<tr>
<td><code>Series.value_counts([normalize, sort, ...])</code></td>
<td>Return a Series containing counts of unique values.</td>
</tr>
</tbody>
</table>

3.3.8 Reindexing / selection / label manipulation

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.align(other[, join, axis, level, ...])</code></td>
<td>Align two objects on their axes with the specified join method.</td>
</tr>
<tr>
<td><code>Series.drop([labels, axis, index, columns, ...])</code></td>
<td>Return Series with specified index labels removed.</td>
</tr>
<tr>
<td><code>Series.droplevel(level[, axis])</code></td>
<td>Return Series/DataFrame with requested index / column level(s) removed.</td>
</tr>
<tr>
<td><code>Series.drop_duplicates([keep, inplace])</code></td>
<td>Return Series with duplicate values removed.</td>
</tr>
<tr>
<td><code>Series.duplicated([keep])</code></td>
<td>Indicate duplicate Series values.</td>
</tr>
<tr>
<td><code>Series.equals(other)</code></td>
<td>Test whether two objects contain the same elements.</td>
</tr>
<tr>
<td><code>Series.first(offset)</code></td>
<td>Select initial periods of time series data based on a date offset.</td>
</tr>
<tr>
<td><code>Series.head([n])</code></td>
<td>Return the first n rows.</td>
</tr>
<tr>
<td><code>Series.idxmax([axis, skipna])</code></td>
<td>Return the row label of the maximum value.</td>
</tr>
<tr>
<td><code>Series.idxmin([axis, skipna])</code></td>
<td>Return the row label of the minimum value.</td>
</tr>
<tr>
<td><code>Series.isin(values)</code></td>
<td>Whether elements in Series are contained in values.</td>
</tr>
<tr>
<td><code>Series.last(offset)</code></td>
<td>Select final periods of time series data based on a date offset.</td>
</tr>
<tr>
<td><code>Series.reindex(index)</code></td>
<td>Conform Series to new index with optional filling logic.</td>
</tr>
<tr>
<td><code>Series.reindex_like(other[, method, copy, ...])</code></td>
<td>Return an object with matching indices as other object.</td>
</tr>
<tr>
<td><code>Series.rename([index, axis, copy, inplace, ...])</code></td>
<td>Alter Series index labels or name.</td>
</tr>
<tr>
<td><code>Series.rename_axis([mapper, index, columns, ...])</code></td>
<td>Set the name of the axis for the index or columns.</td>
</tr>
<tr>
<td><code>Series.reset_index([level, drop, name, inplace])</code></td>
<td>Generate a new DataFrame or Series with the index reset.</td>
</tr>
<tr>
<td><code>Series.sample([n, frac, replace, weights, ...])</code></td>
<td>Return a random sample of items from an axis of object.</td>
</tr>
<tr>
<td><code>Series.set_axis(labels[, axis, inplace])</code></td>
<td>Assign desired index to given axis.</td>
</tr>
<tr>
<td><code>Series.take(indices[, axis, is_copy])</code></td>
<td>Return the elements in the given positional indices along an axis.</td>
</tr>
<tr>
<td><code>Series.tail([n])</code></td>
<td>Return the last n rows.</td>
</tr>
<tr>
<td><code>Series.truncate([before, after, axis, copy])</code></td>
<td>Truncate a Series or DataFrame before and after some index value.</td>
</tr>
<tr>
<td><code>Series.where(cond[, other, inplace, axis, ...])</code></td>
<td>Replace values where the condition is False.</td>
</tr>
<tr>
<td><code>Series.mask(cond[, other, inplace, axis, ...])</code></td>
<td>Replace values where the condition is True.</td>
</tr>
<tr>
<td><code>Series.add_prefix(prefix)</code></td>
<td>Prefix labels with string prefix.</td>
</tr>
<tr>
<td><code>Series.add_suffix(suffix)</code></td>
<td>Suffix labels with string suffix.</td>
</tr>
</tbody>
</table>

continues on next page
Table 41 – continued from previous page

- **Series.filter([items, like, regex, axis])** Subset the dataframe rows or columns according to the specified index labels.

### 3.3.9 Missing data handling

- **Series.backfill([axis, inplace, limit, downcast])** Synonym for `DataFrame.fillna()` with `method='bfill'`.
- **Series.bfill([axis, inplace, limit, downcast])** Synonym for `DataFrame.fillna()` with `method='bfill'`.
- **Series.dropna([axis, inplace, how])** Return a new Series with missing values removed.
- **Series.ffill([axis, inplace, limit, downcast])** Synonym for `DataFrame.fillna()` with `method='ffill'`.
- **Series.fillna([value, method, axis, ...])** Fill NA/NaN values using the specified method.
- **Series.interpolate([method, axis, limit, ...])** Fill NaN values using an interpolation method.
- **Series.isna()** Detect missing values.
- **Series.isnull()** Detect missing values.
- **Series.notna()** Detect existing (non-missing) values.
- **Series.notnull()** Detect existing (non-missing) values.
- **Series.pad([axis, inplace, limit, downcast])** Synonym for `DataFrame.fillna()` with `method='ffill'`.
- **Series.replace([to_replace, value, inplace, ...])** Replace values given in `to_replace` with `value`.

### 3.3.10 Reshaping, sorting

- **Series.argsort([axis, kind, order])** Return the integer indices that would sort the Series values.
- **Series.argmin([axis, skipna])** Return int position of the smallest value in the Series.
- **Series.argmax([axis, skipna])** Return int position of the largest value in the Series.
- **Series.reorder_levels(order)** Rearrange index levels using input order.
- **Series.sort_values([axis, ascending, ...])** Sort by the values.
- **Series.sort_index([axis, level, ascending, ...])** Sort Series by index labels.
- **Series.swaplevel([i, j, copy])** Swap levels i and j in a MultiIndex.
- **Series.unstack([level, fill_value])** Unstack, also known as pivot, Series with MultiIndex to produce DataFrame.
- **Series.explode([ignore_index])** Transform each element of a list-like to a row.
- **Series.searchsorted(value[, side, sorter])** Find indices where elements should be inserted to maintain order.
- **Series.ravel([order])** Return the flattened underlying data as an ndarray.
- **Series.repeat(repeats[, axis])** Repeat elements of a Series.
- **Series.squeeze([axis])** Squeeze 1 dimensional axis objects into scalars.
- **Series.view([dtype])** Create a new view of the Series.
3.3.11 Combining / comparing / joining / merging

- `Series.append(to_append[, ignore_index, ...])`: Concatenate two or more Series.
- `Series.compare(other[, align_axis, ...])`: Compare to another Series and show the differences.
- `Series.update(other)`: Modify Series in place using values from passed Series.

3.3.12 Time Series-related

- `Series.asfreq(freq[, method, how, ...])`: Convert time series to specified frequency.
- `Series.asof(where[, subset])`: Return the last row(s) without any NaNs before `where`.
- `Series.shift([periods, freq, axis, fill_value])`: Shift index by desired number of periods with an optional time `freq`.
- `Series.first_valid_index()`: Return index for first non-NA value or None, if no NA value is found.
- `Series.last_valid_index()`: Return index for last non-NA value or None, if no NA value is found.
- `Series.resample(rule[, axis, closed, label, ...])`: Resample time-series data.
- `Series.tz_convert(tz[, axis, level, copy])`: Convert tz-aware axis to target time zone.
- `Series.tz_localize(tz[, axis, level, copy, ...])`: Localize tz-naive index of a Series or DataFrame to target time zone.
- `Series.at_time(time[, asof, axis])`: Select values at particular time of day (e.g., 9:30AM).
- `Series.between_time(start_time, end_time[, ...])`: Select values between particular times of the day (e.g., 9:00-9:30 AM).
- `Series.tshift([periods, freq, axis])`: (DEPRECATED) Shift the time index, using the index’s frequency if available.
- `Series.slice_shift([periods, axis])`: (DEPRECATED) Equivalent to `shift` without copying data.

3.3.13 Accessors

pandas provides dtype-specific methods under various accessors. These are separate namespaces within `Series` that only apply to specific data types.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Accessor</th>
</tr>
</thead>
<tbody>
<tr>
<td>Datetime, Timedelta, Period</td>
<td><code>dt</code></td>
</tr>
<tr>
<td>String</td>
<td><code>str</code></td>
</tr>
<tr>
<td>Categorical</td>
<td><code>cat</code></td>
</tr>
<tr>
<td>Sparse</td>
<td><code>sparse</code></td>
</tr>
</tbody>
</table>
Datetimelike properties

Series.dt can be used to access the values of the series as datetimelike and return several properties. These can be accessed like Series.dt.<property>.

Datetime properties

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.dt.date</td>
<td>Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).</td>
</tr>
<tr>
<td>Series.dt.time</td>
<td>Returns numpy array of datetime.time.</td>
</tr>
<tr>
<td>Series.dt.timetz</td>
<td>Returns numpy array of datetime.time also containing timezone information.</td>
</tr>
<tr>
<td>Series.dt.year</td>
<td>The year of the datetime.</td>
</tr>
<tr>
<td>Series.dt.month</td>
<td>The month as January=1, December=12.</td>
</tr>
<tr>
<td>Series.dt.day</td>
<td>The day of the datetime.</td>
</tr>
<tr>
<td>Series.dt.hour</td>
<td>The hours of the datetime.</td>
</tr>
<tr>
<td>Series.dt.minute</td>
<td>The minutes of the datetime.</td>

<tr>
<td>Series.dt.weekday</td>
<td>The day of the week with Monday=0, Sunday=6.</td>
</tr>
<tr>
<td>Series.dt.dayofyear</td>
<td>The ordinal day of the year.</td>
</tr>
<tr>
<td>Series.dt.day_of_year</td>
<td>The ordinal day of the year.</td>
</tr>
<tr>
<td>Series.dt.quarter</td>
<td>The quarter of the date.</td>
</tr>
<tr>
<td>Series.dt.is_month_start</td>
<td>Indicates whether the date is the first day of the month.</td>
</tr>
<tr>
<td>Series.dt.is_month_end</td>
<td>Indicates whether the date is the last day of the month.</td>
</tr>
<tr>
<td>Series.dt.is_quarter_start</td>
<td>Indicator for whether the date is the first day of a quarter.</td>
</tr>
<tr>
<td>Series.dt.is_quarter_end</td>
<td>Indicator for whether the date is the last day of a quarter.</td>
</tr>
<tr>
<td>Series.dt.is_year_start</td>
<td>Indicate whether the date is the first day of a year.</td>
</tr>
<tr>
<td>Series.dt.is_year_end</td>
<td>Indicate whether the date is the last day of the year.</td>
</tr>
<tr>
<td>Series.dt.is_leap_year</td>
<td>Boolean indicator if the date belongs to a leap year.</td>
</tr>
<tr>
<td>Series.dt.daysinmonth</td>
<td>The number of days in the month.</td>
</tr>
<tr>
<td>Series.dt.days_in_month</td>
<td>The number of days in the month.</td>
</tr>
<tr>
<td>Series.dt.tz</td>
<td>Return timezone, if any.</td>
</tr>
<tr>
<td>Series.dt.freq</td>
<td>Return the frequency object for this PeriodArray.</td>
</tr>
</tbody>
</table>
pandas.Series.dt.date

Series.dt.date
Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).

pandas.Series.dt.time

Series.dt.time
Returns numpy array of datetime.time. The time part of the Timestamps.

pandas.Series.dt.timetz

Series.dt.timetz
Returns numpy array of datetime.time also containing timezone information. The time part of the Timestamps.

pandas.Series.dt.year

Series.dt.year
The year of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
    ...     pd.date_range("2000-01-01", periods=3, freq="Y")
    ... )
>>> datetime_series
0  2000-12-31
1  2001-12-31
2  2002-12-31
dtype: datetime64[ns]
```

```python
>>> datetime_series.dt.year
0   2000
1   2001
2   2002
dtype: int64
```

pandas.Series.dt.month

Series.dt.month
The month as January=1, December=12.
Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="M")
... )
>>> datetime_series
0  2000-01-31
1  2000-02-29
2  2000-03-31
dtype: datetime64[ns]
>>> datetime_series.dt.month
0    1
1    2
2    3
dtype: int64
```

`pandas.Series.dt.day`

`Series.dt.day`
The day of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="D")
... )
>>> datetime_series
0  2000-01-01
1  2000-01-02
2  2000-01-03
dtype: datetime64[ns]
>>> datetime_series.dt.day
0    1
1    2
2    3
dtype: int64
```
**pandas.Series.dt.hour**

Series.dt.hour

The hours of the datetime.

**Examples**

```python
gate_series = pd.Series(
    ...     pd.date_range("2000-01-01", periods=3, freq="h")
    ... )
gate_series
0 2000-01-01 00:00:00
1 2000-01-01 01:00:00
2 2000-01-01 02:00:00
dtype: datetime64[ns]
gate_series.dt.hour
0 0
1 1
2 2
dtype: int64
```

**pandas.Series.dt.minute**

Series.dt.minute

The minutes of the datetime.

**Examples**

```python
gate_series = pd.Series(
    ...     pd.date_range("2000-01-01", periods=3, freq="T")
    ... )
gate_series
0 2000-01-01 00:00:00
1 2000-01-01 00:01:00
2 2000-01-01 00:02:00
dtype: datetime64[ns]
gate_series.dt.minute
0 0
1 1
2 2
dtype: int64
```
pandas.Series.dt.second

Series.dt.second
The seconds of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="s")
... )
>>> datetime_series
0  2000-01-01 00:00:00
1  2000-01-01 00:00:01
2  2000-01-01 00:00:02
dtype: datetime64[ns]
>>> datetime_series.dt.second
0  0
1  1
2  2
dtype: int64
```

pandas.Series.dt.microsecond

Series.dt.microsecond
The microseconds of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="us")
... )
>>> datetime_series
0  2000-01-01 00:00:00.000000
1  2000-01-01 00:00:00.000001
2  2000-01-01 00:00:00.000002
dtype: datetime64[ns]
>>> datetime_series.dt.microsecond
0  0
1  1
2  2
dtype: int64
```
pandas.Series.dt.nanosecond

Series.dt.nanosecond
The nanoseconds of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...    pd.date_range("2000-01-01", periods=3, freq="ns")
...)
>>> datetime_series
0 2000-01-01 00:00:00.000000000
1 2000-01-01 00:00:00.000000001
2 2000-01-01 00:00:00.000000002
dtype: datetime64[ns]
```

```python
>>> datetime_series.dt.nanosecond
0 0
1 1
2 2
dtype: int64
```

pandas.Series.dt.week

Series.dt.week
The week ordinal of the year.

Deprecated since version 1.1.0.

Series.dt.weekofyear and Series.dt.week have been deprecated. Please use Series.dt.isocalendar().week instead.

pandas.Series.dt.weekofyear

Series.dt.weekofyear
The week ordinal of the year.

Deprecated since version 1.1.0.

Series.dt.weekofyear and Series.dt.week have been deprecated. Please use Series.dt.isocalendar().week instead.

pandas.Series.dt.dayofweek

Series.dt.dayofweek
The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the dt accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:

Series.dt.dayofweek Alias.
Series.dt.weekday Alias.
Series.dt.day_name Returns the name of the day of the week.

Examples

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

pandas.Series.dt.day_of_week

Series.dt.day_of_week

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the dt accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:

Series.dt.dayofweek Alias.
Series.dt.weekday Alias.
Series.dt.day_name Returns the name of the day of the week.

Examples

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```
pandas.Series.dt.weekday

Series.dt.weekday

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the dt accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:

Series.dt.dayofweek Alias.
Series.dt.weekday Alias.
Series.dt.day_name Returns the name of the day of the week.

Examples

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

pandas.Series.dt.dayofyear

Series.dt.dayofyear

The ordinal day of the year.

pandas.Series.dt.day_of_year

Series.dt.day_of_year

The ordinal day of the year.

pandas.Series.dt.quarter

Series.dt.quarter

The quarter of the date.
pandas.Series.dt.is_month_start

Series.dt.is_month_start
Indicates whether the date is the first day of the month.

Returns
Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

is_month_start Return a boolean indicating whether the date is the first day of the month.
is_month_end Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0  2018-02-27
1  2018-02-28
2  2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0 False
1 False
2 True
dtype: bool
>>> s.dt.is_month_end
0 False
1 True
2 False
dtype: bool
```

```python
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```

pandas.Series.dt.is_month_end

Series.dt.is_month_end
Indicates whether the date is the last day of the month.

Returns
Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

is_month_start Return a boolean indicating whether the date is the first day of the month.
is_month_end Return a boolean indicating whether the date is the last day of the month.
Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
... 0 2018-02-27
... 1 2018-02-28
... 2 2018-03-01
... dtype: datetime64[ns]
>>> s.dt.is_month_start
... 0 False
... 1 False
... 2 True
dtype: bool
>>> s.dt.is_month_end
... 0 False
... 1 True
... 2 False
dtype: bool
```

```python
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```

**pandas.Series.dt.is_quarter_start**

Series.dt.**is_quarter_start**

Indicator for whether the date is the first day of a quarter.

**Returns**

**is_quarter_start** [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

*quarter* Return the quarter of the date.

*is_quarter_end* Similar property for indicating the quarter start.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> df = pd.DataFrame({
... 'dates': pd.date_range("2017-03-30", periods=4),
... 'quarter': df.dates.dt.quarter,
... 'is_quarter_start': df.dates.dt.is_quarter_start
... })
```

<table>
<thead>
<tr>
<th>dates</th>
<th>quarter</th>
<th>is_quarter_start</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017-03-30</td>
<td>1</td>
<td>False</td>
</tr>
<tr>
<td>2017-03-31</td>
<td>1</td>
<td>False</td>
</tr>
<tr>
<td>2017-04-01</td>
<td>2</td>
<td>True</td>
</tr>
<tr>
<td>2017-04-02</td>
<td>2</td>
<td>False</td>
</tr>
</tbody>
</table>
>> idx = pd.date_range('2017-03-30', periods=4)
>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
dtype='datetime64[ns]', freq='D')

>> idx.is_quarter_start
array([False, False, True, False])

pandas.Series.dt.is_quarter_end

Series.dt.is_quarter_end
Indicator for whether the date is the last day of a quarter.

Returns

is_quarter_end [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:
quarter Return the quarter of the date.
is_quarter_start Similar property indicating the quarter start.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

>>> df = pd.DataFrame({
...     'dates': pd.date_range("2017-03-30", periods=4),
...     'quarter': df.dates.dt.quarter,
...     'is_quarter_end': df.dates.dt.is_quarter_end
... })

    dates       quarter  is_quarter_end
0 2017-03-30          1        False
1 2017-03-31          1        True
2 2017-04-01          2        False
3 2017-04-02          2        False

>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
dtype='datetime64[ns]', freq='D')

>> idx.is_quarter_end
array([False, True, False, False])
pandas.Series.dt.is_year_start

Series.dt.

is_year_start
Indicate whether the date is the first day of a year.

Returns

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

is_year_end Similar property indicating the last day of the year.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0  2017-12-30
1  2017-12-31
2  2018-01-01
dtype: datetime64[ns]
```

```python
>>> dates.dt.is_year_start
0   False
1   False
2    True
dtype: bool
```

```python
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

```python
>>> idx.is_year_start
array([False, False,  True])
```

pandas.Series.dt.is_year_end

Series.dt.

is_year_end
Indicate whether the date is the last day of the year.

Returns

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

is_year_start Similar property indicating the start of the year.
Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0 2017-12-30
1 2017-12-31
2 2018-01-01
dtype: datetime64[ns]

>>> dates.dt.is_year_end
0 False
1 True
2 False
dtype: bool
```

```python
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
dtype='datetime64[ns]', freq='D')

>>> idx.is_year_end
array([False, True, False])
```

**pandas.Series.dt.is_leap_year**

Series.dt.**is_leap_year**

Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

**Returns**

Series or ndarray  Booleans indicating if dates belong to a leap year.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
dtype='datetime64[ns]', freq='A-DEC')

>>> idx.is_leap_year
array([ True, False, False])

>>> dates_series = pd.Series(idx)
>>> dates_series
0 2012-12-31
1 2013-12-31
2 2014-12-31
dtype: datetime64[ns]

>>> dates_series.dt.is_leap_year
(continues on next page)
pandas.Series.dt.daysinmonth

Series.dt.daysinmonth

The number of days in the month.

pandas.Series.dt.days_in_month

Series.dt.days_in_month

The number of days in the month.

pandas.Series.dt.tz

Series.dt.tz

Return timezone, if any.

Returns
datetime.tzinfo, pytz.tzinfo.BaseTZInfo, dateutil.tz.tzfile, or None Returns None when the array is tz-naive.

pandas.Series.dt.freq

Series.dt.freq

Datetime methods

Series.dt.to_period(*args, **kwargs) Cast to PeriodArray/Index at a particular frequency.

Series.dt.to_pydatetime() Return the data as an array of native Python datetime objects.

Series.dt.tz_localize(*args, **kwargs) Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

Series.dt.tz_convert(*args, **kwargs) Convert tz-aware Datetime Array/Index from one time zone to another.

Series.dt.normalize(*args, **kwargs) Convert times to midnight.

Series.dt.strftime(*args, **kwargs) Convert to Index using specified date_format.

Series.dt.round(*args, **kwargs) Perform round operation on the data to the specified freq.

Series.dt.floor(*args, **kwargs) Perform floor operation on the data to the specified freq.

Series.dt.ceil(*args, **kwargs) Perform ceil operation on the data to the specified freq.

Series.dt.month_name(*args, **kwargs) Return the month names of the DateTimeIndex with specified locale.

continues on next page
pandas.Series.dt.day_name

Series.dt.day_name(*args, **kwargs)
Return the day names of the DateTimeIndex with specified locale.

pandas.Series.dt.to_period

Series.dt.to_period(*args, **kwargs)
Cast to PeriodArray/Index at a particular frequency.
Converts DatetimeArray/Index to PeriodArray/Index.

Parameters

freq [str or Offset, optional] One of pandas’ offset strings or an Offset object. Will be inferred by default.

Returns

PeriodArray/Index

Raises

ValueError When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

See also:

PeriodIndex Immutable ndarray holding ordinal values.
DatetimeIndex.to_pydatetime Return DatetimeIndex as object.

Examples

```python
df = pd.DataFrame({"y": [1, 2, 3]},
                  index=pd.to_datetime(["2000-03-31 00:00:00",
                                      "2000-05-31 00:00:00",
                                      "2000-08-31 00:00:00"]))
>>> df.index.to_period("M")
PeriodIndex(["2000-03", "2000-05", "2000-08"],
            dtype='period[M]')
```

Infer the daily frequency

```python
idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(["2017-01-01", "2017-01-02"],
            dtype='period[D]')
```

pandas.Series.dt.to_pydatetime

Series.dt.to_pydatetime()
Return the data as an array of native Python datetime objects.
Timezone information is retained if present.

Warning: Python’s datetime uses microsecond resolution, which is lower than pandas (nanosecond). The values are truncated.
Returns

**numpy.ndarray**  Object dtype array containing native Python datetime objects.

See also:

**datetime.datetime**  Standard library value for a datetime.

Examples

```python
>>> s = pd.Series(pd.date_range('20180310', periods=2))
>>> s
0  2018-03-10
1  2018-03-11
dtype: datetime64[ns]

>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 11, 0, 0)], dtype=object)
```

Pandas’ nanosecond precision is truncated to microseconds.

```python
>>> s = pd.Series(pd.date_range('20180310', periods=2, freq='ns'))
>>> s
0  2018-03-10 00:00:00.000000000
1  2018-03-10 00:00:00.000000001
dtype: datetime64[ns]

>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 10, 0, 0)], dtype=object)
```

### `pandas.Series.dt.tz_localize`

**Series.dt.tz_localize(*args, **kwargs)**

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone.

This method can also be used to do the inverse – to create a time zone unaware object from an aware object. To that end, pass `tz=None`.

**Parameters**

- **tz**  [str, pytz.timezone, dateutil.tz.tzfile or None]  Time zone to convert timestamps to. Passing `None` will remove the time zone information preserving local time.

- **ambiguous**  [‘infer’, ‘naT’, bool array, default ‘raise’]  When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the `ambiguous` parameter dictates how ambiguous times should be handled.

  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where `True` signifies a DST time, `False` signifies a non-DST time (note that this flag is only applicable for ambiguous times)
• ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

**nonexistent** ['shift_forward', 'shift_backward', ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

• ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
• ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
• ‘NaT’ will return NaT where there are nonexistent times
• timedelta objects will shift nonexistent times by the timedelta
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

Same type as self  Array/Index converted to the specified time zone.

Raises

TypeError  If the Datetime Array/Index is tz-aware and tz is not None.

See also:

DatetimeIndex.tz_convert  Convert tz-aware DatetimeIndex from one time zone to another.

Examples

```python
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')

Localize DatetimeIndex in US/Eastern time zone:

```python
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
```python
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
               '2018-03-02 09:00:00-05:00',
               '2018-03-03 09:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)

With the **tz=None**, we can remove the time zone information while keeping the local time (not converted to UTC):

```python
>>> tz_aware.tz_localize(None)
```python
```
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```python
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:30:00',
                                ...
                                '2018-10-28 02:00:00',
                                ...
                                '2018-10-28 02:30:00'],
                               dtype='datetime64[ns]', freq=None)
```

(continues on next page)
In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly:

```python
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:20:00',
                               '2018-10-28 02:36:00',
                               '2018-10-28 03:46:00']))
```

```python
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
```

0  2018-10-28 01:20:00+02:00
1  2018-10-28 02:36:00+02:00
2  2018-10-28 03:46:00+01:00
dtype: datetime64[ns, CET]

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a timedelta object or `'shift_forward'` or `'shift_backwards'`:

```python
>>> s = pd.to_datetime(pd.Series(['2015-03-29 02:30:00',
                               '2015-03-29 03:30:00']))
```

```python
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
```

0  2015-03-29 03:00:00+02:00
1  2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]

```python
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
```

0  2015-03-29 01:59:59.999999999+01:00
1  2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]

```python
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
```

0  2015-03-29 03:30:00+02:00
1  2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
pandas.Series.dt.tz_convert

Series.dt.tz_convert(*args, **kwargs)
Convert tz-aware Datetime Array/Index from one time zone to another.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding times-
tamps would be converted to this time zone of the Datetime Array/Index. A tz of None
will convert to UTC and remove the timezone information.

Returns

Array or Index

Raises

TypeError If Datetime Array/Index is tz-naive.

See also:

DatetimeIndex.tz A timezone that has a variable offset from UTC.
DatetimeIndex.tz_localize Localize tz-naive DatetimeIndex to a given time zone, or remove time-
zone from a tz-aware DatetimeIndex.

Examples

With the tz parameter, we can change the DatetimeIndex to other time zones:

```python
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                      freq='H', periods=3, tz='Europe/Berlin')
```

```python
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
              '2014-08-01 10:00:00+02:00',
              '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```python
>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
              '2014-08-01 03:00:00-05:00',
              '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the tz=None, we can remove the timezone (after converting to UTC if necessary):

```python
>>> dti = pd.date_range(start='2014-08-01 09:00', freq='H',
...                      periods=3, tz='Europe/Berlin')
```

```python
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
              '2014-08-01 10:00:00+02:00',
              '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```python
>>> dti.tz_convert(None)
DatetimeIndex(['2014-08-01 07:00:00',
              '2014-08-01 08:00:00',
              '2014-08-01 09:00:00'],
              dtype='datetime64[ns, None]', freq='H')
```
pandas.Series.dt.normalize

Series.dt.normalize(*args, **kwargs)

Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the
time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the .dt accessor, and directly on Datetime
Array/Index.

Returns

DatetimeArray, DatetimeIndex or Series The same type as the original data. Series will
have the same name and index. DatetimeIndex will have the same name.

See also:

floor Floor the datetimes to the specified freq.
ceil Ceil the datetimes to the specified freq.
round Round the datetimes to the specified freq.

Examples

```python
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
                      periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
               '2014-08-01 11:00:00+05:30',
               '2014-08-01 12:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

pandas.Series.dt.strftime

Series.dt.strftime(*args, **kwargs)

Convert to Index using specified date_format.

Return an Index of formatted strings specified by date_format, which supports the same string format as the
python standard library. Details of the string format can be found in python string format doc.

Parameters

date_format [str] Date format string (e.g. “%Y-%m-%d”).

Returns

ndarray NumPy ndarray of formatted strings.

See also:
**to_datetime** Convert the given argument to datetime.

**DatetimeIndex.normalize** Return DatetimeIndex with times to midnight.

**DatetimeIndex.round** Round the DatetimeIndex to the specified freq.

**DatetimeIndex.floor** Floor the DatetimeIndex to the specified freq.

### Examples

```python
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
   ...    periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
   'March 10, 2018, 09:00:02 AM'],
   dtype='object')
```

**pandas.Series.dt.round**

Series.dt.round(*args, **kwargs)

Perform round operation on the data to the specified `freq`.

**Parameters**

- `freq` [str or Offset] The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible `freq` values.

- `ambiguous` ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

- `nonexistent` ['shift_forward', ‘shift_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST:
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

**Returns**

- `DatetimeIndex, TimedeltaIndex, or Series` Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**

- `ValueError` if the `freq` cannot be converted.
Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
```
```python
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
               dtype='datetime64[ns]', freq='T')
```
```python
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
               dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.round("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.Series.dt.floor

Series.dt.floor(*args, **kwargs)
Perform floor operation on the data to the specified freq.

Parameters

- freq [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like 'S' (second) not 'ME' (month end). See frequency aliases for a list of possible freq values.
- ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:
  - 'infer' will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - 'NaT' will return NaT where there are ambiguous times
  - 'raise' will raise an AmbiguousTimeError if there are ambiguous times.
- nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - 'shift_forward' will shift the nonexistent time forward to the closest existing time
  - 'shift_backward' will shift the nonexistent time backward to the closest existing time
  - 'NaT' will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - 'raise' will raise an NonExistentTimeError if there are nonexistent times.

Returns
**DatetimeIndex, TimedeltaIndex, or Series**  
Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**

ValueError if the `freq` cannot be converted.

**Examples**

**DatetimeIndex**

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
```

```python
>>> rng  
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00', '2018-01-01 12:01:00'],  
dtype='datetime64[ns]', freq='T')
```

```python
>>> rng.floor('H')  
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00', '2018-01-01 12:00:00'],  
dtype='datetime64[ns]', freq=None)
```

**Series**

```python
>>> pd.Series(rng).dt.floor("H")
```

<p>| | |</p>

</tr>
</tbody>
</table>

**pandas.Series.dt.ceil**

Series.dt.**ceil**(*args, **kwargs*)

Perform ceil operation on the data to the specified `freq`.

**Parameters**

- **freq** [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible `freq` values.

- **ambiguous** ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

- **nonexistent** ['shift_forward', ‘shift_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
[`'NaT'` will return `NaT` where there are nonexistent times
* `timedelta` objects will shift nonexistent times by the `timedelta`
* `'raise'` will raise an `NonExistentTimeError` if there are nonexistent times.

**Returns**

Datet imeIndex, TimedeltaIndex, or Series  Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**

ValueError if the `freq` cannot be converted.

**Examples**

**DatetimeIndex**

```python
g = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
g
datetime_index = ['2018-01-01 11:59:00', '2018-01-01 12:00:00',
                  '2018-01-01 12:01:00'],
dtype='datetime64[ns]', freq='T')
g.ceil('H')
datetime_index = ['2018-01-01 12:00:00', '2018-01-01 12:00:00',
                  '2018-01-01 13:00:00'],
dtype='datetime64[ns]', freq=None)
```

**Series**

```python
pd.Series(g).dt.ceil("H")
```

```python
0 2018-01-01 12:00:00
1 2018-01-01 12:00:00
2 2018-01-01 13:00:00
dtype: datetime64[ns]
```

**pandas.Series.dt.month_name**

Series.dt. **month_name** (*args, **kwargs*)

Return the month names of the DateTimeIndex with specified locale.

**Parameters**

locale [str, optional] Locale determining the language in which to return the month name.

Default is English locale.

**Returns**

Index  Index of month names.
Examples

```python
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
               dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```

**pandas.Series.dt.day_name**

`Series.dt.day_name(*args, **kwargs)`

Return the day names of the `DateTimeIndex` with specified locale.

**Parameters**

- `locale` [str, optional] Locale determining the language in which to return the day name. Default is English locale.

**Returns**

- `Index` Index of day names.

**Examples**

```python
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
               dtype='datetime64[ns]', freq='D')
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

0     0       0        0         0             0            0          0
1     0       0        0         1             0            0          0
2     0       0        0         2             0            0          0
3     0       0        0         3             0            0          0
4     0       0        0         4             0            0          0
```

Timedelta methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.dt.to_pytimedelta()</td>
<td>Return an array of native <code>datetime.timedelta</code> objects.</td>
</tr>
<tr>
<td>Series.dt.total_seconds(*args, **kwargs)</td>
<td>Return total duration of each element expressed in seconds.</td>
</tr>
</tbody>
</table>

pandas.Series.dt.to_pytimedelta

Series.dt.to_pytimedelta()
Return an array of native `datetime.timedelta` objects.

Python’s standard `datetime` library uses a different representation Timedelta’s. This method converts a Series of pandas Timedeltas to `datetime.timedelta` format with the same length as the original Series.

Returns

`numpy.ndarray` Array of 1D containing data with `datetime.timedelta` type.

See also:

`datetime.timedelta` A duration expressing the difference between two date, time, or datetime.
Examples

```python
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit="d"))
>>> s
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]
>>> s.dt.to_pytimedelta()
array([datetime.timedelta(0), datetime.timedelta(days=1),
       datetime.timedelta(days=2), datetime.timedelta(days=3),
       datetime.timedelta(days=4)], dtype=object)
```

*pandas.Series.dt.total_seconds*

```
pandas.Series.dt.
total_seconds
``` *args, **kwargs* 
Return total duration of each element expressed in seconds.

This method is available directly on TimedeltaArray, TimedeltaIndex and on Series containing timedelta values under the `dt` namespace.

**Returns**

- **seconds** *[[ndarray, Float64Index, Series]]* When the calling object is a TimedeltaArray, the return type is ndarray. When the calling object is a TimedeltaIndex, the return type is a Float64Index. When the calling object is a Series, the return type is Series of type float64 whose index is the same as the original.

**See also:**

- datetime.timedelta.total_seconds Standard library version of this method.
- TimedeltaIndex.components Return a DataFrame with components of each Timedelta.

**Examples**

**Series**

```python
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]
>>> s.dt.total_seconds()
0     0.0
1   86400.0
2  172800.0
3  259200.0
4  345600.0
dtype: float64
```
TimedeltaIndex

```python
>>> idx = pd.to_timedelta(np.arange(5), unit='d')
```

```python
>>> idx
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq=None)
```

```python
>>> idx.total_seconds()
Float64Index([0.0, 86400.0, 172800.0, 259200.0, 345600.0],
              dtype='float64')
```

### String handling

`Series.str` can be used to access the values of the series as strings and apply several methods to it. These can be accessed like `Series.str.<function/property>`.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>str.capitalize()</code></td>
<td>Convert strings in the Series/Index to be capitalized.</td>
</tr>
<tr>
<td><code>str.casefold()</code></td>
<td>Convert strings in the Series/Index to be casefolded.</td>
</tr>
<tr>
<td><code>str.cat([others, sep, na_rep, join])</code></td>
<td>Concatenate strings in the Series/Index with given separator.</td>
</tr>
<tr>
<td><code>str.center(width[, fillchar])</code></td>
<td>Pad left and right side of strings in the Series/Index.</td>
</tr>
<tr>
<td><code>str.contains(pat[, case, flags, na, . . . ])</code></td>
<td>Test if pattern or regex is contained within a string of a Series or Index.</td>
</tr>
<tr>
<td><code>str.count(pat[, flags])</code></td>
<td>Count occurrences of pattern in each string of the Series/Index.</td>
</tr>
<tr>
<td><code>str.decode(encoding[, errors])</code></td>
<td>Decode character string in the Series/Index using indicated encoding.</td>
</tr>
<tr>
<td><code>str.encode(encoding[, errors])</code></td>
<td>Encode character string in the Series/Index using indicated encoding.</td>
</tr>
<tr>
<td><code>str.endswith(pat[, na])</code></td>
<td>Test if the end of each string element matches a pattern.</td>
</tr>
<tr>
<td><code>str.extract(pat[, flags, expand])</code></td>
<td>Extract capture groups in the regex <code>pat</code> as columns in a DataFrame.</td>
</tr>
<tr>
<td><code>str.extractall(pat[, flags])</code></td>
<td>Extract capture groups in the regex <code>pat</code> as columns in DataFrame.</td>

</tr>
<tr>
<td><code>Series.str.isnumeric()</code></td>
<td>Check whether all characters in each string are numeric.</td>
</tr>
<tr>
<td><code>Series.str.isdecimal()</code></td>
<td>Check whether all characters in each string are decimal.</td>
</tr>
<tr>
<td><code>Series.str.get_dummies([sep])</code></td>
<td>Return DataFrame of dummy/indicator variables for Series.</td>
</tr>
</tbody>
</table>
**pandas.Series.str.capitalize**

Series.str.capitalize()  
Convert strings in the Series/Index to be capitalized.  
Equivalent to str.capitalize().

**Returns**  
Series or Index of object

**See also:**

- `Series.str.lower` Converts all characters to lowercase.
- `Series.str.upper` Converts all characters to uppercase.
- `Series.str.title` Converts first character of each word to uppercase and remaining to lowercase.
- `Series.str.capitalize` Converts first character to uppercase and remaining to lowercase.
- `Series.str.swapcase` Converts uppercase to lowercase and lowercase to uppercase.
- `Series.str.casefold` Removes all case distinctions in the string.

**Examples**

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
```

```bash
>>> s
0    lower
1   CAPITALS
2  this is a sentence
3       SwApCaSe
dtype: object
```

```bash
>>> s.str.lower()
0    lower
1   capitals
2  this is a sentence
3       swapcase
dtype: object
```

```bash
>>> s.str.upper()
0    LOWER
1   CAPITALS
2  THIS IS A SENTENCE
3      SWAPCASE
dtype: object
```

```bash
>>> s.str.title()
0    Lower
1    Capitals
2  This Is A Sentence
3    Swapcase
dtype: object
```

```bash
>>> s.str.capitalize()
0    Lower
1    Capitals
2  This is a sentence
3    Swapcase
dtype: object
```
>>> s.str.swapcase()
0    LOWER
1    capitals
2   THIS IS A SENTENCE
3    swapcase
dtype: object

pandas.Series.str.casefold

Series.str.casefold()
Convert strings in the Series/Index to be casefolded.

New in version 0.25.0.
Equivalent to str.casefold().

Returns
Series or Index of object

See also:
Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold Removes all case distinctions in the string.

Examples

>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])

>>> s
0    lower
1  CAPITALS
2  this is a sentence
3    SwApCaSe
dtype: object

>>> s.str.lower()
0    lower
1  capitals
2  this is a sentence
3    swapcase
dtype: object

>>> s.str.upper()
0    LOWER
1  CAPITALS
2   THIS IS A SENTENCE
3    SWAPCASE
dtype: object

>>> s.str.title()
0    Lower
(continues on next page)
pandas.Series.str.cat

Series.str.cat(others=None, sep=None, na_rep=None, join='left')
Concatenate strings in the Series/Index with given separator.

If others is specified, this function concatenates the Series/Index and elements of others element-wise. If others is not passed, then all values in the Series/Index are concatenated into a single string with a given sep.

Parameters

others [Series, Index, DataFrame, np.ndarray or list-like] Series, Index, DataFrame, np.ndarray (one- or two-dimensional) and other list-likes of strings must have the same length as the calling Series/Index, with the exception of indexed objects (i.e. Series/Index/DataFrame) if join is not None.

If others is a list-like that contains a combination of Series, Index or np.ndarray (1-dim), then all elements will be unpacked and must satisfy the above criteria individually.

If others is None, the method returns the concatenation of all strings in the calling Series/Index.

sep [str, default ‘’] The separator between the different elements/columns. By default the empty string ‘’ is used.

na_rep [str or None, default None] Representation that is inserted for all missing values:

- If na_rep is None, and others is None, missing values in the Series/Index are omitted from the result.
- If na_rep is None, and others is not None, a row containing a missing value in any of the columns (before concatenation) will have a missing value in the result.

join [{‘left’, ‘right’, ‘outer’, ‘inner’}, default ‘left’] Determines the join-style between the calling Series/Index and any Series/Index/DataFrame in others (objects without an index need to match the length of the calling Series/Index). To disable alignment, use .values on any Series/Index/DataFrame in others.

New in version 0.23.0.

Changed in version 1.0.0: Changed default of join from None to ‘left’.
Returns

str, Series or Index  If others is None, str is returned, otherwise a Series/Index (same type as caller) of objects is returned.

See also:

split  Split each string in the Series/Index.
join  Join lists contained as elements in the Series/Index.

Examples

When not passing others, all values are concatenated into a single string:

```python
>>> s = pd.Series(['a', 'b', np.nan, 'd'])
>>> s.str.cat(sep=' ')
'a b d'
```

By default, NA values in the Series are ignored. Using na_rep, they can be given a representation:

```python
>>> s.str.cat(sep=' ', na_rep='?')
'a b ? d'
```

If others is specified, corresponding values are concatenated with the separator. Result will be a Series of strings.

```python
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',')
0 a,A
1 b,B
2 NaN
3 d,D
dtype: object
```

Missing values will remain missing in the result, but can again be represented using na_rep

```python
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=' ', na_rep='-')
0 a,A
1 b,B
2 -,C
3 d,D
dtype: object
```

If sep is not specified, the values are concatenated without separation.

```python
>>> s.str.cat(['A', 'B', 'C', 'D'], na_rep='-')
0 aA
1 bB
2 -,C
3 dD
dtype: object
```

Series with different indexes can be aligned before concatenation. The join-keyword works as in other methods.

```python
>>> t = pd.Series(['d', 'a', 'e', 'c'], index=[3, 0, 4, 2])
>>> s.str.cat(t, join='left', na_rep='-')
0 aa
1 b-
2 -,c
3 dd
```

(continues on next page)
```python
dtype: object
>>> s.str.cat(t, join='outer', na_rep='-')
0  aa
1  b-
2  -c
3  dd
4  -e
dtype: object
>>> s.str.cat(t, join='inner', na_rep='-')
0  aa
2  -c
3  dd
dtype: object
>>> s.str.cat(t, join='right', na_rep='-')
3  dd
0  aa
4  -e
2  -c
dtype: object
```

For more examples, see [here](#).

**pandas.Series.str.center**

Series.str.center(width, fillchar='')

Pad left and right side of strings in the Series/Index.

Equivalent to str.center().

**Parameters**

- **width** [int] Minimum width of resulting string; additional characters will be filled with fillchar.
- **fillchar** [str] Additional character for filling, default is whitespace.

**Returns**

- **filled** [Series/Index of objects.]

**pandas.Series.str.contains**

Series.str.contains(pat, case=True, flags=0, na=None, regex=True)

Test if pattern or regex is contained within a string of a Series or Index.

Return boolean Series or Index based on whether a given pattern or regex is contained within a string of a Series or Index.

**Parameters**

- **pat** [str] Character sequence or regular expression.
- **case** [bool, default True] If True, case sensitive.
- **flags** [int, default 0 (no flags)] Flags to pass through to the re module, e.g. re.IGNORECASE.
**na** [scalar, optional] Fill value for missing values. The default depends on dtype of the array. For object-dtype, `numpy.nan` is used. For `StringDtype`, `pandas.NA` is used.

**regex** [bool, default True] If True, assumes the pat is a regular expression. If False, treats the pat as a literal string.

**Returns**

**Series or Index of boolean values** A Series or Index of boolean values indicating whether the given pattern is contained within the string of each element of the Series or Index.

**See also:**

- `match` Analogous, but stricter, relying on `re.match` instead of `re.search`.
- `Series.str.startswith` Test if the start of each string element matches a pattern.
- `Series.str.endswith` Same as `startswith`, but tests the end of string.

**Examples**

Returning a Series of booleans using only a literal pattern.

```python
>>> s1 = pd.Series(['Mouse', 'dog', 'house and parrot', '23', np.NaN])
>>> s1.str.contains('og', regex=False)
0   False
1    True
2   False
3   False
4    NaN
dtype: object
```

Returning an Index of booleans using only a literal pattern.

```python
>>> ind = pd.Index(['Mouse', 'dog', 'house and parrot', '23.0', np.NaN])
>>> ind.str.contains('23', regex=False)
Index([False, False, False, True, nan], dtype='object')
```

Specifying case sensitivity using `case`.

```python
>>> s1.str.contains('oG', case=True, regex=True)
0   False
1   False
2   False
3   False
4    NaN
dtype: object
```

Specifying `na` to be `False` instead of `NaN` replaces `NaN` values with `False`. If Series or Index does not contain `NaN` values the resultant dtype will be `bool`, otherwise, an `object` dtype.

```python
>>> s1.str.contains('og', na=False, regex=True)
0   False
1    True
2   False
3   False
4   False
dtype: bool
```

Returning ‘house’ or ‘dog’ when either expression occurs in a string.
>>> s1.str.contains('house|dog', regex=True)
0    False
1     True
2     True
3    False
4      NaN
dtype: object

Ignoring case sensitivity using flags with regex.

>>> import re
>>> s1.str.contains('PARROT', flags=re.IGNORECASE, regex=True)
0    False
1    False
2     True
3    False
4      NaN
dtype: object

Returning any digit using regular expression.

>>> s1.str.contains('\\d', regex=True)
0    False
1    False
2    False
3     True
4      NaN
dtype: object

Ensure pat is a not a literal pattern when regex is set to True. Note in the following example one might expect only s2[1] and s2[3] to return True. However, '.0' as a regex matches any character followed by a 0.

```python
>>> s2 = pd.Series([40, 40.0, 41, 41.0, 35])
>>> s2.str.contains('.0', regex=True)
0    True
1    True
2   False
3    True
4   False
dtype: bool
```

**pandas.Series.str.count**

Series.str.count (pat, flags=0)

Count occurrences of pattern in each string of the Series/Index.

This function is used to count the number of times a particular regex pattern is repeated in each of the string elements of the Series.

**Parameters**

- **pat** [str] Valid regular expression.
- **flags** [int, default 0, meaning no flags] Flags for the re module. For a complete list, see here.
- ****kwargs For compatibility with other string methods. Not used.

**Returns**
Series or Index  Same type as the calling object containing the integer counts.

See also:

re  Standard library module for regular expressions.
str.count  Standard library version, without regular expression support.

Notes

Some characters need to be escaped when passing in `pat`. eg. `$` has a special meaning in regex and must be escaped when finding this literal character.

Examples

```
>>> s = pd.Series(['A', 'B', 'Aaba', 'Baca', np.nan, 'CABA', 'cat'])
>>> s.str.count('a')
0   0
1   0
2   2
3   2
4  NaN
5   0
6   1
dtype: float64
```

Escape `$` to find the literal dollar sign.

```
>>> s = pd.Series(['$', 'B', 'Aab$', '$$ca', 'C$B$', 'cat'])
>>> s.str.count('\$')
0  1
1  0
2  1
3  2
4  2
5  0
dtype: int64
```

This is also available on Index

```
>>> pd.Index(['A', 'A', 'Aaba', 'cat']).str.count('a')
Int64Index([0, 0, 2, 1], dtype='int64')
```

pandas.Series.str.decode

Series.str.decode (encoding, errors='strict')

Decode character string in the Series/Index using indicated encoding.

Equivalent to `str.decode()` in python2 and `bytes.decode()` in python3.

Parameters

encoding  [str]
errors  [str, optional]

Returns

Series or Index
**pandas.Series.str.encode**

Series.str.encode (encoding, errors='strict')

Encode character string in the Series/Index using indicated encoding.

Equivalent to str.encode().

**Parameters**

- **encoding** [str]
- **errors** [str, optional]

**Returns**

- **encoded** [Series/Index of objects]

**pandas.Series.str.endswith**

Series.str.endswith (pat, na=None)

Test if the end of each string element matches a pattern.

Equivalent to str.endswith().

**Parameters**

- **pat** [str] Character sequence. Regular expressions are not accepted.
- **na** [object, default NaN] Object shown if element tested is not a string. The default depends on dtype of the array. For object-dtype, numpy.nan is used. For StringDtype, pandas.NA is used.

**Returns**

- **Series or Index of bool** A Series of booleans indicating whether the given pattern matches the end of each string element.

**See also:**

- str.endswith Python standard library string method.
- Series.str.startswith Same as endswith, but tests the start of string.
- Series.str.contains Tests if string element contains a pattern.

**Examples**

```python
>>> s = pd.Series(['bat', 'bear', 'caT', np.nan])
>>> s
0   bat
1   bear
2    caT
3    NaN
dtype: object

>>> s.str.endswith('t')
0   True
1  False
2  False
3    NaN
dtype: object
```

Specifying `na` to be False instead of `NaN`.
*** s.str.endswith('t', na=False)
0   True
1   False
2   False
3   False
  dtype: bool

pandas.Series.str.extract

Series.str.extract (pat, flags=0, expand=True)
Extract capture groups in the regex pat as columns in a DataFrame.

For each subject string in the Series, extract groups from the first match of regular expression pat.

Parameters

- **pat** [str] Regular expression pattern with capturing groups.
- **flags** [int, default 0 (no flags)] Flags from the re module, e.g. re.IGNORECASE, that modify regular expression matching for things like case, spaces, etc. For more details, see re.
- **expand** [bool, default True] If True, return DataFrame with one column per capture group. If False, return a Series/Index if there is one capture group or DataFrame if there are multiple capture groups.

Returns

DataFrame or Series or Index A DataFrame with one row for each subject string, and one column for each group. Any capture group names in regular expression pat will be used for column names; otherwise capture group numbers will be used. The dtype of each result column is always object, even when no match is found. If expand=False and pat has only one capture group, then return a Series (if subject is a Series) or Index (if subject is an Index).

See also:

extractall Returns all matches (not just the first match).

Examples

A pattern with two groups will return a DataFrame with two columns. Non-matches will be NaN.

```python
>>> s = pd.Series(['a1', 'b2', 'c3'])
>>> s.str.extract(r'([ab])(\d)')
   0   1
0   a  1
1   b  2
2  NaN NaN
```

A pattern may contain optional groups.

```python
>>> s.str.extract(r'([ab])?(\d)')
   0   1
0   a  1
1   b  2
2  NaN NaN
```

Named groups will become column names in the result.
A pattern with one group will return a DataFrame with one column if expand=True.

```python
>>> s.str.extract(r'(?P<letter>[ab])(?P<digit>\d)')
letter digit
0  a  1
1  b  2
2  NaN NaN
```

A pattern with one group will return a Series if expand=False.

```python
>>> s.str.extract(r'\[ab\](\d)', expand=False)
0  1
1  2
2  NaN
dtype: object
```

**pandas.Series.str.extractall**

Series.str.extractall(pat, flags=0)

Extract capture groups in the regex pat as columns in DataFrame.

For each subject string in the Series, extract groups from all matches of regular expression pat. When each subject string in the Series has exactly one match, extractall(pat).xs(0, level='match') is the same as extract(pat).

**Parameters**

- **pat** [str] Regular expression pattern with capturing groups.
- **flags** [int, default 0 (no flags)] A re module flag, for example re.IGNORECASE. These allow to modify regular expression matching for things like case, spaces, etc. Multiple flags can be combined with the bitwise OR operator, for example re.IGNORECASE | re.MULTILINE.

**Returns**

DataFrame A DataFrame with one row for each match, and one column for each group. Its rows have a MultiIndex with first levels that come from the subject Series. The last level is named 'match' and indexes the matches in each item of the Series. Any capture group names in regular expression pat will be used for column names; otherwise capture group numbers will be used.

**See also:**

- **extract** Returns first match only (not all matches).
Examples

A pattern with one group will return a DataFrame with one column. Indices with no matches will not appear in the result.

```python
>>> s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"])
>>> s.str.extractall(r"\[ab\]\(\d\)"

<table>
<thead>
<tr>
<th>match</th>
</tr>
</thead>
<tbody>
<tr>
<td>A 0 1</td>
</tr>
<tr>
<td>1 2</td>
</tr>
<tr>
<td>B 0 1</td>
</tr>
</tbody>
</table>
```

Capture group names are used for column names of the result.

```python
>>> s.str.extractall(r"[ab](?P<digit>\d)"

<table>
<thead>
<tr>
<th>digit</th>
</tr>
</thead>
<tbody>
<tr>
<td>A 0 1</td>
</tr>
<tr>
<td>1 2</td>
</tr>
<tr>
<td>B 0 1</td>
</tr>
</tbody>
</table>
```

A pattern with two groups will return a DataFrame with two columns.

```python
>>> s.str.extractall(r"(?P<letter>[ab])\(?P<digit>\d)"

<table>
<thead>
<tr>
<th>letter digit</th>
</tr>
</thead>
<tbody>
<tr>
<td>A a 1</td>
</tr>
<tr>
<td>1 a 2</td>
</tr>
<tr>
<td>B b 1</td>
</tr>
</tbody>
</table>
```

Optional groups that do not match are NaN in the result.

```python
>>> s.str.extractall(r"(?P<letter>[ab])\(?P<digit>\d)"

<table>
<thead>
<tr>
<th>letter digit</th>
</tr>
</thead>
<tbody>
<tr>
<td>A a 1</td>
</tr>
<tr>
<td>1 a 2</td>
</tr>
<tr>
<td>B b 1</td>
</tr>
<tr>
<td>C NaN 1</td>
</tr>
</tbody>
</table>
```

pandas.Series.str.find

`Series.str.find(sub, start=0, end=None)`

Return lowest indexes in each strings in the Series/Index.

Each of returned indexes corresponds to the position where the substring is fully contained between [start:end]. Return -1 on failure. Equivalent to standard `str.find()`.

Parameters

- `sub` [str] Substring being searched.
- `start` [int] Left edge index.
- `end` [int] Right edge index.

Returns
Series or Index of int.

See also:

- `rfind` Return highest indexes in each strings.

**pandas.Series.str.findall**

Series.str.findall(pat, flags=0)

Find all occurrences of pattern or regular expression in the Series/Index.

Equivalent to applying `re.findall()` to all the elements in the Series/Index.

**Parameters**

- **pat** [str] Pattern or regular expression.
- **flags** [int, default 0] Flags from re module, e.g. `re.IGNORECASE` (default is 0, which means no flags).

**Returns**

- **Series/Index of lists of strings** All non-overlapping matches of pattern or regular expression in each string of this Series/Index.

See also:

- `count` Count occurrences of pattern or regular expression in each string of the Series/Index.
- `extractall` For each string in the Series, extract groups from all matches of regular expression and return a DataFrame with one row for each match and one column for each group.
- `re.findall` The equivalent re function to all non-overlapping matches of pattern or regular expression in string, as a list of strings.

**Examples**

```python
>>> s = pd.Series(['Lion', 'Monkey', 'Rabbit'])

The search for the pattern ‘Monkey’ returns one match:

```python
>>> s.str.findall('Monkey')
0    []
1   [Monkey]
2    []
dtype: object
```

On the other hand, the search for the pattern ‘MONKEY’ doesn’t return any match:

```python
>>> s.str.findall('MONKEY')
0    []
1    []
2    []
dtype: object
```

Flags can be added to the pattern or regular expression. For instance, to find the pattern ‘MONKEY’ ignoring the case:

```python
>>> import re
>>> s.str.findall('MONKEY', flags=re.IGNORECASE)
0    []
```

(continues on next page)
When the pattern matches more than one string in the Series, all matches are returned:

```python
>>> s.str.findall('on')
0  [on]
1  [on]
2  []
dtype: object
```

Regular expressions are supported too. For instance, the search for all the strings ending with the word ‘on’ is shown next:

```python
>>> s.str.findall('on$')
0  [on]
1  []
2  []
dtype: object
```

If the pattern is found more than once in the same string, then a list of multiple strings is returned:

```python
>>> s.str.findall('b')
0  []
1  []
2  [b, b]
dtype: object
```

### pandas.Series.str.fullmatch

**Series.str.fullmatch**(pat, case=True, flags=0, na=None)

Determine if each string entirely matches a regular expression.

New in version 1.1.0.

**Parameters**

- **pat** [str] Character sequence or regular expression.
- **case** [bool, default True] If True, case sensitive.
- **flags** [int, default 0 (no flags)] Regex module flags, e.g. `re.IGNORECASE`.
- **na** [scalar, optional] Fill value for missing values. The default depends on dtype of the array. For object-dtype, `numpy.nan` is used. For `StringDtype`, `pandas.NA` is used.

**Returns**

Series/Index/array of boolean values

**See also:**

- **match** Similar, but also returns `True` when only a prefix of the string matches the regular expression.
- **extract** Extract matched groups.
pandas.Series.str.get

Series.str.get(i)

Extract element from each component at specified position.

Extract element from lists, tuples, or strings in each element in the Series/Index.

Parameters

   i [int] Position of element to extract.

Returns

   Series or Index

Examples

>>> s = pd.Series(["String",
...               (1, 2, 3),
...               ["a", "b", "c"],
...               123,
...               -456,
...               {1: "Hello", "2": "World"}])

>>> s
0   String
1   (1, 2, 3)
2   [a, b, c]
3    123
4    -456
5  {1: 'Hello', '2': 'World'}
dtype: object

>>> s.str.get(1)
0   t
1   2
2   b
3   NaN
4   NaN
5   Hello
dtype: object

>>> s.str.get(-1)
0   g
1   3
2   c
3   NaN
4   NaN
5   None
dtype: object
pandas.Series.str.index

Series.str.index(sub, start=0, end=None)
Return lowest indexes in each string in Series/Index.

Each of the returned indexes corresponds to the position where the substring is fully contained between
[start:end]. This is the same as str.find except instead of returning -1, it raises a ValueError when the
substring is not found. Equivalent to standard str.index.

Parameters

- sub [str] Substring being searched.
- start [int] Left edge index.
- end [int] Right edge index.

Returns

Series or Index of object

See also:

- rindex Return highest indexes in each strings.

pandas.Series.str.join

Series.str.join(sep)
Join lists contained as elements in the Series/Index with passed delimiter.

If the elements of a Series are lists themselves, join the content of these lists using the delimiter passed to the
function. This function is an equivalent to str.join().

Parameters

- sep [str] Delimiter to use between list entries.

Returns

Series/Index: object The list entries concatenated by intervening occurrences of the delimi-
ter.

Raises

- AttributeError If the supplied Series contains neither strings nor lists.

See also:

- str.join Standard library version of this method.
- Series.str.split Split strings around given separator/delimiter.

Notes

If any of the list items is not a string object, the result of the join will be NaN.
**Examples**

Example with a list that contains non-string elements.

```python
>>> s = pd.Series([['lion', 'elephant', 'zebra'],
                  [1.1, 2.2, 3.3],
                  ['cat', np.nan, 'dog'],
                  ['cow', 4.5, 'goat'],
                  ['duck', ['swan', 'fish'], 'guppy']])
```

Join all lists using a `-`. The lists containing object(s) of types other than str will produce a NaN.

```python
>>> s.str.join('-')
```

**pandas.Series.str.len**

`Series.str.len()`

Compute the length of each element in the Series/Index.

The element may be a sequence (such as a string, tuple or list) or a collection (such as a dictionary).

**Returns**

- **Series or Index of int**: A Series or Index of integer values indicating the length of each element in the Series or Index.

**See also:**

- **str.len**: Python built-in function returning the length of an object.
- **Series.size**: Returns the length of the Series.

**Examples**

Returns the length (number of characters) in a string. Returns the number of entries for dictionaries, lists or tuples.

```python
>>> s = pd.Series(['dog',
                  ' ',
                  5,
                  {'foo' : 'bar'},
                  [2, 3, 5, 7],
                  {'one', 'two', 'three'})
```

(continues on next page)
1 {'foo': 'bar'}
2 [2, 3, 5, 7]
3 (one, two, three)
4
dtype: object
5 >>> s.str.len()
6 0 3.0
7 1 0.0
8 2 NaN
9 3 1.0
10 4 4.0
11 5 3.0
12 dtype: float64

**pandas.Series.str.ljust**

Series.str.ljust(*width, fillchar=' '*)

Pad right side of strings in the Series/Index.

Equivalent to str.ljust().

**Parameters**

- **width** [int] Minimum width of resulting string; additional characters will be filled with fillchar.
- **fillchar** [str] Additional character for filling, default is whitespace.

**Returns**

- **filled** [Series/Index of objects.]

**pandas.Series.str.lower**

Series.str.lower()

Convert strings in the Series/Index to lowercase.

Equivalent to str.lower().

**Returns**

- **Series or Index of object**

See also:

- **Series.str.lower** Converts all characters to lowercase.
- **Series.str.upper** Converts all characters to uppercase.
- **Series.str.title** Converts first character of each word to uppercase and remaining to lowercase.
- **Series.str.capitalize** Converts first character to uppercase and remaining to lowercase.
- **Series.str.swapcase** Converts uppercase to lowercase and lowercase to uppercase.
- **Series.str.casefold** Removes all case distinctions in the string.
Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0  lower  
1  CAPITALS
2 this is a sentence  
3  SwApCaSe
dtype: object

>>> s.str.lower()
0  lower  
1  capitals
2 this is a sentence  
3  swapcase
dtype: object

>>> s.str.upper()
0  LOWER  
1  CAPITALS
2 THIS IS A SENTENCE  
3  SWAPCASE
dtype: object

>>> s.str.title()
0  Lower  
1  Capitals
2 This Is A Sentence  
3  Swapcase
dtype: object

>>> s.str.capitalize()
0  Lower  
1  Capitals
2 This is a sentence  
3  Swapcase
dtype: object

>>> s.str.swapcase()
0  LOWER  
1  capitals
2 THIS IS A SENTENCE  
3  sWaPcAsE
dtype: object
```
pandas.Series.str.lstrip

Series.str.<b>lstrip</b>(<i>to_strip=None</i>)

Remove leading characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left side. Equivalent to <code>str.lstrip()</code>.

**Parameters**

- <b>to_strip</b> [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

**Returns**

Series or Index of object

**See also:**

- <code>Series.str.strip</code> Remove leading and trailing characters in Series/Index.
- <code>Series.str.lstrip</code> Remove leading characters in Series/Index.
- <code>Series.str.rstrip</code> Remove trailing characters in Series/Index.

**Examples**

```python
>>> s = pd.Series(['1. Ant. ', '2. Bee!
', '3. Cat?\t', np.nan])
>>> s
0 1. Ant.  
1 2. Bee!
2 3. Cat?\t
3 NaN
dtype: object

>>> s.str.strip()
0 1. Ant.  
1 2. Bee!
2 3. Cat?\t
3 NaN
dtype: object

>>> s.str.lstrip('123.\n\t')
0 Ant.  
1 Bee!
2 Cat?\t
3 NaN
dtype: object

>>> s.str.rstrip('!.? \n\t')
0 1. Ant
1 2. Bee
2 3. Cat
3 NaN
dtype: object

>>> s.str.strip('123.!! \n\t')
0 Ant
(continues on next page)```
1 Bee
2 Cat
3 NaN
dtype: object

**pandas.Series.str.match**

`Series.str.match(pat, case=True, flags=0, na=None)`

Determine if each string starts with a match of a regular expression.

**Parameters**

- **pat** [str] Character sequence or regular expression.
- **case** [bool, default True] If True, case sensitive.
- **flags** [int, default 0 (no flags)] Regex module flags, e.g. `re.IGNORECASE`.
- **na** [scalar, optional] Fill value for missing values. The default depends on dtype of the array. For object-dtype, `numpy.nan` is used. For `StringDtype`, `pandas.NA` is used.

**Returns**

Series/Index/array of boolean values

**See also:**
- `fullmatch` Stricter matching that requires the entire string to match.
- `contains` Analogous, but less strict, relying on `re.search` instead of `re.match`.
- `extract` Extract matched groups.

**pandas.Series.str.normalize**

`Series.str.normalize(form)`

Return the Unicode normal form for the strings in the Series/Index.

For more information on the forms, see the `unicodedata.normalize()`.

**Parameters**

**Returns**

normalized [Series/Index of objects]

**pandas.Series.str.pad**

`Series.str.pad(width, side=’left’, fillchar=’ ‘)`

Pad strings in the Series/Index up to width.

**Parameters**

- **width** [int] Minimum width of resulting string; additional characters will be filled with character defined in `fillchar`.
- **side** [{‘left’, ‘right’, ‘both’}, default ‘left’] Side from which to fill resulting string.
- **fillchar** [str, default ‘ ‘] Additional character for filling, default is whitespace.

**Returns**
Series or Index of object  Returns Series or Index with minimum number of char in object.

See also:

Series.str.rjust  Fills the left side of strings with an arbitrary character. Equivalent to Series.str.pad(side='left').
Series.str.ljust  Fills the right side of strings with an arbitrary character. Equivalent to Series.str.pad(side='right').
Series.str.center  Fills both sides of strings with an arbitrary character. Equivalent to Series.str.pad(side='both').
Series.str.zfill  Pad strings in the Series/Index by prepending ‘0’ character. Equivalent to Series.str.pad(side='left', fillchar='0').

Examples

```python
>>> s = pd.Series(['caribou', 'tiger'])
>>> s
0  caribou
1   tiger
dtype: object

>>> s.str.pad(width=10)
0    caribou
1     tiger
dtype: object

>>> s.str.pad(width=10, side='right', fillchar='-')
0  caribou--
1    tiger--
dtype: object

>>> s.str.pad(width=10, side='both', fillchar='-')
0  -caribou--
1     --tiger
dtype: object
```

pandas.Series.str.partition

Series.str.partition(sep=' ', expand=True)

Split the string at the first occurrence of sep.

This method splits the string at the first occurrence of sep, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing the string itself, followed by two empty strings.

Parameters

- sep [str, default whitespace] String to split on.
- expand [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality. If False, return Series/Index.

Returns

DataFrame/MultiIndex or Series/Index of objects

See also:

rpartition  Split the string at the last occurrence of sep.
**Series.str.split** Split strings around given separators.

**str.partition** Standard library version.

### Examples

```python
def s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
s
0   Linda van der Berg
1   George Pitt-Rivers
dtype: object

>>> s.str.partition()
    0  1  2
0  Linda  van der Berg
1  George  Pitt-Rivers

To partition by the last space instead of the first one:

```python
>>> s.str.rpartition()
    0  1  2
0  Linda    van der Berg
1  George   Pitt-Rivers
```

To partition by something different than a space:

```python
>>> s.str.partition('-')
    0  1  2
0  Linda van der Berg
1  George Pitt - Rivers
```

To return a Series containing tuples instead of a DataFrame:

```python
>>> s.str.partition('-', expand=False)
0 (Linda van der Berg, , )
1 (George Pitt, -, Rivers)
dtype: object
```

Also available on indices:

```python
>>> idx = pd.Index(['X 123', 'Y 999'])
```

```python
>>> idx
Index(['X 123', 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```python
>>> idx.str.partition()
MultiIndex([('X', ' ', '123'),
            ('Y', ' ', '999')],
           )
```

Or an index with tuples with expand=False:

```python
>>> idx.str.partition(expand=False)
Index([('X', ' ', '123'), ('Y', ' ', '999')], dtype='object')
```
pandas.Series.str.repeat

Series.str.repeat(repeats)
Duplicate each string in the Series or Index.

Parameters

- repeats [int or sequence of int] Same value for all (int) or different value per (sequence).

Returns

Series or Index of object Series or Index of repeated string objects specified by input parameter repeats.

Examples

```python
gs = pd.Series(['a', 'b', 'c'])
gs
0    a
1    b
2    c
dtype: object

Single int repeats string in Series
```  
```python
>>> gs.str.repeat(repeats=2)
0  aa
1  bb
2  cc
dtype: object
```

Sequence of int repeats corresponding string in Series
```python
>>> gs.str.repeat(repeats=[1, 2, 3])
0   a
1  bb
2  ccc
dtype: object
```

pandas.Series.str.replace

Series.str.replace(pat, repl, n=-1, case=None, flags=0, regex=None)
Replace each occurrence of pattern/regex in the Series/Index.

Equivalent to str.replace() or re.sub(), depending on the regex value.

Parameters

- pat [str or compiled regex] String can be a character sequence or regular expression.
- repl [str or callable] Replacement string or a callable. The callable is passed the regex match object and must return a replacement string to be used. See re.sub().
- n [int, default -1 (all)] Number of replacements to make from start.
- case [bool, default None] Determines if replace is case sensitive:
  - If True, case sensitive (the default if pat is a string)
  - Set to False for case insensitive
- Cannot be set if `pat` is a compiled regex.

**flags** [int, default 0 (no flags)] Regex module flags, e.g. re.IGNORECASE. Cannot be set if `pat` is a compiled regex.

**regex** [bool, default True] Determines if the passed-in pattern is a regular expression:

- If True, assumes the passed-in pattern is a regular expression.
- If False, treats the pattern as a literal string
- Cannot be set to False if `pat` is a compiled regex or `repl` is a callable.

New in version 0.23.0.

**Returns**

**Series or Index of object** A copy of the object with all matching occurrences of `pat` replaced by `repl`.

**Raises**

**ValueError**

- if `regex` is False and `repl` is a callable or `pat` is a compiled regex
- if `pat` is a compiled regex and `case` or `flags` is set

**Notes**

When `pat` is a compiled regex, all flags should be included in the compiled regex. Use of `case`, `flags`, or `regex=False` with a compiled regex will raise an error.

**Examples**

When `pat` is a string and `regex` is True (the default), the given `pat` is compiled as a regex. When `repl` is a string, it replaces matching regex patterns as with `re.sub()`. NaN value(s) in the Series are left as is:

```python
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f.', 'ba', regex=True)
0   bao
1  baz
2  NaN
dtype: object
```

When `pat` is a string and `regex` is False, every `pat` is replaced with `repl` as with `str.replace()`:

```python
>>> pd.Series(['f.o', 'fuz', np.nan]).str.replace('f.', 'ba', regex=False)
0   bao
1  fuz
2  NaN
dtype: object
```

When `repl` is a callable, it is called on every `pat` using `re.sub()`. The callable should expect one positional argument (a regex object) and return a string.

To get the idea:
pandas: powerful Python data analysis toolkit, Release 1.3.2

>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f', repr, regex=True)
0
<re.Match object; span=(0, 1), match='f'>oo
1
<re.Match object; span=(0, 1), match='f'>uz
2
NaN
dtype: object

Reverse every lowercase alphabetic word:
>>> repl = lambda m: m.group(0)[::-1]
>>> ser = pd.Series(['foo 123', 'bar baz', np.nan])
>>> ser.str.replace(r'[a-z]+', repl, regex=True)
0
oof 123
1
rab zab
2
NaN
dtype: object

Using regex groups (extract second group and swap case):
>>> pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"
>>> repl = lambda m: m.group('two').swapcase()
>>> ser = pd.Series(['One Two Three', 'Foo Bar Baz'])
>>> ser.str.replace(pat, repl, regex=True)
0
tWO
1
bAR
dtype: object

Using a compiled regex with flags
>>> import re
>>> regex_pat = re.compile(r'FUZ', flags=re.IGNORECASE)
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace(regex_pat, 'bar', regex=True)
0
foo
1
bar
2
NaN
dtype: object

pandas.Series.str.rfind
Series.str.rfind(sub, start=0, end=None)
Return highest indexes in each strings in the Series/Index.
Each of returned indexes corresponds to the position where the substring is fully contained between [start:end].
Return -1 on failure. Equivalent to standard str.rfind().
Parameters
sub [str] Substring being searched.
start [int] Left edge index.
end [int] Right edge index.
Returns
Series or Index of int.
See also:
find Return lowest indexes in each strings.

1422

Chapter 3. API reference


pandas.Series.str.rindex

Series.str.rindex(sub, start=0, end=None)
Return highest indexes in each string in Series/Index.

Each of the returned indexes corresponds to the position where the substring is fully contained between [start:end]. This is the same as str.rfind except instead of returning -1, it raises a ValueError when the substring is not found. Equivalent to standard str.rindex.

Parameters
- sub [str] Substring being searched.
- start [int] Left edge index.
- end [int] Right edge index.

Returns
- Series or Index of object

See also:
- index Return lowest indexes in each strings.

pandas.Series.str.rjust

Series.str.rjust(width, fillchar=' ')
Pad left side of strings in the Series/Index.

Equivalent to str.rjust().

Parameters
- width [int] Minimum width of resulting string; additional characters will be filled with fillchar.
- fillchar [str] Additional character for filling, default is whitespace.

Returns
- filled [Series/Index of objects.]

pandas.Series.str.rpartition

Series.str.rpartition(sep=' ', expand=True)
Split the string at the last occurrence of sep.

This method splits the string at the last occurrence of sep, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing two empty strings, followed by the string itself.

Parameters
- sep [str, default whitespace] String to split on.
- expand [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality. If False, return Series/Index.

Returns
- DataFrame/MultiIndex or Series/Index of objects

See also:
- partition Split the string at the first occurrence of sep.
Series.str.split  Split strings around given separators.
str.partition  Standard library version.

Examples

```python
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0  Linda van der Berg
1   George Pitt-Rivers
dtype: object

>>> s.str.partition()
 0 1 2
0 Linda van der Berg
1   George Pitt-Rivers

To partition by the last space instead of the first one:

```python
>>> s.str.rpartition()
 0 1 2
0 Linda van der Berg
1   George Pitt-Rivers
```  

To partition by something different than a space:

```python
>>> s.str.partition('-')
 0 1 2
0 Linda van der Berg
1  George Pitt- Rivers
```  

To return a Series containing tuples instead of a DataFrame:

```python
>>> s.str.partition('-', expand=False)
0 1 2
0 (Linda van der Berg, , )
1 (George Pitt, -, Rivers)
```

dtype: object

Also available on indices:

```python
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')

Which will create a MultiIndex:

```python
>>> idx.str.partition()
MultiIndex([('X', ' ', '123'),
            ('Y', ' ', '999')],
           )
```  

Or an index with tuples with expand=False:

```python
>>> idx.str.partition(expand=False)
Index([('X', ' ', '123'), ('Y', ' ', '999')], dtype='object')
```
pandas.Series.str.rstrip

Series.str.rstrip(to_strip=None)
Remove trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from right side. Equivalent to str.rstrip().

Parameters

to_strip [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

Returns

Series or Index of object

See also:

Series.str.strip Remove leading and trailing characters in Series/Index.
Series.str.lstrip Remove leading characters in Series/Index.
Series.str.rstrip Remove trailing characters in Series/Index.

Examples

```python
>>> s = pd.Series(['1. Ant. ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0    1. Ant.
1    2. Bee!\n2    3. Cat?\t
3      NaN
dtype: object

>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3      NaN
dtype: object

>>> s.str.lstrip('123.\n\t')
0    Ant.
1    Bee!\n2    Cat?\t
3      NaN
dtype: object

>>> s.str.rstrip('.!? \n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3      NaN
dtype: object

>>> s.str.strip('123.!? \n\t')
0    Ant
```

(continues on next page)
pandas.Series.str.slice

Series.str.slice\(\texttt{\{start=None, stop=None, step=None\}}\)
Slice substrings from each element in the Series or Index.

**Parameters**

- **start** [int, optional] Start position for slice operation.
- **stop** [int, optional] Stop position for slice operation.
- **step** [int, optional] Step size for slice operation.

**Returns**

Series or Index of object Series or Index from sliced substring from original string object.

**See also:**

- *Series.str.slice_replace* Replace a slice with a string.
- *Series.str.get* Return element at position. Equivalent to \(\texttt{Series.str.slice(start=i, stop=i+1)}\) with \(i\) being the position.

**Examples**

```python
>>> s = pd.Series(["koala", "dog", "chameleon"])
>>> s
0   koala
1     dog
2  chameleon
dtype: object

>>> s.str.slice(start=1)
0  oala
1   og
2  hameleon
dtype: object

>>> s.str.slice(start=-1)
0    a
1    g
2   n
dtype: object

>>> s.str.slice(stop=2)
0   ko
1     do
2       ch
dtype: object
```
```python
>>> s.str.slice(step=2)
0   kaa
1    dg
2  caeen
    dtype: object
```

```python
>>> s.str.slice(start=0, stop=5, step=3)
0   kl
1    d
2   cm
    dtype: object
```

**Equivalent behaviour to:**

```python
>>> s.str[0:5:3]
0   kl
1    d
2   cm
    dtype: object
```

### pandas.Series.str.slice_replace

`Series.str.slice_replace(start=None, stop=None, repl=None)`

Replace a positional slice of a string with another value.

**Parameters**

- `start` [int, optional] Left index position to use for the slice. If not specified (None), the slice is unbounded on the left, i.e. slice from the start of the string.
- `stop` [int, optional] Right index position to use for the slice. If not specified (None), the slice is unbounded on the right, i.e. slice until the end of the string.
- `repl` [str, optional] String for replacement. If not specified (None), the sliced region is replaced with an empty string.

**Returns**

Series or Index Same type as the original object.

**See also:**

- `Series.str.slice` Just slicing without replacement.

**Examples**

```python
>>> s = pd.Series(['a', 'ab', 'abc', 'abdc', 'abcde'])
>>> s
0   a
1   ab
2   abc
3  abdc
4  abcde
    dtype: object
```

Specify just `start`, meaning replace `start` until the end of the string with `repl`. 

### pandas: powerful Python data analysis toolkit, Release 1.3.2

#### Series.str.slice_replace

```python
>>> s.str.slice_replace(1, repl='X')
0  aX
1  aX
2  aX
3  aX
4  aX
dtype: object
```

Specify just `stop`, meaning the start of the string to `stop` is replaced with `repl`, and the rest of the string is included.

```python
>>> s.str.slice_replace(stop=2, repl='X')
0  X
1  X
2  Xc
3  Xdc
4  Xcde
dtype: object
```

Specify `start` and `stop`, meaning the slice from `start` to `stop` is replaced with `repl`. Everything before or after `start` and `stop` is included as is.

```python
>>> s.str.slice_replace(start=1, stop=3, repl='X')
0  aX
1  aX
2  aX
3  aXc
4  aXde
dtype: object
```

#### pandas.Series.str.split

Series.str.split(pat=None, n=-1, expand=False)

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the beginning, at the specified delimiter string. Equivalent to `str.split()`.

**Parameters**

- `pat` [str, optional] String or regular expression to split on. If not specified, split on whitespace.
- `n` [int, default -1 (all)] Limit number of splits in output. None, 0 and -1 will be interpreted as return all splits.
- `expand` [bool, default False] Expand the split strings into separate columns.
  - If `True`, return DataFrame/MultiIndex expanding dimensionality.
  - If `False`, return Series/Index, containing lists of strings.

**Returns**

Series, Index, DataFrame or MultiIndex  Type matches caller unless `expand=True` (see Notes).

**See also:**

- `Series.str.split` Split strings around given separator/delimiter.
- `Series.str.rsplit` Splits string around given separator/delimiter, starting from the right.
- `Series.str.join` Join lists contained as elements in the Series/Index with passed delimiter.
str.split Standard library version for split.
str.rsplit Standard library version for rsplit.

Notes

The handling of the $n$ keyword depends on the number of found splits:

- If found splits > $n$, make first $n$ splits only
- If found splits <= $n$, make all splits
- If for a certain row the number of found splits < $n$, append None for padding up to $n$ if expand=True

If using expand=True, Series and Index callers return DataFrame and MultiIndex objects, respectively.

Examples

```python
>>> s = pd.Series(
...     [            
...         "this is a regular sentence",  
...         "https://docs.python.org/3/tutorial/index.html",  
...         np.nan
...     ]
... )
>>> s
0    this is a regular sentence
1    https://docs.python.org/3/tutorial/index.html
2      NaN
dtype: object

In the default setting, the string is split by whitespace.

```python
>>> s.str.split()
0    [this, is, a, regular, sentence]
1    [https://docs.python.org/3/tutorial/index.html]
2        NaN
dtype: object
```

Without the $n$ parameter, the outputs of rsplit and split are identical.

```python
>>> s.str.rsplit()
0    [this, is, a, regular, sentence]
1    [https://docs.python.org/3/tutorial/index.html]
2        NaN
dtype: object
```

The $n$ parameter can be used to limit the number of splits on the delimiter. The outputs of split and rsplit are different.

```python
>>> s.str.split(n=2)
0    [this, is a regular sentence]
1    [https://docs.python.org/3/tutorial/index.html]
2        NaN
dtype: object

>>> s.str.rsplit(n=2)
0    [this is a, regular, sentence]
1    [https://docs.python.org/3/tutorial/index.html]
```
(continues on next page)
The `pat` parameter can be used to split by other characters.

```python
>>> s.str.split(pat="/\")
0 [this is a regular sentence]
1 [https:, , docs.python.org, 3, tutorial, index...
2 NaN
dtype: object
```

When using `expand=True`, the split elements will expand out into separate columns. If NaN is present, it is propagated throughout the columns during the split.

```python
>>> s.str.split(expand=True)
0 1 2 3 4
0 this is a regular sentence None None None None
1 https://docs.python.org/3/tutorial/index.html None None None None
2 NaN NaN NaN NaN NaN
```

For slightly more complex use cases like splitting the html document name from a url, a combination of parameter settings can be used.

```python
>>> s.str.rsplit("/\", n=1, expand=True)
0 1
0 this is a regular sentence None
1 https://docs.python.org/3/tutorial index.html
2 NaN NaN
```

Remember to escape special characters when explicitly using regular expressions.

```python
>>> s = pd.Series(["1+1=2"])
>>> s
0 1+1=2
dtype: object
>>> s.str.split(r\"\+|=\", expand=True)
0 1 2
0 1 1 2
```

**pandas.Series.str.rsplit**

Series.str.rsplit \(\text{pat=}_\text{None}, n=-1, \text{expand=False}\)

Splits the string in the Series/Index from the end, at the specified delimiter string. Equivalent to `str.rsplit()`.

**Parameters**

- \text{pat} \ [\text{str, optional}] \ String or regular expression to split on. If not specified, split on whitespace.
- \text{n} \ [\text{int, default -1 (all)}] \ Limit number of splits in output. None, 0 and -1 will be interpreted as return all splits.
- \text{expand} \ [\text{bool, default False}] \ Expand the split strings into separate columns.
  - If True, return DataFrame/MultiIndex expanding dimensionality.
• If False, return Series/Index, containing lists of strings.

Returns

Series, Index, DataFrame or MultiIndex  Type matches caller unless expand=True (see Notes).

See also:

Series.str.split  Split strings around given separator/delimiter.
Series.str.rsplit  Splits string around given separator/delimiter, starting from the right.
Series.str.join  Join lists contained as elements in the Series/Index with passed delimiter.
str.split  Standard library version for split.
str.rsplit  Standard library version for rsplit.

Notes

The handling of the $n$ keyword depends on the number of found splits:

- If found splits > $n$, make first $n$ splits only
- If found splits <= $n$, make all splits
- If for a certain row the number of found splits < $n$, append None for padding up to $n$ if expand=True

If using expand=True, Series and Index callers return DataFrame and MultiIndex objects, respectively.

Examples

```python
>>> s = pd.Series(
...     [  
...         "this is a regular sentence",
...         "https://docs.python.org/3/tutorial/index.html",
...         np.nan
...     ]
... )
>>> s
0   this is a regular sentence
1   https://docs.python.org/3/tutorial/index.html
2     NaN
dtype: object

In the default setting, the string is split by whitespace.

```python
>>> s.str.split()
0      [this, is, a, regular, sentence]
1      [https://docs.python.org/3/tutorial/index.html]
2      NaN
dtype: object

Without the $n$ parameter, the outputs of rsplit and split are identical.

```python
>>> s.str.rsplit()
0      [this, is, a, regular, sentence]
1      [https://docs.python.org/3/tutorial/index.html]
2      NaN
dtype: object

The $n$ parameter can be used to limit the number of splits on the delimiter. The outputs of split and rsplit are different.
```

The `pat` parameter can be used to split by other characters.

When using `expand=True`, the split elements will expand out into separate columns. If NaN is present, it is propagated throughout the columns during the split.

For slightly more complex use cases like splitting the html document name from a url, a combination of parameter settings can be used.

Remember to escape special characters when explicitly using regular expressions.
pandas.Series.str.startswith

Series.str.startswith(pat, na=None)
Test if the start of each string element matches a pattern.

Equivalent to str.startswith().

Parameters

- pat [str] Character sequence. Regular expressions are not accepted.
- na [object, default NaN] Object shown if element tested is not a string. The default depends
  on dtype of the array. For object-dtype, numpy.nan is used. For StringDtype, pandas.NA is used.

Returns

Series or Index of bool  A Series of booleans indicating whether the given pattern matches
the start of each string element.

See also:

str.startswith  Python standard library string method.
Series.str.endswith  Same as startswith, but tests the end of string.
Series.str.contains  Tests if string element contains a pattern.

Examples

```python
>>> s = pd.Series(['bat', 'Bear', 'cat', np.nan])
>>> s
0    bat
1    Bear
2    cat
3     NaN
dtype: object

>>> s.str.startswith('b')
0   True
1   False
2   False
3    NaN
dtype: object

Specifying na to be False instead of NaN.
```

```python
>>> s.str.startswith('b', na=False)
0   False
1   False
2   False
3    NaN
dtype: bool
```
Series.str.strip

Series.str.strip(to_strip=None)
Remove leading and trailing characters.
Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left and right sides. Equivalent to `str.strip()`.

Parameters

to_strip [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

Returns

Series or Index of object

See also:

Series.str.strip Remove leading and trailing characters in Series/Index.
Series.str.lstrip Remove leading characters in Series/Index.
Series.str.rstrip Remove trailing characters in Series/Index.

Examples

```python
>>> s = pd.Series(['1. Ant. ', '2. Bee!

[323x439]', '3. Cat?

[382x439]', np.nan])
>>> s
0 1. Ant.
1 2. Bee!
2 3. Cat?
3 NaN
dtype: object

>>> s.str.strip()
0 1. Ant.
1 2. Bee!
2 3. Cat?
3 NaN
dtype: object

>>> s.str.lstrip('123.')
0   Ant.
1  Bee!
2  Cat?
3   NaN
dtype: object

>>> s.str.rstrip('.!?

[237x183]

[393x183]')
0 1. Ant
1 2. Bee
2 3. Cat
3 NaN
dtype: object

>>> s.str.strip('123.?! 

[248x102]')
0   Ant
1   Bee
2   Cat
3   NaN
dtype: object
```
(continues on next page)
1 Bee
2 Cat
3 NaN
dtype: object

pandas.Series.str.swapcase

Series.str.swapcase()
Convert strings in the Series/Index to be swapcased.

Equivalent to str.swapcase().

Returns
Series or Index of object

See also:
Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold Removes all case distinctions in the string.

Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0 lower
1 CAPITALS
2 this is a sentence
3 SwApCaSe
dtype: object

>>> s.str.lower()
0 lower
1 capitals
2 this is a sentence
3 swapcase
dtype: object

>>> s.str.upper()
0 LOWER
1 CAPITALS
2 THIS IS A SENTENCE
3 SWAPCASE
dtype: object

>>> s.str.title()
0 Lower
1 Capitals
2 This Is A Sentence
3 Swapcase
dtype: object
```
pandas.Series.str.title

Series.str.title()

Convert strings in the Series/Index to titlecase.

Equivalent to str.title().

Returns

Series or Index of object

See also:

Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold Removes all case distinctions in the string.

Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCAsE'])
>>> s
0     lower
1   CAPITALS
2  this is a sentence
3  SwApCAsE
dtype: object
```
```python
>>> s.str.lower()
0    lower
1  capitals
2  this is a sentence
3  swapcase
dtype: object
```
```python
>>> s.str.upper()
0    LOWER
1   CAPITALS
2  THIS IS A SENTENCE
3  sWaPcAsE
```

(continues on next page)
pandas.Series.str.translate

Series.str.**translate**(table)
Map all characters in the string through the given mapping table.

Equivalent to standard **str.translate()**.

**Parameters**

*table* [dict] Table is a mapping of Unicode ordinals to Unicode ordinals, strings, or None. Unmapped characters are left untouched. Characters mapped to None are deleted.

**str.maketrans()** is a helper function for making translation tables.

**Returns**

Series or Index

pandas.Series.str.upper

Series.str.**upper**()
Convert strings in the Series/Index to uppercase.

Equivalent to **str.upper()**.

**Returns**

Series or Index of object

See also:

**Series.str.lower** Converts all characters to lowercase.
**Series.str.upper** Converts all characters to uppercase.
**Series.str.title** Converts first character of each word to uppercase and remaining to lowercase.
**Series.str.capitalize** Converts first character to uppercase and remaining to lowercase.

**Series.str.swapcase** Converts uppercase to lowercase and lowercase to uppercase.

**Series.str.casefold** Removes all case distinctions in the string.

### Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])

>>> s
0    lower
1   CAPITALS
2    this is a sentence
3   SwApCaSe
dtype: object

>>> s.str.lower()
0    lower
1     capitals
2    this is a sentence
3     swapcase
dtype: object

>>> s.str.upper()
0    LOWER
1   CAPITALS
2     THIS IS A SENTENCE
3     SWAPCASE
dtype: object

>>> s.str.title()
0       Lower
1     Capitals
2    This Is A Sentence
3    Swapcase
dtype: object

>>> s.str.capitalize()
0      Lower
1     Capitals
2    This is a sentence
3     Swapcase
dtype: object

>>> s.str.swapcase()
0       LOWER
1     Capitals
2     THIS IS A SENTENCE
3    SwApCaSe
dtype: object
```
pandas.Series.str.wrap

Series.str.

Wrap strings in Series/Index at specified line width.

Parameters

- **width** [int] Maximum line width.
- **expand_tabs** [bool, optional] If True, tab characters will be expanded to spaces (default: True).
- **replace_whitespace** [bool, optional] If True, each whitespace character (as defined by string.whitespace) remaining after tab expansion will be replaced by a single space (default: True).
- **drop_whitespace** [bool, optional] If True, whitespace that, after wrapping, happens to end up at the beginning or end of a line is dropped (default: True).
- **break_long_words** [bool, optional] If True, then words longer than width will be broken in order to ensure that no lines are longer than width. If it is false, long words will not be broken, and some lines may be longer than width (default: True).
- **break_on_hyphens** [bool, optional] If True, wrapping will occur preferably on whitespace and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set break_long_words to false if you want truly inseparable words (default: True).

Returns

Series or Index

Notes

Internally, this method uses a textwrap.TextWrapper instance with default settings. To achieve behavior matching R’s stringr library str_wrap function, use the arguments:

- expand_tabs = False
- replace_whitespace = True
- drop_whitespace = True
- break_long_words = False
- break_on_hyphens = False

Examples

```python
>>> s = pd.Series(['line to be wrapped', 'another line to be wrapped'])
>>> s.str.wrap(12)
0    line to be\nwrapped
1   another line\nnot be\nwrapped
dtype: object
```
**pandas.Series.str.zfill**

Series.str.zfill(width)

Pad strings in the Series/Index by prepending '0' characters.

Strings in the Series/Index are padded with '0' characters on the left of the string to reach a total string length `width`. Strings in the Series/Index with length greater or equal to `width` are unchanged.

**Parameters**

- **width** [int] Minimum length of resulting string; strings with length less than `width` be prepended with '0' characters.

**Returns**

Series/Index of objects.

**See also:**

- `Series.str.rjust` Fills the left side of strings with an arbitrary character.
- `Series.str.ljust` Fills the right side of strings with an arbitrary character.
- `Series.str.pad` Fills the specified sides of strings with an arbitrary character.
- `Series.str.center` Fills both sides of strings with an arbitrary character.

**Notes**

Diffsers from `str.zfill()` which has special handling for '+'/-' in the string.

**Examples**

```python
>>> s = pd.Series(['-1', '1', '1000', 10, np.nan])
>>> s
0   -1
1    1
2  1000
3    10
4  NaN
```

Note that 10 and NaN are not strings, therefore they are converted to NaN. The minus sign in '-1' is treated as a regular character and the zero is added to the left of it (`str.zfill()` would have moved it to the left). 1000 remains unchanged as it is longer than `width`.

```python
>>> s.str.zfill(3)
0   0-1
1   001
2  1000
3    NaN
4    NaN
```
pandas.Series.str.isalnum

Series.str.isalnum()
Check whether all characters in each string are alphanumeric.

This is equivalent to running the Python string method str.isalnum() for each element of the Series/Index. If a string has zero characters, False is returned for that check.

Returns
Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:
Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
  0   True
  1  False
  2  False
  3  False
  dtype: bool

>>> s1.str.isnumeric()
  0  False
  1  False
  2   True
  3  False
  dtype: bool

>>> s1.str.isalnum()
  0   True
  1   True
  2   True
  3  False
  dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>>
```

(continues on next page)
More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0   True
1   False
2   False
3   False
dtype: bool
```

The `s3.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0   True
1   True
2   False
3   False
dtype: bool
```

The `s3.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0   True
1   True
2   False
3   False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '\t\r\n ', ''])
>>> s4.str.isspace()
0   True
1   True
2   False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
0   True
1   False
```

(continues on next page)
pandas.Series.str.isupper

The `s5.str.isupper()` method checks for whether all letters are uppercase (whether only the first letter of each word is capitalized). Words are assumed to be any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.isupper()
0    False
1    False
2      True
3    False
dtype: bool
```

pandas.Series.str.isalpha

Series.str.isalpha()

Check whether all characters in each string are alphabetic.

This is equivalent to running the Python string method `str.isalpha()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.
Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0    False
1   False
2    True
3   False
dtype: bool

>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])

The s3.str.isdecimal method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool

The s.str.isdigit method is the same as s3.str.isdecimal but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
```
The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

### Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\n', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

### Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])

>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```python
>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0    False
1    True
2    False
3    False
dtype: bool
```
pandas.Series.str.isdigit

Series.str.isdigit()

Check whether all characters in each string are digits.

This is equivalent to running the Python string method `str.isdigit()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

- Series.str.isalpha Check whether all characters are alphabetic.
- Series.str.isnumeric Check whether all characters are numeric.
- Series.str.isalnum Check whether all characters are alphanumeric.
- Series.str.isdigit Check whether all characters are digits.
- Series.str.isdecimal Check whether all characters are decimal.
- Series.str.isspace Check whether all characters are whitespace.
- Series.str.islower Check whether all characters are lowercase.
- Series.str.isupper Check whether all characters are uppercase.
- Series.str.istitle Check whether all characters are titlecase.

**Examples**

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0    True  
1   False  
2   False  
3   False  
dtype: bool

>>> s1.str.isnumeric()
0   False  
1   False  
2    True  
3   False  
dtype: bool

>>> s1.str.isalnum()
0    True  
1    True  
2    True  
3   False  
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
```

(continues on next page)
More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0   True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0   True
1   True
2   False
3   False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0   True
1   True
2   True
3   False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\r\n ', ''])
>>> s4.str.isspace()
0   True
1   True
2   False
3   False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```python
>>> s5.str.islower()
0   True
1   False
```
The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

pandas.Series.str.isspace

Series.str.isspace()  
Check whether all characters in each string are whitespace.

This is equivalent to running the Python string method `str.isspace()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

- `Series.str.isalpha`  Check whether all characters are alphabetic.
- `Series.str.isnumeric`  Check whether all characters are numeric.
- `Series.str.isalnum`  Check whether all characters are alphanumeric.
- `Series.str.isdigit`  Check whether all characters are digits.
- `Series.str.isdecimal`  Check whether all characters are decimal.
- `Series.str.isspace`  Check whether all characters are whitespace.
- `Series.str.islower`  Check whether all characters are lowercase.
- `Series.str.isupper`  Check whether all characters are uppercase.
- `Series.str.istitle`  Check whether all characters are titlecase.
Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool

>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '³', '', ''])

The s3.str.isdecimal method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The s.str.isdigit method is the same as s3.str.isdecimal but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
```

(continues on next page)
The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace

```
>>> s4 = pd.Series([' ', '	
', '
', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

Checks for Character Case

```
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```
>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0    False
1    True
2    False
3    False
dtype: bool
```
pandas.Series.str.islower

Series.str.islower()
Check whether all characters in each string are lowercase.

This is equivalent to running the Python string method \texttt{str.islower()} for each element of the Series/Index. If a string has zero characters, \texttt{False} is returned for that check.

\textbf{Returns}

- Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

\textbf{See also:}

- \texttt{Series.str.isalpha} Check whether all characters are alphabetic.
- \texttt{Series.str.isnumeric} Check whether all characters are numeric.
- \texttt{Series.str.isalnum} Check whether all characters are alphanumeric.
- \texttt{Series.str.isdigit} Check whether all characters are digits.
- \texttt{Series.str.isdecimal} Check whether all characters are decimal.
- \texttt{Series.str.isspace} Check whether all characters are whitespace.
- \texttt{Series.str.islower} Check whether all characters are lowercase.
- \texttt{Series.str.isupper} Check whether all characters are uppercase.
- \texttt{Series.str.istitle} Check whether all characters are titlecase.

\textbf{Examples}

Checks for Alphabetic and Numeric Characters

\begin{verbatim}
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0   True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2   True
3   False
dtype: bool

>>> s1.str.isalnum()
0   True
1   True
2   True
3   False
dtype: bool
\end{verbatim}

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

\begin{verbatim}
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
0   False
1   False
2   True
3   False
\end{verbatim}
More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
1    True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])

```python
>>> s5.str.islower()
0    True
1    False
dtype: bool
```
The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0   False
1    True
2   False
3   False
dtype: bool
```

### pandas.Series.str.isupper

`Series.str.isupper()` checks whether all characters in each string are uppercase.

- **Check**: This is equivalent to running the Python string method `str.isupper()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

- **Returns**: Series or Index of boolean values with the same length as the original Series/Index.

- **See also**:
  - `Series.str.isalpha` Check whether all characters are alphabetic.
  - `Series.str.isnumeric` Check whether all characters are numeric.
  - `Series.str.isalnum` Check whether all characters are alphanumeric.
  - `Series.str.isdigit` Check whether all characters are digits.
  - `Series.str.isdecimal` Check whether all characters are decimal.
  - `Series.str.isspace` Check whether all characters are whitespace.
  - `Series.str.islower` Check whether all characters are lowercase.
  - `Series.str.isupper` Check whether all characters are uppercase.
  - `Series.str.istitle` Check whether all characters are titlecase.
Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0   True
1  False
2  False
3  False
dtype: bool

>>> s1.str.isnumeric()
0   False
1  False
2   True
3  False
dtype: bool

>>> s1.str.isalnum()
0   True
1   True
2   True
3  False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
0  False
1  False
2  False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '²', '', ''])

The s3.str.isdecimal method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0   True
1  False
2  False
3  False
dtype: bool
```

The s.str.isdigit method is the same as s3.str.isdecimal but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0   True
```
<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>True</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>False</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>False</td>
<td></td>
</tr>
</tbody>
</table>

dtype: bool

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0   True
1   True
2   True
3  False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	
',''])
>>> s4.str.isspace()
0   True
1   True
2   False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
0   True
1  False
2  False
3  False
dtype: bool
```

```python
>>> s5.str.isupper()
0  False
1  False
2   True
3  False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0  False
1   True
2  False
3  False
dtype: bool
```
**pandas.Series.str.istitle**

Series.str.istitle()

Check whether all characters in each string are titlecase.

This is equivalent to running the Python string method `str.istitle()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

*Series or Index of bool*  Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

Series.str.isalpha  Check whether all characters are alphabetic.
Series.str.isnumeric  Check whether all characters are numeric.
Series.str.isalnum  Check whether all characters are alphanumeric.
Series.str.isdigit  Check whether all characters are digits.
Series.str.isdecimal  Check whether all characters are decimal.
Series.strisspace  Check whether all characters are whitespace.
Series.str.islower  Check whether all characters are lowercase.
Series.str.isupper  Check whether all characters are uppercase.
Series.str.istitle  Check whether all characters are titlecase.

**Examples**

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
 dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
 dtype: bool

>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
 dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
```

(continues on next page)
More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0   True
1   False
2   False
3   False
dtype: bool
```

The `s3.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0   True
1   True
2   False
3   False
dtype: bool
```

The `s3.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0   True
1   True
2   True
3   False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\r\n ', ''])
```

```python
>>> s4.str.isspace()
0   True
1   True
2   False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```python
>>> s5.str.islower()
0   True
1   False
```

(continues on next page)
The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0   False
1    True
2   False
3   False
dtype: bool
```

**pandas.Series.str.isnumeric**

`Series.str.isnumeric()` Check whether all characters in each string are numeric.

This is equivalent to running the Python string method `str.isnumeric()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- `Series.str.isalpha` Check whether all characters are alphabetic.
- `Series.str.isnumeric` Check whether all characters are numeric.
- `Series.str.isalnum` Check whether all characters are alphanumeric.
- `Series.str.isdigit` Check whether all characters are digits.
- `Series.str.isdecimal` Check whether all characters are decimal.
- `Series.str.isspace` Check whether all characters are whitespace.
- `Series.str.islower` Check whether all characters are lowercase.
- `Series.str.isupper` Check whether all characters are uppercase.
- `Series.str.istitle` Check whether all characters are title case.
Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

``` exa

```python
>>> s1.str.isalpha()
0   True
1  False
2  False
3  False
dtype: bool
```

```python
>>> s1.str.isnumeric()
0  False
1  False
2   True
3  False
dtype: bool
```

```python
>>> s1.str.isalnum()
0   True
1   True
2   True
3  False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
```

```python
>>> s2.str.isalnum()
0  False
1  False
2  False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])
```

```python
>>> s3.str.isdecimal()
0   True
1  False
2  False
3  False
dtype: bool
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0   True
1  False
2  False
3  False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0   True
```

(continues on next page)
The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\n', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])

>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool

>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0    False
1    True
2    False
3    False
dtype: bool
```
pandas.Series.str.isdecimal

Series.str.isdecimal()
Check whether all characters in each string are decimal.

This is equivalent to running the Python string method str.isdecimal() for each element of the Series/Index. If a string has zero characters, False is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```python
>>> s1.str.isalpha()
0     True
1    False
2    False
3    False
dtype: bool
```

```python
>>> s1.str.isnumeric()
0    False
1    False
2     True
3    False
dtype: bool
```

```python
>>> s1.str.isalnum()
0     True
1     True
2     True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
```

```python
>>> s2.str.isalnum()
(continues on next page)
```
More Detailed Checks for Numeric Characters

>>> s5.str.isupper()
0 False
1 False
2 True
3 False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0 False
1 True
2 False
3 False
dtype: bool
```

### pandas.Series.str.get_dummies

#### Series.str.get_dummies(sep='|')

Return DataFrame of dummy/indicator variables for Series.

Each string in Series is split by `sep` and returned as a DataFrame of dummy/indicator variables.

**Parameters**

- `sep` [str, default “|”] String to split on.

**Returns**

- `DataFrame` Dummy variables corresponding to values of the Series.

**See also:**

- `get_dummies` Convert categorical variable into dummy/indicator variables.

**Examples**

```python
>>> pd.Series(['a|b', 'a', 'a|c']).str.get_dummies()
a  b  c
0  1  1  0
1  1  0  0
2  1  0  1
```

```python
>>> pd.Series(['a|b', np.nan, 'a|c']).str.get_dummies()
a  b  c
0  1  1  0
1  0  0  0
2  1  0  1
```
Categorical accessor

Categorical-dtype specific methods and attributes are available under the `Series.cat` accessor.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.cat.categories</code></td>
<td>The categories of this categorical.</td>
</tr>
<tr>
<td><code>Series.cat.ordered</code></td>
<td>Whether the categories have an ordered relationship.</td>
</tr>
<tr>
<td><code>Series.cat.codes</code></td>
<td>Return Series of codes as well as the index.</td>
</tr>
</tbody>
</table>

**pandas.Series.cat.categories**

The categories of this categorical.

- Setting assigns new values to each category (effectively a rename of each individual category).
- The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.
- Assigning to `categories` is an inplace operation!

**Raises**

- `ValueError` If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

**See also:**

- `rename_categories` Rename categories.
- `reorder_categories` Reorder categories.
- `add_categories` Add new categories.
- `remove_categories` Remove the specified categories.
- `remove_unused_categories` Remove categories which are not used.
- `set_categories` Set the categories to the specified ones.

**pandas.Series.cat.ordered**

Whether the categories have an ordered relationship.

**pandas.Series.cat.codes**

Return Series of codes as well as the index.

<table>

continues on next page
### pandas.Series.cat.rename_categories

*pandas.Series.cat.rename_categories(*args, **kwargs)*

**Renamed categories.**

**Parameters**

- **new_categories** [list-like, dict-like or callable] New categories which will replace old categories.
  - list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
  - dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.
  - callable: a callable that is called on all items in the old categories and whose return values comprise the new categories.

- **inplace** [bool, default False] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.
  
  Deprecated since version 1.3.0.

**Returns**

- **cat** [Categorical or None] Categorical with removed categories or None if inplace=True.

**Raises**

- **ValueError** If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories.

**See also:**

- reorder_categories Reorder categories.
- add_categories Add new categories.
- remove_categories Remove the specified categories.
- remove_unused_categories Remove categories which are not used.
- set_categories Set the categories to the specified ones.

**Examples**

```python
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like new_categories, extra keys are ignored and categories not in the dictionary are passed through

```python
>>> c.rename_categories({'a': 'A', 'c': 'C'})
['A', 'A', 'b']
Categories (2, object): ['A', 'b']
```

You may also provide a callable to create the new categories
```python
>>> c.rename_categories(lambda x: x.upper())
['A', 'A', 'B']
Categories (2, object): ['A', 'B']
```

### pandas.Series.cat.reorder_categories

```python
Series.cat.reorder_categories(*args, **kwargs)
```
Reorder categories as specified in `new_categories`.

- **new_categories** [Index-like] The categories in new order.
- **ordered** [bool, optional] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.
- **inplace** [bool, default False] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.
  
  Deprecated since version 1.3.0.

**Returns**

- **cat** [Categorical or None] Categorical with removed categories or None if `inplace=True`.

**Raises**

- **ValueError** If the new categories do not contain all old category items or any new ones

**See also:**

- **rename_categories** Rename categories.
- **add_categories** Add new categories.
- **remove_categories** Remove the specified categories.
- **remove_unused_categories** Remove categories which are not used.
- **set_categories** Set the categories to the specified ones.

### pandas.Series.cat.add_categories

```python
Series.cat.add_categories(*args, **kwargs)
```
Add new categories.

- **new_categories** will be included at the last/highest place in the categories and will be unused directly after this call.

**Parameters**

- **new_categories** [category or list-like of category] The new categories to be included.
- **inplace** [bool, default False] Whether or not to add the categories inplace or return a copy of this categorical with added categories.
  
  Deprecated since version 1.3.0.

**Returns**

- **cat** [Categorical or None] Categorical with new categories added or None if `inplace=True`.

**Raises**
ValueError  If the new categories include old categories or do not validate as categories

See also:

rename_categories  Rename categories.
reorder_categories  Reorder categories.
remove_categories  Remove the specified categories.
remove_unused_categories  Remove categories which are not used.
set_categories  Set the categories to the specified ones.

pandas.Series.cat.remove_categories

Series.cat.remove_categories(*args, **kwargs)
Remove the specified categories.

removals must be included in the old categories. Values which were in the removed categories will be set to NaN

Parameters

removals  [category or list of categories] The categories which should be removed.

inplace  [bool, default False] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

Deprecated since version 1.3.0.

Returns

cat  [Categorical or None] Categorical with removed categories or None if inplace=True.

Raises

ValueError  If the removals are not contained in the categories

See also:

rename_categories  Rename categories.
reorder_categories  Reorder categories.
add_categories  Add new categories.
remove_unused_categories  Remove categories which are not used.
set_categories  Set the categories to the specified ones.

pandas.Series.cat.remove_unused_categories

Series.cat.remove_unused_categories(*args, **kwargs)
Remove categories which are not used.

Parameters

inplace  [bool, default False] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

Deprecated since version 1.2.0.

Returns

cat  [Categorical or None] Categorical with unused categories dropped or None if inplace=True.

See also:

rename_categories  Rename categories.
reorder_categories  Reorder categories.
add_categories  Add new categories.
remove_categories  Remove the specified categories.
set_categories  Set the categories to the specified ones.

**pandas.Series.cat.set_categories**

```
Series.cat.set_categories(*args, **kwargs)
```

Set the categories to the specified new_categories.

new_categories can include new categories (which will result in unused categories) or remove old categories
(which results in values set to NaN). If rename==True, the categories will simple be renamed (less or more
items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously
and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this methods does not do checks (e.g., whether the old categories are included in the new
categories on a reorder), which can result in surprising changes, for example when using special string dtypes,
which does not considers a S1 string equal to a single char python string.

**Parameters**

- **new_categories**  [Index-like] The categories in new order.
- **ordered**  [bool, default False] Whether or not the categorical is treated as a ordered categori-
cal. If not given, do not change the ordered information.
- **rename**  [bool, default False] Whether or not the new_categories should be considered as a
rename of the old categories or as reordered categories.
- **inplace**  [bool, default False] Whether or not to reorder the categories in-place or return a
copy of this categorical with reordered categories.

Deprecated since version 1.3.0.

**Returns**

- Categorical with reordered categories or None if inplace.

**Raises**

- **ValueError**  If new_categories does not validate as categories

**See also:**

rename_categories  Rename categories.
reorder_categories  Reorder categories.
add_categories  Add new categories.
remove_categories  Remove the specified categories.
remove_unused_categories  Remove categories which are not used.
pandas.Series.cat.as_ordered

Series.cat.as_ordered(*args, **kwargs)
Set the Categorical to be ordered.

Parameters

    inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a
    copy of this categorical with ordered set to True.

Returns

    Categorical or None  Ordered Categorical or None if inplace=True.

pandas.Series.cat.as_unordered

Series.cat.as_unordered(*args, **kwargs)
Set the Categorical to be unordered.

Parameters

    inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a
    copy of this categorical with ordered set to False.

Returns

    Categorical or None  Unordered Categorical or None if inplace=True.

Sparse accessor

Sparse-dtype specific methods and attributes are provided under the Series.sparse accessor.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.sparse.npoints</td>
<td>The number of non-fill_value points.</td>
</tr>
<tr>
<td>Series.sparse.density</td>
<td>The percent of non-fill_value points, as decimal.</td>
</tr>
<tr>
<td>Series.sparse.fill_value</td>
<td>Elements in data that are fill_value are not stored.</td>
</tr>
<tr>
<td>Series.sparse.sp_values</td>
<td>An ndarray containing the non-fill_value values.</td>
</tr>
</tbody>
</table>

pandas.Series.sparse.npoints

Series.sparse.npoints
The number of non-fill_value points.
Examples

```python
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.npoints
3
```

```python
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.density
0.6
```

pandas.Series.sparse.density

Series.sparse.density
The percent of non-fill_value points, as decimal.

Examples

```python
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.density
0.6
```

pandas.Series.sparse.fill_value

Series.sparse.fill_value
Elements in data that are fill_value are not stored.

For memory savings, this should be the most common value in the array.

pandas.Series.sparse.sp_values

Series.sparse.sp_values
An ndarray containing the non-fill_value values.

Examples

```python
>>> s = SparseArray([0, 0, 1, 0, 2], fill_value=0)
>>> s.sp_values
array([1, 2])
```

### Series.sparse.from_coo

Create a Series with sparse values from a scipy.sparse.coo_matrix.

### Series.sparse.to_coo

Create a scipy.sparse.coo_matrix from a Series with MultiIndex.
**pandas.Series.sparse.from_coo**

**Classmethod** `Series.sparse.from_coo(A, dense_index=False)`

Create a Series with sparse values from a scipy.sparse.coo_matrix.

**Parameters**

- `A` [scipy.sparse.coo_matrix]
- `dense_index` [bool, default False] If False (default), the SparseSeries index consists of only the coords of the non-null entries of the original coo_matrix. If True, the SparseSeries index consists of the full sorted (row, col) coordinates of the coo_matrix.

**Returns**

- `s` [Series] A Series with sparse values.

**Examples**

```python
>>> from scipy import sparse

>>> A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])), shape=(3, 4))

>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>

>>> A.todense()
matrix([[ 0.,  0.,  1.,  2.],
        [ 3.,  0.,  0.,  0.],
        [ 0.,  0.,  0.,  0.]])

>>> ss = pd.Series.sparse.from_coo(A)

>>> ss
0 2 1.0
3 2.0
1 0 3.0
dtype: Sparse[Float64, nan]
```

**pandas.Series.sparse.to_coo**

`Series.sparse.to_coo(row_levels=(0), column_levels=(1), sort_labels=False)`

Create a scipy.sparse.coo_matrix from a Series with MultiIndex.

Use `row_levels` and `column_levels` to determine the row and column coordinates respectively. `row_levels` and `column_levels` are the names (labels) or numbers of the levels. `{row_levels, column_levels}` must be a partition of the MultiIndex level names (or numbers).

**Parameters**

- `row_levels` [tuple/list]
- `column_levels` [tuple/list]
- `sort_labels` [bool, default False] Sort the row and column labels before forming the sparse matrix.
Returns

- y (scipy.sparse.coo_matrix)
- rows (list (row labels))
- columns (list (column labels))

Examples

```python
>>> s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
>>> s.index = pd.MultiIndex.from_tuples(
...    [(1, 2, "a", 0),
...     (1, 2, "a", 1),
...     (1, 1, "b", 0),
...     (1, 1, "b", 1),
...     (2, 1, "b", 0),
...     (2, 1, "b", 1)],
...    names=["A", "B", "C", "D"],
...)
>>> s
A  B  C  D
1  2  a  0   3.0
    1   NaN
1  b  0  1.0
    1   3.0
2  1  b  0   NaN
    1   NaN
dtype: float64

>>> ss = s.astype("Sparse")
>>> ss
A  B  C  D
1  2  a  0   3.0
    1   NaN
1  b  0  1.0
    1   3.0
2  1  b  0   NaN
    1   NaN
dtype: Sparse[float64, nan]

>>> A, rows, columns = ss.sparse.to_coo(
...    row_levels=["A", "B"], column_levels=["C", "D"], sort_labels=True
...)
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format
>>> A.todense()
matrix([[0., 0., 1., 3.],
        [3., 0., 0., 0.],
        [0., 0., 0., 0.]])

>>> rows
[(1, 1), (1, 2), (2, 1)]
```

(continues on next page)
>>> columns
[('a', 0), ('a', 1), ('b', 0), ('b', 1)]

Flags

Flags refer to attributes of the pandas object. Properties of the dataset (like the date is was recorded, the URL it was accessed from, etc.) should be stored in `Series.attrs`.

```
Flags(obj, *, allows_duplicate_labels)
```

Flags that apply to pandas objects.

```
pandas.Flags
class pandas.Flags(obj, *, allows_duplicate_labels)
    Flags that apply to pandas objects.
    New in version 1.2.0.

    Parameters

    obj [Series or DataFrame] The object these flags are associated with.

    allows_duplicate_labels [bool, default True] Whether to allow duplicate labels in this object. By default, duplicate labels are permitted. Setting this to False will cause an `errors.DuplicateLabelError` to be raised when index (or columns for DataFrame) is not unique, or any subsequent operation on introduces duplicates. See Disallowing Duplicate Labels for more.

    Warning: This is an experimental feature. Currently, many methods fail to propagate the allows_duplicate_labels value. In future versions it is expected that every method taking or returning one or more DataFrame or Series objects will propagate allows_duplicate_labels.

Notes

Attributes can be set in two ways

```
>>> df = pd.DataFrame()
>>> df.flags
<Flags(allow_duplicate_labels=True)>
>>> df.flags.allows_duplicate_labels = False
>>> df.flags
<Flags(allow_duplicate_labels=False)>
```

```
>>> df.flags['allows_duplicate_labels'] = True
>>> df.flags
<Flags(allow_duplicate_labels=True)>
```
Attributes

allows_duplicate_labels  Whether this object allows duplicate labels.

pandas.Flags.allows_duplicate_labels

**property**  
Flags.allows_duplicate_labels  Whether this object allows duplicate labels.

Setting `allows_duplicate_labels=False` ensures that the index (and columns of a DataFrame) are unique. Most methods that accept and return a Series or DataFrame will propagate the value of `allows_duplicate_labels`.

See *Duplicate Labels* for more.

See also:

*DataFrame.attrs*  Set global metadata on this object.

*DataFrame.set_flags*  Set global flags on this object.

**Examples**

```python
>>> df = pd.DataFrame({"A": [1, 2]}, index=['a', 'a'])
>>> df.allows_duplicate_labels
True
>>> df.allows_duplicate_labels = False
Traceback (most recent call last):
  ...  
pandas.errors.DuplicateLabelError: Index has duplicates.
  positions
  label a [0, 1]
```

**Metadata**

*Series.attrs* is a dictionary for storing global metadata for this Series.

**Warning:**  
Series.attrs is considered experimental and may change without warning.

*Series.attrs*  Dictionary of global attributes of this dataset.
3.3.14 Plotting

Series.plot is both a callable method and a namespace attribute for specific plotting methods of the form Series.plot.<kind>.

<table>
<thead>
<tr>
<th>Series.plot(kind, ax, figsize, ...)</th>
<th>Series plotting accessor and method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.plot.area(x, y)</td>
<td>Draw a stacked area plot.</td>
</tr>
<tr>
<td>Series.plot.bar(x, y)</td>
<td>Vertical bar plot.</td>
</tr>
<tr>
<td>Series.plot.barh(x, y)</td>
<td>Make a horizontal bar plot.</td>
</tr>
<tr>
<td>Series.plot.box(by)</td>
<td>Make a box plot of the DataFrame columns.</td>
</tr>
<tr>
<td>Series.plot.density([bw_method, ind])</td>
<td>Generate Kernel Density Estimate plot using Gaussian kernels.</td>
</tr>
<tr>
<td>Series.plot.hist(by, bins)</td>
<td>Draw one histogram of the DataFrame’s columns.</td>
</tr>
<tr>
<td>Series.plot.kde(by, bins)</td>
<td>Generate Kernel Density Estimate plot using Gaussian kernels.</td>
</tr>
<tr>
<td>Series.plot.line(x, y)</td>
<td>Plot Series or DataFrame as lines.</td>
</tr>
<tr>
<td>Series.plot.pie(**kwargs)</td>
<td>Generate a pie plot.</td>
</tr>
</tbody>
</table>

**pandas.Series.plot.area**

pandas.Series.plot.area(x=None, y=None, **kwargs)

Draw a stacked area plot.

An area plot displays quantitative data visually. This function wraps the matplotlib area function.

**Parameters**

- x [label or position, optional] Coordinates for the X axis. By default uses the index.
- y [label or position, optional] Column to plot. By default uses all columns.
- stacked [bool, default True] Area plots are stacked by default. Set to False to create a unstacked plot.
- **kwargs Additional keyword arguments are documented in DataFrame.plot().

**Returns**

- matplotlib.axes.Axes or numpy.ndarray Area plot, or array of area plots if subplots is True.

**See also:**

- DataFrame.plot Make plots of DataFrame using matplotlib / pylab.

**Examples**

Draw an area plot based on basic business metrics:

```python
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3, 9, 10, 6],
...     'signups': [5, 5, 6, 12, 14, 13],
...     'visits': [20, 42, 28, 62, 81, 50],
... }, index=pd.date_range(start='2018/01/01', end='2018/07/01',
...     freq='M'))
>>> ax = df.plot.area()
```
Chapter 3. API reference
Area plots are stacked by default. To produce an unstacked plot, pass `stacked=False`:

```python
>>> ax = df.plot.area(stacked=False)
```

Draw an area plot for a single column:

```python
>>> ax = df.plot.area(y='sales')
```

Draw with a different x:

```python
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3],
...     'visits': [20, 42, 28],
...     'day': [1, 2, 3],
... })
>>> ax = df.plot.area(x='day')
```
pandas.Series.plot.bar

Series.plot.bar (x=None, y=None, **kwargs)

Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- **color** [str, array-like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:
  - A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
  - A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance [‘green’, ‘yellow’] each column’s bar will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.
  - A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {‘a’: ‘green’, ‘b’: ‘red’} will color bars for column a in green and bars for column b in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

DataFrame.plot.barh Horizontal bar plot.
DataFrame.plot Make plots of a DataFrame.
matplotlib.pyplot.bar Make a bar plot with matplotlib

Examples

Basic plot.

```python
>>> df = pd.DataFrame({'lab':['A', 'B', 'C'], 'val':[10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.
Plot stacked bar charts for the DataFrame

```python
>>> ax = df.plot.bar(stacked=True)
```

Instead of nesting, the figure can be split by column with `subplots=True`. In this case, a `numpy.ndarray` of `matplotlib.axes.Axes` are returned.

```python
>>> axes = df.plot.bar(rot=0, subplots=True)
>>> axes[1].legend(loc=2)
```

If you don’t like the default colours, you can specify how you’d like each column to be colored.

```python
>>> axes = df.plot.bar(
...        rot=0, subplots=True, color="speed": "red", "lifespan": "green"
...    )
>>> axes[1].legend(loc=2)
```
Here are the histograms for life span and speed for different animals:

- **Life Span**
  - Snail: 10
  - Pig: 10
  - Elephant: 70
  - Rabbit: 20
  - Giraffe: 60
  - Coyote: 20
  - Horse: 70

- **Speed**
  - Snail: 10
  - Pig: 10
  - Elephant: 40
  - Rabbit: 40
  - Giraffe: 60
  - Coyote: 60
  - Horse: 80
Plot a single column.

```python
>>> ax = df.plot.bar(y='speed', rot=0)
```

![Bar plot of speed](image)

Plot only selected categories for the DataFrame.

```python
>>> ax = df.plot.bar(x='lifespan', rot=0)
```

### pandas.Series.plot.barh

Series.plot.barh(x=None, y=None, **kwargs)

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

**Parameters**

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
**color**  [str, array-like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:

- A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
- A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column’s bar will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.
- A dict of the form {column name} [color], so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {'a': 'green', 'b': 'red'} will color bars for column a in green and bars for column b in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

Dataframe.plot.bar Vertical bar plot.

Dataframe.plot Make plots of DataFrame using matplotlib.

matplotlib.axes.Axes.bar Plot a vertical bar plot using matplotlib.

Examples

Basic example

```python
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')
```

Plot a whole DataFrame to a horizontal bar plot

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
            'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
            'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
```

Plot stacked barh charts for the DataFrame

```python
>>> ax = df.plot.barh(stacked=True)
```

We can specify colors for each column

```python
>>> ax = df.plot.barh(color={'speed': 'red', 'lifespan': 'green'})
```

Plot a column of the DataFrame to a horizontal bar plot
3.3. Series

- horse
- coyote
- giraffe
- rabbit
- elephant
- pig
- snail

(speed) (lifespan)
Plot DataFrame versus the desired column

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
... 'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
... 'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(x='lifespan')
```
### pandas.Series.plot.box

**Series.plot.box**(by=None, **kwargs)

Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to 1.5*IQR (IQR = Q3 - Q1) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia’s entry for boxplot.

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

**Parameters**

- **by** [str or sequence] Column in the DataFrame to group by.
- **kwargs** Additional keywords are documented in `DataFrame.plot()`.

**Returns**

`matplotlib.axes.Axes` or numpy.ndarray of them

See also:

- `DataFrame.boxplot` Another method to draw a box plot.
- `Series.plot.box` Draw a box plot from a Series object.
- `matplotlib.pyplot.boxplot` Draw a box plot in matplotlib.

### Examples

Draw a box plot from a DataFrame with four columns of randomly generated data.

```python
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```

### pandas.Series.plot.density

**Series.plot.density**(bw_method=None, ind=None, **kwargs)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

**Parameters**

- **bw_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See `scipy.stats.gaussian_kde` for more information.
- **ind** [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.
- **kwargs** Additional keyword arguments are documented in `pandas.%(this-datatype)s.plot()`.
Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

scipy.stats.gaussian_kde  Representation of a kernel-density estimate using Gaussian kernels. This
is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with
automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large
bandwidth value may result in under-fitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:
For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)

>>> ax = df.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5])
```
Density

1 2 3 4 5 6

x y
pandas.Series.plot.hist

Series.plot.hist(by=None, bins=10, **kwargs)
Draw one histogram of the DataFrame’s columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one matplotlib.axes.Axes. This is useful when the DataFrame’s Series are in a similar scale.

Parameters

- **by** [str or sequence, optional] Column in the DataFrame to group by.
- **bins** [int, default 10] Number of histogram bins to be used.
- **kwargs** Additional keyword arguments are documented in DataFrame.plot().

Returns

class:matplotlib.AxesSubplot Return a histogram plot.

See also:
- DataFrame.hist Draw histograms per DataFrame's Series.
- Series.hist Draw a histogram with Series' data.

Examples

When we draw a dice 6000 times, we expect to get each value around 1000 times. But when we draw two dices and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```python
def = pd.DataFrame(
    ... np.random.randint(1, 7, 6000),
    ... columns = ['one'])
def['two'] = df['one'] + np.random.randint(1, 7, 6000)
ax = df.plot.hist(bins=12, alpha=0.5)
```

pandas.Series.plot.kde

Series.plot.kde(bw_method=None, ind=None, **kwargs)
Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

- **bw_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See scipy.stats.gaussian_kde for more information.
- **ind** [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.
- **kwargs** Additional keyword arguments are documented in pandas.%(this-datatype)s.plot().

Returns
See also:

scipy.stats.gaussian_kde Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

**Examples**

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)

>>> ax = s.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:
3.3. Series
For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame(
...     {'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
...     })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)

>>> ax = df.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5])
```
pandas.Series.plot.line

Series.plot.line(x=None, y=None, **kwargs)
Plot Series or DataFrame as lines.

This function is useful to plot lines using DataFrame’s values as coordinates.

Parameters

x [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

y [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

color [str, array-like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:

  • A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.

  • A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column’s line will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.

  • A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {'a': 'green', 'b': 'red'} will color lines for column a in green and lines for column b in red.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

matplotlib.pyplot.plot Plot y versus x as lines and/or markers.

Examples

```python
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
```

The following example shows the populations for some animals over the years.

```python
>>> df = pd.DataFrame({
...     'pig': [20, 18, 489, 675, 1776],
...     'horse': [4, 25, 281, 600, 1900]
>>> lines = df.plot.line()
```

An example with subplots, so an array of axes is returned.
Let’s repeat the same example, but specifying colors for each column (in this case, for each animal).

```python
>>> axes = df.plot.line(...
                subplots=True, color={"pig": "pink", "horse": "#742802"}
...)
```

The following example shows the relationship between both populations.

```python
>>> lines = df.plot.line(x='pig', y='horse')
```
pandas.Series.plot.pie

Series.plot.pie(**kwargs)
Generate a pie plot.

A pie plot is a proportional representation of the numerical data in a column. This function wraps matplotlib.pyplot.pie() for the specified column. If no column reference is passed and subplots=True a pie plot is drawn for each numerical column independently.

Parameters

y [int or label, optional] Label or position of the column to plot. If not provided, subplots=True argument must be passed.

**kwargs Keyword arguments to pass on to DataFrame.plot().

Returns

matplotlib.axes.Axes or np.ndarray of them A NumPy array is returned when subplots is True.

See also:

Series.plot.pie Generate a pie plot for a Series.
DataFrame.plot Make plots of a DataFrame.

Examples

In the example below we have a DataFrame with the information about planet’s mass and radius. We pass the ‘mass’ column to the pie function to get a pie plot.

```python
>>> df = pd.DataFrame({'mass': [0.330, 4.87, 5.97],
...                    'radius': [2439.7, 6051.8, 6378.1]},
...                   index=['Mercury', 'Venus', 'Earth'])
```

```python
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
```

```python
>>> plot = df.plot.pie(subplots=True, figsize=(11, 6))
```

Series.hist((by, ax, grid, xlabelsize, ...)) Draw histogram of the input series using matplotlib.

3.3.15 Serialization / IO / conversion

<table>

### 3.4 DataFrame

#### 3.4.1 Constructor

```
DataFrame(data=None, index=None, columns=None, dtype=None, copy=None)
```

Two-dimensional, size-mutable, potentially heterogeneous tabular data.

Parameters

- **data** [ndarray (structured or homogeneous), Iterable, dict, or DataFrame] Dict can contain Series, arrays, constants, dataclass or list-like objects. If data is a dict, column order follows insertion-order.

  Changed in version 0.25.0: If data is a list of dicts, column order follows insertion-order.

- **index** [Index or array-like] Index to use for resulting frame. Will default to RangeIndex if no indexing information part of input data and no index provided.

- **columns** [Index or array-like] Column labels to use for resulting frame when data does not have them, defaulting to RangeIndex(0, 1, 2, ..., n). If data contains column labels, will perform column selection instead.

- **dtype** [dtype, default None] Data type to force. Only a single dtype is allowed. If None, infer.

- **copy** [bool or None, default None] Copy data from inputs. For dict data, the default of None behaves like copy=True. For DataFrame or 2d ndarray input, the default of None behaves like copy=False.

  Changed in version 1.3.0.

See also:

- **DataFrame.from_records** Constructor from tuples, also record arrays.
- **DataFrame.from_dict** From dicts of Series, arrays, or dicts.
- **read_csv** Read a comma-separated values (csv) file into DataFrame.
- **read_table** Read general delimited file into DataFrame.
- **read_clipboard** Read text from clipboard into DataFrame.
3.4. Dataframe
Examples

Constructing DataFrame from a dictionary.

```python
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df
  col1 col2
0   1   3
1   2   4
```

Notice that the inferred dtype is int64.

```python
>>> df.dtypes
col1  int64
col2  int64
dtype: object
```

To enforce a single dtype:

```python
>>> df = pd.DataFrame(data=d, dtype=np.int8)
>>> df.dtypes
col1  int8
col2  int8
dtype: object
```

Constructing DataFrame from numpy ndarray:

```python
>>> df2 = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]),
                     columns=['a', 'b', 'c'])
>>> df2
   a  b  c
0  1  2  3
1  4  5  6
2  7  8  9
```

Constructing DataFrame from a numpy ndarray that has labeled columns:

```python
>>> data = np.array([(1, 2, 3), (4, 5, 6), (7, 8, 9)],
                  dtype=[('a', 'i4'), ('b', 'i4'), ('c', 'i4')])
>>> df3 = pd.DataFrame(data, columns=['c', 'a'])
>>> df3
   c  a
0  3  1
1  6  4
2  9  7
```

Constructing DataFrame from dataclass:

```python
>>> from dataclasses import make_dataclass
>>> Point = make_dataclass("Point", [('x', int), ('y', int)])
>>> pd.DataFrame([Point(0, 0), Point(0, 3), Point(2, 3)])
   x  y
0  0  0
1  0  3
2  2  3
```
Attributes

<table>

<td>Return an int representing the number of elements in this object.</td>
</tr>
<tr>
<td><code>style</code></td>
<td>Returns a Styler object.</td>
</tr>
<tr>
<td><code>values</code></td>
<td>Return a Numpy representation of the DataFrame.</td>
</tr>
</tbody>
</table>

`pandas.DataFrame.at`

**property** `DataFrame.at`

Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

**Raises**

- **KeyError** If ‘label’ does not exist in DataFrame.

**See also:**

- `DataFrame.iat` Access a single value for a row/column pair by integer position.
- `DataFrame.loc` Access a group of rows and columns by label(s).
- `Series.at` Access a single value using a label.
Examples

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
                    index=[4, 5, 6], columns=['A', 'B', 'C'])
```

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>0</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td>6</td>
<td>10</td>
<td>20</td>
<td>30</td>
</tr>
</tbody>
</table>

Get value at specified row/column pair

```python
>>> df.at[4, 'B']
2
```

Set value at specified row/column pair

```python
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```

Get value within a Series

```python
>>> df.loc[5].at['B']
4
```

**pandas.DataFrame.attrs**

**property** `DataFrame.attrs`

Dictionary of global attributes of this dataset.

**Warning:** attrs is experimental and may change without warning.

**See also:**

`DataFrame.flags` Global flags applying to this object.

**pandas.DataFrame.axes**

**property** `DataFrame.axes`

Return a list representing the axes of the DataFrame.

It has the row axis labels and column axis labels as the only members. They are returned in that order.
Examples

```python
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.axes
[RangeIndex(start=0, stop=2, step=1), Index(['col1', 'col2'],
dtype='object')]
```

**pandas.DataFrame.columns**

**DataFrame.columns**: *Index*

The column labels of the DataFrame.

**pandas.DataFrame.dtypes**

**property** *DataFrame.dtypes*

Return the dtypes in the DataFrame.

This returns a Series with the data type of each column. The result’s index is the original DataFrame’s columns. Columns with mixed types are stored with the `object` dtype. See the *User Guide* for more.

**Returns**

```
pandas.Series The data type of each column.
```

**Examples**

```python
>>> df = pd.DataFrame({'float': [1.0],
...                    'int': [1],
...                    'datetime': [pd.Timestamp('20180310')],
...                    'string': ['foo']})
>>> df.dtypes
float float64
int int64
datetime datetime64[ns]
string object
dtype: object
```

**pandas.DataFrame.empty**

**property** *DataFrame.empty*

Indicator whether DataFrame is empty.

True if DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

**Returns**

```
bool If DataFrame is empty, return True, if not return False.
```

**See also**

```
Series.dropna Return series without null values.
DataFrame.dropna Return DataFrame with labels on given axis omitted where (all or any) data are missing.
```
Notes

If DataFrame contains only NaNs, it is still not considered empty. See the example below.

Examples

An example of an actual empty DataFrame. Notice the index is empty:

```plaintext
>>> df_empty = pd.DataFrame({'A' : []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []
>>> df_empty.empty
True
```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```plaintext
>>> df = pd.DataFrame({'A' : [np.nan]})
>>> df
   A
0  NaN
>>> df.empty
False
>>> df.dropna().empty
True
```

pandas.DataFrame.flags

**property** DataFrame.flags

Get the properties associated with this pandas object.

The available flags are

- `Flags.allows_duplicate_labels`

See also:

- `Flags` Flags that apply to pandas objects.
- `DataFrame.attrs` Global metadata applying to this dataset.

Notes

“Flags” differ from “metadata”. Flags reflect properties of the pandas object (the Series or DataFrame). Metadata refer to properties of the dataset, and should be stored in `DataFrame.attrs`. 
Examples

```python
>>> df = pd.DataFrame({"A": [1, 2]})
>>> df.flags
<Flags(allow_duplicate_labels=True)>

Flags can be get or set using .

```python
>>> df.flags.allows_duplicate_labels
True
```python
>>> df.flags.allows_duplicate_labels = False
```

Or by slicing with a key

```python
>>> df.flags["allows_duplicate_labels"]
False
>>> df.flags["allows_duplicate_labels"] = True
```

**pandas.DataFrame.iat**

**property** `DataFrame.iat`

Access a single value for a row/column pair by integer position.

Similar to `iloc`, in that both provide integer-based lookups. Use `iat` if you only need to get or set a single value in a DataFrame or Series.

**Raises**

`IndexError` When integer position is out of bounds.

**See also:**

`DataFrame.at` Access a single value for a row/column label pair.

`DataFrame.loc` Access a group of rows and columns by label(s).

`DataFrame.iloc` Access a group of rows and columns by integer position(s).

**Examples**

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                    columns=['A', 'B', 'C'])
```

Get value at specified row/column pair

```python
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair
pandas: powerful Python data analysis toolkit, Release 1.3.2

```python
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series

```python
>>> df.loc[0].iat[1]
2
```

**pandas.DataFrame.iloc**

**Property DataFrame.iloc**

Purely integer-location based indexing for selection by position.

`.iloc[]` is primarily integer position based (from 0 to `length-1` of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. `[4, 3, 0]`.
- A slice object with ints, e.g. `1:7`.
- A boolean array.
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don’t have a reference to the calling object, but would like to base your selection on some value.

`.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except `slice` indexers which allow out-of-bounds indexing (this conforms with python/numpy `slice` semantics).

See more at Selection by Position.

See also:

- `DataFrame.iat` Fast integer location scalar accessor.
- `DataFrame.loc` Purely label-location based indexer for selection by label.
- `Series.iloc` Purely integer-location based indexing for selection by position.

**Examples**

```python
>>> mydict = [{'a': 1, 'b': 2, 'c': 3, 'd': 4},
            {'a': 100, 'b': 200, 'c': 300, 'd': 400},
            {'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000}]
>>> df = pd.DataFrame(mydict)
>>> df
   a   b   c   d
0  1  2.0  3.0  4.0
1 100 200.0 300 400
2 1000 2000.0 3000 4000

Indexing just the rows

With a scalar integer.
>>> type(df.iloc[0])
<class 'pandas.core.series.Series'>
>>> df.iloc[0]
a 1
b 2
c 3
d 4
Name: 0, dtype: int64

With a list of integers.

>>> df.iloc[[0]]
   a  b  c  d
0  1  2  3  4
>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>

>>> df.iloc[[0, 1]]
   a  b  c  d
0  1  2  3  4
1 100 200 300 400

With a slice object.

>>> df.iloc[:3]
   a  b  c  d
0  1  2  3  4
1 100 200 300 400
2 1000 2000 3000 4000

With a boolean mask the same length as the index.

>>> df.iloc[[True, False, True]]
   a  b  c  d
0  1  2  3  4
2 1000 2000 3000 4000

With a callable, useful in method chains. The x passed to the lambda is the DataFrame being sliced. This selects the rows whose index label even.

>>> df.iloc[lambda x: x.index % 2 == 0]
   a  b  c  d
0  1  2  3  4
2 1000 2000 3000 4000

Indexing both axes

You can mix the indexer types for the index and columns. Use : to select the entire axis.

With scalar integers.

>>> df.iloc[0, 1]
2

With lists of integers.
>>> df.iloc[[0, 2], [1, 3]]
   b  d
0  2  4
2 2000 4000

With *slice* objects.

>>> df.iloc[1:3, 0:3]
   a  b  c
1  100 200 300
2 1000 2000 3000

With a boolean array whose length matches the columns.

>>> df.iloc[:, [True, False, True, False]]
   a  c
0  1  3
1 100 300
2 1000 3000

With a callable function that expects the Series or DataFrame.

>>> df.iloc[:, lambda df: [0, 2]]
   a  c
0  1  3
1 100 300
2 1000 3000

**pandas.DataFrame.index**

DataFrame.*index*: *Index*

The index (row labels) of the DataFrame.

**pandas.DataFrame.loc**

*property* DataFrame.loc

Access a group of rows and columns by label(s) or a boolean array.

.loc[] is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a *label* of the index, and *never* as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a': 'f'.

**Warning**: Note that contrary to usual python slices, **both** the start and the stop are included.

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- An alignable boolean Series. The index of the key will be aligned before masking.
• An alignable Index. The Index of the returned selection will be the input.
• A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above)

See more at Selection by Label.

Raises

**KeyError** If any items are not found.

**IndexingError** If an indexed key is passed and its index is unalignable to the frame index.

See also:

*DataFrame.at* Access a single value for a row/column label pair.

*DataFrame.iloc* Access group of rows and columns by integer position(s).

*DataFrame.xs* Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.

*Series.loc* Access group of values using labels.

Examples

Getting values

```python
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                     index=['cobra', 'viper', 'sidewinder'],
...                     columns=['max_speed', 'shield'])
>>> df
            max_speed  shield
    cobra        1        2
    viper        4        5
    sidewinder   7        8
```

Single label. Note this returns the row as a Series.

```python
>>> df.loc['viper']
max_speed  4
shield     5
Name: viper, dtype: int64
```

List of labels. Note using `[]` returns a DataFrame.

```python
>>> df.loc[['viper', 'sidewinder']]
            max_speed  shield
    viper       4       5
    sidewinder   7       8
```

Single label for row and column

```python
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.
>>> df.loc['cobra':'viper', 'max_speed']
cobra 1
viper 4
Name: max_speed, dtype: int64

Boolean list with the same length as the row axis

>>> df.loc[[False, False, True]]
    max_speed shield
sidewinder 7 8

Alignable boolean Series:

>>> df.loc[pd.Series([False, True, False],
                    index=['viper', 'sidewinder', 'cobra'])]
    max_speed shield
sidewinder 7 8

Index (same behavior as df.reindex)

>>> df.loc[pd.Index(['cobra', 'viper'], name='foo')]
    max_speed shield
foo  
cobra 1 2
viper 4 5

Conditional that returns a boolean Series

>>> df.loc[df['shield'] > 6]
    max_speed shield
sidewinder 7 8

Conditional that returns a boolean Series with column labels specified

>>> df.loc[df['shield'] > 6, ['max_speed']]
    max_speed
sidewinder 7

Callable that returns a boolean Series

>>> df.loc[lambda df: df['shield'] == 8]
    max_speed shield
sidewinder 7 8

Setting values

Set value for all items matching the list of labels

>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
    max_speed shield
   cobra 1 2
   viper 4 50
   sidewinder 7 50

Set value for an entire row
Set value for an entire column

```python
>>> df.loc[:, 'max_speed'] = 30
```

Set value for rows matching callable condition

```python
>>> df.loc[df['shield'] > 35] = 0
```

Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```python
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
                    index=[7, 8, 9], columns=['max_speed', 'shield'])
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```python
>>> df.loc[7:9]
```

Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```python
>>> tuples = [
...    ('cobra', 'mark i'), ('cobra', 'mark ii'),
...    ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
...    ('viper', 'mark ii'), ('viper', 'mark iii')
...]

>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
...           [1, 4], [7, 1], [16, 36]]
```
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)

<table>
<thead>
<tr>
<th></th>
<th>max_speed</th>
<th>shield</th>
</tr>
</thead>
<tbody>
<tr>
<td>cobra</td>
<td></td>
<td></td>
</tr>
<tr>
<td>mark i</td>
<td>12</td>
<td>2</td>
</tr>
<tr>
<td>mark ii</td>
<td>0</td>
<td>4</td>
</tr>
<tr>
<td>sidewinder</td>
<td></td>
<td></td>
</tr>
<tr>
<td>mark i</td>
<td>10</td>
<td>20</td>
</tr>
<tr>
<td>mark ii</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>viper</td>
<td></td>
<td></td>
</tr>
<tr>
<td>mark ii</td>
<td>7</td>
<td>1</td>
</tr>
<tr>
<td>mark iii</td>
<td>16</td>
<td>36</td>
</tr>
</tbody>
</table>

Single label. Note this returns a DataFrame with a single index.

>>> df.loc['cobra']

<table>
<thead>
<tr>
<th></th>
<th>max_speed</th>
<th>shield</th>
</tr>
</thead>
<tbody>
<tr>
<td>mark i</td>
<td>12</td>
<td>2</td>
</tr>
<tr>
<td>mark ii</td>
<td>0</td>
<td>4</td>
</tr>
</tbody>
</table>

Single index tuple. Note this returns a Series.

>>> df.loc[('cobra', 'mark ii')]

max_speed 0
shield 4
Name: (cobra, mark ii), dtype: int64

Single label for row and column. Similar to passing in a tuple, this returns a Series.

>>> df.loc['cobra', 'mark i']

max_speed 12
shield 2
Name: (cobra, mark i), dtype: int64

Single tuple. Note using [[]] returns a DataFrame.

>>> df.loc[['cobra', 'mark ii']]  # Single tuple for the index with a single label for the column

<table>
<thead>
<tr>
<th></th>
<th>max_speed</th>
<th>shield</th>
</tr>
</thead>
<tbody>
<tr>
<td>cobra</td>
<td></td>
<td></td>
</tr>
<tr>
<td>mark ii</td>
<td>0</td>
<td>4</td>
</tr>
</tbody>
</table>

Slice from index tuple to single label

>>> df.loc[['cobra', 'mark i']:'viper']

<table>
<thead>
<tr>
<th></th>
<th>max_speed</th>
<th>shield</th>
</tr>
</thead>
<tbody>
<tr>
<td>cobra</td>
<td></td>
<td></td>
</tr>
<tr>
<td>mark i</td>
<td>12</td>
<td>2</td>
</tr>
<tr>
<td>mark ii</td>
<td>0</td>
<td>4</td>
</tr>
<tr>
<td>sidewinder</td>
<td></td>
<td></td>
</tr>
<tr>
<td>mark i</td>
<td>10</td>
<td>20</td>
</tr>
<tr>
<td>mark ii</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>viper</td>
<td></td>
<td></td>
</tr>
<tr>
<td>mark ii</td>
<td>7</td>
<td>1</td>
</tr>
<tr>
<td>mark iii</td>
<td>16</td>
<td>36</td>
</tr>
</tbody>
</table>

Slice from index tuple to index tuple
pandas.DataFrame.ndim

**property** DataFrame.ndim
Return an int representing the number of axes / array dimensions.

Return 1 if Series. Otherwise return 2 if DataFrame.

See also:

ndarray.ndim Number of array dimensions.

**Examples**

```python
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.ndim
1
```

```python
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.ndim
2
```

pandas.DataFrame.shape

**property** DataFrame.shape
Return a tuple representing the dimensionality of the DataFrame.

See also:

ndarray.shape Tuple of array dimensions.

**Examples**

```python
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.shape
(2, 2)
```

```python
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4], ...
... 'col13': [5, 6]})
>>> df.shape
(2, 3)
```
pandas.DataFrame.size

**property** DataFrame.size

Return an int representing the number of elements in this object.

Return the number of rows if Series. Otherwise return the number of rows times number of columns if DataFrame.

See also:

**ndarray.size** Number of elements in the array.

Examples

```python
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.size
3

>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.size
4
```

pandas.DataFrame.style

**property** DataFrame.style

Returns a Styler object.

Contains methods for building a styled HTML representation of the DataFrame.

See also:

**io.formats.style.Styler** Helps style a DataFrame or Series according to the data with HTML and CSS.

pandas.DataFrame.values

**property** DataFrame.values

Return a Numpy representation of the DataFrame.

**Warning:** We recommend using `DataFrame.to_numpy()` instead.

Only the values in the DataFrame will be returned, the axes labels will be removed.

Returns

**numpy.ndarray** The values of the DataFrame.

See also:

**DataFrame.to_numpy** Recommended alternative to this method.

**DataFrame.index** Retrieve the index labels.

**DataFrame.columns** Retrieving the column names.
Notes

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcast to int32. By `numpy.find_common_type()` convention, mixing int64 and uint64 will result in a float64 dtype.

Examples

A DataFrame where all columns are the same type (e.g., int64) results in an array of the same type.

```
>>> df = pd.DataFrame({'age': [3, 29],
...                   'height': [94, 170],
...                   'weight': [31, 115]})

>>> df
age  height  weight
0   3       94       31
1  29      170      115

>>> df.dtypes
age    int64
height  int64
weight  int64
dtype: object

>>> df.values
array([[ 3, 94, 31],
       [ 29, 170, 115]])
```

A DataFrame with mixed type columns (e.g., str/object, int64, float32) results in an ndarray of the broadest type that accommodates these mixed types (e.g., object).

```
>>> df2 = pd.DataFrame([('parrot', 24.0, 'second'),
...                     ('lion', 80.5, 1),
...                     ('monkey', np.nan, None)],
...                    columns=('name', 'max_speed', 'rank'))

>>> df2.dtypes
name       object
max_speed  float64
rank       object
dtype: object

>>> df2.values
array([['parrot', 24.0, 'second'],
       ['lion', 80.5, 1],
       ['monkey', nan, None]], dtype=object)
```
## Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>abs()</td>
<td>Return a Series/DataFrame with absolute numeric value of each element.</td>
</tr>
<tr>
<td>add(other[, axis, level, fill_value])</td>
<td>Get Addition of dataframe and other, element-wise (binary operator <code>add</code>).</td>
</tr>
<tr>
<td>add_prefix(prefix)</td>
<td>Prefix labels with string <code>prefix</code>.</td>
</tr>
<tr>
<td>add_suffix(suffix)</td>
<td>Suffix labels with string <code>suffix</code>.</td>
</tr>
<tr>
<td>agg([func, axis])</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>aggregate([func, axis])</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>align(other[, join, axis, level, copy, ...])</td>
<td>Align two objects on their axes with the specified join method.</td>
</tr>
<tr>
<td>all([axis, bool_only, skipna, level])</td>
<td>Return whether all elements are True, potentially over an axis.</td>
</tr>
<tr>
<td>any([axis, bool_only, skipna, level])</td>
<td>Return whether any element is True, potentially over an axis.</td>
</tr>
<tr>
<td>append(other[, ignore_index, ...])</td>
<td>Append rows of <code>other</code> to the end of caller, returning a new object.</td>
</tr>
<tr>
<td>apply(func[, axis, raw, result_type, args])</td>
<td>Apply a function along an axis of the DataFrame.</td>
</tr>
<tr>
<td>applymap(func[, na_action])</td>
<td>Apply a function to a DataFrame elementwise.</td>
</tr>
<tr>
<td>asfreq(freq[, method, how, normalize, ...])</td>
<td>Convert time series to specified frequency.</td>
</tr>
<tr>
<td>asof(where[, subset])</td>
<td>Return the last row(s) without any NaNs before <code>where</code>.</td>
</tr>
<tr>
<td>assign(**kwargs)</td>
<td>Assign new columns to a DataFrame.</td>
</tr>
<tr>
<td>astype(dtype[, copy, errors])</td>
<td>Cast a pandas object to a specified dtype <code>dtype</code>.</td>
</tr>
<tr>
<td>at_time(time[, asof, axis])</td>
<td>Select values at particular time of day (e.g., 9:30AM).</td>
</tr>
<tr>
<td>backfill([axis, inplace, limit, downcast])</td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='bfill'.</td>
</tr>
<tr>
<td>between_time(start_time, end_time[, ...])</td>
<td>Select values between particular times of the day (e.g., 9:00-9:30 AM).</td>
</tr>
<tr>
<td>bfill([axis, inplace, limit, downcast])</td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='bfill'.</td>
</tr>
<tr>
<td>bool()</td>
<td>Return the bool of a single element Series or DataFrame.</td>
</tr>
<tr>
<td>boxplot([column, by, ax, fontsize, rot, ...])</td>
<td>Make a box plot from DataFrame columns.</td>
</tr>
<tr>
<td>clip([lower, upper, axis, inplace])</td>
<td>Trim values at input threshold(s).</td>
</tr>
<tr>
<td>combine(other, func[, fill_value, overwrite])</td>
<td>Perform column-wise combine with another DataFrame.</td>
</tr>
<tr>
<td>combine_first(other)</td>
<td>Update null elements with value in the same location in <code>other</code>.</td>
</tr>
<tr>
<td>compare(other[, align_axis, keep_shape, ...])</td>
<td>Compare to another DataFrame and show the differences.</td>
</tr>
<tr>
<td>convert_dtypes([infer_objects, ...])</td>
<td>Convert columns to best possible dtypes using dtypes supporting pd.NA.</td>
</tr>
<tr>
<td>copy([deep])</td>
<td>Make a copy of this object’s indices and data.</td>
</tr>
<tr>
<td>corr([method, min_periods])</td>
<td>Compute pairwise correlation of columns, excluding NA/null values.</td>
</tr>
<tr>
<td>corrwith(other[, axis, drop, method])</td>
<td>Compute pairwise correlation.</td>
</tr>
</tbody>
</table>
### Table 65 – continued from previous page

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>count</code></td>
<td>Count non-NA cells for each column or row.</td>
</tr>
<tr>
<td><code>cov(min_periods, ddof)</code></td>
<td>Compute pairwise covariance of columns, excluding NA/null values.</td>
</tr>
<tr>
<td><code>cummax(axis, skipna)</code></td>
<td>Return cumulative maximum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>cummin(axis, skipna)</code></td>
<td>Return cumulative minimum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>cumprod(axis, skipna)</code></td>
<td>Return cumulative product over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>cumsum(axis, skipna)</code></td>
<td>Return cumulative sum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>describe([percentiles, include, exclude, . . .])</code></td>
<td>Generate descriptive statistics.</td>
</tr>
<tr>
<td><code>diff([periods, axis])</code></td>
<td>First discrete difference of element.</td>
</tr>
<tr>
<td><code>div(other[, axis, level, fill_value])</code></td>
<td>Get Floating division of dataframe and other, element-wise (binary operator <code>truediv</code>).</td>
</tr>
<tr>
<td><code>divide(other[, axis, level, fill_value])</code></td>
<td>Get Floating division of dataframe and other, element-wise (binary operator <code>truediv</code>).</td>
</tr>
<tr>
<td><code>dot(other)</code></td>
<td>Compute the matrix multiplication between the DataFrame and other.</td>
</tr>
<tr>
<td><code>drop([labels, axis, index, columns, level, . . .])</code></td>
<td>Drop specified labels from rows or columns.</td>
</tr>
<tr>
<td><code>drop_duplicates([subset, keep, inplace, . . .])</code></td>
<td>Return DataFrame with duplicate rows removed.</td>
</tr>
<tr>
<td><code>droplevel(level[, axis])</code></td>
<td>Return Series/DataFrame with requested index / column level(s) removed.</td>
</tr>
<tr>
<td><code>dropna([axis, how, thresh, subset, inplace])</code></td>
<td>Remove missing values.</td>
</tr>
<tr>
<td><code>duplicated([subset, keep])</code></td>
<td>Return boolean Series denoting duplicate rows.</td>
</tr>
<tr>
<td><code>eq(other[, axis, level])</code></td>
<td>Get Equal to of dataframe and other, element-wise (binary operator <code>eq</code>).</td>
</tr>
<tr>
<td><code>equals(other)</code></td>
<td>Test whether two objects contain the same elements.</td>
</tr>
<tr>
<td><code>eval(expr[, inplace])</code></td>
<td>Evaluate a string describing operations on DataFrame columns.</td>
</tr>
<tr>
<td><code>ewm([com, span, halflife, alpha, . . .])</code></td>
<td>Provide exponential weighted (EW) functions.</td>
</tr>
<tr>
<td><code>expanding([min_periods, center, axis, method])</code></td>
<td>Provide expanding transformations.</td>
</tr>
<tr>
<td><code>explode(column[, ignore_index])</code></td>
<td>Transform each element of a list-like to a row, replicating index values.</td>
</tr>
<tr>
<td><code>ffill(axis, inplace, limit, downcast)</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='ffill'.</td>
</tr>
<tr>
<td><code>fillna([value, method, axis, inplace, . . .])</code></td>
<td>Fill NA/NaN values using the specified method.</td>
</tr>
<tr>
<td><code>filter([items, like, regex, axis])</code></td>
<td>Subset the dataframe rows or columns according to the specified index labels.</td>
</tr>
<tr>
<td><code>first(offset)</code></td>
<td>Select initial periods of time series data based on a date offset.</td>
</tr>
<tr>
<td><code>first_valid_index()</code></td>
<td>Return index for first non-NA value or None, if no NA value is found.</td>
</tr>
<tr>
<td><code>floordiv(other[, axis, level, fill_value])</code></td>
<td>Get Integer division of dataframe and other, element-wise (binary operator <code>floordiv</code>).</td>
</tr>
<tr>
<td><code>from_dict(data[, orient, dttype, columns])</code></td>
<td>Construct DataFrame from dict of array-like or dicts.</td>
</tr>
<tr>
<td><code>from_records(data[, index, exclude, . . .])</code></td>
<td>Convert structured or record ndarray to DataFrame.</td>
</tr>
<tr>
<td><code>ge(other[, axis, level])</code></td>
<td>Get Greater than or equal to of dataframe and other, element-wise (binary operator <code>ge</code>).</td>
</tr>
<tr>
<td><code>get(key[, default])</code></td>
<td>Get item from object for given key (ex: DataFrame column).</td>
</tr>

<tr>
<td>resample(rule[, axis, closed, label, ...])</td>
<td>Resample time-series data.</td>
</tr>
<tr>
<td>reset_index([level, closed, label, ...])</td>
<td>Reset the index, or a level of it.</td>
</tr>
<tr>
<td>rfloordiv(other[, axis, level, fill_value])</td>
<td>Get Integer division of dataframe and other, element-wise (binary operator rfloordiv).</td>
</tr>
<tr>
<td>rmod(other[, axis, level, fill_value])</td>
<td>Get Modulo of dataframe and other, element-wise (binary operator rmod).</td>
</tr>
<tr>
<td>rmul(other[, axis, level, fill_value])</td>
<td>Get Multiplication of dataframe and other, element-wise (binary operator rmul).</td>
</tr>
<tr>
<td>rolling(window[, min_periods, center, ...])</td>
<td>Provide rolling window calculations.</td>
</tr>
<tr>
<td>round([decimals])</td>
<td>Round a DataFrame to a variable number of decimal places.</td>
</tr>
<tr>
<td>rpow(other[, axis, level, fill_value])</td>
<td>Get Exponential power of dataframe and other, element-wise (binary operator rpow).</td>
</tr>
<tr>
<td>rsub(other[, axis, level, fill_value])</td>
<td>Get Subtraction of dataframe and other, element-wise (binary operator rsub).</td>
</tr>
<tr>
<td>rtruediv(other[, axis, level, fill_value])</td>
<td>Get Floating division of dataframe and other, element-wise (binary operator rtruediv).</td>
</tr>
<tr>
<td>sample([n, frac, replace, weights, ...])</td>
<td>Return a random sample of items from an axis of object.</td>
</tr>
<tr>
<td>select_dtypes([include, exclude])</td>
<td>Return a subset of the DataFrame’s columns based on the column dtypes.</td>
</tr>
<tr>
<td>sem([axis, skipna, level, ddof, numeric_only])</td>
<td>Return unbiased standard error of the mean over requested axis.</td>
</tr>
<tr>
<td>set_axis(labels[, axis, inplace])</td>
<td>Assign desired index to given axis.</td>
</tr>
<tr>
<td>set_flags(*[, copy, allows_duplicate_labels])</td>
<td>Return a new object with updated flags.</td>
</tr>
<tr>
<td>set_index(keys[, drop, append, inplace, ...])</td>
<td>Set the DataFrame index using existing columns.</td>
</tr>
<tr>
<td>shift([periods, freq, axis, fill_value])</td>
<td>Shift index by desired number of periods with an optional time freq.</td>
</tr>
<tr>
<td>skew([axis, skipna, level, numeric_only])</td>
<td>Return unbiased skew over requested axis.</td>
</tr>
<tr>
<td>slice_shift([periods, axis])</td>
<td>(DEPRECATED) Equivalent to shift without copying data.</td>
</tr>
<tr>
<td>sort_index([axis, level, ascending, ...])</td>
<td>Sort object by labels (along an axis).</td>
</tr>
<tr>
<td>sort_values(by[, axis, ascending, inplace, ...])</td>
<td>Sort by the values along either axis.</td>
</tr>
<tr>
<td>sparse</td>
<td>alias of pandas.core.arrays.sparse.accessor.SparseFrameAccessor</td>
</tr>
<tr>
<td>squeeze([axis])</td>
<td>Squeeze 1 dimensional axis objects into scalars.</td>

**pandas.DataFrame.abs**

`DataFrame.abs()`

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

Returns

abs  Series/DataFrame containing the absolute value of each element.

See also:

numpy.abs Calculate the absolute value element-wise.

Notes

For complex inputs, \(1.2 + 1j\), the absolute value is \(\sqrt{a^2 + b^2}\).

Examples

Absolute numeric values in a Series.

```python
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1    2.00
2    3.33
3    4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```python
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```python
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0    1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using argsort (from StackOverflow).
pandas: powerful Python data analysis toolkit, Release 1.3.2

```python
>>> df = pd.DataFrame({
    ...     'a': [4, 5, 6, 7],
    ...     'b': [10, 20, 30, 40],
    ...     'c': [100, 50, -30, -50]
    ... })
>>> df
    a  b  c
0  4  10 100
1  5  20  50
2  6  30 -30
3  7  40 -50
>>> df.loc[(df.c - 43).abs().argsort()]
    a  b  c
1  5  20  50
0  4  10 100
2  6  30 -30
3  7  40 -50
```

**pandas.DataFrame.add**

`DataFrame.add(other, axis='columns', level=None, fill_value=None)`

Get Addition of dataframe and other, element-wise (binary operator `add`). Equivalent to `dataframe + other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `radd`.

Among flexible wrappers (`add, sub, mul, div, mod, pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- `fill_value` [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

- `DataFrame` Result of the arithmetic operation.

**See also:**

- `DataFrame.add` Add DataFrames.
- `DataFrame.sub` Subtract DataFrames.
- `DataFrame.mul` Multiply DataFrames.
- `DataFrame.div` Divide DataFrames (float division).
- `DataFrame.truediv` Divide DataFrames (float division).
- `DataFrame.floordiv` Divide DataFrames (integer division).
**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

### Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0</td>
</tr>
<tr>
<td>triangle</td>
<td>3</td>
</tr>
<tr>
<td>rectangle</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td>360</td>
</tr>
<tr>
<td></td>
<td>180</td>
</tr>
<tr>
<td></td>
<td>360</td>
</tr>
</tbody>
</table>

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
<tr>
<td></td>
<td>361</td>
</tr>
<tr>
<td></td>
<td>181</td>
</tr>
<tr>
<td></td>
<td>361</td>
</tr>
</tbody>
</table>

Divide by constant with reverse version.

```python
>>> df.div(10)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0</td>
</tr>
<tr>
<td>triangle</td>
<td>0.3</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.4</td>
</tr>
<tr>
<td></td>
<td>36.0</td>
</tr>
<tr>
<td></td>
<td>18.0</td>
</tr>
<tr>
<td></td>
<td>36.0</td>
</tr>
</tbody>
</table>

```python
>>> df.rdiv(10)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>inf</td>
</tr>
<tr>
<td>triangle</td>
<td>3.333333</td>
</tr>
<tr>
<td>rectangle</td>
<td>2.5</td>
</tr>
<tr>
<td></td>
<td>0.027778</td>
</tr>
<tr>
<td></td>
<td>0.055556</td>
</tr>
<tr>
<td></td>
<td>0.027778</td>
</tr>
</tbody>
</table>

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
<tr>
<td></td>
<td>358</td>
</tr>
<tr>
<td></td>
<td>178</td>
</tr>
<tr>
<td></td>
<td>358</td>
</tr>
</tbody>
</table>
>>> df.sub([1, 2], axis='columns')

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1 358</td>
</tr>
<tr>
<td>triangle</td>
<td>2 178</td>
</tr>
<tr>
<td>rectangle</td>
<td>3 358</td>
</tr>
</tbody>
</table>

>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1 359</td>
</tr>
<tr>
<td>triangle</td>
<td>2 179</td>
</tr>
<tr>
<td>rectangle</td>
<td>3 359</td>
</tr>
</tbody>
</table>

Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]}, index=['circle', 'triangle', 'rectangle'])
```

```output
<table>
<thead>
<tr>
<th>angles</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
</tr>
<tr>
<td>triangle</td>
</tr>
<tr>
<td>rectangle</td>
</tr>
</tbody>
</table>
```

```python
>>> df * other
```

```output
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>NaN 1.0</td>
</tr>
<tr>
<td>triangle</td>
<td>NaN 1.0</td>
</tr>
<tr>
<td>rectangle</td>
<td>NaN 1.0</td>
</tr>
</tbody>
</table>
```

```python
>>> df.mul(other, fill_value=0)
```

```output
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0</td>
</tr>
<tr>
<td>triangle</td>
<td>0.0</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.0</td>
</tr>
</tbody>
</table>
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               index=['A', 'A', 'A', 'B', 'B', 'B'],
                               'circle': ['circle', 'triangle', 'rectangle',
                                          'square', 'pentagon', 'hexagon'])
```

```output
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>A circle</td>
<td>0 360</td>
</tr>
<tr>
<td>triangle</td>
<td>3 180</td>
</tr>
<tr>
<td>rectangle</td>
<td>4 360</td>
</tr>
<tr>
<td>B square</td>
<td>4 360</td>
</tr>
<tr>
<td>pentagon</td>
<td>5 540</td>
</tr>
<tr>
<td>hexagon</td>
<td>6 720</td>
</tr>
</tbody>
</table>
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
```

```output
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>A circle</td>
<td>NaN 1.0</td>
</tr>
<tr>
<td>triangle</td>
<td>1.0 1.0</td>
</tr>
<tr>
<td>rectangle</td>
<td>1.0 1.0</td>
</tr>
</tbody>
</table>
```

(continues on next page)
pandas.DataFrame.add_prefix

DataFrame.add_prefix(prefix)
Prefix labels with string prefix.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

Parameters

prefix [str] The string to add before each label.

Returns

Series or DataFrame New Series or DataFrame with updated labels.

See also:

Series.add_suffix Suffix row labels with string suffix.
DataFrame.add_suffix Suffix column labels with string suffix.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0 1  
1 2  
2 3  
3 4  
dtype: int64

>>> s.add_prefix('item_')
item_0  1  
item_1  2  
item_2  3  
item_3  4  
dtype: int64

>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0 1 3
1 2 4
2 3 5
3 4 6

>>> df.add_prefix('col_')
col_A  col_B
0 1 3
1 2 4
```

(continues on next page)
pandas.DataFrame.add_suffix

DataFrame.add_suffix(suffix)

Suffix labels with string suffix.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

Parameters

suffix [str] The string to add after each label.

Returns

Series or DataFrame New Series or DataFrame with updated labels.

See also:

Series.add_prefix Prefix row labels with string prefix.

DataFrame.add_prefix Prefix column labels with string prefix.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1  
1    2  
2    3  
3    4  
dtype: int64

>>> s.add_suffix('_item')
0_item    1  
1_item    2  
2_item    3  
3_item    4  
dtype: int64

>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B  
0  1  3  
1  2  4  
2  3  5  
3  4  6

>>> df.add_suffix('_col')
   A_col  B_col  
0      1      3  
1      2      4  
2      3      5  
3      4      6
```
**pandas.DataFrame.agg**

Dataframe.agg(func=None, axis=0, *args, **kwargs)

Aggregate using one or more operations over the specified axis.

**Parameters**

- **func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.
  
  Accepted combinations are:
  
  - function
  - string function name
  - list of functions and/or function names, e.g. [np.sum, 'mean']
  - dict of axis labels -> functions, function names or list of such.

- **axis** [{0 or 'index', 1 or 'columns'}, default 0] If 0 or ‘index’: apply function to each column. If 1 or ‘columns’: apply function to each row.

- **args** Positional arguments to pass to func.

- **kwargs** Keyword arguments to pass to func.

**Returns**

- scalar, Series or DataFrame  The return can be:
  
  - scalar : when Series.agg is called with single function
  - Series : when DataFrame.agg is called with a single function
  - DataFrame : when DataFrame.agg is called with several functions

  Return scalar, Series or DataFrame.

The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from numpy aggregation functions (mean, median, prod, sum, std, var), where the default is to compute the aggregation of the flattened array, e.g., numpy.mean(arr_2d) as opposed to numpy.mean(arr_2d, axis=0).

agg is an alias for aggregate. Use the alias.

**See also:**

- `DataFrame.apply`  Perform any type of operations.
- `DataFrame.transform`  Perform transformation type operations.
- `core.groupby.GroupBy`  Perform operations over groups.
- `core.resample.Resampler`  Perform operations over resampled bins.
- `core.window.Rolling`  Perform operations over rolling window.
- `core.window.Expanding`  Perform operations over expanding window.
- `core.window.ExponentialMovingWindow`  Perform operation over exponential weighted window.
Notes

`agg` is an alias for `aggregate`. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> df = pd.DataFrame([[1, 2, 3],
...                     [4, 5, 6],
...                     [7, 8, 9],
...                     [np.nan, np.nan, np.nan]],
...                    columns=['A', 'B', 'C'])

Aggregate these functions over the rows.

```python
>>> df.agg(['sum', 'min'])
A     B     C
sum  12.0  15.0  18.0
min  1.0   2.0   3.0
```

Different aggregations per column.

```python
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
A     B
sum  12.0 NaN
min  1.0  2.0
max  NaN  8.0
```

Aggregate different functions over the columns and rename the index of the resulting DataFrame.

```python
>>> df.agg(x=('A', max), y=('B', 'min'), z=('C', np.mean))
A     B     C
x  7.0   NaN  NaN
y  NaN  2.0   NaN
z  NaN  NaN  6.0
```

Aggregate over the columns.

```python
>>> df.agg("mean", axis="columns")
0  2.0
1  5.0
2  8.0
3  NaN
dtype: float64
```
pandas.DataFrame.aggregate

DataFrame.aggregate (func=None, axis=0, *args, **kwargs)
Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

• function
• string function name
• list of functions and/or function names, e.g. [np.sum, 'mean']
• dict of axis labels -> functions, function names or list of such.

axis [(0 or 'index', 1 or 'columns'), default 0] If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

*args Positional arguments to pass to func.

**kwargs Keyword arguments to pass to func.

Returns

scalar, Series or DataFrame The return can be:

• scalar : when Series.agg is called with single function
• Series : when DataFrame.agg is called with a single function
• DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from numpy aggregation functions (mean, median, prod, sum, std, var), where the default is to compute the aggregation of the flattened array, e.g., numpy.mean(arr_2d) as opposed to numpy.mean(arr_2d, axis=0).

agg is an alias for aggregate. Use the alias.

See also:

DataFrame.apply Perform any type of operations.

DataFrame.transform Perform transformation type operations.

core.groupby.GroupBy Perform operations over groups.

core.resample.Resampler Perform operations over resampled bins.

core.window.Rolling Perform operations over rolling window.

core.window.Expanding Perform operations over expanding window.

core.window.ExponentialMovingWindow Perform operation over exponential weighted window.
Notes

`agg` is an alias for `aggregate`. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> df = pd.DataFrame([[1, 2, 3],
... [4, 5, 6],
... [7, 8, 9],
... [np.nan, np.nan, np.nan]],
... columns=['A', 'B', 'C'])
```

Aggregate these functions over the rows.

```python
>>> df.agg(['sum', 'min'])
   A  B  C
sum 12.0 15.0 18.0
min  1.0  2.0  3.0
```

Different aggregations per column.

```python
>>> df.agg({'A': ['sum', 'min'], 'B': ['min', 'max']})
   A   B
sum 12.0 NaN
min  1.0  2.0
max  NaN  8.0
```

Aggregate different functions over the columns and rename the index of the resulting DataFrame.

```python
>>> df.agg(x=('A', max), y=('B', 'min'), z=('C', np.mean))
   A  B  C
x  7.0 NaN NaN
y NaN  2.0 NaN
z NaN NaN  6.0
```

Aggregate over the columns.

```python
>>> df.agg("mean", axis="columns")
   0  1  2
0  2.0  5.0  8.0
1 NaN            
```

3.4. DataFrame
pandas.DataFrame.align

DataFrame.align (other, join='outer', axis=None, level=None, copy=True, fill_value=None, method=None, limit=None, fill_axis=0, broadcast_axis=None)
Align two objects on their axes with the specified join method.
Join method is specified for each axis Index.

Parameters

other  [DataFrame or Series]
join  [‘outer’, ‘inner’, ‘left’, ‘right’], default ‘outer’
axis  [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None).
level  [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level.
copy  [bool, default True] Always returns new objects. If copy=False and no reindexing is required then original objects are returned.
fill_value  [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.
method  [‘backfill’, ‘bfill’, ‘pad’, ‘ffill’, None], default None] Method to use for filling holes in reindexed Series:
• pad / ffill: propagate last valid observation forward to next valid.
• backfill / bfill: use NEXT valid observation to fill gap.
limit  [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.
fill_axis  [{0 or ‘index’, 1 or ‘columns’}, default 0] Filling axis, method and limit.
broadcast_axis  [{0 or ‘index’, 1 or ‘columns’}, default None] Broadcast values along this axis, if aligning two objects of different dimensions.

Returns

(left, right)  [(DataFrame, type of other)] Aligned objects.

pandas.DataFrame.all

DataFrame.all (axis=0, bool_only=None, skipna=True, level=None, **kwargs)
Return whether all elements are True, potentially over an axis.
Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

Parameters

axis  [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Indicate which axis or axes should be reduced.
• 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
• `1 / 'columns'`: reduce the columns, return a Series whose index is the original index.
• `None`: reduce all axes, return a scalar.

`bool_only` [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

`skipna` [bool, default True] Exclude NA/null values. If the entire row/column is NA and `skipna` is True, then the result will be True, as for an empty row/column. If `skipna` is False, then NA are treated as True, because these are not equal to zero.

`level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**kwargs [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

**Series or DataFrame** If level is specified, then, DataFrame is returned; otherwise, Series is returned.

See also:

*Series.all* Return True if all elements are True.

*DataFrame.any* Return True if one (or more) elements are True.

**Examples**

**Series**

```python
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([], dtype="float64").all()
True
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

**DataFrames**

Create a dataframe from a dictionary.

```python
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
```

```
>>> df
         col1  col2
0      True  True
1      True  False
```

Default behaviour checks if column-wise values all return True.

```python
>>> df.all()
col1   True
col2   False
dtype: bool
```
Specify `axis='columns'` to check if row-wise values all return True.

```python
>>> df.all(axis='columns')
0    True
1    False
dtype: bool
```

Or `axis=None` for whether every value is True.

```python
>>> df.all(axis=None)
False
```

### pandas.DataFrame.any

DataFrame.any (axis=0, bool_only=None, skipna=True, level=None, **kwargs)

Return whether any element is True, potentially over an axis.

Returns False unless there is at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

**Parameters**

- `axis` [(0 or 'index', 1 or 'columns', None), default 0] Indicate which axis or axes should be reduced.
  - 0 / 'index' : reduce the index, return a Series whose index is the original column labels.
  - 1 / 'columns' : reduce the columns, return a Series whose index is the original index.
  - None : reduce all axes, return a scalar.

- `bool_only` [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

- `skipna` [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

- `level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

- `**kwargs` [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

Series or DataFrame If level is specified, then DataFrame is returned; otherwise, Series is returned.

**See also**

- `numpy.any` Numpy version of this method.
- `DataFrame.any` Return whether any element is True over requested axis.
- `Series.any` Return whether any element is True.
- `Series.all` Return whether all elements are True.
- `DataFrame.all` Return whether all elements are True over requested axis.
Examples

Series

For Series input, the output is a scalar indicating whether any element is True.

```python
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([], dtype="float64").any()
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True
```

DataFrame

Whether each column contains at least one True element (the default).

```python
>>> df = pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
>>> df
   A  B  C
0  1  0  0
1  2  2  0
```

```python
>>> df.any()
A   True
B   True
C  False
dtype: bool
```

Aggregating over the columns.

```python
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
   A  B
0 True 1
1 False 2
```

```python
>>> df.any(axis='columns')
0  True
1  True
dtype: bool
```

```python
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})
>>> df
   A  B
0 True 1
1 False 0
```

```python
>>> df.any(axis='columns')
0  True
1  False
dtype: bool
```

Aggregating over the entire DataFrame with `axis=None`. 

3.4. DataFrame
>>> df.any(axis=None)
True

any for an empty DataFrame is an empty Series.

>>> pd.DataFrame([]).any()
Series([], dtype: bool)

pandas.DataFrame.append

DataFrame.append(other, ignore_index=False, verify_integrity=False, sort=False)
Append rows of other to the end of caller, returning a new object.
Columns in other that are not in the caller are added as new columns.

Parameters

other [DataFrame or Series/dict-like object, or list of these] The data to append.
ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.
verify_integrity [bool, default False] If True, raise ValueError on creating index with duplicates.
sort [bool, default False] Sort columns if the columns of self and other are not aligned.

Changed in version 1.0.0: Changed to not sort by default.

Returns

DataFrame A new DataFrame consisting of the rows of caller and the rows of other.

See also:

concat General function to concatenate DataFrame or Series objects.

Notes

If a list of dict/series is passed and the keys are all contained in the DataFrame’s index, the order of the columns in the resulting DataFrame will be unchanged.

Iteratively appending rows to a DataFrame can be more computationally intensive than a single concatenate. A better solution is to append those rows to a list and then concatenate the list with the original DataFrame all at once.

Examples

>>> df = pd.DataFrame([[[1, 2], [3, 4]], index=['x', 'y']])
>>> df
   A  B
  x 1  2
  y 3  4
>>> df2 = pd.DataFrame([[5, 6], [7, 8]], index=['x', 'y']])
>>> df.append(df2)
With `ignore_index` set to True:

```python
>>> df.append(df2, ignore_index=True)
```
```
A  B
0  1  2
1  3  4
2  5  6
3  7  8
```

The following, while not recommended methods for generating DataFrames, show two ways to generate a DataFrame from multiple data sources.

**Less efficient:**

```python
>>> df = pd.DataFrame(columns=['A'])
>>> for i in range(5):
...     df = df.append({'A': i}, ignore_index=True)

```
```
A
0  0
1  1
2  2
3  3
4  4
```

**More efficient:**

```python
>>> pd.concat([pd.DataFrame([i], columns=['A']) for i in range(5)],
...            ignore_index=True)
```
```
A
0  0
1  1
2  2
3  3
4  4
```

### `pandas.DataFrame.apply`

`DataFrame.apply(func, axis=0, raw=False, result_type=None, args=(), **kwargs)`

Apply a function along an axis of the DataFrame.

Objects passed to the function are Series objects whose index is either the DataFrame’s index (`axis=0`) or the DataFrame’s columns (`axis=1`). By default (`result_type=None`), the final return type is inferred from the return type of the applied function. Otherwise, it depends on the `result_type` argument.

**Parameters**

- `func` [function] Function to apply to each column or row.
- `axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis along which the function is applied:
• 0 or ‘index’: apply function to each column.
• 1 or ‘columns’: apply function to each row.

raw [bool, default False] Determines if row or column is passed as a Series or ndarray object:

• False: passes each row or column as a Series to the function.
• True: the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

result_type [('expand', ‘reduce’, ‘broadcast’, None), default None] These only act when axis=1 (columns):

• ‘expand’: list-like results will be turned into columns.
• ‘reduce’: returns a Series if possible rather than expanding list-like results. This is the opposite of ‘expand’.
• ‘broadcast’: results will be broadcast to the original shape of the DataFrame, the original index and columns will be retained.

The default behaviour (None) depends on the return value of the applied function: list-like results will be returned as a Series of those. However if the apply function returns a Series these are expanded to columns.

args [tuple] Positional arguments to pass to func in addition to the array/series.

**kwargs Additional keyword arguments to pass as keywords arguments to func.

Returns

Series or DataFrame Result of applying func along the given axis of the DataFrame.

See also:

DataFrame.applymap For elementwise operations.

DataFrame.aggregate Only perform aggregating type operations.

DataFrame.transform Only perform transforming type operations.

Notes

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

Examples

```python
>>> df = pd.DataFrame([[4, 9]] * 3, columns=['A', 'B'])
>>> df
   A  B
0  4  9
1  4  9
2  4  9
```

Using a numpy universal function (in this case the same as np.sqrt(df)):
>>> df.apply(np.sqrt)
   A  B
0  2.0  3.0
1  2.0  3.0
2  2.0  3.0

Using a reducing function on either axis

>>> df.apply(np.sum, axis=0)
   A  B
0  12
1  27
dtype: int64

>>> df.apply(np.sum, axis=1)
   0  13
   1  13
   2  13
   dtype: int64

Returning a list-like will result in a Series

>>> df.apply(lambda x: [1, 2], axis=1)
   0  [1, 2]
   1  [1, 2]
   2  [1, 2]
   dtype: object

Passing result_type='expand' will expand list-like results to columns of a Dataframe

>>> df.apply(lambda x: [1, 2], axis=1, result_type='expand')
   0  1  2
   1  1  2
   2  1  2

Returning a Series inside the function is similar to passing result_type='expand'. The resulting column names will be the Series index.

>>> df.apply(lambda x: pd.Series([1, 2], index=['foo', 'bar']), axis=1)
   foo  bar
   0  1  2
   1  1  2
   2  1  2

Passing result_type='broadcast' will ensure the same shape result, whether list-like or scalar is returned by the function, and broadcast it along the axis. The resulting column names will be the originals.

>>> df.apply(lambda x: [1, 2], axis=1, result_type='broadcast')
   0  1  2
   1  1  2
   2  1  2
pandas.DataFrame.applymap

DataFrame.applymap(func, na_action=None, **kwargs)

Apply a function to a DataFrame elementwise.

This method applies a function that accepts and returns a scalar to every element of a DataFrame.

Parameters

func  [callable] Python function, returns a single value from a single value.

na_action  [(None, ‘ignore’), default None] If ‘ignore’, propagate NaN values, without passing them to func.

New in version 1.2.

**kwargs  Additional keyword arguments to pass as keywords arguments to func.

New in version 1.3.0.

Returns

DataFrame  Transformed DataFrame.

See also:

DataFrame.apply  Apply a function along input axis of DataFrame.

Examples

```python
def = pd.DataFrame([[1, 2.12], [3.356, 4.567]])

def
   0  1
0  1.000 2.120
1  3.356 4.567

>>> df.applymap(lambda x: len(str(x)))
   0  1
0  3  4
1  5  5

Like Series.map, NA values can be ignored:

```python
def_copy = df.copy()
def_copy.iloc[0, 0] = pd.NA
def_copy.applymap(lambda x: len(str(x)), na_action='ignore')
   0  1
0 <NA>  4
1  5  5
```

Note that a vectorized version of func often exists, which will be much faster. You could square each number elementwise.

```python
>>> df.applymap(lambda x: x**2)
   0  1
0  1.000000  4.494400
1 11.262736 20.857489
```

But it’s better to avoid applymap in that case.
pandas: powerful Python data analysis toolkit, Release 1.3.2

```
>>> df ** 2
    0   1
 0  1.000000  4.494400
 1 11.262736 20.857489
```

pandas.DataFrame.asfreq

DataFrame.asfreq(freq=None, method=None, how=None, normalize=False, fill_value=None)

Convert time series to specified frequency.

Returns the original data conformed to a new index with the specified frequency.

If the index of this DataFrame is a PeriodIndex, the new index is the result of transforming the original index with PeriodIndex.asfreq (so the original index will map one-to-one to the new index).

Otherwise, the new index will be equivalent to pd.date_range(start, end, freq=freq) where start and end are, respectively, the first and last entries in the original index (see pandas.date_range). The values corresponding to any timesteps in the new index which were not present in the original index will be null (NaN), unless a method for filling such unknowns is provided (see the method parameter below).

The resample() method is more appropriate if an operation on each group of timesteps (such as an aggregate) is necessary to represent the data at the new frequency.

Parameters

- **freq** [DateOffset or str] Frequency DateOffset or string.
- **method** [‘backfill’/’bfill’, ‘pad’/’ffill’], default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):
  - ‘pad’ / ‘ffill’: propagate last valid observation forward to next valid
  - ‘backfill’ / ‘bfill’: use NEXT valid observation to fill.
- **how** [‘start’, ‘end’], default end] For PeriodIndex only (see PeriodIndex.asfreq).
- **normalize** [bool, default False] Whether to reset output index to midnight.
- **fill_value** [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

Returns

**DataFrame** DataFrame object reindexed to the specified frequency.

See also:

**reindex** Conform DataFrame to new index with optional filling logic.
Notes

To learn more about the frequency strings, please see this link.

Examples

Start by creating a series with 4 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s': series})
>>> df
    s
2000-01-01 00:00:00  0.0
2000-01-01 00:01:00  NaN
2000-01-01 00:02:00  2.0
2000-01-01 00:03:00  3.0
```

Upsample the series into 30 second bins.

```python
>>> df.asfreq(freq='30S')
    s
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  NaN
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  NaN
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  NaN
2000-01-01 00:03:00  3.0
```

Upsample again, providing a fill value.

```python
>>> df.asfreq(freq='30S', fill_value=9.0)
    s
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  9.0
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  9.0
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  9.0
2000-01-01 00:03:00  3.0
```

Upsample again, providing a method.

```python
>>> df.asfreq(freq='30S', method='bfill')
    s
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  NaN
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  2.0
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  3.0
2000-01-01 00:03:00  3.0
```
pandas.DataFrame.asof

DataFrame.asof(where, subset=None)

Return the last row(s) without any NaNs before where.

The last row (for each element in where, if list) without any NaN is taken. In case of a DataFrame, the last row without NaN considering only the subset of columns (if not None)

If there is no good value, NaN is returned for a Series or a Series of NaN values for a DataFrame

Parameters

where [date or array-like of dates] Date(s) before which the last row(s) are returned.

subset [str or array-like of str, default None] For DataFrame, if not None, only use these columns to check for NaNs.

Returns

scalar, Series, or DataFrame The return can be:

• scalar : when self is a Series and where is a scalar

• Series: when self is a Series and where is an array-like, or when self is a DataFrame and where is a scalar

• DataFrame : when self is a DataFrame and where is an array-like

Return scalar, Series, or DataFrame.

See also:

merge_asof Perform an asof merge. Similar to left join.

Notes

Dates are assumed to be sorted. Raises if this is not the case.

Examples

A Series and a scalar where.

```python
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10   1.0
20   2.0
30  NaN
40   4.0
dtype: float64
```

```python
>>> s.asof(20)
2.0
```

For a sequence where, a Series is returned. The first value is NaN, because the first element of where is before the first index value.
Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

Take all columns into consideration

Take a single column into consideration

pandas.DataFrame.assign

DataFrame.assign(**kwargs)

Assign new columns to a DataFrame.

Returns a new object with all original columns in addition to new ones. Existing columns that are re-assigned will be overwritten.

Parameters

**kwargs [dict of {str: callable or Series}] The column names are keywords. If the values are callable, they are computed on the DataFrame and assigned to the new columns. The callable must not change input DataFrame (though pandas doesn’t check it). If the values are not callable, (e.g. a Series, scalar, or array), they are simply assigned.

Returns

DataFrame A new DataFrame with the new columns in addition to all the existing columns.
Notes

Assigning multiple columns within the same assign is possible. Later items in `**kwargs` may refer to newly created or modified columns in `df`; items are computed and assigned into `df` in order.

Examples

```python
>>> df = pd.DataFrame({'temp_c': [17.0, 25.0]},
                        index=['Portland', 'Berkeley'])
>>> df
     temp_c
Portland   17.0
Berkeley   25.0
```

Where the value is a callable, evaluated on `df`:

```python
>>> df.assign(temp_f=lambda x: x.temp_c * 9 / 5 + 32)
     temp_c     temp_f
Portland   17.0       62.6
Berkeley   25.0       77.0
```

Alternatively, the same behavior can be achieved by directly referencing an existing Series or sequence:

```python
>>> df.assign(temp_f=df['temp_c'] * 9 / 5 + 32)
     temp_c     temp_f
Portland   17.0       62.6
Berkeley   25.0       77.0
```

You can create multiple columns within the same assign where one of the columns depends on another one defined within the same assign:

```python
>>> df.assign(temp_f=lambda x: x['temp_c'] * 9 / 5 + 32, 
               temp_k=lambda x: (x['temp_f'] + 459.67) * 5 / 9)
     temp_c     temp_f     temp_k
Portland   17.0       62.6       290.15
Berkeley   25.0       77.0       298.15
```

**pandas.DataFrame.astype**

DataFrame.astype(dtype, copy=True, errors=’raise’)

Cast a pandas object to a specified dtype dtype.

Parameters

- **dtype** [data type, or dict of column name -> data type] Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use `{col: dtype, ...}`, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame’s columns to column-specific types.

- **copy** [bool, default True] Return a copy when `copy=True` (be very careful setting `copy=False` as changes to values then may propagate to other pandas objects).

- **errors** ['raise', 'ignore'], default ‘raise’] Control raising of exceptions on invalid data for provided dtype.
  - **raise**: allow exceptions to be raised
• ignore: suppress exceptions. On error return original object.

Returns

    casted  [same type as caller]

See also:

to_datetime  Convert argument to datetime.
to_timedelta  Convert argument to timedelta.
to_numeric  Convert argument to a numeric type.
numpy.ndarray.astype  Cast a numpy array to a specified type.

Notes

 Deprecated since version 1.3.0: Using astype to convert from timezone-naive dtype to timezone-aware dtype is deprecated and will raise in a future version. Use Series.dt.tz_localize() instead.

Examples

Create a DataFrame:

```python
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df.dtypes
coll  int64
col2  int64
dtype: object
```

Cast all columns to int32:

```python
>>> df.astype('int32').dtypes
coll  int32
col2  int32
dtype: object
```

Cast col1 to int32 using a dictionary:

```python
>>> df.astype({'col1': 'int32'}).dtypes
coll  int32
col2  int64
dtype: object
```

Create a series:

```python
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0 1
1 2
dtype: int32
>>> ser.astype('int64')
0 1
1 2
dtype: int64
```
Convert to categorical type:

```python
>>> ser.astype('category')
0  1
1  2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```python
>>> from pandas.api.types import CategoricalDtype
>>> cat_dtype = CategoricalDtype(
...     categories=[2, 1], ordered=True
)
>>> ser.astype(cat_dtype)
0  1
1  2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```python
>>> s1 = pd.Series([1, 2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1
# note that s1[0] has changed too
0  10
1  2
dtype: int64
```

Create a series of dates:

```python
>>> ser_date = pd.Series(pd.date_range('20200101', periods=3))
>>> ser_date
0  2020-01-01
1  2020-01-02
2  2020-01-03
dtype: datetime64[ns]
```

**pandas.DataFrame.at_time**

DataFrame.**at_time**(time, asof=False, axis=None)

Select values at particular time of day (e.g., 9:30AM).

**Parameters**

- **time** [datetime.time or str]
- **axis** [[0 or ‘index’, 1 or ‘columns’], default 0]

**Returns**

- Series or DataFrame

**Raises**

- **TypeError** If the index is not a DatetimeIndex

**See also:**

- **between_time** Select values between particular times of the day.
first  Select initial periods of time series based on a date offset.

last  Select final periods of time series based on a date offset.

DatetimeIndex.indexer_at_time  Get just the index locations for values at particular time of the day.

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
      A
2018-04-09 00:00:00  1
2018-04-09 12:00:00  2
2018-04-10 00:00:00  3
2018-04-10 12:00:00  4

>>> ts.at_time('12:00')
      A
2018-04-09 12:00:00  2
2018-04-10 12:00:00  4
```

pandas.DataFrame.backfill

DataFrame.backfill(axis=None, inplace=False, limit=None, downcast=None)

Synonym for DataFrame.fillna() with method='bfill'.

Returns

Series/DataFrame or None  Object with missing values filled or None if inplace=True.

pandas.DataFrame.between_time

DataFrame.between_time(start_time, end_time, include_start=True, include_end=True, axis=None)

Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting start_time to be later than end_time, you can get the times that are not between the two times.

Parameters

start_time  [datetime.time or str] Initial time as a time filter limit.
end_time  [datetime.time or str] End time as a time filter limit.
include_start  [bool, default True] Whether the start time needs to be included in the result.
include_end  [bool, default True] Whether the end time needs to be included in the result.
axis  [(0 or ‘index’, 1 or ‘columns’), default 0] Determine range time on index or columns value.
Returns

**Series or DataFrame** Data from the original object filtered to the specified dates range.

Raises

**TypeError** If the index is not a `DatetimeIndex`

See also:

- `at_time` Select values at a particular time of the day.
- `first` Select initial periods of time series based on a date offset.
- `last` Select final periods of time series based on a date offset.
- `DatetimeIndex.indexer_between_time` Get just the index locations for values between particular times of the day.

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
   A
2018-04-09 00:00:00  1
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3
2018-04-12 01:00:00  4

>>> ts.between_time('0:15', '0:45')
   A
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3
```

You get the times that are *not* between two times by setting `start_time` later than `end_time`:

```python
>>> ts.between_time('0:45', '0:15')
   A
2018-04-09 00:00:00  1
2018-04-12 01:00:00  4
```

`pandas.DataFrame.bfill`

**DataFrame.bfill**(axis=None, inplace=False, limit=None, downcast=None)

**Synonym for DataFrame.fillna() with method='bfill'.**

Returns

**Series/DataFrame or None** Object with missing values filled or None if `inplace=True`. 
pandas.DataFrame.bool

DataFrame.bool()
Return the bool of a single element Series or DataFrame.
This must be a boolean scalar value, either True or False. It will raise a ValueError if the Series or DataFrame does not have exactly 1 element, or that element is not boolean (integer values 0 and 1 will also raise an exception).

Returns
bool  The value in the Series or DataFrame.

See also:

Series.astype  Change the data type of a Series, including to boolean.
DataFrame.astype  Change the data type of a DataFrame, including to boolean.
numpy.bool_  NumPy boolean data type, used by pandas for boolean values.

Examples

The method will only work for single element objects with a boolean value:

```python
>>> pd.Series([True]).bool()
True
>>> pd.Series([False]).bool()
False
```

pandas.DataFrame.boxplot

DataFrame.boxplot(column=None, by=None, ax=None, fontsize=None, rot=0, grid=True, figsize=None, layout=None, return_type=None, backend=None, **kwargs)

Make a box plot from DataFrame columns.

Make a box-and-whisker plot from DataFrame columns, optionally grouped by some other columns. A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. By default, they extend no more than 1.5 * IQR (IQR = Q3 - Q1) from the edges of the box, ending at the farthest data point within that interval. Outliers are plotted as separate dots.

For further details see Wikipedia’s entry for boxplot.

Parameters

column  [str or list of str, optional] Column name or list of names, or vector. Can be any valid input to pandas.DataFrame.groupby().

by  [str or array-like, optional] Column in the DataFrame to pandas.DataFrame.groupby(). One box-plot will be done per value of columns in by.
**ax** [object of class matplotlib.axes.Axes, optional] The matplotlib axes to be used by boxplot.

**fontsize** [float or str] Tick label font size in points or as a string (e.g., *large*).

**rot** [int or float, default 0] The rotation angle of labels (in degrees) with respect to the screen coordinate system.

**grid** [bool, default True] Setting this to True will show the grid.

**figsize** [A tuple (width, height) in inches] The size of the figure to create in matplotlib.

**layout** [tuple (rows, columns), optional] For example, (3, 5) will display the subplots using 3 columns and 5 rows, starting from the top-left.

**return_type** [‘axes’, ‘dict’, ‘both’] The kind of object to return. The default is *axes*.

- ‘axes’ returns the matplotlib axes the boxplot is drawn on.
- ‘dict’ returns a dictionary whose values are the matplotlib Lines of the boxplot.
- ‘both’ returns a namedtuple with the axes and dict.
- when grouping with *by*, a Series mapping columns to *return_type* is returned.

If *return_type* is *None*, a NumPy array of axes with the same shape as *layout* is returned.

**backend** [str, default None] Backend to use instead of the backend specified in the *plotting.backend*. For instance, ‘matplotlib’. Alternatively, to specify the *plotting.backend* for the whole session, set *pd.options.plotting.backend*.

New in version 1.0.0.

**kwargs** All other plotting keyword arguments to be passed to *matplotlib.pyplot.boxplot()*.

**Returns**

- **result** See Notes.

**See also:**

- *Series.plot.hist* Make a histogram.
- *matplotlib.pyplot.boxplot* Matplotlib equivalent plot.

**Notes**

The return type depends on the *return_type* parameter:

- ‘axes’ : object of class matplotlib.axes.Axes
- ‘dict’ : dict of matplotlib.lines.Line2D objects
- ‘both’ : a namedtuple with structure (ax, lines)

For data grouped with *by*, return a Series of the above or a numpy array:

- *Series*
- array (*for return_type* = *None*)
Use `return_type='dict'` when you want to tweak the appearance of the lines after plotting. In this case a dict containing the Lines making up the boxes, caps, fliers, medians, and whiskers is returned.

**Examples**

Boxplots can be created for every column in the dataframe by `df.boxplot()` or indicating the columns to be used:

```python
def df = pd.DataFrame(np.random.randn(10, 4),
... columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
```

Boxplots of variables distributions grouped by the values of a third variable can be created using the option `by`. For instance:

```python
def df = pd.DataFrame(np.random.randn(10, 2),
... columns=['Col1', 'Col2'])
... 'B', 'B', 'B', 'B', 'B'])
>>> boxplot = df.boxplot(by='X')
```

A list of strings (i.e. ['X', 'Y']) can be passed to boxplot in order to group the data by combination of the variables in the x-axis:
Boxplot grouped by X

Col1

Col2

[X]

A B

[X]

A B
pandas: powerful Python data analysis toolkit, Release 1.3.2

```python
>>> df = pd.DataFrame(np.random.randn(10, 3),
...                   columns=['Col1', 'Col2', 'Col3'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```

The layout of boxplot can be adjusted giving a tuple to `layout`:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                        layout=(2, 1))
```

Additional formatting can be done to the boxplot, like suppressing the grid (`grid=False`), rotating the labels in the x-axis (i.e. `rot=45`) or changing the fontsize (i.e. `fontsize=15`):

```python
>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)
```

The parameter `return_type` can be used to select the type of element returned by `boxplot`. When `return_type='axes'` is selected, the matplotlib axes on which the boxplot is drawn are returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
>>> type(boxplot)
<class 'matplotlib.axes._subplots.AxesSubplot'>
```
Boxplot grouped by X

Col1

Col2

A

X

B
When grouping with `by`, a Series mapping columns to `return_type` is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                       return_type='axes')
>>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                       return_type=None)
>>> type(boxplot)
<class 'numpy.ndarray'>
```

**pandas.DataFrame.clip**

`DataFrame.clip(lower=None, upper=None, axis=None, inplace=False, *args, **kwargs)`

Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

**Parameters**

- `lower` [float or array-like, default None] Minimum threshold value. All values below this threshold will be set to it. A missing threshold (e.g. `NA`) will not clip the value.
- `upper` [float or array-like, default None] Maximum threshold value. All values above this threshold will be set to it. A missing threshold (e.g. `NA`) will not clip the value.
- `axis` [int or str axis name, optional] Align object with lower and upper along the given axis.
- `inplace` [bool, default False] Whether to perform the operation in place on the data.
- `*args, **kwargs` Additional keywords have no effect but might be accepted for compatibility with numpy.

**Returns**

- **Series or DataFrame or None** Same type as calling object with the values outside the clip boundaries replaced or None if `inplace=True`.

**See also:**

- `Series.clip` Trim values at input threshold in series.
- `DataFrame.clip` Trim values at input threshold in dataframe.
- `numpy.clip` Clip (limit) the values in an array.
Examples

```python
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0  col_1
0     9    -2
1    -3     -7
2     0      6
3    -1      8
4     5     -5
```

Clips per column using lower and upper thresholds:

```python
>>> df.clip(-4, 6)
   col_0  col_1
0      6    -2
1     -3     -4
2      0      6
3     -1      6
4      5     -4
```

Clips using specific lower and upper thresholds per column element:

```python
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0    2
1   -4
2    -1
3     6
4     3
dtype: int64

>>> df.clip(t, t + 4, axis=0)
   col_0  col_1
0      6    2
1     -3   -4
2      0     3
3      6     8
4      5     3
```

Clips using specific lower threshold per column element, with missing values:

```python
>>> t = pd.Series([2, -4, np.NaN, 6, 3])
>>> t
0    2.0
1   -4.0
2     NaN
3    6.0
4    3.0
dtype: float64

>>> df.clip(t, axis=0)
   col_0  col_1
0      9     2
1     -3   -4
2      0      6
```

(continues on next page)
pandas.DataFrame.combine

DataFrame.combine(other, func, fill_value=None, overwrite=True)

Perform column-wise combine with another DataFrame.

Combines a DataFrame with other DataFrame using func to element-wise combine columns. The row
and column indexes of the resulting DataFrame will be the union of the two.

Parameters

other [DataFrame] The DataFrame to merge column-wise.

func [function] Function that takes two series as inputs and return a Series or a scalar.
Used to merge the two dataframes column by columns.

fill_value [scalar value, default None] The value to fill NaNs with prior to passing any
column to the merge func.

overwrite [bool, default True] If True, columns in self that do not exist in other will
be overwritten with NaNs.

Returns

DataFrame Combination of the provided DataFrames.

See also:

DataFrame.combine_first Combine two DataFrame objects and default to non-null values in
frame calling the method.

Examples

Combine using a simple function that chooses the smaller column.

```python
>>> df1 = pd.DataFrame({"A": [0, 0], "B": [4, 4]})
>>> df2 = pd.DataFrame({"A": [1, 1], "B": [3, 3]})
>>> take_smaller = lambda s1, s2: s1 if s1.sum() < s2.sum() else s2
>>> df1.combine(df2, take_smaller)
   A  B
0  0  3
1  0  3
```

Example using a true element-wise combine function.

```python
>>> df1 = pd.DataFrame({"A": [5, 0], "B": [2, 4]})
>>> df2 = pd.DataFrame({"A": [1, 1], "B": [3, 3]})
>>> df1.combine(df2, np.minimum)
   A  B
0  1  2
1  0  3
```

Using fill_value fills Nones prior to passing the column to the merge function.
pandas: powerful Python data analysis toolkit, Release 1.3.2

```python
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
       A  B
0    0 -5
1    0  4

However, if the same element in both dataframes is None, that None is preserved

```python
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [None, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
       A  B
0    0  -5
1    0   4
```

Example that demonstrates the use of `overwrite` and behavior when the axis differ between the dataframes.

```python
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [-10, 1], }, index=[1, 2])
>>> df1.combine(df2, take_smaller)
      A  B  C
0 NaN NaN NaN
1 NaN  3 -10
2 NaN  3  1

>>> df1.combine(df2, take_smaller, overwrite=False)
      A  B  C
0  0.0 NaN NaN
1  0.0  3 -10
2 NaN  3  1
```

Demonstrating the preference of the passed in dataframe.

```python
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [1, 1], }, index=[1, 2])
>>> df2.combine(df1, take_smaller)
      A  B  C
0   NaN NaN NaN
1   0.0  3 NaN
2 NaN  3.0 NaN

>>> df2.combine(df1, take_smaller, overwrite=False)
      A  B  C
0   NaN NaN NaN
1   0.0  3  1.0
2 NaN  3.0  1.0
```
**pandas.DataFrame.combine_first**

**DataFrame.combine_first(other)**
Update null elements with value in the same location in other.

Combine two DataFrame objects by filling null values in one DataFrame with non-null values from other DataFrame. The row and column indexes of the resulting DataFrame will be the union of the two.

**Parameters**

- **other** [DataFrame] Provided DataFrame to use to fill null values.

**Returns**

- **DataFrame** The result of combining the provided DataFrame with the other object.

**See also:**

- **DataFrame.combine** Perform series-wise operation on two DataFrames using a given function.

**Examples**

```python
define df1 = pd.DataFrame({'A': [None, 0], 'B': [None, 4]})
define df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
define df1.combine_first(df2)
   |   |
   | 0 | 1.0 3.0 |
   | 1 | 0.0 4.0 |

Null values still persist if the location of that null value does not exist in other

```python
define df1 = pd.DataFrame({'A': [None, 0], 'B': [4, None]})
define df2 = pd.DataFrame({'B': [3, 3], 'C': [1, 1], index=[1, 2]})
define df1.combine_first(df2)
   |   |   |
   | A | B | C |
   | 0 | 1.0 4.0 NaN |
   | 1 | 0.0 3.0 1.0 |
   | 2 | NaN 3.0 1.0 |
```

**pandas.DataFrame.compare**

**DataFrame.compare(other, align_axis=1, keep_shape=False, keep_equal=False)**
Compare to another DataFrame and show the differences.

New in version 1.1.0.

**Parameters**

- **other** [DataFrame] Object to compare with.

- **align_axis** [0 or ‘index’, 1 or ‘columns’], default 1] Determine which axis to align the comparison on.
  - **0, or ‘index’** [Resulting differences are stacked vertically] with rows drawn alternately from self and other.
  - **1, or ‘columns’** [Resulting differences are aligned horizontally] with columns drawn alternately from self and other.
**keep_shape** [bool, default False] If true, all rows and columns are kept. Otherwise, only the ones with different values are kept.

**keep_equal** [bool, default False] If true, the result keeps values that are equal. Otherwise, equal values are shown as NaNs.

**Returns**

**DataFrame** DataFrame that shows the differences stacked side by side. The resulting index will be a MultiIndex with ‘self’ and ‘other’ stacked alternately at the inner level.

**Raises**

**ValueError** When the two DataFrames don’t have identical labels or shape.

**See also:**

*Series.compare* Compare with another Series and show differences.

*DataFrame.equals* Test whether two objects contain the same elements.

**Notes**

Matching NaNs will not appear as a difference.

Can only compare identically-labeled (i.e. same shape, identical row and column labels) DataFrames

**Examples**

```python
>>> df = pd.DataFrame(
    ... {
    ...     "col1": ["a", "a", "b", "b", "a"],
    ...     "col2": [1.0, 2.0, 3.0, np.nan, 5.0],
    ...     "col3": [1.0, 2.0, 3.0, 4.0, 5.0]
    ... },
    ... columns=["col1", "col2", "col3"],
    ...)
>>> df
  col1 col2 col3
0    a   1.0  1.0
1    a   2.0  2.0
2    b   3.0  3.0
3    b  NaN  4.0
4    a   5.0  5.0

>>> df2 = df.copy()
>>> df2.loc[0, 'col1'] = 'c'
>>> df2.loc[2, 'col3'] = 4.0
>>> df2
  col1 col2 col3
0    c   1.0  1.0
1    a   2.0  2.0
2    b   3.0  4.0
3    b  NaN  4.0
4    a   5.0  5.0
```

Align the differences on columns
```python
>>> df.compare(df2)
coll  col3
    self  other  self  other
 0      a      c    NaN    NaN
 2      NaN    NaN    3.0    4.0

Stack the differences on rows

```}

```python
>>> df.compare(df2, align_axis=0)
coll  col3
    0    self  a    NaN
          other  c    NaN
    2    self  NaN    3.0
          other  NaN    4.0

Keep the equal values

```}

```python
>>> df.compare(df2, keep_equal=True)
coll  col3
    0    self  a    1.0    1.0
          other  c    NaN    NaN
    2    self  NaN    3.0    4.0

Keep all original rows and columns

```}

```python
>>> df.compare(df2, keep_shape=True)
coll  col2  col3
    0    self  a      NaN    NaN    NaN    NaN
          other  c      NaN    NaN    NaN    NaN
    1    NaN    NaN    NaN    NaN    NaN    NaN
    2    NaN    NaN    NaN    NaN    3.0    4.0
    3    NaN    NaN    NaN    NaN    NaN    NaN
    4    NaN    NaN    NaN    NaN    NaN    NaN

Keep all original rows and columns and also all original values

```}

```python
>>> df.compare(df2, keep_shape=True, keep_equal=True)
coll  col2  col3
    0    self  a      1.0    1.0    1.0    1.0

    4    NaN    NaN      NaN    NaN    NaN    NaN

pandas.DataFrame.convert_dtypes

DataFrame.convert_dtypes(infer_objects=True, convert_string=True, convert_integer=True,
convert_boolean=True, convert_floating=True)
Convert columns to best possible dtypes using dtypes supporting pd.NA.

New in version 1.0.0.

Parameters

- **infer_objects** [bool, default True] Whether object dtypes should be converted to the best possible types.
**convert_string** [bool, default True] Whether object dtypes should be converted to StringDtype().

**convert_integer** [bool, default True] Whether, if possible, conversion can be done to integer extension types.

**convert_boolean** [bool, defaults True] Whether object dtypes should be converted to BooleanDtypes().

**convert_floating** [bool, defaults True] Whether, if possible, conversion can be done to floating extension types. If convert_integer is also True, preference will be given to integer dtypes if the floats can be faithfully casted to integers.

   New in version 1.2.0.

**Returns**

Series or DataFrame Copy of input object with new dtype.

**See also:**

**infer_objects** Infer dtypes of objects.

**to_datetime** Convert argument to datetime.

**to_timedelta** Convert argument to timedelta.

**to_numeric** Convert argument to a numeric type.

**Notes**

By default, convert_dtypes will attempt to convert a Series (or each Series in a DataFrame) to dtypes that support pd.NA. By using the options convert_string, convert_integer, convert_boolean and convert_boolean, it is possible to turn off individual conversions to StringDtype, the integer extension types, BooleanDtype or floating extension types, respectively.

For object-dtyped columns, if infer_objects is True, use the inference rules as during normal Series/DataFrame construction. Then, if possible, convert to StringDtype, BooleanDtype or an appropriate integer or floating extension type, otherwise leave as object.

If the dtype is integer, convert to an appropriate integer extension type.

If the dtype is numeric, and consists of all integers, convert to an appropriate integer extension type. Otherwise, convert to an appropriate floating extension type.

Changed in version 1.2: Starting with pandas 1.2, this method also converts float columns to the nullable floating extension type.

In the future, as new dtypes are added that support pd.NA, the results of this method will change to support those new dtypes.
Examples

```python
>>> df = pd.DataFrame(
...     {
...         "a": pd.Series([1, 2, 3], dtype=np.dtype("int32")),
...         "b": pd.Series(["x", "y", "z"], dtype=np.dtype("O")),
...         "c": pd.Series([True, False, np.nan], dtype=np.dtype("O")),
...         "d": pd.Series(["h", "i", np.nan], dtype=np.dtype("O")),
...         "e": pd.Series([10, np.nan, 20], dtype=np.dtype("float")),
...         "f": pd.Series([np.nan, 100.5, 200], dtype=np.dtype("float")),
...     }
... )
Start with a DataFrame with default dtypes.
>>> df
  a  b  c   d   e  f
0 1  x  True  h 10.0  NaN
1 2  y  False  i  <NA> 100.5
2 3  z  <NA>  <NA> 20.0 200.0

>>> df.dtypes
a    int32
b    object
c    object
d    object
e    float64
f    float64
dtype: object
Convert the DataFrame to use best possible dtypes.
>>> dfn = df.convert_dtypes()
>>> dfn
  a  b  c   d   e  f
0 1  x  True  h  10 <NA>
1 2  y  False  i  <NA> 100.5
2 3  z  <NA>  <NA>  20 200.0

>>> dfn.dtypes
a    Int32
b    string
c    boolean
d    string
e    Int64
f    Float64
dtype: object
Start with a Series of strings and missing data represented by np.nan.
```
Obtain a Series with dtype `StringDtype`.

```
>>> s.convert_dtypes()
0   a
1   b
2  <NA>
dtype: string
```

`pandas.DataFrame.copy`

`DataFrame.copy` *(deep=True)*

Make a copy of this object’s indices and data.

When `deep=True` (default), a new object will be created with a copy of the calling object’s data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When `deep=False`, a new object will be created without copying the calling object’s data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

**Parameters**

- **deep** [bool, default True] Make a deep copy, including a copy of the data and the indices. With `deep=False` neither the indices nor the data are copied.

**Returns**

- **copy** [Series or DataFrame] Object type matches caller.

**Notes**

When `deep=True`, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to `copy.deepcopy` in the Standard Library, which recursively copies object data (see examples below).

While `Index` objects are copied when `deep=True`, the underlying numpy array is not copied for performance reasons. Since `Index` is immutable, the underlying data can be safely shared and a copy is not needed.

**Examples**

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> s
a    1
b    2
dtype: int64

>>> s_copy = s.copy()
>>> s_copy
a    1
b    2
dtype: int64
```

Shallow copy versus default (deep) copy:
```python
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)

Shallow copy shares data and index with original.

```python
>>> s is shallow
False
```python
>>> s.values is shallow.values and s.index is shallow.index
True

Deep copy has own copy of data and index.

```python
>>> s is deep
False
>>> s.values is deep.values or s.index is deep.index
False
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```python
>>> s[0] = 3  
>>> shallow[1] = 4
>>> s
a  3
b  4
dtype: int64
>>> shallow
a  3
b  4
dtype: int64
>>> deep
a  1
b  2
dtype: int64
```

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```python
>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
>>> s
0    [10, 2]
1    [3, 4]
dtype: object
>>> deep
0    [10, 2]
1    [3, 4]
dtype: object
```
pandas.DataFrame.corr

DataFrame.corr (method='pearson', min_periods=1)
Compute pairwise correlation of columns, excluding NA/null values.

Parameters

- **method** [{'pearson', 'kendall', 'spearman'} or callable] Method of correlation:
  - pearson : standard correlation coefficient
  - kendall : Kendall Tau correlation coefficient
  - spearman : Spearman rank correlation
  - callable: callable with input two 1d ndarrays and returning a float. Note that the returned matrix from corr will have 1 along the diagonals and will be symmetric regardless of the callable’s behavior.

- **min_periods** [int, optional] Minimum number of observations required per pair of columns to have a valid result.

Returns

- DataFrame Correlation matrix.

See also:

- DataFrame.corrwith Compute pairwise correlation with another DataFrame or Series.
- Series.corr Compute the correlation between two Series.

Examples

```python
def histogram_intersection(a, b):
    v = np.minimum(a, b).sum().round(decimals=1)
    return v

df = pd.DataFrame([(0.2, 0.3), (0.0, 0.6), (0.6, 0.0), (0.2, 0.1)],
                  columns=['dogs', 'cats'])
df.corr(method=histogram_intersection)
dogs cats
dogs 1.0 0.3
cats 0.3 1.0
```

pandas.DataFrame.corrwith

DataFrame.corrwith (other, axis=0, drop=False, method='pearson')
Compute pairwise correlation.

Pairwise correlation is computed between rows or columns of DataFrame with rows or columns of Series or DataFrame. DataFrames are first aligned along both axes before computing the correlations.

Parameters

- **other** [DataFrame, Series] Object with which to compute correlations.
- **axis** [(0 or ‘index’, 1 or ‘columns’), default 0] The axis to use. 0 or ‘index’ to compute column-wise, 1 or ‘columns’ for row-wise.
- **drop** [bool, default False] Drop missing indices from result.
method [{‘pearson’, ‘kendall’, ‘spearman’} or callable] Method of correlation:

- pearson : standard correlation coefficient
- kendall : Kendall Tau correlation coefficient
- spearman : Spearman rank correlation
- callable: callable with input two 1d ndarrays and returning a float.

Returns

Series Pairwise correlations.

See also:

DataFrame.corr Compute pairwise correlation of columns.

pandas.DataFrame.count

DataFrame.count (axis=0, level=None, numeric_only=False)

Count non-NA cells for each column or row.

The values None, NaN, NaT, and optionally numpy.inf (depending on pandas.options.mode.use_inf_as_na) are considered NA.

Parameters

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] If 0 or ‘index’ counts are generated for each column. If 1 or ‘columns’ counts are generated for each row.

level [int or str, optional] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame. A str specifies the level name.

numeric_only [bool, default False] Include only float, int or boolean data.

Returns

Series or DataFrame For each column/row the number of non-NA/null entries. If level is specified returns a DataFrame.

See also:

Series.count Number of non-NA elements in a Series.

DataFrame.value_counts Count unique combinations of columns.

DataFrame.shape Number of DataFrame rows and columns (including NA elements).

DataFrame.isna Boolean same-sized DataFrame showing places of NA elements.

Examples

Constructing DataFrame from a dictionary:

```python
>>> df = pd.DataFrame({"Person":
...                   ["John", "Myla", "Lewis", "John", "Myla"],
...                   "Age": [24., np.nan, 21., 33, 26],
...                   "Single": [False, True, True, True, False]})
```

```python
>>> df
     Person  Age  Single
0    John   24.0     False
1  Myla    NaN      True
2  Lewis   21.0      True
3    John   33.0      True
4  Myla   26.0      False
```

(continues on next page)
Notice the uncounted NA values:

```python
>>> df.count()
Person  5
Age     4
Single  5
dtype: int64
```

Counts for each row:

```python
>>> df.count(axis='columns')
0  3
1  2
2  3
3  3
4  3
dtype: int64
```

### pandas.DataFrame.cov

**DataFrame.cov** *(min_periods=None, ddof=1)*

Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the covariance matrix of the columns of the DataFrame.

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as NaN.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

**Parameters**

- **min_periods** [int, optional] Minimum number of observations required per pair of columns to have a valid result.

- **ddof** [int, default 1] Delta degrees of freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.

New in version 1.1.0.

**Returns**

- **DataFrame** The covariance matrix of the series of the DataFrame.

**See also:**

- **Series.cov** Compute covariance with another Series.

- **core.window.ExponentialMovingWindow.cov** Exponential weighted sample covariance.
**Notes**

Returns the covariance matrix of the DataFrame’s time series. The covariance is normalized by N-ddof.

For DataFrames that have Series that are missing data (assuming that data is missing at random) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.

**Examples**

```python
>>> df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
                    columns=['dogs', 'cats'])
>>> df.cov()
          dogs  cats
    dogs  0.666667 -1.000000
    cats -1.000000  1.666667

>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
                    columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()
      a         b         c         d         e
    a  0.998438 -0.020161  0.059277 -0.008943  0.014144
    b -0.020161  1.059352 -0.008543 -0.024738  0.009826
    c  0.059277 -0.008543  1.010670 -0.001486 -0.000271
    d -0.008943 -0.024738 -0.001486  0.921297 -0.013692
    e  0.014144  0.009826 -0.000271 -0.013692  0.977795
```

**Minimum number of periods**

This method also supports an optional `min_periods` keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```python
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
                    columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)
      a    b
    a  0.316741 NaN
    b  NaN  1.248003
    c  -0.150812  0.014144
```

pandas.DataFrame.cummax

DataFrame.cummax (axis=None, skipna=True, *args, **kwargs)

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

Parameters

- **axis** [[0 or ‘index’, 1 or ‘columns’], default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- *args, **kwargs Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

- **Series or DataFrame** Return cumulative maximum of Series or DataFrame.

See also:

- core.window.Expanding.max Similar functionality but ignores NaN values.
- DataFrame.max Return the maximum over DataFrame axis.
- DataFrame.cummax Return cumulative maximum over DataFrame axis.
- DataFrame.cummin Return cumulative minimum over DataFrame axis.
- DataFrame.cumsum Return cumulative sum over DataFrame axis.
- DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0  2.0
1  NaN
2  5.0
3 -1.0
4  0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cummax()
0  2.0
1  NaN
2  5.0
3  5.0
4  5.0
dtype: float64
```

To include NA values in the operation, use skipna=False
>>> s.cummax(skipna=False)
0  2.0  
1 NaN 
2 NaN 
3 NaN 
4 NaN 
dtype: float64

Dataframe

>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                     columns=list('AB'))

By default, iterates over rows and finds the maximum in each column. This is equivalent to axis=None or axis='index'.

>>> df.cummax()
   A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0

To iterate over columns and find the maximum in each row, use axis=1

>>> df.cummax(axis=1)
   A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0

pandas.DataFrame.cummin

DataFrame.cummin (axis=None, skipna=True, *args, **kwargs)
Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

Parameters

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

*args, **kwargs Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame Return cumulative minimum of Series or DataFrame.
See also:

`core.window.Expanding.min` Similar functionality but ignores NaN values.

`DataFrame.min` Return the minimum over DataFrame axis.

`DataFrame.cummax` Return cumulative maximum over DataFrame axis.

`DataFrame.cummin` Return cumulative minimum over DataFrame axis.

`DataFrame.cumsum` Return cumulative sum over DataFrame axis.

`DataFrame.cumprod` Return cumulative product over DataFrame axis.

**Examples**

**Series**

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
```

```plaintext
0  2.0
1  NaN
2  5.0
3 -1.0
4  0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cummin()
```

```plaintext
0  2.0
1  NaN
2  2.0
3 -1.0
4 -1.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cummin(skipna=False)
```

```plaintext
0  2.0
1  NaN
2  NaN
3  NaN
4  NaN
dtype: float64
```

**DataFrame**

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
```

```plaintext
       A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```
By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cummin()
   A  B
0 2.0 1.0
1 2.0 NaN
2 1.0 0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```python
>>> df.cummin(axis=1)
   A  B
0 2.0 1.0
1 3.0 NaN
2 1.0 0.0
```

### pandas.DataFrame.cumprod

DataFrame.cumprod(\texttt{axis=None, skipna=True, *args, **kwargs})

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

- **Parameters**
  - \texttt{axis} \{0 or 'index', 1 or 'columns'}, default 0\] The index or the name of the axis. 0 is equivalent to None or 'index'.
  - \texttt{skipna} [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
  - \texttt{*args, **kwargs} Additional keywords have no effect but might be accepted for compatibility with NumPy.

- **Returns**
  - \texttt{Series or DataFrame} Return cumulative product of Series or DataFrame.

See also:

- core.window.Expanding.prod Similar functionality but ignores NaN values.
- DataFrame.prod Return the product over DataFrame axis.
- DataFrame.cummax Return cumulative maximum over DataFrame axis.
- DataFrame.cummin Return cumulative minimum over DataFrame axis.
- DataFrame.cumsum Return cumulative sum over DataFrame axis.
- DataFrame.cumprod Return cumulative product over DataFrame axis.
Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4     0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cumprod()
0    2.0
1    NaN
2   10.0
3  -10.0
4    NaN
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cumprod(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                     columns=list('AB'))
>>> df
      A     B
0  2.00  1.00
1  3.00    NaN
2  1.00  0.00
```

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cumprod()
      A     B
0  2.00  1.00
1  6.00    NaN
2  6.00  0.00
```

To iterate over columns and find the product in each row, use `axis=1`

```python
>>> df.cumprod(axis=1)
          A     B
0  2.000000  1.00
1  6.000000    NaN
2  6.000000  0.00
```
pandas.DataFrame.cumsum

DataFrame.cumsum(axis=None, skipna=True, *args, **kwargs)

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

Parameters

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

*args, **kwargs Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame Return cumulative sum of Series or DataFrame.

See also:

core.window.Expanding.sum Similar functionality but ignores NaN values.

DataFrame.sum Return the sum over DataFrame axis.

DataFrame.cummax Return cumulative maximum over DataFrame axis.

DataFrame.cummin Return cumulative minimum over DataFrame axis.

DataFrame.cumsum Return cumulative sum over DataFrame axis.

DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4     0.0
dtype: float64
```

By default, NA values are ignored.

3.4. DataFrame 1601
To include NA values in the operation, use `skipna=False`

DataFrame

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

To iterate over columns and find the sum in each row, use `axis=1`
pandas.DataFrame.describe

DataFrame.describe(percentiles=None, include=None, exclude=None, date-time_is_numeric=False)

Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset’s distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

percentiles [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

include ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for Series. Here are the options:

- ‘all’ : All columns of the input will be included in the output.
- A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit numpy.number. To limit it instead to object columns submit the numpy.object data type. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To select pandas categorical columns, use 'category'
- None (default) : The result will include all numeric columns.

exclude [list-like of dtypes or None (default), optional] A black list of data types to omit from the result. Ignored for Series. Here are the options:

- A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit numpy.number. To exclude object columns submit the data type numpy.object. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To exclude pandas categorical columns, use 'category'
- None (default) : The result will exclude nothing.

datetime_is_numeric [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

New in version 1.1.0.

Returns

Series or DataFrame Summary statistics of the Series or Dataframe provided.

See also:

DataFrame.count Count number of non-NA/null observations.
DataFrame.max Maximum of the values in the object.
DataFrame.min Minimum of the values in the object.
DataFrame.mean Mean of the values.
DataFrame.std Standard deviation of the observations.
DataFrame.select_dtypes Subset of a DataFrame including/excluding columns based on their dtype.

Notes

For numeric data, the result’s index will include count, mean, std, min, max as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result’s index will include count, unique, top, and freq. The top is the most common value. The freq is the most common value’s frequency. Times- tamps also include the first and last items.

If multiple object values have the highest count, then the count and top results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a DataFrame, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If include='all' is provided as an option, the result will include a union of attributes of each type.

The include and exclude parameters can be used to limit which columns in a DataFrame are analyzed for the output. The parameters are ignored when analyzing a Series.

Examples

Describing a numeric Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
dtype: float64
```

Describing a categorical Series.

```python
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count 4
unique 3
top a
freq 2
dtype: object
```

Describing a timestamp Series.

```python
>>> s = pd.Series([
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01")
... ]
```
... })

```python
>>> s.describe(datetime_is_numeric=True)
count 3
mean 2006-09-01 08:00:00
min 2000-01-01 00:00:00
25% 2004-12-31 12:00:00
50% 2010-01-01 00:00:00
75% 2010-01-01 00:00:00
max 2010-01-01 00:00:00
dtype: object
```

Describing a DataFrame. By default only numeric fields are returned.

```python
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d', 'e', 'f']),
...                     'numeric': [1, 2, 3],
...                     'object': ['a', 'b', 'c']})
>>> df.describe()
categorical       numeric
count 3.0                   3.0
mean NaN                   2.0
std NaN                   1.0
min NaN                   1.0
25% NaN                   1.5
50% NaN                   2.0
75% NaN                   2.5
max NaN                   3.0
```

Describing all columns of a DataFrame regardless of data type.

```python
>>> df.describe(include='all')
categorical       numeric       object
count 3            3.0            3
unique 3           NaN            3
top f             NaN            a
freq 1             NaN            1
mean NaN           2.0            NaN
std NaN            1.0            NaN
min NaN            1.0            NaN
25% NaN            1.5            NaN
50% NaN            2.0            NaN
75% NaN            2.5            NaN
max NaN            3.0            NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```python
>>> df.numeric.describe()
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
Name: numeric, dtype: float64
```
Including only numeric columns in a DataFrame description.

```python
>>> df.describe(include=[np.number])
   numeric
count  3.0
mean   2.0
std    1.0
min    1.0
25%    1.5
50%    2.0
75%    2.5
max    3.0
```

Including only string columns in a DataFrame description.

```python
>>> df.describe(include=[object])
   object
count  3
unique 3
top    a
freq   1
```

Including only categorical columns from a DataFrame description.

```python
>>> df.describe(include=['category'])
   categorical
count   3
unique  3
top     d
freq    1
```

Excluding numeric columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.number])
   categorical  object
   count   3  3
   unique  3  3
   top     f  a
   freq    1  1
```

Excluding object columns from a DataFrame description.

```python
>>> df.describe(exclude=[object])
   categorical  numeric
   count   3  3.0
   unique  3  NaN
   top     f  NaN
   freq    1  NaN
   mean    NaN  2.0
   std     NaN  1.0
   min     NaN  1.0
   25%     NaN  1.5
   50%     NaN  2.0
   75%     NaN  2.5
   max     NaN  3.0
```
DataFrame.diff

DataFrame.diff(periods=1, axis=0)
First discrete difference of element.

Calculates the difference of a Dataframe element compared with another element in the Dataframe (default is element in previous row).

Parameters

- **periods** [int, default 1] Periods to shift for calculating difference, accepts negative values.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Take difference over rows (0) or columns (1).

Returns

Dataframe First differences of the Series.

See also:

- Dataframe.pct_change Percent change over given number of periods.
- Dataframe.shift Shift index by desired number of periods with an optional time freq.
- Series.diff First discrete difference of object.

Notes

For boolean dtypes, this uses operator.xor() rather than operator.sub(). The result is calculated according to current dtype in Dataframe, however dtype of the result is always float64.

Examples

Difference with previous row

```python
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
...                    'b': [1, 1, 2, 3, 5, 8],
...                    'c': [1, 4, 9, 16, 25, 36]})
>>> df
   a  b  c
0  1  1  1
1  2  1  4
2  3  2  9
3  4  3 16
4  5  5 25
5  6  8 36

>>> df.diff()
   a      b      c
0 NaN    NaN    NaN
1  1.0    0.0    3.0
2  1.0    1.0    5.0
3  1.0    1.0    7.0
4  1.0    2.0    9.0
5  1.0    3.0   11.0
```
Difference with previous column

```python
>>> df.diff(axis=1)
   a  b  c
0  NaN 0  0
1  NaN 1  3
2  NaN 1  7
3  NaN 1 13
4  NaN 0 20
5  NaN 2 28
```

Difference with 3rd previous row

```python
>>> df.diff(periods=3)
   a  b  c
0  NaN NaN NaN
1  NaN NaN NaN
2  NaN NaN NaN
3  3.0 2.0 15.0
4  3.0 4.0 21.0
5  3.0 6.0 27.0
```

Difference with following row

```python
>>> df.diff(periods=-1)
   a  b  c
0  1.0 0.0 -3.0
1  1.0 1.0 -5.0
2  1.0 2.0 -7.0
3  1.0 3.0 -9.0
4  1.0 4.0 -11.0
5  NaN NaN NaN
```

Overflow in input dtype

```python
>>> df = pd.DataFrame({'a': [1, 0]}, dtype=np.uint8)
>>> df.diff()
   a
0  NaN
1  255.0
```

### pandas.DataFrame.div

DataFrame.div (other, axis=None, level=None, fill_value=None)

Get Floating division of dataframe and other, element-wise (binary operator truediv).

Equivalent to dataframe / other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rtruediv.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [(0 or ‘index’, 1 or ‘columns’)] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
                     'degrees': [360, 180, 360]},
                    index=['circle', 'triangle', 'rectangle'])
```

```
>> df
angles  degrees
circle    0      360
triangle  3      180
rectangle 4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```

```
    angles  degrees
circle    1      361
triangle  4      181
rectangle 5      361
```

```python
>>> df.add(1)
```

```
    angles  degrees
circle    1      361
triangle  4      181
rectangle 5      361
```
Divide by constant with reverse version.

```python
>>> df.div(10)
angles   degrees
circle   0.0       36.0
triangle 0.3       18.0
rectangle 0.4      36.0
```

```python
>>> df.rdiv(10)
angles   degrees
circle    inf     0.027778
triangle   3.333333  0.055556
rectangle   2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
angles   degrees
circle    -1      358
triangle    2      178
rectangle   3      358
```

```python
>>> df.sub([1, 2], axis='columns')
angles   degrees
circle    -1      358
triangle    2      178
rectangle   3      358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
        axis='index')
angles   degrees
circle    -1      359
triangle    2      179
rectangle   3      359
```

Multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({'angles': [0, 3, 4]},
                     index=['circle', 'triangle', 'rectangle'])
```

```python
>>> df * other
angles   degrees
circle     0      NaN
triangle    9      NaN
rectangle  16      NaN
```

```python
>>> df.mul(other, fill_value=0)
angles   degrees
circle     0      0.0
triangle    9      0.0
rectangle  16      0.0
```
Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                             'degrees': [360, 180, 360, 360, 540, 720],
...                             index=['A', 'A', 'A', 'B', 'B', 'B'],
...                             ['circle', 'triangle', 'rectangle',
...                             'square', 'pentagon', 'hexagon']})

>>> df_multindex
       angles  degrees
A  circle     0     360
     triangle   3     180
     rectangle  4     360
B    square   4     360
     pentagon  5     540
     hexagon  6     720

>>> df.div(df_multindex, level=1, fill_value=0)
       angles  degrees
A  circle    NaN     1.0
     triangle  1.0     1.0
     rectangle 1.0     1.0
B    square  0.0     0.0
     pentagon 0.0     0.0
     hexagon  0.0     0.0
```

`pandas.DataFrame.divide`

DataFrame .divide (other, axis='columns', level=None, fill_value=None)

Get floating division of dataframe and other, element-wise (binary operator `truediv`).

Equivalent to `dataframe / other`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, `rtruediv`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

- `DataFrame.add` Add DataFrames.
- `DataFrame.sub` Subtract DataFrames.
DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
    angles  degrees
  circle    0     360
  triangle   3     180
  rectangle  4     360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
    angles  degrees
  circle    1     361
  triangle   4     181
  rectangle  5     361
```python

```python
>>> df.add(1)
    angles  degrees
  circle    1     361
  triangle   4     181
  rectangle  5     361
```python

Divide by constant with reverse version.

```python
>>> df.div(10)
    angles  degrees
  circle   0.0     36.0
  triangle 0.3     18.0
  rectangle 0.4     36.0
```python

```python
>>> df.rdiv(10)
    angles  degrees
  circle     inf  0.027778
  triangle 3.333333  0.055556
  rectangle 2.500000  0.027778
```python

Subtract a list and Series by axis with operator version.
>>> df = [1, 2]
    angles  degrees
  circle    -1     358
     triangle    2     178
     rectangle    3     358

>>> df.sub([1, 2], axis='columns')
    angles  degrees
  circle     -1     358
     triangle     2     178
     rectangle     3     358

>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
    angles  degrees
  circle     -1     359
     triangle     2     179
     rectangle     3     359

Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4]}, index=['circle', 'triangle', 'rectangle'])

>>> df * other
    angles  degrees
  circle    0    NaN
     triangle    9    NaN
     rectangle   16    NaN

>>> df.mul(other, fill_value=0)
    angles  degrees
  circle    0     0.0
     triangle    9     0.0
     rectangle   16     0.0

Divide by a MultiIndex by level.

>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                              'degrees': [360, 180, 360, 360, 540, 720],
                              index=['A', 'A', 'A', 'B', 'B', 'B'],
                              ['circle', 'triangle', 'rectangle',
                              'square', 'pentagon', 'hexagon'])

>>> df_multindex
    angles  degrees
  A circle    0     360
     triangle    3     180
     rectangle    4     360
  B square    4     360
      pentagon    5     540
     hexagon    6     720
>>> df.div(df_multindex, level=1, fill_value=0)

**pandas.DataFrame.dot**

Data Frame .dot (other)

Compute the matrix multiplication between the DataFrame and other.

This method computes the matrix product between the DataFrame and the values of an other Series, DataFrame or a numpy array.

It can also be called using self @ other in Python >= 3.5.

**Parameters**

- **other** [Series, DataFrame or array-like] The other object to compute the matrix product with.

**Returns**

- **Series or DataFrame** If other is a Series, return the matrix product between self and other as a Series. If other is a DataFrame or a numpy.array, return the matrix product of self and other in a DataFrame of a np.array.

**See also:**

- **Series.dot** Similar method for Series.

**Notes**

The dimensions of DataFrame and other must be compatible in order to compute the matrix multiplication. In addition, the column names of DataFrame and the index of other must contain the same values, as they will be aligned prior to the multiplication.

The dot method for Series computes the inner product, instead of the matrix product here.

**Examples**

Here we multiply a DataFrame with a Series.

```python
>>> df = pd.DataFrame([[0, 1, -2, -1], [1, 1, 1, 1]])
>>> s = pd.Series([1, 1, 2, 1])
>>> df.dot(s)
0   -4
1    5
```

dtype: int64

Here we multiply a DataFrame with another DataFrame.
>>> other = pd.DataFrame([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(other)
   0  1
0  0  4
1  1  2

Note that the dot method give the same result as @

>>> df @ other
   0  1
0  0  4
1  1  2

The dot method works also if other is an np.array.

>>> arr = np.array([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(arr)
   0  1
0  0  4
1  1  2

Note how shuffling of the objects does not change the result.

>>> s2 = s.reindex([1, 0, 2, 3])
>>> df.dot(s2)
   0  1
0 -4
1  5
dtype: int64

pandas.DataFrame.drop

DataFrame.drop(labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise')

Drop specified labels from rows or columns.

Remove rows or columns by specifying label names and corresponding axis, or by specifying directly
index or column names. When using a multi-index, labels on different levels can be removed by specifying
the level. See the user guide <advanced.shown_levels> for more information about the now unused levels.

Parameters

  labels [single label or list-like] Index or column labels to drop.

  axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Whether to drop labels from the index
  (0 or ‘index’) or columns (1 or ‘columns’).

  index [single label or list-like] Alternative to specifying axis (labels, axis=0 is
equivalent to index=labels).

  columns [single label or list-like] Alternative to specifying axis (labels, axis=1
  is equivalent to columns=labels).

  level [int or level name, optional] For MultiIndex, level from which the labels will be
  removed.

  inplace [bool, default False] If False, return a copy. Otherwise, do operation inplace
  and return None.
**errors**  
[['ignore', 'raise'], default 'raise'] If 'ignore', suppress error and only existing labels are dropped.

**Returns**

DataFrame or None  
DataFrame without the removed index or column labels or None if inplace=True.

**Raises**

KeyError  
If any of the labels is not found in the selected axis.

See also:

DataFrame.loc  
Label-location based indexer for selection by label.

DataFrame.dropna  
Return DataFrame with labels on given axis omitted where (all or any) data are missing.

DataFrame.drop_duplicates  
Return DataFrame with duplicate rows removed, optionally only considering certain columns.

Series.drop  
Return Series with specified index labels removed.

**Examples**

```python
>>> df = pd.DataFrame(np.arange(12).reshape(3, 4),
...                    columns=['A', 'B', 'C', 'D'])
```

Drop columns

```python
>>> df.drop(['B', 'C'], axis=1)
```

```text
A  D
0  0  3
1  4  7
2  8 11
```

```python
>>> df.drop(columns=['B', 'C'])
```

```text
A  D
0  0  3
1  4  7
2  8 11
```

Drop a row by index

```python
>>> df.drop([0, 1])
```

```text
A B C D
2 8 9 10 11
```

Drop columns and/or rows of MultiIndex DataFrame

```python
>>> midx = pd.MultiIndex(levels=[['lama', 'cow', 'falcon'], ['speed', 'weight', 'length']])
```
>>> df = pd.DataFrame(index=midx, columns=['big', 'small'],
... data=[[45, 30], [200, 100], [1.5, 1], [30, 20],
... [250, 150], [1.5, 0.8], [320, 250],
... [1, 0.8], [0.3, 0.2]])

>>> df
  big    small
lama  speed  45.0   30.0
       weight 200.0  100.0
       length  1.5   1.0
cow   speed  30.0   20.0
       weight 250.0  150.0
       length  1.5   0.8
falcon speed 320.0  250.0
       weight   1.0   0.8
       length  0.3   0.2

>>> df.drop(index='cow', columns='small')
  big
lama  speed  45.0
       weight 200.0
       length  1.5
falcon speed 320.0
       weight   1.0
       length  0.3

>>> df.drop(index='length', level=1)
  big    small
lama  speed  45.0   30.0
       weight 200.0  100.0
cow   speed  30.0   20.0
       weight 250.0  150.0
falcon speed 320.0  250.0
       weight   1.0   0.8

pandas.DataFrame.drop_duplicates

DataFrame.drop_duplicates (subset=None, keep='first', inplace=False, ignore_index=False)

Return DataFrame with duplicate rows removed.

Considering certain columns is optional. Indexes, including time indexes are ignored.

Parameters

subset [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns.

keep ['first', 'last', False], default 'first'] Determines which duplicates (if any) to keep. - first : Drop duplicates except for the first occurrence. - last : Drop duplicates except for the last occurrence. - False : Drop all duplicates.

inplace [bool, default False] Whether to drop duplicates in place or to return a copy.

ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.
New in version 1.0.0.

Returns

DataFrame or None DataFrame with duplicates removed or None if inplace=True.

See also:

DataFrame.value_counts Count unique combinations of columns.

Examples

Consider dataset containing ramen rating.

```python
>>> df = pd.DataFrame({
...     'brand': ['Yum Yum', 'Yum Yum', 'Indomie', 'Indomie', 'Indomie'],
...     'style': ['cup', 'cup', 'cup', 'pack', 'pack'],
...     'rating': [4, 4, 3.5, 15, 5]
... })
>>> df
  brand style  rating
0  Yum Yum   cup     4.0
1  Yum Yum   cup     4.0
2  Indomie   cup     3.5
3  Indomie   pack    15.0
4  Indomie   pack     5.0
```

By default, it removes duplicate rows based on all columns.

```python
>>> df.drop_duplicates()
  brand style  rating
0  Yum Yum   cup     4.0
2  Indomie   cup     3.5
3  Indomie   pack    15.0
4  Indomie   pack     5.0
```

To remove duplicates on specific column(s), use subset.

```python
>>> df.drop_duplicates(subset=['brand'])
  brand style  rating
0  Yum Yum   cup     4.0
2  Indomie   cup     3.5
```

To remove duplicates and keep last occurrences, use keep.

```python
>>> df.drop_duplicates(subset=['brand', 'style'], keep='last')
  brand style  rating
1  Yum Yum   cup     4.0
2  Indomie   cup     3.5
4  Indomie   pack     5.0
```
DataFrame.drop level

DataFrame.\texttt{drop level}(level, axis=0)

Return Series/DataFrame with requested index / column level(s) removed.

**Parameters**

- **level** [int, str, or list-like] If a string is given, must be the name of a level If list-like, elements must be names or positional indexes of levels.

- **axis** [[0 or ‘index’, 1 or ‘columns’], default 0] Axis along which the level(s) is removed:
  - 0 or ‘index’: remove level(s) in column.
  - 1 or ‘columns’: remove level(s) in row.

**Returns**

Series/DataFrame Series/DataFrame with requested index / column level(s) removed.

**Examples**

```python
>>> df = pd.DataFrame([...
... [1, 2, 3, 4],
... [5, 6, 7, 8],
... [9, 10, 11, 12]
... ]).set_index([0, 1]).rename_axis(["a", "b"])
>>> df.columns = pd.MultiIndex.from_tuples([...
... ("c", "e"), ("d", "f")
... ], names=["level_1", "level_2"])

>>> df
level_1  c  d
  level_2  e  f
    a  b
     1  2  3  4
     5  6  7  8
     9 10 11 12

>>> df.droplevel('a')
level_1  c  d
  level_2  e  f
    b
     2  3  4
     6  7  8
    10 11 12

>>> df.droplevel('level_2', axis=1)
level_1  c  d
  a  b
     1  2  3  4
     5  6  7  8
     9 10 11 12
```

3.4. DataFrame
pandas.DataFrame.dropna

`DataFrame.dropna(axis=0, how='any', thresh=None, subset=None, inplace=False)`

Remove missing values.

See the User Guide for more on which values are considered missing, and how to work with missing data.

**Parameters**

- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Determine if rows or columns which contain missing values are removed.
  - 0, or ‘index’ : Drop rows which contain missing values.
  - 1, or ‘columns’ : Drop columns which contain missing value.

  Changed in version 1.0.0: Pass tuple or list to drop on multiple axes. Only a single axis is allowed.

- **how** [{'any', 'all'}, default ‘any’] Determine if row or column is removed from DataFrame, when we have at least one NA or all NA.
  - ‘any’ : If any NA values are present, drop that row or column.
  - ‘all’ : If all values are NA, drop that row or column.

- **thresh** [int, optional] Require that many non-NA values.

- **subset** [array-like, optional] Labels along other axis to consider, e.g. if you are dropping rows these would be a list of columns to include.

- **inplace** [bool, default False] If True, do operation inplace and return None.

**Returns**

- **DataFrame or None** DataFrame with NA entries dropped from it or None if inplace=True.

**See also:**

- `DataFrame.isna` Indicate missing values.
- `DataFrame.notna` Indicate existing (non-missing) values.
- `DataFrame.fillna` Replace missing values.
- `Series.dropna` Drop missing values.
- `Index.dropna` Drop missing indices.

**Examples**

```python
>>> df = pd.DataFrame({"name": ['Alfred', 'Batman', 'Catwoman'],
... "toy": [np.nan, 'Batmobile', 'Bullwhip'],
... "born": [pd.NaT, pd.Timestamp("1940-04-25"),
... pd.NaT]})
>>> df
     name     toy         born
0   Alfred   NaN          NaT
1   Batman  Batmobile  1940-04-25
2  Catwoman   Bullwhip   NaT
```

Drop the rows where at least one element is missing.
>>> df.dropna()
   name     toy     born
0  Alfred     NaN   NaT
1  Batman  Batmobile 1940-04-25
2  Catwoman  Bullwhip   NaT

Drop the columns where at least one element is missing.

>>> df.dropna(axis='columns')
   name
0  Alfred
1  Batman
2  Catwoman

Drop the rows where all elements are missing.

>>> df.dropna(how='all')
   name     toy     born
0  Alfred     NaN   NaT
1  Batman  Batmobile 1940-04-25
2  Catwoman  Bullwhip   NaT

Keep only the rows with at least 2 non-NA values.

>>> df.dropna(thresh=2)
   name     toy     born
1  Batman  Batmobile 1940-04-25
2  Catwoman  Bullwhip   NaT

Define in which columns to look for missing values.

>>> df.dropna(subset=['name', 'toy'])
   name     toy     born
1  Batman  Batmobile 1940-04-25
2  Catwoman  Bullwhip   NaT

Keep the DataFrame with valid entries in the same variable.

>>> df.dropna(inplace=True)
>>> df
   name     toy     born
1  Batman  Batmobile 1940-04-25

**pandas.DataFrame.duplicated**

DataFrame.duplicated(subset=None, keep='first')
Return boolean Series denoting duplicate rows.
Considering certain columns is optional.

**Parameters**

- **subset** [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns.
- **keep** [['first', 'last', False], default 'first'] Determines which duplicates (if any) to mark.
  - **first**: Mark duplicates as True except for the first occurrence.
• last: Mark duplicates as True except for the last occurrence.
• False: Mark all duplicates as True.

Returns

Series Boolean series for each duplicated rows.

See also:

Index.duplicated Equivalent method on index.
Series.duplicated Equivalent method on Series.
Series.drop_duplicates Remove duplicate values from Series.
DataFrame.drop_duplicates Remove duplicate values from DataFrame.

Examples

Consider dataset containing ramen rating.

```python
>>> df = pd.DataFrame({
...     'brand': ['Yum Yum', 'Yum Yum', 'Indomie', 'Indomie', 'Indomie'],
...     'style': ['cup', 'cup', 'cup', 'pack', 'pack'],
...     'rating': [4, 4, 3.5, 15, 5]
... })
>>> df
   brand style rating
0   Yum Yum cup     4.0
1   Yum Yum cup     4.0
2   Indomie cup     3.5
3   Indomie pack    15.0
4   Indomie pack    5.0
```

By default, for each set of duplicated values, the first occurrence is set on False and all others on True.

```python
>>> df.duplicated()
0   False
1   True
2   False
3   False
4   False
dtype: bool
```

By using ‘last’, the last occurrence of each set of duplicated values is set on False and all others on True.

```python
>>> df.duplicated(keep='last')
0   True
1   False
2   False
3   False
4   False
dtype: bool
```

By setting `keep` on False, all duplicates are True.
```python
>>> df.duplicated(keep=False)
0   True
1   True
2  False
3  False
4  False
dtype: bool
```

To find duplicates on specific column(s), use `subset`.

```python
>>> df.duplicated(subset=['brand'])
0  False
1   True
2  False
3   True
4   True
dtype: bool
```

### pandas.DataFrame.eq

**DataFrame.eq**(other, axis='columns', level=None)

Get Equal to of dataframe and other, element-wise (binary operator `eq`).

Among flexible wrappers (`eq`, `ne`, `le`, `lt`, `ge`, `gt`) to comparison operators.

Equivalent to `==`, `!=`, `<=`, `<`, `>=`, `>` with support to choose axis (rows or columns) and level for comparison.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default ‘columns’] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’).
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

DataFrame of bool Result of the comparison.

See also:

- **DataFrame.eq** Compare DataFrames for equality elementwise.
- **DataFrame.ne** Compare DataFrames for inequality elementwise.
- **DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.
- **DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.
- **DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.
- **DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.
Notes

Mismatched indices will be unioned together. NaN values are considered different (i.e. NaN != NaN).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                     'revenue': [100, 250, 300]},
...                   index=['A', 'B', 'C'])
>>> df
   cost  revenue
  A    250     100
  B    150     250
  C    100     300
```

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
   cost  revenue
  A  False    True
  B  False    False
  C   True    False

>>> df.eq(100)
   cost  revenue
  A  False    True
  B  False    False
  C   True    False
```

When `other` is a Series, the columns of a DataFrame are aligned with the index of other and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
   cost  revenue
  A   True    True
  B   True    False
  C  False    True

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
   cost  revenue
  A   True    False
  B   True    True
  C   True    True
  D   True    True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```python
>>> df == [250, 100]
   cost  revenue
  A   True    True
  B  False    False
  C  False    False

Use the method to control the axis:
```
```python
>>> df.eq([250, 250, 100], axis='index')
cost  revenue
A   True  False
B   False  True
C   True  False

Compare to a DataFrame of different shape.
```
pandas.DataFrame.equals

DataFrame.equals(other)
Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the same shape and elements. NaNs in the same location are considered equal.

The row/column index do not need to have the same type, as long as the values are considered equal. Corresponding columns must be of the same dtype.

Parameters

other [Series or DataFrame] The other Series or DataFrame to be compared with the first.

Returns

bool True if all elements are the same in both objects, False otherwise.

See also:

Series.eq Compare two Series objects of the same length and return a Series where each element is True if the element in each Series is equal, False otherwise.

DataFrame.eq Compare two DataFrame objects of the same shape and return a DataFrame where each element is True if the respective element in each DataFrame is equal, False otherwise.

testing.assert_series_equal Raises an AssertionError if left and right are not equal. Provides an easy interface to ignore inequality in dtypes, indexes and precision among others.

testing.assert_frame_equal Like assert_series_equal, but targets DataFrames.

numpy.array_equal Return True if two arrays have the same shape and elements, False otherwise.

Examples

>>> df = pd.DataFrame({1: [10], 2: [20]})
>>> df
  1  2
0 10 20

DataFrames df and exactly_equal have the same types and values for their elements and column labels, which will return True.

>>> exactly_equal = pd.DataFrame({1: [10], 2: [20]})
>>> exactly_equal
  1  2
0 10 20

>>> df.equals(exactly_equal)
True

DataFrames df and different_column_type have the same element types and values, but have different types for the column labels, which will still return True.

>>> different_column_type = pd.DataFrame({1.0: [10], 2.0: [20]})
>>> different_column_type
  1.0  2.0
0   10   20

(continues on next page)
DataFrames `df` and `different_data_type` have different types for the same values for their elements, and will return False even though their column labels are the same values and types.

```python
>>> different_data_type = pd.DataFrame({1: [10.0], 2: [20.0]})
>>> different_data_type
       1   2
0  10.0 20.0
>>> df.equals(different_data_type)
False
```

### pandas.DataFrame.eval

`DataFrame.eval(expr, inplace=False, **kwargs)`

Evaluate a string describing operations on DataFrame columns.

Operates on columns only, not specific rows or elements. This allows `eval` to run arbitrary code, which can make you vulnerable to code injection if you pass user input to this function.

**Parameters**

- `expr [str]` The expression string to evaluate.
- `inplace [bool, default False]` If the expression contains an assignment, whether to perform the operation inplace and mutate the existing DataFrame. Otherwise, a new DataFrame is returned.
- `**kwargs` See the documentation for `eval()` for complete details on the keyword arguments accepted by `query()`.

**Returns**

- `ndarray, scalar, pandas object, or None` The result of the evaluation or None if `inplace=True`.

**See also:**

- `DataFrame.query` Evaluates a boolean expression to query the columns of a frame.
- `DataFrame.assign` Can evaluate an expression or function to create new values for a column.
- `eval` Evaluate a Python expression as a string using various backends.

**Notes**

For more details see the API documentation for `eval()`. For detailed examples see `enhancing performance with eval`.
Examples

```python
>>> df = pd.DataFrame({'A': range(1, 6), 'B': range(10, 0, -2)})
>>> df
   A  B
0  1 10
1  2  8
2  3  6
3  4  4
4  5  2

>>> df.eval('A + B')
   0   1
   1  10
   2  11
   3  19
   4  23

>>> df.eval('A + B')
   0  1
   1  2
   2  3
   3  4
   4  5

>>> df.eval('C = A + B')
   A  B  C
0  1 10 11
1  2  8 10
2  3  6  9
3  4  4  8
4  5  2  7

>>> df
   A  B
0  1 10
1  2  8
2  3  6
3  4  4
4  5  2
```

Assignment is allowed though by default the original DataFrame is not modified.

```python
>>> df.eval('C = A + B')
   A  B  C
0  1 10 11
1  2  8 10
2  3  6  9
3  4  4  8
4  5  2  7

>>> df
   A  B
0  1 10
1  2  8
2  3  6
3  4  4
4  5  2
```

Use `inplace=True` to modify the original DataFrame.

```python
>>> df.eval('C = A + B', inplace=True)
>>> df
   A  B  C
0  1 10 11
1  2  8 10
2  3  6  9
3  4  4  8
4  5  2  7
```

Multiple columns can be assigned to using multi-line expressions:

```python
>>> df.eval(
...     'C = A + B
...     D = A - B
...     )
   A  B  C  D
0  1 10 11 -9
1  2  8 10 -6
```

(continues on next page)
pandas.DataFrame.ewm

DataFrame.ewm (com=None, span=None, halflife=None, alpha=None, min_periods=0, adjust=True, ignore_na=False, axis=0, times=None)

Provide exponential weighted (EW) functions.

Available EW functions: mean(), var(), std(), corr(), cov().

Exactly one parameter: com, span, halflife, or alpha must be provided.

Parameters

- **com** [float, optional] Specify decay in terms of center of mass, $\alpha = 1/(1 + \text{com})$, for $\text{com} \geq 0$.
- **span** [float, optional] Specify decay in terms of span, $\alpha = 2/(\text{span}+1)$, for $\text{span} \geq 1$.
- **halflife** [float, str, timedelta, optional] Specify decay in terms of half-life, $\alpha = 1 - \exp\left(-\ln(2)/\text{halflife}\right)$, for $\text{halflife} > 0$.
  
  If `times` is specified, the time unit (str or timedelta) over which an observation decays to half its value. Only applicable to `mean()` and halflife value will not apply to the other functions.
  
  New in version 1.1.0.
- **alpha** [float, optional] Specify smoothing factor $\alpha$ directly, $0 < \alpha \leq 1$.
- **min_periods** [int, default 0] Minimum number of observations in window required to have a value (otherwise result is NA).
- **adjust** [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average).
  
  - When `adjust=True` (default), the EW function is calculated using weights $w_i = (1 - \alpha)^i$. For example, the EW moving average of the series $[x_0, x_1, \ldots, x_t]$ would be:
    
    $$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \ldots + (1 - \alpha)^t x_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + \ldots + (1 - \alpha)^t}$$
  
  - When `adjust=False`, the exponentially weighted function is calculated recursively:
    
    $$y_0 = x_0$$
    $$y_t = (1 - \alpha)y_{t-1} + \alpha x_t$$

- **ignore_na** [bool, default False] Ignore missing values when calculating weights; specify `True` to reproduce pre-0.15.0 behavior.
  
  - When `ignore_na=False` (default), weights are based on absolute positions. For example, the weights of $x_0$ and $x_2$ used in calculating the final weighted average of $[x_0, \text{None}, x_2]$ are $(1 - \alpha)^2$ and $1$ if `adjust=True`, and $(1 - \alpha)^2$ and $\alpha$ if `adjust=False`. 

3.4. DataFrame
• When ignore_na=True (reproducing pre-0.15.0 behavior), weights are based on relative positions. For example, the weights of $x_0$ and $x_2$ used in calculating the final weighted average of $[x_0, \text{None}, x_2]$ are $1 - \alpha$ and 1 if adjust=True, and $1 - \alpha$ and $\alpha$ if adjust=False.

axis [{0, 1}, default 0] The axis to use. The value 0 identifies the rows, and 1 identifies the columns.

times [str, np.ndarray, Series, default None] New in version 1.1.0.

Times corresponding to the observations. Must be monotonically increasing and datetime64[ns] dtype.

If str, the name of the column in the DataFrame representing the times.

If 1-D array like, a sequence with the same shape as the observations.

Only applicable to mean().

Returns

DataFrame A Window sub-classed for the particular operation.

See also:

rolling Provides rolling window calculations.

expanding Provides expanding transformations.

Notes

More details can be found at: Exponentially weighted windows.

Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0

>>> df.ewm(com=0.5).mean()
   B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213

Specifying times with a timedelta halflife when computing mean.

```
```python
>>> times = ['2020-01-01', '2020-01-03', '2020-01-10', '2020-01-15', '2020-01-17']
>>> df.ewm(halflife='4 days', times=pd.DatetimeIndex(times)).mean()
   B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213
```

(continues on next page)
pandas.DataFrame.expanding

Dataframe.expanding(min_periods=1, center=None, axis=0, method='single')

Provide expanding transformations.

Parameters

- **min_periods** [int, default 1] Minimum number of observations in window required to have a value (otherwise result is NA).
- **center** [bool, default False] Set the labels at the center of the window.
- **axis** [int or str, default 0]
- **method** [str {'single', 'table'}, default 'single'] Execute the rolling operation per single column or row ('single') or over the entire object ('table').

This argument is only implemented when specifying engine='numba' in the method call.

New in version 1.3.0.

Returns

a Window sub-classed for the particular operation

See also:

- **rolling** Provides rolling window calculations.
- **ewm** Provides exponential weighted functions.

Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting center=True.

Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3 NaN
4  4.0
```
pandas.DataFrame.explode

DataFrame.explode(column, ignore_index=False)
Transform each element of a list-like to a row, replicating index values.

New in version 0.25.0.

Parameters

column [str or tuple or list thereof] Column(s) to explode. For multiple columns, specify a non-empty list with each element be str or tuple, and all specified columns their list-like data on same row of the frame must have matching length.

New in version 1.3.0: Multi-column explode

ignore_index [bool, default False] If True, the resulting index will be labeled 0, 1, . . ., n - 1.

New in version 1.1.0.

Returns

DataFrame Exploded lists to rows of the subset columns; index will be duplicated for these rows.

Raises

ValueError :

• If columns of the frame are not unique.

• If specified columns to explode is empty list.

• If specified columns to explode have not matching count of elements rowwise in the frame.

See also:

DataFrame.unstack Pivot a level of the (necessarily hierarchical) index labels.

DataFrame.melt Unpivot a DataFrame from wide format to long format.

Series.explode Explode a DataFrame from list-like columns to long format.
Notes

This routine will explode list-likes including lists, tuples, sets, Series, and np.ndarray. The result dtype of the subset rows will be object. Scalars will be returned unchanged, and empty list-likes will result in a np.nan for that row. In addition, the ordering of rows in the output will be non-deterministic when exploding sets.

Examples

```python
>>> df = pd.DataFrame({'A': [[0, 1, 2], 'foo', [], [3, 4]],
...                    'B': 1,
...                    'C': [['a', 'b', 'c'], np.nan, [], ['d', 'e']])

>>> df
   A   B   C
0  0  1 [a, b, c]
1  foo 1  NaN
2  [] 1  []
3  [3, 4] 1  [d, e]

Single-column explode.

>>> df.explode('A')
   A   B   C
0  0  1  [a, b, c]
0  1  1  [a, b, c]
0  2  1  [a, b, c]
1  foo 1  NaN
2  NaN 1  []
3  3  1  [d, e]
3  4  1  [d, e]

Multi-column explode.

>>> df.explode(list('AC'))
   A   B   C
0  0  1  a
0  1  1  b
0  2  1  c
1  foo 1  NaN
2  NaN 1  []
3  3  1  d
3  4  1  e
```

pandas.DataFrame.ffill

DataFrame.ffill (axis=None, inplace=False, limit=None, downcast=None)

Synonym for DataFrame.fillna() with method='ffill'.

Returns

Series/DataFrame or None Object with missing values filled or None if inplace=True.
pandas.DataFrame.fillna

DataFrame.fillna(value=None, method=None, axis=None, inplace=False, limit=None, downcast=None)
Fill NA/NaN values using the specified method.

Parameters

value [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a
dict/Series/DataFrame of values specifying which value to use for each index (for a
Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will
not be filled. This value cannot be a list.

method [‘backfill’, ‘bfill’, ‘pad’, ‘ffill’, None], default None Method to use for filling
holes in reindexed Series pad / ffill: propagate last valid observation forward to next
valid backfill / bfill: use next valid observation to fill gap.

axis [0 or ‘index’, 1 or ‘columns’] Axis along which to fill missing values.

inplace [bool, default False] If True, fill in-place. Note: this will modify any other
views on this object (e.g., a no-copy slice for a column in a DataFrame).

limit [int, default None] If method is specified, this is the maximum number of con-
secutive NaNs to forward/backward fill. In other words, if there is a gap
with more than this number of consecutive NaNs, it will only be partially filled.
If method is not specified, this is the maximum number of entries along the entire
axis where NaNs will be filled. Must be greater than 0 if not None.

downcast [dict, default is None] A dict of item->dtype of what to downcast if possible,
or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g.
float64 to int64 if possible).

Returns

DataFrame or None Object with missing values filled or None if inplace=True.

See also:

interpolate Fill NaN values using interpolation.
reindex Conform object to new index.
asfreq Convert TimeSeries to specified frequency.

Examples

```python
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
... [3, 4, np.nan, 1],
... [np.nan, np.nan, np.nan, 5],
... [np.nan, 3, np.nan, 4]],
... columns=list(‘ABCD’))
>>> df
     A   B   C   D
0  NaN  2.0  NaN   0
1   3.0  4.0  NaN   1
2  NaN  NaN  NaN   5
3  NaN  3.0  NaN   4
```

Replace all NaN elements with 0s.
We can also propagate non-null values forward or backward.

Replace all NaN elements in column ‘A’, ‘B’, ‘C’, and ‘D’, with 0, 1, 2, and 3 respectively.

Only replace the first NaN element.

When filling using a DataFrame, replacement happens along the same column names and same indices.

**pandas.DataFrame.filter**

DataFrame.filter(items=None, like=None, regex=None, axis=None)

Subset the dataframe rows or columns according to the specified index labels.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

**Parameters**

- items [list-like] Keep labels from axis which are in items.
like  [str] Keep labels from axis for which “like in label == True”.

regex  [str (regular expression)] Keep labels from axis for which re.search(regex, label) == True.

axis  [{0 or ‘index’, 1 or ‘columns’, None}, default None] The axis to filter on, expressed either as an index (int) or axis name (str). By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame.

Returns

same type as input object

See also:

DataFrame.loc  Access a group of rows and columns by label(s) or a boolean array.

Notes

The items, like, and regex parameters are enforced to be mutually exclusive.

axis  defaults to the info axis that is used when indexing with [].

Examples

```python
>>> df = pd.DataFrame(np.array(([[1, 2, 3], [4, 5, 6]]),
...                           index=['mouse', 'rabbit'],
...                           columns=['one', 'two', 'three'])
>>> df
   one two three
mouse 1  2  3
rabbit 4  5  6

>>> # select columns by name
>>> df.filter(items=['one', 'three'])
   one three
mouse 1  3
rabbit 4  6

>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
   one three
mouse 1  3
rabbit 4  6

>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
   one two three
mouse 1  2  3
rabbit 4  5  6
```
pandas.DataFrame.first

**DataFrame.first(offset)**

Select initial periods of time series data based on a date offset.

When having a DataFrame with dates as index, this function can select the first few rows based on a date offset.

**Parameters**

- **offset** [str, DateOffset or dateutil.relativedelta] The offset length of the data that will be selected. For instance, ‘1M’ will display all the rows having their index within the first month.

**Returns**

- **Series or DataFrame** A subset of the caller.

**Raises**

- **TypeError** If the index is not a DatetimeIndex

**See also:**

- **last** Select final periods of time series based on a date offset.
- **at_time** Select values at a particular time of the day.
- **between_time** Select values between particular times of the day.

**Examples**

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
   A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4

Get the rows for the first 3 days:

```python
>>> ts.first('3D')
   A
2018-04-09  1
2018-04-11  2
```

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.
pandas.DataFrame.first_valid_index

DataFrame.first_valid_index()
Return index for first non-NA value or None, if no NA value is found.

Returns
scalar [type of index]

Notes
If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.DataFrame.floordiv

DataFrame.floordiv(other, axis='columns', level=None, fill_value=None)
Get Integer division of dataframe and other, element-wise (binary operator floordiv).
Equivalent to dataframe // other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rfloordiv.
Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters
other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns
DataFrame Result of the arithmetic operation.

See also:
DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    'index': ['circle', 'triangle', 'rectangle'])
>>> df
                   angles  degrees
    circle         0       360
    triangle       3       180
    rectangle      4       360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
                   angles  degrees
    circle         1       361
    triangle       4       181
    rectangle      5       361
```python
>>> df.add(1)
                   angles  degrees
    circle         1       361
    triangle       4       181
    rectangle      5       361

Divide by constant with reverse version.

```python
>>> df.div(10)
                   angles  degrees
    circle       0.0     36.0
    triangle     0.3     18.0
    rectangle    0.4     36.0
```python
>>> df.rdiv(10)
                   angles  degrees
    circle       inf   0.027778
    triangle   3.333333  0.055556
    rectangle  2.500000  0.027778

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
                   angles  degrees
    circle        -1       358
    triangle        2       178
    rectangle        3       358
```python
>>> df.sub([1, 2], axis='columns')
                   angles  degrees
    circle        -1       358
    triangle        2       178
    rectangle        3       358
```
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                       index=['circle', 'triangle', 'rectangle'])
```

```text
angles
circle 0
triangle 3
rectangle 4
```

```python
>>> df + other
```

```text
angles  degrees
circle   0 NaN
triangle  3 NaN
rectangle 16 NaN
```

```python
>>> df.mul(other, fill_value=0)
```

```text
angles  degrees
circle 0.0
triangle 0.0
rectangle 0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               'index': [['A', 'A', 'A', 'B', 'B', 'B'],
                                         ['circle', 'triangle', 'rectangle',
                                          'square', 'pentagon', 'hexagon']])
```

```text
angles  degrees
A circle 0 360
triangle 3 180
rectangle 4 360
B square 4 360
pentagon 5 540
hexagon 6 720
```

```python
>>> df_multindex
```

```text
angles  degrees
A circle 0 360
triangle 3 180
rectangle 4 360
B square 4 360
pentagon 5 540
hexagon 6 720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
```

```text
angles  degrees
A circle NaN 1.0
triangle 1.0 NaN
rectangle 1.0 1.0
B square 0.0 0.0
pentagon 0.0 0.0
hexagon 0.0 0.0
```
pandas.DataFrame.from_dict

```
classmethod DataFrame.from_dict(data, orient='columns', dtype=None, columns=None) Constructs DataFrame from dict of array-like or dicts.

Creates DataFrame object from dictionary by columns or by index allowing dtype specification.

Parameters

- **data** [dict] Of the form {field : array-like} or {field : dict}.
- **orient** [{'columns', 'index'}, default 'columns'] The “orientation” of the data. If the keys of the passed dict should be the columns of the resulting DataFrame, pass 'columns' (default). Otherwise if the keys should be rows, pass 'index'.
- **dtype** [dtype, default None] Data type to force, otherwise infer.
- **columns** [list, default None] Column labels to use when orient='index'. Raises a ValueError if used with orient='columns'.

Returns

DataFrame

See also:

`DataFrame.from_records` DataFrame from structured ndarray, sequence of tuples or dicts, or `DataFrame`
`DataFrame` DataFrame object creation using constructor.

Examples

By default the keys of the dict become the DataFrame columns:

```
>>> data = {'col_1': [3, 2, 1, 0], 'col_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data)
   col_1  col_2
0      3    a
1      2    b
2      1    c
3      0    d
```

Specify orient='index' to create the DataFrame using dictionary keys as rows:

```
>>> data = {'row_1': [3, 2, 1, 0], 'row_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data, orient='index')
   row_1  row_2
0      3    a
1      2    b
2      1    c
3      0    d
```

When using the ‘index’ orientation, the column names can be specified manually:

```
>>> pd.DataFrame.from_dict(data, orient='index',
...                        columns=['A', 'B', 'C', 'D'])
   A  B  C  D
row_1 3  2  1  0
row_2  a  b  c  d
```
```
pandas.DataFrame.from_records

classmethod DataFrame.from_records(data, index=None, exclude=None, columns=None, coerce_float=False, nrows=None)

Convert structured or record ndarray to DataFrame.

Creates a DataFrame object from a structured ndarray, sequence of tuples or dicts, or DataFrame.

Parameters

- **data** [structured ndarray, sequence of tuples or dicts, or DataFrame] Structured input data.
- **index** [str, list of fields, array-like] Field of array to use as the index, alternately a specific set of input labels to use.
- **exclude** [sequence, default None] Columns or fields to exclude.
- **columns** [sequence, default None] Column names to use. If the passed data do not have names associated with them, this argument provides names for the columns. Otherwise this argument indicates the order of the columns in the result (any names not found in the data will become all-NA columns).
- **coerce_float** [bool, default False] Attempt to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets.
- **nrows** [int, default None] Number of rows to read if data is an iterator.

Returns

DataFrame

See also:

- **DataFrame.from_dict** DataFrame from dict of array-like or dicts.
- **DataFrame** DataFrame object creation using constructor.

Examples

Data can be provided as a structured ndarray:

```python
>>> data = np.array([(3, 'a'), (2, 'b'), (1, 'c'), (0, 'd')],
                  dtype=[('col_1', 'i4'), ('col_2', 'U1')])
>>> pd.DataFrame.from_records(data)
   col_1  col_2
0     3     a
1     2     b
2     1     c
3     0     d
```

Data can be provided as a list of dicts:

```python
>>> data = [{'col_1': 3, 'col_2': 'a'},
          {'col_1': 2, 'col_2': 'b'},
          {'col_1': 1, 'col_2': 'c'},
          {'col_1': 0, 'col_2': 'd'}]
>>> pd.DataFrame.from_records(data)
   col_1  col_2
0     3     a
```

(continues on next page)
Data can be provided as a list of tuples with corresponding columns:

```python
>>> data = [(3, 'a'), (2, 'b'), (1, 'c'), (0, 'd')]
>>> pd.DataFrame.from_records(data, columns=['col_1', 'col_2'])
   col_1 col_2
0      3    a
1      2    b
2      1    c
3      0    d
```

**pandas.DataFrame.ge**

DataFrame.ge(other, axis='columns', level=None)

Get Greater than or equal to of dataframe and other, element-wise (binary operator ge).

Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.

Equivalent to ==, /=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.
DataFrame.ne Compare DataFrames for inequality elementwise.
DataFrame.le Compare DataFrames for less than inequality or equality elementwise.
DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.
DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.
DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.
Notes

Mismatched indices will be unioned together. NaN values are considered different (i.e. NaN != NaN).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
                      'revenue': [100, 250, 300]},
                      index=['A', 'B', 'C'])

>>> df
   cost  revenue
A    250     100
B    150     250
C    100     300

Comparison with a scalar, using either the operator or method:

```python
def == 100
   cost  revenue
A   False    True
B   False   False
C    True   False
```

```python
def.eq(100)
   cost  revenue
A   False    True
B   False   False
C    True   False
```

When other is a Series, the columns of a DataFrame are aligned with the index of other and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
   cost  revenue
A   True    True
B   True   False
C  False    True
```

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
   cost  revenue
A   True   False
B   True    True
C   True    True
D   True    True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in other:

```python
>>> df == [250, 100]
   cost  revenue
A   True    True
B  False   False
C  False   False
```

Use the method to control the axis:
```python
>>> df.eq([250, 250, 100], axis='index')
    cost  revenue
   A   True   False
   B   False   True
   C   True   False

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
index=['A', 'B', 'C', 'D'])
>>> other
   revenue
A    300
B    250
C    100
D    150
```python
```python
>>> df.gt(other)
    cost  revenue
   A   False   False
   B   False   False
   C   False   True
   D   False   False

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
   'revenue': [100, 250, 300, 200, 175, 225],
   index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'], ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
     cost  revenue
    Q1 A   250    100
    B   150    250
    C   100    300
    Q2 A   150    200
    B   300    175
    C   220    225
```python
```python
>>> df.le(df_multindex, level=1)
    cost  revenue
   Q1 A   True   True
   B   True   True
   C   True   True
   Q2 A   False   True
   B   True   False
   C   True   False
```

---

3.4. **DataFrame**

---
pandas: powerful Python data analysis toolkit, Release 1.3.2

**pandas.DataFrame.get**

```
pandas.DataFrame.get(key, default=None)
```

Get item from object for given key (ex: DataFrame column).

Returns default value if not found.

**Parameters**

- `key` [object]

**Returns**

- `value` [same type as items contained in object]

**pandas.DataFrame.groupby**

```
pandas.DataFrame.groupby(by=None, axis=0, level=None, as_index=True, sort=True, group_keys=True, squeeze=<no_default>, observed=False, dropna=True)
```

Group DataFrame using a mapper or by a Series of columns.

A groupby operation involves some combination of splitting the object, applying a function, and combining the results. This can be used to group large amounts of data and compute operations on these groups.

**Parameters**

- `by` [mapping, function, label, or list of labels] Used to determine the groups for the groupby. If `by` is a function, it’s called on each value of the object’s index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the groups (the Series’ values are first aligned; see `pandas.DataFrame.align` method). If an ndarray is passed, the values are used as-is to determine the groups. A label or list of labels may be passed to group by the columns in `self`. Notice that a tuple is interpreted as a (single) key.

- `axis` [[0 or `‘index’`, 1 or `‘columns’`], default 0] Split along rows (0) or columns (1).

- `level` [int, level name, or sequence of such, default None] If the axis is a MultiIndex (hierarchical), group by a particular level or levels.

- `as_index` [bool, default True] For aggregated output, return object with group labels as the index. Only relevant for DataFrame input. `as_index=False` is effectively “SQL-style” grouped output.

- `sort` [bool, default True] Sort group keys. Get better performance by turning this off. Note this does not influence the order of observations within each group. Groupby preserves the order of rows within each group.

- `group_keys` [bool, default True] When calling apply, add group keys to index to identify pieces.

- `squeeze` [bool, default False] Reduce the dimensionality of the return type if possible, otherwise return a consistent type.

  Deprecated since version 1.1.0.

- `observed` [bool, default False] This only applies if any of the groupers are Categoricals.

  If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.
**dropna** [bool, default True] If True, and if group keys contain NA values, NA values together with row/column will be dropped. If False, NA values will also be treated as the key in groups

New in version 1.1.0.

**Returns**

**DataFrameGroupBy** Returns a groupby object that contains information about the groups.

**See also:**

**resample** Convenience method for frequency conversion and resampling of time series.

**Notes**

See the user guide for more.

**Examples**

```python
>>> df = pd.DataFrame({'Animal': ['Falcon', 'Falcon', 'Parrot', 'Parrot'],
...                    'Max Speed': [380., 370., 24., 26.]})
>>> df
   Animal  Max Speed
0   Falcon       380.0
1   Falcon       370.0
2   Parrot        24.0
3   Parrot        26.0
>>> df.groupby(['Animal']).mean()
     Max Speed
Animal
Falcon       375.0
Parrot        25.0
```

**Hierarchical Indexes**

We can groupby different levels of a hierarchical index using the *level* parameter:

```python
>>> arrays = [['Falcon', 'Falcon', 'Parrot', 'Parrot'],
...           ['Captive', 'Wild', 'Captive', 'Wild']]
>>> index = pd.MultiIndex.from_arrays(arrays, names=('Animal', 'Type'))
>>> df = pd.DataFrame({'Max Speed': [390., 350., 30., 20.]},
...                   index=index)
>>> df
   Max Speed
Animal Type
Falcon Captive 390.0
            Wild 350.0
Parrot Captive  30.0
            Wild  20.0
>>> df.groupby(level=0).mean()
     Max Speed
Animal
Falcon       370.0
Parrot        25.0
```

(continues on next page)
We can also choose to include NA in group keys or not by setting \textit{dropna} parameter, the default setting is \textit{True}:

```python
>>> l = [[1, 2, 3], [1, \text{None}, 4], [2, 1, 3], [1, 2, 2]]
>>> df = pd.DataFrame(l, columns=['a', 'b', 'c'])

>>> df.groupby(by=['b']).sum()
    a  c
  b
1.0  2  3
2.0  2  5
```

```python
>>> df.groupby(by=['b'], dropna=False).sum()
    a  c
  b
1.0  2  3
2.0  2  5
NaN 1  4
```

```python
>>> l = [['a', 12, 12], [\text{None}, 12.3, 33.], ['b', 12.3, 123.], ['a', 1, 1]]
>>> df = pd.DataFrame(l, columns=['a', 'b', 'c'])

>>> df.groupby(by='a').sum()
    b  c
  a  
13.0 13.0
b 12.3 123.0

>>> df.groupby(by='a', dropna=False).sum()
    b  c
  a  
13.0 13.0
b 12.3 123.0
NaN 12.3 33.0
```

\textbf{pandas.DataFrame.gt}

\texttt{DataFrame.gt} (\texttt{other}, \texttt{axis}=\texttt{columns}, \texttt{level}=\texttt{None})

Get Greater than of dataframe and other, element-wise (binary operator \texttt{gt}).

Among flexible wrappers (\texttt{eq}, \texttt{ne}, \texttt{le}, \texttt{lt}, \texttt{ge}, \texttt{gt}) to comparison operators.

Equivalent to \texttt{==}, \texttt{/=}, \texttt{<=}, \texttt{<}, \texttt{>=}, \texttt{>} with support to choose axis (rows or columns) and level for comparison.

\textbf{Parameters}

- \texttt{other} [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
**axis** [{0 or ‘index’, 1 or ‘columns’}, default ‘columns’] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’).

**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

*DataFrame of bool*  
Result of the comparison.

**See also:**

- *DataFrame.eq* Compare DataFrames for equality elementwise.
- *DataFrame.ne* Compare DataFrames for inequality elementwise.
- *DataFrame.le* Compare DataFrames for less than inequality or equality elementwise.
- *DataFrame.lt* Compare DataFrames for strictly less than inequality elementwise.
- *DataFrame.ge* Compare DataFrames for greater than inequality or equality elementwise.
- *DataFrame.gt* Compare DataFrames for strictly greater than inequality elementwise.

**Notes**

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

**Examples**

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                   index=['A', 'B', 'C'])

>>> df
    cost  revenue
   A    250      100
   B    150      250
   C    100      300

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
    cost  revenue
   A  False   True
   B  False  False
   C  True  False
```

```python
>>> df.eq(100)
    cost  revenue
   A  False   True
   B  False  False
   C  True  False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
    cost  revenue
   A  True   True
```

(continues on next page)
Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
  cost  revenue
A    True  False
B    True  True
C    True  True
D    True  True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```python
>>> df == [250, 100]
  cost  revenue
A    True  True
B    False  False
C    False  False
```

Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
  cost  revenue
A    True  False
B    False  True
C    True  False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
...                        index=['A', 'B', 'C', 'D'])
>>> other
   revenue
A      300
B      250
C      100
D      150
```

```python
>>> df.gt(other)
  cost  revenue
A    False  False
B    False  False
C    False  True
D    False  False
```

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225]},
...                              index=['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'])
>>> df_multindex
   cost  revenue
Q1   250      100
Q1   250      100
Q1   250      100
Q2   150      300
Q2   300      200
Q2   300      175
Q2   300      225
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.2

```python
B  150  250
C  100  300
Q2 A  150  200
    B  300  175
    C  220  225

>>> df.le(df_multindex, level=1)
   cost  revenue
Q1  A   True   True
    B   True   True
    C   True   True
Q2  A  False   True
    B   True  False
    C   True  False
```

```
pandas.DataFrame.head

DataFrame.
head(n=5)
Return the first n rows.

This function returns the first n rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

For negative values of n, this function returns all rows except the last n rows, equivalent to df[:-n].

Parameters

- n [int, default 5] Number of rows to select.

Returns

- same type as caller The first n rows of the caller object.

See also:

- DataFrame.tail Returns the last n rows.

Examples

```python
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                         'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
    animal
0    alligator
1      bee
2    falcon
3     lion
4    monkey
5    parrot
6      shark
7    whale
8    zebra
```

Viewing the first 5 lines
Viewing the first \( n \) lines (three in this case)

```python
>>> df.head(3)
animal
0  alligator
1    bee
2  falcon
```

For negative values of \( n \)

```python
>>> df.head(-3)
animal
0  alligator
1    bee
2  falcon
3    lion
4  monkey
5 parrot
```

**pandas.DataFrame.hist**

`DataFrame.hist(column=None, by=None, grid=True, xlabelsize=None, xrot=None, ylabelsize=None, yrot=None, ax=None, sharex=False, sharey=False, figsize=None, layout=None, bins=10, backend=None, legend=False, **kwargs)`

Make a histogram of the DataFrame’s columns.

A histogram is a representation of the distribution of data. This function calls `matplotlib.pyplot.hist()`, on each series in the DataFrame, resulting in one histogram per column.

**Parameters**

- `data` [DataFrame] The pandas object holding the data.
- `column` [str or sequence, optional] If passed, will be used to limit data to a subset of columns.
- `by` [object, optional] If passed, then used to form histograms for separate groups.
- `grid` [bool, default True] Whether to show axis grid lines.
- `xlabelsize` [int, default None] If specified changes the x-axis label size.
- `xrot` [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.
- `ylabelsize` [int, default None] If specified changes the y-axis label size.
- `yrot` [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.
- `ax` [Matplotlib axes object, default None] The axes to plot the histogram on.
sharex [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.

sharey [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.

figsize [tuple, optional] The size in inches of the figure to create. Uses the value in `matplotlib.rcParams` by default.

layout [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.

bins [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

backend [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, ‘matplotlib’. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

legend [bool, default False] Whether to show the legend.

New in version 1.1.0.

**kwargs All other plotting keyword arguments to be passed to `matplotlib.pyplot.hist()`.

Returns

`matplotlib.AxesSubplot` or `numpy.ndarray` of them

See also:

`matplotlib.pyplot.hist` Plot a histogram using matplotlib.

Examples

This example draws a histogram based on the length and width of some animals, displayed in three bins

```python
>>> df = pd.DataFrame({
...     'length': [1.5, 0.5, 1.2, 0.9, 3],
...     'width': [0.7, 0.2, 0.15, 0.2, 1.1]
... }, index=['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```
DataFrame.idxmax

DataFrame.idxmax (axis=0, skipna=True)
Return index of first occurrence of maximum over requested axis.
NA/null values are excluded.

Parameters
axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.
skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns
Series Indexes of maxima along the specified axis.

Raises
ValueError
• If the row/column is empty

See also:
Series.idxmax Return index of the maximum element.

Notes
This method is the DataFrame version of ndarray.argmax.

Examples
Consider a dataset containing food consumption in Argentina.

```python
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
...                     'co2_emissions': [37.2, 19.66, 1712]},
...                    index=['Pork', 'Wheat Products', 'Beef'])
>>> df
          consumption   co2_emissions
Pork       10.51          37.20
Wheat Products 103.11        19.66
Beef        55.48        1712.00
```

By default, it returns the index for the maximum value in each column.

```python
>>> df.idxmax()
consumption    Wheat Products
co2_emissions  Beef
dtype: object
```

To return the index for the maximum value in each row, use axis="columns".
pandas.DataFrame.idxmin

DataFrame.idxmin(axis=0, skipna=True)
Return index of first occurrence of minimum over requested axis.
NA/null values are excluded.

Parameters
axis [[0 or ‘index’, 1 or ‘columns’], default 0] The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.
skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns
Series Indexes of minima along the specified axis.

Raises
ValueError
• If the row/column is empty

See also:
Series.idxmin Return index of the minimum element.

Notes
This method is the DataFrame version of ndarray.argmin.

Examples
Consider a dataset containing food consumption in Argentina.

>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
...   'co2_emissions': [37.2, 19.66, 1712]},
...   index=['Pork', 'Wheat Products', 'Beef'])

>>> df
consumption  co2_emissions
Pork         10.51        37.20
Wheat Products 103.11       19.66
Beef          55.48       1712.00

By default, it returns the index for the minimum value in each column.
To return the index for the minimum value in each row, use `axis="columns"`.

```python
>>> df.idxmin(axis="columns")
Pork           consumption
Wheat Products co2_emissions
Beef           consumption
dtype: object
```

**pandas.DataFrame.infer_objects**

DataFrames `.infer_objects()` attempt to infer better dtypes for object columns. Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

**Returns**
- `converted` [same type as input object]

**See also:**
- `to_datetime` Convert argument to datetime.
- `to_timedelta` Convert argument to timedelta.
- `to_numeric` Convert argument to numeric type.
- `convert_dtypes` Convert argument to best possible dtype.

**Examples**

```python
>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df.dtypes
A object
dtype: object

>>> df.infer_objects().dtypes
A int64
dtype: object
```
**pandas.DataFrame.info**

`DataFrame.info(verbos=None, buf=None, max_cols=None, memory_usage=None, show_counts=None, null_counts=None)`

Print a concise summary of a DataFrame.

This method prints information about a DataFrame including the index dtype and columns, non-null values and memory usage.

**Parameters**

- **data** [DataFrame] DataFrame to print information about.
- **verbose** [bool, optional] Whether to print the full summary. By default, the setting in `pandas.options.display.max_info_columns` is followed.
- **buf** [writable buffer, defaults to sys.stdout] Where to send the output. By default, the output is printed to sys.stdout. Pass a writable buffer if you need to further process the output.
- **max_cols** [int, optional] When to switch from the verbose to the truncated output. If the DataFrame has more than `max_cols` columns, the truncated output is used. By default, the setting in `pandas.options.display.max_info_columns` is used.
- **memory_usage** [bool, str, optional] Specifies whether total memory usage of the DataFrame elements (including the index) should be displayed. By default, this follows the `pandas.options.display.memory_usage` setting.

    True always show memory usage. False never shows memory usage. A value of ‘deep’ is equivalent to “True with deep introspection”. Memory usage is shown in human-readable units (base-2 representation). Without deep introspection a memory estimation is made based in column dtype and number of rows assuming values consume the same memory amount for corresponding dtypes. With deep memory introspection, a real memory usage calculation is performed at the cost of computational resources.

- **show_counts** [bool, optional] Whether to show the non-null counts. By default, this is shown only if the DataFrame is smaller than `pandas.options.display.max_info_rows` and `pandas.options.display.max_info_columns`. A value of True always shows the counts, and False never shows the counts.

- **null_counts** [bool, optional] Deprecated since version 1.2.0: Use show_counts instead.

**Returns**

None This method prints a summary of a DataFrame and returns None.

See also:

- `DataFrame.describe` Generate descriptive statistics of DataFrame columns.
- `DataFrame.memory_usage` Memory usage of DataFrame columns.
Examples

```python
>>> int_values = [1, 2, 3, 4, 5]
>>> text_values = ['alpha', 'beta', 'gamma', 'delta', 'epsilon']
>>> float_values = [0.0, 0.25, 0.5, 0.75, 1.0]
>>> df = pd.DataFrame({'int_col': int_values, 'text_col': text_values, 'float_col': float_values})
>>> df
   int_col  text_col   float_col
0      1    alpha    0.000000
1      2     beta    0.250000
2      3   gamma    0.500000
3      4    delta    0.750000
4      5  epsilon    1.000000
```

Prints information of all columns:

```python
>>> df.info((verbose=True))
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Data columns (total 3 columns):
    #   Column     Non-Null Count  Dtype
    ---  -------     --------------  ----
     0   int_col    5 non-null    int64
     1  text_col    5 non-null    object
     2  float_col   5 non-null    float64
dtypes: float64(1), int64(1), object(1)
memory usage: 248.0+ bytes
```

Prints a summary of columns count and its dtypes but not per column information:

```python
>>> df.info((verbose=False))
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Columns: 3 entries, int_col to float_col
dtypes: float64(1), int64(1), object(1)
memory usage: 248.0+ bytes
```

Pipe output of DataFrame.info to buffer instead of sys.stdout, get buffer content and writes to a text file:

```python
>>> import io
>>> buffer = io.StringIO()
>>> df.info(buf=buffer)
>>> s = buffer.getvalue()
>>> with open("df_info.txt", "w", encoding="utf-8") as f:
...     f.write(s)
260
```

The `memory_usage` parameter allows deep introspection mode, specially useful for big DataFrames and fine-tune memory optimization:

```python
>>> random_strings_array = np.random.choice(['a', 'b', 'c'], 10 ** 6)
>>> df = pd.DataFrame({
...     'column_1': np.random.choice(['a', 'b', 'c'], 10 ** 6),
...     'column_2': np.random.choice(['a', 'b', 'c'], 10 ** 6),
...     'column_3': np.random.choice(['a', 'b', 'c'], 10 ** 6)
... })
```

(continues on next page)
... })
```
>>> df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
   #     Column  Non-Null Count   Dtype
---  ------  --------------  ------
   0    column_1  1000000 non-null object
   1    column_2  1000000 non-null object
   2    column_3  1000000 non-null object
dtypes: object(3)
memory usage: 22.9+ MB
```
```
>>> df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
   #     Column  Non-Null Count   Dtype
---  ------  --------------  ------
   0    column_1  1000000 non-null object
   1    column_2  1000000 non-null object
   2    column_3  1000000 non-null object
dtypes: object(3)
memory usage: 165.9 MB
```

### pandas.DataFrame.insert

**DataFrame.insert**(loc, column, value, allow_duplicates=False)

Insert column into DataFrame at specified location.

Raises a ValueError if column is already contained in the DataFrame, unless allow_duplicates is set to True.

**Parameters**

- **loc** [int] Insertion index. Must verify 0 <= loc <= len(columns).
- **column** [str, number, or hashable object] Label of the inserted column.
- **value** [int, Series, or array-like]
- **allow_duplicates** [bool, optional]

**See also:**

- **Index.insert** Insert new item by index.
Examples

```python
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df
          col1  col2
0         1     3
1         2     4
>>> df.insert(1, "newcol", [99, 99])
>>> df
          col1  newcol  col2
0         1       99     3
1         2       99     4
>>> df.insert(0, "col1", [100, 100], allow_duplicates=True)
>>> df
           col1  col1  newcol  col2
0       100      1       99     3
1       100      2       99     4
```

Notice that pandas uses index alignment in case of value from type Series:

```python
>>> df.insert(0, "col0", pd.Series([5, 6], index=[1, 2]))
>>> df
      col0  col1  col1  newcol  col2
0    NaN   100      1       99     3
1  5.0   100      2       99     4
```

**pandas.DataFrame.interpolate**

DataFrame.interpolate(method='linear', axis=0, limit=None, inplace=False, limit_direction=None, limit_area=None, downcast=None, **kwargs)

Fill NaN values using an interpolation method.

Please note that only method='linear' is supported for DataFrame/Series with a MultiIndex.

Parameters

- **method** [str, default 'linear'] Interpolation technique to use. One of:
  - 'linear': Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
  - 'time': Works on daily and higher resolution data to interpolate given length of interval.
  - 'index', 'values': use the actual numerical values of the index.
  - 'pad': Fill in NaNs using existing values.
  - 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'spline', 'barycentric', 'polynomial': Passed to scipy.interpolate.interp1d. These methods use the numerical values of the index. Both 'polynomial' and 'spline' require that you also specify an order (int), e.g. df.interpolate(method='polynomial', order=5).
  - 'krogh', 'piecewise_polynomial', 'spline', 'pchip', 'akima', 'cubicspline': Wrappers around the SciPy interpolation methods of similar names. See Notes.
  - 'from_derivatives': Refers to scipy.interpolate.BPoly.from_derivatives which replaces 'piecewise_polynomial' interpolation method in scipy 0.18.
axis  [{0 or ‘index’, 1 or ‘columns’, None}, default None] Axis to interpolate along.

limit  [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

inplace  [bool, default False] Update the data in place if possible.

limit_direction  [{‘forward’, ‘backward’, ‘both’}, Optional] Consecutive NaNs will be filled in this direction.

If limit is specified:
• If ‘method’ is ‘pad’ or ‘ffill’, ‘limit_direction’ must be ‘forward’.
• If ‘method’ is ‘backfill’ or ‘bfill’, ‘limit_direction’ must be ‘backwards’.

If ‘limit’ is not specified:
• If ‘method’ is ‘backfill’ or ‘bfill’, the default is ‘backward’
• else the default is ‘forward’

Changed in version 1.1.0: raises ValueError if limit_direction is ‘forward’ or ‘both’ and method is ‘backfill’ or ‘bfill’. raises ValueError if limit_direction is ‘backward’ or ‘both’ and method is ‘pad’ or ‘ffill’.

limit_area  [{None, ‘inside’, ‘outside’}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.
• None: No fill restriction.
• ‘inside’: Only fill NaNs surrounded by valid values (interpolate).
• ‘outside’: Only fill NaNs outside valid values (extrapolate).

downcast  [optional, ‘infer’ or None, defaults to None] Downcast dtypes if possible.

``**kwargs``  [optional] Keyword arguments to pass on to the interpolating function.

Returns

Series or DataFrame or None  Returns the same object type as the caller, interpolated at some or all NaN values or None if inplace=True.

See also:

fillna  Fill missing values using different methods.

scipy.interpolate.Akima1DInterpolator  Piecewise cubic polynomials (Akima interpolator).

scipy.interpolate.BPoly.from_derivatives  Piecewise polynomial in the Bernstein basis.

scipy.interpolate.interp1d  Interpolate a 1-D function.

scipy.interpolate.KroghInterpolator  Interpolate polynomial (Krogh interpolator).

scipy.interpolate.PchipInterpolator  PCHIP 1-d monotonic cubic interpolation.

scipy.interpolate.CubicSpline  Cubic spline data interpolator.
Notes

The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the SciPy documentation and SciPy tutorial.

Examples

Filling in NaN in a Series via linear interpolation.

```python
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2   NaN
3    3.0
dtype: float64
>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.

```python
>>> s = pd.Series([np.nan, "single_one", np.nan, ...
...     "fill_two_more", np.nan, np.nan, np.nan, ...
...     4.71, np.nan])
>>> s
0   NaN
1  single_one
2     NaN
3  fill_two_more
4     NaN
5     NaN
6     NaN
7   4.71
8     NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0   NaN
1  single_one
2  single_one
3  fill_two_more
4  fill_two_more
5  fill_two_more
6     NaN
7   4.71
8   4.71
dtype: object
```

Filling in NaN in a Series via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an order (int).
Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it to use for interpolation.

Using polynomial interpolation.

```
>>> df['d'].interpolate(method='polynomial', order=2)
0  1.0
1  4.0
2  9.0
3  16.0
Name: d, dtype: float64
```
See also:

**Dataframe.eq**  Equality test for DataFrame.

**Series.isin**  Equivalent method on Series.

**Series.str.contains**  Test if pattern or regex is contained within a string of a Series or Index.

**Examples**

```python
>>> df = pd.DataFrame({'num_legs': [2, 4], 'num_wings': [2, 0]},
                    index=['falcon', 'dog'])
>>> df
    num_legs num_wings
falcon     2         2
dog        4         0
```

When `values` is a list check whether every value in the DataFrame is present in the list (which animals have 0 or 2 legs or wings)

```python
>>> df.isin([0, 2])
    num_legs num_wings
falcon   True   True
dog      False  True
```

When `values` is a dict, we can pass values to check for each column separately:

```python
>>> df.isin({'num_wings': [0, 3]})
    num_legs num_wings
falcon   False  False
dog      False  True
```

When `values` is a Series or DataFrame the index and column must match. Note that ‘falcon’ does not match based on the number of legs in df2.

```python
>>> other = pd.DataFrame({'num_legs': [8, 2], 'num_wings': [0, 2]},
                       index=['spider', 'falcon'])
>>> df.isin(other)
    num_legs num_wings
falcon   True   True
dog      False  False
```

**pandas.DataFrame.isna**

Dataframe.isna()
Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy. NaN, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings ' ' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

Returns

**DataFrame**  Mask of bool values for each element in DataFrame that indicates whether an element is an NA value.
See also:

**DataFrame.isnull**  Alias of isna.

**DataFrame.notna**  Boolean inverse of isna.

**DataFrame.dropna**  Omit axes labels with missing values.

**isna**  Top-level isna.

### Examples

Show which entries in a DataFrame are NA.

```python
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
    ...                   born=[pd.NaT, pd.Timestamp('1939-05-27'),
    ...                     pd.Timestamp('1940-04-25')],
    ...                   name=['Alfred', 'Batman', ''],
    ...                     toy=[None, 'Batmobile', 'Joker']))

>>> df
          age    born    name    toy
   0      5.0  NaT  Alfred     None
   1      6.0 1939-05-27  Batman  Batmobile
   2  NaN 1940-04-25       Joker

>>> df.isna()
          age    born    name    toy
   0   False    True   False   True
   1   False  False    False   False
   2    True  False    False   False
```

Show which entries in a Series are NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])

>>> ser
0    5.0
1    6.0
2   NaN
dtype: float64

>>> ser.isna()
0    False
1    False
2     True
dtype: bool
```

### pandas.DataFrame.isnull

**DataFrame.isnull()**

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy.NaN, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).
Returns

**DataFrame**  Mask of bool values for each element in DataFrame that indicates whether an element is an NA value.

See also:

*DataFrame.isnull*  Alias of isna.

*DataFrame.notna*  Boolean inverse of isna.

*DataFrame.dropna*  Omit axes labels with missing values.

*isna*  Top-level isna.

Examples

Show which entries in a DataFrame are NA.

```python
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
                            pd.Timestamp('1940-04-25')],
                      name=['Alfred', 'Batman', ''],
                      toy=[None, 'Batmobile', 'Joker']))
```

<table>
<thead>
<tr>
<th>age</th>
<th>born</th>
<th>name</th>
<th>toy</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.0</td>
<td>NaT</td>
<td>Alfred</td>
<td>None</td>
</tr>
<tr>
<td>6.0</td>
<td>1939-05-27</td>
<td>Batman</td>
<td>Batmobile</td>
</tr>
<tr>
<td>NaN</td>
<td>1940-04-25</td>
<td>Joker</td>
<td></td>
</tr>
</tbody>
</table>

```python
>>> df
age    born        name  toy
0 5.0  NaT        Alfred None
1 6.0  1939-05-27 Batman Batmobile
2 NaN  1940-04-25 Joker
```

```python
>>> df.isna()
    age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2   True  False  False  False
```

Show which entries in a Series are NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
```

```python
>>> ser
0  5.0
1  6.0
2  NaN
dtype: float64
```

```python
>>> ser.isna()
0  False
1  False
2   True
dtype: bool
```
pandas.DataFrame.items

DataFrame.items()
Iterate over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

Yields

- **label** [object] The column names for the DataFrame being iterated over.
- **content** [Series] The column entries belonging to each label, as a Series.

See also:

- DataFrame.iterrows iterate over DataFrame rows as (index, Series) pairs.
- DataFrame.itertuples iterate over DataFrame rows as namedtuples of the values.

Examples

```python
>>> df = pd.DataFrame({'species': ['bear', 'bear', 'marsupial'],
...                    'population': [1864, 22000, 80000],
...                    'index':['panda', 'polar', 'koala']})
>>> df
   species   population
panda     bear       1864
polar     bear      22000
koala   marsupial  80000

>>> for label, content in df.items():
...     print(f'label: {label}')
...     print(f'content: {content}')
...     print(' ', sep='   
... label: species
content: panda      bear
polar      bear
koala   marsupial  Name: species, dtype: object
label: population
content: panda     1864
polar     22000
koala     80000
Name: population, dtype: int64
```

pandas.DataFrame.iteritems

DataFrame.iteritems()
Iterate over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

Yields

- **label** [object] The column names for the DataFrame being iterated over.
- **content** [Series] The column entries belonging to each label, as a Series.
See also:

**DataFrame.iterrows** Iterate over DataFrame rows as (index, Series) pairs.

**DataFrame.itertuples** Iterate over DataFrame rows as namedtuples of the values.

**Examples**

```python
>>> df = pd.DataFrame({'species': ['bear', 'bear', 'marsupial'],
                   'population': [1864, 22000, 80000],
                   'index': ['panda', 'polar', 'koala']})
>>> df
   species  population
  panda    bear      1864
  polar    bear      22000
  koala marsupial  80000
>>> for label, content in df.items():
...     print(f'label: {label}
...     print(f'content: {content}', sep='\n')
...     label: species
...     content:
...     panda    bear
...     polar    bear
...     koala marsupial
Name: species, dtype: object
...     label: population
...     content:
...     panda 1864
...     polar 22000
...     koala 80000
Name: population, dtype: int64
```

**pandas.DataFrame.iterrows**

```python
dataFrame.iterrows()
```

Iterate over DataFrame rows as (index, Series) pairs.

Yields

- **index** [label or tuple of label] The index of the row. A tuple for a `MultiIndex`.
- **data** [Series] The data of the row as a Series.

See also:

**DataFrame.itertuples** Iterate over DataFrame rows as namedtuples of the values.

**DataFrame.items** Iterate over (column name, Series) pairs.
Notes

1. Because `iterrows` returns a Series for each row, it does not preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```python
def = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])
row = next(df.iterrows())[1]
row
int 1.0
float 1.5
Name: 0, dtype: float64
print(row['int'].dtype)
flo64
print(df['int'].dtype)
int64
```

To preserve dtypes while iterating over the rows, it is better to use `itertuples()` which returns namedtuples of the values and which is generally faster than `iterrows`.

2. You should never modify something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect.

**pandas.DataFrame.itertuples**

`DataFrame.itertuples(index=True, name='Pandas')`  
Iterate over DataFrame rows as namedtuples.

**Parameters**

- `index` [bool, default True] If True, return the index as the first element of the tuple.
- `name` [str or None, default “Pandas”] The name of the returned namedtuples or None to return regular tuples.

**Returns**

- `iterator` An object to iterate over namedtuples for each row in the DataFrame with the first field possibly being the index and following fields being the column values.

See also:

- `DataFrame.iterrows` Iterate over DataFrame rows as (index, Series) pairs.
- `DataFrame.items` Iterate over (column name, Series) pairs.

**Notes**

The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. On python versions < 3.7 regular tuples are returned for DataFrames with a large number of columns (>254).
Examples

```python
>>> df = pd.DataFrame({'num_legs': [4, 2], 'num_wings': [0, 2]},
                   index=['dog', 'hawk'])
>>> df
   num_legs num_wings
dog       4         0
hawk      2         2
>>> for row in df.itertuples():
    ...       print(row)
    ...
Pandas(Index='dog', num_legs=4, num_wings=0)
Pandas(Index='hawk', num_legs=2, num_wings=2)

By setting the `index` parameter to False we can remove the index as the first element of the tuple:

```python
>>> for row in df.itertuples(index=False):
    ...       print(row)
    ...
Pandas(num_legs=4, num_wings=0)
Pandas(num_legs=2, num_wings=2)
```

With the `name` parameter set we set a custom name for the yielded namedtuples:

```python
>>> for row in df.itertuples(name='Animal'):
    ...       print(row)
    ...
Animal(Index='dog', num_legs=4, num_wings=0)
Animal(Index='hawk', num_legs=2, num_wings=2)
```

**pandas.DataFrame.join**

DataFrame.join(other, on=None, how='left', lsuffix='', rsuffix='', sort=False)

Join columns of another DataFrame.

Join columns with other DataFrame either on index or on a key column. Efficiently join multiple DataFrame objects by index at once by passing a list.

**Parameters**

- **other** [DataFrame, Series, or list of DataFrame] Index should be similar to one of the columns in this one. If a Series is passed, its name attribute must be set, and that will be used as the column name in the resulting joined DataFrame.

- **on** [str, list of str, or array-like, optional] Column or index level name(s) in the caller to join on the index in other, otherwise joins index-on-index. If multiple values given, the other DataFrame must have a MultiIndex. Can pass an array as the join key if it is not already contained in the calling DataFrame. Like an Excel VLOOKUP operation.

- **how** [{‘left’, ‘right’, ‘outer’, ‘inner’}, default ‘left’] How to handle the operation of the two objects.
  - left: use calling frame’s index (or column if on is specified)
  - right: use other’s index.
outer: form union of calling frame’s index (or column if on is specified) with other’s index, and sort it lexicographically.

inner: form intersection of calling frame’s index (or column if on is specified) with other’s index, preserving the order of the calling’s one.

lsuffix [str, default ‘’] Suffix to use from left frame’s overlapping columns.

rsuffix [str, default ‘’] Suffix to use from right frame’s overlapping columns.

sort [bool, default False] Order result DataFrame lexicographically by the join key. If False, the order of the join key depends on the join type (how keyword).

Returns

DataFrame A dataframe containing columns from both the caller and other.

See also:

DataFrame.merge For column(s)-on-column(s) operations.

Notes

Parameters on, lsuffix, and rsuffix are not supported when passing a list of DataFrame objects.

Support for specifying index levels as the on parameter was added in version 0.23.0.

Examples

```python
>>> df = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3', 'K4', 'K5'],
                    'A': ['A0', 'A1', 'A2', 'A3', 'A4', 'A5']})

>>> df
   key  A
0   K0  A0
1   K1  A1
2   K2  A2
3   K3  A3
4   K4  A4
5   K5  A5

>>> other = pd.DataFrame({'key': ['K0', 'K1', 'K2'],
                        'B': ['B0', 'B1', 'B2']})

>>> other
   key  B
0   K0  B0
1   K1  B1
2   K2  B2

Join DataFrames using their indexes.

```python
>>> df.join(other, lsuffix='_caller', rsuffix='_other')
   key_caller  A  key_other  B
0   K0         A0     K0     B0
1   K1         A1     K1     B1
2   K2         A2     K2     B2
```

(continues on next page)
If we want to join using the key columns, we need to set key to be the index in both `df` and `other`. The joined DataFrame will have key as its index.

```python
>>> df.set_index('key').join(other.set_index('key'))
   A   B
key
K0 A0 B0
K1 A1 B1
K2 A2 B2
K3 A3 NaN
K4 A4 NaN
K5 A5 NaN
```

Another option to join using the key columns is to use the `on` parameter. DataFrame.join always uses `other`’s index but we can use any column in `df`. This method preserves the original DataFrame’s index in the result.

```python
>>> df.join(other.set_index('key'), on='key')
   key A   B
0  K0 A0 B0
1  K1 A1 B1
2  K2 A2 B2
3  K3 A3 NaN
4  K4 A4 NaN
5  K5 A5 NaN
```

**pandas.DataFrame.keys**

`DataFrame.keys()` Get the ‘info axis’ (see Indexing for more).

This is index for Series, columns for DataFrame.

Returns

Index Info axis.

**pandas.DataFrame.kurt**

`DataFrame.kurt(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)` Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis [[index (0), columns (1)]] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
numeric_only  [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs  Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.kurtosis

DataFrame.kurtosis (axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
Return unbiased kurtosis over requested axis.
Kurtosis obtained using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis  [[index (0), columns (1)]] Axis for the function to be applied on.
skipna  [bool, default True] Exclude NA/null values when computing the result.
level  [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
numeric_only  [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs  Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.last

DataFrame.last (offset)
Select final periods of time series data based on a date offset.

For a DataFrame with a sorted DatetimeIndex, this function selects the last few rows based on a date offset.

Parameters

offset  [str, DateOffset, dateutil.relativedelta] The offset length of the data that will be selected. For instance, ‘3D’ will display all the rows having their index within the last 3 days.

Returns

Series or DataFrame  A subset of the caller.

Raises

TypeError  If the index is not a DatetimeIndex

See also:

first  Select initial periods of time series based on a date offset.
**at_time**  Select values at a particular time of the day.

**between_time**  Select values between particular times of the day.

**Examples**

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4

Get the rows for the last 3 days:

```python
>>> ts.last('3D')
A
2018-04-13  3
2018-04-15  4
```

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

**pandas.DataFrame.last_valid_index**

Dataframe.last_valid_index()  
Return index for last non-NA value or None, if no NA value is found.

- **Returns**
  - scalar  [type of index]

- **Notes**
  - If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

**pandas.DataFrame.le**

Dataframe.le(other, axis='columns', level=None)  
Get Less than or equal to of dataframe and other, element-wise (binary operator le).

Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.

Equivalent to ==, !=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

- **Parameters**
  - other  [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
  - axis  [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').
level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.

DataFrame.ne Compare DataFrames for inequality elementwise.

DataFrame.le Compare DataFrames for less than inequality or equality elementwise.

DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.

DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.

DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. NaN values are considered different (i.e. NaN != NaN).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                   index=['A', 'B', 'C'])
```

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
   cost  revenue
A  False   True
B  False  False
C   True  False
```
```
```python
>>> df.eq(100)
   cost  revenue
A  False   True
B  False  False
C   True  False
```
```
When other is a Series, the columns of a DataFrame are aligned with the index of other and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
   cost  revenue
A   True    True
B   True  False
C  False    True
```
Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D'], axis='index'))
      cost  revenue
    A   True   False
    B   True   True
    C   True   True
    D   True   True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```python
>>> df == [250, 100]
      cost  revenue
    A   True   True
    B  False  False
    C  False  False
```

Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
      cost  revenue
    A   True   False
    B  False   True
    C   True   False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                        index=['A', 'B', 'C', 'D'])
>>> df.gt(other)
      cost  revenue
    A  False  False
    B  False  False
    C  False   True
    D  False  False
```

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
                               'revenue': [100, 250, 300, 200, 175, 225],
                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
                                      ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
       cost  revenue
    Q1  A  250  100
        B  150  250
        C  100  300
    Q2  A  150  200
        B  300  175
        C  220  225
```
```python
>>> df.le(df_multindex, level=1)
    cost  revenue
Q1  A    True   True
    B    True   True
    C    True   True
Q2  A   False   True
    B    True  False
    C    True  False
```

**pandas.DataFrame.lookup**

Dataframe .lookup(row_labels, col_labels)

Label-based “fancy indexing” function for DataFrame. Given equal-length arrays of row and column labels, return an array of the values corresponding to each (row, col) pair.

Deprecated since version 1.2.0: DataFrame.lookup is deprecated, use DataFrame.melt and DataFrame.loc instead. For further details see *Looking up values by index/column labels*.

**Parameters**

- row_labels [sequence] The row labels to use for lookup.
- col_labels [sequence] The column labels to use for lookup.

**Returns**

- numpy.ndarray The found values.

**pandas.DataFrame.lt**

Dataframe .lt(other, axis='columns', level=None)

Get Less than of dataframe and other, element-wise (binary operator lt).

Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.

Equivalent to ==, /=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

**Parameters**

- other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- axis [{0 or ‘index’, 1 or ‘columns’}, default ‘columns’] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’).
- level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

- DataFrame of bool Result of the comparison.

See also:

- DataFrame.eq Compare DataFrames for equality elementwise.
- DataFrame.ne Compare DataFrames for inequality elementwise.
- DataFrame.le Compare DataFrames for less than inequality or equality elementwise.
**DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.

**DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.

**DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.

**Notes**

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

**Examples**

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                   index=['A', 'B', 'C'])
>>> df
cost  revenue
A     250      100
B     150      250
C     100      300
```

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
    cost  revenue
A   False   True
B   False  False
C   True   False
```

```python
>>> df.eq(100)
cost  revenue
A   False   True
B   False  False
C   True   False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
cost  revenue
A    True    True
B    True  False
C   False    True
```

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
cost  revenue
A    True    False
B    True    True
C    True    True
D    True    True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*:
Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
  cost revenue
A   True  False
B   False  True
C   True  False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                   index=['A', 'B', 'C', 'D'])
>>> other
   revenue
A      300
B      250
C      100
D      150
```

```python
>>> df.gt(other)
  cost revenue
A  False  False
B  False  False
C  False  True
D  False  False
```

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
                               'revenue': [100, 250, 300, 200, 175, 225]},
                              index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
                               ['A', 'B', 'C', 'A', 'B', 'C']])
```

```python
>>> df_multindex
   cost revenue
Q1 A  250   100
   B  150   250
   C  100   300
Q2 A  150   200
   B  300   175
   C  220   225
```

```python
>>> df.le(df_multindex, level=1)
  cost revenue
Q1 A  True  True
   B  True  True
   C  True  True
Q2 A  False  True
   B  True  False
   C  True  False
```
pandas.DataFrame.mad

DataFrame.mad (axis=None, skipna=None, level=None)
Return the mean absolute deviation of the values over the requested axis.

Parameters

- **axis** ([index (0), columns (1)]) Axis for the function to be applied on.
- **skipna** [bool, default None] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.mask

DataFrame.mask (cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=<no_default>)
Replace values where the condition is True.

Parameters

- **cond** [bool Series/DataFrame, array-like, or callable] Where cond is False, keep the original value. Where True, replace with corresponding value from other. If cond is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn’t check it).
- **other** [scalar, Series/DataFrame, or callable] Entries where cond is True are replaced with corresponding value from other. If other is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn’t check it).
- **inplace** [bool, default False] Whether to perform the operation in place on the data.
- **axis** [int, default None] Alignment axis if needed.
- **level** [int, default None] Alignment level if needed.
- **errors** [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.
  - ‘raise’ : allow exceptions to be raised.
  - ‘ignore’ : suppress exceptions. On error return original object.
- **try_cast** [bool, default None] Try to cast the result back to the input type (if possible). Deprecated since version 1.3.0: Manually cast back if necessary.

Returns

Same type as caller or None if inplace=True.

See also:

DataFrame.where() Return an object of same shape as self.
Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if \( \text{cond} \) is False the element is used; otherwise the corresponding element from the DataFrame other is used.

The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the mask documentation in `indexing`.

Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1     1.0
2     2.0
3     3.0
4     4.0
dtype: float64
>>> s.mask(s > 0)
0   0.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64

>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
>>> s.mask(s > 1, 10)
0    0
1    1
2    10
3    10
4    10
dtype: int64

>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  1  2
2  2  3
3  3  4
4  4  5
5  5  6
6  6  7
7  7  8
8  8  9
9  9 10
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0  1
1  1  2
2  4  5
3  6  7
4  8  9
```

(continues on next page)
df.where(m, -df) == np.where(m, df, -df)

A   B
0   True True
1   True True
2   True True
3   True True
4   True True

df.where(m, -df) == df.mask(~m, -df)

A   B
0   True True
1   True True
2   True True
3   True True
4   True True

pandas.DataFrame.max

DataFrame.max (axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return the maximum of the values over the requested axis.

If you want the index of the maximum, use idxmax. This is the equivalent of the numpy.ndarray method argmax.

Parameters

axis ([index (0), columns (1)] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

Series.sum Return the sum.

Series.min Return the minimum.

Series.max Return the maximum.

Series.idxmin Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.
**DataFrame.max**  Return the maximum over the requested axis.

**DataFrame.idxmin**  Return the index of the minimum over the requested axis.

**DataFrame.idxmax**  Return the index of the maximum over the requested axis.

**Examples**

```python
>>> idx = pd.MultiIndex.from_arrays([
    ... ['warm', 'warm', 'cold', 'cold'],
    ... ['dog', 'falcon', 'fish', 'spider'],
    ... names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded animal
  warm  dog  4
  falcon  2
  cold  fish  0
  spider  8
Name: legs, dtype: int64

>>> s.max()
8
```

**pandas.DataFrame.mean**

DataFrame.mean (*axis=None, skipna=None, level=None, numeric_only=None, **kwargs*)

Return the mean of the values over the requested axis.

**Parameters**

- **axis**  [{index (0), columns (1)}] Axis for the function to be applied on.
- **skipna**  [bool, default True] Exclude NA/null values when computing the result.
- **level**  [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **numeric_only**  [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs**  Additional keyword arguments to be passed to the function.

**Returns**

Series or DataFrame (if level specified)
pandas.DataFrame.median

DataFrame.median (axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
Return the median of the values over the requested axis.

Parameters

axis ([index (0), columns (1)]) Axis for the function to be applied on.
skipna [bool, default True] Exclude NA/null values when computing the result.
level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
**kwargs Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.melt

DataFrame.melt (id_vars=None, value_vars=None, var_name=None, value_name='value', col_level=None, ignore_index=True)
Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.
This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (id_vars), while all other columns, considered measured variables (value_vars), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’.

Parameters

id_vars [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.
value_vars [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as id_vars.
var_name [scalar] Name to use for the ‘variable’ column. If None it uses frame.columns.name or ‘variable’.
value_name [scalar, default ‘value’] Name to use for the ‘value’ column.
col_level [int or str, optional] If columns are a MultiIndex then use this level to melt.
ignore_index [bool, default True] If True, original index is ignored. If False, the original index is retained. Index labels will be repeated as necessary.

Returns

DataFrame Unpivoted DataFrame.

See also:
melt Identical method.
pivot_table Create a spreadsheet-style pivot table as a DataFrame.
DataFrame.pivot Return reshaped DataFrame organized by given index / column values.
**DataFrame.explode**  
Explode a DataFrame from list-like columns to long format.

### Examples

```python
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
                    'B': {0: 1, 1: 3, 2: 5},
                    'C': {0: 2, 1: 4, 2: 6}})

>>> df
   A  B  C
0  a  1  2
1  b  3  4
2  c  5  6

>>> df.melt(id_vars=['A'], value_vars=['B'])
    A  variable  value
0  a      B     1
1  b      B     3
2  c      B     5

>>> df.melt(id_vars=['A'], value_vars=['B', 'C'])
    A  variable  value
0  a      B     1
1  b      B     3
2  c      B     5
3  a      C     2
4  b      C     4
5  c      C     6

The names of `variable` and `value` columns can be customized:

```python
>>> df.melt(id_vars=['A'], value_vars=['B'],
           var_name='myVarname', value_name='myValname')
    A  myVarname  myValname
0  a      B     1
1  b      B     3
2  c      B     5

Original index values can be kept around:

```python
>>> df.melt(id_vars=['A'], value_vars=['B', 'C'], ignore_index=False)
    A  variable  value
0  a      B     1
1  b      B     3
2  c      B     5
0  a      C     2
1  b      C     4
2  c      C     6

If you have multi-index columns:

```python
>>> df.columns = [list('ABC'), list('DEF')]
>>> df
   A  B  C
   D  E  F
0  a  1  2
[continues on next page]
```python
>>> df.melt(col_level=0, id_vars=['A'], value_vars=['B'])
   A    variable  value
0  a      B     1
1  b      B     3
2  c      B     5

>>> df.melt(id_vars=[('A', 'D')], value_vars=[('B', 'E')])
   (A, D)    variable_0  variable_1  value
0  a       B       E     1
1  b       B       E     3
2  c       B       E     5
```

### pandas.DataFrame.memory_usage

**DataFrame.memory_usage(index=True, deep=False)**

Return the memory usage of each column in bytes.

The memory usage can optionally include the contribution of the index and elements of `object` dtype.

This value is displayed in `DataFrame.info` by default. This can be suppressed by setting `pandas.options.display.memory_usage` to False.

**Parameters**

- **index** [bool, default True] Specifies whether to include the memory usage of the DataFrame’s index in returned Series. If `index=True`, the memory usage of the index is the first item in the output.

- **deep** [bool, default False] If True, introspect the data deeply by interrogating `object` dtypes for system-level memory consumption, and include it in the returned values.

**Returns**

- **Series** A Series whose index is the original column names and whose values is the memory usage of each column in bytes.

**See also:**

- `numpy.ndarray.nbytes` Total bytes consumed by the elements of an ndarray.
- `Series.memory_usage` Bytes consumed by a Series.
- `Categorical` Memory-efficient array for string values with many repeated values.
- `DataFrame.info` Concise summary of a DataFrame.
### Examples

```python
>>> dtypes = ['int64', 'float64', 'complex128', 'object', 'bool']
>>> data = dict([(t, np.ones(shape=5000, dtype=t).astype(t))
...               for t in dtypes])
>>> df = pd.DataFrame(data)
>>> df.head()

<table>
<thead>
<tr>
<th></th>
<th>int64</th>
<th>float64</th>
<th>complex128</th>
<th>object</th>
<th>bool</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>1.0</td>
<td>1.0+0.0j</td>
<td>1</td>
<td>True</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1.0</td>
<td>1.0+0.0j</td>
<td>1</td>

```

```python
>>> df.memory_usage()
Index 128
int64 40000
float64 40000
complex128 80000
object 40000
bool 5000
dtype: int64
```

```python
>>> df['object'].astype('category').memory_usage(deep=True)
5244
```

The memory footprint of object dtype columns is ignored by default:

```python
>>> df.memory_usage(deep=True)
Index 128
int64 40000
float64 40000
complex128 80000
object 40000
bool 5000
dtype: int64
```

Use a Categorical for efficient storage of an object-dtype column with many repeated values.

```python
>>> df['object'].astype('category').memory_usage(deep=True)
5244
```
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.DataFrame.merge

DataFrame.merge(right, how='inner', on=None, left_on=None, right_on=None, left_index=False, right_index=False, sort=False, suffixes=('_x', '_y'), copy=True, indicator=False, validate=None)

Merge DataFrame or named Series objects with a database-style join.

A named Series object is treated as a DataFrame with a single named column.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes will be ignored. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on. When performing a cross merge, no column specifications to merge on are allowed.

**Parameters**

- **right** [DataFrame or named Series] Object to merge with.

- **how** [left, right, outer, inner, cross], default 'inner' Type of merge to be performed.
  - left: use only keys from left frame, similar to a SQL left outer join; preserve key order.
  - right: use only keys from right frame, similar to a SQL right outer join; preserve key order.
  - outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
  - inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.
  - cross: creates the cartesian product from both frames, preserves the order of the left keys.

  New in version 1.2.0.

- **on** [label or list] Column or index level names to join on. These must be found in both DataFrames. If on is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

- **left_on** [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

- **right_on** [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

- **left_index** [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

- **right_index** [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as left_index.

- **sort** [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword).

- **suffixes** [list-like, default is ("_x", "_y") A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in left and right respectively. Pass a value of None instead of a string to indicate that the
column name from left or right should be left as-is, with no suffix. At least one of
the values must not be None.

copy [bool, default True] If False, avoid copy if possible.

indicator [bool or str, default False] If True, adds a column to the output DataFrame
called “_merge” with information on the source of each row. The column can be
given a different name by providing a string argument. The column will have a
Categorical type with the value of “left_only” for observations whose merge key
only appears in the left DataFrame, “right_only” for observations whose merge key
only appears in the right DataFrame, and “both” if the observation’s merge key is
found in both DataFrames.

validate [str, optional] If specified, checks if merge is of specified type.

- “one_to_one” or “1:1”: check if merge keys are unique in both left and right
datasets.
- “one_to_many” or “1:m”: check if merge keys are unique in left dataset.
- “many_to_one” or “m:1”: check if merge keys are unique in right dataset.
- “many_to_many” or “m:m”: allowed, but does not result in checks.

Returns

DataFrame A DataFrame of the two merged objects.

See also:

merge_ordered Merge with optional filling/interpolation.
merge_asof Merge on nearest keys.
DataFrame.join Similar method using indices.

Notes

Support for specifying index levels as the on, left_on, and right_on parameters was added in version 0.23.0
Support for merging named Series objects was added in version 0.24.0

Examples

```python
>>> df1 = pd.DataFrame({'lkey': ['foo', 'bar', 'baz', 'foo'],
...                     'value': [1, 2, 3, 5]})
>>> df2 = pd.DataFrame({'rkey': ['foo', 'bar', 'baz', 'foo'],
...                     'value': [5, 6, 7, 8]})
>>> df1
  lkey  value
0  foo     1
1  bar     2
2  baz     3
3  foo     5
>>> df2
  rkey  value
0  foo     5
1  bar     6
2  baz     7
3  foo     8
```
Merge df1 and df2 on the lkey and rkey columns. The value columns have the default suffixes, _x and _y, appended.

```python
>>> df1.merge(df2, left_on='lkey', right_on='rkey')
lkey  value_x  rkey  value_y
0  foo         1  foo       5
1  foo         1  foo       8
2  foo         5  foo       5
3  foo         5  foo       8
4  bar         2  bar       6
5  baz         3  baz       7
```

Merge DataFrames df1 and df2 with specified left and right suffixes appended to any overlapping columns.

```python
>>> df1.merge(df2, left_on='lkey', right_on='rkey',
... suffixes=('left', 'right'))
lkey  value_left  rkey  value_right
0  foo           1  foo      5
1  foo           1  foo      8
2  foo           5  foo      5
3  foo           5  foo      8
4  bar           2  bar      6
5  baz           3  baz      7
```

Merge DataFrames df1 and df2, but raise an exception if the DataFrames have any overlapping columns.

```python
>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=(False, False))
Traceback (most recent call last):
  ... ValueError: columns overlap but no suffix specified:
    Index(['value'], dtype='object')
```

```
>>> df1 = pd.DataFrame({'a': ['foo', 'bar']})
>>> df2 = pd.DataFrame({'a': ['foo', 'baz'], 'c': [3, 4]})
>>> df1
  a
0 foo
1 bar

>>> df2
  a   c
0 foo  3
1 baz  4

>>> df1.merge(df2, how='inner', on='a')
  a  b  c
0 foo 1  3

>>> df1.merge(df2, how='left', on='a')
  a  b  c
0 foo 1 3.0
1 bar 2  NaN
```

```
>>> df1 = pd.DataFrame({'left': ['foo', 'bar']})
>>> df2 = pd.DataFrame({'right': [7, 8]})
>>> df1
left
```

**pandas.DataFrame.min**

`DataFrame.min(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return the minimum of the values over the requested axis.

If you want the index of the minimum, use `idxmin`. This is the equivalent of the `numpy.ndarray` method `argmin`.

**Parameters**

- `axis` ([index (0), columns (1)]): Axis for the function to be applied on.
- `skipna` (bool, default True): Exclude NA/null values when computing the result.
- `level` [int or level name, default None]: If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- `numeric_only` [bool, default None]: Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- `**kwargs` Additional keyword arguments to be passed to the function.

**Returns**

Series or DataFrame (if level specified)

See also:

- `Series.sum` Return the sum.
- `Series.min` Return the minimum.
- `Series.max` Return the maximum.
- `Series.idxmin` Return the index of the minimum.
- `Series.idxmax` Return the index of the maximum.
- `DataFrame.sum` Return the sum over the requested axis.
- `DataFrame.min` Return the minimum over the requested axis.
- `DataFrame.max` Return the maximum over the requested axis.
- `DataFrame.idxmin` Return the index of the minimum over the requested axis.
DataFrame.idxmax  Return the index of the maximum over the requested axis.

Examples

```python
def main():
    idx = pd.MultiIndex.from_arrays([
        ['warm', 'warm', 'cold', 'cold'],
        ['dog', 'falcon', 'fish', 'spider'],
    ], names=['blooded', 'animal'])
    s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
    print(s.min())

if __name__ == '__main__':
    main()
```

pandas.DataFrame.mod

DataFrame.mod (other, axis='columns', level=None, fill_value=None)  Get Modulo of dataframe and other, element-wise (binary operator mod).

Equivalent to dataframe % other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rmod.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

- **DataFrame** Result of the arithmetic operation.

See also:

- **DataFrame.add** Add DataFrames.
- **DataFrame.sub** Subtract DataFrames.
- **DataFrame.mul** Multiply DataFrames.
- **DataFrame.div** Divide DataFrames (float division).
**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

**Examples**

```python
>>> df = pd.DataFrame({
    'angles': [0, 3, 4],
    'degrees': [360, 180, 360],
    'index': ['circle', 'triangle', 'rectangle']
})
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```

Divide by constant with reverse version.

```python
>>> df.div(10)
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
```
Multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({'angles': [0, 3, 4]}, index=['circle', 'triangle', 'rectangle'])

other
```

<table>
<thead>
<tr>
<th>angles</th>
<th>circle</th>
<th>triangle</th>
<th>rectangle</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>

```python
>>> other * df
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>NaN</td>
</tr>
<tr>
<td>triangle</td>
<td>9</td>
</tr>
<tr>
<td>rectangle</td>
<td>16</td>
</tr>
</tbody>
</table>

```python
>>> df.mul(other, fill_value=0)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0</td>
</tr>
<tr>
<td>triangle</td>
<td>9.0</td>
</tr>
<tr>
<td>rectangle</td>
<td>16.0</td>
</tr>
</tbody>
</table>

Divide by a MultiIndex by level.

```python
def_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6], 'degrees': [360, 180, 360, 360, 540, 720], index=['A', 'A', 'A', 'B', 'B', 'B']})

def_multindex
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>A circle</td>
<td>0 360</td>
</tr>
<tr>
<td>triangle</td>
<td>3 180</td>
</tr>
<tr>
<td>rectangle</td>
<td>4 360</td>
</tr>
<tr>
<td>B square</td>
<td>4 360</td>
</tr>
<tr>
<td>pentagon</td>
<td>5 540</td>
</tr>
<tr>
<td>hexagon</td>
<td>6 720</td>
</tr>
</tbody>
</table>
```python
>>> df.div(df_multindex, level=1, fill_value=0)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>A circle</td>
<td>NaN</td>
</tr>
<tr>
<td>triangle</td>
<td>1.0</td>
</tr>
<tr>
<td>rectangle</td>
<td>1.0</td>
</tr>
<tr>
<td>B square</td>
<td>0.0</td>
</tr>
<tr>
<td>pentagon</td>
<td>0.0</td>
</tr>
<tr>
<td>hexagon</td>
<td>0.0</td>
</tr>
</tbody>
</table>

**pandas.DataFrame.mode**

Get the mode(s) of each element along the selected axis.

The mode of a set of values is the value that appears most often. It can be multiple values.

**Parameters**

- **axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to iterate over while searching for the mode:
  - 0 or 'index': get mode of each column
  - 1 or 'columns': get mode of each row.
- **numeric_only** [bool, default False] If True, only apply to numeric columns.
- **dropna** [bool, default True] Don’t consider counts of NaN/NaT.

**Returns**

- **DataFrame** The modes of each column or row.

**See also:**

- **Series.mode** Return the highest frequency value in a Series.
- **Series.value_counts** Return the counts of values in a Series.

**Examples**

```python
>>> df = pd.DataFrame([[('bird', 2, 2),
...                     ('mammal', 4, np.nan),
...                     ('arthropod', 8, 0),
...                     ('bird', 2, np.nan)],
...                    index=('falcon', 'horse', 'spider', 'ostrich'),
...                    columns=('species', 'legs', 'wings'))
```

<table>
<thead>
<tr>
<th>species</th>
<th>legs</th>
<th>wings</th>
</tr>
</thead>
<tbody>
<tr>
<td>falcon</td>
<td>bird</td>
<td>2.0</td>
</tr>
<tr>
<td>horse</td>
<td>mammal</td>
<td>4</td>
</tr>
<tr>
<td>spider</td>
<td>arthropod</td>
<td>8</td>
</tr>
<tr>
<td>ostrich</td>
<td>bird</td>
<td>2</td>
</tr>
</tbody>
</table>

By default, missing values are not considered, and the mode of wings are both 0 and 2. Because the resulting DataFrame has two rows, the second row of `species` and `legs` contains NaN.
>>> df.mode()
    species  legs  wings
 0  bird     2.0   0.0
 1  NaN  NaN    2.0

Setting dropna=False NaN values are considered and they can be the mode (like for wings).

>>> df.mode(dropna=False)
    species  legs  wings
 0  bird     2     NaN
 1  NaN  NaN     2.0

Setting numeric_only=True, only the mode of numeric columns is computed, and columns of other types are ignored.

>>> df.mode(numeric_only=True)
   legs  wings
 0  2.0   0.0
 1  NaN   2.0

To compute the mode over columns and not rows, use the axis parameter:

>>> df.mode(axis='columns', numeric_only=True)
  animal  legs  wings
 0  falcon  2.0   NaN
 1    horse  4.0   NaN
 2  spider  0.0   8.0
 3  ostrich  2.0   NaN

**pandas.DataFrame.mul**

DataFrame.mul(other, axis='columns', level=None, fill_value=None)

Get Multiplication of dataframe and other, element-wise (binary operator mul).
Equivalent to dataframe * other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rmul.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

- **DataFrame** Result of the arithmetic operation.

**See also**
**DataFrame.add** Add DataFrames.
**DataFrame.sub** Subtract DataFrames.
**DataFrame.mul** Multiply DataFrames.
**DataFrame.div** Divide DataFrames (float division).
**DataFrame.truediv** Divide DataFrames (float division).
**DataFrame.floordiv** Divide DataFrames (integer division).
**DataFrame.mod** Calculate modulo (remainder after division).
**DataFrame.pow** Calculate exponential power.

**Notes**
Mismatched indices will be unioned together.

**Examples**

```
>>> df = pd.DataFrame({'angles': [0, 3, 4],
... 'degrees': [360, 180, 360]},
... index=['circle', 'triangle', 'rectangle'])
```

```
>>> df
   angles  degrees
circle     0       360
triangle    3       180
rectangle   4       360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
   angles  degrees
circle     1       361
triangle    4       181
rectangle   5       361
```

```
>>> df.add(1)
   angles  degrees
circle     1       361
triangle    4       181
rectangle   5       361
```

Divide by constant with reverse version.

```
>>> df.div(10)
   angles  degrees
circle    0.0      36.0
triangle   0.3      18.0
rectangle  0.4      36.0
```

```
>>> df.rdiv(10)
          angles  degrees
circle     inf      0.027778
triangle   3.333333  0.055556
rectangle   2.500000  0.027778
```
Subtract a list and Series by axis with operator version.

```python
>> df - [1, 2]
   angles  degrees
   circle   -1     358
   triangle   2     178
   rectangle   3     358

>>> df.sub([1, 2], axis='columns')
   angles  degrees
   circle   -1     358
   triangle   2     178
   rectangle   3     358

>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
        axis='index')
   angles  degrees
   circle   -1     359
   triangle   2     179
   rectangle   3     359
```

Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                   index=['circle', 'triangle', 'rectangle'])

>>> df * other
   angles  degrees
   circle    0    NaN
   triangle   9    NaN
   rectangle 16    NaN

>>> df.mul(other, fill_value=0)
   angles  degrees
   circle    0     0.0
   triangle   9     0.0
   rectangle 16     0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               'index': ['A', 'A', 'A', 'B', 'B', 'B'],
                               ['circle', 'triangle', 'rectangle',
                               'square', 'pentagon', 'hexagon']})

>>> df_multindex
   angles  degrees
   A circle    0     360
          triangle  3     180
          rectangle 4     360
   B square    4     360
```

**pandas.DataFrame.multiply**

DataFrame.multiply(\texttt{other, axis='columns', level=None, fill_value=None})

Get Multiplication of dataframe and other, element-wise (binary operator mul).

Equivalent to \texttt{dataframe * other}, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, \texttt{rmul}.

Among flexible wrappers (\texttt{add, sub, mul, div, mod, pow}) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- \texttt{other} [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- \texttt{axis} [[0 or ‘index’, 1 or ‘columns’]] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- \texttt{level} [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- \texttt{fill_value} [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

- DataFrame Result of the arithmetic operation.

See also:

- DataFrame.add Add DataFrames.
- DataFrame.sub Subtract DataFrames.
- DataFrame.mul Multiply DataFrames.
- DataFrame.div Divide DataFrames (float division).
- DataFrame.truediv Divide DataFrames (float division).
- DataFrame.floordiv Divide DataFrames (integer division).
- DataFrame.mod Calculate modulo (remainder after division).
- DataFrame.pow Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
      angles  degrees
circle    0     360
triangle   3     180
rectangle  4     360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
      angles  degrees
circle    1     361
triangle   4     181
rectangle  5     361
```

```python
>>> df.add(1)
      angles  degrees
circle    1     361
triangle   4     181
rectangle  5     361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
      angles  degrees
circle    0     36.0
triangle   0.3   18.0
rectangle  0.4   36.0
```

```python
>>> df.rdiv(10)
      angles  degrees
circle   inf    0.027778
triangle  3.333333  0.055556
rectangle  2.5   0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
      angles  degrees
circle   -1     358
triangle    2     178
rectangle   3     358
```

```python
>>> df.sub([1, 2], axis='columns')
      angles  degrees
circle   -1     358
triangle    2     178
rectangle   3     358
```
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])
>>> df * other
    angles  degrees
circle   0        NaN
triangle 3        NaN
rectangle 4        NaN
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                              'degrees': [360, 180, 360, 360, 540, 720],
                              index=['A', 'A', 'A', 'B', 'B', 'B',
                                     'circle', 'triangle', 'rectangle',
                                     'square', 'pentagon', 'hexagon'])
>>> df_multindex
   angles  degrees
    A circle   0      360
    triangle   3      180
    rectangle  4      360
    B square   4      360
    pentagon   5      540
    hexagon   6      720

>>> df.div(df_multindex, level=1, fill_value=0)
    angles  degrees
A circle   NaN        1.0
triangle   1.0        1.0
rectangle  1.0        1.0
B square   0.0         0.0
pentagon   0.0         0.0
hexagon   0.0         0.0
```
pandas.DataFrame.ne

DataFrame.ne(other, axis='columns', level=None)
Get Not equal to of dataframe and other, element-wise (binary operator ne).
Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.
Equivalent to ==, /=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters
other [scalar, sequence, Series, or DataFrame] Any single or multiple element data
structure, or list-like object.
axis [{0 or ‘index’, 1 or ‘columns’}, default ‘columns’] Whether to compare by the
index (0 or ‘index’) or columns (1 or ‘columns’).
level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns
DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.
DataFrame.ne Compare DataFrames for inequality elementwise.
DataFrame.le Compare DataFrames for less than inequality or equality elementwise.
DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.
DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.
DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes
Mismatched indices will be unioned together. NaN values are considered different (i.e. NaN != NaN).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                     'revenue': [100, 250, 300]},
...                  index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300
>>> df == 100
   cost  revenue
A  False  True
B   True False
C  False  True
```

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
   cost  revenue
A  False  True
B   True False
C  False  True
```
When `other` is a `Series`, the columns of a DataFrame are aligned with the index of `other` and broadcast:

```python
>>> df.eq(100)
   cost  revenue
A  False  True
B  False  False
C  True  False
```

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['cost', 'revenue']), axis='index')
   cost  revenue
A   True  True
B   True  False
C   True  True
D   True  True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```python
>>> df == [250, 100]
   cost  revenue
A   True  True
B  False  False
C  False  False
```

Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
   cost  revenue
A  True  False
B  False  True
C  True  False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                    index=['A', 'B', 'C', 'D'])
>>> other
   revenue
A   300
B   250
C   100
D   150
```

```python
>>> df.gt(other)
   cost (continues on next page)
A False False
B False False
C False True
D False False

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
                               'revenue': [100, 250, 300, 200, 175, 225],
                             index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
                                       ['A', 'B', 'C', 'A', 'B', 'C']])
```

```python
>>> df_multindex
   cost revenue
Q1   A  250  100
    B  150  250
    C  100  300
Q2   A  150  200
    B  300  175
    C  220  225
```

```python
>>> df.le(df_multindex, level=1)
   cost revenue
Q1   A  True  True
    B  True  True
    C  True  True
Q2   A  False True
    B  True  False
    C  True  False
```

**pandas.DataFrame.nlargest**

DataFrame.nlargest(n, columns, keep='first')

Return the first n rows ordered by columns in descending order.

Return the first n rows with the largest values in columns, in descending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to df.sort_values(columns, ascending=False).head(n), but more performant.

**Parameters**

- **n** [int] Number of rows to return.
- **columns** [label or list of labels] Column label(s) to order by.
- **keep** [{‘first’, ‘last’, ‘all’}, default ‘first’] Where there are duplicate values:
  - **first** : prioritize the first occurrence(s)
  - **last** : prioritize the last occurrence(s)
  - **all** [do not drop any duplicates, even it means] selecting more than n items.

**Returns**

DataFrame The first n rows ordered by the given columns in descending order.

**See also:**
**DataFrame.nsmallest**  
Return the first \( n \) rows ordered by *columns* in ascending order.

**DataFrame.sort_values**  
Sort DataFrame by the values.

**DataFrame.head**  
Return the first \( n \) rows without re-ordering.

**Notes**

This function cannot be used with all column types. For example, when specifying columns with *object* or *category* dtypes, `TypeError` is raised.

**Examples**

```python
>>> df = pd.DataFrame({'population': [59000000, 65000000, 434000, 434000, 434000, 337000, 11300, 11300, 11300],
                     'GDP': [1937894, 2583560, 12011, 4520, 12128, 17036, 182, 38, 311],
                     'alpha-2': ['IT', 'FR', 'MT', 'MV', 'BN', 'IS', 'NR', 'TV', 'AI']},
                    index=['Italy', 'France', 'Malta', 'Maldives', 'Brunei', 'Iceland', 'Nauru', 'Tuvalu', 'Anguilla'])
```

```plaintext
<table>
<thead>
<tr>
<th>population</th>
<th>GDP</th>
<th>alpha-2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Italy</td>
<td>59000000</td>
<td>1937894</td>
</tr>
<tr>
<td>France</td>
<td>65000000</td>
<td>2583560</td>
</tr>
<tr>
<td>Malta</td>
<td>434000</td>
<td>12011</td>
</tr>
<tr>
<td>Maldives</td>
<td>434000</td>
<td>4520</td>
</tr>
<tr>
<td>Brunei</td>
<td>434000</td>
<td>12128</td>
</tr>
<tr>
<td>Iceland</td>
<td>337000</td>
<td>17036</td>
</tr>
<tr>
<td>Nauru</td>
<td>11300</td>
<td>182</td>
</tr>
<tr>
<td>Tuvalu</td>
<td>11300</td>
<td>38</td>
</tr>
<tr>
<td>Anguilla</td>
<td>11300</td>
<td>311</td>
</tr>
</tbody>
</table>
```

In the following example, we will use `nlargest` to select the three rows having the largest values in column “population”.

```python
>>> df.nlargest(3, 'population')
```

```plaintext
<table>
<thead>
<tr>
<th>population</th>
<th>GDP</th>
<th>alpha-2</th>
</tr>
</thead>
<tbody>
<tr>
<td>France</td>
<td>65000000</td>
<td>2583560</td>
</tr>
<tr>
<td>Italy</td>
<td>59000000</td>
<td>1937894</td>
</tr>
<tr>
<td>Malta</td>
<td>434000</td>
<td>12011</td>
</tr>
</tbody>
</table>
```

When using `keep='last'`, ties are resolved in reverse order:

```python
>>> df.nlargest(3, 'population', keep='last')
```

```plaintext
<table>
<thead>
<tr>
<th>population</th>
<th>GDP</th>
<th>alpha-2</th>
</tr>
</thead>
<tbody>
<tr>
<td>France</td>
<td>65000000</td>
<td>2583560</td>
</tr>
<tr>
<td>Italy</td>
<td>59000000</td>
<td>1937894</td>
</tr>
<tr>
<td>Brunei</td>
<td>434000</td>
<td>12128</td>
</tr>
</tbody>
</table>
```

When using `keep='all'`, all duplicate items are maintained:
To order by the largest values in column “population” and then “GDP”, we can specify multiple columns like in the next example.

```
>>> df.nlargest(3, ['population', 'GDP'])
    population   GDP
  France  65000000  2583560
  Italy   59000000  1937894
  Brunei  43400000   12128
```

### pandas.DataFrame.notna

DataFrame.notna()  
Detect existing (non-missing) values.  
Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.  

**Returns**  
DataFrame  
Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.  

**See also:**

- **DataFrame.notnull**  
  Alias of notna.  
- **DataFrame.isna**  
  Boolean inverse of notna.  
- **DataFrame.dropna**  
  Omit axes labels with missing values.  

**Examples**

Show which entries in a DataFrame are not NA.

```
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],  
...                    born=[pd.NaT, pd.Timestamp('1939-05-27'),  
...                    pd.Timestamp('1940-04-25')],  
...                    name=['Alfred', 'Batman', ''],  
...                    toy=[None, 'Batmobile', 'Joker']))
>>> df
   age   born    name    toy
0  5.0 NaT   Alfred  None
1  6.0 1939-05-27  Batman  Batmobile
2   NaN 1940-04-25     NaN   Joker
```
Show which entries in a Series are not NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2     NaN
dtype: float64
```

```python
>>> ser.notna()
0  True
1  True
2 False
dtype: bool
```

**pandas.DataFrame.notnull**

`DataFrame.notnull()`  
Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

Returns

* `DataFrame`  Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

**See also:**

* `DataFrame.notnull`  Alias of notna.
* `DataFrame.isna`  Boolean inverse of notna.
* `DataFrame.dropna`  Omit axes labels with missing values.
* `notna`  Top-level notna.

**Examples**

Show which entries in a DataFrame are not NA.

```python
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
... born=[pd.NaT, pd.Timestamp('1939-05-27'),
... pd.Timestamp('1940-04-25')],
... name=['Alfred', 'Batman', ''],
... toy=[None, 'Batmobile', 'Joker'])
>>> df
```

(continues on next page)
Show which entries in a Series are not NA.

```python
def notna()
    ser = pd.Series([5, 6, np.NaN])
    ser
    ser.notna()
```

```
0  5.0
1  6.0
2  NaN
dtype: float64
```

```
0  True
1  True
2  False
dtype: bool
```

**pandas.DataFrame.nsmallest**

**DataFrame.nsmallest** *(n, columns, keep='first')*

Return the first *n* rows ordered by *columns* in ascending order.

Return the first *n* rows with the smallest values in *columns*, in ascending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to `df.sort_values(columns, ascending=True).head(n)`, but more performant.

**Parameters**

- **n** [int] Number of items to retrieve.
- **columns** [list or str] Column name or names to order by.
- **keep** [{'first', 'last', 'all'}, default 'first'] Where there are duplicate values:
  - **first**: take the first occurrence.
  - **last**: take the last occurrence.
  - **all**: do not drop any duplicates, even it means selecting more than *n* items.

**Returns**

DataFrame

**See also:**

DataFrame.nlargest Return the first *n* rows ordered by *columns* in descending order.
**DataFrame.sort_values** Sort DataFrame by the values.

**DataFrame.head** Return the first \( n \) rows without re-ordering.

### Examples

```python
def = pd.DataFrame({'population': [59000000, 65000000, 434000, ... 
        434000, 337000, 337000, 11300, 11300], 
        ... 
        'GDP': [1937894, 2583560, 12011, 4520, 12128, ... 
        17036, 182, 38, 311], 
        ... 
        'alpha-2': ['IT', 'FR', 'MT', 'MV', 'BN', ... 
        'IS', 'NR', 'TV', 'AI']], 
        ... 
        index=['Italy', 'France', 'Malta', ... 
        'Maldives', 'Brunei', 'Iceland', ... 
        'Nauru', 'Tuvalu', 'Anguilla'])
def```

In the following example, we will use `nsmallest` to select the three rows having the smallest values in column “population”.

```python
def.nsmallest(3, 'population')
df```

When using `keep='last'`, ties are resolved in reverse order:

```python
def.nsmallest(3, 'population', keep='last')
df```

When using `keep='all'`, all duplicate items are maintained:

```python
def.nsmallest(3, 'population', keep='all')
df```

To order by the smallest values in column “population” and then “GDP”, we can specify multiple columns like in the next example.
>>> df.nsmallest(3, ['population', 'GDP'])
         population  GDP  alpha-2
    Tuvalu       11300   38   TV
     Anguilla    11300   31   AI
      Nauru      337000  182  NR

pandas.DataFrame.nunique

Dataframe.nunique (axis=0, dropna=True)
Count number of distinct elements in specified axis.
Return Series with number of distinct elements. Can ignore NaN values.

Parameters
axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.
dropna [bool, default True] Don’t include NaN in the counts.

Returns
Series

See also:
Series.nunique Method nunique for Series.
DataFrame.count Count non-NA cells for each column or row.

Examples

>>> df = pd.DataFrame({'A': [4, 5, 6], 'B': [4, 1, 1]})
>>> df.nunique()
A    3
B    2
dtype: int64

>>> df.nunique(axis=1)
          0  1
row 0      1  2
row 1      2  2
dtype: int64

pandas.DataFrame.pad

Dataframe.pad (axis=None, inplace=False, limit=None, downcast=None)
Synonym for DataFrame.fillna() with method='ffill'.

Returns
Series/DataFrame or None Object with missing values filled or None if inplace=True.

3.4. DataFrame 1711
pandas.DataFrame.pct_change

DataFrame.pct_change(periods=1, fill_method='pad', limit=None, freq=None, **kwargs)

Percentage change between the current and a prior element.
Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

Parameters

periods [int, default 1] Periods to shift for forming percent change.
fill_method [str, default ‘pad’] How to handle NAs before computing percent changes.
limit [int, default None] The number of consecutive NAs to fill before stopping.
freq [DateOffset, timedelta, or str, optional] Increment to use from time series API (e.g. ‘M’ or BDay()).
**kwargs Additional keyword arguments are passed into DataFrame.shift or Series.shift.

Returns

chg [Series or DataFrame] The same type as the calling object.

See also:
Series.diff Compute the difference of two elements in a Series.
DataFrame.diff Compute the difference of two elements in a DataFrame.
Series.shift Shift the index by some number of periods.
DataFrame.shift Shift the index by some number of periods.

Examples

Series

```python
>>> s = pd.Series([90, 91, 85])
>>> s
0  90
1  91
2  85
dtype: int64

>>> s.pct_change()
0   NaN
1  0.011111
2 -0.065934
.dtype: float64

>>> s.pct_change(periods=2)
0   NaN
1   NaN
2 -0.055556
.dtype: float64
```
See the percentage change in a Series where filling NAs with last valid observation forward to next valid.
DataFrame

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```python
>>> df = pd.DataFrame({
... 'FR': [4.0405, 4.0963, 4.3149],
... 'GR': [1.7246, 1.7482, 1.8519],
... 'IT': [804.74, 810.01, 860.13]},
... index=['1980-01-01', '1980-02-01', '1980-03-01'])
```

```bash
% df
FR        GR        IT
1980-01-01 4.0405    1.7246    804.74
1980-02-01 4.0963    1.7482    810.01
1980-03-01 4.3149    1.8519    860.13
```

```python
>>> df.pct_change()
FR  GR  IT
1980-01-01 NaN NaN NaN
1980-02-01 0.013810 0.013684 0.006549
1980-03-01 0.053365 0.059318 0.061876
```

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

```python
>>> df = pd.DataFrame({
... '2016': [1769950, 30586265],
... '2015': [1500923, 40912316],
... '2014': [1371819, 41403351]},
... index=['GOOG', 'APPL'])
```

```bash
% df
          2016     2015     2014
GOOG  1769950  1500923  1371819
APPL  30586265 40912316 41403351
```

```python
>>> df.pct_change(axis='columns', periods=-1)
       2016     2015     2014
GOOG   0.179241 0.094112 NaN
APPL  -0.252395 -0.011860 NaN
```
**pandas.DataFrame.pipe**

DataFrame.pipe(func, *args, **kwargs)
Apply func(self, *args, **kwargs).

**Parameters**

- **func** [function] Function to apply to the Series/DataFrame. args, and kwargs are passed into func. Alternatively a (callable, data_keyword) tuple where data_keyword is a string indicating the keyword of callable that expects the Series/DataFrame.

- **args** [iterable, optional] Positional arguments passed into func.

- **kwargs** [mapping, optional] A dictionary of keyword arguments passed into func.

**Returns**

- **object** [the return type of func.]

**See also:**

- **DataFrame.apply** Apply a function along input axis of DataFrame.
- **DataFrame.applymap** Apply a function elementwise on a whole DataFrame.
- **Series.map** Apply a mapping correspondence on a Series.

**Notes**

Use .pipe when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```python
>>> func(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```python
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe(func, arg2=b, arg3=c)
... )
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose f takes its data as arg2:

```python
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe((func, 'arg2'), arg1=a, arg3=c)
... )
```
**pandas.DataFrame.pivot**

DataFrame.pivot(index=None, columns=None, values=None)

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified `index` / `columns` to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the User Guide for more on reshaping.

**Parameters**

- **index** [str or object or a list of str, optional] Column to use to make new frame’s index. If None, uses existing index.
  
  Changed in version 1.1.0: Also accept list of index names.

- **columns** [str or object or a list of str] Column to use to make new frame’s columns.
  
  Changed in version 1.1.0: Also accept list of columns names.

- **values** [str, object or a list of the previous, optional] Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.

**Returns**

DataFrame Returns reshaped DataFrame.

**Raises**

- **ValueError**: When there are any `index`, `columns` combinations with multiple values.

  `DataFrame.pivot_table` when you need to aggregate.

**See also:**

- **DataFrame.pivot_table** Generalization of pivot that can handle duplicate values for one index/column pair.

- **DataFrame.unstack** Pivot based on the index values instead of a column.

- **wide_to_long** Wide panel to long format. Less flexible but more user-friendly than melt.

**Notes**

For finer-tuned control, see hierarchical indexing documentation along with the related stack/unstack methods.

**Examples**

```python
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two', 'two'],
...                    'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
...                    'baz': [1, 2, 3, 4, 5, 6],
...                    'zoo': ['x', 'y', 'z', 'q', 'w', 't']})

>>> df
   foo  bar  baz  zoo
0  one   A  1.0   x
1  one   B  2.0   y
2  one   C  3.0   z
(continues on next page)
```
You could also assign a list of column names or a list of index names.

```python
>>> df = pd.DataFrame(
    ...   "lev1": [1, 1, 1, 2, 2, 2],
    ...   "lev2": [1, 1, 2, 1, 1, 2],
    ...   "lev3": [1, 2, 1, 2, 1, 2],
    ...   "lev4": [1, 2, 3, 4, 5, 6],
    ...   "values": [0, 1, 2, 3, 4, 5])
>>> df
   lev1  lev2  lev3  lev4  values
0    1     1     1     1     0
1    1     1     2     2     1
2    1     2     1     3     2
3    2     1     2     4     3
4    2     1     1     5     4
5    2     2     2     6     5
```

```python
>>> df.pivot(index="lev1", columns=["lev2", "lev3"], values="values")
lev2  1  2
lev3  1  2  1  2
lev1
1  0.0  1.0  2.0  NaN
2  4.0  3.0  NaN  5.0
```

```python
>>> df.pivot(index=["lev1", "lev2"], columns=["lev3"], values="values")
lev3  1  2
lev1 lev2
1    1     0.0  1.0
2    2.0  NaN
2    1     4.0  3.0
2     NaN  5.0
```

A ValueError is raised if there are any duplicates.
>>> df = pd.DataFrame({"foo": ['one', 'one', 'two', 'two'],
...                     "bar": ['A', 'A', 'B', 'C'],
...                     "baz": [1, 2, 3, 4]})

>>> df
   foo  bar  baz
0   one   A   1
1   one   A   2
2   two   B   3
3   two   C   4

Notice that the first two rows are the same for our index and columns arguments.

>>> df.pivot(index='foo', columns='bar', values='baz')
ValueError: Index contains duplicate entries, cannot reshape

pandas.DataFrame.pivot_table

DataFrame.pivot_table(values=None, index=None, columns=None, aggfunc='mean',
                       fill_value=None, margins=False, dropna=True, margins_name='All',
                       observed=False, sort=True)

Create a spreadsheet-style pivot table as a DataFrame.

The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

Parameters

values [column to aggregate, optional]

index [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.

columns [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.

aggfunc [function, list of functions, dict, default numpy.mean] If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions.

fill_value [scalar, default None] Value to replace missing values with (in the resulting pivot table, after aggregation).

margins [bool, default False] Add all row / columns (e.g. for subtotal / grand totals).

dropna [bool, default True] Do not include columns whose entries are all NaN.

margins_name [str, default ‘All’] Name of the row / column that will contain the totals when margins is True.

observed [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.
Changed in version 0.25.0.

**sort** [bool, default True] Specifies if the result should be sorted.

New in version 1.3.0.

**Returns**

**DataFrame** An Excel style pivot table.

**See also:**

**DataFrame.pivot** Pivot without aggregation that can handle non-numeric data.

**DataFrame.melt** Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

**wide_to_long** Wide panel to long format. Less flexible but more user-friendly than melt.

**Examples**

```python
>>> df = pd.DataFrame({
    'A': ['foo', 'foo', 'foo', 'foo', 'foo', ..., 'bar', 'bar', 'bar', 'bar'],
    'B': ['one', 'one', 'one', 'two', 'two', ..., 'one', 'one', 'two', 'two'],
    'C': ['small', 'large', 'large', 'small', ..., 'small', 'large', 'small', 'small'],
    'D': [1, 2, 2, 3, 3, 4, 5, 6, 7],
    'E': [2, 4, 5, 5, 6, 6, 8, 9, 9]
})
```

This first example aggregates values by taking the sum.

```python
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'], columns=['C'], aggfunc=np.sum)
```

We can also fill missing values using the *fill_value* parameter.

```python
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'], columns=['C'], aggfunc=np.sum, fill_value=0)
```

(continues on next page)
The next example aggregates by taking the mean across multiple columns.

```python
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                        aggfunc={'D': np.mean, 'E': np.mean})
```

```
D   E
A C
bar large 5.500000 7.500000
   small 5.500000 8.500000
foo large 2.000000 4.500000
   small 2.333333 4.333333
```

We can also calculate multiple types of aggregations for any given value column.

```python
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                        aggfunc={'D': np.mean, 'E': [min, max, np.mean]})
```

```
D   E
A C
mean max mean min
bar large 5.500000 9.0 7.500000 6.0
   small 5.500000 9.0 8.500000 8.0
foo large 2.000000 5.0 4.500000 4.0
   small 2.333333 6.0 4.333333 2.0
```

**pandas.DataFrame.plot**

**DataFrame.plot(**`*args,**kwargs*/)***

Make plots of Series or DataFrame.

Uses the backend specified by the option `plotting.backend`. By default, matplotlib is used.

**Parameters**

- `data` [Series or DataFrame] The object for which the method is called.
- `x` [label or position, default None] Only used if data is a DataFrame.
- `y` [label, position or list of label, positions, default None] Allows plotting of one column versus another. Only used if data is a DataFrame.
- `kind` [str] The kind of plot to produce:
  - ‘line’ : line plot (default)
  - ‘bar’ : vertical bar plot
  - ‘barh’ : horizontal bar plot
  - ‘hist’ : histogram
- ‘box’: boxplot
- ‘kde’: Kernel Density Estimation plot
- ‘density’: same as ‘kde’
- ‘area’: area plot
- ‘pie’: pie plot
- ‘scatter’: scatter plot (DataFrame only)
- ‘hexbin’: hexbin plot (DataFrame only)

ax [matplotlib axes object, default None] An axes of the current figure.

subplots [bool, default False] Make separate subplots for each column.

sharex [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in; Be aware, that passing in both an ax and sharex=True will alter all x axis labels for all axis in a figure.

sharey [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.

layout [tuple, optional] (rows, columns) for the layout of subplots.

figsize [a tuple (width, height) in inches] Size of a figure object.

use_index [bool, default True] Use index as ticks for x axis.

title [str or list] Title to use for the plot. If a string is passed, print the string at the top of the figure. If a list is passed and subplots is True, print each item in the list above the corresponding subplot.

grid [bool, default None (matlab style default)] Axis grid lines.

legend [bool or {'reverse'}] Place legend on axis subplots.

style [list or dict] The matplotlib line style per column.

logx [bool or ‘sym’, default False] Use log scaling or symlog scaling on x axis. .. versionchanged:: 0.25.0

logy [bool or ‘sym’ default False] Use log scaling or symlog scaling on y axis. .. versionchanged:: 0.25.0

loglog [bool or ‘sym’, default False] Use log scaling or symlog scaling on both x and y axes. .. versionchanged:: 0.25.0

xticks [sequence] Values to use for the xticks.

yticks [sequence] Values to use for the yticks.

xlim [2-tuple/list] Set the x limits of the current axes.

ylim [2-tuple/list] Set the y limits of the current axes.

xlabel [label, optional] Name to use for the xlabel on x-axis. Default uses index name as xlabel, or the x-column name for planar plots.

New in version 1.1.0.

Changed in version 1.2.0: Now applicable to planar plots (scatter, hexbin).
ylabel [label, optional] Name to use for the ylabel on y-axis. Default will show no ylabel, or the y-column name for planar plots.

New in version 1.1.0.

Changed in version 1.2.0: Now applicable to planar plots (scatter, hexbin).

rot [int, default None] Rotation for ticks (xticks for vertical, yticks for horizontal plots).

fontsize [int, default None] Font size for xticks and yticks.

colormap [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

colorbar [bool, optional] If True, plot colorbar (only relevant for ‘scatter’ and ‘hexbin’ plots).

position [float] Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center).

table [bool, Series or DataFrame, default False] If True, draw a table using the data in the DataFrame and the data will be transposed to meet matplotlib’s default layout. If a Series or DataFrame is passed, use passed data to draw a table.

yerr [DataFrame, Series, array-like, dict and str] See Plotting with Error Bars for detail.

xerr [DataFrame, Series, array-like, dict and str] Equivalent to yerr.

stacked [bool, default False in line and bar plots, and True in area plot] If True, create stacked plot.

sort_columns [bool, default False] Sort column names to determine plot ordering.

secondary_y [bool or sequence, default False] Whether to plot on the secondary y-axis if a list/tuple, which columns to plot on secondary y-axis.

mark_right [bool, default True] When using a secondary_y axis, automatically mark the column labels with “(right)” in the legend.

include_bool [bool, default is False] If True, boolean values can be plotted.

backend [str, default None] Backend to use instead of the backend specified in the option plotting.backend. For instance, ‘matplotlib’. Alternatively, to specify the plotting.backend for the whole session, set pd.options.plotting.backend.

New in version 1.0.0.

**kwargs Options to pass to matplotlib plotting method.

Returns

matplotlib.axes.Axes or numpy.ndarray of them If the backend is not the default matplotlib one, the return value will be the object returned by the backend.
Notes

• See matplotlib documentation online for more on this subject
• If kind = ‘bar’ or ‘barh’, you can specify relative alignments for bar plot layout by position keyword. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

**pandas.DataFrame.pop**

**DataFrame.pop** *(item)*

Return item and drop from frame. Raise KeyError if not found.

**Parameters**

- **item** [label] Label of column to be popped.

**Returns**

Series

**Examples**

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                   columns=('name', 'class', 'max_speed'))
```

```plaintext
name class max_speed
0 falcon bird 389.0
1 parrot bird 24.0
2 lion mammal 80.5
3 monkey mammal NaN
```

```python
>>> df.pop('class')
0    bird
1    bird
2  mammal
3  mammal
Name: class, dtype: object
```

```plaintext
name  max_speed
0  falcon  389.0
1  parrot   24.0
2   lion    80.5
3  monkey   NaN
```
DataFrame.pow

DataFrame.pow(other, axis='columns', level=None, fill_value=None)

Get Exponential power of dataframe and other, element-wise (binary operator pow).

Equivalent to dataframe ** other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rpow.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle     0      360
triangle   3      180
rectangle  4      360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle     1      361
triangle   4      181
rectangle  5      361
``` 

```python
>>> df.add(1)
   angles  degrees
circle     1      361
triangle   4      181
rectangle  5      361
``` 

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle   0.0     36.0
triangle 0.3     18.0
rectangle 0.4    36.0
``` 

```python
>>> df.rdiv(10)
   angles  degrees
circle   inf  0.027778
triangle 3.333333  0.055556
rectangle 2.500000  0.027778
``` 

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
   angles  degrees
circle   -1      358
triangle   2      178
rectangle  3      358
``` 

```python
>>> df.sub([1, 2], axis='columns')
   angles  degrees
circle   -1      358
triangle   2      178
rectangle  3      358
``` 

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
   angles  degrees
```

(continues on next page)
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4],
                        ...
                        index=['circle', 'triangle', 'rectangle'])
>>> other
   angles
circle  0
triangle 3
rectangle 4
```

```plaintext
angles
circle 0
triangle 9
rectangle 16
```

```python
>>> df.mul(other, fill_value=0)
   angles  degrees
circle   0.0    0.0
triangle 9.0    0.0
rectangle 16.0  0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame(
    {'angles': [0, 3, 4, 4, 5, 6],
     ...
     'degrees': [360, 180, 360, 360, 540, 720],
     ...
     index=[['A', 'A', 'A', 'B', 'B', 'B'],
             ['circle', 'triangle', 'rectangle',
             'square', 'pentagon', 'hexagon']])
>>> df_multindex
   angles  degrees
A circle 0 360
triangle 3 180
rectangle 4 360
B square 4 360
pentagon 5 540
hexagon 6 720
```

```plaintext
A circle NaN 1.0
triangle 1.0 1.0
rectangle 1.0 1.0
B square 0.0 0.0
pentagon 0.0 0.0
hexagon 0.0 0.0
```
pandas.DataFrame.prod

DataFrame.prod(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)
Return the product of the values over the requested axis.

Parameters

- axis [{index (0), columns (1)] Axis for the function to be applied on.
- skipna [bool, default True] Exclude NA/null values when computing the result.
- level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.
- **kwargs Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

- Series.sum Return the sum.
- Series.min Return the minimum.
- Series.max Return the maximum.
- Series.idxmin Return the index of the minimum.
- Series.idxmax Return the index of the maximum.
- DataFrame.sum Return the sum over the requested axis.
- DataFrame.min Return the minimum over the requested axis.
- DataFrame.max Return the maximum over the requested axis.
- DataFrame.idxmin Return the index of the minimum over the requested axis.
- DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([], dtype="float64").prod()
1.0
```

This can be controlled with the min_count parameter

```python
>>> pd.Series([], dtype="float64").prod(min_count=1)
nan
```
Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0
```

```python
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

**pandas.DataFrame.product**

`DataFrame.product` *(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)*

Return the product of the values over the requested axis.

### Parameters

- **axis** ([index (0), columns (1)]) Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **min_count** [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.
- ****kwargs Additional keyword arguments to be passed to the function.

### Returns

Series or DataFrame (if level specified)

### See also:

- `Series.sum` Return the sum.
- `Series.min` Return the minimum.
- `Series.max` Return the maximum.
- `Series.idxmin` Return the index of the minimum.
- `Series.idxmax` Return the index of the maximum.
- `DataFrame.sum` Return the sum over the requested axis.
- `DataFrame.min` Return the minimum over the requested axis.
- `DataFrame.max` Return the maximum over the requested axis.
- `DataFrame.idxmin` Return the index of the minimum over the requested axis.
- `DataFrame.idxmax` Return the index of the maximum over the requested axis.
Examples

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([], dtype="float64").prod()
1.0
```

This can be controlled with the `min_count` parameter

```python
>>> pd.Series([], dtype="float64").prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0
```
```python
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

**pandas.DataFrame.quantile**

`DataFrame.quantile(q=0.5, axis=0, numeric_only=True, interpolation='linear')`

Return values at the given quantile over requested axis.

**Parameters**

- `q` [float or array-like, default 0.5 (50% quantile)] Value between 0 <= q <= 1, the quantile(s) to compute.
- `axis` [{0, 1, ‘index’, ‘columns’}, default 0] Equals 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.
- `numeric_only` [bool, default True] If False, the quantile of datetime and timedelta data will be computed as well.
- `interpolation` [{‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’}] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j:
  - linear: `i + (j - i) * fraction`, where `fraction` is the fractional part of the index surrounded by i and j.
  - lower: `i`.
  - higher: `j`.
  - nearest: i or j whichever is nearest.
  - midpoint: `(i + j) / 2`.

**Returns**

- `Series` or `DataFrame`
  - **If q is an array, a DataFrame will be returned where the index is q, the columns are the columns of self, and the values are the quantiles.**
  - **If q is a float, a Series will be returned where the index is the columns of self and the values are the quantiles.**
See also:

core.window.Rolling.quantile Rolling quantile.
numpy.percentile Numpy function to compute the percentile.

Examples

```python
>>> df = pd.DataFrame(np.array([[1, 1], [2, 10], [3, 100], [4, 100]]),
...    columns=['a', 'b'])
>>> df.quantile(.1)
a  1.3
b  3.7
Name: 0.1, dtype: float64
>>> df.quantile([.1, .5])
a b
0.1 1.3 3.7
0.5 2.5 55.0
```

Specifying `numeric_only=False` will also compute the quantile of datetime and timedelta data.

```python
>>> df = pd.DataFrame({'A': [1, 2],
...    'B': [pd.Timestamp('2010'), pd.Timestamp('2011')],
...    'C': [pd.Timedelta('1 days'), pd.Timedelta('2 days')]
...})
>>> df.quantile(0.5, numeric_only=False)
A  1.5
B 2010-07-02 12:00:00
C  1 days 12:00:00
Name: 0.5, dtype: object
```

**pandas.DataFrame.query**

DataFrame.query(expr, inplace=False, **kwargs)

Query the columns of a DataFrame with a boolean expression.

**Parameters**

- **expr** [str] The query string to evaluate.

  You can refer to variables in the environment by prefixing them with an `@` character like `@a + b`.

  You can refer to column names that are not valid Python variable names by surrounding them in backticks. Thus, column names containing spaces or punctuation (besides underscores) or starting with digits must be surrounded by backticks. (For example, a column named “Area (cm^2)” would be referenced as `Area (cm^2)`). Column names which are Python keywords (like “list”, “for”, “import”, etc) cannot be used.

  For example, if one of your columns is called `a` and you want to sum it with `b`, your query should be `a + b`.

  New in version 0.25.0: Backtick quoting introduced.

3.4. DataFrame 1729
New in version 1.0.0: Expanding functionality of backtick quoting for more than
only spaces.

**inplace** [bool] Whether the query should modify the data in place or return a modified
copy.

**kwargs** See the documentation for `eval()` for complete details on the keyword
arguments accepted by `DataFrame.query()`.

Returns

DataFrame or None DataFrame resulting from the provided query expression or None
if inplace=True.

See also:

`eval` Evaluate a string describing operations on DataFrame columns.
`DataFrame.eval` Evaluate a string describing operations on DataFrame columns.

Notes

The result of the evaluation of this expression is first passed to `DataFrame.loc` and if that fails be-
cause of a multidimensional key (e.g., a DataFrame) then the result will be passed to `DataFrame._
getitem__()`.

This method uses the top-level `eval()` function to evaluate the passed query.

The `query()` method uses a slightly modified Python syntax by default. For example, the `&` and `|
(bitwise) operators have the precedence of their boolean cousins, `and` and `or`. This is syntactically valid
Python, however the semantics are different.

You can change the semantics of the expression by passing the keyword argument `parser='python'`
This enforces the same semantics as evaluation in Python space. Likewise, you can pass
`engine='python'` to evaluate an expression using Python itself as a backend. This is not recom-
mended as it is inefficient compared to using `numexpr` as the engine.

The `DataFrame.index` and `DataFrame.columns` attributes of the DataFrame instance are
placed in the query namespace by default, which allows you to treat both the index and columns of
the frame as a column in the frame. The identifier `index` is used for the frame index; you can also use
the name of the index to identify it in a query. Please note that Python keywords may not be used as
identifiers.

For further details and examples see the query documentation in `indexing`.

Backtick quoted variables

Backtick quoted variables are parsed as literal Python code and are converted internally to a Python valid
identifier. This can lead to the following problems.

During parsing a number of disallowed characters inside the backtick quoted string are replaced by strings
that are allowed as a Python identifier. These characters include all operators in Python, the space charac-
ter, the question mark, the exclamation mark, the dollar sign, and the euro sign. For other characters that
fall outside the ASCII range (U+0001..U+007F) and those that are not further specified in PEP 3131, the
query parser will raise an error. This excludes whitespace different than the space character, but also the
hashtag (as it is used for comments) and the backtick itself (backtick can also not be escaped).

In a special case, quotes that make a pair around a backtick can confuse the parser. For example, `it's`
> `that's` will raise an error, as it forms a quoted string (`'s > `that'`) with a backtick inside.
See also the Python documentation about lexical analysis (https://docs.python.org/3/reference/lexical_analysis.html) in combination with the source code in pandas.core.computation.parsing.

### Examples

```python
>>> df = pd.DataFrame({'A': range(1, 6),
    ... 'B': range(10, 0, -2),
    ... 'C C': range(10, 5, -1))
>>> df
   A  B  C  C
0  1 10 10
1  2  8  9
2  3  6  8
3  4  4  7
4  5  2  6
>>> df.query('A > B')
   A  B  C  C
4  5  2  6
```

The previous expression is equivalent to

```python
>>> df[df.A > df.B]
   A  B  C  C
4  5  2  6
```

For columns with spaces in their name, you can use backtick quoting.

```python
>>> df.query('B == `C C``')
   A  B  C  C
0  1 10 10
```

The previous expression is equivalent to

```python
>>> df[df.B == df['C C']]  
   A  B  C  C
0  1 10 10
```

pandas.DataFrame.radd

DataFrame.radd(other, axis='columns', level=None, fill_value=None)

Get Addition of dataframe and other, element-wise (binary operator radd).

Equivalent to other + dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, add.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

#### Parameters

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
**fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

- **DataFrame** Result of the arithmetic operation.

**See also:**

- `DataFrame.add` Add DataFrames.
- `DataFrame.sub` Subtract DataFrames.
- `DataFrame.mul` Multiply DataFrames.
- `DataFrame.div` Divide DataFrames (float division).
- `DataFrame.truediv` Divide DataFrames (float division).
- `DataFrame.floordiv` Divide DataFrames (integer division).
- `DataFrame.mod` Calculate modulo (remainder after division).
- `DataFrame.pow` Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

**Examples**

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360],
...                     index=['circle', 'triangle', 'rectangle'])

>>> df
angle  degrees
circle     0     360
triangle   3      180
rectangle  4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
angle  degrees
circle     1     361
triangle   4      181
rectangle  5      361
```

```python
>>> df.add(1)
angle  degrees
circle     1     361
triangle   4      181
rectangle  5      361
```

Divide by constant with reverse version.
```python
>>> df.div(10)
    angles  degrees
circle  0.0    36.0
triangle 0.3    18.0
rectangle 0.4    36.0

>>> df.rdiv(10)
    angles  degrees
circle     inf  0.027778
triangle  3.333333  0.055556
rectangle 2.500000  0.027778

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
    angles  degrees
circle   -1    358
triangle    2    178
rectangle    3    358

```python
>>> df.sub([1, 2], axis='columns')
    angles  degrees
circle   -1    358
triangle    2    178
rectangle    3    358

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
         axis='index')
    angles  degrees
circle   -1    359
triangle    2    179
rectangle    3    359

Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])
>>> df * other
    angles  degrees
circle   0.0    NaN
triangle   9.0    NaN
rectangle 16.0    NaN

>>> df.mul(other, fill_value=0)
    angles  degrees
circle   0.0    0.0
triangle   9.0    0.0
rectangle 16.0    0.0

Divide by a MultiIndex by level.

```python
```

3.4. DataFrame
```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
... 'degrees': [360, 180, 360, 360, 540, 720]},
... index=[['A', 'A', 'A', 'B', 'B', 'B'],
... ['circle', 'triangle', 'rectangle',
... 'square', 'pentagon', 'hexagon']])

>>> df_multindex
angles  degrees
A circle    0       360
triangle    3       180
rectangle   4       360
B square    4       360
pentagon    5       540
hexagon     6       720

>>> df.div(df_multindex, level=1, fill_value=0)
angles  degrees
A circle    NaN      1.0
triangle    1.0      1.0
rectangle   1.0      1.0
B square    0.0      0.0
pentagon    0.0      0.0
hexagon     0.0      0.0
```

**pandas.DataFrame.rank**

DataFrame.rank(\(axis=0\), method='average', numeric_only=None, na_option='keep', ascending=True, pct=False)

Compute numerical data ranks (1 through n) along axis.

By default, equal values are assigned a rank that is the average of the ranks of those values.

**Parameters**

- **axis** [(0 or 'index', 1 or 'columns'), default 0] Index to direct ranking.
- **method** [{'average', 'min', 'max', 'first', 'dense'}, default 'average'] How to rank the group of records that have the same value (i.e. ties):
  - average: average rank of the group
  - min: lowest rank in the group
  - max: highest rank in the group
  - first: ranks assigned in order they appear in the array
  - dense: like 'min', but rank always increases by 1 between groups.
- **numeric_only** [bool, optional] For DataFrame objects, rank only numeric columns if set to True.
- **na_option** [{'keep', 'top', 'bottom'}, default 'keep'] How to rank NaN values:
  - keep: assign NaN rank to NaN values
  - top: assign lowest rank to NaN values
  - bottom: assign highest rank to NaN values
- **ascending** [bool, default True] Whether or not the elements should be ranked in ascending order.
pct [bool, default False] Whether or not to display the returned rankings in percentile form.

Returns

same type as caller Return a Series or DataFrame with data ranks as values.

See also:

core.groupby.GroupBy.rank Rank of values within each group.

Examples

```python
def = pd.DataFrame(data={'Animal': ['cat', 'penguin', 'dog',
                           'spider', 'snake'],
                           'Number_legs': [4, 2, 4, 8, np.nan]})
def
Animal    Number_legs
0   cat         4.0
1  penguin     2.0
2   dog         4.0
3  spider       8.0
4   snake       NaN
```

The following example shows how the method behaves with the above parameters:

- default_rank: this is the default behaviour obtained without using any parameter.
- max_rank: setting method = 'max' the records that have the same values are ranked using the highest rank (e.g.: since ‘cat’ and ‘dog’ are both in the 2nd and 3rd position, rank 3 is assigned.)
- NA_bottom: choosing na_option = 'bottom', if there are records with NaN values they are placed at the bottom of the ranking.
- pct_rank: when setting pct = True, the ranking is expressed as percentile rank.

```python
def['default_rank'] = df['Number_legs'].rank()
def['max_rank'] = df['Number_legs'].rank(method='max')
def['NA_bottom'] = df['Number_legs'].rank(na_option='bottom')
def['pct_rank'] = df['Number_legs'].rank(pct=True)
def
Animal    Number_legs  default_rank  max_rank  NA_bottom  pct_rank
0   cat         4.0       2.5         3.0       2.5       0.625
1  penguin     2.0       1.0         1.0       1.0       0.250
2   dog         4.0       2.5         3.0       2.5       0.625
3  spider       8.0       4.0         4.0       4.0       1.000
4   snake       NaN       NaN         NaN       NaN       NaN
```
**pandas.DataFrame.rdiv**

DataFrame.rdiv(other, axis='columns', level=None, fill_value=None)

Get floating division of dataframe and other, element-wise (binary operator rtruediv).

Equivalent to other / dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, truediv.

Among flexible wrappers (+, -, *, /, //, %, **).

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame Result of the arithmetic operation.

**See also:**

- DataFrame.add Add DataFrames.
- DataFrame.sub Subtract DataFrames.
- DataFrame.mul Multiply DataFrames.
- DataFrame.div Divide DataFrames (float division).
- DataFrame.truediv Divide DataFrames (float division).
- DataFrame.floordiv Divide DataFrames (integer division).
- DataFrame.mod Calculate modulo (remainder after division).
- DataFrame.pow Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
```

```
angles  degrees
circle  0      360
triangle 3      180
rectangle 4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```

```
angles  degrees
circle  1      361
triangle 4      181
rectangle 5      361
```

```python
>>> df.add(1)
```

```
angles  degrees
circle  1      361
triangle 4      181
rectangle 5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
```

```
angles  degrees
circle  0.0     36.0
triangle 0.3     18.0
rectangle 0.4     36.0
```

```python
>>> df.rdiv(10)
```

```
angles  degrees
circle   inf   0.027778
triangle 3.333333  0.055556
rectangle 2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
```

```
angles  degrees
circle  -1      358
triangle  2      178
rectangle  3      358
```

```python
>>> df.sub([1, 2], axis='columns')
```

```
angles  degrees
circle  -1      358
triangle  2      178
rectangle  3      358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
```

(continues on next page)
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])
>>> other
angles
circle   0
triangle  3
rectangle 4

```  

```python
>>> df * other
   angles  degrees
    circle       NaN
     triangle     NaN
    rectangle     NaN

```  

```python
>>> df.mul(other, fill_value=0)
   angles  degrees
    circle     0.0
     triangle   0.0
    rectangle   0.0

```  

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
                               'degrees': [360, 180, 360, 540, 720],
                               index=['A', 'A', 'A', 'B', 'B',
                                      'circle', 'triangle', 'rectangle',
                                      'square', 'pentagon', 'hexagon']})

```  

```python
>>> df_multindex
   angles  degrees
    A circle     0.0  360
     triangle   1.0  180
    rectangle   1.0  360
     B square   1.0  360
      pentagon   0.0  540
     hexagon    0.0   720

```  

```python
>>> df.div(df_multindex, level=1, fill_value=0)
   angles  degrees
     A circle      NaN   1.0
      triangle    1.0    1.0
     rectangle    1.0    1.0
      B square     0.0    0.0
      pentagon     0.0    0.0
     hexagon      0.0    0.0
```
DataFrame.reindex

```
DataFrame.reindex(labels=None, index=None, columns=None, axis=None, method=None, copy=True, level=None, fill_value=nan, limit=None, tolerance=None)
```

Conform Series/DataFrame to new index with optional filling logic.

Places NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

**Parameters**

- **keywords for axes** [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data.
- **method** [[None, ‘backfill’/’bfill’, ‘pad’/’ffill’, ‘nearest’]] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.
  - None (default): don’t fill gaps
  - pad / ffill: Propagate last valid observation forward to next valid.
  - backfill / bfill: Use next valid observation to fill gap.
  - nearest: Use nearest valid observations to fill gap.
- **copy** [bool, default True] Return a new object, even if the passed indexes are the same.
- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.
- **limit** [int, default None] Maximum number of consecutive elements to forward or backward fill.
- **tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation \( \text{abs(index[indexer] - target)} \leq \text{tolerance} \).
  
  Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

**Returns**

Series/DataFrame with changed index.

See also:

- **DataFrame.set_index** Set row labels.
- **DataFrame.reset_index** Remove row labels or move them to new columns.
- **DataFrame.reindex_like** Change to same indices as other DataFrame.
Examples

DataFrame.reindex supports two calling conventions

- (index=index_labels, columns=column_labels, ...)
- (labels, axis={'index', 'columns'}, ...)

We highly recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```python
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({'http_status': [200, 200, 404, 404, 301],
...                    'response_time': [0.04, 0.02, 0.07, 0.08, 1.0],
...                    index=index})
>>> df
                  http_status  response_time
Firefox            200          0.04
Chrome            200          0.02
Safari            404          0.07
IE10              404          0.08
Konqueror          301          1.00
```

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```python
>>> new_index = ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10',
...               'Chrome']
>>> df.reindex(new_index)
     http_status  response_time
Safari   404.0          0.07
Iceweasel   NaN          NaN
Comodo Dragon   NaN          NaN
IE10     404.0          0.08
Chrome   200.0          0.02
```

We can fill in the missing values by passing a value to the keyword fill_value. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword method to fill the NaN values.

```python
>>> df.reindex(new_index, fill_value=0)
     http_status  response_time
Safari   404          0.07
Iceweasel       0          0.00
Comodo Dragon    0          0.00
IE10     404          0.08
Chrome   200          0.02
```

```python
>>> df.reindex(new_index, fill_value='missing')
     http_status  response_time
Safari   404          0.07
Iceweasel      missing      missing
Comodo Dragon  missing      missing
IE10     404          0.08
Chrome   200          0.02
```

We can also reindex the columns.
Or we can use “axis-style” keyword arguments

```python
>>> df.reindex(["http_status", 'user_agent'], axis="columns")
    http_status  user_agent
Firefox       200      NaN
Chrome        200      NaN
Safari        404      NaN
IE10          404      NaN
Konqueror     301      NaN
```

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

```python
>>> date_index = pd.date_range('1/1/2010', periods=6, freq='D')
>>> df2 = pd.DataFrame({"prices": [100, 101, np.nan, 100, 89, 88]}, index=date_index)
```

Suppose we decide to expand the dataframe to cover a wider date range.

```python
>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')
>>> df2.reindex(date_index2)
    prices
2009-12-29    NaN
2009-12-30    NaN
2009-12-31    NaN
2010-01-01    100.0
2010-01-02    101.0
2010-01-03    NaN
2010-01-04    100.0
2010-01-05    89.0
2010-01-06    88.0
```

The index entries that did not have a value in the original data frame (for example, ‘2009-12-29’) are by default filled with `NaN`. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the `NaN` values, pass `bfill` as an argument to the `method` keyword.

```python
>>> df2.reindex(date_index2, method='bfill')
    prices
2009-12-29    NaN
2009-12-30    NaN
2009-12-31    NaN
2010-01-01    100.0
2010-01-02    101.0
2010-01-03    NaN
2010-01-04    100.0
2010-01-05    89.0
2010-01-06    88.0
2010-01-07    NaN
```
Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the fillna() method.

See the user guide for more.

### pandas.DataFrame.reindex_like

DataFrame.reindex_like(other, method=None, copy=True, limit=None, tolerance=None)

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

**Parameters**

- **other** [Object of the same data type] Its row and column indices are used to define the new indices of this object.
- **method** [None, ‘backfill’/’bfill’, ‘pad’/’ffill’, ‘nearest’] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.
  - None (default): don’t fill gaps
  - pad / ffill: propagate last valid observation forward to next valid
  - backfill / bfill: use next valid observation to fill gap
  - nearest: use nearest valid observations to fill gap.
- **copy** [bool, default True] Return a new object, even if the passed indexes are the same.
- **limit** [int, default None] Maximum number of consecutive labels to fill for inexact matches.
- **tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation abs(index[indexer] - target) <= tolerance.

  Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

**Returns**
Series or DataFrame  Same type as caller, but with changed indices on each axis.

See also:

DataFrame.set_index  Set row labels.
DataFrame.reset_index  Remove row labels or move them to new columns.
DataFrame.reindex  Change to new indices or expand indices.

Notes

Same as calling .reindex(index=other.index, columns=other.columns,...).

Examples

```python
>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
... [31, 87.8, 'high'],
... [22, 71.6, 'medium'],
... [35, 95, 'medium']],
... columns=['temp_celsius', 'temp_fahrenheit', 'windspeed'],
... index=pd.date_range(start='2014-02-12',
... end='2014-02-15', freq='D'))
```

```
>> df2 = pd.DataFrame([[28, 'low'],
... [30, 'low'],
... [35.1, 'medium']],
... columns=['temp_celsius', 'windspeed'],
... index=pd.DatetimeIndex(['2014-02-12', '2014-02-13', '2014-02-15']))
```

```
>> df2.reindex_like(df1)
```

```
temp_celsius temp_fahrenheit windspeed
2014-02-12 28.0 NaN low
2014-02-13 30.0 NaN low
2014-02-14 NaN NaN NaN
2014-02-15 35.1 NaN medium
```
pandas.DataFrame.rename

DataFrame.rename(mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False, level=None, errors='ignore')

Alter axes labels.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don’t throw an error.

See the user guide for more.

Parameters

mapper [dict-like or function] Dict-like or function transformations to apply to that axis’ values. Use either mapper and axis to specify the axis to target with mapper, or index and columns.

index [dict-like or function] Alternative to specifying axis (mapper, axis=0 is equivalent to index=mapper).

columns [dict-like or function] Alternative to specifying axis (mapper, axis=1 is equivalent to columns=mapper).

axis [(0 or ‘index’, 1 or ‘columns’), default 0] Axis to target with mapper. Can be either the axis name (‘index’, ‘columns’) or number (0, 1). The default is ‘index’.

copy [bool, default True] Also copy underlying data.

inplace [bool, default False] Whether to return a new DataFrame. If True then value of copy is ignored.

level [int or level name, default None] In case of a MultiIndex, only rename labels in the specified level.

errors [['ignore', 'raise'], default ‘ignore’] If ‘raise’, raise a KeyError when a dict-like mapper, index, or columns contains labels that are not present in the Index being transformed. If ‘ignore’, existing keys will be renamed and extra keys will be ignored.

Returns

DataFrame or None DataFrame with the renamed axis labels or None if inplace=True.

Raises

KeyError If any of the labels is not found in the selected axis and “errors=’raise’”.

See also:

DataFrame.rename_axis Set the name of the axis.
Examples

DataFrame.rename supports two calling conventions

- (index=index_mapper, columns=columns_mapper, ...)
- (mapper, axis={'index', 'columns'}, ...)

We highly recommend using keyword arguments to clarify your intent.

Rename columns using a mapping:

```python
>>> df = pd.DataFrame("
A" : [1, 2, 3], "B" : [4, 5, 6])
>>> df.rename(columns={"A": "a", "B": "c"})
a  c
0  1  4
1  2  5
2  3  6
```

Rename index using a mapping:

```python
>>> df.rename(index={0: "x", 1: "y", 2: "z"})
A  B
x  1  4
y  2  5
z  3  6
```

Cast index labels to a different type:

```python
>>> df.index
RangeIndex(start=0, stop=3, step=1)
>>> df.rename(index=str).index
Index([0', '1', '2'], dtype='object')
```

Using axis-style parameters:

```python
>>> df.rename(str.lower, axis='columns')
a  b
0  1  4
1  2  5
2  3  6
```

```python
>>> df.rename({1: 2, 2: 4}, axis='index')
A  B
0  1  4
2  2  5
4  3  6
```
pandas.DataFrame.rename_axis

DataFrame.rename_axis(*mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False*)

Set the name of the axis for the index or columns.

**Parameters**

- **mapper** [scalar, list-like, optional] Value to set the axis name attribute.
- **index, columns** [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis’ values. Note that the columns parameter is not allowed if the object is a Series. This parameter only apply for DataFrame type objects.
- **axis** [*{0 or 'index', 1 or 'columns'}, default 0*] The axis to rename.
- **copy** [bool, default True] Also copy underlying data.
- **inplace** [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

**Returns**

- **Series, DataFrame, or None** The same type as the caller or None if inplace=True.

**See also:**

- **Series.rename** Alter Series index labels or name.
- **DataFrame.rename** Alter DataFrame index labels or name.
- **Index.rename** Set new names on index.

**Notes**

DataFrame.rename_axis supports two calling conventions

- *(index=index_mapper, columns=columns_mapper, ...)*
- *(mapper, axis=('index', 'columns'), ...)*

The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter copy is ignored.

The second calling convention will modify the names of the corresponding index if mapper is a list or a scalar. However, if mapper is dict-like or a function, it will use the deprecated behavior of modifying the axis labels.

We highly recommend using keyword arguments to clarify your intent.
Examples

Series

```python
>>> s = pd.Series(['dog', 'cat', 'monkey'])
>>> s
0   dog
1   cat
2 monkey
dtype: object
>>> s.rename_axis('animal')
animal
0   dog
1   cat
2 monkey
dtype: object
```

DataFrame

```python
>>> df = pd.DataFrame({'num_legs': [4, 4, 2],
...                     'num_arms': [0, 0, 2]},
...                    ['dog', 'cat', 'monkey'])
>>> df
    num_legs num_arms
dog      4     0
cat      4     0
monkey   2     2
>>> df = df.rename_axis('animal')
>>> df
animal
   num_legs num_arms
dog      4     0
cat      4     0
monkey   2     2
```

MultiIndex

```python
>>> df.index = pd.MultiIndex.from_product([['mammal'], ['dog', 'cat', 'monkey']], names=['type', 'name'])
```

```python
>>> df.rename_axis(index={'type': 'class'})
limitms    num_legs num_arms
class name
(continues on next page)
```

3.4. DataFrame
mammal  dog    4  0
    cat     4  0
monkey  2  2

```python
>>> df.rename_axis(columns=str.upper)
LIMBS         num_legs num_arms
type     name
mammal  dog   4   0
  cat       4   0
monkey    2   2
```

**pandas.DataFrame.reorder_levels**

**DataFrame.reorder_levels** *(order, axis=0)*

Rearrange index levels using input order. May not drop or duplicate levels.

**Parameters**

- **order** [list of int or list of str] List representing new level order. Reference level by number (position) or by key (label).
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Where to reorder levels.

**Returns**

- DataFrame

**pandas.DataFrame.replace**

**DataFrame.replace** *(to_replace=None, value=None, inplace=False, limit=None, regex=False, method='pad' )*  
Replace values given in to_replace with value.

Values of the DataFrame are replaced with other values dynamically.

This differs from updating with .loc or .iloc, which require you to specify a location to update with some value.

**Parameters**

- **to_replace** [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.
  - numeric, str or regex:
    - numeric: numeric values equal to to_replace will be replaced with value
    - str: string exactly matching to_replace will be replaced
    - regex: regexs matching to_replace will be replaced
  - list of str, regex, or numeric:
    - First, if to_replace and value are both lists, they must be the same length.
Second, if `regex=True` then all of the strings in both lists will be interpreted as regexes otherwise they will match directly. This doesn’t matter much for `value` since there are only a few possible substitution regexes you can use.

- str, regex and numeric rules apply as above.

- dict:
  - Dicts can be used to specify different replacement values for different existing values. For example, `{ 'a': 'b', 'y': 'z' }` replaces the value ‘a’ with ‘b’ and ‘y’ with ‘z’. To use a dict in this way the `value` parameter should be `None`.
  - For a DataFrame a dict can specify that different values should be replaced in different columns. For example, `{ 'a': 1, 'b': 'z' }` looks for the value 1 in column ‘a’ and the value ‘z’ in column ‘b’ and replaces these values with whatever is specified in `value`. The `value` parameter should not be `None` in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.
  - For a DataFrame nested dictionaries, e.g., `{ 'a': { 'b': np.nan } }`, are read as follows: look in column ‘a’ for the value ‘b’ and replace it with NaN. The `value` parameter should be `None` to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) cannot be regular expressions.

- None:
  - This means that the `regex` argument must be a string, compiled regular expression, or list, dict, ndarray or Series of such elements. If `value` is also `None` then this must be a nested dictionary or Series.

See the examples section for examples of each of these.

`value` [scalar, dict, list, str, regex, default None] Value to replace any values matching `to_replace` with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

`inplace` [bool, default False] If True, performs operation inplace and returns None.

`limit` [int, default None] Maximum size gap to forward or backward fill.

`regex` [bool or same types as `to_replace`, default False] Whether to interpret `to_replace` and/or `value` as regular expressions. If this is `True` then `to_replace` must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case `to_replace` must be `None`.

`method` [{‘pad’, ‘ffill’, ‘bfill’, ‘None’}] The method to use when for replacement, when `to_replace` is a scalar, list or tuple and `value` is `None`.

Changed in version 0.23.0: Added to DataFrame.

Returns

DataFrame Object after replacement.

Raises

AssertionError
• If regex is not a bool and to_replace is not None.

TypeError
• If to_replace is not a scalar, array-like, dict, or None.
• If to_replace is a dict and value is not a list, dict, ndarray, or Series.
• If to_replace is None and regex is not compilable into a regular expression or is a list, dict, ndarray, or Series.
• When replacing multiple bool or datetime64 objects and the arguments to to_replace does not match the type of the value being replaced.

ValueError
• If a list or an ndarray is passed to to_replace and value but they are not the same length.

See also:

DataFrame.fillna Fill NA values.
DataFrame.where Replace values based on boolean condition.
Series.str.replace Simple string replacement.

Notes

• Regex substitution is performed under the hood with re.sub. The rules for substitution for re.sub are the same.

• Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers are strings, then you can do this.

• This method has a lot of options. You are encouraged to experiment and play with this method to gain intuition about how it works.

• When dict is used as the to_replace value, it is like key(s) in the dict are the to_replace part and value(s) in the dict are the value parameter.

Examples

Scalar `to_replace` and `value`:

```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0   5
1   1
2   2
3   3
4   4
dtype: int64
```
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
...                    'B': [5, 6, 7, 8, 9],
...                    'C': ['a', 'b', 'c', 'd', 'e']})

>>> df.replace(0, 5)
   A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e

List-like `to_replace`

>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e

>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e

```
>>> s.replace([1, 2], method='bfill')
0  0
1  3
2  3
3  3
4  4
dtype: int64
```

dict-like `to_replace`

>>> df.replace({0: 10, 1: 100})
   A  B  C
0  10 5  a
1 100 6  b
2  2  7  c
3  3  8  d
4  4  9  e

>>> df.replace({'A': 0, 'B': 5}, 100)
   A  B  C
0 100 100  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
Regular expression `to_replace`

```python
>>> df = pd.DataFrame({
    'A': ['bat', 'foo', 'bait'],
    'B': ['abc', 'bar', 'xyz']
})
```

```python
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
    A    B
0  new  abc
1    foo  new
2   bait  xyz
```

```python
>>> df.replace({r'^ba.$': 'new', 'foo': 'xyz'})
    A    B
0  new  abc
1  xyz  new
2   bait  xyz
```

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the `to_replace` parameter:

```python
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
```

```python
>>> s.replace({'a': None})
0    10
1  None
2  None
```

When one uses a dict as the `to_replace` value, it is like the value(s) in the dict are equal to the `value` parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None):

```python
>>> s.replace({'a': None})
0    10
1    None
2    None
```

(continues on next page)
When `value=None` and `to_replace` is a scalar, list or tuple, `replace` uses the method parameter (default 'pad') to do the replacement. So this is why the ‘a’ values are being replaced by 10 in rows 1 and 2 and ‘b’ in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad')`:

```
>>> s.replace('a', None)
0  10
1  10
2  10
3  b
4  b
dtype: object
```

**pandas.DataFrame.resample**

Dataframe.resample (rule, axis=0, closed=None, label=None, convention='start', kind=None, loffset=None, base=None, on=None, level=None, origin='start_day', offset=None)

Resample time-series data.

Convenience method for frequency conversion and resampling of time series. The object must have a datetime-like index (`DatetimeIndex`, `PeriodIndex`, or `TimedeltaIndex`), or the caller must pass the label of a datetime-like series/index to the `on/level` keyword parameter.

**Parameters**

- **rule** [DateOffset, Timedelta or str] The offset string or object representing target conversion.
- **axis** [[0 or ‘index’, 1 or ‘columns’], default 0] Which axis to use for up- or down-sampling. For Series this will default to 0, i.e. along the rows. Must be `DatetimeIndex`, `TimedeltaIndex` or `PeriodIndex`.
- **label** [{‘right’, ‘left’}, default None] Which bin edge label to label bucket with. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.
- **convention** [{‘start’, ‘end’, ‘s’, ‘e’}, default ‘start’] For PeriodIndex only, controls whether to use the start or end of rule.
- **kind** [{‘timestamp’, ‘period’}, optional, default None] Pass ‘timestamp’ to convert the resulting index to a DatetimeIndex or ‘period’ to convert it to a PeriodIndex. By default the input representation is retained.
- **loffset** [timedelta, default None] Adjust the resampled time labels.

Deprecation warning since version 1.1.0: You should add the loffset to the `df.index` after the resample. See below.
base [int, default 0] For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0.

Deprecated since version 1.1.0: The new arguments that you should use are ‘offset’ or ‘origin’.

on [str, optional] For a DataFrame, column to use instead of index for resampling. Column must be datetime-like.

level [str or int, optional] For a MultiIndex, level (name or number) to use for resampling. level must be datetime-like.

origin [{’epoch’, ’start’, ’start_day’, ’end’, ’end_day’}, Timestamp] or str, default ’start_day’ The timestamp on which to adjust the grouping. The timezone of origin must match the timezone of the index. If a timestamp is not used, these values are also supported:

• ’epoch’: origin is 1970-01-01
• ’start’: origin is the first value of the timeseries
• ’start_day’: origin is the first day at midnight of the timeseries

New in version 1.1.0.

• ’end’: origin is the last value of the timeseries
• ’end_day’: origin is the ceiling midnight of the last day

New in version 1.3.0.

offset [Timedelta or str, default is None] An offset timedelta added to the origin.

New in version 1.1.0.

Returns
pandas.core.Resampler Resampler object.

See also:

Series.resample Resample a Series.

Dataframe.resample Resample a DataFrame.

groupby Group DataFrame by mapping, function, label, or list of labels.

asfreq Reindex a DataFrame with the given frequency without grouping.

Notes

See the user guide for more.

To learn more about the offset strings, please see this link.
Examples

Start by creating a series with 9 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
2000-01-01 00:00:00    0
2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
2000-01-01 00:08:00    8
Freq: T, dtype: int64
```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```python
>>> series.resample('3T').sum()
2000-01-01 00:00:00    3
2000-01-01 00:03:00   12
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket 2000-01-01 00:03:00 contains the value 3, but the summed value in the resampled bucket with the label 2000-01-01 00:03:00 does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```python
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00    3
2000-01-01 00:06:00   12
2000-01-01 00:09:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```python
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00    0
2000-01-01 00:03:00    6
2000-01-01 00:06:00   15
2000-01-01 00:09:00   15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.

```python
>>> series.resample('30S').asfreq()[0:5] # Select first 5 rows
2000-01-01 00:00:00    0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00    1.0
2000-01-01 00:01:30   NaN
2000-01-01 00:02:00    2.0
Freq: 30S, dtype: float64
```
Upsample the series into 30 second bins and fill the NaN values using the pad method.

```python
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00  0
2000-01-01 00:00:30  0
2000-01-01 00:01:00  1
2000-01-01 00:01:30  1
2000-01-01 00:02:00  2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the bfill method.

```python
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00  0
2000-01-01 00:00:30  1
2000-01-01 00:01:00  1
2000-01-01 00:01:30  2
2000-01-01 00:02:00  2
Freq: 30S, dtype: int64
```

Pass a custom function via apply

```python
>>> def custom_resampler(arraylike):
...     return np.sum(arraylike) + 5
...     series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00  8
2000-01-01 00:03:00  17
2000-01-01 00:06:00  26
Freq: 3T, dtype: int64
```

For a Series with a PeriodIndex, the keyword convention can be used to control whether to use the start or end of rule.

Resample a year by quarter using 'start' convention. Values are assigned to the first quarter of the period.

```python
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
...     freq='A',
...     periods=2))
>>> s
2012 1
2013 2
Freq: A-DEC, dtype: int64
>>> s.resample('Q', convention='start').asfreq()
2012Q1  1.0
2012Q2  NaN
2012Q3  NaN
2012Q4  NaN
2013Q1  2.0
2013Q2  NaN
2013Q3  NaN
2013Q4  NaN
Freq: Q-DEC, dtype: float64
```

Resample quarters by month using 'end' convention. Values are assigned to the last month of the period.

```python
>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01',
...     freq='Q',
...     periods=4))
... (continues on next page)
For DataFrame objects, the keyword `on` can be used to specify the column instead of the index for resampling.

```python
>>> d = {'price': [10, 11, 9, 13, 14, 18, 17, 19],
      'volume': [50, 60, 40, 100, 50, 100, 40, 50]}
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018',
                                       periods=8,
                                       freq='W')
>>> df
   price  volume week_starting
0    10     50      2018-01-07
1    11     60      2018-01-14
2     9     40      2018-01-21
3    13    100      2018-01-28
4    14     50      2018-02-04
5    18    100      2018-02-11
6    17     40      2018-02-18
7    19     50      2018-02-25
>>> df.resample('M', on='week_starting').mean()
               price  volume
week_starting
2018-01-31   10.75   62.5
2018-02-28   17.00   60.0
```

For a DataFrame with MultiIndex, the keyword `level` can be used to specify on which level the resampling needs to take place.

```python
>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = {'price': [10, 11, 9, 13, 14, 18, 17, 19],
       'volume': [50, 60, 40, 100, 50, 100, 40, 50]}
>>> df2 = pd.DataFrame(d2,
                     index=pd.MultiIndex.from_product([days, ['morning', 'afternoon']]))
>>> df2
```

(continues on next page)
...)

```python
>>> df2

<table>
<thead>
<tr>
<th></th>
<th>price</th>
<th>volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>10</td>
<td>50</td>
</tr>
<tr>
<td>morning</td>
<td></td>
<td></td>
</tr>
<tr>
<td>afternoon</td>
<td>11</td>
<td>60</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>9</td>
<td>40</td>
</tr>
<tr>
<td>morning</td>
<td></td>
<td></td>
</tr>
<tr>
<td>afternoon</td>
<td>13</td>
<td>100</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>14</td>
<td>50</td>
</tr>
<tr>
<td>morning</td>
<td></td>
<td></td>
</tr>
<tr>
<td>afternoon</td>
<td>18</td>
<td>100</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>17</td>
<td>40</td>
</tr>
<tr>
<td>morning</td>
<td></td>
<td></td>
</tr>
<tr>
<td>afternoon</td>
<td>19</td>
<td>50</td>
</tr>
</tbody>
</table>
```

```python
>>> df2.resample('D', level=0).sum()

<table>
<thead>
<tr>
<th></th>
<th>price</th>
<th>volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>21</td>
<td>110</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>22</td>
<td>140</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>32</td>
<td>150</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>36</td>
<td>90</td>
</tr>
</tbody>
</table>
```

If you want to adjust the start of the bins based on a fixed timestamp:

```python
>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
>>> ts

0    0
1    3
2    6
3    9
4   12
5   15
6   18
7   21
8   24
Freq: 7T, dtype: int64
```

```python
>>> ts.resample('17min').sum()

0    0
1    9
2   21
3   54
4   24
Freq: 17T, dtype: int64
```

```python
>>> ts.resample('17min', origin='epoch').sum()

0    6
1   18
2   45
3   24
Freq: 17T, dtype: int64
```

```python
>>> ts.resample('17min', origin='2000-01-01').sum()

0    3
1   15
2   45
```

(continues on next page)
If you want to adjust the start of the bins with an offset Timedelta, the two following lines are equivalent:

```python
>>> ts.resample('17min', origin='start').sum()
2000-10-01 23:30:00 9
2000-10-01 23:47:00 21
2000-10-02 00:04:00 54
2000-10-02 00:21:00 24
Freq: 17T, dtype: int64
```

```python
>>> ts.resample('17min', offset='23h30min').sum()
2000-10-01 23:30:00 9
2000-10-01 23:47:00 21
2000-10-02 00:04:00 54
2000-10-02 00:21:00 24
Freq: 17T, dtype: int64
```

If you want to take the largest Timestamp as the end of the bins:

```python
>>> ts.resample('17min', origin='end').sum()
2000-10-01 23:35:00 0
2000-10-01 23:52:00 18
2000-10-02 00:12:00 27
2000-10-02 00:26:00 63
Freq: 17T, dtype: int64
```

In contrast with the `start_day`, you can use `end_day` to take the ceiling midnight of the largest Timestamp as the end of the bins and drop the bins not containing data:

```python
>>> ts.resample('17min', origin='end_day').sum()
2000-10-01 23:38:00 3
2000-10-01 23:55:00 15
2000-10-02 00:12:00 45
2000-10-02 00:29:00 45
Freq: 17T, dtype: int64
```

To replace the use of the deprecated `base` argument, you can now use `offset`, in this example it is equivalent to have `base=2`:

```python
>>> ts.resample('17min', offset='2min').sum()
2000-10-01 23:16:00 0
2000-10-01 23:33:00 9
2000-10-01 23:50:00 36
2000-10-02 00:07:00 39
2000-10-02 00:24:00 24
Freq: 17T, dtype: int64
```

To replace the use of the deprecated `loffset` argument:

```python
>>> from pandas.tseries.frequencies import to_offset
>>> loffset = '19min'
>>> ts_out = ts.resample('17min').sum()
>>> ts_out.index = ts_out.index + to_offset(loffset)
>>> ts_out
```

</tbody>
</table>

Freq: 17T, dtype: int64

pandas.DataFrame.reset_index

DataFrame.reset_index(level=None, drop=False, inplace=False, col_level=0, col_fill='')

Reset the index, or a level of it.

Reset the index of the DataFrame, and use the default one instead. If the DataFrame has a MultiIndex, this method can remove one or more levels.

Parameters

- **level** [int, str, tuple, or list, default None] Only remove the given levels from the index. Removes all levels by default.
- **drop** [bool, default False] Do not try to insert index into dataframe columns. This resets the index to the default integer index.
- **inplace** [bool, default False] Modify the DataFrame in place (do not create a new object).
- **col_level** [int or str, default 0] If the columns have multiple levels, determines which level the labels are inserted into. By default it is inserted into the first level.
- **col_fill** [object, default ‘’] If the columns have multiple levels, determines how the other levels are named. If None then the index name is repeated.

Returns

DataFrame or None DataFrame with the new index or None if inplace=True.

See also:

DataFrame.set_index Opposite of reset_index.
DataFrame.reindex Change to new indices or expand indices.
DataFrame.reindex_like Change to same indices as other DataFrame.

Examples

```python
>>> df = pd.DataFrame([('bird', 389.0),
... ('bird', 24.0),
... ('mammal', 80.5),
... ('mammal', np.nan),
... index=['falcon', 'parrot', 'lion', 'monkey'],
... columns=('class', 'max_speed'))
>>> df
          class  max_speed
falcon    bird   389.0
parrot    bird    24.0
```
When we reset the index, the old index is added as a column, and a new sequential index is used:

```python
>>> df.reset_index()
index class max_speed
0  falcon  bird   389.0
1  parrot  bird    24.0
2   lion  mammal   80.5
3  monkey  mammal     NaN
```

We can use the `drop` parameter to avoid the old index being added as a column:

```python
>>> df.reset_index(drop=True)
class max_speed
0  bird    389.0
1  bird    24.0
2  mammal   80.5
3  mammal   NaN
```

You can also use `reset_index` with `MultiIndex`.

```python
>>> index = pd.MultiIndex.from_tuples(
    [('bird', 'falcon'),
     ('bird', 'parrot'),
     ('mammal', 'lion'),
     ('mammal', 'monkey')],
    names=['class', 'name'])
>>> columns = pd.MultiIndex.from_tuples(
    [('speed', 'max'),
     ('species', 'type')])
>>> df = pd.DataFrame(
    [(389.0, 'fly'),
     (24.0, 'fly'),
     (80.5, 'run'),
     (np.nan, 'jump')],
    index=index,
    columns=columns)
>>> df
speed species
max type class name
bird falcon 389.0 fly
parrot 24.0 fly
mammal lion 80.5 run
monkey mammal NaN jump
```

If the index has multiple levels, we can reset a subset of them:

```python
>>> df.reset_index(level='class')
class speed species
max type name
falcon  bird  389.0  fly
parrot  bird   24.0  fly
lion   mammal   80.5  run
monkey mammal     NaN  jump
```

If we are not dropping the index, by default, it is placed in the top level. We can place it in another level:
When the index is inserted under another level, we can specify under which one with the parameter `col_fill`:

```python
>>> df.reset_index(level='class', col_level=1, col_fill='species')
```

If we specify a nonexistent level for `col_fill`, it is created:

```python
>>> df.reset_index(level='class', col_level=1, col_fill='genus')
```

### pandas.DataFrame.rfloordiv

DataFrame.rfloordiv(other, axis='columns', level=None, fill_value=None)

Get Integer division of dataframe and other, element-wise (binary operator `rfloordiv`).

Equivalent to other // dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, `floordiv`.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

- **axis** [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.

- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.
Returns

**DataFrame** Result of the arithmetic operation.

See also:

- **DataFrame.add** Add DataFrames.
- **DataFrame.sub** Subtract DataFrames.
- **DataFrame.mul** Multiply DataFrames.
- **DataFrame.div** Divide DataFrames (float division).
- **DataFrame.truediv** Divide DataFrames (float division).
- **DataFrame.floordiv** Divide DataFrames (integer division).
- **DataFrame.mod** Calculate modulo (remainder after division).
- **DataFrame.pow** Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
                     'degrees': [360, 180, 360]},
                    index=['circle', 'triangle', 'rectangle'])
>>> df
    angles  degrees
circle     0      360
triangle   3      180
rectangle  4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
    angles  degrees
circle     1      361
triangle   4      181
rectangle  5      361
```

```python
>>> df.add(1)
    angles  degrees
circle     1      361
triangle   4      181
rectangle  5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
    angles  degrees
circle   0.0      36.0
triangle 0.3      18.0
rectangle 0.4     36.0
```
>>> df.rdiv(10)

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>inf</td>
</tr>
<tr>
<td>triangle</td>
<td>3.333333</td>
</tr>
<tr>
<td>rectangle</td>
<td>2.500000</td>
</tr>
</tbody>
</table>

Subtract a list and Series by axis with operator version.

>>> df - [1, 2]

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>

>>> df.sub([1, 2], axis='columns')

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>

>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>

Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])

>>> df * other

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0</td>
</tr>
<tr>
<td>triangle</td>
<td>9</td>
</tr>
<tr>
<td>rectangle</td>
<td>16</td>
</tr>
</tbody>
</table>

>>> df.mul(other, fill_value=0)

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0</td>
</tr>
<tr>
<td>triangle</td>
<td>9</td>
</tr>
<tr>
<td>rectangle</td>
<td>16</td>
</tr>
</tbody>
</table>

Divide by a MultiIndex by level.

>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               index=['A', 'A', 'B', 'B', 'B', 'B'],
                               ['circle', 'triangle', 'rectangle',
                                'square', 'pentagon', 'hexagon']})

(continues on next page)
>>> df_multindex
    angles  degrees
A  circle     0      360
      triangle  3      180
      rectangle 4      360
B  square     4      360
      pentagon  5      540
      hexagon  6      720

>>> df.div(df_multindex, level=1, fill_value=0)
    angles  degrees
A  circle     NaN       1.0
      triangle  1.0      1.0
      rectangle 1.0      1.0
B  square     0.0       0.0
      pentagon  0.0       0.0
      hexagon  0.0       0.0

**pandas.DataFrame.rmod**

DataFrame.rmod\(\)\(\)\(other, axis='columns', level=None, fill_value=None\)\(\)

Get Modulo of dataframe and other, element-wise (binary operator rmod).

Equivalent to other % dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, mod.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

- **axis** [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.

- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

Dataframe Result of the arithmetic operation.

**See also:**

- **DataFrame.add** Add DataFrames.
- **DataFrame.sub** Subtract DataFrames.
- **DataFrame.mul** Multiply DataFrames.
- **DataFrame.div** Divide DataFrames (float division).
- **DataFrame.truediv** Divide DataFrames (float division).
**DataFrame.floordiv**  Divide DataFrames (integer division).

**DataFrame.mod**  Calculate modulo (remainder after division).

**DataFrame.pow**  Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

**Examples**

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                   'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])

>>> df
          angles  degrees
    circle       0     360
   triangle      3     180
rectangle     4     360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
          angles  degrees
    circle       1     361
   triangle      4     181
rectangle     5     361
```  

```python
>>> df.add(1)
          angles  degrees
    circle       1     361
   triangle      4     181
rectangle     5     361
```  

Divide by constant with reverse version.

```python
>>> df.div(10)
          angles  degrees
    circle     0.0    36.0
   triangle    0.3    18.0
rectangle    0.4    36.0
```  

```python
>>> df.rdiv(10)
          angles  degrees
    circle     inf   0.027778
   triangle  3.333333   0.055556
rectangle  2.500000   0.027778
```  

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
          angles  degrees
    circle     -1     358
   triangle      2     178
rectangle     3     358
```
Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])

>>> df * other

 angles  degrees
 circle  0.0  NaN
 triangle 9.0  NaN
 rectangle 16.0  NaN

Divide by a MultiIndex by level.

>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               index=['A', 'A', 'A', 'B', 'B', 'B'],
                               columns=['circle', 'triangle', 'rectangle',
                                        'square', 'pentagon', 'hexagon'])

>>> df.div(df_multindex, level=1, fill_value=0)

 angles  degrees
 A   circle  NaN  1.0
      triangle 1.0  1.0
      rectangle 1.0  1.0

(continues on next page)
pandas.DataFrame.rmul

Dataframe . `rmul (other, axis='columns', level=None, fill_value=None)`

Get Multiplication of dataframe and other, element-wise (binary operator `rmul`).

Equivalent to `other * dataframe`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, `mul`.

Among flexible wrappers (`add, sub, mul, div, mod, pow`) to arithmetic operators: `+, -, *, /, //, %, **`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [[0 or 'index', 1 or 'columns']] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

Dataframe Result of the arithmetic operation.

See also:

`DataFrame.add` Add DataFrames.

`DataFrame.sub` Subtract DataFrames.

`DataFrame.mul` Multiply DataFrames.

`DataFrame.div` Divide DataFrames (float division).

`DataFrame.truediv` Divide DataFrames (float division).

`DataFrame.floordiv` Divide DataFrames (integer division).

`DataFrame.mod` Calculate modulo (remainder after division).

`DataFrame.pow` Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360],
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
     angles  degrees
circle     0      360
triangle   3      180
rectangle  4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
     angles  degrees
circle     1      361
triangle   4      181
rectangle  5      361
```

```python
>>> df.add(1)
     angles  degrees
circle     1      361
triangle   4      181
rectangle  5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
     angles  degrees
circle 0.0       36.0
triangle 0.3     18.0
rectangle 0.4   36.0
```

```python
>>> df.rdiv(10)
     angles  degrees
circle       inf 0.027778
triangle 3.333333 0.055556
rectangle 2.500000 0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
     angles  degrees
circle  -1      358
triangle  2      178
rectangle  3      358
```

```python
>>> df.sub([1, 2], axis='columns')
     angles  degrees
circle  -1      358
triangle  2      178
rectangle  3      358
```
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])
```

```plaintext
>>>
angles
circle 0
triangle 3
rectangle 4
```

```python
>>> df + other
```

```plaintext
>>>
angles
circle 0
triangle 9
rectangle 16
```

```python
>>> df.mul(other, fill_value=0)
```

```plaintext
>>>
angles
circle 0.0
triangle 0.0
rectangle 0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               index=['circle', 'triangle', 'rectangle',
                                      'square', 'pentagon', 'hexagon']})
```

```plaintext
>>>
angles
circle 0
triangle 3
rectangle 4
square 4
pentagon 5
hexagon 6
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
```

```plaintext
>>>
angles
circle NaN
triangle 1.0
rectangle 1.0
square 0.0
pentagon 0.0
hexagon 0.0
```
pandas.DataFrame.rolling

DataFrame.rolling(window, min_periods=None, center=False, win_type=None, on=None, axis=0, closed=None, method='single')

Provide rolling window calculations.

**Parameters**

- **window** [int, offset, or BaseIndexer subclass] Size of the moving window. This is the number of observations used for calculating the statistic. Each window will be a fixed size.
  
  If its an offset then this will be the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes.
  
  If a BaseIndexer subclass is passed, calculates the window boundaries based on the defined get_window_bounds method. Additional rolling keyword arguments, namely min_periods, center, and closed will be passed to get_window_bounds.

- **min_periods** [int, default None] Minimum number of observations in window required to have a value (otherwise result is NA). For a window that is specified by an offset, min_periods will default to 1. Otherwise, min_periods will default to the size of the window.

- **center** [bool, default False] Set the labels at the center of the window.

- **win_type** [str, default None] Provide a window type. If None, all points are evenly weighted. See the notes below for further information.

- **on** [str, optional] For a DataFrame, a datetime-like column or Index level on which to calculate the rolling window, rather than the DataFrame’s index. Provided integer column is ignored and excluded from result since an integer index is not used to calculate the rolling window.

- **axis** [int or str, default 0]

- **closed** [str, default None] Make the interval closed on the ‘right’, ‘left’, ‘both’ or ‘neither’ endpoints. Defaults to ‘right’.
  
  Changed in version 1.2.0: The closed parameter with fixed windows is now supported.

- **method** [str {'single', 'table'}, default 'single'] Execute the rolling operation per single column or row ('single') or over the entire object ('table').
  
  This argument is only implemented when specifying engine='numba' in the method call.
  
  New in version 1.3.0.

**Returns**

- a Window or Rolling sub-classed for the particular operation

**See also:**

- **expanding** Provides expanding transformations.
- **ewm** Provides exponential weighted functions.
Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

To learn more about the offsets & frequency strings, please see this link.

If `win_type=None`, all points are evenly weighted; otherwise, `win_type` can accept a string of any `scipy.signal window function`.

Certain Scipy window types require additional parameters to be passed in the aggregation function. The additional parameters must match the keywords specified in the Scipy window type method signature. Please see the third example below on how to add the additional parameters.

Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
```
```
  B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

Rolling sum with a window length of 2, using the ‘triang’ window type.

```python
>>> df.rolling(2, win_type='triang').sum()
  B
0  NaN
1  0.5
2  1.5
3  NaN
4  NaN
```

Rolling sum with a window length of 2, using the ‘gaussian’ window type (note how we need to specify `std`).

```python
>>> df.rolling(2, win_type='gaussian').sum(std=3)
  B
0  NaN
1  0.986207
2  2.958621
3  NaN
4  NaN
```

Rolling sum with a window length of 2, min_periods defaults to the window length.

```python
>>> df.rolling(2).sum()
  B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN
```

Same as above, but explicitly set the min_periods
```python
>>> df.rolling(2, min_periods=1).sum()
   B
0  0.0  
1  1.0  
2  3.0  
3  2.0  
4  4.0  

Same as above, but with forward-looking windows

```df = pd.api.indexers.FixedForwardWindowIndexer(window_size=2)
``` >>> df.rolling(window=indexer, min_periods=1).sum()
   B
0  1.0  
1  3.0  
2  2.0  
3  4.0  
4  4.0  

A ragged (meaning not-a-regular frequency), time-indexed DataFrame

```python
def = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
                   index=[pd.Timestamp('20130101 09:00:00'),
                          pd.Timestamp('20130101 09:00:02'),
                          pd.Timestamp('20130101 09:00:03'),
                          pd.Timestamp('20130101 09:00:05'),
                          pd.Timestamp('20130101 09:00:06')])
``` >>> df
   B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0

Contrasting to an integer rolling window, this will roll a variable length window corresponding to the time period. The default for min_periods is 1.

```python
>>> df.rolling('2s').sum()
   B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```
pandas.DataFrame.round

**DataFrame.round**(decimals=0, *args, **kwargs)
Round a DataFrame to a variable number of decimal places.

**Parameters**

- *decimals* [int, dict, Series] Number of decimal places to round each column to. If an int is given, round each column to the same number of places. Otherwise dict and Series round to variable numbers of places. Column names should be in the keys if *decimals* is a dict-like, or in the index if *decimals* is a Series. Any columns not included in *decimals* will be left as is. Elements of *decimals* which are not columns of the input will be ignored.

- *args* Additional keywords have no effect but might be accepted for compatibility with numpy.

- **kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

**Returns**

DataFrame A DataFrame with the affected columns rounded to the specified number of decimal places.

**See also:**

- numpy.around Round a numpy array to the given number of decimals.
- Series.round Round a Series to the given number of decimals.

**Examples**

```python
>>> df = pd.DataFrame([(.21, .32), (.01, .67), (.66, .03), (.21, .18)],
                     columns=['dogs', 'cats'])
```

```text
   dogs  cats
0  0.21  0.32
1  0.01  0.67
2  0.66  0.03
3  0.21  0.18
```

By providing an integer each column is rounded to the same number of decimal places

```python
>>> df.round(1)
```

```text
   dogs  cats
0  0.2  0.3
1  0.0  0.7
2  0.7  0.0
3  0.2  0.2
```

With a dict, the number of places for specific columns can be specified with the column names as key and the number of decimal places as value

```python
>>> df.round({'dogs': 1, 'cats': 0})
```

```text
   dogs  cats
0  0.2  0.0
1  0.0  1.0
```

(continues on next page)
Using a Series, the number of places for specific columns can be specified with the column names as index and the number of decimal places as value

```python
>>> decimals = pd.Series([0, 1], index=['cats', 'dogs'])
>>> df.round(decimals)
     dogs  cats
0   0.2  0.0
1   0.0  1.0
2   0.7  0.0
3   0.2  0.0
```

**pandas.DataFrame.rpow**

```
pandas.DataFrame.rpow
```

DataFrame.\texttt{rpow}(other, axis='columns', level=None, fill_value=None)

Get Exponential power of dataframe and other, element-wise (binary operator \texttt{rpow}).
Equivalent to \texttt{other} ** dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, \texttt{pow}.

Among flexible wrappers (\texttt{add}, \texttt{sub}, \texttt{mul}, \texttt{div}, \texttt{mod}, \texttt{pow}) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame Result of the arithmetic operation.

See also:

- \texttt{DataFrame.add} Add DataFrames.
- \texttt{DataFrame.sub} Subtract DataFrames.
- \texttt{DataFrame.mul} Multiply DataFrames.
- \texttt{DataFrame.div} Divide DataFrames (float division).
- \texttt{DataFrame.truediv} Divide DataFrames (float division).
- \texttt{DataFrame.floordiv} Divide DataFrames (integer division).
- \texttt{DataFrame.mod} Calculate modulo (remainder after division).
- \texttt{DataFrame.pow} Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360],
...                     'index': ['circle', 'triangle', 'rectangle']})
```

```
  angles  degrees
circle   0  360
triangle 3  180
rectangle 4  360
```

Add a scalar with operator version which return the same results.

```
>>> df + 1
  angles  degrees
circle   1  361
triangle 4  181
rectangle 5  361
```

```
>>> df.add(1)
  angles  degrees
circle   1  361
triangle 4  181
rectangle 5  361
```

Divide by constant with reverse version.

```
>>> df.div(10)
  angles  degrees
circle  0.0  36.0
triangle 0.3  18.0
rectangle 0.4  36.0
```

```
>>> df.rdiv(10)
  angles  degrees
circle  inf  0.027778
triangle 3.333333  0.055556
rectangle 2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```
>>> df - [1, 2]
  angles  degrees
circle  -1  358
triangle  2  178
rectangle  3  358
```

```
>>> df.sub([1, 2], axis='columns')
  angles  degrees
circle  -1  358
triangle  2  178
rectangle  3  358
```

Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])
```

```plaintext
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0</td>
</tr>
<tr>
<td>triangle</td>
<td>3</td>
</tr>
<tr>

</tr>
</tbody>
</table>
```

---

3.4. DataFrame 1777
pandas.DataFrame.rsub

DataFrame.rsub(other, axis='columns', level=None, fill_value=None)

Get Subtraction of dataframe and other, element-wise (binary operator rsub).

Equivalent to other - dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, sub.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [0 or 'index', 1 or 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
    angles  degrees
circle    0      360
triangle   3      180
rectangle  4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
    angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

```python
>>> df.add(1)
    angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
    angles  degrees
circle   0.0    36.0
triangle 0.3    18.0
rectangle 0.4   36.0
```

```python
>>> df.rdiv(10)
    angles  degrees
circle  inf   0.0278
triangle   3.333  0.0556
rectangle  2.5   0.0278
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
    angles  degrees
circle   -1     358
triangle   2     178
rectangle  3     358
```

```python
>>> df.sub([1, 2], axis='columns')
    angles  degrees
circle   -1     358
triangle   2     178
rectangle  3     358
```

```python
>>> df.sub(pd.Series([1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
    angles  degrees
circle    -1     358
triangle   -1     178
rectangle  -1     358
```

(continues on next page)
Multiply a DataFrame of different shape with operator version.

```python
In [2]: other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])

In [3]: other
Out[3]:
   angles
circle   0
triangle  3
rectangle 4

In [4]: df * other
Out[4]:
   angles  degrees
circle   0       NaN
triangle  9       NaN
rectangle 16      NaN

In [5]: df.mul(other, fill_value=0)
Out[5]:
   angles  degrees
circle   0       0.0
triangle  9       0.0
rectangle 16      0.0
```

Divide by a MultiIndex by level.

```python
In [6]: df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               'index': ['A', 'A', 'A', 'B', 'B', 'B'],
                               'circle', 'triangle', 'rectangle',
                               'square', 'pentagon', 'hexagon']})

In [7]: df_multindex
Out[7]:
   angles  degrees
A  circle   0   360
    triangle 3   180
    rectangle 4   360
B  square  4   360
    pentagon  5   540
    hexagon  6   720

In [8]: df.div(df_multindex, level=1, fill_value=0)
Out[8]:
   angles  degrees
A  circle   NaN   1.0
    triangle 1.0   1.0
    rectangle 1.0   1.0
B  square  0.0   0.0
    pentagon  0.0   0.0
    hexagon  0.0   0.0
```
DataFrame.rtruediv

DataFrame\texttt{.rtruediv}(\textit{other}, \textit{axis}=\textquote{columns}, \textit{level}=\textit{None}, \textit{fill_value}=\textit{None})

Get Floating division of dataframe and other, element-wise (binary operator \texttt{rtruediv}).

Equivalent to \textit{other} / \textit{dataframe}, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, \texttt{truediv}.

Among flexible wrappers (\texttt{add}, \texttt{sub}, \texttt{mul}, \texttt{div}, \texttt{mod}, \texttt{pow}) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- \textit{other} [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- \textit{axis} [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- \textit{level} [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- \textit{fill_value} [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

- DataFrame Result of the arithmetic operation.

**See also:**

- \texttt{DataFrame.add} Add DataFrames.
- \texttt{DataFrame.sub} Subtract DataFrames.
- \texttt{DataFrame.mul} Multiply DataFrames.
- \texttt{DataFrame.div} Divide DataFrames (float division).
- \texttt{DataFrame.truediv} Divide DataFrames (float division).
- \texttt{DataFrame.floordiv} Divide DataFrames (integer division).
- \texttt{DataFrame.mod} Calculate modulo (remainder after division).
- \texttt{DataFrame.pow} Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])

>>> df

<table>
<thead>
<tr>
<th></th>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0</td>
<td>360</td>
</tr>
<tr>
<td>triangle</td>
<td>3</td>
<td>180</td>
</tr>
<tr>
<td>rectangle</td>
<td>4</td>
<td>360</td>
</tr>
</tbody>
</table>
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1

<table>
<thead>
<tr>
<th></th>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
<td>361</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
<td>181</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
<td>361</td>
</tr>
</tbody>
</table>
```

```python
>>> df.add(1)

<table>
<thead>
<tr>
<th></th>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
<td>361</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
<td>181</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
<td>361</td>
</tr>
</tbody>
</table>
```

Divide by constant with reverse version.

```python
>>> df.div(10)

<table>
<thead>
<tr>
<th></th>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0</td>
<td>36.0</td>
</tr>
<tr>
<td>triangle</td>
<td>0.3</td>
<td>18.0</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.4</td>
<td>36.0</td>
</tr>
</tbody>
</table>
```

```python
>>> df.rdiv(10)

<table>
<thead>
<tr>
<th></th>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>inf</td>
<td>0.027778</td>
</tr>
<tr>
<td>triangle</td>
<td>3.333333</td>
<td>0.055556</td>
</tr>
<tr>
<td>rectangle</td>
<td>2.500000</td>
<td>0.027778</td>
</tr>
</tbody>
</table>
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]

<table>
<thead>
<tr>
<th></th>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
<td>358</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
<td>178</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
<td>358</td>
</tr>
</tbody>
</table>
```

```python
>>> df.sub([1, 2], axis='columns')

<table>
<thead>
<tr>
<th></th>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
<td>358</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
<td>178</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
<td>358</td>
</tr>
</tbody>
</table>
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')

<table>
<thead>
<tr>
<th></th>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
<td>358</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
<td>178</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
<td>358</td>
</tr>
</tbody>
</table>
```

(continues on next page)
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                         index=['circle', 'triangle', 'rectangle'])
>>> other
      angles
circle    0
triangle   3
rectangle  4
```

```python
>>> df * other
     angles  degrees
   circle    0       NaN
  triangle   9       NaN
 rectangle 16       NaN
```

```python
>>> df.mul(other, fill_value=0)
     angles  degrees
   circle    0       0.0
  triangle   9       0.0
 rectangle 16       0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                              'degrees': [360, 180, 360, 360, 540, 720],
                              index=['A', 'A', 'A', 'B', 'B', 'B'],
                              ['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon'])
>>> df_multindex
      angles  degrees
     A circle    0   360
triangle    3  180
 rectangle   4  360
     B square    4  360
     pentagon   5  540
 hexagon     6  720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
     angles  degrees
  A circle  NaN       1.0
   triangle 1.0       1.0
     rectangle 1.0  1.0
  B square  0.0       0.0
     pentagon 0.0       0.0
      hexagon 0.0       0.0
```
DataFrame.sample

DataFrame.sample(n=None, frac=None, replace=False, weights=None, random_state=None, axis=None, ignore_index=False)

Return a random sample of items from an axis of object.

You can use random_state for reproducibility.

Parameters

- **n**: [int, optional] Number of items from axis to return. Cannot be used with frac. Default = 1 if frac = None.
- **frac**: [float, optional] Fraction of axis items to return. Cannot be used with n.
- **replace**: [bool, default False] Allow or disallow sampling of the same row more than once.
- **weights**: [str or ndarray-like, optional] Default ‘None’ results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when axis = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.
- **random_state**: [int, array-like, BitGenerator, np.random.RandomState, optional] If int, array-like, or BitGenerator (NumPy>=1.17), seed for random number generator. If np.random.RandomState, use as numpy RandomState object.

Changed in version 1.1.0: array-like and BitGenerator (for NumPy>=1.17) object now passed to np.random.RandomState() as seed
- **axis**: [{0 or ‘index’, 1 or ‘columns’, None}, default None] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames).
- **ignore_index**: [bool, default False] If True, the resulting index will be labeled 0, 1, ..., n - 1.

Returns

- **Series or DataFrame** A new object of same type as caller containing n items randomly sampled from the caller object.

See also:

- DataFrameGroupBy.sample Generates random samples from each group of a DataFrame object.
- SeriesGroupBy.sample Generates random samples from each group of a Series object.
- numpy.random.choice Generates a random sample from a given 1-D numpy array.
Notes

If $\frac{\text{frac}}{1}$, replacement should be set to True.

Examples

```python
>>> df = pd.DataFrame({'num_legs': [2, 4, 8, 0],
...    'num_wings': [2, 0, 0, 0],
...    'num_specimen_seen': [10, 2, 1, 8],
...    index=['falcon', 'dog', 'spider', 'fish'])
>>> df
    num_legs num_wings num_specimen_seen
falcon    2        2              10
dog       4        0              2
spider    8        0              1
fish      0        0              8
```

Extract 3 random elements from the Series df['num_legs']: Note that we use random_state to ensure the reproducibility of the examples.

```python
>>> df['num_legs'].sample(n=3, random_state=1)
fish 0
spider 8
falcon 2
Name: num_legs, dtype: int64
```

A random 50% sample of the DataFrame with replacement:

```python
>>> df.sample(frac=0.5, replace=True, random_state=1)
    num_legs num_wings num_specimen_seen
dog    4        0              2
fish   0        0              8
```

An upsample sample of the DataFrame with replacement: Note that replace parameter has to be True for frac parameter > 1.

```python
>>> df.sample(frac=2, replace=True, random_state=1)
    num_legs num_wings num_specimen_seen
dog    4        0              2
fish   0        0              8
falcon 2        2              10
fish   0        0              8
dog    4        0              2
fish   0        0              8
dog    4        0              2
```

Using a DataFrame column as weights. Rows with larger value in the num_specimen_seen column are more likely to be sampled.

```python
>>> df.sample(n=2, weights='num_specimen_seen', random_state=1)
    num_legs num_wings num_specimen_seen
falcon    2        2              10
fish      0        0              8
```
pandas.DataFrame.select_dtypes

DataFrame.select_dtypes(include=None, exclude=None)
Return a subset of the DataFrame’s columns based on the column dtypes.

Parameters

include, exclude [scalar or list-like] A selection of dtypes or strings to be included/excluded. At least one of these parameters must be supplied.

Returns

DataFrame The subset of the frame including the dtypes in include and excluding the dtypes in exclude.

Raises

ValueError

• If both of include and exclude are empty
• If include and exclude have overlapping elements
• If any kind of string dtype is passed in.

See also:

DataFrame.dtypes Return Series with the data type of each column.

Notes

• To select all numeric types, use np.number or 'number'
• To select strings you must use the object dtype, but note that this will return all object dtype columns
• See the numpy dtype hierarchy
• To select datetimes, use np.datetime64, 'datetime' or 'datetime64'
• To select timedeltas, use np.timedelta64, 'timedelta' or 'timedelta64'
• To select Pandas categorical dtypes, use 'category'
• To select Pandas datetimetz dtypes, use 'datetimetz' (new in 0.20.0) or 'datetime64[ns, tz]'

Examples

```python
def = pd.DataFrame({'a': [1, 2] * 3,
... 'b': [True, False] * 3,
... 'c': [1.0, 2.0] * 3})
def
    a   b   c
0  1   True  1.0
1  2   False 2.0
2  1   True  1.0
3  2   False 2.0
4  1   True  1.0
5  2   False 2.0
```
```python
>>> df.select_dtypes(include='bool')
b
0   True
1   False
2    True
3    False
4    True
5    False

>>> df.select_dtypes(include=['float64'])
c
0    1.0
1    2.0
2    1.0
3    2.0
4    1.0
5    2.0

>>> df.select_dtypes(exclude=['int64'])
   b   c
0   True  1.0
1    False  2.0
2     True  1.0
3    False  2.0
4     True  1.0
5    False  2.0
```

**pandas.DataFrame.sem**

`DataFrame.sem(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)`  
Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

**Parameters**

- **axis**  
  [(index (0), columns (1))]

- **skipna**  
  [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

- **level**  
  [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

- **ddof**  
  [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

- **numeric_only**  
  [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

Series or DataFrame (if level specified)
Notes

To have the same behaviour as `numpy.std`, use `ddof=0` (instead of the default `ddof=1`)

**pandas.DataFrame.set_axis**

*DataFrame.set_axis*(labels, axis=0, inplace=False)

Assign desired index to given axis.

Indexes for column or row labels can be changed by assigning a list-like or Index.

**Parameters**

- **labels** [list-like, Index] The values for the new index.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to update. The value 0 identifies the rows, and 1 identifies the columns.
- **inplace** [bool, default False] Whether to return a new DataFrame instance.

**Returns**

- **renamed** [DataFrame or None] An object of type DataFrame or None if inplace=True.

**See also:**

*DataFrame.rename_axis* Alter the name of the index or columns.

**Examples**

```python
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```

Change the row labels.

```python
>>> df.set_axis(['a', 'b', 'c'], axis='index')
    A   B
   a 1  4
   b 2  5
   c 3  6
```

Change the column labels.

```python
>>> df.set_axis(['I', 'II'], axis='columns')
   I  II
  0 1  4
  1 2  5
  2 3  6
```

Now, update the labels inplace.

```python
>>> df.set_axis(['i', 'ii'], axis='columns', inplace=True)
```

```python
>>> df
   i  ii
  0 1  4
  1 2  5
  2 3  6
```
pandas.DataFrame.set_flags

**DataFrame.set_flags(***, copy=False, allows_duplicate_labels=None)**
Return a new object with updated flags.

**Parameters**

- **allows_duplicate_labels** [bool, optional] Whether the returned object allows duplicate labels.

**Returns**

- **Series or DataFrame** The same type as the caller.

**See also:**

- **DataFrame.attrs** Global metadata applying to this dataset.
- **DataFrame.flags** Global flags applying to this object.

**Notes**

This method returns a new object that’s a view on the same data as the input. Mutating the input or the output values will be reflected in the other.

This method is intended to be used in method chains.

“Flags” differ from “metadata”. Flags reflect properties of the pandas object (the Series or DataFrame). Metadata refer to properties of the dataset, and should be stored in DataFrame.attrs.

**Examples**

```python
>>> df = pd.DataFrame({"A": [1, 2]})
>>> df.flags.allows_duplicate_labels
True
>>> df2 = df.set_flags(allows_duplicate_labels=False)
>>> df2.flags.allows_duplicate_labels
False
```

pandas.DataFrame.set_index

**DataFrame.set_index(***, keys, drop=True, append=False, inplace=False, verify_integrity=False)**
Set the DataFrame index using existing columns.

Set the DataFrame index (row labels) using one or more existing columns or arrays (of the correct length). The index can replace the existing index or expand on it.

**Parameters**

- **keys** [label or array-like or list of labels/arrays] This parameter can be either a single column key, a single array of the same length as the calling DataFrame, or a list containing an arbitrary combination of column keys and arrays. Here, “array” encompasses Series, Index, np.ndarray, and instances of Iterator.

- **drop** [bool, default True] Delete columns to be used as the new index.

- **append** [bool, default False] Whether to append columns to existing index.
 inplace  [bool, default False] If True, modifies the DataFrame in place (do not create a new object).
 verify_integrity  [bool, default False] Check the new index for duplicates. Otherwise defer the check until necessary. Setting to False will improve the performance of this method.

 Returns

 DataFrame or None  Changed row labels or None if inplace=True.

 See also:

 DataFrame.reset_index  Opposite of set_index.
 DataFrame.reindex  Change to new indices or expand indices.
 DataFrame.reindex_like  Change to same indices as other DataFrame.

 Examples

 >>> df = pd.DataFrame({'month': [1, 4, 7, 10],
 ... 'year': [2012, 2014, 2013, 2014],
 ... 'sale': [55, 40, 84, 31]})
 >>> df
 month  year  sale
 0  1  2012  55
 1  4  2014  40
 2  7  2013  84
 3 10  2014  31

 Set the index to become the ‘month’ column:

 >>> df.set_index('month')
 year  sale
 month
 1  2012  55
 4  2014  40
 7  2013  84
10  2014  31

 Create a MultiIndex using columns ‘year’ and ‘month’:

 >>> df.set_index(['year', 'month'])
 sale
 year  month
 2012  1  55
2014  4  40
2013  7  84
2014 10  31

 Create a MultiIndex using an Index and a column:

 >>> df.set_index([pd.Index([1, 2, 3, 4]), 'year'])
 month  sale
 year
 1  2012  55
2  2014  4  40

 (continues on next page)
Create a MultiIndex using two Series:

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> df.set_index([s, s**2])
   month  year  sale
1   1   2012   55
2   4   2014   40
3   9   2013   84
4  16   2014   31
```

**pandas.DataFrame.shift**

`DataFrame.shift(periods=1`, `freq=None`, `axis=0`, `fill_value=<no_default>)`

Shift index by desired number of periods with an optional time `freq`.

When `freq` is not passed, shift the index without realigning the data. If `freq` is passed (in this case, the index must be date or datetime, or it will raise a `NotImplementedError`), the index will be increased using the periods and the `freq`. `freq` can be inferred when specified as “infer” as long as either `freq` or `inferred_freq` attribute is set in the index.

**Parameters**

- `periods` [int] Number of periods to shift. Can be positive or negative.
- `freq` [DateOffset, tseries.offsets, timedelta, or str, optional] Offset to use from the tseries module or time rule (e.g. ‘EOM’). If `freq` is specified then the index values are shifted but the data is not realigned. That is, use `freq` if you would like to extend the index when shifting and preserve the original data. If `freq` is specified as “infer” then it will be inferred from the `freq` or `inferred_freq` attributes of the index. If neither of those attributes exist, a `ValueError` is thrown.
- `axis` [[0 or ‘index’, 1 or ‘columns’, None], default None] Shift direction.
- `fill_value` [object, optional] The scalar value to use for newly introduced missing values. The default depends on the dtype of `self`. For numeric data, `np.nan` is used. For datetime, timedelta, or period data, etc. `NaT` is used. For extension dtypes, `self.dtype.na_value` is used.

Changed in version 1.1.0.

**Returns**

- `DataFrame` Copy of input object, shifted.

See also:

- `Index.shift` Shift values of Index.
- `DatetimeIndex.shift` Shift values of DatetimeIndex.
- `PeriodIndex.shift` Shift values of PeriodIndex.
- `tshift` Shift the time index, using the index’s frequency if available.
### Examples

```python
>>> df = pd.DataFrame(
    {
        "Col1": [10, 20, 15, 30, 45],
        "Col2": [13, 23, 18, 33, 48],
        "Col3": [17, 27, 22, 37, 52],
    },
    index=pd.date_range("2020-01-01", "2020-01-05")
)
```

```plaintext

</table>
```
DataFrame.skew

```
DataFrame.skew(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
```

Return unbiased skew over requested axis. Normalized by N-1.

**Parameters**

- **axis** \[\{index (0), columns (1)\}\] Axis for the function to be applied on.
- **skipna** \[bool, default True\] Exclude NA/null values when computing the result.
- **level** \[int or level name, default None\] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **numeric_only** \[bool, default None\] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- ****kwargs: Additional keyword arguments to be passed to the function.

**Returns**

Series or DataFrame (if level specified)

DataFrame.slice_shift

```
DataFrame.slice_shift(periods=1, axis=0)
```

Equivalent to `shift` without copying data. The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

Deprecated since version 1.2.0: slice_shift is deprecated, use DataFrame/Series.shift instead.

**Parameters**

- **periods** \[int\] Number of periods to move, can be positive or negative.

**Returns**

_shifted_ [same type as caller]

**Notes**

While the `slice_shift` is faster than `shift`, you may pay for it later during alignment.

DataFrame.sort_index

```
DataFrame.sort_index(axis=0, level=None, ascending=True, inplace=False, kind='quicksort',
na_position='last', sort_remaining=True, ignore_index=False, key=None)
```

Sort object by labels (along an axis).

Returns a new DataFrame sorted by label if `inplace` argument is False, otherwise updates the original DataFrame and returns None.

**Parameters**

- **axis** \[\{0 or ‘index’, 1 or ‘columns’\}, default 0\] The axis along which to sort. The value 0 identifies the rows, and 1 identifies the columns.
level [int or level name or list of ints or list of level names] If not None, sort on values in specified index level(s).

ascending [bool or list-like of bools, default True] Sort ascending vs. descending. When the index is a MultiIndex the sort direction can be controlled for each level individually.

inplace [bool, default False] If True, perform operation in-place.

kind [{‘quicksort’, ‘mergesort’, ‘heapsort’, ‘stable’}, default ‘quicksort’] Choice of sorting algorithm. See also numpy.sort() for more information. mergesort and stable are the only stable algorithms. For DataFrames, this option is only applied when sorting on a single column or label.

na_position [{‘first’, ‘last’}, default ‘last’] Puts NaNs at the beginning if first; last puts NaNs at the end. Not implemented for MultiIndex.

sort_remaining [bool, default True] If True and sorting by level and index is multi-level, sort by other levels too (in order) after sorting by specified level.

ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

key [callable, optional] If not None, apply the key function to the index values before sorting. This is similar to the key argument in the builtin sorted() function, with the notable difference that this key function should be vectorized. It should expect an Index and return an Index of the same shape. For MultiIndex inputs, the key is applied per level.

New in version 1.1.0.

Returns

DataFrame or None The original DataFrame sorted by the labels or None if inplace=True.

See also:

Series.sort_index Sort Series by the index.
DataFrame.sort_values Sort DataFrame by the value.
Series.sort_values Sort Series by the value.

Examples

```python
>>> df = pd.DataFrame([1, 2, 3, 4, 5], index=[100, 29, 234, 1, 150],
columns=['A'])
>>> df.sort_index()
   A
1  4
29 2
100 1
150 5
234 3
```

By default, it sorts in ascending order, to sort in descending order, use ascending=False
A key function can be specified which is applied to the index before sorting. For a MultiIndex this is applied to each level separately.

```python
>>> df = pd.DataFrame({'a': [1, 2, 3, 4]}, index=['A', 'b', 'C', 'd'])
>>> df.sort_index(key=lambda x: x.str.lower())
a  
A 1  
b 2  
C 3  
d 4  
```

### pandas.DataFrame.sort_values

DataFrame.sort_values(by, axis=0, ascending=True, inplace=False, kind='quicksort', na_position='last', ignore_index=False, key=None)

Sort by the values along either axis.

**Parameters**

- **by** [str or list of str] Name or list of names to sort by.
  - if `axis` is 0 or `index` then `by` may contain index levels and/or column labels.
  - if `axis` is 1 or `columns` then `by` may contain column levels and/or index labels.
- **axis** [{0 or 'index', 1 or 'columns'}, default 0] Axis to be sorted.
- **ascending** [bool or list of bool, default True] Sort ascending vs. descending. Specify list for multiple sort orders. If this is a list of bools, must match the length of the by.
- **inplace** [bool, default False] If True, perform operation in-place.
- **kind** [{‘quicksort’, ‘mergesort’, ‘heapsort’, ‘stable’}, default ‘quicksort’] Choice of sorting algorithm. See also numpy.sort() for more information. mergesort and stable are the only stable algorithms. For DataFrames, this option is only applied when sorting on a single column or label.
- **na_position** [{‘first’, ‘last’}, default ‘last’] Puts NaNs at the beginning if first; last puts NaNs at the end.
- **ignore_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.
  - New in version 1.0.0.
- **key** [callable, optional] Apply the key function to the values before sorting. This is similar to the key argument in the builtin sorted() function, with the notable difference that this key function should be vectorized. It should expect a Series and return a Series with the same shape as the input. It will be applied to each column in by independently.

3.4. DataFrame
New in version 1.1.0.

Returns

DataFrame or None DataFrame with sorted values or None if inplace=True.

See also:

DataFrame.sort_index Sort a DataFrame by the index.

Series.sort_values Similar method for a Series.

Examples

```py
>>> df = pd.DataFrame({
...     'col1': ['A', 'A', 'B', np.nan, 'D', 'C'],
...     'col2': [2, 1, 9, 8, 7, 4],
...     'col3': [0, 1, 9, 4, 2, 3],
...     'col4': ['a', 'B', 'c', 'D', 'e', 'F']
... })
```

```
>>> df
   col1  col2  col3  col4
0     A    2     0    a
1     A    1     1    B
2     B    9     9    c
3  NaN    8     4    D
4     D    7     2    e
5     C    4     3    F
```

Sort by col1

```py
>>> df.sort_values(by=['col1'])
```

```
   col1  col2  col3  col4
0     A    2     0    a
1     A    1     1    B
2     B    9     9    c
3  NaN    8     4    D
4     D    7     2    e
5     C    4     3    F
```

Sort by multiple columns

```py
>>> df.sort_values(by=['col1', 'col2'])
```

```
   col1  col2  col3  col4
1     A    1     1    B
0     A    2     0    a
2     B    9     9    c
5     C    4     3    F
4     D    7     2    e
3  NaN    8     4    D
```

Sort Descending

```py
>>> df.sort_values(by='col1', ascending=False)
```

```
col1  col2  col3  col4
4     D    7     2    e
5     C    4     3    F
2     B    9     9    c
```
Putting NAs first

```python
>>> df.sort_values(by='col1', ascending=False, na_position='first')
col1  col2  col3  col4
3   NaN  8  4  D
4   D  7  2  e
5   C  4  3  F
2   B  9  9  c
0   A  2  0  a
1   A  1  1  B
```

Sorting with a key function

```python
>>> df.sort_values(by='col4', key=lambda col: col.str.lower())
col1  col2  col3  col4
0   A  2  0  a
1   A  1  1  B
2   B  9  9  c
3   NaN  8  4  D
4   D  7  2  e
5   C  4  3  F
```

Natural sort with the key argument, using the natsort <https://github.com/SethMMorton/natsort> package.

```python
>>> df = pd.DataFrame({
...     "time": ['0hr', '128hr', '72hr', '48hr', '96hr'],
...     "value": [10, 20, 30, 40, 50]
... })
>>> df
   time  value
0  0hr    10
1 128hr   20
2  72hr   30
3  48hr   40
4  96hr   50
>>> from natsort import index_natsorted
>>> df.sort_values(
...     by="time",
...     key=lambda x: np.argsort(index_natsorted(df["time"])))
   time  value
0  0hr    10
3  48hr   40
2  72hr   30
4  96hr   50
1 128hr   20
pandas: powerful Python data analysis toolkit, Release 1.3.2

**pandas.DataFrame.sparse**

DataFrame.sparse()  
DataFrame accessor for sparse data.  
New in version 0.25.0.

**pandas.DataFrame.squeeze**

DataFrame.squeeze(axis=None)  
Squeeze 1 dimensional axis objects into scalars.  
Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.

This method is most useful when you don’t know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call squeeze to ensure you have a Series.

**Parameters**

axis [{0 or ‘index’, 1 or ‘columns’, None}, default None] A specific axis to squeeze.
By default, all length-1 axes are squeezed.

**Returns**

DataFrame, Series, or scalar The projection after squeezing axis or all the axes.

**See also:**

* Series.iloc * Integer-location based indexing for selecting scalars.
* DataFrame.iloc * Integer-location based indexing for selecting Series.
* Series.to_frame * Inverse of DataFrame.squeeze for a single-column DataFrame.

**Examples**

```python
>>> primes = pd.Series([2, 3, 5, 7])
Slicing might produce a Series with a single value:

```n```n```n```n
```python
>>> even_primes = primes[primes % 2 == 0]
>>> even_primes
0    2
dtype: int64

```n```n```n```n
```python
>>> even_primes.squeeze()
2

Squeezing objects with more than one value in every axis does nothing:

```n```n```n```n
```python
>>> odd_primes = primes[primes % 2 == 1]
>>> odd_primes
  1    3
  2    5
  3    7
dtype: int64

```n```n```n```n
1798 Chapter 3. API reference
Squeezing is even more effective when used with DataFrames.

```
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
>>> df
   a b
0 1 2
1 3 4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```
>>> df_a = df['a']
>>> df_a
   a
0 1
1 3
```

So the columns can be squeezed down, resulting in a Series:

```
>>> df_a.squeeze('columns')
0 1
1 3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```
>>> df_0a = df.loc[df.index < 1, ['a']]
>>> df_0a
   a
0 1
```

Squeezing the rows produces a single scalar Series:

```
>>> df_0a.squeeze('rows')
a 1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```
>>> df_0a.squeeze()
1
```
pandas.DataFrame.stack

DataFrame.stack(level=-1, dropna=True)
Stack the prescribed level(s) from columns to index.

Return a reshaped DataFrame or Series having a multi-level index with one or more new inner-most levels compared to the current DataFrame. The new inner-most levels are created by pivoting the columns of the current dataframe:

• if the columns have a single level, the output is a Series;

• if the columns have multiple levels, the new index level(s) is (are) taken from the prescribed level(s) and the output is a DataFrame.

Parameters

level [int, str, list, default -1] Level(s) to stack from the column axis onto the index axis, defined as one index or label, or a list of indices or labels.

dropna [bool, default True] Whether to drop rows in the resulting Frame/Series with missing values. Stacking a column level onto the index axis can create combinations of index and column values that are missing from the original dataframe. See Examples section.

Returns

DataFrame or Series  Stacked dataframe or series.

See also:

DataFrame.unstack  Unstack prescribed level(s) from index axis onto column axis.
DataFrame.pivot  Reshape dataframe from long format to wide format.
DataFrame.pivot_table  Create a spreadsheet-style pivot table as a DataFrame.

Notes

The function is named by analogy with a collection of books being reorganized from being side by side on a horizontal position (the columns of the dataframe) to being stacked vertically on top of each other (in the index of the dataframe).

Examples

Single level columns

>>> df_single_level_cols = pd.DataFrame([[0, 1], [2, 3]],
    index=['cat', 'dog'],
    columns=['weight', 'height'])

Stacking a dataframe with a single level column axis returns a Series:

>>> df_single_level_cols
   weight  height
  cat     0      1
  dog     2      3

(continues on next page)
Multi level columns: simple case

```python
>>> multicoll = pd.MultiIndex.from_tuples([("weight", 'kg'),
... ('weight', 'pounds')])
>>> df_multi_level_cols1 = pd.DataFrame([[1, 2], [2, 4]],
... index=['cat', 'dog'],
... columns=multicoll)
```

Stacking a dataframe with a multi-level column axis:

```python
>>> df_multi_level_cols1
weight
      kg      pounds
cat    1       2
dog    2       4
```

```python
>>> df_multi_level_cols1.stack()
    weight
height
  kg  cat  1
       pounds  2
  dog  kg  2
       pounds  4
```

Missing values

```python
>>> multicoll2 = pd.MultiIndex.from_tuples([("weight", 'kg'),
... ('height', 'm')])
>>> df_multi_level_cols2 = pd.DataFrame([[1.0, 2.0], [3.0, 4.0]],
... index=['cat', 'dog'],
... columns=multicoll2)
```

It is common to have missing values when stacking a dataframe with multi-level columns, as the stacked dataframe typically has more values than the original dataframe. Missing values are filled with NaNs:

```python
>>> df_multi_level_cols2
weight height
  kg  m
cat  1.0  2.0
dog  3.0  4.0
```

```python
>>> df_multi_level_cols2.stack()
    height
weight
  kg  cat  NaN  1.0
       m    2.0  NaN
  dog  kg  NaN  3.0
       m    4.0  NaN
```

Prescribing the level(s) to be stacked

The first parameter controls which level or levels are stacked:

```python
>>> df_multi_level_cols2.stack(0)
    kg  m
height
cat NaN  1.0
  m  2.0  NaN
dog NaN  3.0
  m  4.0  NaN
```
cat height NaN 2.0
weight 1.0 NaN
dog height NaN 4.0
weight 3.0 NaN

```python
>>> df_multi_level_cols2.stack([0, 1])
cat height m 2.0
   weight kg 1.0
dog height m 4.0
   weight kg 3.0
dtype: float64
```

Dropping missing values

```python
>>> df_multi_level_cols3 = pd.DataFrame([[None, 1.0], [2.0, 3.0]],
   index=['cat', 'dog'],
   columns=multicol2)
```

Note that rows where all values are missing are dropped by default but this behaviour can be controlled via the dropna keyword parameter:

```python
>>> df_multi_level_cols3
weight height
kg m
cat NaN 1.0
dog 2.0 3.0

>>> df_multi_level_cols3.stack(dropna=False)
height weight
kg NaN NaN
cat NaN NaN
m 1.0 NaN
dog NaN NaN
m 3.0 NaN

>>> df_multi_level_cols3.stack(dropna=True)
height weight
kg NaN NaN
cat NaN NaN
m 1.0 NaN
dog NaN NaN
m 3.0 NaN
```

pandas.DataFrame.std

DataFrame.std(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)

Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument.

Parameters

- **axis** [{index (0), columns (1)}]
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

Series or DataFrame (if level specified)

Notes

To have the same behaviour as numpy.std, use ddof=0 (instead of the default ddof=1)

pandas.DataFrame.sub

DataFrame.sub (other, axis='columns', level=None, fill_value=None)
Get Subtraction of dataframe and other, element-wise (binary operator sub).
Equivalent to dataframe - other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rsub.
Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.
Notes

Mismatches indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
... 'degrees': [360, 180, 360],
... index=['circle', 'triangle', 'rectangle'])

>>> df
     angles  degrees
circle     0      360
triangle    3      180
rectangle   4      360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
    angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```
Multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({'angles': [0, 3, 4]},
                     index=['circle', 'triangle', 'rectangle'])

other
```

```
angles
circle 0
triangle 3
rectangle 4
```

```python
df + other
```

```
angles degrees
circle 0 NaN
triangle 9 NaN
rectangle 16 NaN
```

```python
df.mul(other, fill_value=0)
```

```
angles degrees
circle 0 0.0
triangle 9 0.0
rectangle 16 0.0
```

Divide by a MultiIndex by level.

```python
df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                             'degrees': [360, 180, 360, 360, 540, 720],
                             index=['A', 'A', 'A', 'B', 'B', 'B'],
                             ['circle', 'triangle', 'rectangle',
                             'square', 'pentagon', 'hexagon'])

```

```
angles degrees
A circle 0 360
triangle 3 180
rectangle 4 360
B square 4 360
pentagon 5 540
hexagon 6 720
```

```python
df.div(df_multindex, level=1, fill_value=0)
```

```
angles degrees
A circle NaN 1.0
triangle 1.0 1.0
rectangle 1.0 1.0
B square 0.0 0.0
pentagon 0.0 0.0
hexagon 0.0 0.0
```
pandas: powerful Python data analysis toolkit, Release 1.3.2

**pandas.DataFrame.subtract**

`DataFrame.subtract(other, axis='columns', level=None, fill_value=None)`

Get Subtraction of dataframe and other, element-wise (binary operator `sub`).

Equivalent to `dataframe - other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `rsub`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

- **DataFrame** Result of the arithmetic operation.

**See also:**

- `DataFrame.add` Add DataFrames.
- `DataFrame.sub` Subtract DataFrames.
- `DataFrame.mul` Multiply DataFrames.
- `DataFrame.div` Divide DataFrames (float division).
- `DataFrame.truediv` Divide DataFrames (float division).
- `DataFrame.floordiv` Divide DataFrames (integer division).
- `DataFrame.mod` Calculate modulo (remainder after division).
- `DataFrame.pow` Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    index=['circle', 'triangle', 'rectangle'])
```

```
angles  degrees
----  ------
circle    0  360
triangle  3  180
rectangle 4  360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```

```
angles  degrees
----  ------
circle    1  361
triangle  4  181
rectangle 5  361
```

```python
>>> df.add(1)
```

```
angles  degrees
----  ------
circle    1  361
triangle  4  181
rectangle 5  361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
```

```
angles  degrees
----  ------
circle 0.0  36.0
triangle 0.3  18.0
rectangle 0.4  36.0
```

```python
>>> df.rdiv(10)
```

```
angles  degrees
----  -------
circle  inf  0.027778
triangle 3.333333  0.055556
rectangle 2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
```

```
angles  degrees
----  ------
circle -1  358
triangle 2  178
rectangle 3  358
```

```python
>>> df.sub([1, 2], axis='columns')
```

```
angles  degrees
----  ------
circle -1  358
triangle 2  178
rectangle 3  358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
```

(continues on next page)
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4],
                         'degrees': [360, 180, 360],
                         'index': ['circle', 'triangle', 'rectangle']})
>>> other
angles  degrees
circle  0      360
triangle 3 180
rectangle 4 360

>>> df * other
angles  degrees
circle   0   NaN
triangle 9   NaN
rectangle 16  NaN

>>> df.mul(other, fill_value=0)
angles  degrees
circle   0   0.0
triangle 9   0.0
rectangle 16  0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               'index': ['A', 'A', 'A', 'B', 'B', 'B']})
>>> df_multindex
angles  degrees
A circle 0      360
triangle 3 180
rectangle 4 360
B square 4 360
pentagon 5 540
hexagon 6 720

>>> df.div(df_multindex, level=1, fill_value=0)
angles  degrees
A circle  NaN   1.0
triangle 1.0  1.0
rectangle 1.0  1.0
B square 0.0  0.0
pentagon 0.0  0.0
hexagon 0.0  0.0
```
DataFrame.sum

DataFrame.sum(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)

Return the sum of the values over the requested axis.

This is equivalent to the method numpy.sum.

Parameters

- **axis** [{index (0), columns (1)}] Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **min_count** [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.
- **kwargs** Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

- Series.sum Return the sum.
- Series.min Return the minimum.
- Series.max Return the maximum.
- Series.idxmin Return the index of the minimum.
- Series.idxmax Return the index of the maximum.
- DataFrame.sum Return the sum over the requested axis.
- DataFrame.min Return the minimum over the requested axis.
- DataFrame.max Return the maximum over the requested axis.
- DataFrame.idxmin Return the index of the minimum over the requested axis.
- DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

```python
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
cold      spider
            0
            8
            4
```

(continues on next page)
By default, the sum of an empty or all-NA Series is 0.

```python
>>> pd.Series([], dtype="float64").sum() # min_count=0 is the default
0.0
```

This can be controlled with the `min_count` parameter. For example, if you’d like the sum of an empty series to be NaN, pass `min_count=1`.

```python
>>> pd.Series([], dtype="float64").sum(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).sum()
0.0
```

```python
>>> pd.Series([np.nan]).sum(min_count=1)
nan
```

**pandas.DataFrame.swapaxes**

DataFrame.swapaxes (axis1, axis2, copy=True)
Interchange axes and swap values axes appropriately.

Returns
y [same as input]

**pandas.DataFrame.swaplevel**

DataFrame.swaplevel (i=-2, j=-1, axis=0)
Swap levels i and j in a MultiIndex.
Default is to swap the two innermost levels of the index.

Parameters
i, j [int or str] Levels of the indices to be swapped. Can pass level name as string.
axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to swap levels on. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.

Returns
DataFrame  DataFrame with levels swapped in MultiIndex.
Examples

```python
>>> df = pd.DataFrame(
...     {
...         "Grade": ["A", "B", "A", "C"],
...     },
...     index=[
...         ["Final exam", "Final exam", "Coursework", "Coursework"],
...         ["History", "Geography", "History", "Geography"],
...         ["January", "February", "March", "April"]
...     },
... )
```

In the following example, we will swap the levels of the indices. Here, we will swap the levels column-wise, but levels can be swapped row-wise in a similar manner. Note that column-wise is the default behaviour. By not supplying any arguments for i and j, we swap the last and second to last indices.

```python
>>> df.swaplevel()
```

By supplying one argument, we can choose which index to swap the last index with. We can for example swap the first index with the last one as follows.

```python
>>> df.swaplevel(0)
```

We can also define explicitly which indices we want to swap by supplying values for both i and j. Here, we for example swap the first and second indices.

```python
>>> df.swaplevel(0, 1)
```
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.DataFrame.tail

DataFrame.tail\( (n=5) \)

Return the last \( n \) rows.

This function returns last \( n \) rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

For negative values of \( n \), this function returns all rows except the first \( n \) rows, equivalent to \( df[n:] \).

**Parameters**

- \( n \) [int, default 5] Number of rows to select.

**Returns**

- type of caller  The last \( n \) rows of the caller object.

**See also:**

- **DataFrame.head**  The first \( n \) rows of the caller object.

**Examples**

```python
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion', ...
'monkey', 'parrot', 'shark', 'whale', 'zebra']})
```

Viewing the last 5 lines

```python
>>> df.tail()
  animal
0  alligator
1       bee
2    falcon
3      lion
4   monkey
5    parrot
6     shark
7    whale
8    zebra
```

Viewing the last \( n \) lines (three in this case)

```python
>>> df.tail(3)
  animal
6    shark
7    whale
8    zebra
```

For negative values of \( n \)
pandas.DataFrame.take

DataFrame.take(indices, axis=0, is_copy=None, **kwargs)

Return the elements in the given positional indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

Parameters

- indices [array-like] An array of ints indicating which positions to take.
- axis [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.
- is_copy [bool] Before pandas 1.0, is_copy=False can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, take always returns a copy, and the keyword is therefore deprecated.

Deprecated since version 1.0.0.

**kwargs For compatibility with numpy.take(). Has no effect on the output.

Returns

- taken [same type as caller] An array-like containing the elements taken from the object.

See also:

- DataFrame.loc Select a subset of a DataFrame by labels.
- DataFrame.iloc Select a subset of a DataFrame by positions.
- numpy.take Take elements from an array along an axis.

Examples

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
                     ('parrot', 'bird', 24.0),
                     ('lion', 'mammal', 80.5),
                     ('monkey', 'mammal', np.nan)],
                    columns=['name', 'class', 'max_speed'],
                    index=[0, 2, 3, 1])
>>> df
   name  class max_speed
0   falcon   bird    389.0
2  parrot   bird      24.0
3    lion  mammal      80.5
1 monkey  mammal       NaN
```
Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That’s because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```python
>>> df.take([0, 3])
   name   class  max_speed
0  falcon   bird     389.0
1   monkey  mammal   NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```python
>>> df.take([1, 2], axis=1)
   class  max_speed
0     bird      389.0
1     bird      24.0
2  mammal      80.5
3  mammal        NaN
```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```python
>>> df.take([-1, -2])
   name   class  max_speed
1   monkey  mammal   NaN
3    lion  mammal     80.5
```

**pandas.DataFrame.to_dict**

`DataFrame.to_dict(orient='dict', into=<class 'dict'>)`

Convert the DataFrame to a dictionary.

The type of the key-value pairs can be customized with the parameters (see below).

**Parameters**

- **orient** [str {'dict', 'list', 'series', 'split', 'records', 'index'}] Determines the type of the values of the dictionary.
  - ‘dict’ (default) : dict like {column -> {index -> value}}
  - ‘list’ : dict like {column -> [values]}
  - ‘series’ : dict like {column -> Series(values)}
  - ‘split’ : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
  - ‘records’ : list like [{column -> value}, . . . , {column -> value}]
  - ‘index’ : dict like {index -> {column -> value}}

Abbreviations are allowed. s indicates `series` and sp indicates `split`.

- **into** [class, default dict] The collections.abc.Mapping subclass used for all Mappings in the return value. Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

**Returns**
dict, list or collections.abc.Mapping  Return a collections.abc.Mapping object representing the DataFrame. The resulting transformation depends on the orient parameter.

See also:

DataFrame.from_dict  Create a DataFrame from a dictionary.

DataFrame.to_json  Convert a DataFrame to JSON format.

Examples

```python
>>> df = pd.DataFrame({'col1': [1, 2],
                       'col2': [0.5, 0.75]},
                       index=['row1', 'row2'])
>>> df
col1  col2
row1   1  0.50
row2   2  0.75
>>> df.to_dict()
{'col1': {'row1': 1, 'row2': 2}, 'col2': {'row1': 0.5, 'row2': 0.75}}

You can specify the return orientation.

```python
>>> df.to_dict('series')
{'col1': row1 1
row2 2
Name: col1, dtype: int64,
'col2': row1 0.50
row2 0.75
Name: col2, dtype: float64}
``` 

```python
>>> df.to_dict('split')
{'index': ['row1', 'row2'], 'columns': ['col1', 'col2'],
'data': [[1, 0.5], [2, 0.75]]}
``` 

```python
>>> df.to_dict('records')
[{'col1': 1, 'col2': 0.5}, {'col1': 2, 'col2': 0.75}]
``` 

```python
>>> df.to_dict('index')
{'row1': {'col1': 1, 'col2': 0.5}, 'row2': {'col1': 2, 'col2': 0.75}}
``` 

You can also specify the mapping type.

```python
>>> from collections import OrderedDict, defaultdict
``` 

```python
>>> df.to_dict('series', into=OrderedDict)
OrderedDict([('col1', OrderedDict([('row1', 1), ('row2', 2)])),
('col2', OrderedDict([('row1', 0.5), ('row2', 0.75)]))])
``` 

If you want a defaultdict, you need to initialize it:

```python
>>> dd = defaultdict(list)
>>> df.to_dict('records', into=dd)
[defaultdict(<class 'list'>, {'col1': 1, 'col2': 0.5}),
defaultdict(<class 'list'>, {'col1': 2, 'col2': 0.75})]
```
DataFrame.to_gbq

DataFrame.to_gbq(destination_table, project_id=None, chunksize=None, reauth=False, if_exists='fail', auth_local_webserver=False, table_schema=None, location=None, progress_bar=True, credentials=None)

Write a DataFrame to a Google BigQuery table.

This function requires the pandas-gbq package.

See the How to authenticate with Google BigQuery guide for authentication instructions.

Parameters

- **destination_table** [str] Name of table to be written, in the form dataset.tablename.
- **project_id** [str, optional] Google BigQuery Account project ID. Optional when available from the environment.
- **chunksize** [int, optional] Number of rows to be inserted in each chunk from the dataframe. Set to None to load the whole dataframe at once.
- **reauth** [bool, default False] Force Google BigQuery to re-authenticate the user. This is useful if multiple accounts are used.
- **if_exists** [str, default 'fail'] Behavior when the destination table exists. Value can be one of:
  - 'fail' If table exists raise pandas_gbq.gbq.TableCreationError.
  - 'replace' If table exists, drop it, recreate it, and insert data.
  - 'append' If table exists, insert data. Create if does not exist.
- **auth_local_webserver** [bool, default False] Use the local webserver flow instead of the console flow when getting user credentials.
  - *New in version 0.2.0 of pandas-gbq.*
- **table_schema** [list of dicts, optional] List of BigQuery table fields to which according DataFrame columns conform to, e.g. [{'name': 'col1', 'type': 'STRING'}, ...]. If schema is not provided, it will be generated according to dtypes of DataFrame columns. See BigQuery API documentation on available names of a field.
  - *New in version 0.3.1 of pandas-gbq.*
- **location** [str, optional] Location where the load job should run. See the BigQuery locations documentation for a list of available locations. The location must match that of the target dataset.
  - *New in version 0.5.0 of pandas-gbq.*
- **progress_bar** [bool, default True] Use the library tqdm to show the progress bar for the upload, chunk by chunk.
  - *New in version 0.5.0 of pandas-gbq.*
- **credentials** [google.auth.credentials.Credentials, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine google.auth.compute_engine.Credentials or Service Account google.oauth2.service_account.Credentials directly.
New in version 0.8.0 of pandas-gbq.

See also:

- pandas_gbq.to_gbq  This function in the pandas-gbq library.
- read_gbq Read a DataFrame from Google BigQuery.

pandas.DataFrame.to_hdf

DataFrame.to_hdf(path_or_buf, key, mode='a', complevel=None, complib=None, append=False, format=None, index=True, min_itemsize=None, nan_rep=None, dropna=None, data_columns=None, errors='strict', encoding='UTF-8')

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different key.

**Warning:** One can store a subclass of DataFrame or Series to HDF5, but the type of the subclass is lost upon storing.

For more information see the user guide.

**Parameters**

**path_or_buf** [str or pandas.HDFStore] File path or HDFStore object.

**key** [str] Identifier for the group in the store.

**mode** [{'a', 'w', 'r+'}, default 'a'] Mode to open file:
- 'w': write, a new file is created (an existing file with the same name would be deleted).
- 'a': append, an existing file is opened for reading and writing, and if the file does not exist it is created.
- 'r+': similar to 'a', but the file must already exist.

**complevel** [{0-9}, optional] Specifies a compression level for data. A value of 0 disables compression.

**complib** [{'zlib', 'lzo', 'bzip2', 'blosc'}, default 'zlib'] Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: ‘blosc:blosclz’): {'blosc:blosclz', 'blosc:l4', 'blosc:lz4hc', 'blosc:snappy', 'blosc:zlib', 'blosc:zstd'}. Specifying a compression library which is not available issues a ValueError.

**append** [bool, default False] For Table formats, append the input data to the existing.

**format** [{'fixed', 'table', None}, default 'fixed'] Possible values:
• ‘table’: Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.

• If None, pd.get_option(‘io.hdf.default_format’) is checked, followed by fall-back to “fixed”

errors [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for open() for a full list of options.

encoding [str, default “UTF-8”]

min_itemsize [dict or int, optional] Map column names to minimum string sizes for columns.

data_columns [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See Query via data columns. Applicable only to format=’table’.

See also:

read_hdf Read from HDF file.

Dataframe.to_parquet Write a DataFrame to the binary parquet format.

Dataframe.to_sql Write to a SQL table.

Dataframe.to_feather Write out feather-format for DataFrames.

Dataframe.to_csv Write out to a csv file.

Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
                   index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')
```

We can add another object to the same file:

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```python
>>> pd.read_hdf('data.h5', 'df')
   A  B
a 1 4
b 2 5
c 3 6
>>> pd.read_hdf('data.h5', 's')
0 1
1 2
2 3
3 4
dtype: int64
```
Deleting file with data:

```python
>>> import os
>>> os.remove('data.h5')
```

**pandas.DataFrame.to_json**

DataFrame.to_json(path_or_buf=None, orient=None, date_format=None, double_precision=10, force_ascii=True, date_unit='ms', default_handler=None, compression='infer', index=True, indent=None, storage_options=None)

Convert the object to a JSON string.

Note NaN’s and None will be converted to null and datetime objects will be converted to UNIX timestamps.

**Parameters**

- **path_or_buf** [str or file handle, optional] File path or object. If not specified, the result is returned as a string.
- **orient** [str] Indication of expected JSON string format.
  - Series:
    - default is ‘index’
    - allowed values are: {'split', 'records', 'index', 'table'}.
  - DataFrame:
    - default is ‘columns’
    - allowed values are: {'split', 'records', 'index', 'columns', 'values', 'table'}.
  - The format of the JSON string:
    - ‘split’ : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> values}
    - ‘records’ : list like [{column -> value}, . . . , {column -> value}]
    - ‘index’ : dict like {index -> {column -> value}}
    - ‘columns’ : dict like {column -> {index -> value}}
    - ‘values’ : just the values array
    - ‘table’ : dict like {‘schema’: {schema}, ‘data’: {data}}
  - Describing the data, where data component is like orient='records'.
- **date_format** [{None, ‘epoch’, ‘iso’}] Type of date conversion. ‘epoch’ = epoch milliseconds, ‘iso’ = ISO8601. The default depends on the orient. For orient='table', the default is ‘iso’. For all other orients, the default is ‘epoch’.
- **double_precision** [int, default 10] The number of decimal places to use when encoding floating point values.
- **force_ascii** [bool, default True] Force encoded string to be ASCII.
**date_unit** [str, default ‘ms’ (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’, ‘ns’ for second, millisecond, microsecond, and nanosecond respectively.

**default_handler** [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

**lines** [bool, default False] If ‘orient’ is ‘records’ write out line-delimited json format. Will throw ValueError if incorrect ‘orient’ since others are not list-like.

**compression** [{'infer', 'gzip', 'bz2', 'zip', 'xz', None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

**index** [bool, default True] Whether to include the index values in the JSON string. Not including the index (index=False) is only supported when orient is ‘split’ or ‘table’.

**indent** [int, optional] Length of whitespace used to indent each record.

New in version 1.0.0.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

**Returns**

None or str If path_or_buf is None, returns the resulting json format as a string. Otherwise returns None.

**See also:**

**read_json** Convert a JSON string to pandas object.

**Notes**

The behavior of indent=0 varies from the stdlib, which does not indent the output but does insert newlines. Currently, indent=0 and the default indent=None are equivalent in pandas, though this may change in a future release.

orient='table' contains a ‘pandas_version’ field under ‘schema’. This stores the version of pandas used in the latest revision of the schema.
Examples

```python
>>> import json
>>> df = pd.DataFrame(
...     [['a', 'b'], ['c', 'd']],
...     index=['row 1', 'row 2'],
...     columns=['col 1', 'col 2'],
... )

>>> result = df.to_json(orient="split")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "columns": [
        "col 1",
        "col 2"
    ],
    "index": [
        "row 1",
        "row 2"
    ],
    "data": [
        ["a", "b"],
        ["c", "d"]
    ]
}

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```python
>>> result = df.to_json(orient="records")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[
    {"col 1": "a",
     "col 2": "b"},
    {"col 1": "c",
     "col 2": "d"}
]

Encoding/decoding a Dataframe using 'index' formatted JSON:

```python
>>> result = df.to_json(orient="index")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
"row 1": {
    "col 1": "a",
    "col 2": "b"
}
```

(continues on next page)
Encoding/decoding a Dataframe using 'columns' formatted JSON:

```
>>> result = df.to_json(orient="columns")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
  "col 1": {
    "row 1": "a",
    "row 2": "c"
  },
  "col 2": {
    "row 1": "b",
    "row 2": "d"
  }
}
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```
>>> result = df.to_json(orient="values")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[ [ "a", "b" ], [ "c", "d" ]
```

Encoding with Table Schema:

```
>>> result = df.to_json(orient="table")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{ "schema": {
    "fields": [
      {
        "name": "index",
        "type": "string"
      },
      {
        "name": "col 1",
        "type": "string"
      },
```
{  
  "name": "col 2",
  "type": "string"
}
"
"primaryKey": [  
  "index"
},
"pandas_version": "0.20.0"
],
"data": [  
  {  
    "index": "row 1",
    "col 1": "a",
    "col 2": "b"
  },
  {  
    "index": "row 2",
    "col 1": "c",
    "col 2": "d"
  }
]
}
Notes

Requires the tabulate package.

Examples

```python
>>> s = pd.Series(["elk", "pig", "dog", "quetzal"], name="animal")
>>> print(s.to_markdown())
<table>
<thead>
<tr>
<th></th>
<th>animal</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>elk</td>
</tr>
<tr>
<td>1</td>
<td>pig</td>
</tr>
<tr>
<td>2</td>
<td>dog</td>
</tr>
<tr>
<td>3</td>
<td>quetzal</td>
</tr>
</tbody>
</table>
```

Output markdown with a tabulate option.

```python
>>> print(s.to_markdown(tablefmt="grid"))
+-----+----------+    
| 0   | elk      |    
| 1   | pig      |    
| 2   | dog      |    
| 3   | quetzal  |    
```

pandas.DataFrame.to_numpy

DataFrame.to_numpy(dtype=None, copy=False, na_value=<no_default>)

Convert the DataFrame to a NumPy array.

By default, the dtype of the returned array will be the common NumPy dtype of all types in the DataFrame. For example, if the dtypes are float16 and float32, the results dtype will be float32. This may require copying data and coercing values, which may be expensive.

Parameters

dtype [str or numpy.dtype, optional] The dtype to pass to numpy.asarray().

copy [bool, default False] Whether to ensure that the returned value is not a view on another array. Note that copy=False does not ensure that to_numpy() is no-copy. Rather, copy=True ensure that a copy is made, even if not strictly necessary.

na_value [Any, optional] The value to use for missing values. The default value depends on dtype and the dtypes of the DataFrame columns.

New in version 1.1.0.

Returns

numpy.ndarray

See also:

numpy.ndarray
**Series.to_numpy**  Similar method for Series.

**Examples**

```python
def df = pd.DataFrame({"A": [1, 2], "B": [3, 4]})
def.to_numpy()
array([[1, 3],
       [2, 4]])
```

With heterogeneous data, the lowest common type will have to be used.

```python
def = pd.DataFrame({"A": [1, 2], "B": [3.0, 4.5]})
def.to_numpy()
array([[1. , 3. ],
       [2. , 4.5]])
```

For a mix of numeric and non-numeric types, the output array will have object dtype.

```python
def['C'] = pd.date_range('2000', periods=2)
def.to_numpy()
array([[1, 3.0, Timestamp('2000-01-01 00:00:00')],
       [2, 4.5, Timestamp('2000-01-02 00:00:00')]], dtype=object)
```

**pandas.DataFrame.to_period**

DataFrame.to_period(freq=None, axis=0, copy=True)

Convert DataFrame from DatetimeIndex to PeriodIndex.

Convert DataFrame from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).

**Parameters**

- **freq**  [str, default] Frequency of the PeriodIndex.
- **axis**  [{0 or 'index', 1 or 'columns'}, default 0] The axis to convert (the index by default).
- **copy**  [bool, default True] If False then underlying input data is not copied.

**Returns**

DataFrame with PeriodIndex

**pandas.DataFrame.to_records**

DataFrame.to_records(index=True, column_dtypes=None, index_dtypes=None)

Convert DataFrame to a NumPy record array.

Index will be included as the first field of the record array if requested.

**Parameters**

- **index**  [bool, default True] Include index in resulting record array, stored in ‘index’ field or using the index label, if set.
column_dtypes [str, type, dict, default None] If a string or type, the data type to store all columns. If a dictionary, a mapping of column names and indices (zero-indexed) to specific data types.

index_dtypes [str, type, dict, default None] If a string or type, the data type to store all index levels. If a dictionary, a mapping of index level names and indices (zero-indexed) to specific data types.

This mapping is applied only if index=True.

Returns

numpy.recarray NumPy ndarray with the DataFrame labels as fields and each row of the DataFrame as entries.

See also:

DataFrame.from_records Convert structured or record ndarray to DataFrame.

numpy.recarray An ndarray that allows field access using attributes, analogous to typed columns in a spreadsheet.

Examples

```python
>>> df = pd.DataFrame({'A': [1, 2], 'B': [0.5, 0.75]},
                   index=['a', 'b'])
>>> df
   A  B
a  1  0.50
b  2  0.75
>>> df.to_records()
rec.array([(a, 1, 0.5), (b, 2, 0.75)],
          dtype=[('index', 'O'), ('A', '<i8'), ('B', '<f8')])
```

If the DataFrame index has no label then the recarray field name is set to ‘index’. If the index has a label then this is used as the field name:

```python
>>> df.index = df.index.rename("I")
>>> df.to_records()
rec.array([(a, 1, 0.5), (b, 2, 0.75)],
          dtype=[('I', 'O'), ('A', '<i8'), ('B', '<f8')])
```

The index can be excluded from the record array:

```python
>>> df.to_records(index=False)
rec.array([(1, 0.5), (2, 0.75)],
          dtype=[('A', '<i8'), ('B', '<f8')])
```

Data types can be specified for the columns:

```python
>>> df.to_records(column_dtypes={"A": "int32"})
rec.array([(1, 0.5), (2, 0.75)],
          dtype=[('I', 'O'), ('A', '<i4'), ('B', '<f8')])
```

As well as for the index:
>>> df.to_records(index_dtypes="<S2")
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
dtype=[('I', 'S2'), ('A', '<i8'), ('B', '<f8')])

>>> index_dtypes = f"<S/df.index.str.len().max()/
>>> df.to_records(index_dtypes=index_dtypes)
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
dtype=[('I', 'S1'), ('A', '<i8'), ('B', '<f8')])

**pandas.DataFrame.to_string**

DataFrame.to_string(buf=None, columns=None, col_space=None, header=True, index=True,
na_rep='NaN', formatters=None, float_format=None, sparsify=None,
index_names=True, justify=None, max_rows=None, min_rows=None,
max_cols=None, show_dimensions=False, decimal='.', line_width=None,
max_colwidth=None, encoding=None)

Render a DataFrame to a console-friendly tabular output.

**Parameters**

- **buf** [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.
- **columns** [sequence, optional, default None] The subset of columns to write. Writes all columns by default.
- **col_space** [int, list or dict of int, optional] The minimum width of each column.
- **header** [bool or sequence, optional] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.
- **index** [bool, optional, default True] Whether to print index (row) labels.
- **na_rep** [str, optional, default ‘NaN’] String representation of NaN to use.
- **formatters** [list, tuple or dict of one-param. functions, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List/tuple must be of length equal to the number of columns.
- **float_format** [one-parameter function, optional, default None] Formatter function to apply to columns’ elements if they are floats. This function must return a unicode string and will be applied only to the non-NaN elements, with NaN being handled by na_rep.

  Changed in version 1.2.0.
- **sparsify** [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.
- **index_names** [bool, optional, default True] Prints the names of the indexes.
- **justify** [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by set_option), ‘right’ out of the box. Valid values are
  - left
  - right
  - center
• justify
• justify-all
• start
• end
• inherit
• match-parent
• initial
• unset.

**max_rows** [int, optional] Maximum number of rows to display in the console.

**min_rows** [int, optional] The number of rows to display in the console in a truncated repr (when number of rows is above max_rows).

**max_cols** [int, optional] Maximum number of columns to display in the console.

**show_dimensions** [bool, default False] Display DataFrame dimensions (number of rows by number of columns).

**decimal** [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

**line_width** [int, optional] Width to wrap a line in characters.

**max_colwidth** [int, optional] Max width to truncate each column in characters. By default, no limit.

New in version 1.0.0.

**encoding** [str, default “utf-8”] Set character encoding.

New in version 1.0.

**Returns**

**str or None** If buf is None, returns the result as a string. Otherwise returns None.

**See also:**

*to_html* Convert DataFrame to HTML.

**Examples**

```python
>>> d = {'col1': [1, 2, 3], 'col2': [4, 5, 6]}
>>> df = pd.DataFrame(d)
>>> print(df.to_string())
coll  col2
0   1   4
1   2   5
2   3   6
```
**pandas.DataFrame.to_timestamp**

**DataFrame.to_timestamp** *(freq=None, how='start', axis=0, copy=True)*

Cast to DatetimeIndex of timestamps, at *beginning* of period.

**Parameters**

- **freq** [str, default frequency of PeriodIndex] Desired frequency.
- **how** [{'s', 'e', 'start', 'end'}] Convention for converting period to timestamp; start of period vs. end.
- **axis** [0 or 'index', 1 or 'columns'], default 0] The axis to convert (the index by default).
- **copy** [bool, default True] If False then underlying input data is not copied.

**Returns**

DataFrame with DatetimeIndex

**pandas.DataFrame.to_xarray**

**DataFrame.to_xarray** ()

Return an xarray object from the pandas object.

**Returns**

*xarray.DataArray or xarray.Dataset* Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

**See also:**

- **DataFrame.to_hdf** Write DataFrame to an HDF5 file.
- **DataFrame.to_parquet** Write a DataFrame to the binary parquet format.

**Notes**

See the xarray docs

**Examples**

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0, 2),
...                     ('parrot', 'bird', 24.0, 2),
...                     ('lion', 'mammal', 80.5, 4),
...                     ('monkey', 'mammal', np.nan, 4)],
...                   columns=['name', 'class', 'max_speed', 'num_legs'])
>>> df
          name class  max_speed  num_legs
0     falcon  bird     389.0           2
1   parrot  bird      24.0           2
2        lion  mammal   80.5           4
3     monkey  mammal    NaN           4
```
>>> df.to_xarray()
<xarray.Dataset>
Dimensions:  (index: 4)
Coordinates:
  * index  (index) int64 0 1 2 3
Data variables:
  name  (index) object 'falcon' 'parrot' 'lion' 'monkey'
  class  (index) object 'bird' 'bird' 'mammal' 'mammal'
  max_speed  (index) float64 389.0 24.0 80.5 nan
  num_legs  (index) int64 2 2 4 4

>>> df['max_speed'].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389., 24., 80.5, nan])
Coordinates:
  * index  (index) int64 0 1 2 3

>>> dates = pd.to_datetime(['2018-01-01', '2018-01-01',
                         '2018-01-02', '2018-01-02'])
>>> df_multiindex = pd.DataFrame({'date': dates,
                  'animal': ['falcon', 'parrot',
                              'falcon', 'parrot'],
                  'speed': [350, 18, 361, 15]})
>>> df_multiindex = df_multiindex.set_index(['date', 'animal'])

>>> df_multiindex
   speed
date animal
2018-01-01 falcon   350
       parrot   18
2018-01-02 falcon   361
       parrot   15

>>> df_multiindex.to_xarray()
<xarray.Dataset>
Dimensions:  (animal: 2, date: 2)
Coordinates:
  * date  (date) datetime64[ns] 2018-01-01 2018-01-02
  * animal  (animal) object 'falcon' 'parrot'
Data variables:
  speed  (date, animal) int64 350 18 361 15

pandas.DataFrame.transform

DataFrame.transform(func, axis=0, *args, **kwargs)

Call func on self producing a DataFrame with transformed values.

Produced DataFrame will have same axis length as self.

Parameters

  func [function, str, list-like or dict-like] Function to use for transforming the data.
  If a function, must either work when passed a DataFrame or when passed to DataFrame.apply. If func is both list-like and dict-like, dict-like behavior takes precedence.
Accepted combinations are:

- function
- string function name
- list-like of functions and/or function names, e.g. [np.exp, 'sqrt']
- dict-like of axis labels -> functions, function names or list-like of such.

**axis** [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

*args Positional arguments to pass to func.

**kwargs Keyword arguments to pass to func.

Returns

DataFrame A DataFrame that must have the same length as self.

Raises

ValueError [If the returned DataFrame has a different length than self.]

See also:

*DataFrame.agg* Only perform aggregating type operations.

*DataFrame.apply* Invoke function on a DataFrame.

Notes

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

Examples

```python
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
   A  B
0  0  1
1  1  2
2  2  3
>>> df.transform(lambda x: x + 1)
   A  B
0  1  2
1  2  3
2  3  4
```

Even though the resulting DataFrame must have the same length as the input DataFrame, it is possible to provide several input functions:

```python
>>> s = pd.Series(range(3))
>>> s
0  0
1  1
2  2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
```

(continues on next page)
You can call transform on a GroupBy object:

```python
>>> df = pd.DataFrame({
...     "Data": [5, 8, 6, 1, 50, 100, 60, 120]
... })
>>> df
         Date  Data
0  2015-05-08    5
1  2015-05-07    8
2  2015-05-06    6
3  2015-05-05    1
4  2015-05-08   50
5  2015-05-07  100
6  2015-05-06   60
7  2015-05-05  120
```

```python
>>> df.groupby('Date')['Data'].transform('sum')
0    55
1   108
2    66
3   121
4    55
5   108
6    66
7   121
Name: Data, dtype: int64
```

```python
>>> df = pd.DataFrame({
...     "c": [1, 1, 1, 2, 2, 2, 2],
...     "type": ["m", "n", "o", "m", "m", "n", "n"]
... })
>>> df
   c  type
0  1   m
1  1   n
2  1   o
3  2   m
4  2   m
5  2   n
6  2   n
```

```python
>>> df['size'] = df.groupby('c')['type'].transform(len)
>>> df
   c  type size
0  1   m   3
1  1   n   3
2  1   o   3
3  2   m   4
4  2   m   4
5  2   n   4
6  2   n   4
```
pandas.DataFrame.transpose

DataFrame.transpose(*args, copy=False)
Transpose index and columns.

Reflect the DataFrame over its main diagonal by writing rows as columns and vice-versa. The property \( T \) is an accessor to the method \( \text{transpose}() \).

Parameters

*args [tuple, optional] Accepted for compatibility with NumPy.

- copy [bool, default False] Whether to copy the data after transposing, even for
  DataFrames with a single dtype.

  Note that a copy is always required for mixed dtype DataFrames, or for DataFrames
  with any extension types.

Returns

DataFrame The transposed DataFrame.

See also:

numpy.transpose Permute the dimensions of a given array.

Notes

Transposing a DataFrame with mixed dtypes will result in a homogeneous DataFrame with the \textit{object} dtype. In such a case, a copy of the data is always made.

Examples

Square DataFrame with homogeneous dtype

```python
>>> d1 = {'col1': [1, 2], 'col2': [3, 4]}
>>> df1 = pd.DataFrame(data=d1)
>>> df1
            col1  col2
0         1     3
1         2     4
```

```python
>>> df1_transposed = df1.T # or df1.transpose()
>>> df1_transposed
       0  1
col1  1  2
col2  3  4
```

When the dtype is homogeneous in the original DataFrame, we get a transposed DataFrame with the same dtype:

```python
>>> df1.dtypes
col1    int64
col2    int64
dtype: object
>>> df1_transposed.dtypes
0    int64
```

(continues on next page)
Non-square DataFrame with mixed dtypes

```python
>>> d2 = {'name': ['Alice', 'Bob'],
...       'score': [9.5, 8],
...       'employed': [False, True],
...       'kids': [0, 0]}
>>> df2 = pd.DataFrame(data=d2)
>>> df2
   name  score  employed  kids
0  Alice   9.5       False   0
1    Bob   8.0        True   0
```

```python
>>> df2_transposed = df2.T # or df2.transpose()
>>> df2_transposed
   0  1
name  Alice Bob
score  9.5   8.0
employed  False  True
kids       0   0
```

When the DataFrame has mixed dtypes, we get a transposed DataFrame with the `object` dtype:

```python
>>> df2.dtypes
name      object
score  float64
employed  bool
kids    int64
dtype: object
>>> df2_transposed.dtypes
0   object
1   object
dtype: object
```

**pandas.DataFrame.truediv**

DataFrame.truediv(other, axis='columns', level=None, fill_value=None)

Get Floating division of dataframe and other, element-wise (binary operator truediv).

Equivalent to dataframe / other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rtruediv.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [(0 or 'index', 1 or 'columns')] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    index=['circle', 'triangle', 'rectangle'])
```

```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0</td>
</tr>
<tr>
<td>triangle</td>
<td>3</td>
</tr>
<tr>
<td>rectangle</td>
<td>4</td>
</tr>
</tbody>
</table>
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```

```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
</tbody>
</table>
```

```python
>>> df.add(1)
```

```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
</tbody>
</table>
```

Divide by constant with reverse version.
Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
   angles  degrees
circle    -1     358
triangle     2     178
rectangle    3     358
```

```python
>>> df.sub([1, 2], axis='columns')
   angles  degrees
circle    -1     358
triangle     2     178
rectangle    3     358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
   angles  degrees
circle    -1     359
triangle     2     179
rectangle    3     359
```

Multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({'angles': [0, 3, 4]},
                     index=['circle', 'triangle', 'rectangle'])
```

```python
>>> df * other
   angles  degrees
circle    0     NaN
triangle    9     NaN
rectangle   16     NaN
```

```python
>>> df.mul(other, fill_value=0)
   angles  degrees
circle    0     0.0
triangle    9     0.0
rectangle   16     0.0
```

Divide by a MultiIndex by level.
```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...  'degrees': [360, 180, 360, 360, 540, 720],
...  index=['A', 'A', 'A', 'B', 'B', 'B'],
...  ['circle', 'triangle', 'rectangle',
...   'square', 'pentagon', 'hexagon']})

>>> df_multindex
   angles  degrees
  A   circle     0   360
       triangle   3   180
       rectangle  4   360
  B   square     4   360
       pentagon   5   540
       hexagon   6   720

>>> df.div(df_multindex, level=1, fill_value=0)
   angles  degrees
  A   circle  NaN  1.0
       triangle  1.0  1.0
       rectangle  1.0  1.0
  B   square  0.0  0.0
       pentagon  0.0  0.0
       hexagon  0.0  0.0
```

**pandas.DataFrame.truncate**

DataFrame.truncate(before=None, after=None, axis=None, copy=True)

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

**Parameters**

- **before** [date, str, int] Truncate all rows before this index value.
- **after** [date, str, int] Truncate all rows after this index value.
- **axis** [{0 or 'index', 1 or 'columns'}, optional] Axis to truncate. Truncates the index (rows) by default.
- **copy** [bool, default is True.] Return a copy of the truncated section.

**Returns**

- **type of caller** The truncated Series or DataFrame.

**See also:**

- **DataFrame.loc** Select a subset of a DataFrame by label.
- **DataFrame.iloc** Select a subset of a DataFrame by position.
Notes

If the index being truncated contains only datetime values, before and after may be specified as strings instead of Timestamps.

Examples

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
...                    'B': ['f', 'g', 'h', 'i', 'j'],
...                    'C': ['k', 'l', 'm', 'n', 'o']},
...                   index=[1, 2, 3, 4, 5])
>>> df
   A  B  C
0  a  f  k
1  b  g  l
2  c  h  m
3  d  i  n
4  e  j  o
```

```python
>>> df.truncate(before=2, after=4)
   A  B  C
0  b  g  l
1  c  h  m
2  d  i  n
```

The columns of a DataFrame can be truncated.

```python
>>> df.truncate(before="A", after="B", axis="columns")
   A  B
0  a  f
1  b  g
2  c  h
3  d  i
4  e  j
```

For Series, only rows can be truncated.

```python
>>> df['A'].truncate(before=2, after=4)
0  b
1  c
2  d
Name: A, dtype: object
```

The index values in truncate can be datetimes or string dates.

```python
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
     A
2016-01-31 23:59:56  1
2016-01-31 23:59:57  1
2016-01-31 23:59:58  1
2016-01-31 23:59:59  1
2016-02-01 00:00:00  1
```
Because the index is a DatetimeIndex containing only dates, we can specify `before` and `after` as strings. They will be coerced to Timestamps before truncation.

```
>>> df.truncate('2016-01-05', '2016-01-10').tail()
   A
2016-01-09 23:59:56 1
2016-01-09 23:59:57 1
2016-01-09 23:59:58 1
2016-01-09 23:59:59 1
2016-01-10 00:00:00 1
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
   A
2016-01-10 23:59:55 1
2016-01-10 23:59:56 1
2016-01-10 23:59:57 1
2016-01-10 23:59:58 1
2016-01-10 23:59:59 1
```

### pandas.DataFrame.tshift

`DataFrame.tshift` (*periods=1, freq=None, axis=0*)

Shift the time index, using the index’s frequency if available.

Deprecated since version 1.1.0: Use `shift` instead.

**Parameters**

- **periods** [int] Number of periods to move, can be positive or negative.
- **freq** [DateOffset, timedelta, or str, default None] Increment to use from the tseries module or time rule expressed as a string (e.g. ‘EOM’).
- **axis** [[0 or ‘index’, 1 or ‘columns’, None], default 0] Corresponds to the axis that contains the Index.

**Returns**

- **shifted** [Series/DataFrame]
Notes

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

pandas.DataFrame.tz_convert

DataFrame.tz_convert (tz, axis=0, level=None, copy=True)

Convert tz-aware axis to target time zone.

Parameters

tz [str or tzinfo object]
axis [the axis to convert]
level [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None.
copy [bool, default True] Also make a copy of the underlying data.

Returns

{klass} Object with time zone converted axis.

Raises

TypeError If the axis is tz-naive.

pandas.DataFrame.tz_localize

DataFrame.tz_localize (tz, axis=0, level=None, copy=True, ambiguous='raise', nonexistent='raise')

Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use Series.dt.tz_localize().

Parameters

tz [str or tzinfo]
axis [the axis to localize]
level [int, str, default None] If axis ia a MultiIndex, localize a specific level. Otherwise must be None.
copy [bool, default True] Also make a copy of the underlying data.
ambiguous [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the ambiguous parameter dictates how ambiguous times should be handled.

- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

**nonexistent** [str, default ‘raise’] A nonexistent time does not exist in a particular time-zone where clocks moved forward due to DST. Valid values are:

• ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
• ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
• ‘NaT’ will return NaT where there are nonexistent times
• timedelta objects will shift nonexistent times by the timedelta
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

**Returns**

Series or DataFrame  Same type as the input.

** Raises **

TypeError  If the TimeSeries is tz-aware and tz is not None.

**Examples**

Localize local times:

```python
>>> s = pd.Series([1],
... index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00 1
dtype: int64
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```python
>>> s = pd.Series(range(7),
... index=pd.DatetimeIndex(['2018-10-28 01:30:00',
... '2018-10-28 02:00:00',
... '2018-10-28 02:30:00',
... '2018-10-28 02:00:00',
... '2018-10-28 02:30:00',
... '2018-10-28 03:00:00',
... '2018-10-28 03:30:00'])))
>>> s.tz_localize('CET', ambiguous='infer')
2018-10-28 01:30:00+02:00 0
2018-10-28 02:00:00+02:00 1
2018-10-28 02:30:00+02:00 2
2018-10-28 02:00:00+01:00 3
2018-10-28 02:30:00+01:00 4
2018-10-28 03:00:00+01:00 5
2018-10-28 03:30:00+01:00 6
dtype: int64
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly
If the DST transition causes nonexistent times, you can shift these dates forward or backward with a timedelta object or 'shift_forward' or 'shift_backward'.

```python
g = pd.Series(range(2),
... index=pd.DatetimeIndex(['2015-03-29 02:30:00',
... '2015-03-29 03:30:00']))
g.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
2015-03-29 03:00:00+02:00 0
2015-03-29 03:30:00+02:00 1
dtype: int64

g.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
2015-03-29 01:59:59.999999999+01:00 0
2015-03-29 03:30:00+02:00 1
dtype: int64

g.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
2015-03-29 03:30:00+02:00 0
2015-03-29 03:30:00+02:00 1
dtype: int64
```

**pandas.DataFrame.unstack**

`DataFrame.unstack(level=-1, fill_value=None)`

Pivot a level of the (necessarily hierarchical) index labels.

Returns a DataFrame having a new level of column labels whose inner-most level consists of the pivoted index labels.

If the index is not a MultiIndex, the output will be a Series (the analogue of stack when the columns are not a MultiIndex).

**Parameters**

- **level** [int, str, or list of these, default -1 (last level)] Level(s) of index to unstack, can pass level name.
- **fill_value** [int, str or dict] Replace NaN with this value if the unstack produces missing values.

**Returns**

Series or DataFrame

See also:

- `DataFrame.pivot` Pivot a table based on column values.
- `DataFrame.stack` Pivot a level of the column labels (inverse operation from `unstack`).
Examples

```python
>>> index = pd.MultiIndex.from_tuples([
    ('one', 'a'), ('one', 'b'),
    ...,
    ('two', 'a'), ('two', 'b')
])

>>> s = pd.Series(np.arange(1.0, 5.0), index=index)

>>> s
one a 1.0
  b 2.0
two a 3.0
  b 4.0
dtype: float64

>>> s.unstack(level=-1)
     a  b
one 1.0 2.0
two 3.0 4.0

>>> s.unstack(level=0)
    one two
     a 1.0 3.0
     b 2.0 4.0

>>> df = s.unstack(level=0)

>>> df.unstack()
     one   two
     a 1.0 3.0
     b 2.0 4.0
dtype: float64
```

**pandas.DataFrame.update**

DataFrame.update(other, join='left', overwrite=True, filter_func=None, errors='ignore')

Modify in place using non-NA values from another DataFrame.

Aligns on indices. There is no return value.

**Parameters**

- **other** [DataFrame, or object coercible into a DataFrame] Should have at least one matching index/column label with the original DataFrame. If a Series is passed, its name attribute must be set, and that will be used as the column name to align with the original DataFrame.

- **join** [‘left’], default ‘left’] Only left join is implemented, keeping the index and columns of the original object.

- **overwrite** [bool, default True] How to handle non-NA values for overlapping keys:
  - True: overwrite original DataFrame’s values with values from other.
  - False: only update values that are NA in the original DataFrame.

- **filter_func** [callable(1d-array) -> bool 1d-array, optional] Can choose to replace values other than NA. Return True for values that should be updated.

- **errors** [‘raise’, ‘ignore’], default ‘ignore’] If ‘raise’, will raise a ValueError if the DataFrame and other both contain non-NA data in the same place.
Returns

None [method directly changes calling object]

Raises

ValueError

• When errors='raise' and there's overlapping non-NA data.

• When errors is not either 'ignore' or 'raise'

NotImplementedError

• If join != 'left'

See also:

dict.update Similar method for dictionaries.

DataFrame.merge For column(s)-on-column(s) operations.

Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3],
...     'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, 5, 6],
...     'C': [7, 8, 9]})
>>> df.update(new_df)
>>> df
   A  B   C
0  1  4
1  2  5
2  3  6
```

The DataFrame's length does not increase as a result of the update, only values at matching index/column labels are updated.

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...     'B': ['x', 'y', 'z']})
>>> new_df = pd.DataFrame({'B': ['d', 'e', 'f', 'g', 'h', 'i']})
>>> df.update(new_df)
>>> df
   A  B   C   D   E   F   G   H   I
0  a  d
1  b  e
2  c  f
```

For Series, its name attribute must be set.

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...     'B': ['x', 'y', 'z']})
>>> new_column = pd.Series(['d', 'e'], name='B', index=[0, 2])
>>> df.update(new_column)
>>> df
   A  B
0  a  d
1  b  y
2  c  e
```

(continues on next page)
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                   'B': ['x', 'y', 'z']})
>>> new_df = pd.DataFrame({'B': ['d', 'e']}, index=[1, 2])
>>> df.update(new_df)
>>> df
   A  B
0 a  x
1 b  d
2 c  e

If other contains NaNs the corresponding values are not updated in the original dataframe.

>>> df = pd.DataFrame({'A': [1, 2, 3],
...                    'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, np.nan, 6]})
>>> df.update(new_df)
>>> df
    A  B
 0  1  4.0
 1  2 500.0
 2  3   6.0

pandas.DataFrame.value_counts

DataFrame.value_counts(subset=None, normalize=False, sort=True, ascending=False, dropna=True)

Return a Series containing counts of unique rows in the DataFrame.

New in version 1.1.0.

Parameters

- **subset** [list-like, optional] Columns to use when counting unique combinations.
- **normalize** [bool, default False] Return proportions rather than frequencies.
- **sort** [bool, default True] Sort by frequencies.
- **ascending** [bool, default False] Sort in ascending order.
- **dropna** [bool, default True] Don’t include counts of rows that contain NA values.

New in version 1.3.0.

Returns

Series

See also:

Series.value_counts Equivalent method on Series.
Notes

The returned Series will have a MultiIndex with one level per input column. By default, rows that contain any NA values are omitted from the result. By default, the resulting Series will be in descending order so that the first element is the most frequently-occurring row.

Examples

```python
>>> df = pd.DataFrame({'num_legs': [2, 4, 4, 6],
...                   'num_wings': [2, 0, 0, 0],
...                   index=['falcon', 'dog', 'cat', 'ant'])
>>> df
   num_legs  num_wings
falcon     2          2
dog        4          0
cat        4          0
ant        6          0

>>> df.value_counts()
   num_legs  num_wings
4          0          2
2          2          1
6          0          1
dtype: int64

>>> df.value_counts(sort=False)
   num_legs  num_wings
2          2          1
4          0          2
6          0          1
dtype: int64

>>> df.value_counts(ascending=True)
   num_legs  num_wings
2          2          1
6          0          1
4          0          2
dtype: int64

>>> df.value_counts(normalize=True)
   num_legs  num_wings
4          0          0.50
2          2          0.25
6          0          0.25
dtype: float64

With dropna set to False we can also count rows with NA values.

```
pandas.DataFrame.var

DataFrame.var (axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)
Return unbiased variance over requested axis.

Parameters

- **axis** [{index (0), columns (1)}]
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

Series or DataFrame (if level specified)

Notes

To have the same behaviour as numpy.std, use ddof=0 (instead of the default ddof=1)
pandas.DataFrame.where

DataFrame.where (cond, other=nan, inplace=False, axis=None, level=None, errors='raise',
                    try_cast=<no_default>)

Replace values where the condition is False.

Parameters

cond [bool Series/DataFrame, array-like, or callable] Where cond is True, keep the
      original value. Where False, replace with corresponding value from other. If cond
      is callable, it is computed on the Series/DataFrame and should return boolean Se-
      ries/DataFrame or array. The callable must not change input Series/DataFrame
      (though pandas doesn’t check it).

other [scalar, Series/DataFrame, or callable] Entries where cond is False are replaced
      with corresponding value from other. If other is callable, it is computed on the
      Series/DataFrame and should return scalar or Series/DataFrame. The callable must
      not change input Series/DataFrame (though pandas doesn’t check it).

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won’t
      affect the results and will always coerce to a suitable dtype.
      • ‘raise’ : allow exceptions to be raised.
      • ‘ignore’ : suppress exceptions. On error return original object.

try_cast [bool, default None] Try to cast the result back to the input type (if possible).

    Deprecated since version 1.3.0: Manually cast back if necessary.

Returns

Same type as caller or None if inplace=True.

See also:

DataFrame.mask () Return an object of same shape as self.

Notes

The where method is an application of the if-then idiom. For each element in the calling DataFrame, if
cond is True the element is used; otherwise the corresponding element from the DataFrame other is
used.

The signature for DataFrame.where () differs from numpy.where (). Roughly df1.where (m,
df2) is equivalent to np.where (m, df1, df2).

For further details and examples see the where documentation in indexing.
Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64

>>> s.mask(s > 0)
0   0.0
1  NaN
2  NaN
3  NaN
4  NaN
dtype: float64

>>> s.where(s > 1, 10)
0  10
1  10
2   2
3   3
4   4
dtype: int64

>>> s.mask(s > 1, 10)
0  0
1  1
2  10
3  10
4  10
dtype: int64

>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9

>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9

>>> df.where(m, -df) == np.where(m, df, -df)
   A  B
0  True True
1  True True
2  True True
3  True True
4  True True

>>> df.where(m, -df) == df.mask(~m, -df)
```

(continues on next page)
DataFrame.xs

DataFrame.xs(key, axis=0, level=None, drop_level=True)
Return cross-section from the Series/DataFrame.
This method takes a key argument to select data at a particular level of a MultiIndex.

Parameters
- key [label or tuple of label] Label contained in the index, or partially in a MultiIndex.
- axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis to retrieve cross-section on.
- level [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.
- drop_level [bool, default True] If False, returns object with same levels as self.

Returns
- Series or DataFrame Cross-section from the original Series or DataFrame corresponding to the selected index levels.

See also:
- DataFrame.loc Access a group of rows and columns by label(s) or a boolean array.
- DataFrame.iloc Purely integer-location based indexing for selection by position.

Notes

xs can not be used to set values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of xs functionality, see MultiIndex Slicers.

Examples

```python
>>> d = {'num_legs': [4, 4, 2, 2],
...      'num_wings': [0, 0, 2, 2],
...      'class': ['mammal', 'mammal', 'mammal', 'bird'],
...      'animal': ['cat', 'dog', 'bat', 'penguin'],
...      'locomotion': ['walks', 'walks', 'flies', 'walks']}
>>> df = pd.DataFrame(data=d)
>>> df = df.set_index(['class', 'animal', 'locomotion'])
```

(continues on next page)
class animal locomotion
mammal cat walks 4 0
dog walks 4 0
bat flies 2 2
bird penguin walks 2 2

Get values at specified index

```python
>>> df.xs('mammal')
animal locomotion  num_legs  num_wings
                    cat walks 4 0
dog walks 4 0
bat flies 2 2
```

Get values at several indexes

```python
>>> df.xs(('mammal', 'dog'))
locomotion  num_legs  num_wings
walks 4 0
```

Get values at specified index and level

```python
>>> df.xs('cat', level=1)
class locomotion  num_legs  num_wings
mammal walks 4 0
```

Get values at several indexes and levels

```python
>>> df.xs(('bird', 'walks'), level=[0, 'locomotion'])
animal penguin 2 2
```

Get values at specified column and axis

```python
>>> df.xs('num_wings', axis=1)
class animal locomotion
mammal cat walks 0
dog walks 0
bat flies 2
bird penguin walks 2
Name: num_wings, dtype: int64

</tbody>
</table>

### 3.4.6 Function application, GroupBy & window

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame.apply(func[, axis, raw, ...])</td>
<td>Apply a function along an axis of the DataFrame.</td>
</tr>
<tr>
<td>DataFrame.applymap(func[, na_action])</td>
<td>Apply a function to a Dataframe elementwise.</td>
</tr>
<tr>
<td>DataFrame.pipe(func, *args, **kwargs)</td>
<td>Apply func(self, *args, **kwargs).</td>
</tr>
<tr>
<td>DataFrame.agg([func, axis])</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>DataFrame.aggregate([func, axis])</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>DataFrame.transform(func[, axis])</td>
<td>Call func on self producing a DataFrame with transformed values.</td>
</tr>
<tr>
<td>DataFrame.groupby([by, axis, level, ...])</td>
<td>Group DataFrame using a mapper or by a Series of columns.</td>
</tr>
<tr>
<td>DataFrame.rolling(window[, min_periods, ...])</td>
<td>Provide rolling window calculations.</td>
</tr>
<tr>
<td>DataFrame.expanding([min_periods, center, ...])</td>
<td>Provide expanding transformations.</td>
</tr>
<tr>
<td>DataFrame.ewm([com, span, halflife, alpha, ...])</td>
<td>Provide exponential weighted (EW) functions.</td>
</tr>
</tbody>
</table>
3.4.7 Computations / descriptive stats

- `DataFrame.abs()`: Return a Series/DataFrame with absolute numeric value of each element.
- `DataFrame.all([axis, bool_only, skipna, level])`: Return whether all elements are True, potentially over an axis.
- `DataFrame.any([axis, bool_only, skipna, level])`: Return whether any element is True, potentially over an axis.
- `DataFrame.clip([lower, upper, axis, inplace])`: Trim values at input threshold(s).
- `DataFrame.corr([method, min_periods])`: Compute pairwise correlation of columns, excluding NA/null values.
- `DataFrame.corrwith(other[, axis, drop, method])`: Compute pairwise correlation.
- `DataFrame.count([axis, level, numeric_only])`: Count non-NA cells for each column or row.
- `DataFrame.cov([min_periods, ddof])`: Compute pairwise covariance of columns, excluding NA/null values.
- `DataFrame.cummax([axis, skipna])`: Return cumulative maximum over a DataFrame or Series axis.
- `DataFrame.cummin([axis, skipna])`: Return cumulative minimum over a DataFrame or Series axis.
- `DataFrame.cumprod([axis, skipna])`: Return cumulative product over a DataFrame or Series axis.
- `DataFrame.cumsum([axis, skipna])`: Return cumulative sum over a DataFrame or Series axis.
- `DataFrame.describe([percentiles, include, ...])`: Generate descriptive statistics.
- `DataFrame.eval(expr[, inplace])`: Evaluate a string describing operations on DataFrame columns.
- `DataFrame.kurt([axis, skipna, level, ...])`: Return unbiased kurtosis over requested axis.
- `DataFrame.kurtosis([axis, skipna, level, ...])`: Return unbiased kurtosis over requested axis.
- `DataFrame.mad([axis, skipna, level])`: Return the mean absolute deviation of the values over the requested axis.
- `DataFrame.max([axis, skipna, level, ...])`: Return the maximum of the values over the requested axis.
- `DataFrame.mean([axis, skipna, level, ...])`: Return the mean of the values over the requested axis.
- `DataFrame.median([axis, skipna, level, ...])`: Return the median of the values over the requested axis.
- `DataFrame.min([axis, skipna, level, ...])`: Return the minimum of the values over the requested axis.
- `DataFrame.mode([axis, numeric_only, dropna])`: Get the mode(s) of each element along the selected axis.
- `DataFrame.pct_change([periods, fill_method, ...])`: Percentage change between the current and a prior element.
- `DataFrame.prod([axis, skipna, level, ...])`: Return the product of the values over the requested axis.
- `DataFrame.product([axis, skipna, level, ...])`: Return the product of the values over the requested axis.
- `DataFrame.quantile([q, axis, numeric_only, ...])`: Return values at the given quantile over requested axis.
- `DataFrame.rank([axis, method, numeric_only, ...])`: Compute numerical data ranks (1 through n) along axis.
- `DataFrame.round([decimals])`: Round a DataFrame to a variable number of decimal places.
- `DataFrame.sem([axis, skipna, level, ddof, ...])`: Return unbiased standard error of the mean over requested axis.
- `DataFrame.skew([axis, skipna, level, ...])`: Return unbiased skew over requested axis.
- `DataFrame.sum([axis, skipna, level, ...])`: Return the sum of the values over the requested axis.

<td><code>DataFrame.align(other[, join, axis, level, ...])</code></td>
<td>Align two objects on their axes with the specified join method.</td>
</tr>
<tr>
<td><code>DataFrame.at_time(time[, asof, axis])</code></td>
<td>Select values at particular time of day (e.g., 9:30AM).</td>
</tr>
<tr>
<td><code>DataFrame.between_time(start_time, end_time)</code></td>
<td>Select values between particular times of the day (e.g., 9:00-9:30 AM).</td>
</tr>
<tr>
<td><code>DataFrame.drop([labels, axis, index, ...])</code></td>
<td>Drop specified labels from rows or columns.</td>
</tr>
<tr>
<td><code>DataFrame.drop_duplicates([subset, keep, ...])</code></td>
<td>Return DataFrame with duplicate rows removed.</td>
</tr>
<tr>
<td><code>DataFrame.duplicated([subset, keep])</code></td>
<td>Return boolean Series denoting duplicate rows.</td>
</tr>
<tr>
<td><code>DataFrame.equals(other)</code></td>
<td>Test whether two objects contain the same elements.</td>
</tr>
<tr>
<td><code>DataFrame.filter([items, like, regex, axis])</code></td>
<td>Subset the dataframe rows or columns according to the specified index labels.</td>
</tr>
<tr>
<td><code>DataFrame.first(offset)</code></td>
<td>Select initial periods of time series data based on a date offset.</td>
</tr>
<tr>
<td><code>DataFrame.head([n])</code></td>
<td>Return the first n rows.</td>
</tr>
<tr>
<td><code>DataFrame.idxmax([axis, skipna])</code></td>
<td>Return index of first occurrence of maximum over requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.idxmin([axis, skipna])</code></td>
<td>Return index of first occurrence of minimum over requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.last(offset)</code></td>
<td>Select final periods of time series data based on a date offset.</td>

3.4.10 Reshaping, sorting, transposing

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame.droplevel</td>
<td>Return Series/DataFrame with requested index / column level(s) removed.</td>
</tr>
<tr>
<td>DataFrame.pivot</td>
<td>Return reshaped DataFrame organized by given index / column values.</td>
</tr>
<tr>
<td>DataFrame.pivot_table</td>
<td>Create a spreadsheet-style pivot table as a DataFrame.</td>
</tr>
<tr>
<td>DataFrame.reorder_levels</td>
<td>Rearrange index levels using input order.</td>
</tr>
<tr>
<td>DataFrame.sort_values</td>
<td>Sort by the values along either axis.</td>
</tr>
<tr>
<td>DataFrame.sort_index</td>
<td>Sort object by labels (along an axis).</td>
</tr>
<tr>
<td>DataFrame.nlargest</td>
<td>Return the first n rows ordered by columns in descending order.</td>
</tr>
<tr>
<td>DataFrame.nsmallest</td>
<td>Return the first n rows ordered by columns in ascending order.</td>
</tr>
<tr>
<td>DataFrame.swaplevel</td>
<td>Swap levels i and j in a MultiIndex.</td>
</tr>
<tr>
<td>DataFrame.stack</td>
<td>Stack the prescribed level(s) from columns to index.</td>
</tr>
<tr>
<td>DataFrame.unstack</td>
<td>Pivot a level of the (necessarily hierarchical) index labels.</td>
</tr>
<tr>
<td>DataFrame.swapaxes</td>
<td>Interchange axes and swap values axes appropriately.</td>
</tr>
<tr>
<td>DataFrame.melt</td>
<td>Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.</td>
</tr>
<tr>
<td>DataFrame.explode</td>
<td>Transform each element of a list-like to a row, replicating index values.</td>
</tr>
<tr>
<td>DataFrame.squeeze</td>
<td>Squeeze 1 dimensional axis objects into scalars.</td>
</tr>
<tr>
<td>DataFrame.to_xarray</td>
<td>Return an xarray object from the pandas object.</td>
</tr>
<tr>
<td>DataFrame.T</td>
<td>Transpose index and columns.</td>
</tr>
</tbody>
</table>
**pandas DataFrame.T**

</tbody>
</table>
### 3.4.13 Flags

Flags refer to attributes of the pandas object. Properties of the dataset (like the date it was recorded, the URL it was accessed from, etc.) should be stored in `DataFrame.attrs`.

```
Flags(obj, *, allows_duplicate_labels) Flags that apply to pandas objects.
```

### 3.4.14 Metadata

`DataFrame.attrs` is a dictionary for storing global metadata for this DataFrame.

**Warning:** `DataFrame.attrs` is considered experimental and may change without warning.

```
DataFrame.attrs Dictionary of global attributes of this dataset.
```

### 3.4.15 Plotting

`DataFrame.plot` is both a callable method and a namespace attribute for specific plotting methods of the form `DataFrame.plot.<kind>`.

```
DataFrame.plot([x, y, kind, ax, . . . .]) DataFrame plotting accessor and method

DataFrame.plot.area([x, y]) Draw a stacked area plot.
DataFrame.plot.bar([x, y]) Vertical bar plot.
DataFrame.plot.barh([x, y]) Make a horizontal bar plot.
DataFrame.plot.box([by]) Make a box plot of the DataFrame columns.
DataFrame.plot.density([bw_method, ind]) Generate Kernel Density Estimate plot using Gaussian kernels.
DataFrame.plot.hexbin(x, y[, C, . . .]) Generate a hexagonal binning plot.
DataFrame.plot.hist([by, bins]) Draw one histogram of the DataFrame’s columns.
DataFrame.plot.kde([bw_method, ind]) Generate Kernel Density Estimate plot using Gaussian kernels.
DataFrame.plot.line([x, y]) Plot Series or DataFrame as lines.
DataFrame.plot.pie(**kwargs) Generate a pie plot.
DataFrame.plot.scatter(x, y[, s, c]) Create a scatter plot with varying marker point size and color.
```
pandas.DataFrame.plot.area

DataFrame.plot.area (x=None, y=None, **kwargs)

Draw a stacked area plot.

An area plot displays quantitative data visually. This function wraps the matplotlib area function.

Parameters

- **x** [label or position, optional] Coordinates for the X axis. By default uses the index.
- **y** [label or position, optional] Column to plot. By default uses all columns.
- **stacked** [bool, default True] Area plots are stacked by default. Set to False to create a unstacked plot.
- **kwargs** Additional keyword arguments are documented in DataFrame.plot().

Returns

- matplotlib.axes.Axes or numpy.ndarray Area plot, or array of area plots if subplots is True.

See also:

DataFrame.plot Make plots of DataFrame using matplotlib / pylab.

Examples

Draw an area plot based on basic business metrics:

```python
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3, 9, 10, 6],
...     'signups': [5, 5, 6, 12, 14, 13],
...     'visits': [20, 42, 28, 62, 81, 50],
... }, index=pd.date_range(start='2018/01/01', end='2018/07/01',
...     freq='M'))
>>> ax = df.plot.area()
```

Area plots are stacked by default. To produce an unstacked plot, pass stacked=False:

```python
>>> ax = df.plot.area(stacked=False)
```

Draw an area plot for a single column:

```python
>>> ax = df.plot.area(y='sales')
```

Draw with a different x:

```python
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3],
...     'visits': [20, 42, 28],
...     'day': [1, 2, 3],
... })
>>> ax = df.plot.area(x='day')
```
3.4. DataFrame
pandas.DataFrame.plot.bar

DataFrame.plot.bar(x=None, y=None, **kwargs)
Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

**Parameters**

- x [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- y [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- color [str, array-like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:
  - A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
  - A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column’s bar will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.
  - A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {'a': 'green', 'b': 'red'} will color bars for column a in green and bars for column b in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

**Returns**

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:
- DataFrame.plot.barh Horizontal bar plot.
- DataFrame.plot Make plots of a DataFrame.
- matplotlib.pyplot.bar Make a bar plot with matplotlib.

Examples

**Basic plot.**

```python
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
    ...        'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
    ...        'lifespan': lifespan}, index=index)
>>> ax = df.plot.bar(rot=0)

Plot stacked bar charts for the DataFrame

>>> ax = df.plot.bar(stacked=True)

Instead of nesting, the figure can be split by column with subplots=True. In this case, a numpy.ndarray of matplotlib.axes.Axes are returned.

>>> axes = df.plot.bar(rot=0, subplots=True)
>>> axes[1].legend(loc=2)

If you don’t like the default colours, you can specify how you’d like each column to be colored.

>>> axes = df.plot.bar(
    ...        rot=0, subplots=True, color={"speed": "red", "lifespan": "green"}
    ...    )
>>> axes[1].legend(loc=2)
Plot a single column.

```python
>>> ax = df.plot.bar(y='speed', rot=0)
```

![Bar chart of speed](image)

Plot only selected categories for the DataFrame.

```python
>>> ax = df.plot.bar(x='lifespan', rot=0)
```

**pandas.DataFrame.plot.barh**

Dataframe.plot.barh(x=None, y=None, **kwargs)

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

**Parameters**

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
**color** [str, array-like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:

- **A single color string referred to by name, RGB or RGBA code**, for instance ‘red’ or ‘#a98d19’.
- **A sequence of color strings referred to by name, RGB or RGBA code**, which will be used for each column recursively. For instance ['green', 'yellow'] each column’s bar will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.
- **A dict of the form {column name} [color]**, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {'a': 'green', 'b': 'red'} will color bars for column a in green and bars for column b in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

**Returns**

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

- **DataFrame.plot.bar** Vertical bar plot.
- **DataFrame.plot** Make plots of DataFrame using matplotlib.
- **matplotlib.axes.Axes.bar** Plot a vertical bar plot using matplotlib.

**Examples**

Basic example

```python
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')
```

Plot a whole DataFrame to a horizontal bar plot

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant', ...
            'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed, ...
            'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
```

Plot stacked barh charts for the DataFrame

```python
>>> ax = df.plot.barh(stacked=True)
```

We can specify colors for each column

```python
>>> ax = df.plot.barh(color={"speed": "red", "lifespan": "green"})
```

Plot a column of the DataFrame to a horizontal bar plot
3.4. DataFrame
Plot DataFrame versus the desired column

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...    'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...    'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(x='lifespan')
```
pandas.DataFrame.plot.box

DataFrame.plot.box(by=None, **kwargs)
Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to 1.5*IQR (IQR = Q3 - Q1) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia’s entry for boxplot.

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

Parameters

by [str or sequence] Column in the DataFrame to group by.

**kwargs Additional keywords are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

DataFrame.boxplot Another method to draw a box plot.
Series.plot.box Draw a box plot from a Series object.
matplotlib.pyplot.boxplot Draw a box plot in matplotlib.

Examples

Draw a box plot from a DataFrame with four columns of randomly generated data.

```python
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```

pandas.DataFrame.plot.density

DataFrame.plot.density(bw_method=None, ind=None, **kwargs)
Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See scipy.stats.gaussian_kde for more information.

ind [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.

**kwargs Additional keyword arguments are documented in pandas.%(this-datatype)s.plot().
Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

scipy.stats.gaussian_kde Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:
For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)
```

```python
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5])
```
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.DataFrame.plot.hexbin

DataFrame.plot.hexbin(x, y, C=None, reduce_C_function=None, gridsize=None, **kwargs)

Generate a hexagonal binning plot.

Generate a hexagonal binning plot of \( x \) versus \( y \). If \( C \) is None (the default), this is a histogram of the number of occurrences of the observations at \( (x[i], y[i]) \).

If \( C \) is specified, specifies values at given coordinates \( (x[i], y[i]) \). These values are accumulated for each hexagonal bin and then reduced according to `reduce_C_function`, having as default the NumPy’s mean function (`numpy.mean()`). (If \( C \) is specified, it must also be a 1-D sequence of the same length as \( x \) and \( y \), or a column label.)

Parameters

- `x` [int or str] The column label or position for \( x \) points.
- `y` [int or str] The column label or position for \( y \) points.
- `C` [int or str, optional] The column label or position for the value of \( (x, y) \) point.
- `reduce_C_function` [callable, default `np.mean`] Function of one argument that reduces all the values in a bin to a single number (e.g. `np.mean`, `np.max`, `np.sum`, `np.std`).
- `gridsize` [int or tuple of (int, int), default 100] The number of hexagons in the \( x \)-direction. The corresponding number of hexagons in the \( y \)-direction is chosen in a way that the hexagons are approximately regular. Alternatively, gridsize can be a tuple with two elements specifying the number of hexagons in the \( x \)-direction and the \( y \)-direction.
- **kwargs Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

- `matplotlib.AxesSubplot` The matplotlib `Axes` on which the hexbin is plotted.

See also:

- `DataFrame.plot` Make plots of a DataFrame.
- `matplotlib.pyplot.hexbin` Hexagonal binning plot using matplotlib, the matplotlib function that is used under the hood.

Examples

The following examples are generated with random data from a normal distribution.

```python
>>> n = 10000
>>> df = pd.DataFrame({'x': np.random.randn(n),
... 'y': np.random.randn(n)})
>>> ax = df.plot.hexbin(x='x', y='y', gridsize=20)
```

The next example uses \( C \) and `np.sum` as `reduce_C_function`. Note that ‘observations’ values ranges from 1 to 5 but the result plot shows values up to more than 25. This is because of the `reduce_C_function`.

```python
>>> n = 500
>>> df = pd.DataFrame({
... 'coord_x': np.random.uniform(-3, 3, size=n),
... 'coord_y': np.random.uniform(30, 50, size=n),
... 'observations': np.random.randint(1,5, size=n)
... })
>>> ax = df.plot.hexbin(x='coord_x',
... y='coord_y',
... (continues on next page)
3.4. DataFrame
... C='observations',
... reduce_C_function=np.sum,
... gridsize=10,
... cmap="viridis")

pandas.DataFrame.plot.hist

DataFrame.plot.hist(by=None, bins=10, **kwargs)

Draw one histogram of the DataFrame's columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one matplotlib.axes.Axes. This is useful when the DataFrame's Series are in a similar scale.

Parameters

by [str or sequence, optional] Column in the DataFrame to group by.

bins [int, default 10] Number of histogram bins to be used.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

class:matplotlib.AxesSubplot Return a histogram plot.
See also:

*DataFrame.hist* Draw histograms per DataFrame's Series.
*Series.hist* Draw a histogram with Series' data.

**Examples**

When we draw a dice 6000 times, we expect to get each value around 1000 times. But when we draw two dices and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```python
>>> df = pd.DataFrame(
...     np.random.randint(1, 7, 6000),
...     columns = ['one'])
>>> df['two'] = df['one'] + np.random.randint(1, 7, 6000)
>>> ax = df.plot.hist(bins=12, alpha=0.5)
```

![Histogram of dice rolls](image)

**3.4. DataFrame**
DataFrame.plot.kde

DataFrame.plot.kde(bw_method=None, ind=None, **kwargs)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

**Parameters**

- **bw_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See scipy.stats.gaussian_kde for more information.
- **ind** [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.
- **kwargs** Additional keyword arguments are documented in pandas.

**Returns**

matplotlib.axes.Axes or numpy.ndarray of them

See also:

scipy.stats.gaussian_kde  Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

**Examples**

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the **ind** parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```
3.4. DataFrame
A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

**pandas.DataFrame.plot.line**

DataFrame.plot.line(x=\textit{None}, y=\textit{None}, **kwargs)

Plot Series or DataFrame as lines.

This function is useful to plot lines using DataFrame’s values as coordinates.

**Parameters**

- `x` [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

- `y` [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
**color** [str, array-like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:

- A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.

- A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column’s line will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.

- A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {'a': 'green', 'b': 'red'} will color lines for column a in green and lines for column b in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

collection of matplotlib.axes.Axes or np.ndarray of them

An ndarray is returned with one matplotlib.axes.Axes per column when `subplots=True`.

See also:

-matplotlib.pyplot.plot Plot y versus x as lines and/or markers.

Examples

```python
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
```

The following example shows the populations for some animals over the years.

```python
>>> df = pd.DataFrame({
...     'pig': [20, 18, 489, 675, 1776],
...     'horse': [4, 25, 281, 600, 1900]
>>> lines = df.plot.line()
```

An example with subplots, so an array of axes is returned.

```python
>>> axes = df.plot.line(subplots=True)
>>> type(axes)
<class 'numpy.ndarray'>
```

Let’s repeat the same example, but specifying colors for each column (in this case, for each animal).

```python
>>> axes = df.plot.line(subplots=True, color={'pig': 'pink', 'horse': '#742802'})
```

The following example shows the relationship between both populations.

```python
>>> lines = df.plot.line(x='pig', y='horse')
```
pandas.DataFrame.plot.pie

DataFrame.plot.pie(**kwargs)
Generate a pie plot.

A pie plot is a proportional representation of the numerical data in a column. This function wraps
matplotlib.pyplot.pie() for the specified column. If no column reference is passed and
subplots=True a pie plot is drawn for each numerical column independently.

Parameters

- **y** [int or label, optional] Label or position of the column to plot. If not provided,
  subplots=True argument must be passed.

- **kwargs** Keyword arguments to pass on to DataFrame.plot().

Returns

matplotlib.axes.Axes or np.ndarray of them A NumPy array is returned when subplots is
True.

See also:

- Series.plot.pie Generate a pie plot for a Series.
- DataFrame.plot Make plots of a DataFrame.

Examples

In the example below we have a DataFrame with the information about planet’s mass and radius. We pass the
‘mass’ column to the pie function to get a pie plot.

```python
>>> df = pd.DataFrame({'mass': [0.330, 4.87 , 5.97],
...                   'radius': [2439.7, 6051.8, 6378.1]},
...                   index=['Mercury', 'Venus', 'Earth'])
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
```

```python
>>> plot = df.plot.pie(subplots=True, figsize=(11, 6))
```

pandas.DataFrame.plot.scatter

DataFrame.plot.scatter(x, y, s=None, c=None, **kwargs)
Create a scatter plot with varying marker point size and color.

The coordinates of each point are defined by two dataframe columns and filled circles are used to represent each
point. This kind of plot is useful to see complex correlations between two variables. Points could be for instance
natural 2D coordinates like longitude and latitude in a map or, in general, any pair of metrics that can be plotted
against each other.

Parameters

- **x** [int or str] The column name or column position to be used as horizontal coordinates for
each point.

- **y** [int or str] The column name or column position to be used as vertical coordinates for each
  point.

- **s** [str, scalar or array-like, optional] The size of each point. Possible values are:
  - A string with the name of the column to be used for marker’s size.
  - A single scalar so all points have the same size.
• A sequence of scalars, which will be used for each point’s size recursively. For instance, when passing [2,14] all points size will be either 2 or 14, alternatively.

Changed in version 1.1.0.

c  [str, int or array-like, optional] The color of each point. Possible values are:

• A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.

• A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each point’s color recursively. For instance ['green','yellow'] all points will be filled in green or yellow, alternatively.

• A column name or position whose values will be used to color the marker points according to a colormap.

**kwargs  Keyword arguments to pass on to DataFrame.plot().

Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

matplotlib.pyplot.scatter  Scatter plot using multiple input data formats.

Examples

Let’s see how to draw a scatter plot using coordinates from the values in a DataFrame’s columns.

```python
>>> df = pd.DataFrame([[5.1, 3.5, 0], [4.9, 3.0, 0], [7.0, 3.2, 1],
... [6.4, 3.2, 1], [5.9, 3.0, 2]],
... columns=['length', 'width', 'species'])
```

```python
>>> ax1 = df.plot.scatter(x='length',
... y='width',
... c='DarkBlue')
```

And now with the color determined by a column as well.

```python
>>> ax2 = df.plot.scatter(x='length',
... y='width',
... c='species',
... colormap='viridis')
```

DataFrame.boxplot([column, by, ax, . . .])  Make a box plot from DataFrame columns.

DataFrame.hist([column, by, grid, . . .])  Make a histogram of the DataFrame’s columns.

3.4.16 Sparse accessor

Sparse-dtype specific methods and attributes are provided under the DataFrame.sparse accessor.

DataFrame.sparse.density  Ratio of non-sparse points to total (dense) data points.
pandas.DataFrame.sparse.density

DataFrame.sparse.density

Ratio of non-sparse points to total (dense) data points.

DataFrame.sparse.from_spmatrix(data[, ...])

Create a new DataFrame from a scipy sparse matrix.

DataFrame.sparse.to_coo()

Return the contents of the frame as a sparse SciPy COO matrix.

DataFrame.sparse.to_dense()

Convert a DataFrame with sparse values to dense.

pandas.DataFrame.sparse.from_spmatrix

classmethod DataFrame.sparse.from_spmatrix(data[, index=None, columns=None])

Create a new DataFrame from a scipy sparse matrix.

New in version 0.25.0.

Parameters

- **data** [scipy.sparse.spmatrix] Must be convertible to csc format.
- **index, columns** [Index, optional] Row and column labels to use for the resulting DataFrame. Defaults to a RangeIndex.

Returns

- **DataFrame** Each column of the DataFrame is stored as a arrays.SparseArray.

Examples

```python
>>> import scipy.sparse
>>> mat = scipy.sparse.eye(3)
>>> pd.DataFrame.sparse.from_spmatrix(mat)
   0  1  2
0  1.0 0.0 0.0
1  0.0 1.0 0.0
2  0.0 0.0 1.0
```

pandas.DataFrame.sparse.to_coo

DataFrame.sparse.to_coo()

Return the contents of the frame as a sparse SciPy COO matrix.

New in version 0.25.0.

Returns

- **coo_matrix** [scipy.sparse.spmatrix] If the caller is heterogeneous and contains booleans or objects, the result will be of dtype=object. See Notes.
Notes

The dtype will be the lowest-common-denominator type (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. By numpy.find_common_type convention, mixing int64 and and uint64 will result in a float64 dtype.

pandas.DataFrame.sparse.to_dense

DataFrame.sparse.to_dense()
Convert a DataFrame with sparse values to dense.
New in version 0.25.0.

Returns

DataFrame A DataFrame with the same values stored as dense arrays.

Examples

```python
>>> df = pd.DataFrame({'A': pd.arrays.SparseArray([0, 1, 0])})
>>> df.sparse.to_dense()
      A
0     0
1     1
2     0
```

### 3.5 pandas arrays

For most data types, pandas uses NumPy arrays as the concrete objects contained with a `Index`, `Series`, or `DataFrame`.

For some data types, pandas extends NumPy’s type system. String aliases for these types can be found at `dtypes`.

<table>
<thead>
<tr>
<th>Kind of Data</th>
<th>pandas Data Type</th>
<th>Scalar</th>
<th>Array</th>
</tr>
</thead>
<tbody>
<tr>
<td>TZ-aware datetime</td>

</tr>
<tr>
<td>Boolean (with NA)</td>
<td>BooleanDtype</td>
<td>bool</td>
<td>Boolean data with missing values</td>
</tr>
</tbody>
</table>

Pandas and third-party libraries can extend NumPy’s type system (see `Extension types`). The top-level `array()` method can be used to create a new array, which may be stored in a `Series`, `Index`, or as a column in a `DataFrame`.

```python
array(data[, dtype, copy]) Create an array.
```

#### 3.5.1 pandas.array

`pandas.array(data, dtype=None, copy=True)`

Create an array.

**Parameters**

- `data`  [Sequence of objects] The scalars inside `data` should be instances of the scalar type for `dtype`. It’s expected that `data` represents a 1-dimensional array of data.

  When `data` is an Index or Series, the underlying array will be extracted from `data`.

- `dtype`  [str, np.dtype, or ExtensionDtype, optional] The dtype to use for the array. This may be a NumPy dtype or an extension type registered with pandas using `pandas.api.extensions.register_extension_dtype()`.

  If not specified, there are two possibilities:

  1. When `data` is a `Series`, `Index`, or `ExtensionArray`, the `dtype` will be taken from the data.

  2. Otherwise, pandas will attempt to infer the `dtype` from the data.
Note that when `data` is a NumPy array, `data.dtype` is not used for inferring the array type. This is because NumPy cannot represent all the types of data that can be held in extension arrays.

Currently, pandas will infer an extension dtype for sequences of

<table>
<thead>
<tr>
<th>Scalar Type</th>
<th>Array Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>pandas. Interval</td>
<td>pandas.arrays.IntervalArray</td>
</tr>
<tr>
<td>pandas. Period</td>
<td>pandas.arrays.PeriodArray</td>
</tr>
<tr>
<td>datetime. date</td>
<td>pandas.arrays.DatetimeArray</td>
</tr>
<tr>
<td>datetime. timedelta</td>
<td>pandas.arrays.TimedeltaArray</td>
</tr>
<tr>
<td>int</td>
<td>pandas.arrays.IntegerArray</td>
</tr>
<tr>
<td>float</td>
<td>pandas.arrays.FloatingArray</td>
</tr>
<tr>
<td>str</td>
<td>pandas.arrays.StringArray or pandas.arrays.ArrowStringArray</td>
</tr>
<tr>
<td>bool</td>
<td>pandas.arrays[BooleanArray]</td>
</tr>
</tbody>
</table>

The ExtensionArray created when the scalar type is `str` is determined by `pd.options.mode.string_storage` if the dtype is not explicitly given.

For all other cases, NumPy’s usual inference rules will be used.

Changed in version 1.0.0: Pandas infers nullable-integer dtype for integer data, string dtype for string data, and nullable-boolean dtype for boolean data.

Changed in version 1.2.0: Pandas now also infers nullable-floating dtype for float-like input data

**copy** [bool, default True] Whether to copy the data, even if not necessary. Depending on the type of `data`, creating the new array may require copying data, even if `copy=False`.

**Returns**

- **ExtensionArray** The newly created array.

**Raises**

- **ValueError** When `data` is not 1-dimensional.

**See also:**

- `numpy.array` Construct a NumPy array.
- `Series` Construct a pandas Series.
- `Index` Construct a pandas Index.
- `arrays.PandasArray` ExtensionArray wrapping a NumPy array.
- `Series.array` Extract the array stored within a Series.
Notes

Omitting the `dtype` argument means pandas will attempt to infer the best array type from the values in the data. As new array types are added by pandas and 3rd party libraries, the “best” array type may change. We recommend specifying `dtype` to ensure that

1. the correct array type for the data is returned
2. the returned array type doesn’t change as new extension types are added by pandas and third-party libraries

Additionally, if the underlying memory representation of the returned array matters, we recommend specifying the `dtype` as a concrete object rather than a string alias or allowing it to be inferred. For example, a future version of pandas or a 3rd-party library may include a dedicated ExtensionArray for string data. In this event, the following would no longer return a `arrays.PandasArray` backed by a NumPy array.

```python
>>> pd.array(['a', 'b'], dtype=str)
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

This would instead return the new ExtensionArray dedicated for string data. If you really need the new array to be backed by a NumPy array, specify that in the `dtype`.

```python
>>> pd.array(['a', 'b'], dtype=np.dtype("<U1"))
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

Finally, Pandas has arrays that mostly overlap with NumPy

- `arrays.DatetimeArray`
- `arrays.TimedeltaArray`

When data with a `datetime64[ns]` or `timedelta64[ns]` dtype is passed, pandas will always return a `DatetimeArray` or `TimedeltaArray` rather than a `PandasArray`. This is for symmetry with the case of timezone-aware data, which NumPy does not natively support.

```python
>>> pd.array(['2015', '2016'], dtype='datetime64[ns]')
<DatetimeArray>
['2015-01-01 00:00:00', '2016-01-01 00:00:00']
Length: 2, dtype: datetime64[ns]
```

```python
>>> pd.array(['1H', '2H'], dtype='timedelta64[ns]')
<TimedeltaArray>
['0 days 01:00:00', '0 days 02:00:00']
Length: 2, dtype: timedelta64[ns]
```

Examples

If a dtype is not specified, pandas will infer the best `dtype` from the values. See the description of `dtype` for the types pandas infers for.

```python
>>> pd.array([1, 2])
<IntegerArray>
[1, 2]
Length: 2, dtype: Int64
```

```python
>>> pd.array([1, 2, np.nan])
<IntegerArray>
```

(continues on next page)
[1, 2, <NA>]  
Length: 3, dtype: Int64

```python
>>> pd.array([1.1, 2.2])
<FloatingArray>
[1.1, 2.2]  
Length: 2, dtype: Float64
```

```python
>>> pd.array(["a", None, "c"])
<StringArray>
['a', <NA>, 'c']  
Length: 3, dtype: string
```

```python
>>> with pd.option_context("string_storage", "pyarrow"):
...    arr = pd.array(["a", None, "c"])
...
```

```python
>>> arr
<ArrowStringArray>
['a', <NA>, 'c']  
Length: 3, dtype: string
```

```python
<PeriodArray>
['2000-01-01', '2000-01-01']  
Length: 2, dtype: period[D]
```

You can use the string alias for `dtype`

```python
>>> pd.array(["a", 'b', 'a'], dtype='category')
['a', 'b', 'a']  
Categories (2, object): ['a', 'b']
```

Or specify the actual `dtype`

```python
>>> pd.array(["a", 'b', 'a'],
...           dtype=pd.CategoricalDtype(["a", 'b', 'c'], ordered=True))
['a', 'b', 'a']  
Categories (3, object): ['a' < 'b' < 'c']
```

If pandas does not infer a dedicated extension type a `arrays.PandasArray` is returned.

```python
>>> pd.array([1 + 1j, 3 + 2j])
<PandasArray>
[(1+1j), (3+2j)]  
Length: 2, dtype: complex128
```

As mentioned in the “Notes” section, new extension types may be added in the future (by pandas or 3rd party libraries), causing the return value to no longer be a `arrays.PandasArray`. Specify the `dtype` as a NumPy `dtype` if you need to ensure there’s no future change in behavior.

```python
>>> pd.array([1, 2], dtype=np.dtype("int32"))
<PandasArray>
[1, 2]  
Length: 2, dtype: int32
```

data must be 1-dimensional. A ValueError is raised when the input has the wrong dimensionality.

3.5. pandas arrays
>>> pd.array(1)
Traceback (most recent call last):
...
ValueError: Cannot pass scalar '1' to 'pandas.array'.

3.5.2 Datetime data

NumPy cannot natively represent timezone-aware datetimes. pandas supports this with the arrays. DatetimeArray extension array, which can hold timezone-naive or timezone-aware values. 

Timestamp, a subclass of datetime.datetime, is pandas’ scalar type for timezone-naive or timezone-aware datetime data.

<table>
<thead>
<tr>
<th>Timestamp([ts_input, freq, tz, unit, year, ...])</th>
<th>Pandas replacement for python datetime.datetime object.</th>
</tr>
</thead>
</table>

pandas.Timestamp

class pandas.Timestamp(ts_input=<object object>, freq=None, tz=None, unit=None, year=None, month=None, day=None, hour=None, minute=None, second=None, microsecond=None, nanosecond=None, tzinfo=None, *, fold=None)
Pandas replacement for python datetime.datetime object.

Timestamp is the pandas equivalent of python’s Datetime and is interchangeable with it in most cases. It’s the type used for the entries that make up a DatetimeIndex, and other timeseries oriented data structures in pandas.

Parameters

ts_input [datetime-like, str, int, float] Value to be converted to Timestamp.
freq [str, DateOffset] Offset which Timestamp will have.
tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will have.
unit [str] Unit used for conversion if ts_input is of type int or float. The valid values are ‘D’, ‘h’, ‘m’, ‘s’, ‘ms’, ‘us’, and ‘ns’. For example, ‘s’ means seconds and ‘ms’ means milliseconds.
year, month, day [int]
hour, minute, second, microsecond [int, optional, default 0]
nanosecond [int, optional, default 0]
tzinfo [datetime.tzinfo, optional, default None]
fold [{0, 1}, default None, keyword-only] Due to daylight saving time, one wall clock time can occur twice when shifting from summer to winter time; fold describes whether the datetime-like corresponds to the first (0) or the second time (1) the wall clock hits the ambiguous time

New in version 1.1.0.
Notes

There are essentially three calling conventions for the constructor. The primary form accepts four parameters. They can be passed by position or keyword.

The other two forms mimic the parameters from `datetime.datetime`. They can be passed by either position or keyword, but not both mixed together.

Examples

Using the primary calling convention:

This converts a datetime-like string

```python
>>> pd.Timestamp('2017-01-01T12')
Timestamp('2017-01-01 12:00:00')
```

This converts a float representing a Unix epoch in units of seconds

```python
>>> pd.Timestamp(1513393355.5, unit='s')
Timestamp('2017-12-16 03:02:35.500000')
```

This converts an int representing a Unix-epoch in units of seconds and for a particular timezone

```python
>>> pd.Timestamp(1513393355, unit='s', tz='US/Pacific')
Timestamp('2017-12-15 19:02:35-0800', tz='US/Pacific')
```

Using the other two forms that mimic the API for `datetime.datetime`:

```python
>>> pd.Timestamp(2017, 1, 1, 12)
Timestamp('2017-01-01 12:00:00')
```

```python
>>> pd.Timestamp(year=2017, month=1, day=1, hour=12)
Timestamp('2017-01-01 12:00:00')
```

**pandas.Timestamp.asm8**

Timestamp.asm8

Return numpy datetime64 format in nanoseconds.

**Examples**

```python
>>> ts = pd.Timestamp(2020, 3, 14, 15)
>>> ts.asm8
numpy.datetime64('2020-03-14T15:00:00.000000000')
```

**pandas.Timestamp.day_of_week**

Timestamp.day_of_week

Return day of the week.

**Examples**

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.day_of_week
5
```

**pandas.Timestamp.day_of_year**

Timestamp.day_of_year

Return the day of the year.

**Examples**

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.day_of_year
74
```
pandas.Timestamp.dayofweek

Timestamp.dayofweek
Return day of the week.

Examples

```python
ts = pd.Timestamp(2020, 3, 14)
ts.day_of_week
5
```

pandas.Timestamp.dayofyear

Timestamp.dayofyear
Return the day of the year.

Examples

```python
ts = pd.Timestamp(2020, 3, 14)
ts.day_of_year
74
```

pandas.Timestamp.days_in_month

Timestamp.days_in_month
Return the number of days in the month.

Examples

```python
ts = pd.Timestamp(2020, 3, 14)
ts.days_in_month
31
```

pandas.Timestamp.daysinmonth

Timestamp.daysinmonth
Return the number of days in the month.
Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.days_in_month
31
```

**pandas.Timestamp.freqstr**

**property** `pandas.Timestamp.freqstr`

Return the total number of days in the month.

**pandas.Timestamp.is_leap_year**

**Timestamp.is_leap_year**

Return True if year is a leap year.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_leap_year
True
```

**pandas.Timestamp.is_month_end**

**Timestamp.is_month_end**

Return True if date is last day of month.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_month_end
False
```

```python
>>> ts = pd.Timestamp(2020, 12, 31)
>>> ts.is_month_end
True
```

**pandas.Timestamp.is_month_start**

**Timestamp.is_month_start**

Return True if date is first day of month.
Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_month_start
False
```

```python
>>> ts = pd.Timestamp(2020, 1, 1)
>>> ts.is_month_start
True
```

**pandas.Timestamp.is_quarter_end**

**is_quarter_end**

Return True if date is last day of the quarter.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_quarter_end
False
```

```python
>>> ts = pd.Timestamp(2020, 3, 31)
>>> ts.is_quarter_end
True
```

**pandas.Timestamp.is_quarter_start**

**is_quarter_start**

Return True if date is first day of the quarter.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_quarter_start
False
```

```python
>>> ts = pd.Timestamp(2020, 4, 1)
>>> ts.is_quarter_start
True
```
pandas.Timestamp.is_year_end

Timestamp.is_year_end
Return True if date is last day of the year.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_year_end
False

>>> ts = pd.Timestamp(2020, 12, 31)
>>> ts.is_year_end
True
```

pandas.Timestamp.is_year_start

Timestamp.is_year_start
Return True if date is first day of the year.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_year_start
False

>>> ts = pd.Timestamp(2020, 1, 1)
>>> ts.is_year_start
True
```

pandas.Timestamp.quarter

Timestamp.quarter
Return the quarter of the year.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.quarter
1
```
pandas.Timestamp.tz

**property** Timestamp.tz

Alias for tzinfo.

**Examples**

```python
>>> ts = pd.Timestamp(1584226800, unit='s', tz='Europe/Stockholm')
>>> ts.tz
<DstTzInfo 'Europe/Stockholm' CET+1:00:00 STD>
```

pandas.Timestamp.week

Timestamp.week

Return the week number of the year.

**Examples**

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.week
11
```

pandas.Timestamp.weekofyear

Timestamp.weekofyear

Return the week number of the year.

**Examples**

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.week
11
```
### Methods

<table>

</table>

continues on next page
pandas.Timestamp.astimezone

Convert tz-aware Timestamp to another time zone.

Parameters

- tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding UTC time.

Returns

- converted [Timestamp]

Raises

- TypeError If Timestamp is tz-naive.

Examples

Create a timestamp object with UTC timezone:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651', tz='UTC')
>>> ts
Timestamp('2020-03-14 15:32:52.192548651+0000', tz='UTC')
```

Change to Tokyo timezone:

```python
>>> ts.tz_convert(tz='Asia/Tokyo')
Timestamp('2020-03-15 00:32:52.192548651+0900', tz='Asia/Tokyo')
```

Can also use astimezone:

```python
>>> ts.astimezone(tz='Asia/Tokyo')
Timestamp('2020-03-15 00:32:52.192548651+0900', tz='Asia/Tokyo')
```

Analogous for pd.NaT:

```python
>>> pd.NaT.tz_convert(tz='Asia/Tokyo')
NaT
```
**pandas**: powerful Python data analysis toolkit, Release 1.3.2

---

**pandas.Timestamp.ceil**

[Timestamp.ceil](freq, ambiguous='raise', nonexistent='raise')

Return a new Timestamp ceiled to this resolution.

**Parameters**

- **freq** [str] Frequency string indicating the ceiling resolution.
- **ambiguous** [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:
  - bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
  - ‘NaT’ will return NaT for an ambiguous time.
  - ‘raise’ will raise an AmbiguousTimeError for an ambiguous time.
- **nonexistent** [[‘raise’, ‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta], default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time.
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time.
  - ‘NaT’ will return NaT where there are nonexistent times.
  - timedelta objects will shift nonexistent times by the timedelta.
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

**Raises**

- ValueError if the freq cannot be converted.

---

**Examples**

Create a timestamp object:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
```

A timestamp can be ceiled using multiple frequency units:

```python
>>> ts.ceil(freq='H') # hour
Timestamp('2020-03-14 16:00:00')
```

```python
>>> ts.ceil(freq='T') # minute
Timestamp('2020-03-14 15:33:00')
```

```python
>>> ts.ceil(freq='S') # seconds
Timestamp('2020-03-14 15:32:53')
```

```python
>>> ts.ceil(freq='U') # microseconds
Timestamp('2020-03-14 15:32:52.192549')
```

freq can also be a multiple of a single unit, like ‘5T’ (i.e. 5 minutes):
>>> ts.ceil(freq='5T')
Timestamp('2020-03-14 15:35:00')

or a combination of multiple units, like ‘1H30T’ (i.e. 1 hour and 30 minutes):

```python
>>> ts.ceil(freq='1H30T')
Timestamp('2020-03-14 16:30:00')
```

Analogous for pd.NaT:

```python
>>> pd.NaT.ceil()
NaT
```

### pandas.Timestamp.combine

classmethod Timestamp.combine(date, time)

Combine date, time into datetime with same date and time fields.

**Examples**

```python
>>> from datetime import date, time
>>> pd.Timestamp.combine(date(2020, 3, 14), time(15, 30, 15))
Timestamp('2020-03-14 15:30:15')
```

### pandas.Timestamp.ctime

Timestamp.ctime()

Return ctime() style string.

### pandas.Timestamp.date

Timestamp.date()

Return date object with same year, month and day.

### pandas.Timestamp.day_name

Timestamp.day_name()

Return the day name of the Timestamp with specified locale.

**Parameters**

locale [str, default None (English locale)] Locale determining the language in which to return the day name.

**Returns**

str

3.5. pandas arrays
Examples

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.day_name()
'Saturday'
```

Analogous for `pd.NaT`:

```python
>>> pd.NaT.day_name()
nan
```

**pandas.Timestamp.dst**

`Timestamp.\texttt{dst}()`

Return `self.tzinfo.dst(self)`.

**pandas.Timestamp.floor**

`Timestamp.\texttt{floor}(freq, \texttt{ambiguous}='raise', \texttt{nonexistent}='raise')`  
Return a new `Timestamp` floored to this resolution.

**Parameters**

- **freq** [str] Frequency string indicating the flooring resolution.
- **ambiguous** [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:
  - bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
  - ‘NaT’ will return NaT for an ambiguous time.
  - ‘raise’ will raise an AmbiguousTimeError for an ambiguous time.
- **nonexistent** [{'raise', 'shift_forward', 'shift_backward', 'NaT', timedelta}, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time.
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time.
  - ‘NaT’ will return NaT where there are nonexistent times.
  - timedelta objects will shift nonexistent times by the timedelta.
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

**Raises**

- ValueError if the freq cannot be converted.
Examples

Create a timestamp object:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
```

A timestamp can be floored using multiple frequency units:

```python
>>> ts.floor(freq='H')  # hour
Timestamp('2020-03-14 15:00:00')

>>> ts.floor(freq='T')  # minute
Timestamp('2020-03-14 15:32:00')

>>> ts.floor(freq='S')  # seconds
Timestamp('2020-03-14 15:32:52')

>>> ts.floor(freq='N')  # nanoseconds
Timestamp('2020-03-14 15:32:52.192548651')
```

efreq can also be a multiple of a single unit, like ‘5T’ (i.e. 5 minutes):

```python
>>> ts.floor(freq='5T')
Timestamp('2020-03-14 15:30:00')
```

or a combination of multiple units, like ‘1H30T’ (i.e. 1 hour and 30 minutes):

```python
>>> ts.floor(freq='1H30T')
Timestamp('2020-03-14 15:00:00')
```

Analogous for pd.NaT:

```python
>>> pd.NaT.floor()
NaT
```

**pandas.Timestamp.fromisocalendar**

`Timestamp.fromisocalendar()`  
`int, int, int -> Construct a date from the ISO year, week number and weekday.`

This is the inverse of the date.isocalendar() function

**pandas.Timestamp.fromisoformat**

`Timestamp.fromisoformat()`  
`string -> datetime from datetime.isoformat() output`
pandas.Timestamp.fromordinal

classmethod Timestamp.fromordinal(ordinal, freq=None, tz=None)
Passed an ordinal, translate and convert to a ts. Note: by definition there cannot be any tz info on the ordinal itself.

Parameters

    ordinal [int] Date corresponding to a proleptic Gregorian ordinal.
    freq [str, DateOffset] Offset to apply to the Timestamp.
    tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for the Timestamp.

Examples

```python
>>> pd.Timestamp.fromordinal(737425)
Timestamp('2020-01-01 00:00:00')
```

pandas.Timestamp.fromtimestamp

classmethod Timestamp.fromtimestamp(ts)
Transform timestamp[, tz] to tz's local time from POSIX timestamp.

Examples

```python
>>> pd.Timestamp.utcfromtimestamp(1584199972)
Timestamp('2020-03-14 15:32:52')
```

Note that the output may change depending on your local time.

pandas.Timestamp.isocalendar

Timestamp.isocalendar()
Return a 3-tuple containing ISO year, week number, and weekday.

pandas.Timestamp.isoformat

Timestamp.isoformat(sep=None)
[sep] -> string in ISO 8601 format, YYYY-MM-DDT[HH[:MM[:SS[.mmm[.uuu]]]]]+HH:MM, sep is used to separate the year from the time, and defaults to ‘T’. The optional argument timespec specifies the number of additional terms of the time to include. Valid options are ‘auto’, ‘hours’, ‘minutes’, ‘seconds’, ‘milliseconds’ and ‘microseconds’.
pandas.Timestamp.isoweekday

```
Timestamp.isoweekday()

Return the day of the week represented by the date. Monday == 1 ... Sunday == 7
```

pandas.Timestamp.month_name

```
Timestamp.month_name()

Return the month name of the Timestamp with specified locale.

Parameters

locale [str, default None (English locale)] Locale determining the language in which to return the month name.

Returns

str

Examples

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.month_name()
'March'
```

Analogous for pd.NaT:

```python
>>> pd.NaT.month_name()
nan
```

pandas.Timestamp.normalize

```
Timestamp.normalize()

Normalize Timestamp to midnight, preserving tz information.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14, 15, 30)
>>> ts.normalize()
Timestamp('2020-03-14 00:00:00')
```

pandas.Timestamp.now

classmethod Timestamp.now(tz=None)

Return new Timestamp object representing current time local to tz.

Parameters

- tz [str or timezone object, default None] Timezone to localize to.
Examples

```python
>>> pd.Timestamp.now()
Timestamp('2020-11-16 22:06:16.378782')
```

Analogous for `pd.NaT`:

```python
>>> pd.NaT.now()
NaT
```

**pandas.Timestamp.replace**

`Timestamp.replace(year=None, month=None, day=None, hour=None, minute=None, second=None, microsecond=None, nanosecond=None, tzinfo=<class 'object'>, fold=None)`

Implements datetime.replace, handles nanoseconds.

Parameters

- `year` [int, optional]
- `month` [int, optional]
- `day` [int, optional]
- `hour` [int, optional]
- `minute` [int, optional]
- `second` [int, optional]
- `microsecond` [int, optional]
- `nanosecond` [int, optional]
- `tzinfo` [tz-convertible, optional]
- `fold` [int, optional]

Returns

Timestamp with fields replaced

Examples

Create a timestamp object:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651', tz='UTC')
>>> ts
Timestamp('2020-03-14 15:32:52.192548651+0000', tz='UTC')
```

Replace year and the hour:

```python
>>> ts.replace(year=1999, hour=10)
Timestamp('1999-03-14 10:32:52.192548651+0000', tz='UTC')
```

Replace timezone (not a conversion):
```python
>>> import pytz

>>> ts.replace(tzinfo=pytz.timezone('US/Pacific'))
Timestamp('2020-03-14 15:32:52.192548651-0700', tz='US/Pacific')

Analogous for pd.NaT:

>>> pd.NaT.replace(tzinfo=pytz.timezone('US/Pacific'))
NaT
```

**pandas.Timestamp.round**

`pandas.Timestamp.round(freq, ambiguous='raise', nonexistent='raise')`

Round the Timestamp to the specified resolution.

**Parameters**

- `freq` [str] Frequency string indicating the rounding resolution.
- `ambiguous` [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:
  - bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
  - ‘NaT’ will return NaT for an ambiguous time.
  - ‘raise’ will raise an AmbiguousTimeError for an ambiguous time.
- `nonexistent` [{‘raise’, ‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta}, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time.
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time.
  - ‘NaT’ will return NaT where there are nonexistent times.
  - timedelta objects will shift nonexistent times by the timedelta.
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

**Returns**

a new Timestamp rounded to the given resolution of `freq`

**Raises**

ValueError if the freq cannot be converted
Examples

Create a timestamp object:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
```

A timestamp can be rounded using multiple frequency units:

```python
>>> ts.round(freq='H')  # hour
Timestamp('2020-03-14 16:00:00')

>>> ts.round(freq='T')  # minute
Timestamp('2020-03-14 15:33:00')

>>> ts.round(freq='S')  # seconds
Timestamp('2020-03-14 15:32:52')

>>> ts.round(freq='L')  # milliseconds
Timestamp('2020-03-14 15:32:52.193000')
```

freq can also be a multiple of a single unit, like ‘5T’ (i.e. 5 minutes):

```python
>>> ts.round(freq='5T')
Timestamp('2020-03-14 15:35:00')
```

or a combination of multiple units, like ‘1H30T’ (i.e. 1 hour and 30 minutes):

```python
>>> ts.round(freq='1H30T')
Timestamp('2020-03-14 15:00:00')
```

Analogous for pd.NaT:

```python
>>> pd.NaT.round()
NaT
```

**pandas.Timestamp.strftime**

```
Timestamp.strftime(format)
```

Return a string representing the given POSIX timestamp controlled by an explicit format string.

**Parameters**

- format [str] Format string to convert Timestamp to string. See strftime documentation for more information on the format string: https://docs.python.org/3/library/datetime.html#strftime-and-strptime-behavior.
Examples

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.strftime('%Y-%m-%d %X')
'2020-03-14 15:32:52'
```

**pandas.Timestamp.strptime**

```python
classmethod Timestamp.strptime(string, format)
```
Function is not implemented. Use `pd.to_datetime()`.

**pandas.Timestamp.time**

```python
Timestamp.time()
```
Return time object with same time but with tzinfo=None.

**pandas.Timestamp.timestamp**

```python
Timestamp.timestamp()
```
Return POSIX timestamp as float.

Examples

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548')
>>> ts.timestamp()
1584199972.192548
```

**pandas.Timestamp.timetuple**

```python
Timestamp.timetuple()
```
Return time tuple, compatible with `time.localtime()`.

**pandas.Timestamp.timetz**

```python
Timestamp.timetz()
```
Return time object with same time and tzinfo.
pandas.Timestamp.to_datetime64

`Timestamp.to_datetime64()`

Return a `numpy.datetime64` object with ‘ns’ precision.

pandas.Timestamp.to_julian_date

`Timestamp.to_julian_date()`

Convert TimeStamp to a Julian Date. 0 Julian date is noon January 1, 4713 BC.

Examples

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52')
>>> ts.to_julian_date()
2458923.147824074
```

pandas.Timestamp.to_numpy

`Timestamp.to_numpy()`

Convert the Timestamp to a NumPy datetime64.

New in version 0.25.0.

This is an alias method for `Timestamp.to_datetime64()`. The dtype and copy parameters are available here only for compatibility. Their values will not affect the return value.

Returns

`numpy.datetime64`

See also:

`DatetimeIndex.to_numpy` Similar method for DatetimeIndex.

Examples

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.to_numpy()
numpy.datetime64('2020-03-14T15:32:52.192548651')
```

Analogous for `pd.NaT`:

```python
>>> pd.NaT.to_numpy()
numpy.datetime64('NaT')
```
**pandas.Timestamp.to_period**

*Timestamp.to_period()*

Return a period of which this timestamp is an observation.

**Examples**

```python
ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
ts.to_period(freq='Y') # Year end frequency
numpy.datetime64('2020-03-14T15:32:52.192548651')
```

```python
ts.to_period(freq='M') # Month end frequency
Period('2020-03', 'M')
```

```python
ts.to_period(freq='W') # Weekly frequency
Period('2020-03-09/2020-03-15', 'W-SUN')
```

```python
ts.to_period(freq='Q') # Quarter end frequency
Period('2020Q1', 'Q-DEC')
```

**pandas.Timestamp.to_pydatetime**

*Timestamp.to_pydatetime()*

Convert a Timestamp object to a native Python datetime object.

If warn=True, issue a warning if nanoseconds is nonzero.

**Examples**

```python
ts = pd.Timestamp('2020-03-14T15:32:52.192548')
ts.to_pydatetime()
datetime.datetime(2020, 3, 14, 15, 32, 52, 192548)
```

Analogous for pd.NaT:

```python
pd.NaT.to_pydatetime()
NaT
```

**pandas.Timestamp.today**

*classmethod Timestamp.today*(cls, tz=None)*

Return the current time in the local timezone. This differs from datetime.today() in that it can be localized to a passed timezone.

**Parameters**

- **tz** [str or timezone object, default None] Timezone to localize to.
Examples

```python
>>> pd.Timestamp.today()
Timestamp('2020-11-16 22:37:39.969883')

Analogous for pd.NaT:

```python
>>> pd.NaT.today()
NaT
```

**pandas.Timestamp.toordinal**

`Timestamp.toordinal()`

Return proleptic Gregorian ordinal. January 1 of year 1 is day 1.

**pandas.Timestamp.tz_convert**

`Timestamp.tz_convert(tz)`

Convert tz-aware Timestamp to another time zone.

*Parameters*

- `tz` [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding UTC time.

*Returns*

- `converted` [Timestamp]

*Raises*

- `TypeError` If Timestamp is tz-naive.

Examples

Create a timestamp object with UTC timezone:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651', tz='UTC')
>>> ts
Timestamp('2020-03-14 15:32:52.192548651+0000', tz='UTC')
```

Change to Tokyo timezone:

```python
>>> ts.tz_convert(tz='Asia/Tokyo')
Timestamp('2020-03-15 00:32:52.192548651+0900', tz='Asia/Tokyo')
```

Can also use `astimezone`:

```python
>>> ts.astimezone(tz='Asia/Tokyo')
Timestamp('2020-03-15 00:32:52.192548651+0900', tz='Asia/Tokyo')
```

Analogous for pd.NaT:

```python
>>> pd.NaT.tz_convert(tz='Asia/Tokyo')
NaT
```
pandas.Timestamp.tz_localize

Timestamp.tz_localize(tz, ambiguous='raise', nonexistent='raise')
Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding local time.

ambiguous [bool, ‘NaT’, default ‘raise’] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the ambiguous parameter dictates how ambiguous times should be handled.

The behavior is as follows:

- bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
- ‘NaT’ will return NaT for an ambiguous time.
- ‘raise’ will raise an AmbiguousTimeError for an ambiguous time.

nonexistent ['shift_forward', 'shift_backward', ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

The behavior is as follows:

- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time.
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time.
- ‘NaT’ will return NaT where there are nonexistent times.
- timedelta objects will shift nonexistent times by the timedelta.
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

 localized [Timestamp]

 Raises

 TypeError If the Timestamp is tz-aware and tz is not None.

Examples

Create a naive timestamp object:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts
Timestamp('2020-03-14 15:32:52.192548651')
```

Add ‘Europe/Stockholm’ as timezone:
>>>
>>> ts.tz_localize(tz='Europe/Stockholm')
Timestamp('2020-03-14 15:32:52.192548651+0100', tz='Europe/Stockholm')

Analogous for pd.NaT:

>>> pd.NaT.tz_localize()
NaT

pandas.Timestamp.tzname

    Timestamp.tzname()
    Return self.tzinfo.tzname(self).

pandas.Timestamp.utcfromtimestamp

    classmethod Timestamp.utcfromtimestamp(ts)
    Construct a naive UTC datetime from a POSIX timestamp.

    Examples

    >>> pd.Timestamp.fromtimestamp(1584199972)
    Timestamp('2020-03-14 15:32:52')

pandas.Timestamp.utcnow

    classmethod Timestamp.utcnow()
    Return a new Timestamp representing UTC day and time.

    Examples

    >>> pd.Timestamp.utcnow()
    Timestamp('2020-11-16 22:50:18.092888+0000', tz='UTC')

pandas.Timestamp.utcoffset

    Timestamp.utcoffset()
    Return self.tzinfo.utcoffset(self).
pandas.Timestamp.utctimetuple

Timestamp.utctimetuple()  
Return UTC time tuple, compatible with time.localtime().

pandas.Timestamp.weekday

Timestamp.weekday()  
Return the day of the week represented by the date. Monday == 0 ... Sunday == 6

Properties

- Timestamp.asm8: Return numpy datetime64 format in nanoseconds.
- Timestamp.day
- Timestamp.dayofweek: Return day of the week.
- Timestamp.day_of_week: Return day of the week.
- Timestamp.dayofyear: Return the day of the year.
- Timestamp.day_of_year: Return the day of the year.
- Timestamp.days_in_month: Return the number of days in the month.
- Timestamp.daysinmonth: Return the number of days in the month.
- Timestamp.fold
- Timestamp.hour
- Timestamp.is_leap_year: Return True if year is a leap year.
- Timestamp.is_month_end: Return True if date is last day of month.
- Timestamp.is_month_start: Return True if date is first day of month.
- Timestamp.is_quarter_end: Return True if date is last day of the quarter.
- Timestamp.is_quarter_start: Return True if date is first day of the quarter.
- Timestamp.is_year_end: Return True if date is last day of the year.
- Timestamp.is_year_start: Return True if date is first day of the year.
- Timestamp.max
- Timestamp.microsecond
- Timestamp.min
- Timestamp.minute
- Timestamp.month
- Timestamp.nanosecond
- Timestamp.quarter: Return the quarter of the year.
- Timestamp.resolution
- Timestamp.second

</tbody>
</table>
pandas.Timestamp.freq

Timestamp.freq

A collection of timestamps may be stored in a arrays.DatetimeArray. For timezone-aware data, the .dtype of a DatetimeArray is a DatetimeTZDtype. For timezone-naive data, np.dtype("datetime64[ns]") is used.

If the data are tz-aware, then every value in the array must have the same timezone.

arrays.DatetimeArray(values[, dtype, freq, copy])
Pandas ExtensionArray for tz-naive or tz-aware datetime data.

pandas.arrays.DatetimeArray

class pandas.arrays.DatetimeArray(values, dtype=dttype('<M8[ns]'), freq=None, copy=False)
Pandas ExtensionArray for tz-naive or tz-aware datetime data.

Warning: DatetimeArray is currently experimental, and its API may change without warning. In particular, DatetimeArray.dtype is expected to change to always be an instance of an ExtensionDtype subclass.

Parameters

values [Series, Index, DatetimeArray, ndarray] The datetime data.

For DatetimeArray values (or a Series or Index boxing one), dtype and freq will be extracted from values.

dtype [numpy.dtype or DatetimeTZDtype] Note that the only NumPy dtype allowed is ‘datetime64[ns]’.

freq [str or Offset, optional] The frequency.

copy [bool, default False] Whether to copy the underlying array of values.

Attributes

None

Methods

None

DatetimeTZDtype([unit, tz]) An ExtensionDtype for timezone-aware datetime data.
pandas.DatetimeTZDtype

class pandas.DatetimeTZDtype(unit='ns', tz=None)
   An ExtensionDtype for timezone-aware datetime data.

   This is not an actual numpy dtype, but a duck type.

   Parameters

   unit [str, default "ns"] The precision of the datetime data. Currently limited to "ns".

   tz [str, int, or datetime.tzinfo] The timezone.

   Raises

   pytz.UnknownTimeZoneError When the requested timezone cannot be found.

Examples

>>> pd.DatetimeTZDtype(tz='UTC')
datetime64[ns, UTC]

>>> pd.DatetimeTZDtype(tz='dateutil/US/Central')
datetime64[ns, tzfile('/usr/share/zoneinfo/US/Central')]

Attributes

<table>
<thead>
<tr>
<th>unit</th>
<th>The precision of the datetime data.</th>
</tr>
</thead>
<tbody>
<tr>
<td>tz</td>
<td>The timezone.</td>
</tr>
</tbody>
</table>

pandas.DatetimeTZDtype.unit

property DatetimeTZDtype.unit
   The precision of the datetime data.

pandas.DatetimeTZDtype.tz

property DatetimeTZDtype.tz
   The timezone.

Methods

None
3.5.3 Timedelta data

NumPy can natively represent timedeltas. pandas provides `Timedelta` for symmetry with `Timestamp`.

```
Timedelta([[value, unit]]) Representa a duration, the difference between two dates or times.
```

**pandas.Timedelta**

```
class pandas.Timedelta(value=<object object>, unit=None, **kwargs)
    Represents a duration, the difference between two dates or times.

    Timedelta is the pandas equivalent of python's datetime.timedelta and is interchangeable with it in most cases.

    Parameters
    value [Timedelta, timedelta, np.timedelta64, str, or int]
    unit [str, default 'ns'] Denote the unit of the input, if input is an integer.

        Possible values:
        • ‘days’ or ‘day’
        • ‘hours’, ‘hour’, ‘hr’, or ‘h’
        • ‘minutes’, ‘minute’, ‘min’, or ‘m’
        • ‘seconds’, ‘second’, or ‘sec’
        • ‘milliseconds’, ‘millisecond’, ‘millis’, or ‘milli’
        • ‘microseconds’, ‘microsecond’, ‘micros’, or ‘micro’

    **kwargs Available kwags: {days, seconds, microseconds, milliseconds, minutes, hours, weeks}. Values for construction in compat with datetime.timedelta. Numpy ints and floats will be coerced to python ints and floats.
```

**Notes**

The `.value` attribute is always in ns.

If the precision is higher than nanoseconds, the precision of the duration is truncated to nanoseconds.

**Attributes**

```
asm8 Return a numpy timedelta64 array scalar view.
components Return a components namedtuple-like.
days Number of days.
delta Return the timedelta in nanoseconds (ns), for internal compatibility.
```

continues on next page
Table 96 – continued from previous page

|microseconds| Number of microseconds (>= 0 and less than 1 second). |
|nanoseconds| Return the number of nanoseconds (n), where 0 <= n < 1 microsecond. |
|resolution_string| Return a string representing the lowest timedelta resolution. |
|seconds| Number of seconds (>= 0 and less than 1 day). |

pandas.Timedelta.asm8

Timedelta.asm8
Return a numpy timedelta64 array scalar view.

Provides access to the array scalar view (i.e. a combination of the value and the units) associated with the numpy.timedelta64().view(), including a 64-bit integer representation of the timedelta in nanoseconds (Python int compatible).

Returns

numpy timedelta64 array scalar view Array scalar view of the timedelta in nanoseconds.

Examples

```python
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.asm8
numpy.timedelta64(86520000003042,'ns')
```

```python
>>> td = pd.Timedelta('2 min 3 s')
>>> td.asm8
numpy.timedelta64(123000000000,'ns')
```

```python
>>> td = pd.Timedelta('3 ms 5 us')
>>> td.asm8
numpy.timedelta64(3005000,'ns')
```

```python
>>> td = pd.Timedelta(42, unit='ns')
>>> td.asm8
numpy.timedelta64(42,'ns')
```

pandas.Timedelta.components

Timedelta.components
Return a components namedtuple-like.
pandas.Timedelta.days

Timedelta.days
Number of days.

pandas.Timedelta.delta

Timedelta.delta
Return the timedelta in nanoseconds (ns), for internal compatibility.

Returns

int Timedelta in nanoseconds.

Examples

```python
>>> td = pd.Timedelta('1 days 42 ns')
>>> td.delta
8640000000042

>>> td = pd.Timedelta('3 s')
>>> td.delta
3000000000

>>> td = pd.Timedelta('3 ms 5 us')
>>> td.delta
3005000

>>> td = pd.Timedelta(42, unit='ns')
>>> td.delta
42
```

pandas.Timedelta.microseconds

Timedelta.microseconds
Number of microseconds (>= 0 and less than 1 second).

pandas.Timedelta.nanoseconds

Timedelta.nanoseconds
Return the number of nanoseconds (n), where 0 <= n < 1 microsecond.

Returns

int Number of nanoseconds.

See also:

Timedelta.components Return all attributes with assigned values (i.e. days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds).
Examples

Using string input

```python
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')

>>> td.nanoseconds
42
```

Using integer input

```python
>>> td = pd.Timedelta(42, unit='ns')
>>> td.nanoseconds
42
```

pandas.Timedelta.resolution_string

`Timedelta.resolution_string` Return a string representing the lowest timedelta resolution.

Each timedelta has a defined resolution that represents the lowest OR most granular level of precision. Each level of resolution is represented by a short string as defined below:

Resolution: Return value
- Days: ‘D’
- Hours: ‘H’
- Minutes: ‘T’
- Seconds: ‘S’
- Milliseconds: ‘L’
- Microseconds: ‘U’
- Nanoseconds: ‘N’

**Returns**

str Timedelta resolution.

Examples

```python
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.resolution_string
'N'

>>> td = pd.Timedelta('1 days 2 min 3 us')
>>> td.resolution_string
'U'

>>> td = pd.Timedelta('2 min 3 s')
>>> td.resolution_string
'S'
```
>>> td = pd.Timedelta(36, unit='us')
>>> td.resolution_string
'U'

pandas.Timedelta.seconds

Timedelta.seconds
   Number of seconds (>= 0 and less than 1 day).

Methods

- `ceil(freq)` Return a new Timedelta ceiled to this resolution.
- `floor(freq)` Return a new Timedelta floored to this resolution.
- `round(freq)` Round the Timedelta to the specified resolution.
- `to_numpy` Convert the Timedelta to a NumPy timedelta64.
- `to_pytimedelta` Convert a pandas Timedelta object into a python timedelta object.
- `to_timedelta64` Return a numpy.timedelta64 object with ‘ns’ precision.
- `total_seconds` Total seconds in the duration.
- `view` Array view compatibility.

pandas.Timedelta.ceil

Timedelta.ceil(freq)
   Return a new Timedelta ceiled to this resolution.

Parameters

- `freq` [str] Frequency string indicating the ceiling resolution.

pandas.Timedelta.floor

Timedelta.floor(freq)
   Return a new Timedelta floored to this resolution.

Parameters

- `freq` [str] Frequency string indicating the flooring resolution.
### pandas.Timedelta.isoformat

**Timedelta.isoformat()**

**Returns**
- `str`

**See also:**
- **Timestamp.isoformat** Function is used to convert the given Timestamp object into the ISO format.

**Notes**

The longest component is days, whose value may be larger than 365. Every component is always included, even if its value is 0. Pandas uses nanosecond precision, so up to 9 decimal places may be included in the seconds component. Trailing 0’s are removed from the seconds component after the decimal. We do not 0 pad components, so it’s ... *TS*H..., not ... *T0S*H...  

**Examples**

```python
>>> td = pd.Timedelta(days=6, minutes=50, seconds=3,
                        milliseconds=10, microseconds=10, nanoseconds=12)
>>> td.isoformat()
'P6DT0H50M3.010010012S'

>>> pd.Timedelta(hours=1, seconds=10).isoformat()
'P0DT1H0M10S'

>>> pd.Timedelta(days=500.5).isoformat()
'P500DT12H0M0S'
```

### pandas.Timedelta.round

**Timedelta.round(freq)**
Round the Timedelta to the specified resolution.

**Parameters**
- `<freq>` [str] Frequency string indicating the rounding resolution.

**Returns**
- a new Timedelta rounded to the given resolution of `<freq>`

**Raises**
- `ValueError` if the `<freq>` cannot be converted
pandas.Timedelta.to_numpy

Timedelta.to_numpy()
Convert the Timedelta to a NumPy timedelta64.
New in version 0.25.0.
This is an alias method for Timedelta.to_timedelta64(). The dtype and copy parameters are available here only for compatibility. Their values will not affect the return value.

Returns
numpy.timedelta64

See also:
Series.to_numpy Similar method for Series.

pandas.Timedelta.to_pytimedelta

Timedelta.to_pytimedelta()
Convert a pandas Timedelta object into a python timedelta object.
Timedelta objects are internally saved as numpy datetime64[ns] dtype. Use to_pytimedelta() to convert to object dtype.

Returns
datetime.timedelta or numpy.array of datetime.timedelta

See also:
to_timedelta Convert argument to Timedelta type.

Notes
Any nanosecond resolution will be lost.

pandas.Timedelta.to_timedelta64

Timedelta.to_timedelta64()
Return a numpy.timedelta64 object with ‘ns’ precision.

pandas.Timedelta.total_seconds

Timedelta.total_seconds()
Total seconds in the duration.
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.Timedelta.view

Timedelta.view()
Array view compatibility.

Properties

- Timedelta.asm8: Return a numpy timedelta64 array scalar view.
- Timedelta.components: Return a components namedtuple-like.
- Timedelta.days: Number of days.
- Timedelta.delta: Return the timedelta in nanoseconds (ns), for internal compatibility.
- Timedelta.freq
- Timedelta.is_populated
- Timedelta.max
- Timedelta.microseconds: Number of microseconds (>= 0 and less than 1 second).
- Timedelta.min
- Timedelta.nanoseconds: Return the number of nanoseconds (n), where 0 <= n < 1 microsecond.
- Timedelta.resolution
- Timedelta.seconds: Number of seconds (>= 0 and less than 1 day).
- Timedelta.value
- Timedelta.view: Array view compatibility.

pandas.Timedelta.freq

Timedelta.freq

pandas.Timedelta.is_populated

Timedelta.is_populated

pandas.Timedelta.max

Timedelta.max = Timedelta('106751 days 23:47:16.854775807')
pandas.Timedelta.min

```python
Timedelta.min = Timedelta('-106752 days +00:12:43.145224193')
```

pandas.Timedelta.resolution

```python
Timedelta.resolution = Timedelta('0 days 00:00:00.000000001')
```

pandas.Timedelta.value

```python
Timedelta.value
```

A collection of timedeltas may be stored in a TimedeltaArray.

```python
arrays.TimedeltaArray(values[, dtype, freq, ...])
```

pandas.arrays.TimedeltaArray

```python
class pandas.arrays.TimedeltaArray(values, dtype=dttype('<m8[ns]'), freq=<no_default>, copy=False)
```

Pandas ExtensionArray for timedelta data.

**Warning:** TimedeltaArray is currently experimental, and its API may change without warning. In particular, TimedeltaArray.dtype is expected to change to be an instance of an ExtensionDtype subclass.

**Parameters**

- values [array-like] The timedelta data.
- dtype [numpy.dtype] Currently, only numpy.dtype("timedelta64[ns]") is accepted.
- freq [Offset, optional]
copy [bool, default False] Whether to copy the underlying array of data.

**Attributes**

None

**Methods**

None

### 3.5.4 Timespan data

pandas represents spans of times as *Period* objects.

### 3.5.5 Period

```python
Period([value, freq, ordinal, year, month, ...]) Represents a period of time.
```

**pandas.Period**

```python
class pandas.Period(value=None, freq=None, ordinal=None, year=None, month=None, quarter=None, day=None, hour=None, minute=None, second=None)
```

Represents a period of time.

**Parameters**

- **value** [Period or str, default None] The time period represented (e.g., ‘4Q2005’).
- **freq** [str, default None] One of pandas period strings or corresponding objects.
- **ordinal** [int, default None] The period offset from the proleptic Gregorian epoch.
- **year** [int, default None] Year value of the period.
- **month** [int, default 1] Month value of the period.
- **quarter** [int, default None] Quarter value of the period.
- **day** [int, default 1] Day value of the period.
- **hour** [int, default 0] Hour value of the period.
- **minute** [int, default 0] Minute value of the period.
- **second** [int, default 0] Second value of the period.

</tbody>
</table>

pandas.Period.day

Period.day
Get day of the month that a Period falls on.

Returns
int

See also:

Period.dayofweek Get the day of the week.
Period.dayofyear Get the day of the year.

Examples

```python
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.day
11
```
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.Period.day_of_week

Period.day_of_week
Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

Returns

int  Day of the week.

See also:

Period.day_of_week  Day of the week the period lies in.
Period.weekday  Alias of Period.day_of_week.
Period.day  Day of the month.
Period.dayofyear  Day of the year.

Examples

```python
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.day_of_week
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```python
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.day_of_week
6
>>> per.start_time.day_of_week
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```python
>>> per = pd.Period('2018-01', 'M')
>>> per.day_of_week
2
>>> per.end_time.day_of_week
2
```

pandas.Period.day_of_year

Period.day_of_year
Return the day of the year.

This attribute returns the day of the year on which the particular date occurs. The return value ranges between 1 to 365 for regular years and 1 to 366 for leap years.

Returns

int  The day of year.

See also:
**Period.day**  Return the day of the month.

**Period.day_of_week**  Return the day of week.

**PeriodIndex.day_of_year**  Return the day of year of all indexes.

### Examples

```python
>>> period = pd.Period("2015-10-23", freq='H')
>>> period.day_of_year
296
>>> period = pd.Period("2012-12-31", freq='D')
>>> period.day_of_year
366
>>> period = pd.Period("2013-01-01", freq='D')
>>> period.day_of_year
1
```

**pandas.Period.dayofweek**

**Period.dayofweek**

Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

**Returns**

```
int  Day of the week.
```

**See also:**

- **Period.day_of_week**  Day of the week the period lies in.
- **Period.weekday**  Alias of Period.day_of_week.
- **Period.day**  Day of the month.
- **Period.dayofyear**  Day of the year.

### Examples

```python
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.day_of_week
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```python
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.day_of_week
6
>>> per.start_time.day_of_week
6
```

For periods with a frequency higher than days, the last day of the period is returned.
pandas: powerful Python data analysis toolkit, Release 1.3.2

```python
>>> per = pd.Period('2018-01', 'M')
>>> per.day_of_week
2
>>> per.end_time.day_of_week
2
```

### pandas.Period.dayofyear

**Period.dayofyear**

Return the day of the year.

This attribute returns the day of the year on which the particular date occurs. The return value ranges between 1 to 365 for regular years and 1 to 366 for leap years.

**Returns**

```
int  The day of year.
```

**See also:**

- **Period.day** Return the day of the month.
- **Period.day_of_week** Return the day of week.
- **PeriodIndex.day_of_year** Return the day of year of all indexes.

**Examples**

```python
>>> period = pd.Period("2015-10-23", freq='H')
>>> period.day_of_year
296
>>> period = pd.Period("2012-12-31", freq='D')
>>> period.day_of_year
366
>>> period = pd.Period("2013-01-01", freq='D')
>>> period.day_of_year
1
```

### pandas.Period.days_in_month

**Period.days_in_month**

Get the total number of days in the month that this period falls on.

**Returns**

```
int
```

**See also:**

- **Period.daysinmonth** Gets the number of days in the month.
- **DatetimeIndex.daysinmonth** Gets the number of days in the month.
- **calendar.monthrange** Returns a tuple containing weekday (0-6 ~ Mon-Sun) and number of days (28-31).
**Examples**

```python
>>> p = pd.Period('2018-2-17')
>>> p.days_in_month
28
```

```python
>>> pd.Period('2018-03-01').days_in_month
31
```

Handles the leap year case as well:

```python
>>> p = pd.Period('2016-2-17')
>>> p.days_in_month
29
```

**pandas.Period.daysinmonth**

Period.daysinmonth

Get the total number of days of the month that the Period falls in.

Returns

int

See also:

Period.days_in_month  Return the days of the month.
Period.dayofyear  Return the day of the year.

**Examples**

```python
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.daysinmonth
31
```

**pandas.Period.hour**

Period.hour

Get the hour of the day component of the Period.

Returns

int  The hour as an integer, between 0 and 23.

See also:

Period.second  Get the second component of the Period.
Period.minute  Get the minute component of the Period.
Examples

```python
>>> p.hour
13
```

Period longer than a day

```python
>>> p = pd.Period("2018-03-11", freq="M")
>>> p.hour
0
```

**pandas.Period.minute**

**Period.minute**
Get minute of the hour component of the Period.

**Returns**

- **int** The minute as an integer, between 0 and 59.

**See also:**

- **Period.hour** Get the hour component of the Period.
- **Period.second** Get the second component of the Period.

Examples

```python
>>> p.minute
3
```

**pandas.Period.qyear**

**Period.qyear**
Fiscal year the Period lies in according to its starting-quarter.

The year and the qyear of the period will be the same if the fiscal and calendar years are the same. When they are not, the fiscal year can be different from the calendar year of the period.

**Returns**

- **int** The fiscal year of the period.

**See also:**

- **Period.year** Return the calendar year of the period.
Examples

If the natural and fiscal year are the same, \textit{qyear} and \textit{year} will be the same.

\begin{verbatim}
>>> per = pd.Period('2018Q1', freq='Q')
>>> per.qyear
2018
>>> per.year
2018
\end{verbatim}

If the fiscal year starts in April (\textit{Q-MAR}), the first quarter of 2018 will start in April 2017. \textit{year} will then be 2018, but \textit{qyear} will be the fiscal year, 2018.

\begin{verbatim}
>>> per = pd.Period('2018Q1', freq='Q-MAR')
>>> per.start_time
Timestamp('2017-04-01 00:00:00')
>>> per.qyear
2018
>>> per.year
2017
\end{verbatim}

\texttt{pandas.Period.second}

\texttt{Period.second}
Get the second component of the Period.

\textbf{Returns}

\begin{verbatim}
int
\end{verbatim}

The second of the Period (ranges from 0 to 59).

\textbf{See also:}

\texttt{Period.hour} Get the hour component of the Period.

\texttt{Period.minute} Get the minute component of the Period.

\textbf{Examples}

\begin{verbatim}
>>> p.second
12
\end{verbatim}

\texttt{pandas.Period.start_time}

\texttt{Period.start_time}
Get the Timestamp for the start of the period.

\textbf{Returns}

\begin{verbatim}
Timestamp
\end{verbatim}

\textbf{See also:}

\texttt{Period.end_time} Return the end Timestamp.

\texttt{Period.dayofyear} Return the day of year.
**Period.daysinmonth**  Return the days in that month.

**Period.dayofweek**  Return the day of the week.

**Examples**

```python
>>> period = pd.Period('2012-1-1', freq='D')
>>> period
Period('2012-01-01', 'D')

>>> period.start_time
Timestamp('2012-01-01 00:00:00')

>>> period.end_time
Timestamp('2012-01-01 23:59:59.999999999')
```

**pandas.Period.week**

**Period.week**
Get the week of the year on the given Period.

**Returns**

```
int
```

**See also:**

**Period.dayofweek**  Get the day component of the Period.

**Period.weekday**  Get the day component of the Period.

**Examples**

```python
>>> p = pd.Period("2018-03-11", "H")
>>> p.week
10

>>> p = pd.Period("2018-02-01", "D")
>>> p.week
5

>>> p = pd.Period("2018-01-06", "D")
>>> p.week
1
```
**pandas.Period.weekday**

**Period.weekday**
Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

Returns

int  Day of the week.

See also:

*Period.dayofweek*  Day of the week the period lies in.

*Period.weekday*  Alias of Period.dayofweek.

*Period.day*  Day of the month.

*Period.dayofyear*  Day of the year.

**Examples**

```python
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.dayofweek
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```python
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.dayofweek
6
>>> per.start_time.dayofweek
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```python
>>> per = pd.Period('2018-01', 'M')
>>> per.dayofweek
2
>>> per.end_time.dayofweek
2
```
Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>asfreq</code></td>
<td>Convert Period to desired frequency, at the start or end of the interval.</td>
</tr>
<tr>
<td><code>strftime</code></td>
<td>Returns the string representation of the <code>Period</code>, depending on the selected <code>fmt</code>.</td>
</tr>
<tr>
<td><code>to_timestamp</code></td>
<td>Return the Timestamp representation of the Period.</td>
</tr>
</tbody>
</table>

### pandas.Period.asfreq

`Period.asfreq()`  
Convert Period to desired frequency, at the start or end of the interval.

**Parameters**

- `freq` [str] The desired frequency.
- `how` [{‘E’, ‘S’, ‘end’, ‘start’}, default ‘end’] Start or end of the timespan.

**Returns**

- `resampled` [Period]

### pandas.Period.strftime

`Period.strftime()`  
Returns the string representation of the `Period`, depending on the selected `fmt`. `fmt` must be a string containing one or several directives. The method recognizes the same directives as the `time.strftime()` function of the standard Python distribution, as well as the specific additional directives `%f, %F, %q`. (formatting & docs originally from scikit.timeries).
### %a, %A, %b, %B
- **%a**: Locale’s abbreviated weekday name.
- **%A**: Locale’s full weekday name.
- **%b**: Locale’s abbreviated month name.
- **%B**: Locale’s full month name.

### %c
- **%c**: Locale’s appropriate date and time representation.

### %d
- **%d**: Day of the month as a decimal number [01,31].

### %f
- **%f**: ‘Fiscal’ year without a century as a decimal number [00,99]
  - (1)
- **%F**: ‘Fiscal’ year with a century as a decimal number
  - (2)

### %H
- **%H**: Hour (24-hour clock) as a decimal number [00,23].

### %I
- **%I**: Hour (12-hour clock) as a decimal number [01,12].

### %j
- **%j**: Day of the year as a decimal number [001,366].

### %m
- **%m**: Month as a decimal number [01,12].

### %M
- **%M**: Minute as a decimal number [00,59].

### %p
- **%p**: Locale’s equivalent of either AM or PM.
  - (3)

### %q
- **%q**: Quarter as a decimal number [01,04]

### %r
- **%r**: Second (no characters if no time zone exists).
  - (4)

### %U
- **%U**: Week number of the year (Sunday as the first day of the week) as a decimal number [00,53].
  - (5)
  - All days in a new year preceding the first Sunday are considered to be in week 0.

### %W
- **%W**: Week number of the year (Monday as the first day of the week) as a decimal number [00,53].
  - (5)
  - All days in a new year preceding the first Monday are considered to be in week 0.

### %x
- **%x**: Locale’s appropriate date representation.

### %X
- **%X**: Locale’s appropriate time representation.

### %y
- **%y**: Year without century as a decimal number [00,99].

### %Y
- **%Y**: Year with century as a decimal number.

### %Z
- **%Z**: Time zone name (no characters if no time zone exists).

### %%
- **%%**: A literal ‘%’ character.

### Notes

1. The %f directive is the same as %y if the frequency is not quarterly. Otherwise, it corresponds to the ‘fiscal’ year, as defined by the qyear attribute.
2. The %F directive is the same as %Y if the frequency is not quarterly. Otherwise, it corresponds to the ‘fiscal’ year, as defined by the qyear attribute.
3. The %p directive only affects the output hour field if the %I directive is used to parse the hour.
4. The range really is 0 to 61; this accounts for leap seconds and the (very rare) double leap seconds.
5. The %U and %W directives are only used in calculations when the day of the week and the year are specified.
Examples

```python
>>> a = Period(freq='Q-JUL', year=2006, quarter=1)
>>> a.strftime('%F-Q%q')
'2006-Q1'
>>> # Output the last month in the quarter of this date
>>> a.strftime('%b-%Y')
'Oct-2005'
>>> a = Period(freq='D', year=2001, month=1, day=1)
>>> a.strftime('%d-%b-%Y')
'01-Jan-2006'
>>> a.strftime('%b. %d, %Y was a %A')
'Jan. 01, 2001 was a Monday'
```

**pandas.Period.to_timestamp**

Period.to_timestamp()  
Return the Timestamp representation of the Period.

Uses the target frequency specified at the part of the period specified by how, which is either Start or Finish.

**Parameters**

- **freq** [str or DateOffset] Target frequency. Default is ‘D’ if self.freq is week or longer and ‘S’ otherwise.

**Returns**

- **Timestamp**

pandas.Period.now

Period.now()

A collection of timedeltas may be stored in a arrays.PeriodArray. Every period in a PeriodArray must have the same freq.

arrays.PeriodArray(values[, dtype, freq, copy]) Pandas ExtensionArray for storing Period data.
pandas.arrays.PeriodArray

class pandas.arrays.PeriodArray (values, dtype=None, freq=None, copy=False)
Pandas ExtensionArray for storing Period data.

Users should use period_array() to create new instances. Alternatively, array() can be used to create new instances from a sequence of Period scalars.

Parameters

values [Union[PeriodArray, Series[period], ndarray[int], PeriodIndex]] The data to store. These should be arrays that can be directly converted to ordinals without inference or copy (PeriodArray, ndarray[int64]), or a box around such an array (Series[period], PeriodIndex).

dtype [PeriodDtype, optional] A PeriodDtype instance from which to extract a freq. If both freq and dtype are specified, then the frequencies must match.

freq [str or DateOffset] The freq to use for the array. Mostly applicable when values is an ndarray of integers, when freq is required. When values is a PeriodArray (or box around), it’s checked that values.freq matches freq.

copy [bool, default False] Whether to copy the ordinals before storing.

See also:

Period Represents a period of time.
PeriodIndex Immutable Index for period data.
period_range Create a fixed-frequency PeriodArray.
array Construct a pandas array.

Notes

There are two components to a PeriodArray

- ordinals : integer ndarray
- freq : pd.tseries.offsets.Offset

The values are physically stored as a 1-D ndarray of integers. These are called “ordinals” and represent some kind of offset from a base.

The freq indicates the span covered by each element of the array. All elements in the PeriodArray have the same freq.

Attributes

None

Methods

None

PeriodDtype([freq]) An ExtensionDtype for Period data.
pandas.PeriodDtype

class pandas.PeriodDtype(freq=None)
    An ExtensionDtype for Period data.

    This is not an actual numpy dtype, but a duck type.

    Parameters

    freq [str or DateOffset] The frequency of this PeriodDtype.

Examples

    >>> pd.PeriodDtype(freq='D')
    period[D]

    >>> pd.PeriodDtype(freq=pd.offsets.MonthEnd())
    period[M]

Attributes

freq
    The frequency object of this PeriodDtype.

pandas.PeriodDtype.freq

    property PeriodDtype.freq
    The frequency object of this PeriodDtype.

Methods

None

3.5.6 Interval data

Arbitrary intervals can be represented as Interval objects.

| Interval     | Immutable object implementing an Interval, a bounded slice-like interval. |
**pandas.Interval**

**class pandas.Interval**

Immutable object implementing an Interval, a bounded slice-like interval.

**Parameters**

- **left** [orderable scalar] Left bound for the interval.
- **right** [orderable scalar] Right bound for the interval.
- **closed** [['right', 'left', 'both', 'neither'], default 'right'] Whether the interval is closed on the left-side, right-side, both or neither. See the Notes for more detailed explanation.

**See also:**

- **IntervalIndex** An Index of Interval objects that are all closed on the same side.
- **cut** Convert continuous data into discrete bins (Categorical of Interval objects).
- **qcut** Convert continuous data into bins (Categorical of Interval objects) based on quantiles.
- **Period** Represents a period of time.

**Notes**

The parameters *left* and *right* must be from the same type, you must be able to compare them and they must satisfy $left \leq right$.

A closed interval (in mathematics denoted by square brackets) contains its endpoints, i.e. the closed interval $[0, 5]$ is characterized by the conditions $0 \leq x \leq 5$. This is what closed='both' stands for. An open interval (in mathematics denoted by parentheses) does not contain its endpoints, i.e. the open interval $(0, 5)$ is characterized by the conditions $0 < x < 5$. This is what closed='neither' stands for. Intervals can also be half-open or half-closed, i.e. $[0, 5)$ is described by $0 \leq x < 5$ (closed='left') and $(0, 5]$ is described by $0 < x \leq 5$ (closed='right').

**Examples**

It is possible to build Intervals of different types, like numeric ones:

```python
>>> iv = pd.Interval(left=0, right=5)
>>> iv
Interval(0, 5, closed='right')
```

You can check if an element belongs to it

```python
>>> 2.5 in iv
True
```

You can test the bounds (closed='right', so $0 < x \leq 5$):

```python
>>> 0 in iv
False
>>> 5 in iv
True
>>> 0.0001 in iv
True
```

Calculate its length

```python
>>> iv.length
5
```
You can operate with + and * over an Interval and the operation is applied to each of its bounds, so the result depends on the type of the bound elements.

```python
>>> shifted_iv = iv + 3
>>> shifted_iv
Interval(3, 8, closed='right')
>>> extended_iv = iv * 10.0
>>> extended_iv
Interval(0.0, 50.0, closed='right')
```

To create a time interval you can use Timestamps as the bounds.

```python
>>> year_2017 = pd.Interval(pd.Timestamp('2017-01-01 00:00:00'),
... pd.Timestamp('2018-01-01 00:00:00'),
... closed='left')
>>> pd.Timestamp('2017-01-01 00:00') in year_2017
True
>>> year_2017.length
Timedelta('365 days 00:00:00')
```

**Attributes**

</tbody>
</table>

**pandas.Interval.closed**

Interval.closed

Whether the interval is closed on the left-side, right-side, both or neither.

**pandas.Interval.closed_left**

Interval.closed_left

Check if the interval is closed on the left side.

For the meaning of closed and open see Interval.

Returns

bool True if the Interval is closed on the left-side.
pandas.Interval.closed_right

Interval.closed_right
Check if the interval is closed on the right side.
For the meaning of closed and open see Interval.

Returns

bool True if the Interval is closed on the left-side.

pandas.Interval.is_empty

Interval.is_empty
Indicates if an interval is empty, meaning it contains no points.
New in version 0.25.0.

Returns

bool or ndarray A boolean indicating if a scalar Interval is empty, or a boolean
ndarray positionally indicating if an Interval in an IntervalArray or
IntervalIndex is empty.

Examples

An Interval that contains points is not empty:

```python
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```python
>>> pd.Interval(0, 0, closed='right').is_empty
True
```
```python
>>> pd.Interval(0, 0, closed='left').is_empty
True
```
```python
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:

```python
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An IntervalArray or IntervalIndex returns a boolean ndarray positionally indicating if an
Interval is empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'),
         pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:
```python
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```

**pandas.Interval.left**

Interval.left

Left bound for the interval.

**pandas.Interval.length**

Interval.length

Return the length of the Interval.

**pandas.Interval.mid**

Interval.mid

Return the midpoint of the Interval.

**pandas.Interval.open_left**

Interval.open_left

Check if the interval is open on the left side.

For the meaning of closed and open see Interval.

Returns

bool True if the Interval is closed on the left-side.

**pandas.Interval.open_right**

Interval.open_right

Check if the interval is open on the right side.

For the meaning of closed and open see Interval.

Returns

bool True if the Interval is closed on the left-side.
pandas.Interval.right

Interval.right
Right bound for the interval.

Methods

overlaps
Check whether two Interval objects overlap.

pandas.Interval.overlaps

Interval.overlaps()
Check whether two Interval objects overlap.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

Parameters

other [Interval] Interval to check against for an overlap.

Returns

bool True if the two intervals overlap.

See also:

IntervalArray.overlaps The corresponding method for IntervalArray.
IntervalIndex.overlaps The corresponding method for IntervalIndex.

Examples

```python
>>> i1 = pd.Interval(0, 2)
>>> i2 = pd.Interval(1, 3)
>>> i1.overlaps(i2)
True
>>> i3 = pd.Interval(4, 5)
>>> i1.overlaps(i3)
False
```

Intervals that share closed endpoints overlap:

```python
>>> i4 = pd.Interval(0, 1, closed='both')
>>> i5 = pd.Interval(1, 2, closed='both')
>>> i4.overlaps(i5)
True
```

Intervals that only have an open endpoint in common do not overlap:

```python
>>> i6 = pd.Interval(1, 2, closed='neither')
>>> i4.overlaps(i6)
False
```

</tbody>
</table>

A collection of intervals may be stored in an `arrays.IntervalArray`.

```python
arrays.IntervalArray(data[, closed, dtype, copy, verify_integrity])
```

Pandas array for interval data that are closed on the same side.

**pandas.arrays.IntervalArray**

**class pandas.arrays.IntervalArray**(data[, closed=None, dtype=None, copy=False, verify_integrity=True])

Pandas array for interval data that are closed on the same side.

New in version 0.24.0.

**Parameters**

- `data` [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalArray.
- `closed` ['left', 'right', 'both', 'neither'], default 'right' Whether the intervals are closed on the left-side, right-side, both or neither.
- `dtype` [dtype or None, default None] If None, dtype will be inferred.
- `copy` [bool, default False] Copy the input data.
- `verify_integrity` [bool, default True] Verify that the IntervalArray is valid.

**See also:**

- `Index` The base pandas Index type.
- `Interval` A bounded slice-like interval; the elements of an IntervalArray.
- `interval_range` Function to create a fixed frequency IntervalIndex.
- `cut` Bin values into discrete Intervals.
- `qcut` Bin values into equal-sized Intervals based on rank or sample quantiles.
Notes

See the user guide for more.

Examples

A new `IntervalArray` can be constructed directly from an array-like of `Interval` objects:

```python
>>> pd.arrays.IntervalArray([pd.Interval(0, 1), pd.Interval(1, 5)])
<IntervalArray>
[(0, 1], (1, 5]]
Length: 2, dtype: interval[int64, right]
```

It may also be constructed using one of the constructor methods: `IntervalArray.from_arrays()`, `IntervalArray.from_breaks()`, and `IntervalArray.from_tuples()`.

Attributes

- `left` property
  Return the left endpoints of each Interval in the `IntervalArray` as an Index.
- `right` property
  Return the right endpoints of each Interval in the `IntervalArray` as an Index.
- `closed` property
  Whether the intervals are closed on the left-side, right-side, both or neither.
- `mid` property
  Return the midpoint of each Interval in the `IntervalArray` as an Index.
- `length` property
  Return an Index with entries denoting the length of each Interval in the `IntervalArray`.
- `is_empty` property
  Indicates if an interval is empty, meaning it contains no points.
- `is_non_overlapping_monotonic` property
  Return True if the `IntervalArray` is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.
pandas: powerful Python data analysis toolkit, Release 1.3.2

**pandas.arrays.IntervalArray.right**

**property IntervalArray.right**  
Return the right endpoints of each Interval in the IntervalArray as an Index.

**pandas.arrays.IntervalArray.closed**

**property IntervalArray.closed**  
Whether the intervals are closed on the left-side, right-side, both or neither.

**pandas.arrays.IntervalArray.mid**

**property IntervalArray.mid**  
Return the midpoint of each Interval in the IntervalArray as an Index.

**pandas.arrays.IntervalArray.length**

**property IntervalArray.length**  
Return an Index with entries denoting the length of each Interval in the IntervalArray.

**pandas.arrays.IntervalArray.is_empty**

IntervalArray.is_empty  
Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

**Returns**

*bool or ndarray*  
A boolean indicating if a scalar Interval is empty, or a boolean ndarray positionally indicating if an Interval in an IntervalArray or IntervalIndex is empty.

**Examples**

An Interval that contains points is not empty:

```python
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```python
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:
>>> pd.Interval(0, 0, closed='both').is_empty
False

An IntervalArray or IntervalIndex returns a boolean ndarray positionally indicating if an Interval is empty:

>>> ivs = [pd.Interval(0, 0, closed='neither'),
         ...        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([True, False])

Missing values are not considered empty:

>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([True, False])

pandas.arrays.IntervalArray.is_non_overlapping_monotonic

**property** IntervalArray.is_non_overlapping_monotonic
Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.

**Methods**

<table>

pandas.arrays.IntervalArray.from_arrays

**classmethod** IntervalArray.from_arrays(left, right, closed='right', copy=False, dtype=None)
Construct from two arrays defining the left and right bounds.

**Parameters**

- left [array-like (1-dimensional)] Left bounds for each interval.
- right [array-like (1-dimensional)] Right bounds for each interval.
- closed [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.
- copy [bool, default False] Copy the data.
**dtype**  [dtype, optional] If None, dtype will be inferred.

**Returns**

IntervalArray

**Raises**

ValueError  When a value is missing in only one of left or right. When a value in left is greater than the corresponding value in right.

See also:

**interval_range**  Function to create a fixed frequency IntervalIndex.

**IntervalArray.from_breaks**  Construct an IntervalArray from an array of splits.

**IntervalArray.from_tuples**  Construct an IntervalArray from an array-like of tuples.

**Notes**

Each element of left must be less than or equal to the right element at the same position. If an element is missing, it must be missing in both left and right. A TypeError is raised when using an unsupported type for left or right. At the moment, ‘category’, ‘object’, and ‘string’ subtypes are not supported.

```python
>>> pd.arrays.IntervalArray.from_arrays([0, 1, 2], [1, 2, 3])
<IntervalArray>
[(0, 1], (1, 2], (2, 3]]
Length: 3, dtype: interval[int64, right]
```

**pandas.arrays.IntervalArray.from_tuples**

**classmethod**  IntervalArray.from_tuples(data, closed='right', copy=False, dtype=None)

Construct an IntervalArray from an array-like of tuples.

**Parameters**

- **data**  [array-like (1-dimensional)] Array of tuples.
- **closed**  [[‘left’, ‘right’, ‘both’, ‘neither’], default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.
- **copy**  [bool, default False] By-default copy the data, this is compat only and ignored.
- **dtype**  [dtype or None, default None] If None, dtype will be inferred.

**Returns**

IntervalArray

See also:

**interval_range**  Function to create a fixed frequency IntervalIndex.

**IntervalArray.from_arrays**  Construct an IntervalArray from a left and right array.

**IntervalArray.from_breaks**  Construct an IntervalArray from an array of splits.
Examples

```python
>>> pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 2)])
<IntervalArray>
[(0, 1], (1, 2]]
Length: 2, dtype: interval[int64, right]
```

**pandas.arrays.IntervalArray.from_breaks**

*classmethod IntervalArray.from_breaks(breaks, closed='right', copy=False, dtype=None)*

Construct an IntervalArray from an array of splits.

- **Parameters**
  - `breaks` [array-like (1-dimensional)] Left and right bounds for each interval.
  - `closed` [‘left’, ‘right’, ‘both’, ‘neither’], default ‘right’ Whether the intervals are closed on the left-side, right-side, both or neither.
  - `copy` [bool, default False] Copy the data.
  - `dtype` [dtype or None, default None] If None, dtype will be inferred.

- **Returns**
  - IntervalArray

See also:

- `interval_range` Function to create a fixed frequency IntervalIndex.
- `IntervalArray.from_arrays` Construct from a left and right array.
- `IntervalArray.from_tuples` Construct from a sequence of tuples.

**Examples**

```python
>>> pd.arrays.IntervalArray.from_breaks([0, 1, 2, 3])
<IntervalArray>
[(0, 1], (1, 2], (2, 3)]
Length: 3, dtype: interval[int64, right]
```

**pandas.arrays.IntervalArray.contains**

*IntervalArray.contains(other)*

Check elementwise if the Intervals contain the value.

Return a boolean mask whether the value is contained in the Intervals of the IntervalArray.

New in version 0.25.0.

- **Parameters**
  - `other` [scalar] The value to check whether it is contained in the Intervals.

- **Returns**
boolean array

See also:

**Interval.contains** Check whether Interval object contains value.

**IntervalArray.overlaps** Check if an Interval overlaps the values in the IntervalArray.

**Examples**

```python
>>> intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]
Length: 3, dtype: interval[int64, right]

>>> intervals.contains(0.5)
array([ True, False, False])
```

**pandas.arrays.IntervalArray.overlaps**

IntervalArray.overlaps(*other*)

Check elementwise if an Interval overlaps the values in the IntervalArray.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

**Parameters**

- **other** [IntervalArray] Interval to check against for an overlap.

**Returns**

- **ndarray** Boolean array positionally indicating where an overlap occurs.

See also:

**Interval.overlaps** Check whether two Interval objects overlap.

**Examples**

```python
>>> data = [(0, 1), (1, 3), (2, 4)]
>>> intervals = pd.arrays.IntervalArray.from_tuples(data)
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]
Length: 3, dtype: interval[int64, right]

>>> intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True, True, False])

Intervals that share closed endpoints overlap:

```python
>>> intervals.overlaps(pd.Interval(1, 3, closed='left'))
array([ True, True, True])
```
Intervals that only have an open endpoint in common do not overlap:

```python
>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False,  True, False])
```

**pandas.arrays.IntervalArray.set_closed**

`IntervalArray.set_closed(closed)`

Return an IntervalArray identical to the current one, but closed on the specified side.

**Parameters**

- `closed` [‘left’, ‘right’, ‘both’, ‘neither’] Whether the intervals are closed on the left-side, right-side, both or neither.

**Returns**

- `new_index` [IntervalArray]

**Examples**

```python
>>> index = pd.arrays.IntervalArray.from_breaks(range(4))
>>> index
<IntervalArray>
[(0, 1], (1, 2], (2, 3)]
Length: 3, dtype: interval[int64, right]
>>> index.set_closed('both')
<IntervalArray>
[[0, 1], [1, 2], [2, 3]]
Length: 3, dtype: interval[int64, both]
```

**pandas.arrays.IntervalArray.to_tuples**

`IntervalArray.to_tuples(na_tuple=True)`

Return an ndarray of tuples of the form (left, right).

**Parameters**

- `na_tuple` [bool, default True] Returns NA as a tuple if True, (nan, nan), or just as the NA value itself if False, nan.

**Returns**

- `tuples`: ndarray
pandas.IntervalDtype

class pandas.IntervalDtype (subtype=None, closed=None)
   An ExtensionDtype for Interval data.
   This is not an actual numpy dtype, but a duck type.
   Parameters

Examples

>>> pd.IntervalDtype(subtype='int64', closed='both')
interval[int64, both]

Attributes

subtype
   The dtype of the Interval bounds.

pandas.IntervalDtype.subtype

property IntervalDtype.subtype
   The dtype of the Interval bounds.

Methods

None

3.5.7 Nullable integer

numpy.ndarray cannot natively represent integer-data with missing values. pandas provides this through arrays.IntegerArray.

arrays.IntegerArray(values, mask[, copy]) Array of integer (optional missing) values.

pandas.arrays.IntegerArray

class pandas.arrays.IntegerArray (values, mask, copy=False)
   Array of integer (optional missing) values.
   Changed in version 1.0.0: Now uses pandas.NA as the missing value rather than numpy.nan.

Warning: IntegerArray is currently experimental, and its API or internal implementation may change without warning.

We represent an IntegerArray with 2 numpy arrays:
• data: contains a numpy integer array of the appropriate dtype
• mask: a boolean array holding a mask on the data, True is missing
To construct an IntegerArray from generic array-like input, use pandas.array() with one of the integer dtypes (see examples).

See Nullable integer data type for more.

Parameters

copy [bool, default False] Whether to copy the values and mask.

Returns

IntegerArray

Examples

Create an IntegerArray with pandas.array().

```python
>>> int_array = pd.array([1, None, 3], dtype=pd.Int32Dtype())
>>> int_array
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: Int32
```

String aliases for the dtypes are also available. They are capitalized.

```python
>>> pd.array([1, None, 3], dtype='Int32')
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: Int32

>>> pd.array([1, None, 3], dtype='UInt16')
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: UInt16
```

Attributes

None

Methods

None

Int8Dtype() An ExtensionDtype for int8 integer data.
Int16Dtype() An ExtensionDtype for int16 integer data.
Int32Dtype() An ExtensionDtype for int32 integer data.
Int64Dtype() An ExtensionDtype for int64 integer data.

class pandas.UInt64Dtype
    An ExtensionDtype for uint64 integer data.
    Changed in version 1.0.0: Now uses pandas.NA as its missing value, rather than numpy.nan.
Attributes

Methods

3.5.8 Categorical data

pandas defines a custom data type for representing data that can take only a limited, fixed set of values. The dtype of a Categorical can be described by a pandas.api.types.CategoricalDtype.

```
CategoricalDtype([categories, ordered])
```

Type for categorical data with the categories and orderedness.

```
pandas.CategoricalDtype
class pandas.CategoricalDtype(categories=None, ordered=False)
```

Type for categorical data with the categories and orderedness.

**Parameters**

- **categories** [sequence, optional] Must be unique, and must not contain any nulls. The categories are stored in an Index, and if an index is provided the dtype of that index will be used.

- **ordered** [bool or None, default False] Whether or not this categorical is treated as a ordered categorical. None can be used to maintain the ordered value of existing categoricals when used in operations that combine categoricals, e.g. astype, and will resolve to False if there is no existing ordered to maintain.

**See also:**

- **Categorical** Represent a categorical variable in classic R / S-plus fashion.

**Notes**

This class is useful for specifying the type of a Categorical independent of the values. See CategoricalDtype for more.

**Examples**

```
>>> t = pd.CategoricalDtype(categories=['b', 'a'], ordered=True)
>>> pd.Series(['a', 'b', 'a', 'c'], dtype=t)
0    a
1    b
2    a
3  NaN
dtype: category
Categories (2, object): ['b' < 'a']
```
An empty CategoricalDtype with a specific dtype can be created by providing an empty index. As follows,

```python
>>> pd.CategoricalDtype(pd.DatetimeIndex([])).categories.dtype
dtype('<M8[ns]')
```

### Attributes

- **categories**
  - An `Index` containing the unique categories allowed.

- **ordered**
  - Whether the categories have an ordered relationship.

### Methods

#### CategoricalDtype.categories

**property** `CategoricalDtype.categories`

An `Index` containing the unique categories allowed.

#### CategoricalDtype.ordered

**property** `CategoricalDtype.ordered`

Whether the categories have an ordered relationship.

Categorical data can be stored in a `pandas.Categorical`

```
Categorical(values[, categories, ordered, ...])
```

Represent a categorical variable in classic R / S-plus fashion.

### pandas.Categorical

**class** `pandas.Categorical`

Represent a categorical variable in classic R / S-plus fashion.

*Categoryalls can only take on only a limited, and usually fixed, number of possible values (categories). In contrast to statistical categorical variables, a `Categorical` might have an order, but numerical operations (additions, divisions, . . . ) are not possible.*

All values of the `Categorical` are either in categories or `np.nan`. Assigning values outside of categories will raise a `ValueError`. Order is defined by the order of the categories, not lexical order of the values.

**Parameters**

- **values** [list-like] The values of the categorical. If categories are given, values not in cate-
gories will be replaced with NaN.

**categories** [Index-like (unique), optional] The unique categories for this categorical. If not given, the categories are assumed to be the unique values of values (sorted, if possible, otherwise in the order in which they appear).

**ordered** [bool, default False] Whether or not this categorical is treated as a ordered categorical. If True, the resulting categorical will be ordered. An ordered categorical respects, when sorted, the order of its categories attribute (which in turn is the categories argument, if provided).

**dtype** [CategoricalDtype] An instance of CategoricalDtype to use for this categorical.

Raises

**ValueError** If the categories do not validate.

**TypeError** If an explicit ordered=True is given but no categories and the values are not sortable.

See also:

*CategoricalDtype* Type for categorical data.

*CategoricalIndex* An Index with an underlying Categorical.

Notes

See the user guide for more.

Examples

```python
>>> pd.Categorical([1, 2, 3, 1, 2, 3])
[1, 2, 3, 1, 2, 3]
Categories (3, int64): [1, 2, 3]

>>> pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'])
['a', 'b', 'c', 'a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']

Missing values are not included as a category.

```python
>>> c = pd.Categorical([1, 2, 3, 1, 2, 3, np.nan])
[1, 2, 3, 1, 2, 3, NaN]
Categories (3, int64): [1, 2, 3]
```n

However, their presence is indicated in the *codes* attribute by code -1.

```python
>>> c.codes
array([ 0,  1,  2,  0,  1,  2, -1], dtype=int8)
```

Ordered *Categoricals* can be sorted according to the custom order of the categories and can have a min and max value.

```python
>>> c = pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'], ordered=True,
... categories=['c', 'b', 'a'])
['a', 'b', 'c', 'a', 'b', 'c']
```
Categories (3, object): ['c' < 'b' < 'a']

```
>>> c.min()
'c'
```

</tbody>
</table>

### pandas.Categorical.categories

**property** `Categorical.categories`  
The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to `categories` is an inplace operation!

**Raises**

- `ValueError` If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories.

**See also:**

- `rename_categories` Rename categories.
- `reorder_categories` Reorder categories.
- `add_categories` Add new categories.
- `remove_categories` Remove the specified categories.
- `remove_unused_categories` Remove categories which are not used.
- `set_categories` Set the categories to the specified ones.

### pandas.Categorical.codes

**property** `Categorical.codes`  
The category codes of this categorical.

Codes are an array of integers which are the positions of the actual values in the categories array.

There is no setter, use the other categorical methods and the normal item setter to change values in the categorical.

**Returns**

pandas.Categorical.ordered

property Categorical.ordered
Whether the categories have an ordered relationship.

pandas.Categorical.dtype

property Categorical.dtype
The CategoricalDtype for this instance.

Methods

from_codes(codes[, categories, ordered, dtype]) Make a Categorical type from codes and categories or dtype.

__array__([dtype]) The numpy array interface.

pandas.Categorical.from_codes

classmethod Categorical.from_codes(codes, categories=None, ordered=None, dtype=None)
Make a Categorical type from codes and categories or dtype.

This constructor is useful if you already have codes and categories/dtype and so do not need the (computation intensive) factorization step, which is usually done on the constructor.

If your data does not follow this convention, please use the normal constructor.

Parameters

codes [array-like of int] An integer array, where each integer points to a category in categories or dtype.categories, or else is -1 for NaN.

categories [index-like, optional] The categories for the categorical. Items need to be unique. If the categories are not given here, then they must be provided in dtype.

ordered [bool, optional] Whether or not this categorical is treated as an ordered categorical. If not given here or in dtype, the resulting categorical will be unordered.

dtype [CategoricalDtype or “category”, optional] If CategoricalDtype, cannot be used together with categories or ordered.

Returns

Categorical
Examples

```python
>>> dtype = pd.CategoricalDtype(['a', 'b'], ordered=True)
>>> pd.Categorical.from_codes(codes=[0, 1, 0, 1], dtype=dtype)
['a', 'b', 'a', 'b']
Categories (2, object): ['a' < 'b']
```

**pandas.Categorical.__array__**

Categorical.__array__(dtype=None)  
The numpy array interface.

Returns

numpy.array  A numpy array of either the specified dtype or, if dtype==None (default),  
the same dtype as categorical.categories.dtype.

The alternative Categorical.from_codes() constructor can be used when you have the categories and integer  
codes already:

```python
Categorical.from_codes(codes[, categories, ...])  Make a Categorical type from codes and categories or  
dtype.
```

The dtype information is available on the Categorical

```
Categorical.dtype  The CategoricalDtype for this instance.
Categorical.categories  The categories of this categorical.
Categorical.ordered  Whether the categories have an ordered relationship.
Categorical.codes  The category codes of this categorical.
```

np.asarray(categorical) works by implementing the array interface. Be aware, that this converts the Cate-  
gorical back to a NumPy array, so categories and order information is not preserved!

```
Categorical.__array__((dtype))  The numpy array interface.
```

A Categorical can be stored in a Series or DataFrame. To create a Series of dtype category, use cat =  
s.astype(dtype) or Series(..., dtype=dtype) where dtype is either

- the string 'category'
- an instance of CategoricalDtype.

If the Series is of dtype CategoricalDtype, Series.cat can be used to change the categorical data. See  
Categorical accessor for more.
3.5.9 Sparse data

Data where a single value is repeated many times (e.g. 0 or NaN) may be stored efficiently as a *arrays.SparseArray*.

```python
arrays.SparseArray(data[, sparse_index, ...]) An ExtensionArray for storing sparse data.
```

### pandas.arrays.SparseArray

**class** `pandas.arrays.SparseArray` *(data, sparse_index=None, index=None, fill_value=None, kind='integer', dtype=None, copy=False)*

An ExtensionArray for storing sparse data.

**Parameters**

- `data` [array-like] A dense array of values to store in the SparseArray. This may contain `fill_value`.
- `sparse_index` [SparseIndex, optional]
- `index` [Index]
- `fill_value` [scalar, optional] Elements in `data` that are `fill_value` are not stored in the SparseArray. For memory savings, this should be the most common value in `data`. By default, `fill_value` depends on the dtype of `data`:

<table>
<thead>
<tr>
<th>dtype</th>
<th>na_value</th>
</tr>
</thead>
<tbody>
<tr>
<td>float</td>
<td>np.nan</td>
</tr>
<tr>
<td>int</td>
<td>0</td>
</tr>
<tr>
<td>bool</td>
<td>False</td>
</tr>
<tr>
<td>datetime64</td>
<td>pd.NaT</td>
</tr>
<tr>
<td>timedelta64</td>
<td>pd.NaT</td>
</tr>
</tbody>
</table>

The fill value is potentially specified in three ways. In order of precedence, these are

1. The `fill_value` argument
2. `dtype.fill_value` if `fill_value` is `None` and `dtype` is a `SparseDtype`
3. `data.dtype.fill_value` if `fill_value` is `None` and `dtype` is not a `SparseDtype` and `data` is a `SparseArray`.

- `kind` [‘integer’, ‘block’], default ‘integer’] The type of storage for sparse locations.
  - ‘block’: Stores a block and `block_length` for each contiguous span of sparse values. This is best when sparse data tends to be clumped together, with large regions of fill-value values between sparse values.
  - ‘integer’: uses an integer to store the location of each sparse value.

- `dtype` [np.dtype or SparseDtype, optional] The dtype to use for the SparseArray. For numpy dtypes, this determines the dtype of `self.sp_values`. For SparseDtype, this determines `self.sp_values` and `self.fill_value`.

- `copy` [bool, default False] Whether to explicitly copy the incoming `data` array.
Examples

```python
>>> from pandas.arrays import SparseArray
>>> arr = SparseArray([0, 0, 1, 2])
>>> arr
[0, 0, 1, 2]
Fill: 0
IntIndex
Indices: array([2, 3], dtype=int32)
```

Attributes

```
None
```

Methods

```
None
```

### pandas.SparseDtype

```
SparseDtype(dtype, fill_value)
```

Dtype for data stored in `SparseArray`.

**class pandas.SparseDtype**(dtype=<class 'numpy.float64'>, fill_value=None)

Dtype for data stored in `SparseArray`.

This dtype implements the pandas ExtensionDtype interface.

**Parameters**

- **dtype** [str, ExtensionDtype, numpy.dtype, type, default numpy.float64] The dtype of the underlying array storing the non-fill value values.
- **fill_value** [scalar, optional] The scalar value not stored in the `SparseArray`. By default, this depends on `dtype`.

<table>
<thead>
<tr>
<th>dtype</th>
<th>na_value</th>
</tr>
</thead>
<tbody>
<tr>
<td>float</td>
<td>np.nan</td>
</tr>
<tr>
<td>int</td>
<td>0</td>
</tr>
<tr>
<td>bool</td>
<td>False</td>
</tr>
<tr>
<td>datetime64</td>
<td>pd.NaT</td>
</tr>
<tr>
<td>timedelta64</td>
<td>pd.NaT</td>
</tr>
</tbody>
</table>

The default value may be overridden by specifying a `fill_value`. 

---

2002 Chapter 3. API reference
The `Series.sparse` accessor may be used to access sparse-specific attributes and methods if the `Series` contains sparse values. See `Sparse accessor` for more.

### 3.5.10 Text data

When working with text data, where each valid element is a string or missing, we recommend using `StringDtype` (with the alias "string").

#### `pandas.arrays.StringArray`

**class** `pandas.arrays.StringArray(values[, copy])`  
Extension array for string data.

New in version 1.0.0.

**Warning:** StringArray is considered experimental. The implementation and parts of the API may change without warning.

**Parameters**

- `values` [array-like] The array of data.
  
  **Warning:** Currently, this expects an object-dtype ndarray where the elements are Python strings or `pandas.NA`. This may change without warning in the future. Use `pandas.array()` with `dtype="string"` for a stable way of creating a `StringArray` from any sequence.

- `copy` [bool, default False] Whether to copy the array of data.

**See also:**

- `array` The recommended function for creating a `StringArray`.
- `Series.str` The string methods are available on Series backed by a `StringArray`. 

### 3.5. pandas arrays
Notes

StringArray returns a BooleanArray for comparison methods.

Examples

```python
>>> pd.array(['This is', 'some text', None, 'data.'], dtype="string")
<StringArray>
['This is', 'some text', <NA>, 'data.]
Length: 4, dtype: string

Unlike arrays instantiated with dtype="object", StringArray will convert the values to strings.

```python
>>> pd.array(['1', 1], dtype="object")
<PandasArray>
['1', 1]
Length: 2, dtype: object
```
```python
>>> pd.array(['1', 1], dtype="string")
<StringArray>
['1', '1']
Length: 2, dtype: string
```

However, instantiating StringArrays directly with non-strings will raise an error.

For comparison methods, StringArray returns a pandas.BooleanArray:

```python
>>> pd.array(['a', None, 'c'], dtype="string") == "a"
<BooleanArray>
[True, <NA>, False]
Length: 3, dtype: boolean
```

Attributes

None

Methods

None

pandas.arrays.ArrowStringArray

class pandas.arrays.ArrowStringArray(values)
    Extension array for string data in a pyarrow.ChunkedArray.

New in version 1.2.0.

Warning: ArrowStringArray is considered experimental. The implementation and parts of the API may change without warning.

Parameters
values [pyarrow.Array or pyarrow.ChunkedArray] The array of data.

See also:
array The recommended function for creating a ArrowStringArray.
Series.str The string methods are available on Series backed by a ArrowStringArray.

Notes

ArrowStringArray returns a BooleanArray for comparison methods.

Examples

```python
>>> pd.array(['This is', 'some text', None, 'data.'], dtype="string[pyarrow]")
<ArrowStringArray>
['This is', 'some text', <NA>, 'data.]
Length: 4, dtype: string
```

Attributes

None

Methods

None

StringDtype([storage]) Extension dtype for string data.

pandas.StringDtype
class pandas.StringDtype (storage=None)
Extension dtype for string data.

New in version 1.0.0.

Warning: StringDtype is considered experimental. The implementation and parts of the API may change without warning.

In particular, StringDtype.na_value may change to no longer be numpy.nan.

Parameters

storage [{"python", "pyarrow"}, optional] If not given, the value of pd.options.mode.string_storage.
Examples

```
>>> pd.StringDtype()
'string[python]
```

```
>>> pd.StringDtype(storage="pyarrow")
'string[pyarrow]
```

Attributes

```
None
```

Methods

```
None
```

The `Series.str` accessor is available for `Series` backed by a `arrays.StringArray`. See String handling for more.

### 3.5.11 Boolean data with missing values

The boolean `dtype` (with the alias "boolean") provides support for storing boolean data (True, False values) with missing values, which is not possible with a `numpy.ndarray`.

```
arrays.BooleanArray(values, mask[, copy]) Array of boolean (True/False) data with missing values.
```

#### pandas.arrays.BooleanArray

```
class pandas.arrays.BooleanArray (values, mask, copy=False) Array of boolean (True/False) data with missing values.
```

This is a pandas Extension array for boolean data, under the hood represented by 2 numpy arrays: a boolean array with the data and a boolean array with the mask (True indicating missing).

BooleanArray implements Kleene logic (sometimes called three-value logic) for logical operations. See Kleene logical operations for more.

To construct an BooleanArray from generic array-like input, use `pandas.array()` specifying `dtype= "boolean"` (see examples below).

New in version 1.0.0.

**Warning**: BooleanArray is considered experimental. The implementation and parts of the API may change without warning.

**Parameters**

```
values [numpy.ndarray] A 1-d boolean-dtype array with the data.
```
**mask** [numpy.ndarray] A 1-d boolean-dtype array indicating missing values (True indicates missing).

**copy** [bool, default False] Whether to copy the values and mask arrays.

**Returns** BooleanArray

### Examples

Create an BooleanArray with `pandas.array()`:

```python
>>> pd.array([True, False, None], dtype="boolean")
<BooleanArray>
[True, False, <NA>]
Length: 3, dtype: boolean
```

### Attributes

None

### Methods

None

### BooleanDtype

Extension dtype for boolean data.

#### pandas.BooleanDtype

**class** pandas.BooleanDtype

Extension dtype for boolean data.

New in version 1.0.0.

**Warning:** BooleanDtype is considered experimental. The implementation and parts of the API may change without warning.

### Examples

```python
>>> pd.BooleanDtype()
BooleanDtype
```
3.6 Index objects

3.6.1 Index

Many of these methods or variants thereof are available on the objects that contain an index (Series/DataFrame) and those should most likely be used before calling these methods directly.

Attributes

| None |

Methods

| None |

Index

Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects.

**Parameters**

| data [array-like (1-dimensional)] |
| dtype [NumPy dtype (default: object)] If dtype is None, we find the dtype that best fits the data. If an actual dtype is provided, we coerce to that dtype if it’s safe. Otherwise, an error will be raised. |
| copy [bool] Make a copy of input ndarray. |
| name [object] Name to be stored in the index. |
| tupleize_cols [bool (default: True)] When True, attempt to create a MultiIndex if possible. |

See also:

- *RangeIndex* Index implementing a monotonic integer range.
- *CategoricalIndex* Index of Categoricals.
- *MultiIndex* A multi-level, or hierarchical Index.
- *IntervalIndex* An Index of Intervals.
- *DatetimeIndex* Index of datetime64 data.
- *TimedeltaIndex* Index of timedelta64 data.
- *PeriodIndex* Index of Period data.
- *Int64Index* A special case of Index with purely integer labels.
- *UInt64Index* A special case of Index with purely unsigned integer labels.
- *Float64Index* A special case of Index with purely float labels.
Notes

An Index instance can only contain hashable objects

Examples

```python
>>> pd.Index([1, 2, 3])
Int64Index([1, 2, 3], dtype='int64')

>>> pd.Index(list('abc'))
Index(['a', 'b', 'c'], dtype='object')
```

Attributes

- **T**: Return the transpose, which is by definition self.
- **array**: The ExtensionArray of the data backing this Series or Index.
- **as18**: Integer representation of the values.
- **dtype**: Return the dtype object of the underlying data.
- **has_duplicates**: Check if the Index has duplicate values.
- **hasnans**: Return if I have any nans; enables various perf speedups.
- **inferred_type**: Return a string of the type inferred from the values.
- **is_all_dates**: Whether or not the index values only consist of dates.
- **is_monotonic**: Alias for is_monotonic_increasing.
- **is_monotonic_decreasing**: Return if the index is monotonic decreasing (only equal or decreasing) values.
- **is_monotonic_increasing**: Return if the index is monotonic increasing (only equal or increasing) values.
- **is_unique**: Return if the index has unique values.
- **name**: Return Index or MultiIndex name.
- **nbytes**: Return the number of bytes in the underlying data.
- **ndim**: Number of dimensions of the underlying data, by definition 1.
- **nlevels**: Number of levels.
- **shape**: Return a tuple of the shape of the underlying data.
- **size**: Return the number of elements in the underlying data.
- **values**: Return an array representing the data in the Index.
pandas.Index.T

**property Index.T**

Return the transpose, which is by definition self.

pandas.Index.array

**Index.array**

The ExtensionArray of the data backing this Series or Index.

**Returns**

**ExtensionArray** An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around `numpy.ndarray`.

.array differs .values which may require converting the data to a different form.

**See also:**

*Index.to_numpy* Similar method that always returns a NumPy array.

*Series.to_numpy* Similar method that always returns a NumPy array.

**Notes**

This table lays out the different array types for each extension dtype within pandas.

<table>
<thead>
<tr>
<th>dtype</th>
<th>array type</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>Categorical</td>
</tr>
<tr>
<td>period</td>
<td>PeriodArray</td>
</tr>
<tr>
<td>interval</td>
<td>IntervalArray</td>
</tr>
<tr>
<td>IntegerNA</td>
<td>IntegerArray</td>
</tr>
<tr>
<td>string</td>
<td>StringArray</td>
</tr>
<tr>
<td>boolean</td>
<td>BooleanArray</td>
</tr>
<tr>
<td>datetime64[ns, tz]</td>
<td>DatetimeArray</td>
</tr>
</tbody>
</table>

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes `.array` will be a `arrays.NumpyExtensionArray` wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use `Series.to_numpy()` instead.
pandas: powerful Python data analysis toolkit, Release 1.3.2

Examples
For regular NumPy types like int, and float, a PandasArray is returned.
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64

For extension types, like Categorical, the actual ExtensionArray is returned
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
['a', 'b', 'a']
Categories (2, object): ['a', 'b']

pandas.Index.asi8
property Index.asi8
Integer representation of the values.
Returns
ndarray An ndarray with int64 dtype.
pandas.Index.dtype
Index.dtype
Return the dtype object of the underlying data.
pandas.Index.has_duplicates
property Index.has_duplicates
Check if the Index has duplicate values.
Returns
bool Whether or not the Index has duplicate values.
Examples
>>> idx = pd.Index([1, 5, 7, 7])
>>> idx.has_duplicates
True
>>> idx = pd.Index([1, 5, 7])
>>> idx.has_duplicates
False
>>> idx = pd.Index(["Watermelon", "Orange", "Apple",
...
"Watermelon"]).astype("category")
>>> idx.has_duplicates
True

3.6. Index objects

2011


>>> idx = pd.Index(['Orange', 'Apple',
...       'Watermelon']).astype('category')
>>> idx.has_duplicates
False

pandas.Index.hasnans

Index hasnans
Return if I have any nans; enables various perf speedups.

pandas.Index.inferred_type

Index inferred_type
Return a string of the type inferred from the values.

pandas.Index.is_all_dates

Index is all dates
Whether or not the index values only consist of dates.

pandas.Index.is_monotonic

property Index is monotonic
Alias for is_monotonic_increasing.

pandas.Index.is_monotonic_decreasing

property Index is monotonic decreasing
Return if the index is monotonic decreasing (only equal or decreasing) values.

Examples

>>> Index([3, 2, 1]).is_monotonic_decreasing
True
>>> Index([3, 2, 2]).is_monotonic_decreasing
True
>>> Index([3, 1, 2]).is_monotonic_decreasing
False
pandas.Index.is_monotonic_increasing

**property** Index.is_monotonic_increasing
Return if the index is monotonic increasing (only equal or increasing) values.

**Examples**

```python
>>> Index([1, 2, 3]).is_monotonic_increasing
True
>>> Index([1, 2, 2]).is_monotonic_increasing
True
>>> Index([1, 3, 2]).is_monotonic_increasing
False
```

pandas.Index.is_unique

`Index.is_unique`
Return if the index has unique values.

pandas.Index.name

**property** Index.name
Return Index or MultiIndex name.

pandas.Index.nbytes

**property** Index.nbytes
Return the number of bytes in the underlying data.

pandas.Index.ndim

**property** Index.ndim
Number of dimensions of the underlying data, by definition 1.

pandas.Index.nlevels

**property** Index.nlevels
Number of levels.
pandas: powerful Python data analysis toolkit, Release 1.3.2

**pandas.Index.shape**

**property Index.shape**
Return a tuple of the shape of the underlying data.

**pandas.Index.size**

**property Index.size**
Return the number of elements in the underlying data.

**pandas.Index.values**

**property Index.values**
Return an array representing the data in the Index.

**Warning:** We recommend using `Index.array` or `Index.to_numpy()`, depending on whether you need a reference to the underlying data or a NumPy array.

**Returns**

array: numpy.ndarray or ExtensionArray

See also:

- `Index.array` Reference to the underlying data.
- `Index.to_numpy` A NumPy array representing the underlying data.

<table>
<thead>
<tr>
<th>empty</th>
<th>names</th>
</tr>
</thead>
</table>

**Methods**

- `all(*args, **kwvars)` Return whether all elements are Truthy.
- `any(*args, **kwvars)` Return whether any element is Truthy.
- `append(other)` Append a collection of Index options together.
- `argmax([axis, skipna])` Return int position of the largest value in the Series.
- `argmin([axis, skipna])` Return int position of the smallest value in the Series.
- `argsort(*args, **kwvars)` Return the integer indices that would sort the index.
- `asof(label)` Return the label from the index, or, if not present, the previous one.
- `asof_locs(where, mask)` Return the locations (indices) of labels in the index.
- `astype(dtype[, copy])` Create an Index with values cast to dtypes.
- `copy([name, deep, dtype, names])` Make a copy of this object.
- `delete(loc)` Make new Index with passed location(-s) deleted.
- `difference(other[, sort])` Return a new Index with elements of index not in other.

<td>Replace values where the condition is False.</td>
</tr>
</tbody>
</table>
pandas.Index.all

Index.all(*args, **kwargs)
Return whether all elements are Truthy.

Parameters
*args Required for compatibility with numpy.
**kwargs Required for compatibility with numpy.

Returns
all [bool or array-like (if axis is specified)] A single element array-like may be converted to bool.

See also:
Index.any Return whether any element in an Index is True.
Series.any Return whether any element in a Series is True.
Series.all Return whether all elements in a Series are True.

Notes
Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

Examples

all
True, because nonzero integers are considered True.

>>> pd.Index([1, 2, 3]).all()
True

False, because 0 is considered False.

>>> pd.Index([0, 1, 2]).all()
False

any
True, because 1 is considered True.

>>> pd.Index([0, 0, 1]).any()
True

False, because 0 is considered False.

>>> pd.Index([0, 0, 0]).any()
False
pandas.Index.any

Index.any(*args, **kwargs)
Return whether any element is Truthy.

Parameters
*args  Required for compatibility with numpy.
**kwargs Required for compatibility with numpy.

Returns
any  [bool or array-like (if axis is specified)] A single element array-like may be converted to bool.

See also:
Index.all Return whether all elements are True.
Series.all Return whether all elements are True.

Notes
Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

Examples
>>> index = pd.Index([0, 1, 2])
>>> index.any()
True

>>> index = pd.Index([0, 0, 0])
>>> index.any()
False

pandas.Index.append

Index.append(other)
Append a collection of Index options together.

Parameters
other  [Index or list/tuple of indices]

Returns
Index
pandas.Index.argmax

_index_.argmax(*args=None, skipna=True, **kwargs)
Return int position of the largest value in the Series.
If the maximum is achieved in multiple locations, the first row position is returned.

Parameters
axis [{None}] Dummy argument for consistency with Series.
skipna [bool, default True] Exclude NA/null values when showing the result.
*args, **kwargs Additional arguments and keywords for compatibility with NumPy.

Returns
int Row position of the maximum value.

See also:
Series.argmax Return position of the maximum value.
Series.argmin Return position of the minimum value.
numpy.ndarray.argmax Equivalent method for numpy arrays.
Series.idxmax Return index label of the maximum values.
Series.idxmin Return index label of the minimum values.

Examples
Consider dataset containing cereal calories

```python
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,  
...  'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
>>> s
Corn Flakes    100.0
Almond Delight 110.0
Cinnamon Toast Crunch    120.0
Cocoa Puff         110.0
dtype: float64
```

```python
>>> s.argmax()
2
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.Index.argmin

Index.argmin(axis=None, skipna=True, *args, **kwargs)

Return int position of the smallest value in the Series.

If the minimum is achieved in multiple locations, the first row position is returned.

Parameters

axis [{None}] Dummy argument for consistency with Series.
skipna [bool, default True] Exclude NA/null values when showing the result.
*args, **kwargs Additional arguments and keywords for compatibility with NumPy.

Returns

int Row position of the minimum value.

See also:

Series.argmin Return position of the minimum value.
Series.argmax Return position of the maximum value.
numpy.ndarray.argmin Equivalent method for numpy arrays.
Series.idxmax Return index label of the maximum values.
Series.idxmin Return index label of the minimum values.

Examples

Consider dataset containing cereal calories

```python
g >>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,
                    ...                   'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
g >>> s
Corn Flakes    100.0
Almond Delight 110.0
Cinnamon Toast Crunch 120.0
Cocoa Puff    110.0
dtype: float64

g >>> s.argmax()
g 2
g >>> s.argmin()
g 0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.
**pandas.Index.argsort**

`Index.argsort(*args, **kwargs)`

Return the integer indices that would sort the index.

**Parameters**

*args Passed to `numpy.ndarray.argsort`.

**kwargs Passed to `numpy.ndarray.argsort`.

**Returns**

`np.ndarray[np.intp]` Integer indices that would sort the index if used as an indexer.

**See also:**

- `numpy.argsort` Similar method for NumPy arrays.
- `Index.sort_values` Return sorted copy of Index.

**Examples**

```bash
>>> idx = pd.Index(['b', 'a', 'd', 'c'])
>>> idx
Index(['b', 'a', 'd', 'c'], dtype='object')

>>> order = idx.argsort()
>>> order
array([1, 0, 3, 2])

>>> idx[order]
Index(['a', 'b', 'c', 'd'], dtype='object')
```

**pandas.Index.asof**

`Index.asof(label)`

Return the label from the index, or, if not present, the previous one.

Assuming that the index is sorted, return the passed index label if it is in the index, or return the previous index label if the passed one is not in the index.

**Parameters**

- `label` [object] The label up to which the method returns the latest index label.

**Returns**

- `object` The passed label if it is in the index. The previous label if the passed label is not in the sorted index or `NaN` if there is no such label.

**See also:**

- `Series.asof` Return the latest value in a Series up to the passed index.
- `merge_asof` Perform an asof merge (similar to left join but it matches on nearest key rather than equal key).
- `Index.get_loc` An `asof` is a thin wrapper around `get_loc` with `method='pad'`.

---

3.6. Index objects 2021
Examples

*Index.asof* returns the latest index label up to the passed label.

```python
def idx = pd.Index(['2013-12-31', '2014-01-02', '2014-01-03'])
>>> idx.asof('2014-01-01')
'2013-12-31'
```

If the label is in the index, the method returns the passed label.

```python
>>> idx.asof('2014-01-02')
'2014-01-02'
```

If all of the labels in the index are later than the passed label, NaN is returned.

```python
>>> idx.asof('1999-01-02')
nan
```

If the index is not sorted, an error is raised.

```python
>>> idx_not_sorted = pd.Index(['2013-12-31', '2015-01-02', ...
>>> idx_not_sorted.asof('2013-12-31')
Traceback (most recent call last):
  ValueError: index must be monotonic increasing or decreasing
```

*pandas.Index.asof_locs*

*Index.asof_locs* (*where*, *mask*)

Return the locations (indices) of labels in the index.

As in the *asof* function, if the label (a particular entry in *where*) is not in the index, the latest index label up to the passed label is chosen and its index returned.

If all of the labels in the index are later than a label in *where*, -1 is returned.

*mask* is used to ignore NA values in the index during calculation.

**Parameters**

- **where** [Index] An Index consisting of an array of timestamps.
- **mask** [np.ndarray[bool]] Array of booleans denoting where values in the original data are not NA.

**Returns**

- np.ndarray[np.intp] An array of locations (indices) of the labels from the Index which correspond to the return values of the *asof* function for every element in *where*. 
pandas.Index.astype

`Index.astype(dtype, copy=True)`  
Create an Index with values cast to dtypes.

The class of a new Index is determined by `dtype`. When conversion is impossible, a `TypeError` exception is raised.

**Parameters**

- **dtype** [numpy dtype or pandas type] Note that any signed integer `dtype` is treated as 'int64', and any unsigned integer `dtype` is treated as 'uint64', regardless of the size.
- **copy** [bool, default True] By default, `astype` always returns a newly allocated object. If `copy` is set to False and internal requirements on `dtype` are satisfied, the original data is used to create a new Index or the original Index is returned.

**Returns**

- **Index** Index with values cast to specified `dtype`.

pandas.Index.copy

`Index.copy(name=None, deep=False, dtype=None, names=None)`  
Make a copy of this object.

Name and `dtype` sets those attributes on the new object.

**Parameters**

- **name** [Label, optional] Set name for new object.
- **deep** [bool, default False]
- **dtype** [numpy dtype or pandas type, optional] Set `dtype` for new object.

    Deprecated since version 1.2.0: use `astype` method instead.

- **names** [list-like, optional] Kept for compatibility with MultiIndex. Should not be used.

**Returns**

- **Index** Index refer to new object which is a copy of this object.

**Notes**

In most cases, there should be no functional difference from using `deep`, but if `deep` is passed it will attempt to deepcopy.
pandas.Index.delete

Index.delete(loc)
Make new Index with passed location(-s) deleted.

Parameters

loc [int or list of int] Location of item(-s) which will be deleted. Use a list of locations to delete more than one value at the same time.

Returns

Index Will be same type as self, except for RangeIndex.

See also:

numpy.delete Delete any rows and column from NumPy array (ndarray).

Examples

```python
>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx.delete(1)
Index(['a', 'c'], dtype='object')

>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx.delete([0, 2])
Index(['b'], dtype='object')
```

pandas.Index.difference

Index.difference(other, sort=None)
Return a new Index with elements of index not in other.

This is the set difference of two Index objects.

Parameters

other [Index or array-like]

sort [False or None, default None] Whether to sort the resulting index. By default, the values are attempted to be sorted, but any TypeError from incomparable elements is caught by pandas.

- None : Attempt to sort the result, but catch any TypeErrors from comparing incomparable elements.
- False : Do not sort the result.

Returns

difference [Index]
Examples

```python
>>> idx1 = pd.Index([2, 1, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.difference(idx2)
Int64Index([1, 2], dtype='int64')
```

```python
>>> idx1.difference(idx2, sort=False)
Int64Index([2, 1], dtype='int64')
```

**pandas.Index.drop**

```python
Index.drop(labels, errors='raise')
```

Make new Index with passed list of labels deleted.

**Parameters**

- **labels** [array-like]
- **errors** [[‘ignore’, ‘raise’], default ‘raise’] If ‘ignore’, suppress error and existing labels are dropped.

**Returns**

- **dropped** [Index] Will be same type as self, except for RangeIndex.

**Raises**

- **KeyError** If not all of the labels are found in the selected axis.

**pandas.Index.drop_duplicates**

```python
Index.drop_duplicates(keep='first')
```

Return Index with duplicate values removed.

**Parameters**

- **keep** [{‘first’, ‘last’, False}, default ‘first’]
  - ‘first’ : Drop duplicates except for the first occurrence.
  - ‘last’ : Drop duplicates except for the last occurrence.
  - False: Drop all duplicates.

**Returns**

- **deduplicated** [Index]

**See also:**

- **Series.drop_duplicates** Equivalent method on Series.
- **DataFrame.drop_duplicates** Equivalent method on DataFrame.
- **Index.duplicated** Related method on Index, indicating duplicate Index values.
Examples

Generate an pandas.Index with duplicate values.

```python
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'])
```

The `keep` parameter controls which duplicate values are removed. The value `‘first’` keeps the first occurrence for each set of duplicated entries. The default value of `keep` is `‘first’`.

```python
>>> idx.drop_duplicates(keep='first')
Index(['lama', 'cow', 'beetle', 'hippo'], dtype='object')
```

The value `‘last’` keeps the last occurrence for each set of duplicated entries.

```python
>>> idx.drop_duplicates(keep='last')
Index(['cow', 'beetle', 'lama', 'hippo'], dtype='object')
```

The value `False` discards all sets of duplicated entries.

```python
>>> idx.drop_duplicates(keep=False)
Index(['cow', 'beetle', 'hippo'], dtype='object')
```

`pandas.Index.droplevel`  

`Index.droplevel(level=0)`  
Return index with requested level(s) removed.  
If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

**Parameters**
- `level` [int, str, or list-like, default 0] If a string is given, must be the name of a level If list-like, elements must be names or indexes of levels.

**Returns**
- `Index` or `MultiIndex`

**Examples**

```python
>>> mi = pd.MultiIndex.from_arrays(  
... [[1, 2], [3, 4], [5, 6]], names=['x', 'y', 'z'])
>>> mi
MultiIndex([(1, 3, 5),  
            (2, 4, 6)],  
           names=['x', 'y', 'z'])
```

```python
>>> mi.droplevel()  
MultiIndex([(3, 5),  
            (4, 6)],  
           names=['y', 'z'])
```

```python
>>> mi.droplevel(2)  
MultiIndex([(1, 3),  
            (2, 4)],  
           names=['x', 'y'])
```
>>> mi.droplevel('z')
MultiIndex([(1, 3),
            (2, 4)],
           names=['x', 'y'])

>>> mi.droplevel(['x', 'y'])
Int64Index([5, 6], dtype='int64', name='z')

**pandas.Index.dropna**

Index.dropna (how='any')

Return Index without NA/NaN values.

- **Parameters**
  - **how** [{'any', 'all'}, default 'any'] If the Index is a MultiIndex, drop the value when any or all levels are NaN.

- **Returns**
  - Index

**pandas.Index.duplicated**

Index.duplicated (keep='first')

Indicate duplicate index values.

Duplicated values are indicated as True values in the resulting array. Either all duplicates, all except the first, or all except the last occurrence of duplicates can be indicated.

- **Parameters**
  - **keep** [{'first', 'last', False}, default 'first'] The value or values in a set of duplicates to mark as missing.
    - 'first': Mark duplicates as True except for the first occurrence.
    - 'last': Mark duplicates as True except for the last occurrence.
    - False: Mark all duplicates as True.

- **Returns**
  - np.ndarray[bool]

See also:

- **Series.duplicated** Equivalent method on pandas.Series.
- **DataFrame.duplicated** Equivalent method on pandas.DataFrame.
- **Index.drop_duplicates** Remove duplicate values from Index.

3.6. Index objects  2027
Examples

By default, for each set of duplicated values, the first occurrence is set to False and all others to True:

```python
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> idx.duplicated()
array([False, False, True, False, True])
```

which is equivalent to

```python
>>> idx.duplicated(keep='first')
array([False, False, True, False, True])
```

By using ‘last’, the last occurrence of each set of duplicated values is set on False and all others on True:

```python
>>> idx.duplicated(keep='last')
array([ True, False, True, False, False])
```

By setting keep on False, all duplicates are True:

```python
>>> idx.duplicated(keep=False)
array([ True, False, True, False, True])
```

pandas.Index.equals

`Index.equals(other)`

Determine if two Index object are equal.

The things that are being compared are:

- The elements inside the Index object.
- The order of the elements inside the Index object.

Parameters

- `other` [Any] The other object to compare against.

Returns

- `bool` True if “other” is an Index and it has the same elements and order as the calling index; False otherwise.

Examples

```python
>>> idx1 = pd.Index([1, 2, 3])
>>> idx1
Int64Index([1, 2, 3], dtype='int64')
>>> idx1.equals(pd.Index([1, 2, 3]))
True
```

The elements inside are compared

```python
>>> idx2 = pd.Index(['1', '2', '3'])
>>> idx2
Index(['1', '2', '3'], dtype='object')
```
The order is compared

```python
>>> ascending_idx = pd.Index([1, 2, 3])
>>> ascending_idx
Int64Index([1, 2, 3], dtype='int64')
>>> descending_idx = pd.Index([3, 2, 1])
>>> descending_idx
Int64Index([3, 2, 1], dtype='int64')
>>> ascending_idx.equals(descending_idx)
False
```

The dtype is not compared

```python
>>> int64_idx = pd.Int64Index([1, 2, 3])
>>> int64_idx
Int64Index([1, 2, 3], dtype='int64')
>>> uint64_idx = pd.UInt64Index([1, 2, 3])
>>> uint64_idx
UInt64Index([1, 2, 3], dtype='uint64')
>>> int64_idx.equals(uint64_idx)
True
```

### pandas.Index.factorize

Index.factorize(sort=False, na_sentinel=-1)

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. `factorize` is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

**Parameters**

- **sort** [bool, default False] Sort uniques and shuffle codes to maintain the relationship.
- **na_sentinel** [int or None, default -1] Value to mark “not found”. If None, will not drop the NaN from the uniques of the values.

Changed in version 1.1.2.

**Returns**

- **codes** [ndarray] An integer ndarray that’s an indexer into uniques. `uniques.take(codes)` will have the same values as `values`.
- **uniques** [ndarray, Index, or Categorical] The unique valid values. When `values` is Categorical, `uniques` is a Categorical. When `values` is some other pandas object, an Index is returned. Otherwise, a 1-D ndarray is returned.

**Note:** Even if there’s a missing value in `values`, `uniques` will not contain an entry for it.

**See also:**
**cut** Discretize continuous-valued array.

**unique** Find the unique value in an array.

### Examples

These examples all show factorize as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> codes
array([0, 0, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the `uniques` will be sorted, and `codes` will be shuffled so that the relationship is maintained.

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> codes
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in `codes` with `na_sentinel` (−1 by default). Note that missing values are never included in `uniques`.

```python
>>> codes, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> codes
array([ 0, -1, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we’ve only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of `uniques` will differ. For Categoricals, a `Categorical` is returned.

```python
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])
>>> uniques
['a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`. For all other pandas objects, an Index of the appropriate type is returned.

```python
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

If NaN is in the values, and we want to include NaN in the uniques of the values, it can be achieved by setting `na_sentinel=None`.
```python
>>> values = np.array([1, 2, 1, np.nan])
>>> codes, uniques = pd.factorize(values)  # default: na_sentinel=-1
>>> codes
array([ 0, 1, 0, -1])
>>> uniques
array([1., 2.])

>>> codes, uniques = pd.factorize(values, na_sentinel=None)
>>> codes
array([0, 1, 0, 2])
>>> uniques
array([ 1., 2., nan])
```

**pandas.Index.fillna**

Index.fillna(value=None, downcast=None)

Fill NA/NaN values with the specified value.

**Parameters**

- **value** [scalar] Scalar value to use to fill holes (e.g. 0). This value cannot be a list-likes.
- **downcast** [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

**Returns**

Index

See also:

- **DataFrame.fillna** Fill NaN values of a DataFrame.
- **Series.fillna** Fill NaN Values of a Series.

**pandas.Index.format**

Index.format(name=False, formatter=None, na_rep='NaN')

Render a string representation of the Index.

**pandas.Index.get_indexer**

Index.get_indexer(target, method=None, limit=None, tolerance=None)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

**Parameters**

- **target** [Index]
- **method** [{None, ‘pad’/‘ffill’, ‘backfill’/‘bfill’, ‘nearest’}, optional]
  - default: exact matches only.
  - pad / ffill: find the PREVIOUS index value if no exact match.
• backfill / bfill: use NEXT index value if no exact match
• nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.

**limit** [int, optional] Maximum number of consecutive labels in target to match for inexact matches.

**tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation \( \text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance} \).

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

**Returns**

**indexer** [np.ndarray[np.intp]] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

**Examples**

```python
code
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1, 2, -1])
```

Notice that the return value is an array of locations in `index` and `x` is marked by -1, as it is not in `index`.

**pandas.Index.get_indexer_for**

Index.get_indexer_for (target, **kwargs)

Guaranteed return of an indexer even when non-unique.

This dispatches to get_indexer or get_indexer_non_unique as appropriate.

**Returns**

**np.ndarray[np.intp]** List of indices.

**pandas.Index.get_indexer_non_unique**

Index.get_indexer_non_unique (target)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

**Parameters**

**target** [Index]

**Returns**

**indexer** [np.ndarray[np.intp]] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.
missing [np.ndarray[np.intp]] An indexer into the target of the values not found. These correspond to the -1 in the indexer array.

**pandas.Index.get_level_values**

Index.get_level_values(level)

Return an Index of values for requested level.

This is primarily useful to get an individual level of values from a MultiIndex, but is provided on Index as well for compatibility.

**Parameters**

- **level** [int or str] It is either the integer position or the name of the level.

**Returns**

- **Index** Calling object, as there is only one level in the Index.

**See also:**

*MultiIndex.get_level_values* Get values for a level of a MultiIndex.

**Notes**

For Index, level should be 0, since there are no multiple levels.

**Examples**

```python
>>> idx = pd.Index(list('abc'))
>>> idx
Index(['a', 'b', 'c'], dtype='object')
Get level values by supplying **level** as integer:

```python
>>> idx.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object')
```

**pandas.Index.get_loc**

Index.get_loc(key, method=None, tolerance=None)

Get integer location, slice or boolean mask for requested label.

**Parameters**

- **key** [label]
- **method** [{None, ‘pad’/’ffill’, ‘backfill’/’bfill’, ‘nearest’}, optional]

  - default: exact matches only.
  - pad / ffill: find the PREVIOUS index value if no exact match.
  - backfill / bfill: use NEXT index value if no exact match
  - nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
tolerance [int or float, optional] Maximum distance from index value for inexact matches. The value of the index at the matching location must satisfy the equation abs(index[loc] - key) <= tolerance.

Returns
loc [int if unique index, slice if monotonic index, else mask]

Examples

```python
>>> unique_index = pd.Index(list('abc'))
>>> unique_index.get_loc('b')
1

>>> monotonic_index = pd.Index(list('abbc'))
>>> monotonic_index.get_loc('b')
slice(1, 3, None)

>>> non_monotonic_index = pd.Index(list('abcb'))
>>> non_monotonic_index.get_loc('b')
array([False,  True, False,  True])
```

pandas.Index.get_slice_bound

Index.get_slice_bound(label, side='left', kind=None)
Calculate slice bound that corresponds to given label.

Returns leftmost (one-past-the-rightmost if side=='right') position of given label.

Parameters
- label [object]
- side ['left', 'right']
- kind ['loc', 'getitem'] or None

Returns
- int Index of label.

pandas.Index.get_value

Index.get_value(series, key)
Fast lookup of value from 1-dimensional ndarray.

Only use this if you know what you’re doing.

Returns
- scalar or Series
pandas.Index.groupby

Index.groupby(values)
Group the index labels by a given array of values.

Parameters
values [array] Values used to determine the groups.

Returns
dict {group name -> group labels}

pandas.Index.holds_integer

Index.holds_integer()
Whether the type is an integer type.

pandas.Index.identical

Index.identical(other)
Similar to equals, but checks that object attributes and types are also equal.

Returns
bool If two Index objects have equal elements and same type True, otherwise False.

pandas.Index.insert

Index.insert(loc, item)
Make new Index inserting new item at location.
Follows Python list.append semantics for negative values.

Parameters
loc [int]
item [object]

Returns
new_index [Index]

pandas.Index.intersection

Index.intersection(other, sort=False)
Form the intersection of two Index objects.
This returns a new Index with elements common to the index and other.

Parameters
other [Index or array-like]
sort [False or None, default False] Whether to sort the resulting index.

- False : do not sort the result.
• None: sort the result, except when self and other are equal or when the values cannot be compared.

Returns

intersection [Index]

Examples

```python
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.intersection(idx2)
Int64Index([3, 4], dtype='int64')
```

**pandas.Index.is_**

Index.is_(other)
More flexible, faster check like is but that works through views.

Note: this is not the same as Index.identical(), which checks that metadata is also the same.

Parameters

other [object] Other object to compare against.

Returns

bool True if both have same underlying data, False otherwise.

See also:

Index.identical Works like Index.is_ but also checks metadata.

**pandas.Index.is_boolean**

Index.is_boolean()
Check if the Index only consists of booleans.

Returns

bool Whether or not the Index only consists of booleans.

See also:

is_integer Check if the Index only consists of integers.
is_floating Check if the Index is a floating type.
is_numeric Check if the Index only consists of numeric data.
is_object Check if the Index is of the object dtype.
is_categorical Check if the Index holds categorical data.
is_interval Check if the Index holds Interval objects.
is_mixed Check if the Index holds data with mixed data types.
Examples

```python
>>> idx = pd.Index([True, False, True])
>>> idx.is_boolean()
True

>>> idx = pd.Index(["True", "False", "True"])  # Note: Incorrect usage
>>> idx.is_boolean()
False

>>> idx = pd.Index([True, False, "True"])
>>> idx.is_boolean()
False
```

**pandas.Index.is_categorical**

Index.is_categorical()  
Check if the Index holds categorical data.

**Returns**

bool True if the Index is categorical.

**See also:**

* CategoricalIndex Index for categorical data.
* is_boolean Check if the Index only consists of boolean.
* is_integer Check if the Index only consists of integers.
* is_floating Check if the Index is a floating type.
* is_numeric Check if the Index only consists of numeric data.
* is_object Check if the Index is of the object dtype.
* is_interval Check if the Index holds Interval objects.
* is_mixed Check if the Index holds data with mixed data types.

Examples

```python
>>> idx = pd.Index(["Watermelon", "Orange", "Apple", ...
... "Watermelon"]).astype("category")
>>> idx.is_categorical()
True

>>> idx = pd.Index([1, 3, 5, 7])
>>> idx.is_categorical()
False

>>> s = pd.Series(["Peter", "Victor", "Elisabeth", "Mar"])
>>> s
0    Peter
1    Victor
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.2

(continued from previous page)

2    Elisabeth
3    Mar
dtype: object
>>> s.index.is_categorical()
False

pandas.Index.is_floating

Index.is_floating()
Check if the Index is a floating type.
The Index may consist of only floats, NaNs, or a mix of floats, integers, or NaNs.

Returns

bool Whether or not the Index only consists of only consists of floats, NaNs, or a mix of floats, integers, or NaNs.

See also:

is_boolean Check if the Index only consists of booleans.
is_integer Check if the Index only consists of integers.
is_numeric Check if the Index only consists of numeric data.
is_object Check if the Index is of the object dtype.
is_categorical Check if the Index holds categorical data.
is_interval Check if the Index holds Interval objects.
is_mixed Check if the Index holds data with mixed data types.

Examples

>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_floating()
True

>>> idx = pd.Index([1.0, 2.0, np.nan, 4.0])
>>> idx.is_floating()
True

>>> idx = pd.Index([1, 2, 3, 4, np.nan])
>>> idx.is_floating()
True

>>> idx = pd.Index([1, 2, 3, 4])
>>> idx.is_floating()
False
pandas.Index.is_integer

Index.is_integer()  
Check if the Index only consists of integers.

Returns

bool Whether or not the Index only consists of integers.

See also:

is_boolean Check if the Index only consists of booleans.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.

is_mixed Check if the Index holds data with mixed data types.

Examples

```python
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx.is_integer()
True

>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_integer()
False

>>> idx = pd.Index(['Apple', 'Mango', 'Watermelon'])
>>> idx.is_integer()
False
```

pandas.Index.is_interval

Index.is_interval()  
Check if the Index holds Interval objects.

Returns

bool Whether or not the Index holds Interval objects.

See also:

IntervalIndex Index for Interval objects.

is_boolean Check if the Index only consists of booleans.

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.
is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_mixed Check if the Index holds data with mixed data types.

Examples

```python
>>> idx = pd.Index([pd.Interval(left=0, right=5),
                  pd.Interval(left=5, right=10)])
>>> idx.is_interval()
True
```

```python
>>> idx = pd.Index([1, 3, 5, 7])
>>> idx.is_interval()
False
```

pandas.Index.is_mixed

Index.is_mixed() Check if the Index holds data with mixed data types.

Returns

bool Whether or not the Index holds data with mixed data types.

See also:

is_boolean Check if the Index only consists of booleans.

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.

Examples

```python
>>> idx = pd.Index(['a', np.nan, 'b'])
>>> idx.is_mixed()
True
```

```python
>>> idx = pd.Index([1.0, 2.0, 3.0, 5.0])
>>> idx.is_mixed()
False
```
pandas.Index.is_numeric

Index.is_numeric()
Check if the Index only consists of numeric data.

Returns
    bool  Whether or not the Index only consists of numeric data.

See also:

is_boolean  Check if the Index only consists of booleans.
is_integer  Check if the Index only consists of integers.
is_floating  Check if the Index is a floating type.
is_object   Check if the Index is of the object dtype.
is_categorical  Check if the Index holds categorical data.
is_interval  Check if the Index holds Interval objects.
is_mixed    Check if the Index holds data with mixed data types.

Examples

```python
>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_numeric()
True

>>> idx = pd.Index([1, 2, 3, 4.0])
>>> idx.is_numeric()
True

>>> idx = pd.Index([1, 2, 3, 4])
>>> idx.is_numeric()
True

>>> idx = pd.Index([1, 2, 3, 4.0, np.nan])
>>> idx.is_numeric()
True

>>> idx = pd.Index([1, 2, 3, 4.0, np.nan, "Apple"])
>>> idx.is_numeric()
False
```
pandas.Index.is_object

Index.is_object()  
Check if the Index is of the object dtype.  

Returns  

bool Whether or not the Index is of the object dtype.  

See also:  

is_boolean Check if the Index only consists of booleans.  

is_integer Check if the Index only consists of integers.  

is_floating Check if the Index is a floating type.  

is_numeric Check if the Index only consists of numeric data.  

is_categorical Check if the Index holds categorical data.  

is_interval Check if the Index holds Interval objects.  

is_mixed Check if the Index holds data with mixed data types.  

Examples

```python  
>>> idx = pd.Index(['Apple', 'Mango', 'Watermelon'])
>>> idx.is_object()
True

>>> idx = pd.Index(['Apple', 'Mango', 2.0])
>>> idx.is_object()
True

>>> idx = pd.Index(['Watermelon', 'Orange', 'Apple', ...
"Watermelon']).astype('category')
>>> idx.is_object()
False

>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_object()
False
```

pandas.Index.is_type_compatible

Index.is_type_compatible(kind)  
Whether the index type is compatible with the provided type.
pandas.Index.isin

Index.isin(values, level=None)
Return a boolean array where the index values are in values.
Compute boolean array of whether each index value is found in the passed set of values. The length of the returned boolean array matches the length of the index.

Parameters
values [set or list-like] Sought values.
level [str or int, optional] Name or position of the index level to use (if the index is a MultiIndex).

Returns
np.ndarray[bool] NumPy array of boolean values.

See also:
Series.isin Same for Series.
DataFrame.isin Same method for DataFrames.

Notes
In the case of MultiIndex you must either specify values as a list-like object containing tuples that are the same length as the number of levels, or specify level. Otherwise it will raise a ValueError.
If level is specified:
• if it is the name of one and only one index level, use that level;
• otherwise it should be a number indicating level position.

Examples

```python
>>> idx = pd.Index([1, 2, 3])
>>> idx
Int64Index([1, 2, 3], dtype='int64')
Check whether each index value in a list of values.

>>> idx.isin([1, 4])
array([True, False, False])
```

```python
>>> midx = pd.MultiIndex.from_arrays([[1, 2, 3], ['red', 'blue', 'green']],
                        names=['number', 'color'])
>>> midx
MultiIndex([(1, 'red'),
            (2, 'blue'),
            (3, 'green')],
           names=['number', 'color'])
Check whether the strings in the ‘color’ level of the MultiIndex are in a list of colors.
```
To check across the levels of a MultiIndex, pass a list of tuples:

```python
midx.isin([(1, 'red'), (3, 'red')])
array([ True, False, False])
```

For a DatetimeIndex, string values in `values` are converted to Timestamps.

```python
dates = ['2000-03-11', '2000-03-12', '2000-03-13']
dti = pd.to_datetime(dates)
dti
DatetimeIndex(['2000-03-11', '2000-03-12', '2000-03-13'],
dtype='datetime64[ns]', freq=None)
```

```python
dti.isin(['2000-03-11'])
array([ True, False, False])
```

### pandas.Index.isna

Index.isna()  
Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None`, `numpy.NaN` or `pd.NaT`, get mapped to `True` values. Everything else get mapped to `False` values. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

**Returns**

- `numpy.ndarray[bool]` A boolean array of whether my values are NA.

**See also:**

- `Index.notna` Boolean inverse of isna.
- `Index.dropna` Omit entries with missing values.
- `isna` Top-level isna.
- `Series.isna` Detect missing values in Series object.

### Examples

Show which entries in a pandas.Index are NA. The result is an array.

```python
idx = pd.Index([5.2, 6.0, np.NaN])
idx
Float64Index([5.2, 6.0, nan], dtype='float64')
```

```python
idx.isna()
array([False, False, True])
```

Empty strings are not considered NA values. None is considered an NA value.
For datetimes, NaT (Not a Time) is considered as an NA value.

```python
c>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
                            pd.NaT, pd.NaT, pd.NaT])
c>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
              dtype='datetime64[ns]', freq=None)
c>> idx.isna()
array([False, True, True, True])
```

### pandas.Index.isnull

**Index.isnull()**

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None`, `numpy.NaN` or `pd.NaT`, get mapped to `True` values. Everything else get mapped to `False` values. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

**Returns**

`numpy.ndarray[bool]` A boolean array of whether my values are NA.

**See also:**

- `Index.notna` Boolean inverse of isna.
- `Index.dropna` Omit entries with missing values.
- `isna` Top-level isna.
- `Series.isna` Detect missing values in Series object.

### Examples

Show which entries in a pandas.Index are NA. The result is an array.

```python
c>> idx = pd.Index([5.2, 6.0, np.NaN])
c>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
c>> idx.isna()
array([False, False, True])
```

Empty strings are not considered NA values. None is considered an NA value.

```python
c>> idx = pd.Index(['black', '', 'red', None])
c>> idx
Index(['black', '', 'red', None], dtype='object')
c>> idx.isna()
array([False, False, False, True])
```
For datetimes, \texttt{NaT} (Not a Time) is considered as an NA value.

```python
>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
...                         pd.Timestamp(''), None, pd.NaT])
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
               dtype='datetime64[ns]', freq=None)
>>> idx.isna()
array([False, True, True, True])
```

\texttt{pandas.Index.item}

\texttt{Index.item()}

Return the first element of the underlying data as a Python scalar.

Returns

\texttt{scalar} The first element of \texttt{Index}s.

Raises

\texttt{ValueError} If the data is not length-1.

\texttt{pandas.Index.join}

\texttt{Index.join\(other, how='left', level=None, return_indexers=False, sort=False\)}

Compute join_index and indexers to conform data structures to the new index.

Parameters

\texttt{other } [Index]

\texttt{how } [\{'left', 'right', 'inner', 'outer'\}]

\texttt{level } [int or level name, default None]

\texttt{return_indexers } [bool, default False]

\texttt{sort } [bool, default False] Sort the join keys lexicographically in the result \texttt{Index}. If False, the order of the join keys depends on the join type (how keyword).

Returns

\texttt{join_index, (left_indexer, right_indexer)}

\texttt{pandas.Index.map}

\texttt{Index.map\(mapper, na_action=None\)}

Map values using input correspondence (a dict, Series, or function).

Parameters

\texttt{mapper } [function, dict, or Series] Mapping correspondence.

\texttt{na_action } [[None, ‘ignore’]] If ‘ignore’, propagate NA values, without passing them to the mapping correspondence.

Returns
applied [Union[Index, MultiIndex], inferred] The output of the mapping function applied to the index. If the function returns a tuple with more than one element a MultiIndex will be returned.

**pandas.Index.max**

`Index.max(axis=None, skipna=True, *args, **kwargs)`

Return the maximum value of the Index.

**Parameters**

- **axis** [int, optional] For compatibility with NumPy. Only 0 or None are allowed.
- **skipna** [bool, default True] Exclude NA/null values when showing the result.
- ***args, **kwargs** Additional arguments and keywords for compatibility with NumPy.

**Returns**

- **scalar** Maximum value.

**See also:**

- `Index.min` Return the minimum value in an Index.
- `Series.max` Return the maximum value in a Series.
- `DataFrame.max` Return the maximum values in a DataFrame.

**Examples**

```python
>>> idx = pd.Index([3, 2, 1])
>>> idx.max()
3

>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.max()
'c'
```

For a MultiIndex, the maximum is determined lexicographically.

```python
>>> idx = pd.MultiIndex.from_product([('a', 'b'), (2, 1)])
>>> idx.max()
('b', 2)
```

**pandas.Index.memory_usage**

`Index.memory_usage(deep=False)`

Memory usage of the values.

**Parameters**

- **deep** [bool, default False] Introspect the data deeply, interrogate `object` dtypes for system-level memory consumption.

**Returns**

- **bytes used**
See also:

numpy.ndarray.nbytes  Total bytes consumed by the elements of the array.

Notes

Memory usage does not include memory consumed by elements that are not components of the array if
deep=False or if used on PyPy

pandas.Index.min

Index.min(\texttt{axis=None, skipna=True, *args, **kwargs})

Return the minimum value of the Index.

Parameters

- \texttt{axis}  \{None\} Dummy argument for consistency with Series.
- \texttt{skipna} [bool, default True] Exclude NA/null values when showing the result.
- \texttt{*args, **kwargs} Additional arguments and keywords for compatibility with NumPy.

Returns

- \texttt{scalar} Minimum value.

See also:

\texttt{Index.max} Return the maximum value of the object.
\texttt{Series.min} Return the minimum value in a Series.
\texttt{DataFrame.min} Return the minimum values in a DataFrame.

Examples

```python
>>> idx = pd.Index([3, 2, 1])
>>> idx.min()
1
```

```python
>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.min()
'a'
```

For a MultiIndex, the minimum is determined lexicographically.

```python
>>> idx = pd.MultiIndex.from_product([('a', 'b'), (2, 1)])
>>> idx.min()
('a', 1)
```
pandas.Index.notna

**Index.notna()**
Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

**Returns**

*numpy.ndarray[bool]* Boolean array to indicate which entries are not NA.

**See also:**

*Index.notnull* Alias of notna.

*Index.isna* Inverse of notna.

*notna* Top-level notna.

**Examples**

Show which entries in an Index are not NA. The result is an array.

```python
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([ True, True, False])
```

Empty strings are not considered NA values. None is considered a NA value.

```python
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([ True, True, True, False])
```

pandas.Index.notnull

**Index.notnull()**
Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

**Returns**

*numpy.ndarray[bool]* Boolean array to indicate which entries are not NA.

**See also:**

*Index.notnull* Alias of notna.
Index.isna  Inverse of notna.

notna  Top-level notna.

Examples

Show which entries in an Index are not NA. The result is an array.

```python
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([ True, True, False])
```

Empty strings are not considered NA values. None is considered a NA value.

```python
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([ True, True, True, False])
```

pandas.Index.nunique

Index.nunique (dropna=True)

Return number of unique elements in the object.
Excludes NA values by default.

Parameters

- **dropna**  [bool, default True] Don’t include NaN in the count.

Returns

- int

See also:

DataFrame.nunique  Method nunique for DataFrame.

Series.count  Count non-NA/null observations in the Series.

Examples

```python
>>> s = pd.Series([1, 3, 5, 7, 7])
>>> s
0  1
1  3
2  5
3  7
4  7
dtype: int64

>>> s.nunique()
4
```
**pandas.Index.putmask**

`Index.putmask(mask, value)`  
Return a new Index of the values set with the mask.

Returns

`Index`

See also:

- `numpy.ndarray.putmask` Changes elements of an array based on conditional and input values.

**pandas.Index.ravel**

`Index.ravel(order='C')`  
Return an ndarray of the flattened values of the underlying data.

Returns

- `numpy.ndarray` Flattened array.

See also:

- `numpy.ndarray.ravel` Return a flattened array.

**pandas.Index.reindex**

`Index.reindex(target, method=None, level=None, limit=None, tolerance=None)`  
Create index with target’s values.

Parameters

- `target` [an iterable]

Returns

- `new_index` [pd.Index] Resulting index.
- `indexer` [np.ndarray[np.intp] or None] Indices of output values in original index.

**pandas.Index.rename**

`Index.rename(name, inplace=False)`  
Alter Index or MultiIndex name.

Able to set new names without level. Defaults to returning new index. Length of names must match number of levels in MultiIndex.

Parameters

- `name` [label or list of labels] Name(s) to set.
- `inplace` [bool, default False] Modifies the object directly, instead of creating a new Index or MultiIndex.

Returns

- `Index or None` The same type as the caller or None if `inplace=True`.

### 3.6. Index objects
See also:

**Index.set_names** Able to set new names partially and by level.

**Examples**

```python
>>> idx = pd.Index(['A', 'C', 'A', 'B'], name='score')
>>> idx.rename('grade')
Index(['A', 'C', 'A', 'B'], dtype='object', name='grade')

>>> idx = pd.MultiIndex.from_product([['python', 'cobra'],
...                                   [2018, 2019]],
...                                   names=['kind', 'year'])
>>> idx
MultiIndex([('python', 2018),
             ('python', 2019),
             ('cobra', 2018),
             ('cobra', 2019)],
            names=['kind', 'year'])

>>> idx.rename(["species", 'year'])
MultiIndex([('python', 2018),
             ('python', 2019),
             ('cobra', 2018),
             ('cobra', 2019)],
            names=['species', 'year'])

>>> idx.rename('species')
Traceback (most recent call last):
  TypeError: Must pass list-like as 'names'.
```

**pandas.Index.repeat**

Index.repeat*(repeats, axis=None)*

Repeat elements of a Index.

Returns a new Index where each element of the current Index is repeated consecutively a given number of times.

**Parameters**

- **repeats** [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Index.
- **axis** [None] Must be None. Has no effect but is accepted for compatibility with numpy.

**Returns**

- **repeated_index** [Index] Newly created Index with repeated elements.

**See also:**

- **Series.repeat** Equivalent function for Series.
- **numpy.repeat** Similar method for numpy.ndarray.
Examples

```python
>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx
Index(['a', 'b', 'c'], dtype='object')
>>> idx.repeat(2)
Index(['a', 'a', 'b', 'b', 'c', 'c'], dtype='object')
>>> idx.repeat([1, 2, 3])
Index(['a', 'b', 'b', 'c', 'c', 'c'], dtype='object')
```

*pandas.Index.searchsorted*

`Index.searchsorted(value, side='left', sorter=None)`

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted Index `self` such that, if the corresponding elements in `value` were inserted before the indices, the order of `self` would be preserved.

**Note:** The Index must be monotonically sorted, otherwise wrong locations will likely be returned. Pandas does not check this for you.

**Parameters**

- **value** [array-like] Values to insert into `self`.
- **side** [{‘left’, ‘right’}, optional] If ‘left’, the index of the first suitable location found is given. If ‘right’, return the last such index. If there is no suitable index, return either 0 or N (where N is the length of `self`).
- **sorter** [1-D array-like, optional] Optional array of integer indices that sort `self` into ascending order. They are typically the result of `np.argsort`.

**Returns**

- int or array of int A scalar or array of insertion points with the same shape as `value`.

**See also:**

- `sort_values` Sort by the values along either axis.
- `numpy.searchsorted` Similar method from NumPy.

**Notes**

Binary search is used to find the required insertion points.
Examples

```python
>>> ser = pd.Series([1, 2, 3])
>>> ser
0 1
1 2
2 3
dtype: int64

>>> ser.searchsorted(4)
3

>>> ser.searchsorted([0, 4])
array([0, 3])

>>> ser.searchsorted([1, 3], side='left')
array([0, 2])

>>> ser.searchsorted([1, 3], side='right')
array([1, 3])

>>> ser
0 2000-03-11
1 2000-03-12
2 2000-03-13
dtype: datetime64[ns]

>>> ser.searchsorted('3/14/2000')
3

>>> ser = pd.Categorical(... ['apple', 'bread', 'bread', 'cheese', 'milk'], ordered=True ...
... )
>>> ser
['apple', 'bread', 'bread', 'cheese', 'milk']
Categories (4, object): ['apple' < 'bread' < 'cheese' < 'milk']

>>> ser.searchsorted('bread')
1

>>> ser.searchsorted(['bread'], side='right')
array([3])
```

If the values are not monotonically sorted, wrong locations may be returned:

```python
>>> ser = pd.Series([2, 1, 3])
>>> ser
0 2
1 1
2 3
dtype: int64
```
pandas: powerful Python data analysis toolkit, Release 1.3.2

```python
>>> ser.searchsorted(1)
0  # wrong result, correct would be 1
```

**pandas.Index.set_names**

Index.set_names(names, level=None, inplace=False)

Set Index or MultiIndex name.

Able to set new names partially and by level.

**Parameters**

- **names** [label or list of label or dict-like for MultiIndex] Name(s) to set.
  
  Changed in version 1.3.0.

- **level** [int, label or list of int or label, optional] If the index is a MultiIndex and names is not dict-like, level(s) to set (None for all levels). Otherwise level must be None.
  
  Changed in version 1.3.0.

- **inplace** [bool, default False] Modifies the object directly, instead of creating a new Index or MultiIndex.

**Returns**

Index or None The same type as the caller or None if inplace=True.

**See also:**

- **Index.rename** Able to set new names without level.

**Examples**

```python
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx
Int64Index([1, 2, 3, 4], dtype='int64')
>>> idx.set_names('quarter')
Int64Index([1, 2, 3, 4], dtype='int64', name='quarter')

>>> idx = pd.MultiIndex.from_product([['python', 'cobra'], [2018, 2019]])
>>> idx
MultiIndex([('python', 2018), ('python', 2019), ('cobra', 2018), ('cobra', 2019)],)
>>> idx.set_names(['kind', 'year'], inplace=True)
>>> idx
MultiIndex([('python', 2018), ('python', 2019), ('cobra', 2018), ('cobra', 2019)],

(continues on next page)
```
When renaming levels with a dict, levels cannot be passed.

```python
>>> idx.set_names({"kind": 'snake'})
MultiIndex([('python', 2018),
            ('python', 2019),
            ('cobra', 2018),
            ('cobra', 2019)],
           names=['snake', 'year'])
```

### pandas.Index.set_value

Index.set_value(arr, key, value)

Fast lookup of value from 1-dimensional ndarray.

Deprecated since version 1.0.

**Notes**

Only use this if you know what you’re doing.

### pandas.Index.shift

Index.shift(periods=1, freq=None)

Shift index by desired number of time frequency increments.

This method is for shifting the values of datetime-like indexes by a specified time increment a given number of times.

**Parameters**

- **periods** [int, default 1] Number of periods (or increments) to shift by, can be positive or negative.
- **freq** [pandas.DateOffset, pandas.Timedelta or str, optional] Frequency increment to shift by. If None, the index is shifted by its own freq attribute. Offset aliases are valid strings, e.g., ‘D’, ‘W’, ‘M’ etc.

**Returns**

- pandas.Index Shifted index.

See also:

- Series.shift Shift values of Series.
Notes

This method is only implemented for datetime-like index classes, i.e., DatetimeIndex, PeriodIndex and TimedeltaIndex.

Examples

Put the first 5 month starts of 2011 into an index.

```python
>>> month_starts = pd.date_range('1/1/2011', periods=5, freq='MS')
>>> month_starts
              dtype='datetime64[ns]', freq='MS')
```

Shift the index by 10 days.

```python
>>> month_starts.shift(10, freq='D')
              dtype='datetime64[ns]', freq=None)
```

The default value of `freq` is the `freq` attribute of the index, which is ‘MS’ (month start) in this example.

```python
>>> month_starts.shift(10)
DatetimeIndex(['2011-11-01', '2011-12-01', '2012-01-01', '2012-02-01', '2012-03-01'],
              dtype='datetime64[ns]', freq='MS')
```

`pandas.Index.slice_indexer`

Index.slice_indexer(start=None, end=None, step=None, kind=None)

Compute the slice indexer for input labels and step.

Index needs to be ordered and unique.

Parameters

- **start** [label, default None] If None, defaults to the beginning.
- **end** [label, default None] If None, defaults to the end.
- **step** [int, default None]
- **kind** [str, default None]

Returns

- **indexer** [slice]

Raises

- **KeyError** [If key does not exist, or key is not unique and index is] not ordered.
Notes

This function assumes that the data is sorted, so use at your own peril.

Examples

This is a method on all index types. For example you can do:

```python
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_indexer(start='b', end='c')
slice(1, 3, None)

>>> idx = pd.MultiIndex.from_arrays([list('abcd'), list('efgh')])
>>> idx.slice_indexer(start='b', end=('c', 'g'))
slice(1, 3, None)
```

pandas.Index.slice_locs

Index.slice_locs(start=None, end=None, step=None, kind=None)

Compute slice locations for input labels.

Parameters

start [label, default None] If None, defaults to the beginning.

end [label, default None] If None, defaults to the end.

step [int, defaults None] If None, defaults to 1.

kind [‘loc’, ‘getitem’) or None]

Returns

start, end [int]

See also:

Index.get_loc Get location for a single label.

Notes

This method only works if the index is monotonic or unique.

Examples

```python
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_locs(start='b', end='c')
(1, 3)
```
pandas.Index.sort

Index.sort(*args, **kwargs)
Use sort_values instead.

pandas.Index.sort_values

Index.sort_values(return_indexer=False, ascending=True, na_position='last', key=None)
Return a sorted copy of the index.
Return a sorted copy of the index, and optionally return the indices that sorted the index itself.

Parameters

return_indexer [bool, default False] Should the indices that would sort the index be returned.
ascending [bool, default True] Should the index values be sorted in an ascending order.
na_position [{‘first’ or ‘last’}, default ‘last’] Argument ‘first’ puts NaNs at the beginning, ‘last’ puts NaNs at the end.
New in version 1.2.0.
key [callable, optional] If not None, apply the key function to the index values before sorting. This is similar to the key argument in the built-in sorted() function, with the notable difference that this key function should be vectorized. It should expect an Index and return an Index of the same shape.
New in version 1.1.0.

Returns

sorted_index [pandas.Index] Sorted copy of the index.
indexer [numpy.ndarray, optional] The indices that the index itself was sorted by.

See also:

Series.sort_values Sort values of a Series.
DataFrame.sort_values Sort values in a DataFrame.

Examples

```python
>>> idx = pd.Index([10, 100, 1, 1000])
>>> idx
Int64Index([10, 100, 1, 1000], dtype='int64')
```
Sort values in ascending order (default behavior).
```
>>> idx.sort_values()
Int64Index([1, 10, 100, 1000], dtype='int64')
```
Sort values in descending order, and also get the indices idx was sorted by.
```python
>>> idx.sort_values(ascending=False, return_indexer=True)
(Int64Index([1000, 100, 10, 1], dtype='int64'), array([3, 1, 0, 2]))
```
pandas.Index.sortlevel

Index.sortlevel(level=None, ascending=True, sort_remaining=None)
For internal compatibility with the Index API.
Sort the Index. This is for compat with MultiIndex

Parameters
 ascending [bool, default True] False to sort in descending order
 level, sort_remaining are compat parameters

Returns
Index

pandas.Index.str

Index.str()
Vectorized string functions for Series and Index.
NAs stay NA unless handled otherwise by a particular method. Patterned after Python’s string methods, with some inspiration from R’s stringr package.

Examples

```python
>>> s = pd.Series(["A_Str_Series"])
>>> s
0   A_Str_Series
dtype: object

>>> s.str.split("_")
0   [A, Str, Series]
dtype: object

>>> s.str.replace("_", "")
0   AStrSeries
dtype: object
```

pandas.Index.symmetric_difference

Index.symmetric_difference(other, result_name=None, sort=None)
Compute the symmetric difference of two Index objects.

Parameters
 other [Index or array-like]
 result_name [str]
 sort [False or None, default None] Whether to sort the resulting index. By default, the values are attempted to be sorted, but any TypeError from incomparable elements is caught by pandas.
• None : Attempt to sort the result, but catch any TypeErrors from comparing incomparable elements.
• False : Do not sort the result.

Returns

symmetric_difference [Index]

Notes

symmetric_difference contains elements that appear in either idx1 or idx2 but not both. Equivalent to the Index created by idx1.difference(idx2) | idx2.difference(idx1) with duplicates dropped.

Examples

```python
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([2, 3, 4, 5])
>>> idx1.symmetric_difference(idx2)
Int64Index([1, 5], dtype='int64')
```

pandas.Index.take

Index.take (indices, axis=0, allow_fill=True, fill_value=None, **kwargs)

Return a new Index of the values selected by the indices.

For internal compatibility with numpy arrays.

Parameters

indices [array-like] Indices to be taken.
axis [int, optional] The axis over which to select values, always 0.
allow_fill [bool, default True]
fill_value [scalar, default None] If allow_fill=True and fill_value is not None, indices specified by -1 are regarded as NA. If Index doesn’t hold NA, raise ValueError.

Returns

Index An index formed of elements at the given indices. Will be the same type as self, except for RangeIndex.

See also:

numpy.ndarray.take Return an array formed from the elements of a at the given indices.
pandas.Index.to_flat_index

Index.to_flat_index()
Identity method.
This is implemented for compatibility with subclass implementations when chaining.

Returns
pd.Index Caller.

See also:
MultiIndex.to_flat_index Subclass implementation.

pandas.Index.to_frame

Index.to_frame(index=True, name=None)
Create a DataFrame with a column containing the Index.

Parameters
index [bool, default True] Set the index of the returned DataFrame as the original Index.
name [object, default None] The passed name should substitute for the index name (if it has one).

Returns
DataFrame DataFrame containing the original Index data.

See also:
Index.to_series Convert an Index to a Series.
Series.to_frame Convert Series to DataFrame.

Examples

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
   animal
      0  Ant
      1  Bear
      2  Cow

By default, the original Index is reused. To enforce a new Index:

```python
>>> idx.to_frame(index=False)
   animal
   0  Ant
   1  Bear
   2  Cow
```

To override the name of the resulting column, specify name:
pandas.Index.to_list

Index.to_list()

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:

numpy.ndarray.tolist Return the array as an a.ndim-levels deep nested list of Python scalars.

pandas.Index.to_native_types

Index.to_native_types(slicer=None, **kwargs)

Format specified values of self and return them.

Deprecated since version 1.2.0.

Parameters

slicer [int, array-like] An indexer into self that specifies which values are used in the formatting process.

kwags [dict] Options for specifying how the values should be formatted. These options include the following:

1) na_rep [str] The value that serves as a placeholder for NULL values
2) quoting [bool or None] Whether or not there are quoted values in self
3) date_format [str] The format used to represent date-like values.

Returns

numpy.ndarray Formatted values.

pandas.Index.to_numpy

Index.to_numpy(dtype=None, copy=False, na_value=<no_default>, **kwargs)

A NumPy ndarray representing the values in this Series or Index.

Parameters

dtype [str or numpy.dtype, optional] The dtype to pass to numpy.asarray().
copy [bool, default False] Whether to ensure that the returned value is not a view on another array. Note that copy=False does not ensure that to_numpy() is no-copy. Rather, copy=True ensure that a copy is made, even if not strictly necessary.

na_value [Any, optional] The value to use for missing values. The default value depends on dtype and the type of the array.

New in version 1.0.0.

**kwargs Additional keywords passed through to the to_numpy method of the underlying array (for extension arrays).

New in version 1.0.0.

Returns

numpy.ndarray

See also:

Series.array Get the actual data stored within.
Index.array Get the actual data stored within.
DataFrame.to_numpy Similar method for DataFrame.

Notes

The returned array will be the same up to equality (values equal in self will be equal in the returned array; likewise for values that are not equal). When self contains an ExtensionArray, the dtype may be different. For example, for a category-dtype Series, to_numpy() will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming copy=False). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, to_numpy() may require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, Series.array should be used instead.

This table lays out the different dtypes and default return types of to_numpy() for various dtypes within pandas.

<table>
<thead>
<tr>
<th>dtype</th>
<th>array type</th>
</tr>
</thead>
<tbody>
<tr>
<td>category[T]</td>
<td>ndarray[T] (same dtype as input)</td>
</tr>
<tr>
<td>period</td>
<td>ndarray[object] (Periods)</td>
</tr>
<tr>
<td>interval</td>
<td>ndarray[object] (Intervals)</td>
</tr>
<tr>
<td>IntegerNA</td>
<td>ndarray[object]</td>
</tr>
<tr>
<td>datetime64[ns]</td>
<td>datetime64[ns]</td>
</tr>
<tr>
<td>datetime64[ns, tz]</td>
<td>ndarray[object] (Timestamps)</td>
</tr>
</tbody>
</table>
Examples

```python
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.to_numpy()
anarray(['a', 'b', 'a'], dtype=object)
```

Specify the `dtype` to control how datetime-aware data is represented. Use `dtype=object` to return an ndarray of pandas `Timestamp` objects, each with the correct tz.

```python
>>> ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> ser.to_numpy(dtype=object)
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET'),
      Timestamp('2000-01-02 00:00:00+0100', tz='CET')],
     dtype=object)
```

Or `dtype='datetime64[ns]'` to return an ndarray of native datetime64 values. The values are converted to UTC and the timezone info is dropped.

```python
>>> ser.to_numpy(dtype="datetime64[ns]")
... array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00...'],
      dtype='datetime64[ns]')
```

**pandas.Index.to_series**

Index.to_series(index=None, name=None)

Create a Series with both index and values equal to the index keys.

Useful with map for returning an indexer based on an index.

**Parameters**

- **index** [Index, optional] Index of resulting Series. If None, defaults to original index.
- **name** [str, optional] Name of resulting Series. If None, defaults to name of original index.

**Returns**

Series The dtype will be based on the type of the Index values.

**See also:**

- **Index.to_frame** Convert an Index to a DataFrame.
- **Series.to_frame** Convert Series to DataFrame.

**Examples**

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
```

By default, the original Index and original name is reused.

```python
>>> idx.to_series()
animal
Ant   Ant
```

(continues on next page)
To enforce a new Index, specify new labels to `index`:

```python
>>> idx.to_series(index=[0, 1, 2])
0    Ant
1  Bear
2    Cow
Name: animal, dtype: object
```

To override the name of the resulting column, specify `name`:

```python
>>> idx.to_series(name='zoo')
animal
Ant    Ant
Bear   Bear
Cow    Cow
Name: zoo, dtype: object
```

### pandas.Index.tolist

**Index.tolist()**

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

**Returns**

list

**See also:**

**numpy.ndarray.tolist** Return the array as an a.ndim-levels deep nested list of Python scalars.

### pandas.Index.transpose

**Index.transpose(*args,**kwargs)**

Return the transpose, which is by definition self.

**Returns**

%(klass)s
pandas.Index.union

Index.union(other, sort=None)

Form the union of two Index objects.

If the Index objects are incompatible, both Index objects will be cast to dtype('object') first.

Changed in version 0.25.0.

Parameters

other [Index or array-like]

sort [bool or None, default None] Whether to sort the resulting Index.

- None : Sort the result, except when
  1. self and other are equal.
  2. self or other has length 0.
  3. Some values in self or other cannot be compared. A RuntimeWarning is issued in this case.

- False : do not sort the result.

Returns

union [Index]

Examples

Union matching dtypes

```python
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.union(idx2)
Int64Index([1, 2, 3, 4, 5, 6], dtype='int64')
```

Union mismatched dtypes

```python
>>> idx1 = pd.Index(['a', 'b', 'c', 'd'])
>>> idx2 = pd.Index([1, 2, 3, 4])
>>> idx1.union(idx2)
Index(['a', 'b', 'c', 'd', 1, 2, 3, 4], dtype='object')
```

MultiIndex case

```python
>>> idx1 = pd.MultiIndex.from_arrays(  
...     [[1, 1, 2, 2], ['Red', 'Blue', 'Red', 'Blue']]
... )
>>> idx1
MultiIndex([(1, 'Red'),  
            (1, 'Blue'),  
            (2, 'Red'),  
            (2, 'Blue')],
           )
>>> idx2 = pd.MultiIndex.from_arrays(  
...     [[3, 3, 2, 2], ['Red', 'Green', 'Red', 'Green']]
... )
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.2

```python
>>> idx2
MultiIndex([(3, 'Red'),
            (3, 'Green'),
            (2, 'Red'),
            (2, 'Green')],
          )
>>> idx1.union(idx2)
MultiIndex([(1, 'Blue'),
            (1, 'Red'),
            (2, 'Blue'),
            (2, 'Green'),
            (2, 'Red'),
            (3, 'Green'),
            (3, 'Red')],
          )
>>> idx1.union(idx2, sort=False)
MultiIndex([(1, 'Red'),
            (1, 'Blue'),
            (2, 'Red'),
            (2, 'Blue'),
            (2, 'Green'),
            (3, 'Red'),
            (3, 'Green'),
            (2, 'Green')],
          )
```

**pandas.Index.unique**

Index.unique(level=None)

Return unique values in the index.

Unique values are returned in order of appearance, this does NOT sort.

**Parameters**

- **level** [int or hashable, optional] Only return values from specified level (for MultiIndex). If int, gets the level by integer position, else by level name.

**Returns**

Index

**See also:**

- **unique** Numpy array of unique values in that column.
- **Series.unique** Return unique values of Series object.
**pandas.Index.value_counts**

Index.<code>value_counts</code>(<code>normalize=False, sort=True, ascending=False, bins=None, dropna=True</code>)

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

**Parameters**

- **normalize** [bool, default False] If True then the object returned will contain the relative frequencies of the unique values.
- **sort** [bool, default True] Sort by frequencies.
- **ascending** [bool, default False] Sort in ascending order.
- **bins** [int, optional] Rather than count values, group them into half-open bins, a convenience for pd.cut, only works with numeric data.
- **dropna** [bool, default True] Don’t include counts of NaN.

**Returns**

Series

See also:

- **Series.count** Number of non-NA elements in a Series.
- **DataFrame.count** Number of non-NA elements in a DataFrame.
- **DataFrame.value_counts** Equivalent method on DataFrames.

**Examples**

```python
>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0    2
1.0    1
2.0    1
4.0    1
dtype: int64
```

With **normalize** set to **True**, returns the relative frequency by dividing all values by the sum of values.

```python
>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0    0.4
1.0    0.2
2.0    0.2
4.0    0.2
dtype: float64
```

**bins**

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.
```python
>>> s.value_counts(bins=3)
(0.996, 2.0]  2
(2.0, 3.0]  2
(3.0, 4.0]  1
dtype: int64
```

**dropna**

With `dropna` set to `False` we can also see NaN index values.

```python
>>> s.value_counts(dropna=False)
3.0 2
1.0 1
2.0 1
4.0 1
NaN 1
dtype: int64
```

### pandas.Index.where

**Index.where** *(cond, other=None)*

Replace values where the condition is False.

The replacement is taken from `other`.

**Parameters**

- **cond** [bool array-like with the same length as self] Condition to select the values on.
- **other** [scalar, or array-like, default None] Replacement if the condition is False.

**Returns**

- **pandas.Index** A copy of self with values replaced from `other` where the condition is False.

**See also:**

- **Series.where** Same method for Series.
- **DataFrame.where** Same method for DataFrame.

**Examples**

```python
>>> idx = pd.Index(['car', 'bike', 'train', 'tractor'])
>>> idx
Index(['car', 'bike', 'train', 'tractor'], dtype='object')
>>> idx.where(idx.isin(['car', 'train']), 'other')
Index(['car', 'other', 'train', 'other'], dtype='object')
```
Properties

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Index.values</td>
<td>Return an array representing the data in the Index.</td>
</tr>
<tr>
<td>Index.is_monotonic</td>
<td>Alias for is_monotonic_increasing.</td>
</tr>
<tr>
<td>Index.is_monotonic_increasing</td>
<td>Return if the index is monotonic increasing (only equal or increasing) values.</td>

<td>Compute slice locations for input labels.</td>
</tr>
</tbody>
</table>

### 3.6.2 Numeric Index

**RangeIndex([start, stop, step, dtype, copy, ...])**  
Immutable Index implementing a monotonic integer range.

**Int64Index([data, dtype, copy, name])**  
Immutable sequence used for indexing and alignment.

**UInt64Index([data, dtype, copy, name])**  
Immutable sequence used for indexing and alignment.

**Float64Index([data, dtype, copy, name])**  
Immutable sequence used for indexing and alignment.

**pandas.RangeIndex**

```python
class pandas.RangeIndex(start=None, stop=None, step=None, dtype=None, copy=False, name=None)
```

Immutable Index implementing a monotonic integer range.

RangeIndex is a memory-saving special case of Int64Index limited to representing monotonic ranges. Using RangeIndex may in some instances improve computing speed.

This is the default index type used by DataFrame and Series when no explicit index is provided by the user.

**Parameters**

- **start**  
  [int (default: 0), range, or other RangeIndex instance] If int and “stop” is not given, interpreted as “stop” instead.

- **stop**  
  [int (default: 0)]

- **step**  
  [int (default: 1)]

- **dtype**  
  [np.int64] Unused, accepted for homogeneity with other index types.

- **copy**  
  [bool, default False] Unused, accepted for homogeneity with other index types.

- **name**  
  [object, optional] Name to be stored in the index.

**See also:**
**Index**  The base pandas Index type.

**Int64Index**  Index of int64 data.

### Attributes

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>start</strong></td>
<td>The value of the <code>start</code> parameter (0 if this was not supplied).</td>
</tr>
<tr>
<td><strong>stop</strong></td>
<td>The value of the <code>stop</code> parameter.</td>
</tr>
<tr>
<td><strong>step</strong></td>
<td>The value of the <code>step</code> parameter (1 if this was not supplied).</td>
</tr>
</tbody>
</table>

**pandas.RangeIndex.start**

**property**  `RangeIndex.start`

The value of the `start` parameter (0 if this was not supplied).

**pandas.RangeIndex.stop**

**property**  `RangeIndex.stop`

The value of the `stop` parameter.

**pandas.RangeIndex.step**

**property**  `RangeIndex.step`

The value of the `step` parameter (1 if this was not supplied).

### Methods

**from_range(data[, name, dtype])**

Create `RangeIndex` from a range object.

**pandas.RangeIndex.from_range**

**classmethod**  `RangeIndex.from_range(data, name=None, dtype=None)`

Create `RangeIndex` from a range object.

**Returns**

`RangeIndex`
pandas.Int64Index
class pandas.Int64Index
(data=None, dtype=None, copy=False, name=None)
Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects. Int64Index is a special case of Index with purely integer labels.

Parameters
   data [array-like (1-dimensional)]
   dtype [NumPy dtype (default: int64)]
   copy [bool] Make a copy of input ndarray.
   name [object] Name to be stored in the index.

See also:
   Index The base pandas Index type.

Notes
An Index instance can only contain hashable objects.

Attributes
   None

Methods
   None

pandas.UInt64Index
class pandas.UInt64Index
(data=None, dtype=None, copy=False, name=None)
Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects. UInt64Index is a special case of Index with purely unsigned integer labels.

Parameters
   data [array-like (1-dimensional)]
   dtype [NumPy dtype (default: uint64)]
   copy [bool] Make a copy of input ndarray.
   name [object] Name to be stored in the index.

See also:
   Index The base pandas Index type.
Notes

An Index instance can only contain hashable objects.

Attributes

None

Methods

None

pandas.Float64Index

class pandas.Float64Index (data=None, dtype=None, copy=False, name=None)

Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects. Float64Index is a special case of Index with purely float labels.

Parameters

data [array-like (1-dimensional)]
dtype [NumPy dtype (default: float64)]
copy [bool] Make a copy of input ndarray.
name [object] Name to be stored in the index.

See also:

Index The base pandas Index type.

Notes

An Index instance can only contain hashable objects.

Attributes

None

Methods

None

RangeIndex.start

The value of the start parameter (0 if this was not supplied).

RangeIndex.stop

The value of the stop parameter.

<tbody>
<tr>
<td><code>RangeIndex.step</code></td>
<td>The value of the <code>step</code> parameter (1 if this was not supplied).</td>
</tr>
<tr>
<td><code>RangeIndex.from_range(data[, name, dtype])</code></td>
<td>Create RangeIndex from a range object.</td>
</tr>
</tbody>
</table>

### 3.6.3 CategoricalIndex

CategoricalIndex can only take on a limited, and usually fixed, number of possible values (categories). Also, like Categorical, it might have an order, but numerical operations (additions, divisions, ...) are not possible.

#### Parameters

- **data** [array-like (1-dimensional)] The values of the categorical. If `categories` are given, values not in `categories` will be replaced with NaN.
- **categories** [index-like, optional] The categories for the categorical. Items need to be unique. If the categories are not given here (and also not in `dtype`), they will be inferred from the `data`.
- **ordered** [bool, optional] Whether or not this categorical is treated as an ordered categorical. If not given here or in `dtype`, the resulting categorical will be unordered.
- **dtype** [CategoricalDtype or “category”, optional] If `CategoricalDtype`, cannot be used together with `categories` or `ordered`.
- **copy** [bool, default False] Make a copy of input ndarray.
- **name** [object, optional] Name to be stored in the index.

#### Raises

- **ValueError** If the categories do not validate.
- **TypeError** If an explicit `ordered=True` is given but no `categories` and the values are not sortable.

#### See also:

- **Index** The base pandas Index type.
- **Categorical** A categorical array.
- **CategoricalDtype** Type for categorical data.
Notes

See the user guide for more.

Examples

```python
>>> pd.CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'])
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], categories=['a', 'b', 'c'], ordered=False, dtype='category')

CategoricalIndex can also be instantiated from a Categorical:

>>> c = pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'])
>>> pd.CategoricalIndex(c)
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], categories=['a', 'b', 'c'], ordered=False, dtype='category')

Ordered CategoricalIndex can have a min and max value.

>>> ci = pd.CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], ordered=True, categories=['c', 'b', 'a'])
>>> ci
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], categories=['c', 'b', 'a'], ordered=True, dtype='category')
>>> ci.min()
'c'
```

Attributes

<table>
<thead>
<tr>
<th>codes</th>
<th>The category codes of this categorical.</th>
</tr>
</thead>
<tbody>
<tr>
<td>categories</td>
<td>The categories of this categorical.</td>
</tr>
<tr>
<td>ordered</td>
<td>Whether the categories have an ordered relationship.</td>
</tr>
</tbody>
</table>

```python
pandas.CategoricalIndex.codes
```

**property** `CategoricalIndex.codes`

The category codes of this categorical.

Codes are an array of integers which are the positions of the actual values in the categories array.

There is no setter, use the other categorical methods and the normal item setter to change values in the categorical.

**Returns**

`ndarray[int]` A non-writable view of the `codes` array.
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.CategoricalIndex.categories

**property** `CategoricalIndex.categories`

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to `categories` is an inplace operation!

**Raises**

```
ValueError
```
If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

**See also:**

- `rename_categories` Rename categories.
- `reorder_categories` Reorder categories.
- `add_categories` Add new categories.
- `remove_categories` Remove the specified categories.
- `remove_unused_categories` Remove categories which are not used.
- `set_categories` Set the categories to the specified ones.

pandas.CategoricalIndex.ordered

**property** `CategoricalIndex.ordered`

Whether the categories have an ordered relationship.

**Methods**

- `rename_categories(*args, **kwargs)` Rename categories.
- `reorder_categories(*args, **kwargs)` Reorder categories as specified in new_categories.
- `add_categories(*args, **kwargs)` Add new categories.
- `remove_categories(*args, **kwargs)` Remove the specified categories.
- `remove_unused_categories(*args, **kwargs)` Remove categories which are not used.
- `set_categories(*args, **kwargs)` Set the categories to the specified new_categories.
- `as_ordered(*args, **kwargs)` Set the Categorical to be ordered.
- `as_unordered(*args, **kwargs)` Set the Categorical to be unordered.
- `map(mapper)` Map values using input correspondence (a dict, Series, or function).
pandas.CategoricalIndex.rename_categories

CategoricalIndex.rename_categories(*args, **kwargs)
Rename categories.

Parameters

new_categories [list-like, dict-like or callable] New categories which will replace old categories.

• list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.

• dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.

• callable : a callable that is called on all items in the old categories and whose return values comprise the new categories.

inplace [bool, default False] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

Deprecated since version 1.3.0.

Returns

cat [Categorical or None] Categorical with removed categories or None if inplace=True.

Raises

ValueError If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

See also:

reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

Examples

```python
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like new_categories, extra keys are ignored and categories not in the dictionary are passed through

```python
>>> c.rename_categories({'a': 'A', 'c': 'C'})
['A', 'A', 'b']
Categories (2, object): ['A', 'b']
```
You may also provide a callable to create the new categories

```python
>>> c.rename_categories(lambda x: x.upper())
['A', 'A', 'B']
Categories (2, object): ['A', 'B']
```

**pandas.CategoricalIndex.reorder_categories**

CategoricalIndex.reorder_categories(*args, **kwargs)
Reorder categories as specified in new_categories.

*new_categories* need to include all old categories and no new category items.

**Parameters**

- **new_categories** [Index-like] The categories in new order.
- **ordered** [bool, optional] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.
- **inplace** [bool, default False] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

**Returns**

- **cat** [Categorical or None] Categorical with removed categories or None if inplace=True.

**Raises**

- **ValueError** If the new categories do not contain all old category items or any new ones

**See also:**

- rename_categories Rename categories.
- add_categories Add new categories.
- remove_categories Remove the specified categories.
- remove_unused_categories Remove categories which are not used.
- set_categories Set the categories to the specified ones.

**pandas.CategoricalIndex.add_categories**

CategoricalIndex.add_categories(*args, **kwargs)
Add new categories.

*new_categories* will be included at the last/highest place in the categories and will be unused directly after this call.

**Parameters**

- **new_categories** [category or list-like of category] The new categories to be included.
- **inplace** [bool, default False] Whether or not to add the categories inplace or return a copy of this categorical with added categories.

Deprecated since version 1.3.0.
Returns

**cat**  [Categorical or None]  Categorical with new categories added or None if `inplace=True`.

Raises

**ValueError**  If the new categories include old categories or do not validate as categories.

See also:

- `rename_categories`  Rename categories.
- `reorder_categories`  Reorder categories.
- `remove_categories`  Remove the specified categories.
- `remove_unused_categories`  Remove categories which are not used.
- `set_categories`  Set the categories to the specified ones.

---

**pandas.CategoricalIndex.remove_categories**

CategoricalIndex.remove_categories(*args, **kwargs)

Remove the specified categories.

*removals* must be included in the old categories. Values which were in the removed categories will be set to NaN.

Parameters

- **removals**  [category or list of categories]  The categories which should be removed.
- **inplace**  [bool, default False]  Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

Deprecation since version 1.3.0.

Returns

**cat**  [Categorical or None]  Categorical with removed categories or None if `inplace=True`.

Raises

**ValueError**  If the removals are not contained in the categories.

See also:

- `rename_categories`  Rename categories.
- `reorder_categories`  Reorder categories.
- `add_categories`  Add new categories.
- `remove_unused_categories`  Remove categories which are not used.
- `set_categories`  Set the categories to the specified ones.
pandas.CategoricalIndex.remove_unused_categories

CategoricalIndex.remove_unused_categories(*args, **kwargs)
Remove categories which are not used.

Parameters

inplace [bool, default False] Whether or not to drop unused categories in place or return a copy of this categorical with unused categories dropped.

Deprecated since version 1.2.0.

Returns

cat [Categorical or None] Categorical with unused categories dropped or None if inplace=True.

See also:
rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.set_categories

CategoricalIndex.set_categories(*args, **kwargs)
Set the categories to the specified new_categories.

new_categories can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If rename==True, the categories will simply be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand, this method does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes, which does not consider a S1 string equal to a single char python string.

Parameters

new_categories [Index-like] The categories in new order.
ordered [bool, default False] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.
rename [bool, default False] Whether or not the new_categories should be considered as a rename of the old categories or as reordered categories.
inplace [bool, default False] Whether or not to reorder the categories in-place or return a copy of this categorical with reordered categories.

Deprecated since version 1.3.0.

Returns

Categorical with reordered categories or None if inplace.
Raises

ValueError If new_categories does not validate as categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.

pandas.CategoricalIndex.as_ordered

CategoricalIndex.as_ordered(*args, **kwargs)
Set the Categorical to be ordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to True.

Returns

Categorical or None Ordered Categorical or None if inplace=True.

pandas.CategoricalIndex.as_unordered

CategoricalIndex.as_unordered(*args, **kwargs)
Set the Categorical to be unordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to False.

Returns

Categorical or None Unordered Categorical or None if inplace=True.

pandas.CategoricalIndex.map

CategoricalIndex.map(mapper)
Map values using input correspondence (a dict, Series, or function).
Maps the values (their categories, not the codes) of the index to new categories. If the mapping correspondence is one-to-one the result is a CategoricalIndex which has the same order property as the original, otherwise an Index is returned.

If a dict or Series is used any unmapped category is mapped to NaN. Note that if this happens an Index will be returned.

Parameters

mapper [function, dict, or Series] Mapping correspondence.
pandas: powerful Python data analysis toolkit, Release 1.3.2

Returns

- **pandas.CategoricalIndex or pandas.Index** Mapped index.

See also:

- **Index.map** Apply a mapping correspondence on an Index.
- **Series.map** Apply a mapping correspondence on a Series.
- **Series.apply** Apply more complex functions on a Series.

Examples

```python
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'])
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'], ordered=False, dtype='category')
>>> idx.map(lambda x: x.upper())
CategoricalIndex(['A', 'B', 'C'], categories=['A', 'B', 'C'], ordered=False, dtype='category')
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'third'})
CategoricalIndex(['first', 'second', 'third'], categories=['first', 'second', 'third'], ordered=False, dtype='category')
```

If the mapping is one-to-one the ordering of the categories is preserved:

```python
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'], ordered=True)
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'], ordered=True, dtype='category')
>>> idx.map({'a': 3, 'b': 2, 'c': 1})
CategoricalIndex([3, 2, 1], categories=[3, 2, 1], ordered=True, dtype='category')
```

If the mapping is not one-to-one an Index is returned:

```python
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'first'})
Index(['first', 'second', 'first'], dtype='object')
```

If a dict is used, all unmapped categories are mapped to NaN and the result is an Index:

```python
>>> idx.map({'a': 'first', 'b': 'second'})
Index(['first', 'second', nan], dtype='object')
```

Categorical components

- **CategoricalIndex.codes** The category codes of this categorical.
- **CategoricalIndex.categories** The categories of this categorical.
- **CategoricalIndex.ordered** Whether the categories have an ordered relationship.
- **CategoricalIndex.rename_categories(*args, ...)** Rename categories.
- **CategoricalIndex reorder_categories(*args, ...)** Reorder categories as specified in new_categories.

<tr>
<td><code>remove_categories(*args, ...)</code></td>
<td>Remove the specified categories.</td>
</tr>
<tr>
<td><code>remove_unused_categories(...)</code></td>
<td>Remove categories which are not used.</td>
</tr>
<tr>
<td><code>set_categories(*args, **kwargs)</code></td>
<td>Set the categories to the specified new_categories.</td>
</tr>
<tr>
<td><code>as_ordered(*args, **kwargs)</code></td>
<td>Set the Categorical to be ordered.</td>
</tr>
<tr>
<td><code>as_unordered(*args, **kwargs)</code></td>
<td>Set the Categorical to be unordered.</td>
</tr>
</tbody>
</table>

**Modifying and computations**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>map(mapper)</code></td>
<td>Map values using input correspondence (a dict, Series, or function).</td>
</tr>
<tr>
<td><code>equals(other)</code></td>
<td>Determine if two CategoricalIndex objects contain the same elements.</td>
</tr>
</tbody>
</table>

### pandas.CategoricalIndex.equals

`CategoricalIndex.equals(other)`

Determine if two CategoricalIndex objects contain the same elements.

**Returns**

- `bool` If two CategoricalIndex objects have equal elements True, otherwise False.

### 3.6.4 IntervalIndex

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>IntervalIndex(data[, closed, dtype, copy, ...])</code></td>
<td>Immutable index of intervals that are closed on the same side.</td>
</tr>
</tbody>
</table>

### pandas.IntervalIndex

**class pandas.IntervalIndex(data, closed=None, dtype=None, copy=False, name=None, verify_integrity=True)**

Immutable index of intervals that are closed on the same side.

New in version 0.20.0.

**Parameters**

- `data` [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalIndex.
- `closed` [‘left’, ‘right’, ‘both’, ‘neither’], default ‘right’ Whether the intervals are closed on the left-side, right-side, both or neither.
- `dtype` [dtype or None, default None] If None, dtype will be inferred.
copy  [bool, default False] Copy the input data.

name  [object, optional] Name to be stored in the index.

verify_integrity  [bool, default True] Verify that the IntervalIndex is valid.

See also:

Index  The base pandas Index type.
Interval  A bounded slice-like interval; the elements of an IntervalIndex.
interval_range  Function to create a fixed frequency IntervalIndex.
cut  Bin values into discrete Intervals.
qcut  Bin values into equal-sized Intervals based on rank or sample quantiles.

Notes

See the user guide for more.

Examples

A new IntervalIndex is typically constructed using interval_range():

```python
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
dtype='interval[int64, right]')
```

It may also be constructed using one of the constructor methods: IntervalIndex.from_arrays(), IntervalIndex.from_breaks(), and IntervalIndex.from_tuples().

See further examples in the doc strings of interval_range and the mentioned constructor methods.

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>closed</td>
<td>Whether the intervals are closed on the left-side, right-side, both or neither.</td>
</tr>
<tr>
<td>is_empty</td>
<td>Indicates if an interval is empty, meaning it contains no points.</td>
</tr>
<tr>
<td>is_non_overlapping_monotonic</td>
<td>Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.</td>
</tr>
<tr>
<td>is_overlapping</td>
<td>Return True if the IntervalIndex has overlapping intervals, else False.</td>
</tr>
<tr>
<td>values</td>
<td>Return an array representing the data in the Index.</td>
</tr>
</tbody>
</table>
pandas.IntervalIndex.closed

IntervalIndex.closed: str
Whether the intervals are closed on the left-side, right-side, both or neither.

pandas.IntervalIndex.is_empty

property IntervalIndex.is_empty
Indicates if an interval is empty, meaning it contains no points.
New in version 0.25.0.

Returns

bool or ndarray A boolean indicating if a scalar Interval is empty, or a boolean ndarray positionally indicating if an Interval in an IntervalArray or IntervalIndex is empty.

Examples

An Interval that contains points is not empty:

```python
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```python
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:

```python
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An IntervalArray or IntervalIndex returns a boolean ndarray positionally indicating if an Interval is empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'),
...        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```
pandas.IntervalIndex.is_non_overlapping_monotonic

IntervalIndex.

is_non_overlapping_monotonic: bool
Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.

pandas.IntervalIndex.is_overlapping

property IntervalIndex.

is_overlapping
Return True if the IntervalIndex has overlapping intervals, else False.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

Returns

bool Boolean indicating if the IntervalIndex has overlapping intervals.

See also:

Interval.overlaps Check whether two Interval objects overlap.
IntervalIndex.overlaps Check an IntervalIndex elementwise for overlaps.

Examples

>>> index = pd.IntervalIndex.from_tuples([(0, 2), (1, 3), (4, 5)])
>>> index
IntervalIndex([(0, 2], (1, 3], (4, 5]
          dtype='interval[int64, right]')
>>> index.is_overlapping
True

Intervals that share closed endpoints overlap:

>>> index = pd.interval_range(0, 3, closed='both')
>>> index
IntervalIndex([[[0, 1], [1, 2], [2, 3]],
              dtype='interval[int64, both]')
>>> index.is_overlapping
True

Intervals that only have an open endpoint in common do not overlap:

>>> index = pd.interval_range(0, 3, closed='left')
>>> index
IntervalIndex([[[0, 1), [1, 2), [2, 3)),
              dtype='interval[int64, left]')
>>> index.is_overlapping
False
pandas.IntervalIndex.values

**property IntervalIndex.values**

Return an array representing the data in the Index.

**Warning:** We recommend using `Index.array` or `Index.to_numpy()`, depending on whether you need a reference to the underlying data or a NumPy array.

Returns

array: numpy.ndarray or ExtensionArray

See also:

- `Index.array` Reference to the underlying data.
- `Index.to_numpy` A NumPy array representing the underlying data.

<table>
<thead>
<tr>
<th>left</th>
<th>right</th>
<th>mid</th>
<th>length</th>
</tr>
</thead>
</table>

Methods

- `from_arrays(left, right[, closed, name, ...])` Construct from two arrays defining the left and right bounds.
- `from_tuples(data[, closed, name, copy, dtype])` Construct an IntervalIndex from an array-like of tuples.
- `from_breaks(breaks[, closed, name, copy, dtype])` Construct an IntervalIndex from an array of splits.
- `contains(*args, **kwargs)` Check elementwise if the Intervals contain the value.
- `overlaps(*args, **kwargs)` Check elementwise if an Interval overlaps the values in the IntervalArray.
- `set_closed(*args, **kwargs)` Return an IntervalArray identical to the current one, but closed on the specified side.
- `to_tuples(*args, **kwargs)` Return an ndarray of tuples of the form (left, right).

pandas.IntervalIndex.from_arrays

**classmethod IntervalIndex.from_arrays**

`left, right, closed='right', name=None, copy=False, dtype=None`

Construct from two arrays defining the left and right bounds.

Parameters

- `left` [array-like (1-dimensional)] Left bounds for each interval.
- `right` [array-like (1-dimensional)] Right bounds for each interval.
- `closed` [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are
closed on the left-side, right-side, both or neither.

copy [bool, default False] Copy the data.
dtype [dtype, optional] If None, dtype will be inferred.

Returns
IntervalIndex

Raises

ValueError When a value is missing in only one of left or right. When a value in left
is greater than the corresponding value in right.

See also:

interval_range Function to create a fixed frequency IntervalIndex.
IntervalIndex.from_breaks Construct an IntervalIndex from an array of splits.
IntervalIndex.from_tuples Construct an IntervalIndex from an array-like of tuples.

Notes

Each element of left must be less than or equal to the right element at the same position. If an element is
missing, it must be missing in both left and right. A TypeError is raised when using an unsupported type
for left or right. At the moment, ‘category’, ‘object’, and ‘string’ subtypes are not supported.

Examples

>>> pd.IntervalIndex.from_arrays([[0, 1, 2], [1, 2, 3]])
IntervalIndex([[0, 1], (1, 2], (2, 3)),
dtype='interval[int64, right]')

pandas.IntervalIndex.from_tuples

classmethod IntervalIndex.from_tuples (data, closed='right', name=None, copy=False,
dtype=None)

Construct an IntervalIndex from an array-like of tuples.

Parameters

data [array-like (1-dimensional)] Array of tuples.
closed [['left', 'right', 'both', 'neither'], default 'right'] Whether the intervals are
closed on the left-side, right-side, both or neither.
copy [bool, default False] By-default copy the data, this is compat only and ignored.
dtype [dtype or None, default None] If None, dtype will be inferred.

Returns
IntervalIndex

See also:

interval_range Function to create a fixed frequency IntervalIndex.
**IntervalIndex.from_arrays**  Construct an IntervalIndex from a left and right array.

**IntervalIndex.from_breaks**  Construct an IntervalIndex from an array of splits.

**Examples**

```python
>>> pd.IntervalIndex.from_tuples([(0, 1), (1, 2)])
IntervalIndex([(0, 1], (1, 2]],
dtype='interval[int64, right]')
```

**pandas.IntervalIndex.from_breaks**

**classmethod**  `IntervalIndex.from_breaks`(breaks, closed='right', name=None, copy=False, dtype=None)

Construct an IntervalIndex from an array of splits.

**Parameters**

- **breaks**  [array-like (1-dimensional)]  Left and right bounds for each interval.
- **closed**  ['left', 'right', 'both', 'neither'], default 'right'  Whether the intervals are closed on the left-side, right-side, both or neither.
- **copy**  [bool, default False]  Copy the data.
- **dtype**  [dtype or None, default None]  If None, dtype will be inferred.

**Returns**

IntervalIndex

**See also:**

- `interval_range`  Function to create a fixed frequency IntervalIndex.
- `IntervalIndex.from_arrays`  Construct from a left and right array.
- `IntervalIndex.from_tuples`  Construct from a sequence of tuples.

**Examples**

```python
>>> pd.IntervalIndex.from_breaks([0, 1, 2, 3])
IntervalIndex([(0, 1], (1, 2], (2, 3]],
dtype='interval[int64, right]')
```

**pandas.IntervalIndex.contains**

**`IntervalIndex.contains`**  (*args, **kwargs*

Check elementwise if the Intervals contain the value.

Return a boolean mask whether the value is contained in the Intervals of the IntervalArray.

New in version 0.25.0.

**Parameters**

- **other**  [scalar]  The value to check whether it is contained in the Intervals.
Returns

boolean array

See also:

Interval.contains Check whether Interval object contains value.
IntervalArray.overlaps Check if an Interval overlaps the values in the IntervalArray.

Examples

```python
>>> intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]]
Length: 3, dtype: interval[int64, right]

>>> intervals.contains(0.5)
array([ True, False, False])
```

pandas.IntervalIndex.overlaps

IntervalIndex.overlaps (*args, **kwargs)

Check elementwise if an Interval overlaps the values in the IntervalArray.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

Parameters

other [IntervalArray] Interval to check against for an overlap.

Returns

ndarray Boolean array positionally indicating where an overlap occurs.

See also:

Interval.overlaps Check whether two Interval objects overlap.

Examples

```python
>>> data = [(0, 1), (1, 3), (2, 4)]
>>> intervals = pd.arrays.IntervalArray.from_tuples(data)
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]]
Length: 3, dtype: interval[int64, right]

>>> intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True, True, False])
```

Intervals that share closed endpoints overlap:
Intervals that only have an open endpoint in common do not overlap:

```python
>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False, True, False])
```

### pandas.IntervalIndex.set_closed

IntervalIndex.set_closed(*args, **kwargs)

Return an IntervalArray identical to the current one, but closed on the specified side.

**Parameters**

- `closed` (str) – Whether the intervals are closed on the left-side, right-side, both or neither.

**Returns**

- `new_index` ([IntervalArray])

**Examples**

```python
>>> index = pd.arrays.IntervalArray.from_breaks(range(4))
>>> index
<IntervalArray>
[(0, 1], (1, 2], (2, 3]]
Length: 3, dtype: interval[int64, right]
>>> index.set_closed('both')
<IntervalArray>
[[0, 1], [1, 2], [2, 3]]
Length: 3, dtype: interval[int64, both]
```

### pandas.IntervalIndex.to_tuples

IntervalIndex.to_tuples(*args, **kwargs)

Return an ndarray of tuples of the form (left, right).

**Parameters**

- `na_tuple` (bool, default True) – Returns NA as a tuple if True, (nan, nan), or just as the NA value itself if False, nan.

**Returns**

- `tuples` (ndarray)
**IntervalIndex components**

- `IntervalIndex.from_arrays(left, right[, ...])`: Construct from two arrays defining the left and right bounds.
- `IntervalIndex.from_tuples(data[, closed, ...])`: Construct an IntervalIndex from an array-like of tuples.
- `IntervalIndex.from_breaks(breaks[, closed, ...])`: Construct an IntervalIndex from an array of splits.
- `IntervalIndex.left`
- `IntervalIndex.right`
- `IntervalIndex.mid`
- `IntervalIndex.closed`: Whether the intervals are closed on the left-side, right-side, both or neither.
- `IntervalIndex.length`
- `IntervalIndex.values`: Return an array representing the data in the Index.
- `IntervalIndex.is_empty`: Indicates if an interval is empty, meaning it contains no points.
- `IntervalIndex.is_non_overlapping_monotonic`: Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.
- `IntervalIndex.is_overlapping`: Return True if the IntervalIndex has overlapping intervals, else False.
- `IntervalIndex.get_loc(key[, method, tolerance])`: Get integer location, slice or boolean mask for requested label.
- `IntervalIndex.get_indexer(target[, method, ...])`: Compute indexer and mask for new index given the current index.
- `IntervalIndex.set_closed(*args, **kwargs)`: Return an IntervalArray identical to the current one, but closed on the specified side.
- `IntervalIndex.contains(*args, **kwargs)`: Check elementwise if the Intervals contain the value.
- `IntervalIndex.overlaps(*args, **kwargs)`: Check elementwise if an Interval overlaps the values in the IntervalArray.
- `IntervalIndex.to_tuples(*args, **kwargs)`: Return an ndarray of tuples of the form (left, right).

**pandas.IntervalIndex.left**

- `IntervalIndex.left`
pandas.IntervalIndex.right

IntervalIndex.right

pandas.IntervalIndex.mid

IntervalIndex.mid

pandas.IntervalIndex.length

property IntervalIndex.length

pandas.IntervalIndex.get_loc

IntervalIndex.get_loc(key, method=None, tolerance=None)
Get integer location, slice or boolean mask for requested label.

Parameters

- key [label]
- method [[None], optional]
  - default: matches where the label is within an interval only.

Returns

int if unique index, slice if monotonic index, else mask

Examples

```python
>>> i1, i2 = pd.Interval(0, 1), pd.Interval(1, 2)
>>> index = pd.IntervalIndex([i1, i2])
>>> index.get_loc(1)
0
```

You can also supply a point inside an interval.

```python
>>> index.get_loc(1.5)
1
```

If a label is in several intervals, you get the locations of all the relevant intervals.

```python
>>> i3 = pd.Interval(0, 2)
>>> overlapping_index = pd.IntervalIndex([i1, i2, i3])
>>> overlapping_index.get_loc(0.5)
array([ True, False,  True])
```

Only exact matches will be returned if an interval is provided.

```python
>>> index.get_loc(pd.Interval(0, 1))
0
```
pandas.IntervalIndex.get_indexer

IntervalIndex.get_indexer(target, method=None, limit=None, tolerance=None)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

Parameters

- target [Index]
- method [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]
  - default: exact matches only.
  - pad / ffill: find the PREVIOUS index value if no exact match.
  - backfill / bfill: use NEXT index value if no exact match
  - nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
- limit [int, optional] Maximum number of consecutive labels in target to match for inexact matches.
- tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation abs(index[indexer] - target) <= tolerance.
  
  Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index's type.

Returns

- indexer [np.ndarray[np.intp]] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

Examples

```python
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1, 2, -1])
```

Notice that the return value is an array of locations in index and x is marked by -1, as it is not in index.

3.6.5 MultiIndex

MultiIndex([levels, codes, sortorder, ...]) A multi-level, or hierarchical, index object for pandas objects.
class pandas.MultiIndex

A multi-level, or hierarchical, index object for pandas objects.

Parameters

levels [sequence of arrays] The unique labels for each level.
codes [sequence of arrays] Integers for each level designating which label at each location.
sortorder [optional int] Level of sortedness (must be lexicographically sorted by that level).
names [optional sequence of objects] Names for each of the index levels. (name is accepted for compat).
copy [bool, default False] Copy the meta-data.
verify_integrity [bool, default True] Check that the levels/codes are consistent and valid.

See also:

- MultiIndex.from_arrays Convert list of arrays to MultiIndex.
- MultiIndex.from_product Create a MultiIndex from the cartesian product of iterables.
- MultiIndex.from_tuples Convert list of tuples to a MultiIndex.
- MultiIndex.from_frame Make a MultiIndex from a DataFrame.
- Index The base pandas Index type.

Notes

See the user guide for more.

Examples

A new MultiIndex is typically constructed using one of the helper methods MultiIndex.from_arrays(), MultiIndex.from_product() and MultiIndex.from_tuples(). For example (using .from_arrays):

```python
>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex([(1, 'red'),
            (1, 'blue'),
            (2, 'red'),
            (2, 'blue')],
           names=['number', 'color'])
```

See further examples for how to construct a MultiIndex in the doc strings of the mentioned helper methods.
Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>names</td>
<td>Names of levels in MultiIndex.</td>
</tr>
<tr>
<td>nlevels</td>
<td>Integer number of levels in this MultiIndex.</td>
</tr>
<tr>
<td>levshape</td>
<td>A tuple with the length of each level.</td>
</tr>
</tbody>
</table>

**pandas.MultiIndex.names**

**property MultiIndex.names**

Names of levels in MultiIndex.

**Examples**

```python
>>> mi = pd.MultiIndex.from_arrays(
... [[1, 2], [3, 4], [5, 6]], names=['x', 'y', 'z'])
>>> mi
MultiIndex([1, 2], [3, 4], [5, 6], names=['x', 'y', 'z'])
>>> mi.names
FrozenList(['x', 'y', 'z'])
```

**pandas.MultiIndex.nlevels**

**property MultiIndex.nlevels**

Integer number of levels in this MultiIndex.

**Examples**

```python
>>> mi = pd.MultiIndex.from_arrays([['a'], ['b'], ['c']])
>>> mi
MultiIndex([('a', 'b', 'c')],
>>> mi.nlevels
3
```

**pandas.MultiIndex.levshape**

**property MultiIndex.levshape**

A tuple with the length of each level.
Examples

```python
>>> mi = pd.MultiIndex.from_arrays([['a'], ['b'], ['c']])
>>> mi
MultiIndex([('a', 'b', 'c')],
           )
>>> mi.levshape
(1, 1, 1)
```

</tr>
</tbody>
</table>

```python
class MultiIndex.from_arrays(arrays, sortorder=None, names=<no_default>)
```

Convert arrays to MultiIndex.

**Parameters**

- **arrays** [list / sequence of array-likes] Each array-like gives one level’s value for each data point. len(arrays) is the number of levels.
- **sortorder** [int or None] Level of sortedness (must be lexicographically sorted by that level).
- **names** [list / sequence of str, optional] Names for the levels in the index.

**Returns**

- **MultiIndex**

See also:

3.6. Index objects
**MultiIndex.from_tuples** Convert list of tuples to MultiIndex.

**MultiIndex.from_product** Make a MultiIndex from cartesian product of iterables.

**MultiIndex.from_frame** Make a MultiIndex from a DataFrame.

### Examples

```python
>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex([(1, 'red'),
            (1, 'blue'),
            (2, 'red'),
            (2, 'blue')],
           names=['number', 'color'])
```

### pandas.MultiIndex.from_tuples

classmethod MultiIndex.from_tuples(tuples, sortorder=None, names=None)

Convert list of tuples to MultiIndex.

**Parameters**

- **tuples** [list / sequence of tuple-likes] Each tuple is the index of one row/column.
- **sortorder** [int or None] Level of sortedness (must be lexicographically sorted by that level).
- **names** [list / sequence of str, optional] Names for the levels in the index.

**Returns**

MultiIndex

**See also:**

**MultiIndex.from_arrays** Convert list of arrays to MultiIndex.

**MultiIndex.from_product** Make a MultiIndex from cartesian product of iterables.

**MultiIndex.from_frame** Make a MultiIndex from a DataFrame.

### Examples

```python
>>> tuples = [(1, 'red'), (1, 'blue'),
            (2, 'red'), (2, 'blue')]
>>> pd.MultiIndex.from_tuples(tuples, names=('number', 'color'))
MultiIndex([(1, 'red'),
            (1, 'blue'),
            (2, 'red'),
            (2, 'blue')],
           names=['number', 'color'])
```
pandas.MultiIndex.from_product

classmethod MultiIndex.from_product(iterables, sortorder=None, names=<no_default>)
Make a MultiIndex from the cartesian product of multiple iterables.

Parameters

iterables [list / sequence of iterables] Each iterable has unique labels for each level of the index.

sortorder [int or None] Level of sortedness (must be lexicographically sorted by that level).

names [list / sequence of str, optional] Names for the levels in the index.

Changed in version 1.0.0: If not explicitly provided, names will be inferred from the elements of iterables if an element has a name attribute

Returns

MultiIndex

See also:

MultiIndex.from_arrays Convert list of arrays to MultiIndex.
MultiIndex.from_tuples Convert list of tuples to MultiIndex.
MultiIndex.from_frame Make a MultiIndex from a DataFrame.

Examples

```python
>>> numbers = [0, 1, 2]
>>> colors = ['green', 'purple']
>>> pd.MultiIndex.from_product([[numbers, colors],
...                             names=['number', 'color'])
MultiIndex([(0, 'green'),
(0, 'purple'),
(1, 'green'),
(1, 'purple'),
(2, 'green'),
(2, 'purple')],
names=['number', 'color'])
```

pandas.MultiIndex.from_frame

classmethod MultiIndex.from_frame(df, sortorder=None, names=None)
Make a MultiIndex from a DataFrame.

Parameters

df [DataFrame] DataFrame to be converted to MultiIndex.

sortorder [int, optional] Level of sortedness (must be lexicographically sorted by that level).

names [list-like, optional] If no names are provided, use the column names, or tuple of column names if the columns is a MultiIndex. If a sequence, overwrite names with the given sequence.

3.6. Index objects
Returns

MultiIndex  The MultiIndex representation of the given DataFrame.

See also:

MultiIndex.from_arrays  Convert list of arrays to MultiIndex.
MultiIndex.from_tuples  Convert list of tuples to MultiIndex.
MultiIndex.from_product  Make a MultiIndex from cartesian product of iterables.

Examples

```python
>>> df = pd.DataFrame([['HI', 'Temp'], ['HI', 'Precip'],
                    ['NJ', 'Temp'], ['NJ', 'Precip']],
                    columns=['a', 'b'])
```

```python
>>> pd.MultiIndex.from_frame(df)
MultiIndex([('HI', 'Temp'),
            ('HI', 'Precip'),
            ('NJ', 'Temp'),
            ('NJ', 'Precip')],
            names=['a', 'b'])
```

Using explicit names, instead of the column names

```python
>>> pd.MultiIndex.from_frame(df, names=['state', 'observation'])
MultiIndex([('HI', 'Temp'),
            ('HI', 'Precip'),
            ('NJ', 'Temp'),
            ('NJ', 'Precip')],
            names=['state', 'observation'])
```

pandas.MultiIndex.set_levels

MultiIndex.set_levels(levels, level=None, inplace=None, verify_integrity=True)
Set new levels on MultiIndex. Defaults to returning new index.

Parameters

- levels  [sequence or list of sequence] New level(s) to apply.
- level  [int, level name, or sequence of int/level names (default None)] Level(s) to set (None for all levels).
- inplace  [bool] If True, mutates in place.
  Deprecated since version 1.2.0.
- verify_integrity  [bool, default True] If True, checks that levels and codes are compatible.
Returns

new index (of same type and class...etc) or None The same type as the caller or None if inplace=True.

Examples

```python
>>> idx = pd.MultiIndex.from_tuples(
...   [(1, "one"),
    (1, "two"),
    (2, "one"),
    (2, "two"),
    (3, "one"),
    (3, "two")
...],
...   names=['foo', "bar"]
...)

>>> idx
MultiIndex([(1, 'one'),
            (1, 'two'),
            (2, 'one'),
            (2, 'two'),
            (3, 'one'),
            (3, 'two')],
           names=['foo', 'bar'])

>>> idx.set_levels([['a', 'b', 'c'], [1, 2]])
MultiIndex([('a', 1),
            ('a', 2),
            ('b', 1),
            ('b', 2),
            ('c', 1),
            ('c', 2)],
           names=['foo', 'bar'])

>>> idx.set_levels([['a', 'b', 'c'], [1, 2]], level=0)
MultiIndex([('a', 'one'),
            ('a', 'two'),
            ('b', 'one'),
            ('b', 'two'),
            ('c', 'one'),
            ('c', 'two')],
           names=['foo', 'bar'])

>>> idx.set_levels([['a', 'b'], ['a', 'b']], level='bar')
MultiIndex([(1, 'a'),
            (1, 'b'),
            (2, 'a'),
            (2, 'b'),
            (3, 'a'),
            (3, 'b')],
           names=['foo', 'bar'])
```

If any of the levels passed to `set_levels()` exceeds the existing length, all of the values from that argument will be stored in the MultiIndex levels, though the values will be truncated in the MultiIndex output.
pandas: powerful Python data analysis toolkit, Release 1.3.2

```python
>>> idx.set_levels([['a', 'b', 'c'], [1, 2, 3, 4]], level=[0, 1])
MultiIndex([('a', 1),
            ('a', 2),
            ('b', 1),
            ('b', 2),
            ('c', 1),
            ('c', 2)],
           names=['foo', 'bar'])
```

```python
>>> idx.set_levels([['a', 'b', 'c'], [1, 2, 3, 4]], level=[0, 1]).levels
FrozenList([['a', 'b', 'c'], [1, 2, 3, 4]])
```

**pandas.MultiIndex.set_codes**

The `set_codes` method of the `MultiIndex` class sets new codes on a MultiIndex. It defaults to returning a new index.

**Parameters**

- `codes` [sequence or list of sequence] New codes to apply.
- `level` [int, level name, or sequence of int/level names (default None)] Level(s) to set (None for all levels).
- `inplace` [bool] If True, mutates in place.
  - Deprecated since version 1.2.0.
- `verify_integrity` [bool, default True] If True, checks that levels and codes are compatible.

**Returns**

- `new index (of same type and class...etc) or None` The same type as the caller or None if `inplace=True`.

**Examples**

```python
>>> idx = pd.MultiIndex.from_tuples(...
    [(1, "one"), (1, "two"), (2, "one"), (2, "two")], names=["foo", "bar"])
...
...
>>> idx
MultiIndex([(1, 'one'),
            (1, 'two'),
            (2, 'one'),
            (2, 'two')],
           names=['foo', 'bar'])
```

```python
>>> idx.set_codes([[1, 0, 1, 0], [0, 0, 1, 1]])
MultiIndex([(1, 'one'),
            (1, 'two'),
            (2, 'one'),
            (1, 'two')],
           names=['foo', 'bar'])
```

```python
>>> idx.set_codes([1, 0, 1, 0], level=0)
MultiIndex([(1, 'one'),
            (1, 'two'),
            (2, 'one'),
            (1, 'two')],
           names=['foo', 'bar'])
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.2

```
>>> idx.set_codes([0, 0, 1, 1], level='bar')
MultiIndex([(1, 'one'),
            (1, 'two'),
            (2, 'one'),
            (2, 'two')],
           names=['foo', 'bar'])

>>> idx.set_codes([[1, 0, 1, 0], [0, 0, 1, 1]], level=[0, 1])
MultiIndex([(2, 'one'),
            (1, 'one'),
            (1, 'two'),
            (2, 'two')],
           names=['foo', 'bar'])
```

```
pandas.MultiIndex.to_frame

MultiIndex.to_frame (index=True, name=None)
Create a DataFrame with the levels of the MultiIndex as columns.

Column ordering is determined by the DataFrame constructor with data as a dict.

Parameters

- **index** [bool, default True] Set the index of the returned DataFrame as the original MultiIndex.
- **name** [list / sequence of str, optional] The passed names should substitute index level names.

Returns

- **DataFrame** [a DataFrame containing the original MultiIndex data.]

See also:

- **DataFrame** Two-dimensional, size-mutable, potentially heterogeneous tabular data.

Examples

```
>>> mi = pd.MultiIndex.from_arrays([['a', 'b'], ['c', 'd']])
>>> mi
MultiIndex([('a', 'c'), ('b', 'd')],
           [])

```

```
>>> df = mi.to_frame()
>>> df
  0  
a c  a  c
b d  b  d
```
```
pandas: powerful Python data analysis toolkit, Release 1.3.2

```python
>>> df = mi.to_frame(index=False)
>>> df
   0  
0 a  c
1 b  d

>>> df = mi.to_frame(name=['x', 'y'])
>>> df
   x  y
a  c  a  c
b  d  b  d
```

**pandas.MultiIndex.to_flat_index**

`MultiIndex.to_flat_index()`  
Convert a MultiIndex to an Index of Tuples containing the level values.

**Returns**

- `pd.Index`  Index with the MultiIndex data represented in Tuples.

**See also:**

* `MultiIndex.from_tuples`  Convert flat index back to MultiIndex.

**Notes**

This method will simply return the caller if called by anything other than a MultiIndex.

**Examples**

```python
>>> index = pd.MultiIndex.from_product([['foo', 'bar'], ['baz', 'qux']], names=['a', 'b'])
>>> index.to_flat_index()
Index([('foo', 'baz'), ('foo', 'qux'), ('bar', 'baz'), ('bar', 'qux')], dtype='object')
```

**pandas.MultiIndex.sortlevel**

`MultiIndex.sortlevel(level=0, ascending=True, sort_remaining=True)`  
Sort MultiIndex at the requested level.

The result will respect the original ordering of the associated factor at that level.

**Parameters**

- `level`  [list-like, int or str, default 0] If a string is given, must be a name of the level. If list-like must be names or ints of levels.
- `ascending`  [bool, default True] False to sort in descending order. Can also be a list to specify a directed ordering.
sort_remaining  [sort by the remaining levels after level]

Returns

sort_index  [pd.MultiIndex] Resulting index.

indexer  [np.ndarray] Indices of output values in original index.

Examples

>>> mi = pd.MultiIndex.from_arrays([[0, 0], [2, 1]])
>>> mi
MultiIndex([(0, 2),
            (0, 1)],
           )

>>> mi.sortlevel()
(MultiIndex([(0, 1),
             (0, 2)],
           ), array([1, 0]))

>>> mi.sortlevel(sort_remaining=False)
(MultiIndex([(0, 2),
             (0, 1)],
           ), array([0, 1]))

>>> mi.sortlevel(1)
(MultiIndex([(0, 1),
             (0, 2)],
           ), array([1, 0]))

>>> mi.sortlevel(1, ascending=False)
(MultiIndex([(0, 2),
             (0, 1)],
           ), array([0, 1]))

pandas.MultiIndex.droplevel

MultiIndex.droplevel(level=0)

Return index with requested level(s) removed.
If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

Parameters

level  [int, str, or list-like, default 0] If a string is given, must be the name of a level If list-like, elements must be names or indexes of levels.

Returns

Index or MultiIndex
Examples

```python
>>> mi = pd.MultiIndex.from_arrays(
    ... [[1, 2], [3, 4], [5, 6]], names=['x', 'y', 'z'])
>>> mi
MultiIndex([(1, 3, 5),
             (2, 4, 6)],
            names=['x', 'y', 'z'])

>>> mi.droplevel()  # Drop all levels.
MultiIndex([(3, 5),
             (4, 6)],
            names=['y', 'z'])

>>> mi.droplevel(2)  # Drop level 2.
MultiIndex([(1, 3),
             (2, 4)],
            names=['x', 'y'])

>>> mi.droplevel('z')  # Drop level 'z'.
MultiIndex([(1, 3),
             (2, 4)],
            names=['x', 'y'])

>>> mi.droplevel(['x', 'y'])  # Drop levels 'x' and 'y'.
Int64Index([5, 6], dtype='int64', name='z')
```

**pandas.DataFrame.swaplevel**

`MultiIndex.swaplevel(i=-2, j=-1)`  
Swap level i with level j.

Calling this method does not change the ordering of the values.

**Parameters**

- i [int, str, default -2] First level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.

- j [int, str, default -1] Second level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.

**Returns**

* MultiIndex* A new MultiIndex.

**See also:**

- **Series.swaplevel** Swap levels i and j in a MultiIndex.
- **Dataframe.swaplevel** Swap levels i and j in a MultiIndex on a particular axis.
Examples

```python
>>> mi = pd.MultiIndex(levels=[['a', 'b'], ['bb', 'aa']],
                     codes=[[0, 0, 1, 1], [0, 1, 0, 1]])
>>> mi
MultiIndex([('a', 'bb'),
             ('a', 'aa'),
             ('b', 'bb'),
             ('b', 'aa')],
            )
>>> mi.swaplevel(0, 1)
MultiIndex([('bb', 'a'),
             ('aa', 'a'),
             ('bb', 'b'),
             ('aa', 'b')],
            )
```

```python
def pandas.MultiIndex.reorder_levels(order)
    Rearrange levels using input order. May not drop or duplicate levels.
    Parameters
    order [list of int or list of str] List representing new level order. Reference level by
    number (position) or by key (label).
    Returns
    MultiIndex

Examples

```python
>>> mi = pd.MultiIndex.from_arrays([[1, 2], [3, 4]], names=['x', 'y'])
>>> mi
MultiIndex([(1, 3),
             (2, 4)],
            names=['x', 'y'])
>>> mi.reorder_levels(order=[1, 0])
MultiIndex([(3, 1),
             (4, 2)],
            names=['y', 'x'])
>>> mi.reorder_levels(order=['y', 'x'])
MultiIndex([(3, 1),
             (4, 2)],
            names=['y', 'x'])
```
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.MultiIndex.remove_unused_levels

MultiIndex.remove_unused_levels()
Create new MultiIndex from current that removes unused levels.
Unused level(s) means levels that are not expressed in the labels. The resulting MultiIndex will have the same outward appearance, meaning the same .values and ordering. It will also be .equals() to the original.

Returns
MultiIndex

Examples

```python
>>> mi = pd.MultiIndex.from_product([range(2), list('ab'))
>>> mi
MultiIndex([(0, 'a'),
            (0, 'b'),
            (1, 'a'),
            (1, 'b')],
           )

>>> mi[2:]
MultiIndex([(1, 'a'),
            (1, 'b')],
           )

The 0 from the first level is not represented and can be removed

>>> mi2 = mi[2:].remove_unused_levels()
>>> mi2.levels
FrozenList([[1], ['a', 'b']])
```

pandas.MultiIndex.get_locs

MultiIndex.get_locs(seq)
Get location for a sequence of labels.

Parameters

seq [label, slice, list, mask or a sequence of such] You should use one of the above for each level. If a level should not be used, set it to slice(None).

Returns

numpy.ndarray NumPy array of integers suitable for passing to iloc.

See also:

MultiIndex.get_loc Get location for a label or a tuple of labels.
MultiIndex.slice_locs Get slice location given start label(s) and end label(s).
Examples

```python
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')])

>>> mi.get_locs('b')
array([1, 2], dtype=int64)

>>> mi.get_locs([slice(None), ['e', 'f']])
array([1, 2], dtype=int64)

>>> mi.get_locs([[True, False, True], slice('e', 'f')])
array([2], dtype=int64)
```

`IndexSlice` Create an object to more easily perform multi-index slicing.

**pandas.IndexSlice**

`pandas.IndexSlice = <pandas.core.indexing._IndexSlice object>`

Create an object to more easily perform multi-index slicing.

See also:

`MultiIndex.remove_unused_levels` New MultiIndex with no unused levels.

Notes

See *Defined Levels* for further info on slicing a MultiIndex.

Examples

```python
>>> midx = pd.MultiIndex.from_product([['A0','A1'], ['B0','B1','B2','B3']])
>>> columns = ['foo', 'bar']
>>> dfmi = pd.DataFrame(np.arange(16).reshape((len(midx), len(columns))),
...                        index=midx, columns=columns)

Using the default slice command:

```python
>>> dfmi.loc[[slice(None), slice('B0','B1')], :]
   foo  bar
A0  B0  0  1
   B1  2  3
A1  B0  8  9
   B1 10 11
```

Using the IndexSlice class for a more intuitive command:

```python
>>> idx = pd.IndexSlice
>>> dfmi.loc[idx[:, 'B0':'B1'], :]
   foo  bar
A0  B0  0  1
   B1  2  3
```
MultiIndex constructors

- `MultiIndex.from_arrays(arrays[, sortorder, ...])` Convert arrays to MultiIndex.
- `MultiIndex.from_tuples(tuples[, sortorder, ...])` Convert list of tuples to MultiIndex.
- `MultiIndex.from_product(iterables[, ...])` Make a MultiIndex from the cartesian product of multiple iterables.
- `MultiIndex.from_frame(df[, sortorder, names])` Make a MultiIndex from a DataFrame.

MultiIndex properties

- `MultiIndex.names` Names of levels in MultiIndex.
- `MultiIndex.levels`
- `MultiIndex.codes`
- `MultiIndex.nlevels` Integer number of levels in this MultiIndex.
- `MultiIndex.levshape` A tuple with the length of each level.
- `MultiIndex.dtypes` Return the dtypes as a Series for the underlying MultiIndex.

</tr>
</tbody>
</table>

pandas.MultiIndex.get_loc

MultiIndex.get_loc(key, method=None)
Get location for a label or a tuple of labels.

The location is returned as an integer/slice or boolean mask.

Parameters

- key [label or tuple of labels (one for each level)]
- method [None]

Returns

- loc [int, slice object or boolean mask] If the key is past the lexsort depth, the return may be a boolean mask array; otherwise it is always a slice or int.

See also:

- Index.get_loc The get_loc method for (single-level) index.
- MultiIndex.slice_locs Get slice location given start label(s) and end label(s).
- MultiIndex.get_locs Get location for a label/slice/list/mask or a sequence of such.
Notes

The key cannot be a slice, list of same-level labels, a boolean mask, or a sequence of such. If you want to use those, use `MultiIndex.get_locs()` instead.

Examples

```python
>>> mi = pd.MultiIndex.from_arrays([[list('abb'), list('def')]])

>>> mi.get_loc('b')
slice(1, 3, None)

>>> mi.get_loc(('b', 'e'))
1
```

**pandas.MultiIndex.get_loc_level**

`MultiIndex.get_loc_level(key, level=0, drop_level=True)`

Get location and sliced index for requested label(s)/level(s).

**Parameters**

- **key**  
  [label or sequence of labels]
- **level**  
  [int/level name or list thereof, optional]
- **drop_level**  
  [bool, default True] If False, the resulting index will not drop any level.

**Returns**

- **loc**  
  [A 2-tuple where the elements are:] Element 0: int, slice object or boolean array Element 1: The resulting sliced multiindex/index. If the key contains all levels, this will be None.

**See also:**

- `MultiIndex.get_loc`  
  Get location for a label or a tuple of labels.
- `MultiIndex.get_locs`  
  Get location for a label/slice/list-mask or a sequence of such.

**Examples**

```python
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')], names=['A', 'B'])

>>> mi.get_loc_level('b')
(slice(1, 3, None), Index(['e', 'f'], dtype='object', name='B'))

>>> mi.get_loc_level('e', level='B')
(array([False, True, False]), Index(['b'], dtype='object', name='A'))

>>> mi.get_loc_level(['b', 'e'])
(1, None)
```
**pandas.MultiIndex.get_indexer**

MultiIndex.get_indexer (target, method=None, limit=None, tolerance=None)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

**Parameters**

- **target** [Index]
- **method** [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]
  - default: exact matches only.
  - pad / ffill: find the PREVIOUS index value if no exact match.
  - backfill / bfill: use NEXT index value if no exact match
  - nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
- **limit** [int, optional] Maximum number of consecutive labels in target to match for inexact matches.
- **tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation abs(index[indexer] - target) <= tolerance.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

**Returns**

- **indexer** [np.ndarray[np.intp]] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

**Examples**

```python
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([1, 2, -1])
```

Notice that the return value is an array of locations in index and x is marked by -1, as it is not in index.

**pandas.MultiIndex.get_level_values**

MultiIndex.get_level_values (level)

Return vector of label values for requested level.

Length of returned vector is equal to the length of the index.

**Parameters**

- **level** [int or str] level is either the integer position of the level in the MultiIndex, or the name of the level.

**Returns**
**values**  [Index] Values is a level of this MultiIndex converted to a single *Index* (or subclass thereof).

### Examples

Create a MultiIndex:

```python
>>> mi = pd.MultiIndex.from_arrays((list('abc'), list('def')))
>>> mi.names = ['level_1', 'level_2']
```

Get level values by supplying level as either integer or name:

```python
>>> mi.get_level_values(0)
Index(["a", "b", "c"], dtype='object', name='level_1')
>>> mi.get_level_values('level_2')
Index(["d", "e", "f"], dtype='object', name='level_2')
```

### 3.6.6 DatetimeIndex

_DatetimeIndex_([data, freq, tz, normalize, ...])  Immutable ndarray-like of datetime64 data.

**pandas.DatetimeIndex**

```python
class pandas.DatetimeIndex(data=None, freq=<no_default>, tz=None, normalize=False, closed=None, ambiguous='raise', dayfirst=False, yearfirst=False, dtype=None, copy=False, name=None)
```

Immutable ndarray-like of datetime64 data.

Represented internally as int64, and which can be boxed to Timestamp objects that are subclasses of datetime and carry metadata.

**Parameters**

- **data**  [array-like (1-dimensional), optional]  Optional datetime-like data to construct index with.
- **freq**  [str or pandas offset object, optional]  One of pandas date offset strings or corresponding objects. The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation.
- **tz**  [pytz.timezone or dateutil.tz.tzfile or datetime.tzinfo or str]  Set the Timezone of the data.
- **normalize**  [bool, default False]  Normalize start/end dates to midnight before generating date range.
- **closed**  [{'left', 'right'}, optional]  Set whether to include start and end that are on the boundary. The default includes boundary points on either end.
- **ambiguous**  ['infer', bool-narray, ‘NaT’, default ‘raise’]  When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the ambiguous parameter dictates how ambiguous times should be handled.
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
• bool-ndarray where True signifies a DST time, False signifies a non-DST time (note
that this flag is only applicable for ambiguous times)
• ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

dayfirst  [bool, default False] If True, parse dates in data with the day first order.

yearfirst  [bool, default False] If True parse dates in data with the year first order.

dtype  [numpy.dtype or DatetimeTZDtype or str, default None] Note that the only NumPy
dtype allowed is ‘datetime64[ns]’.

copy  [bool, default False] Make a copy of input ndarray.

name  [label, default None] Name to be stored in the index.

See also:
Index  The base pandas Index type.
TimedeltaIndex  Index of timedelta64 data.
PeriodIndex  Index of Period data.
to_datetime  Convert argument to datetime.
date_range  Create a fixed-frequency DatetimeIndex.

Notes

To learn more about the frequency strings, please see this link.

**pandas.DatetimeIndex.year**

**property** `DatetimeIndex.year`

The year of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(
    ...     pd.date_range("2000-01-01", periods=3, freq="Y")
    ... )
>>> datetime_series
0  2000-12-31
1  2001-12-31
2  2002-12-31
dtype: datetime64[ns]
>>> datetime_series.dt.year
0  2000
1  2001
2  2002
dtype: int64
```

**pandas.DatetimeIndex.month**

**property** `DatetimeIndex.month`

The month as January=1, December=12.
Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="M")
... )
>>> datetime_series
0  2000-01-31
1  2000-02-29
2  2000-03-31
dtype: datetime64[ns]
>>> datetime_series.dt.month
0  1
1  2
2  3
dtype: int64
```

```python
pandas.DatetimeIndex.day
```

**property** pandas.DatetimeIndex.day

The day of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="D")
... )
>>> datetime_series
0  2000-01-01
1  2000-01-02
2  2000-01-03
dtype: datetime64[ns]
>>> datetime_series.dt.day
0  1
1  2
2  3
dtype: int64
```
pandas.DatetimeIndex.hour

**Property** `DatetimeIndex.hour`

The hours of the datetime.

**Examples**

```python
greater= datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="h")
... )
greater
datetime_series
0 2000-01-01 00:00:00
1 2000-01-01 01:00:00
2 2000-01-01 02:00:00
dtype: datetime64[ns]
>> greater
datetime_series.dt.hour
0 0
1 1
2 2
dtype: int64
```

pandas.DatetimeIndex.minute

**Property** `DatetimeIndex.minute`

The minutes of the datetime.

**Examples**

```python
greater= datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="T")
... )
greater
datetime_series
0 2000-01-01 00:00:00
1 2000-01-01 00:01:00
2 2000-01-01 00:02:00
dtype: datetime64[ns]
>> greater
datetime_series.dt.minute
0 0
1 1
2 2
dtype: int64
```
**pandas.DatetimeIndex.second**

**property DatetimeIndex.second**

The seconds of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="s")
... )
>>> datetime_series
datetime_series
          0  2000-01-01 00:00:00
          1  2000-01-01 00:00:01
          2  2000-01-01 00:00:02
       dtype: datetime64[ns]
```

```python
>>> datetime_series.dt.second
          0  0
          1  1
          2  2
       dtype: int64
```

**pandas.DatetimeIndex.microsecond**

**property DatetimeIndex.microsecond**

The microseconds of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="us")
... )
>>> datetime_series
datetime_series
          0  2000-01-01 00:00:00.000000
          1  2000-01-01 00:00:00.000001
          2  2000-01-01 00:00:00.000002
       dtype: datetime64[ns]
```

```python
>>> datetime_series.dt.microsecond
          0  0
          1  1
          2  2
       dtype: int64
```
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.DatetimeIndex.nanosecond

**property** DatetimeIndex.nanosecond
The nanoseconds of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(
...   pd.date_range("2000-01-01", periods=3, freq="ns")
... )
>>> datetime_series
0 2000-01-01 00:00:00.000000000
1 2000-01-01 00:00:00.000000001
2 2000-01-01 00:00:00.000000002
dtype: datetime64[ns]
>>> datetime_series.dt.nanosecond
0 0
1 1
2 2
dtype: int64
```

pandas.DatetimeIndex.date

**property** DatetimeIndex.date
Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).

pandas.DatetimeIndex.time

**property** DatetimeIndex.time
Returns numpy array of datetime.time. The time part of the Timestamps.

pandas.DatetimeIndex.timetz

**property** DatetimeIndex.timetz
Returns numpy array of datetime.time also containing timezone information. The time part of the Timestamps.

pandas.DatetimeIndex.dayofyear

**property** DatetimeIndex.dayofyear
The ordinal day of the year.
pandas.DatetimeIndex.day_of_year

**property** DatetimeIndex.day_of_year

The ordinal day of the year.

pandas.DatetimeIndex.weekofyear

**property** DatetimeIndex.weekofyear

The week ordinal of the year.

Deprecated since version 1.1.0.

weekofyear and week have been deprecated. Please use DatetimeIndex.isocalendar().week instead.

pandas.DatetimeIndex.week

**property** DatetimeIndex.week

The week ordinal of the year.

Deprecated since version 1.1.0.

weekofyear and week have been deprecated. Please use DatetimeIndex.isocalendar().week instead.

pandas.DatetimeIndex.dayofweek

**property** DatetimeIndex.dayofweek

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the `dt` accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:

Series.dt.dayofweek Alias.

Series.dt.weekday Alias.

Series.dt.day_name Returns the name of the day of the week.

Examples

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31  5
2017-01-01  6
2017-01-02  0
2017-01-03  1
2017-01-04  2
2017-01-05  3
2017-01-06  4
```
pandas: powerful Python data analysis toolkit, Release 1.3.2

(continued from previous page)

2017-01-07  5
2017-01-08  6
Freq: D, dtype: int64

pandas.DatetimeIndex.day_of_week

property DatetimeIndex.day_of_week
The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the dt accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:

Series.dt.dayofweek Alias.
Series.dt.weekday Alias.
Series.dt.day_name Returns the name of the day of the week.

Examples

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

pandas.DatetimeIndex.weekday

property DatetimeIndex.weekday
The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the dt accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:
Series.dt.dayofweek Alias.
Series.dt.weekday Alias.
Series.dt.day_name Returns the name of the day of the week.

Examples

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31  5
2017-01-01  6
2017-01-02  0
2017-01-03  1
2017-01-04  2
2017-01-05  3
2017-01-06  4
2017-01-07  5
2017-01-08  6
Freq: D, dtype: int64
```

pandas.DatetimeIndex.quarter

**property** DatetimeIndex.quarter
The quarter of the date.

pandas.DatetimeIndex.tz

**property** DatetimeIndex.tz
Return timezone, if any.

**Returns**

datetime.tzinfo, pytz.tzinfo.BaseTZInfo, dateutil.tz.tz.tzfile, or None Returns None when the array is tz-naive.

pandas.DatetimeIndex.freq

**property** DatetimeIndex.freq
Return the frequency object if it is set, otherwise None.

pandas.DatetimeIndex.freqstr

**property** DatetimeIndex.freqstr
Return the frequency object as a string if its set, otherwise None.
pandas.DatetimeIndex.is_month_start

**property** DatetimeIndex.is_month_start
Indicates whether the date is the first day of the month.

**Returns**
- **Series or array** For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

**See also:**
- **is_month_start** Return a boolean indicating whether the date is the first day of the month.
- **is_month_end** Return a boolean indicating whether the date is the last day of the month.

**Examples**

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0  2018-02-27
1  2018-02-28
2  2018-03-01
dtype: datetime64[ns]

>>> s.dt.is_month_start
0  False
1  False
2  True
dtype: bool

>>> s.dt.is_month_end
0  False
1  True
2  False
dtype: bool
```

```python
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])

>>> idx.is_month_end
array([False, True, False])
```

pandas.DatetimeIndex.is_month_end

**property** DatetimeIndex.is_month_end
Indicates whether the date is the last day of the month.

**Returns**
- **Series or array** For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

**See also:**
- **is_month_start** Return a boolean indicating whether the date is the first day of the month.
**is_month_end** Return a boolean indicating whether the date is the last day of the month.

**Examples**

This method is available on Series with datetime values under the `dt` accessor, and directly on DatetimeIndex.

```python
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0 2018-02-27
1 2018-02-28
2 2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0 False
1 False
2 True
dtype: bool
>>> s.dt.is_month_end
0 False
1 True
2 False
dtype: bool
```

```python
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```

**pandas.DatetimeIndex.is_quarter_start**

**property** `DatetimeIndex.is_quarter_start`  
Indicator for whether the date is the first day of a quarter.

**Returns**

- `is_quarter_start` [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

- `quarter` Return the quarter of the date.
- `is_quarter_end` Similar property for indicating the quarter start.
Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DateTimeIndex.

```python
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30", periods=4))
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_start=df.dates.dt.is_quarter_start)

<table>
<thead>
<tr>
<th>dates</th>
<th>quarter</th>
<th>is_quarter_start</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017-03-30</td>
<td>1</td>
<td>False</td>
</tr>
<tr>
<td>2017-03-31</td>
<td>1</td>
<td>False</td>
</tr>
<tr>
<td>2017-04-01</td>
<td>2</td>
<td>True</td>
</tr>
<tr>
<td>2017-04-02</td>
<td>2</td>
<td>False</td>
</tr>
</tbody>
</table>
```

```python
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx

DatetimeIndex(["2017-03-30", "2017-03-31", "2017-04-01", "2017-04-02"],
dtype='datetime64[ns]', freq='D')
```

```python
>>> idx.is_quarter_start

array([False, False, True, False])
```

pandas.DatetimeIndex.is_quarter_end

**property** pandas.DatetimeIndex.is_quarter_end

Indicator for whether the date is the last day of a quarter.

**Returns**

* is_quarter_end [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

* quarter Return the quarter of the date.

* is_quarter_start Similar property indicating the quarter start.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DateTimeIndex.

```python
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30", periods=4))
>>> df.assign(quarter=df.dates.dt.quarter,
...           is_quarter_end=df.dates.dt.is_quarter_end)

<table>
<thead>
<tr>
<th>dates</th>
<th>quarter</th>
<th>is_quarter_end</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017-03-30</td>
<td>1</td>
<td>False</td>
</tr>
<tr>
<td>2017-03-31</td>
<td>1</td>
<td>True</td>
</tr>
<tr>
<td>2017-04-01</td>
<td>2</td>
<td>False</td>
</tr>
<tr>
<td>2017-04-02</td>
<td>2</td>
<td>False</td>
</tr>
</tbody>
</table>
```
>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
dtype='datetime64[ns]', freq='D')

>> idx.is_quarter_end
array([False, True, False, False])

pandas.DatetimeIndex.is_year_start

property DatetimeIndex.is_year_start
Indicate whether the date is the first day of a year.

Returns

Series or DatetimeIndex  The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

is_year_end  Similar property indicating the last day of the year.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0  2017-12-30
1  2017-12-31
2  2018-01-01
dtype: datetime64[ns]

>>> dates.dt.is_year_start
0  False
1  False
2  True
dtype: bool

>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
dtype='datetime64[ns]', freq='D')

>> idx.is_year_start
array([False, False, True])
pandas.DatetimeIndex.is_year_end

**property** DatetimeIndex.is_year_end
Indicate whether the date is the last day of the year.

**Returns**

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

is_year_start Similar property indicating the start of the year.

**Examples**

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0 2017-12-30
1 2017-12-31
2 2018-01-01
dtype: datetime64[ns]

>>> dates.dt.is_year_end
0  False
1  True
2  False
dtype: bool
```

```python
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
dtype='datetime64[ns]', freq='D')

>>> idx.is_year_end
array([False, True, False])
```

pandas.DatetimeIndex.is_leap_year

**property** DatetimeIndex.is_leap_year
Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

**Returns**

Series or ndarray Booleans indicating if dates belong to a leap year.
Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
              dtype='datetime64[ns]', freq='A-DEC')
>>> idx.is_leap_year
array([ True, False, False])

>>> dates_series = pd.Series(idx)
>>> dates_series
0 2012-12-31
1 2013-12-31
2 2014-12-31
dtype: datetime64[ns]
>>> dates_series.dt.is_leap_year
0 True
1 False
2 False
dtype: bool
```

```
```

pandas.DatetimeIndex.inferred_freq

DatetimeIndex.inferred_freq: str | None
Tries to return a string representing a frequency guess, generated by infer_freq. Returns None if it can’t autodetect the frequency.

Methods

- **normalize(*args, **kwangs)** Convert times to midnight.
- **strftime(**args, **kwangs)** Convert to Index using specified date_format.
- **snap([freq])** Snap time stamps to nearest occurring frequency.
- **tz_convert(tz)** Convert tz-aware Datetime Array/Index from one time zone to another.
- **tz_localize(tz[, ambiguous, nonexistent])** Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.
- **round(*args, **kwangs)** Perform round operation on the data to the specified freq.
- **floor(*args, **kwangs)** Perform floor operation on the data to the specified freq.
- **ceil(*args, **kwangs)** Perform ceil operation on the data to the specified freq.
- **to_period(*args, **kwangs)** Cast to PeriodArray/Index at a particular frequency.
- **to_perioddelta(freq)** Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified freq.
- **to_pydatetime(*args, **kwangs)** Return Datetime Array/Index as object ndarray of datetime.datetime objects.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>to_series</td>
<td>Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.</td>
</tr>
<tr>
<td>to_frame</td>
<td>Create a DataFrame with a column containing the Index.</td>
</tr>
<tr>
<td>month_name</td>
<td>Return the month names of the DateTimeIndex with specified locale.</td>
</tr>
<tr>
<td>day_name</td>
<td>Return the day names of the DateTimeIndex with specified locale.</td>
</tr>
<tr>
<td>mean</td>
<td>Return the mean value of the Array.</td>
</tr>
</tbody>
</table>

**pandas.DatetimeIndex.normalize**

DatetimeIndex.normalize(*args, **kwargs)

Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the .dt accessor, and directly on Datetime Array/Index.

**Returns**

DatetimeArray, DatetimeIndex or Series  The same type as the original data. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

floor  Floor the datetimes to the specified freq.

ceil  Ceil the datetimes to the specified freq.

round  Round the datetimes to the specified freq.

**Examples**

```python
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H', periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
               '2014-08-01 11:00:00+05:30',
               '2014-08-01 12:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq='H')

>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```
pandas.DatetimeIndex.strftime

DatetimeIndex.strftime(*args, **kwargs)
Convert to Index using specified date_format.

Return an Index of formatted strings specified by date_format, which supports the same string format as the python standard library. Details of the string format can be found in python string format doc.

Parameters

date_format [str] Date format string (e.g. “%Y-%m-%d”).

Returns

ndarray NumPy ndarray of formatted strings.

See also:

to_datetime Convert the given argument to datetime.
DatetimeIndex.normalize Return DatetimeIndex with times to midnight.
DatetimeIndex.round Round the DatetimeIndex to the specified freq.
DatetimeIndex.floor Floor the DatetimeIndex to the specified freq.

Examples

```python
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                     periods=3, freq="s")
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
      'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

pandas.DatetimeIndex.snap

DatetimeIndex.snap(freq='S')
Snap time stamps to nearest occurring frequency.

Returns

DatetimeIndex

pandas.DatetimeIndex.tz_convert

DatetimeIndex.tz_convert(tz)
Convert tz-aware Datetime Array/Index from one time zone to another.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A tz of None will convert to UTC and remove the timezone information.

Returns

Array or Index
**Raises**

*TypeError* If Datetime Array/Index is tz-naive.

**See also:**

*Datet imeIndex.tz* A timezone that has a variable offset from UTC.

*Datet imeIndex.tz_localize* Localize tz-naive DatetimeIndex to a given time zone, or remove timezone from a tz-aware DatetimeIndex.

**Examples**

With the `tz` parameter, we can change the DatetimeIndex to other time zones:

```python
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                      freq='H', periods=3, tz='Europe/Berlin')

>>> dti
DateTimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')

>>> dti.tz_convert('US/Central')
DateTimeIndex(['2014-08-01 02:00:00-05:00',
               '2014-08-01 03:00:00-05:00',
               '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the `tz=None`, we can remove the timezone (after converting to UTC if necessary):

```python
>>> dti = pd.date_range(start='2014-08-01 09:00', freq='H',
...                      periods=3, tz='Europe/Berlin')

>>> dti
DateTimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')

>>> dti.tz_convert(None)
DateTimeIndex(['2014-08-01 07:00:00',
               '2014-08-01 08:00:00',
               '2014-08-01 09:00:00'],
              dtype='datetime64[ns]', freq='H')
```
pandas.DatetimeIndex.tz_localize

DatetimeIndex.tz_localize(tz, ambiguous='raise', nonexistent='raise')

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone.

This method can also be used to do the inverse – to create a time zone unaware object from an aware object. To that end, pass tz=None.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone to convert timestamps to. Passing None will remove the time zone information preserving local time.

ambiguous ['infer', ‘NaT’, bool array, default ‘raise’] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the ambiguous parameter dictates how ambiguous times should be handled.
• ‘infer’ will attempt to infer fall dst-transition hours based on order
• bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
• ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent ['shift_forward', ‘shift_backward, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
• ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
• ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
• ‘NaT’ will return NaT where there are nonexistent times
• timedelta objects will shift nonexistent times by the timedelta
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

Same type as self Array/Index converted to the specified time zone.

Raises

TypeError If the Datetime Array/Index is tz-aware and tz is not None.

See also:

DatetimeIndex.tz_convert Convert tz-aware DatetimeIndex from one time zone to another.
Examples

```python
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
```

```python
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'], dtype='datetime64[ns]', freq='D')
```

Localize DatetimeIndex in US/Eastern time zone:

```python
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
```

```python
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
                '2018-03-02 09:00:00-05:00',
                '2018-03-03 09:00:00-05:00'],
               dtype='datetime64[ns, US/Eastern]', freq=None)
```

With the tz=None, we can remove the time zone information while keeping the local time (not converted to UTC):

```python
>>> tz_aware.tz_localize(None)
```

```python
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'],
               dtype='datetime64[ns]', freq=None)
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```python
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:30:00',
                                '2018-10-28 02:00:00',
                                '2018-10-28 02:30:00',
                                '2018-10-28 02:00:00',
                                '2018-10-28 02:30:00',
                                '2018-10-28 03:00:00',
                                '2018-10-28 03:30:00']))
```

```python
>>> s.dt.tz_localize('CET', ambiguous='infer')
```

```python
0 2018-10-28 01:30:00+02:00
1 2018-10-28 02:00:00+02:00
2 2018-10-28 02:30:00+02:00
3 2018-10-28 02:00:00+01:00
4 2018-10-28 02:30:00+01:00
5 2018-10-28 03:00:00+01:00
6 2018-10-28 03:30:00+01:00
dtype: datetime64[ns, CET]
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly.

```python
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:20:00',
                                '2018-10-28 02:36:00',
                                '2018-10-28 03:46:00']))
```

```python
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
```

```python
0 2018-10-28 01:20:00+02:00
1 2018-10-28 02:36:00+02:00
2 2018-10-28 03:46:00+01:00
dtype: datetime64[ns, CET]
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a timedelta object or 'shift_forward' or 'shift_backwards'.
```python
>>> s = pd.to_datetime(pd.Series(['2015-03-29 02:30:00',
                              '2015-03-29 03:30:00']))
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
0   2015-03-29 03:00:00+02:00
1   2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]

>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
0   2015-03-29 01:59:59.999999999+01:00
1   2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]

>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
0   2015-03-29 03:30:00+02:00
1   2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```

**pandas.DatetimeIndex.round**

```
DatetimeIndex.round(*args, **kwargs)
```

Perform round operation on the data to the specified freq.

**Parameters**

- **freq** [str or Offset] The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

- **ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

- **nonexistent** ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

**Returns**

- DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.
Raises

ValueError if the `freq` cannot be converted.

Examples

**DatetimeIndex**

```python
going = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'], dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'], dtype='datetime64[ns]', freq=None)
```

**Series**

```python
>>> pd.Series(rng).dt.round("H")
0 2018-01-01 12:00:00
1 2018-01-01 12:00:00
2 2018-01-01 12:00:00
dtype: datetime64[ns]
```

**pandas.DatetimeIndex.floor**

```
DatetimeIndex.floor(*args, **kwargs)
```

Perform floor operation on the data to the specified `freq`.

**Parameters**

- `freq` [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible `freq` values.

- `ambiguous` ['infer', bool-narray, ‘NaT', default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-narray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

- `nonexistent` ['shift_forward', 'shift_backward', ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST:
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time

Chapter 3. API reference
• ‘NaT’ will return NaT where there are nonexistent times
• timedelta objects will shift nonexistent times by the timedelta
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series  Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.

Examples

DatetimeIndex

>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
              '2018-01-01 12:01:00'],
             dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)

Series

>>> pd.Series(rng).dt.floor("H")
0 2018-01-01 11:00:00
1 2018-01-01 12:00:00
2 2018-01-01 12:00:00
dtype: datetime64[ns]

pandas.DatetimeIndex.ceil

DatetimeIndex.ceil(*args, **kwargs)
Perform ceil operation on the data to the specified freq.

Parameters

freq [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

ambiguous [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
• ‘infer’ will attempt to infer fall dst-transition hours based on order
• bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
• ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.
nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.

Examples

DatetimexIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
```
```python
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.ceil("H")
0  2018-01-01 12:00:00
1  2018-01-01 12:00:00
2  2018-01-01 13:00:00
dtype: datetime64[ns]
```

pandas.DatetimeIndex.to_period

```
DatetimeIndex.to_period(*args, **kwargs)
```

Cast to PeriodArray/Index at a particular frequency.

Converts DatetimeArray/Index to PeriodArray/Index.

Parameters

- freq [str or Offset, optional] One of pandas’ offset strings or an Offset object. Will be inferred by default.

Returns
PeriodArray/Index

Raises

ValueError  When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

See also:

PeriodIndex  Immutable ndarray holding ordinal values.

DatetimeIndex.to_pydatetime  Return DatetimeIndex as object.

Examples

```python
>>> df = pd.DataFrame({"y": [1, 2, 3],
...                    index=pd.to_datetime(["2000-03-31 00:00:00",
...                                                       "2000-05-31 00:00:00",
...                                                       "2000-08-31 00:00:00"]))
>>> df.index.to_period("M")
PeriodIndex(["2000-03", "2000-05", "2000-08"],
            dtype='period[M]')
```

Infer the daily frequency

```python
>>> idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(["2017-01-01", "2017-01-02"],
            dtype='period[D]')
```

pandas.DatetimeIndex.to_perioddelta

DatetimeIndex.to_perioddelta(freq)
Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified freq. Used for vectorized offsets.

Parameters

freq  [Period frequency]

Returns

TimedeltaArray/Index

pandas.DatetimeIndex.to_pydatetime

DatetimeIndex.to_pydatetime(*args, **kwargs)
Return Datetime Array/Index as object ndarray of datetime.datetime objects.

Returns

datetimes  [ndarray[object]]
pandas.DatetimeIndex.to_series

Datet imeIndex.to_series (keep_tz=<no_default>, index=None, name=None)

Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.

Parameters

keep_tz  [optional, defaults True] Return the data keeping the timezone.

If keep_tz is True:

If the timezone is not set, the resulting Series will have a datetime64[ns] dtype.

Otherwise the Series will have an datetime64[ns, tz] dtype; the tz will be preserved.

If keep_tz is False:

Series will have a datetime64[ns] dtype. TZ aware objects will have the tz removed.

Changed in version 1.0.0: The default value is now True. In a future version, this keyword will be removed entirely. Stop passing the argument to obtain the future behavior and silence the warning.

index  [Index, optional] Index of resulting Series. If None, defaults to original index.

name  [str, optional] Name of resulting Series. If None, defaults to name of original index.

Returns

Series

pandas.DatetimeIndex.to_frame

Datet imeIndex.to_frame (index=True, name=None)

Create a DataFrame with a column containing the Index.

Parameters

index  [bool, default True] Set the index of the returned DataFrame as the original Index.

name  [object, default None] The passed name should substitute for the index name (if it has one).

Returns

DataFrame  DataFrame containing the original Index data.

See also:

Index.to_series Convert an Index to a Series.

Series.to_frame Convert Series to DataFrame.
Examples

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
          animal
    Ant      Ant
    Bear     Bear
    Cow      Cow
```

By default, the original Index is reused. To enforce a new Index:

```python
>>> idx.to_frame(index=False)
          animal
    0   Ant
    1   Bear
    2   Cow
```

To override the name of the resulting column, specify `name`:

```python
>>> idx.to_frame(index=False, name='zoo')
            zoo
    0   Ant
    1   Bear
    2   Cow
```

**pandas.DatetimeIndex.month_name**

```
DatetimeIndex.month_name(*args, **kwargs)
```

Return the month names of the DateTimeIndex with specified locale.

**Parameters**

- `locale` [str, optional] Locale determining the language in which to return the month name. Default is English locale.

**Returns**

- `Index` Index of month names.

**Examples**

```python
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DateRange(['2018-01-31', '2018-02-28', '2018-03-31'], dtype='datetime64[ns]', freq='M')

>>> idx.month_name()
Index([January, February, March], dtype='object')
```
**pandas.DatetimeIndex.day_name**

DatetimeIndex.day_name(*args, **kwargs)

Return the day names of the DateTimeIndex with specified locale.

**Parameters**

- **locale** [str, optional] Locale determining the language in which to return the day name. Default is English locale.

**Returns**

- **Index** Index of day names.

**Examples**

```python
gpd = pd.date_range(start='2018-01-01', freq='D', periods=3)
gpd
DatetimelIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
dtype='datetime64[ns]', freq='D')
gpd.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

**pandas.DatetimeIndex.mean**

DatetimeIndex.mean(*args, **kwargs)

Return the mean value of the Array.

New in version 0.25.0.

**Parameters**

- **skipna** [bool, default True] Whether to ignore any NaT elements.
- **axis** [int, optional, default 0]

**Returns**

- **scalar** Timestamp or Timedelta.

**See also:**

- **numpy.ndarray.mean** Returns the average of array elements along a given axis.
- **Series.mean** Return the mean value in a Series.

**Notes**

mean is only defined for Datetime and Timedelta dtypes, not for Period.
## Time/date components

<table>
<thead>

<td>Tries to return a string representing a frequency guess, generated by infer_freq.</td>
</tr>
</tbody>
</table>

### Selecting

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DatetimeIndex.indexer_at_time(time[, asof])</code></td>
<td>Return index locations of values at particular time of day (e.g.</td>
</tr>
<tr>
<td><code>DatetimeIndex.indexer_between_time(...[, ...])</code></td>
<td>Return index locations of values between particular times of day (e.g., 9:00-9:30AM).</td>
</tr>
</tbody>
</table>
pandas.DataFrame.indexer_at_time

DatetimeIndex.indexer_at_time(time, asof=False)

Return index locations of values at particular time of day (e.g., 9:30AM).

Parameters

- **time** [datetime.time or str] Time passed in either as object (datetime.time) or as string in appropriate format (“%H:%M”, “%H%M”, “%I:%M%p”, “%I%M%p”, “%H:%M:%S”, “%H%M%S”, “%I:%M:%S%p”, “%I%M%S%p”).

Returns

numpy.ndarray[np.intp]

See also:

- **DataFrame.between_time** Get index locations of values between particular times of day.
- **DatetimeIndex.normalize** Convert times to midnight.
- **DatetimeIndex.strftime** Convert to Index using specified date_format.
- **DatetimeIndex.snap** Snap time stamps to nearest occurring frequency.
- **DatetimeIndex.tz_convert** Convert tz-aware Datetime Array/Index from one time zone to another.
- **DatetimeIndex.tz_localize** Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.
- **DatetimeIndex.round** Perform round operation on the data to the specified freq.
- **DatetimeIndex.floor** Perform floor operation on the data to the specified freq.
- **DatetimeIndex.ceil** Perform ceil operation on the data to the specified freq.

3.6.7 TimedeltaIndex

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>TimedeltaIndex([data, unit, freq, closed, ...])</code></td>
<td>Immutable ndarray of timedelta64 data, represented internally as int64, and which can be boxed to timedelta objects.</td>
</tr>
</tbody>
</table>

```python
class pandas.TimedeltaIndex(data=None, unit=None, freq=<no_default>, closed=None, dtype=dtype('<m8[ns]'), copy=False, name=None)
```

Immutable ndarray of timedelta64 data, represented internally as int64, and which can be boxed to timedelta objects.

Parameters

- **data** [array-like (1-dimensional), optional] Optional timedelta-like data to construct index with.
- **unit** [unit of the arg (D,h,m,s,ms,us,ns) denote the unit, optional] Which is an integer/float number.
- **freq** [str or pandas offset object, optional] One of pandas date offset strings or corresponding objects. The string 'infer' can be passed in order to set the frequency of the index as the inferred frequency upon creation.
- **copy** [bool] Make a copy of input ndarray.
- **name** [object] Name to be stored in the index.
See also:

- **Index** The base pandas Index type.
- **Timedelta** Represents a duration between two dates or times.
- **DatetimeIndex** Index of datetime64 data.
- **PeriodIndex** Index of Period data.
- **timedelta_range** Create a fixed-frequency TimedeltaIndex.

Notes

To learn more about the frequency strings, please see this link.

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>days</code></td>
<td>Number of days for each element.</td>
</tr>
<tr>
<td><code>seconds</code></td>
<td>Number of seconds (&gt;= 0 and less than 1 day) for each element.</td>
</tr>
<tr>
<td><code>microseconds</code></td>
<td>Number of microseconds (&gt;= 0 and less than 1 second) for each element.</td>
</tr>
<tr>
<td><code>nanoseconds</code></td>
<td>Number of nanoseconds (&gt;= 0 and less than 1 microsecond) for each element.</td>
</tr>
<tr>
<td><code>components</code></td>
<td>Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.</td>
</tr>
<tr>
<td><code>inferred_freq</code></td>
<td>Tries to return a string representing a frequency guess, generated by infer_freq.</td>
</tr>
</tbody>
</table>

**pandas.TimedeltaIndex.days**

*property* `TimedeltaIndex.days`

Number of days for each element.

**pandas.TimedeltaIndex.seconds**

*property* `TimedeltaIndex.seconds`

Number of seconds (>= 0 and less than 1 day) for each element.

**pandas.TimedeltaIndex.microseconds**

*property* `TimedeltaIndex.microseconds`

Number of microseconds (>= 0 and less than 1 second) for each element.
pandas.TimedeltaIndex.nanoseconds

**property** TimedeltaIndex.nanoseconds
Number of nanoseconds (>= 0 and less than 1 microsecond) for each element.

pandas.TimedeltaIndex.components

**property** TimedeltaIndex.components
Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.

Returns
Dataframe

pandas.TimedeltaIndex.inferred_freq

TimedeltaIndex.inferred_freq
Tries to return a string representing a frequency guess, generated by infer_freq. Returns None if it can’t autodetect the frequency.

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>to_pytimedelta(*args, **kwargs)</td>
<td>Return Timedelta Array/Index as object ndarray of datetime.timedelta objects.</td>

<tr>
<td>mean(*args, **kwargs)</td>
<td>Return the mean value of the Array.</td>
</tr>
</tbody>
</table>

pandas.TimedeltaIndex.to_pytimedelta

TimedeltaIndex.to_pytimedelta(*args, **kwargs)
Return Timedelta Array/Index as object ndarray of datetime.timedelta objects.

Returns

timedeltas [ndarray[object]]
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.TimedeltaIndex.to_series

TimedeltaIndex.to_series(index=None, name=None)
Create a Series with both index and values equal to the index keys.
Useful with map for returning an indexer based on an index.

Parameters

- index [Index, optional] Index of resulting Series. If None, defaults to original index.
- name [str, optional] Name of resulting Series. If None, defaults to name of original index.

Returns

Series The dtype will be based on the type of the Index values.

See also:

- Index.to_frame Convert an Index to a DataFrame.
- Series.to_frame Convert Series to DataFrame.

Examples

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
```

By default, the original Index and original name is reused.

```python
>>> idx.to_series()
animal
Ant   Ant
Bear  Bear
Cow   Cow
Name: animal, dtype: object
```

To enforce a new Index, specify new labels to index:

```python
>>> idx.to_series(index=[0, 1, 2])
0   Ant
1   Bear
2   Cow
Name: animal, dtype: object
```

To override the name of the resulting column, specify name:

```python
>>> idx.to_series(name='zoo')
animal
Ant   Ant
Bear  Bear
Cow   Cow
Name: zoo, dtype: object
```
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.TimedeltaIndex.round

TimedeltaIndex.round(*args, **kwargs)

Perform round operation on the data to the specified freq.

Parameters

freq [str or Offset] The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:
- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'], dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'], dtype='datetime64[ns]', freq=None)
```
Series

```python
>>> pd.Series(rng).dt.round("H")
0 2018-01-01 12:00:00
1 2018-01-01 12:00:00
2 2018-01-01 12:00:00
dtype: datetime64[ns]
```

**pandas.TimedeltaIndex.floor**

TimedeltaIndex.floor(*args, **kwargs)

Perform floor operation on the data to the specified freq.

**Parameters**

- **freq** [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.
- **ambiguous** [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.
- **nonexistent** [‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

**Returns**

- DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**

- ValueError if the freq cannot be converted.
Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
```
```python
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00', '2018-01-01 12:01:00'],
dtype='datetime64[ns]', freq='T')
```
```python
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.floor("H")
```
```
0 2018-01-01 11:00:00
1 2018-01-01 12:00:00
2 2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.TimedeltaIndex.ceil

```python
TimedeltaIndex.ceil(*args, **kwargs)
```

Perform ceil operation on the data to the specified freq.

Parameters

freq [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

ambiguous ['infer', bool-narray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-narray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent ['shift_forward', 'shift_backward', ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.
Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

**ValueError if the freq cannot be converted.**

Examples

**DatetimeIndex**

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00', '2018-01-01 12:01:00'], dtype='datetime64[ns]', freq='T')
```

```python
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00', '2018-01-01 13:00:00'], dtype='datetime64[ns]', freq=None)
```

**Series**

```python
>>> pd.Series(rng).dt.ceil("H")
0  2018-01-01 12:00:00
1  2018-01-01 12:00:00
2  2018-01-01 13:00:00
dtype: datetime64[ns]
```

**pandas.TimedeltaIndex.to_frame**

TimedeltaIndex.to_frame(*index=True, name=None*)
Create a DataFrame with a column containing the Index.

**Parameters**

- **index** [bool, default True] Set the index of the returned DataFrame as the original Index.
- **name** [object, default None] The passed name should substitute for the index name (if it has one).

**Returns**

**DataFrame** DataFrame containing the original Index data.

**See also:**

- **Index.to_series** Convert an Index to a Series.
- **Series.to_frame** Convert Series to DataFrame.
Examples

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
   animal
      0   Ant
      1   Bear
      2   Cow
```

By default, the original Index is reused. To enforce a new Index:

```python
>>> idx.to_frame(index=False)
   animal
      0   Ant
      1   Bear
      2   Cow
```

To override the name of the resulting column, specify `name`:

```python
>>> idx.to_frame(index=False, name='zoo')
   zoo
      0   Ant
      1   Bear
      2   Cow
```

**pandas.TimedeltaIndex.mean**

TimedeltaIndex.mean(*args, **kwargs)

Return the mean value of the Array.

New in version 0.25.0.

Parameters

- **skipna** [bool, default True] Whether to ignore any NaT elements.
- **axis** [int, optional, default 0]

Returns

- **scalar** Timestamp or Timedelta.

See also:

- `numpy.ndarray.mean` Returns the average of array elements along a given axis.
- `Series.mean` Return the mean value in a Series.
Notes

mean is only defined for Datetime and Timedelta dtypes, not for Period.

</table>
**pandas.PeriodIndex**

**class pandas.PeriodIndex**(data=None, ordinal=None, freq=None, dtype=None, copy=False, name=None, **fields)**

Immutable ndarray holding ordinal values indicating regular periods in time.

Index keys are boxed to Period objects which carries the metadata (eg, frequency information).

**Parameters**

- **data** [array-like (1d int np.ndarray or PeriodArray), optional] Optional period-like data to construct index with.
- **copy** [bool] Make a copy of input ndarray.
- **freq** [str or period object, optional] One of pandas period strings or corresponding objects.
- **year** [int, array, or Series, default None]
- **month** [int, array, or Series, default None]
- **quarter** [int, array, or Series, default None]
- **day** [int, array, or Series, default None]
- **hour** [int, array, or Series, default None]
- **minute** [int, array, or Series, default None]
- **second** [int, array, or Series, default None]
- **dtype** [str or PeriodDtype, default None]

**See also:**

- **Index** The base pandas Index type.
- **Period** Represents a period of time.
- **DatetimeIndex** Index with datetime64 data.
- **TimedeltaIndex** Index of timedelta64 data.
- **period_range** Create a fixed-frequency PeriodIndex.

**Examples**

```python
>>> idx = pd.PeriodIndex(year=[2000, 2002], quarter=[1, 3])
>>> idx
PeriodIndex(['2000Q1', '2002Q3'], dtype='period[Q-DEC]')
```

pandas.PeriodIndex.day

@property PeriodIndex.day
    The days of the period.

pandas.PeriodIndex.dayofweek

@property PeriodIndex.dayofweek
    The day of the week with Monday=0, Sunday=6.

pandas.PeriodIndex.day_of_week

@property PeriodIndex.day_of_week
    The day of the week with Monday=0, Sunday=6.

pandas.PeriodIndex.dayofyear

@property PeriodIndex.dayofyear
    The ordinal day of the year.

pandas.PeriodIndex.day_of_year

@property PeriodIndex.day_of_year
    The ordinal day of the year.
pandas.PeriodIndex.days_in_month

**property** PeriodIndex.days_in_month
The number of days in the month.

pandas.PeriodIndex.daysinmonth

**property** PeriodIndex.daysinmonth
The number of days in the month.

pandas.PeriodIndex.freq

**property** PeriodIndex.freq
Return the frequency object if it is set, otherwise None.

pandas.PeriodIndex.freqstr

**property** PeriodIndex.freqstr
Return the frequency object as a string if its set, otherwise None.

pandas.PeriodIndex.hour

**property** PeriodIndex.hour
The hour of the period.

pandas.PeriodIndex.is_leap_year

**property** PeriodIndex.is_leap_year
Logical indicating if the date belongs to a leap year.

pandas.PeriodIndex.minute

**property** PeriodIndex.minute
The minute of the period.

pandas.PeriodIndex.month

**property** PeriodIndex.month
The month as January=1, December=12.
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.PeriodIndex.quarter

**property** PeriodIndex.quarter
The quarter of the date.

pandas.PeriodIndex.second

**property** PeriodIndex.second
The second of the period.

pandas.PeriodIndex.week

**property** PeriodIndex.week
The week ordinal of the year.

pandas.PeriodIndex.weekofyear

**property** PeriodIndex.weekofyear
The week ordinal of the year.

pandas.PeriodIndex.year

**property** PeriodIndex.year
The year of the period.

<table>
<thead>
<tr>
<th>end_time</th>
<th>qyear</th>
<th>start_time</th>
</tr>
</thead>
</table>

Methods

<table>
<thead>
<tr>
<th>asfreq(freq, how)</th>
<th>Convert the PeriodArray to the specified frequency freq.</th>
</tr>
</thead>
<tbody>
<tr>
<td>strftime(*args, **kwargs)</td>
<td>Convert to Index using specified date_format.</td>
</tr>
<tr>
<td>to_timestamp(freq, how)</td>
<td>Cast to DatetimeArray/Index.</td>
</tr>
</tbody>
</table>
pandas.PeriodIndex.asfreq

PeriodIndex.asfreq(freq=None, how='E')
Convert the PeriodArray to the specified frequency freq.

Equivalent to applying pandas.Period.asfreq() with the given arguments to each Period in this PeriodArray.

Parameters

freq [str] A frequency.
how [str {'E', 'S'}, default 'E'] Whether the elements should be aligned to the end or start within a period.

• 'E', 'END', or 'FINISH' for end,
• 'S', 'START', or 'BEGIN' for start.

January 31st ('END') vs. January 1st ('START') for example.

Returns

PeriodArray The transformed PeriodArray with the new frequency.

See also:

pandas.arrays.PeriodArray.asfreq Convert each Period in a PeriodArray to the given frequency.
Period.asfreq Convert a Period object to the given frequency.

Examples

```python
>>> pidx = pd.period_range('2010-01-01', '2015-01-01', freq='A')
>>> pidx

>>> pidx.asfreq('M')
PeriodIndex(['2010-12', '2011-12', '2012-12', '2013-12', '2014-12', '2015-12'], dtype='period[M]')

>>> pidx.asfreq('M', how='S')
```

pandas.PeriodIndex.strftime

PeriodIndex.strftime(*args, **kwargs)
Convert to Index using specified date_format.

Return an Index of formatted strings specified by date_format, which supports the same string format as the python standard library. Details of the string format can be found in python string format doc.

Parameters

date_format [str] Date format string (e.g. “%Y-%m-%d”).
Returns

ndarray  NumPy ndarray of formatted strings.

See also:

to_datetime  Convert the given argument to datetime.

DatetimeIndex.normalize  Return DatetimeIndex with times to midnight.

DatetimeIndex.round  Round the DatetimeIndex to the specified freq.

DatetimeIndex.floor  Floor the DatetimeIndex to the specified freq.

Examples

```python
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                     periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
     'March 10, 2018, 09:00:02 AM'],
    dtype='object')
```

pandas.PeriodIndex.to_timestamp

PeriodIndex.to_timestamp(freq=None, how='start')  Cast to DatetimeArray/Index.

Parameters

freq  [str or DateOffset, optional]  Target frequency. The default is ‘D’ for week or longer, ‘S’ otherwise.

how  [[‘s’, ‘e’, ‘start’, ‘end’]]  Whether to use the start or end of the time period being converted.

Returns

DatetimeArray/Index

### 3.7 Date offsets

#### 3.7.1 DateOffset

*DateOffset* | Standard kind of date increment used for a date range.
pandas.tseries.offsets.DateOffset

class pandas.tseries.offsets.DateOffset

Standard kind of date increment used for a date range.

Works exactly like relativedelta in terms of the keyword args you pass in, use of the keyword n is discouraged—you would be better off specifying n in the keywords you use, but regardless it is there for you. n is needed for DateOffset subclasses.

DateOffset work as follows. Each offset specify a set of dates that conform to the DateOffset. For example, Bday defines this set to be the set of dates that are weekdays (M-F). To test if a date is in the set of a DateOffset dateOffset we can use the is_on_offset method: dateOffset.is_on_offset(date).

If a date is not on a valid date, the rollback and rollforward methods can be used to roll the date to the nearest valid date before/after the date.

DateOffsets can be created to move dates forward a given number of valid dates. For example, Bday(2) can be added to a date to move it two business days forward. If the date does not start on a valid date, first it is moved to a valid date. Thus pseudo code is:

def __add__(date):
    date = rollback(date)  # does nothing if date is valid return date + <n number of periods>
When a date offset is created for a negative number of periods, the date is first rolled forward. The pseudo code is:

def __add__(date):
    date = rollforward(date)  # does nothing is date is valid return date + <n number of periods>
Zero presents a problem. Should it roll forward or back? We arbitrarily have it rollforward:

date + BDay(0) == BDay.rollforward(date)

Since 0 is a bit weird, we suggest avoiding its use.

Parameters

n [int, default 1] The number of time periods the offset represents.

normalize [bool, default False] Whether to round the result of a DateOffset addition down to the previous midnight.

**kwds Temporal parameter that add to or replace the offset value.

Parameters that add to the offset (like Timedelta):

- years
- months
- weeks
- days
- hours
- minutes
- seconds
- microseconds
- nanoseconds

Parameters that replace the offset value:

- year
- month
- day
- weekday
• hour
• minute
• second
• microsecond
• nanosecond.

See also:

dateutil.relativedelta.relativedelta The relativedelta type is designed to be applied to an existing datetime and can replace specific components of that datetime, or represents an interval of time.

Examples

```python
>>> from pandas.tseries.offsets import DateOffset
>>> ts = pd.Timestamp('2017-01-01 09:10:11')
>>> ts + DateOffset(months=3)
Timestamp('2017-04-01 09:10:11')

>>> ts = pd.Timestamp('2017-01-01 09:10:11')
>>> ts + DateOffset(months=2)
Timestamp('2017-03-01 09:10:11')
```

Attributes

<table>
<thead>
<tr>
<th>base</th>
<th>Returns a copy of the calling offset object with n=1 and all other attributes equal.</th>
</tr>
</thead>

pandas.tseries.offsets.CustomBusinessDay

```python
class pandas.tseries.offsets.CustomBusinessDay
    DateOffset subclass representing custom business days excluding holidays.

    Parameters
    ----------
    n [int, default 1]
    normalize [bool, default False] Normalize start/end dates to midnight before generating date range.
    weekmask [str, Default 'Mon Tue Wed Thu Fri'] Weekmask of valid business days, passed to numpy.busdaycalendar.
    holidays [list] List/array of dates to exclude from the set of valid business days, passed to numpy.busdaycalendar.
    calendar [pd.HolidayCalendar or np.busdaycalendar]
    offset [timedelta, default timedelta(0)]
```

3.7.9 BusinessMonthBegin

| BusinessMonthBegin | DateOffset of one month at the first business day. |

pandas.tseries.offsets.BusinessMonthBegin

class pandas.tseries.offsets.BusinessMonthBegin

    DateOffset of one month at the first business day.
Examples

```python
>>> from pandas.tseries.offsets import BMonthBegin
>>> ts = pd.Timestamp('2020-05-24 05:01:15')
>>> ts + BMonthBegin()
Timestamp('2020-06-01 05:01:15')
>>> ts + BMonthBegin(2)
Timestamp('2020-07-01 05:01:15')
>>> ts + BMonthBegin(-3)
Timestamp('2020-03-02 05:01:15')
```

Attributes

```python
base

Returns a copy of the calling offset object with n=1 and all other attributes equal.
```

```python
pandas.tseries.offsets.BusinessMonthBegin.base

BusinessMonthBegin.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.
```

Methods

```python
__call__(*args, **kwargs)

Call self as a function.

rollback

Roll provided date backward to next offset only if not on offset.

rollforward

Roll provided date forward to next offset only if not on offset.
```
pandas.tseries.offsets.BusinessMonthBegin.__call__

BusinessMonthBegin.__call__(*args, **kwargs)
Call self as a function.

pandas.tseries.offsets.BusinessMonthBegin.rollback

BusinessMonthBegin.rollback()
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.BusinessMonthBegin.rollforward

BusinessMonthBegin.rollforward()
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

<table>
<thead>
<tr>
<th>SemiMonthEnd</th>
<th>Two DateOffset’s per month repeating on the last day of the month and day_of_month.</th>
</tr>
</thead>
</table>
class pandas.tseries.offsets.SemiMonthEnd

Two DateOffset's per month repeating on the last day of the month and day_of_month.

Parameters

- n [int]
- normalize [bool, default False]
- day_of_month [int, \{1, 3, \ldots, 27\}, default 15]

Attributes

- base
  Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.SemiMonthEnd.base

SemiMonthEnd.base
  Returns a copy of the calling offset object with n=1 and all other attributes equal.

<table>
<thead>
<tr>
<th>day_of_month</th>
<th>freqstr</th>

Methods

- __call__(*args, **kwargs)
  Call self as a function.
- rollback
  Roll provided date backward to next offset only if not on offset.
- rollforward
  Roll provided date forward to next offset only if not on offset.
pandas.tseries.offsets.SemiMonthEnd.__call__

SemiMonthEnd.__call__(*args, **kwargs)
Call self as a function.

pandas.tseries.offsets.SemiMonthEnd.rollback

SemiMonthEnd.rollback()
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.SemiMonthEnd.rollforward

SemiMonthEnd.rollforward()
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

### 3.7.13 SemiMonthBegin

| SemiMonthBegin | Two DateOffset’s per month repeating on the first day of the month and day_of_month. |

**class pandas.tseries.offsets.SemiMonthBegin**

Two DateOffset’s per month repeating on the first day of the month and day_of_month.

**Parameters**

- **n** [int]
- **normalize** [bool, default False]
- **day_of_month** [int, {2, 3,...,27}, default 15]

**Attributes**

| base | Returns a copy of the calling offset object with n=1 and all other attributes equal. |

**pandas.tseries.offsets.SemiMonthBegin.base**

SemiMonthBegin.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.
Methods

<table>

<td>Roll provided date forward to next offset only if not on offset.</td>
</tr>
</tbody>
</table>

pandas.tseries.offsets.SemiMonthBegin.__call__

SemiMonthBegin.__call__(*args, **kwargs)
Call self as a function.

pandas.tseries.offsets.SemiMonthBegin.rollback

SemiMonthBegin.rollback()
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.SemiMonthBegin.rollforward

SemiMonthBegin.rollforward()
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

</table>

pandas.tseries.offsets.Week

class pandas.tseries.offsets.Week

Weekly offset.

Parameters

weekday [int or None, default None] Always generate specific day of week. 0 for Monday.

Attributes

<table>
<thead>
<tr>
<th>base</th>
<th>Returns a copy of the calling offset object with n=1 and all other attributes equal.</th>
</tr>
</thead>
</table>

pandas.tseries.offsets.Week.base

Week.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.
Methods

__call__(*args, **kwargs) Call self as a function.

**rollback**
Roll provided date backward to next offset only if not on offset.

**rollforward**
Roll provided date forward to next offset only if not on offset.

```python
pandas.tseries.offsets.Week.__call__
```

```
Week.__call__(*args, **kwargs)
Call self as a function.
```

```python
pandas.tseries.offsets.Week.rollback
```

```
Week.rollback()
Roll provided date backward to next offset only if not on offset.
```

Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

```python
pandas.tseries.offsets.Week.rollback
```

```
Week.rollback()
Roll provided date backward to next offset only if not on offset.
```

Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

WeekOfMonth

| WeekOfMonth | Describes monthly dates like “the Tuesday of the 2nd week of each month”. |

pandas.tseries.offsets.WeekOfMonth

class pandas.tseries.offsets.WeekOfMonth

    Describes monthly dates like “the Tuesday of the 2nd week of each month”.

    Parameters

    * n [int]
    * week [int {0, 1, 2, 3, ...}, default 0] A specific integer for the week of the month. e.g. 0 is 1st week of month, 1 is the 2nd week, etc.
    * weekday [int {0, 1, ... , 6}, default 0] A specific integer for the day of the week.
        - 0 is Monday
• 1 is Tuesday
• 2 is Wednesday
• 3 is Thursday
• 4 is Friday
• 5 is Saturday
• 6 is Sunday.

3.7.18 BQuarterBegin

<table>
<thead>
<tr>
<th>BQuarterBegin</th>
<th>DateOffset increments between the first business day of each Quarter.</th>
</tr>
</thead>
</table>

pandas.tseries.offsets.BQuarterBegin

class pandas.tseries.offsets.BQuarterBegin

DateOffset increments between the first business day of each Quarter.

startingMonth = 1 corresponds to dates like 1/01/2007, 4/01/2007, ... startingMonth = 2 corresponds to dates like 2/01/2007, 5/01/2007, ... startingMonth = 3 corresponds to dates like 3/01/2007, 6/01/2007, ...

Examples

```python
>>> from pandas.tseries.offset import BQuarterBegin
>>> ts = pd.Timestamp('2020-05-24 05:01:15')
>>> ts + BQuarterBegin()
Timestamp('2020-06-01 05:01:15')
>>> ts + BQuarterBegin(2)
Timestamp('2020-09-01 05:01:15')
>>> ts + BQuarterBegin(startingMonth=2)
Timestamp('2020-08-03 05:01:15')
>>> ts + BQuarterBegin(-1)
Timestamp('2020-03-02 05:01:15')
```
Attributes

| base                             | Returns a copy of the calling offset object with n=1 and all other attributes equal. |

**pandas.tseries.offsets.BQuarterBegin.base**

BQuarterBegin.base
Returns a copy of the calling offset object with n=1 and all other attributes equal.

<table>
<thead>
<tr>
<th>freqstr</th>
<th>kwds</th>
<th>n</th>
<th>name</th>
<th>nanos</th>
<th>normalize</th>
<th>rule_code</th>
<th>startingMonth</th>

</thead>
</table>

Methods

**__call__(*args, **kwargs)**

Call self as a function.

**rollback**

Roll provided date backward to next offset only if not on offset.

**rollforward**

Roll provided date forward to next offset only if not on offset.

**pandas.tseries.offsets.BQuarterBegin.__call__**

BQuarterBegin.__call__(*args, **kwargs)
Call self as a function.

**pandas.tseries.offsets.BQuarterBegin.rollback**

BQuarterBegin.rollback()
Roll provided date backward to next offset only if not on offset.

**Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.
Roll provided date forward to next offset only if not on offset.

Returns

**TimeStamp**  Rolled timestamp if not on offset, otherwise unchanged timestamp.

</thead>
</table>

3.7. Date offsets 2267
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.tseries.offsets.QuarterEnd

```python
class pandas.tseries.offsets.QuarterEnd
    DateOffset increments between Quarter end dates.

    startingMonth = 1 corresponds to dates like 1/31/2007, 4/30/2007, …
    startingMonth = 2 corresponds to dates like 2/28/2007, 5/31/2007, …
    startingMonth = 3 corresponds to dates like 3/31/2007, 6/30/2007, …
```

Attributes

- `base`
  Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.QuarterEnd.base

```python
QuarterEnd.base
    Returns a copy of the calling offset object with n=1 and all other attributes equal.
```

Methods

- `__call__(*args, **kwargs)`
  Call self as a function.

- `rollback`
  Roll provided date backward to next offset only if not on offset.

- `rollforward`
  Roll provided date forward to next offset only if not on offset.

pandas.tseries.offsets.QuarterEnd.__call__

```python
QuarterEnd.__call__(*args, **kwargs)
    Call self as a function.
```
pandas.tseries.offsets.QuarterEnd.rollback

QuarterEnd.rollback()
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.QuarterEnd.rollforward

QuarterEnd.rollforward()
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

Timestamp('2017-12-29 05:01:15')
>>> ts + BYearEnd(month=11)
Timestamp('2020-11-30 05:01:15')
```

**Examples**

**Attributes**

```python
base
```
Returns a copy of the calling offset object with n=1 and all other attributes equal.

```python
pandas.tseries.offsets.BYearEnd.base
```

**Methods**

```python
__call__(*args, **kwargs)
rollback
rollforward
```
Call self as a function.
Roll provided date backward to next offset only if not on offset.
Roll provided date forward to next offset only if not on offset.

```python
freqstr
kwds
month
n
name
nanos
normalize
rule_code
```
pandas.tseries.offsets.BYearEnd.__call__

BYearEnd.__call__(*args, **kwargs)
Call self as a function.

pandas.tseries.offsets.BYearEnd.rollback

BYearEnd.rollback()
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.BYearEnd.rollforward

BYearEnd.rollforward()
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

**3.7.25 FY5253**

| FY5253 | Describes 52-53 week fiscal year. |

**pandas.tseries.offsets.FY5253**

**class** pandas.tseries.offsets.FY5253

Describes 52-53 week fiscal year. This is also known as a 4-4-5 calendar.

It is used by companies that desire that their fiscal year always end on the same day of the week.

It is a method of managing accounting periods. It is a common calendar structure for some industries, such as retail, manufacturing and parking industry.

For more information see: [https://en.wikipedia.org/wiki/4-4-5_calendar](https://en.wikipedia.org/wiki/4-4-5_calendar)

The year may either:

• end on the last X day of the Y month.
• end on the last X day closest to the last day of the Y month.

X is a specific day of the week. Y is a certain month of the year

**Parameters**

| n [int] |

| weekday [int {0, 1, ..., 6}, default 0] A specific integer for the day of the week. |

• 0 is Monday
• 1 is Tuesday
• 2 is Wednesday
• 3 is Thursday
• 4 is Friday
• 5 is Saturday
• 6 is Sunday.

**startingMonth** [int \(\{1, 2, \ldots, 12\}\), default 1] The month in which the fiscal year ends.

**variation** [str, default “nearest”] Method of employing 4-4-5 calendar.

There are two options:

• “nearest” means year end is **weekday** closest to last day of month in year.
• “last” means year end is final **weekday** of the final month in fiscal year.

3.7.26 FY5253Quarter

| FY5253Quarter | DateOffset increments between business quarter dates for 52-53 week fiscal year (also known as a 4-4-5 calendar). |

pandas.tseries.offsets.FY5253Quarter

class pandas.tseries.offsets.FY5253Quarter

DateOffset increments between business quarter dates for 52-53 week fiscal year (also known as a 4-4-5 calendar).

It is used by companies that desire that their fiscal year always end on the same day of the week.

It is a method of managing accounting periods. It is a common calendar structure for some industries, such as retail, manufacturing and parking industry.

For more information see: https://en.wikipedia.org/wiki/4-4-5_calendar
The year may either:
• end on the last X day of the Y month.
• end on the last X day closest to the last day of the Y month.
X is a specific day of the week. Y is a certain month of the year

startingMonth = 1 corresponds to dates like 1/31/2007, 4/30/2007, ... startingMonth = 2 corresponds to dates like 2/28/2007, 5/31/2007, ... startingMonth = 3 corresponds to dates like 3/30/2007, 6/29/2007, ...

Parameters

**n** [int]

**weekday** [int {0, 1, ..., 6}, default 0] A specific integer for the day of the week.
  • 0 is Monday
  • 1 is Tuesday
  • 2 is Wednesday
  • 3 is Thursday
  • 4 is Friday
  • 5 is Saturday
  • 6 is Sunday.

**startingMonth** [int {1, 2, ..., 12}, default 1] The month in which fiscal years end.

**qtr_with_extra_week** [int {1, 2, 3, 4}, default 1] The quarter number that has the leap or 14 week when needed.

**variation** [str, default “nearest”] Method of employing 4-4-5 calendar.
  There are two options:
  • “nearest” means year end is **weekday** closest to last day of month in year.
  • “last” means year end is final **weekday** of the final month in fiscal year.

Attributes

**base**
Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.FY5253Quarter.base

FY5253Quarter.**base**
Returns a copy of the calling offset object with n=1 and all other attributes equal.
Methods

```
__call__(*args, **kwargs) Call self as a function.
rollback
Roll provided date backward to next offset only if not on offset.
rollforward
Roll provided date forward to next offset only if not on offset.
```

```
pandas.tseries.offsets.FY5253Quarter.__call__
```

FY5253Quarter.__call__(*args, **kwargs)
Call self as a function.

```
pandas.tseries.offsets.FY5253Quarter.rollback
```

FY5253Quarter.rollback()
Roll provided date backward to next offset only if not on offset.

Returns

**TimeStamp**  Rolled timestamp if not on offset, otherwise unchanged timestamp.

```
pandas.tseries.offsets.FY5253Quarter.rollforward
```

FY5253Quarter.rollforward()
Roll provided date forward to next offset only if not on offset.

Returns

**TimeStamp**  Rolled timestamp if not on offset, otherwise unchanged timestamp.

3.7.27 Easter

<table>
<thead>
<tr>
<th>Easter</th>
<th>DateOffset for the Easter holiday using logic defined in dateutil.</th>
</tr>
</thead>
</table>

pandas.tseries.offsets.Easter

class pandas.tseries.offsets.Easter

DateOffset for the Easter holiday using logic defined in dateutil.

Right now uses the revised method which is valid in years 1583-4099.
 Attributes

\[ \texttt{base} \]

Returns a copy of the calling offset object with \( n=1 \) and all other attributes equal.

---

\texttt{pandas.tseries.offsets.Easter.base}

\texttt{Easter.base}

Returns a copy of the calling offset object with \( n=1 \) and all other attributes equal.

<table>
<thead>
<tr>
<th>freqstr</th>
<th>kwds</th>
<th>n</th>
<th>name</th>
<th>nanos</th>
<th>normalize</th>
<th>rule_code</th>
</tr>
</thead>
</table>

 Methods

\texttt{__call__}(*\texttt{args}, **\texttt{kwargs})

Call self as a function.

\texttt{rollback}

Roll provided date backward to next offset only if not on offset.

\texttt{rollforward}

Roll provided date forward to next offset only if not on offset.

---

\texttt{pandas.tseries.offsets.Easter.__call__}

\texttt{Easter.__call__}(*\texttt{args}, **\texttt{kwargs})

Call self as a function.

\texttt{pandas.tseries.offsets.Easter.rollback}

\texttt{Easter.rollback()}

Roll provided date backward to next offset only if not on offset.

 Returns

\texttt{TimeStamp} Rolled timestamp if not on offset, otherwise unchanged timestamp.
pandas.tseries.offsets.Easter.rollforward

Easter.rollforward()

Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

Methods

__call__(*args, **kwargs) Call self as a function.

rollback

Roll provided date backward to next offset only if not on offset.

rollforward

Roll provided date forward to next offset only if not on offset.

pandas.tseries.offsets.Second.__call__

Second.__call__(*args, **kwargs)

Call self as a function.

pandas.tseries.offsets.Second.rollback

Second.rollback()

Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.tseries.offsets.Second.rollforward

Second.rollforward()
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

### 3.8 Frequencies

<table>
<thead>
<tr>
<th>to_offset</th>
<th>Return DateOffset object from string or tuple representation or datetime.timedelta object.</th>
</tr>
</thead>
</table>

2356 Chapter 3. API reference
3.8.1 pandas.tseries.frequencies.to_offset

pandas.tseries.frequencies.to_offset()
Return DateOffset object from string or tuple representation or datetime.timedelta object.

Parameters

freq [str, tuple, datetime.timedelta, DateOffset or None]

Returns

DateOffset or None

Raises

ValueError If freq is an invalid frequency

See also:

DateOffset Standard kind of date increment used for a date range.

Examples

>>> to_offset("5min")
<5 * Minutes>

>>> to_offset("1D1H")
<25 * Hours>

>>> to_offset("2W")
<2 * Weeks: weekday=6>

>>> to_offset("2B")
<2 * BusinessDays>

>>> to_offset(pd.Timedelta(days=1))
<Day>

>>> to_offset(Hour())
Hour()

3.9 Window

Rolling objects are returned by .rolling calls: pandas.DataFrame.rolling(), pandas.Series.rolling(), etc. Expanding objects are returned by .expanding calls: pandas.DataFrame.expanding(), pandas.Series.expanding(), etc. ExponentialMovingWindow objects are returned by .ewm calls: pandas.DataFrame.ewm(), pandas.Series.ewm(), etc.
3.9.1 Rolling window functions

<table>
<thead>
<tr>
<th>Method</th>

<td>Calculate the rolling quantile.</td>
</tr>
<tr>
<td><code>Rolling.sem([ddof])</code></td>
<td>Calculate the rolling standard error of mean.</td>
</tr>
</tbody>
</table>

**pandas.core.window.rolling.Rolling.count**

`Rolling.count()`

Calculate the rolling count of non NaN observations.

**Returns**

Series or DataFrame Return type is the same as the original object.

**See also:**

- `pandas.Series.rolling` Calling rolling with Series data.
- `pandas.DataFrame.rolling` Calling rolling with DataFrames.
- `pandas.Series.count` Aggregating count for Series.
- `pandas.DataFrame.count` Aggregating count for DataFrame.

**Examples**

```python
>>> s = pd.Series([2, 3, np.nan, 10])
>>> s.rolling(2).count()
0    1.0
1    2.0
2    1.0
3    1.0
dtype: float64
>>> s.rolling(3).count()
0    1.0
1    2.0
2    2.0
3    2.0
dtype: float64
>>> s.rolling(4).count()
0    1.0
```

(continues on next page)
Rolling.sum(*args, engine=None, engine_kwars=None, **kwargs)

Calculate the rolling sum.

Parameters

*args For NumPy compatibility and will not have an effect on the result.

engine [str, default None]
- 'cython': Runs the operation through C-extensions from cython.
- 'numba': Runs the operation through JIT compiled code from numba.
- None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.3.0.

engine_kwars [dict, default None]
- For 'cython' engine, there are no accepted engine_kwars
- For 'numba' engine, the engine can accept nopython, nogil and parallel
dictionary keys. The values must either be True or False. The default
eengine_kwars for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}

New in version 1.3.0.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

pandas.Series.rolling Calling rolling with Series data.
pandas.DataFrame.rolling Calling rolling with DataFrames.
pandas.Series.sum Aggregating sum for Series.
pandas.DataFrame.sum Aggregating sum for DataFrame.

Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations
for the Numba engine.
Examples

```python
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64

>>> s.rolling(3).sum()
0    NaN
1    NaN
2    6.0
3    9.0
4    12.0
dtype: float64

>>> s.rolling(3, center=True).sum()
0    NaN
1    6.0
2    9.0
3    12.0
4    NaN
dtype: float64

For DataFrame, each sum is computed column-wise.

```python
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
```
**pandas.core.window.rolling.Rolling.mean**

Rolling.mean (*args, engine=None, engine_kwargs=None, **kwargs*)

Calculate the rolling mean.

**Parameters**

- **args** For NumPy compatibility and will not have an effect on the result.
- **engine** [str, default None]
  - 'cython': Runs the operation through C-extensions from cython.
  - 'numba': Runs the operation through JIT compiled code from numba.
  - None: Defaults to 'cython' or globally setting compute.use_numba
    New in version 1.3.0.
- **engine_kwargs** [dict, default None]
  - For 'cython' engine, there are no accepted engine_kwargs
  - For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}
    New in version 1.3.0.
- **kwargs** For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame Return type is the same as the original object.

**See also:**

- **pandas.Series.rolling** Calling rolling with Series data.
- **pandas.DataFrame.rolling** Calling rolling with DataFrames.
- **pandas.Series.mean** Aggregating mean for Series.
- **pandas.DataFrame.mean** Aggregating mean for DataFrame.

**Notes**

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

**Examples**

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0   NaN
1   1.5
2   2.5
3   3.5
dtype: float64
```
```python
>>> s.rolling(3).mean()
0   NaN
1   NaN
2   2.0
3   3.0
dtype: float64
```

**pandas.core.window.rolling.Rolling.median**

Rolling.median (engine=None, engine_kwargs=None, **kwargs)

Calculate the rolling median.

**Parameters**

- **engine** [str, default None]
  - 'cython': Runs the operation through C-extensions from cython.
  - 'numba': Runs the operation through JIT compiled code from numba.
  - None: Defaults to 'cython' or globally setting compute.use_numba
    New in version 1.3.0.

- **engine_kwargs** [dict, default None]
  - For 'cython' engine, there are no accepted engine_kwargs
  - For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}
    New in version 1.3.0.

- **kwargs** For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame Return type is the same as the original object.

See also:

- pandas.Series.rolling Calling rolling with Series data.
- pandas.DataFrame.rolling Calling rolling with DataFrames.
- pandas.Series.median Aggregating median for Series.
- pandas.DataFrame.median Aggregating median for DataFrame.

**Notes**

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.
Examples

Compute the rolling median of a series with a window size of 3.

```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.rolling(3).median()
0    NaN
1    NaN
2    1.0
3    2.0
4    3.0
dtype: float64
```

**pandas.core.window.rolling.Rolling.var**

Rolling.var (ddof=1, *args, **kwargs)

Calculate the rolling variance.

**Parameters**

- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.
- **args** For NumPy compatibility and will not have an effect on the result.
- **kwargs** For NumPy compatibility and will not have an effect on the result.

**Returns**

- **Series** or **DataFrame** Return type is the same as the original object.

**See also:**

- **numpy.var** Equivalent method for NumPy array.
- **pandas.Series.rolling** Calling rolling with Series data.
- **pandas.DataFrame.rolling** Calling rolling with DataFrames.
- **pandas.Series.var** Aggregating var for Series.
- **pandas.DataFrame.var** Aggregating var for DataFrame.

**Notes**

The default ddof of 1 used in Series.var() is different than the default ddof of 0 in numpy.var().

A minimum of one period is required for the rolling calculation.

The implementation is susceptible to floating point imprecision as shown in the example below.

**Examples**

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
0     NaN
1     NaN
2  3.333333e-01
3  1.000000e+00
4  1.000000e+00
5  1.333333e+00
```
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.core.window.rolling.Rolling.std

Rolling.std(ddof=1, *args, **kwargs)

Calculate the rolling standard deviation.

Parameters

- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- **args** For NumPy compatibility and will not have an effect on the result.
- **kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

- numpy.std Equivalent method for NumPy array.
- pandas.Series.rolling Calling rolling with Series data.
- pandas.DataFrame.rolling Calling rolling with DataFrames.
- pandas.Series.std Aggregating std for Series.
- pandas.DataFrame.std Aggregating std for DataFrame.

Notes

The default ddof of 1 used in Series.std() is different than the default ddof of 0 in numpy.std().

A minimum of one period is required for the rolling calculation.

The implementation is susceptible to floating point imprecision as shown in the example below.

Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0   NaN
1   NaN
2   5.773503e-01
3   1.000000e+00
4   1.000000e+00
5   1.154701e+00
6   2.580957e-08
dtype: float64
```
**pandas.core.window.rolling.Rolling.min**

Rolling.min(*args, engine=None, engine_kwds=None, **kwargs)

Calculate the rolling minimum.

**Parameters**

*args  For NumPy compatibility and will not have an effect on the result.

engine  [str, default None]

- 'cython': Runs the operation through C-extensions from cython.
- 'numba': Runs the operation through JIT compiled code from numba.
- None: Defaults to 'cython' or globally setting compute.use_numba
  
  New in version 1.3.0.

engine_kwds  [dict, default None]

- For 'cython' engine, there are no accepted engine_kwds
- For 'numba' engine, the engine can accept nopython, nogil and parallel
dictionary keys. The values must either be True or False. The default
engine_kwds for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}
  
  New in version 1.3.0.

**kwargs  For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame  Return type is the same as the original object.

See also:

- pandas.Series.rolling  Calling rolling with Series data.
- pandas.DataFrame.rolling  Calling rolling with DataFrames.
- pandas.Series.min  Aggregating min for Series.
- pandas.DataFrame.min  Aggregating min for DataFrame.

Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

Examples

Performing a rolling minimum with a window size of 3.

```python
>>> s = pd.Series([4, 3, 5, 2, 6])
>>> s.rolling(3).min()
0   NaN
1   NaN
2   3.0
3   2.0
4   2.0
dtype: float64
```
pandas.core.window.rolling.Rolling.max

Rolling.max(*args, engine=None, engine_kwarg=None, **kwargs)

Calculate the rolling maximum.

Parameters

*args For NumPy compatibility and will not have an effect on the result.

engine [str, default None]

• 'cython': Runs the operation through C-extensions from cython.

• 'numba': Runs the operation through JIT compiled code from numba.

• None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.3.0.

engine_kwargs [dict, default None]

• For 'cython' engine, there are no accepted engine_kwargs

• For 'numba' engine, the engine can accept nopython, nogil and parallel
dictionary keys. The values must either be True or False. The def-
dfault engine_kwargs for the 'numba' engine is {'nopython': True,
'nogil': False, 'parallel': False}

New in version 1.3.0.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

pandas.Series.rolling Calling rolling with Series data.

pandas.DataFrame.rolling Calling rolling with DataFrames.

pandas.Series.max Aggregating max for Series.

pandas.DataFrame.max Aggregating max for DataFrame.

Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

pandas.core.window.rolling.Rolling.corr

Rolling.corr(other=None, pairwise=None, ddof=1, **kwargs)

Calculate the rolling correlation.

Parameters

other [Series or DataFrame, optional] If not supplied then will default to self and produce
pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other
will be used and the output will be a DataFrame. If True then all pairwise combina-
tions will be calculated and the output will be a MultiIndexed DataFrame in the case of
DataFrame inputs. In the case of missing elements, only complete pairwise observations
will be used.
**ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.

**kwargs For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame Return type is the same as the original object.

See also:

cov Similar method to calculate covariance.

numpy.corrcoef NumPy Pearson’s correlation calculation.

pandas.Series.rolling Calling rolling with Series data.

pandas.DataFrame.rolling Calling rolling with DataFrames.

pandas.Series.corr Aggregating corr for Series.

pandas.DataFrame.corr Aggregating corr for DataFrame.

Notes

This function uses Pearson’s definition of correlation (https://en.wikipedia.org/wiki/Pearson_correlation_coefficient).

When other is not specified, the output will be self correlation (e.g. all 1’s), except for DataFrame inputs with pairwise set to True.

Function will return NaN for correlations of equal valued sequences; this is the result of a 0/0 division error.

When pairwise is set to False, only matching columns between self and other will be used.

When pairwise is set to True, the output will be a MultiIndex DataFrame with the original index on the first level, and the other DataFrame columns on the second level.

In the case of missing elements, only complete pairwise observations will be used.

Examples

The below example shows a rolling calculation with a window size of four matching the equivalent function call using numpy.corrcoef().

```python
>>> v1 = [3, 3, 3, 5, 8]
>>> v2 = [3, 4, 4, 4, 8]
>>> # numpy returns a 2X2 array, the correlation coefficient
>>> # is the number at entry [0][1]
>>> print(f"{np.corrcoef(v1[:-1], v2[:-1])[0][1]:.6f}\n")
0.333333
>>> print(f"{np.corrcoef(v1[1:], v2[1:])[0][1]:.6f}\n")
0.916949
>>> s1 = pd.Series(v1)
>>> s2 = pd.Series(v2)
>>> s1.rolling(4).corr(s2)
0   NaN
1   NaN
2   NaN
3   0.333333
4   0.916949
dtype: float64
```

The below example shows a similar rolling calculation on a DataFrame using the pairwise option.

3.9. Window
```python
>>> matrix = np.array([[51., 35.],
                     [49., 30.],
                     [47., 32.],
                     [46., 31.],
                     [50., 36.]])
>>> print(np.corrcoef(matrix[:-1,0], matrix[:-1,1]).round(7))
[[1. 0.6263001]
 [0.6263001 1.]]
>>> print(np.corrcoef(matrix[1:,0], matrix[1:,1]).round(7))
[[1. 0.5553681]
 [0.5553681 1.]]
>>> df = pd.DataFrame(matrix, columns=['X','Y'])
>>> df
   X   Y
0  51  35
1  49  30
2  47  32
3  46  31
4  50  36
>>> df.rolling(4).corr(pairwise=True)
   X   Y
0 X NaN NaN
  Y NaN NaN
1 X NaN NaN
  Y NaN NaN
2 X NaN NaN
  Y NaN NaN
3 X 1.000000 0.626300
  Y 0.626300 1.000000
4 X 1.000000 0.555368
  Y 0.555368 1.000000
```

pandas.core.window.rolling.Rolling.cov

Rolling.cov (other=None, pairwise=None, ddof=1, **kwargs)
Calculate the rolling sample covariance.

Parameters

other [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N − ddof, where N represents the number of elements.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

pandas.Series.rolling Calling rolling with Series data.
pandas.DataFrame.rolling Calling rolling with DataFrames.
pandas.Series.cov Aggregating cov for Series.
pandas.DataFrame.cov Aggregating cov for DataFrame.
pandas.core.window.rolling.Rolling.skew

Rolling.skew(**kwargs)
Calculate the rolling unbiased skewness.

Parameters

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

scipy.stats.skew Third moment of a probability density.
pandas.Series.rolling Calling rolling with Series data.
pandas.DataFrame.rolling Calling rolling with DataFrames.
pandas.Series.skew Aggregating skew for Series.
pandas.DataFrame.skew Aggregating skew for DataFrame.

Notes

A minimum of three periods is required for the rolling calculation.

pandas.core.window.rolling.Rolling.kurt

Rolling.kurt(**kwargs)
Calculate the rolling Fisher’s definition of kurtosis without bias.

Parameters

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

pandas.Series.rolling Calling rolling with Series data.
pandas.DataFrame.rolling Calling rolling with DataFrames.
pandas.Series.kurt Aggregating kurt for Series.
pandas.DataFrame.kurt Aggregating kurt for DataFrame.

Notes

A minimum of four periods is required for the calculation.
Examples

The example below will show a rolling calculation with a window size of four matching the equivalent function call using scipy.stats.

```python
>>> arr = [1, 2, 3, 4, 999]
>>> import scipy.stats
>>> print(f"(scipy.stats.kurtosis(arr[:-1], bias=False):.6f)")
-1.200000
>>> print(f"(scipy.stats.kurtosis(arr[1:], bias=False):.6f)")
3.999946
>>> s = pd.Series(arr)
>>> s.rolling(4).kurt()
0  NaN
1  NaN
2  NaN
3  -1.200000
4   3.999946
dtype: float64
```

pandas.core.window.rolling.Rolling.apply

Rolling.apply(func, raw=False, engine=None, engine_kwags=None, args=None, kwags=None)

Calculate the rolling custom aggregation function.

Parameters

func [function] Must produce a single value from an ndarray input if raw=True or a single value from a Series if raw=False. Can also accept a Numba JIT function with engine='numba' specified.

Changed in version 1.0.0.

raw [bool, default None]

- False: passes each row or column as a Series to the function.
- True: the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

engine [str, default None]

- 'cython': Runs rolling apply through C-extensions from cython.
- 'numba': Runs rolling apply through JIT compiled code from numba. Only available when raw is set to True.
- None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.0.0.

engine_kwags [dict, default None]

- For 'cython' engine, there are no accepted engine_kwags
- For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwags for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False} and will be applied to both the func and the apply rolling aggregation.

New in version 1.0.0.
**args** [tuple, default None] Positional arguments to be passed into `func`.

**kwargs** [dict, default None] Keyword arguments to be passed into `func`.

**Returns**

**Series or DataFrame** Return type is the same as the original object.

**See also:**

- `pandas.Series.rolling` Calling rolling with Series data.
- `pandas.DataFrame.rolling` Calling rolling with DataFrames.
- `pandas.Series.apply` Aggregating apply for Series.
- `pandas.DataFrame.apply` Aggregating apply for DataFrame.

### pandas.core.window.rolling.Rolling.aggregate

#### Rolling.aggregate(func, *args, **kwargs)

Aggregate using one or more operations over the specified axis.

**Parameters**

**func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series/Dataframe or when passed to Series/Dataframe.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. `[np.sum, 'mean']`
- dict of axis labels -> functions, function names or list of such.

**args** Positional arguments to pass to `func`.

**kwargs** Keyword arguments to pass to `func`.

**Returns**

**scalar, Series or DataFrame** The return can be:

- scalar : when `Series.agg` is called with single function
- Series : when `DataFrame.agg` is called with a single function
- DataFrame : when `DataFrame.agg` is called with several functions

Return scalar, Series or DataFrame.

**See also:**

- `pandas.Series.rolling` Calling object with Series data.
- `pandas.DataFrame.rolling` Calling object with DataFrame data.
Notes

`agg` is an alias for `aggregate`. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See `Mutating with User Defined Function (UDF) methods` for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]})
>>> df
     A  B  C
0  1.0 4.0 7.0
1  2.0 5.0 8.0
2  3.0 6.0 9.0

>>> df.rolling(2).sum()
     A  B  C
0  NaN NaN NaN
1  3.0 9.0 15.0
2  5.0 11.0 17.0

>>> df.rolling(2).agg({'A': 'sum', 'B': 'min'})
     A  B
0  NaN NaN
1  3.0 4.0
2  5.0 5.0
```

**pandas.core.window.rolling.Rolling.quantile**

Rolling. `quantile` (quantile, interpolation='linear', **kwargs)

Calculate the rolling quantile.

**Parameters**

quantile [float] Quantile to compute. 0 <= quantile <= 1.

interpolation [‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points $i$ and $j$:

- linear: $i + (j - i) \times fraction$, where fraction is the fractional part of the index surrounded by $i$ and $j$.
- lower: $i$.
- higher: $j$.
- nearest: $i$ or $j$ whichever is nearest.
- midpoint: $(i + j) / 2$.

**kwargs For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame Return type is the same as the original object.
See also:

- `pandas.Series.rolling` Calling rolling with Series data.
- `pandas.DataFrame.rolling` Calling rolling with DataFrames.
- `pandas.Series.quantile` Aggregating quantile for Series.
- `pandas.DataFrame.quantile` Aggregating quantile for DataFrame.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).quantile(.4, interpolation='lower')
0  NaN
1  1.0
2  2.0
3  3.0
dtype: float64

>>> s.rolling(2).quantile(.4, interpolation='midpoint')
0  NaN
1  1.5
2  2.5
3  3.5
dtype: float64
```

**pandas.core.window.rolling.Rolling.sem**

Rolling. `sem` (`ddof=1`, `*args`, `**kwargs`)  
Calculate the rolling standard error of mean.

**Parameters**

- `ddof` [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is `N - ddof`, where `N` represents the number of elements.
- `*args` For NumPy compatibility and will not have an effect on the result.
- `**kwargs` For NumPy compatibility and will not have an effect on the result.

**Returns**

- Series or DataFrame Return type is the same as the original object.

See also:

- `pandas.Series.rolling` Calling rolling with Series data.
- `pandas.DataFrame.rolling` Calling rolling with DataFrames.
- `pandas.Series.sem` Aggregating sem for Series.
- `pandas.DataFrame.sem` Aggregating sem for DataFrame.
Notes

A minimum of one period is required for the calculation.

Examples

```python
>>> s = pd.Series([0, 1, 2, 3])
>>> s.rolling(2, min_periods=1).sem()
0    NaN
1  0.707107
2  0.707107
3  0.707107
dtype: float64
```

3.9.2 Weighted window functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>

<tr>
<td><code>Window.std(*ddof)</code></td>
<td>Calculate the rolling weighted window standard deviation.</td>
</tr>
</tbody>
</table>

**pandas.core.window.rolling.Window.mean**

`Window.mean(*args, **kwargs)`

Calculate the rolling weighted window mean.

**Parameters**

- **kwargs**  Keyword arguments to configure the SciPy weighted window type.

**Returns**

`Series` or `DataFrame`  Return type is the same as the original object.

**See also:**

- `pandas.Series.rolling`  Calling rolling with Series data.
- `pandas.DataFrame.rolling`  Calling rolling with DataFrames.
- `pandas.Series.mean`  Aggregating mean for Series.
- `pandas.DataFrame.mean`  Aggregating mean for DataFrame.

**pandas.core.window.rolling.Window.sum**

`Window.sum(*args, **kwargs)`

Calculate the rolling weighted window sum.

**Parameters**

- **kwargs**  Keyword arguments to configure the SciPy weighted window type.

**Returns**

`Series` or `DataFrame`  Return type is the same as the original object.

**See also:**
pandas.Series.rolling Calling rolling with Series data.
pandas.DataFrame.rolling Calling rolling with DataFrames.
pandas.Series.sum Aggregating sum for Series.
pandas.DataFrame.sum Aggregating sum for DataFrame.

pandas.core.window.rolling.Window.var

Window.var(ddof=1, *args, **kwargs)
Calculate the rolling weighted window variance.

Parameters

**kwargs Keyword arguments to configure the SciPy weighted window type.

Returns

Series or DataFrame Return type is the same as the original object.

See also:
pandas.Series.rolling Calling rolling with Series data.
pandas.DataFrame.rolling Calling rolling with DataFrames.
pandas.Series.var Aggregating var for Series.
pandas.DataFrame.var Aggregating var for DataFrame.

pandas.core.window.rolling.Window.std

Window.std(ddof=1, *args, **kwargs)
Calculate the rolling weighted window standard deviation.

Parameters

**kwargs Keyword arguments to configure the SciPy weighted window type.

Returns

Series or DataFrame Return type is the same as the original object.

See also:
pandas.Series.rolling Calling rolling with Series data.
pandas.DataFrame.rolling Calling rolling with DataFrames.
pandas.Series.std Aggregating std for Series.
pandas.DataFrame.std Aggregating std for DataFrame.

3.9.3 Expanding window functions

Expanding.count() Calculate the expanding count of non NaN observations.
Expanding.sum(*args[, engine, engine_kwars]) Calculate the expanding sum.
Expanding.mean(*args[, engine, engine_kwars]) Calculate the expanding mean.
Expanding.median([engine, engine_kwars]) Calculate the expanding median.
Expanding.var([ddof]) Calculate the expanding variance.
Expanding.std([ddof]) Calculate the expanding standard deviation.
Expanding.min(*args[, engine, engine_kwars]) Calculate the expanding minimum.
Expanding.max(*args[, engine, engine_kwars]) Calculate the expanding maximum.

**pandas.core.window.expanding.Expanding.count**

`Expanding.count()`  
Calculate the expanding count of non NaN observations.

Returns

Series or DataFrame  
Return type is the same as the original object.

See also:  
`pandas.Series.expanding`  
Calling expanding with Series data.  
`pandas.DataFrame.expanding`  
Calling expanding with DataFrames.  
`pandas.Series.count`  
Aggregating count for Series.  
`pandas.DataFrame.count`  
Aggregating count for DataFrame.

**pandas.core.window.expanding.Expanding.sum**

`Expanding.sum(*args, engine=None, engine_kwars=None, **kwars)`  
Calculate the expanding sum.

Parameters

*args  
For NumPy compatibility and will not have an effect on the result.

engine  
[str, default None]
  - 'cython'  
    - Runs the operation through C-extensions from cython.
  - 'numba'  
    - Runs the operation through JIT compiled code from numba.
  - 'default'  
    - Defaults to 'cython' or globally setting compute.use_numba

New in version 1.3.0.

engine_kwars  
[dict, default None]
  - For 'cython' engine, there are no accepted engine_kwars
  - For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwars for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}

New in version 1.3.0.

**kwars  
For NumPy compatibility and will not have an effect on the result.

Returns

Series or Dataframe  
Return type is the same as the original object.
See also:

- `pandas.Series.expanding` Calling expanding with Series data.
- `pandas.DataFrame.expanding` Calling expanding with DataFrames.
- `pandas.Series.sum` Aggregating sum for Series.
- `pandas.DataFrame.sum` Aggregating sum for DataFrame.

Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

`pandas.core.window.expanding.Expanding.mean`

`Expanding.mean(*args, engine=None, engine_kwargs=None, **kwargs)`

Calculate the expanding mean.

Parameters

- `*args` For NumPy compatibility and will not have an effect on the result.
- `engine` [str, default None]
  - 'cython': Runs the operation through C-extensions from cython.
  - 'numba': Runs the operation through JIT compiled code from numba.
  - None: Defaults to 'cython' or globally setting compute.use_numba

  New in version 1.3.0.

- `engine_kwargs` [dict, default None]
  - For 'cython' engine, there are no accepted engine_kwargs
  - For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}

  New in version 1.3.0.

- `**kwargs` For NumPy compatibility and will not have an effect on the result.

Returns

- Series or DataFrame Return type is the same as the original object.

See also:

- `pandas.Series.expanding` Calling expanding with Series data.
- `pandas.DataFrame.expanding` Calling expanding with DataFrames.
- `pandas.Series.mean` Aggregating mean for Series.
- `pandas.DataFrame.mean` Aggregating mean for DataFrame.
Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.median

Expanding.median(engine=None, engine_kwargs=None, **kwargs)
Calculate the expanding median.

Parameters

- **engine** [str, default None]
  - 'cython': Runs the operation through C-extensions from cython.
  - 'numba': Runs the operation through JIT compiled code from numba.
  - None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.3.0.

- **engine_kwargs** [dict, default None]
  - For 'cython' engine, there are no accepted engine_kwargs
  - For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}

New in version 1.3.0.

- **kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

- Series or DataFrame Return type is the same as the original object.

See also:

- pandas.Series.expanding Calling expanding with Series data.
- pandas.DataFrame.expanding Calling expanding with DataFrames.
- pandas.Series.median Aggregating median for Series.
- pandas.DataFrame.median Aggregating median for DataFrame.

Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.
pandas.core.window.expanding.Expanding.var

Expanding.var(ddof=1, *args, **kwargs)
Calculate the expanding variance.

Parameters

d dof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N − ddof, where N represents the number of elements.

*args For NumPy compatibility and will not have an effect on the result.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

numpy.var Equivalent method for NumPy array.
pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.var Aggregating var for Series.
pandas.DataFrame.var Aggregating var for DataFrame.

Notes

The default ddof of 1 used in Series.var() is different than the default ddof of 0 in numpy.var().
A minimum of one period is required for the rolling calculation.

Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.expanding(3).var()
0    NaN
1    NaN
2    0.333333
3    0.916667
4    0.800000
5    0.700000
6    0.619048
dtype: float64
```

pandas.core.window.expanding.Expanding.std

Expanding.std(ddof=1, *args, **kwargs)
Calculate the expanding standard deviation.

Parameters

d dof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N − ddof, where N represents the number of elements.

*args For NumPy compatibility and will not have an effect on the result.

**kwargs For NumPy compatibility and will not have an effect on the result.
Returns

**Series or DataFrame**  Return type is the same as the original object.

See also:

- `numpy.std`  Equivalent method for NumPy array.
- `pandas.Series.expanding`  Calling expanding with Series data.
- `pandas.DataFrame.expanding`  Calling expanding with DataFrames.
- `pandas.Series.std`  Aggregating std for Series.
- `pandas.DataFrame.std`  Aggregating std for DataFrame.

Notes

The default `ddof` of 1 used in `Series.std()` is different than the default `ddof` of 0 in `numpy.std()`.

A minimum of one period is required for the rolling calculation.

Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])

>>> s.expanding(3).std()
0 NaN
1 NaN
2 0.577350
3 0.957427
4 0.894427
5 0.836660
6 0.786796
dtype: float64
```

---

**pandas.core.window.expanding.Expanding.min**

Calculates the expanding minimum.

**Parameters**

*args  For NumPy compatibility and will not have an effect on the result.

engine  [str, default None]
  - 'cython': Runs the operation through C-extensions from cython.
  - 'numba': Runs the operation through JIT compiled code from numba.
  - None: Defaults to 'cython' or globally setting `compute.use_numba`

New in version 1.3.0.

engine_kwargs  [dict, default None]
  - For 'cython' engine, there are no accepted engine_kwargs
  - For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}
New in version 1.3.0.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.min Aggregating min for Series.
pandas.DataFrame.min Aggregating min for DataFrame.

Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.max

Expanding.\texttt{max}(*args, engine=None, engine_kwars=None, **kwargs)

Calculate the expanding maximum.

Parameters

*args For NumPy compatibility and will not have an effect on the result.

engine [str, default None]

- 'cython': Runs the operation through C-extensions from cython.
- 'numba': Runs the operation through JIT compiled code from numba.
- None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.3.0.

engine_kwars [dict, default None]

- For 'cython' engine, there are no accepted engine_kwars
- For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwars for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}

New in version 1.3.0.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.max Aggregating max for Series.
pandas.DataFrame.max Aggregating max for DataFrame.
Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.corr

Expanding.corr (other=None, pairwise=None, ddof=1, **kwargs)

Calculate the expanding correlation.

Parameters

other [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

cov Similar method to calculate covariance.
numpy.corrcoef NumPy Pearson’s correlation calculation.
pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.corr Aggregating corr for Series.
pandas.DataFrame.corr Aggregating corr for DataFrame.

Notes

This function uses Pearson’s definition of correlation (https://en.wikipedia.org/wiki/Pearson_correlation_coefficient).

When other is not specified, the output will be self correlation (e.g. all 1’s), except for DataFrame inputs with pairwise set to True.

Function will return NaN for correlations of equal valued sequences; this is the result of a 0/0 division error.

When pairwise is set to False, only matching columns between self and other will be used.

When pairwise is set to True, the output will be a MultiIndex DataFrame with the original index on the first level, and the other DataFrame columns on the second level.

In the case of missing elements, only complete pairwise observations will be used.
pandas.core.window.expanding.Expanding.cov

Expanding.cov(other=None, pairwise=None, ddof=1, **kwargs)

Calculate the expanding sample covariance.

Parameters

other [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:
- pandas.Series.expanding Calling expanding with Series data.
- pandas.DataFrame.expanding Calling expanding with DataFrames.
- pandas.Series.cov Aggregating cov for Series.
- pandas.DataFrame.cov Aggregating cov for DataFrame.

pandas.core.window.expanding.Expanding.skew

Expanding.skew(**kwargs)

Calculate the expanding unbiased skewness.

Parameters

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:
- scipy.stats.skew Third moment of a probability density.
- pandas.Series.expanding Calling expanding with Series data.
- pandas.DataFrame.expanding Calling expanding with DataFrames.
- pandas.Series.skew Aggregating skew for Series.
- pandas.DataFrame.skew Aggregating skew for DataFrame.
Notes

A minimum of three periods is required for the rolling calculation.

**pandas.core.window.expanding.Expanding.kurt**

Expanding.\texttt{kurt} (**\texttt{kwargs}**)

Calculate the expanding Fisher’s definition of kurtosis without bias.

**Parameters**

**\texttt{kwargs}** For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame Return type is the same as the original object.

See also:

- \texttt{pandas.Series.expanding} Calling expanding with Series data.
- \texttt{pandas.DataFrame.expanding} Calling expanding with DataFrames.
- \texttt{pandas.Series.kurt} Aggregating kurt for Series.
- \texttt{pandas.DataFrame.kurt} Aggregating kurt for DataFrame.

Notes

A minimum of four periods is required for the calculation.

Examples

The example below will show a rolling calculation with a window size of four matching the equivalent function call using \texttt{scipy.stats}.

```python
>>> arr = [1, 2, 3, 4, 999]
>>> import scipy.stats
>>> print(f"scipy.stats.kurtosis(arr[:-1], bias=\texttt{False}):.6f")
-1.200000
>>> print(f"scipy.stats.kurtosis(arr, bias=\texttt{False}):.6f")
4.999874
>>> s = pd.Series(arr)
>>> s.expanding(4).kurt()
0     NaN
1     NaN
2     NaN
3  -1.200000
4  4.999874
dtype: float64
```
pandas.core.window.expanding.Expanding.apply

Expanding.apply (func, raw=False, engine=None, engine_kwars=None, args=None, kwars=None)

Calculate the expanding custom aggregation function.

Parameters

- **func** [function] Must produce a single value from an ndarray input if raw=True or a single value from a Series if raw=False. Can also accept a Numba JIT function with engine='numba' specified.

  Changed in version 1.0.0.

- **raw** [bool, default None]

  - False: passes each row or column as a Series to the function.
  - True: the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

- **engine** [str, default None]

  - 'cython': Runs rolling apply through C-extensions from cython.
  - 'numba': Runs rolling apply through JIT compiled code from numba. Only available when raw is set to True.
  - None: Defaults to 'cython' or globally setting compute.use_numba

  New in version 1.0.0.

- **engine_kwars** [dict, default None]

  - For 'cython' engine, there are no accepted engine_kwars
  - For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwars for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False} and will be applied to both the func and the apply rolling aggregation.

  New in version 1.0.0.

- **args** [tuple, default None] Positional arguments to be passed into func.

- **kwars** [dict, default None] Keyword arguments to be passed into func.

Returns

- **Series or DataFrame** Return type is the same as the original object.

See also:

- `pandas.Series.expanding` Calling expanding with Series data.
- `pandas.DataFrame.expanding` Calling expanding with DataFrames.
- `pandas.Series.apply` Aggregating apply for Series.
- `pandas.DataFrame.apply` Aggregating apply for DataFrame.
pandas.core.window.expanding.Expanding.aggregate

Expanding.aggregate (func, *args, **kwargs)

Aggregate using one or more operations over the specified axis.

Parameters

- func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series/Dataframe or when passed to Series/Dataframe.apply.
  
  Accepted combinations are:
  
  - function
  - string function name
  - list of functions and/or function names, e.g. [np.sum, 'mean']
  - dict of axis labels -> functions, function names or list of such.

- *args Positional arguments to pass to func.

- **kwargs Keyword arguments to pass to func.

Returns

- scalar, Series or DataFrame The return can be:
  
  - scalar : when Series.agg is called with single function
  - Series : when DataFrame.agg is called with a single function
  - DataFrame : when DataFrame.agg is called with several functions

  Return scalar, Series or DataFrame.

See also:

- pandas.DataFrame.aggregate Similar DataFrame method.
- pandas.Series.aggregate Similar Series method.

Notes

agg is an alias for aggregate. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
def = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6], "C": [7, 8, 9]})
def
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9

def.ewm(alpha=0.5).mean()
   A     B     C
0  1.000000  4.000000  7.000000
```

(continues on next page)
pandas.core.window.expanding.Expanding.quantile

Expanding. quantile(quantile, interpolation='linear', **kwargs)

Calculate the expanding quantile.

Parameters

quantile [float] Quantile to compute. 0 <= quantile <= 1.

interpolation [{'linear', 'lower', 'higher', 'midpoint', 'nearest'}] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j:

- linear: \( i + (j - i) * \text{fraction} \), where \( \text{fraction} \) is the fractional part of the index surrounded by \( i \) and \( j \).
- lower: \( i \).
- higher: \( j \).
- nearest: \( i \) or \( j \) whichever is nearest.
- midpoint: \( (i + j) / 2 \).

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

- pandas.Series.expanding Calling expanding with Series data.
- pandas.DataFrame.expanding Calling expanding with DataFrames.
- pandas.Series.quantile Aggregating quantile for Series.
- pandas.DataFrame.quantile Aggregating quantile for DataFrame.

pandas.core.window.expanding.Expanding.sem

Expanding. sem(ddof=1, *args, **kwargs)

Calculate the expanding standard error of mean.

Parameters

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.

*args For NumPy compatibility and will not have an effect on the result.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

- pandas.Series.expanding Calling expanding with Series data.
- pandas.DataFrame.expanding Calling expanding with DataFrames.
- pandas.Series.sem Aggregating sem for Series.
**pandas.DataFrame.sem** Aggregating sem for DataFrame.

**Notes**

A minimum of one period is required for the calculation.

**Examples**

```python
>>> s = pd.Series([0, 1, 2, 3])

>>> s.expanding().sem()
0    NaN
1  0.707107
2  0.707107
3  0.745356
dtype: float64
```

### 3.9.4 Exponentially-weighted window functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ExponentialMovingWindow.mean(*args, ...)</code></td>
<td>Calculate the ewm (exponential weighted moment) mean.</td>
</tr>
<tr>
<td><code>ExponentialMovingWindow.std(bias)</code></td>
<td>Calculate the ewm (exponential weighted moment) standard deviation.</td>
</tr>
<tr>
<td><code>ExponentialMovingWindow.var(bias)</code></td>
<td>Calculate the ewm (exponential weighted moment) variance.</td>
</tr>
<tr>
<td><code>ExponentialMovingWindow.corr(other, pairwise)</code></td>
<td>Calculate the ewm (exponential weighted moment) sample correlation.</td>
</tr>
<tr>
<td><code>ExponentialMovingWindow.cov(other, ...)</code></td>
<td>Calculate the ewm (exponential weighted moment) sample covariance.</td>
</tr>
</tbody>
</table>

**pandas.core.window.ewm.ExponentialMovingWindow.mean**

Calculate the ewm (exponential weighted moment) mean.

**Parameters**

*args For NumPy compatibility and will not have an effect on the result.

eengine [str, default None]

- 'cython': Runs the operation through C-extensions from cython.
- 'numba': Runs the operation through JIT compiled code from numba.
- None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.3.0.

eengine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted engine_kwargs
• For 'numba' engine, the engine can accept nopython, nogil and parallel
dictionary keys. The values must either be True or False. The de-
fault engine_kwargs for the 'numba' engine is {'nopython': True,
'nogil': False, 'parallel': False}

New in version 1.3.0.

**kwargs  For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame  Return type is the same as the original object.

See also:

pandas.Series.ewm  Calling ewm with Series data.
pandas.DataFrame.ewm  Calling ewm with DataFrames.
pandas.Series.mean  Aggregating mean for Series.
pandas.DataFrame.mean  Aggregating mean for DataFrame.

Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations
for the Numba engine.

pandas.core.window.ewm.ExponentialMovingWindow.std

ExponentialMovingWindow.std(bias=False, *args, **kwargs)

Calculate the ewm (exponential weighted moment) standard deviation.

Parameters

bias  [bool, default False] Use a standard estimation bias correction.

*args  For NumPy compatibility and will not have an effect on the result.

**kwargs  For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame  Return type is the same as the original object.

See also:

pandas.Series.ewm  Calling ewm with Series data.
pandas.DataFrame.ewm  Calling ewm with DataFrames.
pandas.Series.std  Aggregating std for Series.
pandas.DataFrame.std  Aggregating std for DataFrame.

pandas.core.window.ewm.ExponentialMovingWindow.var

ExponentialMovingWindow.var(bias=False, *args, **kwargs)

Calculate the ewm (exponential weighted moment) variance.

Parameters

bias  [bool, default False] Use a standard estimation bias correction.

*args  For NumPy compatibility and will not have an effect on the result.

**kwargs  For NumPy compatibility and will not have an effect on the result.

Returns
Series or DataFrame  Return type is the same as the original object.

See also:

- pandas.Series.ewm  Calling ewm with Series data.
- pandas.DataFrame.ewm  Calling ewm with DataFrames.
- pandas.Series.var  Aggregating var for Series.
- pandas.DataFrame.var  Aggregating var for DataFrame.

**pandas.core.window.ewm.ExponentialMovingWindow.corr**

ExponentialMovingWindow.corr(other=None, pairwise=None, **kwargs)

Calculate the ewm (exponential weighted moment) sample correlation.

**Parameters**

- other  [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.
- pairwise  [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.
- **kwargs  For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame  Return type is the same as the original object.

See also:

- pandas.Series.ewm  Calling ewm with Series data.
- pandas.DataFrame.ewm  Calling ewm with DataFrames.
- pandas.Series.corr  Aggregating corr for Series.
- pandas.DataFrame.corr  Aggregating corr for DataFrame.

**pandas.core.window.ewm.ExponentialMovingWindow.cov**

ExponentialMovingWindow.cov(other=None, pairwise=None, bias=False, **kwargs)

Calculate the ewm (exponential weighted moment) sample covariance.

**Parameters**

- other  [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.
- pairwise  [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.
- bias  [bool, default False] Use a standard estimation bias correction.
- **kwargs  For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame  Return type is the same as the original object.

See also:

- pandas.Series.ewm  Calling ewm with Series data.
3.9.5 Window indexer

Base class for defining custom window boundaries.

```python
def pandas.api.indexers.BaseIndexer(
    index_array=None,
    window_size=0,
    **kwargs

    Base class for window bounds calculations.

    Methods

    get_window_bounds(num_values=0,
                       min_periods=None,
                       center=None,
                       closed=None)

    Computes the bounds of a window.

    Parameters

    num_values [int, default 0] number of values that will be aggregated over
    window_size [int, default 0] the number of rows in a window
    min_periods [int, default None] min_periods passed from the top level rolling API
    center [bool, default None] center passed from the top level rolling API
    closed [str, default None] closed passed from the top level rolling API

    Returns

    A tuple of ndarray[int64],s, indicating the boundaries of each window
```
pandas.api.indexers.FixedForwardWindowIndexer

class pandas.api.indexers.FixedForwardWindowIndexer(index_array=None, window_size=0, **kwargs)

Creates window boundaries for fixed-length windows that include the current row.

Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0

>>> indexer = pd.api.indexers.FixedForwardWindowIndexer(window_size=2)
>>> df.rolling(window=indexer, min_periods=1).sum()
   B
0  1.0
1  3.0
2  2.0
3  4.0
4  4.0
```

Methods

get_window_bounds([num_values, min_periods, ...]) Computes the bounds of a window.

pandas.api.indexers.FixedForwardWindowIndexer.get_window_bounds

FixedForwardWindowIndexer.get_window_bounds(num_values=0, min_periods=None, center=None, closed=None)

Computes the bounds of a window.

Parameters

- **num_values** [int, default 0] number of values that will be aggregated over
- **window_size** [int, default 0] the number of rows in a window
- **min_periods** [int, default None] min_periods passed from the top level rolling API
- **center** [bool, default None] center passed from the top level rolling API
- **closed** [str, default None] closed passed from the top level rolling API
- **win_type** [str, default None] win_type passed from the top level rolling API

Returns

A tuple of ndarray[int64], indicating the boundaries of each window
pandas.api.indexers.VariableOffsetWindowIndexer

class pandas.api.indexers.VariableOffsetWindowIndexer(index_array=None, window_size=0, index=None, offset=None, **kwargs)

Calculate window boundaries based on a non-fixed offset such as a BusinessDay

Methods

get_window_bounds([num_values, min_periods, ...])  Computes the bounds of a window.

pandas.api.indexers.VariableOffsetWindowIndexer.get_window_bounds

VariableOffsetWindowIndexer.get_window_bounds(num_values=0, min_periods=None, center=None, closed=None)

Computes the bounds of a window.

Parameters

- num_values  [int, default 0] number of values that will be aggregated over
- window_size  [int, default 0] the number of rows in a window
- min_periods  [int, default None] min_periods passed from the top level rolling API
- center  [bool, default None] center passed from the top level rolling API
- closed  [str, default None] closed passed from the top level rolling API
- win_type  [str, default None] win_type passed from the top level rolling API

Returns

A tuple of ndarray[int64]s, indicating the boundaries of each window

3.10 GroupBy

GroupBy objects are returned by groupby calls: pandas.DataFrame.groupby(), pandas.Series.groupby(), etc.

3.10.1 Indexing, iteration

<table>
<thead>
<tr>
<th>GroupBy.<strong>iter</strong>()</th>
<th>Groupby iterator.</th>
</tr>
</thead>
<tbody>
<tr>
<td>GroupBy.groups</td>
<td>Dict {group name -&gt; group labels}.</td>
</tr>
<tr>
<td>GroupBy.indices</td>
<td>Dict {group name -&gt; group indices}.</td>
</tr>
<tr>
<td>GroupBy.get_group(name[, obj])</td>
<td>Construct DataFrame from group with provided name.</td>
</tr>
</tbody>
</table>
**pandas: powerful Python data analysis toolkit, Release 1.3.2**

**pandas.core.groupby.GroupBy.__iter__**

GroupBy.__iter__()

Groupby iterator.

Returns

Generator yielding sequence of (name, subsetted object)
for each group

**pandas.core.groupby.GroupBy.groups**

property GroupBy.groups

Dict {group name -> group labels}.

**pandas.core.groupby.GroupBy.indices**

property GroupBy.indices

Dict {group name -> group indices}.

**pandas.core.groupby.GroupBy.get_group**

GroupBy.get_group(name, obj=None)

Construct DataFrame from group with provided name.

Parameters

- name [object] The name of the group to get as a DataFrame.
- obj [DataFrame, default None] The DataFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used.

Returns

- group [same type as obj]

**pandas.Grouper**

class pandas.Grouper(*args, **kwargs)

A Grouper allows the user to specify a groupby instruction for an object.

This specification will select a column via the key parameter, or if the level and/or axis parameters are given, a level of the index of the target object.

If axis and/or level are passed as keywords to both Grouper and groupby, the values passed to Grouper take precedence.

Parameters

- key [str, defaults to None] Groupby key, which selects the grouping column of the target.
- level [name/number, defaults to None] The level for the target index.
- freq [str / frequency object, defaults to None] This will groupby the specified frequency if the target selection (via key or level) is a datetime-like object. For full specification of
available frequencies, please see here.

**axis** [str, int, defaults to 0] Number/name of the axis.

**sort** [bool, default to False] Whether to sort the resulting labels.

**closed** [‘left’ or ‘right’] Closed end of interval. Only when freq parameter is passed.

**label** [‘left’ or ‘right’] Interval boundary to use for labeling. Only when freq parameter is passed.

**convention** [‘start’, ‘end’, ‘e’, ‘s’] If grouper is PeriodIndex and freq parameter is passed.

**base** [int, default 0] Only when freq parameter is passed. For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0.

Deprecated since version 1.1.0: The new arguments that you should use are ‘offset’ or ‘origin’.

**loffset** [str, DateOffset, timedelta object] Only when freq parameter is passed.

Deprecated since version 1.1.0: loffset is only working for .resample(...) and not for Grouper (GH28302). However, loffset is also deprecated for .resample(...) See: DataFrame.resample

**origin** [‘epoch’, ‘start’, ‘start_day’, ‘end’, ‘end_day’], Timestamp] or str, default ‘start’ The timestamp on which to adjust the grouping. The timezone of origin must match the timezone of the index. If a timestamp is not used, these values are also supported:

- ‘epoch’: origin is 1970-01-01
- ‘start’: origin is the first value of the timeseries
- ‘start_day’: origin is the first day at midnight of the timeseries

New in version 1.1.0.

- ‘end’: origin is the last value of the timeseries
- ‘end_day’: origin is the ceiling midnight of the last day

New in version 1.3.0.

**offset** [Timedelta or str, default is None] An offset timedelta added to the origin.

New in version 1.1.0.

**dropna** [bool, default True] If True, and if group keys contain NA values, NA values together with row/column will be dropped. If False, NA values will also be treated as the key in groups.

New in version 1.2.0.

**Returns**

A specification for a groupby instruction
Examples

Syntactic sugar for `df.groupby('A')`

```python
>>> df = pd.DataFrame(
...     {...
...         "Animal": ["Falcon", "Parrot", "Falcon", "Falcon", "Parrot"],
...         "Speed": [100, 5, 200, 300, 15],
...     }...
...)
>>> df
   Animal  Speed
0  Falcon    100
1    Parrot     5
2  Falcon    200
3  Falcon    300
4    Parrot    15
>>> df.groupby(pd.Grouper(key="Animal")).mean()
Animal
Falcon    200.0
Parrot    10.0
```

Specify a resample operation on the column ‘Publish date’

```python
>>> df = pd.DataFrame(
...     {...
...         "Publish date": [
...             pd.Timestamp("2000-01-02"),
...             pd.Timestamp("2000-01-02"),
...             pd.Timestamp("2000-01-09"),
...             pd.Timestamp("2000-01-16"),
...         ],
...         "ID": [0, 1, 2, 3],
...         "Price": [10, 20, 30, 40]
...     }...
...)
>>> df
   Publish date  ID  Price
0  2000-01-02    0    10
1  2000-01-02    1    20
2  2000-01-09    2    30
3  2000-01-16    3    40
>>> df.groupby(pd.Grouper(key="Publish date", freq="1W")).mean()
   ID  Price
Publish date
2000-01-02  0.5  15.0
2000-01-09  2.0  30.0
2000-01-16  3.0  40.0
```

If you want to adjust the start of the bins based on a fixed timestamp:

```python
>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
>>> ts
2000-10-01 23:30:00    0
2000-10-01 23:37:00    3
(continues on next page)
```
ts.groupby(pd.Grouper(freq='17min')).sum()
2000-10-01 23:14:00 0
2000-10-01 23:31:00 9
2000-10-01 23:48:00 21
2000-10-02 00:05:00 54
2000-10-02 00:22:00 24
Freq: 17T, dtype: int64

If you want to adjust the start of the bins with an offset Timedelta, the two following lines are equivalent:

[snip]
2000-10-02 00:07:00 39
2000-10-02 00:24:00 24
Freq: 17T, dtype: int64

</tbody>
</table>

pandas.core.groupby.GroupBy.apply

GroupBy. **apply** *(func, *args, **kwargs)*

Apply function `func` group-wise and combine the results together.

The function passed to `apply` must take a dataframe as its first argument and return a DataFrame, Series or scalar. `apply` will then take care of combining the results back together into a single dataframe or series. `apply` is therefore a highly flexible grouping method.

While `apply` is a very flexible method, its downside is that using it can be quite a bit slower than using more specific methods like `agg` or `transform`. Pandas offers a wide range of method that will be much faster than using `apply` for their specific purposes, so try to use them before reaching for `apply`.

**Parameters**

- `func` [callable] A callable that takes a dataframe as its first argument, and returns a dataframe, a series or a scalar. In addition the callable may take positional and keyword arguments.
- `args, kwargs` [tuple and dict] Optional positional and keyword arguments to pass to `func`.

**Returns**

- `applied` [Series or DataFrame]
See also:

- `pipe` Apply function to the full GroupBy object instead of to each group.
- `aggregate` Apply aggregate function to the GroupBy object.
- `transform` Apply function column-by-column to the GroupBy object.
- `Series.apply` Apply a function to a Series.
- `DataFrame.apply` Apply a function to each row or column of a DataFrame.

Notes

In the current implementation `apply` calls `func` twice on the first group to decide whether it can take a fast or slow code path. This can lead to unexpected behavior if `func` has side-effects, as they will take effect twice for the first group.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`, see the examples below.

Examples

```
>>> df = pd.DataFrame({'A': 'a a b'.split(),
...                   'B': [1,2,3],
...                   'C': [4,6,5]})

>>> g = df.groupby('A')

Notice that `g` has two groups, `a` and `b`. Calling `apply` in various ways, we can get different grouping results:

Example 1: below the function passed to `apply` takes a DataFrame as its argument and returns a DataFrame. `apply` combines the result for each group together into a new DataFrame:

```
>>> g[['B', 'C']].apply(lambda x: x / x.sum())
   B    C
0  0.333333  0.4
1  0.666667  0.6
2  1.000000  1.0
```

Example 2: The function passed to `apply` takes a DataFrame as its argument and returns a Series. `apply` combines the result for each group together into a new DataFrame.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`.

```
>>> g[['B', 'C']].apply(lambda x: x.astype(float).max() - x.min())
   B    C
A
a  1.0  2.0
b  0.0  0.0
```

Example 3: The function passed to `apply` takes a DataFrame as its argument and returns a scalar. `apply` combines the result for each group together into a Series, including setting the index as appropriate:

```
>>> g.apply(lambda x: x.C.max() - x.B.min())
   A
a  5
b  2
dtype: int64
```
pandas: powerful Python data analysis toolkit, Release 1.3.2

**pandas.core.groupby.GroupBy.agg**

`GroupBy.agg(func, *args, **kwargs)`

**pandas.core.groupby.SeriesGroupBy.aggregate**

`SeriesGroupBy.aggregate(func=None, *args, engine=None, engine_kwargs=None, **kwargs)`

Aggregate using one or more operations over the specified axis.

**Parameters**

- `func` [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.

  Accepted combinations are:

  - function
  - string function name
  - list of functions and/or function names, e.g. [np.sum, 'mean']
  - dict of axis labels -> functions, function names or list of such.

  Can also accept a Numba JIT function with `engine='numba'` specified. Only passing a single function is supported with this engine.

  If the 'numba' engine is chosen, the function must be a user defined function with values and index as the first and second arguments respectively in the function signature. Each group’s index will be passed to the user defined function and optionally available for use.

  Changed in version 1.1.0.

- `*args` Positional arguments to pass to `func`.

- `engine` [str, default None]

  - 'cython': Runs the function through C-extensions from cython.
  - 'numba': Runs the function through JIT compiled code from numba.
  - None: Defaults to 'cython' or globally setting `compute.use_numba`

  New in version 1.1.0.

- `engine_kwargs` [dict, default None]

  - For 'cython' engine, there are no accepted `engine_kwargs`
  - For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be True or False. The default `engine_kwargs` for the 'numba' engine is {"nopython": True, 'nogil': False, 'parallel': False} and will be applied to the function.

  New in version 1.1.0.

- `**kwargs` Keyword arguments to be passed into `func`.

**Returns**

Series

See also:

- `Series.groupby.apply` Apply function `func` group-wise and combine the results together.
**Series.groupby.transform** Aggregate using one or more operations over the specified axis.

**Series.aggregate** Transforms the Series on each group based on the given function.

**Notes**

When using `engine='numba'`, there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`, see the examples below.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4])

>>> s
0  1
1  2
2  3
3  4
dtype: int64

>>> s.groupby([1, 1, 2, 2]).min()
1  1
2  3
dtype: int64

>>> s.groupby([1, 1, 2, 2]).agg('min')
1  1
2  3
dtype: int64

>>> s.groupby([1, 1, 2, 2]).agg(['min', 'max'])
    min  max
1    1    2
2    3    4

The output column names can be controlled by passing the desired column names and aggregations as keyword arguments.

```python
defining argument names and aggregations as keywords

```python
>>> s.groupby([1, 1, 2, 2]).agg(
...    minimum='min',
...    maximum='max',
...)

<table>
<thead>
<tr>
<th>minimum</th>
<th>maximum</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>

Changed in version 1.3.0: The resulting dtype will reflect the return value of the aggregating function.

3.10. GroupBy
pandas: powerful Python data analysis toolkit, Release 1.3.2

```python
>>> s.groupby([1, 1, 2, 2]).agg(lambda x: x.astype(float).min())
1   1.0
2   3.0
dtype: float64
```

### pandas.core.groupby.DataFrameGroupBy.aggregate

**DataFrameGroupBy**. aggregate (func=None, *args, engine=None, engine_kwargs=None, **kwargs)

Aggregate using one or more operations over the specified axis.

**Parameters**

- **func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

  Accepted combinations are:
  - function
  - string function name
  - list of functions and/or function names, e.g. [np.sum, 'mean']
  - dict of axis labels -> functions, function names or list of such.

  Can also accept a Numba JIT function with engine='numba' specified. Only passing a single function is supported with this engine.

  If the 'numba' engine is chosen, the function must be a user defined function with values and index as the first and second arguments respectively in the function signature. Each group’s index will be passed to the user defined function and optionally available for use.

  Changed in version 1.1.0.

- **args** Positional arguments to pass to func.

- **engine** [str, default None]

  - 'cython': Runs the function through C-extensions from cython.
  - 'numba': Runs the function through JIT compiled code from numba.
  - None: Defaults to 'cython' or globally setting compute.use_numba

  New in version 1.1.0.

- **engine_kwargs** [dict, default None]

  - For 'cython' engine, there are no accepted engine_kwargs
  - For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False} and will be applied to the function

  New in version 1.1.0.

- **kwargs** Keyword arguments to be passed into func.

**Returns**

DataFrame
See also:

- **DataFrame.groupby.apply** Apply function `func` group-wise and combine the results together.
- **DataFrame.groupby.transform** Aggregate using one or more operations over the specified axis.
- **DataFrame.aggregate** Transforms the Series on each group based on the given function.

**Notes**

When using `engine='numba'`, there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See [Mutating with User Defined Function (UDF) methods](#) for more details.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`, see the examples below.

**Examples**

```python
>>> df = pd.DataFrame(
...     {
...         "A": [1, 1, 2, 2],
...         "B": [1, 2, 3, 4],
...         "C": [0.362838, 0.227877, 1.267767, -0.562860],
...     }
... )

>>> df
   A    B    C
0  1  1.0  0.362838
1  1  2.0  0.227877
2  2  3.0  1.267767
3  2  4.0 -0.562860

The aggregation is for each column.

```python
>>> df.groupby('A').agg('min')
   B    C
A  1.0  0.227877
  2.0 -0.562860
```  

Multiple aggregations

```python
>>> df.groupby('A').agg(['min', 'max'])
   B     C
min max  
A  1.0  2.0  0.362838
  2.0  4.0 -0.562860
```  

Select a column for aggregation
Different aggregations per column

```python
>>> df.groupby('A').agg({'B': ['min', 'max'], 'C': 'sum'})
B   C
min max sum
A  1  2  0.590715
  2  4  0.704907
```

To control the output names with different aggregations per column, pandas supports “named aggregation”

```python
>>> df.groupby("A").agg(
    ... b_min=pd.NamedAgg(column="B", aggfunc="min"),
    ... c_sum=pd.NamedAgg(column="C", aggfunc="sum"))
```

- The keywords are the output column names
- The values are tuples whose first element is the column to select and the second element is the aggregation to apply to that column. Pandas provides the `pandas.NamedAgg` namedtuple with the fields `['column', 'aggfunc']` to make it clearer what the arguments are. As usual, the aggregation can be a callable or a string alias.

See `Named aggregation` for more.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the aggregating function.

```python
>>> df.groupby("A")["B"].agg(lambda x: x.astype(float).min())
B
A  1
  2
```

---

**pandas.core.groupby.SeriesGroupBy.transform**

`SeriesGroupBy.transform(func, *args, engine=None, engine_kwargs=None, **kwargs)`

Call function producing a like-indexed Series on each group and return a Series having the same indexes as the original object filled with the transformed values

**Parameters**

- `f` [function] Function to apply to each group.

  Can also accept a Numba JIT function with `engine='numba'` specified.

  If the 'numba' engine is chosen, the function must be a user defined function with `values` and `index` as the first and second arguments respectively in the function signature. Each group’s index will be passed to the user defined function and optionally available for use.

  Changed in version 1.1.0.
*args  Positional arguments to pass to func.

**kwargs  Keyword arguments to be passed into func.

Returns  Series

See also:

**Series.groupby.apply**  Apply function func group-wise and combine the results together.

**Series.groupby.aggregate**  Aggregate using one or more operations over the specified axis.

**Series.transform**  Call func on self producing a Series with transformed values.

Notes

Each group is endowed the attribute ‘name’ in case you need to know which group you are working on.

The current implementation imposes three requirements on f:

- f must return a value that either has the same shape as the input subframe or can be broadcast to the shape of the input subframe. For example, if f returns a scalar it will be broadcast to have the same shape as the input subframe.
- If this is a DataFrame, f must support application column-by-column in the subframe. If f also supports application to the entire subframe, then a fast path is used starting from the second chunk.
- f must not mutate groups. Mutation is not supported and may produce unexpected results. See Mutating with User Defined Function (UDF) methods for more details.

When using engine='numba', there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed func, see the examples below.
Examples

```python
>>> df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
...                          'foo', 'bar'],
...                   'B' : ['one', 'one', 'two', 'three',
...                          'two', 'two'],
...                   'C' : [1, 5, 5, 2, 5, 5],
...                   'D' : [2.0, 5., 8., 1., 2., 9.]})
>>> grouped = df.groupby('A')
>>> grouped.transform(lambda x: (x - x.mean()) / x.std())
          C         D
0 -1.154701 -0.577350
1  0.577350  0.000000
2  0.577350  1.154701
3 -1.154701 -1.000000
4  0.577350 -0.577350
5  0.577350  1.000000
```

Broadcast result of the transformation

```python
>>> grouped.transform(lambda x: x.max() - x.min())
          C         D
0   4.000000  6.000000
1   3.000000  8.000000
2   4.000000  6.000000
3   3.000000  8.000000
4   4.000000  6.000000
5   3.000000  8.000000
```

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed func, for example:

```python
>>> grouped[['C', 'D']].transform(lambda x: x.astype(int).max())
          C         D
0   5  8
1   5  9
2   5  8
3   5  9
4   5  8
5   5  9
```

pandas.core.groupby.DataFrameGroupBy.transform

DataFrameGroupBy.transform(func, *args, engine=None, engine_kws=None, **kwargs)

Call function producing a like-indexed DataFrame on each group and return a DataFrame having the same indexes as the original object filled with the transformed values.

Parameters

  f [function] Function to apply to each group.

Can also accept a Numba JIT function with engine='numba' specified.

If the 'numba' engine is chosen, the function must be a user defined function with values and index as the first and second arguments respectively in the function signature. Each group’s index will be passed to the user defined function and optionally available for use.

Changed in version 1.1.0.
*args  Positional arguments to pass to func.

engine  [str, default None]
    - 'cython': Runs the function through C-extensions from cython.
    - 'numba': Runs the function through JIT compiled code from numba.
    - None: Defaults to 'cython' or the global setting compute.use_numba

    New in version 1.1.0.

engine_kwargs  [dict, default None]
    - For 'cython' engine, there are no accepted engine_kwargs
    - For 'numba' engine, the engine can accept nopython, nogil and parallel
dictionary keys. The values must either be True or False. The default
engine_kwargs for the 'numba' engine is {'nopython': True,
'nogil': False, 'parallel': False} and will be applied to the func-
tion

    New in version 1.1.0.

**kwargs  Keyword arguments to be passed into func.

Returns

DataFrame

See also:

DataFrame.groupby.apply  Apply function func group-wise and combine the results together.
DataFrame.groupby.aggregate  Aggregate using one or more operations over the specified axis.
DataFrame.transform  Call func on self producing a DataFrame with transformed values.

Notes

Each group is endowed the attribute ‘name’ in case you need to know which group you are working on.

The current implementation imposes three requirements on f:
    - f must return a value that either has the same shape as the input subframe or can be broadcast to the shape
of the input subframe. For example, if f returns a scalar it will be broadcast to have the same shape as the
input subframe.
    - if this is a DataFrame, f must support application column-by-column in the subframe. If f also supports
application to the entire subframe, then a fast path is used starting from the second chunk.
    - f must not mutate groups. Mutation is not supported and may produce unexpected results. See Mutating
with User Defined Function (UDF) methods for more details.

When using engine='numba', there will be no “fall back” behavior internally. The group data and group
index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts
will be tried.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed func, see the examples
below.
Examples

```python
>>> df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar', 'foo', 'bar'],
                   'B' : ['one', 'one', 'two', 'three', 'two', 'two'],
                   'C' : [1, 5, 5, 2, 5, 5],
                   'D' : [2.0, 5., 8., 1., 2., 9.])

>>> grouped = df.groupby('A')

>>> grouped.transform(lambda x: (x - x.mean()) / x.std())

<td>5</td>
<td>0.577350</td>
<td>1.000000</td>
</tr>
</tbody>
</table>

Broadcast result of the transformation

```python
>>> grouped.transform(lambda x: x.max() - x.min())

<table>
<thead>
<tr>
<th></th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>6.0</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>8.0</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>8.0</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>8.0</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>6.0</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
<td>8.0</td>
</tr>
</tbody>
</table>

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed func, for example:

```python
>>> grouped[['C', 'D']].transform(lambda x: x.astype(int).max())

<table>
<thead>
<tr>
<th></th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>5</td>
<td>8</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>9</td>
</tr>
<tr>
<td>2</td>
<td>5</td>
<td>8</td>
</tr>
<tr>
<td>3</td>
<td>5</td>
<td>9</td>
</tr>
<tr>
<td>4</td>
<td>5</td>
<td>8</td>
</tr>
<tr>
<td>5</td>
<td>5</td>
<td>9</td>
</tr>
</tbody>
</table>

pandas.core.groupby.GroupBy.pipe

GroupBy.pipe(func, *args, **kwargs)

Apply a function func with arguments to this GroupBy object and return the function’s result.

Use .pipe when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing

```python
>>> h(g(f(df.groupby('group')), arg1=a), arg2=b, arg3=c)
```

You can write

```python
>>> (df.groupby('group')
... .pipe(f)
... .pipe(g, arg1=a)
... .pipe(h, arg2=b, arg3=c))
```
which is much more readable.

Parameters

- **func** [callable or tuple of (callable, str)] Function to apply to this GroupBy object or, alternatively, a (callable, data_keyword) tuple where data_keyword is a string indicating the keyword of callable that expects the GroupBy object.
- **args** [iterable, optional] Positional arguments passed into func.
- **kwargs** [dict, optional] A dictionary of keyword arguments passed into func.

Returns

- **object** [the return type of func.]

See also:

- **Series.pipe** Apply a function with arguments to a series.
- **DataFrame.pipe** Apply a function with arguments to a dataframe.
- **apply** Apply function to each group instead of to the full GroupBy object.

Notes

See more here

Examples

```python
>>> df = pd.DataFrame({'A': 'a b a b'.split(), 'B': [1, 2, 3, 4]})
>>> df
   A  B
0  a  1
1  b  2
2  a  3
3  b  4

To get the difference between each groups maximum and minimum value in one pass, you can do

```python
>>> df.groupby('A').pipe(lambda x: x.max() - x.min())
   B
A
a  2
b  2
```

<tr>
<td><code>all()</code></td>
<td>Return True if all values in the group are truthful, else False.</td>
</tr>
</tbody>
</table>

**Parameters**

- `skipna` [bool, default True] Flag to ignore nan values during truth testing.

**Returns**

- **Series or DataFrame** DataFrame or Series of boolean values, where a value is True if all elements are True within its respective group, False otherwise.

**See also:**

- **Series.groupby** Apply a function groupby to a Series.
- **DataFrame.groupby** Apply a function groupby to each row or column of a DataFrame.
pandas.core.groupby.GroupBy.any

GroupBy.any (skipna=True)
Return True if any value in the group is truthful, else False.

Parameters

skipna [bool, default True] Flag to ignore nan values during truth testing.

Returns

Series or DataFrame DataFrame or Series of boolean values, where a value is True if any element is True within its respective group, False otherwise.

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.bfill

GroupBy.bfill (limit=None)
Backward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:
Series.backfill Backward fill the missing values in the dataset.
DataFrame.backfill Backward fill the missing values in the dataset.
Series.fillna Fill NaN values of a Series.
DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.GroupBy.backfill

GroupBy.backfill (limit=None)
Backward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:
Series.backfill Backward fill the missing values in the dataset.
DataFrame.backfill Backward fill the missing values in the dataset.
Series.fillna Fill NaN values of a Series.
DataFrame.fillna Fill NaN values of a DataFrame.
**pandas.core.groupby.GroupBy.count**

`GroupBy.count()`  
Compute count of group, excluding missing values.  
**Returns**  
- **Series or DataFrame**: Count of values within each group.  
**See also:**  
- `Series.groupby` Apply a function groupby to a Series.  
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.GroupBy.cumcount**

`GroupBy.cumcount(ascending=True)`  
Number each item in each group from 0 to the length of that group - 1.  
Essentially this is equivalent to  

```python  
self.apply(lambda x: pd.Series(np.arange(len(x)), x.index))  
```

**Parameters**  
- **ascending**: [bool, default `True`] If False, number in reverse, from length of group - 1 to 0.

**Returns**  
- **Series**: Sequence number of each element within each group.  
**See also:**  
- `ngroup` Number the groups themselves.

**Examples**

```python  
>>> df = pd.DataFrame([[a], [a], [a], [b], [b], [a]],  
        columns=['A'])  
>>> df  
   A  
0  a  
1  a  
2  a  
3  b  
4  b  
5  a  
>>> df.groupby('A').cumcount()  
0 0  
1 1  
2 2  
3 0  
4 1  
5 3  
```

```python  
>>> df.groupby('A').cumcount(ascending=False)  
0 3  
1 2  
2 1  
3 1  
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.2

(continued from previous page)

```
4  0
5  0
dtype: int64
```

**pandas.core.groupby.GroupBy.cummax**

GroupBy.cummax(axis=0, **kwargs)
Cumulative max for each group.

Returns
Series or DataFrame

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.GroupBy.cummin**

GroupBy.cummin(axis=0, **kwargs)
Cumulative min for each group.

Returns
Series or DataFrame

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.GroupBy.cumprod**

GroupBy.cumprod(axis=0, *args, **kwargs)
Cumulative product for each group.

Returns
Series or DataFrame

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.GroupBy.cumsum**

GroupBy.cumsum(axis=0, *args, **kwargs)
Cumulative sum for each group.

Returns
Series or DataFrame

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.
pandas.core.groupby.GroupBy.ffill

**GroupBy.ffill**(limit=None)
Forward fill the values.

**Parameters**

- **limit** [int, optional] Limit of how many values to fill.

**Returns**

- **Series or DataFrame** Object with missing values filled.

**See also:**

- **Series.pad** Returns Series with minimum number of char in object.
- **DataFrame.pad** Object with missing values filled or None if inplace=True.
- **Series.fillna** Fill NaN values of a Series.
- **DataFrame.fillna** Fill NaN values of a DataFrame.

pandas.core.groupby.GroupBy.first

**GroupBy.first**(numeric_only=False, min_count=-1)
Compute first of group values.

**Parameters**

- **numeric_only** [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
- **min_count** [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

**Returns**

- **Series or DataFrame** Computed first of values within each group.

pandas.core.groupby.GroupBy.head

**GroupBy.head**(n=5)
Return first n rows of each group.

Similar to .apply(lambda x: x.head(n)), but it returns a subset of rows from the original DataFrame with original index and order preserved (as_index flag is ignored).

Does not work for negative values of n.

**Returns**

- **Series or DataFrame**

**See also:**

- **Series.groupby** Apply a function groupby to a Series.
- **DataFrame.groupby** Apply a function groupby to each row or column of a DataFrame.
Examples

```python
def = pd.DataFrame([[1, 2], [1, 4], [5, 6]],
...     columns=['A', 'B'])
def.groupby('A').head(1)
     A  B
0  1  2
2  5  6
def.groupby('A').head(-1)
Empty DataFrame
Columns: [A, B]
Index: []
```

**pandas.core.groupby.GroupBy.last**

GroupBy.last \((\text{numeric\_only}=\text{False}, \text{min\_count}=-1)\)

Compute last of group values.

**Parameters**

- **numeric_only** [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
- **min_count** [int, default -1] The required number of valid values to perform the operation. If fewer than \text{min\_count} non-NA values are present the result will be NA.

**Returns**

- Series or DataFrame Computed last of values within each group.

**pandas.core.groupby.GroupBy.max**

GroupBy.max \((\text{numeric\_only}=\text{False}, \text{min\_count}=-1)\)

Compute max of group values.

**Parameters**

- **numeric_only** [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
- **min_count** [int, default -1] The required number of valid values to perform the operation. If fewer than \text{min\_count} non-NA values are present the result will be NA.

**Returns**

- Series or DataFrame Computed max of values within each group.

**pandas.core.groupby.GroupBy.mean**

GroupBy.mean \((\text{numeric\_only}<\text{no\_default}>\)  

Compute mean of groups, excluding missing values.

**Parameters**

- **numeric_only** [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

**Returns**

- pandas.Series or pandas.DataFrame
See also:

**Series.groupby** Apply a function groupby to a Series.

**DataFrame.groupby** Apply a function groupby to each row or column of a DataFrame.

### Examples

```python
def = pd.DataFrame({'A': [1, 1, 2, 1, 2],
    'B': [np.nan, 2, 3, 4, 5],
    'C': [1, 2, 1, 1, 2]}, columns=['A', 'B', 'C'])
```

Groupby one column and return the mean of the remaining columns in each group.

```python
>>> df.groupby('A').mean()

B     C
A
1  3.0  1.333333
2  4.0  1.500000
```

Groupby two columns and return the mean of the remaining column.

```python
>>> df.groupby(['A', 'B']).mean()

C
A B
1 2.0 2.0
   4.0 1.0
2 3.0 1.0
   5.0 2.0
```

Groupby one column and return the mean of only particular column in the group.

```python
>>> df.groupby('A')['B'].mean()

A
1  3.0
2  4.0
Name: B, dtype: float64
```

### pandas.core.groupby.GroupBy.median

**GroupBy.median** (*numeric_only*=<no_default>)

Compute median of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

**Parameters**

- **numeric_only** [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

**Returns**

- **Series or DataFrame** Median of values within each group.

See also:

**Series.groupby** Apply a function groupby to a Series.

**DataFrame.groupby** Apply a function groupby to each row or column of a DataFrame.
pandas.core.groupby.GroupBy.min

GroupBy.min(numeric_only=False, min_count=-1)
Compute min of group values.

Parameters
  numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
  min_count [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns
  Series or DataFrame Computed min of values within each group.

pandas.core.groupby.GroupBy.ngroup

GroupBy.ngroup(ascending=True)
Number each group from 0 to the number of groups - 1.

This is the enumerative complemen of cumcount. Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the groupby object, not the order they are first observed.

Parameters
  ascending [bool, default True] If False, number in reverse, from number of group - 1 to 0.

Returns
  Series Unique numbers for each group.

See also:
cumcount Number the rows in each group.

Examples

```python
>>> df = pd.DataFrame({'A': list('aaabba'))
>>> df
   A
0  a
1  a
2  a
3  b
4  b
5  a
>>> df.groupby('A').ngroup()
0   0
1   0
2   0
3   1
4   1
5   0
dtype: int64
>>> df.groupby('A').ngroup(ascending=False)
0   1
1   1
2   1
3   0
```

(continues on next page)
pandas.core.groupby.GroupBy.nth

GroupBy.nth(n, dropna=None)
Take the nth row from each group if n is an int, or a subset of rows if n is a list of ints.

If dropna, will take the nth non-null row, dropna is either ‘all’ or ‘any’; this is equivalent to calling
dropna(how=dropna) before the groupby.

Parameters

n [int or list of ints] A single nth value for the row or a list of nth values.
dropna [{‘any’, ‘all’, None}, default None] Apply the specified dropna operation before
counting which row is the nth row.

Returns

Series or DataFrame N-th value within each group.

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

Examples

```python
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
... 'B': [np.nan, 2, 3, 4, 5]}, columns=['A', 'B'])
>>> g = df.groupby('A')
>>> g.nth(0)
   B
A
1  NaN
2  3.0
>>> g.nth(1)
   B
A
1  2.0
2  5.0
>>> g.nth(-1)
   B
A
1  4.0
2  5.0
>>> g.nth([0, 1])
```
Specifying `dropna` allows count ignoring `NaN`

```python
>>> g.nth(0, dropna='any')
B
A
  1 2.0
  2 3.0
```

`NaNs` denote group exhausted when using `dropna`

```python
>>> g.nth(3, dropna='any')
B
A
  1 NaN
  2 NaN
```

Specifying `as_index=False` in `groupby` keeps the original index.

```python
>>> df.groupby('A', as_index=False).nth(1)
A  B
  1 2.0
  4 5.0
```

### pandas.core.groupby.GroupBy.ohlc

**GroupBy.ohlc()**  
Compute open, high, low and close values of a group, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

**Returns**

- **DataFrame**  
  Open, high, low and close values within each group.

**See also:**

- **Series.groupby**  
  Apply a function groupby to a Series.
- **DataFrame.groupby**  
  Apply a function groupby to each row or column of a DataFrame.

### pandas.core.groupby.GroupBy.pad

**GroupBy.pad(limit=None)**  
Forward fill the values.

**Parameters**

- **limit**  
  [int, optional] Limit of how many values to fill.

**Returns**

- **Series or DataFrame**  
  Object with missing values filled.

**See also:**
**Series.pad** Returns Series with minimum number of char in object.
**DataFrame.pad** Object with missing values filled or None if inplace=True.
**Series.fillna** Fill NaN values of a Series.
**DataFrame.fillna** Fill NaN values of a DataFrame.

**pandas.core.groupby.GroupBy.prod**

GroupBy.prod( numeric_only=<no_default>, min_count=0)
Compute prod of group values.

Parameters

- **numeric_only** [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
- **min_count** [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame  Computed prod of values within each group.

**pandas.core.groupby.GroupBy.rank**

GroupBy.rank( method='average', ascending=True, na_option='keep', pct=False, axis=0)
Provide the rank of values within each group.

Parameters

- **method** [{‘average’, ‘min’, ‘max’, ‘first’, ‘dense’}, default ‘average’]
  - average: average rank of group.
  - min: lowest rank in group.
  - max: highest rank in group.
  - first: ranks assigned in order they appear in the array.
  - dense: like ‘min’, but rank always increases by 1 between groups.
- **ascending** [bool, default True] False for ranks by high (1) to low (N).
- **na_option** [{‘keep’, ‘top’, ‘bottom’}, default ‘keep’]
  - keep: leave NA values where they are.
  - top: smallest rank if ascending.
  - bottom: smallest rank if descending.
- **pct** [bool, default False] Compute percentage rank of data within each group.
- **axis** [int, default 0] The axis of the object over which to compute the rank.

Returns

DataFrame with ranking of values within each group

See also:

- **Series.groupby** Apply a function groupby to a Series.
- **DataFrame.groupby** Apply a function groupby to each row or column of a DataFrame.
pandas.core.groupby.GroupBy.pct_change

GroupBy.pct_change(periods=1, fill_method='pad', limit=None, freq=None, axis=0)
Calculate pct_change of each value to previous entry in group.

Returns

Series or DataFrame  Percentage changes within each group.

See also:

Series.groupby  Apply a function groupby to a Series.
DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.size

GroupBy.size()
Compute group sizes.

Returns

DataFrame or Series  Number of rows in each group as a Series if as_index is True or a
DataFrame if as_index is False.

See also:

Series.groupby  Apply a function groupby to a Series.
DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.sem

GroupBy.sem(ddof=1)
Compute standard error of the mean of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

ddof  [int, default 1]  Degrees of freedom.

Returns

Series or DataFrame  Standard error of the mean of values within each group.

See also:

Series.groupby  Apply a function groupby to a Series.
DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.std

GroupBy.std(ddof=1)
Compute standard deviation of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

ddof  [int, default 1]  Degrees of freedom.

Returns

Series or DataFrame  Standard deviation of values within each group.

See also:

Series.groupby  Apply a function groupby to a Series.
**DataFrame.groupby** Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.GroupBy.sum**

GroupBy.sum(numeric_only=<no_default>, min_count=0)

Compute sum of group values.

**Parameters**

- numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
- min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

**Returns**

- Series or DataFrame Computed sum of values within each group.

**pandas.core.groupby.GroupBy.var**

GroupBy.var(ddof=1)

Compute variance of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

**Parameters**

- ddof [int, default 1] Degrees of freedom.

**Returns**

- Series or DataFrame Variance of values within each group.

**See also:**

- Series.groupby Apply a function groupby to a Series.
- DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.GroupBy.tail**

GroupBy.tail(n=5)

Return last n rows of each group.

Similar to .apply(lambda x: x.tail(n)), but it returns a subset of rows from the original DataFrame with original index and order preserved (as_index flag is ignored).

Does not work for negative values of n.

**Returns**

- Series or DataFrame

**See also:**

- Series.groupby Apply a function groupby to a Series.
- DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.
Examples

```
>>> df = pd.DataFrame([['a', 1], ['a', 2], ['b', 1], ['b', 2]],
                   columns=['A', 'B'])
>>> df.groupby('A').tail(1)
          A  B
1   a  2
3   b  2
>>> df.groupby('A').tail(-1)
Empty DataFrame
Columns: [A, B]
Index: []
```

The following methods are available in both SeriesGroupBy and DataFrameGroupBy objects, but may differ slightly, usually in that the DataFrameGroupBy version usually permits the specification of an axis argument, and often an argument indicating whether to restrict application to columns of a specific data type.

<table>

continues on next page
### DataFrameGroupBy.plot

Class implementing the `.plot` attribute for groupby objects.

### DataFrameGroupBy.quantile

Return group values at the given quantile, a la `numpy.percentile`.

### DataFrameGroupBy.rank

Provide the rank of values within each group.

### DataFrameGroupBy.resample

Provide resampling when using a TimeGrouper.

### DataFrameGroupBy.sample

Return a random sample of items from each group.

### DataFrameGroupBy.shift

Shift each group by periods observations.

### DataFrameGroupBy.size

Compute group sizes.

### DataFrameGroupBy.skew

Return unbiased skew over requested axis.

### DataFrameGroupBy.take

Return the elements in the given positional indices along an axis.

### DataFrameGroupBy.tshift

(DEPRECATED) Shift the time index, using the index’s frequency if available.

---

#### pandas.core.groupby.DataFrameGroupBy.all

**DataFrameGroupBy.all**

Return True if all values in the group are truthful, else False.

**Parameters**

- `skipna` [bool, default True] Flag to ignore nan values during truth testing.

**Returns**

- **Series or DataFrame**: DataFrame or Series of boolean values, where a value is True if all elements are True within its respective group, False otherwise.

**See also:**

- `Series.groupby` Apply a function groupby to a Series.
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.

---

#### pandas.core.groupby.DataFrameGroupBy.any

**DataFrameGroupBy.any**

Return True if any value in the group is truthful, else False.

**Parameters**

- `skipna` [bool, default True] Flag to ignore nan values during truth testing.

**Returns**

- **Series or DataFrame**: DataFrame or Series of boolean values, where a value is True if any element is True within its respective group, False otherwise.

**See also:**

- `Series.groupby` Apply a function groupby to a Series.
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.
pandas.core.groupby.DataFrameGroupBy.backfill

DataFrameGroupBy.backfill(limit=None)
Backward fill the values.

Parameters

- limit [int, optional] Limit of how many values to fill.

Returns

- Series or DataFrame Object with missing values filled.

See also:

Series.backfill Backward fill the missing values in the dataset.
DataFrame.backfill Backward fill the missing values in the dataset.
Series.fillna Fill NaN values of a Series.
DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.bfill

DataFrameGroupBy.bfill(limit=None)
Backward fill the values.

Parameters

- limit [int, optional] Limit of how many values to fill.

Returns

- Series or DataFrame Object with missing values filled.

See also:

Series.backfill Backward fill the missing values in the dataset.
DataFrame.backfill Backward fill the missing values in the dataset.
Series.fillna Fill NaN values of a Series.
DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.corr

property DataFrameGroupBy.corr
Compute pairwise correlation of columns, excluding NA/null values.

Parameters

- method [{‘pearson’, ‘kendall’, ‘spearman’} or callable] Method of correlation:
  - pearson : standard correlation coefficient
  - kendall : Kendall Tau correlation coefficient
  - spearman : Spearman rank correlation
  - callable: callable with input two 1d ndarrays and returning a float. Note that the returned matrix from corr will have 1 along the diagonals and will be symmetric regardless of the callable’s behavior.

- min_periods [int, optional] Minimum number of observations required per pair of columns to have a valid result.

Returns

- DataFrame Correlation matrix.
See also:

DataFrame.corrwith Compute pairwise correlation with another DataFrame or Series.
Series.corr Compute the correlation between two Series.

Examples

```python
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v

>>> df = pd.DataFrame([(0.2, 0.3), (0.0, 0.6), (0.6, 0.0), (0.2, 0.1)],
... columns=['dogs', 'cats'])

>>> df.corr(method=histogram_intersection)
dogs  cats
---+---
dogs 1.0 0.3
cats 0.3 1.0
```

pandas.core.groupby.DataFrameGroupBy.count

DataFrameGroupBy.count()  
Compute count of group, excluding missing values.  

Returns  
DataFrame Count of values within each group.

pandas.core.groupby.DataFrameGroupBy.cov

property DataFrameGroupBy.cov  
Compute pairwise covariance of columns, excluding NA/null values.  

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the covariance matrix of the columns of the DataFrame.  

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as NaN.  

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.  

Parameters  

min_periods [int, optional] Minimum number of observations required per pair of columns to have a valid result.  

ddof [int, default 1] Delta degrees of freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.  

New in version 1.1.0.  

Returns  
DataFrame The covariance matrix of the series of the DataFrame.  

See also:

Series.cov Compute covariance with another Series.
core.window.ExponentialMovingWindow.cov Exponential weighted sample covariance.
core.window.Expanding.cov Expanding sample covariance.
Rolling sample covariance.

Notes

Returns the covariance matrix of the DataFrame’s time series. The covariance is normalized by N-ddof.

For DataFrames that have Series that are missing data (assuming that data is missing at random) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.

Examples

```python
>>> df = pd.DataFrame([1, 2), (0, 3), (2, 0), (1, 1)],
...                       columns=['dogs', 'cats'])
>>> df.cov()
   dogs    cats
dogs  0.666667 -1.000000
cats -1.000000  1.666667
```

```python
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
...                       columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()
     a        b        c        d        e
a  0.998438 -0.020161  0.059277 -0.008943  0.014144
b -0.020161  1.059352 -0.008543 -0.024738  0.009826
c  0.059277 -0.008543  1.010670 -0.001486 -0.000271
d -0.008943 -0.024738 -0.001486  0.921297 -0.013692
e  0.014144  0.009826 -0.000271 -0.013692  0.977795
```

Minimum number of periods

This method also supports an optional min_periods keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```python
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
...                       columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)
     a        b
a  0.316741 NaN
b  NaN  1.248003
```

Minimum number of periods

This method also supports an optional min_periods keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.core.groupby.DataFrameGroupBy.cumcount

DataFrameGroupBy.cumcount (ascending=True)

Number each item in each group from 0 to the length of that group - 1.

Essentially this is equivalent to

```
self.apply(lambda x: pd.Series(np.arange(len(x)), x.index))
```

**Parameters**

- **ascending** [bool, default True] If False, number in reverse, from length of group - 1 to 0.

**Returns**

- **Series** Sequence number of each element within each group.

**See also:**

- `ngroup` Number the groups themselves.

**Examples**

```python
>>> df = pd.DataFrame([["a"],["a"],["a"],["b"],["b"],["a"]],
columns=['A'])
>>> df
   A
0  a
1  a
2  a
3  b
4  b
5  a
>>> df.groupby('A').cumcount()
0  0
1  1
2  2
3  3
4  1
5  3
dtype: int64
>>> df.groupby('A').cumcount(ascending=False)
0  3
1  2
2  1
3  1
4  0
5  0
dtype: int64
```
pandas.core.groupby.DataFrameGroupBy.cummax

DataFrameGroupBy.\texttt{cummax}(\texttt{axis}=0, **\texttt{kwargs})

Cumulative max for each group.

Returns

Series or DataFrame

See also:

\texttt{Series.groupby} Apply a function groupby to a Series.
\texttt{DataFrame.groupby} Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.cummin

DataFrameGroupBy.\texttt{cummin}(\texttt{axis}=0, **\texttt{kwargs})

Cumulative min for each group.

Returns

Series or DataFrame

See also:

\texttt{Series.groupby} Apply a function groupby to a Series.
\texttt{DataFrame.groupby} Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.cumprod

DataFrameGroupBy.\texttt{cumprod}(\texttt{axis}=0, *\texttt{args}, **\texttt{kwargs})

Cumulative product for each group.

Returns

Series or DataFrame

See also:

\texttt{Series.groupby} Apply a function groupby to a Series.
\texttt{DataFrame.groupby} Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.cumsum

DataFrameGroupBy.\texttt{cumsum}(\texttt{axis}=0, *\texttt{args}, **\texttt{kwargs})

Cumulative sum for each group.

Returns

Series or DataFrame

See also:

\texttt{Series.groupby} Apply a function groupby to a Series.
\texttt{DataFrame.groupby} Apply a function groupby to each row or column of a DataFrame.
Generate descriptive statistics.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

- **percentiles** [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

- **include** ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for Series. Here are the options:
  - 'all': All columns of the input will be included in the output.
  - A list-like of dtypes: Limits the results to the provided data types. To limit the result to numeric types submit numpy.number. To limit it instead to object columns submit the numpy.object data type. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To select pandas categorical columns, use 'category'
  - None (default): The result will include all numeric columns.

- **exclude** [list-like of dtypes or None (default), optional] A black list of data types to omit from the result. Ignored for Series. Here are the options:
  - A list-like of dtypes: Excludes the provided data types from the result. To exclude numeric types submit numpy.number. To exclude object columns submit the data type numpy.object. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To exclude pandas categorical columns, use 'category'
  - None (default): The result will exclude nothing.

- **datetime_is_numeric** [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

New in version 1.1.0.

Returns

Series or DataFrame Summary statistics of the Series or Dataframe provided.

See also:

- DataFrame.count Count number of non-NA/null observations.
- DataFrame.max Maximum of the values in the object.
- DataFrame.min Minimum of the values in the object.
- DataFrame.mean Mean of the values.
- DataFrame.std Standard deviation of the observations.
- DataFrame.select_dtypes Subset of a DataFrame including/excluding columns based on their dtypes.
Notes

For numeric data, the result’s index will include `count`, `mean`, `std`, `min`, `max` as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result’s index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value’s frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a DataFrame, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a DataFrame are analyzed for the output. The parameters are ignored when analyzing a Series.

Examples

Describing a numeric Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
dtype: float64
```

Describing a categorical Series.

```python
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count 4
unique 3
top a
freq 2
dtype: object
```

Describing a timestamp Series.

```python
>>> s = pd.Series([...
... np.datetime64("2000-01-01"),
... np.datetime64("2010-01-01"),
... np.datetime64("2010-01-01")
... ])
>>> s.describe(datetime_is_numeric=True)
count 3
mean 2006-09-01 08:00:00
```
Describing a DataFrame. By default only numeric fields are returned.

```python
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d','e','f']),
                    'numeric': [1, 2, 3],
                    'object': ['a', 'b', 'c']})
>>> df.describe()
```

```
categorical  numeric
count 3.0 3.0
mean NaN 2.0
std NaN 1.0
min NaN 1.0
25% NaN 1.5
50% NaN 2.0
75% NaN 2.5
max NaN 3.0
```

Describing all columns of a DataFrame regardless of data type.

```python
>>> df.describe(include='all')
```

```
categorical  numeric  object
count 3.0 3.0 3.0
unique 3.0 NaN 3.0
top f NaN a
freq 1.0 NaN 1.0
mean NaN 2.0 NaN
std NaN 1.0 NaN
min NaN 1.0 NaN
25% NaN 1.5 NaN
50% NaN 2.0 NaN
75% NaN 2.5 NaN
max NaN 3.0 NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```python
>>> df.numeric.describe()
```

```
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a DataFrame description.

```python
>>> df.describe(include=[np.number])
```

```
categorical  numeric
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
```
Including only string columns in a DataFrame description.

```python
>>> df.describe(include=['object'])
     object
  count     3
  unique    3
      top  a
     freq   1
```

Including only categorical columns from a DataFrame description.

```python
>>> df.describe(include=['category'])
    categorical
  count     3
  unique    3
      top  d
     freq   1
```

Excluding numeric columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.number])
    categorical  object
  count     3     3
  unique    3     3
      top    f    a
     freq    1     1
```

Excluding object columns from a DataFrame description.

```python
>>> df.describe(exclude=['object'])
    categorical  numeric
  count     3     3
  unique    3   NaN
      top    f   NaN
     freq    1   NaN
     mean   NaN    2
      std   NaN    1
      min   NaN    1
    25%   NaN    1
    50%   NaN    2
    75%   NaN    2
      max   NaN    3
```
**pandas.core.groupby.DataFrameGroupBy.diff**

**property DataFrameGroupBy.diff**

First discrete difference of element.

Calculates the difference of a DataFrame element compared with another element in the DataFrame (default is element in previous row).

**Parameters**

- **periods** [int, default 1] Periods to shift for calculating difference, accepts negative values.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Take difference over rows (0) or columns (1).

**Returns**

- **Dataframe** First differences of the Series.

**See also:**

- **Dataframe.pct_change** Percent change over given number of periods.
- **Dataframe.shift** Shift index by desired number of periods with an optional time freq.
- **Series.diff** First discrete difference of object.

**Notes**

For boolean dtypes, this uses `operator.xor()` rather than `operator.sub()`. The result is calculated according to current dtype in DataFrame, however dtype of the result is always float64.

**Examples**

**Difference with previous row**

```python
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
                    ...            'b': [1, 1, 2, 3, 5, 8],
                    ...            'c': [1, 4, 9, 16, 25, 36]})
```

```python
>>> df
   a  b  c
0  1  1  1
1  2  1  4
2  3  2  9
3  4  3 16
4  5  5 25
5  6  8 36
```

```python
>>> df.diff()
   a   b   c
0  NaN NaN NaN
1  1.0  0.0  3.0
2  1.0  1.0  5.0
3  1.0  1.0  7.0
4  1.0  2.0  9.0
5  1.0  3.0 11.0
```

**Difference with previous column**

```python
>>> df.diff(axis=1)
   a  b  c
0  NaN 0  0
1  1.0 0  0
2  1.0 1  1
3  1.0 2  2
4  1.0 3  3
5  1.0 4  4
```
1 NaN -1 3  
2 NaN -1 7  
3 NaN -1 13  
4 NaN 0 20  
5 NaN 2 28

Difference with 3rd previous row

```python
>>> df.diff(periods=3)
    a   b   c
0  NaN NaN NaN
1  NaN NaN NaN
2  NaN NaN NaN
3   3.0  2.0  15.0
4   3.0  4.0  21.0
5   3.0  6.0  27.0
```

Difference with following row

```python
>>> df.diff(periods=-1)
    a   b   c
0  -1.0  0.0  -3.0
1  -1.0 -1.0  -5.0
2  -1.0 -1.0  -7.0
3  -1.0 -2.0  -9.0
4  -1.0 -3.0 -11.0
5   NaN  NaN  NaN
```

Overflow in input dtype

```python
>>> df = pd.DataFrame({'a': [1, 0]}, dtype=np.uint8)
>>> df.diff()
    a
0  NaN
1  255.0
```

*pandas.core.groupby.DataFrameGroupBy.ffill*

DataFrameGroupBy.**ffill** (*limit=None*)

Forward fill the values.

**Parameters**

- **limit** [int, optional] Limit of how many values to fill.

**Returns**

- **Series** or **DataFrame** Object with missing values filled.

**See also:**

- **Series.pad** Returns Series with minimum number of char in object.
- **DataFrame.pad** Object with missing values filled or None if inplace=True.
- **Series.fillna** Fill NaN values of a Series.
- **DataFrame.fillna** Fill NaN values of a DataFrame.
### pandas.core.groupby.DataFrameGroupBy.fillna

**property** `DataFrameGroupBy.fillna`

Fill NA/NaN values using the specified method.

**Parameters**

- **value** [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

- **method** [‘backfill’, ‘bfill’, ‘pad’, ‘ffill’, None], default None Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use next valid observation to fill gap.

- **axis** [[0 or ‘index’, 1 or ‘columns’]] Axis along which to fill missing values.

- **inplace** [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

- **limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

- **downcast** [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

**Returns**

DataFrame or None Object with missing values filled or None if `inplace=True`.

**See also:**

- `interpolate` Fill NaN values using interpolation.
- `reindex` Conform object to new index.
- `asfreq` Convert TimeSeries to specified frequency.

**Examples**

```python
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                     [3, 4, np.nan, 1],
...                     [np.nan, np.nan, np.nan, 5],
...                     [np.nan, 3, np.nan, 4]],
...                    columns=list("ABCD"))
>>> df
     A    B    C    D
0   NaN  2.0   NaN  0.0
1   3.0  4.0   NaN  1.0
2   NaN  NaN   NaN  5.0
3   NaN  3.0   NaN  4.0

Replace all NaN elements with 0s.

```python
>>> df.fillna(0)
     A    B    C    D
0  0.0  2.0   NaN  0.0
1  3.0  4.0   NaN  1.0
2  NaN  NaN   NaN  5.0
3  NaN  3.0   NaN  4.0
```

(continues on next page)
We can also propagate non-null values forward or backward.

```python
>>> df.fillna(method="ffill")
   A   B    C   D
0 NaN  2.0  NaN   0
1  3.0  4.0  NaN   1
2  3.0  4.0  NaN   5
3  3.0  3.0  NaN   4
```

Replace all NaN elements in column ‘A’, ‘B’, ‘C’, and ‘D’, with 0, 1, 2, and 3 respectively.

```python
>>> values = {"A": 0, "B": 1, "C": 2, "D": 3}
>>> df.fillna(value=values)
   A   B    C   D
0  0.0  2.0  2.0  0
1  3.0  4.0  2.0  1
2  0.0  1.0  2.0  5
3  0.0  3.0  2.0  4
```

Only replace the first NaN element.

```python
>>> df.fillna(value=values, limit=1)
   A   B    C   D
0  0.0  2.0  2.0  0
1  3.0  4.0  NaN   1
2  NaN  1.0  NaN  5
3  NaN  3.0  NaN  4
```

When filling using a DataFrame, replacement happens along the same column names and same indices

```python
>>> df2 = pd.DataFrame(np.zeros((4, 4)), columns=list("ABCE"))
>>> df.fillna(df2)
   A   B    C   D
0  0.0  2.0  0.0  0
1  3.0  4.0  0.0  1
2  0.0  0.0  0.0  5
3  0.0  3.0  0.0  4
```

```
3.10. GroupBy
```
filtered [DataFrame]

Notes
Each subframe is endowed the attribute ‘name’ in case you need to know which group you are working on.
Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

Examples

```python
>>> df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar',
... 'foo', 'bar'],
... 'B': [1, 2, 3, 4, 5, 6],
... 'C': [2.0, 5., 8., 1., 2., 9.])
>>> grouped = df.groupby('A')
>>> grouped.filter(lambda x: x['B'].mean() > 3.)
  A  B  C
0  bar 2  5.0
1  bar 4  1.0
2  bar 6  9.0
```

pandas.core.groupby.DataFrameGroupBy.hist

property DataFrameGroupBy.hist
Make a histogram of the DataFrame’s columns.

A histogram is a representation of the distribution of data. This function calls matplotlib.pyplot.hist(), on each series in the DataFrame, resulting in one histogram per column.

Parameters

- **data** [DataFrame] The pandas object holding the data.
- **column** [str or sequence, optional] If passed, will be used to limit data to a subset of columns.
- **by** [object, optional] If passed, then used to form histograms for separate groups.
- **grid** [bool, default True] Whether to show axis grid lines.
- **xlabelsize** [int, default None] If specified changes the x-axis label size.
- **xrot** [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.
- **ylabelsize** [int, default None] If specified changes the y-axis label size.
- **yrot** [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.
- **ax** [Matplotlib axes object, default None] The axes to plot the histogram on.
- **sharex** [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.
- **sharey** [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.
figsize [tuple, optional] The size in inches of the figure to create. Uses the value in `matplotlib.rcParams` by default.

layout [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.

bins [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

backend [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, ‘matplotlib’. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

legend [bool, default False] Whether to show the legend.

New in version 1.1.0.

**kwargs All other plotting keyword arguments to be passed to `matplotlib.pyplot.hist()`.

Returns

`matplotlib.AxesSubplot` or `numpy.ndarray` of them

See also:

`matplotlib.pyplot.hist` Plot a histogram using `matplotlib`.

Examples

This example draws a histogram based on the length and width of some animals, displayed in three bins

```python
>>> df = pd.DataFrame({
...     'length': [1.5, 0.5, 1.2, 0.9, 3],
...     'width': [0.7, 0.2, 0.15, 0.2, 1.1],
... }, index=['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```

`pandas.core.groupby.DataFrameGroupBy.idxmax`

`DataFrameGroupBy.idxmax(axis=0, skipna=True)`

Return index of first occurrence of maximum over requested axis.

NA/null values are excluded.

Parameters

axis [[0 or ‘index’, 1 or ‘columns’], default 0] The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

Series Indexes of maxima along the specified axis.

Raises
ValueError

- If the row/column is empty

See also:

Series.idxmax Return index of the maximum element.

Notes

This method is the DataFrame version of `ndarray.argmax`.

Examples

Consider a dataset containing food consumption in Argentina.

```python
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
... 'co2_emissions': [37.2, 19.66, 1712]},
... index=['Pork', 'Wheat Products', 'Beef'])
```

```plaintext
consumption co2_emissions
Pork 10.51 37.20
Wheat Products 103.11 19.66
Beef 55.48 1712.00
```

By default, it returns the index for the maximum value in each column.

```python
>>> df.idxmax()
consumption Wheat Products
co2_emissions Beef
dtype: object
```

To return the index for the maximum value in each row, use `axis="columns"`.

```python
>>> df.idxmax(axis="columns")
Pork co2_emissions
Wheat Products consumption
Beef co2_emissions
dtype: object
```

pandas.core.groupby.DataFrameGroupBy.idxmin

DataFrameGroupBy.idxmin(axis=0, skipna=True)

Return index of first occurrence of minimum over requested axis.

NA/null values are excluded.

Parameters

- **axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.

- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

- **Series** Indexes of minima along the specified axis.
pandas: powerful Python data analysis toolkit, Release 1.3.2

Raises

ValueError

- If the row/column is empty

See also:

Series.idxmin Return index of the minimum element.

Notes

This method is the DataFrame version of ndarray.argmin.

Examples

Consider a dataset containing food consumption in Argentina.

```python
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
...                    'co2_emissions': [37.2, 19.66, 1712]},
...                    index=['Pork', 'Wheat Products', 'Beef'])
>>> df
consumption     co2_emissions
Pork         10.51             37.20
Wheat Products 103.11            19.66
Beef          55.48            1712.00
```

By default, it returns the index for the minimum value in each column.

```python
>>> df.idxmin()
consumption    Pork
co2_emissions Wheat Products
```

To return the index for the minimum value in each row, use `axis="columns"`.

```python
>>> df.idxmin(axis="columns")
Pork   consumption
Wheat Products co2_emissions
Beef   consumption
dtype: object
```

pandas.core.groupby.DataFrameGroupBy.mad

**property** DataFrameGroupBy.mad

Return the mean absolute deviation of the values over the requested axis.

**Parameters**

- `axis` [[index (0), columns (1)]] Axis for the function to be applied on.
- `skipna` [bool, default None] Exclude NA/null values when computing the result.
- `level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**Returns**
Series or DataFrame (if level specified)

**pandas.core.groupby.DataFrameGroupBy.nunique**

DataFrameGroupBy.nunique(*dropna=True*)

Return DataFrame with counts of unique elements in each position.

**Parameters**

*dropna* [bool, default True] Don’t include NaN in the counts.

**Returns**

nunique: DataFrame

**Examples**

```python
>>> df = pd.DataFrame({'id': ['spam', 'egg', 'egg', 'spam',
...                           'ham', 'ham'],
...                    'value1': [1, 5, 5, 2, 5, 5],
...                    'value2': list('abbaxy')})

>>> df
   id  value1  value2
0  spam     1      a
1   egg     5      b
2   egg     5      b
3  spam     2      a
4   ham     5      x
5   ham     5      y

>>> df.groupby('id').nunique()
   value1  value2
id      
egg  1      1
ham  1      2
spam 2      1

Check for rows with the same id but conflicting values:

```python
>>> df.groupby('id').filter(lambda g: (g.nunique() > 1).any())
   id  value1  value2
0  spam     1      a
3  spam     2      a
4   ham     5      x
5   ham     5      y
```
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.core.groupby.DataFrameGroupBy.pad

DataFrameGroupBy.pad(limit=None)
Forward fill the values.

Parameters
  limit [int, optional] Limit of how many values to fill.

Returns
  Series or DataFrame Object with missing values filled.

See also:
  Series.pad Returns Series with minimum number of char in object.
  DataFrame.pad Object with missing values filled or None if inplace=True.
  Series.fillna Fill NaN values of a Series.
  DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.pct_change

DataFrameGroupBy.pct_change(periods=1, fill_method='pad', limit=None, freq=None, axis=0)
Calculate pct_change of each value to previous entry in group.

Returns
  Series or DataFrame Percentage changes within each group.

See also:
  Series.groupby Apply a function groupby to a Series.
  DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.plot

property DataFrameGroupBy.plot
Class implementing the .plot attribute for groupby objects.

pandas.core.groupby.DataFrameGroupBy.quantile

DataFrameGroupBy.quantile(q=0.5, interpolation='linear')
Return group values at the given quantile, a la numpy.percentile.

Parameters
  q [float or array-like, default 0.5 (50% quantile)] Value(s) between 0 and 1 providing the quantile(s) to compute.
  interpolation [{'linear', 'lower', 'higher', 'midpoint', 'nearest'}] Method to use when the desired quantile falls between two points.

Returns
  Series or DataFrame Return type determined by caller of GroupBy object.

See also:
  Series.quantile Similar method for Series.
  DataFrame.quantile Similar method for DataFrame.
  numpy.percentile NumPy method to compute qth percentile.
Examples

```python
>>> df = pd.DataFrame(
...     [['a', 1], ['a', 2], ['a', 3],
...     ['b', 1], ['b', 3], ['b', 5]],
...     columns=['key', 'val'])
>>> df.groupby('key').quantile()
key  val
a   2.0
b   3.0
```

**pandas.core.groupby.DataFrameGroupBy.rank**

`DataFrameGroupBy.rank` *(method='average', ascending=True, na_option='keep', pct=False, axis=0)*

Provide the rank of values within each group.

**Parameters**

- **method** ([{'average', 'min', 'max', 'first', 'dense'}, default 'average']
  - average: average rank of group.
  - min: lowest rank in group.
  - max: highest rank in group.
  - first: ranks assigned in order they appear in the array.
  - dense: like ‘min’, but rank always increases by 1 between groups.

- **ascending** [bool, default True] False for ranks by high (1) to low (N).

- **na_option** [{‘keep’, ‘top’, ‘bottom’}, default ‘keep’]
  - keep: leave NA values where they are.
  - top: smallest rank if ascending.
  - bottom: smallest rank if descending.

- **pct** [bool, default False] Compute percentage rank of data within each group.

- **axis** [int, default 0] The axis of the object over which to compute the rank.

**Returns**

`DataFrame` with ranking of values within each group

**See also:**

- `Series.groupby` : Apply a function groupby to a Series.
- `DataFrame.groupby` : Apply a function groupby to each row or column of a DataFrame.
pandas.core.groupby.DataFrameGroupBy.resample

DataFrameGroupBy.resample(rule, *args, **kwargs)
Provide resampling when using a TimeGrouper.

Given a grouper, the function resamples it according to a string “string” -> “frequency”.

See the frequency aliases documentation for more details.

Parameters

rule [str or DateOffset] The offset string or object representing target grouper conversion.

*args, **kwargs Possible arguments are how, fill_method, limit, kind and on, and other arguments of TimeGrouper.

Returns

Grouper Return a new grouper with our resampler appended.

See also:

Grouper Specify a frequency to resample with when grouping by a key.
DatetimeIndex.resample Frequency conversion and resampling of time series.

Examples

```python
>>> idx = pd.date_range('1/1/2000', periods=4, freq='T')
>>> df = pd.DataFrame(data=4 * [range(2)],
...                   index=idx,
...                   columns=['a', 'b'])
>>> df.iloc[2, 0] = 5
>>> df
     a   b
2000-01-01 00:00:00  0  1
2000-01-01 00:01:00  0  1
2000-01-01 00:02:00  5  1
2000-01-01 00:03:00  0  1

Downsample the DataFrame into 3 minute bins and sum the values of the timestamps falling into a bin.

```}

```python
>>> df.groupby('a').resample('3T').sum()
     a   b
   2000-01-01 00:00:00  0  2
   2000-01-01 00:01:00  0  1
   2000-01-01 00:02:00  5  1
   2000-01-01 00:03:00  0  1
```

Upsample the series into 30 second bins.

```python
>>> df.groupby('a').resample('30S').sum()
     a   b
   2000-01-01 00:00:00  0  1
   2000-01-01 00:00:30  0  0
   2000-01-01 00:01:00  0  1
   2000-01-01 00:01:30  0  0
   2000-01-01 00:02:00  0  0
   2000-01-01 00:02:30  0  0
   2000-01-01 00:03:00  0  1
   2000-01-01 00:02:00  5  1
```
Resample by month. Values are assigned to the month of the period.

```python
>>> df.groupby('a').resample('M').sum()
   a     b
0  2000-01-31 0  3
5  2000-01-31 5  1
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```python
>>> df.groupby('a').resample('3T', closed='right').sum()
   a     b
0 1999-12-31 23:57:00 0  1
   2000-01-01 00:00:00 0  2
5 2000-01-01 00:00:00 5  1
```

Downsample the series into 3 minute bins and close the right side of the bin interval, but label each bin using the right edge instead of the left.

```python
>>> df.groupby('a').resample('3T', closed='right', label='right').sum()
   a     b
0 2000-01-01 00:00:00 0  1
   2000-01-01 00:03:00 0  2
5 2000-01-01 00:03:00 5  1
```

**pandas.core.groupby.DataFrameGroupBy.sample**

DataFrameGroupBy.sample(n=None, frac=None, replace=False, weights=None, random_state=None)

Return a random sample of items from each group.

You can use random_state for reproducibility.

New in version 1.1.0.

**Parameters**

- **n** [int, optional] Number of items to return for each group. Cannot be used with frac and must be no larger than the smallest group unless replace is True. Default is one if frac is None.

- **frac** [float, optional] Fraction of items to return. Cannot be used with n.

- **replace** [bool, default False] Allow or disallow sampling of the same row more than once.

- **weights** [list-like, optional] Default None results in equal probability weighting. If passed a list-like then values must have the same length as the underlying DataFrame or Series object and will be used as sampling probabilities after normalization within each group. Values must be non-negative with at least one positive element within each group.

- **random_state** [int, array-like, BitGenerator, np.random.RandomState, optional] If int, array-like, or BitGenerator (NumPy>=1.17), seed for random number generator If np.random.RandomState, use as numpy RandomState object.

**Returns**

- **Series or DataFrame** A new object of same type as caller containing items randomly sampled within each group from the caller object.

See also:
**DataFrame.sample** Generate random samples from a DataFrame object.

**numpy.random.choice** Generate a random sample from a given 1-D numpy array.

**Examples**

```python
df = pd.DataFrame(
...     {'a': ['red'] * 2 + ['blue'] * 2 + ['black'] * 2, 'b': range(6)}
... )
>>> df
   a  b
0  red 0
1  red 1
2  blue 2
3  blue 3
4  black 4
5  black 5
```

Select one row at random for each distinct value in column a. The `random_state` argument can be used to guarantee reproducibility:

```python
>>> df.groupby('a').sample(n=1, random_state=1)
   a  b
2  blue 2
1  red 1
```

Set `frac` to sample fixed proportions rather than counts:

```python
>>> df.groupby('a')[['b']].sample(frac=0.5, random_state=2)
   b
5  5
2  2
0  0
Name: b, dtype: int64
```

Control sample probabilities within groups by setting weights:

```python
>>> df.groupby('a').sample(
...     n=1,
...     weights=[1, 1, 1, 0, 0, 1],
...     random_state=1,
... )
   a  b
5  black 5
2  blue 2
0  red 0
```
pandas.core.groupby.DataFrameGroupBy.shift

`DataFrameGroupBy.shift(periods=1, freq=None, axis=0, fill_value=None)`

Shift each group by periods observations.

If freq is passed, the index will be increased using the periods and the freq.

**Parameters**

- `periods` [int, default 1] Number of periods to shift.
- `freq` [str, optional] Frequency string.
- `axis` [axis to shift, default 0] Shift direction.
- `fill_value` [optional] The scalar value to use for newly introduced missing values.

**Returns**

- `Series` or `DataFrame` Object shifted within each group.

**See also:**

- `Index.shift` Shift values of Index.
- `tshift` Shift the time index, using the index’s frequency if available.

pandas.core.groupby.DataFrameGroupBy.size

`DataFrameGroupBy.size()`

Compute group sizes.

**Returns**

- `DataFrame` or `Series` Number of rows in each group as a Series if `as_index` is True or a DataFrame if `as_index` is False.

**See also:**

- `Series.groupby` Apply a function groupby to a Series.
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.skew

`property DataFrameGroupBy.skew`  

Return unbiased skew over requested axis.

Normalized by N-1.

**Parameters**

- `axis` [[index (0), columns (1)] Axis for the function to be applied on.
- `skipna` [bool, default True] Exclude NA/null values when computing the result.
- `level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- `numeric_only` [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs Additional keyword arguments to be passed to the function.

**Returns**

- `Series` or `DataFrame` (if level specified)
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.core.groupby.DataFrameGroupBy.take

**property** DataFrameGroupBy.take

Return the elements in the given *positional* indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

**Parameters**

- **indices** [array-like] An array of ints indicating which positions to take.
- **axis** [[0 or ‘index’, 1 or ‘columns’, None], default 0] The axis on which to select elements.
  - 0 means that we are selecting rows, 1 means that we are selecting columns.
- **is_copy** [bool] Before pandas 1.0, is_copy=False can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, take always returns a copy, and the keyword is therefore deprecated.

  Deprecated since version 1.0.0.

- **kwargs** For compatibility with numpy.take(). Has no effect on the output.

**Returns**

- **taken** [same type as caller] An array-like containing the elements taken from the object.

**See also:**

- DataFrame.loc Select a subset of a DataFrame by labels.
- DataFrame.iloc Select a subset of a DataFrame by positions.
- numpy.take Take elements from an array along an axis.

**Examples**

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
    ...                  ('parrot', 'bird', 24.0),
    ...                  ('lion', 'mammal', 80.5),
    ...                  ('monkey', 'mammal', np.nan)],
    ...                  columns=['name', 'class', 'max_speed'],
    ...                  index=[0, 2, 3, 1])
>>> df
    name  class     max_speed
0  falcon  bird       389.0
2  parrot  bird        24.0
3   lion  mammal       80.5
1  monkey  mammal     nan

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That’s because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```python
>>> df.take([0, 3])
    name  class     max_speed
0  falcon  bird       389.0
1  monkey  mammal     NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).
We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```python
>>> df.take([-1, -2])
  name  class  max_speed
1  monkey  mammal     NaN
3   lion  mammal   80.5
```
pandas.core.groupby.SeriesGroupBy.hist

**property SeriesGroupBy.hist**

Draw histogram of the input series using matplotlib.

**Parameters**

- **by** [object, optional] If passed, then used to form histograms for separate groups.
- **ax** [matplotlib axis object] If not passed, uses gca().
- **grid** [bool, default True] Whether to show axis grid lines.
- **xlabelsize** [int, default None] If specified changes the x-axis label size.
- **xrot** [float, default None] Rotation of x axis labels.
- **ylabelsize** [int, default None] If specified changes the y-axis label size.
- **yrot** [float, default None] Rotation of y axis labels.
- **figsize** [tuple, default None] Figure size in inches by default.
- **bins** [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.
- **backend** [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, ‘matplotlib’. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

  New in version 1.0.0.
- **legend** [bool, default False] Whether to show the legend.

  New in version 1.1.0.
- ****kwargs** To be passed to the actual plotting function.

**Returns**

- `matplotlib.AxesSubplot` A histogram plot.

**See also:**

- `matplotlib.axes.Axes.hist` Plot a histogram using matplotlib.

pandas.core.groupby.SeriesGroupBy.nlargest

**property SeriesGroupBy.nlargest**

Return the largest n elements.

**Parameters**

- **n** [int, default 5] Return this many descending sorted values.
- **keep** [‘first’, ‘last’, ‘all’], default ‘first’ When there are duplicate values that cannot all fit in a Series of n elements:
  - **first** [return the first n occurrences in order] of appearance.
  - **last** [return the last n occurrences in reverse] order of appearance.
  - **all** [keep all occurrences. This can result in a Series of] size larger than n.

**Returns**
**Series**  The \( n \) largest values in the Series, sorted in decreasing order.

**See also:**

- `Series.nsmallest`  Get the \( n \) smallest elements.
- `Series.sort_values`  Sort Series by values.
- `Series.head`  Return the first \( n \) rows.

**Notes**

Faster than `.sort_values(ascending=False).head(n)` for small \( n \) relative to the size of the Series object.

**Examples**

```python
>>> countries_population = {"Italy": 59000000, "France": 65000000,
...                        "Malta": 434000, "Maldives": 434000,
...                        "Brunei": 434000, "Iceland": 373000,
...                        "Nauru": 11300, "Tuvalu": 11300,
...                        "Anguilla": 11300, "Montserrat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy     59000000
France    65000000
Malta     434000
Maldives  434000
Brunei    434000
Iceland   373000
Nauru     11300
Tuvalu    11300
Anguilla  11300
Montserrat 5200
dtype: int64
```

The \( n \) largest elements where \( n=5 \) by default.

```python
>>> s.nlargest()
France    65000000
Italy     59000000
Malta     434000
Maldives  434000
Brunei    434000
dtype: int64
```

The \( n \) largest elements where \( n=3 \). Default `keep` value is ‘first’ so Malta will be kept.

```python
>>> s.nlargest(3)
France    65000000
Italy     59000000
Malta     434000
dtype: int64
```

The \( n \) largest elements where \( n=3 \) and keeping the last duplicates. Brunei will be kept since it is the last with value 434000 based on the index order.
The \( n \) largest elements where \( n=3 \) with all duplicates kept. Note that the returned Series has five elements due to the three duplicates.

```python
>>> s.nlargest(3, keep='all')
France    65000000
Italy     59000000
Malta     434000
Maldives  434000
Brunei    434000
dtype: int64
```

```
pandas.core.groupby.SeriesGroupBy.nsmallest
```

**property** `SeriesGroupBy.nsmallest`

Return the smallest \( n \) elements.

**Parameters**

- `n` [int, default 5] Return this many ascending sorted values.
- `keep` [‘first’, ‘last’, ‘all’], default ‘first’ When there are duplicate values that cannot all fit in a Series of \( n \) elements:
  - `first` [return the first \( n \) occurrences in order] of appearance.
  - `last` [return the last \( n \) occurrences in reverse] order of appearance.
  - `all` [keep all occurrences. This can result in a Series of] size larger than \( n \).

**Returns**

- `Series` The \( n \) smallest values in the Series, sorted in increasing order.

**See also:**

- `Series.nlargest` Get the \( n \) largest elements.
- `Series.sort_values` Sort Series by values.
- `Series.head` Return the first \( n \) rows.

**Notes**

Faster than `.sort_values().head(n)` for small \( n \) relative to the size of the Series object.
Examples

```python
>>> countries_population = {
    "Italy": 59000000, "France": 65000000,
    "Brunei": 434000, "Malta": 434000,
    "Maldives": 434000, "Iceland": 337000,
    "Nauru": 11300, "Tuvalu": 11300,
    "Anguilla": 11300, "Montserrat": 5200
}

>>> s = pd.Series(countries_population)

>>> s
Italy  59000000
France  65000000
Brunei   434000
Malta    434000
Maldives  434000
Iceland  337000
Nauru    11300
Tuvalu   11300
Anguilla 11300
Montserrat  5200
dtype: int64

The $n$ smallest elements where $n=5$ by default.

```python
>>> s.nsmallest()
Montserrat   5200
Nauru        11300
Tuvalu       11300
Anguilla     11300
Iceland     337000
dtype: int64
```

The $n$ smallest elements where $n=3$. Default `keep` value is `first` so Nauru and Tuvalu will be kept.

```python
>>> s.nsmallest(3)
Montserrat   5200
Nauru        11300
Tuvalu       11300
dtype: int64
```

The $n$ smallest elements where $n=3$ and keeping the last duplicates. Anguilla and Tuvalu will be kept since they are the last with value 11300 based on the index order.

```python
>>> s.nsmallest(3, keep='last')
Montserrat   5200
Anguilla     11300
Tuvalu       11300
dtype: int64
```

The $n$ smallest elements where $n=3$ with all duplicates kept. Note that the returned Series has four elements due to the three duplicates.

```python
>>> s.nsmallest(3, keep='all')
Montserrat   5200
Nauru        11300
Tuvalu       11300
Anguilla     11300
dtype: int64
```
pandas.core.groupby.SeriesGroupBy.nunique

SeriesGroupBy.nunique(dropna=True)
Return number of unique elements in the group.

Returns

Series Number of unique values within each group.

pandas.core.groupby.SeriesGroupBy.unique

property SeriesGroupBy.unique
Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

Returns

ndarray or ExtensionArray The unique values returned as a NumPy array. See Notes.

See also:

unique Top-level unique method for any 1-d array-like object.
Index.unique Return Index with unique values from an Index object.

Notes

Returns the unique values as a NumPy array. In case of an extension-array backed Series, a new ExtensionArray of that type with just the unique values is returned. This includes

- Categorical
- Period
- Datetime with Timezone
- Interval
- Sparse
- IntegerNA

See Examples section.

Examples

```python
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])
```

```python
>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```python
>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern')
...     for _ in range(3)]).unique()
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]
```

An Categorical will return categories in the order of appearance and with the same dtype.

```python
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
['b', 'a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.2

```python
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'),
                        ordered=True)).unique()
['b', 'a', 'c']
Categories (3, object): ['a' < 'b' < 'c']
```

**pandas.core.groupby.SeriesGroupBy.value_counts**

SeriesGroupBy.value_counts(normalize=False, sort=True, ascending=False, bins=None, dropna=True)

**pandas.core.groupby.SeriesGroupBy.is_monotonic_increasing**

property SeriesGroupBy.is_monotonic_increasing

Alias for is_monotonic.

**pandas.core.groupby.SeriesGroupBy.is_monotonic_decreasing**

property SeriesGroupBy.is_monotonic_decreasing

Return boolean if values in the object are monotonic_decreasing.

Returns

bool

The following methods are available only for DataFrameGroupBy objects.

DataFrameGroupBy.corrwith Compute pairwise correlation.

DataFrameGroupBy.boxplot([[subplots, column, Make box plots from DataFrameGroupBy data.
...]])

**pandas.core.groupby.DataFrameGroupBy.corrwith**

property DataFrameGroupBy.corrwith Compute pairwise correlation.

Pairwise correlation is computed between rows or columns of DataFrame with rows or columns of Series or DataFrame. DataFrames are first aligned along both axes before computing the correlations.

Parameters

other [DataFrame, Series] Object with which to compute correlations.

axis [[0 or ‘index’, 1 or ‘columns’], default 0] The axis to use. 0 or ‘index’ to compute column-wise, 1 or ‘columns’ for row-wise.

drop [bool, default False] Drop missing indices from result.

method [[‘pearson’, ‘kendall’, ‘spearman’] or callable] Method of correlation:

- pearson : standard correlation coefficient
- kendall : Kendall Tau correlation coefficient
- spearman : Spearman rank correlation
- callable: callable with input two 1d ndarrays and returning a float.
**pandas: powerful Python data analysis toolkit, Release 1.3.2**

**Returns**

Series  Pairwise correlations.

**See also:**

**DataFrame.corr**  Compute pairwise correlation of columns.

**pandas.core.groupby.DataFrameGroupBy.boxplot**

`DataFrameGroupBy.boxplot(subplots=True, column=None, fontsize=None, rot=0, grid=True, ax=None, figsize=None, layout=None, sharex=False, sharey=True, backend=None, **kwargs)`

Make box plots from DataFrameGroupBy data.

**Parameters**

- **grouped**  [Grouped DataFrame]
- **subplots**  [bool]
  - False  - no subplots will be used
  - True  - create a subplot for each group.
- **column**  [column name or list of names, or vector]  Can be any valid input to groupby.
- **fontsize**  [int or str]
- **rot**  [label rotation angle]
- **grid**  [Setting this to True will show the grid]
- **ax**  [Matplotlib axis object, default None]
- **figsize**  [A tuple (width, height) in inches]
- **layout**  [tuple (optional)]  The layout of the plot: (rows, columns).
- **sharex**  [bool, default False]  Whether x-axes will be shared among subplots.
- **sharey**  [bool, default True]  Whether y-axes will be shared among subplots.
- **backend**  [str, default None]  Backend to use instead of the backend specified in the option `plotting.backend`. For instance, ‘matplotlib’. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

  New in version 1.0.0.

- **kwargs**  All other plotting keyword arguments to be passed to matplotlib’s boxplot function.

**Returns**

dict of key/value = group key/DataFrame.boxplot return value

or DataFrame.boxplot return value in case subplots=figures=False
Examples

You can create boxplots for grouped data and show them as separate subplots:

```python
>>> import itertools
>>> tuples = [t for t in itertools.product(range(1000), range(4))]
>>> index = pd.MultiIndex.from_tuples(tuples, names=['lvl0', 'lvl1'])
>>> data = np.random.randn(len(index), 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'), index=index)
>>> grouped = df.groupby(level='lvl1')
>>> grouped.boxplot(rot=45, fontsize=12, figsize=(8,10))
```

The `subplots=False` option shows the boxplots in a single figure.

```python
>>> grouped.boxplot(subplots=False, rot=45, fontsize=12)
```

### 3.11 Resampling

Resampler objects are returned by resample calls: `pandas.DataFrame.resample()`, `pandas.Series.resample()`.

#### 3.11.1 Indexing, iteration

- `Resampler.__iter__()` Groupby iterator.
- `Resampler.groups` Dict `{group name -> group labels}`.
- `Resampler.indices` Dict `{group name -> group indices}`.
- `Resampler.get_group(name[, obj])` Construct DataFrame from group with provided name.

```python
pandas.core.resample.Resampler.__iter__
```

Resampler.__iter__()

Groupby iterator.

Returns

Generator yielding sequence of `(name, subsetted object)` for each group
pandas.core.resample.Resampler.groups

property Resampler.groups
    Dict {group name -> group labels}.

pandas.core.resample.Resampler.indices

property Resampler.indices
    Dict {group name -> group indices}.

pandas.core.resample.Resampler.get_group

Resampler.get_group(name, obj=None)
    Construct DataFrame from group with provided name.
    Parameters
        name [object] The name of the group to get as a DataFrame.
        obj [DataFrame, default None] The DataFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used.
    Returns
        group [same type as obj]

3.11.2 Function application

<table>
<thead>
<tr>
<th>Method Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resampler.apply(func, *args, **kwargs)</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>Resampler.aggregate(func, *args, **kwargs)</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>Resampler.transform(arg, *args, **kwargs)</td>
<td>Call function producing a like-indexed Series on each group and return a Series with the transformed values.</td>
</tr>
<tr>
<td>Resampler.pipe(func, *args, **kwargs)</td>
<td>Apply a function <code>func</code> with arguments to this Resampler object and return the function’s result.</td>
</tr>
</tbody>
</table>

pandas.core.resample.Resampler.apply

Resampler.apply(func, *args, **kwargs)
    Aggregate using one or more operations over the specified axis.
    Parameters
        func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.
        Accepted combinations are:
            • function
            • string function name
            • list of functions and/or function names, e.g. [np.sum, 'mean']
            • dict of axis labels -> functions, function names or list of such.
*args  Positional arguments to pass to `func`.

**kwargs  Keyword arguments to pass to `func`.

Returns

**scalar, Series or DataFrame**  The return can be:

- scalar: when `Series.agg` is called with a single function
- Series: when `DataFrame.agg` is called with a single function
- DataFrame: when `DataFrame.agg` is called with several functions

Return scalar, Series or DataFrame.

See also:

- `DataFrame.groupby.aggregate`  Aggregate using callable, string, dict, or list of string/callables.
- `DataFrame.resample.transform`  Transforms the Series on each group based on the given function.
- `DataFrame.aggregate`  Aggregate using one or more operations over the specified axis.

Notes

`agg` is an alias for `aggregate`. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See `Mutating with User Defined Function (UDF) methods` for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> s = pd.Series([1,2,3,4,5],
                 index=pd.date_range('20130101', periods=5,freq='s'))
2013-01-01 00:00:00    1
2013-01-01 00:00:01    2
2013-01-01 00:00:02    3
2013-01-01 00:00:03    4
2013-01-01 00:00:04    5
Freq: S, dtype: int64

>>> r = s.resample('2s')
DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left, 
label=left, convention=start]

>>> r.agg(np.sum)
2013-01-01 00:00:00    3
2013-01-01 00:00:02    7
2013-01-01 00:00:04    5
Freq: 2s, dtype: int64

>>> r.agg(['sum','mean','max'])
    sum  mean  max
2013-01-01 00:00:00    3  1.5  2
2013-01-01 00:00:02    7  3.5  4
2013-01-01 00:00:04    5  5.0  5
```
```python
>>> r.agg({'result': lambda x: x.mean() / x.std(),
          'total': np.sum})
                             total   result
2013-01-01 00:00:00     3  2.121320
2013-01-01 00:00:02     7  4.949747
2013-01-01 00:00:04     5  NaN
```

### pandas.core.resample.Resampler.aggregate

Resampler.aggregate(func, *args, **kwargs)

Aggregate using one or more operations over the specified axis.

**Parameters**

- **func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.
  
  Accepted combinations are:
  
  - function
  
  - string function name
  
  - list of functions and/or function names, e.g. [np.sum, 'mean']
  
  - dict of axis labels -> functions, function names or list of such.

- **args** Positional arguments to pass to func.

- **kwargs** Keyword arguments to pass to func.

**Returns**

- **scalar, Series or DataFrame** The return can be:
  
  - scalar : when Series.agg is called with single function
  
  - Series : when DataFrame.agg is called with a single function
  
  - DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

**See also:**

- DataFrame.groupby.aggregate Aggregate using callable, string, dict, or list of string/callables.
- DataFrame.resample.transform Transforms the Series on each group based on the given function.
- DataFrame.aggregate Aggregate using one or more operations over the specified axis.

**Notes**

agg is an alias for aggregate. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

A passed user-defined-function will be passed a Series for evaluation.
Examples

```python
>>> s = pd.Series([1, 2, 3, 4, 5],
                index=pd.date_range('20130101', periods=5, freq='s'))
2013-01-01 00:00:00 1
2013-01-01 00:00:01 2
2013-01-01 00:00:02 3
2013-01-01 00:00:03 4
2013-01-01 00:00:04 5
Freq: S, dtype: int64
```

```python
>>> r = s.resample('2s')
DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left, label=left, convention=start]
```

```python
>>> r.agg(np.sum)
2013-01-01 00:00:00 3
2013-01-01 00:00:02 7
2013-01-01 00:00:04 5
Freq: 2S, dtype: int64
```

```python
>>> r.agg(['sum', 'mean', 'max'])
      sum  mean  max
2013-01-01 00:00:00 3.0  1.5  2.0
2013-01-01 00:00:02 7.0  3.5  4.0
2013-01-01 00:00:04 5.0  5.0  5.0
```

```python
>>> r.agg({'result': lambda x: x.mean() / x.std(),
         'total': np.sum})
    total  result
2013-01-01 00:00:00  3  2.121320
2013-01-01 00:00:02  7  4.949747
2013-01-01 00:00:04  5  NaN
```

**pandas.core.resample.Resampler.transform**

Resampler.transform(arg, *args, **kwargs)

Call function producing a like-indexed Series on each group and return a Series with the transformed values.

Parameters

arg [function] To apply to each group. Should return a Series with the same index.

Returns

transformed [Series]
Examples

```python
>>> resampled.transform(lambda x: (x - x.mean()) / x.std())
```

**pandas.core.resample.Resampler.pipe**

Resampler.pipe(func, *args, **kwargs)

Apply a function `func` with arguments to this Resampler object and return the function’s result.

Use `pipe` when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing

```python
>>> h(g(f(df.groupby('group')), arg1=a), arg2=b, arg3=c)
```

You can write

```python
>>> (df.groupby('group')
... .pipe(f)
... .pipe(g, arg1=a)
... .pipe(h, arg2=b, arg3=c))
```

which is much more readable.

**Parameters**

- **func** [callable or tuple of (callable, str)] Function to apply to this Resampler object or, alternatively, a `(callable, data_keyword)` tuple where `data_keyword` is a string indicating the keyword of `callable` that expects the Resampler object.
- **args** [iterable, optional] Positional arguments passed into `func`.
- **kwargs** [dict, optional] A dictionary of keyword arguments passed into `func`.

**Returns**

- **object** [the return type of `func`]

See also:

- **Series.pipe** Apply a function with arguments to a series.
- **DataFrame.pipe** Apply a function with arguments to a dataframe.
- **apply** Apply function to each group instead of to the full Resampler object.

**Notes**

See more [here](#)
To get the difference between each 2-day period’s maximum and minimum value in one pass, you can do

```python
>>> df.resample('2D').pipe(lambda x: x.max() - x.min())
A
2012-08-02 1
2012-08-04 1
```

### 3.11.3 Upsampling

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Resampler.ffill([limit])</code></td>
<td>Forward fill the values.</td>
</tr>
<tr>
<td><code>Resampler.backfill([limit])</code></td>
<td>Backward fill the new missing values in the resampled data.</td>
</tr>
<tr>
<td><code>Resampler.bfill([limit])</code></td>
<td>Backward fill the new missing values in the resampled data.</td>
</tr>
<tr>
<td><code>Resampler.pad([limit])</code></td>
<td>Forward fill the values.</td>
</tr>
<tr>
<td><code>Resampler.nearest([limit])</code></td>
<td>Resample by using the nearest value.</td>
</tr>
<tr>
<td><code>Resampler.fillna(method[, limit])</code></td>
<td>Fill missing values introduced by upsampling.</td>
</tr>
<tr>
<td><code>Resampler.asfreq([fill_value])</code></td>
<td>Return the values at the new freq, essentially a reindex.</td>
</tr>
<tr>
<td><code>Resampler.interpolate([method, axis, limit, ...])</code></td>
<td>Interpolate values according to different methods.</td>
</tr>
</tbody>
</table>

**pandas.core.resample.Resampler.ffill**

`Resampler.ffill(limit=None)`  
Forward fill the values.  

**Parameters**

- limit [int, optional] Limit of how many values to fill.

**Returns**

An upsampled Series.

**See also:**

- `Series.fillna` Fill NA/NaN values using the specified method.
- `DataFrame.fillna` Fill NA/NaN values using the specified method.

**pandas.core.resample.Resampler.backfill**

`Resampler.backfill(limit=None)`  
Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

**Parameters**

- limit [int, optional] Limit of how many values to fill.

**Returns**

Series, DataFrame An upsampled Series or DataFrame with backward filled NaN values.

**See also:**

## 3.11. Resampling
**bfill** Alias of backfill.

**fillna** Fill NaN values using the specified method, which can be ‘backfill’.

**nearest** Fill NaN values with nearest neighbor starting from center.

**pad** Forward fill NaN values.

**Series.fillna** Fill NaN values in the Series using the specified method, which can be ‘backfill’.

**DataFrame.fillna** Fill NaN values in the DataFrame using the specified method, which can be ‘backfill’.

### Examples

**Resampling a Series:**

```python
>>> s = pd.Series([1, 2, 3],
                index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00 1
2018-01-01 01:00:00 2
2018-01-01 02:00:00 3
Freq: H, dtype: int64
```

```python
>>> s.resample('30min').backfill()
2018-01-01 00:00:00 1
2018-01-01 00:30:00 2
2018-01-01 01:00:00 2
2018-01-01 01:30:00 3
2018-01-01 02:00:00 3
Freq: 30T, dtype: int64
```

```python
>>> s.resample('15min').backfill(limit=2)
2018-01-01 00:00:00 1.0
2018-01-01 00:15:00 NaN
2018-01-01 00:30:00 2.0
2018-01-01 00:45:00 2.0
2018-01-01 01:00:00 2.0
2018-01-01 01:15:00 NaN
2018-01-01 01:30:00 3.0
2018-01-01 01:45:00 3.0
2018-01-01 02:00:00 3.0
Freq: 15T, dtype: float64
```

**Resampling a DataFrame that has missing values:**

```python
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
                    index=pd.date_range('20180101', periods=3, freq='h'))
>>> df
   a  b
2018-01-01 00:00:00 2.0 1
2018-01-01 01:00:00 NaN 3
2018-01-01 02:00:00 6.0 5
```

```python
>>> df.resample('15min').backfill()
   a  b
2018-01-01 00:00:00 1.0 1
2018-01-01 00:15:00 NaN 3
2018-01-01 00:30:00 2.0 3
2018-01-01 00:45:00 2.0 3
2018-01-01 01:00:00 2.0 3
2018-01-01 01:15:00 NaN 5
2018-01-01 01:30:00 3.0 5
2018-01-01 01:45:00 3.0 5
2018-01-01 02:00:00 3.0 5
Freq: 15T, dtype: float64
```
>>> df.resample('30min').backfill()
       a   b
    2018-01-01 00:00:00 2.0 1
    2018-01-01 00:30:00 NaN 3
    2018-01-01 01:00:00 NaN 3
    2018-01-01 01:30:00 6.0 5
    2018-01-01 02:00:00 6.0 5

>>> df.resample('15min').backfill(limit=2)
       a   b
    2018-01-01 00:00:00 2.0 1.0
    2018-01-01 00:15:00 NaN NaN
    2018-01-01 00:30:00 NaN 3.0
    2018-01-01 00:45:00 NaN 3.0
    2018-01-01 01:00:00 NaN 3.0
    2018-01-01 01:15:00 NaN NaN
    2018-01-01 01:30:00 6.0 5.0
    2018-01-01 01:45:00 6.0 5.0
    2018-01-01 02:00:00 6.0 5.0

pandas.core.resample.Resampler.bfill

Resampler.bfill(limit=None)
Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

Parameters

- limit [int, optional] Limit of how many values to fill.

Returns

Series, DataFrame An upsampled Series or DataFrame with backward filled NaN values.

See also:

- Series.fillna Fill NaN values in the Series using the specified method, which can be ‘backfill’.
- DataFrame.fillna Fill NaN values in the DataFrame using the specified method, which can be ‘backfill’.

Examples

Resampling a Series:

```python
>>> s = pd.Series([1, 2, 3],
...                index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64
```

```python
>>> s.resample('30min').backfill()
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```python
>>> s.resample('15min').backfill(limit=2)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    NaN
2018-01-01 00:30:00    2.0
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
2018-01-01 01:15:00    NaN
2018-01-01 01:30:00    3.0
2018-01-01 01:45:00    3.0
2018-01-01 02:00:00    3.0
Freq: 15T, dtype: float64
```

Resampling a DataFrame that has missing values:

```python
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
...                    index=pd.date_range('20180101', periods=3,
...                    freq='h'))
>>> df
   a    b
2018-01-01 00:00:00  2.0  1.0
2018-01-01 01:00:00  NaN  3.0
2018-01-01 02:00:00  6.0  5.0
```

```python
>>> df.resample('30min').backfill()
   a    b
2018-01-01 00:00:00  2.0  1.0
2018-01-01 00:30:00  NaN  3.0
2018-01-01 01:00:00  NaN  3.0
2018-01-01 01:30:00  6.0  5.0
2018-01-01 02:00:00  6.0  5.0
```

```python
>>> df.resample('15min').backfill(limit=2)
   a    b
2018-01-01 00:00:00  2.0  1.0
2018-01-01 00:15:00  NaN  NaN
2018-01-01 00:30:00  NaN  3.0
2018-01-01 00:45:00  NaN  NaN
2018-01-01 01:00:00  NaN  3.0
2018-01-01 01:15:00  NaN  NaN
2018-01-01 01:30:00  6.0  5.0
2018-01-01 01:45:00  6.0  5.0
(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.core.resample.Resampler.pad

Resampler.pad(limit=None)
Forward fill the values.

Parameters

- limit [int, optional] Limit of how many values to fill.

Returns

An upsampled Series.

See also:

Series.fillna Fill NA/NaN values using the specified method.
DataFrame.fillna Fill NA/NaN values using the specified method.

pandas.core.resample.Resampler.nearest

Resampler.nearest(limit=None)
Resample by using the nearest value.

When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The nearest method will replace NaN values that appeared in the resampled data with the value from the nearest member of the sequence, based on the index value. Missing values that existed in the original data will not be modified. If limit is given, fill only this many values in each direction for each of the original values.

Parameters

- limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame An upsampled Series or DataFrame with NaN values filled with their nearest value.

See also:

backfill Backward fill the new missing values in the resampled data.
pad Forward fill NaN values.
Examples

```python
>>> s = pd.Series([1, 2],
                 index=pd.date_range('20180101', periods=2, freq='1h'))
>>> s
2018-01-01 00:00:00  1
2018-01-01 01:00:00  2
Freq: H, dtype: int64

>>> s.resample('15min').nearest()
2018-01-01 00:00:00  1
2018-01-01 00:15:00  1
2018-01-01 00:30:00  2
2018-01-01 00:45:00  2
2018-01-01 01:00:00  2
Freq: 15T, dtype: int64

Limit the number of upsampled values imputed by the nearest:

```python
>>> s.resample('15min').nearest(limit=1)
2018-01-01 00:00:00  1.0
2018-01-01 00:15:00  1.0
2018-01-01 00:30:00  NaN
2018-01-01 00:45:00  2.0
2018-01-01 01:00:00  2.0
Freq: 15T, dtype: float64
```
**interpolate** Fill NaN values using interpolation.

**Series.fillna** Fill NaN values in the Series using the specified method, which can be ‘bfill’ and ‘ffill’.

**DataFrame.fillna** Fill NaN values in the DataFrame using the specified method, which can be ‘bfill’ and ‘ffill’.

### Examples

Resampling a Series:

```python
>>> s = pd.Series([1, 2, 3],
                 index=pd.date_range('20180101', periods=3, freq='h'))
```

Without filling the missing values you get:

```python
>>> s.resample("30min").asfreq()
```

```python
2018-01-01 00:00:00    1.0
2018-01-01 00:30:00    NaN
2018-01-01 01:00:00    2.0
2018-01-01 01:30:00    NaN
2018-01-01 02:00:00    3.0
Freq: 30T, dtype: float64
```

```python
>>> s.resample('30min').fillna("backfill")
```

```python
2018-01-01 00:00:00    1
2018-01-01 00:30:00    1
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```python
>>> s.resample('15min').fillna("backfill", limit=2)
```

```python
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    NaN
2018-01-01 00:30:00    2.0
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
2018-01-01 01:15:00    NaN
2018-01-01 01:30:00    3.0
2018-01-01 01:45:00    3.0
2018-01-01 02:00:00    3.0
Freq: 15T, dtype: float64
```

```python
>>> s.resample('30min').fillna("pad")
```

```python
2018-01-01 00:00:00    1
2018-01-01 00:30:00    1
```

(continues on next page)
2018-01-01 01:00:00 2
2018-01-01 01:30:00 2
2018-01-01 02:00:00 3
Freq: 30T, dtype: int64

```python
>>> s.resample('30min').fillna("nearest")
2018-01-01 00:00:00 1
2018-01-01 00:30:00 2
2018-01-01 01:00:00 2
2018-01-01 01:30:00 3
2018-01-01 02:00:00 3
Freq: 30T, dtype: int64
```
Missing values present before the upsampling are not affected.

```python
>>> sm = pd.Series([1, None, 3],
                  index=pd.date_range('20180101', periods=3, freq='h'))
```

```python
2018-01-01 00:00:00 1.0
2018-01-01 01:00:00 NaN
2018-01-01 02:00:00 3.0
Freq: H, dtype: float64
```

```python
>>> sm.resample('30min').fillna('backfill')
2018-01-01 00:00:00 1.0
2018-01-01 00:30:00 NaN
2018-01-01 01:00:00 NaN
2018-01-01 01:30:00 3.0
2018-01-01 02:00:00 3.0
Freq: 30T, dtype: float64
```

```python
>>> sm.resample('30min').fillna('pad')
2018-01-01 00:00:00 1.0
2018-01-01 00:30:00 1.0
2018-01-01 01:00:00 NaN
2018-01-01 01:30:00 NaN
2018-01-01 02:00:00 3.0
Freq: 30T, dtype: float64
```

```python
>>> sm.resample('30min').fillna('nearest')
2018-01-01 00:00:00 1.0
2018-01-01 00:30:00 NaN
2018-01-01 01:00:00 NaN
2018-01-01 01:30:00 3.0
2018-01-01 02:00:00 3.0
Freq: 30T, dtype: float64
```

Dataframe resampling is done column-wise. All the same options are available.

```python
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
                    index=pd.date_range('20180101', periods=3, freq='h'))
```

```python
2018-01-01 00:00:00 2.0 1
(continues on next page)"
pandas: powerful Python data analysis toolkit, Release 1.3.2

>>> df.resample('30min').fillna("bfill")
   a     b
2018-01-01 00:00:00 2.0 1
2018-01-01 00:30:00 NaN 3
2018-01-01 01:00:00 NaN 3
2018-01-01 01:30:00 6.0 5
2018-01-01 02:00:00 6.0 5

pandas.core.resample.Resampler.asfreq

Resampler.asfreq(fill_value=None)
Return the values at the new freq, essentially a reindex.

Parameters

fill_value [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

Returns

DataFrame or Series Values at the specified freq.

See also:
Series.asfreq Convert TimeSeries to specified frequency.
DataFrame.asfreq Convert TimeSeries to specified frequency.

pandas.core.resample.Resampler.interpolate

Resampler.interpolate(method='linear', axis=0, limit=None, inplace=False, limit_direction='forward', limit_area=None, downcast=None, **kwargs)
Interpolate values according to different methods.
Fill NaN values using an interpolation method.

Please note that only method='linear' is supported for DataFrame/Series with a MultiIndex.

Parameters

method [str, default 'linear'] Interpolation technique to use. One of:

- ‘linear’: Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- ‘time’: Works on daily and higher resolution data to interpolate given length of interval.
- ‘index’, ‘values’: use the actual numerical values of the index.
- ‘pad’: Fill in NaNs using existing values.
- ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘spline’, ‘barycentric’, ‘polynomial’: Passed to scipy.interpolate.interp1d. These methods use the numerical values of the index. Both ‘polynomial’ and ‘spline’ require that you also specify an order (int), e.g. df.interpolate(method='polynomial', order=5).
• ‘from_derivatives’: Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces ‘piecewise_polynomial’ interpolation method in scipy 0.18.

`axis` [{{0 or ‘index’, 1 or ‘columns’, None}}, default None] Axis to interpolate along.

`limit` [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

`inplace` [bool, default False] Update the data in place if possible.

`limit_direction` [{{‘forward’, ‘backward’, ‘both’}}, Optional] Consecutive NaNs will be filled in this direction.

**If limit is specified:**

- If `method` is ‘pad’ or ‘ffill’, ‘limit_direction’ must be ‘forward’.
- If `method` is ‘backfill’ or ‘bfill’, ‘limit_direction’ must be ‘backwards’.

**If ‘limit’ is not specified:**

- If `method` is ‘backfill’ or ‘bfill’, the default is ‘backward’
- else the default is ‘forward’

Changed in version 1.1.0: raises ValueError if `limit_direction` is ‘forward’ or ‘both’ and method is ‘backfill’ or ‘bfill’. raises ValueError if `limit_direction` is ‘backward’ or ‘both’ and method is ‘pad’ or ‘ffill’.

`limit_area` [{{None, ‘inside’, ‘outside’}}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.

- None: No fill restriction.
- ‘inside’: Only fill NaNs surrounded by valid values (interpolate).
- ‘outside’: Only fill NaNs outside valid values (extrapolate).

`downcast` [optional, ‘infer’ or None, defaults to None] Downcast dtypes if possible.

`**kwargs` [optional] Keyword arguments to pass on to the interpolating function.

**Returns**

Series or DataFrame or None Returns the same object type as the caller, interpolated at some or all NaN values or None if inplace=True.

**See also:**

- `fillna` Fill missing values using different methods.
- `scipy.interpolate.Akima1DInterpolator` Piecewise cubic polynomials (Akima interpolator).
- `scipy.interpolate.BPoly.from_derivatives` Piecewise polynomial in the Bernstein basis.
- `scipy.interpolate.interp1d` Interpolate a 1-D function.
- `scipy.interpolate.KroghInterpolator` Interpolate polynomial (Krogh interpolator).
- `scipy.interpolate.CubicSpline` Cubic spline data interpolator.
Notes

The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the SciPy documentation and SciPy tutorial.

Examples

Filling in NaN in a Series via linear interpolation.

```python
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2   NaN
3    3.0
dtype: float64
>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.

```python
>>> s = pd.Series([np.nan, "single_one", np.nan,
...                  "fill_two_more", np.nan, np.nan, np.nan,
...                  4.71, np.nan])
>>> s
0       NaN
1  single_one
2       NaN
3  fill_two_more
4       NaN
5       NaN
6       NaN
7   4.71
8   NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0       NaN
1   single_one
2   single_one
3  fill_two_more
4  fill_two_more
5  fill_two_more
6       NaN
7   4.71
8   4.71
dtype: object
```

Filling in NaN in a Series via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an order (int).
Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it to use for interpolation.

Using polynomial interpolation.

**pandas.core.resample.Resampler.count**

Resampler.count()  
Compute count of group, excluding missing values.  
**Returns**  
- **Series or DataFrame**  
  Count of values within each group.  
**See also:**  
- `Series.groupby`  
  Apply a function groupby to a Series.  
- `DataFrame.groupby`  
  Apply a function groupby to each row or column of a DataFrame.

**pandas.core.resample.Resampler.nunique**

Resampler.nunique(_method='nunique')  
Return number of unique elements in the group.  
**Returns**  
- **Series**  
  Number of unique values within each group.

**pandas.core.resample.Resampler.first**

Resampler.first(_method='first', min_count=0, *args, **kwargs)  
Compute first of group values.  
**Parameters**  
- **numeric_only** [bool, default False]  Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.  
- **min_count** [int, default -1]  The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.  
**Returns**  
- **Series or DataFrame**  
  Computed first of values within each group.
**pandas.core.resample.Resampler.last**

`Resampler.last(_method='last', min_count=0, *args, **kwargs)`  
Compute last of group values.

**Parameters**

- `numeric_only` [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
- `min_count` [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

**Returns**

- **Series or DataFrame** Computed last of values within each group.

**pandas.core.resample.Resampler.max**

`Resampler.max(_method='max', min_count=0, *args, **kwargs)`  
Compute max of group values.

**Parameters**

- `numeric_only` [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
- `min_count` [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

**Returns**

- **Series or DataFrame** Computed max of values within each group.

**pandas.core.resample.Resampler.mean**

`Resampler.mean(_method='mean', *args, **kwargs)`  
Compute mean of groups, excluding missing values.

**Parameters**

- `numeric_only` [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

**Returns**

- pandas.Series or pandas.DataFrame

See also:

- `Series.groupby` Apply a function groupby to a Series.
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.
Examples

```python
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
                      'B': [np.nan, 2, 3, 4, 5],
                      'C': [1, 2, 1, 1, 2]}, columns=['A', 'B', 'C'])

Groupby one column and return the mean of the remaining columns in each group.

```python
>>> df.groupby('A').mean()
```

```
     B      C
A
1  3.0  1.333333
2  4.0  1.500000
```

Groupby two columns and return the mean of the remaining column.

```python
>>> df.groupby(['A', 'B']).mean()
```

```
    C
   A B
1  2.0  2.0
   4.0  1.0
2  3.0  1.0
   5.0  2.0
```

Groupby one column and return the mean of only particular column in the group.

```python
>>> df.groupby('A')['B'].mean()
```

```
   A
1  3.0
2  4.0
Name: B, dtype: float64
```

**pandas.core.resample.Resampler.median**

Resampler.median(_method='median', *args, **kwargs)

Compute median of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

**Parameters**

- numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

**Returns**

Series or DataFrame Median of values within each group.

**See also:**

- **Series.groupby** Apply a function groupby to a Series.
- **DataFrame.groupby** Apply a function groupby to each row or column of a DataFrame.
pandas.core.resample.Resampler.min

Resampler.min(_method='min', min_count=0, *args, **kwargs)
    Compute min of group values.

Parameters
    numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
    min_count [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns
    Series or DataFrame Computed min of values within each group.

pandas.core.resample.Resampler.ohlc

Resampler.ohlc(_method='ohlc', *args, **kwargs)
    Compute open, high, low and close values of a group, excluding missing values.
    For multiple groupings, the result index will be a MultiIndex

Returns
    DataFrame Open, high, low and close values within each group.

See also:
    Series.groupby Apply a function groupby to a Series.
    DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.resample.Resampler.prod

Resampler.prod(_method='prod', min_count=0, *args, **kwargs)
    Compute prod of group values.

Parameters
    numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
    min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns
    Series or DataFrame Computed prod of values within each group.

pandas.core.resample.Resampler.size

Resampler.size()
    Compute group sizes.

Returns
    DataFrame or Series Number of rows in each group as a Series if as_index is True or a DataFrame if as_index is False.

See also:
    Series.groupby Apply a function groupby to a Series.
    DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.
pandas.core.resample.Resampler.sem

Resampler.sem(_method='sem', *args, **kwargs)
Compute standard error of the mean of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

d dof [int, default 1] Degrees of freedom.

Returns

Series or DataFrame Standard error of the mean of values within each group.

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.resample.Resampler.std

Resampler.std(ddof=1, *args, **kwargs)
Compute standard deviation of groups, excluding missing values.

Parameters

d dof [int, default 1] Degrees of freedom.

Returns

DataFrame or Series Standard deviation of values within each group.

pandas.core.resample.Resampler.sum

Resampler.sum(_method='sum', min_count=0, *args, **kwargs)
Compute sum of group values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed sum of values within each group.

pandas.core.resample.Resampler.var

Resampler.var(ddof=1, *args, **kwargs)
Compute variance of groups, excluding missing values.

Parameters

d dof [int, default 1] Degrees of freedom.

Returns

DataFrame or Series Variance of values within each group.
pandas.core.resample.Resampler.quantile

Resampler.quantile(q=0.5, **kwargs)
Return value at the given quantile.

Parameters

q [float or array-like, default 0.5 (50% quantile)]

Returns

DataFrame or Series  Quantile of values within each group.

See also:

Series.quantile  Return a series, where the index is q and the values are the quantiles.
DataFrame.quantile  Return a DataFrame, where the columns are the columns of self, and the values are the quantiles.
DataFrameGroupBy.quantile  Return a DataFrame, where the columns are groupby columns, and the values are its quantiles.

3.12 Style

Styler objects are returned by pandas.DataFrame.style.

3.12.1 Styler constructor

Styler(data[, precision, table_styles, ...])  Helps style a DataFrame or Series according to the data with HTML and CSS.

Styler.from_custom_template(searchpath[, ...])  Factory function for creating a subclass of Styler.

pandas.io.formats.style.Styler

class pandas.io.formats.style.Styler (data, precision=None, table_styles=None, uuid=None, caption=None, table_attributes=None, cell_ids=True, na_rep=None, uuid_len=5, decimal='.', thousands=None, escape=None)
Helps style a DataFrame or Series according to the data with HTML and CSS.

Parameters

data [Series or DataFrame]  Data to be styled - either a Series or DataFrame.
precision [int]  Precision to round floats to, defaults to pd.options.display.precision.
table_styles [list-like, default None]  List of {selector: (attr, value)} dicts; see Notes.
uuid [str, default None]  A unique identifier to avoid CSS collisions; generated automatically.
caption [str, tuple, default None]  String caption to attach to the table. Tuple only used for LaTeX dual captions.

Table  tag in addition to automatic (by default) id.
cell_ids [bool, default True]  If True, each cell will have an id attribute in their HTML tag. The id takes the form T_<uuid>_row<num_row>_col<num_col> where
<uuid> is the unique identifier, <num_row> is the row number and <num_col> is the column number.

**na_rep** [str, optional] Representation for missing values. If na_rep is None, no special formatting is applied.

New in version 1.0.0.

**uuid_len** [int, default 5] If uuid is not specified, the length of the uuid to randomly generate expressed in hex characters, in range [0, 32].

New in version 1.2.0.

**decimal** [str, default "."] Character used as decimal separator for floats, complex and integers

New in version 1.3.0.

**thousands** [str, optional, default None] Character used as thousands separator for floats, complex and integers

New in version 1.3.0.

**escape** [str, optional] Use ‘html’ to replace the characters &, <, >, ', and " in cell display string with HTML-safe sequences. Use ‘latex’ to replace the characters &, %, $, #, _, {, }, ~, ^, _, and \ in the cell display string with LaTeX-safe sequences.

New in version 1.3.0.

See also:

**DataFrame.style** Return a Styler object containing methods for building a styled HTML representation for the DataFrame.

Notes

Most styling will be done by passing style functions into Styler.apply or Styler.applymap. Style functions should return values with strings containing CSS 'attr: value' that will be applied to the indicated cells.

If using in the Jupyter notebook, Styler has defined a _repr_html_ to automatically render itself. Otherwise call Styler.render to get the generated HTML.

CSS classes are attached to the generated HTML
- Index and Column names include index_name and level<k> where k is its level in a MultiIndex
- Index label cells include
  - row_heading
  - row<n> where n is the numeric position of the row
  - level<k> where k is the level in a MultiIndex
- Column label cells include *col_heading* *col<n>* where n is the numeric position of the column
  - level<k> where k is the level in a MultiIndex
- Blank cells include blank
- Data cells include data
Attributes

<table>

Methods

apply(func[, axis, subset])
Apply a CSS-styling function column-wise, row-wise, or table-wise.

applymap(func[, subset])
Apply a CSS-styling function elementwise.

background_gradient([cmap, low, high, axis, ...])
Color the background in a gradient style.

bar([subset, axis, color, width, align, ...])
Draw bar chart in the cell backgrounds.

clear()
Reset the Styler, removing any previously applied styles.

export()
Export the styles applied to the current Styler.

format([formatter, subset, na_rep, ...])
Format the text display value of cells.

from_custom_template(searchpath[, ...])
Factory function for creating a subclass of Styler.

hide_columns([subset])
Hide the column headers or specific keys in the columns from rendering.

hide_index([subset])
Hide the entire index, or specific keys in the index from rendering.

highlight_between([subset, color, axis, ...])
Highlight a defined range with a style.

highlight_max([subset, color, axis, props])
Highlight the maximum with a style.

highlight_min([subset, color, axis, props])
Highlight the minimum with a style.

highlight_null([null_color, subset, props])
Highlight missing values with a style.

highlight_quantile([subset, color, axis, ...])
Highlight values defined by a quantile with a style.

pipe(func, *args, **kwargs)
Apply func(self, *args, **kwargs), and return the result.

render([sparse_index, sparse_columns])
Render the Styler including all applied styles to HTML.

set_caption(caption)
Set the text added to a <caption> HTML element.

set_na_rep(na_rep)
(DEPRECATED) Set the missing data representation on a Styler.

set_precision(precision)
(DEPRECATED) Set the precision used to display values.

set_properties([subset])
Set defined CSS-properties to each <td> HTML element within the given subset.

set_sticky([axis, pixel_size, levels])
Add CSS to permanently display the index or column headers in a scrolling frame.

set_table_attributes(attributes)
Set the table attributes added to the <table> HTML element.

set_table_styles(table_styles[, axis, overwrite])
Set the table styles included within the <style> HTML element.

set_td_classes(classes)
Set the DataFrame of strings added to the class attribute of <td> HTML elements.

set_tooltips(ttips[, props, css_class])
Set the DataFrame of strings on Styler generating :hover tooltips.

**pandas.io.formats.style.Styler.apply**

**Styler.apply** *(func, axis=0, subset=None, **kwargs)*

Apply a CSS-styling function column-wise, row-wise, or table-wise.

Updates the HTML representation with the result.

**Parameters**

- **func** [function] `func` should take a Series if `axis` in [0,1] and return an object of same length, also with identical index if the object is a Series. `func` should take a DataFrame if `axis` is `None` and return either an ndarray with the same shape or a DataFrame with identical columns and index.

  Changed in version 1.3.0.

- **axis** [[0 or 'index', 1 or 'columns', None], default 0] Apply to each column (`axis=0` or 'index'), to each row (`axis=1` or 'columns'), or to the entire DataFrame at once with `axis=None`.

- **subset** [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.

- **kwargs** [dict] Pass along to `func`.

**Returns**

- **self** [Styler]

**See also:**

- **Styler.applymap** Apply a CSS-styling function elementwise.
Notes

The elements of the output of `func` should be CSS styles as strings, in the format `attribute: value; attribute2: value2; ...` or, if nothing is to be applied to that element, an empty string or `None`.

This is similar to `DataFrame.apply`, except that `axis=None` applies the function to the entire DataFrame at once, rather than column-wise or row-wise.

Examples

```python
>>> def highlight_max(x, color):
...     return np.where(x == np.nanmax(x.to_numpy()), f"color: {color};", "None")
...     return None

>>> df = pd.DataFrame(np.random.randn(5, 2), columns=["A", "B"])
>>> df.style.apply(highlight_max, color='red')
>>> df.style.apply(highlight_max, color='blue', axis=1)
>>> df.style.apply(highlight_max, color='green', axis=None)
```

Using `subset` to restrict application to a single column or multiple columns

```python
>>> df.style.apply(highlight_max, color='red', subset="A")
>>> df.style.apply(highlight_max, color='red', subset=['A', 'B'])
```

Using a 2d input to `subset` to select rows in addition to columns

```python
>>> df.style.apply(highlight_max, color='red', subset=(slice(0, 5, 2), "A"))
```

pandas.io.formats.style.Styler.applymap

`Styler.applymap(func, subset=None, **kwargs)`

Apply a CSS-styling function elementwise.

Updates the HTML representation with the result.

**Parameters**

- `func` [function] `func` should take a scalar and return a scalar.
- `subset` [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.
- `**kwargs` [dict] Pass along to `func`.

**Returns**

- `self` [Styler]

See also:

- `Styler.apply` Apply a CSS-styling function column-wise, row-wise, or table-wise.
Notes

The elements of the output of `func` should be CSS styles as strings, in the format ‘attribute: value; attribute2: value2; …’ or, if nothing is to be applied to that element, an empty string or `None`.

Examples

```python
>>> def color_negative(v, color):
...     return f"color: {color};" if v < 0 else None
>>> df = pd.DataFrame(np.random.randn(5, 2), columns=['A', 'B'])
>>> df.style.applymap(color_negative, color='red')

Using subset to restrict application to a single column or multiple columns

```python
>>> df.style.applymap(color_negative, color='red', subset='A')
```python
>>> df.style.applymap(color_negative, color='red', subset=['A', 'B'])

Using a 2d input to subset to select rows in addition to columns

```python
>>> df.style.applymap(color_negative, color='red', subset=(slice(0, 5, 2), 'A'))
```python

pandas.io.formats.style.Styler.background_gradient

Styler.

```python
background_gradient(cmap='PuBu', low=0, high=0, axis=0, subset=None,
text_color_threshold=0.408, vmin=None, vmax=None, gmap=None)
```python

Color the background in a gradient style.

The background color is determined according to the data in each column, row or frame, or by a given gradient map. Requires matplotlib.

Parameters

- `cmap` [str or colormap] Matplotlib colormap.
- `low` [float] Compress the color range at the low end. This is a multiple of the data range to extend below the minimum; good values usually in [0, 1], defaults to 0.
- `high` [float] Compress the color range at the high end. This is a multiple of the data range to extend above the maximum; good values usually in [0, 1], defaults to 0.
- `axis` [[0 or 'index', 1 or 'columns', None], default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.
- `subset` [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[: , <subset>] where the columns are prioritised, to limit data to before applying the function.
- `text_color_threshold` [float or int] Luminance threshold for determining text color in [0, 1]. Facilitates text visibility across varying background colors. All text is dark if 0, and light if 1, defaults to 0.408.
**vmin** [float, optional] Minimum data value that corresponds to colormap minimum value. If not specified the minimum value of the data (or gmap) will be used.

New in version 1.0.0.

**vmax** [float, optional] Maximum data value that corresponds to colormap maximum value. If not specified the maximum value of the data (or gmap) will be used.

New in version 1.0.0.

**gmap** [array-like, optional] Gradient map for determining the background colors. If not supplied will use the underlying data from rows, columns or frame. If given as an ndarray or list-like must be an identical shape to the underlying data considering **axis** and **subset**. If given as DataFrame or Series must have same index and column labels considering **axis** and **subset**. If supplied, vmin and vmax should be given relative to this gradient map.

New in version 1.3.0.

Returns

**self** [Styler]

See also:

*Styler.text_gradient* Color the text in a gradient style.

Notes

When using low and high the range of the gradient, given by the data if gmap is not given or by gmap, is extended at the low end effectively by \(\text{map.min} - \text{low} \times \text{map.range}\) and at the high end by \(\text{map.max} + \text{high} \times \text{map.range}\) before the colors are normalized and determined.

If combining with vmin and vmax the map.min, map.max and map.range are replaced by values according to the values derived from vmin and vmax.

This method will preselect numeric columns and ignore non-numeric columns unless a gmap is supplied in which case no preselection occurs.

Examples

```python
>>> df = pd.DataFrame(columns=["City", "Temp (c)", "Rain (mm)", "Wind (m/s)
˓
...
... data=["Stockholm", 21.6, 5.0, 3.2],
... ["Oslo", 22.4, 13.3, 3.1],
... ["Copenhagen", 24.5, 0.0, 6.7])
```

Shading the values column-wise, with axis=0, preselecting numeric columns

```python
>>> df.style.background_gradient(axis=0)
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (c)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stockholm</td>
<td>21.600000</td>
<td>5.000000</td>
<td>3.200000</td>
</tr>
<tr>
<td>Oslo</td>
<td>22.400000</td>
<td>13.300000</td>
<td>3.100000</td>
</tr>
<tr>
<td>Copenhagen</td>
<td>24.500000</td>
<td>0.000000</td>
<td>6.700000</td>
</tr>
</tbody>
</table>
Shading all values collectively using `axis=None`

```python
>>> df.style.background_gradient(axis=None)
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (°C)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 Stockholm</td>
<td>21.600000</td>
<td>5.000000</td>
<td>3.200000</td>
</tr>
<tr>
<td>1 Oslo</td>
<td>22.400000</td>
<td>13.300000</td>
<td>3.100000</td>
</tr>
<tr>
<td>2 Copenhagen</td>
<td>24.500000</td>
<td>0.000000</td>
<td>6.700000</td>
</tr>
</tbody>
</table>

Compress the color map from the both low and high ends

```python
>>> df.style.background_gradient(axis=None, low=0.75, high=1.0)
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (°C)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 Stockholm</td>
<td>21.600000</td>
<td>5.000000</td>
<td>3.200000</td>
</tr>
<tr>
<td>1 Oslo</td>
<td>22.400000</td>
<td>13.300000</td>
<td>3.100000</td>
</tr>
<tr>
<td>2 Copenhagen</td>
<td>24.500000</td>
<td>0.000000</td>
<td>6.700000</td>
</tr>
</tbody>
</table>

Manually setting `vmin` and `vmax` gradient thresholds

```python
>>> df.style.background_gradient(axis=None, vmin=6.7, vmax=21.6)
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (°C)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 Stockholm</td>
<td>21.600000</td>
<td>5.000000</td>
<td>3.200000</td>
</tr>
<tr>
<td>1 Oslo</td>
<td>22.400000</td>
<td>13.300000</td>
<td>3.100000</td>
</tr>
<tr>
<td>2 Copenhagen</td>
<td>24.500000</td>
<td>0.000000</td>
<td>6.700000</td>
</tr>
</tbody>
</table>

Setting a `gmap` and applying to all columns with another `cmap`

```python
>>> df.style.background_gradient(axis=0, gmap=df['Temp (°C)'], cmap='YlOrRd')
```

Setting the gradient map for a datafame (i.e. `axis=None`), we need to explicitly state `subset` to match the `gmap` shape

```python
>>> gmap = np.array([[1,2,3], [2,3,4], [3,4,5]])
>>> df.style.background_gradient(axis=None, gmap=gmap, ... cmap='YlOrRd', subset=['Temp (°C)', 'Rain (mm)', 'Wind (m/s)'])
... ```
### pandas.io.formats.style.Styler.bar

`Styler.bar(subset=None, axis=0, color='#d65f5f', width=100, align='left', vmin=None, vmax=None)`

Draw bar chart in the cell backgrounds.

**Parameters**

- **subset** [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.

- **axis** [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.

- **color** [str or 2-tuple/list] If a str is passed, the color is the same for both negative and positive numbers. If 2-tuple/list is used, the first element is the color_negative and the second is the color_positive (eg: ['#d65f5f', '#5fba7d']).

- **width** [float, default 100] A number between 0 or 100. The largest value will cover width percent of the cell’s width.

- **align** [{'left', 'zero', 'mid'}, default 'left'] How to align the bars with the cells.
  - ‘left’: the min value starts at the left of the cell.
  - ‘zero’: a value of zero is located at the center of the cell.
  - ‘mid’: the center of the cell is at (max-min)/2, or if values are all negative (positive) the zero is aligned at the right (left) of the cell.

- **vmin** [float, optional] Minimum bar value, defining the left hand limit of the bar drawing range, lower values are clipped to vmin. When None (default): the minimum value of the data will be used.

- **vmax** [float, optional] Maximum bar value, defining the right hand limit of the bar drawing range, higher values are clipped to vmax. When None (default): the maximum value of the data will be used.

**Returns**

- self [Styler]
pandas.io.formats.style.Styler.clear

Styler.clear()
Reset the Styler, removing any previously applied styles.
Returns None.

pandas.io.formats.style.Styler.export

Styler.export()
Export the styles applied to the current Styler.
Can be applied to a second Styler with Styler.use.

Returns
styles [list]

See also:
Styler.use Set the styles on the current Styler.

pandas.io.formats.style.Styler.format

Styler.format(formatter=None, subset=None, na_rep=None, precision=None, decimal='.', thousands=None, escape=None)
Format the text display value of cells.

Parameters

formatter [str, callable, dict or None] Object to define how values are displayed. See notes.

subset [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.

na_rep [str, optional] Representation for missing values. If na_rep is None, no special formatting is applied.
New in version 1.0.0.

precision [int, optional] Floating point precision to use for display purposes, if not determined by the specified formatter.
New in version 1.3.0.

decimal [str, default “.”] Character used as decimal separator for floats, complex and integers
New in version 1.3.0.

thousands [str, optional, default None] Character used as thousands separator for floats, complex and integers
New in version 1.3.0.
**escape** [str, optional] Use ‘html’ to replace the characters $, <, >, ', and " in cell display string with HTML-safe sequences. Use ‘latex’ to replace the characters $, \%, \#, \_, (, ), \~, \^, and \ in the cell display string with LaTeX-safe sequences. Escaping is done before formatter.

Returns

self [Styler]

Notes

This method assigns a formatting function, formatter, to each cell in the DataFrame. If formatter is None, then the default formatter is used. If a callable then that function should take a data value as input and return a displayable representation, such as a string. If formatter is given as a string this is assumed to be a valid Python format specification and is wrapped to a callable as string.format(x).

The default formatter currently expresses floats and complex numbers with the pandas display precision unless using the precision argument here. The default formatter does not adjust the representation of missing values unless the na_rep argument is used.

The subset argument defines which region to apply the formatting function to. If the formatter argument is given in dict form but does not include all columns within the subset then these columns will have the default formatter applied. Any columns in the formatter dict excluded from the subset will raise a KeyError.

When using a formatter string the dtypes must be compatible, otherwise a ValueError will be raised.

Examples

Using na_rep and precision with the default formatter

```python
>>> df = pd.DataFrame([[np.nan, 1.0, 'A'], [2.0, np.nan, 3.0]])
>>> df.style.format(na_rep='MISS', precision=3)
     0 1  2
0  MISS 1.000 A
1  2.000 MISS 3.000
```

Using a formatter specification on consistent column dtypes

```python
>>> df.style.format('{:.2f}', na_rep='MISS', subset=[0,1])
     0 1 2
0  MISS 1.00 A
1  2.00 MISS 3.000000
```

Using the default formatter for unspecified columns

```python
>>> df.style.format({0: '{:.2f}', 1: '{:.1f}'}, na_rep='MISS', precision=1)
     0 1  2
0  MISS i 1.0 A
1  2.00 MISS 3.0
```

Multiple na_rep or precision specifications under the default formatter.
Using a callable formatter function.

```python
>>> func = lambda s: 'STRING' if isinstance(s, str) else 'FLOAT'
```
pandas: powerful Python data analysis toolkit, Release 1.3.2

New in version 1.3.0.
Returns
MyStyler [subclass of Styler] Has the correct env,``template_html``,
template_html_table and template_html_style class attributes
set.
pandas.io.formats.style.Styler.hide_columns
Styler.hide_columns(subset=None)
Hide the column headers or specific keys in the columns from rendering.
This method has dual functionality:
• if subset is None then the entire column headers row will be hidden whilst the data-values remain
visible.
• if a subset is given then those specific columns, including the data-values will be hidden, whilst
the column headers row remains visible.
Changed in version 1.3.0.
Parameters
subset [label, array-like, IndexSlice, optional] A valid 1d input or single key along the
columns axis within DataFrame.loc[:, <subset>], to limit data to before applying
the function.
Returns
self [Styler]
See also:
Styler.hide_index Hide the entire index, or specific keys in the index.
Examples
Simple application hiding specific columns:
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=["a", "b", "c"])
>>> df.style.hide_columns(["a", "b"])
c
0
3
1
6

Hide column headers and retain the data values:
>>>
>>>
>>>
x

y

2496

midx = pd.MultiIndex.from_product([["x", "y"], ["a", "b", "c"]])
df = pd.DataFrame(np.random.randn(6,6), index=midx, columns=midx)
df.style.format("{:.1f}").hide_columns()

Chapter 3. API reference


Hide specific columns but retain the column headers:

```python
>>> df.style.format("{:..1f}").hide_columns(subset=(slice(None), ["a", "c"]))
x  y
b  b
x a  0.0  0.6
b 1.0 -0.0
c -0.8 -0.4
y a  1.0 -1.2
b 1.2  0.3
c 0.5  2.2
```

Hide specific columns and the column headers:

```python
>>> df.style.format("{:..1f}").hide_columns(subset=(slice(None), ["a", "c"])).hide_columns()
x  y
b  b
x a  0.0  0.6
b 1.0 -0.0
c -0.8 -0.4
y a  1.0 -1.2
b 1.2  0.3
c 0.5  2.2
```

**pandas.io.formats.style.Styler.hide_index**

Styler.hide_index (subset=None)

Hide the entire index, or specific keys in the index from rendering.

This method has dual functionality:

- if subset is None then the entire index will be hidden whilst displaying all data-rows.
- if a subset is given then those specific rows will be hidden whilst the index itself remains visible.

Changed in version 1.3.0.

**Parameters**

- subset [label, array-like, IndexSlice, optional] A valid 1d input or single key along the index axis within DataFrame.loc[<subset>, :], to limit data to before applying the function.

**Returns**

- self [Styler]

**See also:**

Styler.hide_columns  Hide the entire column headers row, or specific columns.
### Examples

Simple application hiding specific rows:

```python
>>> df = pd.DataFrame([[1, 2], [3, 4], [5, 6]], index=["a", "b", "c"])
>>> df.style.hide_index(['a', 'b'])
  0  1  
c  5  6
```

Hide the index and retain the data values:

```python
>>> midx = pd.MultiIndex.from_product([['x', 'y'], ['a', 'b', 'c']])
>>> df = pd.DataFrame(np.random.randn(6, 6), index=midx, columns=midx)
>>> df.style.format("{:.1f}").hide_index()
  x   y
a   b   c   a   b   c
0.1  0.0  0.4  1.3  0.6 -1.4
0.7  1.0  1.3  1.5 -0.0 -0.2
1.4 -0.8  1.6 -0.2 -0.4 -0.3
0.4  1.0 -0.2 -0.8 -1.2  1.1
-0.6  1.2  1.8  1.9  0.3  0.3
0.8  0.5 -0.3  1.2  2.2 -0.8
```

Hide specific rows but retain the index:

```python
>>> df.style.format("{:.1f}").hide_index(subset=(slice(None), ['a', 'c']))
  x   y
x   b  0.7  1.0  1.3  1.5 -0.0 -0.2
y   b -0.6  1.2  1.8  1.9  0.3  0.3
```

Hide specific rows and the index:

```python
>>> df.style.format("{:.1f}").hide_index(subset=(slice(None), ['a', 'c']))
... .hide_index()
  x   y
  a   b   c   a   b   c
0.7  1.0  1.3  1.5 -0.0 -0.2
-0.6  1.2  1.8  1.9  0.3  0.3
```

---

### pandas.io.formats.style.Styler.highlight_between

**Styler.highlight_between**(subset=None, color='yellow', axis=0, left=None, right=None, inclusive='both', props=None)

Highlight a defined range with a style.

New in version 1.3.0.

**Parameters**

- **subset** [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.

- **color** [str, default ‘yellow’] Background color to use for highlighting.
**axis** [{0 or 'index', 1 or 'columns', None}, default 0] If left or right given as sequence, axis along which to apply those boundaries. See examples.

**left** [scalar or datetime-like, or sequence or array-like, default None] Left bound for defining the range.

**right** [scalar or datetime-like, or sequence or array-like, default None] Right bound for defining the range.

**inclusive** [{‘both’, ‘neither’, ‘left’, ‘right’}] Identify whether bounds are closed or open.

**props** [str, default None] CSS properties to use for highlighting. If props is given, color is not used.

**Returns**

self [Styler]

**See also:**

*Styler.highlight_null* Highlight missing values with a style.

*Styler.highlight_max* Highlight the maximum with a style.

*Styler.highlight_min* Highlight the minimum with a style.

*Styler.highlight_quantile* Highlight values defined by a quantile with a style.

**Notes**

If left is None only the right bound is applied. If right is None only the left bound is applied. If both are None all values are highlighted.

axis is only needed if left or right are provided as a sequence or an array-like object for aligning the shapes. If left and right are both scalars then all axis inputs will give the same result.

This function only works with compatible dtypes. For example a datetime-like region can only use equivalent datetime-like left and right arguments. Use subset to control regions which have multiple dtypes.

**Examples**

Basic usage

```python
>>> df = pd.DataFrame({'
...     'One': [1.2, 1.6, 1.5],
...     'Two': [2.9, 2.1, 2.5],
...     'Three': [3.1, 3.2, 3.8],
... })
>>> df.style.highlight_between(left=2.1, right=2.9)
```

<table>
<thead>
<tr>
<th></th>
<th>One</th>
<th>Two</th>
<th>Three</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1.2</td>
<td>2.9</td>
<td>3.1</td>
</tr>
<tr>
<td>1</td>
<td>1.6</td>
<td>2.1</td>
<td>3.2</td>
</tr>
<tr>
<td>2</td>
<td>1.5</td>
<td>2.5</td>
<td>3.8</td>
</tr>
</tbody>
</table>
Using a range input sequence along an axis, in this case setting a left and right for each column individually

```python
>>> df.style.highlight_between(left=[1.4, 2.4, 3.4], right=[1.6, 2.6, 3.6], axis=1, color="#fffd75")
```

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1.2</td>
<td>2.9 3.1</td>
</tr>
<tr>
<td>1</td>
<td>1.6</td>
<td>2.1 3.2</td>
</tr>
<tr>
<td>2</td>
<td>1.5</td>
<td>2.5 3.8</td>
</tr>
</tbody>
</table>

Using axis=None and providing the left argument as an array that matches the input DataFrame, with a constant right

```python
>>> df.style.highlight_between(left=[[2,2,3],[2,2,3],[3,3,3]], right=3.5, axis=None, color="#fffd75")
```

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1.2</td>
<td>2.9 3.1</td>
</tr>
<tr>
<td>1</td>
<td>1.6</td>
<td>2.1 3.2</td>
</tr>
<tr>
<td>2</td>
<td>1.5</td>
<td>2.5 3.8</td>
</tr>
</tbody>
</table>

Using props instead of default background coloring

```python
>>> df.style.highlight_between(left=1.5, right=3.5, props='font-weight:bold;color:#e83e8c')
```

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1.2</td>
<td>2.9 3.1</td>
</tr>
<tr>
<td>1</td>
<td>1.6</td>
<td>2.1 3.2</td>
</tr>
<tr>
<td>2</td>
<td>1.5</td>
<td>2.5 3.8</td>
</tr>
</tbody>
</table>

**pandas.io.formats.style.Styler.highlight_max**

Styler.highlight_max (subset=None, color='yellow', axis=0, props=None)
Highlight the maximum with a style.

**Parameters**

- subset [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.

- color [str, default 'yellow'] Background color to use for highlighting.

- axis [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.
props [str, default None] CSS properties to use for highlighting. If props is given, color is not used.

New in version 1.3.0.

Returns

self [Styler]

See also:

Styler.highlight_null Highlight missing values with a style.
Styler.highlight_min Highlight the minimum with a style.
Styler.highlight_between Highlight a defined range with a style.
Styler.highlight_quantile Highlight values defined by a quantile with a style.

pandas.io.formats.style.Styler.highlight_min

Styler.highlight_min (subset=None, color='yellow', axis=0, props=None)
Highlight the minimum with a style.

Parameters

subset [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.

color [str, default 'yellow'] Background color to use for highlighting.

axis [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.

props [str, default None] CSS properties to use for highlighting. If props is given, color is not used.

New in version 1.3.0.

Returns

self [Styler]

See also:

Styler.highlight_null Highlight missing values with a style.
Styler.highlight_max Highlight the maximum with a style.
Styler.highlight_between Highlight a defined range with a style.
Styler.highlight_quantile Highlight values defined by a quantile with a style.
**pandas.io.formats.style.Styler.highlight_null**

Styler.highlight_null(null_color='red', subset=None, props=None)

Highlight missing values with a style.

**Parameters**

- **null_color** [str, default 'red']
- **subset** [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[; <subset>] where the columns are prioritised, to limit data to before applying the function.
  
  New in version 1.1.0.

- **props** [str, default None] CSS properties to use for highlighting. If props is given, color is not used.
  
  New in version 1.3.0.

**Returns**

self [Styler]

See also:

- **Styler.highlight_max** Highlight the maximum with a style.
- **Styler.highlight_min** Highlight the minimum with a style.
- **Styler.highlight_between** Highlight a defined range with a style.
- **Styler.highlight_quantile** Highlight values defined by a quantile with a style.

**pandas.io.formats.style.Styler.highlight_quantile**

Styler.highlight_quantile(subset=None, color='yellow', axis=0, q_left=0.0, q_right=1.0, interpolation='linear', inclusive='both', props=None)

Highlight values defined by a quantile with a style.

New in version 1.3.0.

**Parameters**

- **subset** [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[; <subset>] where the columns are prioritised, to limit data to before applying the function.

- **color** [str, default 'yellow'] Background color to use for highlighting

- **axis** [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Axis along which to determine and highlight quantiles. If None quantiles are measured over the entire DataFrame. See examples.

- **q_left** [float, default 0] Left bound, in [0, q_right), for the target quantile range.

- **q_right** [float, default 1] Right bound, in (q_left, 1], for the target quantile range.

inclusive [{‘both’, ‘neither’, ‘left’, ‘right’}] Identify whether quantile bounds are closed or open.

props [str, default None] CSS properties to use for highlighting. If props is given, color is not used.

Returns

self [Styler]

See also:

Styler.highlight_null  Highlight missing values with a style.
Styler.highlight_max  Highlight the maximum with a style.
Styler.highlight_min  Highlight the minimum with a style.
Styler.highlight_between  Highlight a defined range with a style.

Notes

This function does not work with str dtypes.

Examples

Using axis=None and apply a quantile to all collective data

```python
>>> df = pd.DataFrame(np.arange(10).reshape(2,5) + 1)
>>> df.style.highlight_quantile(axis=None, q_left=0.8, color="#fffd75")
```

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>6</td>
<td>7</td>
<td>8</td>
<td>9</td>
</tr>
</tbody>
</table>

Or highlight quantiles row-wise or column-wise, in this case by row-wise

```python
>>> df.style.highlight_quantile(axis=1, q_left=0.8, color="#fffd75")
```

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>6</td>
<td>7</td>
<td>8</td>
<td>9</td>
</tr>
</tbody>
</table>

Use props instead of default background coloring

```python
>>> df.style.highlight_quantile(axis=None, q_left=0.2, q_right=0.8, ... props='font-weight:bold;color:#e83e8c')
```

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>6</td>
<td>7</td>
<td>8</td>
<td>9</td>
</tr>
</tbody>
</table>
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.io.formats.style.Styler.pipe

Styler.pipe(func, *args, **kwargs)
Apply func(self, *args, **kwargs), and return the result.

Parameters

func [function] Function to apply to the Styler. Alternatively, a (callable, keyword) tuple where keyword is a string indicating the keyword of callable that expects the Styler.

*args [optional] Arguments passed to func.

**kwargs [optional] A dictionary of keyword arguments passed into func.

Returns

object : The value returned by func.

See also:

DataFrame.pipe Analogous method for DataFrame.

Styler.apply Apply a CSS-styling function column-wise, row-wise, or table-wise.

Notes

Like DataFrame.pipe(), this method can simplify the application of several user-defined functions to a styler. Instead of writing:

f(g(df.style.set_precision(3), arg1=a), arg2=b, arg3=c)

users can write:

(df.style.set_precision(3)
 .pipe(g, arg1=a)
 .pipe(f, arg2=b, arg3=c))

In particular, this allows users to define functions that take a styler object, along with other parameters, and return the styler after making styling changes (such as calling Styler.apply() or Styler.set_properties()). Using .pipe, these user-defined style “transformations” can be interleaved with calls to the built-in Styler interface.

Examples

>>> def format_conversion(styler):
...    return (styler.set_properties(**{'text-align': 'right'})
...             .format({'conversion': '{:.1%}'}))

The user-defined format_conversion function above can be called within a sequence of other style modifications:

>>> df = pd.DataFrame({'trial': list(range(5)),
...                    'conversion': [0.75, 0.85, np.nan, 0.7, 0.72]})

(continues on next page)
... .pipe(format_conversion)
... .set_caption("Results with minimum conversion highlighted.")

pandas.io.formats.style.Styler.render

**Styler.render** *(sparse_index=None, sparse_columns=None, **kwargs)*

Render the **Styler** including all applied styles to HTML.

**Parameters**

- **sparse_index** [bool, optional] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. Defaults to `pandas.options.styler.sparse.index` value.

- **sparse_columns** [bool, optional] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. Defaults to `pandas.options.styler.sparse.columns` value.

- **kwargs** Any additional keyword arguments are passed through to self.template.render. This is useful when you need to provide additional variables for a custom template.

**Returns**

- **rendered** [str] The rendered HTML.

**Notes**

Styler objects have defined the _repr_html_ method which automatically calls self.render() when it’s the last item in a Notebook cell. When calling Styler.render() directly, wrap the result in IPython.display.HTML to view the rendered HTML in the notebook.

Pandas uses the following keys in render. Arguments passed in **kwargs take precedence, so think carefully if you want to override them:

- head
- cellstyle
- body
- uuid
- table_styles
- caption
- table_attributes
pandas.io.formats.style.Styler.set_caption

Styler.set_caption(caption)

Set the text added to a <caption> HTML element.

Parameters

- caption [str, tuple] For HTML output either the string input is used or the first element of the tuple. For LaTeX the string input provides a caption and the additional tuple input allows for full captions and short captions, in that order.

Returns

- self [Styler]

pandas.io.formats.style.Styler.set_na_rep

Styler.set_na_rep(na_rep)

Set the missing data representation on a Styler.

New in version 1.0.0.

Deprecated since version 1.3.0.

Parameters

- na_rep [str]

Returns

- self [Styler]

Notes

This method is deprecated. See Styler.format()

pandas.io.formats.style.Styler.set_precision

Styler.set_precision(precision)

Set the precision used to display values.

Deprecated since version 1.3.0.

Parameters

- precision [int]

Returns

- self [Styler]
Notes

This method is deprecated see *Styler.format*.

**pandas.io.formats.style.Styler.set_properties**

`Styler.set_properties(subset=None, **kwargs)`  
Set defined CSS-properties to each `<td>` HTML element within the given subset.

**Parameters**

- `subset`  
  [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.

- `**kwargs`  
  [dict] A dictionary of property, value pairs to be set for each cell.

**Returns**

self [Styler]

Notes

This is a convenience methods which wraps the `Styler.applymap()` calling a function returning the CSS-properties independently of the data.

**Examples**

```python
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_properties(color="white", align="right")
>>> df.style.set_properties(**{'background-color': 'yellow'})
```

**pandas.io.formats.style.Styler.set_sticky**

`Styler.set_sticky(axis=0, pixel_size=None, levels=None)`  
Add CSS to permanently display the index or column headers in a scrolling frame.

**Parameters**

- `axis`  
  [[0 or ‘index’, 1 or ‘columns’, None], default 0] Whether to make the index or column headers sticky.

- `pixel_size`  
  [int, optional] Required to configure the width of index cells or the height of column header cells when sticking a MultiIndex (or with a named Index). Defaults to 75 and 25 respectively.

- `levels`  
  [list of int] If axis is a MultiIndex the specific levels to stick. If None will stick all levels.

**Returns**

self [Styler]
Notes

This method uses the CSS ‘position: sticky;’ property to display. It is designed to work with visible axes, therefore both:

• `styler.set_sticky(axis="index").hide_index()`
• `styler.set_sticky(axis="columns").hide_columns()`

may produce strange behaviour due to CSS controls with missing elements.

pandas.io.formats.style.Styler.set_table_attributes

`Styler.set_table_attributes(attributes)`

Set the table attributes added to the `<table>` HTML element.

These are items in addition to automatic (by default) id attribute.

Parameters

  **attributes** [str]

Returns

  self [Styler]

See also:

  `Styler.set_table_styles` Set the table styles included within the `<style>` HTML element.

  `Styler.set_td_classes` Set the DataFrame of strings added to the class attribute of `<td>` HTML elements.

Examples

```python
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_table_attributes('class="pure-table"')
# ... <table class="pure-table"> ...
```

pandas.io.formats.style.Styler.set_table_styles

`Styler.set_table_styles(table_styles, axis=0, overwrite=True)`

Set the table styles included within the `<style>` HTML element.

This function can be used to style the entire table, columns, rows or specific HTML selectors.

Parameters

  **table_styles** [list or dict] If supplying a list, each individual table_style should be a dictionary with selector and props keys. selector should be a CSS selector that the style will be applied to (automatically prefixed by the table’s UUID) and props should be a list of tuples with (attribute, value). If supplying a dict, the dict keys should correspond to column names or index values, depending upon the specified axis argument. These will be mapped to row or col CSS selectors. MultiIndex values as dict keys should be in their respective tuple form. The dict values should be a list as specified in the form with CSS selectors and props that will be applied to the specified row or column.
axis [0 or 'index', 1 or 'columns', None], default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'). Only used if table_styles is dict.

New in version 1.2.0.

overwrite [bool, default True] Styles are replaced if True, or extended if False. CSS rules are preserved so most recent styles set will dominate if selectors intersect.

New in version 1.2.0.

Returns

self [Styler]

See also:

Styler.set_td_classes Set the DataFrame of strings added to the class attribute of <td> HTML elements.

Styler.set_table_attributes Set the table attributes added to the <table> HTML element.

Examples

```python
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                    columns=['A', 'B', 'C', 'D'])
>>> df.style.set_table_styles(
...    [{'selector': 'tr:hover',
      'props': [('background-color', 'yellow')]}
... )
```

Or with CSS strings

```python
>>> df.style.set_table_styles(
...    [{'selector': 'tr:hover',
      'props': 'background-color: yellow; font-size: 1em;'}
... )
```

Adding column styling by name

```python
>>> df.style.set_table_styles(
...    {'A': [{'selector': '',
             'props': [('color', 'red')]},
          'B': [{'selector': 'td',
                 'props': 'color: blue;'}]}, overwrite=False)
```

Adding row styling

```python
>>> df.style.set_table_styles(
...    {0: [{'selector': 'td:hover',
          'props': [('font-size', '25px')]}}
... }, axis=1, overwrite=False)
```
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.io.formats.style.Styler.set_td_classes
Styler.set_td_classes(classes)
Set the DataFrame of strings added to the class attribute of <td> HTML elements.
Parameters
classes [DataFrame] DataFrame containing strings that will be translated to CSS
classes, mapped by identical column and index key values that must exist on the
underlying Styler data. None, NaN values, and empty strings will be ignored and
not affect the rendered HTML.
Returns
self [Styler]
See also:
Styler.set_table_styles Set the table styles included within the <style> HTML element.
Styler.set_table_attributes Set the table attributes added to the <table> HTML element.
Notes
Can be used in combination with Styler.set_table_styles to define an internal CSS solution
without reference to external CSS files.
Examples
>>>
>>>
...
...
...
>>>

df = pd.DataFrame(data=[[1, 2, 3], [4, 5, 6]], columns=["A", "B", "C"])
classes = pd.DataFrame([
["min-val red", "", "blue"],
["red", None, "blue max-val"]
], index=df.index, columns=df.columns)
df.style.set_td_classes(classes)

Using MultiIndex columns and a classes DataFrame as a subset of the underlying,
>>> df = pd.DataFrame([[1,2],[3,4]], index=["a", "b"],
...
columns=[["level0", "level0"], ["level1a", "level1b"]])
>>> classes = pd.DataFrame(["min-val"], index=["a"],
...
columns=[["level0"],["level1a"]])
>>> df.style.set_td_classes(classes)

Form of the output with new additional css classes,
>>> df = pd.DataFrame([[1]])
>>> css = pd.DataFrame([["other-class"]])
>>> s = Styler(df, uuid="_", cell_ids=False).set_td_classes(css)
>>> s.hide_index().render()
'<style type="text/css"></style>'
'<table id="T__">'
' <thead>'
'
<tr><th class="col_heading level0 col0" >0</th></tr>'
' </thead>'
' <tbody>'
(continues on next page)

Chapter 3. API reference


pandas.io.formats.style.Styler.set_tooltips

Styler.set_tooltips (ttips, props=None, css_class=None)

Set the DataFrame of strings on Styler generating :hover tooltips.

These string based tooltips are only applicable to <td> HTML elements, and cannot be used for column or index headers.

New in version 1.3.0.

Parameters

   ttips [DataFrame] DataFrame containing strings that will be translated to tooltips, mapped by identical column and index values that must exist on the underlying Styler data. None, NaN values, and empty strings will be ignored and not affect the rendered HTML.

   props [list-like or str, optional] List of (attr, value) tuples or a valid CSS string. If None adopts the internal default values described in notes.

   css_class [str, optional] Name of the tooltip class used in CSS, should conform to HTML standards. Only useful if integrating tooltips with external CSS. If None uses the internal default value ‘pd-t’.

Returns

   self [Styler]

Notes

Tooltips are created by adding <span class="pd-t"> </span> to each data cell and then manipulating the table level CSS to attach pseudo hover and pseudo after selectors to produce the required the results.

The default properties for the tooltip CSS class are:

- visibility: hidden
- position: absolute
- z-index: 1
- background-color: black
- color: white
- transform: translate(-20px, -20px)

The property ‘visibility: hidden;’ is a key prerequisite to the hover functionality, and should always be included in any manual properties specification, using the props argument.

Tooltips are not designed to be efficient, and can add large amounts of additional HTML for larger tables, since they also require that cell_ids is forced to True.
Examples

Basic application

```python
>>> df = pd.DataFrame(data=[[0, 1], [2, 3]])
>>> ttips = pd.DataFrame(...
...   data=[['Min', ''], [np.nan, 'Max']], columns=df.columns, index=df.index)
...)
>>> s = df.style.set_tooltips(ttips).render()
```

Optionally controlling the tooltip visual display

```python
>>> df.style.set_tooltips(ttips, css_class='tt-add', props=[
...   ('visibility', 'hidden'),
...   ('position', 'absolute'),
...   ('z-index', 1)])
>>> df.style.set_tooltips(ttips, css_class='tt-add',
...   props='visibility:hidden; position:absolute; z-index:1;')
```

`s` is the rendered HTML string, which can be used to display the DataFrame with tooltips. The `style` object provides methods to control the display of tooltips, including setting their visibility, position, and other CSS properties.

**pandas.io.formats.style.Styler.set_uuid**

Styler.set_uuid(uuid)

Set the uuid applied to id attributes of HTML elements.

Parameters

- **uuid** [str]

Returns

- **self** [Styler]

Notes

Almost all HTML elements within the table, and including the `<table>` element are assigned id attributes. The format is `T_uuid_<extra>` where `<extra>` is typically a more specific identifier, such as `row1_col2`.

**pandas.io.formats.style.Styler.text_gradient**

Styler.text_gradient(cmap='PuBu', low=0, high=0, axis=0, subset=None, vmin=None, vmax=None, gmap=None)

Color the text in a gradient style.

The text color is determined according to the data in each column, row or frame, or by a given gradient map. Requires matplotlib.

Parameters

- **cmap** [str or colormap] Matplotlib colormap.
- **low** [float] Compress the color range at the low end. This is a multiple of the data range to extend below the minimum; good values usually in [0, 1], defaults to 0.
- **high** [float] Compress the color range at the high end. This is a multiple of the data range to extend above the maximum; good values usually in [0, 1], defaults to 0.
axis [0 or 'index', 1 or 'columns', None], default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.

subset [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.

text_color_threshold [float or int] This argument is ignored (only used in background_gradient). Luminance threshold for determining text color in [0, 1]. Facilitates text visibility across varying background colors. All text is dark if 0, and light if 1, defaults to 0.408.

vmin [float, optional] Minimum data value that corresponds to colormap minimum value. If not specified the minimum value of the data (or gmap) will be used.

New in version 1.0.0.

vmax [float, optional] Maximum data value that corresponds to colormap maximum value. If not specified the maximum value of the data (or gmap) will be used.

New in version 1.0.0.

gmap [array-like, optional] Gradient map for determining the text colors. If not supplied will use the underlying data from rows, columns or frame. If given as an ndarray or list-like must be an identical shape to the underlying data considering axis and subset. If given as DataFrame or Series must have same index and column labels considering axis and subset. If supplied, vmin and vmax should be given relative to this gradient map.

New in version 1.3.0.

Returns

self [Styler]

See also:

Styler.background_gradient Color the background in a gradient style.

Notes

When using low and high the range of the gradient, given by the data if gmap is not given or by gmap, is extended at the low end effectively by map.min - low * map.range and at the high end by map.max + high * map.range before the colors are normalized and determined.

If combining with vmin and vmax the map.min, map.max and map.range are replaced by values according to the values derived from vmin and vmax.

This method will preselect numeric columns and ignore non-numeric columns unless a gmap is supplied in which case no preselection occurs.
Examples

```python
>>> df = pd.DataFrame(columns=['City', 'Temp (°C)', 'Rain (mm)', 'Wind (m/s)'],
                   data=[['Stockholm', 21.6, 5.0, 3.2],
                         ['Oslo', 22.4, 13.3, 3.1],
                         ['Copenhagen', 24.5, 0.0, 6.7]])

Shading the values column-wise, with `axis=0`, preselecting numeric columns

```python
>>> df.style.text_gradient(axis=0)
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (°C)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Stockholm</td>
<td>21.6</td>
<td>5.0</td>
</tr>
<tr>
<td>1</td>
<td>Oslo</td>
<td>22.4</td>
<td>13.3</td>
</tr>
<tr>
<td>2</td>
<td>Copenhagen</td>
<td>24.5</td>
<td>0.0</td>
</tr>
</tbody>
</table>

Shading all values collectively using `axis=None`

```python
>>> df.style.text_gradient(axis=None)
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (°C)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Stockholm</td>
<td>21.6</td>
<td>5.0</td>
</tr>
<tr>
<td>1</td>
<td>Oslo</td>
<td>22.4</td>
<td>13.3</td>
</tr>
<tr>
<td>2</td>
<td>Copenhagen</td>
<td>24.5</td>
<td>0.0</td>
</tr>
</tbody>
</table>

Compress the color map from both the low and high ends

```python
>>> df.style.text_gradient(axis=None, low=0.75, high=1.0)
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (°C)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Stockholm</td>
<td>21.6</td>
<td>5.0</td>
</tr>
<tr>
<td>1</td>
<td>Oslo</td>
<td>22.4</td>
<td>13.3</td>
</tr>
<tr>
<td>2</td>
<td>Copenhagen</td>
<td>24.5</td>
<td>0.0</td>
</tr>
</tbody>
</table>

Manually setting `vmin` and `vmax` gradient thresholds

```python
>>> df.style.text_gradient(axis=None, vmin=6.7, vmax=21.6)
```

Setting a gmap and applying to all columns with another cmap

```python
>>> df.style.text_gradient(axis=0, gmap=df['Temp (°C)'], cmap='YlOrRd')
```

Setting the gradient map for a dataframe (i.e. `axis=None`), we need to explicitly state subset to match the gmap shape
pandas: powerful Python data analysis toolkit, Release 1.3.2

>>> gmap = np.array([[1,2,3], [2,3,4], [3,4,5]])

... df.style.text_gradient(axis=None, gmap=gmap,
... cmap='YlOrRd', subset=['Temp (c)', 'Rain (mm)', 'Wind (m/s)'])

3.12. Style

pandas.io.formats.style.Styler.use

Styler.use(styles)

Set the styles on the current Styler.

Possibly uses styles from Styler.export.

Parameters

styles [list] List of style functions.

Returns

self [Styler]

See also:

Styler.export Export the styles to applied to the current Styler.
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.io.formats.style.Styler.where

Styler.where(cond, value, other=None, subset=None, **kwargs)

Apply CSS-styles based on a conditional function elementwise.

Deprecated since version 1.3.0.

Updates the HTML representation with a style which is selected in accordance with the return value of a function.

Parameters

cond [callable] cond should take a scalar, and optional keyword arguments, and return a boolean.

value [str] Applied when cond returns true.

other [str] Applied when cond returns false.

subset [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.

**kwargs [dict] Pass along to cond.

Returns

self [Styler]

See also:

Styler.applymap Apply a CSS-styling function elementwise.

Styler.apply Apply a CSS-styling function column-wise, row-wise, or table-wise.

Notes

This method is deprecated.

This method is a convenience wrapper for Styler.applymap(), which we recommend using instead.

The example:

```python
>>> df = pd.DataFrame([[1, 2], [3, 4]])
>>> def cond(v, limit=4):
...     return v > 1 and v != limit
>>> df.style.where(cond, value='color:green;', other='color:red;')
```

should be refactored to:

```python
>>> def style_func(v, value, other, limit=4):
...     cond = v > 1 and v != limit
...     return value if cond else other
>>> df.style.applymap(style_func, value='color:green;', other='color:red;')
```

</tbody>
</table>

3.13.1 pandas.plotting.andrews_curves

`pandas.plotting.andrews_curves` *(frame, class_column[, ax, ...])*

Generate a matplotlib plot of Andrews curves, for visualising clusters of multivariate data.

Andrews curves have the functional form:

\[ f(t) = \frac{x_1}{\sqrt{2}} + x_2 \sin(t) + x_3 \cos(t) + x_4 \sin(2t) + x_5 \cos(2t) + \ldots \]

Where x coefficients correspond to the values of each dimension and t is linearly spaced between -π and +π.

Each row of frame then corresponds to a single curve.

**Parameters**

- **frame** [DataFrame] Data to be plotted, preferably normalized to (0.0, 1.0).
- **class_column** [Name of the column containing class names]
- **ax** [matplotlib axes object, default None]
- **samples** [Number of points to plot in each curve]
**color**  [list or tuple, optional] Colors to use for the different classes.

**colormap**  [str or matplotlib colormap object, default None] Colormap to select colors from.
   If string, load colormap with that name from matplotlib.

**kwargs**  Options to pass to matplotlib plotting method.

**Returns**

   *class:matplotlib.axis.Axes*

**Examples**

```python
>>> df = pd.read_csv(
...    'https://raw.github.com/pandas-dev/
...    pandads/master/pandas/tests/io/data/csv/iris.csv'
...)
>>> pd.plotting.andrews_curves(df, 'Name')
```

![Andrews Curves](image.png)
3.13.2 pandas.plotting.autocorrelation_plot

pandas.plotting.autocorrelation_plot (series, ax=None, **kwargs)

Autocorrelation plot for time series.

Parameters

series [Time series]

ax [Matplotlib axis object, optional]

**kwargs Options to pass to matplotlib plotting method.

Returns

class: matplotlib.axis.Axes

Examples

The horizontal lines in the plot correspond to 95% and 99% confidence bands.
The dashed line is 99% confidence band.

```python
>>> spacing = np.linspace(-9 * np.pi, 9 * np.pi, num=1000)
>>> s = pd.Series(0.7 * np.random.rand(1000) + 0.3 * np.sin(spacing))
>>> pd.plotting.autocorrelation_plot(s)
```
3.13.3 pandas.plotting.bootstrap_plot

pandas.plotting.bootstrap_plot (series, fig=None, size=50, samples=500, **kwargs)

Bootstrap plot on mean, median and mid-range statistics.

The bootstrap plot is used to estimate the uncertainty of a statistic by relaying on random sampling with replacement [1]. This function will generate bootstrapping plots for mean, median and mid-range statistics for the given number of samples of the given size.

Parameters

- **series** [pandas.Series] Series from where to get the samplings for the bootstrapping.
- **fig** [matplotlib.figure.Figure, default None] If given, it will use the fig reference for plotting instead of creating a new one with default parameters.
- **size** [int, default 50] Number of data points to consider during each sampling. It must be less than or equal to the length of the series.
- **samples** [int, default 500] Number of times the bootstrap procedure is performed.
- **kwargs** Options to pass to matplotlib plotting method.

Returns

- matplotlib.figure.Figure Matplotlib figure.

See also:

- DataFrame.plot Basic plotting for DataFrame objects.
- Series.plot Basic plotting for Series objects.

Examples

This example draws a basic bootstrap plot for a Series.

```python
>>> s = pd.Series(np.random.uniform(size=100))
>>> pd.plotting.bootstrap_plot(s)
```

3.13.4 pandas.plotting.boxplot

pandas.plotting.boxplot (data, column=None, by=None, ax=None, fontsize=None, rot=0, grid=True, figsize=None, layout=None, return_type=None, **kwargs)

Make a box plot from DataFrame columns.

Make a box-and-whisker plot from DataFrame columns, optionally grouped by some other columns. A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of the box to show the range of the data. By default, they extend no more than 1.5 * IQR (IQR = Q3 - Q1) from the edges of the box, ending at the farthest data point within that interval. Outliers are plotted as separate dots.

For further details see Wikipedia’s entry for boxplot.

Parameters

- **column** [str or list of str, optional] Column name or list of names, or vector. Can be any valid input to pandas.DataFrame.groupby().
- **by** [str or array-like, optional] Column in the DataFrame to pandas.DataFrame.groupby(). One box-plot will be done per value of columns in by.
- **ax** [object of class matplotlib.axes.Axes, optional] The matplotlib axes to be used by boxplot.
**Boxplot**

```python
>>> np.random.seed(1234)
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                   columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
```
Boxplots of variables distributions grouped by the values of a third variable can be created using the option `by`. For instance:

```python
>>> df = pd.DataFrame(np.random.randn(10, 2),
                   columns=['Col1', 'Col2'])
                      'B', 'B', 'B', 'B', 'B'])
>>> boxplot = df.boxplot(by='X')
```

A list of strings (i.e. ['X', 'Y']) can be passed to `boxplot` in order to group the data by combination of the variables in the x-axis:

```python
>>> df = pd.DataFrame(np.random.randn(10, 3),
                   columns=['Col1', 'Col2', 'Col3'])
                      'B', 'B', 'B', 'B', 'B'])
>>> df['Y'] = pd.Series(['A', 'B', 'A', 'B', 'A',
                      'B', 'A', 'B', 'A', 'B'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```

The layout of boxplot can be adjusted giving a tuple to `layout`:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                       layout=(2, 1))
```

Additional formatting can be done to the boxplot, like suppressing the grid (`grid=False`), rotating the labels...
Boxplot grouped by ['X', 'Y']

Col1

Col2

(A, A)  (A, B)  (B, A)  (B, B)  
[X, Y]  

(A, A)  (A, B)  (B, A)  (B, B)  
[X, Y]  

3.13. Plotting
in the x-axis (i.e. rot=45) or changing the fontsize (i.e. fontsize=15):

```python
>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)
```

The parameter `return_type` can be used to select the type of element returned by `boxplot`. When `return_type='axes'` is selected, the matplotlib axes on which the boxplot is drawn are returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
>>> type(boxplot)
<class 'matplotlib.axes._subplots.AxesSubplot'>
```

When grouping with `by`, a Series mapping columns to `return_type` is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       return_type='axes')
>>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       return_type=None)
>>> type(boxplot)
<class 'numpy.ndarray'>
```
3.13.5 pandas.plotting.deregister_matplotlib_converters

pandas.plotting.deregister_matplotlib_converters()

Remove pandas formatters and converters.

Removes the custom converters added by register(). This attempts to set the state of the registry back to the state before pandas registered its own units. Converters for pandas’ own types like Timestamp and Period are removed completely. Converters for types pandas overwrites, like `datetime.datetime`, are restored to their original value.

See also:

- `register_matplotlib_converters` Register pandas formatters and converters with matplotlib.

3.13.6 pandas.plotting.lag_plot

pandas.plotting.lag_plot(series, lag=1, ax=None, **kwds)

Lag plot for time series.

Parameters

- `series` [Time series]
- `lag` [lag of the scatter plot, default 1]
- `ax` [Matplotlib axis object, optional]
- **`kwds`** Matplotlib scatter method keyword arguments.

Returns

- class:`matplotlib.axis.Axes`

Examples

Lag plots are most commonly used to look for patterns in time series data.

Given the following time series

```python
>>> np.random.seed(5)
>>> x = np.cumsum(np.random.normal(loc=1, scale=5, size=50))
>>> s = pd.Series(x)
>>> s.plot()
```

A lag plot with `lag=1` returns

```python
>>> pd.plotting.lag_plot(s, lag=1)
```

3.13.7 pandas.plotting.parallel_coordinates

pandas.plotting.parallel_coordinates(frame, class_column, cols=None, ax=None, color=None, use_columns=False, xticks=None, colormap=None, axvlines=True, axvlines_kwds=None, sort_labels=False, **kwargs)

Parallel coordinates plotting.

Parameters

- `frame` [DataFrame]
class_column  [str] Column name containing class names.
cols  [list, optional] A list of column names to use.
color  [list or tuple, optional] Colors to use for the different classes.
use_columns  [bool, optional] If true, columns will be used as xticks.
xticks  [list or tuple, optional] A list of values to use for xticks.
colormap  [str or matplotlib colormap, default None] Colormap to use for line colors.
axvlines  [bool, optional] If true, vertical lines will be added at each tick.
axvlines_kwds  [keywords, optional] Options to be passed to axvline method for vertical lines.
sort_labels  [bool, default False] Sort class_column labels, useful when assigning colors.
**kwds  Options to pass to matplotlib plotting method.

Returns

class:matplotlib.axis.Axes

Examples

```python
df = pd.read_csv(
    ...
)  
>>> pd.plotting.parallel_coordinates(
    ...
)
```  

3.13.8 pandas.plotting.plot_params

pandas.plotting.plot_params = {'xaxis.compat': False}

Stores pandas plotting options.

Allows for parameter aliasing so you can just use parameter names that are the same as the plot function parameters, but is stored in a canonical format that makes it easy to breakdown into groups later.

3.13.9 pandas.plotting.radviz

pandas.plotting.radviz(frame, class_column, ax=None, color=None, colormap=None, **kwds)

Plot a multidimensional dataset in 2D.

Each Series in the DataFrame is represented as a evenly distributed slice on a circle. Each data point is rendered in the circle according to the value on each Series. Highly correlated Series in the DataFrame are placed closer on the unit circle.

RadViz allow to project a N-dimensional data set into a 2D space where the influence of each dimension can be interpreted as a balance between the influence of all dimensions.

More info available at the original article describing RadViz.

Parameters
frame [DataFrame] Object holding the data.

class_column [str] Column name containing the name of the data point category.

ax [matplotlib.axes.Axes, optional] A plot instance to which to add the information.

color [list[str] or tuple[str], optional] Assign a color to each category. Example: ['blue', 'green'].

colormap [str or matplotlib.colors.Colormap, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

**kwd**s Options to pass to matplotlib scatter plotting method.

Returns
class: matplotlib.axes.Axes

See also:
plotting.andrews_curves Plot clustering visualization.

Examples
>>> df = pd.DataFrame(
...     {
...         'SepalLength': [6.5, 7.7, 5.1, 5.8, 7.6, 5.0, 5.4, 4.6, 6.7, 4.6],
...         'SepalWidth': [3.0, 3.8, 3.8, 2.7, 3.0, 2.3, 3.0, 3.2, 3.3, 3.6],
...         'PetalLength': [5.5, 6.7, 1.9, 5.1, 6.6, 3.3, 4.5, 1.4, 5.7, 1.0],
...         'PetalWidth': [1.8, 2.2, 0.4, 1.9, 2.1, 1.0, 1.5, 0.2, 2.1, 0.2],
...         'Category': ['virginica', 'virginica', 'setosa', 'virginica', 'virginica', 'versicolor', 'versicolor', 'setosa', 'virginica', 'setosa']
...     }
... )
>>> pd.plotting.radviz(df, 'Category')
See also:

deregister_matplotlib_converters Remove pandas formatters and converters.

3.13.11 pandas.plotting.scatter_matrix

pandas.plotting.scatter_matrix(frame, alpha=0.5, figsize=None, ax=None, grid=False,
                               diagonal='hist', marker='.', density_kwds=None, hist_kwds=None,
                               range_padding=0.05, **kwargs)

Draw a matrix of scatter plots.

Parameters

frame [DataFrame] Amount of transparency applied.
alpha [float, optional] A tuple (width, height) in inches.
figsize [float, float, optional] A tuple (width, height) in inches.
ax [Matplotlib axis object, optional] Setting this to True will show the grid.
grid [bool, optional] Pick between ‘kde’ and ‘hist’ for either Kernel Density Estimation
or Histogram plot in the diagonal.
diagonal [{'hist', 'kde'}] Matplotlib marker type, default ‘.’.
density_kwds [keywords] Keyword arguments to be passed to kernel density estimate plot.
hist_kwds [keywords] Keyword arguments to be passed to hist function.
range_padding [float, default 0.05] Relative extension of axis range in x and y with respect
to (x_max - x_min) or (y_max - y_min).
**kwargs Keyword arguments to be passed to scatter function.

Returns

numpy.ndarray A matrix of scatter plots.

Examples

```python
>>> df = pd.DataFrame(np.random.randn(1000, 4), columns=['A', 'B', 'C', 'D'])
>>> pd.plotting.scatter_matrix(df, alpha=0.2)
```

3.13.12 pandas.plotting.table

pandas.plotting.table(ax, data, rowLabels=None, colLabels=None, **kwargs)

Helper function to convert DataFrame and Series to matplotlib.table.

Parameters

ax [Matplotlib axes object] Data for table contents.

rowLabels [DataFrame or Series] Data for table contents.

**kwargs Keyword arguments to be passed to matplotlib.table.table. If rowLabels or colLa-
bels is not specified, data index or column name will be used.

Returns

matplotlib table object
3.14 General utility functions

3.14.1 Working with options

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>describe_option(pat[, _print_desc])</td>
<td>Prints the description for one or more registered options.</td>
</tr>
<tr>
<td>reset_option(pat)</td>
<td>Reset one or more options to their default value.</td>
</tr>
<tr>
<td>get_option(pat)</td>
<td>Retrieves the value of the specified option.</td>
</tr>
<tr>
<td>set_option(pat, value)</td>
<td>Sets the value of the specified option.</td>
</tr>
<tr>
<td>option_context(*args)</td>
<td>Context manager to temporarily set options in the with statement context.</td>
</tr>
</tbody>
</table>

**pandas.describe_option**

```python
pandas.describe_option(pat, _print_desc=False) = <pandas._config.config.CallableDynamicDoc object>
```

Prints the description for one or more registered options.

Call with no arguments to get a listing for all registered options.

Available options:
- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]
- io.excel.ods.[reader, writer]
- io.excel.xls.[reader, writer]
- io.excel.xlsb.[reader]
- io.excel.xlsm.[reader, writer]
- io.excel.xlsx.[reader, writer]
- io.hdf.[default_format, dropna_table]
- io.parquet.[engine]
- io.sql.[engine]
- mode.[chained_assignment, data_manager, sim_interactive, string_storage, use_inf_as_na, use_inf_as_null]
- plotting.[backend]
- plotting.matplotlib.[register_converters]
- styler.render.[max_elements]
- styler.sparse.[columns, index]

**Parameters**
- pat [str] Regexp pattern. All matching keys will have their description displayed.
- _print_desc [bool, default True] If True (default) the description(s) will be printed to stdout. Otherwise, the description(s) will be returned as a unicode string (for testing).

**Returns**
None by default, the description(s) as a unicode string if _print_desc is False

Notes

The available options with its descriptions:

- **compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True. Valid values: False, True [default: True] [currently: True]
- **compute.use_numba** [bool] Use the numba engine option for select operations if it is installed, the default is False. Valid values: False, True [default: False] [currently: False]
- **compute.use_numexpr** [bool] Use the numexpr library to accelerate computation if it is installed, the default is True. Valid values: False, True [default: True] [currently: True]
- **display.chop_threshold** [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
- **display.colheader_justify** ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]
- **display.column_space** No description available. [default: 12] [currently: 12]
- **display.date_dayfirst** [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]
- **display.date_yearfirst** [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]
- **display.encoding** [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]
- **display.expand_frame_repr** [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width. [default: True] [currently: True]
- **display.float_format** [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]
- **display.html.border** [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]
- **display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]
- **display.html.use_mathjax** [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]
- **display.large_repr** ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]
- **display.latex.escape** [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False, True [default: True] [currently: True]
- **display.latex.longtable** [bool] This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False, True [default: True] [currently: True]
- **display.latex.multicolumn** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False, True [default: True] [currently: True]
- **display.latex.multicolumn_format** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False, True [default: 1] [currently: 1]
- **display.latex.multirow** [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False, True [default: False] [currently: False]
- **display.latex.repr** [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]
display.max_categories [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype “category”. [default: 8] [currently: 8]
display.max_columns [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]
display.max_colwidth [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]
display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]
display.max_info_rows [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]
display.max_rows [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]
display.max_seq_items [int or None] When pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]
display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,’deep’ [default: True] [currently: True]
display.min_rows [int] The numbers of rows to show in a truncated view (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows. [default: 10] [currently: 10]
display.multi_sparse [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]
display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]
display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]
display.precision [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to precision in numpy.set_printoptions(). [default: 6] [currently: 6]
display.show_dimensions [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]
display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]
display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]
display.width [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]
io.hdf.default_format [format] default format writing format, if None, then will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]
io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment. The default is warn [default: warn] [currently: warn]

mode.data_manager [string] Internal data manager type; can be “block” or “array”. Defaults to “block”, unless overridden by the ‘PANDAS_DATA_MANAGER’ environment variable (needs to be set before pandas is imported). [default: block] [currently: block]

mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

mode.string_storage [string] The default storage for StringDtype. [default: python] [currently: python]

mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

mode.use_inf_as_null [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)

plotting.backend [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

plotting.matplotlib.register_converters [bool or ‘auto’.] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

styler.render.max_elements [int] The maximum number of data-cell (<td>) elements that will be rendered before trimming will occur over columns, rows or both if needed. [default: 262144] [currently: 262144]

styler.sparse.columns [bool] Whether to sparsify the display of hierarchical columns. Setting to False will display each explicit level element in a hierarchical key for each column. [default: True] [currently: True]

styler.sparse.index [bool] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. [default: True] [currently: True]
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.reset_option

pandas.reset_option(pat) = <pandas._config.config.CallableDynamicDoc object>

Reset one or more options to their default value.

Pass “all” as argument to reset all options.

Available options:
- compute.use_bottleneck, use_numba, use_numexpr
- display.chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format
- display.html.border, table_schema, use_mathjax
- display.large
- display.latex.escape, longtable, multicol, multicol_format, multirow, repr
- display.max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions
- display.unicode.ambiguous_as_wide, east_asian_width
- display.width
- io.excel.ods.reader, writer
- io.excel.xls.reader, writer
- io.excel.xlsb.reader
- io.excel.xlsm.reader, writer
- io.excel.xlsx.reader, writer
- io.hdf.default_format, dropna_table
- io.parquet.engine
- io.sql.engine
- mode.chained_assignment, data_manager, sim_interactive, string_storage, use_inf_as_na, use_inf_as_null
- plotting.backend
- plotting.matplotlib.register_converters
- styler.render.max_elements
- styler.sparse.columns, index

Parameters

pat [str/regex] If specified only options matching prefix* will be reset. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.

Returns

None

Notes

The available options with its descriptions:
- compute.use_bottleneck [bool] Use the bottleneck library to accelerate if it is installed, the default is True
  Valid values: False, True [default: True] [currently: True]
- compute.use_numba [bool] Use the numba engine option for select operations if it is installed, the default is False
  Valid values: False, True [default: False] [currently: False]
- compute.use_numexpr [bool] Use the numexpr library to accelerate computation if it is installed, the default is True
  Valid values: False, True [default: True] [currently: True]
display.chop_threshold [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
display.colheader_justify ['left'/'right'] Controls the justification of column headers. used by DataFrameFormat. [default: right] [currently: right]
display.column_space No description available. [default: 12] [currently: 12]
display.date_dayfirst [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]
display.date_yearfirst [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]
display.encoding [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]
display.expanded_frame_repr [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width. [default: True] [currently: True]
display.float_format [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]
display.html.border [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]
display.html.table_schema [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]
display.html.use_mathjax [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]
display.large_repr ['truncate'/’info’) For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]
display.latex.escape [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]
display.latex.longtable :bool This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: True] [currently: True]
display.latex.multiprint [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]
display.latex.multiprint_columns [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]
display.latex.multitool [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]
display.latex.repr [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]
display.max_categories [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype “category”. [default: 8] [currently: 8]
display.max_columns [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.
In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]
display.max_column_width [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “… ” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]
display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]
display.max_info_rows [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

display.max_rows [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]

display.max_seq_items [int or None] When pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True, False, 'deep' [default: True] [currently: True]

display.min_rows [int] The numbers of rows to show in a truncated view (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows. [default: 10] [currently: 10]

display.multi_sparse [boolean] ‘sparsify’ MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]

display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

display.precision [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to precision in numpy. set_printoptions(). [default: 6] [currently: 6]

display.show_dimensions [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance [default: False] [currently: False]

display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance [default: False] [currently: False]

display.width [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

io.hdf.default_format [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]

io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment. The default is warn [default: warn] [currently: warn]

mode.data_manager [string] Internal data manager type; can be “block” or “array”. Defaults to “block”, unless overridden by the ‘PANDAS_DATA_MANAGER’ environment variable (needs to be set before pandas is imported). [default: block] [currently: block]

mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

mode.string_storage [string] The default storage for StringDtype. [default: python] [currently: python]

mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

mode.use_inf_as_null [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)

plotting.backend [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

plotting.matplotlib.register_converters [bool or ‘auto’] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

styler.render.max_elements [int] The maximum number of data-cell (<td>) elements that will be rendered before trimming will occur over columns, rows or both if needed. [default: 262144] [currently: 262144]

styler.sparse.columns [bool] Whether to sparsify the display of hierarchical columns. Setting to False will display each explicit level element in a hierarchical key for each column. [default: True] [currently: True]

styler.sparse.index [bool] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. [default: True] [currently: True]

**pandas.get_option**

pandas.get_option(pat) = <pandas._config.config.CallableDynamicDoc object>

Retrieves the value of the specified option.

Available options:
- **compute.**[use_bottleneck, use_numba, use_numexpr]
- **display.**[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- **display.html.**[border, table_schema, use_mathjax]
- **display.**[large_repr]
- **display.latex.**[escape, longtable, multicolumn, multicolumn_format, multilrow, repr]
- **display.**[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- **display.unicode.**[ambiguous_as_wide, east_asian_width]
• display.[width]
• io.excel.ods.[reader, writer]
• io.excel.xls.[reader, writer]
• io.excel.xlsb.[reader]
• io.excel.xlsm.[reader, writer]
• io.excel.xlsx.[reader, writer]
• io.hdf.[default_format, dropna_table]
• io.parquet.[engine]
• io.sql.[engine]
• mode.[chained_assignment, data_manager, sim_interactive, string_storage, use_inf_as_na, use_inf_as_null]
• plotting.[backend]
• plotting.matplotlib.[register_converters]
• styler.render.[max_elements]
• styler.sparse.[columns, index]

Parameters

   pat [str] Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.

Returns

   result [the value of the option]

Raises

   OptionError [if no such option exists]

Notes

The available options with its descriptions:

   compute.use_bottleneck [bool] Use the bottleneck library to accelerate if it is installed, the default is True Valid values: False,True [default: True] [currently: True]
   compute.use_numba [bool] Use the numba engine option for select operations if it is installed, the default is False Valid values: False,True [default: False] [currently: False]
   compute.use_numexpr [bool] Use the numexpr library to accelerate computation if it is installed, the default is True Valid values: False,True [default: True] [currently: True]
   display.chop_threshold [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
   display.colheader_justify ['left'/'right'] Controls the justification of column headers. used by DataFrameFor-
   display.column_space No description available. [default: 12] [currently: 12]
   display.date_dayfirst [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]
   display.date_yearfirst [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]
   display.encoding [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]
   display.expand_frame_repr [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width. [default: True] [currently: True]
   display.float_format [callable] The callable should accept a floating point number and return a string with
the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]

display.html.border [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]

display.html.table_schema [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]

display.html.use_mathjax [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]

display.large_repr ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]

display.latex.escape [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: False] [currently: False]

display.latex.longtable [bool] This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]

display.latex.multicolumn [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]

display.latex.multicolumn_format [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: l] [currently: l]

display.latex.multirow [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]

display.latex.repr [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]

display.max_categories [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dttype “category”. [default: 8] [currently: 8]

display.max_columns [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

display.max_colwidth [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]

display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]

display.max_info_rows [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

display.max_rows [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]

display.max_seq_items [int or None] When pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,’deep’ [default: True] [currently: True]

display.min_rows [int] The numbers of rows to show in a truncated view (when max_rows is exceeded). Ig-
nored when max_rows is set to None or 0. When set to None, follows the value of max_rows. [default: 10] [currently: 10]

display.multi_sparse [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]
display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]
display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]
display.precision [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to precision in numpy. set_printoptions(). [default: 6] [currently: 6]
display.show_dimensions [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]
display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]
display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]
display.width [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]
mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]
mode.data_manager [string] Internal data manager type; can be “block” or “array”. Defaults to “block”, unless overridden by the ‘PANDAS_DATA_MANAGER’ environment variable (needs to be set before
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas is imported). [default: block] [currently: block]

mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

mode.string_storage [string] The default storage for StringDtype. [default: python] [currently: python]

mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way). False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

mode.use_inf_as_null [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)

plotting.backend [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

plotting.matplotlib.register_converters [bool or ‘auto’.] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

styler.render.max_elements [int] The maximum number of data-cell (<td>) elements that will be rendered before trimming will occur over columns, rows or both if needed. [default: 262144] [currently: 262144]

styler.sparse.columns [bool] Whether to sparsify the display of hierarchical columns. Setting to False will display each explicit level element in a hierarchical key for each column. [default: True] [currently: True]

styler.sparse.index [bool] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. [default: True] [currently: True]

**pandas.set_option**

pandas.set_option(pat, value) = <pandas._config.config.CallableDynamicDoc object>

Sets the value of the specified option.

Available options:
- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]
- io.excel.ods.[reader, writer]
- io.excel.xls.[reader, writer]
- io.excel.xlsb.[reader]
- io.excel.xlsx.[reader, writer]
- io.hdf.[default_format, dropna_table]
- io.parquet.[engine]
- io.sql.[engine]
- mode.[chained_assignment, data_manager, sim_interactive, string_storage, use_inf_as_na, use_inf_as_null]
- plotting.[backend]
- plotting.matplotlib.[register_converters]
- styler.render.[max_elements]
- styler.sparse.[columns, index]
Parameters

**pat** [str] Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.

**value** [object] New value of option.

Returns

None

Raises

OptionError if no such option exists

Notes

The available options with its descriptions:

- **compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True
  - Valid values: False,True [default: True] [currently: True]

- **compute.use_numba** [bool] Use the numba engine option for select operations if it is installed, the default is True
  - Valid values: False,True [default: False] [currently: False]

- **compute.use_numexpr** [bool] Use the numexpr library to accelerate computation if it is installed, the default is True
  - Valid values: False,True [default: True] [currently: True]

- **display.chop_threshold** [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]

- **display.colheader_justify** ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]

- **display.column_space** No description available. [default: 12] [currently: 12]

- **display.date_dayfirst** [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]

- **display.date_yearfirst** [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]

- **display.encoding** [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console.
  - [default: utf-8] [currently: utf-8]

- **display.expand_frame_repr** [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width. [default: True] [currently: True]

- **display.float_format** [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]

- **display.html.border** [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]

- **display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. [default: False] [currently: False]

- **display.html.use_mathjax** [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. [default: True] [currently: True]

- **display.large_repr** ['truncate’/’info’] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]

- **display.latex.escape** [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters.
  - Valid values: False,True [default: True] [currently: True]

<tr>
<td>display.max_rows</td>
<td>If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>display.max_seq_items</td>
<td>When pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>display.memory_usage</td>
<td>Specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True, False, ‘deep’ [default: True] [currently: True]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>display.min_rows</td>
<td>The numbers of rows to show in a truncated view (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows. [default: 10] [currently: 10]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>display.multi_sparse</td>
<td>“sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>display.notebook_repr_html</td>
<td>When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>display.pprint_nest_depth</td>
<td>Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>display.precision</td>
<td>Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to precision in numpy. set_printoptions(). [default: 6] [currently: 6]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>display.show_dimensions</td>
<td>Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**display.unicode.ambiguous_as_wide**  [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

**display.unicode.east_asian_width**  [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

**display.width**  [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

**io.hdf.default_format**  [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]

**io.hdf.droppna_table**  [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

**mode.chained_assignment**  [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]

**mode.data_manager**  [string] Internal data manager type; can be “block” or “array”. Defaults to “block”, unless overridden by the ‘PANDAS_DATA_MANAGER’ environment variable (needs to be set before pandas is imported). [default: block] [currently: block]

**mode.sim_interactive**  [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

**mode.string_storage**  [string] The default storage for StringDtype. [default: python] [currently: python]

**mode.use_inf_as_na**  [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

**mode.use_inf_as_null**  [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)

**plotting.backend**  [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

**plotting.matplotlib.register_converters**  [bool or ‘auto’.] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring
any converters that pandas overwrote. [default: auto] [currently: auto]

**styalrender.max_elements** [int] The maximum number of data-cell (<td>) elements that will be rendered before trimming will occur over columns, rows or both if needed. [default: 262144] [currently: 262144]

**styal.sparse.columns** [bool] Whether to sparsify the display of hierarchical columns. Setting to False will display each explicit level element in a hierarchical key for each column. [default: True] [currently: True]

**styal.sparse.index** [bool] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. [default: True] [currently: True]

### pandas.option_context

#### class pandas.option_context(*args)

Context manager to temporarily set options in the with statement context.

You need to invoke as `option_context(pat, val, [(pat, val), ...]).`

**Examples**

```python
>>> with option_context('display.max_rows', 10, 'display.max_columns', 5):
...  ...
```

**Methods**

```python
__call__(func)
Call self as a function.
```

```
option_context.__call__(func)
Call self as a function.
```

### 3.14.2 Testing functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>testing.assert_frame_equal(left, right[, ...])</code></td>
<td>Check that left and right DataFrame are equal.</td>
</tr>
<tr>
<td><code>testing.assert_series_equal(left, right[, ...])</code></td>
<td>Check that left and right Series are equal.</td>
</tr>
<tr>
<td><code>testing.assert_index_equal(left, right[, ...])</code></td>
<td>Check that left and right Index are equal.</td>
</tr>
<tr>
<td><code>testing.assert_extension_array_equal(left, right)</code></td>
<td>Check that left and right ExtensionArrays are equal.</td>
</tr>
</tbody>
</table>
pandas.testing.assert_frame_equal

Check that left and right DataFrame are equal.

This function is intended to compare two DataFrames and output any differences. It is mostly intended for use in unit tests. Additional parameters allow varying the strictness of the equality checks performed.

**Parameters**

- `left` [DataFrame] First DataFrame to compare.
- `right` [DataFrame] Second DataFrame to compare.
- `check_dtype` [bool, default True] Whether to check the DataFrame dtype is identical.
- `check_index_type` [bool or {'equiv'}, default 'equiv'] Whether to check the Index class, dtype and inferred_type are identical.
- `check_column_type` [bool or {'equiv'}, default 'equiv'] Whether to check the columns class, dtype and inferred_type are identical. Is passed as the exact argument of `assert_index_equal()`.
- `check_frame_type` [bool, default True] Whether to check the DataFrame class is identical.
- `check_less_precise` [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.
  
  When comparing two numbers, if the first number has magnitude less than 1e-5, we compare the two numbers directly and check whether they are equivalent within the specified precision. Otherwise, we compare the ratio of the second number to the first number and check whether it is equivalent to 1 within the specified precision.

  Deprecated since version 1.1.0: Use `rtol` and `atol` instead to define relative/absolute tolerance, respectively. Similar to `math.isclose()`.
- `check_names` [bool, default True] Whether to check that the `names` attribute for both the `index` and `column` attributes of the DataFrame is identical.
- `by_blocks` [bool, default False] Specify how to compare internal data. If False, compare by columns. If True, compare by blocks.
- `check_exact` [bool, default False] Whether to compare number exactly.
- `check_datetimelike_compat` [bool, default False] Compare datetime-like which is comparable ignoring dtype.
- `check_categorical` [bool, default True] Whether to compare internal Categorical exactly.
- `check_like` [bool, default False] If True, ignore the order of index & columns. Note: index labels must match their respective rows (same as in columns) - same labels must be with the same data.
- `check_freq` [bool, default True] Whether to check the `freq` attribute on a DatetimeIndex or TimedeltaIndex.
New in version 1.1.0.

**check_flags** [bool, default True] Whether to check the flags attribute.

**rtol** [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.

**atol** [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.

**obj** [str, default ‘DataFrame’] Specify object name being compared, internally used to show appropriate assertion message.

See also:

**assert_series_equal** Equivalent method for asserting Series equality.

**DataFrame.equals** Check DataFrame equality.

**Examples**

This example shows comparing two DataFrames that are equal but with columns of differing dtypes.

```python
>>> from pandas._testing import assert_frame_equal
>>> df1 = pd.DataFrame({'a': [1, 2], 'b': [3, 4]})
>>> df2 = pd.DataFrame({'a': [1, 2], 'b': [3.0, 4.0]})
```

df1 equals itself.

```python
>>> assert_frame_equal(df1, df1)
```

df1 differs from df2 as column ‘b’ is of a different type.

```python
>>> assert_frame_equal(df1, df2)
```

```
AssertionError: Attributes of DataFrame.iloc[:, 1] (column name="b") are different
```

Attribute “dtype” are different [left]: int64 [right]: float64

Ignore differing dtypes in columns with check_dtype.

```python
>>> assert_frame_equal(df1, df2, check_dtype=False)
```

**pandas.testing.assert_series_equal**

Check that left and right Series are equal.

**Parameters**

- **left** [Series]
- **right** [Series]
check_dtype [bool, default True] Whether to check the Series dtype is identical.

check_index_type [bool or {'equiv'}, default 'equiv'] Whether to check the Index class, dtype and inferred_type are identical.

check_series_type [bool, default True] Whether to check the Series class is identical.

check_less_precise [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

When comparing two numbers, if the first number has magnitude less than 1e-5, we compare the two numbers directly and check whether they are equivalent within the specified precision. Otherwise, we compare the ratio of the second number to the first number and check whether it is equivalent to 1 within the specified precision.

Deprecated since version 1.1.0: Use rtol and atol instead to define relative/absolute tolerance, respectively. Similar to math.isclose().

check_names [bool, default True] Whether to check the Series and Index names attribute.

check_exact [bool, default False] Whether to compare number exactly.

check_datetimelike_compat [bool, default False] Compare datetime-like which is comparable ignoring dtype.

check_categorical [bool, default True] Whether to compare internal Categorical exactly.

check_category_order [bool, default True] Whether to compare category order of internal Categoricals.

New in version 1.0.2.

check_freq [bool, default True] Whether to check the freq attribute on a DatetimeIndex or TimedeltaIndex.

New in version 1.1.0.

check_flags [bool, default True] Whether to check the flags attribute.

New in version 1.2.0.

rtol [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.

atol [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.

obj [str, default ‘Series’] Specify object name being compared, internally used to show appropriate assertion message.

check_index [bool, default True] Whether to check index equivalence. If False, then compare only values.

New in version 1.3.0.
Examples

```python
>>> from pandas.testing import assert_series_equal
>>> a = pd.Series([1, 2, 3, 4])
>>> b = pd.Series([1, 2, 3, 4])
>>> assert_series_equal(a, b)
```

`pandas.testing.assert_index_equal`

`pandas.testing.assert_index_equal(left, right, exact='equiv', check_names=True, check_less_precise=<no_default>, check_exact=True, check_categorical=True, check_order=True, rtol=1e-05, atol=1e-08, obj='Index')`

Check that left and right Index are equal.

**Parameters**

- `left` [Index]
- `right` [Index]
- `exact` [bool or ‘equiv’], default ‘equiv’ Whether to check the Index class, dtype and inferred_type are identical. If ‘equiv’, then RangeIndex can be substituted for Int64Index as well.
- `check_names` [bool, default True] Whether to check the names attribute.
- `check_less_precise` [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.
  - Deprecated since version 1.1.0: Use `rtol` and `atol` instead to define relative/absolute tolerance, respectively. Similar to `math.isclose()`.
- `check_exact` [bool, default True] Whether to compare number exactly.
- `check_categorical` [bool, default True] Whether to compare internal Categorical exactly.
- `check_order` [bool, default True] Whether to compare the order of index entries as well as their values. If True, both indexes must contain the same elements, in the same order. If False, both indexes must contain the same elements, but in any order.
  - New in version 1.2.0.
- `rtol` [float, default 1e-5] Relative tolerance. Only used when check_exact is False.
  - New in version 1.1.0.
- `atol` [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.
  - New in version 1.1.0.
- `obj` [str, default ‘Index’] Specify object name being compared, internally used to show appropriate assertion message.
Examples

```python
>>> from pandas.testing import assert_index_equal
>>> a = pd.Index([1, 2, 3])
>>> b = pd.Index([1, 2, 3])
>>> assert_index_equal(a, b)
```

`pandas.testing.assert_extension_array_equal`

`pandas.testing.assert_extension_array_equal(left, right, check_dtype=True, index_values=None, check_less_precise=<no_default>, check_exact=False, rtol=1e-05, atol=1e-08)`

Check that left and right ExtensionArrays are equal.

Parameters

- `left, right` [ExtensionArray] The two arrays to compare.
- `check_dtype` [bool, default True] Whether to check if the ExtensionArray dtypes are identical.
- `index_values` [numpy.ndarray, default None] Optional index (shared by both left and right), used in output.
- `check_less_precise` [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.
  
  Deprecated since version 1.1.0: Use `rtol` and `atol` instead to define relative/absolute tolerance, respectively. Similar to `math.isclose()`.
- `check_exact` [bool, default False] Whether to compare number exactly.
- `rtol` [float, default 1e-5] Relative tolerance. Only used when check_exact is False.
  
  New in version 1.1.0.
- `atol` [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.
  
  New in version 1.1.0.

Notes

Missing values are checked separately from valid values. A mask of missing values is computed for each and checked to match. The remaining all-valid values are cast to object dtype and checked.

Examples

```python
>>> from pandas.testing import assert_extension_array_equal
>>> a = pd.Series([1, 2, 3, 4])
>>> b, c = a.array, a.array
>>> assert_extension_array_equal(b, c)
```
## 3.14.3 Exceptions and warnings

<table>
<thead>
<tr>
<th>Exception Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>errors.AccessorRegistrationWarning</td>
<td>Warning for attribute conflicts in accessor registration.</td>
</tr>
<tr>
<td>errors.DtypeWarning</td>
<td>Warning raised when reading different dtypes in a column from a file.</td>
</tr>
<tr>
<td>errors.DuplicateLabelError</td>
<td>Error raised when an operation would introduce duplicate labels.</td>

</tr>
<tr>
<td>errors.UnsortedIndexError</td>
<td>Error raised when attempting to get a slice of a MultiIndex, and the index has not been lexsorted.</td>
</tr>
<tr>
<td>errors.UnsupportedFunctionCall</td>
<td>Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g.</td>
</tr>
</tbody>
</table>

### pandas.errors.AccessorRegistrationWarning

**exception** `pandas.errors.AccessorRegistrationWarning`  
Warning for attribute conflicts in accessor registration.

### pandas.errors.DtypeWarning

**exception** `pandas.errors.DtypeWarning`  
Warning raised when reading different dtypes in a column from a file.

    Raised for a dtype incompatibility. This can happen whenever `read_csv` or `read_table` encounter non-uniform dtypes in a column(s) of a given CSV file.

See also:

- `read_csv` Read CSV (comma-separated) file into a DataFrame.
- `read_table` Read general delimited file into a DataFrame.
Notes

This warning is issued when dealing with larger files because the dtype checking happens per chunk read. Despite the warning, the CSV file is read with mixed types in a single column which will be an object type. See the examples below to better understand this issue.

Examples

This example creates and reads a large CSV file with a column that contains \textit{int} and \textit{str}.

gg df = pd.DataFrame({'a': ['1'] * 100000 + ['X'] * 100000 + ... ['1'] * 100000), ... 'b': ['b'] * 300000})
gg df.to_csv('test.csv', index=False)
>>> df2 = pd.read_csv('test.csv')
... # DtypeWarning: Columns (0) have mixed types

Important to notice that \texttt{df2} will contain both \textit{str} and \textit{int} for the same input, ‘1’.

gg df2.iloc[262140, 0]
'1'
gg type(df2.iloc[262140, 0])
<class 'str'>
gg df2.iloc[262150, 0]
1
gg type(df2.iloc[262150, 0])
<class 'int'>

One way to solve this issue is using the \texttt{dtype} parameter in the \texttt{read_csv} and \texttt{read_table} functions to explicit the conversion:

gg df2 = pd.read_csv('test.csv', sep=',', dtype={'a': str})

No warning was issued.

pandas.errors.DuplicateLabelError

\texttt{exception pandas.errors.DuplicateLabelError}

Error raised when an operation would introduce duplicate labels.

New in version 1.2.0.
Examples

```python
>>> s = pd.Series([0, 1, 2], index=['a', 'b', 'c']).set_flags(...
    allows_duplicate_labels=False
...)
>>> s.reindex(['a', 'a', 'b'])
Traceback (most recent call last):
  ...  
DuplicateLabelError: Index has duplicates.
  positions
    label
      a     [0, 1]
```

pandas.errors.EmptyDataError

**exception pandas.errors.EmptyDataError**

Exception that is thrown in `pd.read_csv` (by both the C and Python engines) when empty data or header is encountered.

pandas.errors.InvalidIndexError

**exception pandas.errors.InvalidIndexError**

Exception raised when attempting to use an invalid index key.

New in version 1.1.0.

pandas.errors.MergeError

**exception pandas.errors.MergeError**

Error raised when problems arise during merging due to problems with input data. Subclass of `ValueError`.

pandas.errors.NearestFrequencyError

**exception pandas.errors.NearestFrequencyError**

Error raised when a null `freq` attribute is used in an operation that needs a non-null frequency, particularly `DatetimeIndex.shift`, `TimedeltaIndex.shift`, `PeriodIndex.shift`.

pandas.errors.NumbaUtilError

**exception pandas.errors.NumbaUtilError**

Error raised for unsupported Numba engine routines.
pandas.errors.OutOfBoundsDatetime

exception pandas.errors.OutOfBoundsDatetime

raised when encountering a timedelta value that cannot be represented as a timedelta64[ns].

pandas.errors.ParserError

exception pandas.errors.ParserError

this is a generic error raised for errors encountered when functions like read_csv or read_html are parsing contents of a file.

see also:
read_csv Read CSV (comma-separated) file into a DataFrame.
read_html Read HTML table into a DataFrame.

pandas.errors.ParserWarning

exception pandas.errors.ParserWarning

warning raised when reading a file that doesn’t use the default ‘c’ parser.

raised by pd.read_csv and pd.read_table when it is necessary to change parsers, generally from the default ‘c’ parser to ‘python’.

it happens due to a lack of support or functionality for parsing a particular attribute of a CSV file with the requested engine.

currently, ‘c’ unsupported options include the following parameters:
1. sep other than a single character (e.g. regex separators)
2. skipfooter higher than 0
3. sep=None with delim_whitespace=False
the warning can be avoided by adding engine='python' as a parameter in pd.read_csv and pd.read_table methods.

see also:
pd.read_csv Read CSV (comma-separated) file into DataFrame.
pd.read_table Read general delimited file into DataFrame.

Examples

using a sep in pd.read_csv other than a single character:

>>> import io
>>> csv = '''a;b;c
... 1;1,8
... 1;2,1'''
>>> df = pd.read_csv(io.StringIO(csv), sep='[;,]')
... # ParserWarning: Falling back to the 'python' engine...
Adding `engine='python'` to `pd.read_csv` removes the Warning:

```python
>>> df = pd.read_csv(io.StringIO(csv), sep=';[,]', engine='python')
```

---

**pandas.errors.PerformanceWarning**

Exception `pandas.errors.PerformanceWarning`

Warning raised when there is a possible performance impact.

**pandas.errors.UnsortedIndexError**

Exception `pandas.errors.UnsortedIndexError`

Error raised when attempting to get a slice of a MultiIndex, and the index has not been lexsorted. Subclass of `KeyError`.

**pandas.errors.UnsupportedFunctionCall**

Exception `pandas.errors.UnsupportedFunctionCall`

Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g. `np.cumsum(groupby_object)`.

### 3.14.4 Data types related functionality

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pandas.api.types.union_categoricals(to_union[, ...,])</code></td>
<td>Combine list-like of Categorical-like, unioning categories.</td>
</tr>
<tr>
<td><code>pandas.api.types.infer_dtype</code></td>
<td>Efficiently infer the type of a passed val, or list-like array of values.</td>
</tr>
<tr>
<td><code>pandas.api.types.pandas_dtype(dtype)</code></td>
<td>Convert input into a pandas only dtype object or a numpy dtype object.</td>
</tr>
</tbody>
</table>

---

**pandas.api.types.union_categoricals**

Combine list-like of Categorical-like, unioning categories.

All categories must have the same dtype.

**Parameters**

- `to_union` [list-like] Categorical, CategoricalIndex, or Series with dtype='category'.
- `sort_categories` [bool, default False] If true, resulting categories will be lexsorted, otherwise they will be ordered as they appear in the data.
- `ignore_order` [bool, default False] If true, the ordered attribute of the Categoricals will be ignored. Results in an unordered categorical.

**Returns**

- Categorical

**Raises**

- TypeError
• all inputs do not have the same dtype
• all inputs do not have the same ordered property
• all inputs are ordered and their categories are not identical
• `sort_categories=True` and Categoricals are ordered

**ValueError**  Empty list of categoricals passed

**Notes**

To learn more about categories, see link

**Examples**

```python
>>> from pandas.api.types import union_categoricals

If you want to combine categoricals that do not necessarily have the same categories, *union_categoricals* will
combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```python
def a = pd.Categorical(["b", "c"])
>>> b = pd.Categorical(["a", "b"])
>>> union_categoricals([a, b])
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

By default, the resulting categories will be ordered as they appear in the *categories* of the data. If you want the
categories to be lexsorted, use `sort_categories=True` argument.

```python
>>> union_categoricals([a, b], sort_categories=True)
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

`union_categoricals` also works with the case of combining two categoricals of the same categories and order
information (e.g. what you could also `append` for).

```python
>>> a = pd.Categorical(["a", "b"], ordered=True)
>>> b = pd.Categorical(["a", "b", "a"], ordered=True)
>>> union_categoricals([a, b])
['a', 'b', 'a', 'b', 'a']
Categories (2, object): ['a' < 'b']
```

Raises *TypeError* because the categories are ordered and not identical.

```python
>>> a = pd.Categorical(["a", "b"], ordered=True)
>>> b = pd.Categorical(["a", "b", "c"], ordered=True)
>>> union_categoricals([a, b])
Traceback (most recent call last):
 ...  
TypeError: to union ordered Categoricals, all categories must be the same
```

New in version 0.20.0

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True`
argument.
```python
>>> a = pd.Categorical(['a', 'b', 'c'], ordered=True)
>>> b = pd.Categorical(['c', 'b', 'a'], ordered=True)
>>> union_categoricals([a, b], ignore_order=True)
['a', 'b', 'c', 'c', 'b', 'a']
Categories (3, object): ['a', 'b', 'c']
```

`union_categoricals` also works with a `CategoricalIndex`, or `Series` containing categorical data, but note that the resulting array will always be a plain `Categorical`

```python
>>> a = pd.Series(['b', 'c'], dtype='category')
>>> b = pd.Series(['a', 'b'], dtype='category')
>>> union_categoricals([a, b])
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

---

**pandas.api.types.infer_dtype**

`pandas.api.types.infer_dtype()`

Efficiently infer the type of a passed val, or list-like array of values. Return a string describing the type.

**Parameters**

- **value** [scalar, list, ndarray, or pandas type]

- **skipna** [bool, default True] Ignore NaN values when inferring the type.

**Returns**

- **str** Describing the common type of the input data.

**Results can include:**

- string
- bytes
- floating
- integer
- mixed-integer
- mixed-integer-float
- decimal
- complex
- categorical
- boolean
- datetime64
- date
- time
- period

---
• mixed
• unknown-array

Raises

TypeError  If ndarray-like but cannot infer the dtype

Notes

• ‘mixed’ is the catchall for anything that is not otherwise specialized
• ‘mixed-integer-float’ are floats and integers
• ‘mixed-integer’ are integers mixed with non-integers
• ‘unknown-array’ is the catchall for something that is an array (has a dtype attribute), but has a dtype unknown to pandas (e.g. external extension array)

Examples

```python
>>> infer_dtype(['foo', 'bar'])
'string'

>>> infer_dtype(['a', np.nan, 'b'], skipna=True)
'string'

>>> infer_dtype(['a', np.nan, 'b'], skipna=False)
'mixed'

>>> infer_dtype([b'foo', b'bar'])
'bytes'

>>> infer_dtype([1, 2, 3])
'integer'

>>> infer_dtype([1, 2, 3.5])
'mixed-integer-float'

>>> infer_dtype([1.0, 2.0, 3.5])
'floating'

>>> infer_dtype(['a', 1])
'mixed-integer'

>>> infer_dtype([Decimal(1), Decimal(2.0)])
'decimal'

>>> infer_dtype([True, False])
'boolean'

>>> infer_dtype([True, False, np.nan])
'boolean'
```
>>> infer_dtypes([pd.Timestamp('20130101')])
'datetime'

>>> infer_dtypes([datetime.date(2013, 1, 1)])
'date'

>>> infer_dtypes([np.datetime64('2013-01-01')])
'datetime64'

>>> infer_dtypes([datetime.timedelta(0, 1, 1)])
'timedelta'

>>> infer_dtypes(pd.Series(list('aabc')).astype('category'))
'categorical'

**api.types.pandas_dtype**

*api.types.pandas_dtype(dtype)*

Convert input into a pandas only dtype object or a numpy dtype object.

**Parameters**

- **dtype** [object to be converted]

**Returns**

- np.dtype or a pandas dtype

**Raises**

- TypeError if not a dtype

**Dtype introspection**

- api.types.is_bool_dtype(arr_or_dtype) Check whether the provided array or dtype is of a boolean dtype.
- api.types.is_categorical_dtype(arr_or_dtype) Check whether an array-like or dtype is of the Categorical dtype.
- api.types.is_complex_dtype(arr_or_dtype) Check whether the provided array or dtype is of a complex dtype.
- api.types.is_datetime64_any_dtype(arr_or_dtype) Check whether the provided array or dtype is of the datetime64 dtype.
- api.types.is_datetime64_dtype(arr_or_dtype) Check whether an array-like or dtype is of the datetime64 dtype.
- api.types.is_datetime64_ns_dtype(arr_or_dtype) Check whether the provided array or dtype is of the datetime64[ns] dtype.
- api.types.is_datetime64tz_dtype(arr_or_dtype) Check whether an array-like or dtype is of a DatetimeTZDtype dtype.
- api.types.is_extension_type(arr) (DEPRECATED) Check whether an array-like is of a pandas extension class instance.
- api.types.is_extension_array_dtype(arr_or_dtype) Check if an object is a pandas extension array type.
- api.types.is_float_dtype(arr_or_dtype) Check whether the provided array or dtype is of a float dtype.

### pandas.api.types.is_bool_dtype

**pandas.api.types.is_bool_dtype(arr_or_dtype)**

Check whether the provided array or dtype is of a boolean dtype.

**Parameters**

- `arr_or_dtype` [array-like] The array or dtype to check.

**Returns**

- `boolean` Whether or not the array or dtype is of a boolean dtype.

**Notes**

An ExtensionArray is considered boolean when the `_is_boolean` attribute is set to True.

**Examples**

```python
>>> is_bool_dtype(str)
False
>>> is_bool_dtype(int)
False
>>> is_bool_dtype(bool)
True
>>> is_bool_dtype(np.bool_)
True
```

(continues on next page)
>>> is_bool_dtype(np.array(['a', 'b']))
False
>>> is_bool_dtype(pd.Series([1, 2]))
False
>>> is_bool_dtype(np.array([True, False]))
True
>>> is_bool_dtype(pd.Categorical([True, False]))
True
>>> is_bool_dtype(pd.arrays.SparseArray([True, False]))
True

pandas.api.types.is_categorical_dtype

pandas.api.types.is_categorical_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the Categorical dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the Categorical dtype.

Examples

>>> is_categorical_dtype(object)
False
>>> is_categorical_dtype(CategoricalDtype())
True
>>> is_categorical_dtype([1, 2, 3])
False
>>> is_categorical_dtype(pd.Categorical([1, 2, 3]))
True
>>> is_categorical_dtype(pd.CategoricalIndex([1, 2, 3]))
True

pandas.api.types.is_complex_dtype

pandas.api.types.is_complex_dtype(arr_or_dtype)
Check whether the provided array or dtype is of a complex dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a complex dtype.
Examples

```python
>>> is_complex_dtype(str)
False
>>> is_complex_dtype(int)
False
>>> is_complex_dtype(np.complex_)
True
>>> is_complex_dtype(np.array(['a', 'b']))
False
>>> is_complex_dtype(pd.Series([1, 2]))
False
>>> is_complex_dtype(np.array([1 + 1j, 5]))
True
```

pandas.api.types.is_datetime64_any_dtype

pandas.api.types.is_datetime64_any_dtype(arr_or_dtype)

Check whether the provided array or dtype is of the datetime64 dtype.

Parameters

- `arr_or_dtype` [array-like] The array or dtype to check.

Returns

- `bool` Whether or not the array or dtype is of the datetime64 dtype.

Examples

```python
>>> is_datetime64_any_dtype(str)
False
>>> is_datetime64_any_dtype(int)
False
>>> is_datetime64_any_dtype(np.datetime64)  # can be tz-naive
True
>>> is_datetime64_any_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_any_dtype(np.array(['a', 'b']))
False
>>> is_datetime64_any_dtype(np.array([1, 2]))
False
>>> is_datetime64_any_dtype(np.array([], dtype="datetime64[ns]"))
True
>>> is_datetime64_any_dtype(pd.DatetimeIndex([1, 2, 3], dtype="datetime64[ns]"))
True
```
pandas.api.types.is_datetime64_dtype

pandas.api.types.is_datetime64_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the datetime64 dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the datetime64 dtype.

Examples

```python
>>> is_datetime64_dtype(object)
False
>>> is_datetime64_dtype(np.datetime64)
True
>>> is_datetime64_dtype(np.array([], dtype=int))
False
>>> is_datetime64_dtype(np.array([], dtype=np.datetime64))
True
>>> is_datetime64_dtype([1, 2, 3])
False
```

pandas.api.types.is_datetime64_ns_dtype

pandas.api.types.is_datetime64_ns_dtype(arr_or_dtype)
Check whether the provided array or dtype is of the datetime64[ns] dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

bool Whether or not the array or dtype is of the datetime64[ns] dtype.

Examples

```python
>>> is_datetime64_ns_dtype(str)
False
>>> is_datetime64_ns_dtype(int)
False
>>> is_datetime64_ns_dtype(np.datetime64)
# no unit
False
>>> is_datetime64_ns_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_ns_dtype(np.array(["a", "b"]))
False
>>> is_datetime64_ns_dtype(np.array([1, 2]))
False
>>> is_datetime64_ns_dtype(np.array([1, 2], dtype="datetime64"))  # no unit
False
>>> is_datetime64_ns_dtype(np.array([1, 2], dtype="datetime64[ps]"))  # wrong unit
False
(continues on next page)
>>> is_datetime64_ns_dtype(pd.DatetimeIndex([1, 2, 3], dtype="datetime64[ns]"))
True

pandas.api.types.is_datetime64tz_dtype

pandas.api.types.is_datetime64tz_dtype(arr_or_dtype)

Check whether an array-like or dtype is of a DatetimeTZDtype dtype.

Parameters

- **arr_or_dtype** [array-like] The array-like or dtype to check.

Returns

- **boolean** Whether or not the array-like or dtype is of a DatetimeTZDtype dtype.

Examples

```python
>>> is_datetime64tz_dtype(object)
False
>>> is_datetime64tz_dtype([1, 2, 3])
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3]))  # tz-naive
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True
```

```python
>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_datetime64tz_dtype(dtype)
True
>>> is_datetime64tz_dtype(s)
True
```

pandas.api.types.is_extension_type

pandas.api.types.is_extension_type(arr)

Check whether an array-like is of a pandas extension class instance.

Deprecated since version 1.0.0: Use is_extension_array_dtype instead.

Extension classes include categoricals, pandas sparse objects (i.e. classes represented within the pandas library and not ones external to it like scipy sparse matrices), and datetime-like arrays.

Parameters

- **arr** [array-like] The array-like to check.

Returns

- **boolean** Whether or not the array-like is of a pandas extension class instance.
Examples

```python
>>> is_extension_type([1, 2, 3])
False
>>> is_extension_type(np.array([1, 2, 3]))
False
>>> cat = pd.Categorical([1, 2, 3])
>>> is_extension_type(cat)
True
>>> is_extension_type(pd.Series(cat))
True
>>> is_extension_type(pd.arrays.SparseArray([1, 2, 3]))
True
>>> from scipy.sparse import bsr_matrix
>>> is_extension_type(bsr_matrix([1, 2, 3]))
False
>>> is_extension_type(pd.DatetimeIndex([1, 2, 3]))
False
>>> is_extension_type(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True
>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_extension_type(s)
True
```

pandas.api.types.is_extension_array_dtype

```
pandas.api.types.is_extension_array_dtype(arr_or_dtype)

Check if an object is a pandas extension array type.

See the Use Guide for more.

Parameters

arr_or_dtype [object] For array-like input, the .dtype attribute will be extracted.

Returns

bool Whether the arr_or_dtype is an extension array type.

Notes

This checks whether an object implements the pandas extension array interface. In pandas, this includes:

• Categorical
• Sparse
• Interval
• Period
• DatetimeArray
• TimedeltaArray

Third-party libraries may implement arrays or types satisfying this interface as well.
```
Examples

```python
>>> from pandas.api.types import is_extension_array_dtype
>>> arr = pd.Categorical(['a', 'b'])
>>> is_extension_array_dtype(arr)
True
>>> is_extension_array_dtype(arr.dtype)
True

>>> arr = np.array(['a', 'b'])
>>> is_extension_array_dtype(arr.dtype)
False
```

**pandas.api.types.is_float_dtype**

*pandas.api.types.is_float_dtype(arr_or_dtype)*

Check whether the provided array or dtype is of a float dtype.

This function is internal and should not be exposed in the public API.

**Parameters**

- **arr_or_dtype** [array-like] The array or dtype to check.

**Returns**

- **boolean** Whether or not the array or dtype is of a float dtype.

Examples

```python
>>> is_float_dtype(str)
False
>>> is_float_dtype(int)
False
>>> is_float_dtype(float)
True
>>> is_float_dtype(np.array(['a', 'b']))
False
>>> is_float_dtype(pd.Series([1, 2]))
False
>>> is_float_dtype(pd.Index([1, 2.]))
True
```

**pandas.api.types.is_int64_dtype**

*pandas.api.types.is_int64_dtype(arr_or_dtype)*

Check whether the provided array or dtype is of the int64 dtype.

**Parameters**

- **arr_or_dtype** [array-like] The array or dtype to check.

**Returns**

- **boolean** Whether or not the array or dtype is of the int64 dtype.
Notes

Depending on system architecture, the return value of `is_int64_dtype(int)` will be True if the OS uses 64-bit integers and False if the OS uses 32-bit integers.

Examples

```python
>>> is_int64_dtype(str)
False
>>> is_int64_dtype(np.int32)
False
>>> is_int64_dtype(np.int64)
True
>>> is_int64_dtype('int8')
False
>>> is_int64_dtype('Int8')
False
>>> is_int64_dtype(pd.Int64Dtype)
True
>>> is_int64_dtype(float)
False
>>> is_int64_dtype(np.uint64)  # unsigned
False
>>> is_int64_dtype(np.array(['a', 'b']))
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.int64))
True
>>> is_int64_dtype(pd.Index([1, 2.]))  # float
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.uint32))  # unsigned
False
```

**pandas.api.types.is_integer_dtype**

`pandas.api.types.is_integer_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of an integer dtype.

Unlike in `in_any_int_dtype`, timedelta64 instances will return False.

The nullable Integer dtypes (e.g. pandas.Int64Dtype) are also considered as integer by this function.

**Parameters**

- `arr_or_dtype` [array-like] The array or dtype to check.

**Returns**

- `boolean` Whether or not the array or dtype is of an integer dtype and not an instance of timedelta64.
Examples

```python
>>> is_integer_dtype(str)
False
>>> is_integer_dtype(int)
True
>>> is_integer_dtype(float)
False
>>> is_integer_dtype(np.uint64)
True
>>> is_integer_dtype('int8')
True
>>> is_integer_dtype('Int8')
True
>>> is_integer_dtype(pd.Int8Dtype)
True
>>> is_integer_dtype(np.datetime64)
False
>>> is_integer_dtype(np.timedelta64)
False
>>> is_integer_dtype(np.array(['a', 'b']))
False
>>> is_integer_dtype(pd.Series([1, 2]))
True
>>> is_integer_dtype(np.array([], dtype=np.timedelta64))
False
>>> is_integer_dtype(pd.Index([1, 2.]))  # float
False
```

3.14. General utility functions
pandas.api.types.is_numeric_dtype

pandas.api.types.is_numeric_dtype(arr_or_dtype)

Check whether the provided array or dtype is of a numeric dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a numeric dtype.

Examples

```python
>>> is_numeric_dtype(str)
False
>>> is_numeric_dtype(int)
True
>>> is_numeric_dtype(float)
True
>>> is_numeric_dtype(np.uint64)
True
>>> is_numeric_dtype(np.datetime64)
False
>>> is_numeric_dtype(np.timedelta64)
False
>>> is_numeric_dtype(np.array(['a', 'b']))
False
>>> is_numeric_dtype(pd.Series([1, 2]))
True
>>> is_numeric_dtype(pd.Index([1, 2.]))
True
>>> is_numeric_dtype(np.array([], dtype=np.timedelta64))
False
```

pandas.api.types.is_object_dtype

pandas.api.types.is_object_dtype(arr_or_dtype)

Check whether an array-like or dtype is of the object dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the object dtype.
Examples

```python
>>> is_object_dtype(object)
True
>>> is_object_dtype(int)
False
>>> is_object_dtype(np.array([], dtype=object))
True
>>> is_object_dtype(np.array([], dtype=int))
False
>>> is_object_dtype([1, 2, 3])
False
```

**pandas.api.types.is_period_dtype**

`pandas.api.types.is_period_dtype(arr_or_dtype)`

Check whether an array-like or dtype is of the Period dtype.

**Parameters**

- `arr_or_dtype` [array-like] The array-like or dtype to check.

**Returns**

- `boolean` Whether or not the array-like or dtype is of the Period dtype.

Examples

```python
>>> is_period_dtype(object)
False
>>> is_period_dtype(PeriodDtype(freq="D"))
True
>>> is_period_dtype([1, 2, 3])
False
>>> is_period_dtype(pd.Period("2017-01-01"))
False
>>> is_period_dtype(pd.PeriodIndex([], freq="A"))
True
```

**pandas.api.types.is_signed_integer_dtype**

`pandas.api.types.is_signed_integer_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of a signed integer dtype.

Unlike in `in_any_int_dtype`, timedelta64 instances will return False.

The nullable Integer dtypes (e.g. pandas.Int64Dtype) are also considered as integer by this function.

**Parameters**

- `arr_or_dtype` [array-like] The array or dtype to check.

**Returns**

- `boolean` Whether or not the array or dtype is of a signed integer dtype and not an instance of timedelta64.
Examples

```python
>>> is_signed_integer_dtypes(str)
False
>>> is_signed_integer_dtypes(int)
True
>>> is_signed_integer_dtypes(float)
False
>>> is_signed_integer_dtypes(np.uint64)  # unsigned
False
>>> is_signed_integer_dtypes('int8')
True
>>> is_signed_integer_dtypes('Int8')
True
>>> is_signed_integer_dtypes(pd.Int8Dtype)
True
>>> is_signed_integer_dtypes(np.datetime64)
False
>>> is_signed_integer_dtypes(np.timedelta64)
False
>>> is_signed_integer_dtypes(np.array(['a', 'b']))
False
>>> is_signed_integer_dtypes(pd.Series([1, 2]))
True
>>> is_signed_integer_dtypes(np.array([], dtype=np.timedelta64))
False
>>> is_signed_integer_dtypes(pd.Index([1, 2.]))  # float
False
>>> is_signed_integer_dtypes(np.array([1, 2], dtype=np.uint32))  # unsigned
False
```

pandas.api.types.is_string_dtypes

`pandas.api.types.is_string_dtypes(arr_or_dtype)`

Check whether the provided array or dtype is of the string dtype.

**Parameters**

`arr_or_dtype` [array-like] The array or dtype to check.

**Returns**

`boolean` Whether or not the array or dtype is of the string dtype.

**Examples**

```python
>>> is_string_dtypes(str)
True
>>> is_string_dtypes(object)
True
>>> is_string_dtypes(int)
False
```
pandas: powerful Python data analysis toolkit, Release 1.3.2

(continued from previous page)

>>> is_string_dtype(pd.Series([1, 2]))
False

pandas.api.types.is_timedelta64_dtype

pandas.api.types.is_timedelta64_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the timedelta64 dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the timedelta64 dtype.

Examples

>>> is_timedelta64_dtype(object)
False
>>> is_timedelta64_dtype(np.timedelta64)
True
>>> is_timedelta64_dtype([1, 2, 3])
False
>>> is_timedelta64_dtype(pd.Series([], dtype="timedelta64[ns]"))
True
>>> is_timedelta64_dtype('0 days')
False

pandas.api.types.is_timedelta64_ns_dtype

pandas.api.types.is_timedelta64_ns_dtype(arr_or_dtype)
Check whether the provided array or dtype is of the timedelta64[ns] dtype.

This is a very specific dtype, so generic ones like np.timedelta64 will return False if passed into this function.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of the timedelta64[ns] dtype.

Examples

>>> is_timedelta64_ns_dtype(np.dtype('m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.dtype('m8[ps]'))  # Wrong frequency
False
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype='m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype=np.timedelta64))
False

3.14. General utility functions
**pandas.api.types.is_unsigned_integer_dtype**

Check whether the provided array or dtype is of an unsigned integer dtype.

The nullable Integer dtypes (e.g. pandas.UInt64Dtype) are also considered as integer by this function.

**Parameters**

- `arr_or_dtype` [array-like] The array or dtype to check.

**Returns**

- boolean Whether or not the array or dtype is of an unsigned integer dtype.

**Examples**

```python
>>> is_unsigned_integer_dtype(str)
False
>>> is_unsigned_integer_dtype(int)  # signed
False
>>> is_unsigned_integer_dtype(float)
False
>>> is_unsigned_integer_dtype(np.uint64)
True
>>> is_unsigned_integer_dtype('uint8')
True
>>> is_unsigned_integer_dtype('UInt8')
True
>>> is_unsigned_integer_dtype(pd.UInt8Dtype)
True
>>> is_unsigned_integer_dtype(np.array(['a', 'b']))
False
>>> is_unsigned_integer_dtype(pd.Series([1, 2]))  # signed
False
>>> is_unsigned_integer_dtype(pd.Index([1, 2.]))  # float
False
>>> is_unsigned_integer_dtype(np.array([1, 2], dtype=np.uint32))
True
```

**pandas.api.types.is_sparse**

Check whether an array-like is a 1-D pandas sparse array.

Check that the one-dimensional array-like is a pandas sparse array. Returns True if it is a pandas sparse array, not another type of sparse array.

**Parameters**

- `arr` [array-like] Array-like to check.

**Returns**

- bool Whether or not the array-like is a pandas sparse array.
Examples

Returns *True* if the parameter is a 1-D pandas sparse array.

```python
>>> is_sparse(pd.arrays.SparseArray([0, 0, 1, 0]))
True
>>> is_sparse(pd.Series(pd.arrays.SparseArray([0, 0, 1, 0])))
True
```

Returns *False* if the parameter is not sparse.

```python
>>> is_sparse(np.array([0, 0, 1, 0]))
False
>>> is_sparse(pd.Series([0, 1, 0, 0]))
False
```

Returns *False* if the parameter is not a pandas sparse array.

```python
>>> from scipy.sparse import bsr_matrix
>>> is_sparse(bsr_matrix([0, 1, 0, 0]))
False
```

Returns *False* if the parameter has more than one dimension.

### Iterable introspection

### `pandas.api.types.is_dict_like`

`pandas.api.types.is_dict_like(obj)`

Check if the object is dict-like.

**Parameters**

- `obj` [The object to check]

**Returns**

- `is_dict_like` [bool] Whether `obj` has dict-like properties.
Examples

```python
>>> is_dict_like({l: 2})
True
>>> is_dict_like([l, 2, 3])
False
>>> is_dict_like(dict)
False
>>> is_dict_like(dict())
True
```

**pandas.api.types.is_file_like**

**pandas.api.types.is_file_like** *(obj)*

Check if the object is a file-like object.

For objects to be considered file-like, they must be an iterator AND have either a *read* and/or *write* method as an attribute.

Note: file-like objects must be iterable, but iterable objects need not be file-like.

**Parameters**

- **obj** [The object to check]

**Returns**

- **is_file_like** [bool] Whether *obj* has file-like properties.

**Examples**

```python
>>> import io
>>> buffer = io.StringIO("data")
>>> is_file_like(buffer)
True
>>> is_file_like([l, 2, 3])
False
```

**pandas.api.types.is_list_like**

**pandas.api.types.is_list_like** *(*)

Check if the object is list-like.

Objects that are considered list-like are for example Python lists, tuples, sets, NumPy arrays, and Pandas Series.

Strings and datetime objects, however, are not considered list-like.

**Parameters**

- **obj** [object] Object to check.

**allow_sets** [bool, default True] If this parameter is False, sets will not be considered list-like.

**Returns**

- **bool** Whether *obj* has list-like properties.
Examples

```python
df = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6]})
>>> df.groupby('a').sum()
   b
a
1  3
2  5
3  7
```

```python
df = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6]})
>>> df['a'].unique()
array([1, 2, 3], dtype=object)
```

```python
df = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6]})
>>> df['a'].is_unique()
False
```

```python
df = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6]})
>>> df['a'].isin([1, 2, 3])
array([True, True, True], dtype=bool)
```

pandas.api.types.is_named_tuple

pandas.api.types.is_named_tuple(obj)
Check if the object is a named tuple.

Parameters

- **obj** [The object to check]

Returns

- is_named_tuple [bool] Whether obj is a named tuple.

Examples

```python
>>> from collections import namedtuple
>>> Point = namedtuple("Point", ["x", "y"])
>>> p = Point(1, 2)
>>> is_named_tuple(p)
True
>>> is_named_tuple((1, 2))
False
```

pandas.api.types.is_iterator

pandas.api.types.is_iterator()
Check if the object is an iterator.

This is intended for generators, not list-like objects.

Parameters

- **obj** [The object to check]

Returns

- is_iter [bool] Whether obj is an iterator.
Examples

```python
>>> is_iterator((x for x in []))
True
>>> is_iterator([1, 2, 3])
False
>>> is_iterator(datetime(2017, 1, 1))
False
>>> is_iterator("foo")
False
>>> is_iterator(1)
False
```

Scalar introspection

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>api.types.is_bool</code></td>
<td>Return True if given object is boolean.</td>
</tr>
<tr>
<td><code>api.types.is_categorical(arr)</code></td>
<td>Check whether an array-like is a Categorical instance.</td>
</tr>
<tr>
<td><code>api.types.is_complex</code></td>
<td>Return True if given object is complex.</td>
</tr>
<tr>
<td><code>api.types.is_float</code></td>
<td>Return True if given object is float.</td>
</tr>
<tr>
<td><code>api.types.is_hashable(obj)</code></td>
<td>Return True if hash(obj) will succeed, False otherwise.</td>
</tr>
<tr>
<td><code>api.types.is_integer</code></td>
<td>Return True if given object is integer.</td>
</tr>
<tr>
<td><code>api.types.is_interval</code></td>
<td></td>
</tr>
<tr>
<td><code>api.types.is_number(obj)</code></td>
<td>Check if the object is a number.</td>
</tr>
<tr>
<td><code>api.types.is_re(obj)</code></td>
<td>Check if the object is a regex pattern instance.</td>
</tr>
<tr>
<td><code>api.types.is_re_compilable(obj)</code></td>
<td>Check if the object can be compiled into a regex pattern instance.</td>
</tr>
<tr>
<td><code>api.types.is_scalar</code></td>
<td>Return True if given object is scalar.</td>
</tr>
</tbody>
</table>

**pandas.api.types.is_bool**

`pandas.api.types.is_bool()`

Return True if given object is boolean.

**Returns**

`bool`

**pandas.api.types.is_categorical**

`pandas.api.types.is_categorical(arr)`

Check whether an array-like is a Categorical instance.

**Parameters**

- `arr` [array-like] The array-like to check.

**Returns**

`boolean` Whether or not the array-like is of a Categorical instance.
Examples

```python
>>> is_categorical([1, 2, 3])
False
```

Categoricals, Series Categoricals, and CategoricalIndex will return True.

```python
>>> cat = pd.Categorical([1, 2, 3])
>>> is_categorical(cat)
True
>>> is_categorical(pd.Series(cat))
True
>>> is_categorical(pd.CategoricalIndex([1, 2, 3]))
True
```

**pandas.api.types.is_complex**

pandas.api.types.is_complex()

Return True if given object is complex.

**Returns**

bool

**pandas.api.types.is_float**

pandas.api.types.is_float()

Return True if given object is float.

**Returns**

bool

**pandas.api.types.is_hashable**

pandas.api.types.is_hashable(obj)

Return True if hash(obj) will succeed, False otherwise.

Some types will pass a test against collections.abc.Hashable but fail when they are actually hashed with hash(). Distinguish between these and other types by trying the call to hash() and seeing if they raise TypeError.

**Returns**

bool

Examples

```python
>>> import collections
>>> a = ([])
>>> isinstance(a, collections.abc.Hashable)
True
>>> is_hashable(a)
False
```
pandas: powerful Python data analysis toolkit, Release 1.3.2

pandas.api.types.is_integer

pandas.api.types.is_integer()
    Return True if given object is integer.
    Returns
        bool

pandas.api.types.is_interval

pandas.api.types.is_interval()

pandas.api.types.is_number

pandas.api.types.is_number(obj)
    Check if the object is a number.
    Returns True when the object is a number, and False if is not.
    Parameters
        obj [any type] The object to check if is a number.
    Returns
        is_number [bool] Whether obj is a number or not.
    See also:
        api.types.is_integer Checks a subgroup of numbers.

Examples

>>> from pandas.api.types import is_number
>>> is_number(1)
True
>>> is_number(7.15)
True
Booleans are valid because they are int subclass.

>>> is_number(False)
True

>>> is_number("foo")
False
>>> is_number("5")
False
**pandas.api.types.is_re**

**pandas.api.types.is_re**(obj)
Check if the object is a regex pattern instance.

**Parameters**

- **obj** [The object to check]

**Returns**

- **is_regex** [bool] Whether *obj* is a regex pattern.

**Examples**

```python
>>> is_re(re.compile(".*"))
True
>>> is_re("foo")
False
```

**pandas.api.types.is_re_compilable**

**pandas.api.types.is_re_compilable**(obj)
Check if the object can be compiled into a regex pattern instance.

**Parameters**

- **obj** [The object to check]

**Returns**

- **is_regex_compilable** [bool] Whether *obj* can be compiled as a regex pattern.

**Examples**

```python
>>> is_re_compilable(".*")
True
>>> is_re_compilable(1)
False
```

**pandas.api.types.is_scalar**

**pandas.api.types.is_scalar**()
Return True if given object is scalar.

**Parameters**

- **val** [object] This includes:
  - numpy array scalar (e.g. np.int64)
  - Python builtin numerics
  - Python builtin byte arrays and strings
  - None
  - datetime.datetime

3.14. General utility functions 2589
- datetime.timedelta
- Period
- decimal.Decimal
- Interval
- DateOffset
- Fraction
- Number.

Returns

bool  Return True if given object is scalar.

Examples

```python
>>> dt = datetime.datetime(2018, 10, 3)
>>> pd.api.types.is_scalar(dt)
True

>>> pd.api.types.is_scalar([2, 3])
False

>>> pd.api.types.is_scalar({0: 1, 2: 3})
False

>>> pd.api.types.is_scalar((0, 2))
False
```

pandas supports PEP 3141 numbers:

```python
>>> from fractions import Fraction
>>> pd.api.types.is_scalar(Fraction(3, 5))
True
```

### 3.14.5 Bug report function

`show_versions([as_json])`  Provide useful information, important for bug reports.

**pandas.show_versions**

pandas.show_versions(as_json=False)

Provide useful information, important for bug reports.

It comprises info about hosting operation system, pandas version, and versions of other installed relative pack-

ages.

**Parameters**

- as_json [str or bool, default False]

  - If False, outputs info in a human readable form to the console.
• If str, it will be considered as a path to a file. Info will be written to that file in JSON format.
• If True, outputs info in JSON format to the console.

3.15 Extensions

These are primarily intended for library authors looking to extend pandas objects.

<table>
<thead>
<tr>
<th>api.extensions.register_extension_dtype</th>
<th>Register an ExtensionType with pandas as class decorator.</th>
</tr>
</thead>
<tbody>
<tr>
<td>api.extensions.register_dataframe_accessor</td>
<td>Register a custom accessor on DataFrame objects.</td>
</tr>
<tr>
<td>api.extensions.register_series_accessor</td>
<td>Register a custom accessor on Series objects.</td>
</tr>
<tr>
<td>api.extensions.register_index_accessor</td>
<td>Register a custom accessor on Index objects.</td>
</tr>
<tr>
<td>api.extensions.ExtensionDtype()</td>
<td>A custom data type, to be paired with an ExtensionArray.</td>
</tr>
</tbody>
</table>

3.15.1 pandas.api.extensions.register_extension_dtype

pandas.api.extensions.register_extension_dtype(cls)

Register an ExtensionType with pandas as class decorator.

This enables operations like .astype(name) for the name of the ExtensionDtype.

Returns

callable A class decorator.

Examples

```python
>>> from pandas.api.extensions import register_extension_dtype
>>> from pandas.api.extensions import ExtensionDtype
>>> @register_extension_dtype
... class MyExtensionDtype(ExtensionDtype):
...     name = "myextension"
```

3.15.2 pandas.api.extensions.register_dataframe_accessor

pandas.api.extensions.register_dataframe_accessor(name)

Register a custom accessor on DataFrame objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

Returns

callable A class decorator.

See also:

- register_dataframe_accessor Register a custom accessor on DataFrame objects.
- register_series_accessor Register a custom accessor on Series objects.
- register_index_accessor Register a custom accessor on Index objects.
Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```python
def __init__(self, pandas_object): # noqa: E999
...
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```python
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```python
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:

```python
In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10),
                      "latitude": np.linspace(0, 20)})
In [2]: ds.geo.center
Out[2]: (5.0, 10.0)
In [3]: ds.geo.plot()  # plots data on a map
```
3.15.3 pandas.api.extensions.register_series_accessor

pandas.api.extensions.register_series_accessor(name)
Register a custom accessor on Series objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this
name conflicts with a preexisting attribute.

Returns
callable A class decorator.

See also:

register_dataframe_accessor Register a custom accessor on DataFrame objects.
register_series_accessor Register a custom accessor on Series objects.
register_index_accessor Register a custom accessor on Index objects.

Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the
signature must be

```python
def __init__(self, pandas_object):  # noqa: E999
    ...
```

For consistency with pandas methods, you should raise an AttributeError if the data passed to your ac-
cessor has an incorrect dtype.

```python
>>> pd.Series(["a", "b"]).dt
Traceback (most recent call last):
... AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```python
import pandas as pd

td_api.extensions.register_dataframe_accessor("geo")

class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

def plot(self):
    # plot this array's data on a map, e.g., using Cartopy
    pass
```

Back in an interactive IPython session:
In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10), ...
...:             "latitude": np.linspace(0, 20)})
In [2]: ds.geo.center
Out[2]: (5.0, 10.0)
In [3]: ds.geo.plot() # plots data on a map

3.15.4 pandas.api.extensions.register_index_accessor

pandas.api.extensions.register_index_accessor(name)
Register a custom accessor on Index objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this
name conflicts with a preexisting attribute.

Returns

callable A class decorator.

See also:

register_dataframe_accessor Register a custom accessor on DataFrame objects.
register_series_accessor Register a custom accessor on Series objects.
register_index_accessor Register a custom accessor on Index objects.

Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the
signature must be

```python
def __init__(self, pandas_object):  # noqa: E999
    ...            
```

For consistency with pandas methods, you should raise an AttributeError if the data passed to your ac-
cessor has an incorrect dtype.

```python
>>> pd.Series(["a", "b"]).dt
Traceback (most recent call last):
...  
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```python
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame

(continues on next page)
Back in an interactive IPython session:

```python
In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10),
                     ...:                 "latitude": np.linspace(0, 20)})
In [2]: ds.geo.center
Out[2]: (5.0, 10.0)
In [3]: ds.geo.plot()  # plots data on a map
```

### 3.15.5 pandas.api.extensions.ExtensionDtype

#### class pandas.api.extensions.ExtensionDtype
A custom data type, to be paired with an ExtensionArray.

**See also:**

- `extensions.register_extension_dtype` Register an ExtensionType with pandas as class decorator.
- `extensions.ExtensionArray` Abstract base class for custom 1-D array types.

**Notes**

The interface includes the following abstract methods that must be implemented by subclasses:
- `type`
- `name`
- `construct_array_type`

The following attributes and methods influence the behavior of the dtype in pandas operations:
- `_is_numeric`
- `_is_boolean`
- `_get_common_dtype`

The `na_value` class attribute can be used to set the default NA value for this type. `numpy.nan` is used by default.

ExtensionDtypes are required to be hashable. The base class provides a default implementation, which relies on the `_metadata` class attribute. `_metadata` should be a tuple containing the strings that define your data type. For example, with `PeriodDtype` that’s the `freq` attribute.

**If you have a parametrized dtype you should set the \`\_metadata\` class property.**

Ideally, the attributes in `_metadata` will match the parameters to your `ExtensionDtype.__init__` (if any). If any of the attributes in `_metadata` don’t implement the standard `__eq__` or `__hash__`, the default implementations here will not work.

For interaction with Apache Arrow (pyarrow), a `__from_arrow__` method can be implemented: this method receives a pyarrow Array or ChunkedArray as only argument and is expected to return the appropriate pandas ExtensionArray for this dtype and the passed values:
class ExtensionDtype:

    def __from_arrow__(
        self, array: Union[pyarrow.Array, pyarrow.ChunkedArray]
    ) -> ExtensionArray:
        ...

This class does not inherit from `abc.ABCMeta` for performance reasons. Methods and properties required by the interface raise `pandas.errors(AbstractMethodError) and no register method is provided for registering virtual subclasses.

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>A character code (one of ‘biufcmMOSUV’), default ‘O’</td>
</tr>
<tr>
<td>na_value</td>
<td>Default NA value to use for this type.</td>
</tr>
<tr>
<td>name</td>
<td>A string identifying the data type.</td>
</tr>
<tr>
<td>names</td>
<td>Ordered list of field names, or None if there are no fields.</td>
</tr>
<tr>
<td>type</td>
<td>The scalar type for the array, e.g.</td>
</tr>
</tbody>
</table>

`pandas.api.extensions.ExtensionDtype.kind`

**property** ExtensionDtype.kind

A character code (one of ‘biufcmMOSUV’), default ‘O’

This should match the NumPy dtype used when the array is converted to an ndarray, which is probably ‘O’ for object if the extension type cannot be represented as a built-in NumPy type.

See also:

`numpy.dtype.kind`

`pandas.api.extensions.ExtensionDtype.na_value`

**property** ExtensionDtype.na_value

Default NA value to use for this type.

This is used in e.g. ExtensionArray.take. This should be the user-facing “boxed” version of the NA value, not the physical NA value for storage. e.g. for JSONArray, this is an empty dictionary.

`pandas.api.extensions.ExtensionDtype.name`

**property** ExtensionDtype.name

A string identifying the data type.

Will be used for display in, e.g. `Series.dtype`
pandas.api.extensions.ExtensionDtype.names

**property** ExtensionDtype.names
Ordered list of field names, or None if there are no fields.

This is for compatibility with NumPy arrays, and may be removed in the future.

pandas.api.extensions.ExtensionDtype.type

**property** ExtensionDtype.type
The scalar type for the array, e.g. int

It’s expected ExtensionArray[item] returns an instance of ExtensionDtype.type for scalar item, assuming that value is valid (not NA). NA values do not need to be instances of type.

Methods

```
class pandas.api.extensions.ExtensionDtype:
    # ExtensionDtype.construct_array_type()
    # Return the array type associated with this dtype.

    def construct_array_type(self):
        return self.type

    # ExtensionDtype.construct_from_string(string)
    # Construct this type from a string.

    def construct_from_string(self, string):
        # This is useful mainly for data types that accept parameters.
        # For example, a period dtype accepts a frequency parameter that can be set as period[H] (where H means hourly frequency).
        # By default, in the abstract class, just the name of the type is expected. But subclasses can overwrite this method to accept parameters.

        # Parameters
        # string [str] The name of the type, for example category.

        # Returns
        # ExtensionDtype Instance of the dtype.

        # Raises
        # TypeError If a class cannot be constructed from this ‘string’.
```
Examples

For extension dtypes with arguments the following may be an adequate implementation.

```python
>>> @classmethod
... def construct_from_string(cls, string):
...     pattern = re.compile(r"my_type\[(?P<arg_name>.+)\]"$
...     match = pattern.match(string)
...     if match:
...         return cls(**match.groupdict())
...     else:
...         raise TypeError(
...             f"Cannot construct a '{cls.__name__}' from '{string}'")
```

`pandas.api.extensions.ExtensionDtype.is_dtype`

`classmethod ExtensionDtype.is_dtype(dtype)`

Check if we match `dtype`.

Parameters

- `dtype` [object] The object to check.

Returns

- `bool`

Notes

The default implementation is True if

1. `cls.construct_from_string(dtype)` is an instance of `cls`.
2. `dtype` is an object and is an instance of `cls`
3. `dtype` has a `dtype` attribute, and any of the above conditions is true for `dtype.dtype`.

`api.extensions.ExtensionArray()`

Abstract base class for custom 1-D array types.

`arrays.PandasArray(values[, copy])`

A pandas ExtensionArray for NumPy data.

3.15.6 `pandas.api.extensions.ExtensionArray`

`class pandas.api.extensions.ExtensionArray`  
Abstract base class for custom 1-D array types.

`pandas` will recognize instances of this class as proper arrays with a custom type and will not attempt to coerce them to objects. They may be stored directly inside a `DataFrame` or `Series`. 
Notes

The interface includes the following abstract methods that must be implemented by subclasses:

- `_from_sequence`
- `_from_factorized`
- `__getitem__`
- `__len__`
- `__eq__`
- `dtype`
- `nbytes`
- `isna`
- `take`
- `copy`
- `_concat_same_type`

A default repr displaying the type, (truncated) data, length, and dtype is provided. It can be customized or replaced by by overriding:

- `__repr__` : A default repr for the ExtensionArray.
- `_formatter` : Print scalars inside a Series or DataFrame.

Some methods require casting the ExtensionArray to an ndarray of Python objects with `self.astype(object)`, which may be expensive. When performance is a concern, we highly recommend overriding the following methods:

- `fillna`
- `dropna`
- `unique`
- `factorize / _values_for_factorize`
- `argsort / _values_for_argsort`
- `searchsorted`

The remaining methods implemented on this class should be performant, as they only compose abstract methods. Still, a more efficient implementation may be available, and these methods can be overridden.

One can implement methods to handle array reductions.

- `_reduce`

One can implement methods to handle parsing from strings that will be used in methods such as `pandas.io.parsers.read_csv`.

- `_from_sequence_of_strings`

This class does not inherit from `abc.ABCMeta` for performance reasons. Methods and properties required by the interface raise `pandas.errors(AbstractMethodError)` and no `register` method is provided for registering virtual subclasses.

ExtensionArrays are limited to 1 dimension.

They may be backed by none, one, or many NumPy arrays. For example, `pandas.Categorical` is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 address may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists. Pandas makes no assumptions on how the data are stored, just that it can be converted to a NumPy array. The ExtensionArray interface does not impose any rules on how this data is stored. However, currently, the backing data cannot be stored in attributes called `.values` or `._values` to ensure full compatibility with pandas internals. But other names as `.data`, `.data`, `.items`, ... can be freely used.

If implementing NumPy’s `__array_ufunc__` interface, pandas expects that

1. You defer by returning `NotImplemented` when any Series are present in `inputs`. Pandas will extract the arrays and call the ufunc again.

2. You define a `_HANDLED_TYPES` tuple as an attribute on the class. Pandas inspect this to determine whether the ufunc is valid for the types present.

See `NumPy universal functions` for more.
By default, ExtensionArrays are not hashable. Immutable subclasses may override this behavior.

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dtype</code></td>
<td>An instance of ‘ExtensionDtype’.</td>
</tr>
<tr>
<td><code>nbytes</code></td>
<td>The number of bytes needed to store this object in memory.</td>
</tr>
<tr>
<td><code>ndim</code></td>
<td>Extension Arrays are only allowed to be 1-dimensional.</td>
</tr>
<tr>
<td><code>shape</code></td>
<td>Return a tuple of the array dimensions.</td>
</tr>
</tbody>
</table>

```python
pandas.api.extensions.ExtensionArray.dtype
```

**property** `ExtensionArray.dtype`

An instance of ‘ExtensionDtype’.

```python
pandas.api.extensions.ExtensionArray.nbytes
```

**property** `ExtensionArray.nbytes`

The number of bytes needed to store this object in memory.

```python
pandas.api.extensions.ExtensionArray.ndim
```

**property** `ExtensionArray.ndim`

Extension Arrays are only allowed to be 1-dimensional.

```python
pandas.api.extensions.ExtensionArray.shape
```

**property** `ExtensionArray.shape`

Return a tuple of the array dimensions.

Methods

<table>

`pandas.api.extensions.ExtensionArray.argsort`

`ExtensionArray.argsort(ascending=True, kind='quicksort', na_position='last', *args, **kwargs)`

Return the indices that would sort this array.

**Parameters**

- `ascending` [bool, default True] Whether the indices should result in an ascending or descending sort.
- `*args, **kwargs`: Passed through to `numpy.argsort()`.

**Returns**

- `np.ndarray[np.intp]` Array of indices that sort `self`. If NaN values are contained, NaN values are placed at the end.

**See also:**

- `numpy.argsort` Sorting implementation used internally.

`pandas.api.extensions.ExtensionArray.astype`

`ExtensionArray.astype(dtype, copy=True)`

Cast to a NumPy array with `dtype`.

**Parameters**

- `dtype` [str or dtype] Typecode or data-type to which the array is cast.
- `copy` [bool, default True] Whether to copy the data, even if not necessary. If False, a copy is made only if the old dtype does not match the new dtype.

**Returns**
array  [ndarray] NumPy ndarray with ‘dtype’ for its dtype.

pandas.api.extensions.ExtensionArray.copy

ExtensionArray.copy()
Return a copy of the array.

Returns

ExtensionArray

pandas.api.extensions.ExtensionArray.dropna

ExtensionArray.dropna()
Return ExtensionArray without NA values.

Returns

valid  [ExtensionArray]

pandas.api.extensions.ExtensionArray.factorize

ExtensionArray.factorize(na_sentinel=-1)
Encode the extension array as an enumerated type.

Parameters

na_sentinel  [int, default -1] Value to use in the codes array to indicate missing values.

Returns

codes  [ndarray] An integer NumPy array that’s an indexer into the original ExtensionArray.

uniques  [ExtensionArray] An ExtensionArray containing the unique values of self.

Note: uniques will not contain an entry for the NA value of the ExtensionArray if there are any missing values present in self.

See also:

factorize  Top-level factorize method that dispatches here.

Notes

pandas.factorize() offers a sort keyword as well.
pandas.api.extensions.ExtensionArrayfillna

ExtensionArray.fillna(value=None, method=None, limit=None)
Fill NA/NaN values using the specified method.

Parameters

- value [scalar, array-like] If a scalar value is passed it is used to fill all missing values. Alternatively, an array-like `value` can be given. It’s expected that the array-like have the same length as `self`.
- method [{'backfill', 'bfill', 'pad', 'ffill', None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap.
- limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled.

Returns

- ExtensionArray With NA/NaN filled.

pandas.api.extensions.ExtensionArray.equals

ExtensionArray.equals(other)
Return if another array is equivalent to this array.

Equivalent means that both arrays have the same shape and dtype, and all values compare equal. Missing values in the same location are considered equal (in contrast with normal equality).

Parameters

- other [ExtensionArray] Array to compare to this Array.

Returns

- boolean Whether the arrays are equivalent.

pandas.api.extensions.ExtensionArray.isin

ExtensionArray.isin(values)
Pointwise comparison for set containment in the given values.
Roughly equivalent to np.array([x in values for x in self])

Parameters

- values [Sequence]

Returns

- np.ndarray[bool]
pandas.api.extensions.ExtensionArray.isna

ExtensionArray.isna()
A 1-D array indicating if each value is missing.

Returns

na_values [Union[np.ndarray, ExtensionArray]] In most cases, this should return a
NumPy ndarray. For exceptional cases like SparseArray, where returning an
ndarray would be expensive, an ExtensionArray may be returned.

Notes

If returning an ExtensionArray, then

• na_values._is_boolean should be True
• na_values should implement ExtensionArray._reduce()
• na_values.any and na_values.all should be implemented

pandas.api.extensions.ExtensionArray.ravel

ExtensionArray.ravel(order='C')
Return a flattened view on this array.

Parameters

Returns

ExtensionArray

Notes

• Because ExtensionArrays are 1D-only, this is a no-op.
• The “order” argument is ignored, is for compatibility with NumPy.

pandas.api.extensions.ExtensionArray.repeat

ExtensionArray.repeat(repeats, axis=None)
Repeat elements of a ExtensionArray.

Returns a new ExtensionArray where each element of the current ExtensionArray is repeated consecu-
tively a given number of times.

Parameters

repeats [int or array of ints] The number of repetitions for each element. This should
be a non-negative integer. Repeating 0 times will return an empty ExtensionArray.

axis [None] Must be None. Has no effect but is accepted for compatibility with numpy.

Returns

repeated_array [ExtensionArray] Newly created ExtensionArray with repeated ele-
ments.
See also:

**Series.repeat**  Equivalent function for Series.

**Index.repeat**  Equivalent function for Index.

**numpy.repeat**  Similar method for numpy.ndarray.

**ExtensionArray.take**  Take arbitrary positions.

**Examples**

```python
>>> cat = pd.Categorical(['a', 'b', 'c'])
>>> cat
['a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']

>>> cat.repeat(2)
['a', 'a', 'b', 'b', 'c', 'c']
Categories (3, object): ['a', 'b', 'c']

>>> cat.repeat([1, 2, 3])
['a', 'b', 'b', 'c', 'c', 'c']
Categories (3, object): ['a', 'b', 'c']
```

**pandas.api.extensions.ExtensionArray.searchsorted**

ExtensionArray.searchsorted(value, side='left', sorter=None)

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted array `self` (a) such that, if the corresponding elements in `value` were inserted before the indices, the order of `self` would be preserved.

Assuming that `self` is sorted:

<table>
<thead>
<tr>
<th><code>side</code></th>
<th>returned index / satisfies</th>
</tr>
</thead>
<tbody>
<tr>
<td>left</td>
<td><code>self[i-1] &lt; value &lt;= self[i]</code></td>
</tr>
<tr>
<td>right</td>
<td><code>self[i-1] &lt;= value &lt; self[i]</code></td>
</tr>
</tbody>
</table>

**Parameters**

- `value`  [array-like] Values to insert into `self`.
- `side`  [{'left', 'right'}, optional] If ‘left’, the index of the first suitable location found is given. If ‘right’, return the last such index. If there is no suitable index, return either 0 or N (where N is the length of `self`).
- `sorter`  [1-D array-like, optional] Optional array of integer indices that sort array `a` into ascending order. They are typically the result of argsort.

**Returns**

- `array of ints`  Array of insertion points with the same shape as `value`.

See also:

**numpy.searchsorted**  Similar method from NumPy.
pandas.api.extensions.ExtensionArray.shift

ExtensionArray.shift(periods=1, fill_value=None)
Shift values by desired number.

Newly introduced missing values are filled with self.dtype.na_value.

Parameters

periods [int, default 1] The number of periods to shift. Negative values are allowed for shifting backwards.

fill_value [object, optional] The scalar value to use for newly introduced missing values. The default is self.dtype.na_value.

Returns

ExtensionArray Shifted.

Notes

If self is empty or periods is 0, a copy of self is returned.

If periods > len(self), then an array of size len(self) is returned, with all values filled with self.dtype.na_value.

pandas.api.extensions.ExtensionArray.take

ExtensionArray.take(indices, *, allow_fill=False, fill_value=None)
Take elements from an array.

Parameters

indices [sequence of int] Indices to be taken.

allow_fill [bool, default False] How to handle negative values in indices.

• False: negative values in indices indicate positional indices from the right (the default). This is similar to numpy.take().

• True: negative values in indices indicate missing values. These values are set to fill_value. Any other other negative values raise a ValueError.

fill_value [any, optional] Fill value to use for NA-indices when allow_fill is True. This may be None, in which case the default NA value for the type, self.dtype.na_value, is used.

For many ExtensionArrays, there will be two representations of fill_value: a user-facing “boxed” scalar, and a low-level physical NA value. fill_value should be the user-facing version, and the implementation should handle translating that to the physical version for processing the take if necessary.

Returns

ExtensionArray

Raises

IndexError When the indices are out of bounds for the array.

ValueError When indices contains negative values other than -1 and allow_fill is True.
See also:

- **numpy.take** Take elements from an array along an axis.
- **api.extensions.take** Take elements from an array.

Notes

ExtensionArray.take is called by `Series.__getitem__, .loc, iloc`, when `indices` is a sequence of values. Additionally, it’s called by `Series.reindex()`, or any other method that causes realignment, with a `fill_value`.

Examples

Here’s an example implementation, which relies on casting the extension array to object dtype. This uses the helper method `pandas.api.extensions.take()`.

```python
def take(self, indices, allow_fill=False, fill_value=None):
    from pandas.core.algorithms import take

    # If the ExtensionArray is backed by an ndarray, then
    # just pass that here instead of coercing to object.
    data = self.astype(object)

    if allow_fill and fill_value is None:
        fill_value = self.dtype.na_value

    # fill_value should always be translated from the scalar
    # type for the array, to the physical storage type for
    # the data, before passing to take.

    result = take(data, indices, fill_value=fill_value,
                  allow_fill=allow_fill)
    return self._from_sequence(result, dtype=self.dtype)
```

**pandas.api.extensions.ExtensionArray.unique**

`ExtensionArray.unique()`

Compute the ExtensionArray of unique values.

- **Returns**
  - `uniques` [ExtensionArray]

**pandas.api.extensions.ExtensionArray.view**

`ExtensionArray.view(dtype=None)`

Return a view on the array.

- **Parameters**
  - `dtype` [str, np.dtype, or ExtensionDtype, optional] Default None.

- **Returns**
  - `ExtensionArray or np.ndarray` A view on the `ExtensionArray`’s data.
pandas.api.extensions.ExtensionArray._concat_same_type

classmethod ExtensionArray._concat_same_type(to_concat)
    Concatenate multiple array of this dtype.

    Parameters
    ----------
    to_concat : [sequence of this type]

    Returns
    -------
    ExtensionArray

pandas.api.extensions.ExtensionArray._formatter

ExtensionArray._formatter(boxed=False)
    Formatting function for scalar values.

    This is used in the default ‘__repr__’. The returned formatting function receives instances of your scalar type.

    Parameters
    ----------
    boxed : [bool, default False] An indicated for whether or not your array is being printed within a Series, DataFrame, or Index (True), or just by itself (False). This may be useful if you want scalar values to appear differently within a Series versus on its own (e.g. quoted or not).

    Returns
    -------
    Callable[[Any], str] A callable that gets instances of the scalar type and returns a string. By default, repr() is used when boxed=False and str() is used when boxed=True.

pandas.api.extensions.ExtensionArray._from_factorized

classmethod ExtensionArray._from_factorized(values, original)
    Reconstruct an ExtensionArray after factorization.

    Parameters
    ----------
    values : [ndarray] An integer ndarray with the factorized values.
    original : [ExtensionArray] The original ExtensionArray that factorize was called on.

    See also:

    factorize Top-level factorize method that dispatches here.
    ExtensionArray.factorize Encode the extension array as an enumerated type.
pandas.api.extensions.ExtensionArray._from_sequence

classmethod ExtensionArray._from_sequence (scalars, *, dtype=None, copy=False)
Construct a new ExtensionArray from a sequence of scalars.

Parameters

scalars [Sequence] Each element will be an instance of the scalar type for this array, cls.dtype.type
or be converted into this type in this method.
dtype [dtype, optional] Construct for this particular dtype. This should be a Dtype compatible with the ExtensionArray.
copy [bool, default False] If True, copy the underlying data.

Returns

ExtensionArray

pandas.api.extensions.ExtensionArray._from_sequence_of_strings

classmethod ExtensionArray._from_sequence_of_strings (strings, *, dtype=None, copy=False)
Construct a new ExtensionArray from a sequence of strings.

Parameters

strings [Sequence] Each element will be an instance of the scalar type for this array, cls.dtype.type.
dtype [dtype, optional] Construct for this particular dtype. This should be a Dtype compatible with the ExtensionArray.
copy [bool, default False] If True, copy the underlying data.

Returns

ExtensionArray

pandas.api.extensions.ExtensionArray._reduce

ExtensionArray._reduce (name, *, skipna=True, **kwargs)
Return a scalar result of performing the reduction operation.

Parameters

name [str] Name of the function, supported values are: { any, all, min, max, sum, mean, median, prod, std, var, sem, kurt, skew }.
skipna [bool, default True] If True, skip NaN values.
**kwargs Additional keyword arguments passed to the reduction function. Currently, ddof is the only supported kwarg.

Returns

scalar

Raises

TypeError [subclass does not define reductions]
pandas.api.extensions.ExtensionArray._values_for_argsort

ExtensionArray._values_for_argsort()

Return values for sorting.

Returns

ndarray The transformed values should maintain the ordering between values within the array.

See also:

ExtensionArray.argsort Return the indices that would sort this array.

pandas.api.extensions.ExtensionArray._values_for_factorize

ExtensionArray._values_for_factorize()

Return an array and missing value suitable for factorization.

Returns

values [ndarray] An array suitable for factorization. This should maintain order and be a supported dtype (Float64, Int64, UInt64, String, Object). By default, the extension array is cast to object dtype.

na_value [object] The value in values to consider missing. This will be treated as NA in the factorization routines, so it will be coded as na_sentinel and not included in uniques. By default, np.nan is used.

Notes

The values returned by this method are also used in pandas.util.hash_pandas_object().

3.15.7 pandas.arrays.PandasArray

class pandas.arrays.PandasArray(values, copy=False)

A pandas ExtensionArray for NumPy data.

This is mostly for internal compatibility, and is not especially useful on its own.

Parameters

values [ndarray] The NumPy ndarray to wrap. Must be 1-dimensional.

copy [bool, default False] Whether to copy values.

Attributes

None
Methods

Additionally, we have some utility methods for ensuring your object behaves correctly.

```python
api.indexers.check_array_indexer(array, indexer)
```

Check if `indexer` is a valid array indexer for `array`.

### 3.15.8 pandas.api.indexers.check_array_indexer

`pandas.api.indexers.check_array_indexer(array, indexer)`

Check if `indexer` is a valid array indexer for `array`.

For a boolean mask, `array` and `indexer` are checked to have the same length. The dtype is validated, and if it is an integer or boolean ExtensionArray, it is checked if there are missing values present, and it is converted to the appropriate numpy array. Other dtypes will raise an error.

Non-array indexers (integer, slice, Ellipsis, tuples, ..) are passed through as is.

New in version 1.0.0.

**Parameters**

- `array` [array-like] The array that is being indexed (only used for the length).
- `indexer` [array-like or list-like] The array-like that’s used to index. List-like input that is not yet a numpy array or an ExtensionArray is converted to one. Other input types are passed through as is.

**Returns**

- `numpy.ndarray` The validated indexer as a numpy array that can be used to index.

**Raises**

- `IndexError` When the lengths don’t match.
- `ValueError` When `indexer` cannot be converted to a numpy ndarray to index (e.g. presence of missing values).

**See also:**

- `api.types.is_bool_dtype` Check if `key` is of boolean dtype.

**Examples**

When checking a boolean mask, a boolean ndarray is returned when the arguments are all valid.

```python
>>> mask = pd.array([True, False])
>>> arr = pd.array([1, 2])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([ True, False])
```

An `IndexError` is raised when the lengths don’t match.
>>> mask = pd.array([True, False, True])
>>> pd.api.indexers.check_array_indexer(arr, mask)
Traceback (most recent call last):
  ...
IndexError: Boolean index has wrong length: 3 instead of 2.

NA values in a boolean array are treated as False.

>>> mask = pd.array([True, pd.NA])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([ True, False])

A numpy boolean mask will get passed through (if the length is correct):

>>> mask = np.array([True, False])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([ True, False])

Similarly for integer indexers, an integer ndarray is returned when it is a valid indexer, otherwise an error is (for integer indexers, a matching length is not required):

>>> indexer = pd.array([0, 2], dtype="Int64")
>>> arr = pd.array([1, 2, 3])
>>> pd.api.indexers.check_array_indexer(arr, indexer)
array([0, 2])

>>> indexer = pd.array([0, pd.NA], dtype="Int64")
>>> pd.api.indexers.check_array_indexer(arr, indexer)
Traceback (most recent call last):
  ...
ValueError: Cannot index with an integer indexer containing NA values

For non-integer/boolean dtypes, an appropriate error is raised:

>>> indexer = np.array([0., 2.], dtype="float64")
>>> pd.api.indexers.check_array_indexer(arr, indexer)
Traceback (most recent call last):
  ...
IndexError: arrays used as indices must be of integer or boolean type

The sentinel pandas.api.extensions.no_default is used as the default value in some methods. Use an is comparison to check if the user provides a non-default value.
4.1 Contributing to pandas

Table of contents:

- Tips for a successful pull request
4.1.1 Where to start?

All contributions, bug reports, bug fixes, documentation improvements, enhancements, and ideas are welcome.

If you are brand new to pandas or open-source development, we recommend going through the GitHub “issues” tab to find issues that interest you. There are a number of issues listed under Docs and good first issue where you could start out. Once you’ve found an interesting issue, you can return here to get your development environment setup.

When you start working on an issue, it’s a good idea to assign the issue to yourself, so nobody else duplicates the work on it. GitHub restricts assigning issues to maintainers of the project only. In most projects, and until recently in pandas, contributors added a comment letting others know they are working on an issue. While this is ok, you need to check each issue individually, and it’s not possible to find the unassigned ones.

For this reason, we implemented a workaround consisting of adding a comment with the exact text `take`. When you do it, a GitHub action will automatically assign you the issue (this will take seconds, and may require refreshing the page to see it). By doing this, it’s possible to filter the list of issues and find only the unassigned ones.

So, a good way to find an issue to start contributing to pandas is to check the list of unassigned good first issues and assign yourself one you like by writing a comment with the exact text `take`.

If for whatever reason you are not able to continue working with the issue, please try to unassign it, so other people know it’s available again. You can check the list of assigned issues, since people may not be working in them anymore. If you want to work on one that is assigned, feel free to kindly ask the current assignee if you can take it (please allow at least a week of inactivity before considering work in the issue discontinued).

Feel free to ask questions on the mailing list or on Gitter.

4.1.2 Bug reports and enhancement requests

Bug reports are an important part of making pandas more stable. Having a complete bug report will allow others to reproduce the bug and provide insight into fixing. See this stackoverflow article and this blogpost for tips on writing a good bug report.

Trying the bug-producing code out on the master branch is often a worthwhile exercise to confirm the bug still exists. It is also worth searching existing bug reports and pull requests to see if the issue has already been reported and/or fixed.

Bug reports must:

1. Include a short, self-contained Python snippet reproducing the problem. You can format the code nicely by using GitHub Flavored Markdown:

```python
>>> from pandas import DataFrame
>>> df = DataFrame(...) 
...
```

2. Include the full version string of pandas and its dependencies. You can use the built-in function:

```python
>>> import pandas as pd
>>> pd.show_versions()
```

3. Explain why the current behavior is wrong/not desired and what you expect instead.

The issue will then show up to the pandas community and be open to comments/ideas from others.
4.1.3 Working with the code

Now that you have an issue you want to fix, enhancement to add, or documentation to improve, you need to learn how to work with GitHub and the pandas code base.

Version control, Git, and GitHub

To the new user, working with Git is one of the more daunting aspects of contributing to pandas. It can very quickly become overwhelming, but sticking to the guidelines below will help keep the process straightforward and mostly trouble free. As always, if you are having difficulties please feel free to ask for help.

The code is hosted on GitHub. To contribute you will need to sign up for a free GitHub account. We use Git for version control to allow many people to work together on the project.

Some great resources for learning Git:

- the GitHub help pages.
- the NumPy documentation.
- Matthew Brett’s Pydagogue.

Getting started with Git

GitHub has instructions for installing git, setting up your SSH key, and configuring git. All these steps need to be completed before you can work seamlessly between your local repository and GitHub.

Forking

You will need your own fork to work on the code. Go to the pandas project page and hit the Fork button. You will want to clone your fork to your machine:

```bash
$ git clone https://github.com/your-user-name/pandas.git pandas-yourname
$ cd pandas-yourname
$ git remote add upstream https://github.com/pandas-dev/pandas.git
```

This creates the directory pandas-yourname and connects your repository to the upstream (main project) pandas repository.

Note that performing a shallow clone (with `--depth==N`, for some $N$ greater or equal to 1) might break some tests and features as `pd.show_versions()` as the version number cannot be computed anymore.

Creating a branch

You want your master branch to reflect only production-ready code, so create a feature branch for making your changes. For example:

```bash
$ git branch shiny-new-feature
$ git checkout shiny-new-feature
```

The above can be simplified to:

```bash
$ git checkout -b shiny-new-feature
```
This changes your working directory to the shiny-new-feature branch. Keep any changes in this branch specific to one bug or feature so it is clear what the branch brings to pandas. You can have many shiny-new-features and switch in between them using the git checkout command.

When creating this branch, make sure your master branch is up to date with the latest upstream master version. To update your local master branch, you can do:

```
git checkout master
git pull upstream master --ff-only
```

When you want to update the feature branch with changes in master after you created the branch, check the section on updating a PR.

### 4.1.4 Contributing your changes to pandas

#### Committing your code

Keep style fixes to a separate commit to make your pull request more readable.

Once you’ve made changes, you can see them by typing:

```
git status
```

If you have created a new file, it is not being tracked by git. Add it by typing:

```
git add path/to/file-to-be-added.py
```

Doing ‘git status’ again should give something like:

```
# On branch shiny-new-feature
#
# modified: /relative/path/to/file-you-added.py
```

Finally, commit your changes to your local repository with an explanatory message. pandas uses a convention for commit message prefixes and layout. Here are some common prefixes along with general guidelines for when to use them:

- ENH: Enhancement, new functionality
- BUG: Bug fix
- DOC: Additions/updates to documentation
- TST: Additions/updates to tests
- BLD: Updates to the build process/scripts
- PERF: Performance improvement
- TYP: Type annotations
- CLN: Code cleanup

The following defines how a commit message should be structured. Please reference the relevant GitHub issues in your commit message using GH1234 or #1234. Either style is fine, but the former is generally preferred:

- a subject line with < 80 chars.
- One blank line.
• Optionally, a commit message body.

Now you can commit your changes in your local repository:

```bash
git commit -m
```

### Pushing your changes

When you want your changes to appear publicly on your GitHub page, push your forked feature branch’s commits:

```bash
git push origin shiny-new-feature
```

Here `origin` is the default name given to your remote repository on GitHub. You can see the remote repositories:

```bash
git remote -v
```

If you added the upstream repository as described above you will see something like:

```
origin git@github.com:yourname/pandas.git (fetch)
origin git@github.com:yourname/pandas.git (push)
upstream git://github.com/pandas-dev/pandas.git (fetch)
upstream git://github.com/pandas-dev/pandas.git (push)
```

Now your code is on GitHub, but it is not yet a part of the pandas project. For that to happen, a pull request needs to be submitted on GitHub.

### Review your code

When you’re ready to ask for a code review, file a pull request. Before you do, once again make sure that you have followed all the guidelines outlined in this document regarding code style, tests, performance tests, and documentation. You should also double check your branch changes against the branch it was based on:

1. Navigate to your repository on GitHub – https://github.com/your-user-name/pandas
2. Click on Branches
3. Click on the Compare button for your feature branch
4. Select the base and compare branches, if necessary. This will be master and shiny-new-feature, respectively.

### Finally, make the pull request

If everything looks good, you are ready to make a pull request. A pull request is how code from a local repository becomes available to the GitHub community and can be looked at and eventually merged into the master version. This pull request and its associated changes will eventually be committed to the master branch and available in the next release. To submit a pull request:

1. Navigate to your repository on GitHub
2. Click on the Pull Request button
3. You can then click on Commits and Files Changed to make sure everything looks okay one last time
4. Write a description of your changes in the Preview Discussion tab
5. Click Send Pull Request.

This request then goes to the repository maintainers, and they will review the code.
Updating your pull request

Based on the review you get on your pull request, you will probably need to make some changes to the code. In that case, you can make them in your branch, add a new commit to that branch, push it to GitHub, and the pull request will be automatically updated. Pushing them to GitHub again is done by:

```
git push origin shiny-new-feature
```

This will automatically update your pull request with the latest code and restart the Continuous Integration tests.

Another reason you might need to update your pull request is to solve conflicts with changes that have been merged into the master branch since you opened your pull request.

To do this, you need to “merge upstream master” in your branch:

```
git checkout shiny-new-feature
git fetch upstream
git merge upstream/master
```

If there are no conflicts (or they could be fixed automatically), a file with a default commit message will open, and you can simply save and quit this file.

If there are merge conflicts, you need to solve those conflicts. See for example at https://help.github.com/articles/resolving-a-merge-conflict-using-the-command-line/ for an explanation on how to do this. Once the conflicts are merged and the files where the conflicts were solved are added, you can run `git commit` to save those fixes.

If you have uncommitted changes at the moment you want to update the branch with master, you will need to `stash` them prior to updating (see the `stash` docs). This will effectively store your changes and they can be reapplied after updating.

After the feature branch has been update locally, you can now update your pull request by pushing to the branch on GitHub:

```
git push origin shiny-new-feature
```

Autofixing formatting errors

We use several styling checks (e.g. `black`, `flake8`, `isort`) which are run after you make a pull request. If there is a scenario where any of these checks fail then you can comment:

```
@github-actions pre-commit
```

on that pull request. This will trigger a workflow which will autofix formatting errors.

Delete your merged branch (optional)

Once your feature branch is accepted into upstream, you’ll probably want to get rid of the branch. First, merge upstream master into your branch so `git` knows it is safe to delete your branch:

```
git fetch upstream
git checkout master
git merge upstream/master
```

Then you can do:
git branch -d shiny-new-feature

Make sure you use a lower-case -d, or else git won’t warn you if your feature branch has not actually been merged. The branch will still exist on GitHub, so to delete it there do:

git push origin --delete shiny-new-feature

4.1.5 Tips for a successful pull request

If you have made it to the Review your code phase, one of the core contributors may take a look. Please note however that a handful of people are responsible for reviewing all of the contributions, which can often lead to bottlenecks.

To improve the chances of your pull request being reviewed, you should:

• Reference an open issue for non-trivial changes to clarify the PR’s purpose
• Ensure you have appropriate tests. These should be the first part of any PR
• Keep your pull requests as simple as possible. Larger PRs take longer to review
• Ensure that CI is in a green state. Reviewers may not even look otherwise
• Keep Updating your pull request, either by request or every few days

4.2 Creating a development environment

To test out code changes, you’ll need to build pandas from source, which requires a C/C++ compiler and Python environment. If you’re making documentation changes, you can skip to contributing to the documentation but if you skip creating the development environment you won’t be able to build the documentation locally before pushing your changes.

Table of contents:

• Creating an environment using Docker
• Creating an environment without Docker
  – Installing a C compiler
  – Creating a Python environment
  – Creating a Python environment (pip)

4.2.1 Creating an environment using Docker

Instead of manually setting up a development environment, you can use Docker to automatically create the environment with just several commands. pandas provides a DockerFile in the root directory to build a Docker image with a full pandas development environment.

Docker Commands

Pass your GitHub username in the DockerFile to use your own fork:
Even easier, you can integrate Docker with the following IDEs:

**Visual Studio Code**
You can use the DockerFile to launch a remote session with Visual Studio Code, a popular free IDE, using the .devcontainer.json file. See [https://code.visualstudio.com/docs/remote/containers](https://code.visualstudio.com/docs/remote/containers) for details.

**PyCharm (Professional)**
Enable Docker support and use the Services tool window to build and manage images as well as run and interact with containers. See [https://www.jetbrains.com/help/pycharm/docker.html](https://www.jetbrains.com/help/pycharm/docker.html) for details.

Note that you might need to rebuild the C extensions if/when you merge with upstream/master using:

```
python setup.py build_ext -j 4
```

### 4.2.2 Creating an environment without Docker

#### Installing a C compiler

pandas uses C extensions (mostly written using Cython) to speed up certain operations. To install pandas from source, you need to compile these C extensions, which means you need a C compiler. This process depends on which platform you’re using.

If you have setup your environment using conda, the packages *c-compiler* and *cxx-compiler* will install a fitting compiler for your platform that is compatible with the remaining conda packages. On Windows and macOS, you will also need to install the SDKs as they have to be distributed separately. These packages will automatically be installed by using the *pandas environment.yml* file.

**Windows**

**Warning:** You DO NOT need to install Visual Studio 2019. You only need “Build Tools for Visual Studio 2019” found by scrolling down to “All downloads” -> “Tools for Visual Studio 2019”. In the installer, select the “C++ build tools” workload.

You can install the necessary components on the commandline using *vs_buildtools.exe*:

```
vs_buildtools.exe --quiet --wait --norestart --nocache ^
--installPath C:\BuildTools ^
--add "Microsoft.VisualStudio.Workload.VCTools;includeRecommended" ^
--add Microsoft.VisualStudio.Component.VC.v141 ^
--add Microsoft.VisualStudio.Component.VC.v141.x86.x64 ^
```

To setup the right paths on the commandline, call "C:\BuildTools\VC\Auxiliary\Build\vcvars64.bat" -vcvars_ver=14.16 10.0.17763.0.

**macOS**
To use the conda-based compilers, you will need to install the Developer Tools using xcode-select --install. Otherwise information about compiler installation can be found here: https://devguide.python.org/setup/#macos

**Linux**

For Linux-based conda installations, you won’t have to install any additional components outside of the conda environment. The instructions below are only needed if your setup isn’t based on conda environments.

Some Linux distributions will come with a pre-installed C compiler. To find out which compilers (and versions) are installed on your system:

```bash
# for Debian/Ubuntu:
dpkg --list | grep compiler
# for Red Hat/RHEL/CentOS/Fedora:
yum list installed | grep -i --color compiler
```

GCC (GNU Compiler Collection), is a widely used compiler, which supports C and a number of other languages. If GCC is listed as an installed compiler nothing more is required. If no C compiler is installed (or you wish to install a newer version) you can install a compiler (GCC in the example code below) with:

```bash
# for recent Debian/Ubuntu:
sudo apt install build-essential
# for Red Hat/RHEL/CentOS/Fedora
yum groupinstall "Development Tools"
```

For other Linux distributions, consult your favorite search engine for compiler installation instructions.

Let us know if you have any difficulties by opening an issue or reaching out on Gitter.

**Creating a Python environment**

Now create an isolated pandas development environment:

- Install either Anaconda, miniconda, or miniforge
- Make sure your conda is up to date (conda update conda)
- Make sure that you have cloned the repository
- cd to the pandas source directory

We’ll now kick off a three-step process:

1. Install the build dependencies
2. Build and install pandas
3. Install the optional dependencies

```bash
# Create and activate the build environment
conda env create -f environment.yml
conda activate pandas-dev

# or with older versions of Anaconda:
source activate pandas-dev

# Build and install pandas
python setup.py build_ext -j 4
python -m pip install -e . --no-build-isolation --no-use-peg517
```
At this point you should be able to import pandas from your locally built version:

```bash
$ python  # start an interpreter
>>> import pandas
>>> print(pandas.__version__)
0.22.0.dev0+29.g4ad6d4d74
```

This will create the new environment, and not touch any of your existing environments, nor any existing Python installation.

To view your environments:

```bash
conda info -e
```

To return to your root environment:

```bash
conda deactivate
```

See the full conda docs here.

**Creating a Python environment (pip)**

If you aren’t using conda for your development environment, follow these instructions. You’ll need to have at least the minimum Python version that pandas supports. You also need to have setuptools 51.0.0 or later to build pandas.

**Unix/macOS with virtualenv**

```bash
# Create a virtual environment
# Use an ENV_DIR of your choice. We'll use ~/virtualenvs/pandas-dev
# Any parent directories should already exist
python3 -m venv ~/virtualenvs/pandas-dev

# Activate the virtualenv
. ~/virtualenvs/pandas-dev/bin/activate

# Install the build dependencies
python -m pip install -r requirements-dev.txt

# Build and install pandas
python setup.py build_ext -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517
```

**Unix/macOS with pyenv**

Consult the docs for setting up pyenv here.

```bash
# Create a virtual environment
# Use an ENV_DIR of your choice. We'll use ~/Users/<yourname>/.pyenv/versions/pandas-dev
pyenv virtualenv <version> <name-to-give-it>

# For instance:
pyenv virtualenv 3.7.6 pandas-dev

# Activate the virtualenv
pyenv activate pandas-dev
```

(continues on next page)
# Now install the build dependencies in the cloned pandas repo
python -m pip install -r requirements-dev.txt

# Build and install pandas
python setup.py build_ext -j 4
cpython -m pip install -e . --no-build-isolation --no-use-pep517

**Windows**

Below is a brief overview on how to set-up a virtual environment with Powershell under Windows. For details please refer to the official virtualenv user guide.

Use an ENV_DIR of your choice. We’ll use ~\virtualenv\pandas-dev where ‘~’ is the folder pointed to by either $env:USERPROFILE (Powershell) or %USERPROFILE% (cmd.exe) environment variable. Any parent directories should already exist.

```bash
# Create a virtual environment
python -m venv $env:USERPROFILE\virtualenvs\pandas-dev

# Activate the virtualenv. Use activate.bat for cmd.exe
-\virtualenvs\pandas-dev\Scripts\Activate.ps1

# Install the build dependencies
python -m pip install -r requirements-dev.txt

# Build and install pandas
python setup.py build_ext -j 4
cpython -m pip install -e . --no-build-isolation --no-use-pep517
```

### 4.3 Contributing to the documentation

Contributing to the documentation benefits everyone who uses pandas. We encourage you to help us improve the documentation, and you don’t have to be an expert on pandas to do so! In fact, there are sections of the docs that are worse off after being written by experts. If something in the docs doesn’t make sense to you, updating the relevant section after you figure it out is a great way to ensure it will help the next person.

**Documentation:**

- About the pandas documentation
- Updating a pandas docstring
- How to build the pandas documentation
  - Requirements
  - Building the documentation
  - Building master branch documentation
- Previewing changes
4.3.1 About the pandas documentation

The documentation is written in reStructuredText, which is almost like writing in plain English, and built using Sphinx. The Sphinx Documentation has an excellent introduction to reST. Review the Sphinx docs to perform more complex changes to the documentation as well.

Some other important things to know about the docs:

- The pandas documentation consists of two parts: the docstrings in the code itself and the docs in this folder doc/.

  The docstrings provide a clear explanation of the usage of the individual functions, while the documentation in this folder consists of tutorial-like overviews per topic together with some other information (what’s new, installation, etc).

- The docstrings follow a pandas convention, based on the Numpy Docstring Standard. Follow the pandas docstring guide for detailed instructions on how to write a correct docstring.

pandas docstring guide

About docstrings and standards

A Python docstring is a string used to document a Python module, class, function or method, so programmers can understand what it does without having to read the details of the implementation.

Also, it is a common practice to generate online (html) documentation automatically from docstrings. Sphinx serves this purpose.

The next example gives an idea of what a docstring looks like:

```python
def add(num1, num2):
    ""
    Add up two integer numbers.

    This function simply wraps the `+` operator, and does not do anything interesting, except for illustrating what the docstring of a very simple function looks like.

    Parameters
    ----------
    num1 : int
        First number to add.
    num2 : int
        Second number to add.

    Returns
    -------
    int
    The sum of `num1` and `num2`.

    See Also
    --------
    subtract : Subtract one integer from another.

    Examples
    --------
    >>> add(2, 2)
    4
```

(continues on next page)
Some standards regarding docstrings exist, which make them easier to read, and allow them be easily exported to other formats such as html or pdf.

The first conventions every Python docstring should follow are defined in PEP-257.

As PEP-257 is quite broad, other more specific standards also exist. In the case of pandas, the NumPy docstring convention is followed. These conventions are explained in this document:

- numpydoc docstring guide (which is based in the original Guide to NumPy/SciPy documentation)

numpydoc is a Sphinx extension to support the NumPy docstring convention.

The standard uses reStructuredText (reST). reStructuredText is a markup language that allows encoding styles in plain text files. Documentation about reStructuredText can be found in:

- Sphinx reStructuredText primer
- Quick reStructuredText reference
- Full reStructuredText specification

pandas has some helpers for sharing docstrings between related classes, see Sharing docstrings.

The rest of this document will summarize all the above guidelines, and will provide additional conventions specific to the pandas project.

Writing a docstring

General rules

Docstrings must be defined with three double-quotes. No blank lines should be left before or after the docstring. The text starts in the next line after the opening quotes. The closing quotes have their own line (meaning that they are not at the end of the last sentence).

On rare occasions reST styles like bold text or italics will be used in docstrings, but is it common to have inline code, which is presented between backticks. The following are considered inline code:

- The name of a parameter
- Python code, a module, function, built-in, type, literal... (e.g. os, list, numpy.abs, datetime, date, True)
- A pandas class (in the form :class:`pandas.Series`)
- A pandas method (in the form :meth:`pandas.Series.sum`)
- A pandas function (in the form :func:`pandas.to_datetime`)

Note: To display only the last component of the linked class, method or function, prefix it with ~. For example, :class:`~pandas.Series` will link to pandas.Series but only display the last part, Series as the link text. See Sphinx cross-referencing syntax for details.
### Good:

```python
def add_values(arr):
    """
    Add the values in `arr`.
    This is equivalent to Python `sum` of :meth:`pandas.Series.sum`.
    Some sections are omitted here for simplicity.
    """
    return sum(arr)
```

### Bad:

```python
def func():
    """Some function.
    With several mistakes in the docstring.
    It has a blank like after the signature `def func():`.
    The text 'Some function' should go in the line after the
    opening quotes of the docstring, not in the same line.
    There is a blank line between the docstring and the first line
    of code `foo = 1`.
    The closing quotes should be in the next line, not in this one.""
    foo = 1
    bar = 2
    return foo + bar
```

### Section 1: short summary

The short summary is a single sentence that expresses what the function does in a concise way.

The short summary must start with a capital letter, end with a dot, and fit in a single line. It needs to express what the object does without providing details. For functions and methods, the short summary must start with an infinitive verb.

**Good:**

```python
def astype(dtype):
    """
    Cast Series type.
    This section will provide further details.
    """
    pass
```

**Bad:**

```python
def astype(dtype):
    """
    Casts Series type.
```

(continues on next page)
def astype(dtype):
    
    Method to cast Series type.
    Does not start with verb.
    pass

Section 2: extended summary

The extended summary provides details on what the function does. It should not go into the details of the parameters, or discuss implementation notes, which go in other sections.

A blank line is left between the short summary and the extended summary. Every paragraph in the extended summary ends with a dot.

The extended summary should provide details on why the function is useful and their use cases, if it is not too generic.

def unstack():
    
    Pivot a row index to columns.

    When using a MultiIndex, a level can be pivoted so each value in the index becomes a column. This is especially useful when a subindex is repeated for the main index, and data is easier to visualize as a pivot table.

    The index level will be automatically removed from the index when added as columns.
    pass
Section 3: parameters

The details of the parameters will be added in this section. This section has the title “Parameters”, followed by a line with a hyphen under each letter of the word “Parameters”. A blank line is left before the section title, but not after, and not between the line with the word “Parameters” and the one with the hyphens.

After the title, each parameter in the signature must be documented, including *args and **kwargs, but not self.

The parameters are defined by their name, followed by a space, a colon, another space, and the type (or types). Note that the space between the name and the colon is important. Types are not defined for *args and **kwargs, but must be defined for all other parameters. After the parameter definition, it is required to have a line with the parameter description, which is indented, and can have multiple lines. The description must start with a capital letter, and finish with a dot.

For keyword arguments with a default value, the default will be listed after a comma at the end of the type. The exact form of the type in this case will be “int, default 0”. In some cases it may be useful to explain what the default argument means, which can be added after a comma “int, default -1, meaning all cpus”.

In cases where the default value is None, meaning that the value will not be used. Instead of "str, default None", it is preferred to write "str, optional". When None is a value being used, we will keep the form “str, default None”. For example, in df.to_csv(compression=None), None is not a value being used, but means that compression is optional, and no compression is being used if not provided. In this case we will use "str, optional". Only in cases like func(value=None) and None is being used in the same way as 0 or foo would be used, then we will specify “str, int or None, default None”.

Good:

```python
class Series:
    def plot(self, kind, color='blue', **kwargs):
        
        Render the data in the Series as a matplotlib plot of the specified kind.

        Parameters
        --------
        kind : str
            Kind of matplotlib plot.
        color : str, default 'blue'
            Color name or rgb code.
        **kwargs
            These parameters will be passed to the matplotlib plotting function.
        
        pass
```

Bad:

```python
class Series:
    def plot(self, kind, **kwargs):
        
        Generate a plot.

        Render the data in the Series as a matplotlib plot of the specified kind.
```

(continues on next page)
Note the blank line between the parameters title and the first parameter. Also, note that after the name of the parameter `kind` and before the colon, a space is missing.

Also, note that the parameter descriptions do not start with a capital letter, and do not finish with a dot.

Finally, the `**kwargs` parameter is missing.

Parameters
----------

`kind`: str
    kind of matplotlib plot

```
pass
```

Parameter types

When specifying the parameter types, Python built-in data types can be used directly (the Python type is preferred to the more verbose string, integer, boolean, etc):

- int
- float
- str
- bool

For complex types, define the subtypes. For `dict` and `tuple`, as more than one type is present, we use the brackets to help read the type (curly brackets for `dict` and normal brackets for `tuple`):

- list of int
- dict of `{str : int}`
- tuple of (str, int, int)
- tuple of (str,)
- set of str

In case where there are just a set of values allowed, list them in curly brackets and separated by commas (followed by a space). If the values are ordinal and they have an order, list them in this order. Otherwise, list the default value first, if there is one:

- `{0, 10, 25}`
- `{‘simple’, ‘advanced’}`
- `{‘low’, ‘medium’, ‘high’}`
- `{‘cat’, ‘dog’, ‘bird’}`

If the type is defined in a Python module, the module must be specified:

- `datetime.date`
- `datetime.datetime`
- `decimal.Decimal`
If the type is in a package, the module must be also specified:

- numpy.ndarray
- scipy.sparse.coo_matrix

If the type is a pandas type, also specify pandas except for Series and DataFrame:

- Series
- DataFrame
- pandas.Index
- pandas.Categorical
- pandas.arrays.SparseArray

If the exact type is not relevant, but must be compatible with a NumPy array, array-like can be specified. If any type that can be iterated is accepted, iterable can be used:

- array-like
- iterable

If more than one type is accepted, separate them by commas, except the last two types, that need to be separated by the word ‘or’:

- int or float
- float, decimal.Decimal or None
- str or list of str

If None is one of the accepted values, it always needs to be the last in the list.

For axis, the convention is to use something like:

- axis : {0 or ‘index’, 1 or ‘columns’, None}, default None

**Section 4: returns or yields**

If the method returns a value, it will be documented in this section. Also if the method yields its output.

The title of the section will be defined in the same way as the “Parameters”. With the names “Returns” or “Yields” followed by a line with as many hyphens as the letters in the preceding word.

The documentation of the return is also similar to the parameters. But in this case, no name will be provided, unless the method returns or yields more than one value (a tuple of values).

The types for “Returns” and “Yields” are the same as the ones for the “Parameters”. Also, the description must finish with a dot.

For example, with a single value:

```python
def sample():
    
    """
    Generate and return a random number.

    The value is sampled from a continuous uniform distribution between
    0 and 1.
    """
    Returns
    -------
```

(continues on next page)
float
    Random number generated.
    ""
    return np.random.random()

With more than one value:

```python
import string

def random_letters():
    ""
    Generate and return a sequence of random letters.
    The length of the returned string is also random, and is also returned.
    
    Returns
    ------
    length : int
        Length of the returned string.
    letters : str
        String of random letters.
    ""
    length = np.random.randint(1, 10)
    letters = ''.join(np.random.choice(string.ascii_lowercase)
                      for i in range(length))
    return length, letters
```

If the method yields its value:

```python
def sample_values():
    ""
    Generate an infinite sequence of random numbers.
    
    The values are sampled from a continuous uniform distribution between 0 and 1.
    
    Yields
    ------
    float
        Random number generated.
    ""
    while True:
        yield np.random.random()
```

**Section 5: see also**

This section is used to let users know about pandas functionality related to the one being documented. In rare cases, if no related methods or functions can be found at all, this section can be skipped.

An obvious example would be the `head()` and `tail()` methods. As `tail()` does the equivalent as `head()` but at the end of the `Series` or `DataFrame` instead of at the beginning, it is good to let the users know about it.

To give an intuition on what can be considered related, here there are some examples:
- `loc` and `iloc`, as they do the same, but in one case providing indices and in the other positions
- `max` and `min`, as they do the opposite
- `iterrows`, `itertuples` and `items`, as it is easy that a user looking for the method to iterate over columns ends up in the method to iterate over rows, and vice-versa
- `fillna` and `dropna`, as both methods are used to handle missing values
- `read_csv` and `to_csv`, as they are complementary
- `merge` and `join`, as one is a generalization of the other
- `astype` and `pandas.to_datetime`, as users may be reading the documentation of `astype` to know how to cast as a date, and the way to do it is with `pandas.to_datetime`
- `where` is related to `numpy.where`, as its functionality is based on it

When deciding what is related, you should mainly use your common sense and think about what can be useful for the users reading the documentation, especially the less experienced ones.

When relating to other libraries (mainly `numpy`), use the name of the module first (not an alias like `np`). If the function is in a module which is not the main one, like `scipy.sparse`, list the full module (e.g. `scipy.sparse.coo_matrix`).

This section has a header, “See Also” (note the capital S and A), followed by the line with hyphens and preceded by a blank line.

After the header, we will add a line for each related method or function, followed by a space, a colon, another space, and a short description that illustrates what this method or function does, why is it relevant in this context, and what the key differences are between the documented function and the one being referenced. The description must also end with a dot.

Note that in “Returns” and “Yields”, the description is located on the line after the type. In this section, however, it is located on the same line, with a colon in between. If the description does not fit on the same line, it can continue onto other lines which must be further indented.

For example:

```python
class Series:
    def head(self):
        """
        Return the first 5 elements of the Series.

        This function is mainly useful to preview the values of the
        Series without displaying the whole of it.
        """
        Returns
        -------
        Series
        Subset of the original series with the 5 first values.

        See Also
        --------
        Series.tail : Return the last 5 elements of the Series.
        Series.iloc : Return a slice of the elements in the Series,
                      which can also be used to return the first or last n.
        """
        return self.iloc[:5]
```
Section 6: notes

This is an optional section used for notes about the implementation of the algorithm, or to document technical aspects of the function behavior.

Feel free to skip it, unless you are familiar with the implementation of the algorithm, or you discover some counter-intuitive behavior while writing the examples for the function.

This section follows the same format as the extended summary section.

Section 7: examples

This is one of the most important sections of a docstring, despite being placed in the last position, as often people understand concepts better by example than through accurate explanations.

Examples in docstrings, besides illustrating the usage of the function or method, must be valid Python code, that returns the given output in a deterministic way, and that can be copied and run by users.

Examples are presented as a session in the Python terminal. >>> is used to present code. . . . is used for code continuing from the previous line. Output is presented immediately after the last line of code generating the output (no blank lines in between). Comments describing the examples can be added with blank lines before and after them.

The way to present examples is as follows:

1. Import required libraries (except numpy and pandas)
2. Create the data required for the example
3. Show a very basic example that gives an idea of the most common use case
4. Add examples with explanations that illustrate how the parameters can be used for extended functionality

A simple example could be:

class Series:
    def head(self, n=5):
        """
        Return the first elements of the Series.

        This function is mainly useful to preview the values of the Series without displaying all of it.
        
        Parameters
        ----------
        n : int
            Number of values to return.
        
        Return
        ------
        pandas.Series
            Subset of the original series with the n first values.
        
        See Also
        --------
        tail : Return the last n elements of the Series.
        
        Examples
        --------
        """

(continues on next page)
>> s = pd.Series(['Ant', 'Bear', 'Cow', 'Dog', 'Falcon',
...       'Lion', 'Monkey', 'Rabbit', 'Zebra'])

>>> s.head()
0    Ant
1   Bear
2    Cow
3    Dog
4  Falcon
   dtype: object

With the `n` parameter, we can change the number of returned rows:

>>> s.head(n=3)
0    Ant
1   Bear
2    Cow
dtype: object

```
return self.iloc[:n]
```

The examples should be as concise as possible. In cases where the complexity of the function requires long examples, is recommended to use blocks with headers in bold. Use double star ** to make a text bold, like in **this example**.

**Conventions for the examples**

Code in examples is assumed to always start with these two lines which are not shown:

```python
import numpy as np
import pandas as pd
```

Any other module used in the examples must be explicitly imported, one per line (as recommended in PEP 8 imports) and avoiding aliases. Avoid excessive imports, but if needed, imports from the standard library go first, followed by third-party libraries (like matplotlib).

When illustrating examples with a single Series use the name s, and if illustrating with a single DataFrame use the name df. For indices, idx is the preferred name. If a set of homogeneous Series or DataFrame is used, name them s1, s2, s3... or df1, df2, df3... If the data is not homogeneous, and more than one structure is needed, name them with something meaningful, for example df_main and df_to_join.

Data used in the example should be as compact as possible. The number of rows is recommended to be around 4, but make it a number that makes sense for the specific example. For example in the head method, it requires to be higher than 5, to show the example with the default values. If doing the mean, we could use something like [1, 2, 3], so it is easy to see that the value returned is the mean.

For more complex examples (grouping for example), avoid using data without interpretation, like a matrix of random numbers with columns A, B, C, D... And instead use a meaningful example, which makes it easier to understand the concept. Unless required by the example, use names of animals, to keep examples consistent. And numerical properties of them.

When calling the method, keywords arguments head(n=3) are preferred to positional arguments head(3).

Good:
class Series:

    def mean(self):
        """
        Compute the mean of the input.

        Examples
        --------
        >>> s = pd.Series([1, 2, 3])
        >>> s.mean()
        2
        """
        pass

    deffillna(self, value):
        """
        Replace missing values by `value`.

        Examples
        --------
        >>> s = pd.Series([1, np.nan, 3])
        >>> s.fillna(0)
        [1, 0, 3]
        """
        pass

    def groupby_mean(self):
        """
        Group by index and return mean.

        Examples
        --------
        >>> s = pd.Series([380., 370., 24., 26],
        ...     name='max_speed',
        ...     index=['falcon', 'falcon', 'parrot', 'parrot'])
        >>> s.groupby_mean()
        index
        falcon   375.0
        parrot   25.0
        Name: max_speed, dtype: float64
        """
        pass

    def contains(self, pattern, case_sensitive=True, na=numpy.nan):
        """
        Return whether each value contains `pattern`.

        In this case, we are illustrating how to use sections, even
        if the example is simple enough and does not require them.

        Examples
        --------
        >>> s = pd.Series('Antelope', 'Lion', 'Zebra', np.nan)
        >>> s.contains(pattern='a')
        0  False
        1  False
        """

(continues on next page)
**Case sensitivity**

With `case_sensitive` set to `False` we can match `'a'` with both `'a'` and `'A'`:

```python
>>> s.contains(pattern='a', case_sensitive=False)
0 True
1 False
2 True
3 NaN
dtype: bool
```

**Missing values**

We can fill missing values in the output using the `'na'` parameter:

```python
>>> s.contains(pattern='a', na=False)
0 False
1 False
2 True
3 False
dtype: bool
```

```
pass
```

---

Bad:

```python
def method(foo=None, bar=None):
    
    A sample DataFrame method.

    Do not import NumPy and pandas.

    Try to use meaningful data, when it makes the example easier to understand.

    Try to avoid positional arguments like in `df.method(1)`.
    They can be all right if previously defined with a meaningful name, like in `present_value(interest_rate)`, but avoid them otherwise.

    When presenting the behavior with different parameters, do not place all the calls one next to the other. Instead, add a short sentence explaining what the example shows.

    Examples
    -------
    >>> import numpy as np
    >>> import pandas as pd
    >>> df = pd.DataFrame(np.random.randn(3, 3),
                        columns=('a', 'b', 'c'))
    >>> df.method(1)
    21
    >>> df.method(bar=14)
```

(continues on next page)
Tips for getting your examples pass the doctests

Getting the examples pass the doctests in the validation script can sometimes be tricky. Here are some attention points:

- Import all needed libraries (except for pandas and NumPy, those are already imported as `import pandas as pd` and `import numpy as np`) and define all variables you use in the example.
- Try to avoid using random data. However random data might be OK in some cases, like if the function you are documenting deals with probability distributions, or if the amount of data needed to make the function result meaningful is too much, such that creating it manually is very cumbersome. In those cases, always use a fixed random seed to make the generated examples predictable. Example:

```
>>> np.random.seed(42)
>>> df = pd.DataFrame({'normal': np.random.normal(100, 5, 20)})
```

- If you have a code snippet that wraps multiple lines, you need to use `...` on the continued lines:

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], index=['a', 'b', 'c'],
...columns=['A', 'B'])
```

- If you want to show a case where an exception is raised, you can do:

```
>>> pd.to_datetime(['712-01-01'])
Traceback (most recent call last):
OutOfBoundsDatetime: Out of bounds nanosecond timestamp: 712-01-01 00:00:00
```

It is essential to include the “Traceback (most recent call last):”, but for the actual error only the error name is sufficient.

- If there is a small part of the result that can vary (e.g. a hash in an object representation), you can use `...` to represent this part.

If you want to show that `s.plot()` returns a matplotlib AxesSubplot object, this will fail the doctest

```
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at 0x7efd0c0b0690>
```

However, you can do (notice the comment that needs to be added)

```
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at ...>
```
Plots in examples

There are some methods in pandas returning plots. To render the plots generated by the examples in the documentation, the `.. plot::` directive exists.

To use it, place the next code after the “Examples” header as shown below. The plot will be generated automatically when building the documentation.

```python
class Series:
    def plot(self):
        ""
        Generate a plot with the ``Series`` data.
        
        Examples
        --------
        .. plot::
            :context: close-figs
            >>> s = pd.Series([1, 2, 3])
            >>> s.plot()
        """
        pass
```

Sharing docstrings

pandas has a system for sharing docstrings, with slight variations, between classes. This helps us keep docstrings consistent, while keeping things clear for the user reading. It comes at the cost of some complexity when writing.

Each shared docstring will have a base template with variables, like `{klass}`. The variables filled in later on using the `doc` decorator. Finally, docstrings can also be appended to with the `doc` decorator.

In this example, we’ll create a parent docstring normally (this is like `pandas.core.generic.NDFrame`). Then we’ll have two children (like `pandas.core.series.Series` and `pandas.core.frame.DataFrame`). We’ll substitute the class names in this docstring.

```python
class Parent:
    @doc(klass="Parent")
    def my_function(self):
        """Apply my function to `{klass}`.""
        ...

class ChildA(Parent):
    @doc(Parent.my_function, klass="ChildA")
    def my_function(self):
        ...

class ChildB(Parent):
    @doc(Parent.my_function, klass="ChildB")
    def my_function(self):
        ...
```

The resulting docstrings are
Notice:

1. We “append” the parent docstring to the children docstrings, which are initially empty.

Our files will often contain a module-level _shared_doc_kwargs with some common substitution values (things like klass, axes, etc).

You can substitute and append in one shot with something like

```python
@doc(template, **_shared_doc_kwargs)
def my_function(self):
    ...
```

where template may come from a module-level _shared_docs dictionary mapping function names to docstrings. Wherever possible, we prefer using doc, since the docstring-writing processes is slightly closer to normal.

See pandas.core.generic.NDFrame.fillna for an example template, and pandas.core.series.Series.fillna and pandas.core.generic.frame.fillna for the filled versions.

- The tutorials make heavy use of the IPython directive sphinx extension. This directive lets you put code in the documentation which will be run during the doc build. For example:

```python
.. ipython:: python
   :width: 100%
   :context: execute

   x = 2
   x**3
```

will be rendered as:

```
In [1]: x = 2
In [2]: x**3
Out[2]: 8
```

Almost all code examples in the docs are run (and the output saved) during the doc build. This approach means that code examples will always be up to date, but it does make the doc building a bit more complex.

- Our API documentation files in doc/source/reference house the auto-generated documentation from the docstrings. For classes, there are a few subtleties around controlling which methods and attributes have pages auto-generated.

We have two autosummary templates for classes.

1. _templates/autosummary/class.rst. Use this when you want to automatically generate a page for every public method and attribute on the class. The Attributes and Methods sections will be automatically added to the class’ rendered documentation by numpydoc. See DataFrame for an example.

2. _templates/autosummary/class_without_autosummary. Use this when you want to pick a subset of methods / attributes to auto-generate pages for. When using this template, you should include an Attributes and Methods section in the class docstring. See CategoricalIndex for an example.
Every method should be included in a toctree in one of the documentation files in doc/source/reference, else Sphinx will emit a warning.

**Note:** The .rst files are used to automatically generate Markdown and HTML versions of the docs. For this reason, please do not edit CONTRIBUTING.md directly, but instead make any changes to doc/source/development/contributing.rst. Then, to generate CONTRIBUTING.md, use pandoc with the following command:

```
pandoc doc/source/development/contributing.rst -t markdown_github > CONTRIBUTING.md
```

The utility script scripts/validate_docstrings.py can be used to get a csv summary of the API documentation. And also validate common errors in the docstring of a specific class, function or method. The summary also compares the list of methods documented in the files in doc/source/reference (which is used to generate the API Reference page) and the actual public methods. This will identify methods documented in doc/source/reference that are not actually class methods, and existing methods that are not documented in doc/source/reference.

**4.3.2 Updating a pandas docstring**

When improving a single function or method’s docstring, it is not necessarily needed to build the full documentation (see next section). However, there is a script that checks a docstring (for example for the DataFrame.mean method):

```
python scripts/validate_docstrings.py pandas.DataFrame.mean
```

This script will indicate some formatting errors if present, and will also run and test the examples included in the docstring. Check the pandas docstring guide for a detailed guide on how to format the docstring.

The examples in the docstring (‘doctests’) must be valid Python code, that in a deterministic way returns the presented output, and that can be copied and run by users. This can be checked with the script above, and is also tested on Travis. A failing doctest will be a blocker for merging a PR. Check the examples section in the docstring guide for some tips and tricks to get the doctests passing.

When doing a PR with a docstring update, it is good to post the output of the validation script in a comment on github.

**4.3.3 How to build the pandas documentation**

**Requirements**

First, you need to have a development environment to be able to build pandas (see the docs on creating a development environment).

**Building the documentation**

So how do you build the docs? Navigate to your local doc/ directory in the console and run:

```
python make.py html
```

Then you can find the HTML output in the folder doc/build/html/.

The first time you build the docs, it will take quite a while because it has to run all the code examples and build all the generated docstring pages. In subsequent evocations, sphinx will try to only build the pages that have been modified.

If you want to do a full clean build, do:
You can tell `make.py` to compile only a single section of the docs, greatly reducing the turn-around time for checking your changes.

```
# omit autosummary and API section
python make.py clean
python make.py --no-api

# compile the docs with only a single section, relative to the "source" folder.
# For example, compiling only this guide (doc/source/development/contributing.rst)
python make.py clean
python make.py --single development/contributing.rst

# compile the reference docs for a single function
python make.py clean
python make.py --single pandas.DataFrame.join

# compile whatsnew and API section (to resolve links in the whatsnew)
python make.py clean
python make.py --whatsnew
```

For comparison, a full documentation build may take 15 minutes, but a single section may take 15 seconds. Subsequent builds, which only process portions you have changed, will be faster.

The build will automatically use the number of cores available on your machine to speed up the documentation build. You can override this:

```
python make.py html --num-jobs 4
```

Open the following file in a web browser to see the full documentation you just built:

```
doc/build/html/index.html
```

And you’ll have the satisfaction of seeing your new and improved documentation!

**Building master branch documentation**

When pull requests are merged into the pandas `master` branch, the main parts of the documentation are also built by Travis-CI. These docs are then hosted here, see also the Continuous Integration section.

### 4.3.4 Previewing changes

Once, the pull request is submitted, GitHub Actions will automatically build the documentation. To view the built site:

1. Wait for the CI / Web and docs check to complete.
2. Click Details next to it.
3. From the Artifacts drop-down, click docs or website to download the site as a ZIP file.
4.4 Contributing to the code base

Table of Contents:

• Code standards
• Pre-commit
• Optional dependencies
  – C (cpplint)
  – Python (PEP8 / black)
  – Import formatting
  – Backwards compatibility
• Type hints
  – Style guidelines
  – pandas-specific types
  – Validating type hints
• Testing with continuous integration
• Test-driven development/code writing
  – Writing tests
  – Transitioning to pytest
  – Using pytest
  – Using hypothesis
  – Testing warnings
• Running the test suite
• Running the performance test suite
• Documenting your code

4.4.1 Code standards

Writing good code is not just about what you write. It is also about how you write it. During Continuous Integration testing, several tools will be run to check your code for stylistic errors. Generating any warnings will cause the test to fail. Thus, good style is a requirement for submitting code to pandas.

There is a tool in pandas to help contributors verify their changes before contributing them to the project:

`./ci/code_checks.sh`

The script verifies the linting of code files, it looks for common mistake patterns (like missing spaces around sphinx directives that make the documentation not being rendered properly) and it also validates the doctests. It is possible to run the checks independently by using the parameters lint, patterns and doctests (e.g. `./ci/code_checks.sh lint`).

In addition, because a lot of people use our library, it is important that we do not make sudden changes to the code.
that could have the potential to break a lot of user code as a result, that is, we need it to be as backwards compatible as possible to avoid mass breakages.

In addition to ./ci/code_checks.sh, some extra checks are run by pre-commit - see here for how to run them.

Additional standards are outlined on the pandas code style guide.

### 4.4.2 Pre-commit

You can run many of these styling checks manually as we have described above. However, we encourage you to use pre-commit hooks instead to automatically run black, flake8, isort when you make a git commit. This can be done by installing pre-commit:

```
pip install pre-commit
```

and then running:

```
pre-commit install
```

from the root of the pandas repository. Now all of the styling checks will be run each time you commit changes without your needing to run each one manually. In addition, using pre-commit will also allow you to more easily remain up-to-date with our code checks as they change.

Note that if needed, you can skip these checks with `git commit --no-verify`.

If you don’t want to use pre-commit as part of your workflow, you can still use it to run its checks with:

```
pre-commit run --files <files you have modified>
```

without needing to have done `pre-commit install` beforehand.

If you want to run checks on all recently committed files on upstream/master you can use:

```
pre-commit run --from-ref=upstream/master --to-ref=HEAD --all-files
```

without needing to have done `pre-commit install` beforehand.

---

Note: If you have conflicting installations of virtualenv, then you may get an error - see here.

Also, due to a bug in virtualenv, you may run into issues if you’re using conda. To solve this, you can downgrade virtualenv to version 20.0.33.

### 4.4.3 Optional dependencies

Optional dependencies (e.g. matplotlib) should be imported with the private helper pandas.compat._optional.import_optional_dependency. This ensures a consistent error message when the dependency is not met.

All methods using an optional dependency should include a test asserting that an ImportError is raised when the optional dependency is not found. This test should be skipped if the library is present.

All optional dependencies should be documented in Optional dependencies and the minimum required version should be set in the pandas.compat._optional.VERSIONS dict.
pandas: powerful Python data analysis toolkit, Release 1.3.2

C (cpplint)

pandas uses the Google standard. Google provides an open source style checker called cpplint, but we use a fork of it that can be found here. Here are some of the more common cpplint issues:

- we restrict line-length to 80 characters to promote readability
- every header file must include a header guard to avoid name collisions if re-included

Continuous Integration will run the cpplint tool and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```
cpplint --extensions=c,h --headers=h --filter=-readability/casting,-runtime/int,-build/include_subdir modified-c-file
```

You can also run this command on an entire directory if necessary:

```
cpplint --extensions=c,h --headers=h --filter=-readability/casting,-runtime/int,-build/include_subdir --recursive modified-c-directory
```

To make your commits compliant with this standard, you can install the ClangFormat tool, which can be downloaded here. To configure, in your home directory, run the following command:

```
clang-format style=google -dump-config > .clang-format
```

Then modify the file to ensure that any indentation width parameters are at least four. Once configured, you can run the tool as follows:

```
clang-format modified-c-file
```

This will output what your file will look like if the changes are made, and to apply them, run the following command:

```
clang-format -i modified-c-file
```

To run the tool on an entire directory, you can run the following analogous commands:

```
clang-format modified-c-directory/*.c modified-c-directory/*.h
clang-format -i modified-c-directory/*.c modified-c-directory/*.h
```

Do note that this tool is best-effort, meaning that it will try to correct as many errors as possible, but it may not correct all of them. Thus, it is recommended that you run cpplint to double check and make any other style fixes manually.

Python (PEP8 / black)

pandas follows the PEP8 standard and uses Black and Flake8 to ensure a consistent code format throughout the project. We encourage you to use pre-commit.

Continuous Integration will run those tools and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```
black pandas
```

```
git diff upstream/master -u -- "*.py" | flake8 --diff
```

to auto-format your code. Additionally, many editors have plugins that will apply black as you edit files.

You should use a black version 21.5b2 as previous versions are not compatible with the pandas codebase.

One caveat about `git diff upstream/master -u -- "*.py" | flake8 --diff`: this command will catch any stylistic errors in your changes specifically, but be beware it may not catch all of them. For example, if
you delete the only usage of an imported function, it is stylistically incorrect to import an unused function. However, style-checking the diff will not catch this because the actual import is not part of the diff. Thus, for completeness, you should run this command, though it may take longer:

```
git diff upstream/master --name-only -- "*.py" | xargs -r flake8
```

Note that on OSX, the `-r` flag is not available, so you have to omit it and run this slightly modified command:

```
git diff upstream/master --name-only -- "*.py" | xargs flake8
```

Windows does not support the `xargs` command (unless installed for example via the MinGW toolchain), but one can imitate the behaviour as follows:

```
for /f %i in ('git diff upstream/master --name-only -- "*.py"') do flake8 %i
```

This will get all the files being changed by the PR (and ending with `.py`), and run `flake8` on them, one after the other.

Note that these commands can be run analogously with `black`.

**Import formatting**

pandas uses `isort` to standardise import formatting across the codebase.

A guide to import layout as per pep8 can be found [here](#).

A summary of our current import sections (in order):

- Future
- Python Standard Library
- Third Party
  - `pandas._libs`, `pandas.compat`, `pandas.util._*`, `pandas.errors` (largely not dependent on `pandas.core`)
  - `pandas.core.dtypes` (largely not dependent on the rest of `pandas.core`)
  - `Rest of pandas.core.*`
- Non-core `pandas.io`, `pandas.plotting`, `pandas.tseries`
- Local application/library specific imports

Imports are alphabetically sorted within these sections.

As part of **Continuous Integration** checks we run:

```
isort --check-only pandas
```

to check that imports are correctly formatted as per the `setup.cfg`.

If you see output like the below in **Continuous Integration** checks:

```
Check import format using isort
ERROR: /home/travis/build/pandas-dev/pandas/pandas/io/pytables.py Imports are incorrectly sorted
Check import format using isort DONE
The command "ci/code_checks.sh" exited with 1
```

You should run:
isort pandas/io/pytables.py

to automatically format imports correctly. This will modify your local copy of the files.
Alternatively, you can run a command similar to what was suggested for black and flake8 right above:

git diff upstream/master --name-only -- *.py | xargs -r isort

Where similar caveats apply if you are on OSX or Windows.
You can then verify the changes look ok, then git commit and push.

Backwards compatibility

Please try to maintain backward compatibility. pandas has lots of users with lots of existing code, so don’t break it if at all possible. If you think breakage is required, clearly state why as part of the pull request. Also, be careful when changing method signatures and add deprecation warnings where needed. Also, add the deprecated sphinx directive to the deprecated functions or methods.

If a function with the same arguments as the one being deprecated exist, you can use the pandas.util._decorators.deprecate:

```python
from pandas.util._decorators import deprecate
deprecate('old_func', 'new_func', '1.1.0')
```

Otherwise, you need to do it manually:

```python
import warnings

def old_func():
    """Summary of the function.

    .. deprecated:: 1.1.0
        Use new_func instead.
    ""
    warnings.warn('Use new_func instead.', FutureWarning, stacklevel=2)
    new_func()

def new_func():
    pass
```

You’ll also need to

1. Write a new test that asserts a warning is issued when calling with the deprecated argument
2. Update all of pandas existing tests and code to use the new argument

See Testing warnings for more.
4.4.4 Type hints

pandas strongly encourages the use of PEP 484 style type hints. New development should contain type hints and pull requests to annotate existing code are accepted as well!

Style guidelines

Types imports should follow the from typing import ... convention. So rather than

```python
import typing
primes: typing.List[int] = []
```

You should write

```python
from typing import List, Optional, Union
primes: List[int] = []
```

Optional should be used where applicable, so instead of

```python
maybe_primes: List[Union[int, None]] = []
```

You should write

```python
maybe_primes: List[Optional[int]] = []
```

In some cases in the code base classes may define class variables that shadow builtins. This causes an issue as described in Mypy 1775. The defensive solution here is to create an unambiguous alias of the builtin and use that without your annotation. For example, if you come across a definition like

```python
class SomeClass1:
    str = None
```

The appropriate way to annotate this would be as follows

```python
str_type = str
```

```python
class SomeClass2:
    str: str_type = None
```

In some cases you may be tempted to use cast from the typing module when you know better than the analyzer. This occurs particularly when using custom inference functions. For example

```python
from typing import cast
from pandas.core.dtypes.common import is_number

def cannot_infer_bad(obj: Union[str, int, float]):
    if is_number(obj):
        ...
    else:  # Reasonably only str objects would reach this but...
        obj = cast(str, obj)  # Mypy complains without this!
    return obj.upper()
```
The limitation here is that while a human can reasonably understand that `is_number` would catch the `int` and `float` types mypy cannot make that same inference just yet (see mypy #5206. While the above works, the use of `cast` is **strongly discouraged**. Where applicable a refactor of the code to appease static analysis is preferable.

```python
def cannot_infer_good(obj: Union[str, int, float]):
    if isinstance(obj, str):
        return obj.upper()
    else:
        ...
```

With custom types and inference this is not always possible so exceptions are made, but every effort should be exhausted to avoid `cast` before going down such paths.

**pandas-specific types**

Commonly used types specific to pandas will appear in `pandas._typing` and you should use these where applicable. This module is private for now but ultimately this should be exposed to third party libraries who want to implement type checking against pandas.

For example, quite a few functions in pandas accept a `dtype` argument. This can be expressed as a string like "object", a `numpy.dtype` like `np.int64` or even a `pandas CategoricalDtype`. Rather than burden the user with having to constantly annotate all of those options, this can simply be imported and reused from the `pandas._typing` module.

```python
from pandas._typing import Dtype
def as_type(dtype: Dtype) -> ...
...
```

This module will ultimately house types for repeatedly used concepts like "path-like", "array-like", "numeric", etc... and can also hold aliases for commonly appearing parameters like `axis`. Development of this module is active so be sure to refer to the source for the most up to date list of available types.

**Validating type hints**

pandas uses `mypy` to statically analyze the code base and type hints. After making any change you can ensure your type hints are correct by running

```bash
mypy pandas
```

**4.4.5 Testing with continuous integration**

The pandas test suite will run automatically on GitHub Actions and Azure Pipelines continuous integration services, once your pull request is submitted. However, if you wish to run the test suite on a branch prior to submitting the pull request, then the continuous integration services need to be hooked to your GitHub repository. Instructions are here for GitHub Actions and Azure Pipelines.

A pull-request will be considered for merging when you have an all ‘green’ build. If any tests are failing, then you will get a red ‘X’, where you can click through to see the individual failed tests. This is an example of a green build.
4.4.6 Test-driven development/code writing

pandas is serious about testing and strongly encourages contributors to embrace test-driven development (TDD). This development process “relies on the repetition of a very short development cycle: first the developer writes an (initially failing) automated test case that defines a desired improvement or new function, then produces the minimum amount of code to pass that test.” So, before actually writing any code, you should write your tests. Often the test can be taken from the original GitHub issue. However, it is always worth considering additional use cases and writing corresponding tests.

Adding tests is one of the most common requests after code is pushed to pandas. Therefore, it is worth getting in the habit of writing tests ahead of time so this is never an issue.

Like many packages, pandas uses pytest and the convenient extensions in numpy.testing.

Note: The earliest supported pytest version is 5.0.1.

Writing tests

All tests should go into the tests subdirectory of the specific package. This folder contains many current examples of tests, and we suggest looking to these for inspiration. If your test requires working with files or network connectivity, there is more information on the testing page of the wiki.

The pandas._testing module has many special assert functions that make it easier to make statements about whether Series or DataFrame objects are equivalent. The easiest way to verify that your code is correct is to explicitly construct the result you expect, then compare the actual result to the expected correct result:

```python
def test_pivot(self):
    data = {
        'index': ['A', 'B', 'C', 'C', 'B', 'A'],
        'columns': ['One', 'One', 'One', 'Two', 'Two', 'Two'],
        'values': [1., 2., 3., 3., 2., 1.]
    }

    frame = DataFrame(data)
    pivoted = frame.pivot(index='index', columns='columns', values='values')
```

(continues on next page)
Transitioning to pytest

pandas existing test structure is mostly class-based, meaning that you will typically find tests wrapped in a class.

```python
class TestReallyCoolFeature:
    pass
```

Going forward, we are moving to a more functional style using the pytest framework, which offers a richer testing framework that will facilitate testing and developing. Thus, instead of writing test classes, we will write test functions like this:

```python
def test_really_cool_feature():
    pass
```

Using pytest

Here is an example of a self-contained set of tests that illustrate multiple features that we like to use.

- functional style: tests are like `test_*` and only take arguments that are either fixtures or parameters
- `pytest.mark` can be used to set metadata on test functions, e.g. `skip` or `xfail`.
- using `parametrize` allow testing of multiple cases
- to set a mark on a parameter, `pytest.param(..., marks=...)` syntax should be used
- `fixture`, code for object construction, on a per-test basis
- using bare assert for scalars and truth-testing
- `tm.assert_series_equal` (and its counter part `tm.assert_frame_equal`), for pandas object comparisons.
- the typical pattern of constructing an `expected` and comparing versus the result

We would name this file `test_cool_feature.py` and put in an appropriate place in the `pandas/tests/` structure.

```python
import pytest
import numpy as np
import pandas as pd

@pytest.mark.parametrize('dtype', ['int8', 'int16', 'int32', 'int64'])
def test_dtypes(dtype):
    assert str(np.dtype(dtype)) == dtype
```

(continues on next page)
@pytest.mark.parametrize('dtype', ['float32', pytest.param('int16', marks=pytest.mark.skip), pytest.param('int32', marks=pytest.mark.xfail(reason='to show how it works'))])

def test_mark(dtype):
    assert str(np.dtype(dtype)) == 'float32'

@ pytest.fixture
def series():
    return pd.Series([1, 2, 3])

@ pytest.fixture(params=['int8', 'int16', 'int32', 'int64'])
def dtype(request):
    return request.param

def test_series(series, dtype):
    result = series.astype(dtype)
    assert result.dtype == dtype
    expected = pd.Series([1, 2, 3], dtype=dtype)
    tm.assert_series_equal(result, expected)

A test run of this yields

```
((pandas) bash-3.2$ pytest test_cool_feature.py -v
=========================== test session starts ===========================
platform darwin -- Python 3.6.2, pytest-3.6.0, py-1.4.31, pluggy-0.4.0
collected 11 items

tester.py::test_dtypes[int8] PASSED
tester.py::test_dtypes[int16] PASSED
tester.py::test_dtypes[int32] PASSED
tester.py::test_dtypes[int64] PASSED
tester.py::test_mark[float32] PASSED
tester.py::test_mark[int16] SKIPPED
tester.py::test_mark[int32] xfail
tester.py::test_series[int8] PASSED
tester.py::test_series[int16] PASSED
tester.py::test_series[int32] PASSED
tester.py::test_series[int64] PASSED

pytest --color=yes
tester.py::test_dtypes[int8] passed
tester.py::test_dtypes[int16] passed
tester.py::test_dtypes[int32] passed
tester.py::test_dtypes[int64] passed
```

Tests that we have parametrized are now accessible via the test name, for example we could run these with `-k int8` to sub-select only those tests which match int8.

```
((pandas) bash-3.2$ pytest test_cool_feature.py -v -k int8
=========================== test session starts ===========================
platform darwin -- Python 3.6.2, pytest-3.6.0, py-1.4.31, pluggy-0.4.0
collected 11 items

test_cool_feature.py::test_dtypes[int8] PASSED
test_cool_feature.py::test_series[int8] PASSED
```

4.4. Contributing to the code base
Using hypothesis

Hypothesis is a library for property-based testing. Instead of explicitly parametrizing a test, you can describe all valid inputs and let Hypothesis try to find a failing input. Even better, no matter how many random examples it tries, Hypothesis always reports a single minimal counterexample to your assertions - often an example that you would never have thought to test.

See Getting Started with Hypothesis for more of an introduction, then refer to the Hypothesis documentation for details.

```python
import json
from hypothesis import given, strategies as st

any_json_value = st.deferred(lambda: st.one_of(
    st.none(), st.booleans(), st.floats(allow_nan=False), st.text(),
    st.lists(any_json_value), st.dictionaries(st.text(), any_json_value)
))

@given(value=any_json_value)
def test_json_roundtrip(value):
    result = json.loads(json.dumps(value))
    assert value == result
```

This test shows off several useful features of Hypothesis, as well as demonstrating a good use-case: checking properties that should hold over a large or complicated domain of inputs.

To keep the pandas test suite running quickly, parametrized tests are preferred if the inputs or logic are simple, with Hypothesis tests reserved for cases with complex logic or where there are too many combinations of options or subtle interactions to test (or think of!) all of them.

Testing warnings

By default, one of pandas CI workers will fail if any unhandled warnings are emitted.

If your change involves checking that a warning is actually emitted, use `tm.assert_produces_warning(ExpectedWarning)`.

```python
import pandas._testing as tm

df = pd.DataFrame()
with tm.assert_produces_warning(FutureWarning):
    df.some_operation()
```

We prefer this to the `pytest.warns` context manager because ours checks that the warning’s stacklevel is set correctly. The stacklevel is what ensure the user’s file name and line number is printed in the warning, rather than something internal to pandas. It represents the number of function calls from user code (e.g. `df.some_operation()`) to the function that actually emits the warning. Our linter will fail the build if you use `pytest.warns` in a test.

If you have a test that would emit a warning, but you aren’t actually testing the warning itself (say because it’s going to be removed in the future, or because we’re matching a 3rd-party library’s behavior), then use `pytest.mark.filterwarnings` to ignore the error.

```python
@pytest.mark.filterwarnings("ignore:msg:category")
def test_thing(self):
    ...
```
If the test generates a warning of class category whose message starts with msg, the warning will be ignored and the test will pass.

If you need finer-grained control, you can use Python’s usual warnings module to control whether a warning is ignored / raised at different places within a single test.

```python
with warnings.catch_warnings():
    warnings.simplefilter("ignore", FutureWarning)
    # Or use warnings.filterwarnings(...)```

Alternatively, consider breaking up the unit test.

4.4.7 Running the test suite

The tests can then be run directly inside your Git clone (without having to install pandas) by typing:

```
pytest pandas
```

The tests suite is exhaustive and takes around 20 minutes to run. Often it is worth running only a subset of tests first around your changes before running the entire suite.

The easiest way to do this is with:

```
pytest pandas/path/to/test.py -k regex_matching_test_name
```

Or with one of the following constructs:

```
pytest pandas/tests/[test-module].py
pytest pandas/tests/[test-module].py::[TestClass]
pytest pandas/tests/[test-module].py::[TestClass]::[test_method]
```

Using pytest-xdist, one can speed up local testing on multicore machines. To use this feature, you will need to install pytest-xdist via:

```
pip install pytest-xdist
```

Two scripts are provided to assist with this. These scripts distribute testing across 4 threads.

On Unix variants, one can type:

```
test_fast.sh
```

On Windows, one can type:

```
test_fast.bat
```

This can significantly reduce the time it takes to locally run tests before submitting a pull request.

For more, see the pytest documentation.

Furthermore one can run

```
pd.test()
```

with an imported pandas to run tests similarly.
4.4.8 Running the performance test suite

Performance matters and it is worth considering whether your code has introduced performance regressions. pandas is in the process of migrating to asv benchmarks to enable easy monitoring of the performance of critical pandas operations. These benchmarks are all found in the pandas/asv_bench directory, and the test results can be found here.

To use all features of asv, you will need either conda or virtualenv. For more details please check the asv installation webpage.

To install asv:

```bash
pip install git+https://github.com/spacetelescope/asv
```

If you need to run a benchmark, change your directory to asv_bench/ and run:

```bash
asv continuous -f 1.1 upstream/master HEAD
```

You can replace HEAD with the name of the branch you are working on, and report benchmarks that changed by more than 10%. The command uses conda by default for creating the benchmark environments. If you want to use virtualenv instead, write:

```bash
asv continuous -f 1.1 -E virtualenv upstream/master HEAD
```

The -E virtualenv option should be added to all asv commands that run benchmarks. The default value is defined in asv.conf.json.

Running the full benchmark suite can be an all-day process, depending on your hardware and its resource utilization. However, usually it is sufficient to paste only a subset of the results into the pull request to show that the committed changes do not cause unexpected performance regressions. You can run specific benchmarks using the -b flag, which takes a regular expression. For example, this will only run benchmarks from a pandas/asv_bench/benchmarks/groupby.py file:

```bash
asv continuous -f 1.1 upstream/master HEAD -b ^groupby
```

If you want to only run a specific group of benchmarks from a file, you can do it using . as a separator. For example:

```bash
asv continuous -f 1.1 upstream/master HEAD -b groupby.GroupByMethods
```

will only run the GroupByMethods benchmark defined in groupby.py.

You can also run the benchmark suite using the version of pandas already installed in your current Python environment. This can be useful if you do not have virtualenv or conda, or are using the setup.py develop approach discussed above; for the in-place build you need to set PYTHONPATH, e.g. PYTHONPATH="$PWD/.." asv [remaining arguments]. You can run benchmarks using an existing Python environment by:

```bash
asv run -e -E existing
```

or, to use a specific Python interpreter:

```bash
asv run -e -E existing:python3.6
```

This will display stderr from the benchmarks, and use your local python that comes from your $PATH.

Information on how to write a benchmark and how to use asv can be found in the asv documentation.
4.4.9 Documenting your code

Changes should be reflected in the release notes located in doc/source/whatsnew/vx.y.z.rst. This file contains an ongoing change log for each release. Add an entry to this file to document your fix, enhancement or (unavoidable) breaking change. Make sure to include the GitHub issue number when adding your entry (using :issue:`1234` where 1234 is the issue/pull request number).

If your code is an enhancement, it is most likely necessary to add usage examples to the existing documentation. This can be done following the section regarding documentation. Further, to let users know when this feature was added, the versionadded directive is used. The sphinx syntax for that is:

.. versionadded:: 1.1.0

This will put the text New in version 1.1.0 wherever you put the sphinx directive. This should also be put in the docstring when adding a new function or method (example) or a new keyword argument (example).

4.5 pandas code style guide

Table of contents:

- Patterns
- Testing
  - Failing tests
  - Do not use pytest.xfail
  - Using pytest.mark.xfail
- Miscellaneous
  - Reading from a url

pandas follows the PEP8 standard and uses Black and Flake8 to ensure a consistent code format throughout the project. We encourage you to use pre-commit to automatically run black, flake8, isort, and related code checks when you make a git commit.

4.5.1 Patterns

We use a flake8 plugin, pandas-dev-flaker, to check our codebase for unwanted patterns. See its README for the up-to-date list of rules we enforce.

4.5.2 Testing

Failing tests

See https://docs.pytest.org/en/latest/skipping.html for background.
**Do not use pytest.xfail**

Do not use this method. It has the same behavior as `pytest.skip`, namely it immediately stops the test and does not check if the test will fail. If this is the behavior you desire, use `pytest.skip` instead.

**Using pytest.mark.xfail**

Use this method if a test is known to fail but the manner in which it fails is not meant to be captured. It is common to use this method for a test that exhibits buggy behavior or a non-implemented feature. If the failing test has flaky behavior, use the argument `strict=False`. This will make it so pytest does not fail if the test happens to pass.

Prefer the decorator `@pytest.mark.xfail` and the argument `pytest.param` over usage within a test so that the test is appropriately marked during the collection phase of pytest. For xfailing a test that involves multiple parameters, a fixture, or a combination of these, it is only possible to xfail during the testing phase. To do so, use the `request` fixture:

```python
import pytest

def test_xfail(request):
    mark = pytest.mark.xfail(raises=TypeError, reason="Indicate why here")
    request.node.add_marker(mark)
```

xfail is not to be used for tests involving failure due to invalid user arguments. For these tests, we need to verify the correct exception type and error message is being raised, using `pytest.raises` instead.

### 4.5.3 Miscellaneous

**Reading from a url**

Good:

```python
from pandas.io.common import urlopen

with urlopen("http://www.google.com") as url:
    raw_text = url.read()
```

### 4.6 pandas maintenance

This guide is for pandas’ maintainers. It may also be interesting to contributors looking to understand the pandas development process and what steps are necessary to become a maintainer.

The main contributing guide is available at [Contributing to pandas](https://pandas.pydata.org/pandas-docs/stable/development/contributing.html).
4.6.1 Roles

pandas uses two levels of permissions: triage and core team members.

Triage members can label and close issues and pull requests.

Core team members can label and close issues and pull request, and can merge pull requests.

GitHub publishes the full list of permissions.

4.6.2 Tasks

pandas is largely a volunteer project, so these tasks shouldn’t be read as “expectations” of triage and maintainers. Rather, they’re general descriptions of what it means to be a maintainer.

- Triage newly filed issues (see Issue triage)
- Review newly opened pull requests
- Respond to updates on existing issues and pull requests
- Drive discussion and decisions on stalled issues and pull requests
- Provide experience / wisdom on API design questions to ensure consistency and maintainability
- Project organization (run / attend developer meetings, represent pandas)

https://matthewrocklin.com/blog/2019/05/18/maintainer may be interesting background reading.

4.6.3 Issue triage

Here’s a typical workflow for triaging a newly opened issue.

1. Thank the reporter for opening an issue

   The issue tracker is many people’s first interaction with the pandas project itself, beyond just using the library. As such, we want it to be a welcoming, pleasant experience.

2. Is the necessary information provided?

   Ideally reporters would fill out the issue template, but many don’t. If crucial information (like the version of pandas they used), is missing feel free to ask for that and label the issue with “Needs info”. The report should follow the guidelines in Bug reports and enhancement requests. You may want to link to that if they didn’t follow the template.

   Make sure that the title accurately reflects the issue. Edit it yourself if it’s not clear.

3. Is this a duplicate issue?

   We have many open issues. If a new issue is clearly a duplicate, label the new issue as “Duplicate” assign the milestone “No Action”, and close the issue with a link to the original issue. Make sure to still thank the reporter, and encourage them to chime in on the original issue, and perhaps try to fix it.

   If the new issue provides relevant information, such as a better or slightly different example, add it to the original issue as a comment or an edit to the original post.

4. Is the issue minimal and reproducible?

   For bug reports, we ask that the reporter provide a minimal reproducible example. See https://matthewrocklin.com/blog/work/2018/02/28/minimal-bug-reports for a good explanation. If the example is not reproducible, or if it’s clearly not minimal, feel free to ask the reporter if they can provide and example or simplify the provided
one. Do acknowledge that writing minimal reproducible examples is hard work. If the reporter is struggling, you can try to write one yourself and we’ll edit the original post to include it.

If a reproducible example can’t be provided, add the “Needs info” label.

If a reproducible example is provided, but you see a simplification, edit the original post with your simpler reproducible example.

5. **Is this a clearly defined feature request?**

Generally, pandas prefers to discuss and design new features in issues, before a pull request is made. Encourage the submitter to include a proposed API for the new feature. Having them write a full docstring is a good way to pin down specifics.

We’ll need a discussion from several pandas maintainers before deciding whether the proposal is in scope for pandas.

6. **Is this a usage question?**

We prefer that usage questions are asked on StackOverflow with the pandas tag. https://stackoverflow.com/questions/tagged/pandas

If it’s easy to answer, feel free to link to the relevant documentation section, let them know that in the future this kind of question should be on StackOverflow, and close the issue.

7. **What labels and milestones should I add?**

Apply the relevant labels. This is a bit of an art, and comes with experience. Look at similar issues to get a feel for how things are labeled.

If the issue is clearly defined and the fix seems relatively straightforward, label the issue as “Good first issue”.

Typically, new issues will be assigned the “Contributions welcome” milestone, unless it’s know that this issue should be addressed in a specific release (say because it’s a large regression).

### 4.6.4 Closing issues

Be delicate here: many people interpret closing an issue as us saying that the conversation is over. It’s typically best to give the reporter some time to respond or self-close their issue if it’s determined that the behavior is not a bug, or the feature is out of scope. Sometimes reporters just go away though, and we’ll close the issue after the conversation has died.

### 4.6.5 Reviewing pull requests

Anybody can review a pull request: regular contributors, triagers, or core-team members. But only core-team members can merge pull requests when they’re ready.

Here are some things to check when reviewing a pull request.

- Tests should be in a sensible location: in the same file as closely related tests.
- New public APIs should be included somewhere in doc/source/reference/.
- New / changed API should use the `versionadded` or `versionchanged` directives in the docstring.
- User-facing changes should have a `whatsnew` in the appropriate file.
- Regression tests should reference the original GitHub issue number like `# GH-1234`.
- The pull request should be labeled and assigned the appropriate milestone (the next patch release for regression fixes and small bug fixes, the next minor milestone otherwise)
• Changes should comply with our Version policy.

4.6.6 Backporting

In the case you want to apply changes to a stable branch from a newer branch then you can comment:

@meeseeksdev backport version-branch

This will trigger a workflow which will backport a given change to a branch (e.g. @meeseeksdev backport 1.2.x)

4.6.7 Cleaning up old issues

Every open issue in pandas has a cost. Open issues make finding duplicates harder, and can make it harder to know what needs to be done in pandas. That said, closing issues isn’t a goal on its own. Our goal is to make pandas the best it can be, and that’s best done by ensuring that the quality of our open issues is high.

Occasionally, bugs are fixed but the issue isn’t linked to in the Pull Request. In these cases, comment that “This has been fixed, but could use a test.” and label the issue as “Good First Issue” and “Needs Test”.

If an older issue doesn’t follow our issue template, edit the original post to include a minimal example, the actual output, and the expected output. Uniformity in issue reports is valuable.

If an older issue lacks a reproducible example, label it as “Needs Info” and ask them to provide one (or write one yourself if possible). If one isn’t provide reasonably soon, close it according to the policies in Closing issues.

4.6.8 Cleaning up old pull requests

Occasionally, contributors are unable to finish off a pull request. If some time has passed (two weeks, say) since the last review requesting changes, gently ask if they’re still interested in working on this. If another two weeks or so passes with no response, thank them for their work and close the pull request. Comment on the original issue that “There’s a stalled PR at #1234 that may be helpful.”, and perhaps label the issue as “Good first issue” if the PR was relatively close to being accepted.

Additionally, core-team members can push to contributors branches. This can be helpful for pushing an important PR across the line, or for fixing a small merge conflict.

4.6.9 Becoming a pandas maintainer

The full process is outlined in our governance documents. In summary, we’re happy to give triage permissions to anyone who shows interest by being helpful on the issue tracker.

The current list of core-team members is at https://github.com/pandas-dev/pandas-governance/blob/master/people.md
4.6.10 Merging pull requests

Only core team members can merge pull requests. We have a few guidelines.

1. You should typically not self-merge your own pull requests. Exceptions include things like small changes to fix CI (e.g. pinning a package version).

2. You should not merge pull requests that have an active discussion, or pull requests that has any −1 votes from a core maintainer. pandas operates by consensus.

3. For larger changes, it’s good to have a +1 from at least two core team members.

In addition to the items listed in Closing issues, you should verify that the pull request is assigned the correct milestone. Pull requests merged with a patch-release milestone will typically be backported by our bot. Verify that the bot noticed the merge (it will leave a comment within a minute typically). If a manual backport is needed please do that, and remove the “Needs backport” label once you’ve done it manually. If you forget to assign a milestone before tagging, you can request the bot to backport it with:

@Meeseeksdev backport <branch>

4.7 Internals

This section will provide a look into some of pandas internals. It’s primarily intended for developers of pandas itself.

4.7.1 Indexing

In pandas there are a few objects implemented which can serve as valid containers for the axis labels:

- **Index**: the generic “ordered set” object, an ndarray of object dtype assuming nothing about its contents. The labels must be hashable (and likely immutable) and unique. Populates a dict of label to location in Cython to do O(1) lookups.

- **Int64Index**: a version of Index highly optimized for 64-bit integer data, such as time stamps

- **Float64Index**: a version of Index highly optimized for 64-bit float data

- **MultiIndex**: the standard hierarchical index object

- **DatetimeIndex**: An Index object with Timestamp boxed elements (impl are the int64 values)

- **TimedeltaIndex**: An Index object with Timedelta boxed elements (impl are the int64 values)

- **PeriodIndex**: An Index object with Period elements

There are functions that make the creation of a regular index easy:

- **date_range**: fixed frequency date range generated from a time rule or DateOffset. An ndarray of Python datetime objects

- **period_range**: fixed frequency date range generated from a time rule or DateOffset. An ndarray of Period objects, representing timespans

The motivation for having an Index class in the first place was to enable different implementations of indexing. This means that it’s possible for you, the user, to implement a custom Index subclass that may be better suited to a particular application than the ones provided in pandas.

From an internal implementation point of view, the relevant methods that an Index must define are one or more of the following (depending on how incompatible the new object internals are with the Index functions):
• `get_loc`: returns an “indexer” (an integer, or in some cases a slice object) for a label
• `slice_locs`: returns the “range” to slice between two labels
• `get_indexer`: Computes the indexing vector for reindexing / data alignment purposes. See the source / docstrings for more on this
• `get_indexer_non_unique`: Computes the indexing vector for reindexing / data alignment purposes when the index is non-unique. See the source / docstrings for more on this
• `reindex`: Does any pre-conversion of the input index then calls `get_indexer`
• `union`, `intersection`: computes the union or intersection of two Index objects
• `insert`: Inserts a new label into an Index, yielding a new object
• `delete`: Delete a label, yielding a new object
• `drop`: Deletes a set of labels
• `take`: Analogous to `ndarray.take`

**MultiIndex**

Internally, the `MultiIndex` consists of a few things: the `levels`, the integer `codes` (until version 0.24 named `labels`), and the level `names`:

```python
In [1]: index = pd.MultiIndex.from_product(
   ...:   [range(3), ["one", "two"],], names=['first', 'second']
   ...: )

In [2]: index
Out[2]:
MultiIndex([(0, 'one'),
            (0, 'two'),
            (1, 'one'),
            (1, 'two'),
            (2, 'one'),
            (2, 'two')],
           names=['first', 'second'])

In [3]: index.levels
Out[3]: FrozenList([[0, 1, 2], ['one', 'two']])

In [4]: index.codes
Out[4]: FrozenList([[0, 0, 1, 2, 2], [0, 1, 0, 1, 0, 1]])

In [5]: index.names
Out[5]: FrozenList(['first', 'second'])
```

You can probably guess that the codes determine which unique element is identified with that location at each layer of the index. It’s important to note that sortedness is determined **solely** from the integer codes and does not check (or care) whether the levels themselves are sorted. Fortunately, the constructors `from_tuples` and `from_arrays` ensure that this is true, but if you compute the levels and codes yourself, please be careful.
pandas: powerful Python data analysis toolkit, Release 1.3.2

Values

pandas extends NumPy’s type system with custom types, like Categorical or datetimes with a timezone, so we have multiple notions of “values”. For 1-D containers (Index classes and Series) we have the following convention:

- cls._values refers is the “best possible” array. This could be an ndarray or ExtensionArray.

So, for example, Series[category]._values is a Categorical.

4.7.2 Subclassing pandas data structures

This section has been moved to Subclassing pandas data structures.

4.8 Test organization

Ideally, there should be one, and only one, obvious place for a test to reside. Until we reach that ideal, these are some rules of thumb for where a test should be located.

1. Does your test depend only on code in pd._libs.tslibs? This test likely belongs in one of:
   - tests.tslibs
   - tests.scalar
   - tests.tseries.offsets

   **Note:** No file in tests.tslibs should import from any pandas modules outside of pd._libs.tslibs.

2. Does your test depend only on code in pd._libs? This test likely belongs in one of:
   - tests.libs
   - tests.groupby.test_libgroupby

3. Is your test for an arithmetic or comparison method? This test likely belongs in one of:
   - tests.arithmetic

   **Note:** These are intended for tests that can be shared to test the behavior of DataFrame/Series/Index/ExtensionArray using the box_with_array fixture.

   - tests.frame.test_arithmetic
   - tests.series.test_arithmetic

4. Is your test for a reduction method (min, max, sum, prod, …)? This test likely belongs in one of:
   - tests.reductions

   **Note:** These are intended for tests that can be shared to test the behavior of DataFrame/Series/Index/ExtensionArray.

   - tests.frame.test_reductions
• tests.series.test_reductions
• tests.test_nanops

5. Is your test for an indexing method? This is the most difficult case for deciding where a test belongs, because there are many of these tests, and many of them test more than one method (e.g. both `Series.__getitem__` and `Series.loc.__getitem__`)

   A) Is the test specifically testing an Index method (e.g. `Index.get_loc`, `Index.get_indexer`)? This test likely belongs in one of:
      • tests.indexes.test_indexing
      • tests.indexes.fooindex.test_indexing

      Within that files there should be a method-specific test class e.g. `TestGetLoc`.

      In most cases, neither `Series` nor `DataFrame` objects should be needed in these tests.

   B) Is the test for a Series or DataFrame indexing method other than `__getitem__` or `__setitem__`, e.g. `xs`, `where`, `take`, `mask`, `lookup`, or `insert`? This test likely belongs in one of:
      • tests.frame.indexing.test_methodname
      • tests.series.indexing.test_methodname

   C) Is the test for any of `loc`, `iloc`, `at`, or `iat`? This test likely belongs in one of:
      • tests.indexing.test_loc
      • tests.indexing.test_iloc
      • tests.indexing.test_at
      • tests.indexing.test_iat

      Within the appropriate file, test classes correspond to either types of indexers (e.g. `TestLocBooleanMask`) or major use cases (e.g. `TestLocSetitemWithExpansion`).

      See the note in section D) about tests that test multiple indexing methods.

   D) Is the test for `Series.__getitem__`, `Series.__setitem__`, `DataFrame.__getitem__`, or `DataFrame.__setitem__`? This test likely belongs in one of:
      • tests.series.test_getitem
      • tests.series.test_setitem
      • tests.frame.test_getitem
      • tests.frame.test_setitem

      If many cases such a test may test multiple similar methods, e.g.

```python
import pandas as pd
import pandas._testing as tm

def test_getitem_listlike_of_ints():
    ser = pd.Series(range(5))
    result = ser[[3, 4]]
    expected = pd.Series([2, 3])
    tm.assert_series_equal(result, expected)

    result = ser.loc[[3, 4]]
    tm.assert_series_equal(result, expected)
```
In cases like this, the test location should be based on the underlying method being tested. Or in the case of a test for a bugfix, the location of the actual bug. So in this example, we know that Series.__getitem__ calls Series.loc.__getitem__, so this is really a test for loc.__getitem__. So this test belongs in tests.indexing.test_loc.

6. Is your test for a DataFrame or Series method?
   A) Is the method a plotting method? This test likely belongs in one of:
      • tests.plotting
   B) Is the method an IO method? This test likely belongs in one of:
      • tests.io
   C) Otherwise This test likely belongs in one of:
      • tests.series.methods.test_mymethod
      • tests.frame.methods.test_mymethod

   **Note:** If a test can be shared between DataFrame/Series using the frame_or_series fixture, by convention it goes in the tests.frame file.

7. Is your test for an Index method, not depending on Series/DataFrame? This test likely belongs in one of:
   • tests.indexes

8) Is your test for one of the pandas-provided ExtensionArrays (Categorical, DatetimeArray, TimedeltaArray, PeriodArray, IntervalArray, PandasArray, FloatArray, BoolArray, StringArray)? This test likely belongs in one of:
   • tests.arrays

9) Is your test for all ExtensionArray subclasses (the “EA Interface”)? This test likely belongs in one of:
   • tests.extension

### 4.9 Debugging C extensions

Pandas uses select C extensions for high performance IO operations. In case you need to debug segfaults or general issues with those extensions, the following steps may be helpful.

First, be sure to compile the extensions with the appropriate flags to generate debug symbols and remove optimizations. This can be achieved as follows:

```
python setup.py build_ext --inplace -j4 --with-debugging-symbols
```
4.9.1 Using a debugger

Assuming you are on a Unix-like operating system, you can use either lldb or gdb to debug. The choice between either is largely dependent on your compilation toolchain - typically you would use lldb if using clang and gdb if using gcc. For macOS users, please note that gcc is on modern systems an alias for clang, so if using Xcode you usually opt for lldb. Regardless of which debugger you choose, please refer to your operating systems instructions on how to install.

After installing a debugger you can create a script that hits the extension module you are looking to debug. For demonstration purposes, let’s assume you have a script called debug_testing.py with the following contents:

```python
import pandas as pd
pd.DataFrame([[1, 2]]).to_json()
```

Place the debug_testing.py script in the project root and launch a Python process under your debugger. If using lldb:

```
lldb python
```

If using gdb:

```
gdb python
```

Before executing our script, let’s set a breakpoint in our JSON serializer in its entry function called objToJSON. The lldb syntax would look as follows:

```
breakpoint set --name objToJSON
```

Similarly for gdb:

```
break objToJSON
```

**Note:** You may get a warning that this breakpoint cannot be resolved in lldb. gdb may give a similar warning and prompt you to make the breakpoint on a future library load, which you should say yes to. This should only happen on the very first invocation as the module you wish to debug has not yet been loaded into memory.

Now go ahead and execute your script:

```
run <the_script>.py
```

Code execution will halt at the breakpoint defined or at the occurrence of any segfault. LLDB’s [GDB to LLDB command map](https://lldb.llvm.org/docs/GDBToLLDB.html) provides a listing of debugger command that you can execute using either debugger.

Another option to execute the entire test suite under lldb would be to run the following:

```
lldb -- python -m pytest
```

Or for gdb

```
gdb --args python -m pytest
```

Once the process launches, simply type `run` and the test suite will begin, stopping at any segmentation fault that may occur.
4.9.2 Checking memory leaks with valgrind

You can use Valgrind to check for and log memory leaks in extensions. For instance, to check for a memory leak in a test from the suite you can run:

```
PYTHONMALLOC=malloc valgrind --leak-check=yes --track-origins=yes --log-file=valgrind-log.txt python -m pytest <path_to_a_test>
```

Note that code execution under valgrind will take much longer than usual. While you can run valgrind against extensions compiled with any optimization level, it is suggested to have optimizations turned off from compiled extensions to reduce the amount of false positives. The `--with-debugging-symbols` flag passed during package setup will do this for you automatically.

**Note:** For best results, you should run use a Python installation configured with Valgrind support (`--with-valgrind`)

4.10 Extending pandas

While pandas provides a rich set of methods, containers, and data types, your needs may not be fully satisfied. pandas offers a few options for extending pandas.

4.10.1 Registering custom accessors

Libraries can use the decorators `pandas.api.extensions.register_dataframe_accessor()`, `pandas.api.extensions.register_series_accessor()`, and `pandas.api.extensions.register_index_accessor()`, to add additional “namespaces” to pandas objects. All of these follow a similar convention: you decorate a class, providing the name of attribute to add. The class’s `__init__` method gets the object being decorated. For example:

```python
@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._validate(pandas_obj)
        self._obj = pandas_obj

    @staticmethod
    def _validate(obj):
        # verify there is a column latitude and a column longitude
        if "latitude" not in obj.columns or "longitude" not in obj.columns:
            raise AttributeError("Must have 'latitude' and 'longitude'.")

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Now users can access your methods using the `geo` namespace:
This can be a convenient way to extend pandas objects without subclassing them. If you write a custom accessor, make a pull request adding it to our ecosystem page.

We highly recommend validating the data in your accessor’s __init__. In our GeoAccessor, we validate that the data contains the expected columns, raising an AttributeError when the validation fails. For a Series accessor, you should validate the dtype if the accessor applies only to certain dtypes.

### 4.10.2 Extension types

| Warning: | The pandas.api.extensions.ExtensionDtype and pandas.api.extensions.ExtensionArray APIs are new and experimental. They may change between versions without warning. |

pandas defines an interface for implementing data types and arrays that extend NumPy’s type system. pandas itself uses the extension system for some types that aren’t built into NumPy (categorical, period, interval, datetime with timezone).

Libraries can define a custom array and data type. When pandas encounters these objects, they will be handled properly (i.e. not converted to an ndarray of objects). Many methods like pandas.isna() will dispatch to the extension type’s implementation.

If you’re building a library that implements the interface, please publicize it on ecosystem.extensions.

The interface consists of two classes.

**ExtensionDtype**

A pandas.api.extensions.ExtensionDtype is similar to a numpy.dtype object. It describes the data type. Implementors are responsible for a few unique items like the name.

One particularly important item is the type property. This should be the class that is the scalar type for your data. For example, if you were writing an extension array for IP Address data, this might be ipaddress.IPv4Address.

See the extension dtype source for interface definition.

pandas.api.extensions.ExtensionDtype can be registered to pandas to allow creation via a string dtype name. This allows one to instantiate Series and .astype() with a registered string name, for example 'category' is a registered string accessor for the CategoricalDtype.

See the extension dtype dtypes for more on how to register dtypes.
**ExtensionArray**

This class provides all the array-like functionality. ExtensionArrays are limited to 1 dimension. An ExtensionArray is linked to an ExtensionDtype via the dtype attribute.

pandas makes no restrictions on how an extension array is created via its __new__ or __init__, and puts no restrictions on how you store your data. We do require that your array be convertible to a NumPy array, even if this is relatively expensive (as it is for Categorical).

They may be backed by none, one, or many NumPy arrays. For example, pandas.Categorical is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 addresses may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists.

See the extension array source for the interface definition. The docstrings and comments contain guidance for properly implementing the interface.

**ExtensionArray operator support**

By default, there are no operators defined for the class ExtensionArray. There are two approaches for providing operator support for your ExtensionArray:

1. Define each of the operators on your ExtensionArray subclass.
2. Use an operator implementation from pandas that depends on operators that are already defined on the underlying elements (scalars) of the ExtensionArray.

**Note:** Regardless of the approach, you may want to set __array_priority__ if you want your implementation to be called when involved in binary operations with NumPy arrays.

For the first approach, you define selected operators, e.g., __add__, __le__, etc. that you want your ExtensionArray subclass to support.

The second approach assumes that the underlying elements (i.e., scalar type) of the ExtensionArray have the individual operators already defined. In other words, if your ExtensionArray named MyExtensionArray is implemented so that each element is an instance of the class MyExtensionElement, then if the operators are defined for MyExtensionElement, the second approach will automatically define the operators for MyExtensionArray.

A mixin class, ExtensionScalarOpsMixin supports this second approach. If developing an ExtensionArray subclass, for example MyExtensionArray, can simply include ExtensionScalarOpsMixin as a parent class of MyExtensionArray, and then call the methods _add_arithmetic_ops() and/or _add_comparison_ops() to hook the operators into your MyExtensionArray class, as follows:

```python
from pandas.api.extensions import ExtensionArray, ExtensionScalarOpsMixin

class MyExtensionArray(ExtensionArray, ExtensionScalarOpsMixin):
    pass

MyExtensionArray._add_arithmetic_ops()
MyExtensionArray._add_comparison_ops()
```
**Note:** Since pandas automatically calls the underlying operator on each element one-by-one, this might not be as performant as implementing your own version of the associated operators directly on the `ExtensionArray`.

For arithmetic operations, this implementation will try to reconstruct a new `ExtensionArray` with the result of the element-wise operation. Whether or not that succeeds depends on whether the operation returns a result that’s valid for the `ExtensionArray`. If an `ExtensionArray` cannot be reconstructed, an ndarray containing the scalars returned instead.

For ease of implementation and consistency with operations between pandas and NumPy ndarrays, we recommend not handling Series and Indexes in your binary ops. Instead, you should detect these cases and return `NotImplemented`. When pandas encounters an operation like `op(Series, ExtensionArray)`, pandas will

1. unbox the array from the `Series(Series.array)`
2. call `result = op(values, ExtensionArray)`
3. re-box the result in a `Series`

**NumPy universal functions**

`Series` implements `__array_ufunc__`. As part of the implementation, pandas unboxes the `ExtensionArray` from the `Series`, applies the ufunc, and re-boxes it if necessary.

If applicable, we highly recommend that you implement `__array_ufunc__` in your extension array to avoid coercion to an ndarray. See the NumPy documentation for an example.

As part of your implementation, we require that you defer to pandas when a pandas container (`Series, DataFrame, Index`) is detected in inputs. If any of those is present, you should return `NotImplemented`. pandas will take care of unboxing the array from the container and re-calling the ufunc with the unwrapped input.

**Testing extension arrays**

We provide a test suite for ensuring that your extension arrays satisfy the expected behavior. To use the test suite, you must provide several pytest fixtures and inherit from the base test class. The required fixtures are found in [https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/conftest.py](https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/conftest.py).

To use a test, subclass it:

```python
from pandas.tests.extension import base
class TestConstructors(base.BaseConstructorsTests):
    pass
```

See [https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/base/__init__.py](https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/base/__init__.py) for a list of all the tests available.
**Compatibility with Apache Arrow**

An `ExtensionArray` can support conversion to/from `pyarrow` arrays (and thus support for example serialization to the Parquet file format) by implementing two methods: `ExtensionArray.__arrow_array__` and `ExtensionDtype.__from_arrow__`.

The `ExtensionArray.__arrow_array__` ensures that `pyarrow` knows how to convert the specific extension array into a `pyarrow.Array` (also when included as a column in a pandas DataFrame):

```python
class MyExtensionArray(ExtensionArray):
    ...
    def __arrow_array__(self, type=None):
        # convert the underlying array values to a pyarrow Array
        import pyarrow
        return pyarrow.array(..., type=type)
```

The `ExtensionDtype.__from_arrow__` method then controls the conversion back from `pyarrow` to a pandas `ExtensionArray`. This method receives a `pyarrow Array` or `ChunkedArray` as only argument and is expected to return the appropriate pandas `ExtensionArray` for this dtype and the passed values:

```python
class ExtensionDtype:
    ...
    def __from_arrow__(self, array: pyarrow.Array/ChunkedArray) -> ExtensionArray:
        ...
```

See more in the Arrow documentation.

Those methods have been implemented for the nullable integer and string extension dtypes included in pandas, and ensure roundtrip to `pyarrow` and the Parquet file format.

### 4.10.3 Subclassing pandas data structures

**Warning:** There are some easier alternatives before considering subclassing pandas data structures.

1. Extensible method chains with `pipe`
2. Use `composition`. See here.
3. Extending by registering an accessor
4. Extending by extension type

This section describes how to subclass pandas data structures to meet more specific needs. There are two points that need attention:

1. Override constructor properties.
2. Define original properties

**Note:** You can find a nice example in geopandas project.
Override constructor properties

Each data structure has several constructor properties for returning a new data structure as the result of an operation. By overriding these properties, you can retain subclasses through pandas data manipulations.

There are 3 possible constructor properties to be defined on a subclass:

- DataFrame/Series._constructor: Used when a manipulation result has the same dimension as the original.
- DataFrame._constructor_sliced: Used when a DataFrame (sub-)class manipulation result should be a Series (sub-)class.
- Series._constructor_expanddim: Used when a Series (sub-)class manipulation result should be a DataFrame (sub-)class, e.g. Series.to_frame().

Below example shows how to define SubclassedSeries and SubclassedDataFrame overriding constructor properties.

```python
class SubclassedSeries(pd.Series):
    @property
    def _constructor(self):
        return SubclassedSeries

    @property
    def _constructor_expanddim(self):
        return SubclassedDataFrame

class SubclassedDataFrame(pd.DataFrame):
    @property
    def _constructor(self):
        return SubclassedDataFrame

    @property
    def _constructor_sliced(self):
        return SubclassedSeries
```

```python
>>> s = SubclassedSeries([1, 2, 3])
>>> type(s)
<class '__main__.SubclassedSeries'>

>>> to_framed = s.to_frame()
>>> type(to_framed)
<class '__main__.SubclassedDataFrame'>

>>> df = SubclassedDataFrame({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]})
>>> df
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9

>>> type(df)
<class '__main__.SubclassedDataFrame'>

>>> sliced1 = df[['A', 'B']]  
>>> sliced1
   A  B
0  1  4
1  2  5
2  3  6
```
Define original properties

To let original data structures have additional properties, you should let pandas know what properties are added. pandas maps unknown properties to data names overriding __getattr__. Defining original properties can be done in one of 2 ways:

1. Define _internal_names and _internal_names_set for temporary properties which WILL NOT be passed to manipulation results.
2. Define _metadata for normal properties which will be passed to manipulation results.

Below is an example to define two original properties, “internal_cache” as a temporary property and “added_property” as a normal property.

```python
class SubclassedDataFrame2(pd.DataFrame):
    # temporary properties
    _internal_names = pd.DataFrame._internal_names + ["internal_cache"]
    _internal_names_set = set(_internal_names)

    # normal properties
    _metadata = ["added_property"]

    @property
def _constructor(self):
        return SubclassedDataFrame2

>>> df = SubclassedDataFrame2({"A": [1, 2, 3], "B": [4, 5, 6], "C": [7, 8, 9]})
>>> df
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9

>>> df.internal_cache = "cached"
>>> df.added_property = "property"

>>> df.internal_cache
cached
```
cached
>>> df.added_property
property

# properties defined in _internal_names is reset after manipulation
>>> df["A", "B"].internal_cache
AttributeError: 'SubclassedDataFrame2' object has no attribute 'internal_cache'

# properties defined in _metadata are retained
>>> df["A", "B"].added_property
property

## 4.10.4 Plotting backends

Starting in 0.25 pandas can be extended with third-party plotting backends. The main idea is letting users select a plotting backend different than the provided one based on Matplotlib. For example:

```python
>>> pd.set_option("plotting.backend", "backend.module")
>>> pd.Series([1, 2, 3]).plot()
```

This would be more or less equivalent to:

```python
>>> import backend.module
>>> backend.module.plot(pd.Series([1, 2, 3]))
```

The backend module can then use other visualization tools (Bokeh, Altair,…) to generate the plots.

Libraries implementing the plotting backend should use entry points to make their backend discoverable to pandas. The key is "pandas_plotting_backends". For example, pandas registers the default "matplotlib" backend as follows.

```python
# in setup.py
setup(  # nogp: F821
    ...,
    entry_points={
        "pandas_plotting_backends": [
            "matplotlib = pandas:plotting._matplotlib",
        ],
    },
)
```

More information on how to implement a third-party plotting backend can be found at https://github.com/pandas-dev/pandas/blob/master/pandas/plotting/__init__.py#L1.
4.11 Developer

This section will focus on downstream applications of pandas.

4.11.1 Storing pandas DataFrame objects in Apache Parquet format

The Apache Parquet format provides key-value metadata at the file and column level, stored in the footer of the Parquet file:

```
5: optional list<KeyValue> key_value_metadata
```

where `KeyValue` is

```
struct KeyValue {
    1: required string key
    2: optional string value
}
```

So that a `pandas.DataFrame` can be faithfully reconstructed, we store a `pandas` metadata key in the `FileMetaData` with the value stored as:

```
{'index_columns': [<descr0>, <descr1>, ...],
 'column_indexes': [<ci0>, <ci1>, ..., <ciN>],
 'columns': [<c0>, <c1>, ...],
 'pandas_version': $VERSION,
 'creator': {
    'library': $LIBRARY,
    'version': $LIBRARY_VERSION
 }}
```

The “descriptor” values `<descr0>` in the 'index_columns' field are strings (referring to a column) or dictionaries with values as described below.

The `<c0>`/<`ci0>` and so forth are dictionaries containing the metadata for each column, including the index columns. This has JSON form:

```
{'name': column_name,
 'field_name': parquet_column_name,
 'pandas_type': pandas_type,
 'numpy_type': numpy_type,
 'metadata': metadata}
```

See below for the detailed specification for these.

Index metadata descriptors

`RangeIndex` can be stored as metadata only, not requiring serialization. The descriptor format for these as is follows:

```
index = pd.RangeIndex(0, 10, 2)
|   
|    "kind": "range",
|    "name": index.name,
|    "start": index.start,
|    "stop": index.stop,
```

(continues on next page)
Other index types must be serialized as data columns along with the other DataFrame columns. The metadata for these is a string indicating the name of the field in the data columns, for example '__index_level_0__'.

If an index has a non-None name attribute, and there is no other column with a name matching that value, then the index.name value can be used as the descriptor. Otherwise (for unnamed indexes and ones with names colliding with other column names) a disambiguating name with pattern matching __index_level__\d+__ should be used.

In cases of named indexes as data columns, name attribute is always stored in the column descriptors as above.

**Column metadata**

pandas_type is the logical type of the column, and is one of:

- Boolean: 'bool'
- Integers: 'int8', 'int16', 'int32', 'int64', 'uint8', 'uint16', 'uint32', 'uint64'
- Floats: 'float16', 'float32', 'float64'
- Date and Time Types: 'datetime', 'datetimetz', 'timedelta'
- String: 'unicode', 'bytes'
- Categorical: 'categorical'
- Other Python objects: 'object'

The numpy_type is the physical storage type of the column, which is the result of str(dtype) for the underlying NumPy array that holds the data. So for datetimetz this is datetime64[ns] and for categorical, it may be any of the supported integer categorical types.

The metadata field is None except for:

- datetimetz: {"timezone": zone, "unit": "ns"}, e.g. {"timezone": 'America/New_York', "unit": "ns"}. The 'unit' is optional, and if omitted it is assumed to be nanoseconds.
- categorical: {"num_categories": K, "ordered": is_ordered, "type": $TYPE}
  - Here 'type' is optional, and can be a nested pandas type specification here (but not categorical)
- unicode: {"encoding": encoding}
  - The encoding is optional, and if not present is UTF-8
- object: {"encoding": encoding}. Objects can be serialized and stored in BYTE_ARRAY Parquet columns. The encoding can be one of:
  - 'pickle'
  - 'bson'
  - 'json'
- timedelta: {"unit": "ns"}. The 'unit' is optional, and if omitted it is assumed to be nanoseconds. This metadata is optional altogether

For types other than these, the 'metadata' key can be omitted. Implementations can assume None if the key is not present.

As an example of fully-formed metadata:
4.12 Policies

4.12.1 Version policy

Changed in version 1.0.0.

pandas uses a loose variant of semantic versioning (SemVer) to govern deprecations, API compatibility, and version numbering.

A pandas release number is made up of MAJOR.MINOR.PATCH.
API breaking changes should only occur in **major** releases. These changes will be documented, with clear guidance on what is changing, why it’s changing, and how to migrate existing code to the new behavior.

Whenever possible, a deprecation path will be provided rather than an outright breaking change.

pandas will introduce deprecations in **minor** releases. These deprecations will preserve the existing behavior while emitting a warning that provide guidance on:

- How to achieve similar behavior if an alternative is available
- The pandas version in which the deprecation will be enforced.

We will not introduce new deprecations in patch releases.

Deprecations will only be enforced in **major** releases. For example, if a behavior is deprecated in pandas 1.2.0, it will continue to work, with a warning, for all releases in the 1.x series. The behavior will change and the deprecation removed in the next major release (2.0.0).

---

**Note:** pandas will sometimes make **behavior changing** bug fixes, as part of minor or patch releases. Whether or not a change is a bug fix or an API-breaking change is a judgement call. We’ll do our best, and we invite you to participate in development discussion on the issue tracker or mailing list.

These policies do not apply to features marked as **experimental** in the documentation. pandas may change the behavior of experimental features at any time.

---

### 4.12.2 Python support

pandas will only drop support for specific Python versions (e.g. 3.6.x, 3.7.x) in pandas **major** or **minor** releases.

---

### 4.13 Roadmap

This page provides an overview of the major themes in pandas’ development. Each of these items requires a relatively large amount of effort to implement. These may be achieved more quickly with dedicated funding or interest from contributors.

An item being on the roadmap does not mean that it will **necessarily** happen, even with unlimited funding. During the implementation period we may discover issues preventing the adoption of the feature.

Additionally, an item **not** being on the roadmap does not exclude it from inclusion in pandas. The roadmap is intended for larger, fundamental changes to the project that are likely to take months or years of developer time. Smaller-scoped items will continue to be tracked on our issue tracker.

See **Roadmap evolution** for proposing changes to this document.

---

#### 4.13.1 Extensibility

pandas **Extension types** allow for extending NumPy types with custom data types and array storage. pandas uses extension types internally, and provides an interface for 3rd-party libraries to define their own custom data types.

Many parts of pandas still unintentionally convert data to a NumPy array. These problems are especially pronounced for nested data.

We’d like to improve the handling of extension arrays throughout the library, making their behavior more consistent with the handling of NumPy arrays. We’ll do this by cleaning up pandas’ internals and adding new methods to the extension array interface.
4.13.2 String data type

Currently, pandas stores text data in an object -dtype NumPy array. The current implementation has two primary drawbacks: First, object -dtype is not specific to strings: any Python object can be stored in an object -dtype array, not just strings. Second: this is not efficient. The NumPy memory model isn’t especially well-suited to variable width text data.

To solve the first issue, we propose a new extension type for string data. This will initially be opt-in, with users explicitly requesting dtype="string". The array backing this string dtype may initially be the current implementation: an object -dtype NumPy array of Python strings.

To solve the second issue (performance), we’ll explore alternative in-memory array libraries (for example, Apache Arrow). As part of the work, we may need to implement certain operations expected by pandas users (for example the algorithm used in Series.str.upper). That work may be done outside of pandas.

4.13.3 Consistent missing value handling

Currently, pandas handles missing data differently for different data types. We use different types to indicate that a value is missing (np.nan for floating-point data, np.nan or None for object-dtype data – typically strings or booleans – with missing values, and pd.NaT for datetimelike data). Integer data cannot store missing data or are cast to float. In addition, pandas 1.0 introduced a new missing value sentinel, pd.NA, which is being used for the experimental nullable integer, boolean, and string data types.

These different missing values have different behaviors in user-facing operations. Specifically, we introduced different semantics for the nullable data types for certain operations (e.g. propagating in comparison operations instead of comparing as False).

Long term, we want to introduce consistent missing data handling for all data types. This includes consistent behavior in all operations (indexing, arithmetic operations, comparisons, etc.). There has been discussion of eventually making the new semantics the default.

This has been discussed at github #28095 (and linked issues), and described in more detail in this design doc.

4.13.4 Apache Arrow interoperability

Apache Arrow is a cross-language development platform for in-memory data. The Arrow logical types are closely aligned with typical pandas use cases.

We’d like to provide better-integrated support for Arrow memory and data types within pandas. This will let us take advantage of its I/O capabilities and provide for better interoperability with other languages and libraries using Arrow.

4.13.5 Block manager rewrite

We’d like to replace pandas current internal data structures (a collection of 1 or 2-D arrays) with a simpler collection of 1-D arrays.

pandas internal data model is quite complex. A DataFrame is made up of one or more 2-dimensional “blocks”, with one or more blocks per dtype. This collection of 2-D arrays is managed by the BlockManager.

The primary benefit of the BlockManager is improved performance on certain operations (construction from a 2D array, binary operations, reductions across the columns), especially for wide DataFrames. However, the BlockManager substantially increases the complexity and maintenance burden of pandas.

By replacing the BlockManager we hope to achieve

- Substantially simpler code
• Easier extensibility with new logical types
• Better user control over memory use and layout
• Improved micro-performance
• Option to provide a C / Cython API to pandas’ internals

See these design documents for more.

4.13.6 Decoupling of indexing and internals

The code for getting and setting values in pandas’ data structures needs refactoring. In particular, we must clearly separate code that converts keys (e.g., the argument to DataFrame.loc) to positions from code that uses these positions to get or set values. This is related to the proposed BlockManager rewrite. Currently, the BlockManager sometimes uses label-based, rather than position-based, indexing. We propose that it should only work with positional indexing, and the translation of keys to positions should be entirely done at a higher level.

Indexing is a complicated API with many subtleties. This refactor will require care and attention. More details are discussed at https://github.com/pandas-dev/pandas/wiki/(Tentative)-rules-for-restructuring-indexing-code

4.13.7 Numba-accelerated operations

Numba is a JIT compiler for Python code. We’d like to provide ways for users to apply their own Numba-jitted functions where pandas accepts user-defined functions (for example, Series.apply(), DataFrame.apply(), DataFrame.applymap(), and in groupby and window contexts). This will improve the performance of user-defined-functions in these operations by staying within compiled code.

4.13.8 Performance monitoring

pandas uses airspeed velocity to monitor for performance regressions. ASV itself is a fabulous tool, but requires some additional work to be integrated into an open source project’s workflow.

The asv-runner organization, currently made up of pandas maintainers, provides tools built on top of ASV. We have a physical machine for running a number of project’s benchmarks, and tools managing the benchmark runs and reporting on results.

We’d like to fund improvements and maintenance of these tools to

• Be more stable. Currently, they’re maintained on the nights and weekends when a maintainer has free time.
• Tune the system for benchmarks to improve stability, following https://pyperf.readthedocs.io/en/latest/system.html
• Build a GitHub bot to request ASV runs before a PR is merged. Currently, the benchmarks are only run nightly.
4.13.9 Roadmap evolution

pandas continues to evolve. The direction is primarily determined by community interest. Everyone is welcome to review existing items on the roadmap and to propose a new item.

Each item on the roadmap should be a short summary of a larger design proposal. The proposal should include

1. Short summary of the changes, which would be appropriate for inclusion in the roadmap if accepted.
2. Motivation for the changes.
3. An explanation of why the change is in scope for pandas.
4. Detailed design: Preferably with example-usage (even if not implemented yet) and API documentation
5. API Change: Any API changes that may result from the proposal.

That proposal may then be submitted as a GitHub issue, where the pandas maintainers can review and comment on the design. The pandas mailing list should be notified of the proposal.

When there’s agreement that an implementation would be welcome, the roadmap should be updated to include the summary and a link to the discussion issue.

4.13.10 Completed items

This section records now completed items from the pandas roadmap.

Documentation improvements

We improved the pandas documentation

- The pandas community worked with others to build the pydata-sphinx-theme, which is now used for https://pandas.pydata.org/docs/ (GH15556).
- Getting started contains a number of resources intended for new pandas users coming from a variety of backgrounds (GH26831).

4.14 Developer meetings

We hold regular developer meetings on the second Wednesday of each month at 18:00 UTC. These meetings and their minutes are open to the public. All are welcome to join.

4.14.1 Minutes

The minutes of past meetings are available in this Google Document.
4.14.2 Calendar

This calendar shows all the developer meetings.

You can subscribe to this calendar with the following links:

- iCal
- Google calendar

Additionally, we’ll sometimes have one-off meetings on specific topics. These will be published on the same calendar.
Chapter 4. Development
CHAPTER FIVE

RELEASE NOTES

This is the list of changes to pandas between each release. For full details, see the commit logs. For install and upgrade instructions, see Installation.

5.1 Version 1.3

5.1.1 What’s new in 1.3.2 (August 15, 2021)

These are the changes in pandas 1.3.2. See Release notes for a full changelog including other versions of pandas.

Fixed regressions

- Performance regression in DataFrame.isin() and Series.isin() for nullable data types (GH42714)
- Regression in updating values of Series using boolean index, created by using DataFrame.pop() (GH42530)
- Regression in DataFrame.from_records() with empty records (GH42456)
- Fixed regression in DataFrame.shift() where TypeError occurred when shifting DataFrame created by concatenation of slices and fills with values (GH42719)
- Regression in DataFrame.agg() when the func argument returned lists and axis=1 (GH42727)
- Regression in DataFrame.drop() does nothing if MultiIndex has duplicates and indexer is a tuple or list of tuples (GH42771)
- Fixed regression where read_csv() raised a ValueError when parameters names and prefix were both set to None (GH42387)
- Fixed regression in comparisons between Timestamp object and datetime64 objects outside the implementation bounds for nanosecond datetime64 (GH42794)
- Fixed regression in Styler.highlight_min() and Styler.highlight_max() where pandas.NA was not successfully ignored (GH42650)
- Fixed regression in concat() where copy=False was not honored in axis=1 Series concatenation (GH42501)
- Regression in Series.nlargest() and Series.nsmallest() with nullable integer or float dtype (GH42816)
- Fixed regression in Series.quantile() with Int64Dtype (GH42626)
Bug fixes

- Bug in `read_excel()` modifies the dtypes dictionary when reading a file with duplicate columns (GH42462)
- 1D slices over extension types turn into N-dimensional slices over ExtensionArrays (GH42430)
- Fixed bug in `Series.rolling()` and `DataFrame.rolling()` not calculating window bounds correctly for the first row when `center=True` and `window` is an offset that covers all the rows (GH42753)
- `Styler.hide_columns()` now hides the index name header row as well as column headers (GH42101)
- `Styler.set_sticky()` has amended CSS to control the column/index names and ensure the correct sticky positions (GH42537)
- Bug in de-serializing datetime indexes in PYTHONOPTIMIZED mode (GH42866)

Contributors

A total of 16 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

5.1.2 What’s new in 1.3.1 (July 25, 2021)

These are the changes in pandas 1.3.1. See Release notes for a full changelog including other versions of pandas.
Fixed regressions

- Pandas could not be built on PyPy (GH42355)
- DataFrame constructed with an older version of pandas could not be unpickled (GH42345)
- Performance regression in constructing a DataFrame from a dictionary of dictionaries (GH42248)
- Fixed regression in DataFrame.agg() dropping values when the DataFrame had an Extension Array dtype, a duplicate index, and axis=1 (GH42380)
- Fixed regression in DataFrame.astype() changing the order of noncontiguous data (GH42396)
- Performance regression in DataFrame in reduction operations requiring casting such as DataFrame.mean() on integer data (GH38592)
- Performance regression in DataFrame.to_dict() and Series.to_dict() when orient argument one of “records”, “dict”, or “split” (GH42352)
- Fixed regression in indexing with a list subclass incorrectly raising TypeError (GH42433, GH42461)
- Fixed regression in DataFrame.isin() and Series.isin() raising TypeError with nullable data containing at least one missing value (GH42405)
- Regression in concat() between objects with bool dtype and integer dtype casting to object instead of to integer (GH42092)
- Bug in Series constructor not accepting a dask.Array (GH38645)
- Fixed regression for SettingWithCopyWarning displaying incorrect stacklevel (GH42570)
- Fixed regression for merge_asof() raising KeyError when one of the by columns is in the index (GH34488)
- Fixed regression in to_datetime() returning pd.NaT for inputs that produce duplicated values, when cache=True (GH42259)
- Fixed regression in SeriesGroupBy.value_counts() that resulted in an IndexError when called on a Series with one row (GH42618)

Bug fixes

- Fixed bug in DataFrame.transpose() dropping values when the DataFrame had an Extension Array dtype and a duplicate index (GH42380)
- Fixed bug in DataFrame.to_xml() raising KeyError when called with index=False and an offset index (GH42458)
- Fixed bug in Styler.set_sticky() not handling index names correctly for single index columns case (GH42537)
- Fixed bug in DataFrame.copy() failing to consolidate blocks in the result (GH42579)
Contributors

A total of 17 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

5.1.3 What’s new in 1.3.0 (July 2, 2021)

These are the changes in pandas 1.3.0. See Release notes for a full changelog including other versions of pandas.

**Warning:** When reading new Excel 2007+ (.xlsx) files, the default argument engine=None to `read_excel()` will now result in using the openpyxl engine in all cases when the option io.excel.xlsx.reader is set to "auto". Previously, some cases would use the xld engine instead. See What’s new 1.2.0 for background on this change.

Enhancements

**Custom HTTP(s) headers when reading csv or json files**

When reading from a remote URL that is not handled by fsspec (e.g. HTTP and HTTPS) the dictionary passed to `storage_options` will be used to create the headers included in the request. This can be used to control the User-Agent header or send other custom headers (GH36688). For example:
In [1]: headers = {"User-Agent": "pandas"}

In [2]: df = pd.read_csv(
    ...:   "https://download.bls.gov/pub/time.series/cu/cu.item",
    ...:   sep="\t",
    ...:   storage_options=headers
    ...: )

Read and write XML documents

We added I/O support to read and render shallow versions of XML documents with `read_xml()` and `DataFrame.to_xml()`. Using lxml as parser, both XPath 1.0 and XSLT 1.0 are available. (GH27554)

In [1]: xml = """<?xml version='1.0' encoding='utf-8'?><data><row><index>0</index><shape>square</shape><degrees>360</degrees><sides>4.0</sides></row><row><index>1</index><shape>circle</shape><degrees>360</degrees><sides/></row><row><index>2</index><shape>triangle</shape><degrees>180</degrees><sides>3.0</sides></row></data>"

In [2]: df = pd.read_xml(xml)
In [3]: df
Out[3]:
<table>
<thead>
<tr>
<th></th>
<th>shape</th>
<th>degrees</th>
<th>sides</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>square</td>
<td>360</td>
<td>4.0</td>
</tr>
<tr>
<td>1</td>
<td>circle</td>
<td>360</td>
<td>NaN</td>
</tr>
<tr>
<td>2</td>
<td>triangle</td>
<td>180</td>
<td>3.0</td>
</tr>
</tbody>
</table>

In [4]: df.to_xml()
Out[4]:
<?xml version='1.0' encoding='utf-8'?>
<data>
  <row>
    <index>0</index>
    <shape>square</shape>
    <degrees>360</degrees>
    <sides>4.0</sides>
  </row>
  <row>
    <index>1</index>
    <shape>circle</shape>
    <degrees>360</degrees>
  </row>
  (continues on next page)
For more, see *Writing XML* in the user guide on IO tools.

**Styler enhancements**

We provided some focused development on *Styler*. See also the *Styler documentation* which has been revised and improved (GH39720, GH39317, GH40493).

- The method *Styler.set_table_styles()* can now accept more natural CSS language for arguments, such as `'color:red;'` instead of `[('color', 'red')]` (GH39563)
- The methods *Styler.highlight_null()*, *Styler.highlight_min()*, and *Styler.highlight_max()* now allow custom CSS highlighting instead of the default background coloring (GH40424)
- *Styler.apply()* now accepts functions that return an ndarray when axis=None, making it now consistent with the axis=0 and axis=1 behavior (GH39359)
- When incorrectly formatted CSS is given via *Styler.apply()* or *Styler.applymap()* , an error is now raised upon rendering (GH39660)
- *Styler.format()* now accepts the keyword argument *escape* for optional HTML and LaTeX escaping (GH40388, GH41619)
- *Styler.background_gradient()* has gained the argument *gmap* to supply a specific gradient map for shading (GH22727)
- *Styler.clear()* now clears *Styler.hidden_index* and *Styler.hidden_columns* as well (GH40484)
- Added the method *Styler.highlight_between()* (GH39821)
- Added the method *Styler.highlight_quantile()* (GH40926)
- Added the method *Styler.text_gradient()* (GH41098)
- Added the method *Styler.set_tooltips()* to allow hover tooltips; this can be used to enhance interactive displays (GH21266, GH40284)
- Added the parameter *precision* to the method *Styler.format()* to control the display of floating point numbers (GH40134)
- *Styler* rendered HTML output now follows the w3 HTML Style Guide (GH39626)
- Many features of the *Styler* class are now either partially or fully usable on a DataFrame with a non-unique indexes or columns (GH41143)
- One has greater control of the display through separate sparsification of the index or columns using the *new styler options*, which are also usable via *option_context()* (GH41142)
- Added the option `styler.render.max_elements` to avoid browser overload when styling large DataFrames (GH40712)
- Added the method `Styler.to_latex()` (GH21673, GH42320), which also allows some limited CSS conversion (GH40731)
- Added the method `Styler.to_html()` (GH13379)
- Added the method `Styler.set_sticky()` to make index and column headers permanently visible in scrolling HTML frames (GH29072)

**DataFrame constructor honors `copy=False` with `dict`**

When passing a dictionary to `DataFrame` with `copy=False`, a copy will no longer be made (GH32960).

```
In [3]: arr = np.array([1, 2, 3])
In [4]: df = pd.DataFrame({"A": arr, "B": arr.copy()}, copy=False)
In [5]: df
Out[5]:
   A  B
0  1  1
1  2  2
2  3  3
```

df["A"] remains a view on `arr`:

```
In [6]: arr[0] = 0
In [7]: assert df.iloc[0, 0] == 0
```

The default behavior when not passing `copy` will remain unchanged, i.e. a copy will be made.

**PyArrow backed string data type**

We’ve enhanced the `StringDtype`, an extension type dedicated to string data. (GH39908)

It is now possible to specify a `storage` keyword option to `StringDtype`. Use pandas options or specify the `dtype` using `dtype='string[pyarrow]'` to allow the StringArray to be backed by a PyArrow array instead of a NumPy array of Python objects.

The PyArrow backed StringArray requires pyarrow 1.0.0 or greater to be installed.

```
In [8]: pd.Series(['abc', None, 'def'], dtype=pd.StringDtype(storage="pyarrow"))
Out[8]:
    0  abc
    1  <NA>
    2  def
dtype: string
```

You can use the alias "string[pyarrow]" as well.
You can also create a PyArrow backed string array using pandas options.

The usual string accessor methods work. Where appropriate, the return type of the Series or columns of a DataFrame will also have string dtype.

String accessor methods returning integers will return a value with `Int64Dtype`
**Centered datetime-like rolling windows**

When performing rolling calculations on DataFrame and Series objects with a datetime-like index, a centered datetime-like window can now be used (GH38780). For example:

```python
In [16]: df = pd.DataFrame(
    ....:     {"A": [0, 1, 2, 3, 4]}, index=pd.date_range("2020", periods=5, freq="1D")
    ....: )
    ....:
In [17]: df
Out[17]:
     A
2020-01-01 0
2020-01-02 1
2020-01-03 2
2020-01-04 3
2020-01-05 4
In [18]: df.rolling("2D", center=True).mean()
Out[18]:
     A
2020-01-01 0.5
2020-01-02 1.5
2020-01-03 2.5
2020-01-04 3.5
2020-01-05 4.0
```

**Other enhancements**

- `DataFrame.rolling()`, `Series.rolling()`, `DataFrame.expanding()`, and `Series.expanding()` now support a method argument with a 'table' option that performs the windowing operation over an entire `DataFrame`. See `Window Overview` for performance and functional benefits (GH15095, GH38995)

- `ExponentialMovingWindow` now support a online method that can perform mean calculations in an online fashion. See `Window Overview` (GH41673)

- Added `MultiIndex.dtypes()` (GH37062)

- Added `end` and `end_day` options for the `origin` argument in `DataFrame.resample()` (GH37804)

- Improved error message when `usecols` and `names` do not match for `read_csv()` and `engine="c"` (GH29042)

- Improved consistency of error messages when passing an invalid `win_type` argument in `Window methods` (GH15969)

- `read_sql_query()` now accepts a `dtype` argument to cast the columnar data from the SQL database based on user input (GH10285)

- `read_csv()` now raising `ParserWarning` if length of header or given names does not match length of data when `usecols` is not specified (GH21768)

- Improved integer type mapping from pandas to SQLAlchemy when using `DataFrame.to_sql()` (GH35076)

- `to_numeric()` now supports downcasting of nullable `ExtensionDtype` objects (GH33013)
- Added support for dict-like names in `MultiIndex.set_names` and `MultiIndex.rename` (GH20421)
- `read_excel()` can now auto-detect .xlsxb files and older .xls files (GH35416, GH41225)
- `ExcelWriter` now accepts an `if_sheet_exists` parameter to control the behavior of append mode when writing to existing sheets (GH40230)
- `Rolling.sum()`, `Expanding.sum()`, `Rolling.mean()`, `Expanding.mean()`, `ExponentialMovingWindow.mean()`, `Rolling.median()`, `Expanding.median()`, `Rolling.max()`, `Expanding.max()`, `Rolling.min()`, and `Expanding.min()` now support Numba execution with the `engine` keyword (GH38895, GH41267)
- `DataFrame.apply()` can now accept NumPy unary operators as strings, e.g. `df.apply("sqrt")`, which was already the case for `Series.apply()` (GH39116)
- `DataFrame.apply()` can now accept non-callable DataFrame properties as strings, e.g. `df.apply("size")`, which was already the case for `Series.apply()` (GH39116)
- `DataFrame.applymap()` can now accept kwargs to pass on to the user-provided `func` (GH39987)
- Passing a `DataFrame` indexer to `iloc` is now disallowed for `Series.__getitem__()` and `DataFrame.__getitem__()` (GH39004)
- `Series.apply()` can now accept list-like or dictionary-like arguments that aren’t lists or dictionaries, e.g. `ser.apply(np.array(["sum", "mean"]))`, which was already the case for `DataFrame.apply()` (GH39140)
- `DataFrame.plot.scatter()` can now accept a categorical column for the argument `c` (GH12380, GH31357)
- `Series.loc()` now raises a helpful error message when the Series has a `MultiIndex` and the indexer has too many dimensions (GH35349)
- `read_stata()` now supports reading data from compressed files (GH26599)
- Added support for parsing ISO 8601-like timestamps with negative signs to `Timedelta` (GH37172)
- Added support for unary operators in `FloatingArray` (GH38749)
- `RangeIndex` can now be constructed by passing a `range` object directly e.g. `pd.RangeIndex(range(3))` (GH12067)
- `Series.round()` and `DataFrame.round()` now work with nullable integer and floating dtypes (GH38844)
- `read_csv()` and `read_json()` expose the argument `encoding_errors` to control how encoding errors are handled (GH39450)
- `GroupBy.any()` and `GroupBy.all()` use Kleene logic with nullable data types (GH37506)
- `GroupBy.any()` and `GroupBy.all()` return a `BooleanDtype` for columns with nullable data types (GH33449)
- `GroupBy.any()` and `GroupBy.all()` raising with `object` data containing `pd.NA` even when `skipna=True` (GH37501)
- `GroupBy.rank()` now supports object-dtype data (GH38278)
- Constructing a `DataFrame` or `Series` with the `data` argument being a Python iterable that is not a NumPy `ndarray` consisting of NumPy scalars will now result in a dtype with a precision the maximum of the NumPy scalars; this was already the case when `data` is a NumPy `ndarray` (GH40908)
- Add keyword `sort` to `pivot_table()` to allow non-sorting of the result (GH39143)
• Add keyword dropna to `DataFrame.value_counts()` to allow counting rows that include NA values (GH41325)

• `Series.replace()` will now cast results to `PeriodDtype` where possible instead of `object` dtype (GH41526)

• Improved error message in `corr` and `cov` methods on `Rolling`, `Expanding`, and `ExponentialMovingWindow` when other is not a `DataFrame` or `Series` (GH41741)

• `Series.between()` can now accept `left` or `right` as arguments to `inclusive` to include only the left or right boundary (GH40245)

• `DataFrame.explode()` now supports exploding multiple columns. Its `column` argument now also accepts a list of str or tuples for exploding on multiple columns at the same time (GH39240)

• `DataFrame.sample()` now accepts the `ignore_index` argument to reset the index after sampling, similar to `DataFrame.drop_duplicates()` and `DataFrame.sort_values()` (GH38581)

Notable bug fixes

These are bug fixes that might have notable behavior changes.

**Categorical.unique now always maintains same dtype as original**

Previously, when calling `Categorical.unique()` with categorical data, unused categories in the new array would be removed, making the dtype of the new array different than the original (GH18291)

As an example of this, given:

```
In [19]: dtype = pd.CategoricalDtype(['bad', 'neutral', 'good'], ordered=True)
In [20]: cat = pd.Categorical(['good', 'good', 'bad', 'bad'], dtype=dtype)
In [21]: original = pd.Series(cat)
In [22]: unique = original.unique()
```

**Previous behavior:**

```
In [1]: unique
['good', 'bad']
Categories (2, object): ['bad' < 'good']
In [2]: original.dtype == unique.dtype
False
```

**New behavior:**

```
In [23]: unique
['good', 'bad']
Categories (3, object): ['bad' < 'neutral' < 'good']
In [24]: original.dtype == unique.dtype
Out[24]: True
```
Preserve dtypes in DataFrame.combine_first()

`DataFrame.combine_first()` will now preserve dtypes (GH7509)

```python
In [25]: df1 = pd.DataFrame({"A": [1, 2, 3], "B": [1, 2, 3]}, index=[0, 1, 2])

In [26]: df1
Out[26]:
   A  B
0  1  1
1  2  2
2  3  3

In [27]: df2 = pd.DataFrame({"B": [4, 5, 6], "C": [1, 2, 3]}, index=[2, 3, 4])

In [28]: df2
Out[28]:
   B  C
2  4  1
3  5  2
4  6  3

In [29]: combined = df1.combine_first(df2)

Previous behavior:

```python
In [1]: combined.dtypes
Out[1]:
A   float64
B   float64
C   float64
dtype: object
```

New behavior:

```python
In [30]: combined.dtypes
Out[30]:
A   float64
B   int64
C   float64
dtype: object
```

Groupby methods agg and transform no longer changes return dtype for callables

Previously the methods `DataFrameGroupBy.aggregate()`, `SeriesGroupBy.aggregate()`, `DataFrameGroupBy.transform()`, and `SeriesGroupBy.transform()` might cast the result dtype when the argument `func` is callable, possibly leading to undesirable results (GH21240). The cast would occur if the result is numeric and casting back to the input dtype does not change any values as measured by `np.allclose`. Now no such casting occurs.

```python
In [31]: df = pd.DataFrame({'key': [1, 1], 'a': [True, False], 'b': [True, True]})

In [32]: df
Out[32]:
   key   a   b
0  1.0  True  True
1  1.0  True  False
```
Previous behavior:

```python
In [5]: df.groupby('key').agg(lambda x: x.sum())
Out[5]:
   a  b
key
  1  True 2
```

New behavior:

```python
In [33]: df.groupby('key').agg(lambda x: x.sum())
Out[33]:
   a  b
key
  1  1  2
```

Float result for `GroupBy.mean()`, `GroupBy.median()`, and `GroupBy.var()`

Previously, these methods could result in different dtypes depending on the input values. Now, these methods will always return a float dtype. (GH41137)

```python
In [34]: df = pd.DataFrame({'a': [True], 'b': [1], 'c': [1.0]})
In [5]: df.groupby(df.index).mean()
Out[5]:
   a  b  c
0  1  1  1.0
```

New behavior:

```python
In [35]: df.groupby(df.index).mean()
Out[35]:
   a  b  c
0  1.0 1.0 1.0
```

Try operating inplace when setting values with `loc` and `iloc`

When setting an entire column using `loc` or `iloc`, pandas will try to insert the values into the existing data rather than create an entirely new array.

```python
In [36]: df = pd.DataFrame(range(3), columns=['A'], dtype='float64')
In [37]: values = df.values
In [38]: new = np.array([5, 6, 7], dtype='int64')
In [39]: df.loc[[0, 1, 2], 'A'] = new
```
In both the new and old behavior, the data in `values` is overwritten, but in the old behavior the dtype of `df["A"]` changed to `int64`.

Previous behavior:

```python
In [1]: df.dtypes
Out[1]:
A    int64
dtype: object
In [2]: np.shares_memory(df["A"].values, new)
Out[2]: False
In [3]: np.shares_memory(df["A"].values, values)
Out[3]: False
```

In pandas 1.3.0, `df` continues to share data with `values`

New behavior:

```python
In [40]: df.dtypes
Out[40]:
A    float64
dtype: object
In [41]: np.shares_memory(df["A"], new)
Out[41]: False
In [42]: np.shares_memory(df["A"], values)
Out[42]: True
```

Never operate inplace when setting `frame[keys] = values`

When setting multiple columns using `frame[keys] = values` new arrays will replace pre-existing arrays for these keys, which will not be over-written (GH39510). As a result, the columns will retain the dtype(s) of `values`, never casting to the dtypes of the existing arrays.

```python
In [43]: df = pd.DataFrame(range(3), columns=["A"], dtype="float64")
In [44]: df[["A"]]. = 5
```

In the old behavior, 5 was cast to `float64` and inserted into the existing array backing `df`:

Previous behavior:

```python
In [1]: df.dtypes
Out[1]:
A    float64
```

In the new behavior, we get a new array, and retain an integer-dtyped 5:

New behavior:

```python
In [45]: df.dtypes
Out[45]:
A    int64
dtype: object
```
Consistent casting with setting into Boolean Series

Setting non-boolean values into a `Series` with `dtype=bool` now consistently casts to `dtype=object` (GH38709)

```python
In [46]: orig = pd.Series([True, False])
In [47]: ser = orig.copy()
In [48]: ser.iloc[1] = np.nan
In [49]: ser2 = orig.copy()
In [50]: ser2.iloc[1] = 2.0

Previous behavior:

```python
In [1]: ser
Out [1]:
0   1.0
1   NaN
dtype: float64

In [2]: ser2
Out [2]:
0   True
1   2.0
dtype: object
```

New behavior:

```python
In [51]: ser
Out[51]:
0   True
1   NaN
dtype: object

In [52]: ser2
Out[52]:
0   True
1   2.0
dtype: object
```

GroupBy.rolling no longer returns grouped-by column in values

The group-by column will now be dropped from the result of a `groupby.rolling` operation (GH32262)

```python
In [53]: df = pd.DataFrame({"A": [1, 1, 2, 3], "B": [0, 1, 2, 3]})

In [54]: df
Out[54]:
   A  B
0  1  0
1  1  1
2  2  2
3  3  3
```
Previous behavior:

```
In [1]: df.groupby("A").rolling(2).sum()
Out[1]:
   A   B
0  0   NaN NaN
1  2.0 1.0
2  NaN NaN
3  NaN NaN
```

New behavior:

```
In [55]: df.groupby("A").rolling(2).sum()
Out[55]:
   B
0  0   NaN
1  1.0
2  2   NaN
3  3   NaN
```

Removed artificial truncation in rolling variance and standard deviation

`Rolling.std()` and `Rolling.var()` will no longer artificially truncate results that are less than \(1\times10^{-8}\) and \(1\times10^{-15}\) respectively to zero (GH37051, GH40448, GH39872).

However, floating point artifacts may now exist in the results when rolling over larger values.

```
In [56]: s = pd.Series([7, 5, 5, 5])
In [57]: s.rolling(3).var()
Out[57]:
   0   NaN
   1   NaN
   2  1.333333e+00
   3  4.440892e-16
```

**GroupBy.rolling with MultiIndex no longer drops levels in the result**

`GroupBy.rolling()` will no longer drop levels of a DataFrame with a MultiIndex in the result. This can lead to a perceived duplication of levels in the resulting MultiIndex, but this change restores the behavior that was present in version 1.1.3 (GH38787, GH38523).

```
In [58]: index = pd.MultiIndex.from_tuples([('idx1', 'idx2')], names=['label1', 'label2'])
In [59]: df = pd.DataFrame({'a': [1], 'b': [2]}, index=index)
In [60]: df
Out[60]:
      a  b  
label1 idx1   idx2
 idx1   1      2
Previous behavior:

```python
In [1]: df.groupby('label1').rolling(1).sum()
Out[1]:
      a  b
label1
idx1   1.0  2.0
```

New behavior:

```python
In [61]: df.groupby('label1').rolling(1).sum()
Out[61]:
      a  b
label1  label1  label2
idx1    idx1    idx2   1.0  2.0
```

Backwards incompatible API changes

Increased minimum versions for dependencies

Some minimum supported versions of dependencies were updated. If installed, we now require:

<table>
<thead>
<tr>
<th>Package</th>
<th>Minimum Version</th>
<th>Required</th>
<th>Changed</th>
</tr>
</thead>
<tbody>
<tr>
<td>numpy</td>
<td>1.17.3</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>pytz</td>
<td>2017.3</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>python-dateutil</td>
<td>2.7.3</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>bottleneck</td>
<td>1.2.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>numexpr</td>
<td>2.7.0</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>pytest (dev)</td>
<td>6.0</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>mypy (dev)</td>
<td>0.812</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>setuptools</td>
<td>38.6.0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For optional libraries the general recommendation is to use the latest version. The following table lists the lowest version per library that is currently being tested throughout the development of pandas. Optional libraries below the lowest tested version may still work, but are not considered supported.
## Other API changes

- Partially initialized `CategoricalDtype` objects (i.e. those with `categories=None`) will no longer compare as equal to fully initialized dtype objects (GH38516)

- Accessing `_constructor_expanddim` on a `DataFrame` and `_constructor_sliced` on a `Series` now raise an `AttributeError`. Previously a `NotImplementedError` was raised (GH38782)

- Added new `engine` and `**engine_kwargs` parameters to `DataFrame.to_sql()` to support other future “SQL engines”. Currently we still only use SQLAlchemy under the hood, but more engines are planned to be supported such as turbodbc (GH36893)

- Removed redundant `freq` from `PeriodIndex` string representation (GH41653)

- `ExtensionDtype.construct_array_type()` is now a required method instead of an optional one for `ExtensionDtype` subclasses (GH24860)

- Calling `hash` on non-hashable pandas objects will now raise `TypeError` with the built-in error message (e.g. unhashable type: 'Series'). Previously it would raise a custom message such as 'Series' objects are mutable, thus they cannot be hashed. Furthermore, `isinstance(<Series>, abc.collections.Hashable)` will now return `False` (GH40013)

- `Styler.from_custom_template()` now has two new arguments for template names, and removed the old name, due to template inheritance having been introducing for better parsing (GH42053). Subclassing modifications to Styler attributes are also needed.

### Dependencies and Optional dependencies

See Dependencies and Optional dependencies for more.

### Table of Changed Dependencies

Build

- Documentation in .pptx and .pdf formats are no longer included in wheels or source distributions. (GH30741)

Deprecations

**Deprecated dropping nuisance columns in DataFrame reductions and DataFrameGroupBy operations**

Calling a reduction (e.g. .min, .max, .sum) on a DataFrame with numeric_only=None (the default), columns where the reduction raises a TypeError are silently ignored and dropped from the result.

This behavior is deprecated. In a future version, the TypeError will be raised, and users will need to select only valid columns before calling the function.

For example:

```python
In [62]: df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': pd.date_range('2016-01-01', periods=4)})
In [63]: df
Out[63]:
   A     B
0  1 2016-01-01
1  2 2016-01-02
2  3 2016-01-03
3  4 2016-01-04
```

**Old behavior:**

```python
In [3]: df.prod()
Out[3]:
Out[3]:
   A
0  24
dtype: int64
```

**Future behavior:**

```python
In [4]: df.prod()...
   ...TypeError: 'DatetimeArray' does not implement reduction 'prod'
In [5]: df[['A']].prod()
Out[5]:
   A
0  24
dtype: int64
```

Similarly, when applying a function to DataFrameGroupBy, columns on which the function raises TypeError are currently silently ignored and dropped from the result.

This behavior is deprecated. In a future version, the TypeError will be raised, and users will need to select only valid columns before calling the function.

For example:
Old behavior:

```python
In [4]: gb.prod(numeric_only=False)
Out[4]:
   A
1  2
2  12
```

Future behavior:

```python
In [5]: gb.prod(numeric_only=False)
...:  
TypeError: datetime64 type does not support prod operations

In [6]: gb["A"].prod(numeric_only=False)
Out[6]:
   A
1  2
2  12
```

Other Deprecations

- Deprecated allowing scalars to be passed to the `Categorical` constructor (GH38433)
- Deprecated constructing `CategoricalIndex` without passing list-like data (GH38944)
- Deprecated allowing subclass-specific keyword arguments in the `Index` constructor, use the specific subclass directly instead (GH14093, GH21311, GH22315, GH26974)
- Deprecated the `astype()` method of datetimelike (`timedelta64[ns]`, `datetime64[ns]`, `Datetime64TZDtype`, `PeriodDtype`) to convert to integer dtypes, use `values.view(...)` instead (GH38544)
- Deprecated `MultiIndex.is_lexsorted()` and `MultiIndex.lexsort_depth()`, use `MultiIndex.is_monotonic_increasing()` instead (GH32259)
- Deprecated keyword `try_cast` in `Series.where()`, `Series.mask()`, `DataFrame.where()`, `DataFrame.mask()`; cast results manually if desired (GH38836)
- Deprecated comparison of `Timestamp` objects with `datetime.date` objects. Instead of e.g. `ts <= mydate` use `ts <= pd.Timestamp(mydate)` or `ts.date() <= mydate` (GH36131)
- Deprecated `Rolling.win_type` returning "freq" (GH38963)
- Deprecated `Rolling.is_datetimelike` (GH38963)
- Deprecated `DataFrame` indexer for `Series.__setitem__()` and `DataFrame.__setitem__()` (GH39004)
- Deprecated `ExponentialMovingWindow.vol()` (GH39220)
- Using `.astype` to convert between `datetime64[ns]` dtype and `DatetimeTZDtype` is deprecated and will raise in a future version, use `obj.tz_localize` or `obj.dt.tz_localize` instead (GH38622)
• Deprecated casting `datetime.date` objects to `datetime64` when used as fill_value in `DataFrame.unstack()`, `DataFrame.shift()`, `Series.shift()`, and `DataFrame.reindex()`. Pass `pd.Timestamp(dateobj)` instead (GH39767)

• Deprecated `Styler.set_na_rep()` and `Styler.set_precision()` in favor of `Styler.format()` with na_rep and precision as existing and new input arguments respectively (GH40134, GH40425)

• Deprecated `Styler.where()` in favor of using an alternative formulation with `Styler.applymap()` (GH40821)

• Deprecated allowing partial failure in `Series.transform()` and `DataFrame.transform()` when func is list-like or dict-like and raises anything but `TypeError`; func raising anything but a `TypeError` will raise in a future version (GH40211)

• Deprecated arguments `error_bad_lines` and `warn_bad_lines` in `read_csv()` and `read_table()` in favor of argument `on_bad_lines` (GH15122)

• Deprecated support for np.ma.mrecords.MaskedRecords in the `DataFrame` constructor, pass `{name: data[name] for name in data.dtype.names}` instead (GH40363)

• Deprecated using `merge()`, `DataFrame.merge()`, and `DataFrame.join()` on a different number of levels (GH34862)

• Deprecated the use of `**kwargs` in `ExcelWriter`; use the keyword argument `engine_kwargs` instead (GH40430)

• Deprecated the `level` keyword for `DataFrame` and `Series` aggregations; use groupby instead (GH39983)

• Deprecated the `inplace` parameter of `Categorical.remove_categories()`, `Categorical.add_categories()`, `Categorical.reorder_categories()`, `Categorical.rename_categories()`, and `Categorical.set_categories()` and will be removed in a future version (GH37643)

• Deprecated `merge()` producing duplicated columns through the `suffixes` keyword and already existing columns (GH22818)

• Deprecated setting `Categorical._codes`, create a new `Categorical` with the desired codes instead (GH40606)

• Deprecated the `convert_float` optional argument in `read_excel()` and `ExcelFile.parse()` (GH41127)

• Deprecated behavior of `DatetimeIndex.union()` with mixed timezones; in a future version both will be cast to UTC instead of object dtype (GH39328)

• Deprecated using `usecols` with out of bounds indices for `read_csv()` with engine="c" (GH25623)

• Deprecated special treatment of lists with first element a Categorical in the `DataFrame` constructor; pass as `pd.DataFrame({col: categorical, ...})` instead (GH38845)

• Deprecated behavior of `DataFrame` constructor when a `dtype` is passed and the data cannot be cast to that dtype. In a future version, this will raise instead of being silently ignored (GH24435)

• Deprecated the `Timestamp.freq` attribute. For the properties that use it (is_month_start, is_month_end, is_quarter_start, is_quarter_end, is_year_start, is_year_end), when you have a freq, use e.g. `freq.is_month_start(ts)` (GH15146)

• Deprecated construction of `Series` or `DataFrame` with `DatetimeTZDtype` data and `datetime64` dtype. Use `Series(data).dt.tz_localize(None)` instead (GH41555, GH33401)

• Deprecated behavior of `Series` construction with large-integer values and small-integer dtype silently over-flowing; use `Series(data).astype(dtype)` instead (GH41734)
• Deprecated behavior of DataFrame construction with floating data and integer dtype casting even when lossy; in a future version this will remain floating, matching Series behavior (GH41770)

• Deprecated inference of timedelta64[ns], datetime64[ns], or DatetimeTZDtype dtypes in Series construction when data containing strings is passed and no dtype is passed (GH33558)

• In a future version, constructing Series or DataFrame with datetime64[ns] data and DatetimeTZDtype will treat the data as wall-times instead of as UTC times (matching DatetimeIndex behavior). To treat the data as UTC times, use pd.Series(data).dt.tz_localize("UTC").dt.tz_convert(dtype.tz) or pd.Series(data.view("int64"), dtype=dtype) (GH33401)

• Deprecated passing lists as key to DataFrame.xs() and Series.xs() (GH41760)

• Deprecated boolean arguments of inclusive in Series.between() to have "left", "right", "neither", "both" as standard argument values (GH40628)

• Deprecated passing arguments as positional for all of the following, with exceptions noted (GH41485):
  - concat() (other than objs)
  - read_csv() (other than filepath_or_buffer)
  - read_table() (other than filepath_or_buffer)
  - DataFrame.clip() and Series.clip() (other than upper and lower)
  - DataFrame.drop_duplicates() (except for subset), Series.drop_duplicates(), Index.drop_duplicates() and MultiIndex.drop_duplicates()
  - DataFrame.drop() (other than labels) and Series.drop()
  - DataFrame.dropna() and Series.dropna()
  - DataFrame.ffill(), Series.ffill(), DataFrame.bfill(), and Series.bfill()
  - DataFrame.fillna() and Series.fillna() (apart from value)
  - DataFrame.interpolate() and Series.interpolate() (other than method)
  - DataFrame.mask() and Series.mask() (other than cond and other)
  - DataFrame.reset_index() (other than level) and Series.reset_index()
  - DataFrame.set_axis() and Series.set_axis() (other than labels)
  - DataFrame.set_index() (other than keys)
  - DataFrame.sort_index() and Series.sort_index()
  - DataFrame.sort_values() (other than by) and Series.sort_values()
  - DataFrame.where() and Series.where() (other than cond and other)
  - Index.set_names() and MultiIndex.set_names() (except for names)
  - MultiIndex.codes() (except for codes)
  - MultiIndex.set_levels() (except for levels)
  - Resampler.interpolate() (other than method)
Performance improvements

• Performance improvement in `IntervalIndex.isin()` (GH38353)
• Performance improvement in `Series.mean()` for nullable data types (GH34814)
• Performance improvement in `Series.isin()` for nullable data types (GH38340)
• Performance improvement in `DataFrame.fillna()` with method="pad" or method="backfill" for nullable floating and nullable integer dtypes (GH39953)
• Performance improvement in `DataFrame.corr()` for method=kendall (GH28329)
• Performance improvement in `DataFrame.corr()` for method=spearman (GH40956, GH41885)
• Performance improvement in `Rolling.corr()` and `Rolling.cov()` (GH39388)
• Performance improvement in `RollingGroupby.corr()`, `ExpandingGroupby.corr()` and `ExpandingGroupby.cov()` (GH39953)
• Performance improvement in `unique()` for object data type (GH37615)
• Performance improvement in `json_normalize()` for basic cases (including separators) (GH40035 GH15621)
• Performance improvement in `ExpandingGroupby` aggregation methods (GH39664)
• Performance improvement in `Styler` where render times are more than 50% reduced and now matches `DataFrame.to_html()` (GH39972 GH39952, GH40425)
• The method `Styler.set_td_classes()` is now as performant as `Styler.apply()` and `Styler.applymap()`, and even more so in some cases (GH40453)
• Performance improvement in `ExponentialMovingWindow.mean()` with times (GH39784)
• Performance improvement in `GroupBy.apply()` when requiring the Python fallback implementation (GH40176)
• Performance improvement in the conversion of a PyArrow Boolean array to a pandas nullable Boolean array (GH41051)
• Performance improvement for concatenation of data with type `CategoricalDtype` (GH40193)
• Performance improvement in `GroupBy.cummin()` and `GroupBy.cummax()` with nullable data types (GH37493)
• Performance improvement in `Series.nunique()` with nan values (GH40865)
• Performance improvement in `DataFrame.transpose()`, `Series.unstack()` with DatetimeTZDtype (GH40149)
• Performance improvement in `Series.plot()` and `DataFrame.plot()` with entry point lazy loading (GH41492)
Bug fixes

Categorical

- Bug in `CategoricalIndex` incorrectly failing to raise `TypeError` when scalar data is passed (GH38614)
- Bug in `CategoricalIndex.reindex` failed when the `Index` passed was not categorical but whose values were all labels in the category (GH28690)
- Bug where constructing a `Categorical` from an object-dtype array of date objects did not round-trip correctly with `astype` (GH38552)
- Bug in constructing a `DataFrame` from an `ndarray` and a `CategoricalDtype` (GH38857)
- Bug in setting categorical values into an object-dtype column in a `DataFrame` (GH39136)
- Bug in `DataFrame.reindex()` was raising an `IndexError` when the new index contained duplicates and the old index was a `CategoricalIndex` (GH38906)
- Bug in `Categorical.fillna()` with a tuple-like category raising `NotImplementedError` instead of `ValueError` when filling with a non-category tuple (GH41914)

Datetimelike

- Bug in `DataFrame` and `Series` constructors sometimes dropping nanoseconds from `Timestamp` (resp. `Timedelta`) data, with `dtype=datetime64[ns]` (resp. `timedelta64[ns]`) (GH38032)
- Bug in `DataFrame.first()` and `Series.first()` with an offset of one month returning an incorrect result when the first day is the last day of a month (GH29623)
- Bug in constructing a `DataFrame` or `Series` with mismatched `datetime64` data and `timedelta64` dtype, or vice-versa, failing to raise a `TypeError` (GH38792, GH38965)
- Bug in `Categorical` incorrectly typecasting `datetime` object to `Timestamp` (GH38878)
- Bug in comparisons between `Timestamp` object and `datetime64` objects just outside the implementation bounds for nanosecond `datetime64` (GH39221)
- Bug in `Timestamp.round()`, `Timestamp.floor()`, `Timestamp.ceil()` for values near the implementation bounds of `Timestamp` (GH39244)
- Bug in `Timedelta.round()`, `Timedelta.floor()`, `Timedelta.ceil()` for values near the implementation bounds of `Timedelta` (GH38964)
- Bug in `date_range()` incorrectly creating `DatetimeIndex` containing `NaT` instead of raising `OutOfBoundsDatetime` in corner cases (GH24124)
- Bug in `infer_freq()` incorrectly fails to infer ‘H’ frequency of `DatetimeIndex` if the latter has a timezone and crosses DST boundaries (GH39556)
• Bug in *Series* backed by *DatetimeArray* or *TimedeltaArray* sometimes failing to set the array’s freq to None (GH41425)

**Timedelta**

• Bug in constructing *Timedelta* from *np.timedelta64* objects with non-nanosecond units that are out of bounds for *timedelta64[ns]* (GH38965)
