pandas: powerful Python data analysis toolkit

Release 1.1.5

Wes McKinney and the Pandas Development Team

Dec 07, 2020
## 1 Getting started

1. **Installation** ................................................................. 3
2. **Intro to pandas** .......................................................... 3
3. **Coming from** ............................................................. 5
4. **Tutorials** ................................................................. 5
    1.4.1 **Installation** .................................................. 5
    1.4.2 **Package overview** ........................................... 10
    1.4.3 **Getting started tutorials** .................................... 13
    1.4.4 **Comparison with other tools** ............................... 58
    1.4.5 **Community tutorials** ........................................ 110

## 2 User Guide

2. **10 minutes to pandas** .................................................. 113
    2.1.1 **Object creation** ............................................. 113
    2.1.2 **Viewing data** ............................................... 115
    2.1.3 **Selection** .................................................... 117
    2.1.4 **Missing data** ................................................ 122
    2.1.5 **Operations** .................................................. 122
    2.1.6 **Merge** ........................................................ 125
    2.1.7 **Grouping** ..................................................... 127
    2.1.8 **Reshaping** ................................................... 128
    2.1.9 **Time series** ................................................ 130
    2.1.10 **Categoricals** .............................................. 132
    2.1.11 **Plotting** ..................................................... 133
    2.1.12 **Getting data in/out** ....................................... 135
    2.1.13 **Gotchas** ..................................................... 137

2. **Intro to data structures** .............................................. 137
    2.2.1 **Series** ........................................................ 137
    2.2.2 **DataFrame** .................................................. 143

2. **Essential basic functionality** ........................................ 160
    2.3.1 **Head and tail** ............................................... 160
    2.3.2 **Attributes and underlying data** ............................ 161
    2.3.3 **Accelerated operations** .................................... 163
    2.3.4 **Flexible binary operations** ................................ 163
    2.3.5 **Descriptive statistics** ..................................... 172
    2.3.6 **Function application** ...................................... 180
    2.3.7 **Reindexing and altering labels** ............................ 193
    2.3.8 **Iteration** ..................................................... 202
    2.3.9 **.dt accessor** ............................................... 205
    2.3.10 **Vectorized string methods** ............................... 209

4 Development

4.1 Contributing to pandas
4.1.1 Where to start?
4.1.2 Bug reports and enhancement requests
4.1.3 Working with the code
4.1.4 Contributing to the documentation
4.1.5 Contributing to the code base
4.1.6 Contributing your changes to pandas
4.1.7 Tips for a successful pull request
4.1.8 pandas code style guide
4.1.9 Patterns
4.1.10 String formatting
4.1.11 Imports (aim for absolute)
4.1.12 Miscellaneous
4.1.13 Roles
4.1.14 Tasks
4.1.15 Issue triage
4.1.16 Closing issues
4.1.17 Reviewing pull requests
4.1.18 Cleaning up old issues
4.1.19 Cleaning up old pull requests
4.1.20 Becoming a pandas maintainer
4.2 pandas maintenance
4.2.1 Registering custom accessors
4.2.2 Subclassing pandas data structures
4.2.3 Extension types
4.2.4 Plotting backends
4.2.5 Miscellaneous
4.3 Internals
4.3.1 Indexing
4.3.2 Subclassing pandas data structures
4.4 Extending pandas
4.4.1 Registering custom accessors
4.4.2 Subclassing pandas data structures
4.4.3 Plotting backends
4.5 Developer
4.5.1 Storing pandas DataFrame objects in Apache Parquet format
4.6 Policies
4.7 Roadmap
4.7.1 Version policy
4.8 Internals
4.8.1 Numba-accelerated operations
5 Release notes

5.1 Version 1.1
5.1.1 What’s new in 1.1.5 (December 07, 2020)
5.1.2 What’s new in 1.1.4 (October 30, 2020)
5.1.3 What’s new in 1.1.3 (October 5, 2020)
5.1.4 What’s new in 1.1.2 (September 8, 2020)
5.1.5 What’s new in 1.1.1 (August 20, 2020)
5.1.6 What’s new in 1.1.0 (July 28, 2020)

5.2 Version 1.0
5.2.1 What’s new in 1.0.5 (June 17, 2020)
5.2.2 What’s new in 1.0.4 (May 28, 2020)
5.2.3 What’s new in 1.0.3 (March 17, 2020)
5.2.4 What’s new in 1.0.2 (March 12, 2020)
5.2.5 What’s new in 1.0.1 (February 5, 2020)
5.2.6 What’s new in 1.0.0 (January 29, 2020)

5.3 Version 0.25
5.3.1 What’s new in 0.25.3 (October 31, 2019)
5.3.2 What’s new in 0.25.2 (October 15, 2019)
5.3.3 What’s new in 0.25.1 (August 21, 2019)
5.3.4 What’s new in 0.25.0 (July 18, 2019)

5.4 Version 0.24
5.4.1 What’s new in 0.24.2 (March 12, 2019)
5.4.2 What’s new in 0.24.1 (February 3, 2019)
5.4.3 What’s new in 0.24.0 (January 25, 2019)

5.5 Version 0.23
5.5.1 What’s new in 0.23.4 (August 3, 2018)
5.5.2 What’s new in 0.23.3 (July 7, 2018)
5.5.3 What’s new in 0.23.2 (July 5, 2018)
5.5.4 What’s new in 0.23.1 (June 12, 2018)
5.5.5 What’s new in 0.23.0 (May 15, 2018)

5.6 Version 0.22
5.6.1 v0.22.0 (December 29, 2017)

5.7 Version 0.21
5.7.1 Version 0.21.1 (December 12, 2017)
5.7.2 Version 0.21.0 (October 27, 2017)

5.8 Version 0.20
5.8.1 Version 0.20.3 (July 7, 2017)
5.8.2 Version 0.20.2 (June 4, 2017)
5.8.3 Version 0.20.1 (May 5, 2017)

5.9 Version 0.19
5.9.1 Version 0.19.2 (December 24, 2016)
5.9.2 Version 0.19.1 (November 3, 2016)
5.9.3 Version 0.19.0 (October 2, 2016)

5.10 Version 0.18
5.10.1 Version 0.18.1 (May 3, 2016)
5.10.2 Version 0.18.0 (March 13, 2016)

5.11 Version 0.17

CHAPTER ONE

GETTING STARTED

1.1 Installation

pandas is part of the Anaconda distribution and can be installed with Anaconda or Miniconda:

```
conda install pandas
```

pandas can be installed via pip from PyPI.

```
pip install pandas
```

1.2 Intro to pandas

* Straight to tutorial... *

When working with tabular data, such as data stored in spreadsheets or databases, pandas is the right tool for you. pandas will help you to explore, clean and process your data. In pandas, a data table is called a `DataFrame`.

* To introduction tutorial *

* To user guide *

* Straight to tutorial... *

pandas supports the integration with many file formats or data sources out of the box (csv, excel, sql, json, parquet, ...). Importing data from each of these data sources is provided by function with the prefix `read_*`. Similarly, the `to_*` methods are used to store data.

* To introduction tutorial *

* To user guide *

* Straight to tutorial... *

Selecting or filtering specific rows and/or columns? Filtering the data on a condition? Methods for slicing, selecting, and extracting the data you need are available in pandas.

* To introduction tutorial *
pandas provides plotting your data out of the box, using the power of Matplotlib. You can pick the plot type (scatter, bar, boxplot,...) corresponding to your data.

There is no need to loop over all rows of your data table to do calculations. Data manipulations on a column work elementwise. Adding a column to a DataFrame based on existing data in other columns is straightforward.

Basic statistics (mean, median, min, max, counts...) are easily calculable. These or custom aggregations can be applied on the entire data set, a sliding window of the data or grouped by categories. The latter is also known as the split-apply-combine approach.

Change the structure of your data table in multiple ways. You can melt() your data table from wide to long/tidy form or pivot() from long to wide format. With aggregations built-in, a pivot table is created with a single command.

Multiple tables can be concatenated both column wise as row wise and database-like join/merge operations are provided to combine multiple tables of data.

pandas has great support for time series and has an extensive set of tools for working with dates, times, and time-indexed data.
Data sets do not only contain numerical data. pandas provides a wide range of functions to cleaning textual data and extract useful information from it.

1.4 Tutorials

For a quick overview of pandas functionality, see 10 Minutes to pandas.

You can also reference the pandas cheat sheet for a succinct guide for manipulating data with pandas.

The community produces a wide variety of tutorials available online. Some of the material is enlisted in the community contributed Community tutorials.

1.4.1 Installation

The easiest way to install pandas is to install it as part of the Anaconda distribution, a cross platform distribution for data analysis and scientific computing. This is the recommended installation method for most users.

Instructions for installing from source, PyPI, ActivePython, various Linux distributions, or a development version are also provided.

Python version support

Officially Python 3.6.1 and above, 3.7, 3.8, and 3.9.

Installing pandas

Installing with Anaconda

Installing pandas and the rest of the NumPy and SciPy stack can be a little difficult for inexperienced users.

The simplest way to install not only pandas, but Python and the most popular packages that make up the SciPy stack (IPython, NumPy, Matplotlib, ...) is with Anaconda, a cross-platform (Linux, Mac OS X, Windows) Python distribution for data analytics and scientific computing.

After running the installer, the user will have access to pandas and the rest of the SciPy stack without needing to install anything else, and without needing to wait for any software to be compiled.
Installation instructions for Anaconda can be found here.
A full list of the packages available as part of the Anaconda distribution can be found here.
Another advantage to installing Anaconda is that you don’t need admin rights to install it. Anaconda can install in the user’s home directory, which makes it trivial to delete Anaconda if you decide (just delete that folder).

**Installing with Miniconda**

The previous section outlined how to get pandas installed as part of the Anaconda distribution. However this approach means you will install well over one hundred packages and involves downloading the installer which is a few hundred megabytes in size.

If you want to have more control on which packages, or have a limited internet bandwidth, then installing pandas with Miniconda may be a better solution.

Conda is the package manager that the Anaconda distribution is built upon. It is a package manager that is both cross-platform and language agnostic (it can play a similar role to a pip and virtualenv combination).

Miniconda allows you to create a minimal self contained Python installation, and then use the Conda command to install additional packages.

First you will need Conda to be installed and downloading and running the Miniconda will do this for you. The installer can be found here.

The next step is to create a new conda environment. A conda environment is like a virtualenv that allows you to specify a specific version of Python and set of libraries. Run the following commands from a terminal window:

```
conda create -n name_of_my_env python
```

This will create a minimal environment with only Python installed in it. To put your self inside this environment run:

```
source activate name_of_my_env
```

On Windows the command is:

```
activate name_of_my_env
```

The final step required is to install pandas. This can be done with the following command:

```
conda install pandas
```

To install a specific pandas version:

```
conda install pandas=0.20.3
```

To install other packages, IPython for example:

```
conda install ipython
```

To install the full Anaconda distribution:

```
conda install anaconda
```

If you need packages that are available to pip but not conda, then install pip, and then use pip to install those packages:

```
conda install pip
pip install django
```
Installing from PyPI

pandas can be installed via pip from PyPI.

```
pip install pandas
```

Installing with ActivePython

Installation instructions for ActivePython can be found here. Versions 2.7, 3.5 and 3.6 include pandas.

Installing using your Linux distribution's package manager.

The commands in this table will install pandas for Python 3 from your distribution.

<table>
<thead>

</tbody>
</table>

However, the packages in the linux package managers are often a few versions behind, so to get the newest version of pandas, it’s recommended to install using the pip or conda methods described above.

Handling ImportErrors

If you encounter an ImportError, it usually means that Python couldn’t find pandas in the list of available libraries. Python internally has a list of directories it searches through, to find packages. You can obtain these directories with:

```
import sys
sys.path
```

One way you could be encountering this error is if you have multiple Python installations on your system and you don’t have pandas installed in the Python installation you’re currently using. In Linux/Mac you can run `which python` on your terminal and it will tell you which Python installation you’re using. If it’s something like “/usr/bin/python”, you’re using the Python from the system, which is not recommended.

It is highly recommended to use conda, for quick installation and for package and dependency updates. You can find simple installation instructions for pandas in this document: installation instructions </getting_started.html>. 

1.4. Tutorials
Installing from source

See the contributing guide for complete instructions on building from the git source tree. Further, see creating a development environment if you wish to create a pandas development environment.

Running the test suite

pandas is equipped with an exhaustive set of unit tests, covering about 97% of the code base as of this writing. To run it on your machine to verify that everything is working (and that you have all of the dependencies, soft and hard, installed), make sure you have pytest >= 5.0.1 and Hypothesis >= 3.58, then run:

```python
>>> pd.test()
running: pytest --skip-slow --skip-network C:\Users\TP\Anaconda3\envs\py36\lib\site-packages\pandas
================================= test session starts =================================
platform win32 -- Python 3.6.2, pytest-3.6.0, py-1.4.34, pluggy-0.4.0
rootdir: C:\Users\TP\Documents\Python\pandasdev\pandas, inifile: setup.cfg
collected 12145 items / 3 skipped

..................................................................S......
........S.................................................................
........................................................................

</thead>
<tbody>
<tr>
<td>setuptools</td>
<td>24.2.0</td>
</tr>
<tr>
<td>NumPy</td>
<td>1.15.4</td>
</tr>
<tr>
<td>python-dateutil</td>
<td>2.7.3</td>
</tr>
<tr>
<td>pytz</td>
<td>2017.2</td>
</tr>
</tbody>
</table>

Recommended dependencies

- **numexpr**: for accelerating certain numerical operations. numexpr uses multiple cores as well as smart chunking and caching to achieve large speedups. If installed, must be Version 2.6.2 or higher.

- **bottleneck**: for accelerating certain types of nan evaluations. bottleneck uses specialized cython routines to achieve large speedups. If installed, must be Version 1.2.1 or higher.

**Note**: You are highly encouraged to install these libraries, as they provide speed improvements, especially when working with large data sets.
Optional dependencies

Pandas has many optional dependencies that are only used for specific methods. For example, pandas.\texttt{read_hdf()} requires the \texttt{pytables} package, while \texttt{DataFrame.to_markdown()} requires the \texttt{tabulate} package. If the optional dependency is not installed, pandas will raise an \texttt{ImportError} when the method requiring that dependency is called.

Optional dependencies for parsing HTML

One of the following combinations of libraries is needed to use the top-level `read_html()` function:

Changed in version 0.23.0.

- BeautifulSoup4 and html5lib
- BeautifulSoup4 and lxml
- BeautifulSoup4 and html5lib and lxml
- Only lxml, although see HTML Table Parsing for reasons as to why you should probably not take this approach.

**Warning:**

- if you install BeautifulSoup4 you must install either lxml or html5lib or both. `read_html()` will not work with only BeautifulSoup4 installed.
- You are highly encouraged to read HTML Table Parsing gotchas. It explains issues surrounding the installation and usage of the above three libraries.

1.4.2 Package overview

**pandas** is a Python package providing fast, flexible, and expressive data structures designed to make working with “relational” or “labeled” data both easy and intuitive. It aims to be the fundamental high-level building block for doing practical, real world data analysis in Python. Additionally, it has the broader goal of becoming the most powerful and flexible open source data analysis / manipulation tool available in any language. It is already well on its way toward this goal.

pandas is well suited for many different kinds of data:

- Tabular data with heterogeneously-typed columns, as in an SQL table or Excel spreadsheet
- Ordered and unordered (not necessarily fixed-frequency) time series data.
- Arbitrary matrix data (homogeneously typed or heterogeneous) with row and column labels
- Any other form of observational / statistical data sets. The data actually need not be labeled at all to be placed into a pandas data structure

The two primary data structures of pandas, *Series* (1-dimensional) and *DataFrame* (2-dimensional), handle the vast majority of typical use cases in finance, statistics, social science, and many areas of engineering. For R users, *DataFrame* provides everything that R’s `data.frame` provides and much more. pandas is built on top of NumPy and is intended to integrate well within a scientific computing environment with many other 3rd party libraries.

Here are just a few of the things that pandas does well:

- Easy handling of missing data (represented as NaN) in floating point as well as non-floating point data
- Size mutability: columns can be inserted and deleted from DataFrame and higher dimensional objects
- Automatic and explicit data alignment: objects can be explicitly aligned to a set of labels, or the user can simply ignore the labels and let Series, DataFrame, etc. automatically align the data for you in computations
- Powerful, flexible group by functionality to perform split-apply-combine operations on data sets, for both aggregating and transforming data
- Make it easy to convert ragged, differently-indexed data in other Python and NumPy data structures into DataFrame objects
• Intelligent label-based slicing, fancy indexing, and subsetting of large data sets

• Intuitive merging and joining data sets

• Flexible reshaping and pivoting of data sets

• Hierarchical labeling of axes (possible to have multiple labels per tick)

• Robust IO tools for loading data from flat files (CSV and delimited), Excel files, databases, and saving / loading data from the ultrafast HDF5 format

• Time series-specific functionality: date range generation and frequency conversion, moving window statistics, date shifting and lagging.

Many of these principles are here to address the shortcomings frequently experienced using other languages / scientific research environments. For data scientists, working with data is typically divided into multiple stages: munging and cleaning data, analyzing / modeling it, then organizing the results of the analysis into a form suitable for plotting or tabular display. pandas is the ideal tool for all of these tasks.

Some other notes

• pandas is fast. Many of the low-level algorithmic bits have been extensively tweaked in Cython code. However, as with anything else generalization usually sacrifices performance. So if you focus on one feature for your application you may be able to create a faster specialized tool.

• pandas is a dependency of statsmodels, making it an important part of the statistical computing ecosystem in Python.

• pandas has been used extensively in production in financial applications.

Data structures

<table>
<thead>
<tr>
<th>Dimensions</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Series</td>
<td>1D labeled homogeneously-typed array</td>
</tr>
<tr>
<td>2</td>
<td>DataFrame</td>
<td>General 2D labeled, size-mutable tabular structure with potentially heterogeneous-typed column</td>
</tr>
</tbody>
</table>

Why more than one data structure?

The best way to think about the pandas data structures is as flexible containers for lower dimensional data. For example, DataFrame is a container for Series, and Series is a container for scalars. We would like to be able to insert and remove objects from these containers in a dictionary-like fashion.

Also, we would like sensible default behaviors for the common API functions which take into account the typical orientation of time series and cross-sectional data sets. When using ndarrays to store 2- and 3-dimensional data, a burden is placed on the user to consider the orientation of the data set when writing functions; axes are considered more or less equivalent (except when C- or Fortran-contiguousness matters for performance). In pandas, the axes are intended to lend more semantic meaning to the data; i.e., for a particular data set there is likely to be a “right” way to orient the data. The goal, then, is to reduce the amount of mental effort required to code up data transformations in downstream functions.

For example, with tabular data (DataFrame) it is more semantically helpful to think of the index (the rows) and the columns rather than axis 0 and axis 1. Iterating through the columns of the DataFrame thus results in more readable code:
```python
for col in df.columns:
    series = df[col]
    # do something with series
```

## Mutability and copying of data

All pandas data structures are value-mutable (the values they contain can be altered) but not always size-mutable. The length of a Series cannot be changed, but, for example, columns can be inserted into a DataFrame. However, the vast majority of methods produce new objects and leave the input data untouched. In general we like to favor immutability where sensible.

## Getting support

The first stop for pandas issues and ideas is the Github Issue Tracker. If you have a general question, pandas community experts can answer through Stack Overflow.

## Community

pandas is actively supported today by a community of like-minded individuals around the world who contribute their valuable time and energy to help make open source pandas possible. Thanks to all of our contributors.

If you’re interested in contributing, please visit the contributing guide.

pandas is a NumFOCUS sponsored project. This will help ensure the success of development of pandas as a world-class open-source project, and makes it possible to donate to the project.

## Project governance

The governance process that pandas project has used informally since its inception in 2008 is formalized in Project Governance documents. The documents clarify how decisions are made and how the various elements of our community interact, including the relationship between open source collaborative development and work that may be funded by for-profit or non-profit entities.

Wes McKinney is the Benevolent Dictator for Life (BDFL).

## Development team

The list of the Core Team members and more detailed information can be found on the people’s page of the governance repo.

## Institutional partners

The information about current institutional partners can be found on pandas website page.
1.4.3 Getting started tutorials

What kind of data does pandas handle?

I want to start using pandas

```python
In [1]: import pandas as pd
```

To load the pandas package and start working with it, import the package. The community agreed alias for pandas is `pd`, so loading pandas as `pd` is assumed standard practice for all of the pandas documentation.
I want to store passenger data of the Titanic. For a number of passengers, I know the name (characters), age (integers) and sex (male/female) data.

```python
In [2]: df = pd.DataFrame({
...:     "Name": ["Braund, Mr. Owen Harris",
...:     "Allen, Mr. William Henry",
...:     "Bonnell, Miss. Elizabeth"],
...:     "Age": [22, 35, 58],
...:     "Sex": ["male", "male", "female"]
...: })
...:
In [3]: df
```

```
Out[3]:
```

<table>
<thead>
<tr>
<th></th>
<th>Name</th>
<th>Age</th>
<th>Sex</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Braund, Mr. Owen Harris</td>
<td>22</td>
<td>male</td>
</tr>
<tr>
<td>1</td>
<td>Allen, Mr. William Henry</td>
<td>35</td>
<td>male</td>
</tr>
<tr>
<td>2</td>
<td>Bonnell, Miss. Elizabeth</td>
<td>58</td>
<td>female</td>
</tr>
</tbody>
</table>

To manually store data in a table, create a DataFrame. When using a Python dictionary of lists, the dictionary keys will be used as column headers and the values in each list as columns of the DataFrame.

A DataFrame is a 2-dimensional data structure that can store data of different types (including characters, integers, floating point values, categorical data and more) in columns. It is similar to a spreadsheet, a SQL table or the data.frame in R.

- The table has 3 columns, each of them with a column label. The column labels are respectively Name, Age and Sex.
- The column Name consists of textual data with each value a string, the column Age are numbers and the column Sex is textual data.

In spreadsheet software, the table representation of our data would look very similar:
Each column in a DataFrame is a Series

I’m just interested in working with the data in the column Age

```python
In [4]: df["Age"]
Out[4]:
0  22
1  35
2  58
Name: Age, dtype: int64
```

When selecting a single column of a pandas DataFrame, the result is a pandas Series. To select the column, use the column label in between square brackets [].

**Note:** If you are familiar to Python dictionaries, the selection of a single column is very similar to selection of dictionary values based on the key.

You can create a Series from scratch as well:

```python
In [5]: ages = pd.Series([22, 35, 58], name="Age")
In [6]: ages
Out[6]:
0  22
1  35
2  58
Name: Age, dtype: int64
```
A pandas Series has no column labels, as it is just a single column of a DataFrame. A Series does have row labels.

**Do something with a DataFrame or Series**

I want to know the maximum Age of the passengers

We can do this on the DataFrame by selecting the Age column and applying `max()`:

```
In [7]: df["Age"].max()
Out[7]: 58
```

Or to the Series:

```
In [8]: ages.max()
Out[8]: 58
```

As illustrated by the `max()` method, you can do things with a DataFrame or Series. pandas provides a lot of functionalities, each of them a method you can apply to a DataFrame or Series. As methods are functions, do not forget to use parentheses()

I’m interested in some basic statistics of the numerical data of my data table

```
In [9]: df.describe()
Out [9]:
                         Age
  count   3.000000
  mean   38.333333
   std   18.230012
   min   22.000000
  25%   28.500000
  50%   35.000000
  75%   46.500000
   max   58.000000
```

The `describe()` method provides a quick overview of the numerical data in a DataFrame. As the Name and Sex columns are textual data, these are by default not taken into account by the `describe()` method.

Many pandas operations return a DataFrame or a Series. The `describe()` method is an example of a pandas operation returning a pandas Series.

Check more options on `describe` in the user guide section about `aggregations with describe`

**Note:** This is just a starting point. Similar to spreadsheet software, pandas represents data as a table with columns and rows. Apart from the representation, also the data manipulations and calculations you would do in spreadsheet software are supported by pandas. Continue reading the next tutorials to get started!

- Import the package, aka `import pandas as pd`
- A table of data is stored as a pandas DataFrame
- Each column in a DataFrame is a Series
- You can do things by applying a method to a DataFrame or Series

A more extended explanation to DataFrame and Series is provided in the *introduction to data structures.*
This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- **PassengerId**: Id of every passenger.
- **Survived**: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- **Pclass**: There are 3 classes: Class 1, Class 2 and Class 3.
- **Name**: Name of passenger.
- **Sex**: Gender of passenger.
- **Age**: Age of passenger.
- **SibSp**: Indication that passenger have siblings and spouse.
- **Parch**: Whether a passenger is alone or have family.
- **Ticket**: Ticket number of passenger.
- **Fare**: Indicating the fare.
- **Cabin**: The cabin of passenger.
- **Embarked**: The embarked category.

### How do I read and write tabular data?

I want to analyze the Titanic passenger data, available as a CSV file.

```python
In [2]: titanic = pd.read_csv("data/titanic.csv")
```

pandas provides the `read_csv()` function to read data stored as a csv into a pandas DataFrame. pandas supports many different file formats or data sources out of the box (csv, excel, sql, json, parquet, ...), each of them with the prefix `read_*`.

Make sure to always have a check on the data after reading in the data. When displaying a DataFrame, the first and last 5 rows will be shown by default:

```python
In [3]: titanic
Out[3]:
   PassengerId  Survived  Pclass   Name          Sex ... Ticket  Fare Cabin  Embarked
   0          1          0       3  Braund, Mr. Owen Harris  male ... A/5 21171 7.2500 NaN S
   1          2          1       1  Cumings, Mrs. John Bradley (Florence Briggs Th... female ... PC 17599 71.2833 C85 C
   2          3          1       3  Heikkinen, Miss. Laina            female ... STON/O2. 3101282 7.9250 NaN S
   3          4          1       1  Futrelle, Mrs. Jacques Heath (Lily May Peel) female ... C123       113803 53.1000 C123 S
   4          5          0       3  Allen, Mr. William Henry           male ... 0 373450 8.0500 NaN S
   886        887          0       2 Montvila, Rev. Juozas ...
```

(continues on next page)
I want to see the first 8 rows of a pandas DataFrame.

```
In [4]: titanic.head(8)
Out[4]:
     PassengerId  Survived  Pclass     Name  Sex  Age Parch  SibSp  Ticket  Fare  Cabin Embarked
0         887       0      3  Braund, Mr. Owen Harris  male  29.0000  0    0         A/5 21171 7.2500 NaN      S
1         888       1      1  Cumings, Mrs. John Bradley (Florence Briggs Th... female  38.9583  0    1            PC 17599 71.2833 C85      C
2         889       0      3  Heikkinen, Miss. Laina  female  26.0000  0    0 STON/O2. 3101282 7.9250 NaN      S
3         890       0      1  Futrelle, Mrs. Jacques Heath (Lily May Peel) female  35.0000  0    0            C123 53.1000 C123      S
4         891       1      3  Allen, Mr. William Henry  male  35.0000  0    0            C123 53.1000 C123      S
5         892       0      3  Moran, Mr. James  male  27.0000  0    0 STON/O2. 3101282 7.9250 NaN      S
6         893       0      2     McCarthy, Mr. Timothy James  male  17.0000  0    0            E46 51.8625 E46      S
7         894       0      3  Palsson, Master. Gosta Leonard  male  24.0000  0    0 STON/O2. 3101282 7.9250 NaN      S
```

To see the first N rows of a DataFrame, use the `head()` method with the required number of rows (in this case 8) as argument.

**Note:** Interested in the last N rows instead? pandas also provides a `tail()` method. For example, `titanic.tail(10)` will return the last 10 rows of the DataFrame.

A check on how pandas interpreted each of the column data types can be done by requesting the pandas `dtypes` attribute:

```
In [5]: titanic.dtypes
Out[5]:
     PassengerId: int64
     Survived: int64
     Pclass: int64
     Name: object
     Sex: object
     Age: float64
     SibSp: int64
     Parch: int64
```

(continues on next page)
For each of the columns, the used data type is enlisted. The data types in this DataFrame are integers (int64), floats (float64) and strings (object).

**Note:** When asking for the dtypes, no brackets are used! dtypes is an attribute of a DataFrame and Series. Attributes of DataFrame or Series do not need brackets. Attributes represent a characteristic of a DataFrame/Series, whereas a method (which requires brackets) do something with the DataFrame/Series as introduced in the *first tutorial*.

My colleague requested the Titanic data as a spreadsheet.

In [6]: titanic.to_excel('titanic.xlsx', sheet_name='passengers', index=False)

Whereas read_* functions are used to read data to pandas, the to_* methods are used to store data. The to_excel() method stores the data as an excel file. In the example here, the sheet_name is named passengers instead of the default Sheet1. By setting index=False the row index labels are not saved in the spreadsheet.

The equivalent read function read_excel() will reload the data to a DataFrame:

In [7]: titanic = pd.read_excel('titanic.xlsx', sheet_name='passengers')

In [8]: titanic.head()

Out[8]:
```
   PassengerId  Survived  Pclass  Name             Sex  ...  Parch  Ticket  Fare  Cabin  Embarked
0            1       0        3  Braund, Mr. Owen Harris  male ...        0  A/5 21171  7.2500  NaN    S
1            2       1        1  Cumings, Mrs. John Bradley  female ...       0  PC 17599 71.2833   C85    C
2            3       0        3          Heikkinen, Miss. Laina  female ...       0  STON/O2. 3101282  7.9250  NaN    S
3            4       1        1  Futrelle, Mrs. Jacques Heath (Lily May Peel)  female ...       0  113803  53.1000  C123    S
4            5       0        3            Allen, Mr. William Henry  male ...       0  373450  8.0500   NaN    S
[5 rows x 12 columns]
```

I’m interested in a technical summary of a DataFrame

In [9]: titanic.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 891 entries, 0 to 890
Data columns (total 12 columns):

<table>
<thead>
<tr>
<th>#</th>
<th>Column</th>
<th>Non-Null Count</th>
<th>Dtype</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>PassengerId</td>
<td>891 non-null</td>
<td>int64</td>
</tr>
<tr>
<td>1</td>
<td>Survived</td>
<td>891 non-null</td>
<td>int64</td>
</tr>
<tr>
<td>2</td>
<td>Pclass</td>
<td>891 non-null</td>
<td>int64</td>
</tr>
</tbody>
</table>
The method `info()` provides technical information about a DataFrame, so let’s explain the output in more detail:

- It is indeed a DataFrame.
- There are 891 entries, i.e. 891 rows.
- Each row has a row label (aka the index) with values ranging from 0 to 890.
- The table has 12 columns. Most columns have a value for each of the rows (all 891 values are non-null). Some columns do have missing values and less than 891 non-null values.
- The columns Name, Sex, Cabin and Embarked consists of textual data (strings, aka object). The other columns are numerical data with some of them whole numbers (aka integer) and others are real numbers (aka float).
- The kind of data (characters, integers,...) in the different columns are summarized by listing the dtypes.
- The approximate amount of RAM used to hold the DataFrame is provided as well.
- Getting data in to pandas from many different file formats or data sources is supported by read_* functions.
- Exporting data out of pandas is provided by different to_* methods.
- The head/tail/info methods and the dtypes attribute are convenient for a first check.

For a complete overview of the input and output possibilities from and to pandas, see the user guide section about reader and writer functions.

```
In [1]: import pandas as pd
```

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- PassengerId: Id of every passenger.
- Survived: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- Pclass: There are 3 classes: Class 1, Class 2 and Class 3.
- Name: Name of passenger.
- Sex: Gender of passenger.
- Age: Age of passenger.
- SibSp: Indication that passenger have siblings and spouse.
- Parch: Whether a passenger is alone or have family.
- Ticket: Ticket number of passenger.
- Fare: Indicating the fare.
- Cabin: The cabin of passenger.
• Embarked: The embarked category.

```python
In [2]: titanic = pd.read_csv("data/titanic.csv")
```

```python
In [3]: titanic.head()
Out[3]:
   PassengerId  Survived  Pclass  Name                       ...
0           1         0        3  Braund, Mr. Owen Harris  ...  0  A/5 21171  7.2500   NaN  S
1           2         1        1  Cumings, Mrs. John Bradley (Florence Briggs Th...  ...  0  PC 17599  71.2833  C85  C
2           3         1        3  Heikkinen, Miss. Laina  ...  0  STON/O2. 3101282  7.9250   NaN  S
3           4         1        1  Futrelle, Mrs. Jacques Heath (Lily May Peel)  ...  0  113803  53.1000  C123  S
4           5         0        3  Allen, Mr. William Henry  ...  0  373450  8.0500   NaN  S
[5 rows x 12 columns]
```

### How do I select a subset of a DataFrame?

### How do I select specific columns from a DataFrame?

I’m interested in the age of the Titanic passengers.

```python
In [4]: ages = titanic["Age"]
```

```python
In [5]: ages.head()
Out[5]:
   0   22.0
   1   38.0
   2   26.0
   3   35.0
   4   35.0
Name: Age, dtype: float64
```

To select a single column, use square brackets `[]` with the column name of the column of interest.

Each column in a DataFrame is a Series. As a single column is selected, the returned object is a pandas Series. We can verify this by checking the type of the output:

```python
In [6]: type(titanic["Age"])
Out[6]: pandas.core.series.Series
```

And have a look at the shape of the output:

```python
In [7]: titanic["Age"].shape
Out[7]: (891,)
```

DataFrame.shape is an attribute (remember tutorial on reading and writing, do not use parentheses for attributes) of a pandas Series and DataFrame containing the number of rows and columns: (nrows, ncols). A pandas Series is 1-dimensional and only the number of rows is returned.

I’m interested in the age and sex of the Titanic passengers.
In [8]: age_sex = titanic["Age", "Sex"]

In [9]: age_sex.head()

Out[9]:
<table>
<thead>
<tr>
<th>Age</th>
<th>Sex</th>
</tr>
</thead>
<tbody>
<tr>
<td>22.0</td>
<td>male</td>
</tr>
<tr>
<td>38.0</td>
<td>female</td>
</tr>
<tr>
<td>26.0</td>
<td>female</td>
</tr>
<tr>
<td>35.0</td>
<td>female</td>
</tr>
<tr>
<td>35.0</td>
<td>male</td>
</tr>
</tbody>
</table>

To select multiple columns, use a list of column names within the selection brackets [].

**Note:** The inner square brackets define a Python list with column names, whereas the outer brackets are used to select the data from a pandas DataFrame as seen in the previous example.

The returned data type is a pandas DataFrame:

In [10]: type(titanic["Age", "Sex"])
Out[10]: pandas.core.frame.DataFrame

In [11]: titanic["Age", "Sex"].shape
Out[11]: (891, 2)

The selection returned a DataFrame with 891 rows and 2 columns. Remember, a DataFrame is 2-dimensional with both a row and column dimension.

For basic information on indexing, see the user guide section on indexing and selecting data.

**How do I filter specific rows from a DataFrame?**

I’m interested in the passengers older than 35 years.

In [12]: above_35 = titanic[titanic["Age"] > 35]

In [13]: above_35.head()

Out[13]:
<table>
<thead>
<tr>
<th>PassengerId</th>
<th>Survived</th>
<th>Pclass</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>-&gt; Sex                  Parch</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>1</td>
<td>1 female</td>
</tr>
<tr>
<td>6</td>
<td>female</td>
<td>7</td>
<td>0</td>
</tr>
<tr>
<td>11</td>
<td>male</td>
<td>12</td>
<td>0</td>
</tr>
<tr>
<td>13</td>
<td>female</td>
<td>14</td>
<td>3</td>
</tr>
<tr>
<td>15</td>
<td>male</td>
<td>16</td>
<td>5</td>
</tr>
<tr>
<td>15</td>
<td>female</td>
<td>16</td>
<td>2</td>
</tr>
</tbody>
</table>

[5 rows x 12 columns]

To select rows based on a conditional expression, use a condition inside the selection brackets [].
The condition inside the selection brackets `titanic["Age"] > 35` checks for which rows the `Age` column has a value larger than 35:

```
In [14]: titanic["Age"] > 35
Out[14]:
   0    False
   1     True
   2    False
   3    False
   4    False
   ...
  886   False
  887   False
  888   False
  889   False
  890   False
Name: Age, Length: 891, dtype: bool
```

The output of the conditional expression (`>`, but also `==`, `!=`, `<`, `<=`, `>=` would work) is actually a pandas Series of boolean values (either `True` or `False`) with the same number of rows as the original DataFrame. Such a Series of boolean values can be used to filter the DataFrame by putting it in between the selection brackets `[]`. Only rows for which the value is `True` will be selected.

We know from before that the original Titanic DataFrame consists of 891 rows. Let’s have a look at the amount of rows which satisfy the condition by checking the `shape` attribute of the resulting DataFrame `above_35`:

```
In [15]: above_35.shape
Out[15]: (217, 12)
```

I’m interested in the Titanic passengers from cabin class 2 and 3.

```
In [16]: class_23 = titanic[titanic["Pclass"].isin([2, 3])]

In [17]: class_23.head()
Out[17]:
   PassengerId  Survived  Pclass  Name       Sex  Age  SibSp  Parch  Ticket  Fare  Cabin  Embarked
0          1         0        3  Braund, Mr. Owen Harris   male  22.0      0       0    A/5 21171  7.2500    NaN     S
2          3         1        3 A/5 21171  7.2500      NaN   female  26.0
4          3         0        3  Heikkinen, Miss. Laina   female  26.0      0       0    STON/O2.3101282  7.9250    NaN     S
5          3         0        3  Heikkinen, Mr. Laina     male  26.0      0       0    STON/O2.3101282  7.9250    NaN     S
7          3         0        3  Palsson, Master. Gosta Leonard   male  2.0      3       0    349909  21.0750    NaN     S
```

Similar to the conditional expression, the `isin()` conditional function returns a `True` for each row the values are in the provided list. To filter the rows based on such a function, use the conditional function inside the selection brackets `[]`. In this case, the condition inside the selection brackets `titanic["Pclass"].isin([2, 3])` checks for which rows the `Pclass` column is either 2 or 3.

The above is equivalent to filtering by rows for which the class is either 2 or 3 and combining the two statements with an `|` (or) operator:

```
In [18]: class_23 = titanic((titanic["Pclass"] == 2) | (titanic["Pclass"] == 3))
```
Note: When combining multiple conditional statements, each condition must be surrounded by parentheses(). Moreover, you can not use or and but need to use the or operator | and the and operator &.

See the dedicated section in the user guide about boolean indexing or about the isin function.

I want to work with passenger data for which the age is known.

```python
In [20]: age_no_na = titanic[titanic["Age"].notna()]
```

```python
In [21]: age_no_na.head()
```

<table>
<thead>
<tr>
<th>PassengerId</th>
<th>Survived</th>
<th>Pclass</th>
<th>Name</th>
<th>Sex</th>
<th>Age</th>
<th>SibSp</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>Braund, Mr. Owen Harris</td>
<td>male</td>
<td>22.0</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>3</td>
<td></td>
<td></td>
<td>NaN</td>
<td></td>
</tr>
<tr>
<td></td>
<td>0</td>
<td></td>
<td>A/5 21171 7.2500 NaN S</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>0</td>
<td>3</td>
<td>Heikkinen, Miss. Laina</td>
<td>female</td>
<td>26.0</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>0</td>
<td></td>
<td>STON/O2. 3101282 7.9250 NaN S</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>0</td>
<td>3</td>
<td>Moran, Mr. James</td>
<td>male</td>
<td>35.0</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>0</td>
<td></td>
<td>373450 8.0500 NaN S</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>0</td>
<td>3</td>
<td>Palsson, Master. Gosta Leonard</td>
<td>male</td>
<td>2.0</td>
<td>3</td>
</tr>
<tr>
<td></td>
<td>0</td>
<td></td>
<td>349909 21.0750 NaN S</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

[5 rows x 12 columns]

The notna() conditional function returns a True for each row the values are not an Null value. As such, this can be combined with the selection brackets [] to filter the data table.

You might wonder what actually changed, as the first 5 lines are still the same values. One way to verify is to check if the shape has changed:

```python
In [22]: age_no_na.shape
Out[22]: (714, 12)
```

For more dedicated functions on missing values, see the user guide section about handling missing data.
How do I select specific rows and columns from a DataFrame?

I’m interested in the names of the passengers older than 35 years.

```python
In [23]: adult_names = titanic.loc[titanic["Age"] > 35, "Name"]
In [24]: adult_names.head()
Out[24]:
   Name
0  Cumings, Mrs. John Bradley (Florence Briggs Th...
1  McCarthy, Mr. Timothy J
6  Bonnell, Miss. Elizabeth
13  Andersson, Mr. Anders Johan
15  Hewlett, Mrs. (Mary D Kingcome)
Name: Name, dtype: object
```

In this case, a subset of both rows and columns is made in one go and just using selection brackets [] is not sufficient anymore. The `loc/iloc` operators are required in front of the selection brackets []. When using `loc/iloc`, the part before the comma is the rows you want, and the part after the comma is the columns you want to select.

When using the column names, row labels or a condition expression, use the `loc` operator in front of the selection brackets[]. For both the part before and after the comma, you can use a single label, a list of labels, a slice of labels, a conditional expression or a colon. Using a colon specifies you want to select all rows or columns.

I’m interested in rows 10 till 25 and columns 3 to 5.

```python
In [25]: titanic.iloc[9:25, 2:5]
Out[25]:
                          Name         Sex
Pclass    Name
9  2  Nasser, Mrs. Nicholas (Adele Achem) female
10 3  Sandstrom, Miss. Marguerite Rut female
11 1  Bonnell, Miss. Elizabeth female
12 3  Saundercock, Mr. William Henry male
13 3  Andersson, Mr. Anders Johan male
14 ... ... ... ...
20 2  Fynney, Mr. Joseph J male
21 2  Beesley, Mr. Lawrence male
22 3  McGowan, Miss. Anna "Annie" female
23 1  Sloper, Mr. William Thompson male
24 3  Palsson, Miss. Torborg Danira female
```

Again, a subset of both rows and columns is made in one go and just using selection brackets [] is not sufficient anymore. When specifically interested in certain rows and/or columns based on their position in the table, use the `iloc` operator in front of the selection brackets[].

When selecting specific rows and/or columns with `loc` or `iloc`, new values can be assigned to the selected data. For example, to assign the name `anonymous` to the first 3 elements of the third column:

```python
In [26]: titanic.iloc[0:3, 3] = "anonymous"
In [27]: titanic.head()
```

(continues on next page)
See the user guide section on different choices for indexing to get more insight in the usage of `loc` and `iloc`.

- When selecting subsets of data, square brackets `[]` are used.
- Inside these brackets, you can use a single column/row label, a list of column/row labels, a slice of labels, a conditional expression or a colon.
- Select specific rows and/or columns using `loc` when using the row and column names
- Select specific rows and/or columns using `iloc` when using the positions in the table
- You can assign new values to a selection based on `loc/iloc`.

A full overview about indexing is provided in the user guide pages on indexing and selecting data.

```python
In [1]: import pandas as pd
In [2]: import matplotlib.pyplot as plt

For this tutorial, air quality data about \( \text{NO}_2 \) is used, made available by openaq and using the py-openaq package. The `air_quality_no2.csv` data set provides \( \text{NO}_2 \) values for the measurement stations `FR04014`, `BETR801` and `London Westminster` in respectively Paris, Antwerp and London.

```python
In [3]: air_quality = pd.read_csv("data/air_quality_no2.csv", 
...:                    index_col=0, parse_dates=True)
...:

In [4]: air_quality.head()
Out[4]:
station_antwerp  station_paris  station_london
datetime
2019-05-07 02:00:00  NaN          NaN          23.0
2019-05-07 03:00:00  50.5          25.0          19.0
2019-05-07 04:00:00  45.0          27.7          19.0
2019-05-07 05:00:00  NaN          50.4          16.0
2019-05-07 06:00:00  NaN          61.9          NaN
```

**Note:** The usage of the `index_col` and `parse_dates` parameters of the `read_csv` function to define the first (0th) column as index of the resulting DataFrame and convert the dates in the column to `Timestamp` objects, respectively.
How to create plots in pandas?

I want a quick visual check of the data.

```
In [5]: air_quality.plot()
Out[5]: <AxesSubplot:xlabel='datetime'>
```

With a DataFrame, pandas creates by default one line plot for each of the columns with numeric data.

I want to plot only the columns of the data table with the data from Paris.

```
In [6]: air_quality["station_paris"].plot()
Out[6]: <AxesSubplot:xlabel='datetime'>
```
To plot a specific column, use the selection method of the *subset data tutorial* in combination with the *plot()* method. Hence, the *plot()* method works on both Series and DataFrame.

I want to visually compare the $NO_2$ values measured in London versus Paris.

```
In [7]: air_quality.plot.scatter(x="station_london",
...: y="station_paris",
...: alpha=0.5)
...:
Out[7]: <AxesSubplot:xlabel='station_london', ylabel='station_paris'>
```
Apart from the default line plot when using the `plot` function, a number of alternatives are available to plot data. Let’s use some standard Python to get an overview of the available plot methods:

```
In [8]: [method_name for method_name in dir(air_quality.plot)
   ...:   if not method_name.startswith('_')]
   ...
Out[8]:
['area',
 'bar',
 'barh',
 'box',
 'density',
 'hexbin',
 'hist',
 'kde',
 'line',
 'pie',
 'scatter']
```

**Note:** In many development environments as well as ipython and jupyter notebook, use the TAB button to get an overview of the available methods, for example `air_quality.plot.+TAB`.

One of the options is `DataFrame.plot.box()`, which refers to a boxplot. The `box` method is applicable on the air quality example data:
For an introduction to plots other than the default line plot, see the user guide section about supported plot styles. I want each of the columns in a separate subplot.

Separate subplots for each of the data columns is supported by the subplots argument of the plot functions. The builtin options available in each of the pandas plot functions that are worthwhile to have a look.
Some more formatting options are explained in the user guide section on plot formatting.

I want to further customize, extend or save the resulting plot.

```python
In [11]: fig, axs = plt.subplots(figsize=(12, 4));
In [12]: air_quality.plot.area(ax=axs);
In [13]: axs.set_ylabel("NO$_2$ concentration");
In [14]: fig.savefig("no2_concentrations.png")
```

Each of the plot objects created by pandas are a matplotlib object. As Matplotlib provides plenty of options to customize plots, making the link between pandas and Matplotlib explicit enables all the power of matplotlib to the plot. This strategy is applied in the previous example:

```python
fig, axs = plt.subplots(figsize=(12, 4))
# Create an empty matplotlib Figure and Axes
air_quality.plot.area(ax=axs)
# Use pandas to put the area plot on the prepared Figure/Axes
axs.set_ylabel("NO$_2$ concentration")
# Do any matplotlib customization you like
fig.savefig("no2_concentrations.png")
# Save the Figure/Axes using the existing matplotlib method.
```

- The `.plot.*` methods are applicable on both Series and DataFrames
- By default, each of the columns is plotted as a different element (line, boxplot, …)
- Any plot created by pandas is a Matplotlib object.

A full overview of plotting in pandas is provided in the visualization pages.

```python
In [1]: import pandas as pd
```

For this tutorial, air quality data about $NO_2$ is used, made available by openaq and using the py-openaq package. The `air_quality_no2.csv` data set provides $NO_2$ values for the measurement stations `FR04014`, `BETR801` and `London Westminster` in respectively Paris, Antwerp and London.

```python
In [2]: air_quality = pd.read_csv("data/air_quality_no2.csv",
...:     index_col=0, parse_dates=True)
...:
In [3]: air_quality.head()
```
How to create new columns derived from existing columns?

I want to express the \( NO_2 \) concentration of the station in London in mg/m\(^3\)

\textit{(If we assume temperature of 25 degrees Celsius and pressure of 1013 hPa, the conversion factor is 1.882)}

\begin{verbatim}
In [4]: air_quality["london_mg_per_cubic"] = air_quality["station_london"] * 1.882
In [5]: air_quality.head()
Out[5]:
station_antwerp station_paris station_london london_mg_per_cubic
datetime
2019-05-07 02:00:00 NaN NaN 23.0 43.286
2019-05-07 03:00:00 50.5 25.0 19.0 35.758
2019-05-07 04:00:00 45.0 27.7 19.0 35.758
2019-05-07 05:00:00 NaN 50.4 16.0 30.112
2019-05-07 06:00:00 NaN 61.9 NaN NaN
\end{verbatim}

To create a new column, use the [] brackets with the new column name at the left side of the assignment.

\textbf{Note:} The calculation of the values is done \texttt{element-wise}. This means all values in the given column are multiplied by the value 1.882 at once. You do not need to use a loop to iterate each of the rows!

I want to check the ratio of the values in Paris versus Antwerp and save the result in a new column

\begin{verbatim}
In [6]: air_quality["ratio_paris_antwerp"] = air_quality["station_paris"] / air_quality["station_antwerp"]
In [7]: air_quality.head()
Out[7]:
station_antwerp station_paris station_london london_mg_per_cubic ratio_paris_antwerp
datetime
2019-05-07 02:00:00 NaN NaN 23.0 43.286
2019-05-07 03:00:00 50.5 25.0 19.0 35.758
2019-05-07 04:00:00 45.0 27.7 19.0 35.758
2019-05-07 05:00:00 NaN 50.4 16.0 30.112
2019-05-07 06:00:00 NaN 61.9 NaN NaN
\end{verbatim}
The calculation is again element-wise, so the `/` is applied for the values in each row.

Also other mathematical operators (+, -, *, /) or logical operators (<, >, =, ...) work element wise. The latter was already used in the subset data tutorial to filter rows of a table using a conditional expression.

I want to rename the data columns to the corresponding station identifiers used by openAQ

```python
In [8]: air_quality_renamed = air_quality.rename(
    ...: columns={"station_antwerp": "BETR801",
    ...: "station_paris": "FR04014",
    ...: "station_london": "London Westminster"})
```

```python
In [9]: air_quality_renamed.head()
Out[9]:
   BETR801  FR04014       London Westminster    london_mg_per_cubic ratio_
paris_antwerp
   date	ime
2019-05-07 02:00:00 NaN  NaN    23.0               43.286
2019-05-07 03:00:00  50.5 25.0   19.0               35.758
   0.495050
2019-05-07 04:00:00  45.0 27.7   19.0               35.758
   0.615556
2019-05-07 05:00:00  NaN   50.4   16.0               30.112
   NaN
2019-05-07 06:00:00  NaN  61.9   NaN                NaN
   NaN
```

The `rename()` function can be used for both row labels and column labels. Provide a dictionary with the keys the current names and the values the new names to update the corresponding names.

The mapping should not be restricted to fixed names only, but can be a mapping function as well. For example, converting the column names to lowercase letters can be done using a function as well:

```python
In [10]: air_quality_renamed = air_quality_renamed.rename(columns=str.lower)
```

```python
In [11]: air_quality_renamed.head()
Out[11]:
   betr801  fr04014  london westminster    london_mg_per_cubic ratio_
paris_antwerp
date	ime
2019-05-07 02:00:00 NaN   NaN        23.0               43.286
2019-05-07 03:00:00 NaN  NaN        25.0               19.0
2019-05-07 04:00:00  NaN    NaN   25.0               19.0
2019-05-07 05:00:00  NaN   NaN   25.0               19.0
2019-05-07 06:00:00  NaN   NaN   61.9                NaN
```

(continues on next page)
Details about column or row label renaming is provided in the user guide section on renaming labels.

- Create a new column by assigning the output to the DataFrame with a new column name in between the [].
- Operations are element-wise, no need to loop over rows.
- Use rename with a dictionary or function to rename row labels or column names.

The user guide contains a separate section on column addition and deletion.

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- PassengerId: Id of every passenger.
- Survived: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- Pclass: There are 3 classes: Class 1, Class 2 and Class 3.
- Name: Name of passenger.
- Sex: Gender of passenger.
- Age: Age of passenger.
- SibSp: Indication that passenger have siblings and spouse.
- Parch: Whether a passenger is alone or have family.
- Ticket: Ticket number of passenger.
- Fare: Indicating the fare.
- Cabin: The cabin of passenger.
- Embarked: The embarked category.

In [2]: titanic = pd.read_csv("data/titanic.csv")

In [3]: titanic.head()

Out[3]:
<table>

How to calculate summary statistics?

Aggregating statistics

What is the average age of the Titanic passengers?

```python
In [4]: titanic["Age"].mean()
Out[4]: 29.6991764705882
```

Different statistics are available and can be applied to columns with numerical data. Operations in general exclude missing data and operate across rows by default.

What is the median age and ticket fare price of the Titanic passengers?

```python
In [5]: titanic[["Age", "Fare"]].median()
Out[5]:
Age  28.0000
Fare 14.4542
dtype: float64
```

The statistic applied to multiple columns of a DataFrame (the selection of two columns return a DataFrame, see the subset data tutorial) is calculated for each numeric column.

The aggregating statistic can be calculated for multiple columns at the same time. Remember the describe function from first tutorial?

```python
In [6]: titanic[["Age", "Fare"]].describe()
Out[6]:
          Age     Fare
count  714.000000  891.000000
mean  29.6991176471 32.204208
std   14.5264971761 49.693429
min   0.4200000000   0.000000
25%  20.1250000000  7.910400
50%  28.0000000000 14.454200
75%  38.0000000000 31.000000
max   80.0000000000 512.329200
```

Instead of the predefined statistics, specific combinations of aggregating statistics for given columns can be defined using the DataFrame.agg() method:

```python
In [7]: titanic.agg({'Age': ['min', 'max', 'median', 'skew'],
                   'Fare': ['min', 'max', 'median', 'mean']})
Out[7]:
          Age     Fare
max  80.000000  512.329200
mean NaN        32.204208
```
Details about descriptive statistics are provided in the user guide section on *descriptive statistics*.

**Aggregating statistics grouped by category**

What is the average age for male versus female Titanic passengers?

```
In [8]: titanic[['Sex', 'Age']].groupby('Sex').mean()
Out[8]:
     Age
Sex
female  27.915709
male    30.726645
```

As our interest is the average age for each gender, a subselection on these two columns is made first: `titanic[['Sex', 'Age']].groupby('Sex').mean()`. Next, the `groupby()` method is applied on the `Sex` column to make a group per category. The average age for each gender is calculated and returned.

Calculating a given statistic (e.g. mean age) for each category in a column (e.g. male/female in the `Sex` column) is a common pattern. The `groupby` method is used to support this type of operations. More general, this fits in the more general **split-apply-combine** pattern:

- **Split** the data into groups
- **Apply** a function to each group independently
- **Combine** the results into a data structure

The apply and combine steps are typically done together in pandas.

In the previous example, we explicitly selected the 2 columns first. If not, the `mean` method is applied to each column containing numerical columns:

```
In [9]: titanic.groupby('Sex').mean()
Out[9]:
          PassengerId  Survived  Pclass  Age  SibSp  Parch  Fare  
Sex
female   431.028662  0.742038  2.159236 27.915709  0.694268  0.649682  44.479818
male     454.147314  0.188908  2.389948 30.726645  0.429809  0.235702  25.523893
```

It does not make much sense to get the average value of the `Pclass` if we are only interested in the average age for each gender, the selection of columns (rectangular brackets `[]` as usual) is supported on the grouped data as well:

```
In [10]: titanic.groupby('Sex')['Age'].mean()
Out[10]:
     Sex
female  27.915709
male    30.726645
Name: Age, dtype: float64
```
Note: The Pclass column contains numerical data but actually represents 3 categories (or factors) with respectively the labels ‘1’, ‘2’ and ‘3’. Calculating statistics on these does not make much sense. Therefore, pandas provides a Categorical data type to handle this type of data. More information is provided in the user guide Categorical data section.

What is the mean ticket fare price for each of the sex and cabin class combinations?

```python
In [11]: titanic.groupby(['Sex', 'Pclass'])['Fare'].mean()
Out[11]:
         Sex  Pclass
female 1  106.125798
        2  21.970121
        3  16.118810
male   1  67.226127
        2  19.741782
        3  12.661633
Name: Fare, dtype: float64
```

Grouping can be done by multiple columns at the same time. Provide the column names as a list to the groupby() method.

A full description on the split-apply-combine approach is provided in the user guide section on groupby operations.

Count number of records by category

What is the number of passengers in each of the cabin classes?

```python
In [12]: titanic['Pclass'].value_counts()
Out[12]:
3    491
1    216
2    184
Name: Pclass, dtype: int64
```

The value_counts() method counts the number of records for each category in a column.

The function is a shortcut, as it is actually a groupby operation in combination with counting of the number of records within each group:

```python
In [13]: titanic.groupby('Pclass')['Pclass'].count()
Out[13]:
Pclass
1    216
2    184
3    491
Name: Pclass, dtype: int64
```

Note: Both size and count can be used in combination with groupby. Whereas size includes NaN values and just provides the number of rows (size of the table), count excludes the missing values. In the value_counts method, use the dropna argument to include or exclude the NaN values.

The user guide has a dedicated section on value_counts, see page on discretization.
Aggregation statistics can be calculated on entire columns or rows

`groupby` provides the power of the *split-apply-combine* pattern

`value_counts` is a convenient shortcut to count the number of entries in each category of a variable

A full description on the split-apply-combine approach is provided in the user guide pages about *groupby operations*.

```python
In [1]: import pandas as pd
```

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- **PassengerId**: Id of every passenger.
- **Survived**: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- **Pclass**: There are 3 classes: Class 1, Class 2 and Class 3.
- **Name**: Name of passenger.
- **Sex**: Gender of passenger.
- **Age**: Age of passenger.
- **SibSp**: Indication that passenger have siblings and spouse.
- **Parch**: Whether a passenger is alone or have family.
- **Ticket**: Ticket number of passenger.
- **Fare**: Indicating the fare.
- **Cabin**: The cabin of passenger.
- **Embarked**: The embarked category.

```python
In [2]: titanic = pd.read_csv("data/titanic.csv")
In [3]: titanic.head()
Out[3]:
   PassengerId  Survived  Pclass   Name                                      Sex   ...   Fare  Cabin  Embarked
0            1          0       3    Braund, Mr. Owen Harris    male ... 7.2500  NaN  S
1            2          1       1  Cumings, Mrs. John Bradley (Florence Briggs Th... female ... 71.2833 C85  C
2            3          1       3  Heikkinen, Miss. Laina    male ... 7.9250  NaN  S
3            4          1       1  Futrelle, Mrs. Jacques Heath (Lily May Peel) female ... 53.1000 C123  S
4            5          0       3  Allen, Mr. William Henry    male ... 8.0500  NaN  S

[5 rows x 12 columns]
```

This tutorial uses air quality data about \( \text{NO}_2 \) and Particulate matter less than 2.5 micrometers, made available by openaq and using the py-openaq package. The `air_quality_long.csv` data set provides \( \text{NO}_2 \) and \( \text{PM}_{2.5} \) values for the measurement stations FR04014, BETR801 and London Westminster in respectively Paris, Antwerp and London.

The air-quality data set has the following columns:

- **city**: city where the sensor is used, either Paris, Antwerp or London
- **country**: country where the sensor is used, either FR, BE or GB
- location: the id of the sensor, either FR04014, BETR801 or London Westminster
- parameter: the parameter measured by the sensor, either NO₂ or Particulate matter
- value: the measured value
- unit: the unit of the measured parameter, in this case `µg/m³`

and the index of the DataFrame is `datetime`, the datetime of the measurement.

**Note:** The air-quality data is provided in a so-called long format data representation with each observation on a separate row and each variable a separate column of the data table. The long/narrow format is also known as the tidy data format.

```
In [4]: air_quality = pd.read_csv("data/air_quality_long.csv", 
...:                     index_col="date.utc", parse_dates=True)
...:

In [5]: air_quality.head()
Out[5]:
    city  country  location  parameter  value  unit
date.utc
2019-06-18 06:00:00+00:00 Antwerpen BE BETR801 pm25 18.0 µg/m³
2019-06-17 08:00:00+00:00 Antwerpen BE BETR801 pm25 6.5 µg/m³
2019-06-17 07:00:00+00:00 Antwerpen BE BETR801 pm25 18.5 µg/m³
2019-06-17 06:00:00+00:00 Antwerpen BE BETR801 pm25 16.0 µg/m³
2019-06-17 05:00:00+00:00 Antwerpen BE BETR801 pm25 7.5 µg/m³
```

### How to reshape the layout of tables?

#### Sort table rows

I want to sort the Titanic data according to the age of the passengers.

```
In [6]: titanic.sort_values(by="Age").head()
Out[6]:
   PassengerId  Survived  Pclass   Name    Sex   Age  SibSp  Parch    Ticket  Fare  Cabin  Embarked
0           803        0      3  Thomas, Master. Assad Alexander  male  0.42     0      1    2625  8.5167  NaN       C
1           755        1      3  Hamalainen, Master. Viljo male  0.67     1      1  250649 14.5000  NaN       S
2           644        1      3   Baclini, Miss. Eugenie female 0.75     1      1  2666 19.2583  NaN       C
3           469        1      3  Baclini, Miss. Helene Barbara female 0.75     1      2  2666 19.2583  NaN       C
4           78         0      2   Caldwell, Master. Alden Gates male 0.83     2      2  248738 29.0000  NaN       S
```

I want to sort the Titanic data according to the cabin class and age in descending order.

```
In [7]: titanic.sort_values(by=['Pclass', 'Age'], ascending=False).head()
Out[7]:
   PassengerId  Survived  Pclass   Name    Sex   Age  SibSp  Parch    Ticket  Fare  Cabin  Embarked
0           469        1      3  Baclini, Miss. Helene Barbara female 0.75     1      2  2666 19.2583  NaN       C
1           280        1      3  Baclini, Miss. Eugenie female 0.75     1      1  2666 19.2583  NaN       C
2           78         0      2   Caldwell, Master. Alden Gates male 0.83     2      2  248738 29.0000  NaN       S
3           230        1      3  Hamalainen, Master. Viljo male 0.67     1      1  250649 14.5000  NaN       S
4           803        0      3  Thomas, Master. Assad Alexander  male  0.42     0      1    2625  8.5167  NaN       C
```
With `Series.sort_values()`, the rows in the table are sorted according to the defined column(s). The index will follow the row order.

More details about sorting of tables is provided in the using guide section on sorting data.

### Long to wide table format

Let’s use a small subset of the air quality data set. We focus on \( NO_2 \) data and only use the first two measurements of each location (i.e. the head of each group). The subset of data will be called `no2_subset`

```python
# filter for no2 data only
In [8]: no2 = air_quality[air_quality[“parameter”] == “no2”]

# use 2 measurements (head) for each location (groupby)
In [9]: no2_subset = no2.sort_index().groupby([“location”]).head(2)

In [10]: no2_subset
```

<table>
<thead>
<tr>
<th>city</th>
<th>country</th>
<th>location</th>
<th>parameter</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>date.utc</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Antwerpen</td>
<td>BE</td>
<td>BETR801</td>
<td>no2</td>
<td>22.5 µg/( \text{m}^3 )</td>
</tr>
<tr>
<td>Paris</td>
<td>FR</td>
<td>FR04014</td>
<td>no2</td>
<td>24.4 µg/( \text{m}^3 )</td>
</tr>
<tr>
<td>London</td>
<td>GB</td>
<td>London Westminster</td>
<td>no2</td>
<td>67.0 µg/( \text{m}^3 )</td>
</tr>
<tr>
<td>Antwerpen</td>
<td>BE</td>
<td>BETR801</td>
<td>no2</td>
<td>53.5 µg/( \text{m}^3 )</td>
</tr>
<tr>
<td>Paris</td>
<td>FR</td>
<td>FR04014</td>
<td>no2</td>
<td>27.4 µg/( \text{m}^3 )</td>
</tr>
<tr>
<td>London</td>
<td>GB</td>
<td>London Westminster</td>
<td>no2</td>
<td>67.0 µg/( \text{m}^3 )</td>
</tr>
</tbody>
</table>

I want the values for the three stations as separate columns next to each other

```python
In [11]: no2_subset.pivot(columns=“location”, values=“value”)
```

```
location       BETR801   FR04014   London Westminster
date.utc 2019-04-09 01:00:00+00:00 22.5 24.4 NaN
```
The `pivot()` function is purely reshaping of the data: a single value for each index/column combination is required. As pandas support plotting of multiple columns (see [plotting tutorial](#)) out of the box, the conversion from long to wide table format enables the plotting of the different time series at the same time:

```{.python}
In [12]: no2.head()
Out[12]:
+-----------------+--------+---------+------+-+--+
| date.utc         | city   | country | location | parameter | value | unit |
+-----------------+--------+---------+------+-+--+
| 2019-06-21 00:00:00+00:00 | Paris  | FR      | FR04014 | no2      | 20.0  | µg/m³|
| 2019-06-20 23:00:00+00:00 | Paris  | FR      | FR04014 | no2      | 21.8  | µg/m³|
| 2019-06-20 22:00:00+00:00 | Paris  | FR      | FR04014 | no2      | 26.5  | µg/m³|
| 2019-06-20 21:00:00+00:00 | Paris  | FR      | FR04014 | no2      | 24.9  | µg/m³|
| 2019-06-20 20:00:00+00:00 | Paris  | FR      | FR04014 | no2      | 21.4  | µg/m³|
```

```{.python}
In [13]: no2.pivot(columns="location", values="value").plot()
Out[13]: <AxesSubplot:xlabel='date.utc'>
```

Note: When the `index` parameter is not defined, the existing index (row labels) is used.

1.4. Tutorials
For more information about `pivot()`, see the user guide section on `pivoting DataFrame objects`.

**Pivot table**

I want the mean concentrations for \(NO_2\) and \(PM_{2.5}\) in each of the stations in table form.

```
In [14]: air_quality.pivot_table(values="value", index="location",
                          ....:      columns="parameter", aggfunc="mean")
```

```
Out[14]:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>no2</th>
<th>pm25</th>
</tr>
</thead>
<tbody>
<tr>
<td>location</td>
<td></td>
<td></td>
</tr>
<tr>
<td>BETR801</td>
<td>26.95</td>
<td>23.17</td>
</tr>
<tr>
<td>FR04014</td>
<td>29.37</td>
<td>NaN</td>
</tr>
<tr>
<td>London Westminster</td>
<td>29.74</td>
<td>13.44</td>
</tr>
</tbody>
</table>
```

In the case of `pivot()`, the data is only rearranged. When multiple values need to be aggregated (in this specific case, the values on different time steps) `pivot_table()` can be used, providing an aggregation function (e.g. mean) on how to combine these values.

Pivot table is a well known concept in spreadsheet software. When interested in summary columns for each variable separately as well, put the `margin` parameter to `True`:

```
In [15]: air_quality.pivot_table(values="value", index="location",
                          ....:      columns="parameter", aggfunc="mean",
                          ....:      margins=True)
```

```
Out[15]:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>no2</th>
<th>pm25</th>
<th>All</th>
</tr>
</thead>
<tbody>
<tr>
<td>location</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>BETR801</td>
<td>26.95</td>
<td>23.17</td>
<td>24.98</td>
</tr>
<tr>
<td>FR04014</td>
<td>29.37</td>
<td>NaN</td>
<td>29.37</td>
</tr>
<tr>
<td>London Westminster</td>
<td>29.74</td>
<td>13.44</td>
<td>21.49</td>
</tr>
<tr>
<td>All</td>
<td>29.43</td>
<td>14.39</td>
<td>24.22</td>
</tr>
</tbody>
</table>
```

For more information about `pivot_table()`, see the user guide section on `pivot tables`.

**Note:** In case you are wondering, `pivot_table()` is indeed directly linked to `groupby()`. The same result can be derived by grouping on both `parameter` and `location`:

```
air_quality.groupby(["parameter", "location"]).mean()
```

Have a look at `groupby()` in combination with `unstack()` at the user guide section on `combining stats and groupby`. 
Wide to long format

Starting again from the wide format table created in the previous section:

```
In [16]: no2_pivoted = no2.pivot(columns="location", values="value").reset_index()
In [17]: no2_pivoted.head()
Out[17]:

<table>
<thead>
<tr>
<th>location</th>
<th>date.utc</th>
<th>BETR801</th>
<th>FR04014</th>
<th>London Westminster</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>2019-04-09 01:00:00+00:00</td>
<td>22.5</td>
<td>24.4</td>
<td>NaN</td>
</tr>
<tr>
<td>1</td>
<td>2019-04-09 02:00:00+00:00</td>
<td>53.5</td>
<td>27.4</td>
<td>67.0</td>
</tr>
<tr>
<td>2</td>
<td>2019-04-09 03:00:00+00:00</td>
<td>54.5</td>
<td>34.2</td>
<td>67.0</td>
</tr>
<tr>
<td>3</td>
<td>2019-04-09 04:00:00+00:00</td>
<td>34.5</td>
<td>48.5</td>
<td>41.0</td>
</tr>
<tr>
<td>4</td>
<td>2019-04-09 05:00:00+00:00</td>
<td>46.5</td>
<td>59.5</td>
<td>41.0</td>
</tr>
</tbody>
</table>
```

I want to collect all air quality $NO_2$ measurements in a single column (long format)

```
In [18]: no_2 = no2_pivoted.melt(id_vars="date.utc")
In [19]: no_2.head()
Out[19]:

<table>
<thead>
<tr>
<th>date.utc</th>
<th>location</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019-04-09 01:00:00+00:00</td>
<td>BETR801</td>
<td>22.5</td>
</tr>
<tr>
<td>2019-04-09 02:00:00+00:00</td>
<td>BETR801</td>
<td>53.5</td>
</tr>
<tr>
<td>2019-04-09 03:00:00+00:00</td>
<td>BETR801</td>
<td>54.5</td>
</tr>
<tr>
<td>2019-04-09 04:00:00+00:00</td>
<td>BETR801</td>
<td>34.5</td>
</tr>
<tr>
<td>2019-04-09 05:00:00+00:00</td>
<td>BETR801</td>
<td>46.5</td>
</tr>
</tbody>
</table>
```

The `pandas.melt()` method on a DataFrame converts the data table from wide format to long format. The column headers become the variable names in a newly created column.

The solution is the short version on how to apply `pandas.melt()`. The method will *melt* all columns NOT mentioned in `id_vars` together into two columns: A column with the column header names and a column with the values itself. The latter column gets by default the name `value`.

The `pandas.melt()` method can be defined in more detail:

```
In [20]: no_2 = no2_pivoted.melt(id_vars="date.utc",

value_vars=['BETR801',
            'FR04014',
            'London Westminster'],

value_name="NO_2",

var_name="id_location")
```

The result in the same, but in more detail defined:

- `value_vars` defines explicitly which columns to *melt* together

1.4. Tutorials
• `value_name` provides a custom column name for the values column instead of the default column name `value`.
• `var_name` provides a custom column name for the column collecting the column header names. Otherwise it takes the index name or a default variable `variable`.

Hence, the arguments `value_name` and `var_name` are just user-defined names for the two generated columns. The columns to melt are defined by `id_vars` and `value_vars`.

Conversion from wide to long format with `pandas.melt()` is explained in the user guide section on reshaping by `melt`.

- Sorting by one or more columns is supported by `sort_values`.
- The `pivot` function is purely restructuring of the data, `pivot_table` supports aggregations.
- The reverse of `pivot` (long to wide format) is `melt` (wide to long format).

A full overview is available in the user guide on the pages about reshaping and pivoting.

```python
In [1]: import pandas as pd
```

For this tutorial, air quality data about $NO_2$ is used, made available by `openaq` and downloaded using the `py-openaq` package.

The `air_quality_no2_long.csv` data set provides $NO_2$ values for the measurement stations `FR04014`, `BETR801` and `London Westminster` in respectively Paris, Antwerp and London.

```python
In [2]: air_quality_no2 = pd.read_csv("data/air_quality_no2_long.csv", parse_dates=True)

In [3]: air_quality_no2 = air_quality_no2["date.utc", "location", "parameter", "value"][

In [4]: air_quality_no2.head()
Out[4]:
   date.utc location parameter  value
0 2019-06-21 00:00:00+00:00  FR04014  no2     20.0
1 2019-06-20 23:00:00+00:00  FR04014  no2     21.8
2 2019-06-20 22:00:00+00:00  FR04014  no2     26.5
3 2019-06-20 21:00:00+00:00  FR04014  no2     24.9
4 2019-06-20 20:00:00+00:00  FR04014  no2     21.4
```

For this tutorial, air quality data about Particulate matter less than 2.5 micrometers is used, made available by `openaq` and downloaded using the `py-openaq` package.

The `air_quality_pm25_long.csv` data set provides $PM_{2.5}$ values for the measurement stations `FR04014`, `BETR801` and `London Westminster` in respectively Paris, Antwerp and London.

```python
In [5]: air_quality_pm25 = pd.read_csv("data/air_quality_pm25_long.csv", parse_dates=True)

In [6]: air_quality_pm25 = air_quality_pm25["date.utc", "location", "parameter", "value"]

In [7]: air_quality_pm25.head()
```
Out[7]:

<table>
<thead>
<tr>
<th>date.utc</th>
<th>location</th>
<th>parameter</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019-06-18 06:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>18.0</td>
</tr>
<tr>
<td>2019-06-17 08:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>6.5</td>
</tr>
<tr>
<td>2019-06-17 07:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>18.5</td>
</tr>
<tr>
<td>2019-06-17 06:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>16.0</td>
</tr>
<tr>
<td>2019-06-17 05:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>7.5</td>
</tr>
</tbody>
</table>

How to combine data from multiple tables?

Concatenating objects

I want to combine the measurements of \(NO_2\) and \(PM_{25}\), two tables with a similar structure, in a single table.

In[8]: air_quality = pd.concat([air_quality_pm25, air_quality_no2], axis=0)

In[9]: air_quality.head()

Out[9]:

<table>
<thead>
<tr>
<th>date.utc</th>
<th>location</th>
<th>parameter</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019-06-18 06:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>18.0</td>
</tr>
<tr>
<td>2019-06-17 08:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>6.5</td>
</tr>
<tr>
<td>2019-06-17 07:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>18.5</td>
</tr>
<tr>
<td>2019-06-17 06:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>16.0</td>
</tr>
<tr>
<td>2019-06-17 05:00:00+00:00</td>
<td>BETR801</td>
<td>pm25</td>
<td>7.5</td>
</tr>
</tbody>
</table>

The `concat()` function performs concatenation operations of multiple tables along one of the axis (row-wise or column-wise).

By default concatenation is along axis 0, so the resulting table combines the rows of the input tables. Let’s check the shape of the original and the concatenated tables to verify the operation:

In[10]: print('Shape of the `air_quality_pm25` table: ', air_quality_pm25.shape)
Shape of the `air_quality_pm25` table: (1110, 4)

In[11]: print('Shape of the `air_quality_no2` table: ', air_quality_no2.shape)
Shape of the `air_quality_no2` table: (2068, 4)

In[12]: print('Shape of the resulting `air_quality` table: ', air_quality.shape)
Shape of the resulting `air_quality` table: (3178, 4)

Hence, the resulting table has 3178 = 1110 + 2068 rows.

**Note:** The `axis` argument will return in a number of pandas methods that can be applied along an axis. A DataFrame has two corresponding axes: the first running vertically downwards across rows (axis 0), and the second running horizontally across columns (axis 1). Most operations like concatenation or summary statistics are by default across rows (axis 0), but can be applied across columns as well.

Sorting the table on the datetime information illustrates also the combination of both tables, with the parameter column defining the origin of the table (either `no2` from table `air_quality_no2` or `pm25` from table `air_quality_pm25`):
In [13]: air_quality = air_quality.sort_values("date.utc")

In [14]: air_quality.head()
Out[14]:
   date.utc location parameter value
0 2019-05-07 01:00:00+00:00 London Westminster no2 23.0
1 2019-05-07 01:00:00+00:00 FR04014 no2  25.0
2 2019-05-07 01:00:00+00:00 BETR801 pm25 12.5
3 2019-05-07 01:00:00+00:00 BETR801 no2  50.5
4 2019-05-07 01:00:00+00:00 London Westminster pm25  8.0

In this specific example, the parameter column provided by the data ensures that each of the original tables can be identified. This is not always the case. The concat function provides a convenient solution with the keys argument, adding an additional (hierarchical) row index. For example:

In [15]: air_quality_ = pd.concat([air_quality_pm25, air_quality_no2],
   ....:     keys=['PM25', 'NO2'])
   ....:

In [16]: air_quality_.head()
Out[16]:
   date.utc location parameter value
         PM25 0 2019-06-18 06:00:00+00:00 BETR801 pm25  18.0
         PM25 1 2019-06-17 08:00:00+00:00 BETR801 pm25   6.5
         PM25 2 2019-06-17 07:00:00+00:00 BETR801 pm25  18.5
         PM25 3 2019-06-17 06:00:00+00:00 BETR801 pm25  16.0
         PM25 4 2019-06-17 05:00:00+00:00 BETR801 pm25   7.5

Note: The existence of multiple row/column indices at the same time has not been mentioned within these tutorials. Hierarchical indexing or MultiIndex is an advanced and powerful pandas feature to analyze higher dimensional data. Multi-indexing is out of scope for this pandas introduction. For the moment, remember that the function reset_index can be used to convert any level of an index to a column, e.g. air_quality.reset_index(level=0)

Feel free to dive into the world of multi-indexing at the user guide section on advanced indexing.

More options on table concatenation (row and column wise) and how concat can be used to define the logic (union or intersection) of the indexes on the other axes is provided at the section on object concatenation.

Join tables using a common identifier

Add the station coordinates, provided by the stations metadata table, to the corresponding rows in the measurements table.

Warning: The air quality measurement station coordinates are stored in a data file air_quality_stations.csv, downloaded using the py-openaq package.

In [17]: stations_coord = pd.read_csv("data/air_quality_stations.csv")
(continues on next page)
In [18]: stations_coord.head()
Out[18]:
   location  coordinates.latitude  coordinates.longitude
0   BELAL01            51.23619                4.38522
1   BELHB23            51.17030                4.34100
2   BELLD01            51.10998                5.00486
3   BELLD02            51.12038                5.02155
4   BELR833            51.32766                4.36226

Note: The stations used in this example (FR04014, BETR801 and London Westminster) are just three entries enlisted in the metadata table. We only want to add the coordinates of these three to the measurements table, each on the corresponding rows of the air_quality table.

In [19]: air_quality.head()
Out[19]:
   date.utc          location        parameter  value
0 2019-05-07 1:00:00+00:00  London Westminster  no2 23.0
1 2019-05-07 1:00:00+00:00   FR04014        no2 25.0
2 2019-05-07 1:00:00+00:00    BETR801      pm25 12.5
3 2019-05-07 1:00:00+00:00    BETR801        no2 50.5
4 2019-05-07 1:00:00+00:00  London Westminster  pm25  8.0

In [20]: air_quality = pd.merge(air_quality, stations_coord,
                          how='left', on='location')

In [21]: air_quality.head()
Out[21]:
         date.utc          location        parameter  value      coordinates.
latitude  coordinates.longitude
0 2019-05-07 1:00:00+00:00  London Westminster  no2 23.0        51.49467 -0.13193
1 2019-05-07 1:00:00+00:00    FR04014        no2 25.0         48.83724 2.39390
2 2019-05-07 1:00:00+00:00    FR04014        no2 25.0         48.83722 2.39390
3 2019-05-07 1:00:00+00:00    BETR801      pm25 12.5         51.20966 4.43182
4 2019-05-07 1:00:00+00:00    BETR801        no2 50.5         51.20966 4.43182

Using the merge() function, for each of the rows in the air_quality table, the corresponding coordinates are added from the air_quality_stations_coord table. Both tables have the column location in common which is used as a key to combine the information. By choosing the left join, only the locations available in the air_quality (left) table, i.e. FR04014, BETR801 and London Westminster, end up in the resulting table. The merge function supports multiple join options similar to database-style operations.

Add the parameter full description and name, provided by the parameters metadata table, to the measurements table

Warning: The air quality parameters metadata are stored in a data file air_quality_parameters.csv, downloaded using the py-openaq package.
In [22]: air_quality_parameters = pd.read_csv("data/air_quality_parameters.csv")

In [23]: air_quality_parameters.head()
Out[23]:
   id   description        name
0  bc    Black Carbon     BC
1  co   Carbon Monoxide  CO
2  no2  Nitrogen Dioxide NO2
3  o3    Ozone            O3
4  pm10  Particulate matter less than 10 micrometers in... PM10

In [24]: air_quality = pd.merge(air_quality, air_quality_parameters,
      ....:   how='left', left_on='parameter', right_on='id')

In [25]: air_quality.head()
Out[25]:
   date.utc  location parameter ...  id
      →    →          →  →  →  →
0 1905-07 01:00:00+00:00    London Westminster  no2 ...  no2
→ Nitrogen Dioxide NO2
1 1905-07 01:00:00+00:00    FR04014        no2 ...  no2
→ Nitrogen Dioxide NO2
2 1905-07 01:00:00+00:00    FR04014        no2 ...  no2
→ Nitrogen Dioxide NO2
3 1905-07 01:00:00+00:00    BETR801   pm25 ...  pm25  Particulate
→ matter less than 2.5 micrometers i... PM2.5
4 1905-07 01:00:00+00:00    BETR801        no2 ...  no2
→ Nitrogen Dioxide NO2
[5 rows x 9 columns]

Compared to the previous example, there is no common column name. However, the parameter column in the air_quality table and the id column in the air_quality_parameters_name both provide the measured variable in a common format. The left_on and right_on arguments are used here (instead of just on) to make the link between the two tables.

pandas supports also inner, outer, and right joins. More information on join/merge of tables is provided in the user guide section on database style merging of tables. Or have a look at the comparison with SQL page.

- Multiple tables can be concatenated both column-wise and row-wise using the concat function.
- For database-like merging/joining of tables, use the merge function.

See the user guide for a full description of the various facilities to combine data tables.

In [1]: import pandas as pd
In [2]: import matplotlib.pyplot as plt

For this tutorial, air quality data about NO₂ and Particulate matter less than 2.5 micrometers is used, made available by openaq and downloaded using the py-openaq package. The air_quality_no2_long.csv data set provides NO₂ values for the measurement stations FR04014, BETR801 and London Westminster in respectively Paris, Antwerp and London.

In [3]: air_quality = pd.read_csv("data/air_quality_no2_long.csv")
In [4]: air_quality = air_quality.rename(columns={"date.utc": "datetime") (continues on next page)
How to handle time series data with ease?

Using pandas datetime properties

I want to work with the dates in the column `datetime` as datetime objects instead of plain text

```python
In [7]: air_quality["datetime"] = pd.to_datetime(air_quality["datetime"])
```

```python
In [8]: air_quality["datetime"]
```

```
0 2019-06-21 00:00:00+00:00
1 2019-06-20 23:00:00+00:00
2 2019-06-20 22:00:00+00:00
3 2019-06-20 21:00:00+00:00
4 2019-06-20 20:00:00+00:00
... 2063 2019-05-07 06:00:00+00:00
2064 2019-05-07 04:00:00+00:00
2065 2019-05-07 03:00:00+00:00
2066 2019-05-07 02:00:00+00:00
2067 2019-05-07 01:00:00+00:00
Name: datetime, Length: 2068, dtype: datetime64[ns, UTC]
```

Initially, the values in `datetime` are character strings and do not provide any datetime operations (e.g. extract the year, day of the week,...). By applying the `to_datetime` function, pandas interprets the strings and convert these to datetime (i.e. `datetime64[ns, UTC]`) objects. In pandas we call these datetime objects similar to `datetime` datetime from the standard library as `pandas.Timestamp`.

**Note:** As many data sets do contain datetime information in one of the columns, pandas input function like `pandas.read_csv()` and `pandas.read_json()` can do the transformation to dates when reading the data using the `parse_dates` parameter with a list of the columns to read as `Timestamp`:

```python
pd.read_csv("../data/air_quality_no2_long.csv", parse_dates=["datetime"])```

Why are these `pandas.Timestamp` objects useful? Let’s illustrate the added value with some example cases.

What is the start and end date of the time series data set we are working with?
Using `pandas.Timestamp` for datetimes enables us to calculate with date information and make them comparable. Hence, we can use this to get the length of our time series:

```
In [10]: air_quality["datetime"].max() - air_quality["datetime"].min()
Out[10]: Timedelta('44 days 23:00:00')
```

The result is a `pandas.Timedelta` object, similar to `datetime.timedelta` from the standard Python library and defining a time duration.

The various time concepts supported by pandas are explained in the user guide section on time related concepts.

I want to add a new column to the DataFrame containing only the month of the measurement

```
In [11]: air_quality["month"] = air_quality["datetime"]["month"]
```

By using Timestamp objects for dates, a lot of time-related properties are provided by pandas. For example the month, but also year, weekofyear, quarter,... All of these properties are accessible by the `dt` accessor.

An overview of the existing date properties is given in the time and date components overview table. More details about the `dt` accessor to return datetime like properties are explained in a dedicated section on the `dt accessor`.

What is the average $NO_2$ concentration for each day of the week for each of the measurement locations?

```
In [13]: air_quality.groupby(
    
                   .. air_quality["datetime"]["weekday", "location"])["value"].mean()
                   ..
Out[13]:
    datetime  location
    0  BETR801    27.875000
        FR04014    24.856250
        London Westminster  23.969697
    1  BETR801    22.214286
        FR04014    21.852650
        London Westminster  21.896552
                  ...
    5  FR04014    25.266154
        London Westminster  24.977612
                  ...
    6  BETR801    21.896552
        FR04014    23.274306
        London Westminster  24.859155
Name: value, Length: 21, dtype: float64
```

Remember the split-apply-combine pattern provided by `groupby` from the tutorial on statistics calculation? Here, we want to calculate a given statistic (e.g. mean $NO_2$) for each weekday and for each measurement location. To group on weekdays, we use the datetime property `weekday` (with Monday=0 and Sunday=6) of pandas Timestamp,
which is also accessible by the `dt` accessor. The grouping on both locations and weekdays can be done to split the calculation of the mean on each of these combinations.

**Danger:** As we are working with a very short time series in these examples, the analysis does not provide a long-term representative result!

Plot the typical $NO_2$ pattern during the day of our time series of all stations together. In other words, what is the average value for each hour of the day?

```
In [14]: fig, axs = plt.subplots(figsize=(12, 4))
In [15]: air_quality.groupby(Air_quality['datetime'].dt.hour)['value'].mean().plot(kind='bar',
                   rot=0,               
                   ax=axs)
Out[15]: <AxesSubplot:xlabel='datetime'>
In [16]: plt.xlabel("Hour of the day"); # custom x label using matplotlib
In [17]: plt.ylabel("$NO_2 (µg/m^3)$");
```

![Graph showing NO2 pattern during the day](image)

Similar to the previous case, we want to calculate a given statistic (e.g. mean $NO_2$) for each hour of the day and we can use the split-apply-combine approach again. For this case, we use the datetime property `hour` of pandas `Timestamp`, which is also accessible by the `dt` accessor.

**Datetime as index**

In the tutorial on reshaping, `pivot` was introduced to reshape the data table with each of the measurements locations as a separate column:

```
In [18]: no_2 = air_quality.pivot(index="datetime", columns="location", values="value")
In [19]: no_2.head()
Out[19]:
<table>
<thead>
<tr>
<th>location</th>
<th>BETR801</th>
<th>FR04014</th>
<th>London Westminster</th>
</tr>
</thead>
<tbody>
<tr>
<td>datetime</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2019-05-07</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
By pivoting the data, the datetime information became the index of the table. In general, setting a column as an index can be achieved by the `set_index` function.

Working with a datetime index (i.e. `DatetimeIndex`) provides powerful functionalities. For example, we do not need the `dt` accessor to get the time series properties, but have these properties available on the index directly:

```python
In [20]: no_2.index.year, no_2.index.weekday
Out[20]:
dtype='int64', name='datetime', length=1033),
Int64Index([1, 1, 1, 1, 1, 1, 1, 1, 1, 1, ... 3, 3, 3, 3, 3, 3, 3, 3, 4],
dtype='int64', name='datetime', length=1033))
```

Some other advantages are the convenient subsetting of time period or the adapted time scale on plots. Let’s apply this on our data.

Create a plot of the $NO_2$ values in the different stations from the 20th of May till the end of 21st of May

```python
In [21]: no_2["2019-05-20":"2019-05-21"].plot();
```
By providing a string that parses to a datetime, a specific subset of the data can be selected on a DatetimeIndex.

More information on the DatetimeIndex and the slicing by using strings is provided in the section on time series indexing.

**Resample a time series to another frequency**

Aggregate the current hourly time series values to the monthly maximum value in each of the stations.

```
In [22]: monthly_max = no_2.resample("M").max()

In [23]: monthly_max
```

```
Out[23]:
<table>
<thead>
<tr>
<th>location</th>
<th>BETR801</th>
<th>FR04014</th>
<th>London Westminster</th>
</tr>
</thead>
<tbody>
<tr>
<td>location BETR801</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2019-05-31 00:00:00+00:00</td>
<td>74.5</td>
<td>97.0</td>
<td>97.0</td>
</tr>
<tr>
<td>2019-06-30 00:00:00+00:00</td>
<td>52.5</td>
<td>84.7</td>
<td>52.0</td>
</tr>
</tbody>
</table>
```

A very powerful method on time series data with a datetime index, is the ability to `resample()` time series to another frequency (e.g., converting secondly data into 5-minutely data).

The `resample()` method is similar to a groupby operation:

- it provides a time-based grouping, by using a string (e.g. M, 5H,..,) that defines the target frequency
- it requires an aggregation function such as `mean, max,..`
An overview of the aliases used to define time series frequencies is given in the *offset aliases overview table*. When defined, the frequency of the time series is provided by the `freq` attribute:

```python
In [24]: monthly_max.index.freq
Out[24]: <MonthEnd>
```

Make a plot of the daily mean $NO_2$ value in each of the stations.

```python
In [25]: no_2.resample("D").mean().plot(style="-o", figsize=(10, 5));
```

More details on the power of time series resampling is provided in the user guide section on *resampling*.

- Valid date strings can be converted to datetime objects using `to_datetime` function or as part of read functions.
- Datetime objects in pandas support calculations, logical operations and convenient date-related properties using the `dt` accessor.
- A `DatetimeIndex` contains these date-related properties and supports convenient slicing.
- `Resample` is a powerful method to change the frequency of a time series.

A full overview on time series is given on the pages on *time series and date functionality*.

```python
In [1]: import pandas as pd
```

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- PassengerId: Id of every passenger.
- Survived: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- Pclass: There are 3 classes: Class 1, Class 2 and Class 3.
- Name: Name of passenger.
- Sex: Gender of passenger.
- Age: Age of passenger.
• SibSp: Indication that passenger have siblings and spouse.
• Parch: Whether a passenger is alone or have family.
• Ticket: Ticket number of passenger.
• Fare: Indicating the fare.
• Cabin: The cabin of passenger.
• Embarked: The embarked category.

```python
In [2]: titanic = pd.read_csv("data/titanic.csv")
In [3]: titanic.head()
Out[3]:
   PassengerId  Survived  Pclass   Name                                      
0          1          0       3  Braund, Mr. Owen Harris
1          2          1       1  Cumings, Mrs. John Bradley (Florence Briggs Th... 
2          3          1       3  Heikkinen, Miss. Laina
3          4          1       1  Futrelle, Mrs. Jacques Heath (Lily May Peel)
4          5          0       3  Allen, Mr. William Henry

[5 rows x 12 columns]
```

### How to manipulate textual data?

Make all name characters lowercase

```python
In [4]: titanic["Name"].str.lower()
Out[4]:
0   braund, mr. owen harris
1  cumings, mrs. john bradley (florence briggs th...
2    heikkinen, miss. laina
3  futrelle, mrs. jacques heath (lily may peel)
4     allen, mr. william henry
   ...  montvila, rev. juozas
886    graham, miss. margaret edith
887  johnston, miss. catherine helen "carrie"
888     behr, mr. karl howell
890  dooley, mr. patrick
Name: Name, Length: 891, dtype: object
```

To make each of the strings in the Name column lowercase, select the Name column (see tutorial on selection of data), add the str accessor and apply the lower method. As such, each of the strings is converted element wise.

Similar to datetime objects in the time series tutorial having a dt accessor, a number of specialized string methods are available when using the str accessor. These methods have in general matching names with the equivalent built-in string methods for single elements, but are applied element-wise (remember element wise calculations?) on each of the values of the columns.

Create a new column Surname that contains the surname of the Passengers by extracting the part before the comma.

1.4. Tutorials
Using the `Series.str.split()` method, each of the values is returned as a list of 2 elements. The first element is the part before the comma and the second element is the part after the comma.

As we are only interested in the first part representing the surname (element 0), we can again use the `str` accessor and apply `Series.str.get()` to extract the relevant part. Indeed, these string functions can be concatenated to combine multiple functions at once!

More information on extracting parts of strings is available in the user guide section on *splitting and replacing strings*.

Extract the passenger data about the Countesses on board of the Titanic.
The string method \texttt{Series.str.contains()} checks for each of the values in the column 	extit{Name} if the string contains the word \textit{Countess} and returns for each of the values \texttt{True} (\textit{Countess} is part of the name) or \texttt{False} (\textit{Countess} is not part of the name). This output can be used to subselect the data using conditional (boolean) indexing introduced in the \textit{subsetting of data tutorial}. As there was only one Countess on the Titanic, we get one row as a result.

\textbf{Note:} More powerful extractions on strings are supported, as the \texttt{Series.str.contains()} and \texttt{Series.str.extract()} methods accept regular expressions, but out of scope of this tutorial.

More information on extracting parts of strings is available in the user guide section on \textit{string matching and extracting}.

Which passenger of the Titanic has the longest name?

To get the longest name we first have to get the lengths of each of the names in the \textit{Name} column. By using pandas string methods, the \texttt{Series.str.len()} function is applied to each of the names individually (element-wise).

Next, we need to get the corresponding location, preferably the index label, in the table for which the name length is the largest. The \texttt{idxmax()} method does exactly that. It is not a string method and is applied to integers, so no \texttt{str} is used.

Based on the index name of the row (307) and the column (\textit{Name}), we can do a selection using the \texttt{loc} operator, introduced in the \textit{tutorial on subsetting}.

In the “Sex” column, replace values of “male” by “M” and values of “female” by “F”
In [13]: titanic["Sex_short"] = titanic["Sex"].replace({"male": "M",
.....:
        "female": "F"})
.....:

In [14]: titanic["Sex_short"]
Out[14]:
   0    M
   1    F
   2    F
   3    F
   4    M
     ..
  886    M
  887    F
  888    F
  889    M
  890    M
Name: Sex_short, Length: 891, dtype: object

Whereas replace() is not a string method, it provides a convenient way to use mappings or vocabularies to translate certain values. It requires a dictionary to define the mapping {from : to}.

\textbf{Warning}: There is also a replace() method available to replace a specific set of characters. However, when having a mapping of multiple values, this would become:

\begin{verbatim}
titanic["Sex_short"] = titanic["Sex"].str.replace("female", "F")
titanic["Sex_short"] = titanic["Sex_short"].str.replace("male", "M")
\end{verbatim}

This would become cumbersome and easily lead to mistakes. Just think (or try out yourself) what would happen if those two statements are applied in the opposite order...

- String methods are available using the \texttt{str} accessor.
- String methods work element wise and can be used for conditional indexing.
- The replace method is a convenient method to convert values according to a given dictionary.

A full overview is provided in the user guide pages on working with text data.

\subsection{1.4.4 Comparison with other tools}

\textbf{Comparison with R / R libraries}

Since \texttt{pandas} aims to provide a lot of the data manipulation and analysis functionality that people use R for, this page was started to provide a more detailed look at the R language and its many third party libraries as they relate to \texttt{pandas}. In comparisons with R and CRAN libraries, we care about the following things:

- \textbf{Functionality / flexibility}: what can/cannot be done with each tool
- \textbf{Performance}: how fast are operations. Hard numbers/benchmarks are preferable
- \textbf{Ease-of-use}: Is one tool easier/harder to use (you may have to be the judge of this, given side-by-side code comparisons)

This page is also here to offer a bit of a translation guide for users of these R packages.

For transfer of DataFrame objects from \texttt{pandas} to R, one option is to use HDF5 files, see \textit{External compatibility} for an example.
Quick reference

We’ll start off with a quick reference guide pairing some common R operations using dplyr with pandas equivalents.

Querying, filtering, sampling

<table>
<thead>
<tr>
<th>R</th>
<th>pandas</th>
</tr>
</thead>
<tbody>
<tr>
<td>dim(df)</td>
<td>df.shape</td>
</tr>
<tr>
<td>head(df)</td>
<td>df.head()</td>
</tr>
<tr>
<td>slice(df, 1:10)</td>
<td>df.iloc[:9]</td>
</tr>
<tr>
<td>filter(df, col1 == 1, col2 == 1)</td>
<td>df.query('col1 == 1 &amp; col2 == 1')</td>
</tr>
<tr>
<td>df[df$col1 == 1 &amp; df$col2 == 1,]</td>
<td>df[(df.col1 == 1) &amp; (df.col2 == 1)]</td>
</tr>
<tr>
<td>select(df, col1, col2)</td>
<td>df[['col1', 'col2']]</td>
</tr>
<tr>
<td>select(df, col1:col3)</td>
<td>df.loc[:, 'col1':'col3']</td>
</tr>
<tr>
<td>select(df, -(col1:col3))</td>
<td>df.drop(cols_to_drop, axis=1) but see'</td>
</tr>
<tr>
<td>distinct(select(df, col1))</td>
<td>df[['col1']].drop_duplicates()</td>
</tr>
<tr>
<td>distinct(select(df, col1, col2))</td>
<td>df[['col1', 'col2']].drop_duplicates()</td>
</tr>
<tr>
<td>sample_n(df, 10)</td>
<td>df.sample(n=10)</td>
</tr>
<tr>
<td>sample_frac(df, 0.01)</td>
<td>df.sample(frac=0.01)</td>
</tr>
</tbody>
</table>

Sorting

<table>
<thead>
<tr>
<th>R</th>
<th>pandas</th>
</tr>
</thead>
<tbody>
<tr>
<td>arrange(df, col1, col2)</td>
<td>df.sort_values(['col1', 'col2'])</td>
</tr>
<tr>
<td>arrange(df, desc(col1))</td>
<td>df.sort_values('col1', ascending=False)</td>
</tr>
</tbody>
</table>

Transforming

<table>
<thead>
<tr>
<th>R</th>
<th>pandas</th>
</tr>
</thead>
<tbody>
<tr>
<td>select(df, col_one = coll)</td>
<td>df.rename(columns={'col1': 'col_one'})['col_one']</td>
</tr>
<tr>
<td>rename(df, col_one = coll)</td>
<td>df.rename(columns={'col1': 'col_one'})</td>
</tr>
<tr>
<td>mutate(df, c=a-b)</td>
<td>df.assign(c=df['a']-df['b'])</td>
</tr>
</tbody>
</table>

1 R’s shorthand for a subrange of columns (select(df, col1:col3)) can be approached cleanly in pandas, if you have the list of columns, for example df[cols[1:3]] or df.drop(cols[1:3]), but doing this by column name is a bit messy.
Grouping and summarizing

<table>
<thead>
<tr>
<th>R</th>
<th>pandas</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>summary(df)</code></td>
<td><code>df.describe()</code></td>
</tr>
<tr>
<td><code>gdf &lt;- group_by(df, col1)</code></td>
<td><code>gdf = df.groupby('col1')</code></td>
</tr>
<tr>
<td><code>summarise(gdf, avg=mean(col1, na.rm=TRUE))</code></td>
<td><code>df.groupby('col1').agg({'col1': 'mean'})</code></td>
</tr>
<tr>
<td><code>summarise(gdf, total=sum(col1))</code></td>
<td><code>df.groupby('col1').sum()</code></td>
</tr>
</tbody>
</table>

Base R

Slicing with R's \( \mathbf{c} \)

R makes it easy to access \texttt{data.frame} columns by name

```r
df <- data.frame(a=rnorm(5), b=rnorm(5), c=rnorm(5), d=rnorm(5), e=rnorm(5))
df[, c("a", "c", "e")]
```

or by integer location

```r
df <- data.frame(matrix(rnorm(1000), ncol=100))
df[, c(1:10, 25:30, 40, 50:100)]
```

Selecting multiple columns by name in \texttt{pandas} is straightforward

```python
In [1]: df = pd.DataFrame(np.random.randn(10, 3), columns=list('abc'))
In [2]: df[['a', 'c']]  
Out[2]:
          a       c
0  0.469112 -1.509059
1 -1.135632 -0.173215
2  0.119209 -0.861849
3 -2.104569  1.071804
4  0.721555 -1.039575
5  0.271860  0.567020
6  0.276232 -0.673690
7  0.113648  0.524988
8  0.404705 -1.715002
9 -1.039268 -1.157892

In [3]: df.loc[:, ['a', 'c']]  
Out[3]:
          a       c
0  0.469112 -1.509059
1 -1.135632 -0.173215
2  0.119209 -0.861849
3 -2.104569  1.071804
4  0.721555 -1.039575
5  0.271860  0.567020
6  0.276232 -0.673690
7  0.113648  0.524988
8  0.404705 -1.715002
9 -1.039268 -1.157892
```
Selecting multiple noncontiguous columns by integer location can be achieved with a combination of the `iloc` indexer attribute and `numpy.r_`.

```python
In [4]: named = list('abcdefg')
In [5]: n = 30
In [6]: columns = named + np.arange(len(named), n).tolist()
In [7]: df = pd.DataFrame(np.random.randn(n, n), columns=columns)
In [8]: df.iloc[:, np.r_[:10, 24:30]]
Out[8]:
   a  b  c  d  e  f  g ... 18  19  20  21  22  23
0 -1.344312 0.844885 1.075770 -0.109050 1.643563 -1.469388 0.357021 ...
   ...          ...          ...          ...          ...          ...          ...
9  25  26  27  28  29
```

```
aggregate
```

In R you may want to split data into subsets and compute the mean for each. Using a data.frame called `df` and splitting it into groups by `by1` and `by2`:

```r
df <- data.frame(
  v1 = c(1,3,5,7,8,3,5,NA, 4, 5, 7, 9),
  v2 = c(11,33,55,77,88,33,55,NA, 44,55,77,99),
  by1 = c("red", "blue", 1, 2, NA, "big", 1, 2, "red", 1, NA, 12),
  by2 = c("wet", "dry", 99, 95, NA, "damp", 95, 99, "red", 99, NA, NA))
aggregate(x=df[, c("v1", "v2")], by=list(mydf$by1, mydf$by2), FUN = mean)

The `groupby()` method is similar to base R `aggregate` function.

```python
In [9]: df = pd.DataFrame(
    ...:     {'v1': [1, 3, 5, 7, 8, 3, 5, np.nan, 4, 5, 7, 9],
    ...:     ...
    ...: )
```

(continues on next page)
In [10]: g = df.groupby(['by1', 'by2'])

In [11]: g[['v1', 'v2']].mean()

Out[11]:

<table>
<thead>
<tr>
<th>by1</th>
<th>by2</th>
<th>v1</th>
<th>v2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>99</td>
<td>5.0</td>
<td>55.0</td>
</tr>
<tr>
<td>2</td>
<td>95</td>
<td>7.0</td>
<td>77.0</td>
</tr>
<tr>
<td></td>
<td>99</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>big</td>
<td>damp</td>
<td>3.0</td>
<td>33.0</td>
</tr>
<tr>
<td>blue</td>
<td>dry</td>
<td>3.0</td>
<td>33.0</td>
</tr>
<tr>
<td>red</td>
<td>red</td>
<td>4.0</td>
<td>44.0</td>
</tr>
<tr>
<td>wet</td>
<td></td>
<td>1.0</td>
<td>11.0</td>
</tr>
</tbody>
</table>

For more details and examples see the groupby documentation.

**match/%in%**

A common way to select data in R is using `%in%` which is defined using the function `match`. The operator `%in%` is used to return a logical vector indicating if there is a match or not:

```r
s <- 0:4
s %in% c(2,4)
```

The `isin()` method is similar to R `%in%` operator:

```python
In [12]: s = pd.Series(np.arange(5), dtype=np.float32)
In [13]: s.isin([2, 4])

Out[13]:
0  False
1  False
2   True
3  False
4   True
dtype: bool
```

The `match` function returns a vector of the positions of matches of its first argument in its second:

```python
s <- 0:4
match(s, c(2,4))
```

For more details and examples see the reshaping documentation.
tapply

tapply is similar to aggregate, but data can be in a ragged array, since the subclass sizes are possibly irregular.
Using a data.frame called baseball, and retrieving information based on the array team:

```r
baseball <-
data.frame(team = gl(5, 5,
  labels = paste("Team", LETTERS[1:5]),
  player = sample(letters, 25),
  batting.average = runif(25, .200, .400))
tapply(baseball$batting.average, baseball.example$team, max)
```

In pandas we may use `pivot_table()` method to handle this:

```python
In [14]: import random
In [15]: import string
In [16]: baseball = pd.DataFrame(......:
  ....: {'team': ["team %d" % (x + 1) for x in range(5)] * 5,
  ....: 'player': random.sample(list(string.ascii_lowercase), 25),
  ....: 'batting avg': np.random.uniform(.200, .400, 25)})
In [17]: baseball.pivot_table(values='batting avg', columns='team', aggfunc=np.max)
```

For more details and examples see the reshaping documentation.

subset

The `query()` method is similar to the base R `subset` function. In R you might want to get the rows of a data.frame where one column’s values are less than another column’s values:

```r
df <- data.frame(a=rnorm(10), b=rnorm(10))
subset(df, a <= b)
df[df$a <= df$b]  # note the comma
```

In pandas, there are a few ways to perform subsetting. You can use `query()` or pass an expression as if it were an index/slice as well as standard boolean indexing:

```python
In [18]: df = pd.DataFrame({'a': np.random.randn(10), 'b': np.random.randn(10)})
In [19]: df.query('a <= b')
```

(continues on next page)
In [20]: df[df['a'] <= df['b']]  
Out[20]:  
   a      b  
0 0.174950 0.552887  
1 -0.023167 0.148084  
3 -0.495291 -0.300218  
4 -0.860736 0.197378  
5 -1.134146 1.720780  
7 -0.290098 0.083515  
8 0.238636 0.946550

In [21]: df.loc[df['a'] <= df['b']]  
Out[21]:  
   a      b  
0 0.174950 0.552887  
1 -0.023167 0.148084  
3 -0.495291 -0.300218  
4 -0.860736 0.197378  
5 -1.134146 1.720780  
7 -0.290098 0.083515  
8 0.238636 0.946550

For more details and examples see the query documentation.

with

An expression using a data.frame called df in R with the columns a and b would be evaluated using with like so:

df <- data.frame(a=rnorm(10), b=rnorm(10))  
with(df, a + b)  
df$a + df$b  # same as the previous expression

In pandas the equivalent expression, using the eval() method, would be:

In [22]: df = pd.DataFrame({'a': np.random.randn(10), 'b': np.random.randn(10)})  
In [23]: df.eval('a + b')  
Out[23]:  
   0 -0.091430  
   1 -2.483890  
   2 -0.252728  
   3 -0.626444  
   4 -0.261740  
   5 2.149503  
   6 -0.332214  
   7 0.799331  
   8 -2.377245  
   9 2.104677  
dtype: float64

In [24]: df['a'] + df['b']  # same as the previous expression  
Out[24]:  
   0 -0.091430  
           (continues on next page)
In certain cases `eval()` will be much faster than evaluation in pure Python. For more details and examples see the `eval` documentation.

### plyr

`plyr` is an R library for the split-apply-combine strategy for data analysis. The functions revolve around three data structures in R, a for arrays, l for lists, and d for data.frame. The table below shows how these data structures could be mapped in Python.

<table>
<thead>
<tr>
<th>R</th>
<th>Python</th>
</tr>
</thead>
<tbody>
<tr>
<td>array</td>
<td>list</td>
</tr>
<tr>
<td>lists</td>
<td>dictionary or list of objects</td>
</tr>
<tr>
<td>data.frame</td>
<td>dataframe</td>
</tr>
</tbody>
</table>

### `ddply`

An expression using a data.frame called `df` in R where you want to summarize `x` by `month`:

```r
require(plyr)
df <- data.frame(
  x = runif(120, 1, 168),
  y = runif(120, 7, 334),
  z = runif(120, 1.7, 20.7),
  month = rep(c(5, 6, 7, 8), 30),
  week = sample(1:4, 120, TRUE)
)
ddply(df, .(month, week), summarize,
      mean = round(mean(x), 2),
      sd = round(sd(x), 2))
```

In pandas the equivalent expression, using the `groupby()` method, would be:

```python
In [25]: df = pd.DataFrame({'x': np.random.uniform(1., 168., 120),
                       'y': np.random.uniform(7., 334., 120),
                       'z': np.random.uniform(1.7, 20.7, 120),
                       'month': [5, 6, 7, 8] * 30,
                       'week': np.random.randint(1, 4, 120))
In [26]: grouped = df.groupby(["month", "week"], axis=0)
```
In [27]: grouped['x'].agg([np.mean, np.std])
Out[27]:

<table>
<thead>
<tr>
<th></th>
<th>mean</th>
<th>std</th>
</tr>
</thead>
<tbody>
<tr>
<td>month</td>
<td>week</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>1</td>
<td>63.653367</td>
</tr>
<tr>
<td>2</td>
<td>78.126605</td>
<td>53.342400</td>
</tr>
<tr>
<td>3</td>
<td>92.091886</td>
<td>57.630110</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
<td>81.747070</td>
</tr>
<tr>
<td>2</td>
<td>70.971205</td>
<td>54.687287</td>
</tr>
<tr>
<td>3</td>
<td>100.968344</td>
<td>54.010081</td>
</tr>
<tr>
<td>7</td>
<td>1</td>
<td>61.576332</td>
</tr>
<tr>
<td>2</td>
<td>61.733510</td>
<td>48.209013</td>
</tr>
<tr>
<td>3</td>
<td>71.688795</td>
<td>37.595638</td>
</tr>
<tr>
<td>8</td>
<td>1</td>
<td>62.741922</td>
</tr>
<tr>
<td>2</td>
<td>91.774627</td>
<td>49.790202</td>
</tr>
<tr>
<td>3</td>
<td>73.936856</td>
<td>60.773900</td>
</tr>
</tbody>
</table>

For more details and examples see the groupby documentation.

**reshape / reshape2**

**melt.array**

An expression using a 3 dimensional array called `a` in R where you want to melt it into a data.frame:

```r
a <- array(c(1:23, NA), c(2,3,4))
data.frame(melt(a))
```

In Python, since `a` is a list, you can simply use list comprehension.

```python
In [28]: a = np.array(list(range(1, 24)) + [np.NAN]).reshape(2, 3, 4)

In [29]: pd.DataFrame([[tuple(list(x) + [val]) for x, val in np.ndenumerate(a)]]
Out[29]:
          0   1   2   3
 0  0    0    0  1.0
 1  0    0    1  2.0
 2  0    0    2  3.0
 3  0    0    3  4.0
 4  0    1    0  5.0
...  ...  ...  ...  
19  1    1    3  20.0
20  1    2    0  21.0
21  1    2    1  22.0
22  1    2    2  23.0
23  1    2    3  NaN

[24 rows x 4 columns]
```
**melt.list**

An expression using a list called `a` in R where you want to melt it into a data.frame:

```r
a <- as.list(c(1:4, NA))
data.frame(melt(a))
```

In Python, this list would be a list of tuples, so `DataFrame()` method would convert it to a dataframe as required.

```python
In [30]: a = list(enumerate(list(range(1, 5)) + [np.NAN]))
In [31]: pd.DataFrame(a)
Out[31]:
   0 1
0  0 1.0
1  1 2.0
2  2 3.0
3  3 4.0
4  4 NaN
```

For more details and examples see the *Into to Data Structures documentation*.

**melt.data.frame**

An expression using a data.frame called `cheese` in R where you want to reshape the data.frame:

```r
cheese <- data.frame(
    first = c('John', 'Mary'),
    last = c('Doe', 'Bo'),
    height = c(5.5, 6.0),
    weight = c(130, 150)
)
melt(cheese, id=c("first", "last"))
```

In Python, the `melt()` method is the R equivalent:

```python
In [32]: cheese = pd.DataFrame({'first': ['John', 'Mary'],
                           ....:                     'last': ['Doe', 'Bo'],
                           ....:                     'height': [5.5, 6.0],
                           ....:                     'weight': [130, 150]})
In [33]: pd.melt(cheese, id_vars=['first', 'last'])
Out[33]:
   first  last variable value
0   John  Doe   height   5.5
1  Mary   Bo   height   6.0
2   John  Doe   weight  130.0
3  Mary   Bo   weight  150.0
In [34]: cheese.set_index(['first', 'last']).stack()  # alternative way
Out[34]:
   first  last
John  Doe   height   5.5
          weight  130.0
Mary  Bo   height   6.0
(continues on next page)
weight  150.0
dtype: float64

For more details and examples see the reshaping documentation.

cast

In R, `acast` is an expression using a data.frame called `df` in R to cast into a higher dimensional array:

```r
df <- data.frame(
  x = runif(12, 1, 168),
  y = runif(12, 7, 334),
  z = runif(12, 1.7, 20.7),
  month = rep(c(5, 6, 7), 4),
  week = rep(c(1, 2), 6)
)
mdf <- melt(df, id=c("month", "week"))
acast(mdf, week ~ month ~ variable, mean)
```

In Python, the best way is to make use of `pivot_table()`:

```python
In [35]: df = pd.DataFrame({'x': np.random.uniform(1., 168., 12),
                      ....:                      'y': np.random.uniform(7., 334., 12),
                      ....:                      'z': np.random.uniform(1.7, 20.7, 12),
                      ....:                      'month': [5, 6, 7] * 4,
                      ....:                      'week': [1, 2] * 6})
In [36]: mdf = pd.melt(df, id_vars=['month', 'week'])
In [37]: pd.pivot_table(mdf, values='value', index=['variable', 'week'],
                      columns=['month'], aggfunc=np.mean)
```

Similarly for `dcast` which uses a data.frame called `df` in R to aggregate information based on Animal and FeedType:

```r
df <- data.frame(
  Animal = c('Animal1', 'Animal2', 'Animal3', 'Animal2', 'Animal1',
             'Animal2', 'Animal3'),
  FeedType = c('A', 'B', 'A', 'A', 'B', 'B', 'A'),
  Amount = c(10, 7, 4, 2, 5, 6, 2)
)
dcast(df, Animal ~ FeedType, sum, fill=NaN)
```
# Alternative method using base R

```r
with(df, tapply(Amount, list(Animal, FeedType), sum))
```

Python can approach this in two different ways. Firstly, similar to above using `pivot_table()`:

```python
In [38]: df = pd.DataFrame({
                      'Animal': ['Animal1', 'Animal2', 'Animal3', 'Animal2', 'Animal1',
                      'Animal2', 'Animal3'],
                      'FeedType': ['A', 'B', 'A', 'A', 'B', 'B', 'A'],
                      'Amount': [10, 7, 4, 2, 5, 6, 2],
                      })

In [39]: df.pivot_table(values='Amount', index='Animal', columns='FeedType',
                    aggfunc='sum')
```

```
Out[39]:
```
```
FeedType A  B
Animal  
Animal1 10.0  5.0
Animal2  2.0  13.0
Animal3  6.0   NaN
```

The second approach is to use the `groupby()` method:

```python
In [40]: df.groupby(['Animal', 'FeedType'])['Amount'].sum()
```

```
Out[40]:
```
```
Animal  FeedType
Animal1 A  10
      B  5
Animal2 A  2
      B  13
Animal3 A  6
Name: Amount, dtype: int64
```

For more details and examples see the reshaping documentation or the groupby documentation.

**factor**

pandas has a data type for categorical data.

```python
cut(c(1,2,3,4,5,6), 3)
factor(c(1,2,3,2,2,3))
```

In pandas this is accomplished with `pd.cut` and `astype("category")`:

```python
In [41]: pd.cut(pd.Series([1, 2, 3, 4, 5, 6]), 3)
```

```
Out[41]:
```
```
0 (0.995, 2.667]
1 (0.995, 2.667]
2 (2.667, 4.333]
3 (2.667, 4.333]
4 (4.333, 6.0]
5 (4.333, 6.0]
dtype: category
(continues on next page)
Categories (3, interval[float64]): [(0.995, 2.667) < (2.667, 4.333) < (4.333, 6.0)]

```
In [42]: pd.Series([1, 2, 3, 2, 2, 3]).astype("category")
Out[42]:
0    1
1    2
2    3
3    2
4    2
5    3
dtype: category
Categories (3, int64): [1, 2, 3]
```

For more details and examples see categorical introduction and the API documentation. There is also a documentation regarding the differences to R's factor.

**Comparison with SQL**

Since many potential pandas users have some familiarity with SQL, this page is meant to provide some examples of how various SQL operations would be performed using pandas.

If you’re new to pandas, you might want to first read through 10 Minutes to pandas to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```
In [1]: import pandas as pd
In [2]: import numpy as np
```

Most of the examples will utilize the `tips` dataset found within pandas tests. We’ll read the data into a DataFrame called `tips` and assume we have a database table of the same name and structure.

```
In [3]: url = ('https://raw.github.com/pandas-dev/pandas/master/pandas/tests/io/data/csv/tips.csv')
   ...
   ...

In [4]: tips = pd.read_csv(url)

In [5]: tips.head()
Out[5]:
          total_bill  tip    sex  smoker  day    time  size
0  16.990000  1.01 Female  No  Sun  Dinner   2
1  10.340000  1.66   Male  No  Sun  Dinner   3
2  21.010000  3.50   Male  No  Sun  Dinner   3
3  23.680000  3.31   Male  No  Sun  Dinner   2
4  24.590000  3.61 Female  No  Sun  Dinner   4
```
SELECT

In SQL, selection is done using a comma-separated list of columns you’d like to select (or a * to select all columns):

```sql
SELECT total_bill, tip, smoker, time
FROM tips
LIMIT 5;
```

With pandas, column selection is done by passing a list of column names to your DataFrame:

```python
In [6]: tips[['total_bill', 'tip', 'smoker', 'time']].head(5)
Out[6]:
   total_bill  tip  smoker  time
0     16.99  1.01   No     Dinner
1     10.34  1.66   No     Dinner
2     21.01  3.50   No     Dinner
3     23.68  3.31   No     Dinner
4     24.59  3.61   No     Dinner
```

Calling the DataFrame without the list of column names would display all columns (akin to SQL’s *).

In SQL, you can add a calculated column:

```sql
SELECT *, tip/total_bill as tip_rate
FROM tips
LIMIT 5;
```

With pandas, you can use the `DataFrame.assign()` method of a DataFrame to append a new column:

```python
In [7]: tips.assign(tip_rate=tips['tip'] / tips['total_bill']).head(5)
Out[7]:
   total_bill  tip  sex  smoker  day  time  size  tip_rate
0   16.99     1.01 Female   No   Sun Dinner  2  0.059447
1   10.34     1.66     Male   No   Sun Dinner  3  0.160542
2   21.01     3.50     Male   No   Sun Dinner  3  0.166587
3   23.68     3.31     Male   No   Sun Dinner  2  0.139780
4   24.59     3.61 Female   No   Sun Dinner  4  0.146808
```

WHERE

Filtering in SQL is done via a WHERE clause.

```sql
SELECT *
FROM tips
WHERE time = 'Dinner'
LIMIT 5;
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using boolean indexing

```python
In [8]: tips[tips['time'] == 'Dinner'].head(5)
Out[8]:
   total_bill  tip  sex  smoker  day  time  size
0   16.99     1.01 Female   No   Sun Dinner  2
1   10.34     1.66     Male   No   Sun Dinner  3
2   21.01     3.50     Male   No   Sun Dinner  3
```

(continues on next page)

1.4. Tutorials 71
The above statement is simply passing a `Series` of True/False objects to the DataFrame, returning all rows with True.

```python
In [9]: is_dinner = tips['time'] == 'Dinner'

In [10]: is_dinner.value_counts()
Out[10]:
True 176
False 68
Name: time, dtype: int64

In [11]: tips[is_dinner].head(5)
Out[11]:
   total_bill  tip    sex  smoker   day  time  size
0      16.99  1.01  Female   No  Sun  Dinner  2
1      10.34  1.66   Male    No  Sun  Dinner  3
2      21.01  3.50   Male    No  Sun  Dinner  3
3      23.68  3.31   Male    No  Sun  Dinner  2
4      24.59  3.61  Female    No  Sun  Dinner  4
```

Just like SQL's OR and AND, multiple conditions can be passed to a DataFrame using `|` (OR) and `&` (AND).

```sql
-- tips of more than $5.00 at Dinner meals
SELECT * FROM tips WHERE time = 'Dinner' AND tip > 5.00;
```

```python
In [12]: tips[(tips['time'] == 'Dinner') & (tips['tip'] > 5.00)].head(10)
Out[12]:
   total_bill  tip    sex  smoker   day  time  size
23       39.42  7.58   Male   No  Sat  Dinner  4
44       30.40  5.60   Male   No  Sun  Dinner  4
47       32.40  6.00   Male   No  Sun  Dinner  4
52       34.81  5.20 Female   No  Sun  Dinner  4
59       48.27  6.73 Female   No  Sun  Dinner  4
116      29.93  5.07   Male   No  Sun  Dinner  4
155      29.85  5.14 Female   No  Sun  Dinner  5
170      50.81 10.00   Male   Yes  Sat  Dinner  3
172       7.25  5.15 Female   Yes  Sun  Dinner  2
```

```sql
-- tips by parties of at least 5 diners OR bill total was more than $45
SELECT * FROM tips WHERE size >= 5 OR total_bill > 45;
```

```python
In [12]: tips[(tips['time'] == 'Dinner') & (tips['tip'] > 5.00)].head(10)
Out[12]:
   total_bill  tip    sex  smoker   day  time  size
23       39.42  7.58   Male   No  Sat  Dinner  4
44       30.40  5.60   Male   No  Sun  Dinner  4
47       32.40  6.00   Male   No  Sun  Dinner  4
52       34.81  5.20 Female   No  Sun  Dinner  4
59       48.27  6.73 Female   No  Sun  Dinner  4
116      29.93  5.07   Male   No  Sun  Dinner  4
155      29.85  5.14 Female   No  Sun  Dinner  5
170      50.81 10.00   Male   Yes  Sat  Dinner  3
172       7.25  5.15 Female   Yes  Sun  Dinner  2
```
# tips by parties of at least 5 diners OR bill total was more than $45

```python
In [13]: tips[(tips['size'] >= 5) | (tips['total_bill'] > 45)]
```

```csv
Out[13]:
total_bill  tip  sex  smoker  day  time  size
59  48.27  6.73  Male  No  Sat  Dinner  4
125  29.80  4.20  Female  No  Thur  Lunch  6
141  34.30  6.70  Male  No  Thur  Lunch  6
142  41.19  5.00  Male  No  Thur  Lunch  5
143  27.05  5.00  Female  No  Thur  Lunch  6
155  29.85  5.14  Female  No  Sun  Dinner  5
156  48.17  5.00  Male  No  Sun  Dinner  6
170  50.81  10.00  Male  Yes  Sat  Dinner  3
182  45.35  3.50  Male  Yes  Sun  Dinner  3
185  20.69  5.00  Male  No  Sun  Dinner  5
187  30.46  2.00  Male  Yes  Sun  Dinner  5
212  48.33  9.00  Male  No  Sat  Dinner  4
216  28.15  3.00  Male  Yes  Sat  Dinner  5
```

### NULL checking

NULL checking is done using the `notna()` and `isna()` methods.

```python
                           'col2': ['F', np.NaN, 'G', 'H', 'I']})

In [15]: frame
```

```csv
Out[15]:
col1  col2
0  A  F
1  B  NaN
2  NaN  G
3  C  H
4  D  I
```

Assume we have a table of the same structure as our DataFrame above. We can see only the records where `col2` IS NULL with the following query:

```sql
SELECT *
FROM frame
WHERE col2 IS NULL;
```

```python
In [16]: frame[frame['col2'].isna()]
```

```csv
Out[16]:
col1  col2
1  B  NaN
```

Getting items where `col1` IS NOT NULL can be done with `notna()`.

```sql
SELECT *
FROM frame
WHERE col1 IS NOT NULL;
```

```python
In [17]: frame[frame['col1'].notna()]
```

```csv
Out[17]:
col1  col2
0  A  F
1  B  NaN
```

(continues on next page)
GROUP BY

In pandas, SQL’s GROUP BY operations are performed using the similarly named `groupby()` method. `groupby()` typically refers to a process where we’d like to split a dataset into groups, apply some function (typically aggregation), and then combine the groups together.

A common SQL operation would be getting the count of records in each group throughout a dataset. For instance, a query getting us the number of tips left by sex:

```sql
SELECT sex, count(*)
FROM tips
GROUP BY sex;
/*
Female 87
Male 157
*/
```

The pandas equivalent would be:

```python
In [18]: tips.groupby('sex').size()
Out[18]:
   sex
Female     87
   Male    157
dtype: int64
```

Notice that in the pandas code we used `size()` and not `count()`. This is because `count()` applies the function to each column, returning the number of not null records within each.

```python
In [19]: tips.groupby('sex').count()
Out[19]:
       total_bill  tip  smoker  day  time  size
   sex
Female       87    87     87    87    87    87
   Male       157   157    157   157   157   157
```

Alternatively, we could have applied the `count()` method to an individual column:

```python
In [20]: tips.groupby('sex')['total_bill'].count()
Out[20]:
   sex
Female     87
   Male    157
Name: total_bill, dtype: int64
```

Multiple functions can also be applied at once. For instance, say we’d like to see how tip amount differs by day of the week. `agg()` allows you to pass a dictionary to your grouped DataFrame, indicating which functions to apply to specific columns.

```sql
SELECT day, AVG(tip), COUNT(*)
FROM tips
```

(continues on next page)
GROUP BY day;

/*
Fri  2.734737  19
Sat  2.993103  87
Sun  3.255132  76
Thur 2.771452  62
*/

In [21]: tips.groupby('day').agg({'tip': np.mean, 'day': np.size})
Out[21]:

<table>
<thead>
<tr>
<th>day</th>
<th>tip</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fri</td>
<td>2.734737</td>
<td>19</td>
</tr>
<tr>
<td>Sat</td>
<td>2.993103</td>
<td>87</td>
</tr>
<tr>
<td>Sun</td>
<td>3.255132</td>
<td>76</td>
</tr>
<tr>
<td>Thur</td>
<td>2.771452</td>
<td>62</td>
</tr>
</tbody>
</table>

Grouping by more than one column is done by passing a list of columns to the `groupby()` method.

```
SELECT smoker, day, COUNT(*), AVG(tip)
FROM tips
GROUP BY smoker, day;

/*
smoker day
No  Fri   4  2.812500
    Sat   45 3.102889
    Sun   57 3.167895
    Thur  45 2.673778
Yes Fri 15 2.714000
    Sat  42 2.875476
    Sun  19 3.516842
    Thur 17 3.030000
*/
```

In [22]: tips.groupby(['smoker', 'day']).agg({'tip': [np.size, np.mean]})
Out[22]:

<table>
<thead>
<tr>
<th>smoker</th>
<th>day</th>
<th>size</th>
<th>mean</th>
</tr>
</thead>
<tbody>
<tr>
<td>No</td>
<td>Fri</td>
<td>4.0</td>
<td>2.812500</td>
</tr>
<tr>
<td></td>
<td>Sat</td>
<td>45.0</td>
<td>3.102889</td>
</tr>
<tr>
<td></td>
<td>Sun</td>
<td>57.0</td>
<td>3.167895</td>
</tr>
<tr>
<td></td>
<td>Thur</td>
<td>45.0</td>
<td>2.673778</td>
</tr>
<tr>
<td>Yes</td>
<td>Fri</td>
<td>15.0</td>
<td>2.714000</td>
</tr>
<tr>
<td></td>
<td>Sat</td>
<td>42.0</td>
<td>2.875476</td>
</tr>
<tr>
<td></td>
<td>Sun</td>
<td>19.0</td>
<td>3.516842</td>
</tr>
<tr>
<td></td>
<td>Thur</td>
<td>17.0</td>
<td>3.030000</td>
</tr>
</tbody>
</table>
JOIN

JOINs can be performed with `join()` or `merge()`. By default, `join()` will join the DataFrames on their indices. Each method has parameters allowing you to specify the type of join to perform (LEFT, RIGHT, INNER, FULL) or the columns to join on (column names or indices).

```python
In [23]: df1 = pd.DataFrame({'key': ['A', 'B', 'C', 'D'],
                      'value': np.random.randn(4))

In [24]: df2 = pd.DataFrame({'key': ['B', 'D', 'D', 'E'],
                      'value': np.random.randn(4))
```

Assume we have two database tables of the same name and structure as our DataFrames.

Now let’s go over the various types of JOINs.

INNER JOIN

```sql
SELECT * 
FROM df1 
INNER JOIN df2 
ON df1.key = df2.key;
```

```
# merge performs an INNER JOIN by default
In [25]: pd.merge(df1, df2, on='key')
Out[25]:
   key  value_x  value_y
0  B  -0.282863  1.212112
1  D  -1.135632 -0.173215
2  D  -1.135632  0.119209
```

`merge()` also offers parameters for cases when you’d like to join one DataFrame’s column with another DataFrame’s index.

```
In [26]: indexed_df2 = df2.set_index('key')

In [27]: pd.merge(df1, indexed_df2, left_on='key', right_index=True)
Out[27]:
   key  value_x  value_y
0  B  -0.282863  1.212112
1  D  -1.135632 -0.173215
2  D  -1.135632  0.119209
```
LEFT OUTER JOIN

```python
# show all records from df1
In [28]: pd.merge(df1, df2, on='key', how='left')
Out[28]:
   key  value_x  value_y
0   A  0.469112      NaN
1   B -0.282863  1.212112
2   C -1.509059      NaN
3   D -1.135632 -0.173215
4   D -1.135632  0.119209
```

RIGHT JOIN

```python
# show all records from df2
In [29]: pd.merge(df1, df2, on='key', how='right')
Out[29]:
   key  value_x  value_y
0   B -0.282863  1.212112
1   D -1.135632 -0.173215
2   D -1.135632  0.119209
3   E      NaN -1.044236
```

FULL JOIN

```python
pandas also allows for FULL JOINs, which display both sides of the dataset, whether or not the joined columns find a match. As of writing, FULL JOINs are not supported in all RDBMS (MySQL).

```
UNION

UNION ALL can be performed using `concat()`.

```
In [31]: df1 = pd.DataFrame({
   ...:     'city': ['Chicago', 'San Francisco', 'New York City'],
   ...:     'rank': range(1, 4))
   ...
In [32]: df2 = pd.DataFrame({
   ...:     'city': ['Chicago', 'Boston', 'Los Angeles'],
   ...:     'rank': [1, 4, 5])
   ...:
```

```
SELECT city, rank
FROM df1
UNION ALL
SELECT city, rank
FROM df2;
/*
city  rank
Chicago 1
San Francisco 2
New York City 3
   Chicago 1
   Boston 4
Los Angeles 5
*/
```

```
In [33]: pd.concat([df1, df2])
Out[33]:
   city rank
0  Chicago    1
1  San Francisco  2
2 New York City  3
0  Chicago    1
1   Boston    4
2  Los Angeles  5
```

SQL’s UNION is similar to UNION ALL, however UNION will remove duplicate rows.

```
SELECT city, rank
FROM df1
UNION
SELECT city, rank
FROM df2;
-- notice that there is only one Chicago record this time
/*
city  rank
Chicago 1
   San Francisco 2
*/
```
In pandas, you can use `concat()` in conjunction with `drop_duplicates()`.

```python
In [34]: pd.concat([df1, df2]).drop_duplicates()
Out[34]:
   city     rank
0  Chicago   1
1   San Francisco   2
2  New York City   3
1     Boston       4
2    Los Angeles   5
```

**pandas equivalents for some SQL analytic and aggregate functions**

**Top n rows with offset**

```sql
-- MySQL
SELECT * FROM tips
ORDER BY tip DESC
LIMIT 10 OFFSET 5;
```

```python
In [35]: tips.nlargest(10 + 5, columns='tip').tail(10)
```

```
<table>
<thead>
<tr>
<th></th>
<th>total_bill</th>
<th>tip</th>
<th>sex</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>183</td>
<td>23.17</td>
<td>6.50</td>
<td>Male</td>

<td>Dinner</td>
<td>4</td>
</tr>
</tbody>
</table>
```

**Top n rows per group**

```sql
-- Oracle's ROW_NUMBER() analytic function
SELECT * FROM (  SELECT *  t.*,  ROW_NUMBER() OVER(PARTITION BY day ORDER BY total_bill DESC) AS rn  FROM tips t )  WHERE rn < 3  ORDER BY day, rn;
```
In [36]: (tips.assign(rn=tips.sort_values(['total_bill'], ascending=False)
       ....:   .groupby(['day'])
       ....:   .cumcount() + 1)
       ....:   .query('rn < 3')
       ....:   .sort_values(['day', 'rn'])
       ....: 
Out[36]:
      total_bill  tip  sex smoker day  time  size  rn
    95     40.17  4.73  Male    Yes  Fri  Dinner  4   1
    90     28.97  3.00  Male    Yes  Fri  Dinner  2   2
   170     50.81 10.00  Male    Yes  Sat  Dinner  3   1
   212     48.33  9.00  Male    No   Sat  Dinner  4   2
   156     48.17  5.00  Male    No   Sun  Dinner  6   1
   182     45.35  3.50  Male    Yes  Sun  Dinner  3   2
   197     43.11  5.00  Female   Yes  Thur  Lunch  4   1
   142     41.19  5.00  Male    No  Thur  Lunch  5   2

the same using rank(method='first') function

In [37]: (tips.assign(rnk=tips.groupby(['day'])['total_bill']
       ....:   .rank(method='first', ascending=False))
       ....:   .query('rnk < 3')
       ....:   .sort_values(['day', 'rnk'])
       ....: 
Out[37]:
      total_bill  tip  sex smoker day  time  size  rnk
    95     40.17  4.73  Male    Yes  Fri  Dinner  4   1.0
    90     28.97  3.00  Male    Yes  Fri  Dinner  2   2.0
   170     50.81 10.00  Male    Yes  Sat  Dinner  3   1.0
   212     48.33  9.00  Male    No   Sat  Dinner  4   2.0
   156     48.17  5.00  Male    No   Sun  Dinner  6   1.0
   182     45.35  3.50  Male    Yes  Sun  Dinner  3   2.0
   197     43.11  5.00  Female   Yes  Thur  Lunch  4   1.0
   142     41.19  5.00  Male    No  Thur  Lunch  5   2.0

-- Oracle's RANK() analytic function

SELECT * FROM (  
    SELECT  
      t.*,  
      RANK() OVER(PARTITION BY sex ORDER BY tip) AS rnk  
    FROM tips t  
    WHERE tip < 2  
)  
WHERE rnk < 3  
ORDER BY sex, rnk;

Let's find tips with (rank < 3) per gender group for (tips < 2). Notice that when using rank(method='min') function rnk_min remains the same for the same tip (as Oracle's RANK() function)

In [38]: (tips[tips['tip'] < 2]
       ....:   .assign(rnk_min=tips.groupby(['sex'])['tip']
       ....:   .rank(method='min'))
       ....:   .query('rnk_min < 3')
       ....:   .sort_values(['sex', 'rnk_min'])
       ....: 
Out[38]:
      total_bill  tip  sex smoker day  time  size  rnk_min
      (continues on next page)
UPDATE

```
UPDATE tips
SET tip = tip*2
WHERE tip < 2;
```

```
In [39]: tips.loc[tips['tip'] < 2, 'tip'] *= 2
```

DELETE

```
DELETE FROM tips
WHERE tip > 9;
```

In pandas we select the rows that should remain, instead of deleting them

```
In [40]: tips = tips.loc[tips['tip'] <= 9]
```

Comparison with SAS

For potential users coming from SAS this page is meant to demonstrate how different SAS operations would be performed in pandas.

If you’re new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```
In [1]: import pandas as pd
In [2]: import numpy as np
```

**Note:** Throughout this tutorial, the pandas DataFrame will be displayed by calling `df.head()`, which displays the first N (default 5) rows of the DataFrame. This is often used in interactive work (e.g. Jupyter notebook or terminal) - the equivalent in SAS would be:

```
proc print data=df(obs=5);
run;
```
Data structures

</tr>
</tbody>
</table>

**DataFrame / Series**

A DataFrame in pandas is analogous to a SAS data set - a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set using SAS’s DATA step, can also be accomplished in pandas.

A Series is the data structure that represents one column of a DataFrame. SAS doesn’t have a separate data structure for a single column, but in general, working with a Series is analogous to referencing a column in the DATA step.

**Index**

Every DataFrame and Series has an Index - which are labels on the rows of the data. SAS does not have an exactly analogous concept. A data set’s rows are essentially unlabeled, other than an implicit integer index that can be accessed during the DATA step (N).

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled Index or MultiIndex can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the Index and just treat the DataFrame as a collection of columns. Please see the indexing documentation for much more on how to use an Index effectively.

**Data input / output**

**Constructing a DataFrame from values**

A SAS data set can be built from specified values by placing the data after a datalines statement and specifying the column names.

```r
data df;
  input x y;
  datalines;
  1 2
  3 4
  5 6
;
run;
```

A pandas DataFrame can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.
**Reading external data**

Like SAS, pandas provides utilities for reading in data from many formats. The `tips` dataset, found within the pandas tests (csv) will be used in many of the following examples.

SAS provides PROC IMPORT to read csv data into a data set.

```sas
proc import datafile='tips.csv' dbms=csv out=tips replace;
  getnames=yes;
run;
```

The pandas method is `read_csv()`, which works similarly.

```python
In [5]: url = ('https://raw.github.com/pandas-dev/
...:'
       'pandas/master/pandas/tests/io/data/csv/tips.csv')
In [6]: tips = pd.read_csv(url)
In [7]: tips.head()
```

Like PROC IMPORT, `read_csv` can take a number of parameters to specify how the data should be parsed. For example, if the data was instead tab delimited, and did not have column names, the pandas command would be:

```python
tips = pd.read_csv('tips.csv', sep='	', header=None)
```

In addition to text/csv, pandas supports a variety of other data formats such as Excel, HDF5, and SQL databases. These are all read via a `pd.read_*` function. See the IO documentation for more details.
Exporting data

The inverse of \texttt{PROC IMPORT} in SAS is \texttt{PROC EXPORT}

\begin{verbatim}
proc export data=tips outfile='tips2.csv' dbms=csv;
run;
\end{verbatim}

Similarly in pandas, the opposite of \texttt{read_csv} is \texttt{to_csv()}, and other data formats follow a similar api.

\begin{verbatim}
tips.to_csv('tips2.csv')
\end{verbatim}

Data operations

Operations on columns

In the DATA step, arbitrary math expressions can be used on new or existing columns.

\begin{verbatim}
data tips;
   set tips;
   total_bill = total_bill - 2;
   new_bill = total_bill / 2;
run;
\end{verbatim}

pandas provides similar vectorized operations by specifying the individual \texttt{Series} in the \texttt{DataFrame}. New columns can be assigned in the same way.

\begin{verbatim}
In [8]: tips['total_bill'] = tips['total_bill'] - 2
In [9]: tips['new_bill'] = tips['total_bill'] / 2.0
In [10]: tips.head()
\end{verbatim}

\begin{verbatim}
Out[10]:
   total_bill  tip  sex  smoker  day  time  size   new_bill
0       14.99  1.01 Female  No  Sun  Dinner   2   7.495
1        8.34  1.66   Male  No  Sun  Dinner   3   4.170
2       19.01  3.50   Male  No  Sun  Dinner   3   9.505
3       21.68  3.31   Male  No  Sun  Dinner   2  10.840
4       22.59  3.61 Female  No  Sun  Dinner   4  11.295
\end{verbatim}

Filtering

Filtering in SAS is done with an \texttt{if} or \texttt{where} statement, on one or more columns.

\begin{verbatim}
data tips;
   set tips;
   if total_bill > 10;
run;
\end{verbatim}

\begin{verbatim}
data tips;
   set tips;
   where total_bill > 10;
   /* equivalent in this case - where happens before the
     DATA step begins and can also be used in PROC statements */
run;
\end{verbatim}
DataFrames can be filtered in multiple ways; the most intuitive of which is using **boolean indexing**

\[
\text{In [11]: tips[tips['total_bill'] > 10].head()}
\]

\[
\begin{array}{cccccccc}
\text{total_bill} & \text{tip} & \text{sex} & \text{smoker} & \text{day} & \text{time} & \text{size} \\
0 & 14.99 & 1.01 & Female & No & Sun & Dinner & 2 \\
2 & 19.01 & 3.50 & Male & No & Sun & Dinner & 3 \\
3 & 21.68 & 3.31 & Male & No & Sun & Dinner & 2 \\
4 & 22.59 & 3.61 & Female & No & Sun & Dinner & 4 \\
5 & 23.29 & 4.71 & Male & No & Sun & Dinner & 4 \\
\end{array}
\]

\textbf{If/then logic}

In SAS, if/then logic can be used to create new columns.

\[
\text{data tips;}
\text{set tips;}
\text{format bucket $4.;}
\text{if total_bill < 10 then bucket = 'low';}
\text{else bucket = 'high';}
\text{run;}
\]

The same operation in pandas can be accomplished using the \texttt{where} method from \texttt{numpy}.

\[
\text{In [12]: tips['bucket'] = np.where(tips['total_bill'] < 10, 'low', 'high')}
\]

\[
\text{In [13]: tips.head()}
\]

\[
\begin{array}{cccccccc}
\text{total_bill} & \text{tip} & \text{sex} & \text{smoker} & \text{day} & \text{time} & \text{size} & \text{bucket} \\
0 & 14.99 & 1.01 & Female & No & Sun & Dinner & high \\
1 & 8.34 & 1.66 & Male & No & Sun & Dinner & low \\
2 & 19.01 & 3.50 & Male & No & Sun & Dinner & high \\
3 & 21.68 & 3.31 & Male & No & Sun & Dinner & high \\
4 & 22.59 & 3.61 & Female & No & Sun & Dinner & high \\
\end{array}
\]

\textbf{Date functionality}

SAS provides a variety of functions to do operations on date/datetime columns.

\[
\text{data tips;}
\text{set tips;}
\text{format date1 date2 date1_plusmonth mmddyy10.;}
\text{date1 = mdy(1, 15, 2013);}
\text{date2 = mdy(2, 15, 2015);}
\text{date1_year = year(date1);}
\text{date2_month = month(date2);}
\text{* shift date to beginning of next interval;}
\text{date1_next = intnx('MONTH', date1, 1);}
\text{* count intervals between dates;}
\text{months_between = intck('MONTH', date1, date2);}
\text{run;}
\]

The equivalent pandas operations are shown below. In addition to these functions pandas supports other Time Series features not available in Base SAS (such as resampling and custom offsets) - see the \texttt{timeseries documentation} for

1.4. Tutorials
more details.

```
In [14]: tips['date1'] = pd.Timestamp('2013-01-15')
In [15]: tips['date2'] = pd.Timestamp('2015-02-15')
In [16]: tips['date1_year'] = tips['date1'].dt.year
In [17]: tips['date2_month'] = tips['date2'].dt.month
In [18]: tips['date1_next'] = tips['date1'] + pd.offsets.MonthBegin()
In [19]: tips['months_between'] = (tips['date2'].dt.to_period('M') - tips['date1'].dt.to_period('M'))
In [20]: tips[['date1', 'date2', 'date1_year', 'date2_month', 'date1_next', 'months_between']].head()
```

```
Out[20]:
          date1         date2         date1_year date2_month date1_next months_between
0 2013-01-15 2015-02-15         2013            2 2013-02-01 <25 * MonthEnds>
```

Selection of columns

SAS provides keywords in the DATA step to select, drop, and rename columns.

```
data tips;
  set tips;
  keep sex total_bill tip;
run;

data tips;
  set tips;
  drop sex;
run;

data tips;
  set tips;
  rename total_bill=total_bill_2;
run;
```

The same operations are expressed in pandas below.

```
# keep
In [21]: tips[['sex', 'total_bill', 'tip']].head()
Out[21]:
    sex  total_bill  tip
0  Female    14.99    1.01
1       Male     8.34    1.66
2       Male    19.01    3.50
3       Male    21.68    3.31
```

(continues on next page)
4 Female 22.59 3.61

# drop
In [22]: tips.drop('sex', axis=1).head()
Out[22]:
<table>
<thead>
<tr>
<th>total_bill</th>
<th>tip</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>14.99</td>
<td>1.01</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>2</td>
</tr>
<tr>
<td>8.34</td>
<td>1.66</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>3</td>
</tr>
<tr>
<td>19.01</td>
<td>3.50</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>3</td>

</tr>
</tbody>
</table>

### Sorting by values

Sorting in SAS is accomplished via **PROC SORT**

```sql
proc sort data=tips;
   by sex total_bill;
run;
```

pandas objects have a **sort_values()** method, which takes a list of columns to sort by.

In [24]: tips = tips.sort_values(['sex', 'total_bill'])

In [25]: tips.head()
Out[25]:
<table>
<thead>
<tr>
<th>total_bill</th>
<th>tip</th>
<th>sex</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.07</td>
<td>1.00</td>
<td>Female</td>
<td>Yes</td>
<td>Sat</td>
<td>Dinner</td>
<td>1</td>
</tr>
<tr>
<td>3.75</td>
<td>1.00</td>
<td>Female</td>
<td>Yes</td>
<td>Fri</td>
<td>Dinner</td>
<td>2</td>
</tr>
<tr>
<td>5.25</td>
<td>1.00</td>
<td>Female</td>
<td>No</td>
<td>Sat</td>
<td>Dinner</td>
<td>1</td>
</tr>
<tr>
<td>6.35</td>
<td>1.50</td>
<td>Female</td>
<td>No</td>
<td>Thur</td>
<td>Lunch</td>
<td>2</td>
</tr>
<tr>
<td>6.51</td>
<td>1.25</td>
<td>Female</td>
<td>No</td>
<td>Thur</td>
<td>Lunch</td>
<td>2</td>
</tr>
</tbody>
</table>

### String processing

**Length**

SAS determines the length of a character string with the **LENGTHN** and **LENGTHC** functions. **LENGTHN** excludes trailing blanks and **LENGTHC** includes trailing blanks.
Python determines the length of a character string with the `len` function. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```text
In [26]: tips['time'].str.len().head()
Out[26]:
   67  6
   92  6
  111  6
  145  5
  135  5
Name: time, dtype: int64

In [27]: tips['time'].str.rstrip().str.len().head()
Out[27]:
   67  6
   92  6
  111  6
  145  5
  135  5
Name: time, dtype: int64
```

### Find

SAS determines the position of a character in a string with the `FINDW` function. `FINDW` takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```text
data _null_; 
set tips; 
put (FINDW(sex,'ale')); 
run;
```

Python determines the position of a character in a string with the `find` function. `find` searches for the first position of the substring. If the substring is found, the function returns its position. Keep in mind that Python indexes are zero-based and the function will return -1 if it fails to find the substring.

```text
In [28]: tips['sex'].str.find("ale").head()
Out[28]:
   67  3
   92  3
  111  3
  145  3
  135  3
Name: sex, dtype: int64
```
### Substring

SAS extracts a substring from a string based on its position with the SUBSTR function.

```sas
data _null_; set tips; put(substr(sex,1,1)); run;
```

With pandas you can use [] notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```python
In [29]: tips['sex'].str[0:1].head()
Out[29]:
   Name: sex, dtype: object
```

### Scan

The SAS SCAN function returns the nth word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```sas
data firstlast;
input String $60.;
First_Name = scan(string, 1);
Last_Name = scan(string, -1);
datalines2;
John Smith;
Jane Cook;
;
run;
```

Python extracts a substring from a string based on its text by using regular expressions. There are much more powerful approaches, but this just shows a simple approach.

```python
In [30]: firstlast = pd.DataFrame({'String': ['John Smith', 'Jane Cook']})
In [31]: firstlast['First_Name'] = firstlast['String'].str.split(" ", expand=True)[0]
In [32]: firstlast['Last_Name'] = firstlast['String'].str.rsplit(" ", expand=True)[0]
In [33]: firstlast
Out[33]:
       String First_Name Last_Name
0  John Smith   John   John
1  Jane Cook    Jane    Jane
```
Upcase, lowcase, and propcase

The SAS UPCASE LOWCASE and PROPCASE functions change the case of the argument.

```r
data firstlast;
input String $60.;
string_up = UPCASE(string);
string_low = LOWCASE(string);
string_prop = PROPCASE(string);
datalines2;
John Smith;
Jane Cook;
;;
run;
```

The equivalent Python functions are upper, lower, and title.

```r
In [34]: firstlast = pd.DataFrame({'String': ['John Smith', 'Jane Cook']})
In [35]: firstlast['string_up'] = firstlast['String'].str.upper()
In [36]: firstlast['string_low'] = firstlast['String'].str.lower()
In [37]: firstlast['string_prop'] = firstlast['String'].str.title()
```

Merging

The following tables will be used in the merge examples

```r
In [39]: df1 = pd.DataFrame({'key': ['A', 'B', 'C', 'D'],
...:                      'value': np.random.randn(4)})
...:
In [40]: df1
Out[40]:
key   value
0     A   0.469112
1     B  -0.282863
2     C  -1.509059
3     D  -1.135632

In [41]: df2 = pd.DataFrame({'key': ['B', 'D', 'D', 'E'],
...:                      'value': np.random.randn(4)})
...:
In [42]: df2
Out[42]:
key   value
0     B   1.212112
1     D  -0.173215
```

(continues on next page)
In SAS, data must be explicitly sorted before merging. Different types of joins are accomplished using the `IN=` dummy variables to track whether a match was found in one or both input frames.

```
proc sort data=df1;
  by key;
run;

proc sort data=df2;
  by key;
run;

data left_join inner_join right_join outer_join;
  merge df1(in=a) df2(in=b);
  if a and b then output inner_join;
  if a then output left_join;
  if b then output right_join;
  if a or b then output outer_join;
run;
```

pandas DataFrames have a `merge()` method, which provides similar functionality. Note that the data does not have to be sorted ahead of time, and different join types are accomplished via the `how` keyword.

```
In [43]: inner_join = df1.merge(df2, on=['key'], how='inner')
In [44]: inner_join
Out[44]:
   key   value_x   value_y
0   B -0.282863  1.212112
1   D -1.135632 -0.173215
2   D -1.135632  0.119209

In [45]: left_join = df1.merge(df2, on=['key'], how='left')
In [46]: left_join
Out[46]:
   key   value_x   value_y
0   A  0.469112  NaN
1   B -0.282863  1.212112
2   C -1.509059  NaN
3   D -1.135632 -0.173215
4   D -1.135632  0.119209
5   E  NaN -1.044236

In [47]: right_join = df1.merge(df2, on=['key'], how='right')
In [48]: right_join
Out[48]:
   key   value_x   value_y
0   B -0.282863  1.212112
1   D -1.135632 -0.173215
2   D -1.135632  0.119209
3   E  NaN -1.044236
```
In [49]: outer_join = df1.merge(df2, on=['key'], how='outer')

In [50]: outer_join
Out[50]:
   key  value_x  value_y
0   A    0.469112  NaN
1   B  -0.282863  1.212112
2   C  -1.509059   NaN
3   D  -1.135632 -0.173215
4   D  -1.135632  0.119209
5   E     NaN   -1.044236

**Missing data**

Like SAS, pandas has a representation for missing data - which is the special float value NaN (not a number). Many of the semantics are the same, for example missing data propagates through numeric operations, and is ignored by default for aggregations.

In [51]: outer_join
Out[51]:
   key  value_x  value_y
0   A    0.469112  NaN
1   B  -0.282863  1.212112
2   C  -1.509059   NaN
3   D  -1.135632 -0.173215
4   D  -1.135632  0.119209
5   E     NaN   -1.044236

In [52]: outer_join['value_x'] + outer_join['value_y']
Out[52]:
0    NaN
1  0.929249
2   NaN
3  -1.308847
4  -1.016424
5    NaN
dtype: float64

In [53]: outer_join['value_x'].sum()
Out[53]: -3.5940742896293765

One difference is that missing data cannot be compared to its sentinel value. For example, in SAS you could do this to filter missing values.

```sas
data outer_join_nulls;
  set outer_join;
  if value_x = .;
run;

data outer_join_no_nulls;
  set outer_join;
  if value_x ^= .;
run;
```

Which doesn’t work in pandas. Instead, the `pd.isna` or `pd.notna` functions should be used for comparisons.
In [54]: outer_join[pd.isna(outer_join['value_x'])]
Out[54]:
   key  value_x  value_y
5    E     NaN   -1.044236

In [55]: outer_join[pd.notna(outer_join['value_x'])]
Out[55]:
   key  value_x  value_y
0    A  0.469112    NaN
1    B -0.282863  1.212112
2    C -1.509059    NaN
3    D -1.135632 -0.173215
4    D -1.135632   0.119209

pandas also provides a variety of methods to work with missing data - some of which would be challenging to express in SAS. For example, there are methods to drop all rows with any missing values, replacing missing values with a specified value, like the mean, or forward filling from previous rows. See the missing data documentation for more.

In [56]: outer_join.dropna()
Out[56]:
   key  value_x  value_y
1    B -0.282863  1.212112
3    D -1.135632 -0.173215
4    D -1.135632   0.119209

In [57]: outer_join.fillna(method='ffill')
Out[57]:
   key  value_x  value_y
0    A  0.469112    NaN
1    B -0.282863  1.212112
2    C -1.509059  1.212112
3    D -1.135632 -0.173215
4    D -1.135632   0.119209
5    E -1.135632 -1.044236

In [58]: outer_join['value_x'].fillna(outer_join['value_x'].mean())
Out[58]:
0    0.469112
1  -0.282863
2  -1.509059
3  -1.135632
4  -1.135632
5  -0.718815
Name: value_x, dtype: float64

**GroupBy**

**Aggregation**

SAS’s PROC SUMMARY can be used to group by one or more key variables and compute aggregations on numeric columns.

```
proc summary data=tips nway;
   class sex smoker;
   var total_bill tip;
```

(continues on next page)
pandas provides a flexible groupby mechanism that allows similar aggregations. See the groupby documentation for more details and examples.

```python
In [59]: tips_summed = tips.groupby(['sex', 'smoker'])[['total_bill', 'tip']].sum()

In [60]: tips_summed.head()
Out[60]:
   total_bill  tip
   sex  smoker
   Female No  869.68  149.77
   Yes     527.27   96.74
   Male No  1725.75  302.00
   Yes     1217.07  183.07
```

### Transformation

In SAS, if the group aggregations need to be used with the original frame, it must be merged back together. For example, to subtract the mean for each observation by smoker group.

```sas
proc summary data=tips missing nway;
   class smoker;
   var total_bill;
   output out=smoker_means mean(total_bill)=group_bill;
run;

proc sort data=tips;
   by smoker;
run;

data tips;
   merge tips(in=a) smoker_means(in=b);
   by smoker;
   adj_total_bill = total_bill - group_bill;
   if a and b;
run;
```

pandas groupby provides a transform mechanism that allows these type of operations to be succinctly expressed in one operation.

```python
In [61]: gb = tips.groupby('smoker')['total_bill']

In [62]: tips['adj_total_bill'] = tips['total_bill'] - gb.transform('mean')

In [63]: tips.head()
Out[63]:
   total_bill  tip  sex  smoker  day  time  size  adj_total_bill
   67    1.07  1.00 Female  Yes  Sat   Dinner  1   -17.686344
   92    3.75  1.00 Female  Yes  Fri   Dinner  2   -15.006344
  111    5.25  1.00 Female  No   Sat   Dinner  1   -11.938278
  145    6.35  1.50 Female  No  Thur   Lunch  2   -10.838278
  135    6.51  1.25 Female  No  Thur   Lunch  2   -10.678278
```
By group processing

In addition to aggregation, pandas \texttt{groupby} can be used to replicate most other by group processing from SAS. For example, this DATA step reads the data by sex/smoker group and filters to the first entry for each.

```sas
proc sort data=tips;
   by sex smoker;
run;

data tips_first;
   set tips;
   by sex smoker;
   if FIRST.sex or FIRST.smoker then output;
run;
```

In pandas this would be written as:

```python
In [64]: tips.groupby(['sex', 'smoker']).first()
Out[64]:
     total_bill  tip  day  time  size  adj_total_bill
sex smoker  
Female No  5.25  1.00  Sat  Dinner  1    -11.938278
     Yes  1.07  1.00  Sat  Dinner  1    -17.686344
Male  No  5.51  2.00  Thur  Lunch  2    -11.678278
    Yes  5.25  5.15  Sun  Dinner  2    -13.506344
```

Other considerations

Disk vs memory

pandas operates exclusively in memory, where a SAS data set exists on disk. This means that the size of data able to be loaded in pandas is limited by your machine’s memory, but also that the operations on that data may be faster.

If out of core processing is needed, one possibility is the \texttt{dask.dataframe} library (currently in development) which provides a subset of pandas functionality for an on-disk \texttt{DataFrame}

Data interop

pandas provides a \texttt{read_sas()} method that can read SAS data saved in the XPORT or SAS7BDAT binary format.

```python
libname xportout xport 'transport-file.xpt';
data xportout.tips;
   set tips(rename=(total_bill=tbill));
   * xport variable names limited to 6 characters;
run;

df = pd.read_sas('transport-file.xpt')
df = pd.read_sas('binary-file.sas7bdat')
```

You can also specify the file format directly. By default, pandas will try to infer the file format based on its extension.

```python
df = pd.read_sas('transport-file.xpt', format='xport')
df = pd.read_sas('binary-file.sas7bdat', format='sas7bdat')
```
XPORT is a relatively limited format and the parsing of it is not as optimized as some of the other pandas readers. An alternative way to interop data between SAS and pandas is to serialize to csv.

```python
# version 0.17, 10M rows
In [8]: %time df = pd.read_sas('big.xpt')
Wall time: 14.6 s
In [9]: %time df = pd.read_csv('big.csv')
Wall time: 4.86 s
```

**Comparison with Stata**

For potential users coming from Stata this page is meant to demonstrate how different Stata operations would be performed in pandas.

If you’re new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows. This means that we can refer to the libraries as `pd` and `np`, respectively, for the rest of the document.

```python
In [1]: import pandas as pd
In [2]: import numpy as np
```

**Note:** Throughout this tutorial, the pandas DataFrame will be displayed by calling `df.head()`, which displays the first N (default 5) rows of the DataFrame. This is often used in interactive work (e.g. Jupyter notebook or terminal) – the equivalent in Stata would be:

```stata
list in 1/5
```

**Data structures**

**General terminology translation**

<table>
<thead>
<tr>
<th>pandas</th>
<th>Stata</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame</td>
<td>data set</td>
</tr>
<tr>

<td>variable</td>
</tr>
<tr>
<td>row</td>
<td>observation</td>
</tr>
<tr>
<td>groupby</td>
<td>bysort</td>
</tr>
<tr>
<td>NaN</td>
<td>.</td>
</tr>
</tbody>
</table>
DataFrame / Series

A DataFrame in pandas is analogous to a Stata data set – a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set in Stata can also be accomplished in pandas.

A Series is the data structure that represents one column of a DataFrame. Stata doesn’t have a separate data structure for a single column, but in general, working with a Series is analogous to referencing a column of a data set in Stata.

Index

Every DataFrame and Series has an Index – labels on the rows of the data. Stata does not have an exactly analogous concept. In Stata, a data set’s rows are essentially unlabeled, other than an implicit integer index that can be accessed with _n.

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled Index or MultiIndex can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the Index and just treat the DataFrame as a collection of columns. Please see the indexing documentation for much more on how to use an Index effectively.

Data input / output

Constructing a DataFrame from values

A Stata data set can be built from specified values by placing the data after an input statement and specifying the column names.

```
input x y
1 2
3 4
5 6
end
```

A pandas DataFrame can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```
In [3]: df = pd.DataFrame({'x': [1, 3, 5], 'y': [2, 4, 6]})
In [4]: df
Out[4]:
x    y
0 1 2
1 3 4
2 5 6
```
Reading external data

Like Stata, pandas provides utilities for reading in data from many formats. The tips data set, found within the pandas tests (csv) will be used in many of the following examples.

Stata provides import delimited to read csv data into a data set in memory. If the tips.csv file is in the current working directory, we can import it as follows.

```
import delimited tips.csv
```

The pandas method is `read_csv()`, which works similarly. Additionally, it will automatically download the data set if presented with a url.

```
In [5]: url = ('https://raw.github.com/pandas-dev/pandas/master/pandas/tests/io/data/csv/tips.csv')
      ...
In [6]: tips = pd.read_csv(url)
In [7]: tips.head()
Out[7]:
   total_bill  tip  sex  smoker  day  time  size
0      16.99  1.01  Female  No Sun  Dinner   2
1      10.34  1.66   Male  No Sun  Dinner   3
2      21.01  3.50   Male  No Sun  Dinner   3
3      23.68  3.31   Male  No Sun  Dinner   2
4      24.59  3.61  Female  No Sun  Dinner   4
```

Like import delimited, `read_csv()` can take a number of parameters to specify how the data should be parsed. For example, if the data were instead tab delimited, did not have column names, and existed in the current working directory, the pandas command would be:

```
tips = pd.read_csv('tips.csv', sep='\t', header=None)
```

Pandas can also read Stata data sets in .dta format with the `read_stata()` function.

```
df = pd.read_stata('data.dta')
```

In addition to text/csv and Stata files, pandas supports a variety of other data formats such as Excel, SAS, HDF5, Parquet, and SQL databases. These are all read via a `pd.read_` function. See the IO documentation for more details.

Exporting data

The inverse of import delimited in Stata is export delimited

```
export delimited tips2.csv
```

Similarly in pandas, the opposite of `read_csv` is `DataFrame.to_csv()`.

```
tips.to_csv('tips2.csv')
```

Pandas can also export to Stata file format with the `DataFrame.to_stata()` method.
tips.to_stata('tips2.dta')

Data operations

Operations on columns

In Stata, arbitrary math expressions can be used with the `generate` and `replace` commands on new or existing columns. The `drop` command drops the column from the data set.

```
replace total_bill = total_bill - 2
generate new_bill = total_bill / 2
drop new_bill
```

pandas provides similar vectorized operations by specifying the individual `Series` in the `DataFrame`. New columns can be assigned in the same way. The `DataFrame.drop()` method drops a column from the `DataFrame`.

```
In [8]: tips['total_bill'] = tips['total_bill'] - 2
In [9]: tips['new_bill'] = tips['total_bill'] / 2
In [10]: tips.head()
Out[10]:
        total_bill  tip     sex  smoker  day  time  size  new_bill
0   14.990000  1.01  Female    No  Sun  Dinner     2   7.495000
1    8.340000  1.66     Male    No  Sun  Dinner     3   4.170000
2   19.010000  3.50     Male    No  Sun  Dinner     3   9.505000
3   21.680000  3.31     Male    No  Sun  Dinner     2  10.840000
4   22.590000  3.61  Female    No  Sun  Dinner     4  11.295000
```

Filtering

Filtering in Stata is done with an `if` clause on one or more columns.

```
list if total_bill > 10
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using `boolean indexing`.

```
In [12]: tips[tips['total_bill'] > 10].head()
Out[12]:
        total_bill  tip     sex  smoker  day  time  size
0   14.990000  1.01  Female    No  Sun  Dinner     2
1    8.340000  1.66     Male    No  Sun  Dinner     3
2   19.010000  3.50     Male    No  Sun  Dinner     3
3   21.680000  3.31     Male    No  Sun  Dinner     2
4   22.590000  3.61  Female    No  Sun  Dinner     4
```
If/then logic

In Stata, an `if` clause can also be used to create new columns.

```stata
generate bucket = "low" if total_bill < 10
replace bucket = "high" if total_bill >= 10
```

The same operation in pandas can be accomplished using the `where` method from `numpy`.

```python
In [13]: tips['bucket'] = np.where(tips['total_bill'] < 10, 'low', 'high')
In [14]: tips.head()
Out[14]:
     total_bill  tip     sex  smoker  day    time  size  bucket
0     14.99  1.01  Female  No  Sun  Dinner   2    high
1      8.34  1.66     Male  No  Sun  Dinner   3    low
2     19.01  3.50     Male  No  Sun  Dinner   3   high
3     21.68  3.31     Male  No  Sun  Dinner   2   high
4     22.59  3.61  Female  No  Sun  Dinner   4   high
```

Date functionality

Stata provides a variety of functions to do operations on date/datetime columns.

```stata
generate date1 = mdy(1, 15, 2013)
generate date2 = date("Feb152015", "MDY")
generate date1_year = year(date1)
generate date2_month = month(date2)

* shift date to beginning of next month
generate date1_next = mdy(month(date1) + 1, 1, year(date1)) if month(date1) != 12
replace date1_next = mdy(1, 1, year(date1) + 1) if month(date1) == 12

generate months_between = mofd(date2) - mofd(date1)

list date1 date2 date1_year date2_month date1_next months_between
```

The equivalent pandas operations are shown below. In addition to these functions, pandas supports other Time Series features not available in Stata (such as time zone handling and custom offsets) – see the `timeseries documentation` for more details.

```python
In [15]: tips['date1'] = pd.Timestamp('2013-01-15')
In [16]: tips['date2'] = pd.Timestamp('2015-02-15')
In [17]: tips['date1_year'] = tips['date1'].dt.year
In [18]: tips['date2_month'] = tips['date2'].dt.month
In [19]: tips['date1_next'] = tips['date1'] + pd.offsets.MonthBegin()
In [20]: tips['months_between'] = (tips['date2'].dt.to_period('M')
                          - tips['date1'].dt.to_period('M'))
```

(continues on next page)
In [21]: tips[['date1', 'date2', 'date1_year', 'date2_month', 'date1_next',
       ....:       'months_between']].head()

Out[21]:

<table>
<thead>
<tr>
<th>date1</th>
<th>date2</th>
<th>date1_year</th>
<th>date2_month</th>
<th>date1_next</th>
<th>months_between</th>
</tr>
</thead>
</table>

Selection of columns

Stata provides keywords to select, drop, and rename columns.

keep sex total_bill tip

drop sex

rename total_bill total_bill_2

The same operations are expressed in pandas below. Note that in contrast to Stata, these operations do not happen in place. To make these changes persist, assign the operation back to a variable.

# keep
In [22]: tips[['sex', 'total_bill', 'tip']].head()
Out[22]:

<table>
<thead>
<tr>
<th>sex</th>
<th>total_bill</th>
<th>tip</th>
</tr>
</thead>
<tbody>
<tr>
<td>Female</td>
<td>14.99</td>
<td>1.01</td>
</tr>
<tr>

</table>
pandas: powerful Python data analysis toolkit, Release 1.1.5

Sorting by values

Sorting in Stata is accomplished via `sort`

```
sort sex total_bill
```

pandas objects have a `DataFrame.sort_values()` method, which takes a list of columns to sort by.

```
In [25]: tips = tips.sort_values(['sex', 'total_bill'])
In [26]: tips.head()
Out[26]:
   total_bill  tip    sex  smoker  day  time  size
0       1.07  1.07 Female  Yes   Sat  Dinner  1
1       3.75  1.00 Female  Yes   Fri  Dinner  2
2       5.25  1.00 Female  No    Sat  Dinner  1
3       6.35  1.50 Female  No    Thur Lunch  2
4       6.51  1.25 Female  No    Thur Lunch  2
```

String processing

Finding length of string

Stata determines the length of a character string with the `strlen()` and `ustrlen()` functions for ASCII and Unicode strings, respectively.

```
generate strlen_time = strlen(time)
generate ustrlen_time = ustrlen(time)
```

Python determines the length of a character string with the `len` function. In Python 3, all strings are Unicode strings. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```
In [27]: tips['time'].str.len().head
Out[27]:
   67    6
   92    6
  111    6
  145    5
  135    5
Name: time, dtype: int64

In [28]: tips['time'].str.rstrip().str.len().head
Out[28]:
   67    6
   92    6
  111    6
  145    5
  135    5
Name: time, dtype: int64
```
Finding position of substring

Stata determines the position of a character in a string with the `strpos()` function. This takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```stata
generate str_position = strpos(sex, "ale")
```

Python determines the position of a character in a string with the `find()` function. `find()` searches for the first position of the substring. If the substring is found, the function returns its position. Keep in mind that Python indexes are zero-based and the function will return -1 if it fails to find the substring.

```python
In [29]: tips['sex'].str.find("ale").head()
Out[29]:
   67    3
   92    3
  111    3
  145    3
  135    3
Name: sex, dtype: int64
```

Extracting substring by position

Stata extracts a substring from a string based on its position with the `substr()` function.

```stata
generate short_sex = substr(sex, 1, 1)
```

With pandas you can use `[]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```python
In [30]: tips['sex'].str[0:1].head()
Out[30]:
   67    F
   92    F
  111    F
  145    F
  135    F
Name: sex, dtype: object
```

Extracting nth word

The Stata `word()` function returns the nth word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```stata
clear
input str20 string
"John Smith"
"Jane Cook"
end

generate first_name = word(name, 1)
generate last_name = word(name, -1)
```

Python extracts a substring from a string based on its text by using regular expressions. There are much more powerful approaches, but this just shows a simple approach.
Changing case

The Stata `strupper()`, `strlower()`, `strproper()`, `ustrupper()`, `ustrlower()`, and `ustrtitle()` functions change the case of ASCII and Unicode strings, respectively.

The equivalent Python functions are `upper`, `lower`, and `title`.

Merging

The following tables will be used in the merge examples
In Stata, to perform a merge, one data set must be in memory and the other must be referenced as a file name on disk. In contrast, Python must have both DataFrames already in memory.

By default, Stata performs an outer join, where all observations from both data sets are left in memory after the merge. One can keep only observations from the initial data set, the merged data set, or the intersection of the two by using the values created in the _merge variable.

```bash
* First create df2 and save to disk
clear
input str1 key
B
D
D
E
end
generate value = rnormal()
save df2.dta

* Now create df1 in memory
clear
input str1 key
A
B
C
D
end
generate value = rnormal()

preserve

* Left join
merge 1:n key using df2.dta
keep if _merge == 1

* Right join
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 2
```

(continues on next page)
* Inner join
    
    ```python
    restore, preserve
    merge 1:n key using df2.dta
    keep if _merge == 3
    ```

* Outer join
    
    ```python
    restore
    merge 1:n key using df2.dta
    ```

Pandas DataFrames have a `DataFrame.merge()` method, which provides similar functionality. Note that different join types are accomplished via the `how` keyword.

```
In [44]: inner_join = df1.merge(df2, on=['key'], how='inner')

In [45]: inner_join
Out[45]:
   key  value_x  value_y
0   B -0.282863  1.212112
1   D -1.135632 -0.173215
2   D -1.135632  0.119209

In [46]: left_join = df1.merge(df2, on=['key'], how='left')

In [47]: left_join
Out[47]:
   key  value_x  value_y
0   A   0.469112   NaN
1   B -0.282863  1.212112
2   C -1.509059   NaN
3   D -1.135632 -0.173215
4   D -1.135632  0.119209

In [48]: right_join = df1.merge(df2, on=['key'], how='right')

In [49]: right_join
Out[49]:
   key  value_x  value_y
0   B -0.282863  1.212112
1   D -1.135632 -0.173215
2   D -1.135632  0.119209
3   E   NaN  -1.044236

In [50]: outer_join = df1.merge(df2, on=['key'], how='outer')

In [51]: outer_join
Out[51]:
   key  value_x  value_y
0   A   0.469112   NaN
1   B -0.282863  1.212112
2   C -1.509059   NaN
3   D -1.135632 -0.173215
4   D -1.135632  0.119209
5   E   NaN  -1.044236
```
### Missing data

Like Stata, pandas has a representation for missing data – the special float value \texttt{NaN} (not a number). Many of the semantics are the same; for example missing data propagates through numeric operations, and is ignored by default for aggregations.

```python
In [52]: outer_join
Out[52]:
   key   value_x   value_y
  0  A    0.469112    NaN
  1  B   -0.282863  1.212112
  2  C   -1.509059    NaN
  3  D  -1.135632  -0.173215
  4  D  -1.135632   0.119209
  5  E    NaN   -1.044236
```

```python
In [53]: outer_join['value_x'] + outer_join['value_y']
Out[53]:
   0    NaN
   1  0.929249
   2    NaN
   3  -1.308847
   4 -1.016424
   5    NaN
dtype: float64
```

```python
In [54]: outer_join['value_x'].sum()
Out[54]: -3.5940742896293765
```

One difference is that missing data cannot be compared to its sentinel value. For example, in Stata you could do this to filter missing values.

```
* Keep missing values
list if value_x == .
* Keep non-missing values
list if value_x != .
```

This doesn’t work in pandas. Instead, the \texttt{pd.isna()} or \texttt{pd.notna()} functions should be used for comparisons.

```python
In [55]: outer_join[pd.isna(outer_join['value_x'])]
Out[55]:
   key   value_x   value_y
   5  E    NaN  -1.044236

In [56]: outer_join[pd.notna(outer_join['value_x'])]
Out[56]:
   key   value_x   value_y
   0  A    0.469112    NaN
   1  B   -0.282863  1.212112
   2  C   -1.509059    NaN
   3  D  -1.135632  -0.173215
   4  D  -1.135632   0.119209
```

Pandas also provides a variety of methods to work with missing data – some of which would be challenging to express in Stata. For example, there are methods to drop all rows with any missing values, replacing missing values with a specified value, like the mean, or forward filling from previous rows. See the \textit{missing data documentation} for more.
# Drop rows with any missing value

```python
In [57]: outer_join.dropna()
Out[57]:
   key     value_x  value_y
0  A       0.469112   NaN
1  B     -0.282863  1.212112
2  C     -1.509059  1.212112
3  D     -1.135632  0.173215
4  D     -1.135632  0.119209
5  E     -1.135632 -1.044236
```

# Fill forwards

```python
In [58]: outer_join.fillna(method='ffill')
Out[58]:
   key     value_x  value_y
0  A       0.469112   NaN
1  B     -0.282863  1.212112
2  C     -1.509059  1.212112
3  D     -1.135632  0.173215
4  D     -1.135632  0.119209
5  E     -1.135632 -1.044236
```

# Impute missing values with the mean

```python
In [59]: outer_join['value_x'].fillna(outer_join['value_x'].mean())
Out[59]:
0   0.469112
1  -0.282863
2  -1.509059
3  -1.135632
4  -1.135632
5  -0.718815
Name: value_x, dtype: float64
```

## GroupBy

### Aggregation

Stata’s `collapse` can be used to group by one or more key variables and compute aggregations on numeric columns.

```
collapse (sum) total_bill tip, by(sex smoker)
```

pandas provides a flexible `groupby` mechanism that allows similar aggregations. See the `groupby documentation` for more details and examples.

```python
In [60]: tips_summed = tips.groupby(['sex', 'smoker'])[['total_bill', 'tip']].sum()
In [61]: tips_summed.head()
Out[61]:
   sex  smoker  total_bill  tip
      Female No     869.68  149.77
        Yes     527.27   96.74
      Male  No     1725.75  302.00
        Yes    1217.07  183.07
```
Transformation

In Stata, if the group aggregations need to be used with the original data set, one would usually use **bysort** with **egen()**. For example, to subtract the mean for each observation by smoker group.

```
bysort sex smoker: egen group_bill = mean(total_bill)
genarate adj_total_bill = total_bill - group_bill
```

Pandas **groupby** provides a **transform** mechanism that allows these type of operations to be succinctly expressed in one operation.

```
In [62]: gb = tips.groupby('smoker')['total_bill']
In [63]: tips['adj_total_bill'] = tips['total_bill'] - gb.transform('mean')
In [64]: tips.head()
Out[64]:
      total_bill  tip  sex  smoker  day   time  size  adj_total_bill
    67   1.07  1.00  Female    Yes  Sat  Dinner  1   -17.686344
    92   3.75  1.00  Female    Yes  Fri  Dinner  2   -15.006344
   111  5.25  1.00  Female     No  Sat  Dinner  1   -11.938278
   145  6.35  1.50  Female     No  Thur  Lunch  2   -10.838278
   135  6.51  1.25  Female     No  Thur  Lunch  2   -10.678278
```

By group processing

In addition to aggregation, pandas **groupby** can be used to replicate most other **bysort** processing from Stata. For example, the following example lists the first observation in the current sort order by sex/smoker group.

```
bysort sex smoker: list if _n == 1
```

In pandas this would be written as:

```
In [65]: tips.groupby(['sex', 'smoker']).first()
Out[65]:
      total_bill  tip  sex  smoker  day   time  size  adj_total_bill
    sex  smoker
    Female   No  5.25  1.00  Female    Yes  Sat  Dinner  1   -11.938278
           Yes  1.07  1.00  Female    Yes  Sat  Dinner  1   -17.686344
    Male    No  5.51  2.00  Female     No  Thur  Lunch  2   -11.678278
           Yes  5.25  5.15  Female     Yes  Sun  Dinner  2   -13.506344
```

Other considerations

Disk vs memory

Pandas and Stata both operate exclusively in memory. This means that the size of data able to be loaded in pandas is limited by your machine’s memory. If out of core processing is needed, one possibility is the dask.dataframe library, which provides a subset of pandas functionality for an on-disk DataFrame.
1.4.5 Community tutorials

This is a guide to many pandas tutorials by the community, geared mainly for new users.

pandas cookbook by Julia Evans

The goal of this 2015 cookbook (by Julia Evans) is to give you some concrete examples for getting started with pandas. These are examples with real-world data, and all the bugs and weirdness that entails. For the table of contents, see the pandas-cookbook GitHub repository.

Learn pandas by Hernan Rojas

A set of lesson for new pandas users: https://bitbucket.org/hrojas/learn-pandas

Practical data analysis with Python

This guide is an introduction to the data analysis process using the Python data ecosystem and an interesting open dataset. There are four sections covering selected topics as munging data, aggregating data, visualizing data and time series.

Exercises for new users

Practice your skills with real data sets and exercises. For more resources, please visit the main repository.

Modern pandas

Tutorial series written in 2016 by Tom Augspurger. The source may be found in the GitHub repository TomAugspurger/effective-pandas.

- Modern Pandas
- Method Chaining
- Indexes
- Performance
- Tidy Data
- Visualization
- Timeseries

Excel charts with pandas, vincent and xlsxwriter

- Using Pandas and XlsxWriter to create Excel charts
Video tutorials

- Pandas: .head() to .tail() (2016) (1:26) GitHub repo
- Data analysis in Python with pandas (2016-2018) GitHub repo and Jupyter Notebook
- Best practices with pandas (2018) GitHub repo and Jupyter Notebook

Various tutorials

- Wes McKinney’s (pandas BDFL) blog
- Statistical analysis made easy in Python with SciPy and pandas DataFrames, by Randal Olson
- Statistical Data Analysis in Python, tutorial videos, by Christopher Fonnesbeck from SciPy 2013
- Financial analysis in Python, by Thomas Wiecki
- Intro to pandas data structures, by Greg Reda
- Pandas and Python: Top 10, by Manish Amde
- Pandas DataFrames Tutorial, by Karlijn Willems
- A concise tutorial with real life examples
The User Guide covers all of pandas by topic area. Each of the subsections introduces a topic (such as “working with missing data”), and discusses how pandas approaches the problem, with many examples throughout.

Users brand-new to pandas should start with 10min.

For a high level summary of the pandas fundamentals, see Intro to data structures and Essential basic functionality.

Further information on any specific method can be obtained in the API reference.

2.1 10 minutes to pandas

This is a short introduction to pandas, geared mainly for new users. You can see more complex recipes in the Cookbook.

Customarily, we import as follows:

```
In [1]: import numpy as np
In [2]: import pandas as pd
```

2.1.1 Object creation

See the Data Structure Intro section.

Creating a Series by passing a list of values, letting pandas create a default integer index:

```
In [3]: s = pd.Series([1, 3, 5, np.nan, 6, 8])
```

```
In [4]: s
Out[4]:
0    1.0
1    3.0
2    5.0
3   NaN
4    6.0
5    8.0
dtype: float64
```

Creating a DataFrame by passing a NumPy array, with a datetime index and labeled columns:

```
In [5]: dates = pd.date_range('20130101', periods=6)
```

```
In [6]: dates
```

(continues on next page)
In [7]: df = pd.DataFrame(np.random.randn(6, 4), index=dates, columns=list('ABCD'))

Out[8]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-01</td>
<td>-0.663423</td>
<td>1.183361</td>
<td>-0.743116</td>
<td>1.807910</td>
</tr>
<tr>
<td>2013-01-02</td>
<td>-1.113582</td>
<td>-0.132407</td>
<td>0.811469</td>
<td>0.662813</td>
</tr>
<tr>
<td>2013-01-03</td>
<td>-1.145375</td>
<td>-0.932671</td>
<td>0.673294</td>
<td>0.246244</td>
</tr>
<tr>
<td>2013-01-04</td>
<td>-0.038060</td>
<td>0.144889</td>
<td>0.071792</td>
<td>-0.037655</td>
</tr>
<tr>
<td>2013-01-05</td>
<td>0.868191</td>
<td>-0.447254</td>
<td>-0.818702</td>
<td>0.407186</td>
</tr>
<tr>
<td>2013-01-06</td>
<td>0.774831</td>
<td>0.614217</td>
<td>1.535992</td>
<td>-0.474756</td>
</tr>
</tbody>
</table>

Creating a DataFrame by passing a dict of objects that can be converted to series-like.

In [9]: df2 = pd.DataFrame({'A': 1.,
                        'B': pd.Timestamp('20130102'),
                        'C': pd.Series(1, index=list(range(4)), dtype='float32'),
                        'D': np.array([3] * 4, dtype='int32'),
                        'E': pd.Categorical(['test', 'train', 'test', 'train']),
                        'F': 'foo'})

Out[10]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
<th>F</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1.0</td>
<td>2013-01-02</td>
<td>1.0</td>
<td>3</td>
<td>test</td>
<td>foo</td>
</tr>
<tr>
<td>1</td>
<td>1.0</td>
<td>2013-01-02</td>
<td>1.0</td>
<td>3</td>
<td>train</td>
<td>foo</td>
</tr>
<tr>
<td>2</td>
<td>1.0</td>
<td>2013-01-02</td>
<td>1.0</td>
<td>3</td>
<td>test</td>
<td>foo</td>
</tr>
<tr>
<td>3</td>
<td>1.0</td>
<td>2013-01-02</td>
<td>1.0</td>
<td>3</td>
<td>test</td>
<td>foo</td>
</tr>
</tbody>
</table>

The columns of the resulting DataFrame have different dtypes.

In [11]: df2.dtypes

Out[11]:

<table>
<thead>
<tr>
<th></th>
<th>dtype</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>float64</td>
</tr>
<tr>
<td>B</td>
<td>datetime64[ns]</td>
</tr>
<tr>
<td>C</td>
<td>float32</td>
</tr>
<tr>
<td>D</td>
<td>int32</td>
</tr>
<tr>
<td>E</td>
<td>category</td>
</tr>
<tr>
<td>F</td>
<td>object</td>
</tr>
</tbody>
</table>

dtype: object

If you’re using IPython, tab completion for column names (as well as public attributes) is automatically enabled.

Here’s a subset of the attributes that will be completed:

In [12]: df2.<TAB>  # noqa: E225, E999

df2.A     df2.abs     df2.add     df2.add_prefix
df2.A     df2.abs     df2.add     df2.add_suffix
df2.abs   df2.abs     df2.add     df2.add_suffix
df2.add   df2.add     df2.add     df2.add_suffix
df2.add   df2.add     df2.add     df2.add_suffix

(continues on next page)
As you can see, the columns A, B, C, and D are automatically tab completed. E and F are there as well; the rest of the attributes have been truncated for brevity.

## 2.1.2 Viewing data

See the Basics section.

Here is how to view the top and bottom rows of the frame:

```
In [13]: df.head()
Out[13]:
   A         B         C         D
2013-01-01 -0.663423  1.183361 -0.743116  1.807910
2013-01-02 -1.113582 -0.132407  0.811469  0.662813
2013-01-03 -1.145375 -0.932671  0.673294  0.246244
2013-01-04 -0.038060  0.144889  0.071792 -0.037655
2013-01-05  0.868191 -0.447254 -0.818702  0.407186
```

```
In [14]: df.tail(3)
Out[14]:
   A         B         C         D
2013-01-04 -0.038060  0.144889  0.071792 -0.037655
2013-01-05  0.868191 -0.447254 -0.818702  0.407186
2013-01-06  0.774831  0.614217  1.535992 -0.474756
```

Display the index, columns:

```
In [15]: df.index
Out[15]:
DateTimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
               '2013-01-05', '2013-01-06'],
              dtype='datetime64[ns]', freq='D')
```

```
In [16]: df.columns
Out[16]: Index(['A', 'B', 'C', 'D'], dtype='object')
```

DataFrame.to_numpy() gives a NumPy representation of the underlying data. Note that this can be an expensive operation when your DataFrame has columns with different data types, which comes down to a fundamental difference between pandas and NumPy: NumPy arrays have one dtype for the entire array, while pandas DataFrames have one dtype per column. When you call DataFrame.to_numpy(), pandas will find the NumPy dtype that can hold all of the dtypes in the DataFrame. This may end up being object, which requires casting every value to a Python object.

For df, our DataFrame of all floating-point values, DataFrame.to_numpy() is fast and doesn’t require copying data.
For df2, the DataFrame with multiple dtypes, DataFrame.to_numpy() is relatively expensive.

Note: DataFrame.to_numpy() does not include the index or column labels in the output.

desc() shows a quick statistic summary of your data:

Transposing your data:

Sorting by an axis:
Sorting by values:

```
In [22]: df.sort_values(by='B')
Out[22]:
            A       B        C       D
2013-01-03 -1.145375 -0.932671  0.673294  0.246244
2013-01-05  0.868191 -0.447254 -0.818702  0.407186
2013-01-02 -1.113582 -0.132407  0.811469  0.662813
2013-01-04 -0.038060  0.144889  0.071792 -0.037655
2013-01-06  0.774831  0.614217  1.535992 -0.474756
2013-01-01 -0.663423  1.183361 -0.743116  1.807910
```

### 2.1.3 Selection

**Note:** While standard Python / Numpy expressions for selecting and setting are intuitive and come in handy for interactive work, for production code, we recommend the optimized pandas data access methods, `.at`, `.iat`, `.loc` and `.iloc`.

See the indexing documentation *Indexing and Selecting Data* and *MultiIndex / Advanced Indexing*.

**Getting**

Selecting a single column, which yields a *Series*, equivalent to `df.A`:

```
In [23]: df['A']
Out[23]:
2013-01-01   -0.663423
2013-01-02   -1.113582
2013-01-03   -1.145375
2013-01-04   -0.038060
2013-01-05    0.868191
2013-01-06    0.774831
Freq: D, Name: A, dtype: float64
```

Selecting via [], which slices the rows.

```
In [24]: df[0:3]
Out[24]:
            A       B        C       D
2013-01-01 -0.663423  1.183361 -0.743116  1.807910
2013-01-02 -1.113582 -0.132407  0.811469  0.662813
2013-01-03 -1.145375 -0.932671  0.673294  0.246244

In [25]: df['20130102':'20130104']
Out[25]:
            A       B        C       D
2013-01-02 -1.113582 -0.132407  0.811469  0.662813
2013-01-03 -1.145375 -0.932671  0.673294  0.246244
2013-01-04 -0.038060  0.144889  0.071792 -0.037655
```
## Selection by label

See more in *Selection by Label*.

For getting a cross section using a label:

```
In [26]: df.loc[dates[0]]
Out[26]:
A   -0.663423
B    1.183361
C   -0.743116
D    1.807910
Name: 2013-01-01 00:00:00, dtype: float64
```

Selecting on a multi-axis by label:

```
In [27]: df.loc[:, ['A', 'B']]
Out[27]:
       A       B
2013-01-01 -0.663423  1.183361
2013-01-02 -1.113582 -0.132407
2013-01-03 -1.145375 -0.932671
2013-01-04 -0.038060  0.144889
2013-01-05  0.868191 -0.447254
2013-01-06  0.774831  0.614217
```

Showing label slicing, both endpoints are included:

```
In [28]: df.loc['20130102':'20130104', ['A', 'B']]
Out[28]:
       A       B
2013-01-02 -1.113582 -0.132407
2013-01-03 -1.145375 -0.932671
2013-01-04 -0.038060  0.144889
```

Reduction in the dimensions of the returned object:

```
In [29]: df.loc['20130102', ['A', 'B']]
Out[29]:
       A       B
2013-01-02 -1.113582 -0.132407
Name: 2013-01-02 00:00:00, dtype: float64
```

For getting a scalar value:

```
In [30]: df.loc[dates[0], 'A']
Out[30]:
-0.6634233760362761
```

For getting fast access to a scalar (equivalent to the prior method):

```
In [31]: df.at[dates[0], 'A']
Out[31]:
-0.6634233760362761
```
Selection by position

See more in Selection by Position.

Select via the position of the passed integers:

```
In [32]: df.iloc[3]
Out[32]:
   A    -0.038060
   B     0.144889
   C     0.071792
   D    -0.037655
Name: 2013-01-04 00:00:00, dtype: float64
```

By integer slices, acting similar to numpy/python:

```
In [33]: df.iloc[3:5, 0:2]
Out[33]:
   A   B
2013-01-04 -0.038060  0.144889
2013-01-05  0.868191 -0.447254
```

By lists of integer position locations, similar to the numpy/python style:

```
In [34]: df.iloc[[1, 2, 4], [0, 2]]
Out[34]:
   A  C
2013-01-02 -1.113582  0.811469
2013-01-03 -1.145375  0.673294
2013-01-05  0.868191 -0.818702
```

For slicing rows explicitly:

```
In [35]: df.iloc[1:3, :]
Out[35]:
   A   B   C   D
2013-01-02 -1.113582 -0.132407  0.811469  0.662813
2013-01-03 -1.145375 -0.932671  0.673294  0.246244
```

For slicing columns explicitly:

```
In [36]: df.iloc[:, 1:3]
Out[36]:
   B   C
2013-01-01  1.183361 -0.743116
2013-01-02 -0.132407  0.811469
2013-01-03 -0.932671  0.673294
2013-01-04  0.144889  0.071792
2013-01-05 -0.447254 -0.818702
2013-01-06  0.614217  1.535992
```

For getting a value explicitly:

```
In [37]: df.iloc[1, 1]
Out[37]: -0.13240676060632406
```

For getting fast access to a scalar (equivalent to the prior method):

2.1. 10 minutes to pandas
Boolean indexing

Using a single column’s values to select data.

In [39]: df['A'] > 0
Out[39]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0.868191</td>
<td>-0.447254</td>
<td>-0.818702</td>
<td>0.407186</td>
</tr>
<tr>
<td></td>
<td>0.774831</td>
<td>0.614217</td>
<td>1.535992</td>
<td>-0.474756</td>
</tr>
</tbody>
</table>

Selecting values from a DataFrame where a boolean condition is met.

In [40]: df > 0
Out[40]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NaN</td>
<td>1.183361</td>
<td>NaN</td>
<td>1.807910</td>
</tr>
<tr>
<td></td>
<td>NaN</td>
<td>NaN</td>
<td>0.811469</td>
<td>0.662813</td>
</tr>
<tr>
<td></td>
<td>NaN</td>
<td>NaN</td>
<td>0.673294</td>
<td>0.246244</td>
</tr>
<tr>
<td></td>
<td>NaN</td>
<td>0.144889</td>
<td>0.071792</td>
<td>NaN</td>
</tr>
<tr>
<td></td>
<td>0.868191</td>
<td>NaN</td>
<td>NaN</td>
<td>0.407186</td>
</tr>
<tr>
<td></td>
<td>0.774831</td>
<td>0.614217</td>
<td>1.535992</td>
<td>NaN</td>
</tr>
</tbody>
</table>

Using the `isin()` method for filtering:

In [41]: df2 = df.copy()

In [42]: df2['E'] = ['one', 'one', 'two', 'three', 'four', 'three']

In [43]: df2
Out[43]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-0.663423</td>
<td>1.183361</td>
<td>-0.743116</td>
<td>1.807910</td>
<td>one</td>
</tr>
<tr>
<td></td>
<td>-1.113582</td>
<td>-0.132407</td>
<td>0.811469</td>
<td>0.662813</td>
<td>one</td>
</tr>
<tr>
<td></td>
<td>-1.145375</td>
<td>-0.932671</td>
<td>0.673294</td>
<td>0.246244</td>
<td>two</td>
</tr>
<tr>
<td></td>
<td>-0.038060</td>
<td>0.144889</td>
<td>0.071792</td>
<td>-0.037655</td>
<td>three</td>
</tr>
<tr>
<td></td>
<td>0.868191</td>
<td>-0.447254</td>
<td>-0.818702</td>
<td>0.407186</td>
<td>four</td>
</tr>
<tr>
<td></td>
<td>0.774831</td>
<td>0.614217</td>
<td>1.535992</td>
<td>-0.474756</td>
<td>three</td>
</tr>
</tbody>
</table>

In [44]: df2['E'].isin(['two', 'four'])
Out[44]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-1.145375</td>
<td>-0.932671</td>
<td>0.673294</td>
<td>0.246244</td>
</tr>
<tr>
<td></td>
<td>0.868191</td>
<td>-0.447254</td>
<td>-0.818702</td>
<td>0.407186</td>
</tr>
</tbody>
</table>
Setting

Setting a new column automatically aligns the data by the indexes.

```
In [45]: sl = pd.Series([1, 2, 3, 4, 5, 6], index=pd.date_range('20130102',
    ...:                     periods=6))

In [46]: sl
Out[46]:
2013-01-02    1
2013-01-03    2
2013-01-04    3
2013-01-05    4
2013-01-06    5
2013-01-07    6
Freq: D, dtype: int64

In [47]: df['F'] = sl
```

Setting values by label:

```
In [48]: df.at[dates[0], 'A'] = 0
```

Setting values by position:

```
In [49]: df.iat[0, 1] = 0
```

Setting by assigning with a NumPy array:

```
In [50]: df.loc[:, 'D'] = np.array([5] * len(df))
```

The result of the prior setting operations.

```
In [51]: df
Out[51]:
       A         B         C         D    F
0  2013-01-01  0.000000 -0.743116  5.000000 NaN
1  2013-01-02 -1.113582 -0.132407  0.811469  1.000000
2  2013-01-03 -1.145375 -0.932671  0.673294  2.000000
3  2013-01-04 -0.038060  0.144889  0.071792  3.000000
4  2013-01-05  0.868191 -0.447254 -0.818702  4.000000
5  2013-01-06  0.774831  0.614217  1.535992  5.000000
```

A `where` operation with setting.

```
In [52]: df2 = df.copy()

In [53]: df2[df2 > 0] = -df2

In [54]: df2
Out[54]:
       A         B         C         D    F
0  2013-01-01  0.000000 -0.743116 -5.000000 NaN
1  2013-01-02 -1.113582 -0.132407 -0.811469 -5.000000
2  2013-01-03 -1.145375 -0.932671 -0.673294 -5.000000
3  2013-01-04 -0.038060  0.144889 -0.071792 -5.000000
4  2013-01-05  0.868191 -0.447254 -0.818702 -5.000000
5  2013-01-06  0.774831 -0.614217 -1.535992 -5.000000
```
2.1.4 Missing data

pandas primarily uses the value np.nan to represent missing data. It is by default not included in computations. See the Missing Data section.

Reindexing allows you to change/add/delete the index on a specified axis. This returns a copy of the data.

```
In [55]: df1 = df.reindex(index=dates[0:4], columns=list(df.columns) + ['E'])
In [56]: df1.loc[dates[0]:dates[1], 'E'] = 1
In [57]: df1
Out[57]:
   A        B        C       D   F  E
0 2013-01-01 0.000000 0.000000 -0.743116 5  NaN 1.0
1 2013-01-02 -1.113582 -0.132407 0.811469 5  1.0 1.0
2 2013-01-03 -1.145375 -0.932671 0.673294 5  2.0  NaN
3 2013-01-04 -0.038060 0.144889 0.071792 5  3.0  NaN
```

To drop any rows that have missing data.

```
In [58]: df1.dropna(how='any')
Out[58]:
   A        B        C       D   F  E
0 2013-01-02 -1.113582 -0.132407 0.811469 5  1.0 1.0
```

Filling missing data.

```
In [59]: df1.fillna(value=5)
Out[59]:
   A        B        C       D   F  E
0 2013-01-01 0.000000 0.000000 -0.743116 5  5.0 1.0
1 2013-01-02 -1.113582 -0.132407 0.811469 5  1.0 1.0
2 2013-01-03 -1.145375 -0.932671 0.673294 5  2.0  5.0
3 2013-01-04 -0.038060 0.144889 0.071792 5  3.0  5.0
```

To get the boolean mask where values are nan.

```
In [60]: pd.isna(df1)
Out[60]:
   A       B       C       D   F   E
0  False  False  False  False  True  False
1  False  False  False  False  False  False
2  False  False  False  False  False  True
3  False  False  False  False  False  True
```

2.1.5 Operations

See the Basic section on Binary Ops.
Stats

Operations in general exclude missing data.

Performing a descriptive statistic:

```
In [61]: df.mean()
Out[61]:
A   -0.108999
B   -0.125538
C    0.255122
D    5.000000
F    3.000000
dtype: float64
```

Same operation on the other axis:

```
In [62]: df.mean(1)
Out[62]:
2013-01-01  1.064221
2013-01-02  1.113096
2013-01-03  1.119050
2013-01-04  1.635724
2013-01-05  1.720447
2013-01-06  2.585008
Freq: D, dtype: float64
```

Operating with objects that have different dimensionality and need alignment. In addition, pandas automatically broadcasts along the specified dimension.

```
In [63]: s = pd.Series([1, 3, 5, np.nan, 6, 8], index=dates).shift(2)
In [64]: s
Out[64]:
2013-01-01 NaN
2013-01-02 NaN
2013-01-03 1.0
2013-01-04 3.0
2013-01-05 5.0
2013-01-06 NaN
Freq: D, dtype: float64
```

```
In [65]: df.sub(s, axis='index')
Out[65]:
     A     B     C     D     F
2013-01-01 NaN  NaN  NaN  NaN  NaN
2013-01-02 NaN  NaN  NaN  NaN  NaN
2013-01-03 -2.145375 -1.932671 -0.326706 4.0  1.0
2013-01-04 -3.038060 -2.855111 -2.928208 2.0  0.0
2013-01-05 -4.131809 -5.447254 -5.818702 0.0 -1.0
2013-01-06 NaN  NaN  NaN  NaN  NaN
```

2.1. 10 minutes to pandas
Apply

Applying functions to the data:

In [66]: df.apply(np.cumsum)

Out[66]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>F</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>5</td>
</tr>
</tbody>
</table>
dtype: int64
String Methods

Series is equipped with a set of string processing methods in the `str` attribute that make it easy to operate on each element of the array, as in the code snippet below. Note that pattern-matching in `str` generally uses regular expressions by default (and in some cases always uses them). See more at Vectorized String Methods.

```python
In [71]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])
In [72]: s.str.lower()
Out[72]:
0    a
1    b
2    c
3   aaba
4   baca
5    NaN
6    caba
7      dog
8      cat
dtype: object
```

2.1.6 Merge

Concat

pandas provides various facilities for easily combining together Series and DataFrame objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

See the Merging section.

Concatenating pandas objects together with `concat()`:

```python
In [73]: df = pd.DataFrame(np.random.randn(10, 4))
In [74]: df
Out[74]:
          0       1       2       3
0  0.472660 -0.958271 -0.778880 -0.056702
1 -1.574474  0.429319  0.551604 -0.066093
2 -0.105045 -0.825942  0.802496  0.631754
3 -0.345822 -0.643899  1.645351 -0.285983
4  1.142615  1.328544 -0.859227  0.727740
5 -1.085945 -1.251934 -1.156944 -0.061001
6  0.152443  1.647270  0.494780  0.880086
7  0.717338  0.350362 -0.808341  0.901297
8 -0.695687  0.549227 -1.561273 -0.376476
9  0.247169  0.754363 -0.523381  0.739077

# break it into pieces
In [75]: pieces = [df[:3], df[3:7], df[7:]]
In [76]: pd.concat(pieces)
Out[76]:
          0       1       2       3
0  0.472660 -0.958271 -0.778880 -0.056702
1 -1.574474  0.429319  0.551604 -0.066093
2 -0.105045 -0.825942  0.802496  0.631754
3 -0.345822 -0.643899  1.645351 -0.285983
4  1.142615  1.328544 -0.859227  0.727740
5 -1.085945 -1.251934 -1.156944 -0.061001
6  0.152443  1.647270  0.494780  0.880086
7  0.717338  0.350362 -0.808341  0.901297
8 -0.695687  0.549227 -1.561273 -0.376476
9  0.247169  0.754363 -0.523381  0.739077
```

(continues on next page)
Note: Adding a column to a DataFrame is relatively fast. However, adding a row requires a copy, and may be expensive. We recommend passing a pre-built list of records to the DataFrame constructor instead of building a DataFrame by iteratively appending records to it. See Appending to dataframe for more.

Join

SQL style merges. See the Database style joining section.

```python
In [77]: left = pd.DataFrame({'key': ['foo', 'foo'], 'lval': [1, 2]})
In [78]: right = pd.DataFrame({'key': ['foo', 'foo'], 'rval': [4, 5]})
In [79]: left
Out[79]:
   key  lval
0  foo   1
1  foo   2
In [80]: right
Out[80]:
   key  rval
0  foo   4
1  foo   5
In [81]: pd.merge(left, right, on='key')
Out[81]:
   key  lval  rval
0  foo   1    4
1  foo   1    5
2  foo   2    4
3  foo   2    5
```

Another example that can be given is:

```python
In [82]: left = pd.DataFrame({'key': ['foo', 'bar'], 'lval': [1, 2]})
In [83]: right = pd.DataFrame({'key': ['foo', 'bar'], 'rval': [4, 5]})
In [84]: left
Out[84]:
   key  lval
0  foo   1
1  bar   2
```

(continues on next page)
In [85]: right
Out[85]:
   key  rval
0   foo    4
1   bar    5

In [86]: pd.merge(left, right, on='key')
Out[86]:
   key  lval  rval
0   foo    1    4
1   bar    2    5

2.1.7 Grouping

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria
- **Applying** a function to each group independently
- **Combining** the results into a data structure

See the [Grouping section](#).

In [87]: df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar', 'foo', 'bar', 'foo', 'foo'],
                        'B': ['one', 'one', 'two', 'three', 'two', 'two', 'one', 'three'],
                        'C': np.random.randn(8),
                        'D': np.random.randn(8)})

In [88]: df
Out[88]:
   A    B        C         D
0  foo  one  0.320577 -1.266356
1  bar  one -0.876538 -0.607409
2  foo  two  1.281261  0.264380
3  bar  three -1.030621  0.857282
4  foo  two -1.602805  0.857282
5  bar  two -0.796773 -0.232921
6  foo  one  0.190090 -0.528351
7  foo  three -0.818863  0.350752

Grouping and then applying the `sum()` function to the resulting groups.

In [89]: df.groupby('A').sum()
Out[89]:
   C     D
A
bar -2.703933  0.016952
foo -0.629740 -2.062103

Grouping by multiple columns forms a hierarchical index, and again we can apply the `sum()` function.
2.1.8 Reshaping

See the sections on Hierarchical Indexing and Reshaping.

Stack

```python
In [91]: tuples = list(zip(*[['bar', 'bar', 'baz', 'baz',
                        'foo', 'foo', 'qux', 'qux'],
                        ['one', 'two', 'one', 'two',
                        'one', 'two', 'one', 'two']]))
In [92]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])
In [93]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])
In [94]: df2 = df[:4]

Out[95]:
   A   B
first second
bar one  0.957597  1.212920
   two -0.116710  -0.581082
baz one  0.125989  0.741504
   two  0.871205   1.278467

The stack() method “compresses” a level in the DataFrame’s columns.

In [96]: stacked = df2.stack()
In [97]: stacked
```

```
   first second
bar one A  0.957597
       B  1.212920
   two A -0.116710
       B -0.581082
baz one A  0.125989
       B  0.741504
   two A  0.871205
       B  1.278467
dtype: float64
```
With a “stacked” DataFrame or Series (having a MultiIndex as the index), the inverse operation of `stack()` is `unstack()`, which by default unstacks the last level:

```python
In [98]: stacked.unstack()
Out [98]:
   A        B
first second
bar one  0.957597  1.212920
two    -0.116710 -0.581082
baz one  0.125989  0.745104
two    0.871205  1.278467
```

```python
In [99]: stacked.unstack(1)
Out [99]:
   second one two
   first
bar  A  0.957597 -0.116710
     B  1.212920 -0.581082
baz  A  0.125989  0.871205
     B  0.745104  1.278467
```

```python
In [100]: stacked.unstack(0)
Out [100]:
   first bar baz
   second
one  A  0.957597  0.125989
     B  1.212920  0.745104
two  A -0.116710  0.871205
     B -0.581082  1.278467
```

**Pivot tables**

See the section on *Pivot Tables*.

```python
In [101]: df = pd.DataFrame({'A': ["one", "one", "two", "three"] * 3,
                  'B': ["A", "B", "C"] * 4,
                  'C': ["foo", "foo", "foo", "bar", "bar", "bar"] * 2,
                  'D': np.random.randn(12),
                  'E': np.random.randn(12)})
```

```python
In [102]: df
Out [102]:
   A     B     C         D         E
0 one  foo  0.987993 -0.355019 -0.996984
1 one  foo -0.785662  0.535308  0.058524
2 two  foo -0.364986 -0.740877  0.379842
3 three A bar  1.218929 -0.814668 -0.170508
4 one  B bar  0.628113  0.569796  0.517058
5 one  C bar  1.234615 -0.065014  0.640430
6 two  foo  0.444063  0.438080 -0.637594
7 three B foo  0.273936  2.059782  0.684543
8 one  C foo -0.639935  1.552669 -0.309562
9 one  A bar -1.851780  0.638724 -0.555912
10 two B bar -0.183182  0.823094  0.598092
11 three C bar -1.461424  1.639158  0.857115
```
We can produce pivot tables from this data very easily:

```python
In [103]: pd.pivot_table(df, values='D', index=['A', 'B'], columns=['C'])
Out[103]:
     C  bar  foo
   A    B
  one  A  -1.851780  0.987993
        B  -0.628113 -0.785662
        C   1.234615 -0.639935
  three A  1.218929   NaN
         B    NaN   0.273936
         C  -1.461424   NaN
  two   A    NaN   0.444063
         B -0.183182   NaN
         C    NaN  -0.364986
```

### 2.1.9 Time series

pandas has simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications. See the [Time Series section](#).

```python
In [104]: rng = pd.date_range('1/1/2012', periods=100, freq='S')
In [105]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)
In [106]: ts.resample('5Min').sum()
Out[106]:
2012-01-01  24372
Freq: 5T, dtype: int64
```

Time zone representation:

```python
In [107]: rng = pd.date_range('3/6/2012 00:00', periods=5, freq='D')
In [108]: ts = pd.Series(np.random.randn(len(rng)), rng)
In [109]: ts
Out[109]:
2012-03-06 -2.412126
2012-03-07 -0.320627
2012-03-08 -0.346299
2012-03-09 -0.387749
2012-03-10 -0.347677
Freq: D, dtype: float64
In [110]: ts_utc = ts.tz_localize('UTC')
In [111]: ts_utc
Out[111]:
2012-03-06 00:00:00+00:00  -2.412126
2012-03-07 00:00:00+00:00  -0.320627
2012-03-08 00:00:00+00:00  -0.346299
2012-03-09 00:00:00+00:00  -0.387749
2012-03-10 00:00:00+00:00  -0.347677
Freq: D, dtype: float64
```
Converting to another time zone:

```
In [112]: ts_utc.tz_convert('US/Eastern')
Out[112]:
2012-03-05 19:00:00-05:00  2.412126
2012-03-06 19:00:00-05:00  0.320627
2012-03-07 19:00:00-05:00  0.346299
2012-03-08 19:00:00-05:00  0.387749
2012-03-09 19:00:00-05:00  0.347677
Freq: D, dtype: float64
```

Converting between time span representations:

```
In [113]: rng = pd.date_range('1/1/2012', periods=5, freq='M')
In [114]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
In [115]: ts
Out[115]:
2012-01-31  1.339713
2012-02-29  0.821134
2012-03-31 -0.169414
2012-04-30 -0.397527
2012-05-31  0.162753
Freq: M, dtype: float64

In [116]: ps = ts.to_period()
In [117]: ps
Out[117]:
2012-01  1.339713
2012-02  0.821134
2012-03 -0.169414
2012-04 -0.397527
2012-05  0.162753
Freq: M, dtype: float64

In [118]: ps.to_timestamp()
Out[118]:
2012-01-01  1.339713
2012-02-01  0.821134
2012-03-01 -0.169414
2012-04-01 -0.397527
2012-05-01  0.162753
Freq: MS, dtype: float64
```

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```
In [119]: prng = pd.period_range('1990Q1', '2000Q4', freq='Q-NOV')
In [120]: ts = pd.Series(np.random.randn(len(prng)), prng)
In [121]: ts.index = (prng.asfreq('M', 'e') + 1).asfreq('H', 's') + 9
In [122]: ts.head()
Out[122]:
(continues on next page)
```

2.1. 10 minutes to pandas
2.1.10 Categoricals

pandas can include categorical data in a DataFrame. For full docs, see the categorical introduction and the API documentation.

```python
In [123]: df = pd.DataFrame({"id": [1, 2, 3, 4, 5, 6], "raw_grade": ['a', 'b', 'b', 'a', 'a', 'e']})

In [124]: df["grade"] = df["raw_grade"].astype("category")

In [125]: df["grade"]
Out[125]:
           grade
0         a
1         b
2         b
3         a
4         a
5         e
Name: grade, dtype: category
Categories (3, object): ['a', 'b', 'e']
```

Convert the raw grades to a categorical data type.

```python
In [126]: df["grade"].cat.categories = ['very good', 'good', 'very bad']

In [127]: df["grade"] = df["grade"].cat.set_categories(['very bad', 'bad', 'medium', 'good', 'very good'])

In [128]: df["grade"]
Out[128]:
0      very good
1         good
2         good
3      very good
4      very good
5     very bad
Name: grade, dtype: category
Categories (5, object): ['very bad', 'bad', 'medium', 'good', 'very good']
```

Sorting is per order in the categories, not lexical order.
Grouping by a categorical column also shows empty categories.

```python
In [130]: df.groupby("grade").size()
Out[130]:
grade
very bad    1
bad         0
medium      0
good        2
very good   3
dtype: int64
```

2.1.11 Plotting

See the Plotting docs.

We use the standard convention for referencing the matplotlib API:

```python
In [131]: import matplotlib.pyplot as plt
In [132]: plt.close('all')
In [133]: ts = pd.Series(np.random.randn(1000),
......:     index=pd.date_range('1/1/2000', periods=1000))
......:
In [134]: ts = ts.cumsum()
In [135]: ts.plot()
Out[135]: <AxesSubplot:>
```
On a DataFrame, the `plot()` method is a convenience to plot all of the columns with labels:

```python
In [136]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index,
                        columns=['A', 'B', 'C', 'D'])
In [137]: df = df.cumsum()
In [138]: plt.figure()
Out[138]: <Figure size 640x480 with 0 Axes>
In [139]: df.plot()
Out[139]: <AxesSubplot:>
In [140]: plt.legend(loc='best')
Out[140]: <matplotlib.legend.Legend at 0x7f0a83e8dd30>
```
### 2.1.12 Getting data in/out

#### CSV

Writing to a csv file.

```python
In [141]: df.to_csv('foo.csv')
```

Reading from a csv file.

```python
In [142]: pd.read_csv('foo.csv')
Out[142]:
<table>
<thead>
<tr>
<th>Unnamed: 0</th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2000-01-01</td>
<td>1.383918</td>
<td>1.294748</td>
<td>2.146369</td>
</tr>
<tr>
<td>1</td>
<td>2000-01-02</td>
<td>1.004835</td>
<td>3.450110</td>
<td>3.902662</td>
</tr>
<tr>
<td>2</td>
<td>2000-01-03</td>
<td>1.785987</td>
<td>5.240357</td>
<td>3.479194</td>
</tr>
<tr>
<td>3</td>
<td>2000-01-04</td>
<td>1.859561</td>
<td>6.037586</td>
<td>4.446283</td>
</tr>
<tr>
<td>4</td>
<td>2000-01-05</td>
<td>3.201273</td>
<td>5.094690</td>
<td>4.033113</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>996</td>
<td>2002-09-23</td>
<td>23.949126</td>
<td>-12.620037</td>
<td>39.339605</td>
</tr>
<tr>
<td>997</td>
<td>2002-09-24</td>
<td>22.880990</td>
<td>-12.797035</td>
<td>39.106664</td>
</tr>
</tbody>
</table>
```

(continues on next page)
HDF5

Reading and writing to HDFStores.

Writing to a HDF5 Store.

```python
In [143]: df.to_hdf('foo.h5', 'df')
```

Reading from a HDF5 Store.

```python
In [144]: pd.read_hdf('foo.h5', 'df')
```

Excel

Reading and writing to MS Excel.

Writing to an excel file.

```python
In [145]: df.to_excel('foo.xlsx', sheet_name='Sheet1')
```

Reading from an excel file.

```python
In [146]: pd.read_excel('foo.xlsx', 'Sheet1', index_col=None, na_values=['NA'])
```
2.1.13 Gotchas

If you are attempting to perform an operation you might see an exception like:

```python
>>> if pd.Series([False, True, False]):
...     print("I was true")
Traceback
...  ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

See *Comparisons* for an explanation and what to do.

See *Gotchas* as well.

2.2 Intro to data structures

We’ll start with a quick, non-comprehensive overview of the fundamental data structures in pandas to get you started. The fundamental behavior about data types, indexing, and axis labeling / alignment apply across all of the objects. To get started, import NumPy and load pandas into your namespace:

```python
In [1]: import numpy as np
In [2]: import pandas as pd
```

Here is a basic tenet to keep in mind: **data alignment is intrinsic.** The link between labels and data will not be broken unless done so explicitly by you.

We’ll give a brief intro to the data structures, then consider all of the broad categories of functionality and methods in separate sections.

2.2.1 Series

*Series* is a one-dimensional labeled array capable of holding any data type (integers, strings, floating point numbers, Python objects, etc.). The axis labels are collectively referred to as the *index*. The basic method to create a Series is to call:

```python
>>> s = pd.Series(data, index=index)
```

Here, `data` can be many different things:

- a Python dict
- an ndarray
- a scalar value (like 5)

The passed `index` is a list of axis labels. Thus, this separates into a few cases depending on what `data` is:

**From ndarray**
If `data` is an `ndarray`, `index` must be the same length as `data`. If no index is passed, one will be created having values `[0, ..., len(data) - 1]`.

```python
In [3]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [4]: s
Out[4]:
a     0.469112
b    -0.282863
c    -1.509059
d    -1.135632
e     1.212112
dtype: float64

In [5]: s.index
Out[5]: Index(['a', 'b', 'c', 'd', 'e'], dtype='object')

In [6]: pd.Series(np.random.randn(5))
Out[6]:
0   -0.173215
1    0.119209
2   -1.044236
3   -0.861849
4   -2.104569
dtype: float64
```

**Note:** pandas supports non-unique index values. If an operation that does not support duplicate index values is attempted, an exception will be raised at that time. The reason for being lazy is nearly all performance-based (there are many instances in computations, like parts of GroupBy, where the index is not used).

### From dict

Series can be instantiated from dicts:

```python
In [7]: d = {'b': 1, 'a': 0, 'c': 2}

In [8]: pd.Series(d)
Out[8]:
b    1
a    0
c    2
dtype: int64
```

**Note:** When the data is a dict, and an index is not passed, the `Series` index will be ordered by the dict’s insertion order, if you’re using Python version >= 3.6 and Pandas version >= 0.23.

If you’re using Python < 3.6 or Pandas < 0.23, and an index is not passed, the `Series` index will be the lexically ordered list of dict keys.

In the example above, if you were on a Python version lower than 3.6 or a Pandas version lower than 0.23, the `Series` would be ordered by the lexical order of the dict keys (i.e. `['a', 'b', 'c']` rather than `['b', 'a', 'c']`).

If an index is passed, the values in `data` corresponding to the labels in the index will be pulled out.
In [9]: d = {'a': 0., 'b': 1., 'c': 2.}

In [10]: pd.Series(d)
Out[10]:
  a    0.0
  b    1.0
  c    2.0
dtype: float64

In [11]: pd.Series(d, index=['b', 'c', 'd', 'a'])
Out[11]:
  b   1.0
  c   2.0
d   NaN
  a   0.0
dtype: float64

Note: NaN (not a number) is the standard missing data marker used in pandas.

From scalar value

If data is a scalar value, an index must be provided. The value will be repeated to match the length of index.

In [12]: pd.Series(5., index=['a', 'b', 'c', 'd', 'e'])
Out[12]:
  a   5.0
  b   5.0
  c   5.0
d   5.0
e   5.0
dtype: float64

Series is ndarray-like

Series acts very similarly to an ndarray, and is a valid argument to most NumPy functions. However, operations such as slicing will also slice the index.

In [13]: s[0]
Out[13]: 0.4691122299071863

In [14]: s[:3]
Out[14]:
  a  0.469112
  b -0.282863
c  -1.509059
dtype: float64

In [15]: s[s > s.median()]
Out[15]:
  a  0.469112
e  1.212112

dtype: float64

In [16]: s[[4, 3, 1]]
Note: We will address array-based indexing like \$s[[4, 3, 1]]\$ in section.

Like a NumPy array, a pandas Series has a \texttt{dtype}.

```
In [18]: s.dtype
Out[18]: dtype('float64')
```

This is often a NumPy dtype. However, pandas and 3rd-party libraries extend NumPy’s type system in a few places, in which case the dtype would be an \texttt{ExtensionDtype}. Some examples within pandas are \texttt{Categorical data} and \texttt{Nullable integer data type}. See \texttt{dtypes} for more.

If you need the actual array backing a Series, use \texttt{Series.array}.

```
In [19]: s.array
Out[19]: <PandasArray>
[ 0.4691122999071863, -0.2828633443286633, -1.5090585031735124, 
  -1.1356323710171934,  1.2121120250208506]
Length: 5, dtype: float64
```

Accessing the array can be useful when you need to do some operation without the index (to disable \texttt{automatic alignment}, for example).

\texttt{Series.array} will always be an \texttt{ExtensionArray}. Briefly, an ExtensionArray is a thin wrapper around one or more \texttt{concrete} arrays like a \texttt{numpy.ndarray}. Pandas knows how to take an \texttt{ExtensionArray} and store it in a Series or a column of a DataFrame. See \texttt{dtypes} for more.

While Series is ndarray-like, if you need an \texttt{actual} ndarray, then use \texttt{Series.to_numpy()}.

```
In [20]: s.to_numpy()
Out[20]: array([ 0.4691, -0.2829, -1.5091, -1.1356,  1.2121])
```

Even if the Series is backed by a \texttt{ExtensionArray}, \texttt{Series.to_numpy()} will return a NumPy ndarray.
Series is dict-like

A Series is like a fixed-size dict in that you can get and set values by index label:

```python
In [21]: s['a']
Out[21]: 0.4691122999071863

In [22]: s['e'] = 12.

In [23]: s
Out[23]:
a    0.469112
b   -0.282863
c   -1.509059
d  -1.135632
e   12.000000
dtype: float64
```

If a label is not contained, an exception is raised:

```python
>>> s['f']
KeyError: 'f'
```

Using the `get` method, a missing label will return None or specified default:

```python
In [26]: s.get('f')
```

```python
In [27]: s.get('f', np.nan)
Out[27]: nan
```

See also the section on attribute access.

Vectorized operations and label alignment with Series

When working with raw NumPy arrays, looping through value-by-value is usually not necessary. The same is true when working with Series in pandas. Series can also be passed into most NumPy methods expecting an ndarray.

```python
In [28]: s + s
Out[28]:
a    0.938225
b   -0.565727
c   -3.018117
d  -2.271265
e   24.000000
dtype: float64

In [29]: s * 2
Out[29]:
a    0.938225
b   -0.565727
```

(continues on next page)
A key difference between Series and ndarray is that operations between Series automatically align the data based on label. Thus, you can write computations without giving consideration to whether the Series involved have the same labels.

The result of an operation between unaligned Series will have the union of the indexes involved. If a label is not found in one Series or the other, the result will be marked as missing NaN. Being able to write code without doing any explicit data alignment grants immense freedom and flexibility in interactive data analysis and research. The integrated data alignment features of the pandas data structures set pandas apart from the majority of related tools for working with labeled data.

**Note:** In general, we chose to make the default result of operations between differently indexed objects yield the union of the indexes in order to avoid loss of information. Having an index label, though the data is missing, is typically important information as part of a computation. You of course have the option of dropping labels with missing data via the dropna function.

### Name attribute

Series can also have a name attribute:

```python
In [32]: s = pd.Series(np.random.randn(5), name='something')

In [33]: s
Out[33]:
  0  -0.494929
  1   1.071804
  2   0.721555
  3  -0.706771
  4  -1.039575
Name: something, dtype: float64
```
In [34]: s.name
Out[34]: 'something'

The Series name will be assigned automatically in many cases, in particular when taking 1D slices of DataFrame as you will see below.

You can rename a Series with the pandas.Series.rename() method.

In [35]: s2 = s.rename("different")
In [36]: s2.name
Out[36]: 'different'

Note that $s$ and $s2$ refer to different objects.

### 2.2.2 DataFrame

**DataFrame** is a 2-dimensional labeled data structure with columns of potentially different types. You can think of it like a spreadsheet or SQL table, or a dict of Series objects. It is generally the most commonly used pandas object.

Like Series, DataFrame accepts many different kinds of input:

- Dict of 1D ndarrays, lists, dicts, or Series
- 2-D numpy.ndarray
- Structured or record ndarray
- A Series
- Another DataFrame

Along with the data, you can optionally pass `index` (row labels) and `columns` (column labels) arguments. If you pass an index and / or columns, you are guaranteeing the index and / or columns of the resulting DataFrame. Thus, a dict of Series plus a specific index will discard all data not matching up to the passed index.

If axis labels are not passed, they will be constructed from the input data based on common sense rules.

**Note:** When the data is a dict, and columns is not specified, the DataFrame columns will be ordered by the dict’s insertion order, if you are using Python version >= 3.6 and Pandas >= 0.23.

If you are using Python < 3.6 or Pandas < 0.23, and columns is not specified, the DataFrame columns will be the lexically ordered list of dict keys.

#### From dict of Series or dicts

The resulting index will be the union of the indexes of the various Series. If there are any nested dicts, these will first be converted to Series. If no columns are passed, the columns will be the ordered list of dict keys.

In [37]: d = {'one': pd.Series([1., 2., 3.], index=['a', 'b', 'c']),
      ....:     'two': pd.Series([1., 2., 3., 4.], index=['a', 'b', 'c', 'd'])
      ....: }
In [38]: df = pd.DataFrame(d)
In [39]: df

(continues on next page)
Out[39]:
   one  two
a  1.0  1.0
b  2.0  2.0
c  3.0  3.0
d  NaN  4.0

In [40]: pd.DataFrame(d, index=['d', 'b', 'a'])
Out[40]:
   one  two
  d    NaN  4.0
  b  2.0  2.0
  a  1.0  1.0

In [41]: pd.DataFrame(d, index=['d', 'b', 'a'], columns=['two', 'three'])
Out[41]:
   two  three
  d    4.0    NaN
  b  2.0    NaN
  a  1.0    NaN

The row and column labels can be accessed respectively by accessing the index and columns attributes:

Note: When a particular set of columns is passed along with a dict of data, the passed columns override the keys in the dict.

In [42]: df.index
Out[42]: Index(['a', 'b', 'c', 'd'], dtype='object')

In [43]: df.columns
Out[43]: Index(['one', 'two'], dtype='object')

From dict of ndarrays / lists

The ndarrays must all be the same length. If an index is passed, it must clearly also be the same length as the arrays. If no index is passed, the result will be range(n), where n is the array length.

In [44]: d = {'one': [1., 2., 3., 4.],
       'two': [4., 3., 2., 1.]};

In [45]: pd.DataFrame(d)
Out[45]:
   one  two
0  1.0  4.0
1  2.0  3.0
2  3.0  2.0
3  4.0  1.0

In [46]: pd.DataFrame(d, index=['a', 'b', 'c', 'd'])
Out[46]:
   one  two
a  1.0  4.0
b 2.0 3.0
c 3.0 2.0
d 4.0 1.0

**From structured or record array**

This case is handled identically to a dict of arrays.

```python
In [47]: data = np.zeros((2, ), dtype=[('A', 'i4'), ('B', 'f4'), ('C', 'a10')])
In [48]: data[:] = [(1, 2., 'Hello'), (2, 3., 'World')]
In [49]: pd.DataFrame(data)
Out[49]:
      A     B       C
0   1.0  2.0  b'Hello'
1   2.0  3.0  b'World'

In [50]: pd.DataFrame(data, index=['first', 'second'])
Out[50]:
      A     B       C
  first 1.0  2.0  b'Hello'
  second 2.0  3.0  b'World'

In [51]: pd.DataFrame(data, columns=['C', 'A', 'B'])
Out[51]:
     C     A     B
0  b'Hello'  1.0  2.0
1  b'World'  2.0  3.0
```

**Note:** DataFrame is not intended to work exactly like a 2-dimensional NumPy ndarray.

**From a list of dicts**

```python
In [52]: data2 = [{'a': 1, 'b': 2}, {'a': 5, 'b': 10, 'c': 20}]
In [53]: pd.DataFrame(data2)
Out[53]:
     a     b     c
0  1.0  2.0  NaN
1  5.0 10.0  20.0

In [54]: pd.DataFrame(data2, index=['first', 'second'])
Out[54]:
     a     b     c
first 1.0  2.0  NaN
second 5.0 10.0  20.0

In [55]: pd.DataFrame(data2, columns=['a', 'b'])
Out[55]:
     a  b
0  1.0  2.0
1  5.0 10.0
```

(continues on next page)
From a dict of tuples

You can automatically create a MultiIndexed frame by passing a tuples dictionary.

```
In [56]: pd.DataFrame({('a', 'b'): {('A', 'B'): 1, ('A', 'C'): 2},
                     ('a', 'a'): {('A', 'C'): 3, ('A', 'B'): 4},
                     ('a', 'c'): {('A', 'B'): 5, ('A', 'C'): 6},
                     ('b', 'a'): {('A', 'C'): 7, ('A', 'B'): 8},
                     ('b', 'b'): {('A', 'D'): 9, ('A', 'B'): 10}})
```

```
Out[56]:
         a   b
      b  a  c  a  b
      A  B  1.0 4.0 5.0 8.0 10.0
      C  NaN     2.0 3.0 6.0 7.0 NaN
      D NaN  NaN NaN NaN    NaN 9.0
```

From a Series

The result will be a DataFrame with the same index as the input Series, and with one column whose name is the original name of the Series (only if no other column name provided).

From a list of dataclasses

New in version 1.1.0.

Data Classes as introduced in PEP557, can be passed into the DataFrame constructor. Passing a list of dataclasses is equivalent to passing a list of dictionaries.

Please be aware, that all values in the list should be dataclasses, mixing types in the list would result in a TypeError.

```
In [57]: from dataclasses import make_dataclass

In [58]: Point = make_dataclass("Point", ["x", int], ["y", int])

In [59]: pd.DataFrame([Point(0, 0), Point(0, 3), Point(2, 3)])
```

```
Out[59]:
   x  y
0  0  0
1  0  3
2  2  3
```

Missing data

Much more will be said on this topic in the Missing data section. To construct a DataFrame with missing data, we use np.nan to represent missing values. Alternatively, you may pass a numpy.MaskedArray as the data argument to the DataFrame constructor, and its masked entries will be considered missing.
Alternate constructors

DataFrame.from_dict

DataFrame.from_dict takes a dict of dicts or a dict of array-like sequences and returns a DataFrame. It operates like the DataFrame constructor except for the orient parameter which is 'columns' by default, but which can be set to 'index' in order to use the dict keys as row labels.

```
In [60]: pd.DataFrame.from_dict(dict([('A', [1, 2, 3]), ('B', [4, 5, 6])]))
Out[60]:
     A  B
0   1  4
1   2  5
2   3  6
```

If you pass orient='index', the keys will be the row labels. In this case, you can also pass the desired column names:

```
In [61]: pd.DataFrame.from_dict(dict([('A', [1, 2, 3]), ('B', [4, 5, 6])]),
                           orient='index', columns=['one', 'two', 'three'])
```

DataFrame.from_records

DataFrame.from_records takes a list of tuples or an ndarray with structured dtype. It works analogously to the normal DataFrame constructor, except that the resulting DataFrame index may be a specific field of the structured dtype. For example:

```
In [62]: data
Out[62]:
array([(1, 2., b'Hello'), (2, 3., b'World')],
      dtype=[('A', '<i4'), ('B', '<f4'), ('C', 'S10')])

In [63]: pd.DataFrame.from_records(data, index='C')
Out[63]:
      A  B
C b'Hello' 1  2.0
b'World' 2 3.0
```

Column selection, addition, deletion

You can treat a DataFrame semantically like a dict of like-indexed Series objects. Getting, setting, and deleting columns works with the same syntax as the analogous dict operations:

```
In [64]: df['one']
Out[64]:
a   1.0  
b   2.0  
c   3.0  
d  NaN  
Name: one, dtype: float64
```
In [65]: df['three'] = df['one'] * df['two']

In [66]: df['flag'] = df['one'] > 2

In [67]: df
Out[67]:
   one  two  three  flag
  a   1.0  1.0   1.0  False
  b   2.0  2.0   4.0  False
  c   3.0  3.0   9.0   True
  d  NaN  4.0  NaN  False

Columns can be deleted or popped like with a dict:

In [68]: del df['two']

In [69]: three = df.pop('three')

In [70]: df
Out[70]:
   one  flag
  a   1.0  False
  b   2.0  False
  c   3.0   True
  d  NaN  False

When inserting a scalar value, it will naturally be propagated to fill the column:

In [71]: df['foo'] = 'bar'

In [72]: df
Out[72]:
   one  flag  foo
  a   1.0  False bar
  b   2.0  False bar
  c   3.0   True bar
  d  NaN  False bar

When inserting a Series that does not have the same index as the DataFrame, it will be conformed to the DataFrame’s index:

In [73]: df['one_trunc'] = df['one'][:2]

In [74]: df
Out[74]:
   one  flag  foo  one_trunc
  a   1.0  False bar  1.0
  b   2.0  False bar  2.0
  c   3.0   True bar  NaN
  d  NaN  False bar  NaN

You can insert raw ndarrays but their length must match the length of the DataFrame’s index.

By default, columns get inserted at the end. The insert function is available to insert at a particular location in the columns:
In [75]: df.insert(1, 'bar', df['one'])

In [76]: df
Out[76]:
one  bar  flag  foo  one_trunc
a 1.0 1.0  False  bar  1.0
b 2.0 2.0  False  bar  2.0
c 3.0 3.0  True  bar  NaN
d NaN NaN  False  bar  NaN

Assigning new columns in method chains

Inspired by dplyr's `mutate` verb, DataFrame has an `assign()` method that allows you to easily create new columns that are potentially derived from existing columns.

In [77]: iris = pd.read_csv('data/iris.data')

In [78]: iris.head()
Out[78]:
       SepalLength  SepalWidth  PetalLength  PetalWidth  Name
0         5.1          3.5          1.4          0.2  Iris-setosa
1         4.9          3.0          1.4          0.2  Iris-setosa
2         4.7          3.2          1.3          0.2  Iris-setosa
3         4.6          3.1          1.5          0.2  Iris-setosa
4         5.0          3.6          1.4          0.2  Iris-setosa

In [79]: (iris.assign(sepal_ratio=iris['SepalWidth'] / iris['SepalLength'])
        .head())
Out[79]:
   SepalLength  SepalWidth  PetalLength  PetalWidth Name  sepal_ratio
0      5.1     3.5          1.4          0.2 Iris-setosa  0.686275
1      4.9     3.0          1.4          0.2 Iris-setosa  0.612245
2      4.7     3.2          1.3          0.2 Iris-setosa  0.680851
3      4.6     3.1          1.5          0.2 Iris-setosa  0.673913
4      5.0     3.6          1.4          0.2 Iris-setosa  0.720000

In the example above, we inserted a precomputed value. We can also pass in a function of one argument to be evaluated on the DataFrame being assigned to.

In [80]: iris.assign(sepal_ratio=lambda x: x['SepalWidth'] / x['SepalLength']).
        .head()
Out[80]:
   SepalLength  SepalWidth  PetalLength  PetalWidth Name  sepal_ratio
0      5.1     3.5          1.4          0.2 Iris-setosa  0.686275
1      4.9     3.0          1.4          0.2 Iris-setosa  0.612245
2      4.7     3.2          1.3          0.2 Iris-setosa  0.680851
3      4.6     3.1          1.5          0.2 Iris-setosa  0.673913
4      5.0     3.6          1.4          0.2 Iris-setosa  0.720000

`assign` always returns a copy of the data, leaving the original DataFrame untouched.

Passing a callable, as opposed to an actual value to be inserted, is useful when you don’t have a reference to the DataFrame at hand. This is common when using `assign` in a chain of operations. For example, we can limit the DataFrame to just those observations with a Sepal Length greater than 5, calculate the ratio, and plot:

2.2. Intro to data structures
In [81]: (iris.query('SepalLength > 5')
    
    .assign(SepalRatio=lambda x: x.SepalWidth / x.SepalLength,
    PetalRatio=lambda x: x.PetalWidth / x.PetalLength)
    
    .plot(kind='scatter', x='SepalRatio', y='PetalRatio'))

Out[81]: <AxesSubplot:xlabel='SepalRatio', ylabel='PetalRatio'>

Since a function is passed in, the function is computed on the DataFrame being assigned to. Importantly, this is the DataFrame that’s been filtered to those rows with sepal length greater than 5. The filtering happens first, and then the ratio calculations. This is an example where we didn’t have a reference to the filtered DataFrame available.

The function signature for `assign` is simply `**kwargs`. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a `Series` or NumPy array), or a function of one argument to be called on the DataFrame. A copy of the original DataFrame is returned, with the new values inserted.

Changed in version 0.23.0.

Starting with Python 3.6 the order of `**kwargs` is preserved. This allows for dependent assignment, where an expression later in `**kwargs` can refer to a column created earlier in the same `assign()`.

In [82]: dfa = pd.DataFrame({'A': [1, 2, 3],
    'B': [4, 5, 6]})

In [83]: dfa.assign(C=lambda x: x['A'] + x['B'],

(continues on next page)
In the second expression, \( x['C'] \) will refer to the newly created column, that’s equal to \( dfa['A'] + dfa['B'] \).

### Indexing / selection

The basics of indexing are as follows:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Syntax</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select column</td>
<td>( df[col] )</td>
<td>Series</td>
</tr>
<tr>
<td>Select row by label</td>
<td>( df.loc[label] )</td>
<td>Series</td>
</tr>
<tr>
<td>Select row by integer location</td>
<td>( df.iloc[loc] )</td>
<td>Series</td>
</tr>
<tr>
<td>Slice rows</td>
<td>( df[5:10] )</td>
<td>DataFrame</td>
</tr>
<tr>
<td>Select rows by boolean vector</td>
<td>( df[bool_vec] )</td>
<td>DataFrame</td>
</tr>
</tbody>
</table>

Row selection, for example, returns a Series whose index is the columns of the DataFrame:

```
In [84]: df.loc['b']
Out[84]:
one    2
bar    2
flag   False
foo    bar
Name: b, dtype: object
```

```
In [85]: df.iloc[2]
Out[85]:
one    3
bar    3
flag   True
Name: c, dtype: object
```

For a more exhaustive treatment of sophisticated label-based indexing and slicing, see the section on indexing. We will address the fundamentals of reindexing / conforming to new sets of labels in the section on reindexing.
Data alignment and arithmetic

Data alignment between DataFrame objects automatically align on both the columns and the index (row labels). Again, the resulting object will have the union of the column and row labels.

```
In [86]: df = pd.DataFrame(np.random.randn(10, 4), columns=['A', 'B', 'C', 'D'])
In [87]: df2 = pd.DataFrame(np.random.randn(7, 3), columns=['A', 'B', 'C'])
In [88]: df + df2
Out[88]:
   A    B    C    D
0  0.045691 -0.014138 1.380871 NaN
1 -0.955398 -1.501007 0.037181 NaN
2 -0.662690 1.534833 -0.859691 NaN
3 -2.452949 1.237274 -0.133712 NaN
4  1.414490 1.951676 -2.320422 NaN
5  0.494922 -1.649727 -1.084601 NaN
6  1.047551 -0.748572 -0.805479 NaN
7   NaN   NaN  NaN  NaN
8   NaN   NaN  NaN  NaN
9   NaN   NaN  NaN  NaN
```

When doing an operation between DataFrame and Series, the default behavior is to align the Series index on the DataFrame columns, thus broadcasting row-wise. For example:

```
In [89]: df - df.iloc[0]
Out[89]:
   A    B    C    D
0  0.000000 0.000000 0.000000 0.000000
1 -1.359261 -0.248717 -0.453372 -1.754659
2  0.253128 0.829678 0.010026 -1.991234
3 -1.311128 0.054325 -1.724913 -1.620544
4  0.573025 1.500742 -0.676070 1.367331
5 -1.741248 0.781993 -1.241620 -2.053136
6 -1.240774 -0.869551 -0.153282 0.000430
7  0.743894 0.411013 0.929563 -0.282386
8 -1.194921 1.320690 0.238224 -1.482644
9  2.293786 1.856228 0.773289 -1.446531
```

In the special case of working with time series data, if the DataFrame index contains dates, the broadcasting will be column-wise:

```
In [90]: index = pd.date_range('1/1/2000', periods=8)
In [91]: df = pd.DataFrame(np.random.randn(8, 3), index=index, columns=list('ABC'))
In [92]: df
Out[92]:
   A      B      C
2000-01-01 1.226825 0.769804 -1.281247
2000-01-02 -0.727707 -0.121306 -0.097883
2000-01-03 0.695775 0.341734 0.959726
2000-01-04 -1.110336 -0.619976 0.149748
2000-01-05 0.732339 0.687738 0.176444
2000-01-06 0.403310 -0.154953 0.301624
2000-01-07 -2.179861 -1.369849 -0.954208
```

(continues on next page)
In [93]: `type(df['A'])`
Out[93]: pandas.core.series.Series

In [94]: df - df['A']
Out[94]:
2000-01-01 00:00:00 2000-01-02 00:00:00 2000-01-03 00:00:00 2000-01-04

2000-01-05 NaN NaN NaN NaN NaN
2000-01-06 NaN NaN NaN NaN NaN
2000-01-07 NaN NaN NaN NaN NaN
2000-01-08 NaN NaN NaN NaN NaN
[8 rows x 11 columns]

Warning:

`df - df['A']`

is now deprecated and will be removed in a future release. The preferred way to replicate this behavior is

```
df.sub(df['A'], axis=0)
```

For explicit control over the matching and broadcasting behavior, see the section on flexible binary operations.

Operations with scalars are just as you would expect:

In [95]: df * 5 + 2
Out [95]:

<td>False</td>
</tr>
</tbody>
</table>
Transposing

To transpose, access the `T` attribute (also the `transpose` function), similar to an ndarray:

```python
# only show the first 5 rows
In [104]: df[:5].T
Out[104]:
A   -1.226825  -0.727707   0.695775  -1.110336  -0.732339
B    0.769804  -0.121306   0.341734  -0.619976   0.687738
C   -1.281247  -0.097883   0.959726   0.149748   0.176444
```

DataFrame interoperability with NumPy functions

Elementwise NumPy ufuncs (log, exp, sqrt, ...) and various other NumPy functions can be used with no issues on Series and DataFrame, assuming the data within are numeric:

```python
In [105]: np.exp(df)
Out[105]:
     A       B       C
2000-01-01 0.293222 2.159342 0.277691
2000-01-02 0.483015 0.885763 0.906755
2000-01-03 2.005262 1.407386 2.610980
2000-01-04 0.329448 0.537957 1.161542
2000-01-05 0.480783 1.989212 1.192968
2000-01-06 1.496770 0.856457 1.352053
2000-01-07 0.113057 0.254145 0.385117
2000-01-08 4.317584 0.174966 0.437538

In [106]: np.asarray(df)
Out[106]:
array([[-1.2268,  0.7698, -1.2812],
       [-0.7277, -0.1213, -0.0979],
       [ 0.6958,  0.3417,  0.9597],
       [-1.1103, -0.62   ,  0.1497],
       [-0.7323,  0.6877,  0.1764],
       [ 0.4033, -0.155  ,  0.3016],
       [-2.1799, -1.3698, -0.9542],
       [ 1.4627, -1.7432, -0.8266]])
```

DataFrame is not intended to be a drop-in replacement for ndarray as its indexing semantics and data model are quite different in places from an n-dimensional array.

*Series* implements `__array_ufunc__`, which allows it to work with NumPy's universal functions.

The ufunc is applied to the underlying array in a Series.

```python
In [107]: ser = pd.Series([1, 2, 3, 4])

In [108]: np.exp(ser)
Out[108]:
0   2.718282
1   7.389056
2  20.085537
3  54.598150
dtype: float64
```
Changed in version 0.25.0: When multiple Series are passed to a ufunc, they are aligned before performing the operation.

Like other parts of the library, pandas will automatically align labeled inputs as part of a ufunc with multiple inputs. For example, using numpy.remainder() on two Series with differently ordered labels will align before the operation.

In [109]: ser1 = pd.Series([1, 2, 3], index=['a', 'b', 'c'])

In [110]: ser2 = pd.Series([1, 3, 5], index=['b', 'a', 'c'])

In [111]: ser1
Out[111]:
    a  1
    b  2
    c  3
    dtype: int64

In [112]: ser2
Out[112]:
    b  1
    a  3
    c  5
    dtype: int64

In [113]: np.remainder(ser1, ser2)
Out[113]:
    a  1
    b  0
    c  3
    dtype: int64

As usual, the union of the two indices is taken, and non-overlapping values are filled with missing values.

In [114]: ser3 = pd.Series([2, 4, 6], index=['b', 'c', 'd'])

In [115]: ser3
Out[115]:
    b  2
    c  4
    d  6
    dtype: int64

In [116]: np.remainder(ser1, ser3)
Out[116]:
    a  NaN
    b  0.0
    c  3.0
    d  NaN
    dtype: float64

When a binary ufunc is applied to a Series and Index, the Series implementation takes precedence and a Series is returned.

In [117]: ser = pd.Series([1, 2, 3])

In [118]: idx = pd.Index([4, 5, 6])

(continues on next page)
NumPy ufuncs are safe to apply to `Series` backed by non-ndarray arrays, for example `arrays.SparseArray` (see `Sparse calculation`). If possible, the ufunc is applied without converting the underlying data to an ndarray.

**Console display**

Very large DataFrames will be truncated to display them in the console. You can also get a summary using `info()`. (Here I am reading a CSV version of the `baseball` dataset from the `plyr` R package):

```python
In [120]: baseball = pd.read_csv('data/baseball.csv')
In [121]: print(baseball)
   id   player   year   stint   team   lg   g   ab   r   h  X2b  X3b   hr   rbi   sb
   cs  bb   so  ibb  hbp   sh  sf   gidp
0  88641 womacto01  2006  2   CHN  NL  19   50  6  14   1   0    1   2.0  1.0
   1.0  4   4.0  0.0  0.0   3.0  0.0  0.0
1  88643 schilcu01  2006  1   BOS  AL  31   2   0   1   0    0    0  0.0  0.0
   0.0  0   1.0  0.0  0.0   0.0  0.0  0.0
   ...   ...   ...   ...   ...   ...   ...   ...   ...   ...   ...   ...   ...   ...
98  89533 aloumo01  2007  1   NYN  NL  87   328 51  112  19   1  13  49.0  3.0
   0.0  27  30.0  5.0  2.0  0.0  3.0  13.0
99  89534 alomasa02  2007  1   NYN  NL   8   22  1   3   1   0   0  0.0  0.0
   0.0  0   3.0  0.0  0.0   0.0  0.0  0.0
[100 rows x 23 columns]
In [122]: baseball.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 100 entries, 0 to 99
Data columns (total 23 columns):
# Column     Non-Null Count  Dtype
--- -------- -------------- ------
   0  id        100 non-null   int64
   1  player    100 non-null  object
   2  year      100 non-null   int64
   3  stint     100 non-null   int64
   4  team      100 non-null  object
   5   lg       100 non-null   object
   6    g       100 non-null   int64
   7    ab      100 non-null   int64
   8     r      100 non-null   int64
   9      h      100 non-null   int64
  10    X2b     100 non-null   int64
  11    X3b     100 non-null   int64
  12     hr      100 non-null   int64
  13    rbi     100 non-null  float64
  14     sb      100 non-null  float64
  15      cs      100 non-null  float64
```

(continues on next page)
However, using `to_string` will return a string representation of the DataFrame in tabular form, though it won’t always fit the console width:

```python
In [123]: print(baseball.iloc[-20:, :12].to_string())
```

Wide DataFrames will be printed across multiple rows by default:

```python
In [124]: pd.DataFrame(np.random.randn(3, 12))
```

You can change how much to print on a single row by setting the `display.width` option:

```python
In [125]: pd.set_option('display.width', 40)  # default is 80
In [126]: pd.DataFrame(np.random.randn(3, 12))
```

(continues on next page)
You can adjust the max width of the individual columns by setting `display.max_colwidth`.

```python
In [127]: datafile = {'filename': ['filename_01', 'filename_02'],
               'path': ['media/user_name/storage/folder_01/filename_01',
                        'media/user_name/storage/folder_02/filename_02']}

In [128]: pd.set_option('display.max_colwidth', 30)

In [129]: pd.DataFrame(datafile)
Out[129]:
          filename path
0  filename_01 media/user_name/storage/fo...
1  filename_02 media/user_name/storage/fo...

In [130]: pd.set_option('display.max_colwidth', 100)

In [131]: pd.DataFrame(datafile)
Out[131]:
          filename                   path
0  filename_01  media/user_name/storage/folder_01/filename_01
1  filename_02  media/user_name/storage/folder_02/filename_02
```

You can also disable this feature via the `expand_frame_repr` option. This will print the table in one block.

DataFrame column attribute access and IPython completion

If a DataFrame column label is a valid Python variable name, the column can be accessed like an attribute:

```python
In [132]: df = pd.DataFrame({'foo1': np.random.randn(5),
                      'foo2': np.random.randn(5)})

In [133]: df
Out[133]:
       foo1    foo2
0  1.171216 -0.858447
1  0.520260  0.306996
2 -1.197071 -0.028665
3 -1.066969  0.384316
4 -0.303421  1.574159

In [134]: df.foo1
Out[134]:
0  1.171216
1  0.520260
2 -1.197071
3 -1.066969
```

(continues on next page)
The columns are also connected to the IPython completion mechanism so they can be tab-completed:

```python
In [5]: df.fo<TAB> # noqa: E225, E999
df.foo1 df.foo2
```

## 2.3 Essential basic functionality

Here we discuss a lot of the essential functionality common to the pandas data structures. To begin, let’s create some example objects like we did in the 10 minutes to pandas section:

```python
In [1]: index = pd.date_range('1/1/2000', periods=8)
In [2]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
In [3]: df = pd.DataFrame(np.random.randn(8, 3), index=index, columns=['A', 'B', 'C'])
```

### 2.3.1 Head and tail

To view a small sample of a Series or DataFrame object, use the `head()` and `tail()` methods. The default number of elements to display is five, but you may pass a custom number.

```python
In [4]: long_series = pd.Series(np.random.randn(1000))
In [5]: long_series.head()
Out[5]:
0  -1.157892
1  -1.344312
2   0.844885
3   1.075770
4  -0.109050
dtype: float64

In [6]: long_series.tail(3)
Out[6]:
997  -0.289388
998  -1.020544
999   0.589993
dtype: float64
```
2.3.2 Attributes and underlying data

Pandas objects have a number of attributes enabling you to access the metadata

- **shape**: gives the axis dimensions of the object, consistent with ndarray

- **Axis labels**
  - **Series**: *index* (only axis)
  - **DataFrame**: *index* (rows) and *columns*

Note, **these attributes can be safely assigned to**!

```
In [7]: df[:2]
Out[7]:
     A     B     C
2000-01-01 -0.173215 0.119209 -1.044236
2000-01-02 -0.861849 -2.104569 -0.494929
```

```
In [8]: df.columns = [x.lower() for x in df.columns]
In [9]: df
Out[9]:
     a     b     c
2000-01-01 -0.173215 0.119209 -1.044236
2000-01-02 -0.861849 -2.104569 -0.494929
2000-01-03  1.071804  0.721555  0.706771
2000-01-04 -1.039575  0.271860 -0.424972
2000-01-05  0.567020  0.276232 -1.087401
2000-01-06 -0.673690  0.113648 -1.478427
2000-01-07  0.524988  0.404705  0.577046
2000-01-08 -1.715002 -1.039268 -0.370647
```

Pandas objects (**Index**, **Series**, **DataFrame**) can be thought of as containers for arrays, which hold the actual data and do the actual computation. For many types, the underlying array is a **numpy.ndarray**. However, pandas and 3rd party libraries may extend NumPy’s type system to add support for custom arrays (see **dtypes**).

To get the actual data inside a **Index** or **Series**, use the **.array** property

```
In [10]: s.array
Out[10]:
<PandasArray>
[ 0.4691122999071863, -0.2828633443286633, -1.5090585031735124,
 -1.1356323710171934,  1.2121120250208506]
Length: 5, dtype: float64
```

```
In [11]: s.index.array
Out[11]:
<PandasArray>
['a', 'b', 'c', 'd', 'e']
Length: 5, dtype: object
```

**array** will always be an **ExtensionArray**. The exact details of what an **ExtensionArray** is and why pandas uses them are a bit beyond the scope of this introduction. See **dtypes** for more.

If you know you need a NumPy array, use **to_numpy()** or **numpy.asarray()**.

```
In [12]: s.to_numpy()
Out[12]:
array([ 0.4691, -0.2829, -1.5091, -1.1356,  1.2121])
```

(continues on next page)
When the Series or Index is backed by an `ExtensionArray`, `to_numpy()` may involve copying data and coercing values. See dytypes for more.

`to_numpy()` gives some control over the dtype of the resulting `numpy.ndarray`. For example, consider datetimes with timezones. NumPy doesn’t have a dtype to represent timezone-aware datetimes, so there are two possibly useful representations:

1. An object-dtype `numpy.ndarray` with `Timestamp` objects, each with the correct tz
2. A `datetime64[ns]`-dtype `numpy.ndarray`, where the values have been converted to UTC and the timezone discarded

Timezones may be preserved with `dtype=object`

```python
In [14]: ser = pd.Series(pd.date_range('2000', periods=2, tz='CET'))
In [15]: ser.to_numpy(dtype=object)
Out[15]:
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
dtype=object)
```

Or thrown away with `dtype='datetime64[ns]'`

```python
In [16]: ser.to_numpy(dtype='datetime64[ns]')
Out[16]:
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
dtype='datetime64[ns]')
```

Getting the “raw data” inside a `DataFrame` is possibly a bit more complex. When your `DataFrame` only has a single data type for all the columns, `DataFrame.to_numpy()` will return the underlying data:

```python
In [17]: df.to_numpy()
Out[17]:
array([[-0.1732,  0.1192, -1.0442],
       [-0.8618, -2.1046, -0.4949],
       [ 1.0718,  0.7216, -0.7068],
       [-1.0396,  0.2719, -0.425 ],
       [ 0.5670,  0.2762, -1.0874],
       [-0.6737,  0.1136, -1.4784],
       [ 0.5250,  0.4047,  0.577 ],
       [-1.7150, -1.0393, -0.3706]])
```

If a DataFrame contains homogeneously-typed data, the ndarray can actually be modified in-place, and the changes will be reflected in the data structure. For heterogeneous data (e.g. some of the DataFrame’s columns are not all the same dtype), this will not be the case. The values attribute itself, unlike the axis labels, cannot be assigned to.

**Note:** When working with heterogeneous data, the dtype of the resulting ndarray will be chosen to accommodate all of the data involved. For example, if strings are involved, the result will be of object dtype. If there are only floats and integers, the resulting array will be of float dtype.

In the past, pandas recommended `Series.values` or `DataFrame.values` for extracting the data from a Series
or DataFrame. You’ll still find references to these in old code bases and online. Going forward, we recommend avoiding `.values` and using `.array` or `.to_numpy()`. `.values` has the following drawbacks:

1. When your Series contains an extension type, it’s unclear whether `Series.values` returns a NumPy array or the extension array. `Series.array` will always return an ExtensionArray, and will never copy data. `Series.to_numpy()` will always return a NumPy array, potentially at the cost of copying / coercing values.

2. When your DataFrame contains a mixture of data types, `DataFrame.values` may involve copying data and coercing values to a common dtype, a relatively expensive operation. `DataFrame.to_numpy()`, being a method, makes it clearer that the returned NumPy array may not be a view on the same data in the DataFrame.

### 2.3.3 Accelerated operations

pandas has support for accelerating certain types of binary numerical and boolean operations using the `numexpr` library and the `bottleneck` libraries.

These libraries are especially useful when dealing with large data sets, and provide large speedups. `numexpr` uses smart chunking, caching, and multiple cores. `bottleneck` is a set of specialized cython routines that are especially fast when dealing with arrays that have `nans`.

Here is a sample (using 100 column x 100,000 row DataFrames):

<table>
<thead>
<tr>
<th>Operation</th>
<th>0.11.0 (ms)</th>
<th>Prior Version (ms)</th>
<th>Ratio to Prior</th>
</tr>
</thead>
<tbody>
<tr>
<td>df1 &gt; df2</td>
<td>13.32</td>
<td>125.35</td>
<td>0.1063</td>
</tr>
<tr>
<td>df1 * df2</td>
<td>21.71</td>
<td>36.63</td>
<td>0.5928</td>
</tr>
<tr>
<td>df1 + df2</td>
<td>22.04</td>
<td>36.50</td>
<td>0.6039</td>
</tr>
</tbody>
</table>

You are highly encouraged to install both libraries. See the section `Recommended Dependencies` for more installation info.

These are both enabled to be used by default, you can control this by setting the options:

```python
pd.set_option('compute.use_bottleneck', False)
pd.set_option('compute.use_numexpr', False)
```

### 2.3.4 Flexible binary operations

With binary operations between pandas data structures, there are two key points of interest:

- Broadcasting behavior between higher- (e.g. DataFrame) and lower-dimensional (e.g. Series) objects.
- Missing data in computations.

We will demonstrate how to manage these issues independently, though they can be handled simultaneously.

**Matching / broadcasting behavior**

DataFrame has the methods `add()`, `sub()`, `mul()`, `div()` and related functions `radd()`, `rsub()`, ... for carrying out binary operations. For broadcasting behavior, Series input is of primary interest. Using these functions, you can use to either match on the `index` or `columns` via the `axis` keyword:

```python
In [18]: df = pd.DataFrame({
       ....:  'one': pd.Series(np.random.randn(3), index=['a', 'b', 'c']),
       ....:  'two': pd.Series(np.random.randn(4), index=['a', 'b', 'c', 'd']),
})
```
Furthermore you can align a level of a MultiIndexed DataFrame with a Series.

In [26]: dfmi = df.copy()

In [27]: dfmi.index = pd.MultiIndex.from_tuples([(1, 'a'), (1, 'b'),
....:           (1, 'c'), (2, 'a')],
....:           names=['first', 'second'])

In [28]: dfmi.sub(column, axis=0, level='second')

(continues on next page)
Series and Index also support the `divmod()` builtin. This function takes the floor division and modulo operation at the same time returning a two-tuple of the same type as the left hand side. For example:

```python
In [29]: s = pd.Series(np.arange(10))
In [30]: s
Out[30]:
0  0
1  1
2  2
3  3
4  4
5  5
6  6
7  7
8  8
9  9
dtype: int64
In [31]: div, rem = divmod(s, 3)
In [32]: div
Out[32]:
0  0
1  0
2  0
3  1
4  1
5  1
6  2
7  2
8  2
9  3
dtype: int64
In [33]: rem
Out[33]:
0  0
1  1
2  2
3  0
4  1
5  2
6  0
7  1
8  2
9  0
dtype: int64
```
In [34]: idx = pd.Index(np.arange(10))

In [35]: idx
Out[35]: Int64Index([0, 1, 2, 3, 4, 5, 6, 7, 8, 9], dtype='int64')

In [36]: div, rem = divmod(idx, 3)

In [37]: div
Out[37]: Int64Index([0, 0, 0, 1, 1, 1, 2, 2, 2, 3], dtype='int64')

In [38]: rem
Out[38]: Int64Index([0, 1, 2, 0, 1, 2, 0, 1, 2, 0], dtype='int64')

We can also do elementwise `divmod()`:

In [39]: div, rem = divmod(s, [2, 2, 3, 3, 4, 4, 5, 5, 6, 6])

In [40]: div
Out[40]:
0    0
1    0
2    0
3    1
4    1
5    1
6    1
7    1
8    1
9    1
dtype: int64

In [41]: rem
Out[41]:
0    0
1    1

Missing data / operations with fill values

In Series and DataFrame, the arithmetic functions have the option of inputting a *fill_value*, namely a value to substitute when at most one of the values at a location are missing. For example, when adding two DataFrame objects, you may wish to treat NaN as 0 unless both DataFrames are missing that value, in which case the result will be NaN (you can later replace NaN with some other value using *fillna* if you wish).

In [42]: df
Out[42]:
   one   two   three
a 1.394981 1.772517     NaN
b 0.343054 1.912123 -0.050390
c 0.695246 1.478369  1.227435
d  NaN 0.279344 -0.613172

In [43]: df2
Out[43]:
   one   two   three
a 1.394981 1.772517  1.000000
b 0.343054 1.912123 -0.050390
c 0.695246 1.478369  1.227435
d  NaN 0.279344 -0.613172

In [44]: df + df2
Out[44]:
   one   two   three
a 2.789963 3.545034     NaN
b 0.686107 3.824246 -0.100780
c 1.390491 2.956737  2.454870
d  NaN 0.558688 -1.226343

In [45]: df.add(df2, fill_value=0)
Out[45]:
   one   two   three
a 2.789963 3.545034  1.000000
b 0.686107 3.824246 -0.100780
c 1.390491 2.956737  2.454870
d  NaN 0.558688 -1.226343

Flexible comparisons

Series and DataFrame have the binary comparison methods *eq, ne, lt, gt, le, and ge* whose behavior is analogous to the binary arithmetic operations described above:

In [46]: df.gt(df2)
Out[46]:
   one   two   three
a False  False  False
b False  False  False
c False  False  False
d False  False  False

In [47]: df2.ne(df)
Out[47]:
   one   two   three
a False  False   True
(continues on next page)
These operations produce a pandas object of the same type as the left-hand-side input that is of dtype `bool`. These boolean objects can be used in indexing operations, see the section on Boolean indexing.

**Boolean reductions**

You can apply the reductions: `empty`, `any()`, `all()`, and `bool()` to provide a way to summarize a boolean result.

```
In [48]: (df > 0).all()
Out[48]:
one    False
two     True
three   False
dtype: bool

In [49]: (df > 0).any()
Out[49]:
one     True
two     True
three   True
dtype: bool
``` 

You can reduce to a final boolean value.

```
In [50]: (df > 0).any().any()
Out[50]:
True
```

You can test if a pandas object is empty, via the `empty` property.

```
In [51]: df.empty
Out[51]: False

In [52]: pd.DataFrame(columns=list('ABC')).empty
Out[52]: True
```

To evaluate single-element pandas objects in a boolean context, use the method `bool()`:

```
In [53]: pd.Series([True]).bool()
Out[53]: True

In [54]: pd.Series([False]).bool()
Out[54]: False

In [55]: pd.DataFrame([[True]]).bool()
Out[55]: True

In [56]: pd.DataFrame([[False]]).bool()
Out[56]: False
```

**Warning:** You might be tempted to do the following:
See *gotchas* for a more detailed discussion.

**Comparing if objects are equivalent**

Often you may find that there is more than one way to compute the same result. As a simple example, consider `df + df` and `df * 2`. To test that these two computations produce the same result, given the tools shown above, you might imagine using `(df + df == df * 2).all()`. But in fact, this expression is False:

```
In [57]: df + df == df * 2
Out[57]:
    one  two  three
  a  True  True  False
  b  True  True  True
  c  True  True  True
d  False  True  True

In [58]: (df + df == df * 2).all()  
Out[58]:
    one     False
    two     True
    three    False
dtype: bool
```

Notice that the boolean DataFrame `df + df == df * 2` contains some False values! This is because NaNs do not compare as equals:

```
In [59]: np.nan == np.nan
Out[59]: False
```

So, NDFrames (such as Series and DataFrames) have an `equals()` method for testing equality, with NaNs in corresponding locations treated as equal.

```
In [60]: (df + df).equals(df * 2)
Out[60]: True
```

Note that the Series or DataFrame index needs to be in the same order for equality to be True:

```
In [61]: df1 = pd.DataFrame({'col': ['foo', 0, np.nan]})
In [62]: df2 = pd.DataFrame({'col': [np.nan, 0, 'foo']}, index=[2, 1, 0])
In [63]: df1.equals(df2)
Out[63]: False
```

(continues on next page)
Comparing array-like objects

You can conveniently perform element-wise comparisons when comparing a pandas data structure with a scalar value:

```
In [65]: pd.Series(['foo', 'bar', 'baz']) == 'foo'
Out[65]:
0   True
1  False
2  False
dtype: bool
```

```
In [66]: pd.Index(['foo', 'bar', 'baz']) == 'foo'
Out[66]: array([ True, False, False])
```

Pandas also handles element-wise comparisons between different array-like objects of the same length:

```
In [67]: pd.Series(['foo', 'bar', 'baz']) == pd.Index(['foo', 'bar', 'qux'])
Out[67]:
0   True
1   True
2  False
dtype: bool
```

```
In [68]: pd.Series(['foo', 'bar', 'baz']) == np.array(['foo', 'bar', 'qux'])
Out[68]:
0   True
1   True
2  False
dtype: bool
```

Trying to compare `Index` or `Series` objects of different lengths will raise a `ValueError`:

```
In [55]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo', 'bar'])
ValueError: Series lengths must match to compare
```

```
In [56]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo'])
ValueError: Series lengths must match to compare
```

Note that this is different from the NumPy behavior where a comparison can be broadcast:

```
In [69]: np.array([1, 2, 3]) == np.array([2])
Out[69]: array([False, True, False])
```

or it can return False if broadcasting can not be done:

```
In [70]: np.array([1, 2, 3]) == np.array([1, 2])
Out[70]: False
```
Combining overlapping data sets

A problem occasionally arising is the combination of two similar data sets where values in one are preferred over the other. An example would be two data series representing a particular economic indicator where one is considered to be of “higher quality”. However, the lower quality series might extend further back in history or have more complete data coverage. As such, we would like to combine two DataFrame objects where missing values in one DataFrame are conditionally filled with like-labeled values from the other DataFrame. The function implementing this operation is `combine_first()`, which we illustrate:

```
In [71]: df1 = pd.DataFrame({'A': [1., np.nan, 3., 5., np.nan],
                       'B': [np.nan, 2., 3., np.nan, 6.]})

In [72]: df2 = pd.DataFrame({'A': [5., 2., 4., np.nan, 3., 7.],
                       'B': [np.nan, np.nan, 3., 4., 6., 8.]})

In [73]: df1
Out[73]:
   A     B
0  1.0   NaN
1   NaN  2.0
2  3.0   3.0
3  5.0   NaN
4   NaN  6.0

In [74]: df2
Out[74]:
   A     B
0  5.0   NaN
1  2.0   NaN
2  4.0   3.0
3  NaN   4.0
4  3.0   6.0
5  7.0   8.0

In [75]: df1.combine_first(df2)
Out[75]:
   A     B
0  1.0   NaN
1  2.0   2.0
2  3.0   3.0
3  5.0   4.0
4  3.0   6.0
5  7.0   8.0
```

General DataFrame combine

The `combine_first()` method above calls the more general `DataFrame.combine()`. This method takes another DataFrame and a combiner function, aligns the input DataFrame and then passes the combiner function pairs of Series (i.e., columns whose names are the same).

So, for instance, to reproduce `combine_first()` as above:

```
In [76]: def combiner(x, y):
    ....:     return np.where(pd.isna(x), y, x)

(continues on next page)

2.3. Essential basic functionality
2.3.5 Descriptive statistics

There exists a large number of methods for computing descriptive statistics and other related operations on `Series`, `DataFrame`. Most of these are aggregations (hence producing a lower-dimensional result) like `sum()`, `mean()`, and `quantile()`, but some of them, like `cumsum()` and `cumprod()`, produce an object of the same size. Generally speaking, these methods take an `axis` argument, just like `ndarray.{sum, std, ...}`, but the axis can be specified by name or integer:

- **Series**: no axis argument needed
- **DataFrame**: “index” (axis=0, default), “columns” (axis=1)

For example:

```python
In [77]: df
Out[77]:
     one    two      three
   a  1.394981  1.772517    NaN
   b  0.343054  1.912123 -0.050390
   c  0.695246  1.478369  1.227435
   d   NaN      0.279344 -0.613172

In [78]: df.mean(0)
Out[78]:
     one      two      three
   0.811094  1.360588  0.187958
   dtype: float64

In [79]: df.mean(1)
Out[79]:
     a      b      c      d
   1.583749  0.734929  1.133683 -0.166914
   dtype: float64
```

All such methods have a `skipna` option signaling whether to exclude missing data (True by default):

```python
In [80]: df.sum(0, skipna=False)
Out[80]:
     one      two      three
   NaN  5.442353    NaN
   dtype: float64

In [81]: df.sum(axis=1, skipna=True)
Out[81]:
     a      b      c      d
   3.167498  2.204786  3.401050 -0.333828
   dtype: float64
```
Combined with the broadcasting / arithmetic behavior, one can describe various statistical procedures, like standardization (rendering data zero mean and standard deviation of 1), very concisely:

```
In [82]: ts_stand = (df - df.mean()) / df.std()
In [83]: ts_stand.std()
Out[83]:
   one   two   three
0  1.00  1.00  1.00
dtype: float64
In [84]: xs_stand = df.sub(df.mean(1), axis=0).div(df.std(1), axis=0)
In [85]: xs_stand.std(1)
Out[85]:
    a    b    c    d
0  1.0  1.0  1.0  1.0
dtype: float64
```

Note that methods like `cumsum()` and `cumprod()` preserve the location of NaN values. This is somewhat different from `expanding()` and `rolling()`. For more details please see this note.

```
In [86]: df.cumsum()
Out[86]:
          one   two   three
   a  1.394981 1.772517   NaN
   b  1.738035 3.684640 -0.050390
   c  2.433281 5.163008  1.177045
   d   NaN    5.442353  0.563873
```

Here is a quick reference summary table of common functions. Each also takes an optional `level` parameter which applies only if the object has a `hierarchical index`. 

---

2.3. Essential basic functionality 173
### pandas: powerful Python data analysis toolkit, Release 1.1.5

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>

</tr>
<tr>
<td>cummin</td>
<td>Cumulative minimum</td>
</tr>
</tbody>
</table>

Note that by chance some NumPy methods, like `mean`, `std`, and `sum`, will exclude NAs on Series input by default:

```
In [87]: np.mean(df['one'])
Out[87]: 0.8110935116651192
In [88]: np.mean(df['one'].to_numpy())
Out[88]: nan
```

`Series.nunique()` will return the number of unique non-NA values in a Series:

```
In [89]: series = pd.Series(np.random.randn(500))
In [90]: series[20:500] = np.nan
In [91]: series[10:20] = 5
In [92]: series.nunique()
Out[92]: 11
```

**Summarizing data: describe**

There is a convenient `describe()` function which computes a variety of summary statistics about a Series or the columns of a DataFrame (excluding NAs of course):

```
In [93]: series = pd.Series(np.random.randn(1000))
In [94]: series[:2] = np.nan
In [95]: series.describe()
Out[95]:
count      500.000000
```

(continues on next page)
mean -0.021292
std 1.015906
min -2.683763
25% -0.699070
50% -0.069718
75% 0.714483
max 3.160915
dtype: float64

In [96]: frame = pd.DataFrame(np.random.randn(1000, 5),
                         columns=['a', 'b', 'c', 'd', 'e'])

In [97]: frame.iloc[::2] = np.nan

In [98]: frame.describe()
Out[98]:

    a         b         c         d         e
count 500.000000 500.000000 500.000000 500.000000 500.000000
mean  0.033387  0.030045 -0.043719 -0.051686  0.005979
std   1.017152  0.978743  1.025270  1.015988  1.006695
25%  -0.647623 -0.576449 -0.712369 -0.691338 -0.691115
50%   0.047578 -0.021499 -0.023888 -0.032652 -0.025363
75%   0.729907  0.775880  0.618896  0.670047  0.649748
max   2.740139  2.752332  3.004229  2.728702  3.240991

dtype: float64

You can select specific percentiles to include in the output:

In [99]: series.describe(percentiles=[.05, .25, .75, .95])
Out[99]:

    count 500.000000
    mean  0.033387
    std  1.017152
    min  -3.000951
    5%   -1.645423
    25%  -0.647623
    50%   0.047578
    75%   0.729907
    95%   1.714409
    max   2.740139
dtype: float64

By default, the median is always included.

For a non-numerical Series object, describe() will give a simple summary of the number of unique values and most frequently occurring values:

In [100]: s = pd.Series(['a', 'a', 'b', 'b', 'a', 'a', np.nan, 'c', 'd', 'a'])

In [101]: s.describe()
Out[101]:

    count 9
unique 4
top a
tfreq 5
dtype: object

2.3. Essential basic functionality 175
Note that on a mixed-type DataFrame object, `describe()` will restrict the summary to include only numerical columns or, if none are, only categorical columns:

```python
In [102]: frame = pd.DataFrame({'a': ['Yes', 'Yes', 'No', 'No'], 'b': range(4)})
In [103]: frame.describe()
Out[103]:
         b
count  4.000000
mean   1.500000
std    1.290994
min    0.000000
25%    0.750000
50%    1.500000
75%    2.250000
max    3.000000
```

This behavior can be controlled by providing a list of types as `include/exclude` arguments. The special value `all` can also be used:

```python
In [104]: frame.describe(include=['object'])
Out[104]:
           a
count    4
unique   2
top      Yes
freq     2

In [105]: frame.describe(include=['number'])
Out[105]:
         b
count  4.000000
mean   1.500000
std    1.290994
min    0.000000
25%    0.750000
50%    1.500000
75%    2.250000
max    3.000000

In [106]: frame.describe(include='all')
Out[106]:
          a       b
count    4  4.000000
unique   2     NaN
top      Yes   NaN
freq     2     NaN
mean    NaN  1.500000
std      NaN  1.290994
min     NaN  0.000000
25%     NaN  0.750000
50%     NaN  1.500000
75%     NaN  2.250000
max     NaN  3.000000
```

That feature relies on `select_dtypes`. Refer to there for details about accepted inputs.
Index of min/max values

The `idxmin()` and `idxmax()` functions on Series and DataFrame compute the index labels with the minimum and maximum corresponding values:

```python
In [107]: s1 = pd.Series(np.random.randn(5))

In [108]: s1
Out[108]:
0   1.118076
1  -0.352051
2  -1.242883
3  -1.277155
4  -0.641184
dtype: float64

In [109]: s1.idxmin(), s1.idxmax()
Out[109]: (3, 0)

In [110]: df1 = pd.DataFrame(np.random.randn(5, 3), columns=['A', 'B', 'C'])

In [111]: df1
Out[111]:
   A         B         C
0 -0.327863 -0.946180 -0.137570
1 -0.186235 -0.257213 -0.486567
2 -0.507027 -0.871259 -0.111110
3  2.000339 -2.430505  0.089759
4 -0.321434 -0.033695  0.096271

In [112]: df1.idxmin(axis=0)
Out[112]:
A  2
B  3
C  1
dtype: int64

In [113]: df1.idxmax(axis=1)
Out[113]:
0  C
1  A
2  C
3  A
4  C
dtype: object
```

When there are multiple rows (or columns) matching the minimum or maximum value, `idxmin()` and `idxmax()` return the first matching index:

```python
In [114]: df3 = pd.DataFrame([2, 1, 1, 3, np.nan], columns=['A'], index=list('edcba'))

In [115]: df3
Out[115]:
   A
  e  2.0
d  1.0
c  1.0
b  3.0
```

(continues on next page)
Note: `idxmin` and `idxmax` are called `argmin` and `argmax` in NumPy.

### Value counts (histogramming) / mode

The `value_counts()` Series method and top-level function computes a histogram of a 1D array of values. It can also be used as a function on regular arrays:

```python
In [117]: data = np.random.randint(0, 7, size=50)

In [118]: data
Out[118]: array([6, 6, 2, 3, 5, 3, 2, 5, 4, 5, 4, 3, 4, 5, 0, 2, 0, 4, 2, 0, 3, 2,
2, 5, 6, 5, 3, 4, 6, 4, 3, 5, 6, 4, 3, 6, 2, 6, 3, 4, 2, 1,
6, 2, 6, 1, 5, 4])

In [119]: s = pd.Series(data)

In [120]: s.value_counts()
Out[120]:
6    10
2    10
4     9
5     8
3     8
0     3
1     2
dtype: int64

In [121]: pd.value_counts(data)
Out[121]:
6    10
2    10
4     9
5     8
3     8
0     3
1     2
dtype: int64
```

New in version 1.1.0.

The `value_counts()` method can be used to count combinations across multiple columns. By default all columns are used but a subset can be selected using the `subset` argument.

```python
In [122]: data = {"a": [1, 2, 3, 4], "b": ["x", "x", "y", "y"]}

In [123]: frame = pd.DataFrame(data)
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.1.5

(continued from previous page)

In [124]: frame.value_counts()
Out[124]:
a b
4 y
1
3 y
1
2 x
1
1 x
1
dtype: int64

Similarly, you can get the most frequently occurring value(s), i.e. the mode, of the values in a Series or DataFrame:
In [125]: s5 = pd.Series([1, 1, 3, 3, 3, 5, 5, 7, 7, 7])
In [126]: s5.mode()
Out[126]:
0
3
1
7
dtype: int64
In [127]: df5 = pd.DataFrame({"A": np.random.randint(0, 7, size=50),
.....:
"B": np.random.randint(-10, 15, size=50)})
.....:
In [128]: df5.mode()
Out[128]:
A
B
0 1.0 -9
1 NaN 10
2 NaN 13

Discretization and quantiling
Continuous values can be discretized using the cut() (bins based on values) and qcut() (bins based on sample
quantiles) functions:
In [129]: arr = np.random.randn(20)
In [130]: factor = pd.cut(arr, 4)
In [131]: factor
Out[131]:
[(-0.251, 0.464], (-0.968, -0.251], (0.464, 1.179], (-0.251, 0.464], (-0.968, -0.251],
˓→ ..., (-0.251, 0.464], (-0.968, -0.251], (-0.968, -0.251], (-0.968, -0.251], (-0.
˓→968, -0.251]]
Length: 20
Categories (4, interval[float64]): [(-0.968, -0.251] < (-0.251, 0.464] < (0.464, 1.
˓→179] <
(1.179, 1.893]]
In [132]: factor = pd.cut(arr, [-5, -1, 0, 1, 5])
In [133]: factor
Out[133]:
[(0, 1], (-1, 0], (0, 1], (0, 1], (-1, 0], ..., (-1, 0], (-1, 0], (-1, 0], (-1, 0], (˓→1, 0]]
(continues on next page)

2.3. Essential basic functionality

179


qcut() computes sample quantiles. For example, we could slice up some normally distributed data into equal-size quartiles like so:

```python
In [134]: arr = np.random.randn(30)

In [135]: factor = pd.qcut(arr, [0, .25, .5, .75, 1])

In [136]: factor
Out[136]:
(0.569, 1.184], (-2.278, -0.301], (-2.278, -0.301], (0.569, 1.184], (0.569, 1.184], ...
Length: 30
Categories (4, interval[float64]): [(-2.278, -0.301] < (-0.301, 0.569] < (0.569, 1.184] < (1.184, 2.346])
```

We can also pass infinite values to define the bins:

```python
In [138]: arr = np.random.randn(20)

In [139]: factor = pd.cut(arr, [-np.inf, 0, np.inf])

In [140]: factor
Out[140]:
(1.184, 2.346] 8
(-2.278, -0.301] 8
(0.569, 1.184] 7
(-0.301, 0.569] 7
dtype: int64
```

2.3.6 Function application

To apply your own or another library’s functions to pandas objects, you should be aware of the three methods below. The appropriate method to use depends on whether your function expects to operate on an entire DataFrame or Series, row- or column-wise, or elementwise.

1. **Tablewise Function Application**: `pipe()`
2. **Row or Column-wise Function Application**: `apply()`
3. **Aggregation API**: `agg()` and `transform()`
4. **Applying Elementwise Functions**: `applymap()`
Tablewise function application

DataFrames and Series can be passed into functions. However, if the function needs to be called in a chain, consider using the `pipe()` method.

First some setup:

```python
In [141]: def extract_city_name(df):
.....:     """
.....:     Chicago, IL -> Chicago for city_name column
.....:     """
.....:     df['city_name'] = df['city_and_code'].str.split(",").str.get(0)
.....:     return df
.....:
In [142]: def add_country_name(df, country_name=None):
.....:     """
.....:     Chicago -> Chicago-US for city_name column
.....:     """
.....:     col = 'city_name'
.....:     df['city_and_country'] = df[col] + country_name
.....:     return df
.....:
In [143]: df_p = pd.DataFrame({'city_and_code': ['Chicago, IL']})
```

`extract_city_name` and `add_country_name` are functions taking and returning DataFrames.

Now compare the following:

```python
In [144]: add_country_name(extract_city_name(df_p), country_name='US')
Out[144]:
   city_and_code city_name  city_and_country
0  Chicago, IL      Chicago   ChicagoUS
```

Is equivalent to:

```python
In [145]: (df_p.pipe(extract_city_name)
.....:     .pipe(add_country_name, country_name="US"))
Out[145]:
   city_and_code city_name  city_and_country
0  Chicago, IL      Chicago   ChicagoUS
```

Pandas encourages the second style, which is known as method chaining. `pipe` makes it easy to use your own or another library’s functions in method chains, alongside pandas’ methods.

In the example above, the functions `extract_city_name` and `add_country_name` each expected a `DataFrame` as the first positional argument. What if the function you wish to apply takes its data as, say, the second argument? In this case, provide `pipe` with a tuple of `(callable, data_keyword)`. `pipe` will route the `DataFrame` to the argument specified in the tuple.

For example, we can fit a regression using statsmodels. Their API expects a formula first and a `DataFrame` as the second argument, `data`. We pass in the function, keyword pair `(sm.ols, 'data')` to `pipe`:

```
In [146]: import statsmodels.formula.api as sm
In [147]: bb = pd.read_csv('data/baseball.csv', index_col='id')
```

(continues on next page)
In [148]: (bb.query('h > 0')
.....: .assign(ln_h=lambda df: np.log(df.h))
.....: .pipe(sm.ols, 'data', 'hr ~ ln_h + year + g + C(lg)')
.....: .fit()
.....: .summary()
.....: )
.....:
Out[148]:<class 'statsmodels.iolib.summary.Summary'>

Notes:
[1] Standard Errors assume that the covariance matrix of the errors is correctly
--specified.
[2] The condition number is large, 1.49e+07. This might indicate that there are
strong multicollinearity or other numerical problems.

The pipe method is inspired by unix pipes and more recently dplyr and magrittr, which have introduced the popular
(%) (read pipe) operator for R. The implementation of pipe here is quite clean and feels right at home in python.
We encourage you to view the source code of pipe()
Row or column-wise function application

Arbitrary functions can be applied along the axes of a DataFrame using the `apply()` method, which, like the descriptive statistics methods, takes an optional `axis` argument:

```python
In [149]: df.apply(np.mean)
Out[149]:
    one   0.811094
    two   1.360588
    three 0.187958
dtype: float64

In [150]: df.apply(np.mean, axis=1)
Out[150]:
    a  1.583749
    b  0.734929
    c  1.133683
d -0.166914
dtype: float64

In [151]: df.apply(lambda x: x.max() - x.min())
Out[151]:
    one   1.051928
    two   1.632779
    three 1.840607
dtype: float64

In [152]: df.apply(np.cumsum)
Out[152]:
       one    two    three
    a  1.394981  1.772517     NaN
    b  1.738035  3.684640  -0.050390
    c  2.433281  5.163008  1.177045
    d   NaN     5.442353  0.563873

In [153]: df.apply(np.exp)
Out[153]:
       one    two    three
    a  4.034899  5.885648     NaN
    b  1.409244  6.767440  0.950858
    c  2.004201  4.385785  3.412466
    d   NaN     1.322262  0.541630
```

The `apply()` method will also dispatch on a string method name.

```python
In [154]: df.apply('mean')
Out[154]:
    one  0.811094
    two  1.360588
    three 0.187958
dtype: float64

In [155]: df.apply('mean', axis=1)
Out[155]:
    a  1.583749
    b  0.734929
    c  1.133683
d -0.166914
```

(continues on next page)
The return type of the function passed to `apply()` affects the type of the final output from DataFrame.apply for the default behaviour:

- If the applied function returns a `Series`, the final output is a `DataFrame`. The columns match the index of the `Series` returned by the applied function.
- If the applied function returns any other type, the final output is a `Series`.

This default behaviour can be overridden using the `result_type`, which accepts three options: `reduce`, `broadcast`, and `expand`. These will determine how list-likes return values expand (or not) to a `DataFrame`.

`apply()` combined with some cleverness can be used to answer many questions about a data set. For example, suppose we wanted to extract the date where the maximum value for each column occurred:

```
In [156]: tsdf = pd.DataFrame(np.random.randn(1000, 3), columns=['A', 'B', 'C'],
                          index=pd.date_range('1/1/2000', periods=1000))
.....:
.....:

In [157]: tsdf.apply(lambda x: x.idxmax())
Out[157]:
A 2000-08-06
B 2001-01-18
C 2001-07-18
dtype: datetime64[ns]
```

You may also pass additional arguments and keyword arguments to the `apply()` method. For instance, consider the following function you would like to apply:

```python
def subtract_and_divide(x, sub, divide=1):
    return (x - sub) / divide
```

You may then apply this function as follows:

```
df.apply(subtract_and_divide, args=(5,), divide=3)
```

Another useful feature is the ability to pass `Series` methods to carry out some `Series` operation on each column or row:

```
In [158]: tsdf
Out[158]:
   A        B        C
2000-01-01 -0.158131 -0.232466  0.321604
2000-01-02 -1.810340  3.105758  0.433834
2000-01-03 -1.209847  1.156793 -0.136794
2000-01-04  NaN      NaN      NaN
2000-01-05  NaN      NaN      NaN
2000-01-06  NaN      NaN      NaN
2000-01-07  NaN      NaN      NaN
2000-01-08  0.653602  1.788750  1.008298
2000-01-09  1.007996  0.462824  0.254472
2000-01-10  0.307473  0.600337  1.643950

In [159]: tsdf.apply(pd.Series.interpolate)
Out[159]:
   A        B        C
2000-01-01 -0.158131 -0.232466  0.321604
```

(continues on next page)
Finally, `apply()` takes an argument `raw` which is False by default, which converts each row or column into a Series before applying the function. When set to True, the passed function will instead receive an ndarray object, which has positive performance implications if you do not need the indexing functionality.

**Aggregation API**

The aggregation API allows one to express possibly multiple aggregation operations in a single concise way. This API is similar across pandas objects, see `groupby API`, the `window functions API`, and the `resample API`. The entry point for aggregation is `DataFrame.aggregate()`, or the alias `DataFrame.agg()`.

We will use a similar starting frame from above:

```
In [160]: tsdf = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
                          index=pd.date_range('1/1/2000', periods=10))
In [161]: tsdf.iloc[3:7] = np.nan
In [162]: tsdf
```

<table>
<thead>
<tr>

<td>2.169758</td>
<td>-1.333363</td>
<td>0.283157</td>
</tr>
</tbody>
</table>

Using a single function is equivalent to `apply()`. You can also pass named methods as strings. These will return a Series of the aggregated output:

```
In [163]: tsdf.agg(np.sum)
Out[163]:
A    3.033606
B   -1.803879
C     1.575510
dtype: float64
```

```
In [164]: tsdf.agg('sum')
Out[164]:
A    3.033606
```
B  -1.803879
C   1.575510
dtype: float64

# these are equivalent to a `sum()` because we are aggregating
# on a single function
In [165]: tsdf.sum()
Out[165]:
A    3.033606
B  -1.803879
C    1.575510
dtype: float64

Single aggregations on a Series this will return a scalar value:

In [166]: tsdf['A'].agg('sum')
Out[166]: 3.033606102414146

Aggregating with multiple functions

You can pass multiple aggregation arguments as a list. The results of each of the passed functions will be a row in the resulting DataFrame. These are naturally named from the aggregation function.

In [167]: tsdf.agg(['sum'])
Out[167]:
       A   B   C
sum 3.033606 -1.803879 1.57551

Multiple functions yield multiple rows:

In [168]: tsdf.agg(['sum', 'mean'])
Out[168]:
      A   B   C
sum 3.033606 -1.803879  1.575510
mean 0.505601 -0.300647  0.262585

On a Series, multiple functions return a Series, indexed by the function names:

In [169]: tsdf['A'].agg(['sum', 'mean'])
Out[169]:
sum 3.033606
dtype: float64
mean 0.505601
Name: A, dtype: float64

Passing a lambda function will yield a `<lambda>` named row:

In [170]: tsdf['A'].agg(['sum', lambda x: x.mean()])
Out[170]:
sum    3.033606
<lambda> 0.505601
Name: A, dtype: float64

Passing a named function will yield that name for the row:
Aggregating with a dict

Passing a dictionary of column names to a scalar or a list of scalars, to DataFrame.agg allows you to customize which functions are applied to which columns. Note that the results are not in any particular order, you can use an OrderedDict instead to guarantee ordering.

Pandas aggregates columns and values based on the provided function. For example, to calculate the mean and sum of a column in a DataFrame, you can use:

```python
In [172]: tsdf['A'].agg(['sum', mymean])
Out[172]:
           sum     mymean
Name: A, dtype: float64
```

To aggregate with a list of scalars, you can provide a list-like object:

```python
In [173]: tsdf.agg({'A': 'mean', 'B': 'sum'})
Out[173]:
   A  B
0  0.505601 -1.803879
```

Using a dictionary with lists of scalars is also supported:

```python
In [174]: tsdf.agg({'A': ['mean', 'min'], 'B': 'sum'})
Out[174]:
   A   B
mean 0.505601      NaN
min -0.749892      NaN
sum   NaN -1.803879
```

Mixed dtypes

When presented with mixed dtypes that cannot aggregate, .agg will only take the valid aggregations. This is similar to how .groupby.agg works.

```python
In [157]: mdf = pd.DataFrame({'A': [1, 2, 3],
                        'B': [1., 2., 3.],
                        'C': ['foo', 'bar', 'baz'],
                        'D': pd.date_range('20130101', periods=3))

In [158]: mdf.dtypes
Out[158]:
A    int64
B    float64
C     object
D  datetime64[ns]
dtype: object

In [159]: mdf.agg(['min', 'sum'])
Out[159]:
(continues on next page)
```

2.3. Essential basic functionality
Custom describe

With `.agg()` it is possible to easily create a custom describe function, similar to the built in `describe` function.

```python
In [178]: from functools import partial
In [179]: q_25 = partial(pd.Series.quantile, q=0.25)
In [180]: q_25.__name__ = '25%'
In [181]: q_75 = partial(pd.Series.quantile, q=0.75)
In [182]: q_75.__name__ = '75%'
In [183]: tsdf.agg(['count', 'mean', 'std', 'min', q_25, 'median', q_75, 'max'])
```

```
Out[183]:
   A         B         C
count 6.000000  6.000000  6.000000
mean  0.505601 -0.300647  0.262585
std   1.103362  0.887508  0.606860
min  -0.749892 -1.333363 -0.757304
25%  -0.239885 -0.979600  0.128907
median 0.303398 -0.278111  0.225365
75%   1.146791  0.151678  0.722709
max   2.169758  1.004194  0.896839
```

Transform API

The `transform()` method returns an object that is indexed the same (same size) as the original. This API allows you to provide multiple operations at the same time rather than one-by-one. Its API is quite similar to the `.agg` API.

We create a frame similar to the one used in the above sections.

```python
In [184]: tsdf = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
                        index=pd.date_range('1/1/2000', periods=10))
In [185]: tsdf.iloc[3:7] = np.nan
In [186]: tsdf
Out[186]:
   A         B         C
2000-01-01 -0.428759 -0.864890 -0.675341
2000-01-02 -0.168731  1.338144 -1.279321
2000-01-03 -1.621034  0.438107  0.903794
2000-01-04       NaN       NaN       NaN
2000-01-05       NaN       NaN       NaN
2000-01-06       NaN       NaN       NaN
2000-01-07       NaN       NaN       NaN
```

(continues on next page)
Transform the entire frame. `.transform()` allows input functions as: a NumPy function, a string function name or a user defined function.

```python
In [187]: tsdf.transform(np.abs)
Out[187]:
   A    B    C
2000-01-01  0.428759  0.864890  0.675341

2000-01-10  0.030876  0.371900  0.061932
```

```python
In [189]: tsdf.transform(lambda x: x.abs())
Out[189]:
   A    B    C
2000-01-01  0.428759  0.864890  0.675341
2000-01-02  0.168731  1.338144  1.279321
2000-01-03  1.621034  0.438107  0.903794
2000-01-04  NaN     NaN     NaN
2000-01-05  NaN     NaN     NaN
2000-01-06  NaN     NaN     NaN
2000-01-07  NaN     NaN     NaN
2000-01-08  0.254374  1.240447  0.201052
2000-01-09  0.157795  0.791197  1.144209
2000-01-10  0.030876  0.371900  0.061932
```

Here `.transform()` received a single function; this is equivalent to a ufunc application.

```python
In [190]: np.abs(tsdf)
Out[190]:
   A    B    C
2000-01-01  0.428759  0.864890  0.675341
2000-01-02  0.168731  1.338144  1.279321
```

(continues on next page)
Passing a single function to `.transform()` with a Series will yield a single Series in return.

```python
In [191]: tsdf['A'].transform(np.abs)
Out[191]:
2000-01-01  0.428759
2000-01-02  0.168731
2000-01-03  1.621034
2000-01-04  NaN
2000-01-05  NaN
2000-01-06  NaN
2000-01-07  NaN
2000-01-08  0.254374
2000-01-09  0.157795
2000-01-10  0.030876
Freq: D, Name: A, dtype: float64
```

**Transform with multiple functions**

Passing multiple functions will yield a column MultiIndexed DataFrame. The first level will be the original frame column names; the second level will be the names of the transforming functions.

```python
In [192]: tsdf.transform([np.abs, lambda x: x + 1])
Out[192]:
          absolute <lambda>  absolute <lambda>  absolute <lambda>  absolute <lambda>
2000-01-01  0.428759  0.571241  0.864890  0.135110  0.675341  0.324659
2000-01-02  0.168731  0.831269  1.338144  2.338144  1.279321 -0.279321
2000-01-03  1.621034 -0.621034  0.438107  1.438107  0.903794  1.903794
2000-01-04  NaN     NaN      NaN     NaN      NaN     NaN
2000-01-05  NaN     NaN      NaN     NaN      NaN     NaN
2000-01-06  NaN     NaN      NaN     NaN      NaN     NaN
2000-01-07  NaN     NaN      NaN     NaN      NaN     NaN
2000-01-08  0.254374  1.254374  1.240447 -0.240447  0.201052  0.798948
2000-01-09  0.157795  0.842205  0.791197  1.791197  1.144209 -0.144209
2000-01-10  0.030876  0.969124  0.371900  1.371900  0.061932  1.061932
```

Passing multiple functions to a Series will yield a DataFrame. The resulting column names will be the transforming functions.

```python
In [193]: tsdf['A'].transform([np.abs, lambda x: x + 1])
Out[193]:
          absolute <lambda>
2000-01-01  0.428759  0.571241
2000-01-02  0.168731  0.831269
2000-01-03  1.621034 -0.621034
```

(continues on next page)
Transforming with a dict

Passing a dict of functions will allow selective transforming per column.

```
In [194]: tsdf.transform({'A': np.abs, 'B': lambda x: x + 1})
Out[194]:
   A     B
2000-01-01  0.428759  0.135110
2000-01-02  0.168731  2.338144
2000-01-03  1.621034  1.438107
2000-01-04    NaN     NaN
2000-01-05    NaN     NaN
2000-01-06    NaN     NaN
2000-01-07    NaN     NaN
2000-01-08  0.254374 -0.240447
2000-01-09  0.157795  1.791197
2000-01-10  0.030876  1.371900
```

Passing a dict of lists will generate a MultiIndexed DataFrame with these selective transforms.

```
In [195]: tsdf.transform({'A': np.abs, 'B': [lambda x: x + 1, 'sqrt']})
Out[195]:
   absolute <lambda>  sqrt
2000-01-01  0.428759  0.135110   NaN
2000-01-02  0.168731  2.338144  1.156782
2000-01-03  1.621034  1.438107  0.661897
2000-01-04    NaN     NaN        NaN
2000-01-05    NaN     NaN        NaN
2000-01-06    NaN     NaN        NaN
2000-01-07    NaN     NaN        NaN
2000-01-08  0.254374 -0.240447   NaN
2000-01-09  0.157795  1.791197  0.889493
2000-01-10  0.030876  1.371900  0.609836
```

Applying elementwise functions

Since not all functions can be vectorized (accept NumPy arrays and return another array or value), the methods `applymap()` on DataFrame and analogously `map()` on Series accept any Python function taking a single value and returning a single value. For example:

```
In [196]: df4
Out[196]:
   one     two      three
a  1.394981  1.772517     NaN
b  0.343054  1.912123 -0.050390
```
c 0.695246 1.478369 1.227435
d NaN 0.279344 -0.613172

In [197]: def f(x):
       :.....: return len(str(x))
       :.....:

In [198]: df4['one'].map(f)
Out[198]:
a 18
b 19
c 18
d 3
Name: one, dtype: int64

In [199]: df4.applymap(f)
Out[199]:
       one  two  three
a  18   17  13
b  19   18  20
c  18   18  16
d   3   19  19

Series.map() has an additional feature; it can be used to easily “link” or “map” values defined by a secondary series. This is closely related to merging/joining functionality:

In [200]: s = pd.Series(["six", "seven", "six", "seven", "six"],
       :.....:     index=['a', 'b', 'c', 'd', 'e'])
       :.....:

In [201]: t = pd.Series({"six": 6., "seven": 7.})

In [202]: s
Out[202]:
a   six
b   seven
c   six
d   seven
e   six
dtype: object

In [203]: s.map(t)
Out[203]:
a  6.0
b  7.0
c  6.0
d  7.0
e  6.0
dtype: float64
2.3.7 Reindexing and altering labels

`reindex()` is the fundamental data alignment method in pandas. It is used to implement nearly all other features relying on label-alignment functionality. To reindex means to conform the data to match a given set of labels along a particular axis. This accomplishes several things:

- Reorders the existing data to match a new set of labels
- Inserts missing value (NA) markers in label locations where no data for that label existed
- If specified, fill data for missing labels using logic (highly relevant to working with time series data)

Here is a simple example:

```python
In [204]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
In [205]: s
Out[205]:
        a    1.695148
        b    1.328614
        c    1.234686
        d   -0.385845
        e   -1.326508
        dtype: float64
In [206]: s.reindex(['e', 'b', 'f', 'd'])
Out[206]:
        e   -1.326508
        b    1.328614
        f   NaN
        d   -0.385845
        dtype: float64
```

Here, the `f` label was not contained in the Series and hence appears as `NaN` in the result.

With a DataFrame, you can simultaneously reindex the index and columns:

```python
In [207]: df
Out[207]:
    one   two   three
   a  1.394981  1.772517  NaN
   b  0.343054  1.912123 -0.050390
   c  0.695246  1.478369  1.227435
   d  NaN       0.279344 -0.613172
In [208]: df.reindex(index=['c', 'f', 'b'], columns=['three', 'two', 'one'])
Out[208]:
    three   two   one
    c  1.227435  1.478369  0.695246
    f   NaN      NaN      NaN
    b -0.050390  1.912123  0.343054
```

You may also use `reindex` with an `axis` keyword:

```python
In [209]: df.reindex(['c', 'f', 'b'], axis='index')
Out[209]:
    one   two   three
   c  0.695246  1.478369  1.227435
   f  NaN      NaN      NaN
   b  0.343054  1.912123 -0.050390
```
Note that the Index objects containing the actual axis labels can be shared between objects. So if we have a Series and a DataFrame, the following can be done:

```
In [210]: rs = s.reindex(df.index)

In [211]: rs
Out[211]:
   a   1.695148
   b   1.328614
   c   1.234686
   d  -0.385845
   dtype: float64

In [212]: rs.index is df.index
Out[212]: True
```

This means that the reindexed Series’s index is the same Python object as the DataFrame’s index.

```
In [213]: df.reindex(['c', 'f', 'b'], axis='index')
Out[213]:
   one   two   three
a  NaN  1.772517  1.394981
b  0.343054  1.912123 -0.050390
c  0.695246  1.478369  1.227435
```

```
In [214]: df.reindex(['three', 'two', 'one'], axis='columns')
Out[214]:
   three   two   one
a  NaN  1.772517  1.394981
b -0.050390  1.912123  0.343054
c  1.227435  1.478369  0.695246
d -0.613172  0.279344  NaN
```

See also:

```
MultiIndex / Advanced Indexing is an even more concise way of doing reindexing.
```

Note: When writing performance-sensitive code, there is a good reason to spend some time becoming a reindexing ninja: many operations are faster on pre-aligned data. Adding two unaligned DataFrames internally triggers a reindexing step. For exploratory analysis you will hardly notice the difference (because reindex has been heavily optimized), but when CPU cycles matter sprinkling a few explicit reindex calls here and there can have an impact.

Reindexing to align with another object

You may wish to take an object and reindex its axes to be labeled the same as another object. While the syntax for this is straightforward albeit verbose, it is a common enough operation that the reindex_like() method is available to make this simpler:

```
In [215]: df2
Out[215]:
   one   two
a  1.394981  1.772517
(continues on next page)```
Aligning objects with each other with `align`

The `align()` method is the fastest way to simultaneously align two objects. It supports a `join` argument (related to joining and merging):

- `join='outer'`: take the union of the indexes (default)
- `join='left'`: use the calling object’s index
- `join='right'`: use the passed object’s index
- `join='inner'`: intersect the indexes

It returns a tuple with both of the reindexed Series:

```
In [218]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
In [219]: s1 = s[:4]
In [220]: s2 = s[1:]
In [221]: s1.align(s2)
Out[221]:
(a  -0.186646
 b  -1.692424
 c  -0.303893
d  -1.425662
e   NaN
dtype: float64,
(a  NaN
 b  NaN
 c  NaN
d  NaN
e  1.114285
dtype: float64)
```

```
In [222]: s1.align(s2, join='inner')
Out[222]:
(b  -1.692424
 c  -0.303893
```

(continues on next page)
In [223]: s1.align(s2, join='left')
Out[223]:
(a -0.186646
 b -1.692424
c -0.303893
d -1.425662
dtype: float64,
a NaN
 b -1.692424
c -0.303893
d -1.425662
dtype: float64)

For DataFrames, the join method will be applied to both the index and the columns by default:

In [224]: df.align(df2, join='inner')
Out[224]:
( one two
 a 1.394981 1.772517
 b 0.343054 1.912123
c 0.695246 1.478369,
    one two
 a 1.394981 1.772517
 b 0.343054 1.912123
 c 0.695246 1.478369)

You can also pass an axis option to only align on the specified axis:

In [225]: df.align(df2, join='inner', axis=0)
Out[225]:
( one two three
 a 1.394981 NaN 1.772517
 b 0.343054 1.912123 -0.050390
 c 0.695246 1.478369 1.227435,
    one two
 a 1.394981 1.772517
 b 0.343054 1.912123
 c 0.695246 1.478369
 d NaN -0.613172 0.279344,
(continues on next page)
Filling while reindexing

`reindex()` takes an optional parameter `method` which is a filling method chosen from the following table:

<table>
<thead>
<tr>
<th>Method</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>pad / ffill</td>
<td>Fill values forward</td>
</tr>
<tr>
<td>bfill / backfill</td>
<td>Fill values backward</td>
</tr>
<tr>
<td>nearest</td>
<td>Fill from the nearest index value</td>
</tr>
</tbody>
</table>

We illustrate these fill methods on a simple Series:

```
In [227]: rng = pd.date_range('1/3/2000', periods=8)
In [228]: ts = pd.Series(np.random.randn(8), index=rng)
In [229]: ts2 = ts[[0, 3, 6]]
In [230]: ts
Out[230]:
2000-01-03  0.183051
2000-01-04  0.400528
2000-01-05 -0.015083
2000-01-06  2.395489
2000-01-07  1.414806
2000-01-08  0.118428
2000-01-09  0.733639
2000-01-10 -0.936077
Freq: D, dtype: float64
```

```
In [231]: ts2
Out[231]:
2000-01-03  0.183051
2000-01-06  2.395489
2000-01-09  0.733639
Freq: 3D, dtype: float64
```

```
In [232]: ts2.reindex(ts.index)
Out[232]:
2000-01-03  0.183051
2000-01-04  NaN
2000-01-05  NaN
2000-01-06  2.395489
2000-01-07  NaN
2000-01-08  NaN
2000-01-09  0.733639
2000-01-10  NaN
Freq: D, dtype: float64
```

```
In [233]: ts2.reindex(ts.index, method='ffill')
```

(continues on next page)
These methods require that the indexes are ordered increasing or decreasing.

Note that the same result could have been achieved using `fillna` (except for `method='nearest'`) or `interpolate`:

```python
In [236]: ts2.reindex(ts.index).fillna(method='ffill')
Out[236]:
2000-01-03  0.183051
2000-01-04  0.183051
2000-01-05  0.183051
2000-01-06  2.395489
2000-01-07  2.395489
2000-01-08  2.395489
2000-01-09  0.733639
2000-01-10  0.733639
Freq: D, dtype: float64
```

`reindex()` will raise a ValueError if the index is not monotonically increasing or decreasing. `fillna()` and `interpolate()` will not perform any checks on the order of the index.
Limits on filling while reindexing

The limit and tolerance arguments provide additional control over filling while reindexing. Limit specifies the maximum count of consecutive matches:

```
In [237]: ts2.reindex(ts.index, method='ffill', limit=1)
Out[237]:
2000-01-03  0.183051
2000-01-04  0.183051
2000-01-05  NaN
2000-01-06  2.395489
2000-01-07  2.395489
2000-01-08  NaN
2000-01-09  0.733639
2000-01-10  0.733639
Freq: D, dtype: float64
```

In contrast, tolerance specifies the maximum distance between the index and indexer values:

```
In [238]: ts2.reindex(ts.index, method='ffill', tolerance='1 day')
Out[238]:
2000-01-03  0.183051
2000-01-04  0.183051
2000-01-05  NaN
2000-01-06  2.395489
2000-01-07  2.395489
2000-01-08  NaN
2000-01-09  0.733639
2000-01-10  0.733639
Freq: D, dtype: float64
```

Notice that when used on a `DatetimeIndex`, `TimedeltaIndex` or `PeriodIndex`, tolerance will coerced into a `Timedelta` if possible. This allows you to specify tolerance with appropriate strings.

Dropping labels from an axis

A method closely related to reindex is the `drop()` function. It removes a set of labels from an axis:

```
In [239]: df.drop(['a', 'd'], axis=0)
Out[239]:
    one   two   three
a  1.394981  1.772517  NaN
b  0.343054  1.912123 -0.050390
c  0.695246  1.478369  1.227435
d  NaN     0.279344 -0.613172
```

```
In [240]: df.drop(['one'], axis=1)
Out[240]:
    two   three
b  1.912123 -0.050390
c  1.478369  1.227435
```

(continues on next page)
Note that the following also works, but is a bit less obvious / clean:

```python
In [242]: df.reindex(df.index.difference(['a', 'd']))
Out[242]:
    one  two  three
  b  0.343054 1.912123 -0.050390
  c  0.695246 1.478369  1.227435
```

### Renaming / mapping labels

The `rename()` method allows you to relabel an axis based on some mapping (a dict or Series) or an arbitrary function.

```python
In [243]: s
Out[243]:
    a   -0.186646
    b  -1.692424
    c  -0.303893
    d  -1.425662
    e   1.114285
    dtype: float64
In [244]: s.rename(str.upper)
Out[244]:
    A   -0.186646
    B  -1.692424
    C  -0.303893
    D  -1.425662
    E   1.114285
    dtype: float64
```

If you pass a function, it must return a value when called with any of the labels (and must produce a set of unique values). A dict or Series can also be used:

```python
In [245]: df.rename(columns={'one': 'foo', 'two': 'bar'},
                  index={'a': 'apple', 'b': 'banana', 'd': 'durian'})
Out[245]:
            foo  bar  three
      apple  1.394981 1.772517   NaN
     banana  0.343054 1.912123 -0.050390
         c  0.695246 1.478369  1.227435
        durian    NaN    0.279344 -0.613172
```

If the mapping doesn’t include a column/index label, it isn’t renamed. Note that extra labels in the mapping don’t throw an error.

`DataFrame.rename()` also supports an “axis-style” calling convention, where you specify a single `mapper` and the `axis` to apply that mapping to.

```python
In [246]: df.rename({'one': 'foo', 'two': 'bar'}, axis='columns')
Out[246]:
```
In 

```
In [247]: df.rename({'a': 'apple', 'b': 'banana', 'd': 'durian'}, axis='index')
```

```
Out[247]:
   one     two    three
apple  1.394981 1.772517  NaN
banana 0.343054 1.912123 -0.050390
c       0.695246 1.478369  1.227435
durian  NaN      0.279344 -0.613172
```

The `rename()` method also provides an `inplace` named parameter that is by default `False` and copies the underlying data. Pass `inplace=True` to rename the data in place.

Finally, `rename()` also accepts a scalar or list-like for altering the Series.name attribute.

```
In [248]: s.rename("scalar-name")
```

```
Out[248]:
a -0.186646
b -1.692424
c -0.303893
d -1.425662
e  1.114285
Name: scalar-name, dtype: float64
```

New in version 0.24.0.

The methods `DataFrame.rename_axis()` and `Series.rename_axis()` allow specific names of a MultiIndex to be changed (as opposed to the labels).

```
In [249]: df = pd.DataFrame({'x': [1, 2, 3, 4, 5, 6],
                      'y': [10, 20, 30, 40, 50, 60],
                      index=pd.MultiIndex.from_product([['a', 'b', 'c'], [1, 2]],
                      names=['let', 'num']))
```

```
In [250]: df.rename_axis(index={'let': 'abc'})
```

```
Out[250]:
x     y
let num
a  1   1  10
    2   2  20
b  1   1  30
    2   2  40
c  1   5  50
    2   6  60
```

```
In [251]: df.rename_axis(index={"let": 'abc'})
```

```
Out[251]:
x     y
abc num
a  1   1  10
    2   2  20
```
In [252]: df.rename_axis(index=str.upper)
Out[252]:
   x  y
LET NUM
a 1  1 10
   2  2 20
b 1  3 30
   2  4 40
c 1  5 50
   2  6 60

2.3.8 Iteration

The behavior of basic iteration over pandas objects depends on the type. When iterating over a Series, it is regarded as array-like, and basic iteration produces the values. DataFrames follow the dict-like convention of iterating over the “keys” of the objects.

In short, basic iteration (for i in object) produces:

- **Series**: values
- **DataFrame**: column labels

Thus, for example, iterating over a DataFrame gives you the column names:

```python
In [253]: df = pd.DataFrame({'col1': np.random.randn(3),
     ....:                     'col2': np.random.randn(3)}, index=['a', 'b', 'c'])
     ....:     index=['a', 'b', 'c'])
In [254]: for col in df:
     ....:     print(col)
     ....:     col1
col2
```

Pandas objects also have the dict-like `items()` method to iterate over the (key, value) pairs.

To iterate over the rows of a DataFrame, you can use the following methods:

- **`iterrows()`**: Iterate over the rows of a DataFrame as (index, Series) pairs. This converts the rows to Series objects, which can change the dtypes and has some performance implications.
- **`itertuples()`**: Iterate over the rows of a DataFrame as namedtuples of the values. This is a lot faster than `iterrows()`, and is in most cases preferable to use to iterate over the values of a DataFrame.

**Warning**: Iterating through pandas objects is generally **slow**. In many cases, iterating manually over the rows is not needed and can be avoided with one of the following approaches:

- Look for a vectorized solution: many operations can be performed using built-in methods or NumPy functions, (boolean) indexing,...
• When you have a function that cannot work on the full DataFrame/Series at once, it is better to use `apply()` instead of iterating over the values. See the docs on `function application`.

• If you need to do iterative manipulations on the values but performance is important, consider writing the inner loop with cython or numba. See the `enhancing performance` section for some examples of this approach.

**Warning:** You should **never modify** something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect!

For example, in the following case setting the value has no effect:

```python
In [255]: df = pd.DataFrame({'a': [1, 2, 3], 'b': ['a', 'b', 'c']})
In [256]: for index, row in df.iterrows:
     ....:     row['a'] = 10
     ....:
In [257]: df
Out[257]:
   a   b
0  1   a
1  2   b
2  3   c
```

**items**

Consistent with the dict-like interface, `items()` iterates through key-value pairs:

- **Series**: (index, scalar value) pairs
- **DataFrame**: (column, Series) pairs

For example:

```python
In [258]: for label, ser in df.items:
     ....:     print(label)
     ....:     print(ser)
     ....:
a
0  1
1  2
2  3
Name: a, dtype: int64
b
0  a
1  b
2  c
Name: b, dtype: object
```

2.3. Essential basic functionality  203
iterrows

`iterrows()` allows you to iterate through the rows of a DataFrame as Series objects. It returns an iterator yielding each index value along with a Series containing the data in each row:

```
In [259]: for row_index, row in df.iterrows():
    .....:    print(row_index, row, sep='\n')
    .....:
0        a  1
        b  a
Name: 0, dtype: object
1        a  2
        b  b
Name: 1, dtype: object
2        a  3
        b  c
Name: 2, dtype: object
```

Note: Because `iterrows()` returns a Series for each row, it does not preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```
In [260]: df_orig = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])

In [261]: df_orig.dtypes
Out[261]:
int    int64
float  float64
dtype: object

In [262]: row = next(df_orig.iterrows())[1]

In [263]: row
Out[263]:
int  1
float 1.5
Name: 0, dtype: float64
```

All values in `row`, returned as a Series, are now upcasted to floats, also the original integer value in column x:

```
In [264]: row['int'].dtype
Out[264]: dtype('float64')

In [265]: df_orig['int'].dtype
Out[265]: dtype('int64')
```

To preserve dtypes while iterating over the rows, it is better to use `itertuples()` which returns namedtuples of the values and which is generally much faster than `iterrows()`.

For instance, a contrived way to transpose the DataFrame would be:

```
In [266]: df2 = pd.DataFrame({'x': [1, 2, 3], 'y': [4, 5, 6]})

In [267]: print(df2)
```

(continues on next page)
x  y  
0 1 4  
1 2 5  
2 3 6  

In [268]: print(df2.T)  
   0 1 2  
  x 1 2 3  
  y 4 5 6  

In [269]: df2_t = pd.DataFrame({idx: values for idx, values in df2.iterrows()})  

In [270]: print(df2_t)  
   0 1 2  
  x 1 2 3  
  y 4 5 6  

**itertuples**

The *itertuples()* method will return an iterator yielding a namedtuple for each row in the DataFrame. The first element of the tuple will be the row’s corresponding index value, while the remaining values are the row values.

For instance:

```
In [271]: for row in df.itertuples():  
   ...:     print(row)  
   ...:  
  Pandas(Index=0, a=1, b='a')  
  Pandas(Index=1, a=2, b='b')  
  Pandas(Index=2, a=3, b='c')
```

This method does not convert the row to a Series object; it merely returns the values inside a namedtuple. Therefore, *itertuples()* preserves the data type of the values and is generally faster as *iterrows()*.

**Note:** The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. With a large number of columns (>255), regular tuples are returned.

**2.3.9 .dt accessor**

Series has an accessor to succinctly return datetime like properties for the *values* of the Series, if it is a datetime/period like Series. This will return a Series, indexed like the existing Series.

```
# datetime  
In [272]: s = pd.Series(pd.date_range('20130101 09:10:12', periods=4))  

In [273]: s  
Out[273]:  
  0 2013-01-01 09:10:12  
  1 2013-01-02 09:10:12  
  2 2013-01-03 09:10:12  
  3 2013-01-04 09:10:12  
  dtype: datetime64[ns]
```
In [274]: s.dt.hour
Out[274]:
0  9
1  9
2  9
3  9
dtype: int64

In [275]: s.dt.second
Out[275]:
0  12
1  12
2  12
3  12
dtype: int64

In [276]: s.dt.day
Out[276]:
0  1
1  2
2  3
3  4
dtype: int64

This enables nice expressions like this:

In [277]: s[s.dt.day == 2]
Out[277]:
1  2013-01-02 09:10:12
0  2013-01-01 09:10:12
1  2013-01-02 09:10:12
2  2013-01-03 09:10:12
3  2013-01-04 09:10:12
dtype: datetime64[ns]

You can easily produces tz aware transformations:

In [278]: stz = s.dt.tz_localize('US/Eastern')
In [279]: stz
Out[279]:
0  2013-01-01 09:10:12-05:00
1  2013-01-02 09:10:12-05:00
2  2013-01-03 09:10:12-05:00
3  2013-01-04 09:10:12-05:00
dtype: datetime64[ns, US/Eastern]

In [280]: stz.dt.tz
Out[280]: <DstTzInfo 'US/Eastern' LMT-1 day, 19:04:00 STD>

You can also chain these types of operations:

In [281]: s.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out[281]:
0  2013-01-01 04:10:12-05:00
1  2013-01-02 04:10:12-05:00
2  2013-01-03 04:10:12-05:00
3  2013-01-04 04:10:12-05:00
dtype: datetime64[ns, US/Eastern]
You can also format datetime values as strings with `Series.dt.strftime()` which supports the same format as the standard `strftime()`.

```python
# DatetimeIndex
In [282]: s = pd.Series(pd.date_range('20130101', periods=4))

In [283]: s
Out[283]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
3 2013-01-04
dtype: datetime64[ns]

In [284]: s.dt.strftime('%Y/%m/%d')
Out[284]:
0 2013/01/01
1 2013/01/02
2 2013/01/03
3 2013/01/04
dtype: object
```

### PeriodIndex

```python
# PeriodIndex
In [285]: s = pd.Series(pd.period_range('20130101', periods=4))

In [286]: s
Out[286]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
3 2013-01-04
dtype: period[D]

In [287]: s.dt.strftime('%Y/%m/%d')
Out[287]:
0 2013/01/01
1 2013/01/02
2 2013/01/03
3 2013/01/04
dtype: object
```

The `.dt` accessor works for period and timedelta dtypes.

```python
# period
In [288]: s = pd.Series(pd.period_range('20130101', periods=4, freq='D'))

In [289]: s
Out[289]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
3 2013-01-04
dtype: period[D]

In [290]: s.dt.year
Out[290]:
0 2013
1 2013
```

(continues on next page)

2.3. Essential basic functionality
In [291]: s.dt.day
Out[291]:
0 1
1 2
2 3
3 4
dtype: int64

# timedelta
In [292]: s = pd.Series(pd.timedelta_range('1 day 00:00:05', periods=4, freq='s'))

In [293]: s
Out[293]:
0 1 days 00:00:05
1 1 days 00:00:06
2 1 days 00:00:07
3 1 days 00:00:08
dtype: timedelta64[ns]

In [294]: s.dt.days
Out[294]:
0 1
1 1
2 1
3 1
dtype: int64

In [295]: s.dt.seconds
Out[295]:
0 5
1 6
2 7
3 8
dtype: int64

In [296]: s.dt.components
Out[296]:
<table>
<thead>
<tr>
<th>days</th>
<th>hours</th>
<th>minutes</th>
<th>seconds</th>
<th>milliseconds</th>
<th>microseconds</th>
<th>nanoseconds</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>5</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>6</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>7</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>8</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Note: Series.dt will raise a TypeError if you access with a non-datetime-like values.
2.3.10 Vectorized string methods

Series is equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the Series’s `str` attribute and generally have names matching the equivalent (scalar) built-in string methods. For example:

```
In [297]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'],
                   dtype="string")
...:

In [298]: s.str.lower()
Out[298]:
0    a
1    b
2    c
3    aaba
4    baca
5     <NA>
6    caba
7     dog
8     cat
dtype: string
```

Powerful pattern-matching methods are provided as well, but note that pattern-matching generally uses regular expressions by default (and in some cases always uses them).

**Note:** Prior to pandas 1.0, string methods were only available on `object`-dtype Series. Pandas 1.0 added the `StringDtype` which is dedicated to strings. See Text data types for more.

Please see Vectorized String Methods for a complete description.

2.3.11 Sorting

Pandas supports three kinds of sorting: sorting by index labels, sorting by column values, and sorting by a combination of both.

**By index**

The `Series.sort_index()` and `DataFrame.sort_index()` methods are used to sort a pandas object by its index levels.

```
In [299]: df = pd.DataFrame({
     ......:   'one': pd.Series(np.random.randn(3), index=['a', 'b', 'c']),
     ......:   'two': pd.Series(np.random.randn(4), index=['a', 'b', 'c', 'd']),
     ......:   'three': pd.Series(np.random.randn(3), index=['b', 'c', 'd']))
     ......:

In [300]: unsorted_df = df.reindex(index=['a', 'd', 'c', 'b'],
     ......:                   columns=['three', 'two', 'one'])
     ......:

In [301]: unsorted_df
```

(continues on next page)
Out[301]:
    three  two  one
   a NaN  -1.152244  0.562973
   d -0.252916  -0.109597  NaN
   c  1.273388  -0.167123  0.640382
   b -0.098217   0.009797 -1.299504

# DataFrame
In [302]: unsorted_df.sort_index()
Out[302]:
    three  two  one
   a NaN  -1.152244  0.562973
   b -0.098217   0.009797 -1.299504
   c  1.273388  -0.167123  0.640382
   d -0.252916  -0.109597  NaN

In [303]: unsorted_df.sort_index(ascending=False)
Out[303]:
    three  two  one
   d -0.252916  -0.109597  NaN
   c  1.273388  -0.167123  0.640382
   b -0.098217   0.009797 -1.299504
   a NaN  -1.152244  0.562973

In [304]: unsorted_df.sort_index(axis=1)
Out[304]:
    one  three  two
   a  0.562973  NaN  -1.152244
   d  NaN   -0.252916  -0.109597
   c  0.640382  1.273388  -0.167123
   b -1.299504  -0.098217   0.009797

# Series
In [305]: unsorted_df['three'].sort_index()
Out[305]:
   a  NaN
   b -0.098217
   c  1.273388
d -0.252916
Name: three, dtype: float64

New in version 1.1.0.

Sorting by index also supports a key parameter that takes a callable function to apply to the index being sorted. For MultiIndex objects, the key is applied per-level to the levels specified by level.

In [306]: s1 = pd.DataFrame({'
   ....:     "a": ['B', 'a', 'C'],
   ....:     "b": [1, 2, 3],
   ....:     "c": [2, 3, 4]
   ....: }).set_index(list("ab"))
   ....: 
   ....: 
In [307]: s1
Out[307]:
   a  b
   c
In [308]: s1.sort_index(level="a")
Out[308]:
    c
   a b
B 1 2
C 3 4
a 2 3

In [309]: s1.sort_index(level="a", key=lambda idx: idx.str.lower())
Out[309]:
    c
   a b
   a 2 3
   B 1 2
   C 3 4

For information on key sorting by value, see value sorting.

By values

The Series.sort_values() method is used to sort a Series by its values. The DataFrame.sort_values() method is used to sort a DataFrame by its column or row values. The optional by parameter to DataFrame.sort_values() may used to specify one or more columns to use to determine the sorted order.

In [310]: df1 = pd.DataFrame({
                'one': [2, 1, 1, 1],
                'two': [1, 3, 2, 4],
                'three': [5, 4, 3, 2]})

In [311]: df1.sort_values(by='two')
Out[311]:
     one  two  three
0     2     1     5
2     1     2     3
1     1     3     4
3     1     4     2

The by parameter can take a list of column names, e.g.:

In [312]: df1[['one', 'two', 'three']].sort_values(by=['one', 'two'])
Out[312]:
      one  two  three
2     1     2     3
1     1     3     4
3     1     4     2
0     2     1     5

These methods have special treatment of NA values via the na_position argument:

In [313]: s[2] = np.nan

(continued on next page)
New in version 1.1.0.

Sorting also supports a key parameter that takes a callable function to apply to the values being sorted.

```
In [316]: s1 = pd.Series(['B', 'a', 'C'])
In [317]: s1.sort_values()
Out[317]:
0 B
1 a
2 C
```

```
In [318]: s1.sort_values(key=lambda x: x.str.lower())
Out[318]:
1 a
0 B
2 C
```

key will be given the Series of values and should return a Series or array of the same shape with the transformed values. For DataFrame objects, the key is applied per column, so the key should still expect a Series and return a Series, e.g.

```
In [319]: df = pd.DataFrame({'a': ['B', 'a', 'C'], 'b': [1, 2, 3]})
In [320]: df.sort_values(by='a')
Out[320]:
   a  b
0  B  1
2 C 3
1 a 2

In [321]: df.sort_values(by='a', key=lambda col: col.str.lower())
Out[321]:
   a  b
0 1  B
1 2  C
2 0  a

The name or type of each column can be used to apply different functions to different columns.

By indexes and values

New in version 0.23.0.

Strings passed as the by parameter to DataFrame.sort_values() may refer to either columns or index level names.

```python
# Build MultiIndex
In [322]: idx = pd.MultiIndex.from_tuples([('a', 1), ('a', 2), ('a', 2),
                                    ('b', 2), ('b', 1), ('b', 1)])

In [323]: idx.names = ['first', 'second']

# Build DataFrame
In [324]: df_multi = pd.DataFrame({'A': np.arange(6, 0, -1)},
                            index=idx)

In [325]: df_multi
Out[325]:
     A
  first second
a  2  5
   1  6
  b  2  4
   1  3
   1  2

Sort by ‘second’ (index) and ‘A’ (column)

In [326]: df_multi.sort_values(by=['second', 'A'])
Out[326]:
     A
  first second
b  1  1
a  1  6
b  2  3
a  2  4
   2  5
```

2.3. Essential basic functionality
searchsorted

Series has the `searchsorted()` method, which works similarly to `numpy.ndarray.searchsorted()`.

```python
In [327]: ser = pd.Series([1, 2, 3])
In [328]: ser.searchsorted([0, 3])
Out[328]: array([0, 2])
In [329]: ser.searchsorted([0, 4])
Out[329]: array([0, 3])
In [330]: ser.searchsorted([1, 3], side='right')
Out[330]: array([1, 3])
In [331]: ser.searchsorted([1, 3], side='left')
Out[331]: array([0, 2])
In [332]: ser = pd.Series([3, 1, 2])
In [333]: ser.searchsorted([0, 3], sorter=np.argsort(ser))
Out[333]: array([0, 2])
```

smallest / largest values

Series has the `nsmallest()` and `nlargest()` methods which return the smallest or largest \( n \) values. For a large Series this can be much faster than sorting the entire Series and calling `head(n)` on the result.

```python
In [334]: s = pd.Series(np.random.permutation(10))
In [335]: s
Out[335]:
0    2
1    0
2    3
3    7
4    1
5    5
6    9
7    6
8    8
9    4
dtype: int64
In [336]: s.sort_values()
Out[336]:
1    0
4    1
0    2
2    3
```

(continues on next page)
9 4
5 5
7 6
3 7
8 8
6 9
dtype: int64

In [337]: s.nsmallest(3)
Out[337]:
1 0
4 1
0 2

dtype: int64

In [338]: s.nlargest(3)
Out[338]:
6 9
8 8
3 7

dtype: int64

DataFrame also has the `nlargest` and `nsmallest` methods.

In [339]: df = pd.DataFrame({'a': [-2, -1, 1, 10, 8, 11, -1],
                      'b': list('abdceff'),
                      'c': [1.0, 2.0, 4.0, 3.2, np.nan, 3.0, 4.0]})

In [340]: df.nlargest(3, 'a')
Out[340]:
a b c
5 11 f 3.0
3 10 c 3.2
4 8 e NaN

In [341]: df.nlargest(5, ['a', 'c'])
Out[341]:
a b c
5 11 f 3.0
3 10 c 3.2
4 8 e NaN
2 1 d 4.0
6 -1 f 4.0

In [342]: df.nsmallest(3, 'a')
Out[342]:
a b c
0 -2 a 1.0
1 -1 b 2.0
6 -1 f 4.0

In [343]: df.nsmallest(5, ['a', 'c'])
Out[343]:
a b c
0 -2 a 1.0
1 -1 b 2.0
pandas: powerful Python data analysis toolkit, Release 1.1.5

Sorting by a MultiIndex column

You must be explicit about sorting when the column is a MultiIndex, and fully specify all levels to by.

In [344]: df1.columns = pd.MultiIndex.from_tuples(['a', 'one'],
......: ['a', 'two'],
......: ['b', 'three'])

In [345]: df1.sort_values(by=('a', 'two'))
Out[345]:
    a  b
a
0  2  1  5
2  1  2  3
1  1  3  4
3  1  4  2

2.3.12 Copying

The copy() method on pandas objects copies the underlying data (though not the axis indexes, since they are immutable) and returns a new object. Note that it is seldom necessary to copy objects. For example, there are only a handful of ways to alter a DataFrame in-place:

- Inserting, deleting, or modifying a column.
- Assigning to the index or columns attributes.
- For homogeneous data, directly modifying the values via the values attribute or advanced indexing.

To be clear, no pandas method has the side effect of modifying your data; almost every method returns a new object, leaving the original object untouched. If the data is modified, it is because you did so explicitly.

2.3.13 dtypes

For the most part, pandas uses NumPy arrays and dtypes for Series or individual columns of a DataFrame. NumPy provides support for float, int, bool, timedelta64[ns] and datetime64[ns] (note that NumPy does not support timezone-aware datetimes).

Pandas and third-party libraries extend NumPy’s type system in a few places. This section describes the extensions pandas has made internally. See Extension types for how to write your own extension that works with pandas. See ecosystem.extensions for a list of third-party libraries that have implemented an extension.

The following table lists all of pandas extension types. For methods requiring dtype arguments, strings can be specified as indicated. See the respective documentation sections for more on each type.
Pandas has two ways to store strings.

1. **object** dtype, which can hold any Python object, including strings.
2. **StringDtype**, which is dedicated to strings.

Generally, we recommend using **StringDtype**. See **Text data types** for more.

Finally, arbitrary objects may be stored using the **object** dtype, but should be avoided to the extent possible (for performance and interoperability with other libraries and methods. See **object conversion**).

A convenient **dtypes** attribute for DataFrame returns a Series with the data type of each column.

```
In [346]: dft = pd.DataFrame({'A': np.random.rand(3),
         'B': 1,
         'C': 'foo',
         'D': pd.Timestamp('20010102'),
         'E': pd.Series([1.0] * 3).astype('float32'),
         'F': False,
         'G': pd.Series([1] * 3, dtype='int8'))

In [347]: dft
```

```
Out[347]:
   A   B   C     D     E   F   G
0  0.7  1.0  foo 2001-01-02  1.0   False  1
1  0.2  1.0  foo 2001-01-02  1.0   False  1
2  0.5  1.0  foo 2001-01-02  1.0   False  1
```
On a Series object, use the `dtype` attribute.

If a pandas object contains data with multiple dtypes in a single column, the dtype of the column will be chosen to accommodate all of the data types (object is the most general).

The number of columns of each type in a DataFrame can be found by calling `DataFrame.dtypes.value_counts()`.

```
In [348]: dft.dtypes
Out[348]:
A    float64
B     int64
C   object
D  datetime64[ns]
E   float32
F     bool
G    int8
dtype: object
```

```
In [349]: dft['A'].dtype
Out[349]: dtype('float64')
```

```
In [350]: pd.Series([1, 2, 3, 4, 5, 6.])
Out[350]:
0    1.0
1    2.0
2    3.0
3    4.0
4    5.0
5    6.0
dtype: float64
```

```
In [351]: pd.Series([1, 2, 3, 6., 'foo'])
Out[351]:
0    1
1    2
2    3
3    6
4    foo
dtype: object
```

```
In [352]: dft.dtypes.value_counts()
Out[352]:
datetime64[ns]    1
float32           1
int8              1
bool              1
int64             1
object             1
float64           1
dtype: int64
```
Numeric dtypes will propagate and can coexist in DataFrames. If a dtype is passed (either directly via the dtype keyword, a passed ndarray, or a passed Series), then it will be preserved in DataFrame operations. Furthermore, different numeric dtypes will NOT be combined. The following example will give you a taste.

```
In [353]: df1 = pd.DataFrame(np.random.randn(8, 1), columns=['A'], dtype='float32')

In [354]: df1
Out[354]:
       A
0  0.224364
1  1.890546
2  0.182879
3  0.787847
4 -0.188449
5  0.667715
6 -0.011736
7 -0.399073

In [355]: df1.dtypes
Out[355]:
A    float32
dtype: object

In [356]: df2 = pd.DataFrame({'A': pd.Series(np.random.randn(8), dtype='float16'),
                        'B': pd.Series(np.random.randn(8)),
                        'C': pd.Series(np.array(np.random.randn(8),
                                                dtype='uint8'))})

In [357]: df2
Out[357]:
       A   B   C
0  0.823242  0.256090   0
1  1.607422  1.426469   0
2 -0.333740 -0.416203 255
3 -0.063477  1.139976   0
4 -1.014648 -1.193477   0
5  0.678711  0.096706   0
6 -0.040863 -1.956850   1
7 -0.357422 -0.714337   0

In [358]: df2.dtypes
Out[358]:
A    float16
B    float64
C    uint8
dtype: object
```
By default integer types are `int64` and float types are `float64`, regardless of platform (32-bit or 64-bit). The following will all result in `int64` dtypes.

```
In [359]: pd.DataFrame([1, 2], columns=['a']).dtypes
Out[359]:
   a    int64
dtype: object

In [360]: pd.DataFrame({'a': [1, 2]}).dtypes
Out[360]:
   a    int64
dtype: object

In [361]: pd.DataFrame({'a': 1}, index=list(range(2))).dtypes
Out[361]:
   a    int64
dtype: object
```

Note that Numpy will choose platform-dependent types when creating arrays. The following WILL result in `int32` on 32-bit platform.

```
In [362]: frame = pd.DataFrame(np.array([1, 2]))
```

**upcasting**

Types can potentially be upcasted when combined with other types, meaning they are promoted from the current type (e.g. `int` to `float`).

```
In [363]: df3 = df1.reindex_like(df2).fillna(value=0.0) + df2

In [364]: df3
Out[364]:
   A        B        C
0  1.047606  0.256090  0.00
1  3.497968  1.426469  0.00
2 -0.150862 -0.416203 255.00
3  0.724370  1.139976  0.00
4 -1.203098 -1.193477  0.00
5  1.346426  0.096706  0.00
6 -0.052599 -1.956850  1.00
7 -0.756495 -0.714337  0.00

In [365]: df3.dtypes
Out[365]:
    A    float32
    B    float64
    C    float64
dtype: object
```

`DataFrame.to_numpy()` will return the lower-common-denominator of the dtypes, meaning the dtype that can accommodate ALL of the types in the resulting homogeneous dtyped NumPy array. This can force some upcasting.

```
In [366]: df3.to_numpy().dtype
Out[366]: dtype('float64')
```
**astype**

You can use the `astype()` method to explicitly convert dtypes from one to another. These will by default return a copy, even if the dtype was unchanged (pass `copy=False` to change this behavior). In addition, they will raise an exception if the astype operation is invalid.

Upcasting is always according to the `numpy` rules. If two different dtypes are involved in an operation, then the more general one will be used as the result of the operation.

In [367]: df3
Out[367]:
   A    B    C  
0  0.0476 0.2561 0.0  
1  3.4979 1.4264 0.0  
2 -0.1509 -0.4162 255.0
3  0.7243 1.1399 0.0  
4 -1.2031 -1.1935 0.0  
5  1.3464 0.0967 0.0  
6 -0.0526 -1.9569 1.0  
7 -0.7565 -0.7143 0.0  

In [368]: df3.dtypes
Out[368]:
   A  B  C
dtype: object

# conversion of dtypes
In [369]: df3.astype('float32').dtypes
Out[369]:
   A  B  C
dtype: object

Convert a subset of columns to a specified type using `astype()`.

In [370]: dft = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6], 'c': [7, 8, 9]})

In [371]: dft[['a', 'b']] = dft[['a', 'b']].astype(np.uint8)

In [372]: dft
Out[372]:
   a  b  c
0  1  4  7
1  2  5  8
2  3  6  9

In [373]: dft.dtypes
Out[373]:
   a  uint8
   b  uint8
   c  int64
dtype: object

Convert certain columns to a specific dtype by passing a dict to `astype()`.

2.3. Essential basic functionality
In [374]: dft1 = pd.DataFrame({'a': [1, 0, 1], 'b': [4, 5, 6], 'c': [7, 8, 9]})

In [375]: dft1 = dft1.astype({'a': np.bool, 'c': np.float64})

In [376]: dft1
Out[376]:
   a  b  c
0 True 4 7.0
1 False 5 8.0
2 True 6 9.0

In [377]: dft1.dtypes
Out[377]:
a bool
b int64
c float64
dtype: object

Note: When trying to convert a subset of columns to a specified type using `astype()` and `loc()`, upcasting occurs. `loc()` tries to fit in what we are assigning to the current dtypes, while [] will overwrite them taking the dtype from the right hand side. Therefore the following piece of code produces the unintended result.

In [378]: dft = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6], 'c': [7, 8, 9]})

In [379]: dft.loc[:, ['a', 'b']].astype(np.uint8).dtypes
Out[379]:
a uint8
b uint8
dtype: object

In [380]: dft.loc[:, ['a', 'b']] = dft.loc[:, ['a', 'b']].astype(np.uint8)

In [381]: dft.dtypes
Out[381]:
a int64
b int64
c int64
dtype: object

Object conversion

pandas offers various functions to try to force conversion of types from the object dtype to other types. In cases where the data is already of the correct type, but stored in an object array, the `DataFrame.infer_objects()` and `Series.infer_objects()` methods can be used to soft convert to the correct type.

In [382]: import datetime

In [383]: df = pd.DataFrame([[1, 2],
......: ['a', 'b'],
......: [datetime.datetime(2016, 3, 2),
......: datetime.datetime(2016, 3, 2)])

(continues on next page)
Because the data was transposed the original inference stored all columns as object, which `infer_objects` will correct.

```python
In [387]: df.infer_objects().dtypes
Out[387]:
0    int64
1     object
2  datetime64[ns]
dtype: object
```

The following functions are available for one dimensional object arrays or scalars to perform hard conversion of objects to a specified type:

- `to_numeric()` (conversion to numeric dtypes)

```python
In [388]: m = ['1.1', 2, 3]
In [389]: pd.to_numeric(m)
Out[389]: array([1.1, 2. , 3. ])
```

- `to_datetime()` (conversion to datetime objects)

```python
In [390]: import datetime
In [391]: m = ['2016-07-09', datetime.datetime(2016, 3, 2)]
In [392]: pd.to_datetime(m)
Out[392]: DatetimeIndex(['2016-07-09', '2016-03-02'], dtype='datetime64[ns]', freq=None)
```

- `to_timedelta()` (conversion to timedelta objects)

```python
In [393]: m = ['5us', pd.Timedelta('1day')]
In [394]: pd.to_timedelta(m)
Out[394]: TimedeltaIndex(['0 days 00:00:00.000005', '1 days 00:00:00'], dtype='timedelta64[ns]', freq=None)
```

To force a conversion, we can pass in an `errors` argument, which specifies how pandas should deal with elements that cannot be converted to desired dtype or object. By default, `errors='raise'`, meaning that any errors encountered will be raised during the conversion process. However, if `errors='coerce'`, these errors will be ignored and pandas will convert problematic elements to `pd.NaT` (for datetime and timedelta) or `np.nan` (for numeric).
This might be useful if you are reading in data which is mostly of the desired dtype (e.g. numeric, datetime), but occasionally has non-conforming elements intermixed that you want to represent as missing:

```python
In [395]: import datetime
In [396]: m = ['apple', datetime.datetime(2016, 3, 2)]
In [397]: pd.to_datetime(m, errors='coerce')
Out[397]: DatetimeIndex(['NaT', '2016-03-02'], dtype='datetime64[ns]', freq=None)
In [398]: m = ['apple', 2, 3]
In [399]: pd.to_numeric(m, errors='coerce')
Out[399]: array([nan, 2., 3.])
In [400]: m = ['apple', pd.Timedelta('1day')]
In [401]: pd.to_timedelta(m, errors='coerce')
Out[401]: TimedeltaIndex(['NaT', '1 days'], dtype='timedelta64[ns]', freq=None)
```

The `errors` parameter has a third option of `errors='ignore'`, which will simply return the passed in data if it encounters any errors with the conversion to a desired data type:

```python
In [402]: import datetime
In [403]: m = ['apple', datetime.datetime(2016, 3, 2)]
In [404]: pd.to_datetime(m, errors='ignore')
Out[404]: Index(['apple', 2016-03-02 00:00:00], dtype='object')
In [405]: m = ['apple', 2, 3]
In [406]: pd.to_numeric(m, errors='ignore')
Out[406]: array(['apple', 2, 3], dtype=object)
In [407]: m = ['apple', pd.Timedelta('1day')]
In [408]: pd.to_timedelta(m, errors='ignore')
Out[408]: array(['apple', '1 days 00:00:00'], dtype=object)
```

In addition to object conversion, `to_numeric()` provides another argument `downcast`, which gives the option of downcasting the newly (or already) numeric data to a smaller dtype, which can conserve memory:

```python
In [409]: m = ['1', 2, 3]
In [410]: pd.to_numeric(m, downcast='integer')  # smallest signed int dtype
Out[410]: array([1, 2, 3], dtype=int8)
In [411]: pd.to_numeric(m, downcast='signed')  # same as 'integer'
Out[411]: array([1, 2, 3], dtype=int8)
In [412]: pd.to_numeric(m, downcast='unsigned')  # smallest unsigned int dtype
Out[412]: array([1, 2, 3], dtype=uint8)
In [413]: pd.to_numeric(m, downcast='float')  # smallest float dtype
Out[413]: array([1., 2., 3.], dtype=float32)
```

As these methods apply only to one-dimensional arrays, lists or scalars; they cannot be used directly on multi-
dimensional objects such as DataFrames. However, with `apply()`, we can “apply” the function over each column efficiently:

```
In [414]: import datetime

In [415]: df = pd.DataFrame([[
    ....:    '2016-07-09', datetime.datetime(2016, 3, 2)] * 2, dtype='O')
    ....:]

In [416]: df
Out[416]:
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

In [417]: df.apply(pd.to_datetime)
Out[417]:
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

In [418]: df = pd.DataFrame([[1.1, 2, 3]] * 2, dtype='O')

In [419]: df
Out[419]:
<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1.1</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>1.1</td>
<td>2</td>
</tr>
</tbody>
</table>

In [420]: df.apply(pd.to_numeric)
Out[420]:
<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1.1</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>1.1</td>
<td>2</td>
</tr>
</tbody>
</table>

In [421]: df = pd.DataFrame([['5us', pd.Timedelta('1day')]] * 2, dtype='O')

In [422]: df
Out[422]:
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

In [423]: df.apply(pd.to_timedelta)
Out[423]:
<p>| |</p>
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
```
gotchas

Performing selection operations on integer type data can easily upcast the data to floating. The dtype of the input data will be preserved in cases where nans are not introduced. See also Support for integer NA.

```python
In [424]: dfi = df3.astype('int32')

In [425]: dfi['E'] = 1

In [426]: dfi
Out[426]:
    A  B  C  E
0  1  0  0  1
1  3  1  0  1
2  0  0 255  1
3  0  1  0  1
4 -1 -1  0  1
5  1  0  0  1
6  0 -1  1  1
7  0  0  0  1

In [427]: dfi.dtypes
Out[427]:
A  int32
B  int32
C  int32
E  int64
dtype: object

In [428]: casted = dfi[dfi > 0]

In [429]: casted
Out[429]:
    A  B  C  E
0  1.0 NaN NaN  1
1  3.0  1.0 NaN  1
2  NaN  NaN  255.0  1
3  NaN  1.0 NaN  1
4  NaN  NaN  NaN  1
5  1.0  NaN  NaN  1
6  NaN  NaN   1.0  1
7  NaN  NaN  NaN  1

In [430]: casted.dtypes
Out[430]:
A  float64
B  float64
C  float64
E  int64
dtype: object
```

While float dtypes are unchanged.

```python
In [431]: dfa = df3.copy()

In [432]: dfa['A'] = dfa['A'].astype('float32')

In [433]: dfa.dtypes
```

(continues on next page)
2.3.14 Selecting columns based on dtype

The `select_dtypes()` method implements subsetting of columns based on their dtype.

First, let’s create a `DataFrame` with a slew of different dtypes:

```python
In [437]: df = pd.DataFrame({'string': list('abc'),
                        .....: 'int64': list(range(1, 4)),
                        .....: 'uint8': np.arange(3, 6).astype('u1'),
                        .....: 'float64': np.arange(4.0, 7.0),
                        .....: 'bool1': [True, False, True],
                        .....: 'bool2': [False, True, False],
                        .....: 'dates': pd.date_range('now', periods=3),
                        .....: 'category': pd.Series(list("ABC"))
                        .....: .astype('category')})
```

```python
In [438]: df['tdeltas'] = df.dates.diff()
In [439]: df['uint64'] = np.arange(3, 6).astype('u8')
In [440]: df['other_dates'] = pd.date_range('20130101', periods=3)
In [441]: df['tz_aware_dates'] = pd.date_range('20130101', periods=3, tz='US/Eastern')
In [442]: df
```

```
Out[442]:
      string  int64  uint8  float64  bool1  bool2  dates  category
tdeltas   ...    ...    ...     ...     ...    ...     ...     ...     ...
tz_aware_dates   ...    ...    ...     ...     ...    ...     ...     ...
```

(continues on next page)
And the dtypes:

```python
In [443]: df.dtypes
Out[443]:
<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>string</td>
<td>object</td>
</tr>
<tr>
<td></td>
<td>int64</td>
<td>int64</td>
</tr>
<tr>
<td></td>
<td>uint8</td>
<td>uint8</td>
</tr>
<tr>
<td></td>
<td>float64</td>
<td>float64</td>
</tr>
<tr>
<td></td>
<td>bool</td>
<td>bool</td>
</tr>
<tr>
<td></td>
<td>bool2</td>
<td>bool</td>
</tr>
<tr>
<td></td>
<td>dates</td>
<td>datetime64[ns]</td>
</tr>
<tr>
<td></td>
<td>category</td>
<td>category</td>
</tr>
<tr>
<td></td>
<td>tdeltas</td>
<td>timedelta64[ns]</td>
</tr>
<tr>
<td></td>
<td>uint64</td>
<td>uint64</td>
</tr>
<tr>
<td></td>
<td>other_dates</td>
<td>datetime64[ns]</td>
</tr>
<tr>
<td></td>
<td>tz_aware_dates</td>
<td>datetime64[ns, US/Eastern]</td>
</tr>
<tr>
<td>dtype: object</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

`select_dtypes()` has two parameters `include` and `exclude` that allow you to say “give me the columns with these dtypes” (`include`) and/or “give the columns without these dtypes” (`exclude`).

For example, to select boolean columns:

```python
In [444]: df.select_dtypes(include=[bool])
Out[444]:
    bool1  bool2
0    True  False
1   False   True
2   True  False
```

You can also pass the name of a dtype in the NumPy dtype hierarchy:

```python
In [445]: df.select_dtypes(include=['bool'])
Out[445]:
    bool1  bool2
0    True  False
1   False   True
2   True  False
```

`select_dtypes()` also works with generic dtypes as well.

For example, to select all numeric and boolean columns while excluding unsigned integers:

```python
In [446]: df.select_dtypes(include=['number', 'bool'], exclude=['unsignedinteger'])
Out[446]:
    int64  float64  bool1  bool2  tdeltas
t0  1   4.0    True  False    NaT
1  2    5.0   False   True   1 days
2  3    6.0   True  False   1 days
```

To select string columns you must use the `object` dtype:
In [447]: df.select_dtypes(include=['object'])
Out[447]:
   string
  0   a
  1   b
  2   c

To see all the child dtypes of a generic dtype like `numpy.number` you can define a function that returns a tree of child dtypes:

```
In [448]: def subdtypes(dtype):
    ...
    subs = dtype.__subclasses__()
    ...
    if not subs:
        ...
        return dtype
    ...
    return [dtype, [subdtypes(dt) for dt in subs]]
```

All NumPy dtypes are subclasses of `numpy.generic`:

```
In [449]: subdtypes(np.generic)
Out[449]:
[numpy.generic,
 [[numpy.number,
   [[numpy.integer,
     [[numpy.signedinteger,
       [numpy.int8,
        numpy.int16,
        numpy.int32,
        numpy.int64,
        numpy.longlong,
        numpy.timedelta64]],
      [numpy.unsignedinteger,
        [numpy.uint8,
        numpy.uint16,
        numpy.uint32,
        numpy.uint64,
        numpy.ulonglong]]],
    [numpy.inexact,
     [[numpy.floating,
       [numpy.float16, numpy.float32, numpy.float64, numpy.float128]],
      [numpy.complexfloating,
        [numpy.complex64, numpy.complex128, numpy.complex256]]]]],
   [numpy.flexible,
    [[numpy.character, [numpy.bytes_, numpy.str_]],
     [numpy.void, [numpy.record]]],
    numpy.bool_,
    numpy.datetime64,
    numpy.object_]]
```

Note: Pandas also defines the types `category` and `datetime64[ns, tz]`, which are not integrated into the normal NumPy hierarchy and won’t show up with the above function.
2.4 IO tools (text, CSV, HDF5, ...)

The pandas I/O API is a set of top level reader functions accessed like `pandas.read_csv()` that generally return a pandas object. The corresponding writer functions are object methods that are accessed like `DataFrame.to_csv()`. Below is a table containing available readers and writers.

<table>
<thead>
<tr>
<th>Format Type</th>
<th>Data Description</th>
<th>Reader</th>
<th>Writer</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>CSV</td>
<td>read_csv</td>
<td>to_csv</td>
</tr>
<tr>
<td>text</td>
<td>Fixed-Width Text File</td>
<td>read_fwf</td>
<td></td>
</tr>
<tr>
<td>text</td>
<td>JSON</td>
<td>read_json</td>
<td>to_json</td>
</tr>
<tr>
<td>text</td>
<td>HTML</td>
<td>read_html</td>
<td>to_html</td>
</tr>
<tr>
<td>text</td>
<td>Local clipboard</td>
<td>read_clipboard</td>
<td>to_clipboard</td>
</tr>
<tr>
<td>binary</td>
<td>OpenDocument</td>
<td>read_excel</td>
<td></td>
</tr>
<tr>
<td>binary</td>
<td>HDF5 Format</td>
<td>read_hdf</td>
<td>to_hdf</td>
</tr>
<tr>
<td>binary</td>
<td>Feather Format</td>
<td>read_feather</td>
<td>to_feather</td>
</tr>
<tr>
<td>binary</td>
<td>Parquet Format</td>
<td>read_parquet</td>
<td>to_parquet</td>
</tr>
<tr>
<td>binary</td>
<td>ORC Format</td>
<td>read_orc</td>
<td></td>
</tr>
<tr>
<td>binary</td>
<td>Msgpack</td>
<td>read_msgpack</td>
<td>to_msgpack</td>
</tr>
<tr>
<td>binary</td>
<td>Stata</td>
<td>read_stata</td>
<td>to_stata</td>
</tr>
<tr>
<td>binary</td>
<td>SAS</td>
<td>read_sas</td>
<td></td>
</tr>
<tr>
<td>binary</td>
<td>SPSS</td>
<td>read_spss</td>
<td></td>
</tr>
<tr>
<td>binary</td>
<td>Python Pickle Format</td>
<td>read_pickle</td>
<td>to_pickle</td>
</tr>
<tr>
<td>SQL</td>
<td>SQL</td>
<td>read_sql</td>
<td>to_sql</td>
</tr>
<tr>
<td>SQL</td>
<td>Google BigQuery</td>
<td>read_gbq</td>
<td>to_gbq</td>
</tr>
</tbody>
</table>

Here is an informal performance comparison for some of these IO methods.

Note: For examples that use the `StringIO` class, make sure you import it with `from io import StringIO` for Python 3.

2.4.1 CSV & text files

The workhorse function for reading text files (a.k.a. flat files) is `read_csv()`. See the cookbook for some advanced strategies.

Parsing options

`read_csv()` accepts the following common arguments:
Basic

filepath_or_buffer [various] Either a path to a file (a str, pathlib.Path, or py._path.local.LocalPath), URL (including http, ftp, and S3 locations), or any object with a read() method (such as an open file or StringIO).

sep [str, defaults to ',' for read_csv(), \t for read_table()] Delimiter to use. If sep is None, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python's built-in sniffer tool, csv.Sniffer. In addition, separators longer than 1 character and different from '"s+' will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: '"\r\t'.

delimiter [str, default None] Alternative argument name for sep.

delim_whitespace [boolean, default False] Specifies whether or not whitespace (e.g. ' ' or '\t') will be used as the delimiter. Equivalent to setting sep='"s+'. If this option is set to True, nothing should be passed in for the delimiter parameter.

Column and index locations and names

header [int or list of ints, default 'infer'] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to header=0 and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to header=None. Explicitly pass header=0 to be able to replace existing names.

The header can be a list of ints that specify row locations for a MultiIndex on the columns e.g. [0,1,3]. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if skip_blank_lines=True, so header=0 denotes the first line of data rather than the first line of the file.

names [array-like, default None] List of column names to use. If file contains no header row, then you should explicitly pass header=None. Duplicates in this list are not allowed.

index_col [int, str, sequence of int / str, or False, default None] Column(s) to use as the row labels of the DataFrame, either given as string name or column index. If a sequence of int / str is given, a MultiIndex is used.

Note: index_col=False can be used to force pandas to not use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

The default value of None instructs pandas to guess. If the number of fields in the column header row is equal to the number of fields in the body of the data file, then a default index is used. If it is one larger, then the first field is used as an index.

usecols [list-like or callable, default None] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in names or inferred from the document header row(s). For example, a valid list-like usecols parameter would be [0, 1, 2] or ['foo', 'bar', 'baz'].

Element order is ignored, so usecols=[0, 1] is the same as [1, 0]. To instantiate a DataFrame from data with element order preserved use pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']] for columns in ['foo', 'bar'] order or pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']] for ['bar', 'foo'] order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True:
In [1]: `import pandas as pd`

In [2]: `from io import StringIO`

In [3]: `data = ('col1,col2,col3
   ....: 'a,b,1
   ....: 'a,b,2
   ....: 'c,d,3')`

In [4]: `pd.read_csv(StringIO(data))`

Out[4]:
```
<table>
<thead>
<tr>
<th>col1</th>
<th>col2</th>
<th>col3</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>a</td>
<td>b</td>
</tr>
<tr>
<td>1</td>
<td>a</td>
<td>b</td>
</tr>
<tr>
<td>2</td>
<td>c</td>
<td>d</td>
</tr>
</tbody>
</table>
```

In [5]: `pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ['COL1', 'COL3'])`

Out[5]:
```
<table>
<thead>
<tr>
<th>col1</th>
<th>col3</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1</td>
</tr>
<tr>
<td>a</td>
<td>2</td>
</tr>
<tr>
<td>c</td>
<td>3</td>
</tr>
</tbody>
</table>
```

Using this parameter results in much faster parsing time and lower memory usage.

**squeeze** [boolean, default False] If the parsed data only contains one column then return a Series.

**prefix** [str, default None] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1,…

**mangle_dupe_cols** [boolean, default True] Duplicate columns will be specified as ‘X’ , ‘X.1’…’X.N’, rather than ‘X’…’X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

### General parsing configuration

**dtype** [Type name or dict of column -> type, default None] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32} (unsupported with engine='python'). Use str or object together with suitable na_values settings to preserve and not interpret dtype.

**engine** [{'c', 'python'}] Parser engine to use. The C engine is faster while the Python engine is currently more feature-complete.

**converters** [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

**true_values** [list, default None] Values to consider as True.

**false_values** [list, default None] Values to consider as False.

**skipinitialspace** [boolean, default False] Skip spaces after delimiter.

**skiprows** [list-like or integer, default None] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

   If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise:
In [6]: data = ('col1,col2,col3
   ...:  'a,b,1
   ...:  'a,b,2
   ...:  'c,d,3')
...

In [7]: pd.read_csv(StringIO(data))
Out[7]:
   col1 col2 col3
0    a    b    1
1    a    b    2
2    c    d    3

In [8]: pd.read_csv(StringIO(data), skiprows=lambda x: x % 2 != 0)
Out[8]:
   col1 col2 col3
0    a    b    2

skipfooter [int, default 0] Number of lines at bottom of file to skip (unsupported with engine='c').
nrows [int, default None] Number of rows of file to read. Useful for reading pieces of large files.
low_memory [boolean, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the dtype parameter. Note that the entire file is read into a single DataFrame regardless, use the chunksize or iterator parameter to return the data in chunks. (Only valid with C parser)
memory_map [boolean, default False] If a filepath is provided for filepath_or_buffer, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

NA and missing data handling

na_values [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. See na_values const below for a list of the values interpreted as NaN by default.
keep_default_na [boolean, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether na_values is passed in, the behavior is as follows:
   • If keep_default_na is True, and na_values are specified, na_values is appended to the default NaN values used for parsing.
   • If keep_default_na is True, and na_values are not specified, only the default NaN values are used for parsing.
   • If keep_default_na is False, and na_values are specified, only the NaN values specified na_values are used for parsing.
   • If keep_default_na is False, and na_values are not specified, no strings will be parsed as NaN.

Note that if na_filter is passed in as False, the keep_default_na and na_values parameters will be ignored.
na_filter [boolean, default True] Detect missing value markers (empty strings and the value of na_values). In data without any NAs, passing na_filter=False can improve the performance of reading a large file.
verbose [boolean, default False] Indicate number of NA values placed in non-numeric columns.
skip_blank_lines [boolean, default True] If True, skip over blank lines rather than interpreting as NaN values.
Datetime handling

**parse_dates** [boolean or list of ints or names or list of lists or dict, default False.]
- If True -> try parsing the index.
- If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- If {'foo': [1, 3]} -> parse columns 1, 3 as date and call result ‘foo’. A fast-path exists for iso8601-formatted dates.

**infer_datetime_format** [boolean, default False] If True and parse_dates is enabled for a column, attempt to infer the datetime format to speed up the processing.

**keep_date_col** [boolean, default False] If True and parse_dates specifies combining multiple columns then keep the original columns.

**date_parser** [function, default None] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses dateutil.parser.parser to do the conversion. pandas will try to call date_parser in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by parse_dates) as arguments; 2) concatenate (row-wise) the string values from the columns defined by parse_dates into a single array and pass that; and 3) call date_parser once for each row using one or more strings (corresponding to the columns defined by parse_dates) as arguments.

**dayfirst** [boolean, default False] DD/MM format dates, international and European format.

**cache_dates** [boolean, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

Iteration

**iterator** [boolean, default False] Return TextFileReader object for iteration or getting chunks with get_chunk().

**chunksize** [int, default None] Return TextFileReader object for iteration. See iterating and chunking below.

Quoting, compression, and file format

**compression** [{'infer', 'gzip', 'bz2', 'zip', 'xz', None, dict}, default 'infer'] For on-the-fly decompression of on-disk data. If ‘infer’, then use gzip, bz2, zip, or xz if filepath_or_buffer is a string ending in ‘gz’, ‘bz2’, ‘.zip’, or ‘.xz’, respectively, and no decompression otherwise. If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression. Can also be a dict with key 'method' set to one of {'zip', 'gzip', 'bz2'}, and other keys set to compression settings. As an example, the following could be passed for faster compression: compression={'method': 'gzip', 'compresslevel': 1}).

Changed in version 0.24.0: ‘infer’ option added and set to default.

Changed in version 1.1.0: dict option extended to support gzip andbz2.

**thousands** [str, default None] Thousands separator.

**decimal** [str, default ‘.’] Character to recognize as decimal point. E.g. use ‘,’ ‘.’ for European data.

**float_precision** [string, default None] Specifies which converter the C engine should use for floating-point values. The options are None for the ordinary converter, high for the high-precision converter, and round_trip for the round-trip converter.
lineterminator  [str (length 1), default None] Character to break file into lines. Only valid with C parser.

quotechar  [str (length 1)] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

quoting  [int or csv.QUOTE_* instance, default 0] Control field quoting behavior per csv.QUOTE_* constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

doublequote  [boolean, default True] When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements inside a field as a single quotechar element.

escapechar  [str (length 1), default None] One-character string used to escape delimiter when quoting is QUOTE_NONE.

comment  [str, default None] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as skip_blank_lines=True), fully commented lines are ignored by the parameter header but not by skiprows. For example, if comment='#', parsing '#empty
a,b,c
1,2,3' with header=0 will result in 'a,b,c' being treated as the header.

encoding  [str, default None] Encoding to use for UTF when reading/writing (e.g. 'utf-8'). List of Python standard encodings.

dialect  [str or csv.Dialect instance, default None] If provided, this parameter will override values (default or not) for the following parameters: delimiter, doublequote, escapechar, skipinitialspace, quotechar, and quoting. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

Error handling

error_bad_lines  [boolean, default True] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will dropped from the DataFrame that is returned. See bad lines below.

warn_bad_lines  [boolean, default True] If error_bad_lines is False, and warn_bad_lines is True, a warning for each “bad line” will be output.

Specifying column data types

You can indicate the data type for the whole DataFrame or individual columns:

In [9]: import numpy as np

In [10]: data = ('a,b,c,d
       : 1,2,3,4
       : 5,6,7,8
       : 9,10,11')

In [11]: print(data)
a,b,c,d
1,2,3,4
5,6,7,8
9,10,11

In [12]: df = pd.read_csv(StringIO(data), dtype=object)
Fortunately, pandas offers more than one way to ensure that your column(s) contain only one dtype. If you’re unfamiliar with these concepts, you can see here to learn more about dtypes, and here to learn more about object conversion in pandas.

For instance, you can use the converters argument of read_csv():

```python
In [17]: data = ("col_1
.....:   "1
.....:   "2
.....:   "A
.....:   "4.22")

In [18]: df = pd.read_csv(StringIO(data), converters={'col_1': str})

In [19]: df
Out[19]:
          col_1
0          1
1          2
2         'A'
3        4.22

In [20]: df['col_1'].apply(type).value_counts()
Out[20]:
<class 'str'> 4
Name: col_1, dtype: int64
```

Or you can use the to_numeric() function to coerce the dtypes after reading in the data,

```python
In [21]: df2 = pd.read_csv(StringIO(data))

In [22]: df2['col_1'] = pd.to_numeric(df2['col_1'], errors='coerce')
```
which will convert all valid parsing to floats, leaving the invalid parsing as NaN.

Ultimately, how you deal with reading in columns containing mixed dtypes depends on your specific needs. In the case above, if you wanted to NaN out the data anomalies, then to_numeric() is probably your best option. However, if you wanted for all the data to be coerced, no matter the type, then using the converters argument of read_csv() would certainly be worth trying.

Note: In some cases, reading in abnormal data with columns containing mixed dtypes will result in an inconsistent dataset. If you rely on pandas to infer the dtypes of your columns, the parsing engine will go and infer the dtypes for different chunks of the data, rather than the whole dataset at once. Consequently, you can end up with column(s) with mixed dtypes. For example,

```
In [25]: col_1 = list(range(500000)) + ['a', 'b'] + list(range(500000))
In [26]: df = pd.DataFrame({'col_1': col_1})
In [27]: df.to_csv('foo.csv')
In [28]: mixed_df = pd.read_csv('foo.csv')
```

```
In [29]: mixed_df['col_1'].apply(type).value_counts()
Out[29]:
<class 'int'> 737858
<class 'str'> 262144
Name: col_1, dtype: int64
```

```
In [30]: mixed_df['col_1'].dtype
Out[30]: dtype('O')
```

will result with mixed_df containing an int dtype for certain chunks of the column, and str for others due to the mixed dtypes from the data that was read in. It is important to note that the overall column will be marked with a dtype of object, which is used for columns with mixed dtypes.
### Specifying categorical dtype

Categorical columns can be parsed directly by specifying `dtype='category'` or `dtype=CategoricalDtype(categories, ordered)`.

```python
In [31]: data = ('col1,col2,col3
    .....:  'a,b,1
    .....:  'a,b,2
    .....:  'c,d,3')
    
In [32]: pd.read_csv(StringIO(data))
Out[32]:
   col1  col2  col3
0    a     b     1
1    a     b     2
2    c     d     3

In [33]: pd.read_csv(StringIO(data)).dtypes
Out[33]:
       col1     col2     col3
dtype: object     object     int64

In [34]: pd.read_csv(StringIO(data), dtype='category').dtypes
Out[34]:
       col1     col2     col3
dtype: object     object     int64

Individual columns can be parsed as a `Categorical` using a dict specification:

```python
In [35]: pd.read_csv(StringIO(data), dtype={'col1': 'category'}).dtypes
Out[35]:
       col1     col2     col3
dtype: object     object     int64

Specifying `dtype='category'` will result in an unordered `Categorical` whose categories are the unique values observed in the data. For more control on the categories and order, create a `CategoricalDtype` ahead of time, and pass that for that column’s `dtype`.

```python
In [36]: from pandas.api.types import CategoricalDtype
In [37]: dtype = CategoricalDtype(['d', 'c', 'b', 'a'], ordered=True)
In [38]: pd.read_csv(StringIO(data), dtype={'col1': dtype}).dtypes
Out[38]:
       col1     col2     col3
dtype: object     object     int64

When using `dtype=CategoricalDtype`, “unexpected” values outside of `dtype.categories` are treated as missing values.
In [39]: dtype = CategoricalDtype(['a', 'b', 'd'])  # No 'c'

In [40]: pd.read_csv(StringIO(data), dtype={'col1': dtype}).col1
Out[40]:
0    a
1    a
2  NaN
Name: col1, dtype: category
Categories (3, object): ['a', 'b', 'd']

This matches the behavior of Categorical.set_categories().

**Note:** With **dtype='category'**, the resulting categories will always be parsed as strings (object dtype). If the categories are numeric they can be converted using the `to_numeric()` function, or as appropriate, another converter such as `to_datetime()`.

When **dtype** is a **CategoricalDtype** with homogeneous categories (all numeric, all datetimes, etc.), the conversion is done automatically.

In [41]: df = pd.read_csv(StringIO(data), dtype='category')

In [42]: df.dtypes
Out[42]:
col1    category
col2    category
col3    category
dtype: object

In [43]: df['col3']
Out[43]:
0  1
1  2
2  3
Name: col3, dtype: category
Categories (3, object): ['1', '2', '3']

In [44]: df['col3'].cat.categories = pd.to_numeric(df['col3'].cat.categories)

In [45]: df['col3']
Out[45]:
0  1
1  2
2  3
Name: col3, dtype: category
Categories (3, int64): [1, 2, 3]
Naming and using columns

Handling column names

A file may or may not have a header row. pandas assumes the first row should be used as the column names:

```python
In [46]: data = ('a,b,c
   ....:   '1,2,3
   ....:   '4,5,6
   ....:   '7,8,9')
   ....:

In [47]: print(data)
a,b,c 1,2,3 4,5,6 7,8,9

In [48]: pd.read_csv(StringIO(data))
Out[48]:
   a b c
0 1 2 3
1 4 5 6
2 7 8 9

By specifying the names argument in conjunction with header you can indicate other names to use and whether or not to throw away the header row (if any):

```python
In [49]: print(data)
a,b,c 1,2,3 4,5,6 7,8,9

In [50]: pd.read_csv(StringIO(data), names=['foo', 'bar', 'baz'], header=0)
Out[50]:
   foo bar baz
0   1   2   3
1   4   5   6
2   7   8   9

In [51]: pd.read_csv(StringIO(data), names=['foo', 'bar', 'baz'], header=None)
Out[51]:
   foo bar baz
0   a   b   c
1   1   2   3
2   4   5   6
3   7   8   9

If the header is in a row other than the first, pass the row number to header. This will skip the preceding rows:

```python
In [52]: data = ('skip this skip it
   ....:   'a,b,c
   ....:   '1,2,3
   ....:   '4,5,6
   ....:   '7,8,9')
   ....:

(continues on next page)
In [53]: pd.read_csv(StringIO(data), header=1)
Out[53]:
   a  b  c
0  1  2  3
1  4  5  6
2  7  8  9

Note: Default behavior is to infer the column names: if no names are passed the behavior is identical to header=0 and column names are inferred from the first non-blank line of the file, if column names are passed explicitly then the behavior is identical to header=None.

Duplicate names parsing

If the file or header contains duplicate names, pandas will by default distinguish between them so as to prevent overwriting data:

In [54]: data = ('a,b,a
       ....:   0,1,2
       ....:   3,4,5')
       ....:
In [55]: pd.read_csv(StringIO(data))
Out[55]:
   a  b  a.1
0  0  1  2
1  3  4  5

There is no more duplicate data because mangle_dupe_cols=True by default, which modifies a series of duplicate columns ‘X’, …, ‘X’ to become ‘X’, ‘X.1’, …, ‘X.N’. If mangle_dupe_cols=False, duplicate data can arise:

In [2]: data = 'a,b,a
       ....:   0,1,2
       ....:   3,4,5'
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
Out[3]:
   a  b  a
0  2  1  2
1  5  4  5

To prevent users from encountering this problem with duplicate data, a ValueError exception is raised if mangle_dupe_cols != True:

In [2]: data = 'a,b,a
       ....:   0,1,2
       ....:   3,4,5'
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
... ValueError: Setting mangle_dupe_cols=False is not supported yet
Filtering columns (usecols)

The `usecols` argument allows you to select any subset of the columns in a file, either using the column names, position numbers or a callable:

```
In [56]: data = 'a,b,c,d
1,2,3,foo
4,5,6,bar
7,8,9,baz'
In [57]: pd.read_csv(StringIO(data))
Out[57]:
   a  b  c  d
0  1  2  3  foo
1  4  5  6  bar
2  7  8  9  baz
In [58]: pd.read_csv(StringIO(data), usecols=['b', 'd'])
Out[58]:
   b  d
0  2  foo
1  5  bar
2  8  baz
In [59]: pd.read_csv(StringIO(data), usecols=[0, 2, 3])
Out[59]:
   a  c  d
0  1  3  foo
1  4  6  bar
2  7  9  baz
In [60]: pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ['A', 'C'])
Out[60]:
   a  c
0  1  3
1  4  6
2  7  9
```

The `usecols` argument can also be used to specify which columns not to use in the final result:

```
In [61]: pd.read_csv(StringIO(data), usecols=lambda x: x not in ['a', 'c'])
Out[61]:
   b  d
0  2  foo
1  5  bar
2  8  baz
```

In this case, the callable is specifying that we exclude the “a” and “c” columns from the output.

Comments and empty lines

Ignoring line comments and empty lines

If the `comment` parameter is specified, then completely commented lines will be ignored. By default, completely blank lines will be ignored as well.

```
In [62]: data = ("\n....: a,b,c\n....:  \
")
```

(continues on next page)
In [63]: print(data)

a,b,c

# commented line
1,2,3
4,5,6

In [64]: pd.read_csv(StringIO(data), comment='#')
Out[64]:
   a  b  c
0  1  2  3
1  4  5  6

If skip_blank_lines=False, then read_csv will not ignore blank lines:

In [65]: data = ('a,b,c
       ...
       '1,2,3
       ...
       '4,5,6')

In [66]: pd.read_csv(StringIO(data), skip_blank_lines=False)
Out[66]:
     a  b  c
0  NaN NaN NaN
1  1.0 2.0 3.0
2  NaN NaN NaN
3  NaN NaN NaN
4  4.0 5.0 6.0

Warning: The presence of ignored lines might create ambiguities involving line numbers; the parameter header uses row numbers (ignoring commented/empty lines), while skiprows uses line numbers (including commented/empty lines):

In [67]: data = ('#comment
       ...
       'a,b,c
       ...
       'A,B,C
       ...
       '1,2,3')

In [68]: pd.read_csv(StringIO(data), comment='#', header=1)
Out[68]:
     A  B  C
0   1   2   3

In [69]: data = ('A,B,C
       ...
       '1,2,3
       ...
       '4,5,6')

2.4.  IO tools (text, CSV, HDF5, ...)

243
In [70]: pd.read_csv(StringIO(data), comment='#', skiprows=2)
Out[70]:
   a  b  c
0  1  2  3

If both header and skiprows are specified, header will be relative to the end of skiprows. For example:

In [71]: data = ('# empty
....:  
# second empty line
....:  
# third empty line
....:  
X,Y,Z
....:  
1,2,3
....:  
A,B,C
....:  
1,2.4.
....:  
5.,NaN,10.0
....:  
')

In [72]: print(data)
# empty
# second empty line
# third empty line
X,Y,Z
1,2,3
A,B,C
1,2.4.
5.,NaN,10.0

In [73]: pd.read_csv(StringIO(data), comment='#', skiprows=4, header=1)
Out[73]:
   A  B  C
0  1.0  2.0  4.0
1  5.0  NaN  10.0

Comments

Sometimes comments or meta data may be included in a file:

In [74]: print(open('tmp.csv').read())
ID,level,category
Patient1,123000,x # really unpleasant
Patient2,23000,y # wouldn't take his medicine
Patient3,1234018,z # awesome

By default, the parser includes the comments in the output:

In [75]: df = pd.read_csv('tmp.csv')
In [76]: df
(continues on next page)
We can suppress the comments using the `comment` keyword:

```python
In [77]: df = pd.read_csv('tmp.csv', comment='#')
```

```python
In [78]: df
Out[78]:
   ID    level  category
0  0 Patient1 123000     x # really unpleasant
1  1 Patient2 23000      y # wouldn't take his medicine
2  2 Patient3 1234018    z # awesome
```

### Dealing with Unicode data

The `encoding` argument should be used for encoded unicode data, which will result in byte strings being decoded to unicode in the result:

```python
In [79]: from io import BytesIO
In [80]: data = (b'word,length
   ....: b'Träumen,7
   ....: b'Grüße,5'
   ....:
In [81]: data = data.decode('utf8').encode('latin-1')
In [82]: df = pd.read_csv(BytesIO(data), encoding='latin-1')
In [83]: df
Out[83]:
   word  length
0  Träumen    7
1    Grüße    5
```

Some formats which encode all characters as multiple bytes, like UTF-16, won't parse correctly at all without specifying the encoding. Full list of Python standard encodings.
Index columns and trailing delimiters

If a file has one more column of data than the number of column names, the first column will be used as the DataFrame's row names:

```python
In [85]: data = ('a,b,c
       ....:  '4,apple,bat,5.7\n       ....:  '8,orange,cow,10')
       ....:

In [86]: pd.read_csv(StringIO(data))
Out[86]:
   a    b    c
4 apple bat 5.7
8 orange cow 10.0
```

Ordinarily, you can achieve this behavior using the `index_col` option.

There are some exception cases when a file has been prepared with delimiters at the end of each data line, confusing the parser. To explicitly disable the index column inference and discard the last column, pass `index_col=False`:

```python
In [87]: data = ('index,a,b,c
       ....:  '4,apple,bat,5.7\n       ....:  '8,orange,cow,10')
       ....:

In [88]: pd.read_csv(StringIO(data), index_col=0)
Out[88]:
     a    b    c
index
4  apple bat 5.7
8 orange cow 10.0
```

If a subset of data is being parsed using the `usecols` option, the `index_col` specification is based on that subset, not the original data.
**Date Handling**

### Specifying date columns

To better facilitate working with datetime data, `read_csv()` uses the keyword arguments `parse_dates` and `date_parser` to allow users to specify a variety of columns and date/time formats to turn the input text data into `datetime` objects.

The simplest case is to just pass in `parse_dates=True`:

```python
# Use a column as an index, and parse it as dates.
In [97]: df = pd.read_csv('foo.csv', index_col=0, parse_dates=True)

In [98]: df
```

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>2009-01-01</td>
<td>a</td>
</tr>
<tr>
<td></td>
<td>2009-01-02</td>
<td>b</td>
</tr>
<tr>
<td></td>
<td>2009-01-03</td>
<td>c</td>
</tr>
</tbody>
</table>

# These are Python datetime objects
```

```bash
In [99]: df.index
```

```
Out[99]: DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype='datetime64[ns]', name='date', freq=None)
```

It is often the case that we may want to store date and time data separately, or store various date fields separately. the `parse_dates` keyword can be used to specify a combination of columns to parse the dates and/or times from.

You can specify a list of column lists to `parse_dates`, the resulting date columns will be prepended to the output (so as to not affect the existing column order) and the new column names will be the concatenation of the component column names:
In [100]: print(open('tmp.csv').read())
KORD,19990127, 19:00:00, 18:56:00, 0.8100
KORD,19990127, 20:00:00, 19:56:00, 0.0100
KORD,19990127, 21:00:00, 20:56:00, -0.5900
KORD,19990127, 21:00:00, 21:18:00, -0.9900
KORD,19990127, 22:00:00, 21:56:00, -0.5900
KORD,19990127, 23:00:00, 22:56:00, -0.5900

In [101]: df = pd.read_csv('tmp.csv', header=None, parse_dates=[[1, 2], [1, 3]])

In [102]: df
Out[102]:
    1_2  1_3    0
0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD  0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD  0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59

By default the parser removes the component date columns, but you can choose to retain them via the keep_date_col keyword:

In [103]: df = pd.read_csv('tmp.csv', header=None, parse_dates=[[1, 2], [1, 3]], keep_date_col=True)

In [104]: df
Out[104]:
    1_2  1_3  1  2  3  4
0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD 19990127 19:00:00 18:56:00 0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 19990127 20:00:00 19:56:00 0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD 19990127 21:00:00 20:56:00 -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD 19990127 21:00:00 21:18:00 -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD 19990127 22:00:00 21:56:00 -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD 19990127 23:00:00 22:56:00 -0.59

Note that if you wish to combine multiple columns into a single date column, a nested list must be used. In other words, parse_dates=[1, 2] indicates that the second and third columns should each be parsed as separate date columns while parse_dates=[[1, 2]] means the two columns should be parsed into a single column.

You can also use a dict to specify custom name columns:

In [105]: date_spec = {'nominal': [1, 2], 'actual': [1, 3]}

In [106]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec)

In [107]: df
Out[107]:
    nominal  actual    0
0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD  0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD  0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59

It is important to remember that if multiple text columns are to be parsed into a single date column, then a new column
is prepended to the data. The `index_col` specification is based off of this new set of columns rather than the original
data columns:

```python
In [108]: date_spec = {'nominal': [1, 2], 'actual': [1, 3]}

In [109]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec,
.....:                   index_col=0)  # index is the nominal column
.....:

In [110]: df
Out[110]:

   nominal  actual       0       4
0  1999-01-27 19:00:00 1999-01-27 18:56:00 KORD  0.81
1  1999-01-27 20:00:00 1999-01-27 19:56:00 KORD  0.01
2  1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
3  1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
4  1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
5  1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59
```

**Note:** If a column or index contains an unparsable date, the entire column or index will be returned unaltered as an
object data type. For non-standard datetime parsing, use `to_datetime()` after `pd.read_csv`.

**Note:** `read_csv` has a fast_path for parsing datetime strings in iso8601 format, e.g. “2000-01-01T00:01:02+00:00”
and similar variations. If you can arrange for your data to store datetimes in this format, load times will be significantly
faster, ~20x has been observed.

**Date parsing functions**

Finally, the parser allows you to specify a custom `date_parser` function to take full advantage of the flexibility of
the date parsing API:

```python
In [111]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec,
.....:                   date_parser=pd.io.date_converters.parse_date_time)
.....:

In [112]: df
Out[112]:

   nominal  actual       0       4
0  1999-01-27 19:00:00 1999-01-27 18:56:00 KORD  0.81
1  1999-01-27 20:00:00 1999-01-27 19:56:00 KORD  0.01
2  1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
3  1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
4  1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
5  1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59
```

Pandas will try to call the `date_parser` function in three different ways. If an exception is raised, the next one is
tried:

1. `date_parser` is first called with one or more arrays as arguments, as defined using `parse_dates` (e.g.,
   `date_parser([2013, 2013], [1, 2])).`
2. If #1 fails, date_parser is called with all the columns concatenated row-wise into a single array (e.g., date_parser(['2013 1', '2013 2'])).

3. If #2 fails, date_parser is called once for every row with one or more string arguments from the columns indicated with parse_dates (e.g., date_parser('2013', '1') for the first row, date_parser('2013', '2') for the second, etc.).

Note that performance-wise, you should try these methods of parsing dates in order:

1. Try to infer the format using infer_datetime_format=True (see section below).

2. If you know the format, use pd.to_datetime(): date_parser=lambda x: pd.to_datetime(x, format=...).

3. If you have a really non-standard format, use a custom date_parser function. For optimal performance, this should be vectorized, i.e., it should accept arrays as arguments.

You can explore the date parsing functionality in date_converters.py and add your own. We would love to turn this module into a community supported set of date/time parsers. To get you started, date_converters.py contains functions to parse dual date and time columns, year/month/day columns, year/month/day/hour/minute/second columns. It also contains a generic_parser function so you can curry it with a function that deals with a single date rather than the entire array.

Parsing a CSV with mixed timezones

Pandas cannot natively represent a column or index with mixed timezones. If your CSV file contains columns with a mixture of timezones, the default result will be an object-dtype column with strings, even with parse_dates.

```
In [113]: content = """\n.....: a
.....: 2000-01-01T00:00:00+05:00
.....: 2000-01-01T00:00:00+06:00"
.....:

In [114]: df = pd.read_csv(StringIO(content), parse_dates=['a'])

In [115]: df['a']
Out[115]:
0  2000-01-01 00:00:00+05:00
1  2000-01-01 00:00:00+06:00
Name: a, dtype: object
```

To parse the mixed-timezone values as a datetime column, pass a partially-applied to_datetime() with utc=True as the date_parser.

```
In [116]: df = pd.read_csv(StringIO(content), parse_dates=['a'],
                           date_parser=lambda col: pd.to_datetime(col, utc=True))

In [117]: df['a']
Out[117]:
0  1999-12-31 19:00:00+00:00
1  1999-12-31 18:00:00+00:00
Name: a, dtype: datetime64[ns, UTC]
```
Inferring datetime format

If you have parse_dates enabled for some or all of your columns, and your datetime strings are all formatted the same way, you may get a large speed up by setting infer_datetime_format=True. If set, pandas will attempt to guess the format of your datetime strings, and then use a faster means of parsing the strings. 5-10x parsing speeds have been observed. pandas will fallback to the usual parsing if either the format cannot be guessed or the format that was guessed cannot properly parse the entire column of strings. So in general, infer_datetime_format should not have any negative consequences if enabled.

Here are some examples of datetime strings that can be guessed (All representing December 30th, 2011 at 00:00:00):

- “20111230”
- “2011/12/30”
- “20111230 00:00:00”
- “12/30/2011 00:00:00”
- “30/Dec/2011 00:00:00”
- “30/December/2011 00:00:00”

Note that infer_datetime_format is sensitive to dayfirst. With dayfirst=True, it will guess “01/12/2011” to be December 1st. With dayfirst=False (default) it will guess “01/12/2011” to be January 12th.

```python
# Try to infer the format for the index column
In [118]: df = pd.read_csv('foo.csv', index_col=0, parse_dates=True, 
                      ....: infer_datetime_format=True)

In [119]: df
```

<table>
<thead>
<tr>
<th>date</th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01</td>
<td>a</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2009-01-02</td>
<td>b</td>
<td>3</td>
<td>4</td>
</tr>
<tr>
<td>2009-01-03</td>
<td>c</td>
<td>4</td>
<td>5</td>
</tr>
</tbody>
</table>

International date formats

While US date formats tend to be MM/DD/YYYY, many international formats use DD/MM/YYYY instead. For convenience, a dayfirst keyword is provided:

```python
In [120]: print(open('tmp.csv').read())
```

date,value,cat
1/6/2000,5,a
2/6/2000,10,b
3/6/2000,15,c

```python
In [121]: pd.read_csv('tmp.csv', parse_dates=[0])
```

<table>
<thead>
<tr>
<th>date</th>
<th>value</th>
<th>cat</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-06</td>
<td>5</td>
<td>a</td>
</tr>
<tr>
<td>2000-02-06</td>
<td>10</td>
<td>b</td>
</tr>
<tr>
<td>2000-03-06</td>
<td>15</td>
<td>c</td>
</tr>
</tbody>
</table>

(continues on next page)
In [122]: pd.read_csv('tmp.csv', dayfirst=True, parse_dates=[0])
Out[122]:
           date  value  cat
0 2000-06-01       5    a
1 2000-06-02      10    b
2 2000-06-03      15    c

Specifying method for floating-point conversion

The parameter `float_precision` can be specified in order to use a specific floating-point converter during parsing with the C engine. The options are the ordinary converter, the high-precision converter, and the round-trip converter (which is guaranteed to round-trip values after writing to a file). For example:

```python
In [123]: val = '0.3066101993807095471566981359501369297504425048828125'
In [124]: data = 'a,b,c\n
1,2,\n'.format(val)
In [125]: abs(pd.read_csv(StringIO(data), engine='c',
       float_precision=None)['c'][0] - float(val))
   ....:
Out[125]: 1.1102230246251565e-16
In [126]: abs(pd.read_csv(StringIO(data), engine='c',
       float_precision='high')['c'][0] - float(val))
   ....:
Out[126]: 5.551115123125783e-17
In [127]: abs(pd.read_csv(StringIO(data), engine='c',
       float_precision='round_trip')['c'][0] - float(val))
   ....:
Out[127]: 0.0
```

Thousand separators

For large numbers that have been written with a thousands separator, you can set the `thousands` keyword to a string of length 1 so that integers will be parsed correctly:

By default, numbers with a thousands separator will be parsed as strings:

```python
In [128]: print(open('tmp.csv').read())
ID|level|category
Patient1|123,000|x
Patient2|23,000|y
Patient3|1,234,018|z
In [129]: df = pd.read_csv('tmp.csv', sep='|')
In [130]: df
Out[130]:
   ID     level category
0 Patient1  123,000    x
1 Patient2   23,000    y
2 Patient3 1,234,018    z
```

(continues on next page)
The thousands keyword allows integers to be parsed correctly:

```python
In [132]: print(open('tmp.csv').read())
ID|level|category
Patient1|123,000|x
Patient2|23,000|y
Patient3|1,234,018|z
```

```python
In [133]: df = pd.read_csv('tmp.csv', sep='|', thousands=',')
```

```python
In [134]: df
Out[134]:
          ID   level category
0  Patient1  123000       x
1  Patient2   23000       y
2  Patient3  1234018      z
```

```python
In [135]: df.level.dtype
Out[135]: dtype('int64')
```

**NA values**

To control which values are parsed as missing values (which are signified by NaN), specify a string in `na_values`. If you specify a list of strings, then all values in it are considered to be missing values. If you specify a number (a float, like 5.0 or an integer like 5), the corresponding equivalent values will also imply a missing value (in this case effectively [5.0, 5] are recognized as NaN).

To completely override the default values that are recognized as missing, specify `keep_default_na=False`.

The default NaN recognized values are `['-1.#IND', '1.#QNAN', '1.#IND', '-1.#QNAN', '#N/A N/A', '#N/A', 'N/A', 'null', 'NaN', '-NaN', 'nan', '-nan', '']`.

Let us consider some examples:

```python
pd.read_csv('path_to_file.csv', na_values=[5])
```

In the example above 5 and 5.0 will be recognized as NaN, in addition to the defaults. A string will first be interpreted as a numerical 5, then as a NaN.

```python
pd.read_csv('path_to_file.csv', keep_default_na=False, na_values=[''])
```

Above, only an empty field will be recognized as NaN.

```python
pd.read_csv('path_to_file.csv', keep_default_na=False, na_values=['"NA", "0"'])
```

Above, both NA and 0 as strings are NaN.

```python
pd.read_csv('path_to_file.csv', na_values=["Nope")
```

The default values, in addition to the string "Nope" are recognized as NaN.
Infinity

Inf like values will be parsed as np.inf (positive infinity), and -inf as -np.inf (negative infinity). These will ignore the case of the value, meaning Inf, will also be parsed as np.inf.

Returning Series

Using the squeeze keyword, the parser will return output with a single column as a Series:

```python
In [136]: print(open('tmp.csv').read())
level
Patient1,123000
Patient2,23000
Patient3,1234018

In [137]: output = pd.read_csv('tmp.csv', squeeze=True)

In [138]: output
Out[138]:
Patient1 123000
Patient2 23000
Patient3 1234018
Name: level, dtype: int64

In [139]: type(output)
Out[139]: pandas.core.series.Series
```

Boolean values

The common values True, False, TRUE, and FALSE are all recognized as boolean. Occasionally you might want to recognize other values as being boolean. To do this, use the true_values and false_values options as follows:

```python
In [140]: data = ('a,b,c
.....:  '1,Yes,2
.....:  '3,No,4')

In [141]: print(data)
a,b,c
1,Yes,2
3,No,4

In [142]: pd.read_csv(StringIO(data))
Out[142]:
a b c
0 1  Yes  2
1 3  No  4

In [143]: pd.read_csv(StringIO(data), true_values=['Yes'], false_values=['No'])
Out[143]:
a b c
0 1  True  2
1 3  False  4
```
Handling “bad” lines

Some files may have malformed lines with too few fields or too many. Lines with too few fields will have NA values filled in the trailing fields. Lines with too many fields will raise an error by default:

```python
In [144]: data = ('a,b,c
.....:
.....:
.....:
.....:
.....:

In [145]: pd.read_csv(StringIO(data))
```

```

(continues on next page)
Dialect

The dialect keyword gives greater flexibility in specifying the file format. By default it uses the Excel dialect but you can specify either the dialect name or a csv.Dialect instance.

Suppose you had data with unenclosed quotes:

In [146]: print(data)
label1,label2,label3
index1,"a,c,e
index2,b,d,f

By default, read_csv uses the Excel dialect and treats the double quote as the quote character, which causes it to fail when it finds a newline before it finds the closing double quote.

We can get around this using dialect:

In [147]: import csv
In [148]: dia = csv.excel()
In [149]: dia.quoting = csv.QUOTE_NONE
In [150]: pd.read_csv(StringIO(data), dialect=dia)
Out[150]:
        label1  label2  label3
index1    a      c      e
index2    b      d      f

All of the dialect options can be specified separately by keyword arguments:
Another common dialect option is skipinitialspace, to skip any whitespace after a delimiter:

```
In [153]: data = 'a, b, c\n1, 2, 3\n4, 5, 6'
In [154]: print(data)
a, b, c
1, 2, 3
4, 5, 6
In [155]: pd.read_csv(StringIO(data), skipinitialspace=True)
Out[155]:
a b c
0 1 2 3
1 4 5 6
```

The parsers make every attempt to “do the right thing” and not be fragile. Type inference is a pretty big deal. If a column can be coerced to integer dtypes without altering the contents, the parser will do so. Any non-numeric columns will come through as object dtypes as with the rest of pandas objects.

### Quotes and Escape Characters

Quotes (and other escape characters) in embedded fields can be handled in any number of ways. One way is to use backslashes; to properly parse this data, you should pass the escapechar option:

```
In [156]: data = 'a,b\nhello, "Bob", nice to see you",5'
In [157]: print(data)
a, b
"hello, "Bob", nice to see you",5
In [158]: pd.read_csv(StringIO(data), escapechar='\')
Out[158]:
a b
0 hello, "Bob", nice to see you 5
```

### Files with fixed width columns

While `read_csv()` reads delimited data, the `read_fwf()` function works with data files that have known and fixed column widths. The function parameters to `read_fwf` are largely the same as `read_csv` with two extra parameters, and a different usage of the delimiter parameter:

- **cols**: A list of pairs (tuples) giving the extents of the fixed-width fields of each line as half-open intervals (i.e., [from, to]). String value “infer” can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data. Default behavior, if not specified, is to infer.
- **widths**: A list of field widths which can be used instead of ‘cols’ if the intervals are contiguous.
• delimiter: Characters to consider as filler characters in the fixed-width file. Can be used to specify the filler
character of the fields if it is not spaces (e.g., ‘~’).

Consider a typical fixed-width data file:

```python
In [159]: print(open('bar.csv').read())
id8141 360.242940 149.910199 11950.7
id1594 444.953632 166.985655 11788.4
id1849 364.136849 183.628767 11806.2
id1230 413.836124 184.375703 11916.8
id1948 502.953953 173.237159 12468.3
```

In order to parse this file into a DataFrame, we simply need to supply the column specifications to the `read_fwf`
function along with the file name:

```python
# Column specifications are a list of half-intervals
In [160]: colspecs = [(0, 6), (8, 20), (21, 33), (34, 43)]

In [161]: df = pd.read_fwf('bar.csv', colspecs=colspecs, header=None, index_col=0)
```

```plaintext
In [162]: df
Out[162]:
   0  1  2  3
0  id8141 360.242940 149.910199 11950.7
1  id1594 444.953632 166.985655 11788.4
2  id1849 364.136849 183.628767 11806.2
3  id1230 413.836124 184.375703 11916.8
4  id1948 502.953953 173.237159 12468.3
```

Note how the parser automatically picks column names X.<column number> when header=None argument is spec-
ified. Alternatively, you can supply just the column widths for contiguous columns:

```python
# Widths are a list of integers
In [163]: widths = [6, 14, 13, 10]

In [164]: df = pd.read_fwf('bar.csv', widths=widths, header=None)
```

```plaintext
In [165]: df
Out[165]:
   0  1  2  3
0  id8141 360.242940 149.910199 11950.7
1  id1594 444.953632 166.985655 11788.4
2  id1849 364.136849 183.628767 11806.2
3  id1230 413.836124 184.375703 11916.8
4  id1948 502.953953 173.237159 12468.3
```

The parser will take care of extra white spaces around the columns so it’s ok to have extra separation between the
columns in the file.

By default, `read_fwf` will try to infer the file's colspecs by using the first 100 rows of the file. It can do it
only in cases when the columns are aligned and correctly separated by the provided delimiter (default delimiter is
whitespace).

```python
In [166]: df = pd.read_fwf('bar.csv', header=None, index_col=0)
```

```plaintext
In [167]: df
Out[167]:
   0  1  2  3
0  id8141 360.242940 149.910199 11950.7
1  id1594 444.953632 166.985655 11788.4
2  id1849 364.136849 183.628767 11806.2
3  id1230 413.836124 184.375703 11916.8
4  id1948 502.953953 173.237159 12468.3
```
read_fwf supports the dtype parameter for specifying the types of parsed columns to be different from the inferred type.

```python
In [168]: pd.read_fwf('bar.csv', header=None, index_col=0).dtypes
Out[168]:
1 float64
2 float64
3 float64
dtype: object

In [169]: pd.read_fwf('bar.csv', header=None, dtype={2: 'object'}).dtypes
Out[169]:
0 object
1 float64
2 object
3 float64
dtype: object
```

Indexes

Files with an “implicit” index column

Consider a file with one less entry in the header than the number of data column:

```python
In [170]: print(open('foo.csv').read())
A,B,C
20090101,a,1,2
20090102,b,3,4
20090103,c,4,5
```

In this special case, read_csv assumes that the first column is to be used as the index of the DataFrame:

```python
In [171]: pd.read_csv('foo.csv')
Out[171]:
     A  B  C
20090101 a 1 2
20090102 b 3 4
20090103 c 4 5
```

Note that the dates weren’t automatically parsed. In that case you would need to do as before:

```python
In [172]: df = pd.read_csv('foo.csv', parse_dates=True)

In [173]: df.index
Out[173]: DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype='datetime64[ns]', freq=None)
```
### Reading an index with a MultiIndex

Suppose you have data indexed by two columns:

```
In [174]: print(open('data/mindex_ex.csv').read())
year,indiv,zit,xit
1977,"A",1.2,.6
1977,"B",1.5,.5
1977,"C",1.7,.8
1978,"A",.2,.06
1978,"B",.7,.2
1978,"C",.8,.3
1978,"D",.9,.5
1978,"E",1.4,.9
1979,"C",.2,.15
1979,"D",.14,.05
1979,"E",.5,.15
1979,"F",1.2,.5
1979,"G",3.4,1.9
1979,"H",5.4,2.7
1979,"I",6.4,1.2
```

The `index_col` argument to `read_csv` can take a list of column numbers to turn multiple columns into a MultiIndex for the index of the returned object:

```
In [175]: df = pd.read_csv("data/mindex_ex.csv", index_col=[0, 1])
```

```
In [176]: df
Out[176]:
    zit  xit
year indiv
1977 A  1.20  0.60
      B  1.50  0.50
      C  1.70  0.80
1978 A  0.20  0.06
      B  0.70  0.20
      C  0.80  0.30
      D  0.90  0.50
      E  1.40  0.90
1979 C  0.20  0.15
      D  0.14  0.05
      E  0.50  0.15
      F  1.20  0.50
      G  3.40  1.90
      H  5.40  2.70
      I  6.40  1.20
```

```
In [177]: df.loc[1978]
Out[177]:
    zit  xit
indiv
A  0.2  0.06
B  0.7  0.20
C  0.8  0.30
D  0.9  0.50
E  1.4  0.90
```
Reading columns with a MultiIndex

By specifying list of row locations for the `header` argument, you can read in a MultiIndex for the columns. Specifying non-consecutive rows will skip the intervening rows.

```python
In [178]: from pandas._testing import makeCustomDataframe as mkdf

In [179]: df = mkdf(5, 3, r_idx_nlevels=2, c_idx_nlevels=4)

In [180]: df.to_csv('mi.csv')

In [181]: print(open('mi.csv').read())
C0,,C_l0_g0,C_l0_g1,C_l0_g2
C1,,C_l1_g0,C_l1_g1,C_l1_g2
C2,,C_l2_g0,C_l2_g1,C_l2_g2
C3,,C_l3_g0,C_l3_g1,C_l3_g2
R0,R1,,
R_l0_g0,R_l1_g0,R0C0,R0C1,R0C2
R_l0_g1,R_l1_g1,R1C0,R1C1,R1C2
R_l0_g2,R_l1_g2,R2C0,R2C1,R2C2
R_l0_g3,R_l1_g3,R3C0,R3C1,R3C2
R_l0_g4,R_l1_g4,R4C0,R4C1,R4C2

In [182]: pd.read_csv('mi.csv', header=[0, 1, 2, 3], index_col=[0, 1])
Out[182]:
C0   C_l0_g0   C_l0_g1   C_l0_g2
C1   C_l1_g0   C_l1_g1   C_l1_g2
C2   C_l2_g0   C_l2_g1   C_l2_g2
C3   C_l3_g0   C_l3_g1   C_l3_g2
R0   R1  
R_l0_g0 R_l1_g0  R0C0 R0C1 R0C2
R_l0_g1 R_l1_g1  R1C0 R1C1 R1C2
R_l0_g2 R_l1_g2  R2C0 R2C1 R2C2
R_l0_g3 R_l1_g3  R3C0 R3C1 R3C2
R_l0_g4 R_l1_g4  R4C0 R4C1 R4C2

read_csv is also able to interpret a more common format of multi-columns indices.

```python
In [183]: print(open('mi2.csv').read())
,a,a,a,b,c,c
,q,r,s,t,u,v
one,1,2,3,4,5,6
two,7,8,9,10,11,12

In [184]: pd.read_csv('mi2.csv', header=[0, 1], index_col=0)
Out[184]:

```

Note: If an `index_col` is not specified (e.g. you don’t have an index, or wrote it with `df.to_csv(..., index=False)`), then any names on the columns index will be lost.
Automatically “sniffing” the delimiter

read_csv is capable of inferring delimited (not necessarily comma-separated) files, as pandas uses the csv.Sniffer class of the csv module. For this, you have to specify sep=None.

```
In [185]: print(open('tmp2.sv').read())
:0:1:2:3
0:0.4691122999071863:-0.2826833443286633:-1.5090585031735124:-1.1356327310171934

```

Reading multiple files to create a single DataFrame

It’s best to use concat() to combine multiple files. See the cookbook for an example.

Iterating through files chunk by chunk

Suppose you wish to iterate through a (potentially very large) file lazily rather than reading the entire file into memory, such as the following:

```
In [187]: print(open('tmp.sv').read())
|0|1|2|3|
0|0.4691122999071863|-0.2826833443286633|-1.5090585031735124|-1.1356327310171934
1|1.2121120250208506|-0.17321464905330858|0.11920871129693428|-1.0442359662799567
2|-0.8618489633477999|-2.1045692188948086|-0.4949292740687813|1.071803807037338
3|-0.721551622443669|-0.7067711336300845|-1.0395749851146963|0.2718598855428298
4|-0.42497232978883753:0.567020349793672:0.2762320192771873:-0.874006912859915
5|-0.6736897080883706:0.1136484096888855:-1.4784265524372235:0.5249876671147047
6:0.4047052186802365:0.5770459859204836:-1.7150021661146375:-1.0392684835147725
7:-0.370468582364464:1.1578922506419993:1.34311812731667:0.844885141248841
8:1.0757897837155533:-0.10904997528022223:1.6435630703622064:-1.4693879595399115
9:0.3570205643309086:-0.6746001037299882:-1.776903716971867:-0.9689138124473498
```

(continues on next page)
In [188]: table = pd.read_csv('tmp.sv', sep='|')

In [189]: table
Out[189]:
    Unnamed: 0  0  1  2  3
0      0  0.469112 -0.282863 -1.509059 -1.135632
1      1  1.212112 -0.173215  0.119209 -1.044236
2      2 -0.861849 -2.104569 -0.494929  1.071804
3      3  0.721555 -0.706771 -1.039575  0.271860
4      4 -0.424972  0.567020  0.276232 -1.087401
5      5 -0.673690  0.113648 -1.478427  0.524988
6      6  0.404705  0.577046 -1.715002 -1.039268
7      7 -0.370647 -1.157892 -1.344312  0.844885
8      8  1.075770 -0.109050  1.643563 -1.469388
9      9  0.357021 -0.674600 -1.776904 -0.968914

By specifying a chunksize to read_csv, the return value will be an iterable object of type TextFileReader:

In [190]: reader = pd.read_csv('tmp.sv', sep='|', chunksize=4)

In [191]: reader
Out[191]: <pandas.io.parsers.TextFileReader at 0x7fbfab4640d0>

In [192]: for chunk in reader:
   ....:     print(chunk)
   ....:     Unnamed: 0  0  1  2  3
0 0  0.469112 -0.282863 -1.509059 -1.135632
1 1  1.212112 -0.173215  0.119209 -1.044236
2 2 -0.861849 -2.104569 -0.494929  1.071804
3 3  0.721555 -0.706771 -1.039575  0.271860
4 4 -0.424972  0.567020  0.276232 -1.087401
5 5 -0.673690  0.113648 -1.478427  0.524988
6 6  0.404705  0.577046 -1.715002 -1.039268
7 7 -0.370647 -1.157892 -1.344312  0.844885
8 8  1.075770 -0.109050  1.643563 -1.469388
9 9  0.357021 -0.674600 -1.776904 -0.968914

Specifying iterator=True will also return the TextFileReader object:

In [193]: reader = pd.read_csv('tmp.sv', sep='|', iterator=True)

In [194]: reader.get_chunk(5)
Out[194]:
    Unnamed: 0  0  1  2  3
0 0  0.469112 -0.282863 -1.509059 -1.135632
1 1  1.212112 -0.173215  0.119209 -1.044236
2 2 -0.861849 -2.104569 -0.494929  1.071804
3 3  0.721555 -0.706771 -1.039575  0.271860
4 4 -0.424972  0.567020  0.276232 -1.087401
Specifying the parser engine

Under the hood pandas uses a fast and efficient parser implemented in C as well as a Python implementation which is currently more feature-complete. Where possible pandas uses the C parser (specified as `engine='c'`), but may fall back to Python if C-unsupported options are specified. Currently, C-unsupported options include:

- `sep` other than a single character (e.g. regex separators)
- `skipfooter`
- `sep=None` with `delim_whitespace=False`

Specifying any of the above options will produce a `ParserWarning` unless the python engine is selected explicitly using `engine='python'`.

Reading remote files

You can pass in a URL to a CSV file:

```python
df = pd.read_csv('https://download.bls.gov/pub/time.series/cu/cu.item',
                 sep='\t')
```

S3 URLs are handled as well but require installing the S3Fs library:

```python
df = pd.read_csv('s3://pandas-test/tips.csv')
```

If your S3 bucket requires credentials you will need to set them as environment variables or in the `~/.aws/credentials` config file, refer to the S3Fs documentation on credentials.

Writing out data

Writing to CSV format

The `Series` and `DataFrame` objects have an instance method `to_csv` which allows storing the contents of the object as a comma-separated-values file. The function takes a number of arguments. Only the first is required.

- `path_or_buf`: A string path to the file to write or a file object. If a file object it must be opened with `newline=''
- `sep`: Field delimiter for the output file (default ‘,’)
- `na_rep`: A string representation of a missing value (default ‘’)
- `float_format`: Format string for floating point numbers
- `columns`: Columns to write (default None)
- `header`: Whether to write out the column names (default True)
- `index`: whether to write row (index) names (default True)
- `index_label`: Column label(s) for index column(s) if desired. If None (default), and `header` and `index` are True, then the index names are used. (A sequence should be given if the `DataFrame` uses MultiIndex).
- `mode`: Python write mode, default ‘w’
- `encoding`: a string representing the encoding to use if the contents are non-ASCII, for Python versions prior to 3
- `line_terminator`: Character sequence denoting line end (default `os.linesep`)
• **quoting**: Set quoting rules as in csv module (default csv.QUOTE_MINIMAL). Note that if you have set a *float_format* then floats are converted to strings and csv.QUOTE_NONNUMERIC will treat them as non-numeric

• **quotechar**: Character used to quote fields (default ‘”’)

• **doublequote**: Control quoting of quotechar in fields (default True)

• **escapechar**: Character used to escape *sep* and *quotechar* when appropriate (default None)

• **chunksize**: Number of rows to write at a time

• **date_format**: Format string for datetime objects

### Writing a formatted string

The DataFrame object has an instance method `to_string` which allows control over the string representation of the object. All arguments are optional:

- **buf** default None, for example a StringIO object
- **columns** default None, which columns to write
- **col_space** default None, minimum width of each column.
- **na_rep** default NaN, representation of NA value
- **formatters** default None, a dictionary (by column) of functions each of which takes a single argument and returns a formatted string
- **float_format** default None, a function which takes a single (float) argument and returns a formatted string; to be applied to floats in the DataFrame.
- **sparsify** default True, set to False for a DataFrame with a hierarchical index to print every MultiIndex key at each row.
- **index_names** default True, will print the names of the indices
- **index** default True, will print the index (ie, row labels)
- **header** default True, will print the column labels
- **justify** default left, will print column headers left- or right-justified

The Series object also has a `to_string` method, but with only the *buf*, *na_rep*, *float_format* arguments. There is also a *length* argument which, if set to True, will additionally output the length of the Series.

### 2.4.2 JSON

Read and write JSON format files and strings.
Writing JSON

A Series or DataFrame can be converted to a valid JSON string. Use `to_json` with optional parameters:

- **path_or_buf**: the pathname or buffer to write the output This can be None in which case a JSON string is returned
- **orient**:
  - **Series**:
    - default is index
    - allowed values are {split, records, index}
  - **DataFrame**:
    - default is columns
    - allowed values are {split, records, index, columns, values, table}

The format of the JSON string

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>split</td>
<td>dict like {index -&gt; [index], columns -&gt; [columns], data -&gt; [values]}</td>
</tr>
<tr>
<td>records</td>
<td>list like [[column -&gt; value], ..., [column -&gt; value]]</td>
</tr>
<tr>
<td>index</td>
<td>dict like {index -&gt; [column -&gt; value]}</td>
</tr>
<tr>
<td>columns</td>
<td>dict like {column -&gt; [index -&gt; value]}</td>
</tr>
<tr>
<td>values</td>
<td>just the values array</td>
</tr>
</tbody>
</table>

- **date_format**: string, type of date conversion, ‘epoch’ for timestamp, ‘iso’ for ISO8601.
- **double_precision**: The number of decimal places to use when encoding floating point values, default 10.
- **force_ascii**: force encoded string to be ASCII, default True.
- **date_unit**: The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’ or ‘ns’ for seconds, milliseconds, microseconds and nanoseconds respectively. Default ‘ms’.
- **default_handler**: The handler to call if an object cannot otherwise be converted to a suitable format for JSON. Takes a single argument, which is the object to convert, and returns a serializable object.
- **lines**: If records orient, then will write each record per line as json.

Note NaN’s, NaT’s and None will be converted to null and datetime objects will be converted based on the date_format and date_unit parameters.

```python
In [195]: dfj = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))
In [196]: json = dfj.to_json()
In [197]: json
Out[197]: '{"A":{"0":-1.2945235903,"1":0.2766617129,"2":-0.0139597524,"3":-0.0061535699,"4":0.8957173022},"B":{"0":0.4137381054,"1":-0.472034511,"2":-0.3625429925,"3":-0.923060654,"4":0.8052440254}}'
```
### Orient options

There are a number of different options for the format of the resulting JSON file / string. Consider the following 

<table>
<thead>
<tr>
<th>DataFrames and Series</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>In [198]:</strong> dfjo = pd.DataFrame(dict(A=range(1, 4), B=range(4, 7), C=range(7, 10)), columns=list('ABC'), index=list('xyz'))</td>
</tr>
<tr>
<td><strong>Out [199]:</strong></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>x</td>
</tr>
<tr>
<td>y</td>
</tr>
<tr>
<td>z</td>
</tr>
<tr>
<td><strong>In [200]:</strong> sjo = pd.Series(dict(x=15, y=16, z=17), name='D')</td>
</tr>
<tr>
<td><strong>Out [201]:</strong></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>Name: D, dtype: int64</td>
</tr>
</tbody>
</table>

**Column oriented** (the default for DataFrame) serializes the data as nested JSON objects with column labels acting as the primary index:

<table>
<thead>
<tr>
<th>DataFrames and Series</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>In [202]:</strong> dfjo.to_json(orient=&quot;columns&quot;)</td>
</tr>
<tr>
<td><strong>Out [202]:</strong> '{&quot;A&quot;:{&quot;x&quot;:1,&quot;y&quot;:2,&quot;z&quot;:3},&quot;B&quot;:{&quot;x&quot;:4,&quot;y&quot;:5,&quot;z&quot;:6},&quot;C&quot;:{&quot;x&quot;:7,&quot;y&quot;:8,&quot;z&quot;:9}}'</td>
</tr>
</tbody>
</table>

# Not available for Series

**Index oriented** (the default for Series) similar to column oriented but the index labels are now primary:

<table>
<thead>
<tr>
<th>DataFrames and Series</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>In [203]:</strong> dfjo.to_json(orient=&quot;index&quot;)</td>
</tr>
<tr>
<td><strong>In [204]:</strong> sjo.to_json(orient=&quot;index&quot;)</td>
</tr>
<tr>
<td><strong>Out [204]:</strong> '{&quot;x&quot;:15,&quot;y&quot;:16,&quot;z&quot;:17}</td>
</tr>
</tbody>
</table>

**Record oriented** serializes the data to a JSON array of column -> value records, index labels are not included. This is useful for passing DataFrame data to plotting libraries, for example the JavaScript library d3.js:

<table>
<thead>
<tr>
<th>DataFrames and Series</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>In [205]:</strong> dfjo.to_json(orient=&quot;records&quot;)</td>
</tr>
<tr>
<td><strong>In [206]:</strong> sjo.to_json(orient=&quot;records&quot;)</td>
</tr>
<tr>
<td><strong>Out [206]:</strong> '[15,16,17]</td>
</tr>
</tbody>
</table>

**Value oriented** is a bare-bones option which serializes to nested JSON arrays of values only, column and index labels are not included:

<table>
<thead>
<tr>
<th>DataFrames and Series</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>In [207]:</strong> dfjo.to_json(orient=&quot;values&quot;)</td>
</tr>
<tr>
<td><strong>Out [207]:</strong> '[[1,4,7],[2,5,8],[3,6,9]]'</td>
</tr>
<tr>
<td># Not available for Series</td>
</tr>
</tbody>
</table>

2.4. IO tools (text, CSV, HDF5, …)
Split oriented serializes to a JSON object containing separate entries for values, index and columns. Name is also
included for Series:

```python
In [208]: dfjo.to_json(orient="split")
Out[208]: '{"columns": ["A", "B", "C"], "index": ["x", "y", "z"], 
"data": [[1, 4, 7], [2, 5, 8], [3, 6, 9]]}
```

```python
In [209]: sjo.to_json(orient="split")
Out[209]: '{"name": "D", "index": ["x", "y", "z"], "data": [15, 16, 17]}'
```

Table oriented serializes to the JSON Table Schema, allowing for the preservation of metadata including but not
limited to dtypes and index names.

Note: Any orient option that encodes to a JSON object will not preserve the ordering of index and column labels
during round-trip serialization. If you wish to preserve label ordering use the split option as it uses ordered containers.

Date handling

Writing in ISO date format:

```python
In [210]: dfd = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))
In [211]: dfd['date'] = pd.Timestamp('20130101')
In [212]: dfd = dfd.sort_index(1, ascending=False)
In [213]: json = dfd.to_json(date_format='iso')
In [214]: json
Out[214]: '{"date": {"0": "2013-01-01T00:00:00.000Z", "1": "2013-01-01T00:00:00.000Z", "2": 
"2013-01-01T00:00:00.000Z", "3": "2013-01-01T00:00:00.000Z", "4": "2013-01-01T00:00.000Z"}, 
"B": {"0": 2.5656459463, "1": 1.3403088498, "2": -0.2261692849, "3": 0.8138502857, "4": 
-0.8273169356}, "A": {"0": -1.2064117817, "1": 1.4312559863, "2": -1.1702987971, "3": 0. 
4108345112, "4": 0.1320031703}}'
```

Writing in ISO date format, with microseconds:

```python
In [215]: json = dfd.to_json(date_format='iso', date_unit='us')
In [216]: json
Out[216]: '{"date": {"0": "2013-01-01T00:00:00.000000Z", "1": "2013-01-01T00:00:00.000000Z", "2": 
"2013-01-01T00:00:00.000000Z", "3": "2013-01-01T00:00:00.000000Z", "4": "2013-01-01T00:00.000000Z"}, 
"B": {"0": 2.5656459463, "1": 1.3403088498, "2": -0.2261692849, "3": 0.8138502857, "4": 
-0.8273169356}, "A": {"0": -1.2064117817, "1": 1.4312559863, "2": -1.1702987971, "3": 0. 
4108345112, "4": 0.1320031703}}'
```

Epoch timestamps, in seconds:

```python
In [217]: json = dfd.to_json(date_format='epoch', date_unit='s')
In [218]: json
Out[218]: '{"date": {"0": 1356998400, "1": 1356998400, "2": 1356998400, "3": 1356998400, "4": 
1356998400}, "B": {"0": 2.5656459463, "1": 1.3403088498, "2": -0.2261692849, "3": 0. 
8138502857, "4": -0.8273169356}, "A": {"0": -1.2064117817, "1": 1.4312559863, "2": -1. 
1702987971, "3": 0.4108345112, "4": 0.1320031703}}'
```
pandas: powerful Python data analysis toolkit, Release 1.1.5

Writing to a file, with a date index and a date column:
In [219]: dfj2 = dfj.copy()
In [220]: dfj2['date'] = pd.Timestamp('20130101')
In [221]: dfj2['ints'] = list(range(5))
In [222]: dfj2['bools'] = True
In [223]: dfj2.index = pd.date_range('20130101', periods=5)
In [224]: dfj2.to_json('test.json')
In [225]: with open('test.json') as fh:
.....:
print(fh.read())
.....:
{"A":{"1356998400000":-1.2945235903,"1357084800000":0.2766617129,"1357171200000":-0.
˓→0139597524,"1357257600000":-0.0061535699,"1357344000000":0.8957173022},"B":{
˓→"1356998400000":0.4137381054,"1357084800000":-0.472034511,"1357171200000":-0.
˓→3625429925,"1357257600000":-0.923060654,"1357344000000":0.8052440254},"date":{
˓→"1356998400000":1356998400000,"1357084800000":1356998400000,"1357171200000":
˓→1356998400000,"1357257600000":1356998400000,"1357344000000":1356998400000},"ints":{
˓→"1356998400000":0,"1357084800000":1,"1357171200000":2,"1357257600000":3,
˓→"1357344000000":4},"bools":{"1356998400000":true,"1357084800000":true,"1357171200000
˓→":true,"1357257600000":true,"1357344000000":true}}

Fallback behavior
If the JSON serializer cannot handle the container contents directly it will fall back in the following manner:
• if the dtype is unsupported (e.g. np.complex_) then the default_handler, if provided, will be called for
each value, otherwise an exception is raised.
• if an object is unsupported it will attempt the following:
– check if the object has defined a toDict method and call it. A toDict method should return a dict
which will then be JSON serialized.
– invoke the default_handler if one was provided.
– convert the object to a dict by traversing its contents.
OverflowError or give unexpected results.

However this will often fail with an

In general the best approach for unsupported objects or dtypes is to provide a default_handler. For example:
>>> DataFrame([1.0, 2.0, complex(1.0, 2.0)]).to_json()
RuntimeError: Unhandled numpy dtype 15

# raises

can be dealt with by specifying a simple default_handler:
In [226]: pd.DataFrame([1.0, 2.0, complex(1.0, 2.0)]).to_json(default_handler=str)
Out[226]: '{"0":{"0":"(1+0j)","1":"(2+0j)","2":"(1+2j)"}}'

2.4. IO tools (text, CSV, HDF5, . . . )

269


Reading JSON

Reading a JSON string to pandas object can take a number of parameters. The parser will try to parse a DataFrame if typ is not supplied or is None. To explicitly force Series parsing, pass typ=series

- filepath_or_buffer: a VALID JSON string or file handle / StringIO. The string could be a URL. Valid URL schemes include http, ftp, S3, and file. For file URLs, a host is expected. For instance, a local file could be file://localhost/path/to/table.json
- typ: type of object to recover (series or frame), default ‘frame’
- orient:
  Series:
  - default is index
  - allowed values are {split, records, index}
  DataFrame
  - default is columns
  - allowed values are {split, records, index, columns, values, table}

The format of the JSON string

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>split</td>
<td>dict like {index -&gt; [index], columns -&gt; [columns], data -&gt; [values]}</td>
</tr>
<tr>
<td>records</td>
<td>list like [{column -&gt; value}, ...., {column -&gt; value}]</td>
</tr>
<tr>
<td>index</td>
<td>dict like {index -&gt; {column -&gt; value}}</td>
</tr>
<tr>
<td>columns</td>
<td>dict like {column -&gt; {index -&gt; value}}</td>
</tr>
<tr>
<td>values</td>
<td>just the values array</td>
</tr>
<tr>
<td>table</td>
<td>adhering to the JSON Table Schema</td>
</tr>
</tbody>
</table>

- dtype: if True, infer dtypes, if a dict of column to dtype, then use those, if False, then don’t infer dtypes at all, default is True, apply only to the data.
- convert_axes: boolean, try to convert the axes to the proper dtypes, default is True
- convert_dates: a list of columns to parse for dates; If True, then try to parse date-like columns, default is True.
- keep_default_dates: boolean, default True. If parsing dates, then parse the default date-like columns.
- numpy: direct decoding to NumPy arrays. default is False; Supports numeric data only, although labels may be non-numeric. Also note that the JSON ordering MUST be the same for each term if numpy=True.
- precise_float: boolean, default False. Set to enable usage of higher precision (strtod) function when decoding string to double values. Default (False) is to use fast but less precise built-in functionality.
- date_unit: string, the timestamp unit to detect if converting dates. Default None. By default the timestamp precision will be detected, if this is not desired then pass one of ‘s’, ‘ms’, ‘us’ or ‘ns’ to force timestamp precision to seconds, milliseconds, microseconds or nanoseconds respectively.
- lines: reads file as one json object per line.
- encoding: The encoding to use to decode py3 bytes.
- chunksize: when used in combination with lines=True, return a JsonReader which reads in chunksize lines per iteration.
The parser will raise one of `ValueError/TypeError/AssertionError` if the JSON is not parseable.

If a non-default `orient` was used when encoding to JSON be sure to pass the same option here so that decoding produces sensible results, see `Orient Options` for an overview.

**Data conversion**

The default of `convert_axes=True, dtype=True, and convert_dates=True` will try to parse the axes, and all of the data into appropriate types, including dates. If you need to override specific dtypes, pass a dict to `dtype`. `convert_axes` should only be set to `False` if you need to preserve string-like numbers (e.g. ‘1’, ‘2’) in an axes.

**Note:** Large integer values may be converted to dates if `convert_dates=True` and the data and/or column labels appear ‘date-like’. The exact threshold depends on the `date_unit` specified. ‘date-like’ means that the column label meets one of the following criteria:

- it ends with '_at'
- it ends with '_time'
- it begins with 'timestamp'
- it is 'modified'
- it is 'date'

**Warning:** When reading JSON data, automatic coercing into dtypes has some quirks:

- an index can be reconstructed in a different order from serialization, that is, the returned order is not guaranteed to be the same as before serialization
- a column that was `float` data will be converted to `integer` if it can be done safely, e.g. a column of 1.
- bool columns will be converted to `integer` on reconstruction

Thus there are times where you may want to specify specific dtypes via the `dtype` keyword argument.

Reading from a JSON string:

```python
In  [227]: pd.read_json(json)
Out[227]:
    date          B         A
0 2013-01-01  2.565646  -1.206412
1 2013-01-01  1.340309   1.431256
2 2013-01-01  0.226169  -1.170299
3 2013-01-01  0.813850  -0.362543
4 2013-01-01  0.827317   0.132003
```

Reading from a file:

```python
In  [228]: pd.read_json('test.json')
Out[228]:
    A       B  date   ints  bools
 2013-01-01  -1.294524  0.413738 2013-01-01    0   True
 2013-01-02   0.276662  -0.472035 2013-01-01    1   True
 2013-01-03  -0.013960  -0.362543 2013-01-01    2   True
```

(continues on next page)
Don’t convert any data (but still convert axes and dates):

```
In [229]: pd.read_json('test.json', dtype=object).dtypes
Out[229]:
A   object
B   object
date object
ints object
bools object
dtype: object
```

Specify dtypes for conversion:

```
In [230]: pd.read_json('test.json', dtype={'A': 'float32', 'bools': 'int8'}).dtypes
Out[230]:
A   float32
B   float64
date    datetime64[ns]
ints     int64
bools    int8
dtype: object
```

Preserve string indices:

```
In [231]: si = pd.DataFrame(np.zeros((4, 4)), columns=list(range(4)),
                      index=[str(i) for i in range(4)])

In [232]: si
Out[232]:
        0  1  2  3
0  0.0  0.0  0.0  0.0
1  0.0  0.0  0.0  0.0
2  0.0  0.0  0.0  0.0
3  0.0  0.0  0.0  0.0

In [233]: si.index
Out[233]: Index(['0', '1', '2', '3'], dtype='object')

In [234]: si.columns
Out[234]: Int64Index([0, 1, 2, 3], dtype='int64')

In [235]: json = si.to_json()

In [236]: sij = pd.read_json(json, convert_axes=False)

In [237]: sij
Out[237]:
    0  1  2  3
0  0  0  0  0
1  0  0  0  0
2  0  0  0  0
3  0  0  0  0
```
Dates written in nanoseconds need to be read back in nanoseconds:

```
In [240]: json = dfj2.to_json(date_unit='ns')

# Try to parse timestamps as milliseconds -> Won't Work
In [241]: dfju = pd.read_json(json, date_unit='ms')

In [242]: dfju
Out[242]:
   A                B          date  ints  bools
0 -1.294524  0.413738 2013-01-01    0  True
1 0.276662 -0.472035 2013-01-01    1  True
2 -0.013960 -0.362543 2013-01-01    2  True
3 -0.006154 -0.923061 2013-01-01    3  True
4  0.895717  0.805244 2013-01-01    4  True
```

# Let pandas detect the correct precision
```
In [243]: dfju = pd.read_json(json)

In [244]: dfju
Out[244]:
   A                B          date  ints  bools
0 -1.294524  0.413738 2013-01-01    0  True
1 0.276662 -0.472035 2013-01-01    1  True
2 -0.013960 -0.362543 2013-01-01    2  True
3 -0.006154 -0.923061 2013-01-01    3  True
4  0.895717  0.805244 2013-01-01    4  True
```

# Or specify that all timestamps are in nanoseconds
```
In [245]: dfju = pd.read_json(json, date_unit='ns')

In [246]: dfju
Out[246]:
   A                B          date  ints  bools
0 -1.294524  0.413738 2013-01-01    0  True
1 0.276662 -0.472035 2013-01-01    1  True
2 -0.013960 -0.362543 2013-01-01    2  True
3 -0.006154 -0.923061 2013-01-01    3  True
4  0.895717  0.805244 2013-01-01    4  True
```
The Numpy parameter

Note: This param has been deprecated as of version 1.0.0 and will raise a FutureWarning.
This supports numeric data only. Index and columns labels may be non-numeric, e.g. strings, dates etc.

If `numpy=True` is passed to `read_json` an attempt will be made to sniff an appropriate dtype during deserialization and to subsequently decode directly to NumPy arrays, bypassing the need for intermediate Python objects.

This can provide speedups if you are deserialising a large amount of numeric data:

```
In [247]: randfloats = np.random.uniform(-100, 1000, 10000)
In [248]: randfloats.shape = (1000, 10)
In [249]: dffloats = pd.DataFrame(randfloats, columns=list('ABCDEFGHIJ'))
In [250]: jsonfloats = dffloats.to_json()

In [251]: %timeit pd.read_json(jsonfloats)
   9.7 ms +- 26.1 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [252]: %timeit pd.read_json(jsonfloats, numpy=True)
   6.72 ms +- 27.1 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

The speedup is less noticeable for smaller datasets:

```
In [253]: jsonfloats = dffloats.head(100).to_json()

In [254]: %timeit pd.read_json(jsonfloats)
   6.04 ms +- 24.1 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [255]: %timeit pd.read_json(jsonfloats, numpy=True)
   5.17 ms +- 17.8 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

Warning: Direct NumPy decoding makes a number of assumptions and may fail or produce unexpected output if these assumptions are not satisfied:

- data is numeric.
- data is uniform. The dtype is sniffed from the first value decoded. A ValueError may be raised, or incorrect output may be produced if this condition is not satisfied.
- labels are ordered. Labels are only read from the first container, it is assumed that each subsequent row / column has been encoded in the same order. This should be satisfied if the data was encoded using `to_json` but may not be the case if the JSON is from another source.
Normalization

pandas provides a utility function to take a dict or list of dicts and `normalize` this semi-structured data into a flat table.

```
In [256]: data = [{'id': 1, 'name': {'first': 'Coleen', 'last': 'Volk'}},
       ....:     {'id': 2, 'name': 'Faye Raker'}]

In [257]: pd.json_normalize(data)
Out[257]:
          id  name.first  name.last  name.given  name.family
0       1.0          Coleen     Volk          NaN          NaN
1       NaN          NaN        NaN          Mose        Regner
2       2.0          NaN        NaN          NaN           NaN

In [258]: data = [{'state': 'Florida',
          ....:         'shortname': 'FL',
          ....:         'info': {'governor': 'Rick Scott'},
          ....:         'county': [{'name': 'Dade', 'population': 12345},
          ....:                     {'name': 'Broward', 'population': 40000},
          ....:                     {'name': 'Palm Beach', 'population': 60000}]},
    ....:     {'state': 'Ohio',
          ....:         'shortname': 'OH',
          ....:         'info': {'governor': 'John Kasich'},
          ....:         'county': [{'name': 'Summit', 'population': 1234},
          ....:                     {'name': 'Cuyahoga', 'population': 1337}]}

In [259]: pd.json_normalize(data, 'county', ['state', 'shortname', ['info', 'governor']])
Out[259]:
           name population    state    shortname info.governor
0          Dade     12345  Florida    FL          Rick Scott
1         Broward     40000  Florida    FL          Rick Scott
2      Palm Beach     60000  Florida    FL          Rick Scott
3         Summit      1234  Ohio        OH          John Kasich
4     Cuyahoga        1337  Ohio        OH          John Kasich

The `max_level` parameter provides more control over which level to end normalization. With `max_level=1` the following snippet normalizes until 1st nesting level of the provided dict.

```
In [260]: data = [{'CreatedBy': {'Name': 'User001'},
          ....:         'Lookup': {'TextField': 'Some text',
          ....:                        'UserField': {'Id': 'ID001',
          ....:                                           'Name': 'Name001'}},
          ....:         'Image': {'a': 'b'}}]

In [261]: pd.json_normalize(data, max_level=1)
Out[261]:
          CreatedBy.Name  Lookup.TextField  Lookup.UserField  Image.a
0          User001          Some text          {'Id': 'ID001', 'Name': 'Name001'}          b
```
Line delimited json

pandas is able to read and write line-delimited json files that are common in data processing pipelines using Hadoop or Spark.

For line-delimited json files, pandas can also return an iterator which reads in chunksize lines at a time. This can be useful for large files or to read from a stream.

```python
In [262]: jsonl = '"
.....:
   "a": 1, "b": 2
.....:
   "a": 3, "b": 4
.....:
"

In [263]: df = pd.read_json(jsonl, lines=True)

In [264]: df
Out[264]:
a b
0 1 2
1 3 4

In [265]: df.to_json(orient='records', lines=True)
Out[265]: '{"a":1,"b":2}\n{"a":3,"b":4}'

# reader is an iterator that returns 'chunksize' lines each iteration
In [266]: reader = pd.read_json(StringIO(jsonl), lines=True, chunksize=1)

In [267]: reader
Out[267]: <pandas.io.json._json.JsonReader at 0x7fbfb296c220>

In [268]: for chunk in reader:
.....:   print(chunk)
.....:
Empty DataFrame
Columns: []
Index: []
a b
0 1 2
1 3 4
```

Table schema

Table Schema is a spec for describing tabular datasets as a JSON object. The JSON includes information on the field names, types, and other attributes. You can use the orient table to build a JSON string with two fields, schema and data.

```python
In [269]: df = pd.DataFrame({'A': [1, 2, 3],
                      'B': ['a', 'b', 'c'],
                      'C': pd.date_range('2016-01-01', freq='d', periods=3),
                      index=pd.Index(range(3), name='idx'))

In [270]: df
Out[270]:
```
The `schema` field contains the `fields` key, which itself contains a list of column name to type pairs, including the Index or MultiIndex (see below for a list of types). The `schema` field also contains a `primaryKey` field if the (Multi)index is unique.

The second field, `data`, contains the serialized data with the `records` orient. The index is included, and any datetimes are ISO 8601 formatted, as required by the Table Schema spec.

The full list of types supported are described in the Table Schema spec. This table shows the mapping from pandas types:

<table>
<thead>
<tr>
<th>Pandas type</th>
<th>Table Schema type</th>
</tr>
</thead>
<tbody>
<tr>
<td>int64</td>
<td>integer</td>
</tr>
<tr>
<td>float64</td>
<td>number</td>
</tr>
<tr>
<td>bool</td>
<td>boolean</td>
</tr>
<tr>
<td>datetime64[ns]</td>
<td>datetime</td>
</tr>
<tr>
<td>timedelta64[ns]</td>
<td>duration</td>
</tr>
<tr>
<td>categorical</td>
<td>any</td>
</tr>
<tr>
<td>object</td>
<td>str</td>
</tr>
</tbody>
</table>

A few notes on the generated table schema:

- The `schema` object contains a `pandas_version` field. This contains the version of pandas’ dialect of the schema, and will be incremented with each revision.

- All dates are converted to UTC when serializing. Even timezone naive values, which are treated as UTC with an offset of 0.

- datetimes with a timezone (before serializing), include an additional field `tz` with the time zone name (e.g. 'US/Central').
In [276]: build_table_schema(s_tz)
Out[276]:
{'fields': [{'name': 'index', 'type': 'integer'},
            {'name': 'values', 'type': 'datetime', 'tz': 'US/Central'}],
      'primaryKey': ['index'],
      'pandas_version': '0.20.0'}

• Periods are converted to timestamps before serialization, and so have the same behavior of being converted to
UTC. In addition, periods will contain and additional field freq with the period’s frequency, e.g. 'A-DEC'.

In [277]: s_per = pd.Series(1, index=pd.period_range('2016', freq='A-DEC',
...: periods=4))

In [278]: build_table_schema(s_per)
Out[278]:
{'fields': [{'name': 'index', 'type': 'datetime', 'freq': 'A-DEC'},
            {'name': 'values', 'type': 'integer'}],
      'primaryKey': ['index'],
      'pandas_version': '0.20.0'}

• Categoricals use the any type and an enum constraint listing the set of possible values. Additionally, an
ordered field is included:

In [279]: s_cat = pd.Series(pd.Categorical(['a', 'b', 'a']))
In [280]: build_table_schema(s_cat)
Out[280]:
{'fields': [{'name': 'index', 'type': 'integer'},
            {'name': 'values', 'type': 'any',
             'constraints': {'enum': ['a', 'b']},
             'ordered': False}],
      'primaryKey': ['index'],
      'pandas_version': '0.20.0'}

• A primaryKey field, containing an array of labels, is included if the index is unique:

In [281]: s_dupe = pd.Series([1, 2], index=[1, 1])
In [282]: build_table_schema(s_dupe)
Out[282]:
{'fields': [{'name': 'index', 'type': 'integer'},
            {'name': 'values', 'type': 'integer'}],
      'pandas_version': '0.20.0'}

• The primaryKey behavior is the same with MultiIndexes, but in this case the primaryKey is an array:

In [283]: s_multi = pd.Series(1, index=pd.MultiIndex.from_product([('a', 'b'),
...: (0, 1)]))

In [284]: build_table_schema(s_multi)
Out[284]:
(continues on next page)
The default naming roughly follows these rules:

- For series, the `object.name` is used. If that’s none, then the name is `values`
- For DataFrames, the stringified version of the column name is used
- For Index (not MultiIndex), `index.name` is used, with a fallback to `index` if that is None.
- For MultiIndex, `mi.names` is used. If any level has no name, then `level_<i>` is used.

New in version 0.23.0.

`read_json` also accepts `orient='table'` as an argument. This allows for the preservation of metadata such as dtypes and index names in a round-trippable manner.

```python
In [285]: df = pd.DataFrame({'foo': [1, 2, 3, 4],
....:                     'bar': ['a', 'b', 'c', 'd'],
....:                     'baz': pd.date_range('2018-01-01', freq='d', periods=4),
....:                     'qux': pd.Categorical(['a', 'b', 'c', 'c']),
....:                     }, index=pd.Index(range(4), name='idx'))

In [286]: df
Out[286]:
   foo  bar    baz         qux
idx  
0    1    a 2018-01-01    a
1    2    b 2018-01-02    b
2    3    c 2018-01-03    c
3    4    d 2018-01-04    c

In [287]: df.dtypes
Out[287]:
foo       int64
bar      object
baz  datetime64[ns]
qux    category
dtype: object

In [288]: df.to_json('test.json', orient='table')

In [289]: new_df = pd.read_json('test.json', orient='table')

In [290]: new_df
Out[290]:
   foo  bar    baz         qux
idx  
0    1    a 2018-01-01    a
1    2    b 2018-01-02    b
2    3    c 2018-01-03    c
3    4    d 2018-01-04    c

In [291]: new_df.dtypes
```

(continues on next page)
Please note that the literal string ‘index’ as the name of an `Index` is not round-trippable, nor are any names beginning with 'level_' within a `MultiIndex`. These are used by default in `DataFrame.to_json()` to indicate missing values and the subsequent read cannot distinguish the intent.

```python
In [292]: df.index.name = 'index'
In [293]: df.to_json('test.json', orient='table')
In [294]: new_df = pd.read_json('test.json', orient='table')
In [295]: print(new_df.index.name)
None
```

### 2.4.3 HTML

#### Reading HTML content

**Warning:** We highly encourage you to read the *HTML Table Parsing gotchas* below regarding the issues surrounding the BeautifulSoup4/html5lib/lxml parsers.

The top-level `read_html()` function can accept an HTML string/file/URL and will parse HTML tables into list of pandas `DataFrames`. Let’s look at a few examples.

**Note:** `read_html` returns a list of `DataFrame` objects, even if there is only a single table contained in the HTML content.

Read a URL with no options:

```python
In [296]: url = 'https://www.fdic.gov/bank/individual/failed/banklist.html'
In [297]: dfs = pd.read_html(url)
In [298]: dfs
Out[298]:
```

(continues on previous page)
Note: The data from the above URL changes every Monday so the resulting data above and the data below may be slightly different.

Read in the content of the file from the above URL and pass it to `read_html` as a string:

```python
In [299]: with open(file_path, 'r') as f:
    ....:     dfs = pd.read_html(f.read())
    ....:
In [300]: dfs
Out[300]:
<table>
<thead>
<tr>
<th>Bank Name</th>
<th>City ST</th>
<th>...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Banks of Wisconsin d/b/a Bank of Kenosha</td>
<td>Kenosha WI</td>
<td>...</td>
</tr>
<tr>
<td>Central Arizona Bank</td>
<td>Scottsdale AZ</td>
<td>...</td>
</tr>
<tr>
<td>Western State Bank</td>
<td>May 14, 2013</td>
<td>May 20, 2013</td>
</tr>
<tr>
<td>Sunrise Bank</td>
<td>Valdosta GA</td>
<td>...</td>
</tr>
<tr>
<td>Synovus Bank</td>
<td>May 10, 2013</td>
<td>May 21, 2013</td>
</tr>
<tr>
<td>Pisgah Community Bank</td>
<td>Asheville NC</td>
<td>...</td>
</tr>
<tr>
<td>Capital Bank, N.A.</td>
<td>May 10, 2013</td>
<td>May 14, 2013</td>
</tr>
<tr>
<td>Douglas County Bank</td>
<td>Douglasville GA</td>
<td>...</td>
</tr>
<tr>
<td>Hamilton State Bank</td>
<td>April 26, 2013</td>
<td>May 16, 2013</td>
</tr>
<tr>
<td>Superior Bank, FSB</td>
<td>Hinsdale IL</td>
<td>...</td>
</tr>
<tr>
<td>Malta National Bank</td>
<td>Malta OH</td>
<td>...</td>
</tr>
<tr>
<td>North Valley Bank</td>
<td>May 3, 2001</td>
<td>November 18, 2002</td>
</tr>
<tr>
<td>First Alliance Bank &amp; Trust Co.</td>
<td>Manchester NH</td>
<td>Southern New</td>
</tr>
<tr>
<td>Hampshire Bank &amp; Trust</td>
<td>February 2, 2001</td>
<td>February 18, 2003</td>
</tr>
<tr>
<td>National State Bank of Metropolis</td>
<td>Metropolis IL</td>
<td>...</td>
</tr>
<tr>
<td>Banterra Bank of Marion</td>
<td>December 14, 2000</td>
<td>March 17, 2005</td>
</tr>
<tr>
<td>Bank of Honolulu</td>
<td>Honolulu HI</td>
<td>...</td>
</tr>
<tr>
<td>Bank of the Orient</td>
<td>October 13, 2000</td>
<td>March 17, 2005</td>
</tr>
</tbody>
</table>
```

[505 rows x 7 columns]
You can even pass in an instance of `StringIO` if you so desire:

```
In [301]: with open(file_path, 'r') as f:
   ....:     sio = StringIO(f.read())
   ....:
In [302]: dfs = pd.read_html(sio)

In [303]: dfs
Out[303]:
[ Bank Name City ST ... ]
  Acquiring Institution Closing Date Updated Date
  0   Banks of Wisconsin d/b/a Bank of Kenosha Kenosha WI ...
  1 North Shore Bank, FSB May 31, 2013 May 31, 2013
  2   Central Arizona Bank Scottsdale AZ ...
  3  Western State Bank   May 14, 2013 May 20, 2013
  4   Sunrise Bank   Valdosta GA ...
  5 Synovus Bank May 10, 2013 May 21, 2013
  6   Capital Bank, N.A. May 10, 2013 May 14, 2013
  7   Pisgah Community Bank Asheville NC ...
  8  Hamilton State Bank   April 26, 2013 May 16, 2013
      ...         ...         ...     ...
  500 Superior Bank, FSB Hinsdale IL ...
  502 North Valley Bank May 3, 2001 November 18, 2002
  503 First Alliance Bank & Trust Co. Manchester NH ... Southern New...
  504 Hampshire Bank & Trust February 2, 2001 February 18, 2003
  505 National State Bank of Metropolis Metropolis IL ...
  506 Banterra Bank of Marion December 14, 2000 March 17, 2005
  507 Bank of the Orient October 13, 2000 March 17, 2005
[505 rows x 7 columns]
```

**Note:** The following examples are not run by the IPython evaluator due to the fact that having so many network-accessing functions slows down the documentation build. If you spot an error or an example that doesn’t run, please do not hesitate to report it over on pandas GitHub issues page.

Read a URL and match a table that contains specific text:

```
match = 'Metcalf Bank'
df_list = pd.read_html(url, match=match)
```

Specify a header row (by default `<th>` or `<td>` elements located within a `<thead>` are used to form the column index, if multiple rows are contained within `<thead>` then a MultiIndex is created); if specified, the header row is taken from the data minus the parsed header elements (`<th>` elements).

```
dfs = pd.read_html(url, header=0)
```

Specify an index column:

```
dfs = pd.read_html(url, index_col=0)
```

Specify a number of rows to skip:
dfs = pd.read_html(url, skiprows=0)

Specify a number of rows to skip using a list (range works as well):

dfs = pd.read_html(url, skiprows=range(2))

Specify an HTML attribute:

dfs1 = pd.read_html(url, attrs={'id': 'table'})
dfs2 = pd.read_html(url, attrs={'class': 'sortable'})
print(np.array_equal(dfs1[0], dfs2[0]))  # Should be True

Specify values that should be converted to NaN:

dfs = pd.read_html(url, na_values=['No Acquirer'])

Specify whether to keep the default set of NaN values:

dfs = pd.read_html(url, keep_default_na=False)

Specify converters for columns. This is useful for numerical text data that has leading zeros. By default columns that are numerical are cast to numeric types and the leading zeros are lost. To avoid this, we can convert these columns to strings.

url_mcc = 'https://en.wikipedia.org/wiki/Mobile_country_code'
dfs = pd.read_html(url_mcc, match='Telekom Albania', header=0,
   converters={'MNC': str})

Use some combination of the above:

dfs = pd.read_html(url, match='Metcalf Bank', index_col=0)

Read in pandas to_html output (with some loss of floating point precision):

df = pd.DataFrame(np.random.randn(2, 2))
s = df.to_html(float_format='\{0:.40g\}'.format)
dfin = pd.read_html(s, index_col=0)

The lxml backend will raise an error on a failed parse if that is the only parser you provide. If you only have a single parser you can provide just a string, but it is considered good practice to pass a list with one string if, for example, the function expects a sequence of strings. You may use:

dfs = pd.read_html(url, 'Metcalf Bank', index_col=0, flavor=['lxml'])

Or you could pass flavor='lxml' without a list:

dfs = pd.read_html(url, 'Metcalf Bank', index_col=0, flavor='lxml')

However, if you have bs4 and html5lib installed and pass None or ['lxml', 'bs4'] then the parse will most likely succeed. Note that as soon as a parse succeeds, the function will return.

dfs = pd.read_html(url, 'Metcalf Bank', index_col=0, flavor=['lxml', 'bs4'])

2.4. IO tools (text, CSV, HDF5, ...)
Writing to HTML files

`DataFrame` objects have an instance method `to_html` which renders the contents of the `DataFrame` as an HTML table. The function arguments are as in the method `to_string` described above.

**Note:** Not all of the possible options for `DataFrame.to_html` are shown here for brevity’s sake. See `to_html()` for the full set of options.

```python
In [304]: df = pd.DataFrame(np.random.randn(2, 2))

In [305]: df
Out[305]:
    0     1
0 -0.184744  0.496971
1 -0.856240  1.857977

In [306]: print(df.to_html())  # raw html
<table border="1" class="dataframe">
    <thead>
        <tr style="text-align: right;">
            <th></th>
            <th>0</th>
            <th>1</th>
        </tr>
    </thead>
    <tbody>
        <tr>
            <th>0</th>
            <td>-0.184744</td>
            <td>0.496971</td>
        </tr>
        <tr>
            <th>1</th>
            <td>-0.856240</td>
            <td>1.857977</td>
        </tr>
    </tbody>
</table>
```

HTML:

The columns argument will limit the columns shown:

```python
In [307]: print(df.to_html(columns=[0]))
<table border="1" class="dataframe">
    <thead>
        <tr style="text-align: right;">
            <th></th>
            <th>0</th>
        </tr>
    </thead>
    <tbody>
        <tr>
            <th>0</th>
            <td>-0.184744</td>
        </tr>
        <tr>
            <th>1</th>
            <td>-0.856240</td>
        </tr>
    </tbody>
</table>
```

(continues on next page)
HTML:

`float_format` takes a Python callable to control the precision of floating point values:

```
In [308]: print(df.to_html(float_format='{:0.10f}'.format))
```

```
etable border="1" class="dataframe"
<thead>
<tr style="text-align: right;">
 <th></th>
 <th>0</th>
 <th>1</th>
</tr>
</thead>
<tbody>
<tr>
 <td>0</td>
 <td>-0.1847438576</td>
 <td>0.4969711327</td>
</tr>
<tr>
 <td>1</td>
 <td>-0.8562396763</td>
 <td>1.8579766508</td>
</tr>
</tbody>
```

HTML:

`bold_rows` will make the row labels bold by default, but you can turn that off:

```
In [309]: print(df.to_html(bold_rows=False))
```

```
etable border="1" class="dataframe"
<thead>
<tr style="text-align: right;">
 <th></th>
 <th>0</th>
 <th>1</th>
</tr>
</thead>
<tbody>
<tr>
 <td>0</td>
 <td>-0.184744</td>
 <td>0.496971</td>
</tr>
<tr>
 <td>1</td>
 <td>-0.856240</td>
 <td>1.857977</td>
</tr>
```

(continues on next page)
The **classes** argument provides the ability to give the resulting HTML table CSS classes. Note that these classes are **appended** to the existing 'dataframe' class.

```python
In [310]: print(df.to_html(classes=['awesome_table_class', 'even_more_awesome_class']))
```

```html
<table border="1" class="dataframe awesome_table_class even_more_awesome_class">
<thead>
<tr style="text-align: right;">  
<th></th>  
<th>0</th>  
<th>1</th>  
</tr>  
</thead>
<tbody>
<tr>
<th>0</th>  
<td>-0.184744</td>  
<td>0.496971</td>  
</tr>
<tr>
<th>1</th>  
<td>-0.856240</td>  
<td>1.857977</td>  
</tr>
</tbody>
</table>
```

The **render_links** argument provides the ability to add hyperlinks to cells that contain URLs.

New in version 0.24.

```python
In [311]: url_df = pd.DataFrame({'name': ['Python', 'Pandas'],  
                           'url': ['https://www.python.org/', 'https://pandas.pydata.org']})

In [312]: print(url_df.to_html(render_links=True))
```

```html
<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;">  
<th></th>  
<th>name</th>  
<th>url</th>  
</tr>  
</thead>
<tbody>
<tr>
<th>0</th>  
<td>Python</td>  
<td><a href="https://www.python.org/" target="_blank">https://www.python.org/</a></td>  
</tr>
<tr>
<th>1</th>  
<td>Pandas</td>  
<td><a href="https://pandas.pydata.org/">https://pandas.pydata.org/</a></td>  
</tr>
</tbody>
</table>
```
Finally, the `escape` argument allows you to control whether the “<”, “>” and “&” characters escaped in the resulting HTML (by default it is `True`). So to get the HTML without escaped characters pass `escape=False`.

```
In [313]: df = pd.DataFrame({'a': list('&<>'), 'b': np.random.randn(3)})
```

**Escaped:**

```
In [314]: print(df.to_html())
```

```
<table border="1" class="dataframe">
<thead>
  <tr style="text-align: right;"> 
    <th></th>
    <th>a</th>
    <th>b
  </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>&amp;</td>
      <td>-0.474063</td>
    </tr>
    <tr>
      <th>1</th>
      <td>&lt;</td>
      <td>-0.230305</td>
    </tr>
    <tr>
      <th>2</th>
      <td>&gt;</td>
      <td>-0.400654</td>
    </tr>
  </tbody>
</table>
```

**Not escaped:**

```
In [315]: print(df.to_html(escape=False))
```

```
<table border="1" class="dataframe">
<thead>
  <tr style="text-align: right;"> 
    <th></th>
    <th>a</th>
    <th>b
  </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>&amp;</td>
      <td>-0.474063</td>
    </tr>
    <tr>
      <th>1</th>
      <td>&lt;</td>
      <td>-0.230305</td>
    </tr>
    <tr>
      <th>2</th>
      <td>&gt;</td>
      <td>-0.400654</td>
    </tr>
  </tbody>
</table>
```

(continues on next page)
### HTML Table Parsing Gotchas

There are some versioning issues surrounding the libraries that are used to parse HTML tables in the top-level pandas `io` function `read_html`.

#### Issues with lxml

- **Benefits**
  - lxml is very fast.
  - lxml requires Cython to install correctly.

- **Drawbacks**
  - lxml does not make any guarantees about the results of its parse *unless* it is given strictly valid markup.
  - In light of the above, we have chosen to allow you, the user, to use the lxml backend, but this backend will use html5lib if lxml fails to parse.
  - It is therefore **highly recommended** that you install both BeautifulSoup4 and html5lib, so that you will still get a valid result (provided everything else is valid) even if lxml fails.

#### Issues with BeautifulSoup4 using lxml as a backend

- The above issues hold here as well since BeautifulSoup4 is essentially just a wrapper around a parser backend.

#### Issues with BeautifulSoup4 using html5lib as a backend

- **Benefits**
  - html5lib is far more lenient than lxml and consequently deals with real-life markup in a much saner way rather than just, e.g., dropping an element without notifying you.
  - html5lib generates valid HTML5 markup from invalid markup automatically. This is extremely important for parsing HTML tables, since it guarantees a valid document. However, that does NOT mean that it is “correct”, since the process of fixing markup does not have a single definition.
  - html5lib is pure Python and requires no additional build steps beyond its own installation.

---

Note: Some browsers may not show a difference in the rendering of the previous two HTML tables.
• Drawbacks
  – The biggest drawback to using html5lib is that it is slow as molasses. However consider the fact that many tables on the web are not big enough for the parsing algorithm runtime to matter. It is more likely that the bottleneck will be in the process of reading the raw text from the URL over the web, i.e., IO (input-output). For very large tables, this might not be true.

2.4.4 Excel files

The read_excel() method can read Excel 2003 (.xls) files using the xlrd Python module. Excel 2007+ (.xlsx) files can be read using either xlrd or openpyxl. Binary Excel (.xlsb) files can be read using pyxlsb. The to_excel() instance method is used for saving a DataFrame to Excel. Generally the semantics are similar to working with csv data. See the cookbook for some advanced strategies.

Reading Excel files

In the most basic use-case, read_excel takes a path to an Excel file, and the sheet_name indicating which sheet to parse.

```python
# Returns a DataFrame
pd.read_excel('path_to_file.xls', sheet_name='Sheet1')
```

ExcelFile class

To facilitate working with multiple sheets from the same file, the ExcelFile class can be used to wrap the file and can be passed into read_excel. There will be a performance benefit for reading multiple sheets as the file is read into memory only once.

```python
xlsx = pd.ExcelFile('path_to_file.xls')
df = pd.read_excel(xlsx, 'Sheet1')
```

The ExcelFile class can also be used as a context manager.

```python
with pd.ExcelFile('path_to_file.xls') as xls:
    df1 = pd.read_excel(xls, 'Sheet1')
    df2 = pd.read_excel(xls, 'Sheet2')
```

The sheet_names property will generate a list of the sheet names in the file.

The primary use-case for an ExcelFile is parsing multiple sheets with different parameters:

```python
data = {}
# For when Sheet1's format differs from Sheet2
with pd.ExcelFile('path_to_file.xls') as xls:
    data['Sheet1'] = pd.read_excel(xls, 'Sheet1', index_col=None, na_values=['NA'])
    data['Sheet2'] = pd.read_excel(xls, 'Sheet2', index_col=1)
```

Note that if the same parsing parameters are used for all sheets, a list of sheet names can simply be passed to read_excel with no loss in performance.
# using the ExcelFile class

data = {}
with pd.ExcelFile('path_to_file.xls') as xls:
    data['Sheet1'] = pd.read_excel(xls, 'Sheet1', index_col=None, na_values=['NA'])
    data['Sheet2'] = pd.read_excel(xls, 'Sheet2', index_col=None, na_values=['NA'])

# equivalent using the read_excel function

data = pd.read_excel('path_to_file.xls', ['Sheet1', 'Sheet2'], index_col=None, na_values=['NA'])

ExcelFile can also be called with a `xlrd.book.Book` object as a parameter. This allows the user to control how the excel file is read. For example, sheets can be loaded on demand by calling `xlrd.open_workbook()` with `on_demand=True`.

```python
import xlrd
xlrd_book = xlrd.open_workbook('path_to_file.xls', on_demand=True)
with pd.ExcelFile(xlrd_book) as xls:
    df1 = pd.read_excel(xls, 'Sheet1')
    df2 = pd.read_excel(xls, 'Sheet2')
```

### Specifying sheets

**Note:** The second argument is `sheet_name`, not to be confused with `ExcelFile.sheet_names`.

**Note:** An ExcelFile’s attribute `sheet_names` provides access to a list of sheets.

- The arguments `sheet_name` allows specifying the sheet or sheets to read.
- The default value for `sheet_name` is 0, indicating to read the first sheet
- Pass a string to refer to the name of a particular sheet in the workbook.
- Pass an integer to refer to the index of a sheet. Indices follow Python convention, beginning at 0.
- Pass a list of either strings or integers, to return a dictionary of specified sheets.
- Pass a `None` to return a dictionary of all available sheets.

```python
# Returns a DataFrame
pd.read_excel('path_to_file.xls', 'Sheet1', index_col=None, na_values=['NA'])
```

Using the sheet index:

```python
# Returns a DataFrame
pd.read_excel('path_to_file.xls', 0, index_col=None, na_values=['NA'])
```

Using all default values:

```python
# Returns a DataFrame
pd.read_excel('path_to_file.xls')
```

Using None to get all sheets:
# Returns a dictionary of DataFrames
```
pd.read_excel('path_to_file.xls', sheet_name=None)
```

Using a list to get multiple sheets:
```
# Returns the 1st and 4th sheet, as a dictionary of DataFrames.
pd.read_excel('path_to_file.xls', sheet_name=['Sheet1', 3])
```

read_excel can read more than one sheet, by setting `sheet_name` to either a list of sheet names, a list of sheet positions, or `None` to read all sheets. Sheets can be specified by sheet index or sheet name, using an integer or string, respectively.

### Reading a MultiIndex

read_excel can read a MultiIndex index, by passing a list of columns to `index_col` and a MultiIndex column by passing a list of rows to `header`. If either the index or columns have serialized level names those will be read in as well by specifying the rows/columns that make up the levels.

For example, to read in a MultiIndex index without names:
```
In [316]: df = pd.DataFrame({'a': [1, 2, 3, 4], 'b': [5, 6, 7, 8]},
                      index=pd.MultiIndex.from_product([['a', 'b'], ['c', 'd']]))

In [317]: df.to_excel('path_to_file.xlsx')

In [318]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1])
```

If the index has level names, they will parsed as well, using the same parameters.

```
In [320]: df.index = df.index.set_names(['lvl1', 'lvl2'])

In [321]: df.to_excel('path_to_file.xlsx')

In [322]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1])
```

If the source file has both MultiIndex index and columns, lists specifying each should be passed to `index_col` and `header`:
In[324]: df.columns = pd.MultiIndex.from_product([[\'a\'], [\'b\', \'d\']], names=[\'c1\', \'c2\'])

In[325]: df.to_excel(\'path_to_file.xlsx\')

In[326]: df = pd.read_excel(\'path_to_file.xlsx\', index_col=[0, 1], header=[0, 1])

In[327]: df

Out[327]:
c1  a
   b  d
lvl1 lvl2
a  c  1  5
   d  2  6
b  c  3  7
   d  4  8

Parsing specific columns

It is often the case that users will insert columns to do temporary computations in Excel and you may not want to read in those columns. read_excel takes a usecols keyword to allow you to specify a subset of columns to parse.

Deprecated since version 0.24.0.

Passing in an integer for usecols has been deprecated. Please pass in a list of ints from 0 to usecols inclusive instead.

If usecols is an integer, then it is assumed to indicate the last column to be parsed.

pd.read_excel(\'path_to_file.xls\', 'Sheet1', usecols=2)

You can also specify a comma-delimited set of Excel columns and ranges as a string:

pd.read_excel(\'path_to_file.xls\', 'Sheet1', usecols='A,C:E')

If usecols is a list of integers, then it is assumed to be the file column indices to be parsed.

pd.read_excel(\'path_to_file.xls\', 'Sheet1', usecols=[0, 2, 3])

Element order is ignored, so usecols=[0, 1] is the same as [1, 0].

New in version 0.24.

If usecols is a list of strings, it is assumed that each string corresponds to a column name provided either by the user in names or inferred from the document header row(s). Those strings define which columns will be parsed:

pd.read_excel(\'path_to_file.xls\', 'Sheet1', usecols=[\'foo\', \'bar\'])

Element order is ignored, so usecols=[\'baz\', \'joe\'] is the same as [\'joe\', \'baz\'].

New in version 0.24.

If usecols is callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True.

pd.read_excel(\'path_to_file.xls\', 'Sheet1', usecols=\lambda x: x.ishalpha())
Parsing dates

Datetime-like values are normally automatically converted to the appropriate dtype when reading the excel file. But if you have a column of strings that look like dates (but are not actually formatted as dates in excel), you can use the parse_dates keyword to parse those strings to datetimes:

```python
pd.read_excel('path_to_file.xls', 'Sheet1', parse_dates=['date_strings'])
```

Cell converters

It is possible to transform the contents of Excel cells via the converters option. For instance, to convert a column to boolean:

```python
pd.read_excel('path_to_file.xls', 'Sheet1', converters={'MyBools': bool})
```

This options handles missing values and treats exceptions in the converters as missing data. Transformations are applied cell by cell rather than to the column as a whole, so the array dtype is not guaranteed. For instance, a column of integers with missing values cannot be transformed to an array with integer dtype, because NaN is strictly a float. You can manually mask missing data to recover integer dtype:

```python
def cfun(x):
    return int(x) if x else -1

pd.read_excel('path_to_file.xls', 'Sheet1', converters={'MyInts': cfun})
```

Dtype specifications

As an alternative to converters, the type for an entire column can be specified using the dtype keyword, which takes a dictionary mapping column names to types. To interpret data with no type inference, use the type str or object.

```python
pd.read_excel('path_to_file.xls', dtype={'MyInts': 'int64', 'MyText': str})
```

Writing Excel files

Writing Excel files to disk

To write a DataFrame object to a sheet of an Excel file, you can use the to_excel instance method. The arguments are largely the same as to_csv described above, the first argument being the name of the excel file, and the optional second argument the name of the sheet to which the DataFrame should be written. For example:

```python
df.to_excel('path_to_file.xlsx', sheet_name='Sheet1')
```

Files with a .xls extension will be written using xlwt and those with a .xlsx extension will be written using xlsxwriter (if available) or openpyxl.

The DataFrame will be written in a way that tries to mimic the REPL output. The index_label will be placed in the second row instead of the first. You can place it in the first row by setting the merge_cells option in to_excel() to False:
In order to write separate DataFrames to separate sheets in a single Excel file, one can pass an ExcelWriter.

```python
with pd.ExcelWriter('path_to_file.xlsx') as writer:
    df1.to_excel(writer, sheet_name='Sheet1')
    df2.to_excel(writer, sheet_name='Sheet2')
```

**Note:** Wrting a little more performance out of read_excel Internally, Excel stores all numeric data as floats. Because this can produce unexpected behavior when reading in data, pandas defaults to trying to convert integers to floats if it doesn’t lose information (1.0 --> 1). You can pass convert_float=False to disable this behavior, which may give a slight performance improvement.

### Writing Excel files to memory

Pandas supports writing Excel files to buffer-like objects such as StringIO or BytesIO using ExcelWriter.

```python
from io import BytesIO
bio = BytesIO()

# By setting the 'engine' in the ExcelWriter constructor.
writer = pd.ExcelWriter(bio, engine='xlsxwriter')
df.to_excel(writer, sheet_name='Sheet1')

# Save the workbook
writer.save()

# Seek to the beginning and read to copy the workbook to a variable in memory
bio.seek(0)
workbook = bio.read()
```

**Note:** engine is optional but recommended. Setting the engine determines the version of workbook produced. Setting engine='xlrd' will produce an Excel 2003-format workbook (xls). Using either 'openpyxl' or 'xlsxwriter' will produce an Excel 2007-format workbook (xlsx). If omitted, an Excel 2007-formatted workbook is produced.

### Excel writer engines

Pandas chooses an Excel writer via two methods:

1. the engine keyword argument
2. the filename extension (via the default specified in config options)

By default, pandas uses the XlsxWriter for .xlsx, openpyxl for .xlsm, and xlwt for .xls files. If you have multiple engines installed, you can set the default engine through setting the config options io.excel.xlsx.writer and io.excel.xls.writer. pandas will fall back on openpyxl for .xls files if Xlsxwriter is not available.

To specify which writer you want to use, you can pass an engine keyword argument to to_excel and to ExcelWriter. The built-in engines are:
• openpyxl: version 2.4 or higher is required
• xlsxwriter
• xlwt

```python
# By setting the 'engine' in the DataFrame 'to_excel()' methods.
df.to_excel('path_to_file.xlsx', sheet_name='Sheet1', engine='xlsxwriter')

# By setting the 'engine' in the ExcelWriter constructor.
writer = pd.ExcelWriter('path_to_file.xlsx', engine='xlsxwriter')

# Or via pandas configuration.
from pandas import options
# noqa: E402
options.io.excel.xlsx.writer = 'xlsxwriter'
df.to_excel('path_to_file.xlsx', sheet_name='Sheet1')
```

### Style and formatting

The look and feel of Excel worksheets created from pandas can be modified using the following parameters on the DataFrame’s `to_excel` method.

- `float_format`: Format string for floating point numbers (default None).
- `freeze_panes`: A tuple of two integers representing the bottommost row and rightmost column to freeze. Each of these parameters is one-based, so (1, 1) will freeze the first row and first column (default None).

Using the Xlsxwriter engine provides many options for controlling the format of an Excel worksheet created with the `to_excel` method. Excellent examples can be found in the Xlsxwriter documentation here: https://xlsxwriter.readthedocs.io/working_with_pandas.html

#### 2.4.5 OpenDocument Spreadsheets

New in version 0.25.

The `read_excel()` method can also read OpenDocument spreadsheets using the odfpy module. The semantics and features for reading OpenDocument spreadsheets match what can be done for Excel files using engine='odf'.

```python
# Returns a DataFrame
pd.read_excel('path_to_file.ods', engine='odf')
```

**Note:** Currently pandas only supports reading OpenDocument spreadsheets. Writing is not implemented.

#### 2.4.6 Binary Excel (.xlsb) files

New in version 1.0.0.

The `read_excel()` method can also read binary Excel files using the pyxlsb module. The semantics and features for reading binary Excel files mostly match what can be done for Excel files using engine='pyxlsb'. pyxlsb does not recognize datetime types in files and will return floats instead.

```python
# Returns a DataFrame
pd.read_excel('path_to_file.xlsb', engine='pyxlsb')
```

2.4. IO tools (text, CSV, HDF5, …)
Note: Currently pandas only supports *reading* binary Excel files. Writing is not implemented.

2.4.7 Clipboard

A handy way to grab data is to use the `read_clipboard()` method, which takes the contents of the clipboard buffer and passes them to the `read_csv` method. For instance, you can copy the following text to the clipboard (CTRL-C on many operating systems):

```
A B C
x 1 4 p
y 2 5 q
z 3 6 r
```

And then import the data directly to a DataFrame by calling:

```python
>>> clipdf = pd.read_clipboard()
>>> clipdf
   A  B  C
0  x  1  4  p
1  y  2  5  q
2  z  3  6  r
```

The `to_clipboard` method can be used to write the contents of a DataFrame to the clipboard. Following which you can paste the clipboard contents into other applications (CTRL-V on many operating systems). Here we illustrate writing a DataFrame into clipboard and reading it back.

```python
>>> df = pd.DataFrame({'A': [1, 2, 3],
                   'B': [4, 5, 6],
                   'C': ['p', 'q', 'r'],
                   'index': ['x', 'y', 'z']})
>>> df
   A  B  C
0  x  1  4  p
1  y  2  5  q
2  z  3  6  r
>>> df.to_clipboard()
>>> pd.read_clipboard()
   A  B  C
0  x  1  4  p
1  y  2  5  q
2  z  3  6  r
```

We can see that we got the same content back, which we had earlier written to the clipboard.

Note: You may need to install xclip or xsel (with PyQt5, PyQt4 or qtpy) on Linux to use these methods.
2.4.8 Pickling

All pandas objects are equipped with `to_pickle` methods which use Python’s `cPickle` module to save data structures to disk using the pickle format.

```
In [328]: df
Out[328]:
   c1  a
   c2  b  d
lv11 lv12
   a  c  1  5
   d  2  6
   b  c  3  7
   d  4  8
In [329]: df.to_pickle('foo.pkl')
```

The `read_pickle` function in the `pandas` namespace can be used to load any pickled pandas object (or any other pickled object) from file:

```
In [330]: pd.read_pickle('foo.pkl')
Out[330]:
   c1  a
   c2  b  d
lv11 lv12
   a  c  1  5
   d  2  6
   b  c  3  7
   d  4  8
```

**Warning**: Loading pickled data received from untrusted sources can be unsafe.

See: [https://docs.python.org/3/library/pickle.html](https://docs.python.org/3/library/pickle.html)

**Warning**: `read_pickle()` is only guaranteed backwards compatible back to pandas version 0.20.3

Compressed pickle files

`read_pickle()`, `DataFrame.to_pickle()` and `Series.to_pickle()` can read and write compressed pickle files. The compression types of `gzip`, `bz2`, `xz` are supported for reading and writing. The `zip` file format only supports reading and must contain only one data file to be read.

The compression type can be an explicit parameter or be inferred from the file extension. If ‘infer’, then use `gzip`, `bz2`, `zip`, or `xz` if filename ends in `'.gz'`, `'.bz2'`, `'.zip'`, or `'.xz'`, respectively.

The compression parameter can also be a `dict` in order to pass options to the compression protocol. It must have a 'method' key set to the name of the compression protocol, which must be one of `{'zip', 'gzip', 'bz2'}`. All other key-value pairs are passed to the underlying compression library.

```
In [331]: df = pd.DataFrame({
      ....:     'A': np.random.randn(1000),
      ....:     'B': 'foo',
      ....:     'C': pd.date_range('20130101', periods=1000, freq='s'))
```
In [332]: df
Out[332]:
   A    B             C
0 -0.288267  foo  2013-01-01 00:00:00
1 -0.084905  foo  2013-01-01 00:00:01
2  0.004772  foo  2013-01-01 00:00:02
3  1.382989  foo  2013-01-01 00:00:03
4  0.343635  foo  2013-01-01 00:00:04
..        ...           ...   ...
995 -0.220893 foo  2013-01-01 00:16:35
996  0.492996 foo  2013-01-01 00:16:36
997 -0.461625 foo  2013-01-01 00:16:37
998  1.361779 foo  2013-01-01 00:16:38
999 -1.197988 foo  2013-01-01 00:16:39
[1000 rows x 3 columns]

Using an explicit compression type:

In [333]: df.to_pickle("data.pkl.compress", compression="gzip")

In [334]: rt = pd.read_pickle("data.pkl.compress", compression="gzip")

In [335]: rt
Out[335]:
   A    B             C
0 -0.288267  foo  2013-01-01 00:00:00
1 -0.084905  foo  2013-01-01 00:00:01
2  0.004772  foo  2013-01-01 00:00:02
3  1.382989  foo  2013-01-01 00:00:03
4  0.343635  foo  2013-01-01 00:00:04
..        ...           ...   ...
995 -0.220893 foo  2013-01-01 00:16:35
996  0.492996 foo  2013-01-01 00:16:36
997 -0.461625 foo  2013-01-01 00:16:37
998  1.361779 foo  2013-01-01 00:16:38
999 -1.197988 foo  2013-01-01 00:16:39
[1000 rows x 3 columns]

Inferring compression type from the extension:

In [336]: df.to_pickle("data.pkl.xz", compression="infer")

In [337]: rt = pd.read_pickle("data.pkl.xz", compression="infer")

In [338]: rt
Out[338]:
   A    B             C
0 -0.288267  foo  2013-01-01 00:00:00
1 -0.084905  foo  2013-01-01 00:00:01
2  0.004772  foo  2013-01-01 00:00:02
3  1.382989  foo  2013-01-01 00:00:03
4  0.343635  foo  2013-01-01 00:00:04
..        ...           ...   ...
995 -0.220893 foo  2013-01-01 00:16:35
996  0.492996 foo  2013-01-01 00:16:36
997 -0.461625 foo  2013-01-01 00:16:37
998  1.361779 foo  2013-01-01 00:16:38
999 -1.197988 foo  2013-01-01 00:16:39
[1000 rows x 3 columns]
The default is to ‘infer’:

```
In [339]: df.to_pickle("data.pkl.gz")
```

```
In [340]: rt = pd.read_pickle("data.pkl.gz")
```

```
In [341]: rt
```

```
Out [341]:
       A         B         C
0  -0.288267  foo 2013-01-01 00:00:00
1  -0.084905  foo 2013-01-01 00:00:01
2   0.004772  foo 2013-01-01 00:00:02
3   1.382989  foo 2013-01-01 00:00:03
4   0.343635  foo 2013-01-01 00:00:04
...          ...         ...         ...
995 -0.220893  foo 2013-01-01 00:16:35
996  0.492996  foo 2013-01-01 00:16:36
997 -0.461625  foo 2013-01-01 00:16:37
998  1.361779  foo 2013-01-01 00:16:38
999 -1.197988  foo 2013-01-01 00:16:39
[1000 rows x 3 columns]
```

```
In [342]: df["A"].to_pickle("s1.pkl.bz2")
```

```
In [343]: rt = pd.read_pickle("s1.pkl.bz2")
```

```
In [344]: rt
```

```
Out [344]:
   0  -0.288267
   1  -0.084905
   2   0.004772
   3   1.382989
   4   0.343635
      ...         ...
995 -0.220893
996  0.492996
997 -0.461625
998  1.361779
999 -1.197988
Name: A, Length: 1000, dtype: float64
```

Passing options to the compression protocol in order to speed up compression:

```
In [345]: df.to_pickle(
        .....:       "data.pkl.gz",
        .....:       compression={"method": "gzip", 'compresslevel': 1}
        .....:     )
```

2.4. IO tools (text, CSV, HDF5, …)
2.4.9 msgpack

pandas support for msgpack has been removed in version 1.0.0. It is recommended to use pyarrow for on-the-wire transmission of pandas objects.

Example pyarrow usage:

```python
>>> import pandas as pd
>>> import pyarrow as pa

>>> df = pd.DataFrame({'A': [1, 2, 3]})
>>> context = pa.default_serialization_context()
>>> df_bytestring = context.serialize(df).to_buffer().to_pybytes()
```

For documentation on pyarrow, see here.

2.4.10 HDF5 (PyTables)

HDFStore is a dict-like object which reads and writes pandas using the high performance HDF5 format using the excellent PyTables library. See the cookbook for some advanced strategies.

**Warning:** Pandas uses PyTables for reading and writing HDF5 files, which allows serializing object-dtype data with pickle. Loading pickled data received from untrusted sources can be unsafe.

See: https://docs.python.org/3/library/pickle.html for more.

```
In [346]: store = pd.HDFStore('store.h5')

In [347]: print(store)
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

Objects can be written to the file just like adding key-value pairs to a dict:

```
In [348]: index = pd.date_range('1/1/2000', periods=8)
In [349]: s = pd.Series(np.random.randn(5), index=[a', 'b', 'c', 'd', 'e'])
In [350]: df = pd.DataFrame(np.random.randn(8, 3), index=index,
                  columns=['A', 'B', 'C'])

# store.put('s', s) is an equivalent method
In [351]: store['s'] = s

In [352]: store['df'] = df

In [353]: store
Out[353]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

In a current or later Python session, you can retrieve stored objects:

```
# store.get('df') is an equivalent method
In [354]: store['df']
```

(continues on next page)
Deletion of the object specified by the key:

```python
In [356]: del store['df']
```

Closing a Store and using a context manager:

```python
In [358]: store.close()
```

```python
In [359]: store
```

```python
Out[359]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

```python
In [360]: store.is_open
```

```python
Out[360]: False
```

```python
# Working with, and automatically closing the store using a context manager
In [361]: with pd.HDFStore('store.h5') as store:
    ....:    store.keys()
    ....:    
```
Read/write API

HDFStore supports a top-level API using read_hdf for reading and to_hdf for writing, similar to how read_csv and to_csv work.

```python
In [362]: df_tl = pd.DataFrame({'A': list(range(5)), 'B': list(range(5)))

In [363]: df_tl.to_hdf('store_tl.h5', 'table', append=True)

In [364]: pd.read_hdf('store_tl.h5', 'table', where=['index>2'])
Out[364]:
   A  B
0  3  3
1  4  4

HDFStore will by default not drop rows that are all missing. This behavior can be changed by setting dropna=True.

```python
In [365]: df_with_missing = pd.DataFrame({'col1': [0, np.nan, 2],
                                  'col2': [1, np.nan, np.nan]})

In [366]: df_with_missing
Out[366]:
   col1  col2
0   0.0   1.0
1   NaN   NaN
2   2.0   NaN

In [367]: df_with_missing.to_hdf('file.h5', 'df_with_missing',
                           format='table', mode='w')

In [368]: pd.read_hdf('file.h5', 'df_with_missing')
Out[368]:
   col1  col2
0   0.0   1.0
1   NaN   NaN
2   2.0   NaN

In [369]: df_with_missing.to_hdf('file.h5', 'df_with_missing',
                           format='table', mode='w', dropna=True)

In [370]: pd.read_hdf('file.h5', 'df_with_missing')
Out[370]:
   col1  col2
0   0.0   1.0
1   NaN   NaN
2   2.0   NaN
```
Fixed format

The examples above show storing using put, which write the HDF5 to PyTables in a fixed array format, called the fixed format. These types of stores are not appendable once written (though you can simply remove them and rewrite). Nor are they queryable: they must be retrieved in their entirety. They also do not support dataframes with non-unique column names. The fixed format stores offer very fast writing and slightly faster reading than table stores. This format is specified by default when using put or to_hdf or by format='fixed' or format='f'.

Warning: A fixed format will raise a TypeError if you try to retrieve using a where:

```python
>>> pd.DataFrame(np.random.randn(10, 2)).to_hdf('test_fixed.h5', 'df')
>>> pd.read_hdf('test_fixed.h5', 'df', where='index>5')
TypeError: cannot pass a where specification when reading a fixed format.

...this store must be selected in its entirety
```

Table format

HDFStore supports another PyTables format on disk, the table format. Conceptually a table is shaped very much like a DataFrame, with rows and columns. A table may be appended to in the same or other sessions. In addition, delete and query type operations are supported. This format is specified by format='table' or format='t' to append or put or to_hdf.

This format can be set as an option as well pd.set_option('io.hdf.default_format','table') to enable put/append/to_hdf to by default store in the table format.

```
In [371]: store = pd.HDFStore('store.h5')
In [372]: df1 = df[0:4]
In [373]: df2 = df[4:]

# append data (creates a table automatically)
In [374]: store.append('df', df1)
In [375]: store.append('df', df2)
In [376]: store
Out[376]: <class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# select the entire object
In [377]: store.select('df')
Out[377]:
```

(continues on next page)
Note: You can also create a table by passing format='table' or format='t' to a put operation.

Hierarchical keys

Keys to a store can be specified as a string. These can be in a hierarchical path-name like format (e.g. foo/bar/bah), which will generate a hierarchy of sub-stores (or Groups in PyTables parlance). Keys can be specified without the leading '/' and are always absolute (e.g. ‘foo’ refers to ‘/foo’). Removal operations can remove everything in the sub-store and below, so be careful.

You can walk through the group hierarchy using the walk method which will yield a tuple for each group key along with the relative keys of its contents.

New in version 0.24.0.
Warning:  Hierarchical keys cannot be retrieved as dotted (attribute) access as described above for items stored under the root node.

```python
In [8]: store.foo.bar.bah
AttributeError: 'HDFStore' object has no attribute 'foo'
```

# you can directly access the actual PyTables node but using the root node

```python
In [9]: store.root.foo.bar.bah
Out[9]:
/foo/bar/bah (Group) ''
  children := ['block0_items' (Array), 'block0_values' (Array), 'axis0' (Array), ...
  'axis1' (Array)]
```

Instead, use explicit string based keys:

```python
In [387]: store['foo/bar/bah']
Out[387]:
   A     B     C
2000-01-01 1.334065 0.521036 0.930384
2000-01-02 -1.613932 1.088104 -0.632963
2000-01-03 -0.585314 -0.275038 -0.937512
2000-01-04 0.632369 -1.249657 0.975593
2000-01-05 1.060617 -0.143682 0.218423
2000-01-06 3.050329 1.317933 -0.963725
2000-01-07 -0.539452 -0.771133 0.023751
2000-01-08 0.649464 -1.736427 0.197288
```
Storing types

Storing mixed types in a table

Storing mixed-dtype data is supported. Strings are stored as a fixed-width using the maximum size of the appended column. Subsequent attempts at appending longer strings will raise a `ValueError`.

Passing `min_itemsize=\{'values\': size\}` as a parameter to `append` will set a larger minimum for the string columns. Storing floats, strings, ints, bools, `datetime64` are currently supported. For string columns, passing `nan_rep = 'nan'` to `append` will change the default nan representation on disk (which converts to/from `np.nan`), this defaults to `nan`.

```python
In [388]: df_mixed = pd.DataFrame({'A': np.random.randn(8),
                             'B': np.random.randn(8),
                             'C': np.array(np.random.randn(8), dtype='float32'),
                             'string': 'string',
                             'int': 1,
                             'bool': True,
                             'datetime64': pd.Timestamp('20010102')},
                             index=list(range(8)))

In [389]: df_mixed.loc[df_mixed.index[3:5], ['A', 'B', 'string', 'datetime64']] = np.nan

In [390]: store.append('df_mixed', df_mixed, min_itemsize=\{'values\': 50\})

In [391]: df_mixed1 = store.select('df_mixed')

In [392]: df_mixed1

Out[392]:
   A       B       C    string     int    bool  datetime64
0  0.116008  0.743946-0.398501  string    1  True  2001-01-02

(continues on next page)
Storing MultiIndex DataFrames

Storing MultiIndex DataFrames as tables is very similar to storing/selecting from homogeneous index DataFrames.

In [395]: index = pd.MultiIndex(levels=[[['foo', 'bar', 'baz', 'qux']],
                             codes=[[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3],
                                     [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],
                             names=['foo', 'bar'])

In [396]: df_mi = pd.DataFrame(np.random.randn(10, 3), index=index,
                          columns=['A', 'B', 'C'])

In [397]: df_mi
Out[397]:
           A          B          C
foo bar  
foo one  0.667450  0.169405 -1.358046
         -0.105563  0.492195  0.076693
         0.213685  0.285283 -1.210529
two    
three  1.408386  0.415777 -0.342447
        0.222031  0.052607  2.093214
        1.064908  1.778161 -0.913867

         0.081323 -0.268494  0.168016
         -0.898283 -0.218499  1.408028
         -1.267828 -0.689263  0.520955
two    
three  0.667450  0.169405 -1.358046
        -0.105563  0.492195  0.076693
        0.213685 -0.285283 -1.210529
baz    
qux one 0.081323 -0.268494  0.168016
       -0.898283 -0.218499  1.408028
       -1.267828 -0.689263  0.520955

In [398]: store.append('df_mi', df_mi)

In [399]: store.select('df_mi')
Out[399]:
           A          B          C
foo bar  
foo one  0.667450  0.169405 -1.358046
         -0.105563  0.492195  0.076693
         0.213685 -0.285283 -1.210529
two    
three  1.408386  0.415777 -0.342447
        0.222031  0.052607  2.093214
        1.064908  1.778161 -0.913867
three  
bar one -0.300004 -0.399846 -1.234765
         0.081323 -0.268494  0.168016
         -0.898283 -0.218499  1.408028
         -1.267828 -0.689263  0.520955
two    
three  0.667450  0.169405 -1.358046
        -0.105563  0.492195  0.076693
        0.213685 -0.285283 -1.210529
baz    
qux one 0.081323 -0.268494  0.168016
       -0.898283 -0.218499  1.408028
       -1.267828 -0.689263  0.520955

(continues on next page)
# the levels are automatically included as data columns
In [400]: store.select('df_mi', 'foo=bar')
Out[400]:
          A       B       C
foo bar
bar one -1.408386  0.941577 -0.342447
  two  0.222031  0.052607  2.093214

Note: The index keyword is reserved and cannot be use as a level name.

## Querying

### Querying a table

select and delete operations have an optional criterion that can be specified to select/delete only a subset of the data. This allows one to have a very large on-disk table and retrieve only a portion of the data.

A query is specified using the Term class under the hood, as a boolean expression.

- index and columns are supported indexers of DataFrames.
- if data_columns are specified, these can be used as additional indexers.
- level name in a MultiIndex, with default name level_0, level_1,... if not provided.

Valid comparison operators are:

- =, ==, !=, >, >=, <, <=

Valid boolean expressions are combined with:

- |: or
- &: and
- ( and ) : for grouping

These rules are similar to how boolean expressions are used in pandas for indexing.

Note:

- = will be automatically expanded to the comparison operator ==
- ~ is the not operator, but can only be used in very limited circumstances
- If a list/tuple of expressions is passed they will be combined via &

The following are valid expressions:

- 'index >= date'
- "columns = ['A', 'D']"
• "columns in ['A', 'D']"
• 'columns = A'
• 'columns == A'
• ~(columns = ['A', 'B'])
• 'index > df.index[3] & string = "bar"'
• '(index > df.index[3] & index <= df.index[6]) | string = "bar"'
• 'ts >= Timestamp('2012-02-01')"
• "major_axis>=20130101"

The indexers are on the left-hand side of the sub-expression:
columns, major_axis, ts

The right-hand side of the sub-expression (after a comparison operator) can be:

• functions that will be evaluated, e.g. Timestamp('2012-02-01')
• strings, e.g. "bar"
• date-like, e.g. 20130101, or "20130101"
• lists, e.g. "['A', 'B']"
• variables that are defined in the local names space, e.g. date

Note: Passing a string to a query by interpolating it into the query expression is not recommended. Simply assign the string of interest to a variable and use that variable in an expression. For example, do this

```python
string = "HolyMoly"
store.select('df', 'index == string')
```

instead of this

```python
string = "HolyMoly"
store.select('df', f'index == {string}')
```

The latter will not work and will raise a SyntaxError. Note that there’s a single quote followed by a double quote in the string variable.

If you must interpolate, use the '%r' format specifier

```python
store.select('df', 'index == $r $ string')
```

which will quote string.

Here are some examples:

```python
In [401]: dfq = pd.DataFrame(np.random.randn(10, 4), columns=list('ABCD'),
index=pd.date_range('20130101', periods=10))
......:
In [402]: store.append('dfq', dfq, format='table', data_columns=True)
```

Use boolean expressions, with in-line function evaluation.
Use inline column reference.

```
In [404]: store.select('dfq', where="A>0 or C>0")
Out[404]:
          A          B          C          D
2013-01-01  0.620028  0.159416 -0.263043 -0.639244
2013-01-04 -0.536722  1.005707  0.296917  0.139796
2013-01-05 -1.083889  0.811865  1.648435 -0.164377
2013-01-07  0.948196  0.183573  0.145277  0.308146
2013-01-08 -1.043530 -0.708145  1.430905 -0.850136
2013-01-09  0.813949  1.508891 -1.556154  0.187597
2013-01-10  1.176488 -1.246093 -0.002726 -0.444249
```

The columns keyword can be supplied to select a list of columns to be returned, this is equivalent to passing a 'columns=list_of_columns_to_filter':

```
In [405]: store.select('df', "columns=['A', 'B']")
Out[405]:
           A          B
2000-01-01  1.334065  0.521036
2000-01-02 -1.613932  1.088104
2000-01-03 -0.585314 -0.275038
2000-01-04  0.632369 -1.249657
2000-01-05  1.060617 -0.143682
2000-01-06  3.050329  1.317933
2000-01-07 -0.539452 -0.771133
2000-01-08  0.649464 -1.736427
```

start and stop parameters can be specified to limit the total search space. These are in terms of the total number of rows in a table.

**Note:** select will raise a `ValueError` if the query expression has an unknown variable reference. Usually this means that you are trying to select on a column that is not a data_column.

select will raise a `SyntaxError` if the query expression is not valid.
Query timedelta64[ns]

You can store and query using the timedelta64[ns] type. Terms can be specified in the format: `<float><unit>`, where float may be signed (and fractional), and unit can be D, s, ms, us, ns for the timedelta. Here’s an example:

```python
In [406]: from datetime import timedelta
In [407]: dftd = pd.DataFrame({'A': pd.Timestamp('20130101'),
                           'B': [pd.Timestamp('20130101') + timedelta(days=i,
                                seconds=10) for i in range(10)]})
In [408]: dftd['C'] = dftd['A'] - dftd['B']
In [409]: dftd
Out[409]:
   A          B          C
0 2013-01-01 2013-01-01 00:00:10 -1 days +23:59:50
1 2013-01-01 2013-01-02 00:00:10 -2 days +23:59:50
2 2013-01-01 2013-01-03 00:00:10 -3 days +23:59:50
3 2013-01-01 2013-01-04 00:00:10 -4 days +23:59:50
4 2013-01-01 2013-01-05 00:00:10 -5 days +23:59:50
5 2013-01-01 2013-01-06 00:00:10 -6 days +23:59:50

```

Query MultiIndex

Selecting from a MultiIndex can be achieved by using the name of the level.

```python
In [412]: df_mi.index.names
Out[412]: FrozenList(['foo', 'bar'])
In [413]: store.select('df_mi', "foo=baz and bar=two")
Out[413]:
   A          B          C
foo bar   baz two 1.064908 1.778161 -0.913867
```

If the MultiIndex levels names are None, the levels are automatically made available via the level_n keyword.
with n the level of the MultiIndex you want to select from.

```python
In [414]: index = pd.MultiIndex(
      ....:     levels=["foo", "bar", "baz", "qux"], ["one", "two", "three"],
      ....:     codes=[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3], [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],
      ....:     )
      ....:
In [415]: df_mi_2 = pd.DataFrame(np.random.randn(10, 3),
      ....:     index=index, columns=["A", "B", "C"], )
      ....:
In [416]: df_mi_2
Out[416]:
       A       B       C
foo  0.856838  1.491776  0.001283
  two -0.459055 -1.222598 -0.455304
  three -0.781163  0.826204 -0.530057
bar  0.296135  1.366810  1.073372
  two  0.661740  0.443531  0.559313
baz  0.661740  0.443531  0.559313
  two  0.337920 -0.634027  0.421107
  three -0.994957  0.755314  2.119746
qux  0.661740  0.443531  0.559313
  two -2.628174  0.089460  0.133636
  three  0.604303  1.053434  1.109090
In [417]: store.append("df_mi_2", df_mi_2)
# the levels are automatically included as data columns with keyword level_n
In [418]: store.select("df_mi_2", "level_0=foo and level_1=two")
Out[418]:
       A       B       C
foo two  0.701816 -1.097917  0.102588
```

Indexing

You can create/modify an index for a table with create_table_index after data is already in the table (after and append/put operation). Creating a table index is **highly** encouraged. This will speed your queries a great deal when you use a select with the indexed dimension as the where.

**Note:** Indexes are automagically created on the indexables and any data columns you specify. This behavior can be turned off by passing `index=False` to append.

```python
# we have automagically already created an index (in the first section)
In [419]: i = store.root.df.table.cols.index.index
In [420]: i.optlevel, i.kind
Out[420]: (6, 'medium')
# change an index by passing new parameters
In [421]: store.create_table_index('df', optlevel=9, kind='full')
In [422]: i = store.root.df.table.cols.index.index
```

(continues on next page)
Oftentimes when appending large amounts of data to a store, it is useful to turn off index creation for each append, then recreate at the end.

```
In [424]: df_1 = pd.DataFrame(np.random.randn(10, 2), columns=list('AB'))
In [425]: df_2 = pd.DataFrame(np.random.randn(10, 2), columns=list('AB'))
In [426]: st = pd.HDFStore('appends.h5', mode='w')
In [427]: st.append('df', df_1, data_columns=['B'], index=False)
In [428]: st.append('df', df_2, data_columns=['B'], index=False)
In [429]: st.get_storer('df').table
Out[429]: /df/table (Table(20,)) ''
   description := {
   "index": Int64Col(shape=(), dflt=0, pos=0),
   "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
   "B": Float64Col(shape=(), dflt=0.0, pos=2)}
   byteorder := 'little'
   chunkshape := (2730,)
```

Then create the index when finished appending.

```
In [430]: st.create_table_index('df', columns=['B'], optlevel=9, kind='full')
In [431]: st.get_storer('df').table
Out[431]: /df/table (Table(20,)) ''
   description := {
   "index": Int64Col(shape=(), dflt=0, pos=0),
   "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
   "B": Float64Col(shape=(), dflt=0.0, pos=2)}
   byteorder := 'little'
   chunkshape := (2730,)
   autoindex := True
   colindexes := {
   "B": Index(9, full, shuffle, zlib(1)).is_csi=True}
In [432]: st.close()
```

See here for how to create a completely-sorted-index (CSI) on an existing store.
Query via data columns

You can designate (and index) certain columns that you want to be able to perform queries (other than the indexable columns, which you can always query). For instance say you want to perform this common operation, on-disk, and return just the frame that matches this query. You can specify `data_columns = True` to force all columns to be `data_columns`.

```
In [433]: df_dc = df.copy()
In [434]: df_dc['string'] = 'foo'
In [435]: df_dc.loc[df_dc.index[4:6], 'string'] = np.nan
In [436]: df_dc.loc[df_dc.index[7:9], 'string'] = 'bar'
In [437]: df_dc['string2'] = 'cool'
In [438]: df_dc.loc[df_dc.index[1:3], ['B', 'C']] = 1.0
In [439]: df_dc
Out[439]:
   A     B     C    string  string2
0  1.33  0.52  0.93      foo      cool
1 -1.61  1.00  1.00      foo      cool
2 -0.59 -1.25  0.97      foo      cool
3  0.63  0.72  0.97      foo      cool
4  1.06  0.21  0.96     NaN      cool
5  3.05  1.32  0.96     NaN      cool
6 -0.53  0.02  0.19      foo      cool
```

# on-disk operations

```
In [440]: store.append('df_dc', df_dc, data_columns=['B', 'C', 'string', 'string2'])
In [441]: store.select('df_dc', where='B > 0')
Out[441]:
   A     B     C    string  string2
0  1.33  0.52  0.93      foo      cool
1 -1.61  1.00  1.00      foo      cool
2 -0.59 -1.25  0.97      foo      cool
```

# getting creative

```
In [442]: store.select('df_dc', 'B > 0 & C > 0 & string == foo')
Out[442]:
   A     B     C    string  string2
0  1.33  0.52  0.93      foo      cool
1 -1.61  1.00  1.00      foo      cool
2 -0.59 -1.25  0.97      foo      cool
```

# this is in-memory version of this type of selection

```
In [443]: df_dc[(df_dc.B > 0) & (df_dc.C > 0) & (df_dc.string == 'foo')]
Out[443]:
   A     B     C    string  string2
0  1.33  0.52  0.93      foo      cool
1 -1.61  1.00  1.00      foo      cool
2 -0.59 -1.25  0.97      foo      cool
```
There is some performance degradation by making lots of columns into data columns, so it is up to the user to designate these. In addition, you cannot change data columns (nor indexables) after the first append/put operation (Of course you can simply read in the data and create a new table!).

**Iterator**

You can pass iterator=True or chunksize=number_in_a_chunk to select and select_as_multiple to return an iterator on the results. The default is 50,000 rows returned in a chunk.

---

**Note:** You can also use the iterator with read_hdf which will open, then automatically close the store when finished iterating.
Note, that the chunksize keyword applies to the source rows. So if you are doing a query, then the chunksize will subdivide the total rows in the table and the query applied, returning an iterator on potentially unequal sized chunks.

Here is a recipe for generating a query and using it to create equal sized return chunks.

```python
In [446]: dfeq = pd.DataFrame({'number': np.arange(1, 11)})

In [447]: dfeq
Out[447]:
   number
0      1
1      2
2      3
3      4
4      5
5      6
6      7
7      8
8      9
9     10

In [448]: store.append('dfeq', dfeq, data_columns=['number'])

In [449]: def chunks(l, n):
   .....:     return [l[i:i+n] for i in range(0, len(l), n)]

In [450]: evens = [2, 4, 6, 8, 10]

In [451]: coordinates = store.select_as_coordinates('dfeq', 'number=evens')

In [452]: for c in chunks(coordinates, 2):
   .....:     print(store.select('dfeq', where=c))
   .....:
number
 1  2
 3  4
 5  6
 7  8
 9 10
```

**Advanced queries**

**Select a single column**

To retrieve a single indexable or data column, use the method `select_column`. This will, for example, enable you to get the index very quickly. These return a `Series` of the result, indexed by the row number. These do not currently accept the `where` selector.

```python
In [453]: store.select_column('df_dc', 'index')
Out[453]:
0  2000-01-01
1  2000-01-02
2  2000-01-03
```
Sometimes you want to get the coordinates (a.k.a the index locations) of your query. This returns an `Int64Index` of the resulting locations. These coordinates can also be passed to subsequent `where` operations.

```python
In [455]: df_coord = pd.DataFrame(np.random.randn(1000, 2),
                           index=pd.date_range('20000101', periods=1000))
In [456]: store.append('df_coord', df_coord)
In [457]: c = store.select_as_coordinates('df_coord', 'index > 20020101')
In [458]: c
Out[458]:
Int64Index([732, 733, 734, 735, 736, 737, 738, 739, 740, 741,
            ... 990, 991, 992, 993, 994, 995, 996, 997, 998, 999],
           dtype='int64', length=268)
In [459]: store.select('df_coord', where=c)
Out[459]:
    0         1
2002-01-02 -0.165548  0.646989
2002-01-03  0.782753 -0.123409
2002-01-04 -0.391932 -0.740915
2002-01-05  1.211070 -0.668715
2002-01-06  0.341987 -0.685867
... ... ...
2002-09-22  1.788110 -0.405908
2002-09-23 -0.801912  0.768460
2002-09-24  0.466284 -0.457411
2002-09-25 -0.364060  0.785367
2002-09-26 -1.463093  1.187315
[268 rows x 2 columns]
```
Selecting using a where mask

Sometime your query can involve creating a list of rows to select. Usually this mask would be a resulting index from an indexing operation. This example selects the months of a datetimeindex which are 5.

```
In [460]: df_mask = pd.DataFrame(np.random.randn(1000, 2),
                        index=pd.date_range('20000101', periods=1000))

In [461]: store.append('df_mask', df_mask)

In [462]: c = store.select_column('df_mask', 'index')

In [463]: where = c[pd.DatetimeIndex(c).month == 5].index

In [464]: store.select('df_mask', where=where)
```

Out [464]:
```
   0       1
2000-05-01 1.735883 -2.615261
2000-05-02 0.422173  2.425154
2000-05-03 0.632453 -0.165640
2000-05-04 -1.017207  0.005696
2000-05-05 0.299606  0.070606
...     ...     ...
2002-05-27 0.234503  1.199126
2002-05-28 -3.021833 -1.016828
2002-05-29 0.522794  0.063465
2002-05-30 -1.653736  0.031709
2002-05-31 -0.968402 -0.393583
```

[93 rows x 2 columns]

Storer object

If you want to inspect the stored object, retrieve via `get_storer`. You could use this programmatically to say get the number of rows in an object.

```
In [465]: store.get_storer('df_dc').nrows
```

Out [465]: 8

Multiple table queries

The methods `append_to_multiple` and `select_as_multiple` can perform appending/selecting from multiple tables at once. The idea is to have one table (call it the selector table) that you index most/all of the columns, and perform your queries. The other table(s) are data tables with an index matching the selector table’s index. You can then perform a very fast query on the selector table, yet get lots of data back. This method is similar to having a very wide table, but enables more efficient queries.

The `append_to_multiple` method splits a given single DataFrame into multiple tables according to `d`, a dictionary that maps the table names to a list of ‘columns’ you want in that table. If `None` is used in place of a list, that table will have the remaining unspecified columns of the given DataFrame. The argument `selector` defines which table is the selector table (which you can make queries from). The argument `dropna` will drop rows from the input DataFrame to ensure tables are synchronized. This means that if a row for one of the tables being written to is entirely `np.Nan`, that row will be dropped from all tables.
If `dropna` is False, **THE USER IS RESPONSIBLE FOR SYNCHRONIZING THE TABLES**. Remember that entirely `np.NaN` rows are not written to the HDFStore, so if you choose to call `dropna=False`, some tables may have more rows than others, and therefore `select_as_multiple` may not work or it may return unexpected results.

```python
In [466]: df_mt = pd.DataFrame(np.random.randn(8, 6),
    ....:     index=pd.date_range('1/1/2000', periods=8),
    ....:     columns=['A', 'B', 'C', 'D', 'E', 'F'])
    ....:
In [467]: df_mt['foo'] = 'bar'
In [468]: df_mt.loc[df_mt.index[1], ('A', 'B')] = np.nan

# you can also create the tables individually
In [469]: store.append_to_multiple({'df1_mt': ['A', 'B'], 'df2_mt': None},
    ....:     df_mt, selector='df1_mt')

In [470]: store
Out[470]: <class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# individual tables were created
In [471]: store.select('df1_mt')
```

```plaintext

```

2.4. IO tools (text, CSV, HDF5, …)
Delete from a table

You can delete from a table selectively by specifying a `where`. In deleting rows, it is important to understand the PyTables deletes rows by erasing the rows, then moving the following data. Thus deleting can potentially be a very expensive operation depending on the orientation of your data. To get optimal performance, it’s worthwhile to have the dimension you are deleting be the first of the `indexables`.

Data is ordered (on the disk) in terms of the `indexables`. Here’s a simple use case. You store panel-type data, with dates in the `major_axis` and ids in the `minor_axis`. The data is then interleaved like this:

- `date_1`
  - `id_1`
  - `id_2`
  - `...
  - `id_n`
- `date_2`
  - `id_1`
  - `...
  - `id_n`

It should be clear that a delete operation on the `major_axis` will be fairly quick, as one chunk is removed, then the following data moved. On the other hand a delete operation on the `minor_axis` will be very expensive. In this case it would almost certainly be faster to rewrite the table using a `where` that selects all but the missing data.

Warning: Please note that HDF5 DOES NOT RECLAIM SPACE in the h5 files automatically. Thus, repeatedly deleting (or removing nodes) and adding again, WILL TEND TO INCREASE THE FILE SIZE.

To repack and clean the file, use `ptrepack`.

Notes & caveats

Compression

PyTables allows the stored data to be compressed. This applies to all kinds of stores, not just tables. Two parameters are used to control compression: `complevel` and `complib`.

- `complevel` specifies if and how hard data is to be compressed. `complevel=0` and `complevel=None` disables compression and `0<complevel<10` enables compression.
- `complib` specifies which compression library to use. If nothing is specified the default library `zlib` is used. A compression library usually optimizes for either good compression rates or speed and the results will depend on the type of data. Which type of compression to choose depends on your specific needs and data. The list of supported compression libraries:
  - `zlib`: The default compression library. A classic in terms of compression, achieves good compression rates but is somewhat slow.
  - `lz4`: Fast compression and decompression.
  - `bzip2`: Good compression rates.
blosc: Fast compression and decompression.

Support for alternative blosc compressors:
- blosc:blosclz This is the default compressor for blosc
- blosc:lz4: A compact, very popular and fast compressor.
- blosc:lz4hc: A tweaked version of LZ4, produces better compression ratios at the expense of speed.
- blosc:snappy: A popular compressor used in many places.
- blosc:zlib: A classic; somewhat slower than the previous ones, but achieving better compression ratios.
- blosc:zstd: An extremely well balanced codec; it provides the best compression ratios among the others above, and at reasonably fast speed.

If `complib` is defined as something other than the listed libraries a `ValueError` exception is issued.

**Note:** If the library specified with the `complib` option is missing on your platform, compression defaults to `zlib` without further ado.

Enable compression for all objects within the file:

```python
store_compressed = pd.HDFStore('store_compressed.h5', complevel=9, compleib='blosc:blosclz')
```

Or on-the-fly compression (this only applies to tables) in stores where compression is not enabled:

```python
store.append('df', df, compleib='zlib', complevel=5)
```

**ptrepack**

PyTables offers better write performance when tables are compressed after they are written, as opposed to turning on compression at the very beginning. You can use the supplied PyTables utility `ptrepack`. In addition, `ptrepack` can change compression levels after the fact.

```bash
ptrepack --chunkshape=auto --propindexes --complevel=9 --complib=blosc in.h5 out.h5
```

Furthermore `ptrepack in.h5 out.h5` will *repack* the file to allow you to reuse previously deleted space. Alternatively, one can simply remove the file and write again, or use the `copy` method.

**Caveats**

**Warning:** `HDFStore` is not-threadsafe for writing. The underlying PyTables only supports concurrent reads (via threading or processes). If you need reading and writing *at the same time*, you need to serialize these operations in a single thread in a single process. You will corrupt your data otherwise. See the (GH2397) for more information.

- If you use locks to manage write access between multiple processes, you may want to use `fsync()` before releasing write locks. For convenience you can use `store.flush(fsync=True)` to do this for you.
- Once a table is created columns (DataFrame) are fixed; only exactly the same columns can be appended.
• Be aware that timezones (e.g., `pytz.timezone('US/Eastern')`) are not necessarily equal across timezone versions. So if data is localized to a specific timezone in the HDFStore using one version of a timezone library and that data is updated with another version, the data will be converted to UTC since these timezones are not considered equal. Either use the same version of timezone library or use `tz_convert` with the updated timezone definition.

**Warning:** PyTables will show a `NaturalNameWarning` if a column name cannot be used as an attribute selector. *Natural* identifiers contain only letters, numbers, and underscores, and may not begin with a number. Other identifiers cannot be used in a `where` clause and are generally a bad idea.

**DataTypes**

`HDFStore` will map an object dtype to the PyTables underlying dtype. This means the following types are known to work:

<table>
<thead>
<tr>
<th>Type</th>
<th>Represents missing values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>floating</code>: float64, float32, float16</td>
<td>np.nan</td>
</tr>
<tr>
<td><code>integer</code>: int64, int32, int8, uint64, uint32, uint8</td>
<td></td>
</tr>
<tr>
<td><code>boolean</code></td>
<td></td>
</tr>
<tr>
<td><code>datetime64[ns]</code></td>
<td>NaT</td>
</tr>
<tr>
<td><code>timedelta64[ns]</code></td>
<td>NaT</td>
</tr>
<tr>
<td><code>categorical</code>: see the section below</td>
<td></td>
</tr>
<tr>
<td><code>object</code>: strings</td>
<td>np.nan</td>
</tr>
</tbody>
</table>

`unicode` columns are not supported, and **WILL FAIL**.

**Categorical data**

You can write data that contains `category` dtypes to a `HDFStore`. Queries work the same as if it was an object array. However, the `category` dtype data is stored in a more efficient manner.

```python
In [474]: dfcat = pd.DataFrame({'A': pd.Series(list('aabbcdba')).astype('category'),
                        'B': np.random.randn(8)})

In [475]: dfcat
Out[475]:
   A  B
0  a  0.477849
1  a  0.283128
2  b -2.045700
3  b -0.338206
4  c -0.423113
5  d  2.314361
6  b -0.033100
7  a -0.965461

In [476]: dfcat.dtypes
Out[476]:
A    category
B  float64
```
dtype: object

In [477]: cstore = pd.HDFStore('cats.h5', mode='w')

In [478]: cstore.append('dfcat', dfcat, format='table', data_columns=['A'])

In [479]: result = cstore.select('dfcat', where="A in ['b', 'c']")

In [480]: result
Out[480]:
    A  B
2  b  -2.045700
3  b  -0.338206
4  c  -0.423113
6  b  -0.033100

In [481]: result.dtypes
Out[481]:
   A  category
   B  float64

dtype: object

String columns

min_itemsize

The underlying implementation of HDFStore uses a fixed column width (itemsize) for string columns. A string column itemsize is calculated as the maximum of the length of data (for that column) that is passed to the HDFStore, in the first append. Subsequent appends, may introduce a string for a column larger than the column can hold, an Exception will be raised (otherwise you could have a silent truncation of these columns, leading to loss of information). In the future we may relax this and allow a user-specified truncation to occur.

Pass min_itemsize on the first table creation to a-priori specify the minimum length of a particular string column. min_itemsize can be an integer, or a dict mapping a column name to an integer. You can pass values as a key to allow all indexables or data_columns to have this min_itemsize.

Passing a min_itemsize dict will cause all passed columns to be created as data_columns automatically.

Note: If you are not passing any data_columns, then the min_itemsize will be the maximum of the length of any string passed

In [482]: dfs = pd.DataFrame({'A': 'foo', 'B': 'bar'}, index=list(range(5)))

In [483]: dfs
Out[483]:
   A  B
0  foo  bar
1  foo  bar
2  foo  bar
3  foo  bar
4  foo  bar

# A and B have a size of 30
In [484]: store.append('dfs', dfs, min_itemsize=30)

In [485]: store.get_storer('dfs').table
Out[485]:
/dfs/table (Table(5,)) ''
    description := {
        "index": Int64Col(shape=(), dflt=0, pos=0),
        "values_block_0": StringCol(itemsize=30, shape=(2,), dflt=b'', pos=1)
    }
    byteorder := 'little'
    chunkshape := (963,)
    autoindex := True
    colindexes := {
        "index": Index(6, medium, shuffle, zlib(1)).is_csi=False
    }

# A is created as a data_column with a size of 30
# B is size is calculated
In [486]: store.append('dfs2', dfs, min_itemsize={'A': 30})

In [487]: store.get_storer('dfs2').table
Out[487]:
/dfs2/table (Table(5,)) ''
    description := {
        "index": Int64Col(shape=(), dflt=0, pos=0),
        "values_block_0": StringCol(itemsize=3, shape=(1,), dflt=b'', pos=1),
        "A": StringCol(itemsize=30, shape=(), dflt=b'', pos=2)
    }
    byteorder := 'little'
    chunkshape := (1598,)
    autoindex := True
    colindexes := {
        "index": Index(6, medium, shuffle, zlib(1)).is_csi=False,
        "A": Index(6, medium, shuffle, zlib(1)).is_csi=False
    }

nan_rep

String columns will serialize a np.nan (a missing value) with the nan_rep string representation. This defaults to the string value nan. You could inadvertently turn an actual nan value into a missing value.

nan_rep

In [488]: dfss = pd.DataFrame({"A": ["foo", "bar", 'nan']})

In [489]: dfss
Out[489]:
          A
0       foo
1       bar
2      NaN

In [490]: store.append('dfss', dfss)

In [491]: store.select('dfss')
Out[491]:
          A
0       foo
1       bar
2      NaN

# here you need to specify a different nan rep
In [492]: store.append('dfss2', dfss, nan_rep='_nan_')
In [493]: store.select('dfss2')
Out[493]:
   A
0  foo
1  bar
2  nan

External compatibility

HDFStore writes table format objects in specific formats suitable for producing loss-less round trips to pandas objects. For external compatibility, HDFStore can read native PyTables format tables.

It is possible to write an HDFStore object that can easily be imported into R using the rhdf5 library (Package website). Create a table format store like this:

    In [494]:
    df_for_r = pd.DataFrame({'first': np.random.rand(100),
                             ....:
                             'second': np.random.rand(100),
                             ....:
                             'class': np.random.randint(0, 2, (100, ))},
                             ....:
                             index=range(100))

    In [495]:
    df_for_r.head()
Out[495]:
   first  second  class
0  0.864919  0.852910   0
1  0.030579  0.412962   1
2  0.015226  0.978410   0
3  0.498512  0.686761   0
4  0.232163  0.328185   1

    In [496]:
    store_export = pd.HDFStore('export.h5')

    In [497]:
    store_export.append('df_for_r', df_for_r, data_columns=df_dc.columns)

    In [498]:
    store_export
Out[498]:
<class 'pandas.io.pytables.HDFStore'>
   File path: export.h5

In R this file can be read into a data.frame object using the rhdf5 library. The following example function reads the corresponding column names and data values from the values and assembles them into a data.frame:

    # Load values and column names for all datasets from corresponding nodes and
    # insert them into one data.frame object.
    library(rhdf5)

    loadhdf5data <- function(h5File) {
        listing <- h5ls(h5File)
        # Find all data nodes, values are stored in _values and corresponding column
        # titles in _items
        data_nodes <- grep("_values", listing$name)
        name_nodes <- grep("_items", listing$name)

        # Insert values
        values <- h5get(listing, data_nodes)
        values <- values[, names(values)]

        # Insert titles
        titles <- h5get(listing, name_nodes)
        titles <- unlist(titles)

        # Assemble values and titles into a data.frame
        data.frame(values, titles)
    }

2.4. IO tools (text, CSV, HDF5, …)
data_paths = paste(listing$group[\text{data\_nodes}], listing$name[\text{data\_nodes}], sep = "/")
name_paths = paste(listing$group[\text{name\_nodes}], listing$name[\text{name\_nodes}], sep = "/")
columns = list()
for (idx in seq(data_paths)) {
    # NOTE: matrices returned by h5read have to be transposed to obtain
    # required Fortran order!
    data <- data.frame(t(h5read(h5File, data_paths[idx])))
    names <- t(h5read(h5File, name_paths[idx]))
    entry <- data.frame(data)
    colnames(entry) <- names
    columns <- append(columns, entry)
}
data <- data.frame(columns)
return(data)

Now you can import the DataFrame into R:

```r
> data = loadhdf5data("transfer.hdf5")
> head(data)
   first  second  class
 1 0.417 0.3266 0.000
 2 0.720 0.5270 0.000
 3 0.000 0.8859 0.100
 4 0.302 0.3572 0.100
 5 0.147 0.9085 0.100
 6 0.092 0.6234 0.100
```

**Note:** The R function lists the entire HDF5 file’s contents and assembles the `data.frame` object from all matching nodes, so use this only as a starting point if you have stored multiple `DataFrame` objects to a single HDF5 file.

**Performance**

- `tables` format come with a writing performance penalty as compared to fixed stores. The benefit is the ability to append/delete and query (potentially very large amounts of data). Write times are generally longer as compared with regular stores. Query times can be quite fast, especially on an indexed axis.

- You can pass `chunksize=<int>` to `append`, specifying the write chunksize (default is 50000). This will significantly lower your memory usage on writing.

- You can pass `expectedrows=<int>` to the first `append`, to set the TOTAL number of rows that PyTables will expect. This will optimize read/write performance.

- Duplicate rows can be written to tables, but are filtered out in selection (with the last items being selected; thus a table is unique on major, minor pairs)

- A `PerformanceWarning` will be raised if you are attempting to store types that will be pickled by PyTables (rather than stored as endemic types). See Here for more information and some solutions.
## 2.4.11 Feather

Feather provides binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy.

Feather is designed to faithfully serialize and de-serialize DataFrames, supporting all of the pandas dtypes, including extension dtypes such as categorical and datetime with tz.

Several caveats:

- The format will NOT write an Index, or MultiIndex for the DataFrame and will raise an error if a non-default one is provided. You can .reset_index() to store the index or .reset_index(drop=True) to ignore it.
- Duplicate column names and non-string columns names are not supported
- Actual Python objects in object dtype columns are not supported. These will raise a helpful error message on an attempt at serialization.

See the Full Documentation.

```python
In [499]: df = pd.DataFrame({'a': list('abc'), 'b': list(range(1, 4)), 'c': np.arange(3, 6).astype('uint8'), 'd': np.arange(4.0, 7.0, dtype='float64'), 'e': [True, False, True], 'f': pd.Categorical(list('abc')), 'g': pd.date_range('20130101', periods=3), 'h': pd.date_range('20130101', periods=3, tz='US/Eastern'), 'i': pd.date_range('20130101', periods=3, freq='ns')})
Out[499]:
a  b  c  d  e  f         g         h
0  a  1  3  4.0  True 2013-01-01 2013-01-01 00:00:00-05:00 2013-01-01 00:00:00.
1  b  2  4  5.0  False 2013-01-02 2013-01-02 00:00:00-05:00 2013-01-01 00:00:00.
2  c  3  5  6.0  True 2013-01-03 2013-01-03 00:00:00-05:00 2013-01-01 00:00:00.

In [500]: df.dtypes
Out[500]:
a          object
b              int64
c             uint8
d            float64
e              bool
f          category
g     datetime64[ns]
h  datetime64[ns, US/Eastern]
i    datetime64[ns]
dtype: object
```

Write to a feather file.
Read from a feather file.

```python
In [503]: result = pd.read_feather('example.feather')
```

```
In [504]: result
Out[504]:
    a  b  c  d  e   f   g   h
   0  a  1  3  4.0 True a 2013-01-01 2013-01-01 00:00:00-05:00 2013-01-01 00:00:00.000000
   1  b  2  4  5.0  False b 2013-01-02 2013-01-02 00:00:00-05:00 2013-01-01 00:00:00.000000
   2  c  3  5  6.0 True  c 2013-01-03 2013-01-03 00:00:00-05:00 2013-01-01 00:00:00.000000
```

# we preserve dtypes

```python
In [505]: result.dtypes
Out[505]:
    a    object
    b   int64
    c  uint8
    d  float64
    e    bool
    f  category
    g  datetime64[ns]
    h  datetime64[ns, US/Eastern]
    i  datetime64[ns]
```

### 2.4.12 Parquet

Apache Parquet provides a partitioned binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy. Parquet can use a variety of compression techniques to shrink the file size as much as possible while still maintaining good read performance.

Parquet is designed to faithfully serialize and de-serialize DataFrame, supporting all of the pandas dtypes, including extension dtypes such as datetime with tz.

Several caveats.

- Duplicate column names and non-string columns names are not supported.
- The pyarrow engine always writes the index to the output, but fastparquet only writes non-default indexes. This extra column can cause problems for non-Pandas consumers that are not expecting it. You can force including or omitting indexes with the `index` argument, regardless of the underlying engine.
- Index level names, if specified, must be strings.
- In the pyarrow engine, categorical dtypes for non-string types can be serialized to parquet, but will de-serialize as their primitive dtype.
- The pyarrow engine preserves the `ordered` flag of categorical dtypes with string types. fastparquet does not preserve the `ordered` flag.
- Non supported types include `Interval` and actual Python object types. These will raise a helpful error message on an attempt at serialization. `Period` type is supported with pyarrow >= 0.16.0.
• The pyarrow engine preserves extension data types such as the nullable integer and string data type (requiring pyarrow >= 0.16.0, and requiring the extension type to implement the needed protocols, see the extension types documentation).

You can specify an engine to direct the serialization. This can be one of pyarrow, or fastparquet, or auto. If the engine is NOT specified, then the pd.options.io.parquet.engine option is checked; if this is also auto, then pyarrow is tried, and falling back to fastparquet.

See the documentation for pyarrow and fastparquet.

Note: These engines are very similar and should read/write nearly identical parquet format files. Currently pyarrow does not support timedelta data, fastparquet>=0.1.4 supports timezone aware datetimes. These libraries differ by having different underlying dependencies (fastparquet by using numba, while pyarrow uses a c-library).

```
In [506]: df = pd.DataFrame({'a': list('abc'),
......:                      'b': list(range(1, 4)),
......:                      'c': np.arange(3, 6).astype('u1'),
......:                      'd': np.arange(4.0, 7.0, dtype='float64'),
......:                      'e': [True, False, True],
......:                      'f': pd.date_range('20130101', periods=3),
......:                      'g': pd.date_range('20130101', periods=3, tz='US/Eastern'),
......:                      'h': pd.Categorical(list('abc')),
......:                      'i': pd.Categorical(list('abc'), ordered=True))

In [507]: df
Out[507]:
   a    b    c    d   e          f                g          h          i
0  a    1    3   4.0  True 2013-01-01 00:00:00-05:00  a  a
1  b    2    4   5.0  False 2013-01-02 00:00:00-05:00  b  b
2  c    3    5   6.0  True 2013-01-03 00:00:00-05:00  c  c

In [508]: df.dtypes
Out[508]:
   a             object
   b         int64
   c        uint8
   d   float64
   e           bool
   f  datetime64[ns]
   g  datetime64[ns, US/Eastern]
   h        category
   i        category
dtype: object
```

Write to a parquet file.

```
In [509]: df.to_parquet('example_pa.parquet', engine='pyarrow')
In [510]: df.to_parquet('example_fp.parquet', engine='fastparquet')
```

Read from a parquet file.

```
In [511]: result = pd.read_parquet('example_fp.parquet', engine='fastparquet')
```
Read only certain columns of a parquet file.

```python
In [514]: result = pd.read_parquet('example_fp.parquet', engine='fastparquet', columns=['a', 'b'])

In [515]: result = pd.read_parquet('example_pa.parquet', engine='pyarrow', columns=['a', 'b'])

In [516]: result.dtypes
Out[516]:
    a   object
    b   int64

dtype: object
```

Handling indexes

Serializing a DataFrame to parquet may include the implicit index as one or more columns in the output file. Thus, this code:

```python
In [517]: df = pd.DataFrame({'a': [1, 2], 'b': [3, 4]})

In [518]: df.to_parquet('test.parquet', engine='pyarrow')
```

creates a parquet file with three columns if you use pyarrow for serialization: a, b, and __index_level_0__. If you’re using fastparquet, the index may or may not be written to the file.

This unexpected extra column causes some databases like Amazon Redshift to reject the file, because that column doesn’t exist in the target table.

If you want to omit a dataframe’s indexes when writing, pass `index=False` to `to_parquet()`:

```python
In [519]: df.to_parquet('test.parquet', index=False)
```

This creates a parquet file with just the two expected columns, a and b. If your DataFrame has a custom index, you won’t get it back when you load this file into a DataFrame.

Passing `index=True` will always write the index, even if that’s not the underlying engine’s default behavior.
Partitioning Parquet files

New in version 0.24.0.

Parquet supports partitioning of data based on the values of one or more columns.

```
In [520]: df = pd.DataFrame({'a': [0, 0, 1, 1], 'b': [0, 1, 0, 1]})
In [521]: df.to_parquet(path='test', engine='pyarrow',
                  partition_cols=['a'], compression=None)
```

The path specifies the parent directory to which data will be saved. The partition_cols are the column names by which the dataset will be partitioned. Columns are partitioned in the order they are given. The partition splits are determined by the unique values in the partition columns. The above example creates a partitioned dataset that may look like:

```
test
   a=0
     0bac803e32dc42ae83fddf029cbdebc.parquet
     ...
   a=1
     e6ab24a4f45147b49b54a662f0c412a3.parquet
     ...
```

2.4.13 ORC

New in version 1.0.0.

Similar to the parquet format, the ORC Format is a binary columnar serialization for data frames. It is designed to make reading data frames efficient. Pandas provides only a reader for the ORC format, read_orc(). This requires the pyarrow library.

2.4.14 SQL queries

The pandas.io.sql module provides a collection of query wrappers to both facilitate data retrieval and to reduce dependency on DB-specific API. Database abstraction is provided by SQLAlchemy if installed. In addition you will need a driver library for your database. Examples of such drivers are psycopg2 for PostgreSQL or pymysql for MySQL. For SQLite this is included in Python’s standard library by default. You can find an overview of supported drivers for each SQL dialect in the SQLAlchemy docs.

If SQLAlchemy is not installed, a fallback is only provided for sqlite (and for mysql for backwards compatibility, but this is deprecated and will be removed in a future version). This mode requires a Python database adapter which respect the Python DB-API.

See also some cookbook examples for some advanced strategies.

The key functions are:

- `read_sql_table`: Read SQL database table into a DataFrame.
- `read_sql_query`: Read SQL query into a DataFrame.
- `read_sql`: Read SQL query or database table into a DataFrame.
- `DataFrame.to_sql`: Write records stored in a DataFrame to a SQL database.

Note: The function `read_sql()` is a convenience wrapper around `read_sql_table()` and

2.4. IO tools (text, CSV, HDF5, …)
read_sql_query() (and for backward compatibility) and will delegate to specific function depending on the provided input (database table name or sql query). Table names do not need to be quoted if they have special characters.

In the following example, we use the SQLite SQL database engine. You can use a temporary SQLite database where data are stored in “memory”.

To connect with SQLAlchemy you use the create_engine() function to create an engine object from database URI. You only need to create the engine once per database you are connecting to. For more information on create_engine() and the URI formatting, see the examples below and the SQLAlchemy documentation.

```python
# Create your engine.
In [523]: engine = create_engine('sqlite:////:memory:)
```

If you want to manage your own connections you can pass one of those instead:

```python
with engine.connect() as conn, conn.begin():
    data = pd.read_sql_table('data', conn)
```

Writing DataFrames

Assuming the following data is in a DataFrame data, we can insert it into the database using to_sql().

```python
In [524]: data
Out[524]:
   id  Date    Col_1  Col_2  Col_3
0  26 2012-10-18   X   25.7   True
1  42 2012-10-19   Y  -12.4   False
2  63 2012-10-20   Z    5.73   True
```

```python
In [525]: data.to_sql('data', engine)
```

With some databases, writing large DataFrames can result in errors due to packet size limitations being exceeded. This can be avoided by setting the chunksize parameter when calling to_sql. For example, the following writes data to the database in batches of 1000 rows at a time:

```python
In [526]: data.to_sql('data', engine, chunksize=1000)
```
**SQL data types**

`to_sql()` will try to map your data to an appropriate SQL data type based on the dtype of the data. When you have columns of dtype `object`, pandas will try to infer the data type.

You can always override the default type by specifying the desired SQL type of any of the columns by using the `dtype` argument. This argument needs a dictionary mapping column names to SQLAlchemy types (or strings for the sqlite3 fallback mode). For example, specifying to use the `sqlalchemy.String` type instead of the default `Text` type for string columns:

```python
In [527]: from sqlalchemy.types import String
In [528]: data.to_sql('data_dtype', engine, dtype={'Col_1': String})
```

**Note:** Due to the limited support for timedelta’s in the different database flavors, columns with type `timedelta64` will be written as integer values as nanoseconds to the database and a warning will be raised.

**Note:** Columns of `category` dtype will be converted to the dense representation as you would get with `np.asarray(categorical)` (e.g. for string categories this gives an array of strings). Because of this, reading the database table back in does **not** generate a categorical.

**Datetime data types**

Using SQLAlchemy, `to_sql()` is capable of writing datetime data that is timezone naive or timezone aware. However, the resulting data stored in the database ultimately depends on the supported data type for datetime data of the database system being used.

The following table lists supported data types for datetime data for some common databases. Other database dialects may have different data types for datetime data.

<table>
<thead>
<tr>
<th>Database</th>
<th>SQL Datetime Types</th>
<th>Timezone Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLite</td>
<td>TEXT</td>
<td>No</td>
</tr>
<tr>
<td>MySQL</td>
<td>TIMESTAMP or DATETIME</td>
<td>No</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>TIMESTAMP or TIMESTAMP WITH TIME ZONE</td>
<td>Yes</td>
</tr>
</tbody>
</table>

When writing timezone aware data to databases that do not support timezones, the data will be written as timezone naive timestamps that are in local time with respect to the timezone.

`read_sql_table()` is also capable of reading datetime data that is timezone aware or naive. When reading `TIMESTAMP WITH TIME ZONE` types, pandas will convert the data to UTC.
Insertion method

New in version 0.24.0.

The parameter `method` controls the SQL insertion clause used. Possible values are:

- **None**: Uses standard SQL `INSERT` clause (one per row).
- **'multi'**: Pass multiple values in a single `INSERT` clause. It uses a special SQL syntax not supported by all backends. This usually provides better performance for analytic databases like Presto and Redshift, but has worse performance for traditional SQL backend if the table contains many columns. For more information check the SQLAlchemy documentation.
- **callable with signature** `(pd_table, conn, keys, data_iter)`: This can be used to implement a more performant insertion method based on specific backend dialect features.

Example of a callable using PostgreSQL COPY clause:

```python
# Alternative to to_sql() *method* for DBs that support COPY FROM
import csv
from io import StringIO

def psql_insert_copy(table, conn, keys, data_iter):
    """
    Execute SQL statement inserting data
    ""
    Parameters
    ----------
    table : pandas.io.sql.SQLTable
    conn : sqlalchemy.engine.Engine or sqlalchemy.engine.Connection
    keys : list of str
        Column names
    data_iter : Iterable that iterates the values to be inserted
    ""
    # gets a DBAPI connection that can provide a cursor
dbapi_conn = conn.connection
    with dbapi_conn.cursor() as cur:
        s_buf = StringIO()
        writer = csv.writer(s_buf)
        writer.writerows(data_iter)
        s_buf.seek(0)

        columns = ', '.join('"{}"'.format(k) for k in keys)
        if table.schema:
            table_name = '{schema}.{name}'.format(table.schema, table.name)
        else:
            table_name = table.name

        sql = 'COPY {} ({} FROM STDIN WITH CSV'.format(table_name, columns)
        cur.copy_expert(sql=sql, file=s_buf)
```
Reading tables

`read_sql_table()` will read a database table given the table name and optionally a subset of columns to read.

**Note:** In order to use `read_sql_table()`, you must have the SQLAlchemy optional dependency installed.

```
In [529]: pd.read_sql_table('data', engine)
Out[529]:
    index  id     Date  Col_1  Col_2  Col_3
0      0   26  2010-10-18  X     27.50  True
1      1   42  2010-10-19  Y    -12.50  False
2      2   63  2010-10-20  Z      5.73  True
```

**Note:** Note that pandas infers column dtypes from query outputs, and not by looking up data types in the physical database schema. For example, assume `userid` is an integer column in a table. Then, intuitively, `select userid ...` will return integer-valued series, while `select cast(userid as text) ...` will return object-valued (str) series. Accordingly, if the query output is empty, then all resulting columns will be returned as object-valued (since they are most general). If you foresee that your query will sometimes generate an empty result, you may want to explicitly typecast afterwards to ensure dtype integrity.

You can also specify the name of the column as the `DataFrame` index, and specify a subset of columns to be read.

```
In [530]: pd.read_sql_table('data', engine, index_col='id')
Out[530]:
    index  Date  Col_1  Col_2  Col_3
id
26   0  2010-10-18  X     27.50  True
42   1  2010-10-19  Y    -12.50  False
63   2  2010-10-20  Z      5.73  True
```

```
In [531]: pd.read_sql_table('data', engine, columns=['Col_1', 'Col_2'])
Out[531]:
   Col_1  Col_2
0    X  27.50
1    Y -12.50
2    Z   5.73
```

And you can explicitly force columns to be parsed as dates:

```
In [532]: pd.read_sql_table('data', engine, parse_dates=['Date'])
Out[532]:
    index  id     Date  Col_1  Col_2  Col_3
0      0   26  2010-10-18  X     27.50  True
1      1   42  2010-10-19  Y    -12.50  False
2      2   63  2010-10-20  Z      5.73  True
```

If needed you can explicitly specify a format string, or a dict of arguments to pass to `pandas.to_datetime()`:

```
pd.read_sql_table('data', engine, parse_dates=['Date': '%Y-%m-%d'])
pd.read_sql_table('data', engine, parse_dates={'Date': {'format': '%Y-%m-%d %H:%M:%S'}})
```

You can check if a table exists using `has_table()`
Schema support

Reading from and writing to different schema’s is supported through the `schema` keyword in the `read_sql_table()` and `to_sql()` functions. Note however that this depends on the database flavor (sqlite does not have schema’s). For example:

```python
df.to_sql('table', engine, schema='other_schema')
pd.read_sql_table('table', engine, schema='other_schema')
```

Querying

You can query using raw SQL in the `read_sql_query()` function. In this case you must use the SQL variant appropriate for your database. When using SQLAlchemy, you can also pass SQLAlchemy Expression language constructs, which are database-agnostic.

```python
In [533]: pd.read_sql_query('SELECT * FROM data', engine)
Out[533]:
    index id Date  Col_1  Col_2  Col_3
0       0  26 2010-10-18 00:00:00.000000  X    27.5  1
1       1  42 2010-10-19 00:00:00.000000  Y   -12.5  0
2       2  63 2010-10-20 00:00:00.000000  Z     5.73  1
```

Of course, you can specify a more “complex” query.

```python
In [534]: pd.read_sql_query("SELECT id, Col_1, Col_2 FROM data WHERE id = 42;","",engine)
Out[534]:
    id  Col_1  Col_2
0   42     Y   -12.5
```

The `read_sql_query()` function supports a `chunksize` argument. Specifying this will return an iterator through chunks of the query result:

```python
In [535]: df = pd.DataFrame(np.random.randn(20, 3), columns=list('abc'))
In [536]: df.to_sql('data_chunks', engine, index=False)
In [537]: for chunk in pd.read_sql_query("SELECT * FROM data_chunks", engine, chunksize=5):
   ....:     print(chunk)
   ....:
   ....:         a   b   c
0   0.092961 -0.674003 1.104153
1  -0.092732 -0.156246 -0.585167
2  -0.358119 -0.862331 -1.672907
3   0.550313 -1.507513 -0.617232
4   0.650576  1.033221  0.492464
   a   b   c
0  -1.627786 -0.692062 1.039548
1  -1.802313 -0.890905 -0.881794
2   0.630492  0.016739  0.014500
3  -0.438358  0.647275 -0.052075
4   0.673137  1.227539  0.203534
   a   b   c
0   0.861658  0.867852 -0.465016
(continues on next page)
You can also run a plain query without creating a DataFrame with `execute()`. This is useful for queries that don’t return values, such as INSERT. This is functionally equivalent to calling `execute` on the SQLAlchemy engine or db connection object. Again, you must use the SQL syntax variant appropriate for your database.

```python
from pandas.io import sql
sql.execute('SELECT * FROM table_name', engine)
sql.execute('INSERT INTO table_name VALUES(?, ?, ?)', engine, params=[('id', 1, 12.2, True)])
```

### Engine connection examples

To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to.

```python
from sqlalchemy import create_engine
engine = create_engine('postgresql://scott:tiger@localhost:5432/mydatabase')
engine = create_engine('mysql+mysqldb://scott:tiger@localhost/foo')
engine = create_engine('oracle://scott:tiger@127.0.0.1:1521/sidname')
engine = create_engine('mssql+pyodbc://mydsn')

# sqlite://<nohostname>/<path>
# where <path> is relative:
engine = create_engine('sqlite:///foo.db')

# or absolute, starting with a slash:
engine = create_engine('sqlite:///absolute/path/to/foo.db')
```

For more information see the examples the SQLAlchemy documentation.
**Advanced SQLAlchemy queries**

You can use SQLAlchemy constructs to describe your query.

Use `sqlalchemy.text()` to specify query parameters in a backend-neutral way

```python
In [538]: import sqlalchemy as sa

In [539]: pd.read_sql(sa.text('SELECT * FROM data where Col_1=:col1'), engine, params={'col1': 'X'})

Out[539]:
   index  id  Date           Col_1  Col_2  Col_3
0      0  26 2010-10-18 00:00:00.000000  X  27.5  1
```

If you have an SQLAlchemy description of your database you can express where conditions using SQLAlchemy expressions

```python
In [540]: metadata = sa.MetaData()

In [541]: data_table = sa.Table('data', metadata,
                           sa.Column('index', sa.Integer),
                           sa.Column('Date', sa.DateTime),
                           sa.Column('Col_1', sa.String),
                           sa.Column('Col_2', sa.Float),
                           sa.Column('Col_3', sa.Boolean),
                           )

In [542]: pd.read_sql(sa.select([data_table]).where(data_table.c.Col_3 is True), engine)

Out[542]:
Empty DataFrame
Columns: [index, Date, Col_1, Col_2, Col_3]
Index: []
```

You can combine SQLAlchemy expressions with parameters passed to `read_sql()` using `sqlalchemy.bindparam()`

```python
In [543]: import datetime as dt

In [544]: expr = sa.select([data_table]).where(data_table.c.Date > sa.bindparam('date'))

In [545]: pd.read_sql(expr, engine, params={'date': dt.datetime(2010, 10, 18)})

Out[545]:
   index  Date  Col_1  Col_2  Col_3
0      1  2010-10-19  Y -12.50  False
1      2  2010-10-20  Z   5.73   True
```
Sqlite fallback

The use of sqlite is supported without using SQLAlchemy. This mode requires a Python database adapter which respect the Python DB-API.

You can create connections like so:

```python
import sqlite3
con = sqlite3.connect(':memory:)
```

And then issue the following queries:

```python
data.to_sql('data', con)
pd.read_sql_query("SELECT * FROM data", con)
```

2.4.15 Google BigQuery

**Warning:** Starting in 0.20.0, pandas has split off Google BigQuery support into the separate package pandas-gbq. You can **pip install pandas-gbq** to get it.

The pandas-gbq package provides functionality to read/write from Google BigQuery. pandas integrates with this external package. if pandas-gbq is installed, you can use the pandas methods **pd.read_gbq** and **DataFrame.to_gbq**, which will call the respective functions from pandas-gbq.

Full documentation can be found [here](#).

2.4.16 Stata format

**Writing to stata format**

The method **to_stata()** will write a DataFrame into a .dta file. The format version of this file is always 115 (Stata 12).

```python
In [546]: df = pd.DataFrame(np.random.randn(10, 2), columns=list('AB'))
In [547]: df.to_stata('stata.dta')
```

_**Stata**_ data files have limited data type support; only strings with 244 or fewer characters, **int8, int16, int32, float32** and **float64** can be stored in .dta files. Additionally, _**Stata**_ reserves certain values to represent missing data. Exporting a non-missing value that is outside of the permitted range in Stata for a particular data type will retype the variable to the next larger size. For example, **int8** values are restricted to lie between -127 and 100 in Stata, and so variables with values above 100 will trigger a conversion to **int16**. **nan** values in floating points data types are stored as the basic missing data type (. in Stata).

**Note:** It is not possible to export missing data values for integer data types.

The _**Stata**_ writer gracefully handles other data types including **int64, bool, uint8, uint16, uint32** by casting to the smallest supported type that can represent the data. For example, data with a type of **uint8** will be cast to **int8** if all values are less than 100 (the upper bound for non-missing **int8** data in _**Stata**_), or, if values are outside of this range, the variable is cast to **int16**.
**Warning:** Conversion from `int64` to `float64` may result in a loss of precision if `int64` values are larger than $2^{53}$.

**Warning:** `StataWriter` and `to_stata()` only support fixed width strings containing up to 244 characters, a limitation imposed by the version 115 `dta` file format. Attempting to write `Stata` `dta` files with strings longer than 244 characters raises a `ValueError`.

### Reading from Stata format

The top-level function `read_stata` will read a `dta` file and return either a `DataFrame` or a `StataReader` that can be used to read the file incrementally.

```python
In [548]: pd.read_stata('stata.dta')
Out[548]:
          A         B
index
0  0.608228  1.064810
1 -0.780506 -2.736887
2  0.143539  1.170191
3 -1.573076  0.075792
4 -1.722223 -0.774650
5  0.803627  0.221665
6  0.584637  0.147264
7  1.057825 -0.284136
8  0.912395  1.552808
9  0.189376 -0.109830
```

Specifying a `chunksize` yields a `StataReader` instance that can be used to read `chunksize` lines from the file at a time. The `StataReader` object can be used as an iterator.

```python
In [549]: reader = pd.read_stata('stata.dta', chunksize=3)
In [550]:
.....:   for df in reader:
.....:       print(df.shape)
.....:   (3, 3)
.....:   (3, 3)
.....:   (3, 3)
.....:   (1, 3)
```

For more fine-grained control, use `iterator=True` and specify `chunksize` with each call to `read()`.

```python
In [551]: reader = pd.read_stata('stata.dta', iterator=True)
In [552]: chunk1 = reader.read(5)
In [553]: chunk2 = reader.read(5)
```

Currently the `index` is retrieved as a column.

The parameter `convert_categoricals` indicates whether value labels should be read and used to create a `Categorical` variable from them. Value labels can also be retrieved by the function `value_labels`, which requires `read()` to be called before use.
The parameter `convert_missing` indicates whether missing value representations in Stata should be preserved. If `False` (the default), missing values are represented as `np.nan`. If `True`, missing values are represented using `StataMissingValue` objects, and columns containing missing values will have `object` data type.

**Note:** `read_stata()` and `StataReader` support .dta formats 113-115 (Stata 10-12), 117 (Stata 13), and 118 (Stata 14).

**Note:** Setting `preserve_dtypes=False` will upcast to the standard pandas data types: `int64` for all integer types and `float64` for floating point data. By default, the Stata data types are preserved when importing.

### Categorical data

Categorical data can be exported to *Stata* data files as value labeled data. The exported data consists of the underlying category codes as integer data values and the categories as value labels. *Stata* does not have an explicit equivalent to a `Categorical` and information about whether the variable is ordered is lost when exporting.

**Warning:** *Stata* only supports string value labels, and so `str` is called on the categories when exporting data. Exporting Categorical variables with non-string categories produces a warning, and can result a loss of information if the `str` representations of the categories are not unique.

Labeled data can similarly be imported from *Stata* data files as Categorical variables using the keyword argument `convert_categoricals` (True by default). The keyword argument `order_categoricals` (True by default) determines whether imported Categorical variables are ordered.

**Note:** When importing categorical data, the values of the variables in the *Stata* data file are not preserved since Categorical variables always use integer data types between -1 and n-1 where n is the number of categories. If the original values in the *Stata* data file are required, these can be imported by setting `convert_categoricals=False`, which will import original data (but not the variable labels). The original values can be matched to the imported categorical data since there is a simple mapping between the original *Stata* data values and the category codes of imported Categorical variables: missing values are assigned code -1, and the smallest original value is assigned 0, the second smallest is assigned 1 and so on until the largest original value is assigned the code n-1.

**Note:** *Stata* supports partially labeled series. These series have value labels for some but not all data values. Importing a partially labeled series will produce a Categorical with string categories for the values that are labeled and numeric categories for values with no label.
2.4.17 SAS formats

The top-level function `read_sas()` can read (but not write) SAS xport (.XPT) and (since v0.18.0) SAS7BDAT (.sas7bdat) format files.

SAS files only contain two value types: ASCII text and floating point values (usually 8 bytes but sometimes truncated). For xport files, there is no automatic type conversion to integers, dates, or categoricals. For SAS7BDAT files, the format codes may allow date variables to be automatically converted to dates. By default the whole file is read and returned as a DataFrame.

Specify a `chunksize` or use `iterator=True` to obtain reader objects (XportReader or SAS7BDATReader) for incrementally reading the file. The reader objects also have attributes that contain additional information about the file and its variables.

Read a SAS7BDAT file:

```python
df = pd.read_sas('sas_data.sas7bdat')
```

Obtain an iterator and read an XPORT file 100,000 lines at a time:

```python
def do_something(chunk):
    pass
rdr = pd.read_sas('sas_xport.xpt', chunk=100000)
for chunk in rdr:
    do_something(chunk)
```

The specification for the xport file format is available from the SAS web site.

No official documentation is available for the SAS7BDAT format.

2.4.18 SPSS formats

New in version 0.25.0.

The top-level function `read_spss()` can read (but not write) SPSS sav (.sav) and zsav (.zsav) format files.

SPSS files contain column names. By default the whole file is read, categorical columns are converted into `pd.Categorical`, and a DataFrame with all columns is returned.

Specify the `usecols` parameter to obtain a subset of columns. Specify `convert_categoricals=False` to avoid converting categorical columns into `pd.Categorical`.

Read an SPSS file:

```python
df = pd.read_spss('spss_data.sav')
```

Extract a subset of columns contained in `usecols` from an SPSS file and avoid converting categorical columns into `pd.Categorical`:

```python
df = pd.read_spss('spss_data.sav', usecols=['foo', 'bar'], convert_categoricals=False)
```

More information about the `sav` and `zsav` file format is available here.
2.4.19 Other file formats

pandas itself only supports IO with a limited set of file formats that map cleanly to its tabular data model. For reading and writing other file formats into and from pandas, we recommend these packages from the broader community.

**netCDF**

xarray provides data structures inspired by the pandas DataFrame for working with multi-dimensional datasets, with a focus on the netCDF file format and easy conversion to and from pandas.

2.4.20 Performance considerations

This is an informal comparison of various IO methods, using pandas 0.24.2. Timings are machine dependent and small differences should be ignored.

```python
In [1]: sz = 1000000
In [3]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 2 columns):
A 1000000 non-null float64
B 1000000 non-null int64
dtypes: float64(1), int64(1)
memory usage: 15.3 MB
```

Given the next test set:

```python
import numpy as np
import os
sz = 1000000
sz = 1000000
np.random.seed(42)
def test_sql_write(df):
    if os.path.exists('test.sql'):
        os.remove('test.sql')
    sql_db = sqlite3.connect('test.sql')
df.to_sql(name='test_table', con=sql_db)
sql_db.close()

def test_sql_read():
    sql_db = sqlite3.connect('test.sql')
pd.read_sql_query("select * from test_table", sql_db)
sql_db.close()

def test_hdf_fixed_write(df):
    df.to_hdf('test_fixed.hdf', 'test', mode='w')
```

(continues on next page)
When writing, the top-three functions in terms of speed are `test_feather_write`, `test_hdf_fixed_write` and `test_hdf_fixed_write_compress`.

In [4]: %timeit test_sql_write(df)
pandas: powerful Python data analysis toolkit, Release 1.1.5

3.29 s ± 43.2 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [5]: %timeit test_hdf_fixed_write(df)
19.4 ms ± 560 µs per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [6]: %timeit test_hdf_fixed_write_compress(df)
19.6 ms ± 308 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [11]: %timeit test_pickle_write(df)
30.1 ms ± 229 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [12]: %timeit test_pickle_write_compress(df)
4.29 s ± 15.9 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [13]: %timeit test_parquet_write(df)
67.6 ms ± 706 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

When reading, the top three are test_feather_read, test_pickle_read and test_hdf_fixed_read.

In [14]: %timeit test_sql_read()
1.77 s ± 17.7 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [15]: %timeit test_hdf_fixed_read()
19.4 ms ± 436 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [16]: %timeit test_hdf_fixed_read_compress()
19.5 ms ± 222 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [17]: %timeit test_hdf_table_read()
38.6 ms ± 857 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [18]: %timeit test_hdf_table_read_compress()
38.8 ms ± 1.49 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [19]: %timeit test_csv_read()
452 ms ± 9.04 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [20]: %timeit test_feather_read()
12.4 ms ± 99.7 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

In [21]: %timeit test_pickle_read()
18.4 ms ± 191 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

In [22]: %timeit test_pickle_read_compress()
915 ms ± 7.48 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)
For this test case `test.pkl.compress`, `test.parquet` and `test.feather` took the least space on disk. Space on disk (in bytes)

### 2.5 Indexing and selecting data

The axis labeling information in pandas objects serves many purposes:

- Identifies data (i.e. provides *metadata*) using known indicators, important for analysis, visualization, and interactive console display.
- Enables automatic and explicit data alignment.
- Allows intuitive getting and setting of subsets of the data set.

In this section, we will focus on the final point: namely, how to slice, dice, and generally get and set subsets of pandas objects. The primary focus will be on Series and DataFrame as they have received more development attention in this area.

**Note:** The Python and NumPy indexing operators `[]` and attribute operator `.` provide quick and easy access to pandas data structures across a wide range of use cases. This makes interactive work intuitive, as there’s little new to learn if you already know how to deal with Python dictionaries and NumPy arrays. However, since the type of the data to be accessed isn’t known in advance, directly using standard operators has some optimization limits. For production code, we recommended that you take advantage of the optimized pandas data access methods exposed in this chapter.

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See *Returning a View versus Copy*.

See the *MultiIndex / Advanced Indexing* for *MultiIndex* and more advanced indexing documentation.

See the *cookbook* for some advanced strategies.
2.5.1 Different choices for indexing

Object selection has had a number of user-requested additions in order to support more explicit location based indexing. Pandas now supports three types of multi-axis indexing.

- **.loc** is primarily label based, but may also be used with a boolean array. **.loc** will raise **KeyError** when the items are not found. Allowed inputs are:
  - A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a *label* of the index. This use is not an integer position along the index.).
  - A list or array of labels ['a', 'b', 'c'].
  - A slice object with labels 'a':':'f' (Note that contrary to usual python slices, both the start and the stop are included, when present in the index! See *Slicing with labels* and *Endpoints are inclusive*.)
  - A boolean array (any NA values will be treated as False).
  - A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above).

See more at *Selection by Label*.

- **.iloc** is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array. **.iloc** will raise **IndexError** if a requested indexer is out-of-bounds, except slice indexers which allow out-of-bounds indexing. (this conforms with Python/NumPy slice semantics). Allowed inputs are:
  - An integer e.g. 5.
  - A list or array of integers [4, 3, 0].
  - A slice object with ints 1:7.
  - A boolean array (any NA values will be treated as False).
  - A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above).

See more at *Selection by Position*, *Advanced Indexing* and *Advanced Hierarchical*.

- **.loc**, **.iloc**, and also [] indexing can accept a callable as indexer. See more at *Selection By Callable*.

Getting values from an object with multi-axes selection uses the following notation (using **.loc** as an example, but the following applies to **.iloc** as well). Any of the axes accessories may be the null slice :. Axes left out of the specification are assumed to be :, e.g. `p.loc['a']` is equivalent to `p.loc['a', :, :]`.

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Indexers</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series</td>
<td><code>s.loc[indexer]</code></td>
</tr>
<tr>
<td>DataFrame</td>
<td><code>df.loc[row_indexer, column_indexer]</code></td>
</tr>
</tbody>
</table>

2.5.2 Basics

As mentioned when introducing the data structures in the last section, the primary function of indexing with [] (a.k.a. **__getitem__** for those familiar with implementing class behavior in Python) is selecting out lower-dimensional slices. The following table shows return type values when indexing pandas objects with []:

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Selection</th>
<th>Return Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series</td>
<td><code>series[label]</code></td>
<td>scalar value</td>
</tr>
<tr>
<td>DataFrame</td>
<td><code>frame[colname]</code></td>
<td>Series corresponding to colname</td>
</tr>
</tbody>
</table>
pandas: powerful Python data analysis toolkit, Release 1.1.5

Here we construct a simple time series data set to use for illustrating the indexing functionality:

```python
In [1]: dates = pd.date_range('1/1/2000', periods=8)
In [2]: df = pd.DataFrame(np.random.randn(8, 4),
                      index=dates, columns=['A', 'B', 'C', 'D'])
In [3]: df
```

```
Out[3]:
          A         B         C         D
2000-01-01  0.469112 -0.282863 -1.509059 -1.135632
2000-01-02  1.212112 -0.173215  0.119209 -0.044236
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
2000-01-04  0.721555 -0.706771 -1.039575  0.271860
2000-01-05 -0.424972  0.567020  0.276232 -1.087401
2000-01-06 -0.673690  0.113648 -1.478427  0.524988
2000-01-07  0.404705  0.577046 -1.715002 -1.039268
2000-01-08 -0.370647 -1.157892 -1.344312  0.844885
```

**Note:** None of the indexing functionality is time series specific unless specifically stated.

Thus, as per above, we have the most basic indexing using []:

```python
In [4]: s = df['A']
In [5]: s[dates[5]]
Out[5]: -0.6736897080883706
```

You can pass a list of columns to [] to select columns in that order. If a column is not contained in the DataFrame, an exception will be raised. Multiple columns can also be set in this manner:

```python
In [6]: df
Out[6]:
          A         B         C         D
2000-01-01  0.469112 -0.282863 -1.509059 -1.135632
2000-01-02  1.212112 -0.173215  0.119209 -0.044236
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
2000-01-04  0.721555 -0.706771 -1.039575  0.271860
2000-01-05 -0.424972  0.567020  0.276232 -1.087401
2000-01-06 -0.673690  0.113648 -1.478427  0.524988
2000-01-07  0.404705  0.577046 -1.715002 -1.039268
2000-01-08 -0.370647 -1.157892 -1.344312  0.844885
```

**In [7]:** df[['B', 'A']] = df[['A', 'B']]  

**In [8]:** df
```
Out[8]:
          A         B         C         D
2000-01-01  0.469112 -0.282863 -1.509059 -1.135632
2000-01-02  1.212112 -0.173215  0.119209 -0.044236
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
2000-01-04  0.721555 -0.706771 -1.039575  0.271860
2000-01-05 -0.424972  0.567020  0.276232 -1.087401
2000-01-06 -0.673690  0.113648 -1.478427  0.524988
2000-01-07  0.404705  0.577046 -1.715002 -1.039268
2000-01-08 -0.370647 -1.157892 -1.344312  0.844885
```

(continues on next page)
You may find this useful for applying a transform (in-place) to a subset of the columns.

**Warning:** pandas aligns all AXES when setting `Series` and `DataFrame` from `.loc` and `.iloc`. This will not modify `df` because the column alignment is before value assignment.

```python
In [9]: df[['A', 'B']]
Out [9]:
  A  B
2000-01-01 -0.282863 0.469112
2000-01-02 -0.173215 1.212112
2000-01-03 -2.104569 -0.861849
2000-01-04 -0.706771 0.721555
2000-01-05 0.567020 -0.424972
2000-01-06 0.113648 -0.673690
2000-01-07 0.577046 0.404705
2000-01-08 -1.157892 -0.370647

In [10]: df.loc[:, ['B', 'A']] = df[['A', 'B']]

In [11]: df[['A', 'B']]  
Out [11]:
  A  B
2000-01-01 -0.282863 0.469112
2000-01-02 -0.173215 1.212112
2000-01-03 -2.104569 -0.861849
2000-01-04 -0.706771 0.721555
2000-01-05 0.567020 -0.424972
2000-01-06 0.113648 -0.673690
2000-01-07 0.577046 0.404705
2000-01-08 -1.157892 -0.370647

The correct way to swap column values is by using raw values:

```python
In [12]: df.loc[:, ['B', 'A']] = df[['A', 'B']].to_numpy()

In [13]: df[['A', 'B']]  
Out [13]:
  A  B
2000-01-01 0.469112 -0.282863
2000-01-02 1.212112 -0.173215
2000-01-03 -0.861849 -2.104569
2000-01-04 0.721555 -0.706771
2000-01-05 -0.424972 0.567020
2000-01-06 -0.673690 0.113648
2000-01-07 0.404705 0.577046
2000-01-08 -0.370647 -1.157892
```

2.5. Indexing and selecting data
2.5.3 Attribute access

You may access an index on a Series or column on a DataFrame directly as an attribute:

```python
In [14]: sa = pd.Series([1, 2, 3], index=list('abc'))
In [15]: dfa = df.copy()
In [16]: sa.b
Out[16]: 2
```

```python
In [17]: dfa.A
Out[17]:
2000-01-01  0.469112
2000-01-02  1.212112
2000-01-03 -0.861849
2000-01-04  0.721555
2000-01-05 -0.424972
2000-01-06 -0.673690
2000-01-07  0.404705
2000-01-08 -0.370647
Freq: D, Name: A, dtype: float64
```

```python
In [18]: sa.a = 5
In [19]: sa
Out[19]:
a  5
b  2
c  3
dtype: int64
```

```python
In [20]: dfa.A = list(range(len(dfa.index)))  # ok if A already exists
In [21]: dfa
Out[21]:
   A          B         C         D
2000-01-01 -0.282863 -1.509059 -1.135632
2000-01-02 -0.173215  0.119209 -1.044236
2000-01-03 -2.104569 -0.494929  1.071804
2000-01-04 -0.706771 -1.039575  0.271860
2000-01-05  0.567020  0.276232 -1.087401
2000-01-06  0.113648 -1.478427  0.524988
2000-01-07  0.577046 -1.715002 -1.039268
2000-01-08 -1.157892 -1.344312  0.844885
```

```python
In [22]: dfa['A'] = list(range(len(dfa.index)))  # use this form to create a new column
In [23]: dfa
Out[23]:
   A          B         C         D
2000-01-01 -0.282863 -1.509059 -1.135632
2000-01-02 -0.173215  0.119209 -1.044236
2000-01-03 -2.104569 -0.494929  1.071804
2000-01-04 -0.706771 -1.039575  0.271860
2000-01-05  0.567020  0.276232 -1.087401
2000-01-06  0.113648 -1.478427  0.524988
2000-01-07  0.577046 -1.715002 -1.039268
2000-01-08 -1.157892 -1.344312  0.844885
```

(continues on next page)
### Warning:

- You can use this access only if the index element is a valid Python identifier, e.g. `s.1` is not allowed. See here for an explanation of valid identifiers.

- The attribute will not be available if it conflicts with an existing method name, e.g. `s.min` is not allowed, but `s['min']` is possible.

- Similarly, the attribute will not be available if it conflicts with any of the following list: `index`, `major_axis`, `minor_axis`, `items`.

- In any of these cases, standard indexing will still work, e.g. `s['1'], s['min'], and s['index']` will access the corresponding element or column.

If you are using the IPython environment, you may also use tab-completion to see these accessible attributes.

You can also assign a `dict` to a row of a `DataFrame`:

```python
In [24]: x = pd.DataFrame({'x': [1, 2, 3], 'y': [3, 4, 5]})
In [25]: x.iloc[1] = {'x': 9, 'y': 99}
In [26]: x
```

```
Out[26]:
   x  y
0  1  3
1  9 99
2  3  5
```

You can use attribute access to modify an existing element of a Series or column of a DataFrame, but be careful; if you try to use attribute access to create a new column, it creates a new attribute rather than a new column. In 0.21.0 and later, this will raise a `UserWarning`:

```python
In [1]: df = pd.DataFrame({'one': [1., 2., 3.]})
In [2]: df.two = [4, 5, 6]
UserWarning: Pandas doesn't allow Series to be assigned into nonexistent columns → see https://pandas.pydata.org/pandas-docs/stable/indexing.html#attribute_access
In [3]: df
```

```
Out[3]:
   one
0  1.0
1  2.0
2  3.0
```
2.5.4 Slicing ranges

The most robust and consistent way of slicing ranges along arbitrary axes is described in the Selection by Position section detailing the .iloc method. For now, we explain the semantics of slicing using the [] operator.

With Series, the syntax works exactly as with an ndarray, returning a slice of the values and the corresponding labels:

<table>
<thead>
<tr>
<th>In [27]: s[:5]</th>
<th>Out [27]:</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01 0.469112</td>
<td></td>
</tr>
<tr>
<td>2000-01-02 1.212112</td>
<td></td>
</tr>
<tr>
<td>2000-01-03 -0.861849</td>
<td></td>
</tr>
<tr>
<td>2000-01-04 0.721555</td>
<td></td>
</tr>
<tr>
<td>2000-01-05 -0.424972</td>
<td></td>
</tr>
<tr>
<td>Freq: D, Name: A, dtype: float64</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>In [28]: s[::2]</th>
<th>Out [28]:</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01 0.469112</td>
<td></td>
</tr>
<tr>
<td>2000-01-03 -0.861849</td>
<td></td>
</tr>
<tr>
<td>2000-01-05 -0.424972</td>
<td></td>
</tr>
<tr>
<td>2000-01-07 0.404705</td>
<td></td>
</tr>
<tr>
<td>Freq: 2D, Name: A, dtype: float64</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>In [29]: s[::-1]</th>
<th>Out [29]:</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-08 -0.370647</td>
<td></td>
</tr>
<tr>
<td>2000-01-07 0.404705</td>
<td></td>
</tr>
<tr>
<td>2000-01-06 -0.673690</td>
<td></td>
</tr>
<tr>
<td>2000-01-05 -0.424972</td>
<td></td>
</tr>
<tr>
<td>2000-01-04 0.721555</td>
<td></td>
</tr>
<tr>
<td>2000-01-03 -0.861849</td>
<td></td>
</tr>
<tr>
<td>2000-01-02 1.212112</td>
<td></td>
</tr>
<tr>
<td>2000-01-01 0.469112</td>
<td></td>
</tr>
<tr>
<td>Freq: -1D, Name: A, dtype: float64</td>
<td></td>
</tr>
</tbody>
</table>

Note that setting works as well:

| In [30]: s2 = s.copy() |
| In [31]: s2[:5] = 0 |

<table>
<thead>
<tr>
<th>In [32]: s2</th>
<th>Out [32]:</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01 0.000000</td>
<td></td>
</tr>
<tr>
<td>2000-01-02 0.000000</td>
<td></td>
</tr>
<tr>
<td>2000-01-03 0.000000</td>
<td></td>
</tr>
<tr>
<td>2000-01-04 0.000000</td>
<td></td>
</tr>
<tr>
<td>2000-01-05 0.000000</td>
<td></td>
</tr>
<tr>
<td>2000-01-06 -0.673690</td>
<td></td>
</tr>
<tr>
<td>2000-01-07 0.404705</td>
<td></td>
</tr>
<tr>
<td>2000-01-08 -0.370647</td>
<td></td>
</tr>
<tr>
<td>Freq: D, Name: A, dtype: float64</td>
<td></td>
</tr>
</tbody>
</table>

With DataFrame, slicing inside of [] slices the rows. This is provided largely as a convenience since it is such a common operation.
### 2.5.5 Selection by label

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See *Returning a View versus Copy.*

**Warning:** `.loc` is strict when you present slicers that are not compatible (or convertible) with the index type. For example using integers in a `DatetimeIndex`. These will raise a `TypeError`.

```python
In [34]: df[::-1]
Out[34]:
       A     B     C     D
2000-01-01  0.469112 -0.282863 -1.509059 -1.135632
2000-01-02  1.212112 -0.173215  0.119209 -1.044236
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804

In [35]: dfl = pd.DataFrame(np.random.randn(5, 4),
                   columns=list('ABCD'),
                   index=pd.date_range('20130101', periods=5))

In [36]: dfl.loc[2:3]

TypeError: cannot do slice indexing on <class 'pandas.tseries.index.DatetimeIndex'> with these indexers [2] of <type 'int'>
```

String likes in slicing *can* be convertible to the type of the index and lead to natural slicing.

```python
In [37]: dfl.loc['20130102':'20130104']
Out[37]:
       A     B     C     D
2013-01-02  0.357021 -0.674600 -1.776904 -0.968914
2013-01-03 -1.294524  0.413738  0.276232 -1.087401
2013-01-04 -0.013960 -0.362543 -0.006154 -1.042363
```

### 2.5.5 Selection by label
Warning: Starting in 0.21.0, pandas will show a `FutureWarning` if indexing with a list with missing labels. In the future this will raise a `KeyError`. See list-like Using `loc` with missing keys in a list is Deprecated.

Pandas provides a suite of methods in order to have purely label based indexing. This is a strict inclusion based protocol. Every label asked for must be in the index, or a `KeyError` will be raised. When slicing, both the start bound AND the stop bound are included, if present in the index. Integers are valid labels, but they refer to the label and not the position.

The `.loc` attribute is the primary access method. The following are valid inputs:

- A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a label of the index. This use is not an integer position along the index).
- A list or array of labels ['a', 'b', 'c'].
- A slice object with labels 'a':'f' (Note that contrary to usual python slices, both the start and the stop are included, when present in the index! See Slicing with labels.
- A boolean array.
- A callable, see Selection By Callable.

```
In [38]: s1 = pd.Series(np.random.randn(6), index=list('abcdef'))
In [39]: s1
Out[39]:
   a    1.431256
   b    1.340309
   c   -1.170299
   d   -0.226169
   e    0.410835
   f    0.813850
dtype: float64
In [40]: s1.loc['c':]
Out[40]:
   c   -1.170299
   d   -0.226169
   e    0.410835
   f    0.813850
dtype: float64
In [41]: s1.loc['b']
Out[41]: 1.3403088497993827
```

Note that setting works as well:

```
In [42]: s1.loc['c'] = 0
In [43]: s1
Out[43]:
   a    1.431256
   b    1.340309
   c    0.000000
   d    0.000000
```

(continues on next page)
With a DataFrame:

```
In [44]: df1 = pd.DataFrame(np.random.randn(6, 4),
                         index=list('abcdef'),
                         columns=list('ABCD'))

In [45]: df1
Out[45]:
   A   B   C   D
a 0.13  -0.83  -0.08  -1.19
b 1.13  -1.44  -1.42   1.61
c 1.02   0.57   0.87  -2.21
d 0.97  -2.01  -0.41  -0.08
e 0.55  -1.22  -1.23   0.77
f -1.28  -0.73  -0.12  -0.09

In [46]: df1.loc[['a', 'b', 'd'], :]
Out[46]:
   A   B   C   D
a 0.13  -0.83  -0.08  -1.19
b 1.13  -1.44  -1.42   1.61
d 0.97  -2.01  -0.41  -0.08

Accessing via label slices:

```
In [47]: df1.loc['d', 'A':'C']
Out[47]:
   A   B   C
d 0.97  -2.01  -0.41
e 0.55  -1.22  -1.23
f -1.28  -0.73  -0.12

For getting a cross section using a label (equivalent to df.xs('a')):

```
In [48]: df1.loc['a']
Out[48]:
   A   B   C   D
Name: a, dtype: float64
```

For getting values with a boolean array:

```
In [49]: df1.loc['a'] > 0
Out[49]:
   A   B   C   D
Name: a, dtype: bool
```
NA values in a boolean array propagate as False:

Changed in version 1.0.2: mask = pd.array([True, False, True, False, pd.NA, False], dtype="boolean") mask df1[mask]

For getting a value explicitly:

```python
# this is also equivalent to ``df1.at['a','A']``
In [51]: df1.loc['a', 'A']
Out[51]: 0.13200317033032932
```

### Slicing with labels

When using `.loc` with slices, if both the start and the stop labels are present in the index, then elements located between the two (including them) are returned:

```python
In [52]: s = pd.Series(list('abcde'), index=[0, 3, 2, 5, 4])
In [53]: s.loc[3:5]
Out[53]:
3  b
2  c
5  d
dtype: object
```

If at least one of the two is absent, but the index is sorted, and can be compared against start and stop labels, then slicing will still work as expected, by selecting labels which rank between the two:

```python
In [54]: s.sort_index()
Out[54]:
0  a
2  c
3  b
4  e
5  d
dtype: object
In [55]: s.sort_index().loc[1:6]
Out[55]:
2  c
3  b
4  e
5  d
dtype: object
```
However, if at least one of the two is absent and the index is not sorted, an error will be raised (since doing otherwise would be computationally expensive, as well as potentially ambiguous for mixed type indexes). For instance, in the above example, s.loc[1:6] would raise KeyError.

For the rationale behind this behavior, see *Endpoints are inclusive.*

### 2.5.6 Selection by position

| Warning: | Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See *Returning a View versus Copy.* |

Pandas provides a suite of methods in order to get **purely integer based indexing**. The semantics follow closely Python and NumPy slicing. These are 0-based indexing. When slicing, the start bound is included, while the upper bound is excluded. Trying to use a non-integer, even a valid label will raise an IndexError.

The `.iloc` attribute is the primary access method. The following are valid inputs:

- An integer e.g. 5.
- A list or array of integers [4, 3, 0].
- A slice object with ints 1:7.
- A boolean array.
- A callable, see *Selection By Callable.*

```python
In [56]: s1 = pd.Series(np.random.randn(5), index=list(range(0, 10, 2)))
In [57]: s1
Out[57]:
    0   0.695775
    2   0.341734
    4   0.959726
    6  -1.110336
    8  -0.619976
   dtype: float64
In [58]: s1.iloc[:3]
Out[58]:
    0   0.695775
    2   0.341734
    4   0.959726
   dtype: float64
In [59]: s1.iloc[3]
Out[59]: -1.110336102891167
```

Note that setting works as well:

```python
In [60]: s1.iloc[:3] = 0
In [61]: s1
Out[61]:
    0   0.000000
    2   0.000000
    4   0.000000
```

(continues on next page)
With a DataFrame:

```python
In [62]: df1 = pd.DataFrame(np.random.randn(6, 4),
    ....:                      index=list(range(0, 12, 2)),
    ....:                      columns=list(range(0, 8, 2)))

In [63]: df1
Out[63]:
   2  4  6
0  0.149748 -0.732339  0.687738  0.176444
2  0.403310 -0.154951  0.301624 -2.179861
4 -1.369849 -0.954208  1.462696 -1.743161
6 -0.826591 -0.345352  1.314232  0.690579
8  0.995761  2.396780  0.014871  3.357427
10 -0.317441 -1.236269  0.896171 -0.487602
```

Select via integer slicing:

```python
In [64]: df1.iloc[:3]
Out[64]:
   2  4  6
0  0.149748 -0.732339  0.687738  0.176444
2  0.403310 -0.154951  0.301624 -2.179861
4 -1.369849 -0.954208  1.462696 -1.743161

In [65]: df1.iloc[1:5, 2:4]
Out[65]:
   4  6
2  0.301624 -2.179861
4  1.462696 -1.743161
6  1.314232  0.690579
8  0.014871  3.357427

In [66]: df1.iloc[[1, 3, 5], [1, 3]]
Out[66]:
   2  6
2 -0.154951 -2.179861
6 -0.345352  0.690579
10 -1.236269 -0.487602

In [67]: df1.iloc[1:3, :]
Out[67]:
   2  4  6
2  0.403310 -0.154951  0.301624 -2.179861
4 -1.369849 -0.954208  1.462696 -1.743161

In [68]: df1.iloc[:, 1:3]
Out[68]:
   2  4
```

# this is also equivalent to `df1.iat[1,1]`

```python
In [69]: df1.iloc[1, 1]
Out[69]: -0.1549507744249032
```

For getting a cross section using an integer position (equiv to `df.xs(1)`):

```python
In [70]: df1.iloc[1]
Out[70]:
0    0.403310
2   -0.154951
4    0.301624
6   -2.179861
Name: 2, dtype: float64
```

Out of range slice indexes are handled gracefully just as in Python/Numpy.

```python
In [71]: x = list('abcdef')
In [72]: x
Out[72]: ['a', 'b', 'c', 'd', 'e', 'f']
In [73]: x[4:10]
Out[73]: ['e', 'f']
In [74]: x[8:10]
Out[74]: []
In [75]: s = pd.Series(x)
In [76]: s
Out[76]:
0   a
1   b
2   c
3   d
4   e
5   f
dtype: object
In [77]: s.iloc[4:10]
Out[77]:
4   e
5   f
dtype: object
In [78]: s.iloc[8:10]
Out[78]: Series([], dtype: object)
```

Note that using slices that go out of bounds can result in an empty axis (e.g. an empty DataFrame being returned).
In [79]: df1 = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))

In [80]: df1
Out[80]:
   A    B
0 -0.082240 -2.182937
1  0.380396  0.084844
2  0.432390  1.519970
3 -0.493662  0.600178
4  0.274230  0.132885

In [81]: df1.iloc[:, 2:3]
Out[81]:
Empty DataFrame
Columns: []
Index: [0, 1, 2, 3, 4]

In [82]: df1.iloc[:, 1:3]
Out[82]:
   B
0 -2.182937
1  0.084844
2  1.519970
3  0.600178
4  0.132885

In [83]: df1.iloc[4:6]
Out[83]:
   A    B
4  0.27423  0.132885

A single indexer that is out of bounds will raise an IndexError. A list of indexers where any element is out of bounds will raise an IndexError.

>>> df1.iloc[[4, 5, 6]]
IndexError: positional indexers are out-of-bounds

>>> df1.iloc[:, 4]
IndexError: single positional indexer is out-of-bounds

### 2.5.7 Selection by callable

.loc, .iloc, and also [] indexing can accept a callable as indexer. The callable must be a function with one argument (the calling Series or DataFrame) that returns valid output for indexing.

In [84]: df1 = pd.DataFrame(np.random.randn(6, 4),
                   columns=list('ABCD'))

In [85]: df1
Out[85]:
   A    B    C    D
a -0.023688  2.410179  1.450520  0.206053
b -0.251905 -2.213588  1.063327  1.266143

(continues on next page)
You can use callable indexing in Series.

```
In [90]: df1['A'].loc[lambda s: s > 0]
Out[90]:
   c   e
0  0.299368  1.289997
```

Using these methods / indexers, you can chain data selection operations without using a temporary variable.

```
In [91]: bb = pd.read_csv('data/baseball.csv', index_col='id')
In [92]: (bb.groupby(['year', 'team']).sum()
   ....: .loc[lambda df: df['r'] > 100])
   ....: 
Out[92]:
```

### 2.5. Indexing and selecting data

(c) 0.299368 -0.863838 0.408204 -1.048089
d -0.025747 -0.988387 0.094055 1.262731
e 1.289997 0.082423 -0.055758 0.536580
f -0.489682 0.369374 -0.034571 -2.484478

In [86]: df1.loc[lambda df: df['A'] > 0, :]
Out[86]:
   A     B     C     D
c  0.299368 -0.863838  0.408204 -1.048089
e  1.289997  0.082423 -0.055758  0.536580

In [87]: df1.loc[:, lambda df: ['A', 'B']]
Out[87]:
   A     B
a -0.023688  2.410179
b -0.251905 -2.213588
c  0.299368 -0.863838
d -0.025747 -0.988387
e  1.289997  0.082423
f -0.489682  0.369374

In [88]: df1.iloc[:, lambda df: [0, 1]]
Out[88]:
   A     B
a -0.023688  2.410179
b -0.251905 -2.213588
c  0.299368 -0.863838
d -0.025747 -0.988387
e  1.289997  0.082423
f -0.489682  0.369374

In [89]: df1[lambda df: df.columns[0]]
Out[89]:
   A
a -0.023688
b -0.251905
c  0.299368
d -0.025747
e  1.289997
f -0.489682
Name: A, dtype: float64

You can use callable indexing in Series.

```
In [90]: df1['A'].loc[lambda s: s > 0]
Out[90]:
   c   e
0  0.299368  1.289997
```

Using these methods / indexers, you can chain data selection operations without using a temporary variable.
Warning: Starting in 0.20.0, the `.ix` indexer is deprecated, in favor of the more strict `.iloc` and `.loc` indexers.

`.ix` offers a lot of magic on the inference of what the user wants to do. To wit, `.ix` can decide to index *positionally* OR via *labels* depending on the data type of the index. This has caused quite a bit of user confusion over the years.

The recommended methods of indexing are:
- `.loc` if you want to *label* index.
- `.iloc` if you want to *positionally* index.

```
In [93]: dfd = pd.DataFrame({
    ...:         'A': [1, 2, 3],
    ...:         'B': [4, 5, 6],
    ...:     index=list('abc')
    ...: })
```

```
In [94]: dfd
Out[94]:
      A  B
     a 1  4
     b 2  5
     c 3  6
```

Previous behavior, where you wish to get the 0th and the 2nd elements from the index in the ‘A’ column.

```
In [3]: dfd.ix[[0, 2], 'A']
Out[3]:
     a  1
     c  3
Name: A, dtype: int64
```
Using `loc`. Here we will select the appropriate indexes from the index, then use *label* indexing.

In [95]: dfd.loc[dfd.index[[0, 2]], 'A']
Out[95]:
a 1
b 3
Name: A, dtype: int64

This can also be expressed using `iloc`, by explicitly getting locations on the indexers, and using *positional* indexing to select things.

In [96]: dfd.iloc[[0, 2], dfd.columns.get_loc('A')]
Out[96]:
a 1
b 3
Name: A, dtype: int64

For getting *multiple* indexers, using `get_indexer`:

In [97]: dfd.iloc[[0, 2], dfd.columns.get_indexer(['A', 'B'])]

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>c</td>
<td>3</td>
<td>6</td>
</tr>
</tbody>
</table>

### 2.5.9 Indexing with list with missing labels is deprecated

**Warning:** Starting in 0.21.0, using `loc` or `[]` with a list with one or more missing labels, is deprecated, in favor of `reindex`.

In prior versions, using `loc[list-of-labels]` would work as long as *at least 1* of the keys was found (otherwise it would raise a `KeyError`). This behavior is deprecated and will show a warning message pointing to this section. The recommended alternative is to use `reindex()`.

For example.

In [98]: s = pd.Series([1, 2, 3])
In [99]: s
Out[99]:
0 1
1 2
2 3
dtype: int64

Selection with all keys found is unchanged.

In [100]: s.loc[[1, 2]]
Out[100]:
1 2
2 3
dtype: int64

Previous behavior

### 2.5. Indexing and selecting data
Current behavior

```
In [4]: s.loc[[1, 2, 3]]
Out[4]:
1  2.0
2  3.0
3  NaN
dtype: float64
```

```
In [4]: s.loc[[1, 2, 3]]
Passing list-likes to .loc with any non-matching elements will raise KeyError in the future, you can use .reindex() as an alternative.
```

```
Out[4]:
1  2.0
2  3.0
3  NaN
dtype: float64
```

Reindexing

The idiomatic way to achieve selecting potentially not-found elements is via `.reindex()`. See also the section on `reindexing`.

```
In [101]: s.reindex([1, 2, 3])
Out[101]:
1  2.0
2  3.0
3  NaN
dtype: float64
```

```
Alternatively, if you want to select only `valid` keys, the following is idiomatic and efficient; it is guaranteed to preserve the dtype of the selection.
```

```
In [102]: labels = [1, 2, 3]

In [103]: s.loc[s.index.intersection(labels)]
Out[103]:
1  2
2  3
dtype: int64
```

```
Having a duplicated index will raise for a `.reindex()`:
```

```
In [104]: s = pd.Series(np.arange(4), index=['a', 'a', 'b', 'c'])

In [105]: labels = ['c', 'd']

In [17]: s.reindex(labels)
ValueError: cannot reindex from a duplicate axis
```

Generally, you can intersect the desired labels with the current axis, and then reindex.
However, this would still raise if your resulting index is duplicated.

2.5.10 Selecting random samples

A random selection of rows or columns from a Series or DataFrame with the `sample()` method. The method will sample rows by default, and accepts a specific number of rows/columns to return, or a fraction of rows.

```
In [107]: s = pd.Series([0, 1, 2, 3, 4, 5])
# When no arguments are passed, returns 1 row.
In [108]: s.sample()
Out[108]:
   0
   4
   5
   3
   2
 dtype: int64
# One may specify either a number of rows:
In [109]: s.sample(n=3)
Out[109]:
   0
   4
   1
 dtype: int64
# Or a fraction of the rows:
In [110]: s.sample(frac=0.5)
Out[110]:
   5
   3
   1
 dtype: int64
```

By default, `sample` will return each row at most once, but one can also sample with replacement using the `replace` option:

```
In [111]: s = pd.Series([0, 1, 2, 3, 4, 5])
# Without replacement (default):
In [112]: s.sample(n=6, replace=True)
Out[112]:
   0
   1
   5
   3
   2
```

(continues on next page)
By default, each row has an equal probability of being selected, but if you want rows to have different probabilities, you can pass the sample function sampling weights as weights. These weights can be a list, a NumPy array, or a Series, but they must be of the same length as the object you are sampling. Missing values will be treated as a weight of zero, and inf values are not allowed. If weights do not sum to 1, they will be re-normalized by dividing all weights by the sum of the weights. For example:

```python
In [114]: s = pd.Series([0, 1, 2, 3, 4, 5])

In [115]: example_weights = [0, 0, 0.2, 0.2, 0.2, 0.4]

In [116]: s.sample(n=3, weights=example_weights)
```

When applied to a DataFrame, you can use a column of the DataFrame as sampling weights (provided you are sampling rows and not columns) by simply passing the name of the column as a string.

```python
In [119]: df2 = pd.DataFrame({'col1': [9, 8, 7, 6],
                      'weight_column': [0.5, 0.4, 0.1, 0]})

In [120]: df2.sample(n=3, weights='weight_column')
```

sample also allows users to sample columns instead of rows using the axis argument.

```python
In [121]: df3 = pd.DataFrame({'col1': [1, 2, 3], 'col2': [2, 3, 4]})
```
Finally, one can also set a seed for `sample`'s random number generator using the `random_state` argument, which will accept either an integer (as a seed) or a NumPy RandomState object.

```python
In [123]: df4 = pd.DataFrame({'col1': [1, 2, 3], 'col2': [2, 3, 4]})

# With a given seed, the sample will always draw the same rows.
In [124]: df4.sample(n=2, random_state=2)
Out[124]:
   col1  col2
0    2    3
1    1    2

In [125]: df4.sample(n=2, random_state=2)
Out[125]:
   col1  col2
0    2    3
1    1    2
```

### 2.5.11 Setting with enlargement

The `.loc[]` operations can perform enlargement when setting a non-existent key for that axis. In the `Series` case this is effectively an appending operation.

```python
In [126]: se = pd.Series([1, 2, 3])
In [127]: se
Out[127]:
0  1.0
1  2.0
2  3.0
dtype: float64

In [129]: se
Out[129]:
0  1.0
1  2.0
2  3.0
5  5.0
dtype: float64
```

A `DataFrame` can be enlarged on either axis via `.loc`.

```python
In [130]: dfi = pd.DataFrame(np.arange(6).reshape(3, 2), columns=['A', 'B'])
.....:
```

### 2.5. Indexing and selecting data
In [131]: dfi
Out[131]:
   A  B
0  0  1
1  2  3
2  4  5

In [132]: dfi.loc[:, 'C'] = dfi.loc[:, 'A']

In [133]: dfi
Out[133]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4

This is like an append operation on the DataFrame.

In [134]: dfi.loc[3] = 5

In [135]: dfi
Out[135]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
3  5  5  5

2.5.12 Fast scalar value getting and setting

Since indexing with [] must handle a lot of cases (single-label access, slicing, boolean indexing, etc.), it has a bit of overhead in order to figure out what you’re asking for. If you only want to access a scalar value, the fastest way is to use the at and iat methods, which are implemented on all of the data structures.

Similarly to loc, at provides label based scalar lookups, while, iat provides integer based lookups analogously to iloc

In [136]: s.iat[5]
Out[136]: 5

In [137]: df.at[dates[5], 'A']
Out[137]: -0.6736897080883706

In [138]: df.iat[3, 0]
Out[138]: 0.7215551622443669

You can also set using these same indexers.

In [139]: df.at[dates[5], 'E'] = 7

In [140]: df.iat[3, 0] = 7

at may enlarge the object in-place as above if the indexer is missing.
In [141]: df.at[dates[-1] + pd.Timedelta('1 day'), 0] = 7

In [142]: df

Out[142]:
     A       B      C       D      E   0
0  2000-01-01  0.469112 -0.282863 -1.509059 -1.135632 NaN NaN
1  2000-01-02  1.212112 -0.173215  0.119209 -1.044236 NaN NaN
2  2000-01-03 -0.861849 -2.104569 -0.494929  1.071804 NaN NaN
3  2000-01-04   7.000000 -0.706771 -1.039575  0.271860 NaN NaN
4  2000-01-05 -0.424972  0.567020  0.276232 -1.087401 NaN NaN
5  2000-01-06 -0.673690  0.113648 -1.478427  0.524988  7.0 NaN
6  2000-01-07  0.404705  0.577046 -1.715002 -1.039268 NaN NaN
7  2000-01-08 -0.370647 -1.157892 -1.344312  0.844885 NaN NaN
8  2000-01-09   NaN   NaN   NaN   NaN   NaN  7.0

2.5.13 Boolean indexing

Another common operation is the use of boolean vectors to filter the data. The operators are: | for or, & for and, and ~ for not. These must be grouped by using parentheses, since by default Python will evaluate an expression such as df['A'] > 2 & df['B'] < 3 as df['A'] > (2 & df['B']) < 3, while the desired evaluation order is (df['A'] > 2) & (df['B'] < 3).

Using a boolean vector to index a Series works exactly as in a NumPy ndarray:

In [143]: s = pd.Series(range(-3, 4))

In [144]: s

Out[144]:
0     -3
1     -2
2     -1
3      0
4      1
5      2
6      3
dtype: int64

In [145]: s[s > 0]

Out[145]:
4
5
6
dtype: int64

In [146]: s[(s < -1) | (s > 0.5)]

Out[146]:
0     -3
1     -2
4      1
5      2
6      3
dtype: int64

In [147]: s[~(s < 0)]

Out[147]:
3
0

(continues on next page)
You may select rows from a DataFrame using a boolean vector the same length as the DataFrame’s index (for example, something derived from one of the columns of the DataFrame):

```
In [148]: df[df['A'] > 0]
Out[148]:
   A       B      C       D       E
0  0.469112 -0.282863 -1.509059 -1.135632 NaN
1  1.212112 -0.173215  0.119209 -1.044236 NaN
2  7.000000 -0.706771 -1.039575  0.271860 NaN
3  0.404705  0.577046 -1.715002 -1.039268 NaN
```

List comprehensions and the `map` method of Series can also be used to produce more complex criteria:

```
In [149]: df2 = pd.DataFrame({
                    'a': ['one', 'one', 'two', 'three', 'two', 'one', 'six
˓→'],
                    'b': ['x', 'y', 'y', 'x', 'y', 'x', 'x'],
                    'c': np.random.randn(7)})
# only want 'two' or 'three'
In [150]: criterion = df2['a'].map(lambda x: x.startswith('t'))
In [151]: df2[criterion]
Out[151]:
   a b c
0 two y 0.041290
1 three x 0.361719
2 two y -0.238075

# equivalent but slower
In [152]: df2[[x.startswith('t') for x in df2['a']]]
Out[152]:
   a b c
0 two y 0.041290
1 three x 0.361719
2 two y -0.238075

# Multiple criteria
In [153]: df2[criterion & (df2['b'] == 'x')]
Out[153]:
   a b c
0 two y 0.041290
1 three x 0.361719
2 two y -0.238075
```

With the choice methods `Selection by Label`, `Selection by Position`, and `Advanced Indexing` you may select along more than one axis using boolean vectors combined with other indexing expressions.

```
In [154]: df2.loc[criterion & (df2['b'] == 'x'), 'b':'c']
Out[154]:
   b  c
0  0.041290  0.361719
1  0.361719
2 -0.238075
3 nan
```

With the choice methods `Selection by Label`, `Selection by Position`, and `Advanced Indexing` you may select along more than one axis using boolean vectors combined with other indexing expressions.
2.5.14 Indexing with isin

Consider the `isin()` method of `Series`, which returns a boolean vector that is true wherever the `Series` elements exist in the passed list. This allows you to select rows where one or more columns have values you want:

```python
In [155]: s = pd.Series(np.arange(5), index=np.arange(5)[::-1], dtype='int64')
In [156]: s
Out[156]:
4 0
3 1
2 2
1 3
0 4
dtype: int64
In [157]: s.isin([2, 4, 6])
Out[157]:
4 False
3 False
2 True
1 False
0 True
dtype: bool
In [158]: s[s.isin([2, 4, 6])]
Out[158]:
2 2
0 4
dtype: int64
```

The same method is available for `Index` objects and is useful for the cases when you don’t know which of the sought labels are in fact present:

```python
In [159]: s_isin = s.index.isin([2, 4, 6])
In [160]: s[s.index.isin([2, 4, 6])]
Out[160]:
4 0
2 2
dtype: int64
```

```python
# compare it to the following
In [161]: s.reindex([2, 4, 6])
Out[161]:
2 2.0
4 0.0
6 NaN
dtype: float64
```

In addition to that, `MultiIndex` allows selecting a separate level to use in the membership check:

```python
In [161]: s_mi = pd.Series(np.arange(6),
                    index=pd.MultiIndex.from_product([[0, 1], ['a', 'b', 'c'])

In [162]: s_mi
Out[162]:
0 a 0
```

(continues on next page)
DataFrame also has an `isin()` method. When calling `isin`, pass a set of values as either an array or dict. If values is an array, `isin` returns a DataFrame of booleans that is the same shape as the original DataFrame, with True wherever the element is in the sequence of values.

```
In [165]: df = pd.DataFrame({'vals': [1, 2, 3, 4], 'ids': ['a', 'b', 'f', 'n'],
                     'ids2': ['a', 'n', 'c', 'n']})

In [166]: values = ['a', 'b', 1, 3]

In [167]: df.isin(values)
Out[167]:
   vals  ids  ids2
0   True  True  True
1   False  True  False
2    True  False  False
3   False  False  False
```

Oftentimes you’ll want to match certain values with certain columns. Just make values a dict where the key is the column, and the value is a list of items you want to check for.

```
In [168]: values = {'ids': ['a', 'b'], 'vals': [1, 3]}

In [169]: df.isin(values)
Out[169]:
   vals  ids  ids2
0   True  True  True
1   False  True  False
2    True  False  False
3   False  False  False
```

Combine DataFrame’s `isin` with the `any()` and `all()` methods to quickly select subsets of your data that meet a given criteria. To select a row where each column meets its own criterion:

```
In [170]: values = {'ids': ['a', 'b'], 'ids2': ['a', 'c'], 'vals': [1, 3]}
```
In [171]: row_mask = df.isin(values).all(1)
In [172]: df[row_mask]
Out[172]:
   vals  ids  ids2
0   1    a    a

2.5.15 The where() Method and Masking

Selecting values from a Series with a boolean vector generally returns a subset of the data. To guarantee that selection output has the same shape as the original data, you can use the where method in Series and DataFrame.

To return only the selected rows:

In [173]: s[s > 0]
Out[173]:
   3    1
   2    2
   1    3
   0    4
dtype: int64

To return a Series of the same shape as the original:

In [174]: s.where(s > 0)
Out[174]:
   4   NaN
   3    1.0
   2    2.0
   1    3.0
   0    4.0
dtype: float64

Selecting values from a DataFrame with a boolean criterion now also preserves input data shape. where is used under the hood as the implementation. The code below is equivalent to df.where(df < 0).

In [175]: df[df < 0]
Out[175]:
          A         B         C         D
2000-01-01 -2.104139 -1.309525   NaN   NaN
2000-01-02 -0.352480 -1.192319   NaN   NaN
2000-01-03 -0.864883 -0.227870 -1.169184   NaN
2000-01-04   NaN -1.222082 -1.233203   NaN
2000-01-05   NaN -0.605656 -1.169184   NaN
2000-01-06   NaN -0.948458 -0.684718   NaN
2000-01-07 -2.670153 -0.114722 -0.048788 -0.808838
2000-01-08   NaN   NaN -0.048788 -0.808838

In addition, where takes an optional other argument for replacement of values where the condition is False, in the returned copy.

In [176]: df.where(df < 0, -df)
Out[176]:
          A         B         C         D
2000-01-01 -2.104139 -1.309525   NaN   NaN
2000-01-02 -0.352480 -1.192319   NaN   NaN
2000-01-03 -0.864883 -0.227870 -1.169184   NaN
2000-01-04   NaN -1.222082 -1.233203   NaN
2000-01-05   NaN -0.605656 -1.169184   NaN
2000-01-06   NaN -0.948458 -0.684718   NaN
2000-01-07 -2.670153 -0.114722 -0.048788 -0.808838
2000-01-08   NaN   NaN -0.048788 -0.808838

2.5. Indexing and selecting data
You may wish to set values based on some boolean criteria. This can be done intuitively like so:

```python
In [177]: s2 = s.copy()
In [178]: s2[s2 < 0] = 0
In [179]: s2
Out[179]:
   0   1   2   3
0  4  0  0  0
1  0  0  3  2
2  1  3  0  4
dtype: int64
```

By default, `where` returns a modified copy of the data. There is an optional parameter `inplace` so that the original data can be modified without creating a copy:

```python
In [183]: df_orig = df.copy()
In [184]: df_orig.where(df > 0, -df, inplace=True)
In [185]: df_orig
Out[185]:
   A   B    C   D
0 2  1  3.09525 0.485855 0.245166
1 2  0.390389 0.299674 0.281059
2 2  0.485855 0.245166 1.655824
3 2  0.299674 0.227870 0.600705
4 2  0.600705 0.192319 1.655824
5 2  0.192319 0.227870 0.600705
6 2  0.600705 0.192319 1.655824
```

(continues on next page)
Note: The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2).

```
In [186]: df.where(df < 0, -df) == np.where(df < 0, df, -df)
Out[186]:
   A    B    C    D
2000-01-01  True  True  True  True
2000-01-02  True  True  True  True
2000-01-03  True  True  True  True
2000-01-04  True  True  True  True
2000-01-05  True  True  True  True
2000-01-06  True  True  True  True
2000-01-07  True  True  True  True
2000-01-08  True  True  True  True
```

Alignment

Furthermore, `where` aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via `.loc` (but on the contents rather than the axis labels).

```
In [187]: df2 = df.copy()
In [188]: df2[df2[1:4] > 0] = 3
In [189]: df2
Out[189]:
   A    B    C    D
2000-01-01 -2.104139 -1.309525 0.485855 0.245166
2000-01-02 -0.352480 0.390389 -0.352480 1.655824
2000-01-03 -0.864883 0.299674 -0.864883 0.281059
2000-01-04 0.846958 0.846958 0.600705 0.846958
2000-01-05 0.669692 0.669692 0.669692 0.342416
2000-01-06 0.868584 -0.948458 2.297780 -0.684718
2000-01-07 -2.670153 -0.114722 0.168904 -2.670153
2000-01-08 0.801196 1.392071 -0.048788 -0.808838
```

Where can also accept `axis` and `level` parameters to align the input when performing the `where`.

```
In [190]: df2 = df.copy()
In [191]: df2.where(df2 > 0, df2['A'], axis='index')
Out[191]:
   A    B    C    D
2000-01-01 -2.104139 -2.104139 0.485855 0.245166
2000-01-02 -0.352480 -0.352480 -0.352480 1.655824
2000-01-03 -0.864883 -0.864883 -0.864883 0.846958
2000-01-04 0.846958 0.846958 0.600705 0.846958
2000-01-05 0.669692 0.669692 0.669692 0.342416
2000-01-06 0.868584 -0.948458 2.297780 -0.684718
2000-01-07 -2.670153 -0.114722 0.168904 -2.670153
2000-01-08 0.801196 1.392071 -0.048788 -0.808838
```

2.5. Indexing and selecting data
This is equivalent to (but faster than) the following.

```python
In [192]: df2 = df.copy()
In [193]: df.apply(lambda x, y: x.where(x > 0, y), y=df['A'])
Out[193]:
          A       B       C       D
2000-01-01 -2.104139 -2.104139  0.485855  0.245166
2000-01-02 -0.352480  0.390389 -0.352480  1.655824
2000-01-03 -0.864883  0.299674 -0.864883  0.281059
2000-01-04  0.846958  0.846958  0.600705  0.846958
2000-01-05  0.669692  0.669692  0.669692  0.342416
2000-01-06  0.868584  0.868584  2.297780  0.868584
2000-01-07 -2.670153 -2.670153  0.168904 -2.670153
2000-01-08  0.801196  1.392071  0.801196  0.801196
```

`where` can accept a callable as condition and other arguments. The function must be with one argument (the calling Series or DataFrame) and that returns valid output as condition and other argument.

```python
In [194]: df3 = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]})
In [195]: df3.where(lambda x: x > 4, lambda x: x + 10)
Out[195]:
         A   B   C
0      11  14   7
1      12   5   8
2      13   6   9
```

**Mask**

`mask()` is the inverse boolean operation of `where`.

```python
In [196]: s.mask(s >= 0)
Out[196]:
   4  NaN
   3  NaN
   2  NaN
   1  NaN
   0  NaN
dtype: float64
In [197]: df.mask(df >= 0)
Out[197]:
          A       B       C       D
2000-01-01 -2.104139 -1.309525  NaN   NaN
2000-01-02 -0.352480  NaN -1.192319  NaN
2000-01-03 -0.864883  NaN  -0.227870  NaN
2000-01-04  NaN  -1.222082  NaN  -1.233203
2000-01-05  NaN  -0.605656 -1.169184  NaN
2000-01-06  NaN -0.948458  NaN  -0.684718
2000-01-07 -2.670153  NaN  -0.048788 -0.808838
2000-01-08  NaN  NaN   NaN   NaN
```

376 Chapter 2. User Guide
2.5.16 The `query()` Method

*DataFrame* objects have a `query()` method that allows selection using an expression.

You can get the value of the frame where column *b* has values between the values of columns *a* and *c*. For example:

```
In [198]: n = 10
In [199]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
In [200]: df
Out[200]:
   a         b         c
0 0.438921  0.118680  0.863670
1 0.138138  0.577363  0.686602
2 0.595307  0.564592  0.520630
3 0.913052  0.926075  0.616184
4 0.078718  0.854477  0.898725
5 0.076404  0.523211  0.591538
6 0.792342  0.216974  0.564056
7 0.397890  0.454131  0.915716
8 0.074315  0.437913  0.019794
9 0.559209  0.502065  0.026437
```

# pure python
```
In [201]: df[(df['a'] < df['b']) & (df['b'] < df['c'])]
Out[201]:
   a         b         c
1 0.138138  0.577363  0.686602
4 0.078718  0.854477  0.898725
5 0.076404  0.523211  0.591538
7 0.397890  0.454131  0.915716
```

# query
```
In [202]: df.query('(a < b) & (b < c)')
Out[202]:
   a         b         c
1 0.138138  0.577363  0.686602
4 0.078718  0.854477  0.898725
5 0.076404  0.523211  0.591538
7 0.397890  0.454131  0.915716
```

Do the same thing but fall back on a named index if there is no column with the name *a*.

```
In [203]: df = pd.DataFrame(np.random.randint(n / 2, size=(n, 2)), columns=list('bc'))
In [204]: df.index.name = 'a'
In [205]: df
Out[205]:
   b  c
a
0 0 4
1 1 1
2 3 4
3 4 3
4 1 4
5 0 3
```

(continues on next page)
In [206]: df.query('a < b and b < c')
Out[206]:
   b  c
0  2  3
1  3  4

If instead you don’t want to or cannot name your index, you can use the name `index` in your query expression:

In [207]: df = pd.DataFrame(np.random.randint(n, size=(n, 2)), columns=list('bc'))
In [208]: df
Out[208]:
   b  c
0  3  1
1  3  0
2  5  6
3  5  2
4  7  4
5  0  1
6  2  5
7  0  1
8  6  0
9  7  9
In [209]: df.query('index < b < c')
Out[209]:
   b  c
2  5  6

Note: If the name of your index overlaps with a column name, the column name is given precedence. For example,

In [210]: df = pd.DataFrame({'a': np.random.randint(5, size=5)})
In [211]: df.index.name = 'a'
In [212]: df.query('a > 2')  # uses the column 'a', not the index
Out[212]:
   a
0  3
1  3
3  3

You can still use the index in a query expression by using the special identifier ‘index’:

In [213]: df.query('index > 2')
Out[213]:
   a
   a
3  3
4  2
If for some reason you have a column named `index`, then you can refer to the index as `ilevel_0` as well, but at this point you should consider renaming your columns to something less ambiguous.

**MultiIndex** query() Syntax

You can also use the levels of a DataFrame with a `MultiIndex` as if they were columns in the frame:

```
In [214]: n = 10
In [215]: colors = np.random.choice(['red', 'green'], size=n)
In [216]: foods = np.random.choice(['eggs', 'ham'], size=n)
In [217]: colors
Out[217]: array(['red', 'red', 'red', 'green', 'green', 'green', 'green', 'green', 'green', 'green'], dtype='<U5')
In [218]: foods
Out[218]: array(['ham', 'ham', 'eggs', 'eggs', 'eggs', 'ham', 'ham', 'eggs', 'eggs', 'eggs'], dtype='<U4')
In [219]: index = pd.MultiIndex.from_arrays([colors, foods], names=['color', 'food'])
In [220]: df = pd.DataFrame(np.random.randn(n, 2), index=index)
In [221]: df
Out[221]:
   0      1
color food
red  ham 0.194889 -0.381994
     ham 0.318587  2.089075
     eggs -0.728293 -0.090255
green eggs -0.748199  1.318931
        eggs -2.029766  0.792652
        ham 0.461007 -0.542749
        eggs -0.305384 -0.479195
        eggs  0.095031 -0.270099
        eggs -0.707140 -0.773882
        eggs  0.229453  0.304418
In [222]: df.query('color == "red"')
Out[222]:
   0      1
color food
red  ham 0.194889 -0.381994
     ham 0.318587  2.089075
     eggs -0.728293 -0.090255
```

If the levels of the MultiIndex are unnamed, you can refer to them using special names:

```
In [223]: df.index.names = [None, None]
In [224]: df
Out[224]:
   0      1
color food
red  ham 0.194889 -0.381994
     ham 0.318587  2.089075
     eggs -0.728293 -0.090255
```

(continues on next page)
The convention is `ilevel_0`, which means “index level 0” for the 0th level of the index.

**query() Use Cases**

A use case for `query()` is when you have a collection of `DataFrame` objects that have a subset of column names (or index levels/names) in common. You can pass the same query to both frames without having to specify which frame you’re interested in querying.

```python
In [226]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
In [227]: df
Out[227]:
   a    b    c
0  0.22  0.73  0.14
1  0.30  0.66  0.71
2  0.61  0.14  0.94
3  0.19  0.12  0.62
4  0.98  0.06  0.18
5  0.56  0.48  0.37
6  0.50  0.36  0.20
7  0.52  0.32  0.86
8  0.30  0.27  0.58
9  0.25  0.48  0.37

In [228]: df2 = pd.DataFrame(np.random.rand(n + 2, 3), columns=df.columns)
In [229]: df2
Out[229]:
   a    b    c
0  0.36  0.22  0.59
1  0.30  0.95  0.96
2  0.12  0.34  0.31
3  0.52  0.32  0.86
4  0.51  0.48  0.38
5  0.19  0.50  0.61
6  0.89  0.62  0.67
```
In [230]: expr = '0.0 <= a <= c <= 0.5'

In [231]: map(lambda frame: frame.query(expr), [df, df2])
Out[231]: <map at 0x7fbfb1967490>

query()  Python versus pandas Syntax Comparison

Full numpy-like syntax:

```python
In [232]: df = pd.DataFrame(np.random.randint(10, size=(10, 3)), columns=list('abc'))

In [233]: df
Out[233]:
   a  b  c
0   7  8  9
1   1  0  7
2   2  7  2
3   3  2  2
4   4  6  3
5   5  8  2
6   6  1  7
7   7  1  5
8   8  9  0
9   9  5  0
```

```python
In [234]: df.query('(a < b) & (b < c)')
```

```python
In [235]: df[(df['a'] < df['b']) & (df['b'] < df['c'])]
```

Slightly nicer by removing the parentheses (by binding making comparison operators bind tighter than & and |).

```python
In [236]: df.query('a < b & b < c')
```

Use English instead of symbols:

```python
In [237]: df.query('a < b and b < c')
```

Pretty close to how you might write it on paper:

```
2.5. Indexing and selecting data
```
In [238]: df.query('a < b < c')
Out[238]:
  a  b  c
0  7  8  9

The in and not in operators

`query()` also supports special use of Python’s in and not in comparison operators, providing a succinct syntax for calling the isin method of a Series or DataFrame.

# get all rows where columns "a" and "b" have overlapping values
In [239]: df = pd.DataFrame({'a': list('aabbccddeeff'), 'b': list('aabbccddeeff'),
                          'c': np.random.randint(5, size=12),
                          'd': np.random.randint(9, size=12)})

In [240]: df
Out[240]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
7  d  b  2  1
8  e  c  4  3
9  e  c  2  0
10 f  c  0  6
11 f  c  1  2

In [241]: df.query('a in b')
Out[241]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2

# How you’d do it in pure Python
In [242]: df[df['a'].isin(df['b'])]
Out[242]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2

In [243]: df.query('a not in b')
Out[243]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2

(continues on next page)
You can combine this with other expressions for very succinct queries:

# rows where cols a and b have overlapping values
# and col c's values are less than col d's
In [245]: df.query('a in b and c < d')
Out[245]:
   a   b   c   d
0  a   a   2   6
1  a   a   4   7
2  b   a   1   6
4  c   b   3   6
5  c   b   0   2

# pure Python
In [246]: df[(df['b'].isin(df['a'])) & (df['c'] < df['d'])]
Out[246]:
   a   b   c   d
0  a   a   2   6
1  a   a   4   7
2  b   a   1   6
4  c   b   3   6
5  c   b   0   2
10 f   c   0   6
11 f   c   1   2

Note: Note that in and not in are evaluated in Python, since numexpr has no equivalent of this operation. However, only the in/not in expression itself is evaluated in vanilla Python. For example, in the expression

```
df.query('a in b + c + d')
```

(b + c + d) is evaluated by numexpr and then the in operation is evaluated in plain Python. In general, any operations that can be evaluated using numexpr will be.
Special use of the == operator with list objects

Comparing a list of values to a column using ==/!= works similarly to in/not in.

```python
In [247]: df.query('b == ["a", "b", "c"]')
Out[247]:
      a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
7  d  b  2  1
8  e  c  4  3
9  e  c  2  0
10 f  c  0  6
11 f  c  1  2
```

# pure Python

```python
In [248]: df[df['b'].isin(['a', 'b', 'c'])]
Out[248]:
      a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
7  d  b  2  1
8  e  c  4  3
9  e  c  2  0
10 f  c  0  6
11 f  c  1  2
```

```python
In [249]: df.query('c == [1, 2]')
Out[249]:
      a  b  c  d
0  a  a  2  6
2  b  a  1  6
3  b  a  2  1
7  d  b  2  1
9  e  c  2  0
11 f  c  1  2
```

```python
In [250]: df.query('c != [1, 2]')
Out[250]:
      a  b  c  d
1  a  a  4  7
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
8  e  c  4  3
10 f  c  0  6
```

# using in/not in

(continues on next page)
In [251]: df.query('[1, 2] in c')
Out[251]:
    a  b  c  d
0  a  a  2  6
2  b  a  1  6
3  b  a  2  1
7  d  b  2  1
9  e  c  2  0
11 f  c  1  2

In [252]: df.query('[1, 2] not in c')
Out[252]:
    a  b  c  d
1  a  a  4  7
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
8  e  c  4  3
10 f  c  0  6

# pure Python
In [253]: df[df['c'].isin([1, 2])]
Out[253]:
    a  b  c  d
 0  a  a  2  6
 2  b  a  1  6
 3  b  a  2  1
 7  d  b  2  1
 9  e  c  2  0
11 f  c  1  2

Boolean operators

You can negate boolean expressions with the word not or the ~ operator.

In [254]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
In [255]: df['bools'] = np.random.rand(len(df)) > 0.5
In [256]: df.query('~bools')
Out[256]:
    a  b  c  bools
 2 0.697753 0.212799 0.329209  False
 7 0.275396 0.691034 0.826619  False
 8 0.190649 0.558748 0.262467  False
In [257]: df.query('not bools')
Out[257]:
    a  b  c  bools
 2 0.697753 0.212799 0.329209  False
 7 0.275396 0.691034 0.826619  False
 8 0.190649 0.558748 0.262467  False
In [258]: df.query('not bools') == df[~df['bools']]
Of course, expressions can be arbitrarily complex too:

```python
# short query syntax
In [259]: shorter = df.query('a < b < c and (not bools) or bools > 2')

# equivalent in pure Python
In [260]: longer = df[(df['a'] < df['b'])
       .....: & (df['b'] < df['c'])
       .....: & (~df['bools'])
       .....: | (df['bools'] > 2)]

In [261]: shorter
Out[261]:
   a   b    c   bools
 0  7  0.275396  0.691034  0.826619  False

In [262]: longer
Out[262]:
   a   b    c   bools
 0  7  0.275396  0.691034  0.826619  False

In [263]: shorter == longer
Out[263]:
   a   b    c   bools
 0  7  True  True  True  True
```

**Performance of `query()`**

`DataFrame.query()` using `numexpr` is slightly faster than Python for large frames.

![DataFrame.query() Performance Graph](image)
Note: You will only see the performance benefits of using the `numexpr` engine with `DataFrame.query()` if your frame has more than approximately 200,000 rows.

This plot was created using a `DataFrame` with 3 columns each containing floating point values generated using `numpy.random.randn()`.

### 2.5.17 Duplicate data

If you want to identify and remove duplicate rows in a DataFrame, there are two methods that will help: `duplicated` and `drop_duplicates`. Each takes as an argument the columns to use to identify duplicated rows.

- `duplicated` returns a boolean vector whose length is the number of rows, and which indicates whether a row is duplicated.
- `drop_duplicates` removes duplicate rows.

By default, the first observed row of a duplicate set is considered unique, but each method has a `keep` parameter to specify targets to be kept.

- `keep='first'` (default): mark / drop duplicates except for the first occurrence.
- `keep='last'`: mark / drop duplicates except for the last occurrence.
- `keep=False`: mark / drop all duplicates.

```python
In [264]: df2 = pd.DataFrame({'a': ['one', 'one', 'two', 'two', 'two', 'three', 'four →'],
                           'b': ['x', 'y', 'x', 'y', 'x', 'x', 'x'],
                           'c': np.random.randn(7)})

In [265]: df2
Out[265]:
   a    b       c
0 one  x  -1.067137
1 one  y     0.479708
2 two  x   0.264424
3 two  y  -0.877157
4 two  x  -1.891367
5 three x  1.808369
6 four  x   0.598845
```

(continues on next page)
In [266]: df2.duplicated('a')
Out[266]:
0   False
1    True
2    False
3    True
4    True
5     False
6     False
dtype: bool

In [267]: df2.duplicated('a', keep='last')
Out[267]:
0    True
1   False
2    True
3    True
4    False
5    False
6    False
dtype: bool

In [268]: df2.duplicated('a', keep=False)
Out[268]:
0    True
1    True
2    True
3    True
4    True
5    False
6    False
dtype: bool

In [269]: df2.drop_duplicates('a')
Out[269]:
a b c
0 one x -1.067137
2 two x -0.211056
4 two x -0.390820
5 three x -1.964475
6 four x 1.298329

In [270]: df2.drop_duplicates('a', keep='last')
Out[270]:
a b c
1 one y 0.309500
4 two x -0.390820
5 three x -1.964475
6 four x 1.298329

In [271]: df2.drop_duplicates('a', keep=False)
Also, you can pass a list of columns to identify duplications.

```
In [272]: df2.duplicated(['a', 'b'])
Out[272]:
0   False
1   False
2   False
3   False
4    True
5   False
6   False
dtype: bool
```

```
In [273]: df2.drop_duplicates(['a', 'b'])
Out[273]:
   a  b  c
0  one  x -1.067137
1  one  y  0.309500
2  two  x -0.211056
3  two  y -1.842023
5  three  x -1.964475
6   four  x  1.298329
```

To drop duplicates by index value, use `Index.duplicated` then perform slicing. The same set of options are available for the `keep` parameter.

```
In [274]: df3 = pd.DataFrame({'a': np.arange(6),
                      'b': np.random.randn(6)},
                      index=['a', 'a', 'b', 'c', 'b', 'a'])

In [275]: df3
Out[275]:
   a  b
a 0  1.440455
a 1  2.456086
b 2  1.038402
 c 3 -0.894409
b 4  0.683536
a 5  3.082764

In [276]: df3.index.duplicated()
Out[276]: array([False,  True, False, False,  True,  True])

In [277]: df3[~df3.index.duplicated()]
Out[277]:
   a  b
a 0  1.440455
b 2  1.038402
 c 3 -0.894409
```
2.5.18 Dictionary-like get() method

Each of Series or DataFrame have a get method which can return a default value.

```
In [280]: s = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
In [281]: s.get('a')  # equivalent to s['a']
Out[281]: 1
In [282]: s.get('x', default=-1)
Out[282]: -1
```

2.5.19 The lookup() method

Sometimes you want to extract a set of values given a sequence of row labels and column labels, and the lookup method allows for this and returns a NumPy array. For instance:

```
In [283]: dflookup = pd.DataFrame(np.random.rand(20, 4), columns=['A', 'B', 'C', 'D'])
In [284]: dflookup.lookup(list(range(0, 10, 2)), ['B', 'C', 'A', 'B', 'D'])
Out[284]: array([0.3506, 0.4779, 0.4825, 0.9197, 0.5019])
```

2.5.20 Index objects

The pandas Index class and its subclasses can be viewed as implementing an ordered multiset. Duplicates are allowed. However, if you try to convert an Index object with duplicate entries into a set, an exception will be raised.

Index also provides the infrastructure necessary for lookups, data alignment, and reindexing. The easiest way to create an Index directly is to pass a list or other sequence to Index:

```
In [285]: index = pd.Index(['e', 'd', 'a', 'b'])
In [286]: index
Out[286]: Index(['e', 'd', 'a', 'b'], dtype='object')
In [287]: 'd' in index
Out[287]: True
```
You can also pass a name to be stored in the index:

```python
In [288]: index = pd.Index(['e', 'd', 'a', 'b'], name='something')
```

```python
In [289]: index.name
Out[289]: 'something'
```

The name, if set, will be shown in the console display:

```python
In [290]: index = pd.Index(list(range(5)), name='rows')
In [291]: columns = pd.Index(['A', 'B', 'C'], name='cols')
In [292]: df = pd.DataFrame(np.random.randn(5, 3), index=index, columns=columns)
In [293]: df
Out[293]:
   cols   A      B      C
   rows
   0  1.29599  0.18578  0.43626
   1  0.67810  0.31137 -0.52838
   2 -0.67481 -1.10353 -0.65616
   3  1.88996  2.07651 -1.10219
   4 -1.21179 -0.79175  0.63472
```

```python
In [294]: df['A']
Out[294]:
   rows
   0  1.29599
   1  0.67810
   2 -0.67481
   3  1.88996
   4 -1.21179
Name: A, dtype: float64
```

### Setting metadata

Indexes are “mostly immutable”, but it is possible to set and change their metadata, like the index name (or, for MultiIndex, levels and codes).

You can use the rename, set_names, set_levels, and set_codes to set these attributes directly. They default to returning a copy; however, you can specify inplace=True to have the data change in place.

See Advanced Indexing for usage of MultiIndexes.

```python
In [295]: ind = pd.Index([1, 2, 3])
In [296]: ind.rename("apple")
Out[296]: Int64Index([1, 2, 3], dtype='int64', name='apple')
In [297]: ind
Out[297]: Int64Index([1, 2, 3], dtype='int64')
In [298]: ind.set_names(['apple'], inplace=True)
In [299]: ind.name = "bob"
```

(continues on next page)
set_names, set_levels, and set_codes also take an optional level argument

In [301]: index = pd.MultiIndex.from_product([range(3), ['one', 'two']], names=['first →', 'second'])

In [302]: index
Out[302]: MultiIndex([(0, 'one'), (0, 'two'), (1, 'one'), (1, 'two'), (2, 'one'), (2, 'two')], names=['first', 'second'])

In [303]: index.levels[1]
Out[303]: Index(['one', 'two'], dtype='object', name='second')

In [304]: index.set_levels(["a", "b"], level=1)
Out[304]: MultiIndex([(0, 'a'), (0, 'b'), (1, 'a'), (1, 'b'), (2, 'a'), (2, 'b')], names=['first', 'second'])

Set operations on Index objects

The two main operations are union (|) and intersection (&). These can be directly called as instance methods or used via overloaded operators. Difference is provided via the .difference() method.

In [305]: a = pd.Index(['c', 'b', 'a'])
In [306]: b = pd.Index(['c', 'e', 'd'])
In [307]: a | b
Out[307]: Index(['a', 'b', 'c', 'd', 'e'], dtype='object')
In [308]: a & b
Out[308]: Index(['c'], dtype='object')
In [309]: a.difference(b)
Out[309]: Index(['a', 'b'], dtype='object')

Also available is the symmetric_difference (^) operation, which returns elements that appear in either idx1 or idx2, but not in both. This is equivalent to the Index created by idx1.difference(idx2).union(idx2. difference(idx1)), with duplicates dropped.

In [310]: idx1 = pd.Index([1, 2, 3, 4])
(continues on next page)
Note: The resulting index from a set operation will be sorted in ascending order.

When performing `Index.union()` between indexes with different dtypes, the indexes must be cast to a common dtype. Typically, though not always, this is object dtype. The exception is when performing a union between integer and float data. In this case, the integer values are converted to float.

### Missing values

**Important:** Even though `Index` can hold missing values (NaN), it should be avoided if you do not want any unexpected results. For example, some operations exclude missing values implicitly.

`Index.fillna` fills missing values with specified scalar value.
2.5.21 Set / reset index

Occasionally you will load or create a data set into a DataFrame and want to add an index after you’ve already done so. There are a couple of different ways.

Set an index

DataFrame has a `set_index()` method which takes a column name (for a regular Index) or a list of column names (for a MultiIndex). To create a new, re-indexed DataFrame:

```python
In [323]: data
Out[323]:
   a   b   c   d
0  bar  one  z  1.0
1  bar  two  y  2.0
2  foo  one  x  3.0
3  foo  two  w  4.0

In [324]: indexed1 = data.set_index('c')
In [325]: indexed1
Out[325]:
   a   b   d
   c
   z  bar  one  1.0
   y  bar  two  2.0
   x  foo  one  3.0
   w  foo  two  4.0

In [326]: indexed2 = data.set_index(['a', 'b'])
In [327]: indexed2
Out[327]:
   c   d
   c  a  b
   z  bar  one  1.0
   y  bar  two  2.0
   x  foo  one  3.0
   w  foo  two  4.0
```

The `append` keyword option allow you to keep the existing index and append the given columns to a MultiIndex:

```python
In [328]: frame = data.set_index('c', drop=False)
In [329]: frame = frame.set_index(['a', 'b'], append=True)
In [330]: frame
Out[330]:
   c   d
   c  a  b
   z  bar  one  1.0
   y  bar  two  2.0
   x  foo  one  3.0
   w  foo  two  4.0
```

Other options in `set_index` allow you not drop the index columns or to add the index in-place (without creating a new object):
In [331]: data.set_index('c', drop=False)
Out[331]:
    a    b    c    d
  c
  z  bar  one  z  1.0
  y  bar  two  y  2.0
  x  foo  one  x  3.0
  w  foo  two  w  4.0

In [332]: data.set_index(['a', 'b'], inplace=True)
In [333]: data
Out[333]:
    c    d
  a    b
  bar  one  z  1.0
        two  y  2.0
  foo  one  x  3.0
        two  w  4.0

Reset the index

As a convenience, there is a new function on DataFrame called \texttt{reset\_index()} which transfers the index values into the DataFrame’s columns and sets a simple integer index. This is the inverse operation of \texttt{set\_index()}.

In [334]: data
Out[334]:
    c    d
  a    b
  bar  one  z  1.0
        two  y  2.0
  foo  one  x  3.0
        two  w  4.0

In [335]: data.reset_index()
Out[335]:
    a    b    c    d
  0  bar  one  z  1.0
  1  bar  two  y  2.0
  2  foo  one  x  3.0
  3  foo  two  w  4.0

The output is more similar to a SQL table or a record array. The names for the columns derived from the index are the ones stored in the \texttt{names} attribute.

You can use the \texttt{level} keyword to remove only a portion of the index:

In [336]: frame
Out[336]:
    c    d
  c  a    b
  z  bar  one  z  1.0
        y  2.0
  x  foo  one  x  3.0
        w  4.0

(continues on next page)
reset_index takes an optional parameter drop which if true simply discards the index, instead of putting index values in the DataFrame’s columns.

Adding an ad hoc index

If you create an index yourself, you can just assign it to the index field:

```python
data.index = index
```

### 2.5.22 Returning a view versus a copy

When setting values in a pandas object, care must be taken to avoid what is called chained indexing. Here is an example.

```python
In [338]: dfmi = pd.DataFrame([list('abcd'), 
                         list('efgh'), 
                         list('ijkl'), 
                         list('mnop')], 
                         columns=pd.MultiIndex.from_product([['one', 'two'], ['first', 'second']]))

In [339]: dfmi
Out[339]:
          one two
first second first second
0       a   b   c   d
1       e   f   g   h
2       i   j   k   l
3       m   n   o   p
```

Compare these two access methods:

```python
In [340]: dfmi['one']['second']
Out[340]:
0  b
1  f
2  j
3  n
Name: second, dtype: object
```

```python
In [341]: dfmi.loc[:, ('one', 'second')]
Out[341]:
          one two
first second first second
0       a   b   c   d
1       e   f   g   h
2       i   j   k   l
3       m   n   o   p
```

(continues on next page)
These both yield the same results, so which should you use? It is instructive to understand the order of operations on these and why method 2 (`.loc`) is much preferred over method 1 (chained `[]`).

dfmi['one'] selects the first level of the columns and returns a DataFrame that is singly-indexed. Then another Python operation dfmi_with_one['second'] selects the series indexed by 'second'. This is indicated by the variable dfmi_with_one because pandas sees these operations as separate events. e.g. separate calls to __getitem__, so it has to treat them as linear operations, they happen one after another.

Contrast this to df.loc[:, ('one', 'second')] which passes a nested tuple of (slice(None), ('one', 'second')) to a single call to __getitem__. This allows pandas to deal with this as a single entity. Furthermore this order of operations can be significantly faster, and allows one to index both axes if so desired.

### Why does assignment fail when using chained indexing?

The problem in the previous section is just a performance issue. What’s up with the SettingWithCopy warning? We don’t usually throw warnings around when you do something that might cost a few extra milliseconds!

But it turns out that assigning to the product of chained indexing has inherently unpredictable results. To see this, think about how the Python interpreter executes this code:

```python
dfmi.loc[:, ('one', 'second')] = value
# becomes
dfmi.loc.__setitem__((slice(None), ('one', 'second')), value)
```

But this code is handled differently:

```python
dfmi['one']['second'] = value
# becomes
dfmi.__getitem__('one').__setitem__('second', value)
```

See that __getitem__ in there? Outside of simple cases, it’s very hard to predict whether it will return a view or a copy (it depends on the memory layout of the array, about which pandas makes no guarantees), and therefore whether the __setitem__ will modify dfmi or a temporary object that gets thrown out immediately afterward. That’s what SettingWithCopy is warning you about!

**Note:** You may be wondering whether we should be concerned about the `loc` property in the first example. But `dfmi.loc` is guaranteed to be `dfmi` itself with modified indexing behavior, so `dfmi.loc.__getitem__/dfmi.loc.__setitem__` operate on `dfmi` directly. Of course, `dfmi.loc.__getitem__(idx)` may be a view or a copy of `dfmi`.

Sometimes a SettingWithCopy warning will arise at times when there’s no obvious chained indexing going on. **These** are the bugs that SettingWithCopy is designed to catch! Pandas is probably trying to warn you that you’ve done this:

```python
def do_something(df):
    foo = df[['bar', 'baz']]  # Is foo a view? A copy? Nobody knows!
    # ... many lines here ...
# We don't know whether this will modify df or not!
foo['quux'] = value
return foo

Yikes!

## Evaluation order matters

When you use chained indexing, the order and type of the indexing operation partially determine whether the result is a slice into the original object, or a copy of the slice.

Pandas has the SettingWithCopyWarning because assigning to a copy of a slice is frequently not intentional, but a mistake caused by chained indexing returning a copy where a slice was expected.

If you would like pandas to be more or less trusting about assignment to a chained indexing expression, you can set the `mode.chained_assignment` to one of these values:

- 'warn', the default, means a SettingWithCopyWarning is printed.
- 'raise' means pandas will raise a SettingWithCopyException you have to deal with.
- None will suppress the warnings entirely.

```python
In [342]: dfb = pd.DataFrame({'a': ['one', 'one', 'two',
                           'three', 'two', 'one', 'six'],
                           'c': np.arange(7)})

# This will show the SettingWithCopyWarning
# but the frame values will be set
In [343]: dfb['c'][dfb['a'].str.startswith('o')] = 42

This however is operating on a copy and will not work.
```

```python
>>> pd.set_option('mode.chained_assignment','warn')
>>> dfb[dfb['a'].str.startswith('o')]['c'] = 42
Traceback (most recent call last)
...  
SettingWithCopyWarning:
  A value is trying to be set on a copy of a slice from a DataFrame.
  Try using .loc[row_index,col_indexer] = value instead

A chained assignment can also crop up in setting in a mixed dtype frame.

**Note:** These setting rules apply to all of `.loc/.iloc`.

The following is the recommended access method using `.loc` for multiple items (using mask) and a single item using a fixed index:

```python
In [344]: dfc = pd.DataFrame({'a': ['one', 'one', 'two',
                               'three', 'two', 'one', 'six'],
                               'c': np.arange(7)})

In [345]: dfd = dfc.copy()
```
# Setting multiple items using a mask
In [346]: mask = dfd['a'].str.startswith('o')

In [347]: dfd.loc[mask, 'c'] = 42

In [348]: dfd

Out[348]:

<table>
<thead>
<tr>
<th>a</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>one</td>
</tr>
<tr>
<td>1</td>
<td>one</td>
</tr>
<tr>
<td>2</td>
<td>two</td>
</tr>
<tr>
<td>3</td>
<td>three</td>
</tr>
<tr>
<td>4</td>
<td>two</td>
</tr>
<tr>
<td>5</td>
<td>one</td>
</tr>
<tr>
<td>6</td>
<td>six</td>
</tr>
</tbody>
</table>

# Setting a single item
In [349]: dfd = dfc.copy()

In [350]: dfd.loc[2, 'a'] = 11

In [351]: dfd

Out[351]:

<table>
<thead>
<tr>
<th>a</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>one</td>
</tr>
<tr>
<td>1</td>
<td>one</td>
</tr>
<tr>
<td>2</td>
<td>11</td>
</tr>
<tr>
<td>3</td>
<td>three</td>
</tr>
<tr>
<td>4</td>
<td>two</td>
</tr>
<tr>
<td>5</td>
<td>one</td>
</tr>
<tr>
<td>6</td>
<td>six</td>
</tr>
</tbody>
</table>

The following can work at times, but it is not guaranteed to, and therefore should be avoided:

In [352]: dfd = dfc.copy()

In [353]: dfd['a'][2] = 111

In [354]: dfd

Out[354]:

<table>
<thead>
<tr>
<th>a</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>one</td>
</tr>
<tr>
<td>1</td>
<td>one</td>
</tr>
<tr>
<td>2</td>
<td>111</td>
</tr>
<tr>
<td>3</td>
<td>three</td>
</tr>
<tr>
<td>4</td>
<td>two</td>
</tr>
<tr>
<td>5</td>
<td>one</td>
</tr>
<tr>
<td>6</td>
<td>six</td>
</tr>
</tbody>
</table>

Last, the subsequent example will not work at all, and so should be avoided:

```python
>>> pd.set_option('mode.chained_assignment','raise')
>>> dfd.loc[0]['a'] = 1111
Traceback (most recent call last)
... SettingWithCopyException:
```
2.6 MultIndex / advanced indexing

This section covers indexing with a MultiIndex and other advanced indexing features.

See the Indexing and Selecting Data for general indexing documentation.

Warning: Whether a copy or a reference is returned for a setting operation may depend on the context. This is sometimes called chained assignment and should be avoided. See Returning a View versus Copy.

See the cookbook for some advanced strategies.

2.6.1 Hierarchical indexing (MultiIndex)

Hierarchical / Multi-level indexing is very exciting as it opens the door to some quite sophisticated data analysis and manipulation, especially for working with higher dimensional data. In essence, it enables you to store and manipulate data with an arbitrary number of dimensions in lower dimensional data structures like Series (1d) and DataFrame (2d).

In this section, we will show what exactly we mean by “hierarchical” indexing and how it integrates with all of the pandas indexing functionality described above and in prior sections. Later, when discussing group by and pivoting and reshaping data, we’ll show non-trivial applications to illustrate how it aids in structuring data for analysis.

See the cookbook for some advanced strategies.

Changed in version 0.24.0: MultiIndex.labels has been renamed to MultiIndex.codes and MultiIndex.set_labels to MultiIndex.set_codes.

Creating a MultiIndex (hierarchical index) object

The MultiIndex object is the hierarchical analogue of the standard Index object which typically stores the axis labels in pandas objects. You can think of MultiIndex as an array of tuples where each tuple is unique. A MultiIndex can be created from a list of arrays (using MultiIndex.from_arrays()), an array of tuples (using MultiIndex.from_tuples()), a crossed set of iterables (using MultiIndex.from_product()), or a DataFrame (using MultiIndex.from_frame()). The Index constructor will attempt to return a MultiIndex when it is passed a list of tuples. The following examples demonstrate different ways to initialize MultiIndexes.

In [1]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
   ...:     ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
   ...
In [2]: tuples = list(zip(*arrays))
In [3]: tuples
Out[3]:
[('bar', 'one'),
 ('bar', 'two'),
 ('baz', 'one'),
 ('baz', 'two'),
 ('foo', 'one'),
 ('foo', 'two'),
 ('qux', 'one'),
 ('qux', 'two')]

In [4]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [5]: index
Out[5]:
MultiIndex([('bar', 'one'),
 ('bar', 'two'),
 ('baz', 'one'),
 ('baz', 'two'),
 ('foo', 'one'),
 ('foo', 'two'),
 ('qux', 'one'),
 ('qux', 'two')],
 names=['first', 'second'])

In [6]: s = pd.Series(np.random.randn(8), index=index)

In [7]: s
Out[7]:
first  second
bar    one   0.469112
      two  -0.282863
baz    one  -1.509059
      two  -1.135632
foo    one   1.212112
      two  -0.173215
qux    one   0.119209
      two  -1.044236
dtype: float64

When you want every pairing of the elements in two iterables, it can be easier to use the `MultiIndex.from_product()` method:

In [8]: iterables = [['bar', 'baz', 'foo', 'qux'], ['one', 'two']]

In [9]: pd.MultiIndex.from_product(iterables, names=['first', 'second'])
Out[9]:
MultiIndex([('bar', 'one'),
 ('bar', 'two'),
 ('baz', 'one'),
 ('baz', 'two'),
 ('foo', 'one'),
 ('foo', 'two'),
 ('qux', 'one'),
 ('qux', 'two')],
 names=['first', 'second'])
You can also construct a MultiIndex from a DataFrame directly, using the method `MultiIndex.from_frame()`. This is a complementary method to `MultiIndex.to_frame()`.

New in version 0.24.0.

```python
In [10]: df = pd.DataFrame([['bar', 'one'], ['bar', 'two'],
                         ['foo', 'one'], ['foo', 'two']],
                         columns=['first', 'second'])
In [11]: pd.MultiIndex.from_frame(df)
MultiIndex([('bar', 'one'),
            ('bar', 'two'),
            ('foo', 'one'),
            ('foo', 'two')],
            names=['first', 'second'])
```

As a convenience, you can pass a list of arrays directly into Series or DataFrame to construct a MultiIndex automatically:

```python
In [12]: arrays = [np.array(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux']),
               np.array(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'])]
In [13]: s = pd.Series(np.random.randn(8), index=arrays)
In [14]: s
bar one -0.861849
two -2.104569
baz one -0.494929
two 1.071804
foo one 0.721555
two -0.706771
qux one -1.039575
two 0.271860
dtype: float64
In [15]: df = pd.DataFrame(np.random.randn(8, 4), index=arrays)
In [16]: df
   0   1   2   3
bar one -0.424972  0.567020  0.276232 -1.087401
two -0.673690  0.113648 -1.478427  0.524988
baz one  0.404705  0.577046 -1.715002 -1.039268
two  1.071804 -1.157892 -1.344312  0.844885
foo one  1.075770 -0.109050  1.643563 -1.469388
two  0.357021 -0.674600 -1.776994 -0.968914
qux one -1.294524  0.413738  0.276662 -0.472035
two -0.013960 -0.362543 -0.006154 -0.923061
```

All of the MultiIndex constructors accept a names argument which stores string names for the levels themselves. If no names are provided, None will be assigned:

```python
In [17]: df.index.names
Out[17]: FrozenList([None, None])
```
This index can back any axis of a pandas object, and the number of `levels` of the index is up to you:

```
In [18]: df = pd.DataFrame(np.random.randn(3, 8), index=['A', 'B', 'C'],
                      columns=index)
In [19]: df
Out[19]:
   first  bar  baz  foo  qux
first   one  two  one  two
A  0.895717  0.805244 -1.206412  2.565646  1.431256
   one  two  one  two
B  0.410835  0.813850  0.132003 -0.827317 -0.076467
   one  two  one  two
C -1.413681  1.607920  1.024180  0.569605  0.875906

In [20]: pd.DataFrame(np.random.randn(6, 6), index=index[:6], columns=index[:6])
Out[20]:
   first  bar  baz  foo
   second  one  two  one  two
first   one  two  one  two
bar -0.410001 -0.078638  0.545952 -1.219217 -1.226825  0.769804
    two -1.281247 -0.727707 -0.121306 -0.097883  0.695775  0.341734
baz  0.959726 -1.110336 -0.619976  0.149748 -0.732339  0.687738
    two  0.176444  0.403310 -0.154951  0.301624 -2.179861 -1.369849
foo -0.954208  1.462969 -1.743161 -0.826591 -0.345352  1.314232
    two  0.690579  0.995761  2.396780  0.014871  3.357427 -0.317441
```

We’ve “sparsified” the higher levels of the indexes to make the console output a bit easier on the eyes. Note that how the index is displayed can be controlled using the `multi_sparse` option in `pandas.set_options()`:

```
In [21]: with pd.option_context('display.multi_sparse', False):
     ....:    df
     ....:```

It’s worth keeping in mind that there’s nothing preventing you from using tuples as atomic labels on an axis:

```
In [22]: pd.Series(np.random.randn(8), index=tuples)
Out[22]:
   (bar, one) -1.236269
   (bar, two)  0.896171
   (baz, one) -0.487602
   (baz, two) -0.082240
   (foo, one) -2.182937
   (foo, two)  0.380396
   (qux, one)  0.084844
   (qux, two)  0.432390
dtype: float64
```

The reason that the MultiIndex matters is that it can allow you to do grouping, selection, and reshaping operations as we will describe below and in subsequent areas of the documentation. As you will see in later sections, you can find yourself working with hierarchically-indexed data without creating a MultiIndex explicitly yourself. However, when loading data from a file, you may wish to generate your own MultiIndex when preparing the data set.
### Reconstructing the level labels

The method `get_level_values()` will return a vector of the labels for each location at a particular level:

```python
In [23]: index.get_level_values(0)
Out[23]: Index(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'], dtype='object', name='first')

In [24]: index.get_level_values('second')
Out[24]: Index(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'], dtype='object', name='second')
```

### Basic indexing on axis with Multiindex

One of the important features of hierarchical indexing is that you can select data by a “partial” label identifying a subgroup in the data. Partial selection “drops” levels of the hierarchical index in the result in a completely analogous way to selecting a column in a regular DataFrame:

```python
In [25]: df['bar']
Out[25]:
   second  one  two
   A  0.895717  0.805244
   B  0.410835  0.813850
   C -1.413681  1.607920

In [26]: df['bar', 'one']
Out[26]:
   A  0.895717
   B  0.410835
   C -1.413681
Name: (bar, one), dtype: float64

In [27]: df['bar']['one']
Out[27]:
   A  0.895717
   B  0.410835
   C -1.413681
Name: one, dtype: float64

In [28]: s['qux']
Out[28]:
   one  -1.039575
   two   0.271860
Name: qux, dtype: float64
```

See [Cross-section with hierarchical index](#) for how to select on a deeper level.
Defined levels

The `MultiIndex` keeps all the defined levels of an index, even if they are not actually used. When slicing an index, you may notice this. For example:

```python
In [29]: df.columns.levels  # original MultiIndex
Out[29]: FrozenList([['bar', 'baz', 'foo', 'qux'], ['one', 'two']])

In [30]: df[['foo','qux']].columns.levels  # sliced
Out[30]: FrozenList([['bar', 'baz', 'foo', 'qux'], ['one', 'two']])
```

This is done to avoid a recomputation of the levels in order to make slicing highly performant. If you want to see only the used levels, you can use the `get_level_values()` method.

```python
In [31]: df[['foo', 'qux']].columns.to_numpy()
Out[31]: array([('foo', 'one'), ('foo', 'two'), ('qux', 'one'), ('qux', 'two')], dtype=object)
# for a specific level
In [32]: df[['foo', 'qux']].columns.get_level_values(0)
Out[32]: Index(['foo', 'foo', 'qux', 'qux'], dtype='object', name='first')
```

To reconstruct the `MultiIndex` with only the used levels, the `remove_unused_levels()` method may be used.

```python
In [33]: new_mi = df[['foo', 'qux']].columns.remove_unused_levels()
In [34]: new_mi.levels
Out[34]: FrozenList([['foo', 'qux'], ['one', 'two']])
```

Data alignment and using `reindex`

Operations between differently-indexed objects having `MultiIndex` on the axes will work as you expect; data alignment will work the same as an Index of tuples:

```python
In [35]: s + s[-2]
Out[35]:
bar    -1.723698
  two   -4.209138
baz    -0.989859
  two   2.143608
foo    1.443110
  two  -1.413542
qux    NaN
  two   NaN
dtype: float64

In [36]: s + s[::2]
Out[36]:
bar    -1.723698
  two  NaN
baz    -0.989859
  two  NaN
foo    1.443110
  two  NaN
qux    -2.079150
```

(continues on next page)
The `reindex()` method of `Series/DataFrames` can be called with another `MultiIndex`, or even a list or array of tuples:

```
In [37]: s.reindex(index[:3])
Out[37]:
first second
bar one   -0.861849  
two        -2.104569
baz one    -0.494929
dtype: float64
```
```
In [38]: s.reindex([('foo', 'two'), ('bar', 'one'), ('qux', 'one'), ('baz', 'one')])
Out[38]:
foo two  -0.706771
bar one  -0.861849
qux one  -1.039575
baz one  -0.494929
dtype: float64
```

### 2.6.2 Advanced indexing with hierarchical index

Syntactically integrating `MultiIndex` in advanced indexing with `.loc` is a bit challenging, but we’ve made every effort to do so. In general, MultiIndex keys take the form of tuples. For example, the following works as you would expect:

```
In [39]: df = df.T

In [40]: df
Out[40]:
   A     B     C
first second
bar one  0.895717 0.410835 -1.413681
two      0.805244 0.813850  1.607920
baz one  -1.206412 0.132003  1.024180
two      2.565646 -0.827317  0.569605
foo one  1.431256 -0.076467  0.875906
two      1.340309 -1.187678 -2.211372
qux one  -1.170299 1.130127  0.974466
two      -0.226169 1.436737 -2.006747

In [41]: df.loc[('bar', 'two')]
Out[41]:
   A     B     C
foo two -0.706771
bar one  0.861849
qux one  1.039575
baz one  0.494929
dtype: float64
```

Note that `df.loc['bar', 'two']` would also work in this example, but this shorthand notation can lead to ambiguity in general.

If you also want to index a specific column with `.loc`, you must use a tuple like this:
In [42]: df.loc[('bar', 'two'), 'A']
Out[42]: 0.8052440253863785

You don’t have to specify all levels of the MultiIndex by passing only the first elements of the tuple. For example, you can use “partial” indexing to get all elements with bar in the first level as follows:

In [43]: df.loc['bar']
Out[43]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>first</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>second</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>one</td>
<td>0.895717</td>
<td>0.410835</td>
<td>-1.413681</td>
</tr>
<tr>
<td>two</td>
<td>0.805244</td>
<td>0.813850</td>
<td>1.607920</td>
</tr>
</tbody>
</table>

This is a shortcut for the slightly more verbose notation df.loc[('bar',),] (equivalent to df.loc['bar',] in this example).

“Partial” slicing also works quite nicely.

In [44]: df.loc['baz':'foo']
Out[44]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>first</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>second</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>baz</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>one</td>
<td>-1.206412</td>
<td>0.132003</td>
<td>1.024180</td>
</tr>
<tr>
<td>two</td>
<td>2.565646</td>
<td>-0.827317</td>
<td>0.569605</td>
</tr>
<tr>
<td>foo</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>one</td>
<td>1.431256</td>
<td>-0.076467</td>
<td>0.875906</td>
</tr>
<tr>
<td>two</td>
<td>1.340309</td>
<td>-1.187678</td>
<td>-2.211372</td>
</tr>
</tbody>
</table>

You can slice with a ‘range’ of values, by providing a slice of tuples.

In [45]: df.loc[['baz', 'two']:'foo']
Out[45]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>first</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>second</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>baz</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>two</td>
<td>2.565646</td>
<td>-0.827317</td>
<td>0.569605</td>
</tr>
<tr>
<td>foo</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>one</td>
<td>1.431256</td>
<td>-0.076467</td>
<td>0.875906</td>
</tr>
<tr>
<td>two</td>
<td>1.340309</td>
<td>-1.187678</td>
<td>-2.211372</td>
</tr>
<tr>
<td>qux</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>one</td>
<td>-1.170299</td>
<td>1.130127</td>
<td>0.974466</td>
</tr>
</tbody>
</table>

In [46]: df.loc[('baz', 'two'):'foo']
Out[46]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>first</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>second</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>baz</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>two</td>
<td>2.565646</td>
<td>-0.827317</td>
<td>0.569605</td>
</tr>
<tr>
<td>foo</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>one</td>
<td>1.431256</td>
<td>-0.076467</td>
<td>0.875906</td>
</tr>
<tr>
<td>two</td>
<td>1.340309</td>
<td>-1.187678</td>
<td>-2.211372</td>
</tr>
<tr>
<td>qux</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>one</td>
<td>-1.170299</td>
<td>1.130127</td>
<td>0.974466</td>
</tr>
</tbody>
</table>

Passing a list of labels or tuples works similar to reindexing:

In [47]: df.loc[['bar', 'two'], ('qux', 'one')]
Out[47]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>first</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>second</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>bar</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>two</td>
<td>0.805244</td>
<td>0.813850</td>
<td>1.607920</td>
</tr>
<tr>
<td>qux</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>one</td>
<td>-1.170299</td>
<td>1.130127</td>
<td>0.974466</td>
</tr>
</tbody>
</table>

Note: It is important to note that tuples and lists are not treated identically in pandas when it comes to indexing. Whereas a tuple is interpreted as one multi-level key, a list is used to specify several keys. Or in other words, tuples
go horizontally (traversing levels), lists go vertically (scanning levels).

Importantly, a list of tuples indexes several complete MultiIndex keys, whereas a tuple of lists refer to several values within a level:

```
In [48]: s = pd.Series([1, 2, 3, 4, 5, 6],
                   index=pd.MultiIndex.from_product(["A", "B"], ["c", "d", "e
c"]))
...
In [49]: s.loc[[("A", "c"), ("B", "d")]]  # list of tuples
Out[49]:
A  c  1
B  d  5
dtype: int64
In [50]: s.loc[(["A", "B"], ["c", "d")]]  # tuple of lists
Out[50]:
A  c  1
d  2
B  c  4
d  5
dtype: int64
```

**Using slicers**

You can slice a MultiIndex by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see *Selection by Label*, including slices, lists of labels, labels, and boolean indexers.

You can use `slice(None)` to select all the contents of *that* level. You do not need to specify all the deeper levels, they will be implied as `slice(None)`.

As usual, both sides of the slicers are included as this is label indexing.

```
In [51]: def mklbl(prefix, n):
    ....:     return ["%s%s" % (prefix, i) for i in range(n)]
    ....:
In [52]: miindex = pd.MultiIndex.from_product([mklbl('A', 4),
                                            mklbl('B', 2),
                                            mklbl('C', 4),
                                            mklbl('D', 2)])
```

(continues on next page)
....:

In [53]: mcolumns = pd.MultiIndex.from_tuples([('a', 'foo'), ('a', 'bar'),
....: ('b', 'foo'), ('b', 'bah')],
....: names=['lvl0', 'lvl1'])
....:

In [54]: dfmi = pd.DataFrame(np.arange(len(miindex) * len(micolumns)).reshape((len(miindex), len(micolumns))),
....: index=miindex,
....: columns=micolumns).sort_index().sort_index(axis=1)
....:

In [55]: dfmi
Out[55]:
lvl0   a   b
lvl1  bar  foo  bah  foo
A0    B0   C0    D0   1  0  3  2
   D1   5   4   7   6
   C1   D0   9   8  11  10
   D1  13  12  15  14
   C2   D0  17  16  19  18
   ...
   ...
   ...
   ...
   ...
   ...
A3    B1   C1    D1  237 236 239 238
   C2    D0  241 240 243 242
   D1  245 244 247 246
   C3    D0  249 248 251 250
   D1  253 252 255 254
   ...
   ...
   ...
   ...
   ...
   ...
   ...
   ...
   ...
[64 rows x 4 columns]

Basic MultiIndex slicing using slices, lists, and labels.

In [56]: dfmi.loc[(slice('A1', 'A3'), slice(None), ['C1', 'C3']), :]
Out[56]:
lvl0   a   b
lvl1  bar  foo  bah  foo
A1    B0   C0    D0  73  72  75  74
   D1   77  76  79  78
   C3   D0  89  88  91  90
   D1  93  92  95  94
   B1   C1   D0  105 104 107 106
   ...
   ...
   ...
   ...
   ...
   ...
A3    B0    C3    D1  221 220 223 222
   B1    C1    D0  233 232 235 234
   D1  237 236 239 238
   C3    D0  249 248 251 250
   D1  253 252 255 254
[24 rows x 4 columns]

You can use pandas.IndexSlice to facilitate a more natural syntax using :, rather than using slice(None).

In [57]: idx = pd.IndexSlice
In [58]: dfmi.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]
Out[58]:
(continues on next page)
It is possible to perform quite complicated selections using this method on multiple axes at the same time.

```
In [59]: dfmi.loc['A1', (slice(None), 'foo')]
Out[59]:
lvl0  a  b
lvl1  foo foo
A0  B0  C0  D0  8  10
  D1  12  14
  C3  D0  24  26
  D1  28  30
B1  C1  D0  40  42
...  ...  ...  ...
A3  B0  C3  D1  220 222
B1  C1  D0  232 234
  D1  236 238
C3  D0  248 250
  D1  252 254
[16 rows x 2 columns]
```

```
In [60]: dfmi.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]
Out[60]:
lvl0  a  b
lvl1  foo foo
A0  B0  C0  D0  8  10
  D1  12  14
  C3  D0  24  26
  D1  28  30
A3  B0  C3  D1  220 222
B1  C1  D0  232 234
  D1  236 238
C3  D0  248 250
  D1  252 254
[32 rows x 2 columns]
```

Using a boolean indexer you can provide selection related to the values.
In [61]: mask = dfmi[('a', 'foo')] > 200

In [62]: dfmi.loc[idx[mask, :, ['C1', 'C3']], idx[:, 'foo']]
Out[62]:
lvl0 a b
lvl1 foo foo
A3 B0 C1 D1  204  206
  C3 D0  216  218
  D1  220  222
B1 C1 D0  232  234
  D1  236  238
C3 D0  248  250
  D1  252  254

You can also specify the `axis` argument to `.loc` to interpret the passed slicers on a single axis.

In [63]: dfmi.loc(axis=0)[:, :, ['C1', 'C3']]
Out[63]:
lvl0  a   b
lvl1  foo  foo
A0 B0 C1 D0  9  8 11 10
  D1  13  12 15 14
  C3 D0  25  24 27 26
  D1  29  28 31 30
B1 C1 D0  41  40 43 42
...
A3 B0 C3 D1 221 220 223 222
B1 C1 D0 233 232 235 234
  D1 237 236 239 238
C3 D0 249 248 251 250
  D1 253 252 255 254
[32 rows x 4 columns]

Furthermore, you can set the values using the following methods.

In [64]: df2 = dfmi.copy()

In [65]: df2.loc(axis=0)[:, :, ['C1', 'C3']] = -10

In [66]: df2
Out[66]:
lvl0  a   b
lvl1  foo  foo
A0 B0 C0 D0  1  0  3  2
  D1  5  4  7  6
  C1 D0 -10  10 -10  10
  D1 -10  10  10  10
  C2 D0  17  16 19  18
...
A3 B1 C3 D1 -10  10 -10  10
  D1  241 240 243 242
C3 D0 -10  10  10  10
  D1 -10 -10  10 -10
[64 rows x 4 columns]
You can use a right-hand-side of an alignable object as well.

```
In [67]: df2 = dfmi.copy()

In [68]: df2.loc[idx[:, :, ['C1', 'C3']], :] = df2 * 1000

In [69]: df2
Out[69]:
   lvl0   a   b
   lvl1
c0     bar  foo bah  foo
   A0     1   0   3   2
   D1     5   4   7   6

   D1     13000 12000 15000 14000
   C2     17   16   19  18
   ...  ...  ...  ...  ...
   A3     237000 236000 239000 238000
   C2     241  240  243  242
   D1     245  244  247  246
   C3     249000 248000 251000 250000
   D1     253000 252000 255000 254000

[64 rows x 4 columns]
```

**Cross-section**

The `xs()` method of `DataFrame` additionally takes a level argument to make selecting data at a particular level of a `MultiIndex` easier.

```
In [70]: df
Out[70]:
   A       B       C
first second
bar     0.895717  0.410835 -1.413681
two    0.805244  0.813850  1.607920
baz    -1.206412  0.132003  1.024180
two    2.565646 -0.827317  0.569605
foo     1.431256 -0.076467  0.875906
two    1.340309 -1.187678 -2.211372
qux    -1.170299  1.130127  0.974466
two   -0.226169 -1.436737 -2.006747

In [71]: df.xs('one', level='second')
Out[71]:
   A       B       C
first
bar     0.895717  0.410835 -1.413681
baz    -1.206412  0.132003  1.024180
foo     1.431256 -0.076467  0.875906
qux    -1.170299  1.130127  0.974466
```

# using the slicers
```
In [72]: df.loc[(slice(None), 'one'), :]
Out[72]:
   A       B       C
first second
bar     0.895717  0.410835 -1.413681
baz    -1.206412  0.132003  1.024180
foo     1.431256 -0.076467  0.875906
qux    -1.170299  1.130127  0.974466
```

(continues on next page)
You can also select on the columns with `xs`, by providing the axis argument.

```python
In [73]: df = df.T

In [74]: df.xs('one', level='second', axis=1)
Out[74]:
   first  bar  baz  foo  qux
A  0.895717 -1.206412 1.431256 -1.170299
B  0.410835  0.132003 -0.076467  1.130127
C -1.413681  1.024180  0.875906  0.974466
```

```python
# using the slicers
In [75]: df.loc[:, (slice(None), 'one')]
Out[75]:
   first  bar  baz  foo  qux
A  0.895717 -1.206412 1.431256 -1.170299
B  0.410835  0.132003 -0.076467  1.130127
C -1.413681  1.024180  0.875906  0.974466
```

`xs` also allows selection with multiple keys.

```python
In [76]: df.xs(('one', 'bar'), level=('second', 'first'), axis=1)
Out[76]:
   first  bar
second one
A  0.895717
B  0.410835
C -1.413681
```

```python
# using the slicers
In [77]: df.loc[:, ('bar', 'one')]
Out[77]:
   A  0.895717
   B  0.410835
   C -1.413681
Name: (bar, one), dtype: float64
```

You can pass `drop_level=False` to `xs` to retain the level that was selected.

```python
In [78]: df.xs('one', level='second', axis=1, drop_level=False)
Out[78]:
   first  bar  baz  foo  qux
second one  one  one  one  one
A  0.895717 -1.206412 1.431256 -1.170299
B  0.410835  0.132003 -0.076467  1.130127
C -1.413681  1.024180  0.875906  0.974466
```

Compare the above with the result using `drop_level=True` (the default value).
### Advanced reindexing and alignment

Using the parameter `level` in the `reindex()` and `align()` methods of pandas objects is useful to broadcast values across a level. For instance:

```python
In [80]: midx = pd.MultiIndex(levels=[['zero', 'one'], ['x', 'y']],
                      codes=[[1, 1, 0, 0], [1, 0, 1, 0]])

In [81]: df = pd.DataFrame(np.random.randn(4, 2), index=midx)

In [82]: df
Out[82]:
          0   1
one y    1.519970 -0.493662
   x    0.600178  0.274230
zero y   0.132885 -0.023688
   x    2.410179  1.450520

In [83]: df2 = df.mean(level=0)

In [84]: df2
Out[84]:
          0   1
one 1.060074 -0.109716
zero 1.271532  0.713416

In [85]: df2.reindex(df.index, level=0)
Out[85]:
          0   1
one y 1.519970 -0.493662
   x  0.600178  0.274230
zero y 0.132885 -0.023688
   x  2.410179  1.450520

# aligning
In [86]: df_aligned, df2_aligned = df.align(df2, level=0)

In [87]: df_aligned
Out[87]:
          0   1
one y 1.519970 -0.493662
   x  0.600178  0.274230
zero y 0.132885 -0.023688
   x  2.410179  1.450520

In [88]: df2_aligned
Out[88]:
          0   1
one y 1.519970 -0.493662
   x  0.600178  0.274230
zero y 0.132885 -0.023688
   x  2.410179  1.450520
```

(continues on next page)
Swapping levels with `swaplevel`

The `swaplevel()` method can switch the order of two levels:

```python
In [89]: df[:5]
Out[89]:
     0  1
     
      one y  1.519970 -0.493662
       x  0.600178  0.274230
     zero y  0.132885 -0.023688
       x  2.410179  1.450520

In [90]: df[:5].swaplevel(0, 1, axis=0)
Out[90]:
     0  1
     
      y one    1.519970 -0.493662
      x one    0.600178  0.274230
      y zero    0.132885 -0.023688
      x zero    2.410179  1.450520
```

Reordering levels with `reorder_levels`

The `reorder_levels()` method generalizes the `swaplevel` method, allowing you to permute the hierarchical index levels in one step:

```python
In [91]: df[:5].reorder_levels([1, 0], axis=0)
Out[91]:
     0  1
     
      y one    1.519970 -0.493662
      x one    0.600178  0.274230
      y zero    0.132885 -0.023688
      x zero    2.410179  1.450520
```

Renaming names of an `Index` or `MultiIndex`

The `rename()` method is used to rename the labels of a `MultiIndex`, and is typically used to rename the columns of a `DataFrame`. The `columns` argument of `rename` allows a dictionary to be specified that includes only the columns you wish to rename.

```python
In [92]: df.rename(columns={0: "col0", 1: "col1"})
Out[92]:
   col0  col1
     y   1.519970 -0.493662
     x   0.600178  0.274230
   zero  0.132885 -0.023688
     x   2.410179  1.450520
```

This method can also be used to rename specific labels of the main index of the `DataFrame`. 

2.6. MultiIndex / advanced indexing
The `rename_axis()` method is used to rename the name of a `Index` or `MultiIndex`. In particular, the names of the levels of a MultiIndex can be specified, which is useful if `reset_index()` is later used to move the values from the MultiIndex to a column.

```
In [94]: df.rename_axis(index=['abc', 'def'])
Out[94]:
   0  1
  abc def
one y  1.519970 -0.493662
    x  0.600178  0.274230
zero y  0.132885 -0.023688
    x  2.410179  1.450520
```

Note that the columns of a DataFrame are an index, so that using `rename_axis` with the `columns` argument will change the name of that index.

```
In [95]: df.rename_axis(columns="Cols").columns
Out[95]: RangeIndex(start=0, stop=2, step=1, name='Cols')
```

Both `rename` and `rename_axis` support specifying a dictionary, Series or a mapping function to map labels/names to new values.

When working with an `Index` object directly, rather than via a DataFrame, `Index.set_names()` can be used to change the names.

```
In [96]: mi = pd.MultiIndex.from_product([[1, 2], ['a', 'b']], names=['x', 'y'])
In [97]: mi.names
Out[97]: FrozenList(['x', 'y'])
In [98]: mi2 = mi.rename("new name", level=0)
In [99]: mi2
Out[99]: MultiIndex([(1, 'a'),
                   (1, 'b'),
                   (2, 'a'),
                   (2, 'b')],
                   names=['new name', 'y'])
```

You cannot set the names of the MultiIndex via a level.

```
In [100]: mi.levels[0].name = "name via level"
---------------------------------------------------------------------------
RuntimeError                              Traceback (most recent call last)
<ipython-input-100-35d32a9a5218> in <module>
----> 1 mi.levels[0].name = "name via level"
/pandas/pandas/core/indexes/base.py in name(self, value)
```

(continues on next page)
2.6.3 Sorting a MultiIndex

For MultiIndex-ed objects to be indexed and sliced effectively, they need to be sorted. As with any index, you can use `sort_index()`.

```
In [101]: import random

In [102]: random.shuffle(tuples)

In [103]: s = pd.Series(np.random.randn(8), index=pd.MultiIndex.from_tuples(tuples))

In [104]: s
Out[104]:
baz one  0.206053
  bar two -0.251905
  qux two -2.213588
   one  1.063327
  bar one  1.266143
  foo one  0.299368
   two -0.863838
  baz two  0.408204
dtype: float64

In [105]: s.sort_index()
Out[105]:
  bar one  1.266143
   two -0.251905
  baz one  0.206053
   two  0.408204
  foo one  0.299368
   two -0.863838
  qux one  1.063327
   two -2.213588
dtype: float64

In [106]: s.sort_index(level=0)
Out[106]:
  bar one  1.266143
   two -0.251905
  baz one  0.206053
   two  0.408204
  foo one  0.299368
   two -0.863838
```
You may also pass a level name to `sort_index` if the `MultiIndex` levels are named.

On higher dimensional objects, you can sort any of the other axes by level if they have a `MultiIndex`:  

Indexing will work even if the data are not sorted, but will be rather inefficient (and show a `PerformanceWarning`). It will also return a copy of the data rather than a view:
In [112]: dfm = pd.DataFrame({'jim': [0, 0, 1, 1],
        'joe': ['x', 'x', 'z', 'y'],
        'jolie': np.random.rand(4))

In [113]: dfm = dfm.set_index(['jim', 'joe'])

In [114]: dfm
Out[114]:
    jolie
        jim  joe
    0   x  0.490671
        x  0.120248
    1   z  0.537020
        y  0.110968

In [4]: dfm.loc[(1, 'z')]
PerformanceWarning: indexing past lexsort depth may impact performance.
Out[4]:
    jolie
        jim  joe
    1   z  0.64094

Furthermore, if you try to index something that is not fully lexsorted, this can raise:

In [5]: dfm.loc[(0, 'y'):(1, 'z')]
UnsortedIndexError: 'Key length (2) was greater than MultiIndex lexsort depth (1)'

The `is_lexsorted()` method on a MultiIndex shows if the index is sorted, and the `lexsort_depth` property returns the sort depth:

In [115]: dfm.index.is_lexsorted()
Out[115]: False

In [116]: dfm.index.lexsort_depth
Out[116]: 1

In [117]: dfm = dfm.sort_index()

In [118]: dfm
Out[118]:
    jolie
        jim  joe
    0   x  0.490671
        x  0.120248
    1   y  0.110968
        z  0.537020

In [119]: dfm.index.is_lexsorted()
Out[119]: True

In [120]: dfm.index.lexsort_depth
Out[120]: 2

And now selection works as expected.
2.6.4 Take methods

Similar to NumPy ndarrays, pandas Index, Series, and DataFrame also provides the `take()` method that retrieves elements along a given axis at the given indices. The given indices must be either a list or an `ndarray` of integer index positions. `take` will also accept negative integers as relative positions to the end of the object.

For DataFrames, the given indices should be a 1d list or `ndarray` that specifies row or column positions.
It is important to note that the `take` method on pandas objects are not intended to work on boolean indices and may return unexpected results.

Finally, as a small note on performance, because the `take` method handles a narrower range of inputs, it can offer performance that is a good deal faster than fancy indexing.
2.6.5 Index types

We have discussed MultiIndex in the previous sections pretty extensively. Documentation about DatetimeIndex and PeriodIndex are shown here, and documentation about TimedeltaIndex is found here.

In the following sub-sections we will highlight some other index types.

CategoricalIndex

CategoricalIndex is a type of index that is useful for supporting indexing with duplicates. This is a container around a Categorical and allows efficient indexing and storage of an index with a large number of duplicated elements.

```
In [145]: from pandas.api.types import CategoricalDtype

In [146]: df = pd.DataFrame({'A': np.arange(6),
                      'B': list('aabbc')})

In [147]: df['B'] = df['B'].astype(CategoricalDtype(list('cab')))

In [148]: df
Out[148]:
          A  B
0       0  a
1       1  a
2       2  b
3       3  b
4       4  c
5       5  a

In [149]: df.dtypes
Out[149]:
A    int64
B  category
dtype: object

In [150]: df['B'].cat.categories
Out[150]: Index(['c', 'a', 'b'], dtype='object')
```

Setting the index will create a CategoricalIndex.

```
In [151]: df2 = df.set_index('B')

In [152]: df2.index
Out[152]: CategoricalIndex(['c', 'a', 'b'], categories=['c', 'a', 'b'],
                          ordered=False, name='B', dtype='category')
```

Indexing with __getitem__/.iloc/.loc works similarly to an Index with duplicates. The indexers must be in the category or the operation will raise a KeyError.
The `CategoricalIndex` is preserved after indexing:

```python
In [154]: df2.loc['a'].index
Out[154]: CategoricalIndex(['a', 'a', 'a'], categories=['c', 'a', 'b'], ordered=False, name='B', dtype='category')
```

Sorting the index will sort by the order of the categories (recall that we created the index with `CategoricalDtype(list('cab'))`, so the sorted order is cab).

```python
In [155]: df2.sort_index()
Out[155]:
   A   B
   c   4
   a   6
   b   5
```

Groupby operations on the index will preserve the index nature as well.

```python
In [156]: df2.groupby(level=0).sum()
Out[156]:
   A   B
   c   4
   a   6
   b   5
```

Reindexing operations will return a resulting index based on the type of the passed indexer. Passing a list will return a plain-old Index; indexing with a Categorical will return a CategoricalIndex, indexed according to the categories of the passed Categorical dtype. This allows one to arbitrarily index these even with values not in the categories, similarly to how you can reindex any pandas index.

```python
In [158]: df3 = pd.DataFrame({'A': np.arange(3),
                                'B': pd.Series(list('abc')).astype('category')})

In [159]: df3 = df3.set_index('B')
```

(continues on next page)
```python
In [161]: df3.reindex(['a', 'e'])
Out[161]:
   A  B
a 0.0 NaN

In [162]: df3.reindex(['a', 'e']).index
Out[162]: Index(['a', 'e'], dtype='object', name='B')

In [163]: df3.reindex(pd.Categorical(['a', 'e'], categories=list('abe')))  
Out[163]:
   A  B
a 0.0 NaN

In [164]: df3.reindex(pd.Categorical(['a', 'e'], categories=list('abe')).index
Out[164]: CategoricalIndex(['a', 'e'], categories=['a', 'b', 'e'], ordered=False,  
                           name='B', dtype='category')

Warning: Reshaping and Comparison operations on a CategoricalIndex must have the same categories or a TypeError will be raised.

In [165]: df4 = pd.DataFrame({'A': np.arange(2),  
                         'B': list('ba')})
.....:

In [166]: df4['B'] = df4['B'].astype(CategoricalDtype(list('ab')))  

In [167]: df4 = df4.set_index('B')

In [168]: df4.index
Out[168]: CategoricalIndex(['b', 'a'], categories=['a', 'b'], ordered=False, name='B')

In [169]: df5 = pd.DataFrame({'A': np.arange(2),  
                         'B': list('bc')})
.....:

In [170]: df5['B'] = df5['B'].astype(CategoricalDtype(list('bc')))  

In [171]: df5 = df5.set_index('B')

In [172]: df5.index
Out[172]: CategoricalIndex(['b', 'c'], categories=['b', 'c'], ordered=False, name='B')

In [1]: pd.concat([df4, df5])
TypeError: categories must match existing categories when appending
```
**Int64Index and RangelIndex**

*Int64Index* is a fundamental basic index in pandas. This is an immutable array implementing an ordered, sliceable set.

*RangeIndex* is a sub-class of Int64Index that provides the default index for all NDFrame objects. RangeIndex is an optimized version of Int64Index that can represent a monotonic ordered set. These are analogous to Python range types.

**Float64Index**

By default a *Float64Index* will be automatically created when passing floating, or mixed-integer-floating values in index creation. This enables a pure label-based slicing paradigm that makes [], ix, loc for scalar indexing and slicing work exactly the same.

```python
In [173]: indexf = pd.Index([1.5, 2, 3, 4.5, 5])

In [174]: indexf
Out[174]: Float64Index([1.5, 2.0, 3.0, 4.5, 5.0], dtype='float64')

In [175]: sf = pd.Series(range(5), index=indexf)

In [176]: sf
Out[176]:
1.5 0
2.0 1
3.0 2
4.5 3
5.0 4
dtype: int64
```

Scalar selection for [], .loc will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to 3.0).

```python
In [177]: sf[3]
Out[177]: 2

In [178]: sf[3.0]
Out[178]: 2

In [179]: sf.loc[3]
Out[179]: 2

In [180]: sf.loc[3.0]
Out[180]: 2
```

The only positional indexing is via iloc.

```python
In [181]: sf.iloc[3]
Out[181]: 3
```

A scalar index that is not found will raise a KeyError. Slicing is primarily on the values of the index when using [], ix, loc, and always positional when using iloc. The exception is when the slice is boolean, in which case it will always be positional.
In [182]: sf[[2:4]]
Out[182]:
```
2.0 1
3.0 2
dtype: int64
```

In [183]: sf.loc[[2:4]]
Out[183]:
```
2.0 1
3.0 2
dtype: int64
```

In [184]: sf.iloc[[2:4]]
Out[184]:
```
3.0 2
4.5 3
dtype: int64
```

In float indexes, slicing using floats is allowed.

In [185]: sf[[2.1:4.6]]
Out[185]:
```
3.0 2
4.5 3
dtype: int64
```

In [186]: sf.loc[[2.1:4.6]]
Out[186]:
```
3.0 2
4.5 3
dtype: int64
```

In non-float indexes, slicing using floats will raise a `TypeError`.

In [1]: pd.Series(range(5))[3.5]
```
TypeError: the label [3.5] is not a proper indexer for this index type (Int64Index)
```

In [1]: pd.Series(range(5))[3.5:4.5]
```
TypeError: the slice start [3.5] is not a proper indexer for this index type (Int64Index)
```

Here is a typical use-case for using this type of indexing. Imagine that you have a somewhat irregular timedelta-like indexing scheme, but the data is recorded as floats. This could, for example, be millisecond offsets.

```python
In [187]: dfir = pd.concat([pd.DataFrame(np.random.randn(5, 2),
                        index=np.arange(5) * 250.0,
                        columns=list('AB')),
                        pd.DataFrame(np.random.randn(6, 2),
                        index=np.arange(4, 10) * 250.1,
                        columns=list('AB'))])
```
Selection operations then will always work on a value basis, for all selection operators.

In [189]: dfir[0:1000.4]
Out[189]:
   A         B
0.0 -0.435772 -1.188928
250.0 -0.808286 -0.284634
500.0 -1.815703  1.347213
750.0 -0.243487  0.514704
1000.0  1.162969 -0.287725
1000.4 -0.179734  0.993962

In [190]: dfir.loc[0:1001, 'A']
Out[190]:
0.0     -0.435772
250.0    -0.808286
500.0    -1.815703
750.0    -0.243487
1000.0   1.162969
1000.4   -0.179734
Name: A, dtype: float64

In [191]: dfir.loc[1000.4]
Out[191]:
   A       B
1000.4 -0.179734
   0.993962
Name: 1000.4, dtype: float64

You could retrieve the first 1 second (1000 ms) of data as such:

In [192]: dfir[0:1000]
Out[192]:
   A         B
0.0 -0.435772 -1.188928
250.0 -0.808286 -0.284634
500.0 -1.815703  1.347213
750.0 -0.243487  0.514704
1000.0  1.162969 -0.287725

If you need integer based selection, you should use iloc:

In [193]: dfir.iloc[0:5]
Out[193]:
   A         B
0.0 -0.435772 -1.188928
250.0 -0.808286 -0.284634
500.0 -1.815703  1.347213

IntervalIndex

`IntervalIndex` together with its own `dtype`, `IntervalDtype` as well as the `Interval` scalar type, allow first-class support in `pandas` for interval notation.

The `IntervalIndex` allows some unique indexing and is also used as a return type for the categories in `cut()` and `qcut()`.

Indexing with an IntervalIndex

An `IntervalIndex` can be used in `Series` and in `DataFrame` as the index.

```
In [194]: df = pd.DataFrame({'A': [1, 2, 3, 4]},
                      index=pd.IntervalIndex.from_breaks([0, 1, 2, 3, 4]))

In [195]: df
Out[195]:
    A
(0, 1]  1
(1, 2]  2
(2, 3]  3
(3, 4]  4
```

Label based indexing via `.loc` along the edges of an interval works as you would expect, selecting that particular interval.

```
In [196]: df.loc[2]
Out[196]:
    A
Name: (1, 2], dtype: int64

In [197]: df.loc[[2, 3]]
Out[197]:
    A
Name: (2, 3], dtype: int64
```

If you select a label `contained` within an interval, this will also select the interval.

```
In [198]: df.loc[2.5]
Out[198]:
    A
Name: (2, 3], dtype: int64

In [199]: df.loc[[2.5, 3.5]]
Out[199]:
    A
Name: (2, 3], dtype: int64
```
Selecting using an `Interval` will only return exact matches (starting from pandas 0.25.0).

```python
In [200]: df.loc[pd.Interval(1, 2)]
Out[200]:
   A
Name: (1, 2], dtype: int64

Trying to select an `Interval` that is not exactly contained in the `IntervalIndex` will raise a `KeyError`.

```python
In [7]: df.loc[pd.Interval(0.5, 2.5)]
---------------------------------------------------------------------------
KeyError: Interval(0.5, 2.5, closed='right')
```

Selecting all `Intervals` that overlap a given `Interval` can be performed using the `overlaps()` method to create a boolean indexer.

```python
In [201]: idxr = df.index.overlaps(pd.Interval(0.5, 2.5))
In [202]: idxr
Out[202]: array([True, True, True, False])
In [203]: df[idxr]
Out[203]:
   A
(0, 1] 1
(1, 2] 2
(2, 3] 3
```

**Binning data with `cut` and `qcut`**

`cut()` and `qcut()` both return a `Categorical` object, and the bins they create are stored as an `IntervalIndex` in its `.categories` attribute.

```python
In [204]: c = pd.cut(range(4), bins=2)
In [205]: c
Out[205]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3.0], (1.5, 3.0]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]
In [206]: c.categories
Out[206]:
IntervalIndex([(-0.003, 1.5], (1.5, 3.0]],
               closed='right',
               dtype='interval[float64]')
```

`cut()` also accepts an `IntervalIndex` for its `bins` argument, which enables a useful pandas idiom. First, we call `cut()` with some data and `bins` set to a fixed number, to generate the bins. Then, we pass the values of `.categories` as the `bins` argument in subsequent calls to `cut()`, supplying new data which will be binned into the same bins.

```python
In [207]: pd.cut([0, 3, 5, 1], bins=c.categories)
Out[207]:
[(-0.003, 1.5], (1.5, 3.0], NaN, (-0.003, 1.5]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]
```

Any value which falls outside all bins will be assigned a `NaN` value.
Generating ranges of intervals

If we need intervals on a regular frequency, we can use the `interval_range()` function to create an `IntervalIndex` using various combinations of start, end, and periods. The default frequency for `interval_range` is a 1 for numeric intervals, and calendar day for datetime-like intervals:

```python
In [208]: pd.interval_range(start=0, end=5)
Out[208]:
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
closed='right',
dtype='interval[int64]')
```

```python
In [209]: pd.interval_range(start=pd.Timestamp('2017-01-01'), periods=4)
Out[209]:
IntervalIndex([(2017-01-01, 2017-01-02], (2017-01-02, 2017-01-03],
(2017-01-03, 2017-01-04],
closed='right',
dtype='interval[datetime64[ns]]')
```

```python
In [210]: pd.interval_range(end=pd.Timedelta('3 days'), periods=3)
Out[210]:
IntervalIndex([(0 days 00:00:00, 1 days 00:00:00], (1 days 00:00:00, 2 days 00:00:00],
(2 days 00:00:00, 3 days 00:00:00)],
closed='right',
dtype='interval[timedelta64[ns]]')
```

The `freq` parameter can be used to specify non-default frequencies, and can utilize a variety of frequency aliases with datetime-like intervals:

```python
In [211]: pd.interval_range(start=0, periods=5, freq=1.5)
Out[211]:
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0],
(6.0, 7.5]],
closed='right',
dtype='interval[float64]')
```

```python
In [212]: pd.interval_range(start=pd.Timestamp('2017-01-01'), periods=4, freq='W')
Out[212]:
IntervalIndex([(2017-01-01, 2017-01-08], (2017-01-08, 2017-01-15],
(2017-01-15, 2017-01-22],
closed='right',
dtype='interval[datetime64[ns]]')
```

```python
In [213]: pd.interval_range(start=pd.Timedelta('0 days'), periods=3, freq='9H')
Out[213]:
IntervalIndex([(0 days 00:00:00, 0 days 09:00:00],
(0 days 09:00:00, 0 days 18:00:00],
(0 days 18:00:00, 1 days 03:00:00)],
closed='right',
dtype='interval[timedelta64[ns]]')
```

Additionally, the `closed` parameter can be used to specify which side(s) the intervals are closed on. Intervals are closed on the right side by default:

```python
In [214]: pd.interval_range(start=0, end=4, closed='both')
Out[214]:
IntervalIndex([(0, 1], [1, 2], [2, 3], [3, 4]],
closed='both',
dtype='interval[int64]')
```

(continues on next page)
New in version 0.23.0.

Specifying `start`, `end`, and `periods` will generate a range of evenly spaced intervals from `start` to `end` inclusively, with `periods` number of elements in the resulting `IntervalIndex`:

```python
In [215]: pd.interval_range(start=0, end=4, closed='neither')
Out[215]:
IntervalIndex([(0, 1), (1, 2), (2, 3), (3, 4)],
             closed='neither',
             dtype='interval[int64]')
```

```python
In [216]: pd.interval_range(start=0, end=6, periods=4)
Out[216]:
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]],
             closed='right',
             dtype='interval[float64]')
```

```python
In [217]: pd.interval_range(pd.Timestamp('2018-01-01'),
                        pd.Timestamp('2018-02-28'), periods=3)
```

2.6.6 Miscellaneous indexing FAQ

**Integer indexing**

Label-based indexing with integer axis labels is a thorny topic. It has been discussed heavily on mailing lists and among various members of the scientific Python community. In pandas, our general viewpoint is that labels matter more than integer locations. Therefore, with an integer axis index only label-based indexing is possible with the standard tools like `.loc`. The following code will generate exceptions:

```python
In [218]: s = pd.Series(range(5))
In [219]: s[-1]
```

```
ValueError: -1 is not in range
```

The above exception was the direct cause of the following exception:

```python
KeyError Traceback (most recent call last)
<ipython-input-219-76c3dce40054> in <module>
----> 1 s[-1]
```

(continues on next page)
This deliberate decision was made to prevent ambiguities and subtle bugs (many users reported finding bugs when the API change was made to stop “falling back” on position-based indexing).
Non-monotonic indexes require exact matches

If the index of a Series or DataFrame is monotonically increasing or decreasing, then the bounds of a label-based slice can be outside the range of the index, much like slice indexing a normal Python list. Monotonicity of an index can be tested with the `is_monotonic_increasing()` and `is_monotonic_decreasing()` attributes.

```
In [223]: df = pd.DataFrame(index=[2, 3, 3, 4, 5], columns=['data'],
                                 data=list(range(5)))

In [224]: df.index.is_monotonic_increasing
Out[224]: True

# no rows 0 or 1, but still returns rows 2, 3 (both of them), and 4:
In [225]: df.loc[0:4, :]
Out[225]:
   data
2  0
3  1
3  2
4  3

# slice is are outside the index, so empty DataFrame is returned
In [226]: df.loc[13:15, :]
Out[226]:
Empty DataFrame
Columns: [data]
Index: []
```

On the other hand, if the index is not monotonic, then both slice bounds must be unique members of the index.

```
In [227]: df = pd.DataFrame(index=[2, 3, 1, 4, 3, 5], columns=['data'], data=list(range(6)))

In [228]: df.index.is_monotonic_increasing
Out[228]: False

# OK because 2 and 4 are in the index
In [229]: df.loc[2:4, :]
Out[229]:
   data
2  0
3  1
3  2
4  3

# 0 is not in the index
In [9]: df.loc[0:4, :]
KeyError: 0

# 3 is not a unique label
In [11]: df.loc[2:3, :]
KeyError: 'Cannot get right slice bound for non-unique label: 3'
```

`Index.is_monotonic_increasing` and `Index.is_monotonic_decreasing` only check that an index is weakly monotonic. To check for strict monotonicity, you can combine one of those with the `is_unique()` attribute.
Endpoints are inclusive

Compared with standard Python sequence slicing in which the slice endpoint is not inclusive, label-based slicing in pandas is inclusive. The primary reason for this is that it is often not possible to easily determine the “successor” or next element after a particular label in an index. For example, consider the following Series:

```python
In [234]: s = pd.Series(np.random.randn(6), index=list('abcdef'))
In [235]: s
Out[235]:
  a    0.301379
  b    1.240445
  c   -0.846068
  d   -0.043312
  e   -1.658747
  f   -0.819549
  dtype: float64
```

Suppose we wished to slice from `c` to `e`, using integers this would be accomplished as such:

```python
In [236]: s[2:5]
Out[236]:
  c   -0.846068
  d   -0.043312
  e   -1.658747
  dtype: float64
```

However, if you only had `c` and `e`, determining the next element in the index can be somewhat complicated. For example, the following does not work:

```python
s.loc['c':'e' + 1]
```

A very common use case is to limit a time series to start and end at two specific dates. To enable this, we made the design choice to make label-based slicing include both endpoints:

```python
In [237]: s.loc['c':'e']
Out[237]:
  c   -0.846068
  d   -0.043312
  e   -1.658747
  dtype: float64
```

This is most definitely a “practicality beats purity” sort of thing, but it is something to watch out for if you expect label-based slicing to behave exactly in the way that standard Python integer slicing works.
Indexing potentially changes underlying Series dtype

The different indexing operation can potentially change the dtype of a `Series`.

```python
In [238]: series1 = pd.Series([1, 2, 3])
In [239]: series1.dtype
Out[239]: dtype('int64')
In [240]: res = series1.reindex([0, 4])
In [241]: res.dtype
Out[241]: dtype('float64')
In [242]: res
Out[242]:
0  1.0
4  NaN
dtype: float64
```

```python
In [243]: series2 = pd.Series([True])
In [244]: series2.dtype
Out[244]: dtype('bool')
In [245]: res = series2.reindex_like(series1)
In [246]: res.dtype
Out[246]: dtype('O')
In [247]: res
Out[247]:
0   True
1   NaN
2   NaN
dtype: object
```

This is because the (re)indexing operations above silently inserts NaNs and the dtype changes accordingly. This can cause some issues when using numpy ufuncs such as `numpy.logical_and`.

See the this old issue for a more detailed discussion.
2.7 Merge, join, concatenate and compare

pandas provides various facilities for easily combining together Series or DataFrame with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

In addition, pandas also provides utilities to compare two Series or DataFrame and summarize their differences.

2.7.1 Concatenating objects

The `concat()` function (in the main pandas namespace) does all of the heavy lifting of performing concatenation operations along an axis while performing optional set logic (union or intersection) of the indexes (if any) on the other axes. Note that I say “if any” because there is only a single possible axis of concatenation for Series.

Before diving into all of the details of `concat` and what it can do, here is a simple example:

```
In [1]: df1 = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
                      'B': ['B0', 'B1', 'B2', 'B3'],
                      'C': ['C0', 'C1', 'C2', 'C3'],
                      'D': ['D0', 'D1', 'D2', 'D3'],
                      index=[0, 1, 2, 3])

In [2]: df2 = pd.DataFrame({'A': ['A4', 'A5', 'A6', 'A7'],
                      'B': ['B4', 'B5', 'B6', 'B7'],
                      'C': ['C4', 'C5', 'C6', 'C7'],
                      'D': ['D4', 'D5', 'D6', 'D7'],
                      index=[4, 5, 6, 7])

In [3]: df3 = pd.DataFrame({'A': ['A8', 'A9', 'A10', 'A11'],
                      'B': ['B8', 'B9', 'B10', 'B11'],
                      'C': ['C8', 'C9', 'C10', 'C11'],
                      'D': ['D8', 'D9', 'D10', 'D11'],
                      index=[8, 9, 10, 11])

In [4]: frames = [df1, df2, df3]

In [5]: result = pd.concat(frames)
```
Like its sibling function on ndarrays, `numpy.concatenate`, `pandas.concat` takes a list or dict of homogeneously-typed objects and concatenates them with some configurable handling of “what to do with the other axes”:

```python
pd.concat(objs, axis=0, join='outer', ignore_index=False, keys=None, levels=None, names=None, verify_integrity=False, copy=True)
```

- **objs**: a sequence or mapping of Series or DataFrame objects. If a dict is passed, the sorted keys will be used as the `keys` argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a ValueError will be raised.

- **axis**: {0, 1, ...}, default 0. The axis to concatenate along.

- **join**: {'inner', 'outer'}, default 'outer'. How to handle indexes on other axis(es). Outer for union and inner for intersection.

- **ignore_index**: boolean, default False. If True, do not use the index values on the concatenation axis. The resulting axis will be labeled 0, ..., n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.

- **keys**: sequence, default None. Construct hierarchical index using the passed keys as the outermost level. If multiple levels passed, should contain tuples.

- **levels**: list of sequences, default None. Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys.

- **names**: list, default None. Names for the levels in the resulting hierarchical index.

- **verify_integrity**: boolean, default False. Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.

- **copy**: boolean, default True. If False, do not copy data unnecessarily.
Without a little bit of context many of these arguments don’t make much sense. Let’s revisit the above example. Suppose we wanted to associate specific keys with each of the pieces of the chopped up DataFrame. We can do this using the `keys` argument:

```
In [6]: result = pd.concat(frames, keys=['x', 'y', 'z'])
```

As you can see (if you’ve read the rest of the documentation), the resulting object’s index has a hierarchical index. This means that we can now select out each chunk by key:

```
In [7]: result.loc['y']
```

```
Out[7]:
   A  B  C  D
4  A4  B4  C4  D4
5  A5  B5  C5  D5
6  A6  B6  C6  D6
7  A7  B7  C7  D7
```

It’s not a stretch to see how this can be very useful. More detail on this functionality below.

**Note:** It is worth noting that `concat()` (and therefore `append()`) makes a full copy of the data, and that constantly reusing this function can create a significant performance hit. If you need to use the operation over several datasets, use a list comprehension.

```
frames = [ process_your_file(f) for f in files ]
result = pd.concat(frames)
```
Set logic on the other axes

When gluing together multiple DataFrames, you have a choice of how to handle the other axes (other than the one being concatenated). This can be done in the following two ways:

- Take the union of them all, `join='outer'`. This is the default option as it results in zero information loss.
- Take the intersection, `join='inner'`.

Here is an example of each of these methods. First, the default `join='outer'` behavior:

```python
In [8]: df4 = pd.DataFrame({'B': ['B2', 'B3', 'B6', 'B7'],
                        'D': ['D2', 'D3', 'D6', 'D7'],
                        'F': ['F2', 'F3', 'F6', 'F7']},
                        index=[2, 3, 6, 7])

In [9]: result = pd.concat([df1, df4], axis=1, sort=False)
```

![Diagram of df1 and df4 concatenation with outer join]

**Warning:** Changed in version 0.23.0.

The default behavior with `join='outer'` is to sort the other axis (columns in this case). In a future version of pandas, the default will be to not sort. We specified `sort=False` to opt in to the new behavior now.

Here is the same thing with `join='inner'`:

```python
In [10]: result = pd.concat([df1, df4], axis=1, join='inner')
```

![Diagram of df1 and df4 concatenation with inner join]

Lastly, suppose we just wanted to reuse the *exact index* from the original DataFrame:
In [11]: result = pd.concat([df1, df4], axis=1).reindex(df1.index)

Similarly, we could index before the concatenation:

In [12]: pd.concat([df1, df4.reindex(df1.index)], axis=1)
Out[12]:
   A  B  C  D  B  D  F
0 A0 B0 C0 D0 NaN NaN NaN
1 A1 B1 C1 D1 NaN NaN NaN
2 A2 B2 C2 D2 B2 D2 F2
3 A3 B3 C3 D3 B3 D3 F3

Concatenating using append

A useful shortcut to `concat()` are the `append()` instance methods on `Series` and `DataFrame`. These methods actually predated `concat`. They concatenate along `axis=0`, namely the index:

In [13]: result = df1.append(df2)

In the case of `DataFrame`, the indexes must be disjoint but the columns do not need to be:

In [14]: result = df1.append(df4, sort=False)
append may take multiple objects to concatenate:

```python
In [15]: result = df1.append([df2, df3])
```
Ignoring indexes on the concatenation axis

For DataFrame objects which don’t have a meaningful index, you may wish to append them and ignore the fact that they may have overlapping indexes. To do this, use the `ignore_index` argument:

In [16]: result = pd.concat([df1, df4], ignore_index=True, sort=False)

This is also a valid argument to `DataFrame.append()`:

In [17]: result = df1.append(df4, ignore_index=True, sort=False)
Concatenating with mixed ndims

You can concatenate a mix of Series and DataFrame objects. The Series will be transformed to DataFrame with the column name as the name of the Series.

```
In [18]: s1 = pd.Series(['X0', 'X1', 'X2', 'X3'], name='X')
In [19]: result = pd.concat([df1, s1], axis=1)
```

<table>
<thead>
<tr>
<th>df1</th>
<th>s1</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>
</tr>
<tr>
<td>0</td>
<td>A0</td>
<td>B0</td>
</tr>
<tr>
<td>1</td>
<td>A1</td>
<td>B1</td>
</tr>
<tr>
<td>2</td>
<td>A2</td>
<td>B2</td>
</tr>
<tr>
<td>3</td>
<td>A3</td>
<td>B3</td>
</tr>
</tbody>
</table>

**Note:** Since we're concatenating a Series to a DataFrame, we could have achieved the same result with `DataFrame.assign()`. To concatenate an arbitrary number of pandas objects (DataFrame or Series), use `concat`.

If unnamed Series are passed they will be numbered consecutively.

```
In [20]: s2 = pd.Series(['_0', '_1', '_2', '_3'])
In [21]: result = pd.concat([df1, s2, s2, s2], axis=1)
```

<table>
<thead>
<tr>
<th>df1</th>
<th>s2</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>
</tr>
<tr>
<td>0</td>
<td>A0</td>
<td>B0</td>
</tr>
<tr>
<td>1</td>
<td>A1</td>
<td>B1</td>
</tr>
<tr>
<td>2</td>
<td>A2</td>
<td>B2</td>
</tr>
<tr>
<td>3</td>
<td>A3</td>
<td>B3</td>
</tr>
</tbody>
</table>

Passing `ignore_index=True` will drop all name references.

```
In [22]: result = pd.concat([df1, s1], axis=1, ignore_index=True)
```
More concatenating with group keys

A fairly common use of the keys argument is to override the column names when creating a new DataFrame based on existing Series. Notice how the default behaviour consists on letting the resulting DataFrame inherit the parent Series’ name, when these existed.

```
In [23]: s3 = pd.Series([0, 1, 2, 3], name='foo')
In [24]: s4 = pd.Series([0, 1, 2, 3])
In [25]: s5 = pd.Series([0, 1, 4, 5])
In [26]: pd.concat([s3, s4, s5], axis=1)
Out[26]:
   foo  0  1  2  3
0    0  0  0  0
1    1  1  1  1
2    2  2  4  2
3    3  3  5  5
```

Through the keys argument we can override the existing column names.

```
In [27]: pd.concat([s3, s4, s5], axis=1, keys=['red', 'blue', 'yellow'])
Out[27]:
   red  blue  yellow
0   0    0      0
1   1    1      1
2   2    2      4
3   3    3      5
```

Let’s consider a variation of the very first example presented:

```
In [28]: result = pd.concat(frames, keys=['x', 'y', 'z'])
```
You can also pass a dict to `concat` in which case the dict keys will be used for the `keys` argument (unless other keys are specified):

```python
In [29]: pieces = {'x': df1, 'y': df2, 'z': df3}
In [30]: result = pd.concat(pieces)
```
The MultiIndex created has levels that are constructed from the passed keys and the index of the DataFrame pieces:

In [31]: result = pd.concat(pieces, keys=['z', 'y'])
If you wish to specify other levels (as will occasionally be the case), you can do so using the `levels` argument:

```python
In [33]: result = pd.concat(pieces, keys=['x', 'y', 'z'],
          .....:       levels=[['z', 'y', 'x', 'w']],
          .....:       names=['group_key'])
```

This is fairly esoteric, but it is actually necessary for implementing things like GroupBy where the order of a categorical variable is meaningful.

### Appending rows to a DataFrame

While not especially efficient (since a new object must be created), you can append a single row to a DataFrame by passing a Series or dict to `append`, which returns a new DataFrame as above.

```python
In [35]: s2 = pd.Series(['X0', 'X1', 'X2', 'X3'], index=['A', 'B', 'C', 'D'])
In [36]: result = df1.append(s2, ignore_index=True)
```
You should use `ignore_index` with this method to instruct DataFrame to discard its index. If you wish to preserve the index, you should construct an appropriately-indexed DataFrame and append or concatenate those objects.

You can also pass a list of dicts or Series:

```python
In [37]: dicts = [("A": 1, "B": 2, "C": 3, "X": 4),
           ....:  ("A": 5, "B": 6, "C": 7, "Y": 8)]
           ....:
In [38]: result = df1.append(dicts, ignore_index=True, sort=False)
```

**2.7.2 Database-style DataFrame or named Series joining/merging**

pandas has full-featured, **high performance** in-memory join operations idiomatically very similar to relational databases like SQL. These methods perform significantly better (in some cases well over an order of magnitude better) than other open source implementations (like `base::merge.data.frame` in R). The reason for this is careful algorithmic design and the internal layout of the data in DataFrame.

See the cookbook for some advanced strategies.

Users who are familiar with SQL but new to pandas might be interested in a comparison with SQL.

pandas provides a single function, `merge()`, as the entry point for all standard database join operations between DataFrame or named Series objects:
pd.merge(left, right, how='inner', on=None, left_on=None, right_on=None,
left_index=False, right_index=False, sort=True,
suffixes=('_x', '_y'), copy=True, indicator=False,
validate=None)

- **left**: A DataFrame or named Series object.
- **right**: Another DataFrame or named Series object.
- **on**: Column or index level names to join on. Must be found in both the left and right DataFrame and/or Series objects. If not passed and left_index and right_index are False, the intersection of the columns in the DataFrames and/or Series will be inferred to be the join keys.
- **left_on**: Columns or index levels from the left DataFrame or Series to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the DataFrame or Series.
- **right_on**: Columns or index levels from the right DataFrame or Series to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the DataFrame or Series.
- **left_index**: If True, use the index (row labels) from the left DataFrame or Series as its join key(s). In the case of a DataFrame or Series with a MultiIndex (hierarchical), the number of levels must match the number of join keys from the right DataFrame or Series.
- **right_index**: Same usage as left_index for the right DataFrame or Series.
- **how**: One of 'left', 'right', 'outer', 'inner'. Defaults to inner. See below for more detailed description of each method.
- **sort**: Sort the result DataFrame by the join keys in lexicographical order. Defaults to True, setting to False will improve performance substantially in many cases.
- **suffixes**: A tuple of string suffixes to apply to overlapping columns. Defaults to ('_x', '_y').
- **copy**: Always copy data (default True) from the passed DataFrame or named Series objects, even when reindexing is not necessary. Cannot be avoided in many cases but may improve performance / memory usage. The cases where copying can be avoided are somewhat pathological but this option is provided nonetheless.
- **indicator**: Add a column to the output DataFrame called _merge with information on the source of each row. _merge is Categorical-type and takes on a value of left_only for observations whose merge key only appears in 'left' DataFrame or Series, right_only for observations whose merge key only appears in 'right' DataFrame or Series, and both if the observation’s merge key is found in both.
- **validate**: string, default None. If specified, checks if merge is of specified type.
  - “one_to_one” or “1:1”: checks if merge keys are unique in both left and right datasets.
  - “one_to_many” or “1:m”: checks if merge keys are unique in left dataset.
  - “many_to_one” or “m:1”: checks if merge keys are unique in right dataset.
  - “many_to_many” or “m:m”: allowed, but does not result in checks.

**Note**: Support for specifying index levels as the on, left_on, and right_on parameters was added in version 0.23.0. Support for merging named Series objects was added in version 0.24.0.

The return type will be the same as left. If left is a DataFrame or named Series and right is a subclass of DataFrame, the return type will still be DataFrame.

merge is a function in the pandas namespace, and it is also available as a DataFrame instance method merge(), with the calling DataFrame being implicitly considered the left object in the join.
The related `join()` method, uses `merge` internally for the index-on-index (by default) and column(s)-on-index join. If you are joining on index only, you may wish to use `DataFrame.join` to save yourself some typing.

**Brief primer on merge methods (relational algebra)**

Experienced users of relational databases like SQL will be familiar with the terminology used to describe join operations between two SQL-table like structures (DataFrame objects). There are several cases to consider which are very important to understand:

- **one-to-one** joins: for example when joining two DataFrame objects on their indexes (which must contain unique values).
- **many-to-one** joins: for example when joining an index (unique) to one or more columns in a different DataFrame.
- **many-to-many** joins: joining columns on columns.

**Note:** When joining columns on columns (potentially a many-to-many join), any indexes on the passed DataFrame objects will be discarded.

It is worth spending some time understanding the result of the **many-to-many** join case. In SQL / standard relational algebra, if a key combination appears more than once in both tables, the resulting table will have the **Cartesian product** of the associated data. Here is a very basic example with one unique key combination:

```
In [39]: left = pd.DataFrame({'

<table>
<thead>
<tr>
<th>key</th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>A0</td>
<td>B0</td>
</tr>
<tr>
<td>1</td>
<td>A1</td>
<td>B1</td>
</tr>
<tr>
<td>2</td>
<td>A2</td>
<td>B2</td>
</tr>
<tr>
<td>3</td>
<td>A3</td>
<td>B3</td>
</tr>
</tbody>
</table>

In [40]: right = pd.DataFrame({'

<table>
<thead>
<tr>
<th>key</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>C0</td>
<td>D0</td>
</tr>
<tr>
<td>1</td>
<td>C1</td>
<td>D1</td>
</tr>
<tr>
<td>2</td>
<td>C2</td>
<td>D2</td>
</tr>
<tr>
<td>3</td>
<td>C3</td>
<td>D3</td>
</tr>
</tbody>
</table>

In [41]: result = pd.merge(left, right, on='key')
```

Here is a more complicated example with multiple join keys. Only the keys appearing in `left` and `right` are present (the intersection), since `how='inner'` by default.

```
In [42]: left = pd.DataFrame({'

<table>
<thead>
<tr>
<th>key</th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>A0</td>
<td>B0</td>
</tr>
<tr>
<td>1</td>
<td>A1</td>
<td>B1</td>
</tr>
<tr>
<td>2</td>
<td>A2</td>
<td>B2</td>
</tr>
<tr>
<td>3</td>
<td>A3</td>
<td>B3</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>key2</th>
<th>'K0', 'K1', 'K2'</th>
</tr>
</thead>
<tbody>
<tr>
<td>'A'</td>
<td>['A0', 'A1', 'A2', 'A3']</td>
</tr>
<tr>
<td>'B'</td>
<td>['B0', 'B1', 'B2', 'B3']</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>key</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>C0</td>
<td>D0</td>
</tr>
<tr>
<td>1</td>
<td>C1</td>
<td>D1</td>
</tr>
<tr>
<td>2</td>
<td>C2</td>
<td>D2</td>
</tr>
<tr>
<td>3</td>
<td>C3</td>
<td>D3</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>key2</th>
<th>'K0', 'K1', 'K2'</th>
</tr>
</thead>
<tbody>
<tr>
<td>'A'</td>
<td>['A0', 'A1', 'A2', 'A3']</td>
</tr>
<tr>
<td>'B'</td>
<td>['B0', 'B1', 'B2', 'B3']</td>
</tr>
</tbody>
</table>

(continues on next page)
```
The `how` argument to `merge` specifies how to determine which keys are to be included in the resulting table. If a key combination does not appear in either the left or right tables, the values in the joined table will be `NA`. Here is a summary of the `how` options and their SQL equivalent names:

<table>
<thead>
<tr>
<th>Merge method</th>
<th>SQL Join Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>left</td>
<td>LEFT OUTER JOIN</td>
<td>Use keys from left frame only</td>
</tr>
<tr>
<td>right</td>
<td>RIGHT OUTER JOIN</td>
<td>Use keys from right frame only</td>
</tr>
<tr>
<td>outer</td>
<td>FULL OUTER JOIN</td>
<td>Use union of keys from both frames</td>
</tr>
<tr>
<td>inner</td>
<td>INNER JOIN</td>
<td>Use intersection of keys from both frames</td>
</tr>
</tbody>
</table>

```python
In [45]: result = pd.merge(left, right, how='left', on=['key1', 'key2'])
```

In [46]: result = pd.merge(left, right, how='right', on=['key1', 'key2'])

2.7. Merge, join, concatenate and compare
In [47]: `result = pd.merge(left, right, how='outer', on=['key1', 'key2'])`

You can merge a mult-indexed Series and a DataFrame, if the names of the MultiIndex correspond to the columns from the DataFrame. Transform the Series to a DataFrame using `Series.reset_index()` before merging, as shown in the following example.

In [49]: `df = pd.DataFrame({'Let': ['A', 'B', 'C'], 'Num': [1, 2, 3]})`

In [50]: `df`  
   Out[50]:     Let  Num
   0   A    1
   1   B    2
   2   C    3

In [51]: `ser = pd.Series(  
       ....:     ['a', 'b', 'c', 'd', 'e', 'f'],  
       ....:     index=pd.MultiIndex.from_arrays(  
       ....:         [["A", "B", "C"] * 2, [1, 2, 3, 4, 5, 6]], names=['Let', 'Num']  
       ....:     )  
       ....:`

(continues on next page)
Here is another example with duplicate join keys in DataFrames:

```python
In [54]: left = pd.DataFrame({'A': [1, 2], 'B': [2, 2]})
In [55]: right = pd.DataFrame({'A': [4, 5, 6], 'B': [2, 2, 2]})
In [56]: result = pd.merge(left, right, on='B', how='outer')
```

Warning: Joining / merging on duplicate keys can cause a returned frame that is the multiplication of the row dimensions, which may result in memory overflow. It is the user’s responsibility to manage duplicate values in keys before joining large DataFrames.

2.7. Merge, join, concatenate and compare

```
In [52]: ser
Out[52]:
   Let  Num
   A    1  a
   B    2  b
   C    3  c
   A    4  d
   B    5  e
   C    6  f
dtype: object

In [53]: pd.merge(df, ser.reset_index(), on=['Let', 'Num'])
Out[53]:
   Let  Num
   0   A  1  a
   1   B  2  b
   2   C  3  c
```

2.7. Merge, join, concatenate and compare
Checking for duplicate keys

Users can use the `validate` argument to automatically check whether there are unexpected duplicates in their merge keys. Key uniqueness is checked before merge operations and so should protect against memory overflows. Checking key uniqueness is also a good way to ensure user data structures are as expected.

In the following example, there are duplicate values of B in the right DataFrame. As this is not a one-to-one merge – as specified in the `validate` argument – an exception will be raised.

```python
In [57]: left = pd.DataFrame({'A': [1, 2], 'B': [1, 2]})
In [58]: right = pd.DataFrame({'A': [4, 5, 6], 'B': [2, 2, 2]})
```

```python
In [53]: result = pd.merge(left, right, on='B', how='outer', validate="one_to_one")
...: MergeError: Merge keys are not unique in right dataset; not a one-to-one merge
```

If the user is aware of the duplicates in the right DataFrame but wants to ensure there are no duplicates in the left DataFrame, one can use the `validate='one_to_many'` argument instead, which will not raise an exception.

```python
In [59]: pd.merge(left, right, on='B', how='outer', validate='one_to_many')
Out[59]:
   A_x  B   A_y
0  1  1   NaN
1  2  2  4.0
2  2  2  5.0
3  2  2  6.0
```

The merge indicator

`merge()` accepts the argument `indicator`. If True, a Categorical-type column called `_merge` will be added to the output object that takes on values:

<table>
<thead>
<tr>
<th>Observation Origin</th>
<th>_merge value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Merge key only in 'left' frame</td>
<td>left_only</td>
</tr>
<tr>
<td>Merge key only in 'right' frame</td>
<td>right_only</td>
</tr>
<tr>
<td>Merge key in both frames</td>
<td>both</td>
</tr>
</tbody>
</table>

```python
In [60]: df1 = pd.DataFrame({'col1': [0, 1], 'col_left': ['a', 'b']})
In [61]: df2 = pd.DataFrame({'col1': [1, 2, 2], 'col_right': [2, 2, 2]})
In [62]: pd.merge(df1, df2, on='col1', how='outer', indicator=True)
Out[62]:
   col1  col_left  col_right   _merge
0     0        a      NaN   left_only
1     1        b      2.0   both
2     2   NaN      2.0   right_only
3     2   NaN      2.0   right_only
```

The `indicator` argument will also accept string arguments, in which case the indicator function will use the value of the passed string as the name for the indicator column.
In [63]: pd.merge(df1, df2, on='col1', how='outer', indicator='indicator_column')
Out[63]:
   col1 col_left  col_right indicator_column
0  0    a     NaN        left_only
1  1     b     2.0        both
2  2     NaN   2.0       right_only
3  2     NaN   2.0       right_only

### Merge dtypes

Merging will preserve the dtype of the join keys.

In [64]: left = pd.DataFrame({'key': [1], 'v1': [10]})

In [65]: left
Out[65]:
   key  v1
0    1 10

In [66]: right = pd.DataFrame({'key': [1, 2], 'v1': [20, 30]})

In [67]: right
Out[67]:
   key  v1
0    1 20
1    2 30

We are able to preserve the join keys:

In [68]: pd.merge(left, right, how='outer')
Out[68]:
   key  v1_x  v1_y
0    1   10.0  20
1    2   NaN   30

In [69]: pd.merge(left, right, how='outer').dtypes
Out[69]:
   key  int64
   v1_x float64
   v1_y  int64
dtype: object

Of course if you have missing values that are introduced, then the resulting dtype will be upcast.

In [70]: pd.merge(left, right, how='outer', on='key')
Out[70]:
   key  vl_x  vl_y
0    1  10.0  20
1    2  NaN   30

In [71]: pd.merge(left, right, how='outer', on='key').dtypes
Out[71]:
   key  int64
   vl_x  float64
   vl_y  int64
dtype: object

2.7. Merge, join, concatenate and compare
Merging will preserve category dtypes of the mergands. See also the section on *categoricals*.

The left frame.

```python
In [72]: from pandas.api.types import CategoricalDtype

In [73]: X = pd.Series(np.random.choice(['foo', 'bar'], size=(10,)))

In [74]: X = X.astype(CategoricalDtype(categories=['foo', 'bar']))

In [75]: left = pd.DataFrame({'X': X,
                          'Y': np.random.choice(['one', 'two', 'three'],
                                                size=(10,))})

In [76]: left
Out[76]:
   X Y
0  bar  one
1  foo  one
2  foo  three
3  bar  three
4  foo  one
5  bar  one
6  bar  three
7  bar  three
8  bar  three
9  foo  three

In [77]: left.dtypes
Out[77]:
   X  category
   Y  object
dtype: object
```

The right frame.

```python
In [78]: right = pd.DataFrame({'X': pd.Series(['foo', 'bar'],
                                          dtype=CategoricalDtype(['foo', 'bar'])),
                          'Z': [1, 2]})

In [79]: right
Out[79]:
   X   Z
0  foo  1
1  bar  2

In [80]: right.dtypes
Out[80]:
   X  category
   Z  int64
dtype: object
```

The merged result:

```python
In [81]: result = pd.merge(left, right, how='outer')
(continues on next page)```
In [82]: result
Out[82]:
    X    Y    Z
0   bar  one  2
1   bar  three  2
2   bar  one  2
3   bar  three  2
4   bar  three  2
5   bar  three  2
6   foo  one  1
7   foo  three  1
8   foo  one  1
9   foo  three  1

In [83]: result.dtypes
Out[83]:
    X      category
    Y      object
    Z    int64
dtype: object

Note: The category dtypes must be *exactly* the same, meaning the same categories and the ordered attribute. Otherwise the result will coerce to the categories’ dtype.

Note: Merging on category dtypes that are the same can be quite performant compared to object dtype merging.

**Joining on index**

`DataFrame.join()` is a convenient method for combining the columns of two potentially differently-indexed DataFrames into a single result DataFrame. Here is a very basic example:

In [84]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
                         'B': ['B0', 'B1', 'B2'],
                         'index': ['K0', 'K1', 'K2']})

In [85]: right = pd.DataFrame({'C': ['C0', 'C2', 'C3'],
                          'D': ['D0', 'D2', 'D3'],
                          'index': ['K0', 'K2', 'K3']})

In [86]: result = left.join(right)
The same as above, but with how='inner'.

In [88]: result = left.join(right, how='inner')

The data alignment here is on the indexes (row labels). This same behavior can be achieved using merge plus additional arguments instructing it to use the indexes:

In [89]: result = pd.merge(left, right, left_index=True, right_index=True, how='outer')

In [90]: result = pd.merge(left, right, left_index=True, right_index=True, how='inner');
Joining key columns on an index

`join()` takes an optional `on` argument which may be a column or multiple column names, which specifies that the passed DataFrame is to be aligned on that column in the DataFrame. These two function calls are completely equivalent:

```python
left.join(right, on=key_or_keys)
pd.merge(left, right, left_on=key_or_keys, right_index=True,
          how='left', sort=False)
```

Obviously you can choose whichever form you find more convenient. For many-to-one joins (where one of the DataFrame's is already indexed by the join key), using `join` may be more convenient. Here is a simple example:

```python
left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
                    'B': ['B0', 'B1', 'B2', 'B3'],
                    'key': ['K0', 'K1', 'K0', 'K1']})
right = pd.DataFrame({'C': ['C0', 'C1'],
                      'D': ['D0', 'D1']},
                    index=['K0', 'K1'])
result = left.join(right, on='key')
```

To join on multiple keys, the passed DataFrame must have a MultiIndex:

```python
left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
                    'B': ['B0', 'B1', 'B2', 'B3'],
                    'key1': ['K0', 'K0', 'K1', 'K2'],
                    'key2': ['K0', 'K1', 'K0', 'K1']},
                    index=['K0', 'K1', 'K0', 'K1'])
right = pd.DataFrame({'C': ['C0', 'C1'],
                      'D': ['D0', 'D1']},
                    index=['K0', 'K1'])
result = left.join(right, on=['key1', 'key2'])
```
....:
    'key2': ['K0', 'K1', 'K0', 'K1'])
....:

In [96]: index = pd.MultiIndex.from_tuples([('K0', 'K0'), ('K1', 'K0'), ('K2', 'K0'), ('K2', 'K1')])

In [97]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
                           'D': ['D0', 'D1', 'D2', 'D3']},
                           index=index)

Now this can be joined by passing the two key column names:

In [98]: result = left.join(right, on=['key1', 'key2'])

The default for DataFrame.join is to perform a left join (essentially a “VLOOKUP” operation, for Excel users), which uses only the keys found in the calling DataFrame. Other join types, for example inner join, can be just as easily performed:

In [99]: result = left.join(right, on=['key1', 'key2'], how='inner')

As you can see, this drops any rows where there was no match.
Joining a single Index to a MultiIndex

You can join a singly-indexed DataFrame with a level of a MultiIndexed DataFrame. The level will match on the name of the index of the singly-indexed frame against a level name of the MultiIndexed frame.

```
In [100]: left = pd.DataFrame({
    ...:                  'A': ['A0', 'A1', 'A2'],
    ...:                  'B': ['B0', 'B1', 'B2']},
    ...:                  index=pd.Index(['K0', 'K1', 'K2'], name='key'))
    ...:

In [101]: index = pd.MultiIndex.from_tuples([('K0', 'Y0'), ('K1', 'Y1'), ('K2', 'Y2'), ('K2', 'Y3')],
    ...:                  names=['key', 'Y'])
    ...:

In [102]: right = pd.DataFrame({
    ...:                  'C': ['C0', 'C1', 'C2', 'C3'],
    ...:                  'D': ['D0', 'D1', 'D2', 'D3']},
    ...:                  index=index)
    ...:

In [103]: result = left.join(right, how='inner')
```

This is equivalent but less verbose and more memory efficient / faster than this.

```
In [104]: result = pd.merge(left.reset_index(), right.reset_index(),
    ...:                  on=['key'], how='inner').set_index(['key', 'Y'])
    ...:
```

This is equivalent but less verbose and more memory efficient / faster than this.
Joining with two MultiIndexes

This is supported in a limited way, provided that the index for the right argument is completely used in the join, and is a subset of the indices in the left argument, as in this example:

```
In [105]: leftindex = pd.MultiIndex.from_product([list('abc'), list('xy'), [1, 2]], names=['abc', 'xy', 'num'])

In [106]: left = pd.DataFrame({'v1': range(12)}, index=leftindex)

In [107]: left
Out[107]:
   v1  abc  xy  num
  a  1   x   1   0
      2   1
      y   1   2
      2   3
  b  1   x   1   4
      2   5
      y   1   6
      2   7
  c  1   x   1   8
      2   9
      y   1  10
      2  11

In [108]: rightindex = pd.MultiIndex.from_product([list('abc'), list('xy')], names=['abc', 'xy'])

In [109]: right = pd.DataFrame({'v2': [100 * i for i in range(1, 7)]}, index=rightindex)

In [110]: right
Out[110]:
   v2  abc  xy
  a  100   x   1
      y  200
  b  300   x   2
      y  400
  c  500   x   3
      y  600

In [111]: left.join(right, on=['abc', 'xy'], how='inner')
Out[111]:
   v1  v2
  a  1   0  100
      2   1  100
      y  1   2  200
      2   3  200
  b  1   4  300
      2   5  300
      y  1   6  400
      2   7  400
```

(continues on next page)
If that condition is not satisfied, a join with two multi-indexes can be done using the following code.

```
In [112]: leftindex = pd.MultiIndex.from_tuples([(‘K0’, ‘X0’), (‘K0’, ‘X1’),
                                           (‘K1’, ‘X2’)),
                                           names=[‘key’, ‘X’])

In [113]: left = pd.DataFrame({‘A’: [‘A0’, ‘A1’, ‘A2’],
                          index=leftindex)

In [114]: rightindex = pd.MultiIndex.from_tuples([(‘K0’, ‘Y0’), (‘K1’, ‘Y1’),
                                             (‘K2’, ‘Y2’), (‘K2’, ‘Y3’)),
                                             names=[‘key’, ‘Y’])

In [115]: right = pd.DataFrame({‘C’: [‘C0’, ‘C1’, ‘C2’, ‘C3’],
                           index=rightindex)

In [116]: result = pd.merge(left.reset_index(), right.reset_index(),
                          on=[‘key’], how=’inner’).set_index([‘key’, ‘X’, ‘Y’])
```

Merging on a combination of columns and index levels

New in version 0.23.

Strings passed as the on, left_on, and right_on parameters may refer to either column names or index level names. This enables merging DataFrame instances on a combination of index levels and columns without resetting indexes.

```
In [117]: left_index = pd.Index([‘K0’, ‘K0’, ‘K1’, ‘K2’], name=’key1’)
                         ‘key2’: [‘K0’, ‘K1’, ‘K0’, ‘K1’]},
                         index=left_index)
```
In [119]: right_index = pd.Index(['K0', 'K1', 'K2', 'K2'], name='key1')

In [120]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
                          'D': ['D0', 'D1', 'D2', 'D3'],
                          'key2': ['K0', 'K0', 'K0', 'K1'],
                          index=right_index)

In [121]: result = left.merge(right, on=['key1', 'key2'])

Note: When DataFrames are merged on a string that matches an index level in both frames, the index level is preserved as an index level in the resulting DataFrame.

Note: When DataFrames are merged using only some of the levels of a MultiIndex, the extra levels will be dropped from the resulting merge. In order to preserve those levels, use reset_index on those level names to move those levels to columns prior to doing the merge.

Note: If a string matches both a column name and an index level name, then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

Overlapping value columns

The merge suffixes argument takes a tuple of list of strings to append to overlapping column names in the input DataFrames to disambiguate the result columns:

In [122]: left = pd.DataFrame({'k': ['K0', 'K1', 'K2'], 'v': [1, 2, 3]})

In [123]: right = pd.DataFrame({'k': ['K0', 'K0', 'K3'], 'v': [4, 5, 6]})

In [124]: result = pd.merge(left, right, on='k')
Joining multiple DataFrames

A list or tuple of DataFrames can also be passed to `join()` to join them together on their indexes.

```python
In [129]: right2 = pd.DataFrame({'v': [7, 8, 9]}, index=['K1', 'K1', 'K2'])
In [130]: result = left.join([right, right2])
```
Merging together values within Series or DataFrame columns

Another fairly common situation is to have two like-indexed (or similarly indexed) `Series` or `DataFrame` objects and wanting to “patch” values in one object from values for matching indices in the other. Here is an example:

```python
In [131]: df1 = pd.DataFrame([[np.nan, 3., 5.], [-4.6, np.nan, np.nan],
                        [np.nan, 7., np.nan]])
In [132]: df2 = pd.DataFrame([[-42.6, np.nan, -8.2], [-5., 1.6, 4]],
                        index=[1, 2])
```

For this, use the `combine_first()` method:

```python
In [133]: result = df1.combine_first(df2)
```

Note that this method only takes values from the right `DataFrame` if they are missing in the left `DataFrame`. A related method, `update()`, alters non-NA values in place:

```python
In [134]: df1.update(df2)
```
2.7.3 Timeseries friendly merging

Merging ordered data

A `merge_ordered()` function allows combining time series and other ordered data. In particular it has an optional `fill_method` keyword to fill/interpolate missing data:

```python
In [135]: left = pd.DataFrame({
    ....:     'k': ['K0', 'K1', 'K1', 'K2'],
    ....:     'lv': [1, 2, 3, 4],
    ....:     's': ['a', 'b', 'c', 'd']})

In [136]: right = pd.DataFrame({
    ....:     'k': ['K1', 'K2', 'K4'],
    ....:     'rv': [1, 2, 3]})

In [137]: pd.merge_ordered(left, right, fill_method='ffill', left_by='s')
Out[137]:
   k  lv  s  rv
0 K0  1.0 a  NaN
1 K1  1.0 a  1.0
2 K2  1.0 a  2.0
3 K4  1.0 a  3.0
4 K1  2.0 b  1.0
5 K2  2.0 b  2.0
6 K4  2.0 b  3.0
7 K1  3.0 c  1.0
8 K2  3.0 c  2.0
9 K4  3.0 c  3.0
10 K1 NaN d  1.0
11 K2  4.0 d  2.0
12 K4  4.0 d  3.0
```

Merging asof

A `merge_asof()` is similar to an ordered left-join except that we match on nearest key rather than equal keys. For each row in the `left` DataFrame, we select the last row in the `right` DataFrame whose `on` key is less than the `left`'s key. Both DataFrames must be sorted by the key.

Optionally an asof merge can perform a group-wise merge. This matches the `by` key equally, in addition to the nearest match on the `on` key.

For example; we might have `trades` and `quotes` and we want to `asof` merge them.

```python
In [138]: trades = pd.DataFrame({
    ....:     'time': pd.to_datetime(["20160525 13:30:00.023",
    ....:                              "20160525 13:30:00.038",
    ....:                              "20160525 13:30:00.048",
    ....:                              "20160525 13:30:00.048",
    ....:                              "20160525 13:30:00.048"]),
    ....:     'ticker': ["MSFT", "MSFT",
    ....:                  "GOOG", "GOOG", "AAPL"],
    ....:     'price': [51.95, 51.95,
    ....:                  720.77, 720.92, 98.00],
    ....:     'quantity': [75, 155,
    ....:                     100, 100, 100]})
```

(continues on next page)
In [139]: quotes = pd.DataFrame({
    ....:     'time': pd.to_datetime(['20160525 13:30:00.023',
    ....:                             '20160525 13:30:00.023',
    ....:                             '20160525 13:30:00.030',
    ....:                             '20160525 13:30:00.041',
    ....:                             '20160525 13:30:00.048',
    ....:                             '20160525 13:30:00.049',
    ....:                             '20160525 13:30:00.072',
    ....:                             '20160525 13:30:00.075'],
    ....:     'ticker': ['GOOG', 'MSFT', 'MSFT',
    ....:                'MSFT', 'GOOG', 'AAPL', 'GOOG',
    ....:                'MSFT'],
    ....:     'bid': [720.50, 51.95, 51.97, 51.99,
    ....:              720.50, 97.99, 720.50, 52.01],
    ....:     'ask': [720.93, 51.96, 51.98, 52.00,
    ....:               720.93, 98.01, 720.88, 52.03],
    ....:     columns=['time', 'ticker', 'bid', 'ask']})

### 2.7.4 Comparing objects

The `compare()` and `compare()` methods allow you to compare two DataFrame or Series, respectively, and summarize their differences.

This feature was added in *V1.1.0*.

For example, you might want to compare two *DataFrame* and stack their differences side by side.

```
In [145]: df = pd.DataFrame(
.....:     {
.....:         "col1": ["a", "a", "b", "b", "a"],
.....:         "col2": [1.0, 2.0, 3.0, np.nan, 5.0],
.....:         "col3": [1.0, 2.0, 3.0, 4.0, 5.0]
.....:     },
.....:     columns=["col1", "col2", "col3"],
.....:     )
```

```
In [146]: df
```

```
```

<table>
<thead>
<tr>
<th>col1</th>
<th>col2</th>
<th>col3</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1.0</td>
<td>1.0</td>
</tr>
<tr>
<td>a</td>
<td>2.0</td>
<td>2.0</td>
</tr>
<tr>
<td>b</td>
<td>3.0</td>
<td>3.0</td>
</tr>
</tbody>
</table>
```

(continues on next page)
In [147]: df2 = df.copy()

In [148]: df2.loc[0, 'col1'] = 'c'

In [149]: df2.loc[2, 'col3'] = 4.0

In [150]: df2
Out[150]:
   col1 col2 col3
0    c   1.0  1.0
1    a   2.0  2.0
2    b   3.0  4.0
3    b   NaN  4.0
4    a   5.0  5.0

In [151]: df.compare(df2)
Out[151]:
  col1 col3
  self other self other
0   a   c   NaN   NaN
2  NaN   NaN   3.0   4.0

By default, if two corresponding values are equal, they will be shown as NaN. Furthermore, if all values in an entire row / column, the row / column will be omitted from the result. The remaining differences will be aligned on columns.

If you wish, you may choose to stack the differences on rows.

In [152]: df.compare(df2, align_axis=0)
Out[152]:
  col1  col3
  self  other  self  other
0   a   NaN
other   c   NaN
2  NaN   3.0
other   NaN   4.0

If you wish to keep all original rows and columns, set keep_shape argument to True.

In [153]: df.compare(df2, keep_shape=True)
Out[153]:
  col1  col2  col3
  self  other  self  other  self  other
0   a   c   NaN   NaN   NaN   NaN
1   NaN   NaN   NaN   NaN   NaN   NaN
2   NaN   NaN   NaN   NaN   3.0   4.0
3   NaN   NaN   NaN   NaN   NaN   NaN
4   NaN   NaN   NaN   NaN   NaN   NaN

You may also keep all the original values even if they are equal.
2.8 Reshaping and pivot tables

2.8.1 Reshaping by pivoting DataFrame objects

Pivot

```
import pandas._testing as tm

def unpivot(frame):
    N, K = frame.shape
    data = {'value': frame.to_numpy().ravel('F'),
            'variable': np.asarray(frame.columns).repeat(N),
            'date': np.tile(np.asarray(frame.index), K)}
    return pd.DataFrame(data, columns=['date', 'variable', 'value'])
```

Data is often stored in so-called “stacked” or “record” format:

```
In [1]: df
Out[1]:
                          date  variable  value
0  2000-01-03            A  0.469112
1  2000-01-04           -0.282863
2  2000-01-05           -1.509059
3  2000-01-03            B -1.135632
4  2000-01-04            1.212112
5  2000-01-05           -0.173215
6  2000-01-03            C  0.119209
7  2000-01-04          -1.044236
8  2000-01-05          -1.044236
9  2000-01-03         -0.861849
10 2000-01-04        -2.104569
11 2000-01-05          1.071804
```

For the curious here is how the above DataFrame was created:

```
import pandas as pd

def unpivot(frame):
    N, K = frame.shape
    data = {'value': frame.to_numpy().ravel('F'),
            'variable': np.asarray(frame.columns).repeat(N),
            'date': np.tile(np.asarray(frame.index), K)}
    return pd.DataFrame(data, columns=['date', 'variable', 'value'])
```

(continues on next page)
df = unpivot(tm.makeTimeDataFrame(3))

To select out everything for variable A we could do:

```python
In [2]: df[df['variable'] == 'A']
Out[2]:
       date  variable   value
0 2000-01-03       A  0.469112
1 2000-01-04       A -0.282863
2 2000-01-05       A -1.509059
```

But suppose we wish to do time series operations with the variables. A better representation would be where the columns are the unique variables and an index of dates identifies individual observations. To reshape the data into this form, we use the `DataFrame.pivot()` method (also implemented as a top level function `pivot()`):

```python
In [3]: df.pivot(index='date', columns='variable', values='value')
Out[3]:
      variable A  B   C   D
      date
2000-01-03 0.469112 -1.135632 0.119209 -2.104569
2000-01-04 -0.282863  1.212112 -1.044236 -0.494929
2000-01-05 -1.509059 -0.173215 -0.861849  1.071804
```

If the `values` argument is omitted, and the input DataFrame has more than one column of values which are not used as column or index inputs to `pivot`, then the resulting “pivoted” DataFrame will have hierarchical columns whose topmost level indicates the respective value column:

```python
In [4]: df['value2'] = df['value'] * 2
In [5]: pivoted = df.pivot(index='date', columns='variable')
In [6]: pivoted
Out[6]:
     value     value2
      variable  A  B   C   D  A  B   C  
                   D  A  B   C  D
      date
2000-01-03 0.469112 -1.135632 0.119209 -2.104569 0.938225 -2.271265 0.238417 -4.209138
2000-01-04 -0.282863  1.212112 -1.044236 -0.494929 -0.565727  2.424224 -2.088472 -0.989859
2000-01-05 -1.509059 -0.173215 -0.861849  1.071804 -3.018117 -0.346429 -1.723698  2.143608
```

You can then select subsets from the pivoted DataFrame:

```python
In [7]: pivoted['value2']
Out[7]:
     variable  A  B   C   D
      date
2000-01-03 0.938225 -2.271265 0.238417 -4.209138
2000-01-04 -0.565727  2.424224 -2.088472 -0.989859
2000-01-05 -3.018117 -0.346429 -1.723698  2.143608
```
Note that this returns a view on the underlying data in the case where the data are homogeneously-typed.

**Note:** `pivot()` will error with a `ValueError: Index contains duplicate entries, cannot reshape` if the index/column pair is not unique. In this case, consider using `pivot_table()` which is a generalization of `pivot` that can handle duplicate values for one index/column pair.

### 2.8.2 Reshaping by stacking and unstacking

**Stack**

```
df2
```

```
stacked = df2.stack()
```

Closely related to the `pivot()` method are the related `stack()` and `unstack()` methods available on `Series` and `DataFrame`. These methods are designed to work together with `MultiIndex` objects (see the section on [hierarchical indexing](#)). Here are essentially what these methods do:

- **stack:** “pivot” a level of the (possibly hierarchical) column labels, returning a `DataFrame` with an index with a new inner-most level of row labels.

- **unstack:** (inverse operation of `stack`) “pivot” a level of the (possibly hierarchical) row index to the column axis, producing a reshaped `DataFrame` with a new inner-most level of column labels.
Unstack

The clearest way to explain is by example. Let’s take a prior example data set from the hierarchical indexing section:

```python
In [8]: tuples = list(zip(*[['bar', 'bar', 'baz', 'baz',
                              'foo', 'foo', 'qux', 'qux'],
                             ['one', 'two', 'one', 'two',
                              'one', 'two', 'one', 'two']]))
In [9]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])
In [10]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])
In [11]: df2 = df[:4]
In [12]: df2
Out[12]:
        A         B
first second
bar  one  0.721555 -0.706771
     two -1.039575  0.271860
baz  one -0.424972  0.567020
     two  0.276232 -1.087401
```

The stack function “compresses” a level in the DataFrame’s columns to produce either:

- A Series, in the case of a simple column Index.
- A DataFrame, in the case of a MultiIndex in the columns.

If the columns have a MultiIndex, you can choose which level to stack. The stacked level becomes the new lowest level in a MultiIndex on the columns:
In [13]: stacked = df2.stack()

In [14]: stacked
Out[14]:
first  second
bar  one A 0.721555
     B -0.706771
two A -1.039575
     B 0.271860
baz  one A -0.424972
     B 0.567020
two A 0.276232
     B -1.087401
dtype: float64

With a “stacked” DataFrame or Series (having a MultiIndex as the index), the inverse operation of stack is unstack, which by default unstacks the last level:

In [15]: stacked.unstack()
Out[15]:
   first  second
bar   one    A 0.721555 -0.706771
        B -1.039575  0.271860
baz   one    A -0.424972  0.567020
        B  0.276232 -1.087401

define unstack(1) unstack(0)

In [16]: stacked.unstack(1)
Out[16]:
   second  one two
first
bar   A 0.721555 -1.039575
        B -0.706771  0.271860
baz   A -0.424972  0.276232
        B  0.567020 -1.087401

define unstack(0)

In [17]: stacked.unstack(0)
Out[17]:
   first  bar  baz
second
one   A 0.721555 -0.424972
        B -0.706771  0.567020
two  A -1.039575  0.276232
        B  0.271860 -1.087401

2.8. Reshaping and pivot tables
Unstack(1)

If the indexes have names, you can use the level names instead of specifying the level numbers:

```python
In [18]: stacked.unstack('second')
Out[18]:
        second  one    two
    first
bar   A  0.721555 -1.039575
      B -0.706771  0.271860
baz   A -0.424972  0.276232
      B  0.567020 -1.087401
```

476 Chapter 2. User Guide
Notice that the stack and unstack methods implicitly sort the index levels involved. Hence a call to stack and then unstack, or vice versa, will result in a sorted copy of the original DataFrame or Series:

```python
In [19]: index = pd.MultiIndex.from_product([[2, 1], ['a', 'b']])
In [20]: df = pd.DataFrame(np.random.randn(4), index=index, columns=['A'])
In [21]: df
Out[21]:
   A
0  2.80452
1 -0.71669
2 -0.43755
3  0.44915

In [22]: all(df.unstack().stack() == df.sort_index())
Out[22]: True
```

The above code will raise a TypeError if the call to sort_index is removed.

**Multiple levels**

You may also stack or unstack more than one level at a time by passing a list of levels, in which case the end result is as if each level in the list were processed individually.

```python
In [23]: columns = pd.MultiIndex.from_tuples([
    ('A', 'cat', 'long'), ('B', 'cat', 'long'),
    ('A', 'dog', 'short'), ('B', 'dog', 'short')],
    names=['exp', 'animal', 'hair_length'])

(continues on next page)"
In [24]: df = pd.DataFrame(np.random.randn(4, 4), columns=columns)

In [25]: df
Out[25]:
exp  A  B  A  B
animal  cat  cat  dog  dog
hair_length  long  long  short  short
0  1.075770 -0.109050 1.643563 -1.469388
1  0.357021 -0.674600 -1.776904 -0.968914
2 -1.294524 0.413738 0.276662 -0.472035
3 -0.013960 -0.362543 -0.006154 -0.923061

In [26]: df.stack(level=['animal', 'hair_length'])
Out[26]:
exp  A  B
animal hair_length
0  cat  long  1.075770 -0.109050
  dog  short  1.643563 -1.469388
1  cat  long  0.357021 -0.674600
  dog  short -1.776904 -0.968914
2  cat  long -1.294524 0.413738
  dog  short  0.276662 -0.472035
3  cat  long -0.013960 -0.362543
  dog  short -0.006154 -0.923061

The list of levels can contain either level names or level numbers (but not a mixture of the two).

# df.stack(level=['animal', 'hair_length'])
# from above is equivalent to:
In [27]: df.stack(level=[1, 2])
Out[27]:
exp  A  B
animal hair_length
0  cat  long  1.075770 -0.109050
  dog  short  1.643563 -1.469388
1  cat  long  0.357021 -0.674600
  dog  short -1.776904 -0.968914
2  cat  long -1.294524 0.413738
  dog  short  0.276662 -0.472035
3  cat  long -0.013960 -0.362543
  dog  short -0.006154 -0.923061

Missing data

These functions are intelligent about handling missing data and do not expect each subgroup within the hierarchical
index to have the same set of labels. They also can handle the index being unsorted (but you can make it sorted by
calling sort_index, of course). Here is a more complex example:

In [28]: columns = pd.MultiIndex.from_tuples([('A', 'cat'), ('B', 'dog'),
   ....:     ('B', 'cat'), ('A', 'dog')],
   ....:     names=['exp', 'animal'])
   ....:

In [29]: index = pd.MultiIndex.from_product([('bar', 'baz', 'foo', 'qux'),
   ....:     ('one', 'two')],
   ....:     (continues on next page)
In 

```
df2 = df.iloc[[0, 1, 2, 4, 5, 7]]
```

In 

```
df2
```

Out

```
animal  cat  dog
first   second
bar  one  A   0.895717  0.805244  -1.206412  2.565646
      two  A   1.431256  1.340309  -1.170299  0.226169
      two  B   1.431256  -0.226169  1.340309
baz  one  A   0.410835  0.813850  0.132003  -0.827317
      two  A   1.413681  1.607920  1.024180  0.569605
      two  B   0.875906  -2.211372  0.974466  -2.006747
foo  one  A  -1.413681  1.607920  1.024180  0.569605
      two  A   0.875906  -2.211372  0.974466  -2.006747
      two  B   0.875906  0.974466  -2.211372
qux  two  A  -1.226825  0.769804  -1.281247  -0.727707
      B   -1.226825  0.769804  -1.281247  -0.727707
```

As mentioned above, `stack` can be called with a `level` argument to select which level in the columns to stack:

```
In [33]: df2.stack('exp')
```

Out

```
animal  exp
first   second
bar  one  A   0.895717  2.565646
      B   -1.206412  0.805244
      two  A   1.431256  -0.226169
            B  -1.170299  1.340309
baz  one  A   0.410835  -0.827317
      B   0.132003  0.813850
foo  one  A  -1.413681  0.569605
      B   1.024180  1.607920
      two  A   0.875906  -2.006747
            B   0.974466  -2.211372
qux  two  A  -1.226825  -0.727707
      B   -1.281247  0.769804
```

```
In [34]: df2.stack('animal')
```

Out

```
exp
animal  A  B
first   second
bar  one  A   0.895717  2.565646
      B   -1.206412  0.805244
      two  A   1.431256  -0.226169
            B  -1.170299  1.340309
baz  one  A   0.410835  0.132003
      B   0.132003  0.813850
foo  one  A  -1.413681  0.569605
      B   1.024180  1.607920
      two  A   0.875906  -2.006747
            B   0.974466  -2.211372
qux  two  A  -1.226825  -0.727707
      B   -1.281247  0.769804
```

Unstacking can result in missing values if subgroups do not have the same set of labels. By default, missing values will be replaced with the default fill value for that data type, NaN for float, NaT for datetimelike, etc. For integer types,
by default data will converted to float and missing values will be set to NaN.

```python
In [35]: df3 = df.iloc[[0, 1, 4, 7], [1, 2]]

In [36]: df3
Out[36]:
exp  B
animal  dog  cat
first  second
bar  one  0.805244 -1.206412
     two  1.340309 -1.170299
foo  one  1.607920  1.024180
     two  0.769804 -1.281247

In [37]: df3.unstack()
Out[37]:
exp  B
animal  dog  cat
first  second
bar  one  two  one  two
     one  two  one  two
     one  two  one  two
     one  two  one  two
foo  NaN  1.024180 NaN  NaN
     NaN  0.769804 NaN  -1.281247
qux  NaN  0.769804 NaN  -1.281247
```

Alternatively, unstack takes an optional `fill_value` argument, for specifying the value of missing data.

```python
In [38]: df3.unstack(fill_value=-1e9)
Out[38]:
exp  B
animal  dog  cat
first  second
bar  8.052440e-01  1.340309e+00 -1.206412e+00 -1.170299e+00
foo  1.607920e+00 -1.000000e+09  1.024180e+00 -1.000000e+09
qux -1.000000e+09  7.698036e-01 -1.000000e+09 -1.281247e+00
```

### With a MultiIndex

Unstacking when the columns are a `MultiIndex` is also careful about doing the right thing:

```python
In [39]: df[:3].unstack(0)
Out[39]:
exp  A  B  A
animal  cat  dog  cat  dog
first  second
bar  one  baz  bar  baz  bar  baz  bar  baz
     one  baz  bar  baz  bar  baz  bar  baz
     one  baz  bar  baz  bar  baz  bar  baz
     one  baz  bar  baz  bar  baz  bar  baz
foo  NaN  1.024180 NaN  NaN
     NaN  0.769804 NaN  -1.281247
qux  NaN  0.769804 NaN  -1.281247
```

```python
In [40]: df2.unstack(1)
Out[40]:
exp  A  B  A
animal  cat  dog  cat  dog
second  first
bar  one  two  one  two  one  two  one  two  one  two
     one  two  one  two  one  two  one  two  one  two
     one  two  one  two  one  two  one  two  one  two
     one  two  one  two  one  two  one  two  one  two
```

(continues on next page)
2.8.3 Reshaping by melt

The top-level `melt()` function and the corresponding `DataFrame.melt()` are useful to massage a DataFrame into a format where one or more columns are identifier variables, while all other columns, considered measured variables, are “unpivoted” to the row axis, leaving just two non-identifier columns, “variable” and “value”. The names of those columns can be customized by supplying the `var_name` and `value_name` parameters.

For instance,

```
In [41]: cheese = pd.DataFrame({'first': ['John', 'Mary'],
                           'last': ['Doe', 'Bo'],
                           'height': [5.5, 6.0],
                           'weight': [130, 150])
```

```
In [42]: cheese
Out[42]:
    first  last  height  weight
0     John  Doe    5.5     130
1     Mary   Bo    6.0     150
```

```
In [43]: cheese.melt(id_vars=['first', 'last'])
Out[43]:
    first  last  variable  value
0     John  Doe     height    5.5
1     Mary   Bo     height    6.0
2     John  Doe     weight    130
3     Mary   Bo     weight    150
```
When transforming a DataFrame using `melt()`, the index will be ignored. The original index values can be kept around by setting the `ignore_index` parameter to `False` (default is `True`). This will however duplicate them.

New in version 1.1.0.

Another way to transform is to use the `wide_to_long()` panel data convenience function. It is less flexible than `melt()`, but more user-friendly.
2.8.4 Combining with stats and GroupBy

It should be no shock that combining `pivot / stack / unstack` with `GroupBy` and the basic `Series` and `DataFrame` statistical functions can produce some very expressive and fast data manipulations.

```
In [54]: df
Out[54]:
   exp   A   B
animal
   cat  dog  cat  dog
first second
bar  one  0.895717  0.805244 -1.206412  2.565646
     two  1.431256  1.340309 -1.170299 -0.226169
baz  one  0.410835  0.813850  0.132003 -0.827317
     two -0.076467 -1.187678  1.130127  1.436737
foo  one -1.413681  1.607920  1.024180  0.569605
     two  0.875906 -2.211372  0.974466 -2.006747
qux  one -0.410001 -0.078638  0.545952 -1.219217
     two -1.226825  0.769804 -1.281247 -0.727707

In [55]: df.stack().mean(1).unstack()
Out[55]:
   animal
   cat  dog
first second
bar  one -0.155347  1.685445
     two  0.130479  0.557070
baz  one  0.271419 -0.006733
     two  0.526830 -1.312207
foo  one -0.194750  1.088763
     two  0.925186 -2.109060
qux  one  0.067976 -0.648927
     two -1.254036  0.021048
```

# same result, another way
```
In [56]: df.groupby(level=1, axis=1).mean()
Out[56]:
   animal
   cat  dog
first second
bar  one -0.155347  1.685445
     two  0.130479  0.557070
baz  one  0.271419 -0.006733
     two  0.526830 -1.312207
foo  one -0.194750  1.088763
     two  0.925186 -2.109060
qux  one  0.067976 -0.648927
     two -1.254036  0.021048
```

(continues on next page)
2.8.5 Pivot tables

While `pivot()` provides general purpose pivoting with various data types (strings, numerics, etc.), pandas also provides `pivot_table()` for pivoting with aggregation of numeric data.

The function `pivot_table()` can be used to create spreadsheet-style pivot tables. See the cookbook for some advanced strategies.

It takes a number of arguments:

- **data**: a DataFrame object.
- **values**: a column or a list of columns to aggregate.
- **index**: a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.
- **columns**: a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.
- **aggfunc**: function to use for aggregation, defaulting to `numpy.mean`.

Consider a dataset like this:

```python
import import datetime
df = pd.DataFrame({'A': ['one', 'one', 'two', 'three'] * 6,
                   'B': ['A', 'B', 'C'] * 8,
                   'C': ['foo', 'foo', 'foo', 'bar', 'bar', 'bar'] * 4,
                   'D': np.random.randn(24),
                   'E': np.random.randn(24),
                   'F': [datetime.datetime(2013, i, 1) for i in range(1, 13)] + [datetime.datetime(2013, i, 15) for i in range(1, 13)]})
```
We can produce pivot tables from this data very easily:

```python
In [62]: pd.pivot_table(df, values='D', index=['A', 'B'], columns=['C'])
Out[62]:
   C   bar   foo
A B
one A  1.120915 -0.514058
   B -0.338421  0.002759
   C -0.538846  0.699535
three A -1.181568  NaN
   B  NaN  0.433512
   C  0.588783  NaN
two A  NaN  1.000985
   B  0.158248  NaN
   C  NaN  0.176180
```

```python
In [63]: pd.pivot_table(df, values='D', index=['B'], columns=['A', 'C'], aggfunc=np.sum)
```

```python
In [64]: pd.pivot_table(df, values=['D', 'E'], index=['B'], columns=['A', 'C'], 
                   aggfunc=np.sum)
```

(continues on next page)
The result object is a DataFrame having potentially hierarchical indexes on the rows and columns. If the values column name is not given, the pivot table will include all of the data that can be aggregated in an additional level of hierarchy in the columns:

```
In [65]: pd.pivot_table(df, index=['A', 'B'], columns=['C'])
Out[65]:

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>bar</td>
<td>foo</td>
<td>bar</td>
<td>foo</td>
</tr>
<tr>
<td>A B</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>one</td>
<td>A</td>
<td>1.120915</td>
<td>-0.514058</td>
<td>1.393057</td>
</tr>
<tr>
<td></td>
<td>B</td>
<td>-0.338421</td>
<td>0.002759</td>
<td>0.684140</td>
</tr>
<tr>
<td></td>
<td>C</td>
<td>-0.538846</td>
<td>0.699535</td>
<td>-0.988442</td>
</tr>
<tr>
<td>three</td>
<td>A</td>
<td>-1.181568</td>
<td>NaN</td>
<td>0.961289</td>
</tr>
<tr>
<td></td>
<td>B</td>
<td>NaN</td>
<td>0.433512</td>
<td>NaN</td>
</tr>
<tr>
<td></td>
<td>C</td>
<td>0.588783</td>
<td>NaN</td>
<td>-0.131830</td>
</tr>
<tr>
<td>two</td>
<td>A</td>
<td>NaN</td>
<td>1.000985</td>
<td>NaN</td>
</tr>
<tr>
<td></td>
<td>B</td>
<td>0.158248</td>
<td>NaN</td>
<td>-0.097147</td>
</tr>
<tr>
<td></td>
<td>C</td>
<td>NaN</td>
<td>0.176180</td>
<td>NaN</td>
</tr>
</tbody>
</table>
```

Also, you can use Grouper for index and columns keywords. For detail of Grouper, see Grouping with a Grouper specification.

```
In [66]: pd.pivot_table(df, values='D', index=pd.Grouper(freq='M', key='F'), columns='C')
```

You can render a nice output of the table omitting the missing values by calling to_string if you wish:

```
In [67]: table = pd.pivot_table(df, index=['A', 'B'], columns=['C'])
In [68]: print(table.to_string(na_rep=''))
```

(continues on next page)
Note that `pivot_table` is also available as an instance method on `DataFrame`, i.e. `DataFrame.pivot_table()`.

### Adding margins

If you pass `margins=True` to `pivot_table`, special `All` columns and rows will be added with partial group aggregates across the categories on the rows and columns:

```
In [69]: df.pivot_table(index=['A', 'B'], columns='C', margins=True, aggfunc=np.std)
Out[69]:
   C    D   E
<table>
<thead>
<tr>
<th></th>
<th>bar</th>
<th>foo</th>
<th>All</th>
<th>bar</th>
<th>foo</th>
<th>All</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>1.804346</td>
<td>1.210272</td>
<td>1.569879</td>
<td>0.179483</td>
<td>0.418374</td>
<td>0.858005</td>
</tr>
<tr>
<td>B</td>
<td>0.690376</td>
<td>1.353355</td>
<td>0.898998</td>
<td>1.083825</td>
<td>0.968138</td>
<td>1.101401</td>
</tr>
<tr>
<td>C</td>
<td>0.273641</td>
<td>0.418926</td>
<td>0.771139</td>
<td>0.446140</td>
<td>1.422136</td>
<td></td>
</tr>
<tr>
<td>three</td>
<td>0.794212</td>
<td>NaN</td>
<td>0.794212</td>
<td>2.049040</td>
<td>NaN</td>
<td>0.858005</td>
</tr>
<tr>
<td>B</td>
<td>NaN</td>
<td>0.363548</td>
<td>0.363548</td>
<td>NaN</td>
<td>1.625237</td>
<td>1.625237</td>
</tr>
<tr>
<td>C</td>
<td>3.915454</td>
<td>NaN</td>
<td>3.915454</td>
<td>1.035215</td>
<td>NaN</td>
<td>1.035215</td>
</tr>
<tr>
<td>two</td>
<td>NaN</td>
<td>0.442298</td>
<td>0.442298</td>
<td>NaN</td>
<td>0.447104</td>
<td>0.447104</td>
</tr>
<tr>
<td>B</td>
<td>0.202765</td>
<td>NaN</td>
<td>0.202765</td>
<td>0.560757</td>
<td>NaN</td>
<td>0.560757</td>
</tr>
<tr>
<td>C</td>
<td>NaN</td>
<td>1.819408</td>
<td>1.819408</td>
<td>NaN</td>
<td>0.650439</td>
<td>0.650439</td>
</tr>
<tr>
<td>All</td>
<td>1.556686</td>
<td>0.952552</td>
<td>1.246608</td>
<td>1.250924</td>
<td>0.899904</td>
<td>1.059389</td>
</tr>
</tbody>
</table>
```

### 2.8.6 Cross tabulations

Use `crosstab()` to compute a cross-tabulation of two (or more) factors. By default `crosstab` computes a frequency table of the factors unless an array of values and an aggregation function are passed.

It takes a number of arguments:

- **index**: array-like, values to group by in the rows.
- **columns**: array-like, values to group by in the columns.
- **values**: array-like, optional, array of values to aggregate according to the factors.
- **aggfunc**: function, optional, If no values array is passed, computes a frequency table.
- **rownames**: sequence, default None, must match number of row arrays passed.
- **colnames**: sequence, default None, if passed, must match number of column arrays passed.
- **margins**: boolean, default False, Add row/column margins (subtotals)
- **normalize**: boolean, {‘all’, ‘index’, ‘columns’}, or {0,1}, default False. Normalize by dividing all values by the sum of values.
Any Series passed will have their name attributes used unless row or column names for the cross-tabulation are specified.

For example:

```python
In [70]: foo, bar, dull, shiny, one, two = 'foo', 'bar', 'dull', 'shiny', 'one', 'two'
In [71]: a = np.array([foo, foo, bar, bar, foo, foo], dtype=object)
In [72]: b = np.array([one, one, two, one, two, one], dtype=object)
In [73]: c = np.array([dull, dull, shiny, dull, dull, shiny], dtype=object)
In [74]: pd.crosstab(a, [b, c], rownames=['a'], colnames=['b', 'c'])
```

```
Out[74]:
         b    one  two
    c      dull    shiny
    bar     1     0     0
    foo     2     1     1
```

If `crosstab` receives only two Series, it will provide a frequency table.

```python
In [75]: df = pd.DataFrame({'A': [1, 2, 2, 2, 2], 'B': [3, 3, 4, 4, 4],
    ....: 'C': [1, 1, np.nan, 1, 1]})
    ....:
In [76]: df
Out[76]:
     A  B  C
0   1  3  1.0
1   2  3  1.0
2   2  4  NaN
3   2  4  1.0
4   2  4  1.0
In [77]: pd.crosstab(df['A'], df['B'])
```

```
Out[77]:
    B  3  4
   A
   1  1  0
   2  1  3
```

crosstab can also be implemented to Categorical data.

```python
In [78]: foo = pd.Categorical(['a', 'b'], categories=['a', 'b', 'c'])
In [79]: bar = pd.Categorical(['d', 'e'], categories=['d', 'e', 'f'])
In [80]: pd.crosstab(foo, bar)
```

```
Out[80]:
     col_0  d  e
   row_0
      a   1  0
      b   0  1
```

If you want to include all of data categories even if the actual data does not contain any instances of a particular category, you should set `dropna=False`. 
For example:

```python
In [81]: pd.crosstab(foo, bar, dropna=False)
Out[81]:
       col_0 d e f
      row_0  
    a    1 0 0
    b    0 1 0
    c    0 0 0
```

**Normalization**

Frequency tables can also be normalized to show percentages rather than counts using the `normalize` argument:

```python
In [82]: pd.crosstab(df['A'], df['B'], normalize=True)
Out[82]:
      B  3  4
     A  
    1  0.2  0.0
    2  0.2  0.6
```
	normalize can also normalize values within each row or within each column:

```python
In [83]: pd.crosstab(df['A'], df['B'], normalize='columns')
Out[83]:
      B  3  4
     A  
    1  0.5  0.0
    2  0.5  1.0
```

crosstab can also be passed a third Series and an aggregation function (`aggfunc`) that will be applied to the values of the third Series within each group defined by the first two Series:

```python
In [84]: pd.crosstab(df['A'], df['B'], values=df['C'], aggfunc=np.sum)
Out[84]:
      B  3  4
     A  
    1  1.0 NaN
    2  1.0  2.0
```

**Adding margins**

Finally, one can also add margins or normalize this output.

```python
In [85]: pd.crosstab(df['A'], df['B'], values=df['C'], aggfunc=np.sum, normalize=True, margins=True)
```

```python
Out[85]:
      B   3  4  All
     A  
    1  0.25  0.0  0.25
    2  0.25  0.5  0.75
   All  0.50  0.5  1.00
```
### 2.8.7 Tiling

The `cut()` function computes groupings for the values of the input array and is often used to transform continuous variables to discrete or categorical variables:

```python
In [86]: ages = np.array([10, 15, 13, 12, 23, 25, 28, 59, 60])
In [87]: pd.cut(ages, bins=3)
Out[87]:
[(9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (26.667, 43.333], (43.333, 60.0], (43.333, 60.0]
Categories (3, interval[float64]): [(9.95, 26.667] < (26.667, 43.333] < (43.333, 60.0]
```

If the `bins` keyword is an integer, then equal-width bins are formed. Alternatively we can specify custom bin-edges:

```python
In [88]: c = pd.cut(ages, bins=[0, 18, 35, 70])
In [89]: c
Out[89]:
[(0, 18], (0, 18], (0, 18], (0, 18], (18, 35], (18, 35], (18, 35], (35, 70], (35, 70]
Categories (3, interval[int64]): [(0, 18] < (18, 35] < (35, 70]
```

If the `bins` keyword is an `IntervalIndex`, then these will be used to bin the passed data:

```python
pd.cut([25, 20, 50], bins=c.categories)
```

### 2.8.8 Computing indicator / dummy variables

To convert a categorical variable into a “dummy” or “indicator” DataFrame, for example a column in a DataFrame (a Series) which has k distinct values, can derive a DataFrame containing k columns of 1s and 0s using `get_dummies()`:

```python
In [90]: df = pd.DataFrame({'key': list('bbacab'), 'data1': range(6)})
In [91]: pd.get_dummies(df['key'])
Out[91]:
   a  b  c
0  0  1  0
1  0  1  0
2  1  0  0
3  0  0  1
4  1  0  0
5  0  1  0
```

Sometimes it’s useful to prefix the column names, for example when merging the result with the original DataFrame:

```python
In [92]: dummies = pd.get_dummies(df['key'], prefix='key')
In [93]: dummies
Out[93]:
     key_a  key_b  key_c
0       0      1      0
1       1      0      0
2       1      0      0
3       0      0      1
```

(continues on next page)
In [94]: df[['data1']].join(dummies)
Out[94]:
   data1   key_a   key_b   key_c
0      0       0       1       0
1      1       0       1       0
2      2       1       0       0
3      3       0       0       1
4      4       1       0       0
5      5       0       1       0

This function is often used along with discretization functions like `cut`:

In [95]: values = np.random.randn(10)

In [96]: values
Out[96]:
array([ 0.4082, -1.0481, -0.0257, -0.9884,  0.0941,  1.2627,  1.29 ,
       0.0824, -0.0558,  0.5366])

In [97]: bins = [0, 0.2, 0.4, 0.6, 0.8, 1]

In [98]: pd.get_dummies(pd.cut(values, bins))
Out[98]:
   (0.0, 0.2] (0.2, 0.4] (0.4, 0.6] (0.6, 0.8] (0.8, 1.0]
0        0        0        1        0        0
1        0        0        0        0        0
2        0        0        0        0        0
3        0        0        0        0        0
4        1        0        0        0        0
5        0        0        0        0        0
6        0        0        0        0        0
7        1        0        0        0        0
8        0        0        0        0        0
9        0        0        1        0        0

See also `Series.str.get_dummies`.

`get_dummies()` also accepts a DataFrame. By default all categorical variables (categorical in the statistical sense, those with `object` or `categorical` dtype) are encoded as dummy variables.

In [99]: df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['c', 'c', 'b'],
                  ...:                  'C': [1, 2, 3]})

In [100]: pd.get_dummies(df)
Out[100]:
   C  A_a  A_b  B_b  B_c
0  1    1    0    0    1
1  2    0    1    0    1
2  3    1    0    1    0

All non-object columns are included untouched in the output. You can control the columns that are encoded with the `columns` keyword.

2.8. Reshaping and pivot tables
In [101]: pd.get_dummies(df, columns=['A'])
Out[101]:
    B  C  A_a  A_b  
0  c  1   1   0
1  c  2   0   1
2  b  3   1   0

Notice that the B column is still included in the output, it just hasn’t been encoded. You can drop B before calling get_dummies if you don’t want to include it in the output.

As with the Series version, you can pass values for the prefix and prefix_sep. By default the column name is used as the prefix, and '_' as the prefix separator. You can specify prefix and prefix_sep in 3 ways:

- string: Use the same value for prefix or prefix_sep for each column to be encoded.
- list: Must be the same length as the number of columns being encoded.
- dict: Mapping column name to prefix.

In [102]: simple = pd.get_dummies(df, prefix='new_prefix')
In [103]: simple
Out[103]:
     C  new_prefix_a  new_prefix_b  new_prefix_b  new_prefix_c
0  1.0          1.0            0.0            0.0
1  0.0          0.0            1.0            0.0
2  1.0          0.0            0.0            1.0

In [104]: from_list = pd.get_dummies(df, prefix=['from_A', 'from_B'])
In [105]: from_list
Out[105]:
     C  from_A_a  from_A_b  from_B_b  from_B_c
0  1.0        1.0          0.0          1.0
1  0.0        0.0          0.0          1.0
2  1.0        0.0          0.0          0.0

In [106]: from_dict = pd.get_dummies(df, prefix={'B': 'from_B', 'A': 'from_A'})
In [107]: from_dict
Out[107]:
     C  from_A_a  from_A_b  from_B_b  from_B_c
0  1.0        1.0          0.0          1.0
1  0.0        0.0          1.0          0.0
2  0.0        0.0          1.0          0.0

Sometimes it will be useful to only keep k-1 levels of a categorical variable to avoid collinearity when feeding the result to statistical models. You can switch to this mode by turn on drop_first.

In [108]: s = pd.Series(list('abcaa'))
In [109]: pd.get_dummies(s)
Out[109]:
   a  b  c
0  1  0  0
1  0  1  0
2  0  0  1
3  1  0  0

(continues on next page)
When a column contains only one level, it will be omitted in the result.

```python
In [111]: df = pd.DataFrame({'A': list('aaaaa'), 'B': list('ababc')})
In [112]: pd.get_dummies(df)
Out[112]:
   A_a  B_a  B_b  B_c
0   1   1   0   0
1   1   0   1   0
2   1   1   0   0
3   1   0   1   0
4   1   0   0   1
```

By default new columns will have `np.uint8` dtype. To choose another dtype, use the `dtype` argument:

```python
In [114]: df = pd.DataFrame({'A': list('abc'), 'B': [1.1, 2.2, 3.3]})
In [115]: pd.get_dummies(df, dtype=bool).dtypes
Out[115]:
B    float64
A_a   bool
A_b   bool
A_c   bool
dtype: object
```

New in version 0.23.0.
2.8.9 Factorizing values

To encode 1-d values as an enumerated type use `factorize()`:

```
In [116]: x = pd.Series(['A', 'A', np.nan, 'B', 3.14, np.inf])
```
```
In [117]: x
Out[117]:
0   A
1   A
2  NaN
3   B
4  3.14
5   inf
dtype: object
```
```
In [118]: labels, uniques = pd.factorize(x)
```
```
In [119]: labels
Out[119]: array([ 0, 0, -1, 1, 2, 3])
```
```
In [120]: uniques
Out[120]: Index(['A', 'B', 3.14, inf], dtype='object')
```

Note that `factorize` is similar to `numpy.unique`, but differs in its handling of NaN:

```
Note: The following `numpy.unique` will fail under Python 3 with a `TypeError` because of an ordering bug. See also here.
```
```
In [1]: x = pd.Series(['A', 'A', np.nan, 'B', 3.14, np.inf])
```
```
In [2]: pd.factorize(x, sort=True)
```
```
Out[2]:
(array([ 2, 2, -1, 3, 0, 1]),
 Index([3.14, inf, 'A', 'B'], dtype='object'))
```
```
In [3]: np.unique(x, return_inverse=True)[::-1]
```
```
Out[3]: (array([3, 3, 0, 4, 1, 2]), array([nan, 3.14, inf, 'A', 'B'], dtype=object))
```

Note: If you just want to handle one column as a categorical variable (like R’s factor), you can use `df["cat_col"] = pd.Categorical(df["col"])` or `df["cat_col"] = df["col"].astype("category")`. For full docs on `Categorical`, see the `Categorical introduction` and the `API documentation`.

2.8.10 Examples

In this section, we will review frequently asked questions and examples. The column names and relevant column values are named to correspond with how this DataFrame will be pivoted in the answers below.

```
In [121]: np.random.seed([3, 1415])
```
```
In [122]: n = 20
```
```
In [123]: cols = np.array(['key', 'row', 'item', 'col'])
```
In [124]: df = cols + pd.DataFrame((np.random.randint(5, size=(n, 4))) // [2, 1, 2, 1]).astype(str))

In [125]: df.columns = cols

In [126]: df = df.join(pd.DataFrame(np.random.rand(n, 2).round(2)).add_prefix('val'))

In [127]: df

Out[127]:

<table>
<thead>
<tr>
<th>key</th>
<th>row</th>
<th>item</th>
<th>col</th>
<th>val0</th>
<th>val1</th>
</tr>
</thead>
<tbody>
<tr>
<td>key0</td>
<td>row3</td>
<td>item1</td>
<td>col3</td>
<td>0.81</td>
<td>0.04</td>
</tr>
<tr>
<td>key1</td>
<td>row2</td>
<td>item1</td>
<td>col2</td>
<td>0.44</td>
<td>0.07</td>
</tr>
<tr>
<td>key1</td>
<td>row0</td>
<td>item1</td>
<td>col0</td>
<td>0.77</td>
<td>0.01</td>
</tr>
<tr>
<td>key0</td>
<td>row4</td>
<td>item0</td>
<td>col2</td>
<td>0.15</td>
<td>0.59</td>
</tr>
<tr>
<td>key1</td>
<td>row0</td>
<td>item2</td>
<td>col1</td>
<td>0.81</td>
<td>0.64</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>key0</td>
<td>row3</td>
<td>item1</td>
<td>col1</td>
<td>0.31</td>
<td>0.23</td>
</tr>
<tr>
<td>key0</td>
<td>row0</td>
<td>item2</td>
<td>col3</td>
<td>0.86</td>
<td>0.01</td>
</tr>
<tr>
<td>key0</td>
<td>row4</td>
<td>item0</td>
<td>col3</td>
<td>0.64</td>
<td>0.21</td>
</tr>
<tr>
<td>key2</td>
<td>row2</td>
<td>item2</td>
<td>col0</td>
<td>0.13</td>
<td>0.45</td>
</tr>
<tr>
<td>key0</td>
<td>row2</td>
<td>item0</td>
<td>col4</td>
<td>0.37</td>
<td>0.70</td>
</tr>
</tbody>
</table>

Pivoting with single aggregations

Suppose we wanted to pivot df such that the col values are columns, row values are the index, and the mean of val0 are the values? In particular, the resulting DataFrame should look like:

<table>
<thead>
<tr>
<th>col</th>
<th>col0</th>
<th>col1</th>
<th>col2</th>
<th>col3</th>
<th>col4</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>row0</td>
<td>0.77</td>
<td>0.605</td>
<td>NaN</td>
<td>0.860</td>
<td>0.65</td>
</tr>
<tr>
<td>row2</td>
<td>0.13</td>
<td>NaN</td>
<td>0.395</td>
<td>0.500</td>
<td>0.25</td>
</tr>
<tr>
<td>row3</td>
<td>NaN</td>
<td>0.310</td>
<td>NaN</td>
<td>0.545</td>
<td>NaN</td>
</tr>
<tr>
<td>row4</td>
<td>NaN</td>
<td>0.100</td>
<td>0.395</td>
<td>0.760</td>
<td>0.24</td>
</tr>
</tbody>
</table>

This solution uses pivot_table(). Also note that aggfunc='mean' is the default. It is included here to be explicit.

In [128]: df.pivot_table(
   ...:       values='val0', index='row', columns='col', aggfunc='mean')
   ...:

Out[128]:

<table>
<thead>
<tr>
<th>col</th>
<th>col0</th>
<th>col1</th>
<th>col2</th>
<th>col3</th>
<th>col4</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>row0</td>
<td>0.77</td>
<td>0.605</td>
<td>NaN</td>
<td>0.860</td>
<td>0.65</td>
</tr>
<tr>
<td>row2</td>
<td>0.13</td>
<td>NaN</td>
<td>0.395</td>
<td>0.500</td>
<td>0.25</td>
</tr>
<tr>
<td>row3</td>
<td>NaN</td>
<td>0.310</td>
<td>NaN</td>
<td>0.545</td>
<td>NaN</td>
</tr>
<tr>
<td>row4</td>
<td>NaN</td>
<td>0.100</td>
<td>0.395</td>
<td>0.760</td>
<td>0.24</td>
</tr>
</tbody>
</table>

Note that we can also replace the missing values by using the fill_value parameter.
In [129]: df.pivot_table(
       .....:     values='val0', index='row', columns='col', aggfunc='mean', fill_value=0)
       .....:
Out[129]:
<table>
<thead>
<tr>
<th>col</th>
<th>col0</th>
<th>col1</th>
<th>col2</th>
<th>col3</th>
<th>col4</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>row0</td>
<td>0.77</td>
<td>0.605</td>
<td>0.000</td>
<td>0.860</td>
<td>0.65</td>
</tr>
<tr>
<td>row2</td>
<td>0.13</td>
<td>0.000</td>
<td>0.395</td>
<td>0.500</td>
<td>0.25</td>
</tr>
<tr>
<td>row3</td>
<td>0.00</td>
<td>0.310</td>
<td>0.000</td>
<td>0.545</td>
<td>0.00</td>
</tr>
<tr>
<td>row4</td>
<td>0.00</td>
<td>0.100</td>
<td>0.395</td>
<td>0.760</td>
<td>0.24</td>
</tr>
</tbody>
</table>

Also note that we can pass in other aggregation functions as well. For example, we can also pass in \texttt{sum}.

In [130]: df.pivot_table(
       .....:     values='val0', index='row', columns='col', aggfunc='sum', fill_value=0)
       .....:
Out[130]:
<table>
<thead>
<tr>
<th>col</th>
<th>col0</th>
<th>col1</th>
<th>col2</th>
<th>col3</th>
<th>col4</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>row0</td>
<td>0.77</td>
<td>1.21</td>
<td>0.00</td>
<td>0.86</td>
<td>0.65</td>
</tr>
<tr>
<td>row2</td>
<td>0.13</td>
<td>0.00</td>
<td>0.79</td>
<td>0.50</td>
<td>0.50</td>
</tr>
<tr>
<td>row3</td>
<td>0.00</td>
<td>0.31</td>
<td>1.09</td>
<td>0.00</td>
<td></td>
</tr>
<tr>
<td>row4</td>
<td>0.00</td>
<td>0.10</td>
<td>1.52</td>
<td>0.24</td>
<td></td>
</tr>
</tbody>
</table>

Another aggregation we can do is calculate the frequency in which the columns and rows occur together a.k.a. “cross tabulation”. To do this, we can pass \texttt{size} to the \texttt{aggfunc} parameter.

In [131]: df.pivot_table(index='row', columns='col', fill_value=0, aggfunc='size')
Out[131]:
<table>
<thead>
<tr>
<th>col</th>
<th>col0</th>
<th>col1</th>
<th>col2</th>
<th>col3</th>
<th>col4</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>row0</td>
<td>1</td>
<td>2</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>row2</td>
<td>1</td>
<td>0</td>
<td>2</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>row3</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>row4</td>
<td>0</td>
<td>1</td>
<td>2</td>
<td>2</td>
<td>1</td>
</tr>
</tbody>
</table>

**Pivoting with multiple aggregations**

We can also perform multiple aggregations. For example, to perform both a \texttt{sum} and \texttt{mean}, we can pass in a list to the \texttt{aggfunc} argument.

In [132]: df.pivot_table(
       .....:     values='val0', index='row', columns='col', aggfunc=['mean', 'sum'])
       .....:
Out[132]:
<table>
<thead>
<tr>
<th>mean</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>col</td>
<td>col0</td>
</tr>
<tr>
<td>row</td>
<td></td>
</tr>
<tr>
<td>row0</td>
<td>0.77</td>
</tr>
<tr>
<td>row2</td>
<td>0.13</td>
</tr>
<tr>
<td>row3</td>
<td>NaN</td>
</tr>
<tr>
<td>row4</td>
<td>NaN</td>
</tr>
</tbody>
</table>

Note to aggregate over multiple value columns, we can pass in a list to the \texttt{values} parameter.
In [133]: df.pivot_table(
       .....:   values=['val0', 'val1'], index='row', columns='col', aggfunc=['mean'])
       .....:
Out[133]:
   mean
   val0
col  col0  col1  col2  col3  col4  col0  col1  col2  col3  col4
row  
row0 0.77  0.605  NaN   0.86  0.65  0.01  0.745 NaN   0.01  0.02
row2 0.13  NaN   0.395  0.500  0.25  0.45  NaN   0.34  0.440  0.79
row3 NaN  0.310  NaN   0.545  NaN   0.230 NaN   0.075 NaN   
row4 NaN  0.100  0.395  0.760  0.24  NaN   0.070  0.42  0.300  0.46

Note to subdivide over multiple columns we can pass in a list to the columns parameter.

In [134]: df.pivot_table(
       .....:   values=['val0'], index='row', columns=['item', 'col'], aggfunc=['mean'])
       .....:
Out[134]:
   mean
   val0
   item item0 item1 item2
   col  col2  col3  col4  col0  col1  col2  col3  col4  col0  col1  col3  col4
row  
row0 NaN   NaN   NaN   0.77 NaN   NaN   NaN   NaN   NaN   0.605  0.86  0.65
row2 0.35  NaN   NaN   0.44 NaN   0.13  NaN   0.50  0.13
row3 NaN  0.31  NaN   0.81 NaN   NaN  NaN  NaN  0.28 NaN
row4 0.15  0.64 NaN   0.88 NaN   0.24 NaN   NaN  NaN  NaN

2.8.11 Exploding a list-like column

New in version 0.25.0.

Sometimes the values in a column are list-like.

In [135]: keys = ['panda1', 'panda2', 'panda3']
In [136]: values = [['eats', 'shoots'], ['shoots', 'leaves'], ['eats', 'leaves']]
In [137]: df = pd.DataFrame({'keys': keys, 'values': values})
In [138]: df
Out[138]:
   keys   values
0 panda1 [eats, shoots]
1 panda2 [shoots, leaves]
2 panda3 [eats, leaves]

We can ‘explode’ the values column, transforming each list-like to a separate row, by using explode(). This will replicate the index values from the original row:

In [139]: df['values'].explode()
Out[139]:
0   eats
0   shoots
1   shoots
(continues on next page)
You can also explode the column in the DataFrame.

```python
In [140]: df.explode('values')
Out[140]:
   keys  values
0  panda1    eats
0  panda1  shoots
1  panda2  shoots
1  panda2  leaves
2  panda3    eats
2  panda3  leaves
```

`Series.explode()` will replace empty lists with `np.nan` and preserve scalar entries. The dtype of the resulting `Series` is always `object`.

```python
In [141]: s = pd.Series([[1, 2, 3], 'foo', [], ['a', 'b']])
In [142]: s
Out[142]:
0     [1, 2, 3]
1      foo
2        []
3    [a, b]
 dtype: object
In [143]: s.explode()
Out[143]:
0  1
0  2
0  3
1  foo
2  NaN
3   a
3   b
dtype: object
```

Here is a typical use case. You have comma separated strings in a column and want to expand this.

```python
In [144]: df = pd.DataFrame([{'var1': 'a,b,c', 'var2': 1},
                      {'var1': 'd,e,f', 'var2': 2}])
In [145]: df
Out[145]:
   var1  var2
0  a,b,c    1
1  d,e,f    2
```

Creating a long form DataFrame is now straightforward using explode and chained operations.
In [146]: df.assign(var1=df.var1.str.split(',')).explode('var1')
Out[146]:
   var1  var2
0    a    1
0    b    1
0    c    1
1    d    2
1    e    2
1    f    2

2.9 Working with text data

2.9.1 Text data types

New in version 1.0.0.

There are two ways to store text data in pandas:

1. **object**-dtype NumPy array.
2. **StringDtype** extension type.

We recommend using **StringDtype** to store text data.

Prior to pandas 1.0, **object** dtype was the only option. This was unfortunate for many reasons:

1. You can accidentally store a mixture of strings and non-strings in an **object** dtype array. It’s better to have a dedicated dtype.
2. **object** dtype breaks dtype-specific operations like `DataFrame.select_dtypes()`. There isn’t a clear way to select just text while excluding non-text but still object-dtype columns.
3. When reading code, the contents of an **object** dtype array is less clear than ’string’.

Currently, the performance of **object** dtype arrays of strings and `arrays.StringArray` are about the same. We expect future enhancements to significantly increase the performance and lower the memory overhead of `StringArray`.

**Warning:** `StringArray` is currently considered experimental. The implementation and parts of the API may change without warning.

For backwards-compatibility, **object** dtype remains the default type we infer a list of strings to

In [1]: pd.Series(['a', 'b', 'c'])
Out[1]:
0    a
1    b
2    c
dtype: object

To explicitly request string dtype, specify the dtype

In [2]: pd.Series(['a', 'b', 'c'], dtype="string")
Out[2]:
0    a
(continues on next page)
1  b  
2  c  
dtype: string

In [3]: pd.Series(['a', 'b', 'c'], dtype=pd.StringDtype())
Out[3]:
0  a
1  b
2  c
dtype: string

Or astype after the Series or DataFrame is created

In [4]: s = pd.Series(['a', 'b', 'c'])

In [5]: s
Out[5]:
0  a  
1  b  
2  c  
dtype: object

In [6]: s.astype("string")
Out[6]:
0  a  
1  b  
2  c  
dtype: string

Changed in version 1.1.0.
You can also use StringDtype/"string" as the dtype on non-string data and it will be converted to string dtype:

In [7]: s = pd.Series(['a', 2, np.nan], dtype="string")

In [8]: s
Out[8]:
0  a  
1  2  
2  <NA>

dtype: string

In [9]: type(s[1])
Out[9]: str

or convert from existing pandas data:

In [10]: s1 = pd.Series([1, 2, np.nan], dtype="Int64")

In [11]: s1
Out[11]:
0  1
1  2  
2  <NA>

dtype: Int64
In [12]: s2 = s1.astype("string")

In [13]: s2
Out[13]:
0  1  
1  2  
2  <NA>
dtype: string

In [14]: type(s2[0])
Out[14]: str

**Behavior differences**

These are places where the behavior of StringDtype objects differ from object dtype

1. For StringDtype, *string accessor methods* that return numeric output will always return a nullable integer dtype, rather than either int or float dtype, depending on the presence of NA values. Methods returning boolean output will return a nullable boolean dtype.

In [15]: s = pd.Series(["a", None, "b"], dtype="string")

In [16]: s
Out[16]:
0  a  
1  <NA> 
2  b  
dtype: string

In [17]: s.str.count("a")
Out[17]:
0  1  
1  <NA> 
2  0  
dtype: Int64

In [18]: s.dropna().str.count("a")
Out[18]:
0  1  
2  0  
dtype: Int64

Both outputs are Int64 dtype. Compare that with object-dtype

In [19]: s2 = pd.Series(["a", None, "b"], dtype="object")

In [20]: s2.str.count("a")
Out[20]:
0  1.0  
1  NaN  
2  0.0  
dtype: float64

In [21]: s2.dropna().str.count("a")
Out[21]:
(continues on next page)
When NA values are present, the output dtype is float64. Similarly for methods returning boolean values.

```python
In [22]: s.str.isdigit()
Out[22]:
0   False
1    <NA>
2   False
dtype: boolean

In [23]: s.str.match("a")
Out[23]:
0   True
1    <NA>
2   False
dtype: boolean
```

2. Some string methods, like `Series.str.decode()` are not available on `StringArray` because `StringArray` only holds strings, not bytes.

3. In comparison operations, `arrays.StringArray` and `Series` backed by a `StringArray` will return an object with `BooleanDtype`, rather than a `bool` dtype object. Missing values in a `StringArray` will propagate in comparison operations, rather than always comparing unequal like `numpy.nan`.

Everything else that follows in the rest of this document applies equally to `string` and `object` dtype.

### 2.9.2 String methods

Series and Index are equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the `str` attribute and generally have names matching the equivalent (scalar) built-in string methods:

```python
In [24]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'],
                      dtype="string")

In [25]: s.str.lower()
Out[25]:
0    a
1    b
2    c
3   aaba
4   baca
5    <NA>
6    caba
7    dog
8     cat
dtype: string

In [26]: s.str.upper()
Out[26]:
0    A
```
1    B
2    C
3   AABA
4    BACA
5      <NA>
6    CABA
7     DOG
8      CAT
dtype: string

In [27]: s.str.len()
Out[27]:
0   1
1   1
2   1
3   4
4   4
5   <NA>
6   4
7   3
8   3
dtype: Int64

In [28]: idx = pd.Index(['jack', 'jill ', ' jesse ', 'frank'])
In [29]: idx.str.strip()
Out[29]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')
In [30]: idx.str.lstrip()
Out[30]: Index(['jack', 'jill ', 'jesse ', 'frank'], dtype='object')
In [31]: idx.str.rstrip()
Out[31]: Index([' jack', 'jill', ' jesse', 'frank'], dtype='object')

The string methods on Index are especially useful for cleaning up or transforming DataFrame columns. For instance, you may have columns with leading or trailing whitespace:

In [32]: df = pd.DataFrame(np.random.randn(3, 2),
    ....:     columns=[' Column A ', ' Column B '], index=range(3))
    ....:

In [33]: df
Out[33]:
     Column A     Column B
0   0.469112  -0.282863
1  -1.509059  -1.135632
2   1.212112  -0.173215

Since df.columns is an Index object, we can use the .str accessor

In [34]: df.columns.str.strip()
Out[34]: Index([' Column A ', ' Column B '], dtype='object')
In [35]: df.columns.str.lower()
Out[35]: Index([' column a ', ' column b '], dtype='object')

These string methods can then be used to clean up the columns as needed. Here we are removing leading and trailing...
whitespaces, lower casing all names, and replacing any remaining whitespaces with underscores:

```python
In [36]: df.columns = df.columns.str.strip().str.lower().str.replace(' ', '_')
In [37]: df
Out[37]:
       column_a  column_b
0  0.469112   -0.282863
1 -1.509059   -1.135632
2  1.212112   -0.173215
```

**Note:** If you have a `Series` where lots of elements are repeated (i.e. the number of unique elements in the `Series` is a lot smaller than the length of the `Series`), it can be faster to convert the original `Series` to one of type `category` and then use `.str.<method>` or `.dt.<property>` on that. The performance difference comes from the fact that, for `Series` of type `category`, the string operations are done on the `.categories` and not on each element of the `Series`.

Please note that a `Series` of type `category` with string `.categories` has some limitations in comparison to `Series` of type string (e.g. you can’t add strings to each other: `s + " " + s` won’t work if `s` is a `Series` of type `category`). Also, `.str` methods which operate on elements of type `list` are not available on such a `Series`.

**Warning:** Before v.0.25.0, the `.str`-accessor did only the most rudimentary type checks. Starting with v.0.25.0, the type of the Series is inferred and the allowed types (i.e. strings) are enforced more rigorously.

Generally speaking, the `.str` accessor is intended to work only on strings. With very few exceptions, other uses are not supported, and may be disabled at a later point.

### 2.9.3 Splitting and replacing strings

Methods like `split` return a `Series` of lists:

```python
In [38]: s2 = pd.Series(['a_b_c', 'c_d_e', np.nan, 'f_g_h'], dtype='string')

In [39]: s2.str.split('_')
Out[39]:
       0    1    2    3
0  [a, b, c]  <NA>  <NA>  <NA>
1  [c, d, e]  <NA>  <NA>  <NA>
2     <NA>  <NA>  <NA>  <NA>
3  [f, g, h]  <NA>  <NA>  <NA>
```

Elements in the split lists can be accessed using `get` or `[]` notation:

```python
In [40]: s2.str.split('_').str.get(1)
Out[40]:
0   b
1   d
2   <NA>
3   g
dtype: object

In [41]: s2.str.split('_').str[1]
Out[41]:
0   b
1   d
2   <NA>
3   g
dtype: object
```

(continues on next page)
It is easy to expand this to return a DataFrame using `expand`.

```
In [42]: s2.str.split('_', expand=True)
Out[42]:
   0   1   2
0   a   b   c
1   c   d   e
2  <NA> <NA> <NA>
3   f   g   h
```

When original `Series` has `StringDtype`, the output columns will all be `StringDtype` as well.

It is also possible to limit the number of splits:

```
In [43]: s2.str.split('_', expand=True, n=1)
Out[43]:
     0   1
0   a b c
1   c d e
2  <NA> <NA>
3   f g h
```

`rsplit` is similar to `split` except it works in the reverse direction, i.e., from the end of the string to the beginning of the string:

```
In [44]: s2.str.rsplit('_', expand=True, n=1)
Out[44]:
     0   1
0  a_b c
1   c_d e
2  <NA> <NA>
3   f g h
```

`replace` by default replaces regular expressions:

```
In [45]: s3 = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca',
...:                   '', np.nan, 'CABA', 'dog', 'cat'],
...:                  dtype='string')

In [46]: s3
Out[46]:
  0    A
  1    B
  2    C
  3   Aaba
  4    Baca
  5 <NA>
  6   CABA
  7    dog
```
Some caution must be taken to keep regular expressions in mind! For example, the following code will cause trouble because of the regular expression meaning of $:

```python
# Consider the following badly formatted financial data
In [48]: dollars = pd.Series(["12", "-$10", "$10,000"], dtype="string")

# This does what you'd naively expect:
In [49]: dollars.str.replace('$', '')
Out[49]:
0  12
1 -10
2 10,000
dtype: string

# But this doesn't:
In [50]: dollars.str.replace('-$', '-')
Out[50]:
0  12
1  -$10
2 $10,000
dtype: string

# We need to escape the special character (for >1 len patterns)
In [51]: dollars.str.replace(r'\$', '-')
Out[51]:
0  12
1  -$10
2 $10,000
dtype: string
```

New in version 0.23.0.

If you do want literal replacement of a string (equivalent to `str.replace()`), you can set the optional `regex` parameter to `False`, rather than escaping each character. In this case both `pat` and `repl` must be strings:

```python
# These lines are equivalent
In [52]: dollars.str.replace(r'\$', '-', False)
Out[52]:
0  12
1  -10
2  $10,000
dtype: string
```
The `replace` method can also take a callable as replacement. It is called on every `pat` using `re.sub()`. The callable should expect one positional argument (a regex object) and return a string.

```python
# Reverse every lowercase alphabetic word
In [54]: pat = r'[a-z]+'

In [55]: def repl(m):
       ....:     return m.group(0)[::-1]

In [56]: pd.Series(['foo 123', 'bar baz', np.nan],
       ....:     dtype='string').str.replace(pat, repl)

Out[56]:
0     oof 123
1       rab zab
2       <NA>
```

# Using regex groups
```
In [57]: pat = r'(\w+) (\w+) (\w+)'

In [58]: def repl(m):
       ....:     return m.group('two').swapcase()

In [59]: pd.Series(['Foo Bar Baz', np.nan],
       ....:     dtype='string').str.replace(pat, repl)

Out[59]:
0       bar
1       <NA>
```

The `replace` method also accepts a compiled regular expression object from `re.compile()` as a pattern. All flags should be included in the compiled regular expression object.

```
In [60]: import re

In [61]: regex_pat = re.compile(r'^\w+|dog', flags=re.IGNORECASE)

In [62]: s3.str.replace(regex_pat, 'XX-XX ')
```

(continues on next page)
Including a flags argument when calling replace with a compiled regular expression object will raise a ValueError.

```
In [63]: s3.str.replace(regex_pat, 'XX-XX ', flags=re.IGNORECASE)
---------------------------------------------------------------------------
ValueError: case and flags cannot be set when pat is a compiled regex
```

## 2.9.4 Concatenation

There are several ways to concatenate a `Series` or `Index`, either with itself or others, all based on `cat()`, resp. `Index.str.cat`.

### Concatenating a single Series into a string

The content of a `Series` (or `Index`) can be concatenated:

```
In [64]: s = pd.Series(['a', 'b', 'c', 'd'], dtype="string")
In [65]: s.str.cat(sep=',')
Out[65]: 'a,b,c,d'
```

If not specified, the keyword `sep` for the separator defaults to the empty string, `sep='':`

```
In [66]: s.str.cat()
Out[66]: 'abcd'
```

By default, missing values are ignored. Using `na_rep`, they can be given a representation:

```
In [67]: t = pd.Series(['a', 'b', np.nan, 'd'], dtype="string")
In [68]: t.str.cat(sep=',')
Out[68]: 'a,b,d'
In [69]: t.str.cat(sep=',', na_rep='-',)
Out[69]: 'a,b,-,d'
```
Concatenating a Series and something list-like into a Series

The first argument to `cat()` can be a list-like object, provided that it matches the length of the calling `Series` (or `Index`).

```python
In [70]: s.str.cat(['A', 'B', 'C', 'D'])
Out[70]:
   0   aA
   1   bB
   2   cC
   3   dD
dtype: string
```

Missing values on either side will result in missing values in the result as well, *unless* `na_rep` is specified:

```python
In [71]: s.str.cat(t)
Out[71]:
   0   aa
   1   bb
   2   <NA>
   3   dd
dtype: string
```

```python
In [72]: s.str.cat(t, na_rep='-')
Out[72]:
   0   aa
   1   bb
   2   c-
   3   dd
dtype: string
```

Concatenating a Series and something array-like into a Series

New in version 0.23.0.

The parameter `others` can also be two-dimensional. In this case, the number or rows must match the lengths of the calling `Series` (or `Index`).

```python
In [73]: d = pd.concat([t, s], axis=1)
In [74]: s
Out[74]:
   0   a
   1   b
   2   c
   3   d
dtype: string
```

```python
In [75]: d
Out[75]:
   0  1
   0   a a
   1   b b
   2   <NA> c
   3   d d
```

(continues on next page)
In [76]: s.str.cat(d, na_rep='\'-\')
Out[76]:
  0   aaa
  1   bbb
  2   c-c
  3   ddd
dtype: string

Concatenating a Series and an indexed object into a Series, with alignment

New in version 0.23.0.

For concatenation with a Series or DataFrame, it is possible to align the indexes before concatenation by setting the join-keyword.

In [77]: u = pd.Series(['b', 'd', 'a', 'c'], index=[1, 3, 0, 2],
....:
  ....:   dtype="string")

In [78]: s
Out[78]:
  0   a
  1   b
  2   c
  3   d
dtype: string

In [79]: u
Out[79]:
  1   b
  3   d
  0   a
  2   c
dtype: string

In [80]: s.str.cat(u)
Out[80]:
  0   aa
  1   bb
  2   cc
  3   dd
dtype: string

In [81]: s.str.cat(u, join='left')
Out[81]:
  0   aa
  1   bb
  2   cc
  3   dd
dtype: string

**Warning:** If the join keyword is not passed, the method `cat()` will currently fall back to the behavior before version 0.23.0 (i.e. no alignment), but a `FutureWarning` will be raised if any of the involved indexes differ, since this default will change to `join='left'` in a future version.
The usual options are available for `join` (one of 'left', 'outer', 'inner', 'right'). In particular, alignment also means that the different lengths do not need to coincide anymore.

```
In [82]: v = pd.Series(['z', 'a', 'b', 'd', 'e'], index=[-1, 0, 1, 3, 4],
          ....:          dtype="string")
          ....:

In [83]: s
Out[83]:
   0  a
   1  b
   2  c
   3  d
dtype: string

In [84]: v
Out[84]:
-1  z
  0  a
  1  b
  3  d
  4  e
dtype: string

In [85]: s.str.cat(v, join='left', na_rep='-')
Out[85]:
   0  aa
   1  bb
   2  c-
   3  dd
dtype: string

In [86]: s.str.cat(v, join='outer', na_rep='-',)
Out[86]:
  -1  -z
   0  aa
   1  bb
   2  c-
   3  dd
   4  -e
dtype: string
```

The same alignment can be used when `others` is a DataFrame:

```
In [87]: f = d.loc[[3, 2, 1, 0], :]

In [88]: s
Out[88]:
   0  a
   1  b
   2  c
   3  d
dtype: string

In [89]: f
Out[89]:
   0  1
   3  d
dtype: string
```

(continues on next page)
2  <NA>  c
1   b   b
0   a   a

In [90]: s.str.cat(f, join='left', na_rep='-')
Out[90]:
0   aaa
1   bbb
2   c-c
3   ddd
dtype: string

Concatenating a Series and many objects into a Series

Several array-like items (specifically: Series, Index, and 1-dimensional variants of np.ndarray) can be combined in a list-like container (including iterators, dict-views, etc.).

In [91]: s
Out[91]:
0  a
1  b
2  c
3  d
dtype: string

In [92]: u
Out[92]:
1  b
3  d
0  a
2  c
dtype: string

In [93]: s.str.cat([u, u.to_numpy()], join='left')
Out[93]:
0   aab
1   bbd
2   cca
3   ddc
dtype: string

All elements without an index (e.g. np.ndarray) within the passed list-like must match in length to the calling Series (or Index), but Series and Index may have arbitrary length (as long as alignment is not disabled with join=None):

In [94]: v
Out[94]:
-1  z
0  a
1  b
3  d
4  e
dtype: string

In [95]: s.str.cat([v, u.to_numpy()], join='outer', na_rep='-')
If using `join='right'` on a list-like of `other` that contains different indexes, the union of these indexes will be used as the basis for the final concatenation:

```python
In [96]: u.loc[[3]]
Out[96]:
3  d
dtype: string

In [97]: v.loc[[0, -1]]
Out[97]:
-1  z
  0  a
dtype: string

In [98]: s.str.cat([u.loc[[3]], v.loc[[0, -1]]], join='right', na_rep='--')
Out[98]:
-1  --z
  0  a-a
  3  dd-
dtype: string
```

### 2.9.5 Indexing with `.str`

You can use `[ ]` notation to directly index by position locations. If you index past the end of the string, the result will be a `NaN`.

```python
In [99]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'],
                  dtype='string')
In [100]: s.str[0]
Out[100]:
0  A
1  B
2  C
3  A
4  B
5  <NA>
6  C
7  d
8  c
dtype: string

In [101]: s.str[1]
Out[101]:
0  A
1  B
2  C
3  A
4  B
5  <NA>
6  C
7  d
8  c
dtype: string
```

(continues on next page)
0  <NA>
1  <NA>
2  <NA>
3    a
4    a
5  <NA>
6    A
7    o
8    a
dtype: string

2.9.6 Extracting substrings

Extract first match in each subject \((\text{extract})\)

**Warning:** Before version 0.23, argument \(expand\) of the \texttt{extract} method defaulted to \texttt{False}. When \(expand=False\), \texttt{expand} returns a Series, Index, or DataFrame, depending on the subject and regular expression pattern. When \(expand=True\), it always returns a DataFrame, which is more consistent and less confusing from the perspective of a user. \(expand=True\) has been the default since version 0.23.0.

The \texttt{extract} method accepts a regular expression with at least one capture group.

Extracting a regular expression with more than one group returns a DataFrame with one column per group.

```
In [102]: pd.Series(['a1', 'b2', 'c3'],
                      dtype="string").str.extract(r'([ab])([^\d])', expand=False)
```

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>letter</td>
<td>digit</td>
</tr>
<tr>
<td>0</td>
<td>a 1</td>
</tr>
<tr>
<td>1</td>
<td>b 2</td>
</tr>
<tr>
<td>2 &lt;NA&gt; &lt;NA&gt;</td>
<td></td>
</tr>
</tbody>
</table>

Elements that do not match return a row filled with NaN. Thus, a Series of messy strings can be “converted” into a like-indexed Series or DataFrame of cleaned-up or more useful strings, without necessitating \texttt{get()} to access tuples or \texttt{re.match} objects. The dtype of the result is always object, even if no match is found and the result only contains NaN.

Named groups like

```
In [103]: pd.Series(['a1', 'b2', 'c3'],
                      dtype="string").str.extract(r'(?P<letter>[ab])(?P<digit>[0-9])', expand=False)
```

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>letter</td>
<td>digit</td>
</tr>
<tr>
<td>0</td>
<td>a 1</td>
</tr>
<tr>
<td>1</td>
<td>b 2</td>
</tr>
<tr>
<td>2 &lt;NA&gt; &lt;NA&gt;</td>
<td></td>
</tr>
</tbody>
</table>

and optional groups like
can also be used. Note that any capture group names in the regular expression will be used for column names; otherwise capture group numbers will be used.

Extracting a regular expression with one group returns a DataFrame with one column if expand=True.

```
In [105]: pd.Series(['a1', 'b2', 'c3'],
                dtype='string').str.extract(r'\[ab\](\d)', expand=True)
```

```
Out[105]:
          0
0        1
1        2
2   <NA>
```

It returns a Series if expand=False.

```
In [106]: pd.Series(['a1', 'b2', 'c3'],
                dtype='string').str.extract(r'\[ab\](\d)', expand=False)
```

```
          0 1 2
0   <NA> 1
1  <NA> 2
2   <NA>
dtype: string
```

Calling on an Index with a regex with exactly one capture group returns a DataFrame with one column if expand=True.

```
In [107]: s = pd.Series(['a1', 'b2', 'c3'], ['A11', 'B22', 'C33'],
                    dtype='string')
```

```
In [108]: s
Out[108]:
          0 1 2
A11  a1
B22  b2
C33  c3
dtype: string
```

```
In [109]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=True)
```

```
Out[109]:
     letter
0       A
1       B
2   <NA>
```

It returns an Index if expand=False.
Calling on an `Index` with a regex with more than one capture group returns a `DataFrame` if `expand=True`.

```
In [111]: s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=True)
```

```
Out[111]:
    letter  1
    0    A  11
    1    B  22
    2    C  33
```

It raises `ValueError` if `expand=False`.

```
>>> s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=False)
ValueError: only one regex group is supported with Index
```

The table below summarizes the behavior of `extract(expand=False)` (input subject in first column, number of groups in regex in first row)

<table>
<thead>
<tr>
<th></th>
<th>1 group</th>
<th>&gt;1 group</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Index</code></td>
<td><code>Index</code></td>
<td><code>ValueError</code></td>
</tr>
<tr>
<td><code>Series</code></td>
<td><code>Series</code></td>
<td><code>DataFrame</code></td>
</tr>
</tbody>
</table>

**Extract all matches in each subject (extractall)**

Unlike `extract` (which returns only the first match),

```
In [112]: s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"],
       ....:       dtype="string")
       ....:

In [113]: s
Out[113]:
    A    a1a2
    B    b1
    C    c1
dtype: string

In [114]: two_groups = "(?P<letter>[a-z])(?P<digit>[0-9]+)"

In [115]: s.str.extract(two_groups, expand=True)
Out[115]:
    letter digit
    A    a    1
    B    b    1
    C    c    1
```

the `extractall` method returns every match. The result of `extractall` is always a `DataFrame` with a `MultiIndex` on its rows. The last level of the `MultiIndex` is named `match` and indicates the order in the subject.

```
In [116]: s.str.extractall(two_groups)
```

(continues on next page)
When each subject string in the Series has exactly one match,

```
In [117]: s = pd.Series(['a3', 'b3', 'c2'], dtype='string')
In [118]: s
Out[118]:
0 a
1 b
2 c
dtype: string
```

then `extractall(pat).xs(0, level='match')` gives the same result as `extract(pat)`.

```
In [119]: extract_result = s.str.extract(two_groups, expand=True)
In [120]: extract_result
Out[120]:
   letter digit
0   a   3
1   b   3
2   c   2

In [121]: extractall_result = s.str.extractall(two_groups)
In [122]: extractall_result
Out[122]:
   letter digit
  match
0 0   a   3
1 0   b   3
2 0   c   2
```

Index also supports `.str.extractall`. It returns a DataFrame which has the same result as a Series.str.extractall with a default index (starts from 0).

```
In [124]: pd.Index(['a1a2', 'b1', 'c1']).str.extractall(two_groups)
Out[124]:
   letter digit
  match
0 0   a   1
1 1   a   2
2 0   c   1
```
In [125]: pd.Series(['a1a2', 'b1', 'c1'], dtype='string').str.extractall(two_groups)
Out[125]:
                     letter digit
      match
   0    0  a  1
   1    1  a  2
   1  0  b  1
   2  0  c  1

2.9.7 Testing for strings that match or contain a pattern

You can check whether elements contain a pattern:

In [126]: pattern = r'[0-9][a-z]'

In [127]: pd.Series(['1', '2', '3a', '3b', '03c', '4dx'],
       ...:     dtype='string').str.contains(pattern)

Out[127]:
0    False
1    False
2    True
3    True
4   False
5    True
dtype: bool

Or whether elements match a pattern:

In [128]: pd.Series(['1', '2', '3a', '3b', '03c', '4dx'],
       ...:     dtype='string').str.match(pattern)

Out[128]:
0    False
1    False
2    True
3    True
4   False
5    True
dtype: bool

New in version 1.1.0.

In [129]: pd.Series(['1', '2', '3a', '3b', '03c', '4dx'],
       ...:     dtype='string').str.fullmatch(pattern)

Out[129]:
0    False
1    False
2    True
3    True
4   False
5   False
dtype: bool
Note: The distinction between match, fullmatch, and contains is strictness: fullmatch tests whether the entire string matches the regular expression; match tests whether there is a match of the regular expression that begins at the first character of the string; and contains tests whether there is a match of the regular expression at any position within the string.

The corresponding functions in the re package for these three match modes are re.fullmatch, re.match, and re.search, respectively.

Methods like match, fullmatch, contains, startswith, and endswith take an extra na argument so missing values can be considered True or False:

```
In [130]: s4 = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'],
                        dtype="string")

In [131]: s4.str.contains('A', na=False)
```

```
Out[131]:
0    True
1     False
2     False
3     True
4     False
5     False
6     True
7     False
8     False
dtype: bool
```

### 2.9.8 Creating indicator variables

You can extract dummy variables from string columns. For example if they are separated by a '|':

```
In [132]: s = pd.Series(['a', 'a|b', np.nan, 'a|c'], dtype="string")

In [133]: s.str.get_dummies(sep='|')
```

```
Out[133]:
a  b  c
0  1  0  0
1  1  1  0
2  0  0  0
3  1  0  1
```

String Index also supports get_dummies which returns a MultiIndex.

```
In [134]: idx = pd.Index(['a', 'a|b', np.nan, 'a|c'])

In [135]: idx.str.get_dummies(sep='|')
```

```
Out[135]:
MultiIndex([(1, 0, 0),
            (1, 1, 0),
            (0, 0, 0),
            (1, 0, 1)],
           names=['a', 'b', 'c'])
```
See also `get_dummies()`.

### 2.9.9 Method summary

<table>
<thead>
<tr>

2.10 Working with missing data

In this section, we will discuss missing (also referred to as NA) values in pandas.

**Note:** The choice of using NaN internally to denote missing data was largely for simplicity and performance reasons. Starting from pandas 1.0, some optional data types start experimenting with a native NA scalar using a mask-based approach. See here for more.

See the cookbook for some advanced strategies.

2.10.1 Values considered “missing”

As data comes in many shapes and forms, pandas aims to be flexible with regard to handling missing data. While NaN is the default missing value marker for reasons of computational speed and convenience, we need to be able to easily detect this value with data of different types: floating point, integer, boolean, and general object. In many cases, however, the Python None will arise and we wish to also consider that “missing” or “not available” or “NA”.

**Note:** If you want to consider inf and -inf to be “NA” in computations, you can set pandas.options.mode.use_inf_as_na = True.

```python
In [1]: df = pd.DataFrame(np.random.randn(5, 3), index=['a', 'c', 'e', 'f', 'h'],                  
                  columns=['one', 'two', 'three'])

In [2]: df['four'] = 'bar'

In [3]: df['five'] = df['one'] > 0

In [4]: df

Out[4]:
   one  two  three  four  five
a  0.469112 -0.282863 -1.509059  bar  True
b -1.135632  1.212112 -0.173215  bar  False
c  0.119209 -1.044236 -0.861849  bar  True
d -2.104569 -0.494929  1.071804  bar  False
e  0.721555 -0.706771 -1.039575  bar  True

In [5]: df2 = df.reindex(['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h'])
```

(continues on next page)
In [6]: df2
Out[6]:
    one    two    three    four    five
  a  0.469112  -0.282863  -1.509059  bar  True
  b    NaN       NaN       NaN    NaN    NaN
  c -1.135632   1.212112  -0.173215  bar False
  d    NaN       NaN       NaN    NaN    NaN
  e  0.119209  -1.044236  -0.861849  bar  True
  f -2.104569  -0.494929   1.071804  bar False
  g    NaN       NaN       NaN    NaN    NaN
  h  0.721555  -0.706771  -1.039575  bar  True

To make detecting missing values easier (and across different array dtypes), pandas provides the `isna()` and `notna()` functions, which are also methods on Series and DataFrame objects:

In [7]: df2['one']
Out[7]:
    a    b    c    d    e    f    g    h
Name: one, dtype: float64

In [8]: pd.isna(df2['one'])
Out[8]:
    a    b    c    d    e    f    g    h
Name: one, dtype: bool

In [9]: df2['four'].notna()
Out[9]:
    a    b    c    d    e    f    g    h
Name: four, dtype: bool

In [10]: df2.isna()
Out[10]:
    one    two    three    four    five
Name: False, dtype: float64

(continues on next page)
Warning: One has to be mindful that in Python (and NumPy), the nan’s don’t compare equal, but None’s do. Note that pandas/NumPy uses the fact that np.nan != np.nan, and treats None like np.nan.

```
In [11]: None == None  # noqa: E711
Out[11]: True

In [12]: np.nan == np.nan
Out[12]: False
```

So as compared to above, a scalar equality comparison versus a None/np.nan doesn’t provide useful information.

```
In [13]: df2['one'] == np.nan
Out[13]:
a  False
b  False
c  False
d  False
e  False
f  False
g  False
h  False
Name: one, dtype: bool
```

**Integer dtypes and missing data**

Because NaN is a float, a column of integers with even one missing values is cast to floating-point dtype (see *Support for integer NA* for more). Pandas provides a nullable integer array, which can be used by explicitly requesting the dtype:

```
In [14]: pd.Series([1, 2, np.nan, 4], dtype=pd.Int64Dtype())
Out[14]:
0   1
1   2
2  <NA>
3   4
dtype: Int64
```

Alternatively, the string alias dtype='Int64' (note the capital "I") can be used.

See *Nullable integer data type* for more.
Datetimes

For datetime64[ns] types, NaT represents missing values. This is a pseudo-native sentinel value that can be represented by NumPy in a singular dtype (datetime64[ns]). pandas objects provide compatibility between NaT and NaN.

```python
In [15]: df2 = df.copy()
In [16]: df2['timestamp'] = pd.Timestamp('20120101')
In [17]: df2
Out[17]:
     one   two    three   four   five       timestamp
a  0.469112 -0.282863 -1.509059   bar   True  2012-01-01
b  1.470332  0.121321  1.012315   bar   True  2012-01-01
c  1.590756 -1.891932 -1.502768   bar   True  2012-01-01
d -0.213569  0.123125  2.023152   bar   True  2012-01-01
```

```python
In [18]: df2.loc[['a', 'c', 'h'], ['one', 'timestamp']] = np.nan
In [19]: df2
Out[19]:
     one   two    three   four   five       timestamp
a   NaN -0.282863 -1.509059   bar   True   NaT
b  1.470332  0.121321  1.012315   bar   True  2012-01-01
c   NaN  1.213212 -0.173215   bar False  2012-01-01
d  1.590756 -1.891932 -1.502768   bar   True  2012-01-01
e  0.213569  0.123125  2.023152   bar   True  2012-01-01
```

```python
In [20]: df2.dtypes.value_counts()
Out[20]:
float64    3
datetime64[ns]    1
tbool        1
object       1
dtype: int64
```

### 2.10.2 Inserting missing data

You can insert missing values by simply assigning to containers. The actual missing value used will be chosen based on the dtype.

For example, numeric containers will always use NaN regardless of the missing value type chosen:

```python
In [21]: s = pd.Series([1, 2, 3])
In [22]: s.loc[0] = None
In [23]: s
Out[23]:
0   NaN
1   2.0
2   3.0
dtype: float64
```

Likewise, datetime containers will always use NaT.
For object containers, pandas will use the value given:

```python
In [24]: s = pd.Series(['a', 'b', 'c'])
In [25]: s.loc[0] = None
In [26]: s.loc[1] = np.nan
In [27]: s
Out[27]:
0  None
1  NaN
2   c
dtype: object
```

### 2.10.3 Calculations with missing data

Missing values propagate naturally through arithmetic operations between pandas objects.

```python
In [28]: a
Out[28]:
     one  two
a    NaN -0.282863
c    NaN  1.212112
e  0.119209 -1.044236
f -2.104569 -0.494929
h -2.104569 -0.706771

In [29]: b
Out[29]:
     one  two  three
a    NaN -0.282863 -1.509059
c    NaN  1.212112 -0.173215
e  0.119209 -1.044236 -0.861849
f -2.104569 -0.494929  1.071804
h    NaN -0.706771 -1.039575

In [30]: a + b
Out[30]:
     one  three  two
a    NaN    NaN -0.565727
c    NaN    NaN  2.424224
e  0.238417    NaN -2.088472
f -4.209138    NaN -0.989859
h    NaN    NaN -1.413542
```

The descriptive statistics and computational methods discussed in the data structure overview (and listed here and here) are all written to account for missing data. For example:

- When summing data, NA (missing) values will be treated as zero.
- If the data are all NA, the result will be 0.
- Cumulative methods like `cumsum()` and `cumprod()` ignore NA values by default, but preserve them in the resulting arrays. To override this behaviour and include NA values, use `skipna=False`.  

2.10. Working with missing data

525
In [31]: df
Out[31]:
   one    two    three
a  NaN  -0.282863  -1.509059
c  NaN   1.212112  -0.173215
e  0.119209  -1.044236  -0.861849
f -2.104569  -0.494929   1.071804
h  NaN  -0.706771  -1.039575

In [32]: df['one'].sum()
Out[32]: -1.9853605075978744

In [33]: df.mean(1)
Out[33]:
a   -0.895961
b    0.519449
c   -0.595625
d   -0.509232
e   -0.873173
dtype: float64

In [34]: df.cumsum()
Out[34]:
   one    two    three
a  NaN  -0.282863  -1.509059
c  NaN   0.929249  -1.682273
e  NaN   0.119209  -2.544122
f -1.985361 -0.609917  -1.472318
h  NaN -1.316688  -2.511893

In [35]: df.cumsum(skipna=False)
Out[35]:
   one    two    three
a  NaN  -0.282863  -1.509059
c  NaN   0.929249  -1.682273
e  NaN  -0.114987  -2.544122
f  NaN  -0.609917  -1.472318
h  NaN -1.316688  -2.511893

2.10.4 Sum/prod of empties/nans

**Warning:** This behavior is now standard as of v0.22.0 and is consistent with the default in numpy; previously sum/prod of all-NA or empty Series/DataFrames would return NaN. See v0.22.0 whatstnew for more.

The sum of an empty or all-NA Series or column of a DataFrame is 0.

In [36]: pd.Series([np.nan]).sum()
Out[36]: 0.0

In [37]: pd.Series([], dtype="float64").sum()
Out[37]: 0.0

The product of an empty or all-NA Series or column of a DataFrame is 1.
2.10.5 NA values in GroupBy

NA groups in GroupBy are automatically excluded. This behavior is consistent with R, for example:

```python
In [40]: df
Out[40]:
   one  two  three
a  NaN -0.282863 -1.509059
b  NaN  1.212112 -0.173215
c  0.119209 -1.044236 -0.861849
d -2.104569 -0.494929  1.071804
e  NaN -0.706771 -1.039575

In [41]: df.groupby('one').mean()
Out[41]:
   two    three
   one
-2.104569 -0.494929  1.071804
0.119209 -1.044236 -0.861849
```

See the groupby section [here](#) for more information.

**Cleaning / filling missing data**

Pandas objects are equipped with various data manipulation methods for dealing with missing data.

2.10.6 Filling missing values: fillna

`fillna()` can “fill in” NA values with non-NA data in a couple of ways, which we illustrate:

**Replace NA with a scalar value**

```python
In [42]: df2
Out[42]:
   one  two  three  four  five  timestamp
a  NaN -0.282863 -1.509059  bar  True  NaNT
b  NaN  1.212112 -0.173215  bar  False  NaNT
c  0.119209 -1.044236 -0.861849  bar  True  2012-01-01
d -2.104569 -0.494929  1.071804  bar  False  2012-01-01
h  NaN -0.706771 -1.039575  bar  True  NaNT

In [43]: df2.fillna(0)
Out[43]:
   one  two  three  four  five  timestamp
a  0.000000 -0.282863 -1.509059  bar  True   0
b  1.212112 -0.173215  NaN  bar  False   0
c  0.119209 -1.044236 -0.861849  bar  True  2012-01-01 00:00:00
d -2.104569 -0.494929  1.071804  bar  False  2012-01-01 00:00:00
```

(continues on next page)
Fill gaps forward or backward

Using the same filling arguments as reindexing, we can propagate non-NA values forward or backward:

```python
In [45]: df
Out[45]:
     one       two       three
a  NaN -0.282863 -1.509059
b  NaN  1.212112  -0.173215
c  NaN -1.044236 -0.861849
d  NaN  0.499492  1.071804
e  NaN  1.212112  -0.173215
f  NaN  0.499492  1.071804
g  NaN  0.706771  -1.039575
h  NaN  0.706771  -1.039575
```

```python
In [46]: df.fillna(method='pad')
Out[46]:
     one       two       three
a  NaN -0.282863 -1.509059
b  NaN  1.212112  -0.173215
c  NaN  1.044236  -0.861849
d  NaN  0.499492   1.071804
e  NaN  1.212112  -0.173215
f  NaN  0.499492  -1.071804
g  NaN  0.706771  -1.039575
h  NaN  0.706771  -1.039575
```

Limit the amount of filling

If we only want consecutive gaps filled up to a certain number of data points, we can use the limit keyword:

```python
In [47]: df
Out[47]:
     one       two       three
a  NaN -0.282863 -1.509059
b  NaN  1.212112  -0.173215
c  NaN -1.044236 -0.861849
d  NaN  0.499492  1.071804
e  NaN  1.212112  -0.173215
f  NaN  0.499492  -1.071804
g  NaN  0.706771  -1.039575

In [48]: df.fillna(method='pad', limit=1)
Out[48]:
     one       two       three
a  NaN -0.282863 -1.509059
b  NaN  1.212112  -0.173215
c  NaN  1.044236  -0.861849
d  NaN  0.499492  1.071804
e  NaN  1.212112  -0.173215
f  NaN  0.499492  -1.071804
g  NaN  0.706771  -1.039575
h  NaN  0.706771  -1.039575
```

To remind you, these are the available filling methods:
With time series data, using pad/ffill is extremely common so that the “last known value” is available at every time point.

`ffill()` is equivalent to `fillna(method='ffill')` and `bfill()` is equivalent to `fillna(method='bfill')`

### 2.10.7 Filling with a PandasObject

You can also fillna using a dict or Series that is alignable. The labels of the dict or index of the Series must match the columns of the frame you wish to fill. The use case of this is to fill a DataFrame with the mean of that column.

```
In [49]: dff = pd.DataFrame(np.random.randn(10, 3), columns=list('ABC'))
In [50]: dff.iloc[3:5, 0] = np.nan
In [51]: dff.iloc[4:6, 1] = np.nan
In [52]: dff.iloc[5:8, 2] = np.nan
In [53]: dff
Out[53]:
    A      B      C
0  0.271860 -0.424972  0.567020
1  0.276232 -1.087401 -0.673690
2  0.113648 -1.478427  0.524988
3  NaN       0.577046 -1.715002
4  NaN       NaN       NaN
5  -1.344312 NaN       -1.157892
6  -0.109050  1.643563  NaN
7  0.357021  -0.674600  NaN
8  -0.968914 -1.294524  0.413738
9  0.276662  -0.472035 -0.013960

In [54]: dff.fillna(dff.mean())
Out[54]:
    A      B      C
0  0.271860 -0.424972  0.567020
1  0.276232 -1.087401 -0.673690
2  0.113648 -1.478427  0.524988
3  -0.140857  0.577046 -1.715002
4  -0.140857 -0.401419 -1.157892
5  -1.344312 -0.401419 -0.293543
6  -0.109050  1.643563  NaN
7  0.357021  -0.674600  NaN
8  -0.968914 -1.294524  0.413738
9  0.276662  -0.472035 -0.013960

In [55]: dff.fillna(dff.mean()['B':'C'])
Out[55]:
    A      B      C
0  0.271860 -0.424972  0.567020
```

(continues on next page)
Same result as above, but is aligning the ‘fill’ value which is a Series in this case.

```python
In [56]: dff.where(pd.notna(dff), dff.mean(), axis='columns')
```

```
Out[56]:
     A      B      C
0  0.271860 -0.424972  0.567020
1  0.276232 -1.087401 -0.673690
2  0.113648 -1.478427  0.524988
3 -0.140857  0.577046 -1.715002
4 -0.140857 -0.401419 -1.157892
5 -1.344312 -0.401419 -0.293543
6 -0.109050  1.643563 -0.293543
7  0.357021 -0.674600 -0.293543
8 -0.968914 -1.294524  0.413738
9  0.276662 -0.472035 -0.013960
```

2.10.8 Dropping axis labels with missing data: dropna

You may wish to simply exclude labels from a data set which refer to missing data. To do this, use `dropna()`:

```python
In [57]: df
```

```
Out[57]:
     one      two      three
a NaN    -0.282863 -1.509059
c NaN    1.212112 -0.173215
e NaN     0.000000    0.000000
f NaN     0.000000    0.000000
h NaN    -0.706771 -1.039575
```

```python
In [58]: df.dropna(axis=0)
```

```
Out[58]:
Empty DataFrame
Columns: [one, two, three]
Index: []
```

```python
In [59]: df.dropna(axis=1)
```

```
Out[59]:
     two      three
a -0.282863 -1.509059
c 1.212112 -0.173215
e 0.000000    0.000000
f 0.000000    0.000000
h -0.706771 -1.039575
```
An equivalent `dropna()` is available for Series. DataFrame.dropna has considerably more options than Series.dropna, which can be examined in the API.

2.10.9 Interpolation

New in version 0.23.0: The `limit_area` keyword argument was added.

Both Series and DataFrame objects have `interpolate()` that, by default, performs linear interpolation at missing data points.
In [64]: ts.interpolate()
Out[64]:
2000-01-31    0.469112
2000-02-29    0.434469
2000-03-31    0.399826
2000-04-28    0.365184
2000-05-31    0.330541
          ...
2007-12-31   -6.950267
2008-01-31   -7.904475
2008-02-29   -6.441779
2008-03-31   -8.184940
2008-04-30   -9.011531
Freq: BM, Length: 100, dtype: float64

In [65]: ts.interpolate().count()
Out[65]: 100

In [66]: ts.interpolate().plot()
Out[66]: <AxesSubplot:>

Chapter 2. User Guide
Index aware interpolation is available via the method keyword:

```
In [67]: ts2
Out[67]:
2000-01-31    0.469112
2000-02-29     NaN
2002-07-31    -5.785037
2005-01-31     NaN
2008-04-30    -9.011531
dtype: float64

In [68]: ts2.interpolate()
Out[68]:
2000-01-31    0.469112
2000-02-29   -2.657962
2002-07-31    -5.785037
2005-01-31   -7.398284
2008-04-30   -9.011531
dtype: float64

In [69]: ts2.interpolate(method='time')
Out[69]:
2000-01-31    0.469112
2000-02-29    0.270241
2002-07-31   -5.785037
```

(continues on next page)
For a floating-point index, use `method='values'`:

```
In [70]: ser
Out[70]:
0.0  0.0
1.0  NaN
10.0 10.0
dtype: float64

In [71]: ser.interpolate()
Out[71]:
0.0  0.0
1.0  5.0
10.0 10.0
dtype: float64

In [72]: ser.interpolate(method='values')
Out[72]:
0.0  0.0
1.0  1.0
10.0 10.0
dtype: float64
```

You can also interpolate with a DataFrame:

```
In [73]: df = pd.DataFrame({'A': [1, 2.1, np.nan, 4.7, 5.6, 6.8],
                       'B': [.25, np.nan, np.nan, 4, 12.2, 14.4]})

In [74]: df
Out[74]:
   A    B
0  1.0  0.25
1  2.1  NaN
2  NaN  NaN
3  4.7  4.00
4  5.6  12.20
5  6.8  14.40

In [75]: df.interpolate()
Out[75]:
   A    B
0  1.0  0.25
1  2.1  1.50
2  3.4  2.75
3  4.7  4.00
4  5.6  12.20
5  6.8  14.40
```

The `method` argument gives access to fancier interpolation methods. If you have `scipy` installed, you can pass the name of a 1-d interpolation routine to `method`. You’ll want to consult the full scipy interpolation documentation and reference guide for details. The appropriate interpolation method will depend on the type of data you are working with.
• If you are dealing with a time series that is growing at an increasing rate, `method='quadratic'` may be appropriate.
• If you have values approximating a cumulative distribution function, then `method='pchip'` should work well.
• To fill missing values with goal of smooth plotting, consider `method='akima'`.

**Warning:** These methods require `scipy`.

```python
In [76]: df.interpolate(method='barycentric')
Out[76]:
   A    B
0  1.0  0.250
1  2.1 -7.660
2  3.5 -4.515
3  4.7  4.000
4  5.6 12.200
5  6.8 14.400
```

```python
In [77]: df.interpolate(method='pchip')
Out[77]:
   A     B
0 1.000 0.2500
1 2.100 0.6728
2 3.435 1.9289
3 4.700 4.0000
4 5.600 12.2000
5 6.800 14.4000
```

```python
In [78]: df.interpolate(method='akima')
Out[78]:
   A     B
0 1.000 0.2500
1 2.100 -0.8733
2 3.407 0.3200
3 4.700 4.0000
4 5.600 12.2000
5 6.800 14.4000
```

When interpolating via a polynomial or spline approximation, you must also specify the degree or order of the approximation:

```python
In [79]: df.interpolate(method='spline', order=2)
Out[79]:
   A     B
0 1.000 0.2500
1 2.100 -0.4286
2 3.407 1.2070
3 4.700 4.0000
4 5.600 12.2000
5 6.800 14.4000
```

```python
In [80]: df.interpolate(method='polynomial', order=2)
Out[80]:
   A     B
```

(continues on next page)
Compare several methods:

```python
In [81]: np.random.seed(2)
In [82]: ser = pd.Series(np.arange(1, 10.1, 0.25) ** 2 + np.random.randn(37))
In [83]: missing = np.array([4, 13, 14, 15, 16, 17, 18, 20, 29])
In [84]: ser[missing] = np.nan
In [85]: methods = ['linear', 'quadratic', 'cubic']
In [86]: df = pd.DataFrame({m: ser.interpolate(method=m) for m in methods})
In [87]: df.plot()
Out[87]: <AxesSubplot:>
```

Another use case is interpolation at new values. Suppose you have 100 observations from some distribution. And let's
suppose that you’re particularly interested in what’s happening around the middle. You can mix pandas’ `reindex` and `interpolate` methods to interpolate at the new values.

```python
In [88]: ser = pd.Series(np.sort(np.random.uniform(size=100)))

# interpolate at new_index
In [89]: new_index = ser.index | pd.Index([49.25, 49.5, 49.75, 50.25, 50.5, 50.75])

In [90]: interp_s = ser.reindex(new_index).interpolate(method='pchip')

In [91]: interp_s[49:51]
Out[91]:
49.00  0.471410
49.25  0.476841
49.50  0.481780
49.75  0.485998
50.00  0.489266
50.25  0.491814
50.50  0.493995
50.75  0.495763
51.00  0.497074
dtype: float64
```

### Interpolation limits

Like other pandas fill methods, `interpolate()` accepts a `limit` keyword argument. Use this argument to limit the number of consecutive NaN values filled since the last valid observation:

```python
In [92]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan, np.nan, 13, np.nan, np.nan])

In [93]: ser
Out[93]:
0    NaN
1    NaN
2     5.0
3    NaN
4    NaN
5    NaN
6    13.0
7    NaN
8    NaN
dtype: float64

# fill all consecutive values in a forward direction
In [94]: ser.interpolate()
Out[94]:
0    NaN
1    NaN
2     5.0
3     7.0
4     9.0
5    11.0
6    13.0
7    13.0
(continues on next page)```
# fill one consecutive value in a forward direction
In [95]: ser.interpolate(limit=1)
Out[95]:
0   NaN
1   NaN
2   5.0
3   7.0
4   NaN
5   NaN
6   13.0
7   13.0
8   NaN
dtype: float64

By default, NaN values are filled in a forward direction. Use limit_direction parameter to fill backward or from both directions.

# fill one consecutive value backwards
In [96]: ser.interpolate(limit=1, limit_direction='backward')
Out[96]:
0   NaN
1   5.0
2   5.0
3   NaN
4   NaN
5   11.0
6   13.0
7   NaN
8   NaN
dtype: float64

# fill one consecutive value in both directions
In [97]: ser.interpolate(limit=1, limit_direction='both')
Out[97]:
0   NaN
1   5.0
2   5.0
3   7.0
4   NaN
5   11.0
6   13.0
7   13.0
8   NaN
dtype: float64

# fill all consecutive values in both directions
In [98]: ser.interpolate(limit_direction='both')
Out[98]:
0   5.0
1   5.0
2   5.0
3   7.0
4   9.0
(continues on next page)
By default, NaN values are filled whether they are inside (surrounded by) existing valid values, or outside existing valid values. Introduced in v0.23 the limit_area parameter restricts filling to either inside or outside values.

```python
# fill one consecutive inside value in both directions
In [99]: ser.interpolate(limit_direction='both', limit_area='inside', limit=1)
Out[99]:
0   NaN
1   NaN
2    5.0
3    7.0
4   NaN
5   NaN
6   NaN
7   NaN
8   NaN
dtype: float64
```

```python
# fill all consecutive outside values backward
In [100]: ser.interpolate(limit_direction='backward', limit_area='outside')
Out[100]:
0    5.0
1    5.0
2    5.0
3   NaN
4   NaN
5   NaN
6   13.0
7   NaN
8   NaN
dtype: float64
```

```python
# fill all consecutive outside values in both directions
In [101]: ser.interpolate(limit_direction='both', limit_area='outside')
Out[101]:
0    5.0
1    5.0
2    5.0
3   NaN
4   NaN
5   NaN
6   13.0
7   13.0
8   13.0
dtype: float64
```
2.10.10 Replacing generic values

Often times we want to replace arbitrary values with other values. `replace()` in Series and `replace()` in DataFrame provides an efficient yet flexible way to perform such replacements.

For a Series, you can replace a single value or a list of values by another value:

```
In [102]: ser = pd.Series([0., 1., 2., 3., 4.])
In [103]: ser.replace(0, 5)
Out[103]:
0    5.0
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

You can replace a list of values by a list of other values:

```
In [104]: ser.replace([0, 1, 2, 3, 4], [4, 3, 2, 1, 0])
Out[104]:
0    4.0
1    3.0
2    2.0
3    1.0
4    0.0
dtype: float64
```

You can also specify a mapping dict:

```
In [105]: ser.replace({0: 10, 1: 100})
Out[105]:
0   10.0
1  100.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

For a DataFrame, you can specify individual values by column:

```
In [106]: df = pd.DataFrame({'a': [0, 1, 2, 3, 4], 'b': [5, 6, 7, 8, 9]})
In [107]: df.replace({'a': 0, 'b': 5}, 100)
Out[107]:
   a  b
0  100 100
1   1   6
2   2   7
3   3   8
4   4   9
```

Instead of replacing with specified values, you can treat all given values as missing and interpolate over them:
2.10.11 String/regular expression replacement

**Note:** Python strings prefixed with the `r` character such as `r'hello world'` are so-called “raw” strings. They have different semantics regarding backslashes than strings without this prefix. Backslashes in raw strings will be interpreted as an escaped backslash, e.g., `r'\'` == `'\'`. You should read about them if this is unclear.

Replace the `.` with NaN (str -> str):

```python
In [109]: d = {'a': list(range(4)), 'b': list('ab..'), 'c': ['a', 'b', np.nan, 'd']}
In [110]: df = pd.DataFrame(d)
In [111]: df.replace('.', np.nan)
```

Now do it with a regular expression that removes surrounding whitespace (regex -> regex):

```python
In [112]: df.replace(r'\s*\.', np.nan, regex=True)
```

Replace a few different values (list -> list):

```python
In [113]: df.replace(['a', '.'], ['b', np.nan])
```

list of regex -> list of regex:

```python
In [114]: df.replace(['r'\'.', r'(a)'], ['dot', r'\1stuff'], regex=True)
```
Only search in column 'b' (dict -> dict):

```
In [115]: df.replace({'b': '.'}, {'b': np.nan})
Out[115]:
   a  b  c
0  0    a    a
1  1    b    b
2  2   NaN  NaN
3  3   NaN    d
```

Same as the previous example, but use a regular expression for searching instead (dict of regex -> dict):

```
In [116]: df.replace({'b': r'\s*\.\s*'}, {'b': np.nan}, regex=True)
Out[116]:
   a  b  c
0  0    a    a
1  1    b    b
2  2   NaN  NaN
3  3   NaN    d
```

You can pass nested dictionaries of regular expressions that use regex=True:

```
In [117]: df.replace({'b': {'b': r''}}, regex=True)
Out[117]:
   a  b  c
0  0    a    a
1  1    .    b
2  2  NaN  NaN
3  3  NaN    d
```

Alternatively, you can pass the nested dictionary like so:

```
In [118]: df.replace(regex={'b': {r'\s*\.\s*': np.nan}})
Out[118]:
   a  b  c
0  0    a    a
1  1    b    b
2  2  NaN  NaN
3  3  NaN    d
```

You can also use the group of a regular expression match when replacing (dict of regex -> dict of regex), this works for lists as well.

```
In [119]: df.replace({'b': r'\s*\(\\)\s*'}, {'b': r'\1ty'}, regex=True)
Out[119]:
   a  b  c
0  0    a    a
1  1    b  .ty
2  2  .ty  NaN
3  3  .ty    d
```
You can pass a list of regular expressions, of which those that match will be replaced with a scalar (list of regex -> regex).

```
In [120]: df.replace([r'\s*\.\s*', r'a|b'], np.nan, regex=True)
Out[120]:
   a  b  c
0  NaN NaN
1  NaN NaN
2  NaN NaN
3  3  NaN  d
```

All of the regular expression examples can also be passed with the `to_replace` argument as the `regex` argument. In this case the `value` argument must be passed explicitly by name or `regex` must be a nested dictionary. The previous example, in this case, would then be:

```
In [121]: df.replace(regex=[r'\s*\.\s*', r'a|b'], value=np.nan)
Out[121]:
   a  b  c
0  NaN NaN
1  NaN NaN
2  NaN NaN
3  3  NaN  d
```

This can be convenient if you do not want to pass `regex=True` every time you want to use a regular expression.

**Note:** Anywhere in the above `replace` examples that you see a regular expression a compiled regular expression is valid as well.

### 2.10.12 Numeric replacement

`replace()` is similar to `fillna()`.

```
In [122]: df = pd.DataFrame(np.random.randn(10, 2))
In [123]: df[np.random.rand(df.shape[0]) > 0.5] = 1.5
In [124]: df.replace(1.5, np.nan)
Out[124]:
     0  1
[0] NaN NaN
[1] NaN NaN
[2] NaN NaN
[3] NaN NaN
[4] -0.844214 -1.021415
[5] 0.432396 -0.323580
[6] 0.423825 0.799180
[7] 1.262614 0.751965
[8] NaN NaN
[9] NaN NaN
```

Replacing more than one value is possible by passing a list.

```
In [125]: df00 = df.iloc[0, 0]
```

(continues on next page)
In [126]: df.replace([1.5, df00], [np.nan, 'a'])
Out[126]:
     0   1
0    a  -1.02141
1  0.432396 -0.32358
2  0.423825  0.79918
3  1.26261  0.751965
4  NaN    NaN
5  NaN    NaN
6 -0.498174 -1.0608
7  0.591667 -0.183257
8  1.01985 -1.48247
9  NaN    NaN

In [127]: df[1].dtype
Out[127]: dtype('float64')

You can also operate on the DataFrame in place:

In [128]: df.replace(1.5, np.nan, inplace=True)

Warning: When replacing multiple bool or datetime64 objects, the first argument to replace (to_replace) must match the type of the value being replaced. For example,

>>> s = pd.Series([True, False, True])
>>> s.replace({'a string': 'new value', True: False}) # raises
TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'

will raise a TypeError because one of the dict keys is not of the correct type for replacement.

However, when replacing a single object such as,

In [129]: s = pd.Series([True, False, True])

In [130]: s.replace('a string', 'another string')
Out[130]:
0    True
1    False
2    True
dtype: bool

the original NDFrame object will be returned untouched. We’re working on unifying this API, but for backwards compatibility reasons we cannot break the latter behavior. See GH6354 for more details.
Missing data casting rules and indexing

While pandas supports storing arrays of integer and boolean type, these types are not capable of storing missing data. Until we can switch to using a native NA type in NumPy, we’ve established some “casting rules”. When a reindexing operation introduces missing data, the Series will be cast according to the rules introduced in the table below.

<table>
<thead>
<tr>
<th>data type</th>
<th>Cast to</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>float</td>
</tr>
<tr>
<td>boolean</td>
<td>object</td>
</tr>
<tr>
<td>float</td>
<td>no cast</td>
</tr>
<tr>
<td>object</td>
<td>no cast</td>
</tr>
</tbody>
</table>

For example:

```python
In [131]: s = pd.Series(np.random.randn(5), index=[0, 2, 4, 6, 7])
In [132]: s > 0
Out[132]:
0  True
2  True
4  True
6  True
7  True
dtype: bool
In [133]: (s > 0).dtype
Out[133]: dtype('bool')
In [134]: crit = (s > 0).reindex(list(range(8)))
In [135]: crit
Out[135]:
0   True
1   NaN
2   True
3   NaN
4   True
5   NaN
6   True
7   True
dtype: object
In [136]: crit.dtype
Out[136]: dtype('O')
```

Ordinarily NumPy will complain if you try to use an object array (even if it contains boolean values) instead of a boolean array to get or set values from an ndarray (e.g. selecting values based on some criteria). If a boolean vector contains NAs, an exception will be generated:

```python
In [137]: reindexed = s.reindex(list(range(8))).fillna(0)
In [138]: reindexed[crit]
---------------------------------------------------------------------------
ValueError
Traceback (most recent call last)
<ipython-input-138-0dac417a4890> in <module>
-----> 1 reindexed[crit]
TypeError: can't compare type object to float

ValueError: can't compare type object to float
```

(continues on next page)
However, these can be filled in using \texttt{fillna()} and it will work fine:

```
In [139]: reindexed[crit.fillna(False)]
Out[139]:
0    0.126504
1    0.000000
2    0.696198
3    0.000000
4    0.697416
5    0.000000
6    0.601516
7    0.003659
dtype: float64
```

```
In [140]: reindexed[crit.fillna(True)]
Out[140]:
0    0.126504
1    0.000000
2    0.696198
3    0.000000
4    0.697416
5    0.000000
6    0.601516
7    0.003659
dtype: float64
```

Pandas provides a nullable integer dtype, but you must explicitly request it when creating the series or column. Notice that we use a capital “I” in the \texttt{dtype=“Int64”}.

```
In [141]: s = pd.Series([0, 1, np.nan, 3, 4], dtype="Int64")
```

```
In [142]: s
Out[142]:
0    0
1    1
2    <NA>
3    3
4    4
dtype: Int64
```

See \texttt{Nullable integer data type} for more.
### 2.10.13 Experimental NA scalar to denote missing values

**Warning:** Experimental: the behaviour of `pd.NA` can still change without warning.

New in version 1.0.0.

Starting from pandas 1.0, an experimental `pd.NA` value (singleton) is available to represent scalar missing values. At this moment, it is used in the nullable `integer`, boolean and `dedicated string` data types as the missing value indicator.

The goal of `pd.NA` is provide a “missing” indicator that can be used consistently across data types (instead of `np.nan`, `None` or `pd.NaT` depending on the data type).

For example, when having missing values in a Series with the nullable integer dtype, it will use `pd.NA`:

```python
In [143]: s = pd.Series([1, 2, None], dtype="Int64")
In [144]: s
Out[144]:
0    1
1    2
2    <NA>
dtype: Int64

In [145]: s[2]
Out[145]: <NA>

In [146]: s[2] is pd.NA
Out[146]: True
```

Currently, pandas does not yet use those data types by default (when creating a DataFrame or Series, or when reading in data), so you need to specify the dtype explicitly. An easy way to convert to those dtypes is explained [here](#).

**Propagation in arithmetic and comparison operations**

In general, missing values *propagate* in operations involving `pd.NA`. When one of the operands is unknown, the outcome of the operation is also unknown.

For example, `pd.NA` propagates in arithmetic operations, similarly to `np.nan`:

```python
In [147]: pd.NA + 1
Out[147]: <NA>

In [148]: "a" * pd.NA
Out[148]: <NA>
```

There are a few special cases when the result is known, even when one of the operands is `NA`.

```python
In [149]: pd.NA ** 0
Out[149]: 1

In [150]: 1 ** pd.NA
Out[150]: 1
```

In equality and comparison operations, `pd.NA` also propagates. This deviates from the behaviour of `np.nan`, where comparisons with `np.nan` always return `False`.  

---

2.10. Working with missing data 547
In [151]: pd.NA == 1
Out[151]: <NA>

In [152]: pd.NA == pd.NA
Out[152]: <NA>

In [153]: pd.NA < 2.5
Out[153]: <NA>

To check if a value is equal to pd.NA, the `isna()` function can be used:

In [154]: pd.isna(pd.NA)
Out[154]: True

An exception on this basic propagation rule are reductions (such as the mean or the minimum), where pandas defaults to skipping missing values. See above for more.

Logical operations

For logical operations, `pd.NA` follows the rules of the three-valued logic (or Kleene logic, similarly to R, SQL and Julia). This logic means to only propagate missing values when it is logically required.

For example, for the logical “or” operation (`|`), if one of the operands is True, we already know the result will be True, regardless of the other value (so regardless the missing value would be True or False). In this case, `pd.NA` does not propagate:

In [155]: True | False
Out[155]: True

In [156]: True | pd.NA
Out[156]: True

In [157]: pd.NA | True
Out[157]: True

On the other hand, if one of the operands is False, the result depends on the value of the other operand. Therefore, in this case `pd.NA` propagates:

In [158]: False | True
Out[158]: True

In [159]: False | False
Out[159]: False

In [160]: False | pd.NA
Out[160]: <NA>

The behaviour of the logical “and” operation (`&`) can be derived using similar logic (where now `pd.NA` will not propagate if one of the operands is already False):

In [161]: False & True
Out[161]: False

In [162]: False & False
Out[162]: False

(continues on next page)
NA in a boolean context

Since the actual value of an NA is unknown, it is ambiguous to convert NA to a boolean value. The following raises an error:

```
In [167]: bool(pd.NA)
---------------------------------------------------------------------------
TypeError                      Traceback (most recent call last)
<ipython-input-167-5477a57d5abb> in <module>
----> 1 bool(pd.NA)
/pandas/pandas/_libs/missing.pyx in pandas._libs.missing.NAType.__bool__()

TypeError: boolean value of NA is ambiguous
```

This also means that `pd.NA` cannot be used in a context where it is evaluated to a boolean, such as if `condition:` ... where `condition` can potentially be `pd.NA`. In such cases, `isna()` can be used to check for `pd.NA` or `condition` being `pd.NA` can be avoided, for example by filling missing values beforehand.

A similar situation occurs when using Series or DataFrame objects in if statements, see Using if/truth statements with pandas.

NumPy ufuncs

`pandas.NA` implements NumPy’s `__array_ufunc__` protocol. Most ufuncs work with NA, and generally return NA:

```
In [168]: np.log(pd.NA)
Out[168]: <NA>

In [169]: np.add(pd.NA, 1)
Out[169]: <NA>
```

**Warning:** Currently, ufuncs involving an ndarray and `NA` will return an object-dtype filled with NA values.

```
In [170]: a = np.array([1, 2, 3])

In [171]: np.greater(a, pd.NA)
Out[171]: array([<NA>, <NA>, <NA>], dtype=object)
```

The return type here may change to return a different array type in the future.

2.10. Working with missing data 549
Conversion

If you have a DataFrame or Series using traditional types that have missing data represented using `np.nan`, there are convenience methods `convert_dtypes()` in Series and `convert_dtypes()` in DataFrame that can convert data to use the newer dtypes for integers, strings and booleans listed here. This is especially helpful after reading in data sets when letting the readers such as `read_csv()` and `read_excel()` infer default dtypes.

In this example, while the dtypes of all columns are changed, we show the results for the first 10 columns.

```
In [172]: bb = pd.read_csv('data/baseball.csv', index_col='id')
In [173]: bb[bb.columns[:10]].dtypes
Out[173]:
player    object
year       int64
stint      int64
team       object
lg         object
g          int64
ab          int64
r           int64
h          int64
X2b        int64
dtype: object
```

```
In [174]: bbn = bb.convert_dtypes()
In [175]: bbn[bbn.columns[:10]].dtypes
Out[175]:
player     string
year       Int64
stint      Int64
team       string
lg          string
g          Int64
ab         Int64
r           Int64
h           Int64
X2b        Int64
dtype: object
```

2.11 Categorical data

This is an introduction to pandas categorical data type, including a short comparison with R’s `factor`.

`Categoricals` are a pandas data type corresponding to categorical variables in statistics. A categorical variable takes on a limited, and usually fixed, number of possible values (categories; levels in R). Examples are gender, social class, blood type, country affiliation, observation time or rating via Likert scales.

In contrast to statistical categorical variables, categorical data might have an order (e.g. ‘strongly agree’ vs ‘agree’ or ‘first observation’ vs. ‘second observation’), but numerical operations (additions, divisions, . . .) are not possible.
All values of categorical data are either in categories or np.nan. Order is defined by the order of categories, not lexical order of the values. Internally, the data structure consists of a categories array and an integer array of codes which point to the real value in the categories array.

The categorical data type is useful in the following cases:

- A string variable consisting of only a few different values. Converting such a string variable to a categorical variable will save some memory, see here.
- The lexical order of a variable is not the same as the logical order (“one”, “two”, “three”). By converting to a categorical and specifying an order on the categories, sorting and min/max will use the logical order instead of the lexical order, see here.
- As a signal to other Python libraries that this column should be treated as a categorical variable (e.g. to use suitable statistical methods or plot types).

See also the API docs on categoricals.

### 2.11.1 Object creation

#### Series creation

Categorical Series or columns in a DataFrame can be created in several ways:

By specifying dtype="category" when constructing a Series:

```python
In [1]: s = pd.Series(["a", "b", "c", "a"], dtype="category")
In [2]: s
Out[2]:
0  a
1  b
2  c
3  a
dtype: category
Categories (3, object): [a', 'b', 'c']
```

By converting an existing Series or column to a category dtype:

```python
In [3]: df = pd.DataFrame({"A": ["a", "b", "c", "a"]})
In [4]: df["B"] = df["A"].astype('category')
In [5]: df
Out[5]:
   A  B
0  a  a
1  b  b
2  c  c
3  a  a
```

By using special functions, such as cut(), which groups data into discrete bins. See the example on tiling in the docs.

```python
In [6]: df = pd.DataFrame({"value": np.random.randint(0, 100, 20)})
In [7]: labels = ["{0} - {1}".format(i, i + 9) for i in range(0, 100, 10)]
```

(continues on next page)
In [8]: df['group'] = pd.cut(df.value, range(0, 105, 10), right=False, labels=labels)

In [9]: df.head(10)
Out[9]:
   value  group
0   65   60 - 69
1   49   40 - 49
2   56   50 - 59
3   43   40 - 49
4   43   40 - 49
5   91   90 - 99
6   32   30 - 39
7   87   80 - 89
8   36   30 - 39
9    8   0 - 9

By passing a `pandas.Categorical` object to a `Series` or assigning it to a `DataFrame`.

In [10]: raw_cat = pd.Categorical(['a', 'b', 'c', 'a'], categories=['b', 'c', 'd'], ordered=False)

In [11]: s = pd.Series(raw_cat)

In [12]: s
Out[12]:
0    NaN
1    b
2    c
3    NaN
dtype: category
Categories (3, object): ['b', 'c', 'd']

In [13]: df = pd.DataFrame({'A': ['a', 'b', 'c', 'a']})

In [14]: df['B'] = raw_cat

In [15]: df
Out[15]:
   A  B
0  a  NaN
1  b  b
2  c  c
3  a  NaN

Categorical data has a specific category `dtype`:

In [16]: df.dtypes
Out[16]:
A  object
B  category
dtype: object
**DataFrame creation**

Similar to the previous section where a single column was converted to categorical, all columns in a DataFrame can be batch converted to categorical either during or after construction.

This can be done during construction by specifying `dtype="category"` in the DataFrame constructor:

```python
In [17]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')}, dtype="category")
In [18]: df.dtypes
Out[18]:
A category
B category
dtype: object
```

Note that the categories present in each column differ; the conversion is done column by column, so only labels present in a given column are categories:

```python
In [19]: df['A']
Out[19]:
0   a
1   b
2   c
3   a
Name: A, dtype: category
Categories (3, object): ['a', 'b', 'c']
```

```python
In [20]: df['B']
Out[20]:
0   b
1   c
2   c
3   d
Name: B, dtype: category
Categories (3, object): ['b', 'c', 'd']
```

New in version 0.23.0.

Analogously, all columns in an existing DataFrame can be batch converted using `DataFrame.astype()`:

```python
In [21]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})
In [22]: df_cat = df.astype('category')
In [23]: df_cat.dtypes
Out[23]:
A category
B category
dtype: object
```

This conversion is likewise done column by column:

```python
In [24]: df_cat['A']
Out[24]:
0   a
1   b
2   c
3   a
```

(continues on next page)
Name: A, dtype: category
Categories (3, object): ['a', 'b', 'c']

In [25]: df_cat['B']
Out[25]:
   0  b
   1  c
   2  c
   3  d
Name: B, dtype: category
Categories (3, object): ['b', 'c', 'd']

**Controlling behavior**

In the examples above where we passed `dtype='category'`, we used the default behavior:

1. Categories are inferred from the data.
2. Categories are unordered.

To control those behaviors, instead of passing 'category', use an instance of `CategoricalDtype`.

```python
In [26]: from pandas.api.types import CategoricalDtype
In [27]: s = pd.Series(['a', 'b', 'c', 'a'])
In [28]: cat_type = CategoricalDtype(categories=['b', 'c', 'd'], ordered=True)
In [29]: s_cat = s.astype(cat_type)
In [30]: s_cat
Out[30]:
   0  NaN
   1  b
   2  c
   3  NaN
dtype: category
Categories (3, object): ['b' < 'c' < 'd']
```

Similarly, a `CategoricalDtype` can be used with a DataFrame to ensure that categories are consistent among all columns.

```python
In [31]: from pandas.api.types import CategoricalDtype
In [32]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})
In [33]: cat_type = CategoricalDtype(categories=list('abcd'), ordered=True)
In [34]: df_cat = df.astype(cat_type)
In [35]: df_cat['A']
```

(continues on next page)
2.11. Categorical data

Note: To perform table-wise conversion, where all labels in the entire DataFrame are used as categories for each column, the categories parameter can be determined programmatically by categories = pd.unique(df.to_numpy().ravel()).

If you already have codes and categories, you can use the from_codes() constructor to save the factorize step during normal constructor mode:

Regaining original data

To get back to the original Series or NumPy array, use Series.astype(original_dtype) or np.asarray(categorical):

(continues on next page)
Categories (3, object): ['a', 'b', 'c']

In [43]: s2.astype(str)
Out[43]:
0  a
1  b
2  c
3  a
dtype: object

In [44]: np.asarray(s2)
Out[44]: array(['a', 'b', 'c', 'a'], dtype=object)

**Note:** In contrast to R’s `factor` function, categorical data is not converting input values to strings; categories will end up the same data type as the original values.

**Note:** In contrast to R’s `factor` function, there is currently no way to assign/change labels at creation time. Use `categories` to change the categories after creation time.

### 2.11.2 CategoricalDtype

A categorical’s type is fully described by

1. **categories**: a sequence of unique values and no missing values
2. **ordered**: a boolean

This information can be stored in a `CategoricalDtype`. The `categories` argument is optional, which implies that the actual categories should be inferred from whatever is present in the data when the `pandas.Categorical` is created. The categories are assumed to be unordered by default.

In [45]: from pandas.api.types import CategoricalDtype

In [46]: CategoricalDtype(['a', 'b', 'c'])
Out[46]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=False)

In [47]: CategoricalDtype(['a', 'b', 'c'], ordered=True)
Out[47]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=True)

In [48]: CategoricalDtype()
Out[48]: CategoricalDtype(categories=None, ordered=False)

A `CategoricalDtype` can be used in any place pandas expects a `dtype`. For example `pandas.read_csv()`, `pandas.DataFrame.astype()`, or in the `Series` constructor.

**Note:** As a convenience, you can use the string `'category'` in place of a `CategoricalDtype` when you want the default behavior of the categories being unordered, and equal to the set values present in the array. In other words, `dtype='category'` is equivalent to `dtype=CategoricalDtype()`.
Equality semantics

Two instances of CategoricalDtype compare equal whenever they have the same categories and order. When comparing two unordered categoricals, the order of the categories is not considered.

```python
In [49]: c1 = CategoricalDtype(['a', 'b', 'c'], ordered=False)
Out[49]: CategoricalDtype(['a', 'b', 'c'], ordered=False)

# Equal, since order is not considered when ordered=False
In [50]: c1 == CategoricalDtype(['b', 'c', 'a'], ordered=False)
Out[50]: True

# Unequal, since the second CategoricalDtype is ordered
In [51]: c1 == CategoricalDtype(['a', 'b', 'c'], ordered=True)
Out[51]: False
```

All instances of CategoricalDtype compare equal to the string 'category'.

```python
In [52]: c1 == 'category'
Out[52]: True
```

**Warning:** Since dtype='category' is essentially CategoricalDtype(None, False), and since all instances CategoricalDtype compare equal to 'category', all instances of CategoricalDtype compare equal to a CategoricalDtype(None, False), regardless of categories or ordered.

### 2.11.3 Description

Using `describe()` on categorical data will produce similar output to a Series or DataFrame of type string.

```python
In [53]: cat = pd.Categorical(['a', 'c', 'c', np.nan], categories=['b', 'a', 'c'])
In [54]: df = pd.DataFrame({'cat': cat, 's': ['a', 'c', 'c', np.nan]})
In [55]: df.describe()
Out[55]:
    cat s
   count 3 3
  unique 2 2
    top  c  c
   freq 2 2

In [56]: df['cat'].describe()
Out[56]:
   count   3
  unique   2
    top  c
   freq   2
Name: cat, dtype: object
```
2.11.4 Working with categories

Categorical data has a categories and a ordered property, which list their possible values and whether the ordering matters or not. These properties are exposed as s.cat.categories and s.cat.ordered. If you don’t manually specify categories and ordering, they are inferred from the passed arguments.

```python
In [57]: s = pd.Series(['a', 'b', 'c', 'a'], dtype='category')
In [58]: s.cat.categories
Out[58]: Index(['a', 'b', 'c'], dtype='object')
In [59]: s.cat.ordered
Out[59]: False
```

It’s also possible to pass in the categories in a specific order:

```python
In [60]: s = pd.Series(pd.Categorical(['a', 'b', 'c', 'a'], categories=['c', 'b', 'a']))
   ....:
   ....:
In [61]: s.cat.categories
Out[61]: Index(['c', 'b', 'a'], dtype='object')
In [62]: s.cat.ordered
Out[62]: False
```

**Note:** New categorical data are not automatically ordered. You must explicitly pass `ordered=True` to indicate an ordered Categorical.

**Note:** The result of `unique()` is not always the same as `Series.cat.categories`, because `Series.unique()` has a couple of guarantees, namely that it returns categories in the order of appearance, and it only includes values that are actually present.

```python
In [63]: s = pd.Series(list('babc')).astype(CategoricalDtype(list('abcd'))) # categories
```

```python
In [64]: s
Out[64]:
0   b
1   a
2   b
3   c
dtype: category
Categories (4, object): ['a', 'b', 'c', 'd']
```

```python
In [65]: s.cat.categories
Out[65]: Index(['a', 'b', 'c', 'd'], dtype='object')
```

```python
# uniques
In [66]: s.unique()
Out[66]:
['b', 'a', 'c']
Categories (3, object): ['b', 'a', 'c']
```
Renaming categories

Renaming categories is done by assigning new values to the `Series.cat.categories` property or by using the `rename_categories()` method:

```python
In [67]: s = pd.Series(["a", "b", "c", "a"], dtype="category")
In [68]: s
Out[68]:
0    a
1    b
2    c
3    a
dtype: category
Categories (3, object): ['a', 'b', 'c']
In [69]: s.cat.categories = ["Group %s" % g for g in s.cat.categories]
In [70]: s
Out[70]:
0    Group a
1    Group b
2    Group c
3    Group a
dtype: category
Categories (3, object): ['Group a', 'Group b', 'Group c']
In [71]: s = s.cat.rename_categories([1, 2, 3])
In [72]: s
Out[72]:
0    1
1    2
2    3
3    1
dtype: category
Categories (3, int64): [1, 2, 3]
```

Note: In contrast to R’s `factor`, categorical data can have categories of other types than string.

Note: Be aware that assigning new categories is an inplace operation, while most other operations under `Series.cat` per default return a new `Series` of dtype `category`.

2.11. Categorical data
Categories must be unique or a `ValueError` is raised:

```python
In [75]: try:
    ....:     s.cat.categories = [1, 1, 1]
    ....:     except ValueError as e:
    ....:         print("ValueError:", str(e))
    ....:
ValueError: Categorical categories must be unique
```

Categories must also not be NaN or a `ValueError` is raised:

```python
In [76]: try:
    ....:     s.cat.categories = [1, 2, np.nan]
    ....:     except ValueError as e:
    ....:         print("ValueError:", str(e))
    ....:
ValueError: Categorical categories cannot be null
```

### Appending new categories

Appending categories can be done by using the `add_categories()` method:

```python
In [77]: s = s.cat.add_categories([4])

In [78]: s.cat.categories
Out[78]: Index(['x', 'y', 'z', 4], dtype='object')

In [79]: s
Out[79]:
0  x
1  y
2  z
3  x
dtype: category
Categories (4, object): ['x', 'y', 'z', 4]
```

### Removing categories

Removing categories can be done by using the `remove_categories()` method. Values which are removed are replaced by `np.nan`:

```python
In [80]: s = s.cat.remove_categories([4])

In [81]: s
Out[81]:
0  x
1  y
2  z
3  x
dtype: category
Categories (3, object): ['x', 'y', 'z']
```
Removing unused categories

Removing unused categories can also be done:

```python
In [82]: s = pd.Series(pd.Categorical(["a", "b", "a"],
....................: categories=["a", "b", "c", "d"]))
....................:

In [83]: s
Out[83]:
0   a
1   b
2   a
dtype: category
Categories (4, object): ['a', 'b', 'c', 'd']

In [84]: s.cat.remove_unused_categories()
Out[84]:
0   a
1   b
2   a
dtype: category
Categories (2, object): ['a', 'b']
```

Setting categories

If you want to do remove and add new categories in one step (which has some speed advantage), or simply set the categories to a predefined scale, use `set_categories()`.

```python
In [85]: s = pd.Series(["one", "two", "four", ",-"], dtype="category")

In [86]: s
Out[86]:
0   one
1   two
2   four
3   -
dtype: category
Categories (4, object): ['-', 'four', 'one', 'two']

In [87]: s = s.cat.set_categories(["one", "two", "three", "four"])  
In [88]: s
Out[88]:
0   one
1   two
2   four
3   NaN
dtype: category
Categories (4, object): ['one', 'two', 'three', 'four']
```

**Note:** Be aware that `Categorical.set_categories()` cannot know whether some category is omitted intentionally or because it is misspelled or (under Python3) due to a type difference (e.g., NumPy S1 dtype and Python strings). This can result in surprising behaviour!
2.11.5 Sorting and order

If categorical data is ordered (s.cat.ordered == True), then the order of the categories has a meaning and certain operations are possible. If the categorical is unordered, .min()/.max() will raise a TypeError.

```python
In [89]: s = pd.Series(pd.Categorical(["a", "b", "c", "a"], ordered=False))
In [90]: s.sort_values(inplace=True)
In [91]: s = pd.Series(["a", "b", "c", "a"]).astype(CategoricalDtype(ordered=True))
In [92]: s.sort_values(inplace=True)
In [93]: s
Out[93]:
0  a
1  b
2  c
3  a
   dtype: category
   Categories (3, object): ["a" < "b" < "c"]
In [94]: s.min(), s.max()
Out[94]: ("a", "c")
```

You can set categorical data to be ordered by using as_ordered() or unordered by using as_unordered(). These will by default return a new object.

```python
In [95]: s.cat.as_ordered()
Out[95]:
0  a
1  b
2  c
   dtype: category
   Categories (3, object): ["a" < "b" < "c"]
In [96]: s.cat.as_unordered()
Out[96]:
0  a
1  b
2  c
   dtype: category
   Categories (3, object): ["a", "b", "c"]
```

Sorting will use the order defined by categories, not any lexical order present on the data type. This is even true for strings and numeric data:

```python
In [97]: s = pd.Series([1, 2, 3, 1], dtype="category")
In [98]: s = s.cat.set_categories([2, 3, 1], ordered=True)
In [99]: s
```

(continues on next page)
Reordering

Reordering the categories is possible via the `Categorical.reorder_categories()` and the `Categorical.set_categories()` methods. For `Categorical.reorder_categories()`, all old categories must be included in the new categories and no new categories are allowed. This will necessarily make the sort order the same as the categories order.

```
In [103]: s = pd.Series([1, 2, 3, 1], dtype="category")

In [104]: s = s.cat.reorder_categories([2, 3, 1], ordered=True)

In [105]: s
Out[105]:
0  1
1  2
2  3
3  1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [106]: s.sort_values(inplace=True)

In [107]: s
Out[107]:
1  2
2  3
0  1
3  1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [108]: s.min(), s.max()
Out[108]: (2, 1)
```
Note: Note the difference between assigning new categories and reordering the categories: the first renames categories and therefore the individual values in the Series, but if the first position was sorted last, the renamed value will still be sorted last. Reordering means that the way values are sorted is different afterwards, but not that individual values in the Series are changed.

Note: If the Categorical is not ordered, Series.min() and Series.max() will raise TypeError. Numeric operations like +, -, *, / and operations based on them (e.g. Series.median()), which would need to compute the mean between two values if the length of an array is even) do not work and raise a TypeError.

### Multi column sorting

A categorical dtyped column will participate in a multi-column sort in a similar manner to other columns. The ordering of the categorical is determined by the categories of that column.

```python
In [109]: dfs = pd.DataFrame({'A': pd.Categorical(list('bbeebbaa'),
                        categories=['e', 'a', 'b'],
                        ordered=True),
                        'B': [1, 2, 1, 2, 2, 1, 2, 1]})
```

```
In [110]: dfs.sort_values(by=['A', 'B'])
Out[110]:
   A B
0 b 1
1 b 2
2 e 1
3 e 2
4 b 2
5 b 1
6 a 2
7 a 1
```

Reordering the categories changes a future sort.

```python
In [111]: dfs['A'] = dfs['A'].cat.reorder_categories(['a', 'b', 'e'])
In [112]: dfs.sort_values(by=['A', 'B'])
Out[112]:
   A B
0 b 1
1 b 2
2 e 1
3 e 2
4 b 2
5 b 1
6 a 2
7 a 1
```
2.11.6 Comparisons

Comparing categorical data with other objects is possible in three cases:

- Comparing equality (== and !=) to a list-like object (list, Series, array, ...) of the same length as the categorical data.
- All comparisons (==, !=, >, >=, <, and <=) of categorical data to another categorical Series, when `ordered==True` and the `categories` are the same.
- All comparisons of a categorical data to a scalar.

All other comparisons, especially “non-equality” comparisons of two categoricals with different categories or a categorical with any list-like object, will raise a `TypeError`.

**Note:** Any “non-equality” comparisons of categorical data with a `Series`, `np.array`, `list` or categorical data with different categories or ordering will raise a `TypeError` because custom categories ordering could be interpreted in two ways: one with taking into account the ordering and one without.

```
In [113]: cat = pd.Series([1, 2, 3]).astype(
....:     CategoricalDtype([3, 2, 1], ordered=True)
....: )
....:

In [114]: cat_base = pd.Series([2, 2, 2]).astype(
....:     CategoricalDtype([3, 2, 1], ordered=True)
....: )
....:

In [115]: cat_base2 = pd.Series([2, 2, 2]).astype(
....:     CategoricalDtype(ordered=True)
....: )
....:

In [116]: cat
Out[116]:
0  1
1  2
2  3
dtype: category
Categories (3, int64): [3 < 2 < 1]

In [117]: cat_base
Out[117]:
0  2
1  2
2  2
dtype: category
Categories (3, int64): [3 < 2 < 1]

In [118]: cat_base2
Out[118]:
0  2
1  2
2  2
dtype: category
Categories (1, int64): [2]
```
Comparing to a categorical with the same categories and ordering or to a scalar works:

```
In [119]: cat > cat_base
Out[119]:
0   True
1   False
2   False
dtype: bool

In [120]: cat > 2
Out[120]:
0   True
1   False
2   False
dtype: bool
```

Equality comparisons work with any list-like object of same length and scalars:

```
In [121]: cat == cat_base
Out[121]:
0  False
1   True
2  False
dtype: bool

In [122]: cat == np.array([1, 2, 3])
Out[122]:
0   True
1   True
2   True
dtype: bool

In [123]: cat == 2
Out[123]:
0  False
1   True
2  False
dtype: bool
```

This doesn’t work because the categories are not the same:

```
In [124]: try:
....:     cat > cat_base2
....: except TypeError as e:
....:     print("TypeError: ", str(e))
....:
TypeError: Categoricals can only be compared if 'categories' are the same. Categories are different lengths
```

If you want to do a “non-equality” comparison of a categorical series with a list-like object which is not categorical data, you need to be explicit and convert the categorical data back to the original values:

```
In [125]: base = np.array([1, 2, 3])

In [126]: try:
....:     cat > base
....: except TypeError as e:
....:     print("TypeError: ", str(e))
```
.....:
TypeError: Cannot compare a Categorical for op __gt__ with type <class 'numpy.ndarray'>.
If you want to compare values, use 'np.asarray(cat) <op> other'.

In [127]: np.asarray(cat) > base
Out[127]: array([False, False, False])

When you compare two unordered categoricals with the same categories, the order is not considered:

In [128]: c1 = pd.Categorical(['a', 'b'], categories=['a', 'b'], ordered=False)
In [129]: c2 = pd.Categorical(['b', 'a'], categories=['b', 'a'], ordered=False)
In [130]: c1 == c2
Out[130]: array([ True, True])

2.11.7 Operations

Apart from Series.min(), Series.max() and Series.mode(), the following operations are possible with categorical data:

Series methods like Series.value_counts() will use all categories, even if some categories are not present in the data:

In [131]: s = pd.Series(pd.Categorical(['a', 'b', 'c', 'c'], categories=['c', 'a', 'b', 'd']))
......:
In [132]: s.value_counts()
Out[132]:
c 2
b 1
a 1
d 0
dtype: int64

Groupby will also show “unused” categories:

In [133]: cats = pd.Categorical(['a', 'b', 'b', 'b', 'c', 'c', 'c'], categories=['a', 'b', 'c', 'd'])
In [134]: df = pd.DataFrame({'cats': cats, 'values': [1, 2, 2, 2, 3, 4, 5]})
In [135]: df.groupby("cats").mean()
Out[135]:
values
cats
a  1.0
b  2.0
c  4.0
d  NaN

In [136]: cats2 = pd.Categorical(['a', 'a', 'b', 'b'], categories=['a', 'b', 'c'])
In [137]: df2 = pd.DataFrame(
          "cats": cats2,
          "B": ["c", "d", "c", "d"],
          "values": [1, 2, 3, 4])
In [138]: df2.groupby(["cats", "B"]).mean()
Out[138]:
          values
    cats  B
    a     c   1.0
          d   2.0
    b     c   3.0
          d   4.0
    c     c   NaN
          d   NaN

Pivot tables:

In [139]: raw_cat = pd.Categorical(["a", "a", "b", "b"], categories=["a", "b", "c"])
In [140]: df = pd.DataFrame(
          "A": raw_cat,
          "B": ["c", "d", "c", "d"],
          "values": [1, 2, 3, 4])
In [141]: pd.pivot_table(df, values='values', index=["A", "B"])
Out[141]:
          values
    A  B
    a  c   1
          d   2
    b  c   3
          d   4

2.11.8 Data munging

The optimized pandas data access methods .loc, .iloc, .at, and .iat, work as normal. The only difference is the return type (for getting) and that only values already in categories can be assigned.

Getting

If the slicing operation returns either a DataFrame or a column of type Series, the category dtype is preserved.

In [142]: idx = pd.Index(["h", "i", "j", "k", "l", "m", "n")
In [143]: cats = pd.Series(["a", "b", "b", "b", "b", "c", "c", "c"],
                      dtype="category", index=idx)
In [144]: values = [1, 2, 2, 2, 3, 4, 5]
In [145]: df = pd.DataFrame(
          "cats": cats, "values": values), index=idx)
An example where the category type is not preserved is if you take one single row: the resulting Series is of dtype object:

```python
In [150]: df.loc["h", :]
Out[150]:
cats   a
values 1
Name: h, dtype: object
```

Returning a single item from categorical data will also return the value, not a categorical of length “1”.

```python
In [151]: df.iat[0, 0]
Out[151]: 'a'

In [152]: df["cats"].cat.categories = ["x", "y", "z"]

In [153]: df.at["h", "cats"]  # returns a string
Out[153]: 'x'
```

**Note:** The is in contrast to R’s `factor` function, where `factor(c(1, 2, 3))[1]` returns a single value `factor`.

To get a single value Series of type category, you pass in a list with a single value:

```python
In [154]: df.loc["h", "cats"]
Out[154]:
h   x
```

(continues on next page)
Name: cats, dtype: category
Categories (3, object): ['x', 'y', 'z']

String and datetime accessors

The accessors .dt and .str will work if the s.cat.categories are of an appropriate type:

```
In [155]: str_s = pd.Series(list('aabb'))
In [156]: str_cat = str_s.astype('category')
In [157]: str_cat
Out[157]:
0  a
1  a
2  b
3  b
dtype: category
Categories (2, object): ['a', 'b']

In [158]: str_cat.str.contains("a")
Out[158]:
0   True
1   True
2  False
3  False
dtype: bool

In [159]: date_s = pd.Series(pd.date_range('1/1/2015', periods=5))
In [160]: date_cat = date_s.astype('category')

In [161]: date_cat
Out[161]:
0  2015-01-01
1  2015-01-02
2  2015-01-03
3  2015-01-04
4  2015-01-05
dtype: category

In [162]: date_cat.dt.day
Out[162]:
0   1
1   2
2   3
3   4
4   5
dtype: int64
```

Note: The returned Series (or DataFrame) is of the same type as if you used the .str.<method> / .dt.<method> on a Series of that type (and not of type category!).
That means, that the returned values from methods and properties on the accessors of a `Series` and the returned values from methods and properties on the accessors of this `Series` transformed to one of type `category` will be equal:

```plaintext
In [163]: ret_s = str_s.str.contains("a")
In [164]: ret_cat = str_cat.str.contains("a")
In [165]: ret_s.dtype == ret_cat.dtype
Out[165]: True
In [166]: ret_s == ret_cat
Out[166]:
   0  True
   1  True
   2  True
   3  True
dtype: bool
```

**Note:** The work is done on the `categories` and then a new `Series` is constructed. This has some performance implication if you have a `Series` of type string, where lots of elements are repeated (i.e. the number of unique elements in the `Series` is a lot smaller than the length of the `Series`). In this case it can be faster to convert the original `Series` to one of type `category` and use `.str.<method>` or `.dt.<property>` on that.

### Setting

Setting values in a categorical column (or `Series`) works as long as the value is included in the `categories`:

```plaintext
In [167]: idx = pd.Index(["h", "i", "j", "k", "l", "m", "n")
In [168]: cats = pd.Categorical(["a", "a", "a", "a", "a", "a", "a"], categories=["a", "b")
In [169]: values = [1, 1, 1, 1, 1, 1, 1]
In [170]: df = pd.DataFrame({"cats": cats, "values": values}, index=idx)
In [171]: df.iloc[2:4, :] = ["b", 2], ["b", 2]
In [172]: df
Out[172]:
   cats  values
  h    a      1
  i    a      1
  j    b      2
  k    b      2
  l    a      1
  m    a      1
  n    a      1
In [173]: try:
      ....:   df.iloc[2:4, :] = ["c", 3], ["c", 3]
      ....:     except ValueError as e:
```

(continues on next page)
Setting values by assigning categorical data will also check that the categories match:

```python
In [174]: df.loc["j":"k", "cats"] = pd.Categorical(["a", "a"], categories=["a", "b"])

In [175]: df

Out[175]:
   cats  values
   h     a  1
   i     a  1
   j     a  2
   k     a  2
   l     a  1
   m     a  1
   n     a  1
```

```python
In [176]: try:

    ....:    df.loc["j":"k", "cats"] = pd.Categorical(["b", "b"],
    ....:           categories=["a", "b", "c"])

    ....:    except ValueError as e:

    ....:        print("ValueError": str(e))

    ....:

ValueError: Cannot set a Categorical with another, without identical categories
```

Assigning a Categorical to parts of a column of other types will use the values:

```python
In [177]: df = pd.DataFrame({"a": [1, 1, 1, 1, 1], "b": ["a", "a", "a", "a", "a"]})

In [178]: df.loc[1:2, "a"] = pd.Categorical(["b", "b"], categories=["a", "b"])

In [179]: df.loc[2:3, "b"] = pd.Categorical(["b", "b"], categories=["a", "b"])

In [180]: df

Out[180]:
   a  b
0  1 a
1  2 a
2  3 b
3  4 a
```

```python
In [181]: df.dtypes

Out[181]:
   a  object
   b  object
dtype: object
```
Merging / concatenation

By default, combining Series or DataFrames which contain the same categories results in category dtype, otherwise results will depend on the dtype of the underlying categories. Merges that result in non-categorical dtypes will likely have higher memory usage. Use .astype or union_categoricals to ensure category results.

```
In [182]: from pandas.api.types import union_categoricals

# same categories
In [183]: s1 = pd.Series(['a', 'b'], dtype='category')
In [184]: s2 = pd.Series(['a', 'b', 'a'], dtype='category')
In [185]: pd.concat([s1, s2])
Out[185]:
     0  a
     1  b
     2  a
dtype: category
Categories (2, object): ['a', 'b']

# different categories
In [186]: s3 = pd.Series(['b', 'c'], dtype='category')
In [187]: pd.concat([s1, s3])
Out[187]:
     0  a
     1  b
     0  b
     1  c
dtype: object

# Output dtype is inferred based on categories values
In [188]: int_cats = pd.Series([1, 2], dtype='category')
In [189]: float_cats = pd.Series([3.0, 4.0], dtype='category')
In [190]: pd.concat([int_cats, float_cats])
Out[190]:
    0  1.0
    1  2.0
    0  3.0
    1  4.0
dtype: float64
In [191]: pd.concat([s1, s3]).astype('category')
Out[191]:
     0  a
     1  b
     0  b
     1  c
dtype: category
Categories (3, object): ['a', 'b', 'c']
In [192]: union_categoricals([s1.array, s3.array])
```

(continues on next page)
The following table summarizes the results of merging Categoricals:

<table>
<thead>
<tr>
<th>arg1</th>
<th>arg2</th>
<th>identical</th>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>category</td>
<td>True</td>
<td>category</td>
</tr>
<tr>
<td>category (object)</td>
<td>category (object)</td>
<td>False</td>
<td>object (dtype is inferred)</td>
</tr>
<tr>
<td>category (int)</td>
<td>category (float)</td>
<td>False</td>
<td>float (dtype is inferred)</td>
</tr>
</tbody>
</table>

See also the section on *merge dtypes* for notes about preserving merge dtypes and performance.

**Unioning**

If you want to combine categoricals that do not necessarily have the same categories, the `union_categoricals()` function will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```
In [193]: from pandas.api.types import union_categoricals

In [194]: a = pd.Categorical(['b', 'c'])
In [195]: b = pd.Categorical(['a', 'b'])
In [196]: union_categoricals([a, b])
Out[196]:
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

By default, the resulting categories will be ordered as they appear in the data. If you want the categories to be lexsorted, use `sort_categories=True` argument.

```
In [197]: union_categoricals([a, b], sort_categories=True)
Out[197]:
['b', 'c', 'a', 'b']
Categories (3, object): ['a', 'b', 'c']
```

`union_categoricals` also works with the “easy” case of combining two categoricals of the same categories and order information (e.g. what you could also append for).

```
In [198]: a = pd.Categorical(['a', 'b'], ordered=True)
In [199]: b = pd.Categorical(['a', 'b', 'a'], ordered=True)
In [200]: union_categoricals([a, b])
Out[200]:
['a', 'b', 'a', 'b', 'a']
Categories (2, object): ['a' < 'b']
```

The below raises `TypeError` because the categories are ordered and not identical.

```
In [1]: a = pd.Categorical(['a', 'b'], ordered=True)
In [2]: b = pd.Categorical(['a', 'b', 'c'], ordered=True)
In [3]: union_categoricals([a, b])
```
Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.

```python
In [201]: a = pd.Categorical(["a", "b", "c"], ordered=True)
In [202]: b = pd.Categorical(["c", "b", "a"], ordered=True)
In [203]: union_categoricals([a, b], ignore_order=True)
Out[203]: ['a', 'b', 'c', 'c', 'b', 'a']
Categories (3, object): ['a', 'b', 'c']
```

`union_categoricals()` also works with a `CategoricalIndex`, or `Series` containing categorical data, but note that the resulting array will always be a plain `Categorical`:

```python
In [204]: a = pd.Series(["b", "c"], dtype='category')
In [205]: b = pd.Series(["a", "b"], dtype='category')
In [206]: union_categoricals([a, b])
Out[206]: ['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

**Note:** `union_categoricals` may recode the integer codes for categories when combining categoricals. This is likely what you want, but if you are relying on the exact numbering of the categories, be aware.

```python
In [207]: c1 = pd.Categorical(["b", "c"])
In [208]: c2 = pd.Categorical(["a", "b"])
In [209]: c1
Out[209]: ['b', 'c']
Categories (2, object): ['b', 'c']
# "b" is coded to 0
In [210]: c1.codes
Out[210]: array([0, 1], dtype=int8)
In [211]: c2
Out[211]: ['a', 'b']
Categories (2, object): ['a', 'b']
# "b" is coded to 1
In [212]: c2.codes
Out[212]: array([0, 1], dtype=int8)
In [213]: c = union_categoricals([c1, c2])
In [214]: c
```

(continues on next page)
2.11.9 Getting data in/out

You can write data that contains category dtypes to a HDFStore. See here for an example and caveats.

It is also possible to write data to and reading data from Stata format files. See here for an example and caveats.

Writing to a CSV file will convert the data, effectively removing any information about the categorical (categories and ordering). So if you read back the CSV file you have to convert the relevant columns back to category and assign the right categories and categories ordering.

In [216]: import io

In [217]: s = pd.Series(pd.Categorical(['a', 'b', 'b', 'a', 'a', 'd']))

# rename the categories
In [218]: s.cat.categories = ["very good", "good", "bad"]

# reorder the categories and add missing categories
In [219]: s = s.cat.set_categories(["very bad", "bad", "medium", "good", "very good"])

In [220]: df = pd.DataFrame({'cats': s, 'vals': [1, 2, 3, 4, 5, 6]})

In [221]: csv = io.StringIO()

In [222]: df.to_csv(csv)

In [223]: df2 = pd.read_csv(io.StringIO(csv.getvalue()))

In [224]: df2.dtypes

Out[224]:
       cats     vals
0      object     int64

In [225]: df2["cats"]

Out[225]:
0    very good
1      good
2    good
3    very good
4    very good
5      bad
Name: cats, dtype: object

# Redo the category

(continues on next page)
In [226]: df2["cats"] = df2["cats"].astype("category")

In [227]: df2["cats"].cat.set_categories(["very bad", "bad", "medium", "good", "very good"], inplace=True)

In [228]: df2.dtypes
Out[228]:
Unnamed: 0 int64
cats category
vals int64
dtype: object

In [229]: df2["cats"]
Out[229]:
0 very good
1 good
2 good
3 very good
4 very good
5 bad
Name: cats, dtype: category
Categories (5, object): ['very bad', 'bad', 'medium', 'good', 'very good']

The same holds for writing to a SQL database with to_sql.

2.11.10 Missing data

pandas primarily uses the value np.nan to represent missing data. It is by default not included in computations. See the Missing Data section.

Missing values should not be included in the Categorical’s categories, only in the values. Instead, it is understood that NaN is different, and is always a possibility. When working with the Categorical’s codes, missing values will always have a code of -1.

In [230]: s = pd.Series(["a", "b", np.nan, "a"], dtype="category")

# only two categories
In [231]: s
Out[231]:
0   a
1   b
2  NaN
3   a
dtype: category
Categories (2, object): ['a', 'b']

In [232]: s.cat.codes
Out[232]:
0  0
1  1
2 -1
3  0
dtype: int8
Methods for working with missing data, e.g. `isna()`, `fillna()`, `dropna()`, all work normally:

```
In [233]: s = pd.Series(['a', 'b', np.nan], dtype='category')
In [234]: s
Out[234]:
0  a
1  b
2  NaN
dtype: category
Categories (2, object): ['a', 'b']
In [235]: pd.isna(s)
Out[235]:
0  False
1  False
2   True
dtype: bool
In [236]: s.fillna('a')
Out[236]:
0  a
1  b
2  a
dtype: category
Categories (2, object): ['a', 'b']
```

### 2.11.11 Differences to R’s `factor`

The following differences to R’s `factor` functions can be observed:

- R’s `levels` are named `categories`.
- R’s `levels` are always of type string, while `categories` in pandas can be of any dtype.
- It’s not possible to specify labels at creation time. Use `s.cat.rename_categories(new_labels)` afterwards.
- In contrast to R’s `factor` function, using categorical data as the sole input to create a new categorical series will **not** remove unused categories but create a new categorical series which is equal to the passed in one!
- R allows for missing values to be included in its `levels` (pandas’ `categories`). Pandas does not allow NaN `categories`, but missing values can still be in the `values`.

### 2.11.12 Gotchas

#### Memory usage

The memory usage of a `Categorical` is proportional to the number of categories plus the length of the data. In contrast, an `object` dtype is a constant times the length of the data.

```
In [237]: s = pd.Series(['foo', 'bar'] * 1000)
# object dtype
In [238]: s.nbytes
Out[238]: 16000
```

(continues on next page)
# category dtype
In [239]: s.astype('category').nbytes
Out[239]: 2016

Note: If the number of categories approaches the length of the data, the `Categorical` will use nearly the same or more memory than an equivalent `object` dtype representation.

In [240]: s = pd.Series(['foo%04d' % i for i in range(2000)])

# object dtype
In [241]: s.nbytes
Out[241]: 16000

# category dtype
In [242]: s.astype('category').nbytes
Out[242]: 20000

**Categorical is not a numpy array**

Currently, categorical data and the underlying `Categorical` is implemented as a Python object and not as a low-level NumPy array dtype. This leads to some problems. NumPy itself doesn’t know about the new `dtype`:

In [243]: try:
   ....:   np.dtype("category")
   ....:   except TypeError as e:
   ....:       print("TypeError: ", str(e))
   ....:
TypeError: data type 'category' not understood

In [244]: dtype = pd.Categorical(["a"]).dtype

In [245]: try:
   ....:   np.dtype(dtype)
   ....:   except TypeError as e:
   ....:       print("TypeError: ", str(e))
   ....:
TypeError: Cannot interpret 'CategoricalDtype(categories=['a'], ordered=False)' as a data type

Dtype comparisons work:

In [246]: dtype == np.str_
Out[246]: False

In [247]: np.str_ == dtype
Out[247]: False

To check if a Series contains Categorical data, use `hasattr(s, 'cat'):`
Using NumPy functions on a Series of type category should not work as Categoricals are not numeric data (even in the case that .categories is numeric).

```
In [250]: s = pd.Series(pd.Categorical([1, 2, 3, 4]))
In [251]: try:
   ....:    np.sum(s)
   ....: except TypeError as e:
   ....:    print("TypeError: ", str(e))
```

```
TypeError: Categorical cannot perform the operation sum
```

**Note:** If such a function works, please file a bug at https://github.com/pandas-dev/pandas!

dtype in apply

Pandas currently does not preserve the dtype in apply functions: If you apply along rows you get a Series of object dtype (same as getting a row -> getting one element will return a basic type) and applying along columns will also convert to object. NaN values are unaffected. You can use fillna to handle missing values before applying a function.

```
In [252]: df = pd.DataFrame({"a": [1, 2, 3, 4],
   ....:         "b": ["a", "b", "c", "d"],
   ....:         "cats": pd.Categorical([1, 2, 3, 2])})
In [253]: df.apply(lambda row: type(row["cats"]), axis=1)
Out[253]:
0    <class 'int'>
1    <class 'int'>
2    <class 'int'>
3    <class 'int'>
dtype: object
```

```
In [254]: df.apply(lambda col: col.dtype, axis=0)
Out[254]:
a    int64
b    object
cats  category
dtype: object
```
## Categorical index

CategoricalIndex is a type of index that is useful for supporting indexing with duplicates. This is a container around a Categorical and allows efficient indexing and storage of an index with a large number of duplicated elements. See the advanced indexing docs for a more detailed explanation.

Setting the index will create a CategoricalIndex:

```python
In [255]: cats = pd.Categorical([1, 2, 3, 4], categories=[4, 2, 3, 1])
In [256]: strings = ["a", "b", "c", "d"]
In [257]: values = [4, 2, 3, 1]
In [258]: df = pd.DataFrame({"strings": strings, "values": values}, index=cats)
In [259]: df.index
Out[259]: CategoricalIndex([1, 2, 3, 4], categories=[4, 2, 3, 1], ordered=False, dtype='category')

# This now sorts by the categories order
In [260]: df.sort_index()
```

### Side effects

Constructing a Series from a Categorical will not copy the input Categorical. This means that changes to the Series will in most cases change the original Categorical:

```python
In [261]: cat = pd.Categorical([1, 2, 3, 10], categories=[1, 2, 3, 4, 10])
In [262]: s = pd.Series(cat, name="cat")
In [263]: cat
Out[263]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
In [264]: s.iloc[0:2] = 10
In [265]: cat
Out[265]:
[10, 10, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
In [266]: df = pd.DataFrame(s)
In [267]: df["cat"].cat.categories = [1, 2, 3, 4, 5]
In [268]: cat
Out[268]:
```
Use `copy=True` to prevent such a behaviour or simply don’t reuse `Categoricals`:

```python
In [269]: cat = pd.Categorical([1, 2, 3, 10], categories=[1, 2, 3, 4, 10])
In [270]: s = pd.Series(cat, name="cat", copy=True)
In [271]: cat
Out[271]: [1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
In [272]: s.iloc[0:2] = 10
In [273]: cat
Out[273]: [1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
```

**Note:** This also happens in some cases when you supply a NumPy array instead of a `Categorical`: using an int array (e.g. `np.array([1,2,3,4])`) will exhibit the same behavior, while using a string array (e.g. `np.array(["a","b","c","a"])`) will not.

### 2.12 Nullable integer data type

New in version 0.24.0.

**Note:** IntegerArray is currently experimental. Its API or implementation may change without warning.

Changed in version 1.0.0: Now uses `pandas.NA` as the missing value rather than `numpy.nan`.

In *Working with missing data*, we saw that pandas primarily uses `NaN` to represent missing data. Because `NaN` is a float, this forces an array of integers with any missing values to become floating point. In some cases, this may not matter much. But if your integer column is, say, an identifier, casting to float can be problematic. Some integers cannot even be represented as floating point numbers.

#### 2.12.1 Construction

Pandas can represent integer data with possibly missing values using `arrays.IntegerArray`. This is an extension types implemented within pandas.

```python
In [1]: arr = pd.array([1, 2, None], dtype=pd.Int64Dtype())
In [2]: arr
Out[2]: <IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64
```
Or the string alias "Int64" (note the capital "I", to differentiate from NumPy's 'int64' dtype:

In [3]: pd.array([1, 2, np.nan], dtype="Int64")
Out[3]:
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64

All NA-like values are replaced with pandas.NA.

In [4]: pd.array([1, 2, np.nan, None, pd.NA], dtype="Int64")
Out[4]:
<IntegerArray>
[1, 2, <NA>, <NA>, <NA>]
Length: 5, dtype: Int64

This array can be stored in a DataFrame or Series like any NumPy array.

In [5]: pd.Series(arr)
Out[5]:
0 1
1 2
2 <NA>
dtype: Int64

You can also pass the list-like object to the Series constructor with the dtype.

**Warning:** Currently pandas.array() and pandas.Series() use different rules for dtype inference. pandas.array() will infer a nullable integer dtype

In [6]: pd.array([1, None])
Out[6]:
<IntegerArray>
[1, <NA>]
Length: 2, dtype: Int64

In [7]: pd.array([1, 2])
Out[7]:
<IntegerArray>
[1, 2]
Length: 2, dtype: Int64

For backwards-compatibility, Series infers these as either integer or float dtype

In [8]: pd.Series([1, None])
Out[8]:
0 1.0
1 NaN
dtype: float64

In [9]: pd.Series([1, 2])
Out[9]:
0 1
1 2
dtype: int64

We recommend explicitly providing the dtype to avoid confusion.
In [10]: pd.array([1, None], dtype="Int64")
Out[10]:
<IntegerArray>
[1, <NA>]
Length: 2, dtype: Int64

In [11]: pd.Series([1, None], dtype="Int64")
Out[11]:
0 1
1 <NA>
dtype: Int64

In the future, we may provide an option for Series to infer a nullable-integer dtype.

2.12.2 Operations

Operations involving an integer array will behave similar to NumPy arrays. Missing values will be propagated, and the data will be coerced to another dtype if needed.

In [12]: s = pd.Series([1, 2, None], dtype="Int64")
   # arithmetic
   In [13]: s + 1
   Out[13]:
    0 2
    1 3
    2 <NA>
dtype: Int64
   # comparison
   In [14]: s == 1
   Out[14]:
    0 True
    1 False
    2 <NA>
dtype: boolean
   # indexing
   In [15]: s.iloc[1:3]
   Out[15]:
    1 2
    2 <NA>
dtype: Int64
   # operate with other dtypes
   In [16]: s + s.iloc[1:3].astype('Int8')
   Out[16]:
    0 <NA>
    1 4
    2 <NA>
dtype: Int64
   # coerce when needed
   In [17]: s + 0.01
   Out[17]:
(continues on next page)
These dtypes can operate as part of DataFrame.

```
In [18]: df = pd.DataFrame({'A': s, 'B': [1, 1, 3], 'C': list('aab'))

In [19]: df
Out[19]:
     A   B   C
0  1.0  1  a
1  2.0  1  a
2  NaN  3  b
```

```
In [20]: df.dtypes
Out[20]:
       A   B   C
dtype: float64
       int64
       object
```

These dtypes can be merged & reshaped & casted.

```
In [21]: pd.concat([df['A'], df['B', 'C']], axis=1).dtypes
Out[21]:
       A   B   C
dtype: float64
       int64
       object
```

```
In [22]: df['A'].astype(float)
Out[22]:
     0  1.0
     1  2.0
     2  NaN
Name: A, dtype: float64
```

Reduction and groupby operations such as 'sum' work as well.

```
In [23]: df.sum()
Out[23]:
   A
0  3
1  5
2  NaN
C
Name: aab, dtype: object
```

```
In [24]: df.groupby('B').A.sum()
Out[24]:
   B
1  3
3  0
Name: A, dtype: Int64
```
2.12.3 Scalar NA Value

`arrays.IntegerArray` uses `pandas.NA` as its scalar missing value. Slicing a single element that’s missing will return `pandas.NA`.

```python
In [25]: a = pd.array([1, None], dtype="Int64")
In [26]: a[1]
Out[26]: <NA>
```

2.13 Nullable Boolean data type

New in version 1.0.0.

2.13.1 Indexing with NA values

`pandas` allows indexing with NA values in a boolean array, which are treated as `False`. Changed in version 1.0.2.

```python
In [1]: s = pd.Series([1, 2, 3])
In [2]: mask = pd.array([True, False, pd.NA], dtype="boolean")
In [3]: s[mask]
Out[3]:
0 1
dtype: int64
```

If you would prefer to keep the NA values you can manually fill them with `fillna(True)`.

```python
In [4]: s[mask.fillna(True)]
Out[4]:
0 1
2 3
dtype: int64
```

2.13.2 Kleene logical operations

`arrays.BooleanArray` implements Kleene Logic (sometimes called three-value logic) for logical operations like & (and), | (or) and ^ (exclusive-or).

This table demonstrates the results for every combination. These operations are symmetrical, so flipping the left- and right-hand side makes no difference in the result.
When an NA is present in an operation, the output value is NA only if the result cannot be determined solely based on the other input. For example, True | NA is True, because both True | True and True | False are True. In that case, we don’t actually need to consider the value of the NA.

On the other hand, True & NA is NA. The result depends on whether the NA really is True or False, since True & True is True, but True & False is False, so we can’t determine the output.

This differs from how np.nan behaves in logical operations. Pandas treated np.nan is always false in the output.

```
In [5]: pd.Series([True, False, np.nan], dtype="object") | True
Out[5]:
0    True
1    True
2  False
dtype: bool

In [6]: pd.Series([True, False, np.nan], dtype="boolean") | True
Out[6]:
0    True
1    True
2    True
dtype: boolean
```

In and

```
In [7]: pd.Series([True, False, np.nan], dtype="object") & True
Out[7]:
0    True
1    True
2    False
dtype: bool

In [8]: pd.Series([True, False, np.nan], dtype="boolean") & True
```

(continues on next page)
2.14 Visualization

We use the standard convention for referencing the matplotlib API:

```python
In [1]: import matplotlib.pyplot as plt
In [2]: plt.close('all')
```

We provide the basics in pandas to easily create decent looking plots. See the ecosystem section for visualization libraries that go beyond the basics documented here.

**Note:** All calls to `np.random` are seeded with 123456.

2.14.1 Basic plotting: plot

We will demonstrate the basics, see the *cookbook* for some advanced strategies.

The `plot` method on Series and DataFrame is just a simple wrapper around `plt.plot()`:

```python
In [3]: ts = pd.Series(np.random.randn(1000),
                      index=pd.date_range('1/1/2000', periods=1000))
```

```
NameError: Traceback (most recent call last)
<ipython-input-3-00eeb137fb11> in <module>
    1 ts = pd.Series(np.random.randn(1000),
                    index=pd.date_range('1/1/2000', periods=1000))
NameError: name 'pd' is not defined
```

```python
In [4]: ts = ts.cumsum()
```

```
NameError: Traceback (most recent call last)
<ipython-input-4-a7771f529bde> in <module>
    1 ts = ts.cumsum()
NameError: name 'ts' is not defined
```

```python
In [5]: ts.plot()
```

```
NameError: Traceback (most recent call last)
<ipython-input-5-8a34b37f0ce9> in <module>
    1 ts.plot()
```
If the index consists of dates, it calls `gcf().autofmt_xdate()` to try to format the x-axis nicely as per above.

On DataFrame, `plot()` is a convenience to plot all of the columns with labels:

```python
In [6]: df = pd.DataFrame(np.random.randn(1000, 4),
                   index=ts.index, columns=list('ABCD'))
```

```
NameError: name 'ts' is not defined
```

```python
In [7]: df = df.cumsum()
```

```
NameError: name 'pd' is not defined
```

```python
In [8]: df = df.cumsum()
```

```
NameError: name 'pd' is not defined
```
You can plot one column versus another using the `x` and `y` keywords in `plot()`:

```python
In [10]: df3 = pd.DataFrame(np.random.randn(1000, 2), columns=['B', 'C']).cumsum()
NameError: name 'pd' is not defined
```

```python
In [11]: df3['A'] = pd.Series(list(range(len(df))))
NameError: name 'pd' is not defined
```
2.14.2 Other plots

Plotting methods allow for a handful of plot styles other than the default line plot. These methods can be provided as the kind keyword argument to plot(), and include:

- 'bar' or 'barh' for bar plots
- 'hist' for histogram
- 'box' for boxplot
- 'kde' or 'density' for density plots
• 'area' for area plots
• 'scatter' for scatter plots
• 'hexbin' for hexagonal bin plots
• 'pie' for pie plots

For example, a bar plot can be created the following way:

```python
In [13]: plt.figure();
In [14]: df.iloc[5].plot(kind='bar');
```

You can also create these other plots using the methods `DataFrame.plot.<kind>` instead of providing the `kind` keyword argument. This makes it easier to discover plot methods and the specific arguments they use:

```python
In [15]: df = pd.DataFrame()
In [16]: df.plot.<TAB>  # noqa: E225, E999
df.plot.area   df.plot.barh   df.plot.density   df.plot.hist   df.plot.line   df.plot.scatter
df.plot.bar    df.plot.box    df.plot.hexbin   df.plot.kde    df.plot.pie
```

In addition to these `kind`s, there are the `DataFrame.hist()`, and `DataFrame.boxplot()` methods, which use a separate interface.
Finally, there are several plotting functions in pandas.plotting that take a Series or DataFrame as an argument. These include:

- Scatter Matrix
- Andrews Curves
- Parallel Coordinates
- Lag Plot
- Autocorrelation Plot
- Bootstrap Plot
- RadViz

Plots may also be adorned with errorbars or tables.

**Bar plots**

For labeled, non-time series data, you may wish to produce a bar plot:

```python
In [17]: plt.figure();
In [18]: df.iloc[5].plot.bar()
---------------------------------------------------------------------------
NameError Traceback (most recent call last)
<ipython-input-18-d1a2cddc601a> in <module>
----> 1 df.iloc[5].plot.bar()

NameError: name 'df' is not defined
```

```python
In [19]: plt.axhline(0, color='k');
```
Calling a DataFrame's `plot.bar()` method produces a multiple bar plot:

```
In [20]: df2 = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])
---------------------------------------------------------------------------
NameError Traceback (most recent call last)
<ipython-input-20-6133adb252fc> in <module>
----> 1 df2 = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])

NameError: name 'pd' is not defined
```

```
In [21]: df2.plot.bar();
```
To produce a stacked bar plot, pass `stacked=True`:

```python
In [22]: df2.plot.bar(stacked=True);
```
To get horizontal bar plots, use the `barh` method:

```python
In [23]: df2.plot.barh(stacked=True);
```
Histories

Histograms can be drawn by using the `DataFrame.plot.hist()` and `Series.plot.hist()` methods.

```python
In [24]: df4 = pd.DataFrame({'a': np.random.randn(1000) + 1, 'b': np.random.randn(1000),
                      'c': np.random.randn(1000) - 1}, columns=['a', 'b', 'c'])

NameError: name 'pd' is not defined
```

```python
In [25]: plt.figure();

In [26]: df4.plot.hist(alpha=0.5)
```

(continues on next page)
A histogram can be stacked using `stacked=True`. Bin size can be changed using the `bins` keyword.

```python
In [27]: plt.figure();

In [28]: df4.plot.hist(stacked=True, bins=20)
---------------------------------------------------------------------------
NameError Traceback (most recent call last)
<ipython-input-28-9a4bef475383> in <module>
     1 df4.plot.hist(stacked=True, bins=20)
NameError: name 'df4' is not defined
```
You can pass other keywords supported by matplotlib `hist`. For example, horizontal and cumulative histograms can be drawn by `orientation='horizontal'` and `cumulative=True`.

```python
In [29]: plt.figure();

In [30]: df4['a'].plot.hist(orientation='horizontal', cumulative=True)
```

```
NameError Traceback (most recent call last)
<ipython-input-30-c49999bfb88a> in <module>
----> 1 df4['a'].plot.hist(orientation='horizontal', cumulative=True)

NameError: name 'df4' is not defined
```
See the `hist` method and the `matplotlib hist documentation` for more.

The existing interface `DataFrame.hist` to plot histogram still can be used.

```python
In [31]: plt.figure();

In [32]: df['A'].diff().hist()
---------------------------------------------------------------------------
NameError                       Traceback (most recent call last)
<ipython-input-32-620f128ae072> in <module>
    1 df['A'].diff().hist()
NameError: name 'df' is not defined
```
DataFrame.hist() plots the histograms of the columns on multiple subplots:

```python
In [33]: plt.figure()
Out[33]: <Figure size 640x480 with 0 Axes>

In [34]: df.diff().hist(color='k', alpha=0.5, bins=50)
---------------------------------------------------------------------------
NameError                       Traceback (most recent call last)
<ipython-input-34-742660109d1c> in <module>
----> 1 df.diff().hist(color='k', alpha=0.5, bins=50)
NameError: name 'df' is not defined
```
The `by` keyword can be specified to plot grouped histograms:

```python
In [35]: data = pd.Series(np.random.randn(1000))
NameError: name 'pd' is not defined

In [36]: data.hist(by=np.random.randint(0, 4, 1000), figsize=(6, 4))
NameError: name 'data' is not defined
```
Box plots

Boxplot can be drawn calling `Series.plot.box()` and `DataFrame.plot.box()`, or `DataFrame.boxplot()` to visualize the distribution of values within each column.

For instance, here is a boxplot representing five trials of 10 observations of a uniform random variable on [0,1).

```python
In [37]: df = pd.DataFrame(np.random.rand(10, 5), columns=['A', 'B', 'C', 'D', 'E'])
NameError                               Traceback (most recent call last)
<ipython-input-37-a2f471686f35> in <module>
----> 1 df = pd.DataFrame(np.random.rand(10, 5), columns=['A', 'B', 'C', 'D', 'E'])

NameError: name 'pd' is not defined

In [38]: df.plot.box()
NameError                               Traceback (most recent call last)
<ipython-input-38-8765cf6ed5ce> in <module>
----> 1 df.plot.box()

NameError: name 'df' is not defined
```
Boxplot can be colorized by passing `color` keyword. You can pass a `dict` whose keys are `boxes`, `whiskers`, `medians` and `caps`. If some keys are missing in the `dict`, default colors are used for the corresponding artists. Also, boxplot has `sym` keyword to specify fliers style.

When you pass other type of arguments via `color` keyword, it will be directly passed to `matplotlib` for all the `boxes`, `whiskers`, `medians` and `caps` colorization.

The colors are applied to every boxes to be drawn. If you want more complicated colorization, you can get each drawn artists by passing `return_type`.

```
In [39]: color = {'boxes': 'DarkGreen', 'whiskers': 'DarkOrange',
            ....:           'medians': 'DarkBlue', 'caps': 'Gray'}
            ....:

In [40]: df.plot.box(color=color, sym='r+')
```

```
NameError                                 Traceback (most recent call last)
<ipython-input-40-2a54c0d52eaf> in <module>
      ---> 1 df.plot.box(color=color, sym='r+')

NameError: name 'df' is not defined
```
Also, you can pass other keywords supported by matplotlib boxplot. For example, horizontal and custom-positioned boxplot can be drawn by `vert=False` and `positions` keywords.

```python
In [41]: df.plot.box(vert=False, positions=[1, 4, 5, 6, 8])
```

```
NameError Traceback (most recent call last)
<ipython-input-41-6b82106697f4> in <module>
      1 df.plot.box(vert=False, positions=[1, 4, 5, 6, 8])
NameError: name 'df' is not defined
```
See the `boxplot` method and the `matplotlib` `boxplot` documentation for more.

The existing interface `DataFrame.boxplot` to plot boxplot still can be used.

```python
In [42]: df = pd.DataFrame(np.random.rand(10, 5))
---------------------------------------------------------------------------
NameError             Traceback (most recent call last)
<ipython-input-42-fd2300c25153> in <module>
----> 1 df = pd.DataFrame(np.random.rand(10, 5))
NameError: name 'pd' is not defined

In [43]: plt.figure();

In [44]: bp = df.boxplot()
---------------------------------------------------------------------------
NameError             Traceback (most recent call last)
<ipython-input-44-5b6d837d4b1a> in <module>
----> 1 bp = df.boxplot()
NameError: name 'df' is not defined
```
You can create a stratified boxplot using the `by` keyword argument to create groupings. For instance,

```python
In [45]: df = pd.DataFrame(np.random.rand(10, 2), columns=['Col1', 'Col2'])
NameError: name 'pd' is not defined

NameError: name 'pd' is not defined

In [47]: plt.figure();
```

```python
In [48]: bp = df.boxplot(by='X')
NameError: name 'df' is not defined
```

(continues on next page)
You can also pass a subset of columns to plot, as well as group by multiple columns:

```
In [49]: df = pd.DataFrame(np.random.rand(10, 3), columns=['Col1', 'Col2', 'Col3'])
NameError: name 'pd' is not defined
NameError: name 'pd' is not defined
```

(continues on next page)
In boxplot, the return type can be controlled by the return_type, keyword. The valid choices are {'axes', 'dict', 'both', None}. Faceting, created by DataFrame.boxplot with the by keyword, will affect the output type as well:
Groupby.boxplot always returns a Series of return_type.

In [54]: np.random.seed(1234)

In [55]: df_box = pd.DataFrame(np.random.randn(50, 2))

NameError Traceback (most recent call last)
<ipython-input-55-043b0e16e969> in <module>
----> 1 df_box = pd.DataFrame(np.random.randn(50, 2))

NameError: name 'pd' is not defined

In [56]: df_box['g'] = np.random.choice(['A', 'B'], size=50)

NameError Traceback (most recent call last)
<ipython-input-56-e39101f788cc> in <module>
----> 1 df_box['g'] = np.random.choice(['A', 'B'], size=50)

NameError: name 'df_box' is not defined

In [57]: df_box.loc[df_box['g'] == 'B', 1] += 3

NameError Traceback (most recent call last)
<ipython-input-57-996ee2e7f114> in <module>
----> 1 df_box.loc[df_box['g'] == 'B', 1] += 3

NameError: name 'df_box' is not defined

In [58]: bp = df_box.boxplot(by='g')

NameError Traceback (most recent call last)
<ipython-input-58-8fc769e009a9> in <module>
----> 1 bp = df_box.boxplot(by='g')

NameError: name 'df_box' is not defined
The subplots above are split by the numeric columns first, then the value of the $g$ column. Below the subplots are first split by the value of $g$, then by the numeric columns.

```
In [59]: bp = df_box.groupby('g').boxplot()
NameError
```

```
  Traceback (most recent call last)
<ipython-input-59-900c71ff9ec1> in <module>
----> 1 bp = df_box.groupby('g').boxplot()

NameError: name 'df_box' is not defined
```
Area plot

You can create area plots with `Series.plot.area()` and `DataFrame.plot.area()`. Area plots are stacked by default. To produce stacked area plot, each column must be either all positive or all negative values.

When input data contains NaN, it will be automatically filled by 0. If you want to drop or fill by different values, use `dataframe.dropna()` or `dataframe.fillna()` before calling `plot`.

```python
In [60]: df = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])
```
```
NameError Traceback (most recent call last)
<ipython-input-60-1599b5508584> in <module>
----> 1 df = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])

NameError: name 'pd' is not defined
```

```python
In [61]: df.plot.area();
```
To produce an unstacked plot, pass `stacked=False`. Alpha value is set to 0.5 unless otherwise specified:

```python
In [62]: df.plot.area(stacked=False);
```
Scatter plot

Scatter plot can be drawn by using the `DataFrame.plot.scatter()` method. Scatter plot requires numeric columns for the x and y axes. These can be specified by the x and y keywords.

```python
In [63]: df = pd.DataFrame(np.random.rand(50, 4), columns=['a', 'b', 'c', 'd'])
---------------------------------------------------------------------------
NameError                       Traceback (most recent call last)
<ipython-input-63-a5ddb87a0bbe> in <module>
 ----> 1 df = pd.DataFrame(np.random.rand(50, 4), columns=['a', 'b', 'c', 'd'])

NameError: name 'pd' is not defined

In [64]: df.plot.scatter(x='a', y='b');
```
To plot multiple column groups in a single axes, repeat `plot` method specifying target `ax`. It is recommended to specify `color` and `label` keywords to distinguish each groups.

```python
In [65]: ax = df.plot.scatter(x='a', y='b', color='DarkBlue', label='Group 1');
In [66]: df.plot.scatter(x='c', y='d', color='DarkGreen', label='Group 2', ax=ax);
```
The keyword `c` may be given as the name of a column to provide colors for each point:

```python
In [67]: df.plot.scatter(x='a', y='b', c='c', s=50);
```
You can pass other keywords supported by matplotlib `scatter`. The example below shows a bubble chart using a column of the DataFrame as the bubble size.

```
In [68]: df.plot.scatter(x='a', y='b', s=df['c'] * 200);
```

See the `scatter` method and the `matplotlib` scatter documentation for more.

**Hexagonal bin plot**

You can create hexagonal bin plots with `DataFrame.plot.hexbin()`. Hexbin plots can be a useful alternative to scatter plots if your data are too dense to plot each point individually.

```python
In [69]: df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])
NameError Traceback (most recent call last)
<ipython-input-69-e243cb9efde5> in <module>
----> 1 df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])
NameError: name 'pd' is not defined

In [70]: df['b'] = df['b'] + np.arange(1000)
NameError Traceback (most recent call last)
<ipython-input-70-09ef1c00dd7f> in <module>
----> 1 df['b'] = df['b'] + np.arange(1000)
NameError: name 'df' is not defined

In [71]: df.plot.hexbin(x='a', y='b', gridsize=25)
```

(continues on next page)
A useful keyword argument is `gridsize`; it controls the number of hexagons in the x-direction, and defaults to 100. A larger `gridsize` means more, smaller bins.

By default, a histogram of the counts around each \((x, y)\) point is computed. You can specify alternative aggregations by passing values to the `C` and `reduce_C_function` arguments. `C` specifies the value at each \((x, y)\) point and `reduce_C_function` is a function of one argument that reduces all the values in a bin to a single number (e.g. `mean`, `max`, `sum`, `std`). In this example the positions are given by columns `a` and `b`, while the value is given by column `z`. The bins are aggregated with NumPy’s `max` function.
In [73]: df['b'] = df['b'] = df['b'] + np.arange(1000)
---------------------------------------------------------------------------
NameError Traceback (most recent call last)
<ipython-input-73-2214dd14e63e> in <module>
----> 1 df['b'] = df['b'] = df['b'] + np.arange(1000)

NameError: name 'df' is not defined

In [74]: df['z'] = np.random.uniform(0, 3, 1000)
---------------------------------------------------------------------------
NameError Traceback (most recent call last)
<ipython-input-74-a84ae78b3d08> in <module>
----> 1 df['z'] = np.random.uniform(0, 3, 1000)

NameError: name 'df' is not defined

In [75]: df.plot.hexbin(x='a', y='b', C='z', reduce_C_function=np.max, gridsize=25)
---------------------------------------------------------------------------
NameError Traceback (most recent call last)
<ipython-input-75-76020970b51d> in <module>
----> 1 df.plot.hexbin(x='a', y='b', C='z', reduce_C_function=np.max, gridsize=25)

NameError: name 'df' is not defined

See the `hexbin` method and the `matplotlib` hexbin documentation for more.
Pie plot

You can create a pie plot with `DataFrame.plot.pie()` or `Series.plot.pie()`. If your data includes any NaN, they will be automatically filled with 0. A `ValueError` will be raised if there are any negative values in your data.

```
In [76]: series = pd.Series(3 * np.random.rand(4),
                      index=['a', 'b', 'c', 'd'], name='series')
```

```
NameError: name 'pd' is not defined
```

```
In [77]: series.plot.pie(figsize=(6, 6))
```

```
NameError: name 'series' is not defined
```

For pie plots it’s best to use square figures, i.e. a figure aspect ratio 1. You can create the figure with equal width and
height, or force the aspect ratio to be equal after plotting by calling `ax.set_aspect('equal')` on the returned `axes` object.

Note that pie plot with `DataFrame` requires that you either specify a target column by the `y` argument or `subplots=True`. When `y` is specified, pie plot of selected column will be drawn. If `subplots=True` is specified, pie plots for each column are drawn as subplots. A legend will be drawn in each pie plots by default; specify `legend=False` to hide it.

```
In [78]: df = pd.DataFrame(3 * np.random.rand(4, 2),
                  index=['a', 'b', 'c', 'd'], columns=['x', 'y'])
......:
NameError: name 'pd' is not defined

In [79]: df.plot.pie(subplots=True, figsize=(8, 4))
NameError: name 'df' is not defined
```
You can use the `labels` and `colors` keywords to specify the labels and colors of each wedge.

**Warning:** Most pandas plots use the `label` and `color` arguments (note the lack of “s” on those). To be consistent with `matplotlib.pyplot.pie()` you must use `labels` and `colors`.

If you want to hide wedge labels, specify `labels=None`. If `fontsize` is specified, the value will be applied to wedge labels. Also, other keywords supported by `matplotlib.pyplot.pie()` can be used.

```python
In [80]: series.plot.pie(labels=['AA', 'BB', 'CC', 'DD'], colors=['r', 'g', 'b', 'c'],
    autopct='%.2f', fontsize=20, figsize=(6, 6))
```

```
NameError: name 'series' is not defined
```

If you pass values whose sum total is less than 1.0, matplotlib draws a semicircle.

```python
In [81]: series = pd.Series([0.1] * 4, index=['a', 'b', 'c', 'd'], name='series2')
```

(continues on next page)
See the matplotlib pie documentation for more.
### 2.14.3 Plotting with missing data

Pandas tries to be pragmatic about plotting **DataFrames** or **Series** that contain missing data. Missing values are dropped, left out, or filled depending on the plot type.

<table>
<thead>
<tr>
<th>Plot Type</th>
<th>NaN Handling</th>
</tr>
</thead>
<tbody>
<tr>
<td>Line</td>
<td>Leave gaps at NaNs</td>
</tr>
<tr>
<td>Line (stacked)</td>
<td>Fill 0's</td>
</tr>
<tr>
<td>Bar</td>
<td>Fill 0's</td>
</tr>
<tr>
<td>Scatter</td>
<td>Drop NaNs</td>
</tr>
<tr>
<td>Histogram</td>
<td>Drop NaNs (column-wise)</td>
</tr>
<tr>
<td>Box</td>
<td>Drop NaNs (column-wise)</td>
</tr>
<tr>
<td>Area</td>
<td>Fill 0's</td>
</tr>
<tr>
<td>KDE</td>
<td>Drop NaNs (column-wise)</td>
</tr>
<tr>
<td>Hexbin</td>
<td>Drop NaNs</td>
</tr>
<tr>
<td>Pie</td>
<td>Fill 0's</td>
</tr>
</tbody>
</table>

If any of these defaults are not what you want, or if you want to be explicit about how missing values are handled, consider using `fillna()` or `dropna()` before plotting.

### 2.14.4 Plotting tools

These functions can be imported from `pandas.plotting` and take a **Series** or **DataFrame** as an argument.

**Scatter matrix plot**

You can create a scatter plot matrix using the `scatter_matrix` method in `pandas.plotting`:

```
In [83]: from pandas.plotting import scatter_matrix

In [84]: df = pd.DataFrame(np.random.randn(1000, 4), columns=['a', 'b', 'c', 'd'])

---------------------------------------------------------------------------
NameError                                 Traceback (most recent call last)
<ipython-input-84-d09bb7ca2382> in <module>
----> 1 df = pd.DataFrame(np.random.randn(1000, 4), columns=['a', 'b', 'c', 'd'])

NameError: name 'pd' is not defined

In [85]: scatter_matrix(df, alpha=0.2, figsize=(6, 6), diagonal='kde');
```
Density plot

You can create density plots using the `Series.plot.kde()` and `DataFrame.plot.kde()` methods.

```python
In [86]: ser = pd.Series(np.random.randn(1000))
---------------------------------------------------------------------------
NameError                      Traceback (most recent call last)
<ipython-input-86-58c851be3369> in <module>  
----> 1 ser = pd.Series(np.random.randn(1000))
NameError: name 'pd' is not defined

In [87]: ser.plot.kde()  
---------------------------------------------------------------------------
NameError                      Traceback (most recent call last)
<ipython-input-87-270b2425f93c> in <module>  
----> 1 ser.plot.kde()
NameError: name 'ser' is not defined
```
Andrews curves

Andrews curves allow one to plot multivariate data as a large number of curves that are created using the attributes of samples as coefficients for Fourier series, see the Wikipedia entry for more information. By coloring these curves differently for each class it is possible to visualize data clustering. Curves belonging to samples of the same class will usually be closer together and form larger structures.

**Note:** The “Iris” dataset is available [here](#).

```python
In [88]: from pandas.plotting import andrews_curves
In [89]: data = pd.read_csv('data/iris.data')
NameError: name 'pd' is not defined
In [90]: plt.figure()
Out[90]: <Figure size 640x480 with 0 Axes>
In [91]: andrews_curves(data, 'Name')
```

(continues on next page)
Parallel coordinates

Parallel coordinates is a plotting technique for plotting multivariate data, see the Wikipedia entry for an introduction. Parallel coordinates allows one to see clusters in data and to estimate other statistics visually. Using parallel coordinates points are represented as connected line segments. Each vertical line represents one attribute. One set of connected line segments represents one data point. Points that tend to cluster will appear closer together.

In [92]: from pandas.plotting import parallel_coordinates

In [93]: data = pd.read_csv('data/iris.data')

NameError Traceback (most recent call last)
<ipython-input-93-ea4716c8ea20> in <module>
----> 1 data = pd.read_csv('data/iris.data')

NameError: name 'pd' is not defined
Lag plot

Lag plots are used to check if a data set or time series is random. Random data should not exhibit any structure in the lag plot. Non-random structure implies that the underlying data are not random. The lag argument may be passed, and when lag=1 the plot is essentially data[::1] vs. data[1:].

In [96]: from pandas.plotting import lag_plot
In [97]: plt.figure()
Out[97]: <Figure size 640x480 with 0 Axes>
In [98]: spacing = np.linspace(-99 * np.pi, 99 * np.pi, num=1000)

In [99]: data = pd.Series(0.1 * np.random.rand(1000) + 0.9 * np.sin(spacing))
NameError Traceback (most recent call last)
<ipython-input-99-a1dee79fc325> in <module>
----> 1 data = pd.Series(0.1 * np.random.rand(1000) + 0.9 * np.sin(spacing))
NameError: name 'pd' is not defined

In [100]: lag_plot(data)
NameError Traceback (most recent call last)
<ipython-input-100-76d4c87cecf0> in <module>
----> 1 lag_plot(data)
NameError: name 'data' is not defined
Autocorrelation plot

Autocorrelation plots are often used for checking randomness in time series. This is done by computing autocorrelations for data values at varying time lags. If time series is random, such autocorrelations should be near zero for any and all time-lag separations. If time series is non-random then one or more of the autocorrelations will be significantly non-zero. The horizontal lines displayed in the plot correspond to 95% and 99% confidence bands. The dashed line is 99% confidence band. See the Wikipedia entry for more about autocorrelation plots.

```
In [101]: from pandas.plotting import autocorrelation_plot

In [102]: plt.figure()
Out[102]: <Figure size 640x480 with 0 Axes>

In [103]: spacing = np.linspace(-9 * np.pi, 9 * np.pi, num=1000)

In [104]: data = pd.Series(0.7 * np.random.rand(1000) + 0.3 * np.sin(spacing))

NameError Traceback (most recent call last)
<ipython-input-104-8a50b1acf632> in <module>
----> 1 data = pd.Series(0.7 * np.random.rand(1000) + 0.3 * np.sin(spacing))

NameError: name 'pd' is not defined

In [105]: autocorrelation_plot(data)

NameError Traceback (most recent call last)
<ipython-input-105-eccad460986f> in <module>
----> 1 autocorrelation_plot(data)

NameError: name 'data' is not defined
```
Bootstrap plot

Bootstrap plots are used to visually assess the uncertainty of a statistic, such as mean, median, midrange, etc. A random subset of a specified size is selected from a data set, the statistic in question is computed for this subset and the process is repeated a specified number of times. Resulting plots and histograms are what constitutes the bootstrap plot.

```python
In [106]: from pandas.plotting import bootstrap_plot

In [107]: data = pd.Series(np.random.rand(1000))
NameError: name 'pd' is not defined

In [108]: bootstrap_plot(data, size=50, samples=500, color='grey')
NameError: name 'data' is not defined
```
RadViz

RadViz is a way of visualizing multi-variate data. It is based on a simple spring tension minimization algorithm. Basically you set up a bunch of points in a plane. In our case they are equally spaced on a unit circle. Each point represents a single attribute. You then pretend that each sample in the data set is attached to each of these points by a spring, the stiffness of which is proportional to the numerical value of that attribute (they are normalized to unit interval). The point in the plane, where our sample settles to (where the forces acting on our sample are at an equilibrium) is where a dot representing our sample will be drawn. Depending on which class that sample belongs it will be colored differently. See the R package Radviz for more information.

Note: The “Iris” dataset is available here.

```python
In [109]: from pandas.plotting import radviz
In [110]: data = pd.read_csv('data/iris.data')
---------------------------------------------------------------------------
NameError Traceback (most recent call last)
<ipython-input-110-ea4716c8ea20> in <module>
----> 1 data = pd.read_csv('data/iris.data')
NameError: name 'pd' is not defined
In [111]: plt.figure()
Out[111]: <Figure size 640x480 with 0 Axes>
```

(continues on next page)
In [112]: radviz(data, 'Name')
NameError: name 'data' is not defined

2.14.5 Plot formatting

Setting the plot style

From version 1.5 and up, matplotlib offers a range of pre-configured plotting styles. Setting the style can be used to easily give plots the general look that you want. Setting the style is as easy as calling matplotlib.style.use(my_plot_style) before creating your plot. For example you could write matplotlib.style.use('ggplot') for ggplot-style plots.

You can see the various available style names at matplotlib.style.available and it’s very easy to try them out.
General plot style arguments

Most plotting methods have a set of keyword arguments that control the layout and formatting of the returned plot:

```python
In [113]: plt.figure();
In [114]: ts.plot(style='k--', label='Series');
```

For each kind of plot (e.g. `line`, `bar`, `scatter`) any additional arguments keywords are passed along to the corresponding `matplotlib` function (`ax.plot()`, `ax.bar()`, `ax.scatter()`). These can be used to control additional styling, beyond what pandas provides.

Controlling the legend

You may set the `legend` argument to `False` to hide the legend, which is shown by default.

```python
In [115]: df = pd.DataFrame(np.random.randn(1000, 4), 
                     index=ts.index, columns=list('ABCD'))
```

(continues on next page)
NameError: name 'pd' is not defined

In [116]: df = df.cumsum()
---------------------------------------------------------------------------
NameError Traceback (most recent call last)
<ipython-input-116-08208d45ae16> in <module>
----> 1 df = df.cumsum()

NameError: name 'df' is not defined

In [117]: df.plot(legend=False)
---------------------------------------------------------------------------
NameError Traceback (most recent call last)
<ipython-input-117-c885e70fbb28> in <module>
----> 1 df.plot(legend=False)

NameError: name 'df' is not defined
Controlling the labels

New in version 1.1.0.

You may set the `xlabel` and `ylabel` arguments to give the plot custom labels for x and y axis. By default, pandas will pick up index name as xlabel, while leaving it empty for ylabel.

```python
In [118]: df.plot()
NameError: name 'df' is not defined

In [119]: df.plot(xlabel="new x", ylabel="new y")
NameError: name 'df' is not defined
```
Scales

You may pass `logy` to get a log-scale Y axis.

```python
In [120]: ts = pd.Series(np.random.randn(1000),
             index=pd.date_range('1/1/2000', periods=1000))
In [121]: ts = np.exp(ts.cumsum())
In [122]: ts.plot(logy=True)
```

NameError: name 'pd' is not defined

NameError: name 'ts' is not defined

NameError: name 'ts' is not defined
See also the `logx` and `loglog` keyword arguments.

**Plotting on a secondary y-axis**

To plot data on a secondary y-axis, use the `secondary_y` keyword:

```python
In [123]: df['A'].plot()
---------------------------------------------------------------------------
NameError Traceback (most recent call last)
<ipython-input-123-142941d65816> in <module>                  ----> 1 df['A'].plot()

NameError: name 'df' is not defined

In [124]: df['B'].plot(secondary_y=True, style='g')
---------------------------------------------------------------------------
NameError Traceback (most recent call last)
<ipython-input-124-d13b0146b561> in <module>                  ----> 1 df['B'].plot(secondary_y=True, style='g')

NameError: name 'df' is not defined
```
To plot some columns in a DataFrame, give the column names to the `secondary_y` keyword:

```python
In [125]: plt.figure()
Out[125]: <Figure size 640x480 with 0 Axes>

In [126]: ax = df.plot(secondary_y=['A', 'B'])
---------------------------------------------------------------------------
NameError                      Traceback (most recent call last)
<ipython-input-126-c7f4eaf8c12b> in
----> 1 ax = df.plot(secondary_y=['A', 'B'])
NameError: name 'df' is not defined

In [127]: ax.set_ylabel('CD scale')
---------------------------------------------------------------------------
NameError                      Traceback (most recent call last)
<ipython-input-127-0396311d12a3> in
----> 1 ax.set_ylabel('CD scale')
NameError: name 'ax' is not defined

In [128]: ax.right_ax.set_ylabel('AB scale')
```

(continues on next page)
Note that the columns plotted on the secondary y-axis is automatically marked with “(right)” in the legend. To turn off the automatic marking, use the mark_right=False keyword:

```python
In [129]: plt.figure()
Out[129]: <Figure size 640x480 with 0 Axes>

In [130]: df.plot(secondary_y=['A', 'B'], mark_right=False)
NameError: name 'df' is not defined
```
Custom formatters for timeseries plots

Changed in version 1.0.0.

Pandas provides custom formatters for timeseries plots. These change the formatting of the axis labels for dates and times. By default, the custom formatters are applied only to plots created by pandas with DataFrame.plot() or Series.plot(). To have them apply to all plots, including those made by matplotlib, set the option pd.options.plotting.matplotlib.register_converters = True or use pandas.plotting.register_matplotlib_converters().

Suppressing tick resolution adjustment

pandas includes automatic tick resolution adjustment for regular frequency time-series data. For limited cases where pandas cannot infer the frequency information (e.g., in an externally created twinx), you can choose to suppress this behavior for alignment purposes.

Here is the default behavior, notice how the x-axis tick labeling is performed:

```
In [131]: plt.figure()
Out[131]: <Figure size 640x480 with 0 Axes>

In [132]: df['A'].plot()
```

(continues on next page)
Using the `x_compat` parameter, you can suppress this behavior:

```python
In [133]: plt.figure()
Out[133]: <Figure size 640x480 with 0 Axes>

In [134]: df['A'].plot(x_compat=True)
```

NameError Traceback (most recent call last)
<ipython-input-134-3060a6ce70ed> in <module>
----> 1 df['A'].plot(x_compat=True)

NameError: name 'df' is not defined
If you have more than one plot that needs to be suppressed, the `use` method in `pandas.plotting.plot_params` can be used in a `with statement`:

```python
In [135]: plt.figure()
Out[135]: <Figure size 640x480 with 0 Axes>

In [136]: with pd.plotting.plot_params.use('x_compat', True):
   ....:     df['A'].plot(color='r')
   ....:     df['B'].plot(color='g')
   ....:     df['C'].plot(color='b')
   ....:
NameError: name 'pd' is not defined
```
Automatic date tick adjustment

`TimedeltaIndex` now uses the native `matplotlib` tick locator methods, it is useful to call the automatic date tick adjustment from `matplotlib` for figures whose ticklabels overlap.

See the `autofmt_xdate` method and the `matplotlib` documentation for more.
Subplots

Each Series in a DataFrame can be plotted on a different axis with the subplots keyword:

```
In [137]: df.plot(subplots=True, figsize=(6, 6));
```

Using layout and targeting multiple axes

The layout of subplots can be specified by the `layout` keyword. It can accept `(rows, columns)`. The `layout` keyword can be used in `hist` and `boxplot` also. If the input is invalid, a `ValueError` will be raised.

The number of axes which can be contained by rows x columns specified by `layout` must be larger than the number of required subplots. If layout can contain more axes than required, blank axes are not drawn. Similar to a NumPy array’s `reshape` method, you can use `-1` for one dimension to automatically calculate the number of rows or columns needed, given the other.
The above example is identical to using:

```
In [139]: df.plot(subplots=True, layout=(2, -1), figsize=(6, 6), sharex=False);
```

The required number of columns (3) is inferred from the number of series to plot and the given number of rows (2). You can pass multiple axes created beforehand as list-like via `ax` keyword. This allows more complicated layouts. The passed axes must be the same number as the subplots being drawn.

When multiple axes are passed via the `ax` keyword, `layout`, `sharex` and `sharey` keywords don’t affect to the output. You should explicitly pass `sharex=False` and `sharey=False`, otherwise you will see a warning.

```
In [140]: fig, axes = plt.subplots(4, 4, figsize=(9, 9))
In [141]: plt.subplots_adjust(wspace=0.5, hspace=0.5)
In [142]: target1 = [axes[0][0], axes[1][1], axes[2][2], axes[3][3]]
In [143]: target2 = [axes[3][0], axes[2][1], axes[1][2], axes[0][3]]
In [144]: df.plot(subplots=True, ax=target1, legend=False, sharex=False, sharey=False);
```

(continues on next page)
Another option is passing an `ax` argument to `Series.plot()` to plot on a particular axis:
In [146]: fig, axes = plt.subplots(nrows=2, ncols=2)
In [147]: plt.subplots_adjust(wspace=0.2, hspace=0.5)
In [148]: df['A'].plot(ax=axes[0, 0]);
In [149]: axes[0, 0].set_title('A');
In [150]: df['B'].plot(ax=axes[0, 1]);
In [151]: axes[0, 1].set_title('B');
In [152]: df['C'].plot(ax=axes[1, 0]);
In [153]: axes[1, 0].set_title('C');
In [154]: df['D'].plot(ax=axes[1, 1]);
In [155]: axes[1, 1].set_title('D');
Plotting with error bars

Plotting with error bars is supported in DataFrame.plot() and Series.plot().

Horizontal and vertical error bars can be supplied to the xerr and yerr keyword arguments to plot(). The error values can be specified using a variety of formats:

- As a DataFrame or dict of errors with column names matching the columns attribute of the plotting DataFrame or matching the name attribute of the Series.
- As a str indicating which of the columns of plotting DataFrame contain the error values.
- As raw values (list, tuple, or np.ndarray). Must be the same length as the plotting DataFrame/Series.

Asymmetrical error bars are also supported, however raw error values must be provided in this case. For a $N$ length Series, a $2xN$ array should be provided indicating lower and upper (or left and right) errors. For a $MxN$ DataFrame, asymmetrical errors should be in a $Mx2xN$ array.

Here is an example of one way to easily plot group means with standard deviations from the raw data.

```python
# Generate the data
In [156]: ix3 = pd.MultiIndex.from_arrays([
    ...:     ['a', 'a', 'a', 'a', 'b', 'b', 'b', 'b'],
    ...:     ['foo', 'foo', 'bar', 'bar', 'foo', 'foo', 'bar', 'bar'],
    ...:     names=['letter', 'word'])

NameError Traceback (most recent call last)
<ipython-input-156-9f015fa171f2> in <module>
----> 1 ix3 = pd.MultiIndex.from_arrays([
     2 ['a', 'a', 'a', 'a', 'b', 'b', 'b', 'b'],
     3 ['foo', 'foo', 'bar', 'bar', 'foo', 'foo', 'bar', 'bar'],
     4 names=['letter', 'word'])

NameError: name 'pd' is not defined

In [157]: df3 = pd.DataFrame({'data1': [3, 2, 4, 3, 2, 4, 3, 2],
    ...: 'data2': [6, 5, 7, 5, 4, 5, 6, 5]}, index=ix3)

NameError Traceback (most recent call last)
<ipython-input-157-a2b5068f0300> in <module>
----> 1 df3 = pd.DataFrame({'data1': [3, 2, 4, 3, 2, 4, 3, 2],
    2 'data2': [6, 5, 7, 5, 4, 5, 6, 5]}, index=ix3)

NameError: name 'pd' is not defined

# Group by index labels and take the means and standard deviations
# for each group
In [158]: gp3 = df3.groupby(level=('letter', 'word'))

NameError Traceback (most recent call last)
<ipython-input-158-3f049b0a1791> in <module>
----> 1 gp3 = df3.groupby(level=('letter', 'word'))

NameError: name 'df3' is not defined

In [159]: means = gp3.mean()
```

(continues on next page)
Plotting tables

Plotting with matplotlib table is now supported in `DataFrame.plot()` and `Series.plot()` with a table keyword. The `table` keyword can accept bool, `DataFrame` or `Series`. The simple way to draw a table is to specify `table=True`. Data will be transposed to meet matplotlib's default layout.

```python
In [165]: fig, ax = plt.subplots(1, 1, figsize=(7, 6.5))

In [166]: df = pd.DataFrame(np.random.rand(5, 3), columns=['a', 'b', 'c'])

---------------------------------------------------------------------------
NameError                       Traceback (most recent call last)
<ipython-input-166-05c0fbdb11a1> in <module>
----> 1 df = pd.DataFrame(np.random.rand(5, 3), columns=['a', 'b', 'c'])

NameError: name 'pd' is not defined

In [167]: ax.xaxis.tick_top()  # Display x-axis ticks on top.

In [168]: df.plot(table=True, ax=ax)

---------------------------------------------------------------------------
NameError                       Traceback (most recent call last)
<ipython-input-168-8624f4234fa9> in <module>
----> 1 df.plot(table=True, ax=ax)

NameError: name 'pd' is not defined
```
Also, you can pass a different DataFrame or Series to the `table` keyword. The data will be drawn as displayed in print method (not transposed automatically). If required, it should be transposed manually as seen in the example below.

```python
In [169]: fig, ax = plt.subplots(1, 1, figsize=(7, 6.75))

In [170]: ax.xaxis.tick_top()  # Display x-axis ticks on top.

In [171]: df.plot(table=np.round(df.T, 2), ax=ax)
```

```
NameError Traceback (most recent call last)
<ipython-input-171-d7698dba6372> in <module>
----> 1 df.plot(table=np.round(df.T, 2), ax=ax)

NameError: name 'df' is not defined
```

(continues on next page)
There also exists a helper function `pandas.plotting.table`, which creates a table from `DataFrame` or `Series`, and adds it to an `matplotlib.Axes` instance. This function can accept keywords which the `matplotlib` table has.

```python
In [172]: from pandas.plotting import table

In [173]: fig, ax = plt.subplots(1, 1)

In [174]: table(ax, np.round(df.describe(), 2),
       loc='upper right', colWidths=[0.2, 0.2, 0.2])
```

NameError: name 'df' is not defined
NameError Traceback (most recent call last)
<ipython-input-174-c7487f392c87> in <module>
----> 1 table(ax, np.round(df.describe(), 2),
                        2            loc='upper right', colWidths=[0.2, 0.2, 0.2])

NameError: name 'df' is not defined

In [175]: df.plot(ax=ax, ylim=(0, 2), legend=None)
---------------------------------------------------------------------------
NameError Traceback (most recent call last)
<ipython-input-175-068255ff0f3e> in <module>
    ----> 1 df.plot(ax=ax, ylim=(0, 2), legend=None)

NameError: name 'df' is not defined

Note: You can get table instances on the axes using axes.tables property for further decorations. See the matplotlib table documentation for more.
Colormaps

A potential issue when plotting a large number of columns is that it can be difficult to distinguish some series due to repetition in the default colors. To remedy this, DataFrame plotting supports the use of the `colormap` argument, which accepts either a Matplotlib colormap or a string that is a name of a colormap registered with Matplotlib. A visualization of the default matplotlib colormaps is available here.

As matplotlib does not directly support colormaps for line-based plots, the colors are selected based on an even spacing determined by the number of columns in the DataFrame. There is no consideration made for background color, so some colormaps will produce lines that are not easily visible.

To use the cubehelix colormap, we can pass `colormap='cubehelix'`.

```python
In [176]: df = pd.DataFrame(np.random.randn(1000, 10), index=ts.index)
---------------------------------------------------------------------------
NameError Traceback (most recent call last)
<ipython-input-176-73acce6fcaeb> in
----> 1 df = pd.DataFrame(np.random.randn(1000, 10), index=ts.index)

NameError: name 'pd' is not defined

In [177]: df = df.cumsum()
---------------------------------------------------------------------------
NameError Traceback (most recent call last)
<ipython-input-177-08208d45ae16> in
----> 1 df = df.cumsum()

NameError: name 'df' is not defined

In [178]: plt.figure()
Out[178]: <Figure size 640x480 with 0 Axes>

In [179]: df.plot(colormap='cubehelix')
---------------------------------------------------------------------------
NameError Traceback (most recent call last)
<ipython-input-179-0aab5a23aeee> in
----> 1 df.plot(colormap='cubehelix')

NameError: name 'df' is not defined
```
Alternatively, we can pass the colormap itself:

```
In [180]: from matplotlib import cm

In [181]: plt.figure()
Out[181]: <Figure size 640x480 with 0 Axes>

In [182]: df.plot(colormap=cm.cubehelix)
NameError: name 'df' is not defined
```
Colormaps can also be used other plot types, like bar charts:

```python
In [183]: dd = pd.DataFrame(np.random.randn(10, 10)).applymap(abs)
NameError Traceback (most recent call last)
<ipython-input-183-2d4edaa33d2e> in <module>
----> 1 dd = pd.DataFrame(np.random.randn(10, 10)).applymap(abs)
NameError: name 'pd' is not defined

In [184]: dd = dd.cumsum()
NameError Traceback (most recent call last)
<ipython-input-184-cf596e929dc1> in <module>
----> 1 dd = dd.cumsum()
NameError: name 'dd' is not defined

In [185]: plt.figure()
Out[185]: <Figure size 640x480 with 0 Axes>

In [186]: dd.plot.bar(colormap='Greens')
NameError Traceback (most recent call last)
<ipython-input-186-d5bc68809546> in <module>
```

(continues on next page)
----> 1 dd.plot.bar(colormap='Greens')

NameError: name 'dd' is not defined

Parallel coordinates charts:

In [187]: plt.figure()
Out[187]: <Figure size 640x480 with 0 Axes>

In [188]: parallel_coordinates(data, 'Name', colormap='gist_rainbow')

```
2.14.6 Plotting directly with matplotlib

In some situations it may still be preferable or necessary to prepare plots directly with matplotlib, for instance when a certain type of plot or customization is not (yet) supported by pandas. Series and DataFrame objects behave like arrays and can therefore be passed directly to matplotlib functions without explicit casts.

pandas also automatically registers formatters and locators that recognize date indices, thereby extending date and time support to practically all plot types available in matplotlib. Although this formatting does not provide the same level of refinement you would get when plotting via pandas, it can be faster when plotting a large number of points.

```python
In [191]: price = pd.Series(np.random.randn(150).cumsum(),
                   index=pd.date_range('2000-1-1', periods=150, freq='B'))

---------------------------------------------------------------------------

2.14.7 Plotting backends

Starting in version 0.25, pandas can be extended with third-party plotting backends. The main idea is letting users select a plotting backend different than the provided one based on Matplotlib.

This can be done by passing `backend.module` as the argument `backend` in `plot` function. For example:

```python
>>> Series([1, 2, 3]).plot(backend='backend.module')
```

Alternatively, you can also set this option globally, so you don’t need to specify the keyword in each `plot` call. For example:

```python
>>> pd.set_option('plotting.backend', 'backend.module')
>>> pd.Series([1, 2, 3]).plot()
```

Or:

```python
>>> pd.options.plotting.backend = 'backend.module'
>>> pd.Series([1, 2, 3]).plot()
```

This would be more or less equivalent to:

```python
>>> import backend.module
>>> backend.module.plot(pd.Series([1, 2, 3]))
```
The backend module can then use other visualization tools (Bokeh, Altair, hvplot...) to generate the plots. Some libraries implementing a backend for pandas are listed on the ecosystem visualization page. Developers guide can be found at https://pandas.pydata.org/docs/dev/development/extending.html#plotting-backends

# 2.15 Computational tools

## 2.15.1 Statistical functions

### Percent change

Series and DataFrame have a method `pct_change()` to compute the percent change over a given number of periods (using `fill_method` to fill NA/null values before computing the percent change).

```python
In [1]: ser = pd.Series(np.random.randn(8))

In [2]: ser.pct_change()
Out[2]:
       0    NaN
       1  -1.602976
       2   4.334938
       3  -0.247456
       4  -2.067345
       5  -1.142903
       6  -1.688214
       7  -9.759729
       dtype: float64

In [3]: df = pd.DataFrame(np.random.randn(10, 4))

In [4]: df.pct_change(periods=3)
Out[4]:
      0      1      2      3
0   NaN    NaN    NaN    NaN
1   NaN    NaN    NaN    NaN
2   NaN    NaN    NaN    NaN
3  -0.218320 -1.054001  1.987147 -0.510183
4  -0.439121 -1.816454  0.649715 -4.822809
5  -0.127833 -3.042065 -5.866604 -1.776977
6  -2.596833 -1.959538 -2.111697 -3.798900
7  -0.117826 -2.169058  0.036094 -0.067696
8   2.492606 -1.357320 -1.205802 -1.558697
9  -1.012977  2.324558 -1.003744 -0.371806
```
Covariance

*Series.cov()* can be used to compute covariance between series (excluding missing values).

```
In [5]: s1 = pd.Series(np.random.randn(1000))
In [6]: s2 = pd.Series(np.random.randn(1000))
In [7]: s1.cov(s2)
Out[7]: 0.0006801088174310875
```

Analogously, *DataFrame.cov()* to compute pairwise covariances among the series in the DataFrame, also excluding NA/null values.

**Note:** Assuming the missing data are missing at random this results in an estimate for the covariance matrix which is unbiased. However, for many applications this estimate may not be acceptable because the estimated covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimated correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.

```
In [8]: frame = pd.DataFrame(np.random.randn(1000, 5), columns=['a', 'b', 'c', 'd', 'e'])
In [9]: frame.cov()
Out[9]:
   a       b       c       d       e
a  1.000882 -0.003177 -0.002698 -0.006889 0.031912
b -0.003177  1.024721  0.000191  0.009212 0.000857
c -0.002698  0.000191  0.950735 -0.031743 -0.005087
d -0.006889  0.009212 -0.031743  1.002983 -0.047952
e  0.031912  0.000857 -0.005087  0.047952  1.042487
```

*DataFrame.cov()* also supports an optional *min_periods* keyword that specifies the required minimum number of observations for each column pair in order to have a valid result.

```
In [10]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])
In [11]: frame.loc[frame.index[:5], 'a'] = np.nan
In [12]: frame.loc[frame.index[5:10], 'b'] = np.nan
In [13]: frame.cov()
Out[13]:
   a     b     c
a 1.123670 -0.412851 0.018169
b -0.412851 1.154141 0.305260
c 0.018169 0.305260 1.301149

In [14]: frame.cov(min_periods=12)
Out[14]:
   a     b     c
a 1.123670 NaN 0.018169
b NaN 1.154141 0.305260
c 0.018169 0.305260 1.301149
```
Correlation

Correlation may be computed using the `corr()` method. Using the `method` parameter, several methods for computing correlations are provided:

<table>
<thead>
<tr>
<th>Method name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pearson</td>
<td>Standard correlation coefficient</td>
</tr>
<tr>
<td>kendall</td>
<td>Kendall Tau correlation coefficient</td>
</tr>
<tr>
<td>spearman</td>
<td>Spearman rank correlation coefficient</td>
</tr>
</tbody>
</table>

All of these are currently computed using pairwise complete observations. Wikipedia has articles covering the above correlation coefficients:

- Pearson correlation coefficient
- Kendall rank correlation coefficient
- Spearman’s rank correlation coefficient

**Note:** Please see the caveats associated with this method of calculating correlation matrices in the covariance section.

```
In [15]: frame = pd.DataFrame(np.random.randn(1000, 5),
    ....:     columns=['a', 'b', 'c', 'd', 'e'])

In [16]: frame.iloc[::2] = np.nan

# Series with Series
In [17]: frame['a'].corr(frame['b'])
Out[17]: 0.013479040400098775

In [18]: frame['a'].corr(frame['b'], method='spearman')
Out[18]: -0.007289885159540637

# Pairwise correlation of DataFrame columns
In [19]: frame.corr()
Out[19]:
       a         b         c         d         e
a  1.000000 -0.049269 -0.042239 -0.028525
b -0.049269  1.000000 -0.20433 -0.011139  0.005654
c -0.042239 -0.20433  1.000000  0.18587 -0.054269
d -0.028525  0.005654 -0.054269  1.000000 -0.017060
e  0.013479 -0.049269 -0.042239 -0.028525  1.000000
```

Note that non-numeric columns will be automatically excluded from the correlation calculation.

Like `cov`, `corr` also supports the optional `min_periods` keyword:

```
In [20]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])

In [21]: frame.loc[frame.index[:5], 'a'] = np.nan

In [22]: frame.loc[frame.index[5:10], 'b'] = np.nan

In [23]: frame.corr()
```

(continues on next page)
New in version 0.24.0.

The method argument can also be a callable for a generic correlation calculation. In this case, it should be a single function that produces a single value from two ndarray inputs. Suppose we wanted to compute the correlation based on histogram intersection:

```python
# histogram intersection
In [25]: def histogram_intersection(a, b):
    ....:     return np.minimum(np.true_divide(a, a.sum()),
    ....:                         np.true_divide(b, b.sum())).sum()
    ....:

In [26]: frame.corr(method=histogram_intersection)
```

A related method `corrwith()` is implemented on DataFrame to compute the correlation between like-labeled Series contained in different DataFrame objects.

```python
In [27]: index = ['a', 'b', 'c', 'd', 'e']

In [28]: columns = ['one', 'two', 'three', 'four']

In [29]: df1 = pd.DataFrame(np.random.randn(5, 4), index=index, columns=columns)

In [30]: df2 = pd.DataFrame(np.random.randn(4, 4), index=index[:4], columns=columns)

In [31]: df1.corrwith(df2)
```

(continues on next page)
Data ranking

The `rank()` method produces a data ranking with ties being assigned the mean of the ranks (by default) for the group:

```python
In [33]: s = pd.Series(np.random.randn(5), index=list('abcde'))
In [34]: s['d'] = s['b']  # so there's a tie
In [35]: s.rank()
Out[35]:
    a    5.0
    b    2.5
    c    1.0
    d    2.5
    e    4.0
Name: rank, dtype: float64
```

`rank()` is also a DataFrame method and can rank either the rows (`axis=0`) or the columns (`axis=1`). NaN values are excluded from the ranking.

```python
In [36]: df = pd.DataFrame(np.random.randn(10, 6))
In [38]: df.rank(1)
Out[38]:
     0    1    2    3    4    5
0   4.0  3.0  1.5  5.0  1.5  6.0
1   2.0  6.0  4.5  1.0  4.5  3.0
2   1.0  6.0  3.5  5.0  3.5  2.0
3   4.0  5.0  1.5  3.0  1.5  6.0
4   5.0  3.0  1.5  4.0  1.5  6.0
5   1.0  2.0  5.0  3.0    NaN  4.0
6   4.0  5.0  3.0  1.0    NaN  2.0
7   2.0  5.0  3.0  4.0    NaN  1.0
8   2.0  5.0  3.0  4.0    NaN  1.0
9   2.0  3.0  1.0  4.0    NaN  5.0
```

```python
In [33]: e NaN
dtype: float64
```
rank optionally takes a parameter ascending which by default is true; when false, data is reverse-ranked, with larger values assigned a smaller rank.

rank supports different tie-breaking methods, specified with the method parameter:

- average: average rank of tied group
- min: lowest rank in the group
- max: highest rank in the group
- first: ranks assigned in the order they appear in the array

## 2.15.2 Window functions

For working with data, a number of window functions are provided for computing common window or rolling statistics. Among these are count, sum, mean, median, correlation, variance, covariance, standard deviation, skewness, and kurtosis.

The rolling() and expanding() functions can be used directly from DataFrameGroupBy objects, see the groupby docs.

**Note:** The API for window statistics is quite similar to the way one works with GroupBy objects, see the documentation here.

We work with rolling, expanding and exponentially weighted data through the corresponding objects, Rolling, Expanding and ExponentialMovingWindow.

```python
In [40]: s = pd.Series(np.random.randn(1000),
                  index=pd.date_range('1/1/2000', periods=1000))
In [41]: s = s.cumsum()

In [42]: s
Out [42]:
2000-01-01   -0.268824
2000-01-02   -1.771855
2000-01-03   -0.818003
2000-01-04   -0.659244
2000-01-05   -1.942133
             ...   
2002-09-22  -67.457323
2002-09-23  -69.253182
2002-09-24  -70.296818
2002-09-25  -70.844674
2002-09-26  -72.475016
Freq: D, Length: 1000, dtype: float64
```

These are created from methods on Series and DataFrame.

```python
In [43]: r = s.rolling(window=60)
In [44]: r
Out[44]: Rolling [window=60, center=False, axis=0]
```

These object provide tab-completion of the available methods and properties.
Generally these methods all have the same interface. They all accept the following arguments:

- **window**: size of moving window
- **min_periods**: threshold of non-null data points to require (otherwise result is NA)
- **center**: boolean, whether to set the labels at the center (default is False)

We can then call methods on these rolling objects. These return like-indexed objects:

```
In [45]: r.mean()
Out[45]:
          2000-01-01    NaN
          2000-01-02    NaN
          2000-01-03    NaN
          2000-01-04    NaN
          2000-01-05    NaN
             ...        ...
          2002-09-22  -62.914971
          2002-09-23  -63.061867
          2002-09-24  -63.213876
          2002-09-25  -63.375074
          2002-09-26  -63.539734
Freq: D, Length: 1000, dtype: float64
```

```
In [46]: s.plot(style='k--')
Out[46]: <AxesSubplot:>
```

```
In [47]: r.mean().plot(style='k')
Out[47]: <AxesSubplot:>
```
They can also be applied to DataFrame objects. This is really just syntactic sugar for applying the moving window
operator to all of the DataFrame’s columns:

```python
In [48]: df = pd.DataFrame(np.random.randn(1000, 4),
    ....:     index=pd.date_range('1/1/2000', periods=1000),
    ....:     columns=['A', 'B', 'C', 'D'])
    ....:
In [49]: df = df.cumsum()
In [50]: df.rolling(window=60).sum().plot(subplots=True)
Out[50]:
array([<AxesSubplot:>, <AxesSubplot:>, <AxesSubplot:>, <AxesSubplot:>],
       dtype=object)
```
## Method summary

We provide a number of common statistical functions:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>count()</td>
<td>Number of non-null observations</td>
</tr>
<tr>
<td>sum()</td>
<td>Sum of values</td>
</tr>
<tr>
<td>mean()</td>
<td>Mean of values</td>
</tr>
<tr>
<td>median()</td>
<td>Arithmetic median of values</td>
</tr>
<tr>
<td>min()</td>
<td>Minimum</td>
</tr>
<tr>
<td>max()</td>
<td>Maximum</td>
</tr>
<tr>
<td>std()</td>
<td>Sample standard deviation</td>
</tr>
<tr>
<td>var()</td>
<td>Sample variance</td>
</tr>
<tr>
<td>skew()</td>
<td>Sample skewness (3rd moment)</td>
</tr>
<tr>
<td>kurt()</td>
<td>Sample kurtosis (4th moment)</td>
</tr>
<tr>
<td>quantile()</td>
<td>Sample quantile (value at %)</td>
</tr>
<tr>
<td>apply()</td>
<td>Generic apply</td>
</tr>
<tr>
<td>cov()</td>
<td>Sample covariance (binary)</td>
</tr>
<tr>
<td>corr()</td>
<td>Sample correlation (binary)</td>
</tr>
</tbody>
</table>

**Note:** Please note that `std()` and `var()` use the sample variance formula by default, i.e. the sum of squared
differences is divided by \( \text{window\_size} - 1 \) and not by \( \text{window\_size} \) during averaging. In statistics, we use sample when the dataset is drawn from a larger population that we don’t have access to. Using it implies that the data in our window is a random sample from the population, and we are interested not in the variance inside the specific window but in the variance of some general window that our windows represent. In this situation, using the sample variance formula results in an unbiased estimator and so is preferred.

Usually, we are instead interested in the variance of each window as we slide it over the data, and in this case we should specify \( \text{ddof}=0 \) when calling these methods to use population variance instead of sample variance. Using sample variance under the circumstances would result in a biased estimator of the variable we are trying to determine.

The same caveats apply to using any supported statistical sample methods.

**Rolling apply**

The \texttt{apply()} function takes an extra \texttt{func} argument and performs generic rolling computations. The \texttt{func} argument should be a single function that produces a single value from an \texttt{ndarray} input. Suppose we wanted to compute the mean absolute deviation on a rolling basis:

```python
In [51]: def mad(x):
    ....:     return np.fabs(x - x.mean()).mean()
    ....:

In [52]: s.rolling(window=60).apply(mad, raw=True).plot(style='k')
```

![Graph showing rolling mean absolute deviation](image)

**2.15. Computational tools**
New in version 1.0.

Additionally, apply() can leverage Numba if installed as an optional dependency. The apply aggregation can be executed using Numba by specifying engine='numba' and engine_kwargs arguments (raw must also be set to True). Numba will be applied in potentially two routines:

1. If func is a standard Python function, the engine will JIT the passed function. func can also be a JITed function in which case the engine will not JIT the function again.

2. The engine will JIT the for loop where the apply function is applied to each window.

The engine_kwargs argument is a dictionary of keyword arguments that will be passed into the numba.jit decorator. These keyword arguments will be applied to both the passed function (if a standard Python function) and the apply for loop over each window. Currently only nogil, nopython, and parallel are supported, and their default values are set to False, True and False respectively.

**Note:** In terms of performance, the first time a function is run using the Numba engine will be slow as Numba will have some function compilation overhead. However, the compiled functions are cached, and subsequent calls will be fast. In general, the Numba engine is performant with a larger amount of data points (e.g. 1+ million).

```python
In [1]: data = pd.Series(range(1_000_000))
In [2]: roll = data.rolling(10)
In [3]: def f(x):
   ...:     return np.sum(x) + 5
   # Run the first time, compilation time will affect performance
In [4]: %timeit roll.apply(f, engine='numba', raw=True)  # noqa: E225
   1.23 s ± 0 ns per loop (mean ± std. dev. of 1 run, 1 loop each)
   # Function is cached and performance will improve
In [5]: %timeit roll.apply(f, engine='numba', raw=True)  
   188 ms ± 1.93 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)
In [6]: %timeit roll.apply(f, engine='cython', raw=True)  
   3.92 s ± 59 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)
```

## Rolling windows

Passing win_type to .rolling generates a generic rolling window computation, that is weighted according the win_type. The following methods are available:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sum()</td>
<td>Sum of values</td>
</tr>
<tr>
<td>mean()</td>
<td>Mean of values</td>
</tr>
</tbody>
</table>

The weights used in the window are specified by the win_type keyword. The list of recognized types are the scipy.signal window functions:

- boxcar
- triang
- blackman
- hamming
- bartlett
• parzen
• bohman
• blackmanharris
• nuttall
• barthann
• kaiser (needs beta)
• gaussian (needs std)
• general_gaussian (needs power, width)
• slepian (needs width)
• exponential (needs tau).

In [53]: ser = pd.Series(np.random.randn(10),
      index=pd.date_range('1/1/2000', periods=10))

In [54]: ser.rolling(window=5, win_type='triang').mean()
Out[54]:
2000-01-01       NaN
2000-01-02       NaN
2000-01-03       NaN
2000-01-04       NaN

(continues on next page)
For some windowing functions, additional parameters must be specified:

```python
In [57]: ser.rolling(window=5, win_type='gaussian').mean(std=0.1)
Out[57]:
2000-01-01 NaN
2000-01-02 NaN
2000-01-03 NaN
2000-01-04 NaN
2000-01-05 -1.309989
2000-01-06 -1.153000
2000-01-07 0.606382
2000-01-08 -0.681101
2000-01-09 -0.289724
2000-01-10 -0.996632
Freq: D, dtype: float64
```

Note: For `.sum()` with a `win_type`, there is no normalization done to the weights for the window. Passing custom weights of `[1, 1, 1]` will yield a different result than passing weights of `[2, 2, 2]`, for example. When passing a `win_type` instead of explicitly specifying the weights, the weights are already normalized so that the largest weight is 1.

In contrast, the nature of the `.mean()` calculation is such that the weights are normalized with respect to each other. Weights of `[1, 1, 1]` and `[2, 2, 2]` yield the same result.

### Time-aware rolling

It is possible to pass an offset (or convertible) to a `.rolling()` method and have it produce variable sized windows based on the passed time window. For each time point, this includes all preceding values occurring within the indicated time delta.

This can be particularly useful for a non-regular time frequency index.

```python
In [58]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
   ...: index=pd.date_range('20130101 09:00:00',
   ...: periods=5,
   ...: freq='s'))

In [59]: dft
Out[59]:
   B
2013-01-01 09:00:00 0.0
2013-01-01 09:00:01 1.0
2013-01-01 09:00:02 2.0
2013-01-01 09:00:03 NaN
2013-01-01 09:00:04 4.0
```
This is a regular frequency index. Using an integer window parameter works to roll along the window frequency.

```python
In [60]: dft.rolling(2).sum()
Out[60]:
          B
2013-01-01 09:00:00 NaN
2013-01-01 09:00:01 1.0
2013-01-01 09:00:02 3.0
2013-01-01 09:00:03 NaN
2013-01-01 09:00:04 NaN
```

```python
In [61]: dft.rolling(2, min_periods=1).sum()
Out[61]:
          B
2013-01-01 09:00:00 0.0
2013-01-01 09:00:01 1.0
2013-01-01 09:00:02 3.0
2013-01-01 09:00:03 2.0
2013-01-01 09:00:04 4.0
```

Specifying an offset allows a more intuitive specification of the rolling frequency.

```python
In [62]: dft.rolling('2s').sum()
Out[62]:
          B
2013-01-01 09:00:00 0.0
2013-01-01 09:00:01 1.0
2013-01-01 09:00:02 3.0
2013-01-01 09:00:03 2.0
2013-01-01 09:00:04 4.0
```

Using a non-regular, but still monotonic index, rolling with an integer window does not impart any special calculation.

```python
In [63]:
df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4],
                   'foo': [0, 1, 2, np.nan, 4]},
                   index=[pd.Timestamp('20130101 09:00:00'),
                          pd.Timestamp('20130101 09:00:02'),
                          pd.Timestamp('20130101 09:00:03'),
                          pd.Timestamp('20130101 09:00:05'),
                          pd.Timestamp('20130101 09:00:06')],
                   name='foo'))

In [64]: df
Out[64]:
   B  foo
2013-01-01 09:00:00 0.0 0.0
2013-01-01 09:00:02 1.0 1.0
2013-01-01 09:00:03 2.0 2.0
2013-01-01 09:00:05 NaN NaN
2013-01-01 09:00:06 4.0 4.0
```

```python
In [65]: df.rolling(2).sum()
Out[65]:
   B  foo
2013-01-01 09:00:00 NaN NaN
2013-01-01 09:00:02 1.0 1.0
```

(continues on next page)
Using the time-specification generates variable windows for this sparse data.

```python
In [66]: dft.rolling('2s').sum()
Out[66]:
    foo
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

Furthermore, we now allow an optional `on` parameter to specify a column (rather than the default of the index) in a DataFrame.

```python
In [67]: dft = dft.reset_index()
In [68]: dft
Out[68]:
     foo  B
0  2013-01-01 09:00:00  0.0
1  2013-01-01 09:00:02  1.0
2  2013-01-01 09:00:03  2.0
3  2013-01-01 09:00:05  NaN
4  2013-01-01 09:00:06  4.0

In [69]: dft.rolling('2s', on='foo').sum()
Out[69]:
     foo  B
0  2013-01-01 09:00:00  0.0
1  2013-01-01 09:00:02  1.0
2  2013-01-01 09:00:03  3.0
3  2013-01-01 09:00:05  NaN
4  2013-01-01 09:00:06  4.0
```

**Custom window rolling**

New in version 1.0.

In addition to accepting an integer or offset as a `window` argument, `rolling` also accepts a `BaseIndexer` subclass that allows a user to define a custom method for calculating window bounds. The `BaseIndexer` subclass will need to define a `get_window_bounds` method that returns a tuple of two arrays, the first being the starting indices of the windows and second being the ending indices of the windows. Additionally, `num_values`, `min_periods`, `center`, `closed` and will automatically be passed to `get_window_bounds` and the defined method must always accept these arguments.

For example, if we have the following DataFrame:

```python
In [70]: use_expanding = [True, False, True, False, True]
In [71]: use_expanding
```

(continues on next page)
Out[71]: [True, False, True, False, True]

In [72]: df = pd.DataFrame({'values': range(5)})

In [73]: df
Out[73]:
   values
0      0
1      1
2      2
3      3
4      4

and we want to use an expanding window where use_expanding is True otherwise a window of size 1, we can create the following BaseIndexer subclass:

In [2]: from pandas.api.indexers import BaseIndexer
...
...: class CustomIndexer(BaseIndexer):
...:
...:     def get_window_bounds(self, num_values, min_periods, center, closed):
...:         start = np.empty(num_values, dtype=np.int64)
...:         end = np.empty(num_values, dtype=np.int64)
...:         for i in range(num_values):
...:             if self.use_expanding[i]:
...:                 start[i] = 0
...:                 end[i] = i + 1
...:             else:
...:                 start[i] = i
...:                 end[i] = i + self.window_size
...:         return start, end
...:

In [3]: indexer = CustomIndexer(window_size=1, use_expanding=use_expanding)

In [4]: df.rolling(indexer).sum()
Out[4]:
   values
0   0.0
1   1.0
2   3.0
3   3.0
4  10.0

You can view other examples of BaseIndexer subclasses here

New in version 1.1.

One subclass of note within those examples is the VariableOffsetWindowIndexer that allows rolling operations over a non-fixed offset like a BusinessDay.

In [74]: from pandas.api.indexers import VariableOffsetWindowIndexer

In [75]: df = pd.DataFrame(range(10), index=pd.date_range('2020', periods=10))

In [76]: offset = pd.offsets.BDay(1)
For some problems knowledge of the future is available for analysis. For example, this occurs when each data point is a full time series read from an experiment, and the task is to extract underlying conditions. In these cases it can be useful to perform forward-looking rolling window computations. The `FixedForwardWindowIndexer` class is available for this purpose. This `BaseIndexer` subclass implements a closed fixed-width forward-looking rolling window, and we can use it as follows:

**Rolling window endpoints**

The inclusion of the interval endpoints in rolling window calculations can be specified with the `closed` parameter:

<table>
<thead>
<tr>
<th>closed</th>
<th>Description</th>
<th>Default for</th>
</tr>
</thead>
<tbody>
<tr>
<td>right</td>
<td>close right endpoint</td>
<td>time-based windows</td>
</tr>
<tr>
<td>left</td>
<td>close left endpoint</td>
<td></td>
</tr>
<tr>
<td>both</td>
<td>close both endpoints</td>
<td>fixed windows</td>
</tr>
<tr>
<td>neither</td>
<td>open endpoints</td>
<td></td>
</tr>
</tbody>
</table>

For example, having the right endpoint open is useful in many problems that require that there is no contamination from present information back to past information. This allows the rolling window to compute statistics “up to that point in time”, but not including that point in time.
Currently, this feature is only implemented for time-based windows. For fixed windows, the closed parameter cannot be set and the rolling window will always have both endpoints closed.

**Iteration over window:**

New in version 1.1.0.

*Rolling* and *Expanding* objects now support iteration. Be noted that *min_periods* is ignored in iteration.

**Time-aware rolling vs. resampling**

Using `.rolling()` with a time-based index is quite similar to *resampling*. They both operate and perform reductive operations on time-indexed pandas objects.

When using `.rolling()` with an offset. The offset is a time-delta. Take a backwards-in-time looking window, and aggregate all of the values in that window (including the end-point, but not the start-point). This is the new value at that point in the result. These are variable sized windows in time-space for each point of the input. You will get a same sized result as the input.
When using `.resample()` with an offset, construct a new index that is the frequency of the offset. For each frequency bin, aggregate points from the input within a backwards-in-time looking window that fall in that bin. The result of this aggregation is the output for that frequency point. The windows are fixed size in the frequency space. Your result will have the shape of a regular frequency between the min and the max of the original input object.

To summarize, `.rolling()` is a time-based window operation, while `.resample()` is a frequency-based window operation.

Centering windows

By default the labels are set to the right edge of the window, but a `center` keyword is available so the labels can be set at the center.

```

```

Binary window functions

`cov()` and `corr()` can compute moving window statistics about two Series or any combination of DataFrame/Series or DataFrame/DataFrame. Here is the behavior in each case:

- two Series: compute the statistic for the pairing.
- DataFrame/Series: compute the statistics for each column of the DataFrame with the passed Series, thus returning a DataFrame.
- DataFrame/DataFrame: by default compute the statistic for matching column names, returning a DataFrame. If the keyword argument `pairwise=True` is passed then computes the statistic for each pair of columns, returning a MultiIndexed DataFrame whose index are the dates in question (see the next section).

For example:
In [90]: df = pd.DataFrame(np.random.randn(1000, 4),
    ....:                     index=pd.date_range('1/1/2000', periods=1000),
    ....:                     columns=['A', 'B', 'C', 'D'])
In [91]: df = df.cumsum()
In [92]: df2 = df[:20]
In [93]: df2.rolling(window=5).corr(df2['B'])
Out[93]:
          A       B       C       D
2000-01-01 NaN  0.768775 -0.977990  0.800252

Computing rolling pairwise covariances and correlations

In financial data analysis and other fields it’s common to compute covariance and correlation matrices for a collection of time series. Often one is also interested in moving-window covariance and correlation matrices. This can be done by passing the pairwise keyword argument, which in the case of DataFrame inputs will yield a MultiIndexed DataFrame whose index are the dates in question. In the case of a single DataFrame argument the pairwise argument can even be omitted:

Note: Missing values are ignored and each entry is computed using the pairwise complete observations. Please see the covariance section for caveats associated with this method of calculating covariance and correlation matrices.

In [94]: covs = (df[['B', 'C', 'D']].rolling(window=50)
    ....:                     .cov(df[['A', 'B', 'C']], pairwise=True))
In [95]: covs.loc['2002-09-22':]

[20 rows x 4 columns]

You can efficiently retrieve the time series of correlations between two columns by reshaping and indexing:

In [98]: correls.unstack(1)[('A', 'C')].plot()
Out[98]: <AxesSubplot:>

pandas: powerful Python data analysis toolkit, Release 1.1.5
2.15.3 Aggregation

Once the Rolling, Expanding or ExponentialMovingWindow objects have been created, several methods are available to perform multiple computations on the data. These operations are similar to the aggregating API, groupby API, and resample API.

```
In [99]: dfa = pd.DataFrame(np.random.randn(1000, 3),
       index=pd.date_range('1/1/2000', periods=1000),
       columns=['A', 'B', 'C'])
       ....:

In [100]: r = dfa.rolling(window=60, min_periods=1)

In [101]: r
Out[101]: Rolling [window=60,min_periods=1,center=False,axis=0]

In [102]: r.aggregate(np.sum)
Out[102]:
   A    B    C
2000-01-01 -0.289838 -0.370545 -1.284206
```

We can aggregate by passing a function to the entire DataFrame, or select a Series (or multiple Series) via standard __getitem__.
As you can see, the result of the aggregation will have the selected columns, or all columns if none are selected.
Applying multiple functions

With windowed Series you can also pass a list of functions to do aggregation with, outputting a DataFrame:

```
In [105]: r['A'].agg([np.sum, np.mean, np.std])
Out[105]:
          sum     mean    std
2000-01-01 -0.289838 -0.289838 NaN
2000-01-02 -0.216612 -0.108306 0.256725
2000-01-03  1.154661  0.384887 0.873311
2000-01-04  2.969393  0.742348 1.009734
2000-01-05  4.690630  0.938126 0.977914
     ...     ...     ...
2002-09-22  2.860036  0.047667 1.132051
2002-09-23  3.510163  0.058503 1.134296
2002-09-24  6.524983  0.108750 1.144204
2002-09-25  6.409626  0.106827 1.142913
2002-09-26  5.093787  0.084896 1.151416
[1000 rows x 3 columns]
```

On a windowed DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [106]: r.agg([np.sum, np.mean])
Out[106]:
         A      B      C
          sum     mean    sum     mean    sum     mean
2000-01-01 -0.289838 -0.289838 -0.370545 -0.370545 -1.284206 -1.284206
2000-01-02 -0.216612 -0.108306 -1.675528 -0.837764 -1.169415 -0.584708
2000-01-03  1.154661  0.384887 -1.634017 -0.544672 -1.566620 -0.522207
2000-01-04  2.969393  0.742348 -4.003274 -1.000819 -1.816179 -0.454045
2000-01-05  4.690630  0.938126 -4.682017 -0.936403 -2.717209 -0.543442
     ...     ...     ...     ...     ...     ...
2002-09-22  2.860036  0.047667 -9.270337 -0.154506 6.415245  0.106921
2002-09-23  3.510163  0.058503 -8.151439 -0.135857 5.177219  0.086287
2002-09-24  6.524983  0.108750 -10.168078 -0.169468 5.792639  0.096544
2002-09-25  6.409626  0.106827 -9.956226 -0.165937 5.704050  0.095068
2002-09-26  5.093787  0.084896 -7.074515 -0.117909 6.905823  0.115097
[1000 rows x 6 columns]
```

Passing a dict of functions has different behavior by default, see the next section.

Applying different functions to DataFrame columns

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a DataFrame:

```
In [107]: r.agg({'A': np.sum, 'B': lambda x: np.std(x, ddof=1)})
Out[107]:
          A         B
2000-01-01 -0.289838 NaN
2000-01-02 -0.216612 0.660747
2000-01-03  1.154661 0.689929
2000-01-04  2.969393 1.072199
2000-01-05  4.690630 0.939657
     ...     ...
2002-09-22  2.860036 0.047667
2002-09-23  3.510163 0.058503
2002-09-24  6.524983 0.108750
2002-09-25  6.409626 0.106827
2002-09-26  5.093787 0.084896
[continues on next page]
```
The function names can also be strings. In order for a string to be valid it must be implemented on the windowed object:

```python
In [108]: r.agg({"A": 'sum', 'B': 'std'})
Out[108]:
        A       B
2000-01-01 -0.289838 NaN
2000-01-02 -0.216612 0.660747
2000-01-03  1.154661  0.689929
2000-01-04  2.969393  1.072199
2000-01-05  4.690630  0.939657
2002-09-22  2.860036  1.132051
2002-09-23  3.510163  1.132381
2002-09-24  6.524983  1.080963
2002-09-25  6.409626  1.082911
2002-09-26  5.093787  1.136199
```

Furthermore you can pass a nested dict to indicate different aggregations on different columns:

```python
In [109]: r.agg({'A': ['sum', 'std'], 'B': ['mean', 'std']})
Out[109]:
        A       B
          sum     std mean    std
2000-01-01 -0.289838 NaN -0.370545 NaN
2000-01-02 -0.216612 0.256725 -0.837764 0.660747
2000-01-03  1.154661 0.873311 -0.544672 0.689929
2000-01-04  2.969393 1.009734 -1.000819 1.072199
2000-01-05  4.690630 0.977914 -0.936403 0.939657
2002-09-22  2.860036 1.132051 -0.154506 1.113208
2002-09-23  3.510163 1.132381 -0.135857 1.132381
2002-09-24  6.524983 1.144204 -0.169468 1.080963
2002-09-25  6.409626 1.142913 -0.165937 1.082911
2002-09-26  5.093787 1.151416 -0.117909 1.136199
```

[1000 rows x 2 columns]
2.15.4 Expanding windows

A common alternative to rolling statistics is to use an *expanding* window, which yields the value of the statistic with all the data available up to that point in time.

These follow a similar interface to `.rolling`, with the `.expanding` method returning an `Expanding` object.

As these calculations are a special case of rolling statistics, they are implemented in pandas such that the following two calls are equivalent:

```
In [110]: df.rolling(window=len(df), min_periods=1).mean()[:5]
Out[110]:
   A         B      C         D
2000-01-01  0.314226 -0.001675  0.071823  0.892566
2000-01-02  0.654522 -0.171495  0.179278  0.853361
2000-01-03  0.708733 -0.064489 -0.238271  1.371111
2000-01-04  0.987613  0.163472 -0.919693  1.566485
2000-01-05  1.426971  0.288267 -1.358877  1.808650

In [111]: df.expanding(min_periods=1).mean()[:5]
Out[111]:
   A         B      C         D
2000-01-01  0.314226 -0.001675  0.071823  0.892566
2000-01-02  0.654522 -0.171495  0.179278  0.853361
2000-01-03  0.708733 -0.064489 -0.238271  1.371111
2000-01-04  0.987613  0.163472 -0.919693  1.566485
2000-01-05  1.426971  0.288267 -1.358877  1.808650
```

These have a similar set of methods to `.rolling` methods.

**Method summary**

</tbody>
</table>

**Note:** Using sample variance formulas for `std()` and `var()` comes with the same caveats as using them with rolling windows. See [this section](#) for more information.

The same caveats apply to using any supported statistical sample methods.
Aside from not having a `window` parameter, these functions have the same interfaces as their `.rolling` counterparts. Like above, the parameters they all accept are:

- `min_periods`: threshold of non-null data points to require. Defaults to minimum needed to compute statistic. No NaNs will be output once `min_periods` non-null data points have been seen.
- `center`: boolean, whether to set the labels at the center (default is False).

**Note:** The output of the `.rolling` and `.expanding` methods do not return a NaN if there are at least `min_periods` non-null values in the current window. For example:

```
In [112]: sn = pd.Series([1, 2, np.nan, 3, np.nan, 4])

In [113]: sn
Out[113]:
0   1.0
1   2.0
2  NaN
3   3.0
4  NaN
5   4.0
dtype: float64

In [114]: sn.rolling(2).max()
Out[114]:
0   NaN
1   2.0
2  NaN
3  NaN
4  NaN
5  NaN
dtype: float64

In [115]: sn.rolling(2, min_periods=1).max()
Out[115]:
0   1.0
1   2.0
2   2.0
3   3.0
4   3.0
5   4.0
dtype: float64
```

In case of expanding functions, this differs from `cumsum()`, `cumprod()`, `cummax()`, and `cummin()`, which return NaN in the output wherever a NaN is encountered in the input. In order to match the output of `cumsum` with expanding, use `fillna()`:

```
In [116]: sn.expanding().sum()
Out[116]:
0   1.0
1   3.0
2   3.0
3   6.0
4   6.0
5  10.0
dtype: float64

In [117]: sn.cumsum()
```
An expanding window statistic will be more stable (and less responsive) than its rolling window counterpart as the increasing window size decreases the relative impact of an individual data point. As an example, here is the mean() output for the previous time series dataset:

```
In [118]: s.plot(style='k--')
Out[118]: <AxesSubplot>

In [120]: s.expanding().mean().plot(style='k')
Out[120]: <AxesSubplot>
```
2.15.5 Exponentially weighted windows

A related set of functions are exponentially weighted versions of several of the above statistics. A similar interface to `.rolling` and `.expanding` is accessed through the `.ewm` method to receive an `ExponentialMovingWindow` object. A number of expanding EW (exponentially weighted) methods are provided:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mean()</td>
<td>EW moving average</td>
</tr>
<tr>
<td>var()</td>
<td>EW moving variance</td>
</tr>
<tr>
<td>std()</td>
<td>EW moving standard deviation</td>
</tr>
<tr>
<td>corr()</td>
<td>EW moving correlation</td>
</tr>
<tr>
<td>cov()</td>
<td>EW moving covariance</td>
</tr>
</tbody>
</table>

In general, a weighted moving average is calculated as

\[ y_t = \frac{\sum_{i=0}^{t} w_i x_{t-i}}{\sum_{i=0}^{t} w_i} \],

where \( x_t \) is the input, \( y_t \) is the result and the \( w_i \) are the weights.

The EW functions support two variants of exponential weights. The default, `adjust=True`, uses the weights \( w_i = \)

\[(1 - \alpha)^i\] which gives

\[y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + ... + (1 - \alpha)^t x_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + ... + (1 - \alpha)^t}\]

When adjust=False is specified, moving averages are calculated as

\[y_0 = x_0\]
\[y_t = (1 - \alpha)y_{t-1} + \alpha x_t,\]

which is equivalent to using weights

\[w_i = \begin{cases} 
\alpha(1 - \alpha)^i & \text{if } i < t \\
(1 - \alpha)^i & \text{if } i = t.
\end{cases}\]

**Note:** These equations are sometimes written in terms of \(\alpha' = 1 - \alpha\), e.g.

\[y_t = \alpha' y_{t-1} + (1 - \alpha') x_t.\]

The difference between the above two variants arises because we are dealing with series which have finite history. Consider a series of infinite history, with adjust=True:

\[y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + ...}{\frac{1}{1-(1-\alpha)}}\]

Noting that the denominator is a geometric series with initial term equal to 1 and a ratio of \(1 - \alpha\) we have

\[y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + ...}{1-(1-\alpha)} \alpha\]
\[= \alpha x_t + [(1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + ...] \alpha\]
\[= \alpha x_t + (1 - \alpha)[x_{t-1} + (1 - \alpha)x_{t-2} + ...] \alpha\]
\[= \alpha x_t + (1 - \alpha)y_{t-1}\]

which is the same expression as adjust=False above and therefore shows the equivalence of the two variants for infinite series. When adjust=False, we have \(y_0 = x_0\) and \(y_t = \alpha x_t + (1 - \alpha)y_{t-1}\). Therefore, there is an assumption that \(x_0\) is not an ordinary value but rather an exponentially weighted moment of the infinite series up to that point.

One must have \(0 < \alpha \leq 1\), and while it is possible to pass \(\alpha\) directly, it’s often easier to think about either the span, center of mass (com) or half-life of an EW moment:

\[
\alpha = \begin{cases} 
\frac{2}{s+1}, & \text{for span } s \geq 1 \\
\frac{1}{1+c}, & \text{for center of mass } c \geq 0 \\
1 - \exp \left(-\frac{\log 0.5}{h}\right), & \text{for half-life } h > 0
\end{cases}
\]

One must specify precisely one of span, center of mass, half-life and alpha to the EW functions:

- **Span** corresponds to what is commonly called an “N-day EW moving average”.
- **Center of mass** has a more physical interpretation and can be thought of in terms of span: \(c = (s - 1)/2\).
- **Half-life** is the period of time for the exponential weight to reduce to one half.
- **Alpha** specifies the smoothing factor directly.
New in version 1.1.0.

You can also specify `halflife` in terms of a `timedelta` convertible unit to specify the amount of time it takes for an observation to decay to half its value when also specifying a sequence of `times`.

```
In [121]: df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})

In [122]: df
Out[122]:
   B
0  0
1  1
2  2
3 NaN
4  4

In [123]: times = ['2020-01-01', '2020-01-03', '2020-01-10', '2020-01-15', '2020-01-17']

In [124]: df.ewm(halflife='4 days', times=pd.DatetimeIndex(times)).mean()
Out[124]:
   B
0  0
1  0.585786
2  1.523889
3  1.523889
4  3.233686
```

The following formula is used to compute exponentially weighted mean with an input vector of times:

\[
y_t = \frac{\sum_{i=0}^{t} 0.5^{\frac{t-i}{\lambda}} x_{t-i}}{0.5^{\frac{t-0}{\lambda}}},
\]

Here is an example for a univariate time series:

```
In [125]: s.plot(style='k--')
Out[125]: <AxesSubplot:>

In [126]: s.ewm(span=20).mean().plot(style='k')
Out[126]: <AxesSubplot:>
```
ExponentialMovingWindow has a `min_periods` argument, which has the same meaning it does for all the .expanding and .rolling methods: no output values will be set until at least `min_periods` non-null values are encountered in the (expanding) window.

ExponentialMovingWindow also has an `ignore_na` argument, which determines how intermediate null values affect the calculation of the weights. When `ignore_na=False` (the default), weights are calculated based on absolute positions, so that intermediate null values affect the result. When `ignore_na=True`, weights are calculated by ignoring intermediate null values. For example, assuming `adjust=True`, if `ignore_na=False`, the weighted average of 3, NaN, 5 would be calculated as

$$\frac{(1 - \alpha)^2 \cdot 3 + 1 \cdot 5}{(1 - \alpha)^2 + 1}.$$  

Whereas if `ignore_na=True`, the weighted average would be calculated as

$$\frac{(1 - \alpha) \cdot 3 + 1 \cdot 5}{(1 - \alpha) + 1}.$$  

The `var()`, `std()`, and `cov()` functions have a `bias` argument, specifying whether the result should contain biased or unbiased statistics. For example, if `bias=True`, `ewmvar(x)` is calculated as `ewmvar(x) = ewma(x**2) - ewma(x)**2`; whereas if `bias=False` (the default), the biased variance statistics are scaled by debiasing factors

$$\frac{\left(\sum_{t=0}^{T} w_t \right)^2}{\left(\sum_{t=0}^{T} w_t \right)^2 - \sum_{t=0}^{T} w_t^2}.$$  

2.15. Computational tools 695
(For $w_i = 1$, this reduces to the usual $N/(N-1)$ factor, with $N = t + 1$.) See Weighted Sample Variance on Wikipedia for further details.

### 2.16 Group by: split-apply-combine

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting**: the data into groups based on some criteria.
- **Applying**: a function to each group independently.
- **Combining**: the results into a data structure.

Out of these, the split step is the most straightforward. In fact, in many situations we may wish to split the data set into groups and do something with those groups. In the apply step, we might wish to do one of the following:

- **Aggregation**: compute a summary statistic (or statistics) for each group. Some examples:
  - Compute group sums or means.
  - Compute group sizes / counts.

- **Transformation**: perform some group-specific computations and return a like-indexed object. Some examples:
  - Standardize data (zscore) within a group.
  - Filling NAs within groups with a value derived from each group.

- **Filtration**: discard some groups, according to a group-wise computation that evaluates True or False. Some examples:
  - Discard data that belongs to groups with only a few members.
  - Filter out data based on the group sum or mean.

- Some combination of the above: GroupBy will examine the results of the apply step and try to return a sensibly combined result if it doesn’t fit into either of the above two categories.

Since the set of object instance methods on pandas data structures are generally rich and expressive, we often simply want to invoke, say, a DataFrame function on each group. The name GroupBy should be quite familiar to those who have used a SQL-based tool (or `itertools`), in which you can write code like:

```sql
SELECT Column1, Column2, mean(Column3), sum(Column4) FROM SomeTable GROUP BY Column1, Column2
```

We aim to make operations like this natural and easy to express using pandas. We’ll address each area of GroupBy functionality then provide some non-trivial examples / use cases.

See the *cookbook* for some advanced strategies.
2.16.1 Splitting an object into groups

Pandas objects can be split on any of their axes. The abstract definition of grouping is to provide a mapping of labels to group names. To create a GroupBy object (more on what the GroupBy object is later), you may do the following:

```python
In [1]: df = pd.DataFrame([('bird', 'Falconiformes', 389.0),
                       ('bird', 'Psittaciformes', 24.0),
                       ('mammal', 'Carnivora', 80.2),
                       ('mammal', 'Primates', np.nan),
                       ('mammal', 'Carnivora', 58)],
                   index=['falcon', 'parrot', 'lion', 'monkey', 'leopard'],
                   columns=('class', 'order', 'max_speed'))

In [2]: df
Out[2]:
   class     order     max_speed
falcon  bird  Falconiformes   389.0
parrot  bird  Psittaciformes   24.0
lion    mammal  Carnivora  80.2
monkey  mammal  Primates  NaN
leopard mammal  Carnivora   58.0

# default is axis=0
In [3]: grouped = df.groupby('class')

In [4]: grouped = df.groupby('order', axis='columns')

In [5]: grouped = df.groupby(['class', 'order'])
```

The mapping can be specified many different ways:

- A Python function, to be called on each of the axis labels.
- A list or NumPy array of the same length as the selected axis.
- A dict or Series, providing a label -> group name mapping.
- For DataFrame objects, a string indicating a column to be used to group. Of course `df.groupby('A')` is just syntactic sugar for `df.groupby(df['A'])`, but it makes life simpler.
- For DataFrame objects, a string indicating an index level to be used to group.
- A list of any of the above things.

Collectively we refer to the grouping objects as the keys. For example, consider the following DataFrame:

```python
In [6]: df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar',
                                'foo', 'bar', 'foo', 'foo'],
                       'B': ['one', 'one', 'two', 'three',
                             'two', 'two', 'one', 'three'],
                       'C': np.random.randn(8),
                       'D': np.random.randn(8))
```

(continues on next page)
On a DataFrame, we obtain a GroupBy object by calling `groupby()`. We could naturally group by either the A or B columns, or both:

```python
In [8]: grouped = df.groupby('A')
In [9]: grouped = df.groupby(['A', 'B'])
```

New in version 0.24.

If we also have a MultiIndex on columns A and B, we can group by all but the specified columns:

```python
In [10]: df2 = df.set_index(['A', 'B'])
In [11]: grouped = df2.groupby(level=df2.index.names.difference(['B']))
In [12]: grouped.sum()
```

These will split the DataFrame on its index (rows). We could also split by the columns:

```python
In [13]: def get_letter_type(letter):
    ....:     if letter.lower() in 'aeiou':
    ....:         return 'vowel'
    ....:     else:
    ....:         return 'consonant'
    ....:
In [14]: grouped = df.groupby(get_letter_type, axis=1)
```

*pandas* Index objects support duplicate values. If a non-unique index is used as the group key in a groupby operation, all values for the same index value will be considered to be in one group and thus the output of aggregation functions will only contain unique index values:

```python
In [15]: lst = [1, 2, 3, 1, 2, 3]
In [16]: s = pd.Series([1, 2, 3, 10, 20, 30], lst)
In [17]: grouped = s.groupby(level=0)
In [18]: grouped.first()
```
Note that **no splitting occurs** until it’s needed. Creating the GroupBy object only verifies that you’ve passed a valid mapping.

**Note:** Many kinds of complicated data manipulations can be expressed in terms of GroupBy operations (though can’t be guaranteed to be the most efficient). You can get quite creative with the label mapping functions.

### GroupBy sorting

By default the group keys are sorted during the `groupby` operation. You may however pass `sort=False` for potential speedups:

```
In [21]: df2 = pd.DataFrame({'X': ['B', 'B', 'A', 'A'], 'Y': [1, 2, 3, 4]})

In [22]: df2.groupby(['X']).sum()
Out[22]:
   Y
  X   
  A  7
  B  3

In [23]: df2.groupby(['X'], sort=False).sum()
Out[23]:
   Y
  X   
  B  3
  A  7
```

Note that `groupby` will preserve the order in which *observations* are sorted *within* each group. For example, the groups created by `groupby()` below are in the order they appeared in the original DataFrame:

```
In [24]: df3 = pd.DataFrame({'X': ['A', 'B', 'A', 'B'], 'Y': [1, 4, 3, 2]})

In [25]: df3.groupby(['X']).get_group('A')
```

(continues on next page)
In [26]: df3.groupby(['X']).get_group('B')
Out[26]:
   X  Y
0  A  1
2  A  3

New in version 1.1.0.

**GroupBy dropna**

By default NA values are excluded from group keys during the `groupby` operation. However, in case you want to include NA values in group keys, you could pass `dropna=False` to achieve it.

In [27]: df_list = 
   [[1, 2, 3], [1, None, 4], [2, 1, 3], [1, 2, 2]]

In [28]: df_dropna = pd.DataFrame(df_list, columns=['a', 'b', 'c'])

In [29]: df_dropna
Out[29]:
   a  b  c
0  1  2.0 3
1  1  NaN 4
2  2  1.0 3
3  1  2.0 2

# Default `dropna` is set to True, which will exclude NaNs in keys
In [30]: df_dropna.groupby(by=['b'], dropna=True).sum()
Out[30]:
   a   c
b
1.0 2  3
2.0 2  5

# In order to allow NaN in keys, set `dropna` to False
In [31]: df_dropna.groupby(by=['b'], dropna=False).sum()
Out[31]:
   a   c
b
1.0 2  3
2.0 2  5
NaN 1  4

The default setting of `dropna` argument is `True` which means NA are not included in group keys.
GroupBy object attributes

The `groups` attribute is a dict whose keys are the computed unique groups and corresponding values being the axis labels belonging to each group. In the above example we have:

```python
In [32]: df.groupby('A').groups
Out[32]: {'bar': [1, 3, 5], 'foo': [0, 2, 4, 6, 7]}

In [33]: df.groupby(get_letter_type, axis=1).groups
Out[33]: {'consonant': ['B', 'C', 'D'], 'vowel': ['A']}
```

Calling the standard Python `len` function on the GroupBy object just returns the length of the `groups` dict, so it is largely just a convenience:

```python
In [34]: grouped = df.groupby(['A', 'B'])
In [35]: grouped.groups
Out[35]: {('bar', 'one'): [1], ('bar', 'three'): [3], ('bar', 'two'): [5], ('foo', 'one'): [0, 6], ('foo', 'three'): [7], ('foo', 'two'): [2, 4]}
In [36]: len(grouped)
Out[36]: 6
```

GroupBy will tab complete column names (and other attributes):

```python
In [37]: df
Out[37]:
   height  weight  gender
2000-01-01 42.849980 157.500553  male
2000-01-02 49.607315 177.340407  male
2000-01-03 56.293531 171.524640  male
2000-01-04 48.421077 144.251986  female
2000-01-05 46.556882 152.526206  male
2000-01-06 68.448851 168.272968  female
2000-01-07 70.757698 136.431469  male
2000-01-08 58.909500 176.499753  female
2000-01-09 76.435631 174.094104  female
2000-01-10 45.306120 177.540920  male

In [38]: gb = df.groupby('gender')
In [39]: gb.<TAB>  # noqa: E225, E999
   gb.agg  gb.boxplot  gb.cummin  gb.describe  gb.filter  gb.get_group
   gb.height  gb.last  gb.median  gb.ngroups  gb.plot  gb.rank
   gb.std  gb.transform
   gb.aggregate  gb.count  gb.cumprod  gb.dtype  gb.first  gb.groups
   gb.hist  gb.max  gb.min  gb.nth  gb.prod  gb.resample
   gb.sum  gb.var
   gb.apply  gb.cummmax  gb.cumsum  gb.fillna  gb.gender  gb.head
   gb.indices  gb.mean  gb.name  gb.ohlc  gb.quantile  gb.size
   gb.tail  gb.weight
```

2.16. Group by: split-apply-combine
With *hierarchically-indexed data*, it’s quite natural to group by one of the levels of the hierarchy.

Let’s create a Series with a two-level MultiIndex.

```python
In [40]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
               ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]

In [41]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])

In [42]: s = pd.Series(np.random.randn(8), index=index)

In [43]: s
```

```
Out[43]:
first  second
bar    one   -0.919854
       two   -0.042379
baz    one    1.247642
       two   -0.009920
foo    one    0.290213
       two    0.495767
qux    one    0.362949
       two    1.548106
dtype: float64
```

We can then group by one of the levels in `s`.

```python
In [44]: grouped = s.groupby(level=0)

In [45]: grouped.sum()
```

```
Out[45]:
first
bar   -0.962232
baz    1.237723
foo    0.785980
qux    1.911055
dtype: float64
```

If the MultiIndex has names specified, these can be passed instead of the level number:

```python
In [46]: s.groupby(level='second').sum()
```

```
Out[46]:
second
one    0.980950
two    1.991575
dtype: float64
```

The aggregation functions such as `sum` will take the level parameter directly. Additionally, the resulting index will be named according to the chosen level:

```python
In [47]: s.sum(level='second')
```

```
Out[47]:
second
one    0.980950
two    1.991575
dtype: float64
```
Grouping with multiple levels is supported.

```python
In [48]: s
Out[48]:
first second third
bar  doo  one  -1.131345  
   two   -0.089329  
baz  bee  one   0.337863  
   two  -0.945867  
foo  bop  one  -0.932132  
   two   1.956030  
qux  bop  one   0.017587  
   two  -0.016692  
dtype: float64
```

```python
In [49]: s.groupby(level=['first', 'second']).sum()
Out[49]:
first second
bar  doo  -1.220674
baz  bee  -0.608004
foo  bop   1.023898
qux  bop   0.000895
```

Index level names may be supplied as keys.

```python
In [50]: s.groupby(['first', 'second']).sum()
Out[50]:
first second
bar  doo  -1.220674
baz  bee  -0.608004
foo  bop   1.023898
qux  bop   0.000895
```

More on the `sum` function and aggregation later.

## Grouping DataFrame with Index levels and columns

A DataFrame may be grouped by a combination of columns and index levels by specifying the column names as strings and the index levels as `pd.Grouper` objects.

```python
In [51]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],  
       ....:     ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
   ....: 
   ....: 
In [52]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])
In [53]: df = pd.DataFrame({'A': [1, 1, 1, 1, 2, 2, 3, 3],  
       ....:     'B': np.arange(8),  
       ....:     index=index)
   ....: 
In [54]: df
Out[54]:
  A  B
first second
```
The following example groups `df` by the second index level and the A column.

```python
In [55]: df.groupby([pd.Grouper(level=1), 'A']).sum()
Out[55]:
   B
second  A
  one  1  2  2  4  3  6
  two  1  4  2  5  3  7
```

Index levels may also be specified by name.

```python
In [56]: df.groupby([pd.Grouper(level='second'), 'A']).sum()
Out[56]:
   B
second  A
  one  1  2  2  4  3  6
  two  1  4  2  5  3  7
```

Index level names may be specified as keys directly to `groupby`.

```python
In [57]: df.groupby(['second', 'A']).sum()
Out[57]:
   B
second  A
  one  1  2  2  4  3  6
  two  1  4  2  5  3  7
```
**DataFrame column selection in GroupBy**

Once you have created the GroupBy object from a DataFrame, you might want to do something different for each of the columns. Thus, using [[]] similar to getting a column from a DataFrame, you can do:

```python
In [58]: grouped = df.groupby(['A'])
In [59]: grouped_C = grouped['C']
In [60]: grouped_D = grouped['D']
```

This is mainly syntactic sugar for the alternative and much more verbose:

```python
In [61]: df['C'].groupby(df['A'])
Out[61]: <pandas.core.groupby.generic.SeriesGroupBy object at 0x7fbfaffe13a0>
```

Additionally this method avoids recomputing the internal grouping information derived from the passed key.

### 2.16.2 Iterating through groups

With the GroupBy object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

```python
In [62]: grouped = df.groupby('A')
In [63]: for name, group in grouped:
   ....:     print(name)
   ....:     print(group)
   ....:
bar
   A   B   C   D
  1  bar  one  0.254161 1.511763
  3  bar  three  0.215897 -0.990582
  5  bar  two  -0.077118 1.211526
foo
   A   B   C   D
  0  foo  one  -0.575247 1.346061
  2  foo  two  -1.143704 1.627081
  4  foo  two  1.193555 -0.441652
  6  foo  one  -0.408530 0.268520
  7  foo  three  -0.862495 0.024580
```

In the case of grouping by multiple keys, the group name will be a tuple:

```python
In [64]: for name, group in df.groupby(['A', 'B']):
   ....:     print(name)
   ....:     print(group)
   ....:
('bar', 'one')
   A   B   C   D
  1  bar  one  0.254161 1.511763
('bar', 'three')
   A   B   C   D
  3  bar  three  0.215897 -0.990582
('bar', 'two')
   A   B   C   D
```

(continues on next page)
See *Iterating through groups*.

### 2.16.3 Selecting a group

A single group can be selected using `get_group()`:

```
In [65]: grouped.get_group('bar')
Out[65]:
   A   B   C   D
1  bar  one  0.254161  1.511763
3  bar  three  0.215897  -0.990582
5  bar  two  -0.077118  1.211526
```

Or for an object grouped on multiple columns:

```
In [66]: df.groupby(['A', 'B']).get_group(('bar', 'one'))
Out[66]:
   A   B   C   D
1  bar  one  0.254161  1.511763
```

### 2.16.4 Aggregation

Once the GroupBy object has been created, several methods are available to perform a computation on the grouped data. These operations are similar to the aggregating API, window functions API, and resample API.

An obvious one is aggregation via the `aggregate()` or equivalently `agg()` method:

```
In [67]: grouped = df.groupby('A')
In [68]: grouped.aggregate(np.sum)
Out[68]:
   C   D
A
bar  0.392940  1.732707
foo -1.796421  2.824590
```

```
In [69]: grouped = df.groupby(['A', 'B'])
In [70]: grouped.aggregate(np.sum)
Out[70]:
   C   D
```

(continues on next page)
As you can see, the result of the aggregation will have the group names as the new index along the grouped axis. In the case of multiple keys, the result is a *MultiIndex* by default, though this can be changed by using the `as_index` option:

```
In [71]: grouped = df.groupby(['A', 'B'], as_index=False)

In [72]: grouped.aggregate(np.sum)
Out[72]:
```

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td>one</td>
<td>0.254161</td>
<td>1.511763</td>
</tr>
<tr>
<td></td>
<td>three</td>
<td>0.215897</td>
<td>-0.990582</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>-0.077118</td>
<td>1.211526</td>
</tr>
<tr>
<td>foo</td>
<td>one</td>
<td>-0.983776</td>
<td>1.614581</td>
</tr>
<tr>
<td></td>
<td>three</td>
<td>-0.862495</td>
<td>0.024580</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>0.049851</td>
<td>1.185429</td>
</tr>
</tbody>
</table>

```
In [73]: df.groupby('A', as_index=False).sum()
Out[73]:
```

<table>
<thead>
<tr>
<th>A</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td>0.392940</td>
<td>1.732707</td>
</tr>
<tr>
<td>foo</td>
<td>-1.796421</td>
<td>2.824590</td>
</tr>
</tbody>
</table>

Note that you could use the `reset_index` DataFrame function to achieve the same result as the column names are stored in the resulting *MultiIndex*:

```
In [74]: df.groupby(['A', 'B']).sum().reset_index()
Out[74]:
```

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td>one</td>
<td>0.254161</td>
<td>1.511763</td>
</tr>
<tr>
<td></td>
<td>three</td>
<td>0.215897</td>
<td>-0.990582</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>-0.077118</td>
<td>1.211526</td>
</tr>
<tr>
<td>foo</td>
<td>one</td>
<td>-0.983776</td>
<td>1.614581</td>
</tr>
<tr>
<td></td>
<td>three</td>
<td>-0.862495</td>
<td>0.024580</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>0.049851</td>
<td>1.185429</td>
</tr>
</tbody>
</table>

Another simple aggregation example is to compute the size of each group. This is included in GroupBy as the `size` method. It returns a Series whose index are the group names and whose values are the sizes of each group.

```
In [75]: grouped.size()
Out[75]:
```

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td>one</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>three</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>1</td>
</tr>
<tr>
<td>foo</td>
<td>one</td>
<td>2</td>
</tr>
<tr>
<td></td>
<td>three</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>2</td>
</tr>
</tbody>
</table>
In [76]: grouped.describe()
Out[76]:

+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+

Note: Aggregation functions will not return the groups that you are aggregating over if they are named columns, when as_index=True, the default. The grouped columns will be the indices of the returned object.

Passing as_index=False will return the groups that you are aggregating over, if they are named columns.

Aggregating functions are the ones that reduce the dimension of the returned objects. Some common aggregating functions are tabulated below:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mean()</td>
<td>Compute mean of groups</td>
</tr>
<tr>
<td>sum()</td>
<td>Compute sum of group values</td>
</tr>
<tr>
<td>size()</td>
<td>Compute group sizes</td>
</tr>
<tr>
<td>count()</td>
<td>Compute count of group</td>
</tr>
<tr>
<td>std()</td>
<td>Standard deviation of groups</td>
</tr>
<tr>
<td>var()</td>
<td>Compute variance of groups</td>
</tr>
<tr>
<td>sem()</td>
<td>Standard error of the mean of groups</td>
</tr>
<tr>
<td>describe()</td>
<td>Generates descriptive statistics</td>
</tr>
<tr>
<td>first()</td>
<td>Compute first of group values</td>
</tr>
<tr>
<td>last()</td>
<td>Compute last of group values</td>
</tr>
<tr>
<td>nth()</td>
<td>Take nth value, or a subset if n is a list</td>
</tr>
<tr>
<td>min()</td>
<td>Compute min of group values</td>
</tr>
<tr>
<td>max()</td>
<td>Compute max of group values</td>
</tr>
</tbody>
</table>

The aggregating functions above will exclude NA values. Any function which reduces a Series to a scalar value is an aggregation function and will work, a trivial example is df.groupby('A').agg(lambda ser: 1). Note that nth() can act as a reducer or a filter, see here.
Applying multiple functions at once

With grouped `Series` you can also pass a list or dict of functions to do aggregation with, outputting a DataFrame:

```python
In [77]: grouped = df.groupby('A')
In [78]: grouped['C'].agg([np.sum, np.mean, np.std])
```

```
Out[78]:
     sum    mean    std
A   bar  0.392940 0.130980 0.181231
    foo -1.796421 -0.359284  0.912265
```

On a grouped `DataFrame`, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```python
In [79]: grouped.agg([np.sum, np.mean, np.std])
```

```
Out[79]:
       C       D
     sum    mean    std  sum    mean    std
A   bar  0.392940 0.130980 0.181231  1.732707 0.577569 1.366330
    foo -1.796421 -0.359284  0.912265  2.824590 0.564918 0.884785
```

The resulting aggregations are named for the functions themselves. If you need to rename, then you can add in a chained operation for a `Series` like this:

```python
In [80]: (grouped['C'].agg([np.sum, np.mean, np.std])
Pandas does allow you to provide multiple lambdas. In this case, pandas will mangle the name of the (nameless) lambda functions, appending \_<i> to each subsequent lambda.

```python
In [83]: grouped['C'].agg([lambda x: x.max() - x.min(),
                        lambda x: x.median() - x.mean()])
```

```plaintext
Out[83]:
<lambda_0> <lambda_1>
A 0.331279 0.084917
foo 2.337259 -0.215962
```

## Named aggregation

New in version 0.25.0.

To support column-specific aggregation with control over the output column names, pandas accepts the special syntax in `GroupBy.agg()`, known as "named aggregation", where

- The keywords are the output column names
- The values are tuples whose first element is the column to select and the second element is the aggregation to apply to that column. Pandas provides the `pandas.NamedAgg` namedtuple with the fields ['column', 'aggfunc'] to make it clearer what the arguments are. As usual, the aggregation can be a callable or a string alias.

```python
In [84]: animals = pd.DataFrame({'kind': ['cat', 'dog', 'cat', 'dog'],
                           'height': [9.1, 6.0, 9.5, 34.0],
                           'weight': [7.9, 7.5, 9.9, 198.0]})

In [85]: animals.groupby("kind").agg(
                               min_height=pd.NamedAgg(column='height', aggfunc='min'),
                               max_height=pd.NamedAgg(column='height', aggfunc='max'),
                               average_weight=pd.NamedAgg(column='weight', aggfunc=np.mean),
                               )
```

```plaintext
Out[85]:
kind min_height max_height average_weight
0 cat 9.1 7.9
1 dog 6.0 7.5
2 cat 9.5 9.9
3 dog 34.0 198.0
```
pandas.NamedAgg is just a namedtuple. Plain tuples are allowed as well.

```python
In [87]: animals.groupby("kind").agg(
    ....:     min_height=('height', 'min'),
    ....:     max_height=('height', 'max'),
    ....:     average_weight=('weight', np.mean),
    ....:     )
```

```python
Out[87]:
min_height  max_height  average_weight
kind
cat    9.1       9.5       8.90
dog    6.0     34.0      102.75
```

If your desired output column names are not valid python keywords, construct a dictionary and unpack the keyword arguments.

```python
In [88]: animals.groupby("kind").agg(**{
    ....:     'total weight': pd.NamedAgg(column='weight', aggfunc=sum),
    ....:     })
```

```python
Out[88]:
total weight
kind
cat 17.8
dog 205.5
```

Additional keyword arguments are not passed through to the aggregation functions. Only pairs of (column, aggfunc) should be passed as **kwargs. If your aggregation functions requires additional arguments, partially apply them with functools.partial().

**Note:** For Python 3.5 and earlier, the order of **kwargs in a functions was not preserved. This means that the output column ordering would not be consistent. To ensure consistent ordering, the keys (and so output columns) will always be sorted for Python 3.5.

Named aggregation is also valid for Series groupby aggregations. In this case there’s no column selection, so the values are just the functions.

```python
In [89]: animals.groupby("kind").height.agg(
    ....:     min_height='min',
    ....:     max_height='max',
    ....:     )
```

```python
Out[89]:
min_height  max_height
kind
cat    9.1       9.5
dog    6.0     34.0
```
Applying different functions to DataFrame columns

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a DataFrame:

```python
In [90]: grouped.agg({'C': np.sum,
       ....:     'D': lambda x: np.std(x, ddof=1)})
Out[90]:
     C     D
     A  0.392940  1.366330
     B -1.796421  0.884785
```

The function names can also be strings. In order for a string to be valid it must be either implemented on `GroupBy` or available via `dispatching`:

```python
In [91]: grouped.agg({'C': 'sum', 'D': 'std'})
Out[91]:
     C     D
     A  0.392940  1.366330
     B -1.796421  0.884785
```

Cython-optimized aggregation functions

Some common aggregations, currently only `sum`, `mean`, `std`, and `sem`, have optimized Cython implementations:

```python
In [92]: df.groupby('A').sum()
Out[92]:
     C     D
     A  0.392940  1.732707
     B -1.796421  2.824590

In [93]: df.groupby(['A', 'B']).mean()
Out[93]:
     C     D
     A B
     bar one  0.254161  1.511763
       three -0.215897 -0.990582
       two -0.077118  1.211526
     foo one -0.491888  0.807291
       three -0.862495  0.024580
       two  0.024925  0.592714
```

Of course `sum` and `mean` are implemented on pandas objects, so the above code would work even without the special versions via dispatching (see below).
2.16.5 Transformation

The `transform` method returns an object that is indexed the same (same size) as the one being grouped. The transform function must:

- Return a result that is either the same size as the group chunk or broadcastable to the size of the group chunk (e.g., a scalar, `grouped.transform(lambda x: x.iloc[-1])`).

- Operate column-by-column on the group chunk. The transform is applied to the first group chunk using `chunk.apply`.

- Not perform in-place operations on the group chunk. Group chunks should be treated as immutable, and changes to a group chunk may produce unexpected results. For example, when using `fillna`, `inplace` must be `False` (`grouped.transform(lambda x: x.fillna(inplace=False))`).

- (Optionally) operates on the entire group chunk. If this is supported, a fast path is used starting from the second chunk.

For example, suppose we wished to standardize the data within each group:

```
In [94]: index = pd.date_range('10/1/1999', periods=1100)
In [95]: ts = pd.Series(np.random.normal(0.5, 2, 1100), index)
In [96]: ts = ts.rolling(window=100, min_periods=100).mean().dropna()
In [97]: ts.head()
Out[97]:
2000-01-08  0.779333
2000-01-09  0.778852
2000-01-10  0.786476
2000-01-11  0.782797
2000-01-12  0.798110
Freq: D, dtype: float64
In [98]: ts.tail()
Out[98]:
2002-09-30  0.660294
2002-10-01  0.631095
2002-10-02  0.673601
2002-10-03  0.709213
2002-10-04  0.719369
Freq: D, dtype: float64
In [99]: transformed = (ts.groupby(lambda x: x.year)
               ....: .transform(lambda x: (x - x.mean()) / x.std()))
```

We would expect the result to now have mean 0 and standard deviation 1 within each group, which we can easily check:

```python
# Original Data
In [100]: grouped = ts.groupby(lambda x: x.year)
In [101]: grouped.mean()
Out[101]:
2000    0.442441
2001    0.526246
2002    0.459365
```

(Continues on next page)
```python
dtype: float64

In [102]: grouped.std()
Out[102]:
   2000   0.131752
   2001   0.210945
   2002   0.128753
   dtype: float64

# Transformed Data
In [103]: grouped_trans = transformed.groupby(lambda x: x.year)

In [104]: grouped_trans.mean()
Out[104]:
   2000   1.168208e-15
   2001   1.454544e-15
   2002   1.726657e-15
   dtype: float64

In [105]: grouped_trans.std()
Out[105]:
   2000   1.0
   2001   1.0
   2002   1.0
   dtype: float64
```

We can also visually compare the original and transformed data sets.

```python
In [106]: compare = pd.DataFrame({'Original': ts, 'Transformed': transformed})

In [107]: compare.plot()
Out[107]: <AxesSubplot:>
```
Transformation functions that have lower dimension outputs are broadcast to match the shape of the input array.

```
In [108]: ts.groupby(lambda x: x.year).transform(lambda x: x.max() - x.min())
```

```
Out[108]:
2000-01-08 0.623893
2000-01-09 0.623893
2000-01-10 0.623893
2000-01-11 0.623893
2000-01-12 0.623893
...
2002-09-30 0.558275
2002-10-01 0.558275
2002-10-02 0.558275
2002-10-03 0.558275
2002-10-04 0.558275
Freq: D, Length: 1001, dtype: float64
```

Alternatively, the built-in methods could be used to produce the same outputs.

```
In [109]: max = ts.groupby(lambda x: x.year).transform('max')
In [110]: min = ts.groupby(lambda x: x.year).transform('min')
In [111]: max - min
```

(continues on next page)
Another common data transform is to replace missing data with the group mean.

In [112]: data_df
Out[112]:
   A         B         C
0 1.539708 -1.166480  0.533026
1 1.302092 -0.505754   NaN
2 -0.371983  1.104803 -1.161657
3 -1.309622  1.118697 -1.161657
4 -1.924296  0.396437  0.812436
..        ...        ...

In [123]: grouped_trans.size()  # Verify non-NA count equals group size
Out[123]:
   GR 228
   JP 267
   UK 247
   US 258
dtype: int64

Note: Some functions will automatically transform the input when applied to a GroupBy object, but returning an object of the same shape as the original. Passing as_index=False will not affect these transformation methods.

For example: fillna, ffill, bfill, shift.

In [124]: grouped.ffill()
Out[124]:
   A          B          C
0  1.539708 -1.166480  0.533026

997 -0.394469 -0.642343  0.011374
998 -1.174126  1.857148 -0.774753

(continues on next page)
Window and resample operations

It is possible to use `resample()`, `expanding()` and `rolling()` as methods on groupbys.

The example below will apply the `rolling()` method on the samples of the column B based on the groups of column A.

```
                          'B': np.arange(20)})

In [126]: df_re
Out[126]:
   A  B
0  0  0
1  1  1
2  1  2
3  1  3
4  1  4
... ...
15 5 15
16 5 16
17 5 17
18 5 18
19 5 19

[20 rows x 2 columns]
```

```
In [127]: df_re.groupby('A').rolling(4).B.mean()
Out[127]:
   A         B
1  NaN      NaN
2  NaN      NaN
3  1.5  1.5
4  2.5  2.5
5  13.5  13.5
6  14.5  14.5
7  15.5  15.5
8  16.5  16.5
9  17.5  17.5
Name: B, Length: 20, dtype: float64
```

The `expanding()` method will accumulate a given operation (`sum()` in the example) for all the members of each particular group.

```
In [128]: df_re.groupby('A').expanding().sum()
Out[128]:
   A  B
```

(continues on next page)
Suppose you want to use the `resample()` method to get a daily frequency in each group of your dataframe and wish to complete the missing values with the `ffill()` method.

```
In [129]: df_re = pd.DataFrame({'date': pd.date_range(start='2016-01-01', periods=4, freq='W'),
                      'group': [1, 1, 2, 2],
                      'val': [5, 6, 7, 8]}).set_index('date')

In [130]: df_re
Out[130]:
   group  val
date
2016-01-03  1   5
2016-01-10  1   6
2016-01-17  2   7
2016-01-24  2   8

In [131]: df_re.groupby('group').resample('1D').ffill()
Out[131]:
   group  val
date
1    2016-01-03  1   5
      2016-01-04  1   5
      2016-01-05  1   5
      2016-01-06  1   5
      2016-01-07  1   5
      ...   ...   ...
2    2016-01-20  2   7
      2016-01-21  2   7
      2016-01-22  2   7
      2016-01-23  2   7
      2016-01-24  2   8
```

[16 rows x 2 columns]
### 2.16.6 Filtration

The `filter` method returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

```python
In [132]: sf = pd.Series([1, 1, 2, 3, 3, 3])
In [133]: sf.groupby(sf).filter(lambda x: x.sum() > 2)
Out[133]:
3 3
4 3
5 3
dtype: int64
```

The argument of `filter` must be a function that, applied to the group as a whole, returns `True` or `False`.

Another useful operation is filtering out elements that belong to groups with only a couple members.

```python
In [134]: dff = pd.DataFrame({'A': np.arange(8), 'B': list('aabbbbcc'))
In [135]: dff.groupby('B').filter(lambda x: len(x) > 2)
Out[135]:
   A  B
2  2  b
3  3  b
4  4  b
5  5  b
```

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with NaNs.

```python
In [136]: dff.groupby('B').filter(lambda x: len(x) > 2, dropna=False)
Out[136]:
    A  B
   0 NaN NaN
   1 NaN NaN
   2 2.0  b
   3 3.0  b
   4 4.0  b
   5 5.0  b
   6 NaN NaN
   7 NaN NaN
```

For DataFrames with multiple columns, filters should explicitly specify a column as the filter criterion.

```python
In [137]: dff['C'] = np.arange(8)
In [138]: dff.groupby('B').filter(lambda x: len(x['C']) > 2)
Out[138]:
   A  B  C
2  2  b  2
3  3  b  3
4  4  b  4
5  5  b  5
```

**Note:** Some functions when applied to a groupby object will act as a `filter` on the input, returning a reduced shape of the original (and potentially eliminating groups), but with the index unchanged. Passing `as_index=False` will not
affect these transformation methods.

For example: head, tail.

```
In [139]: df.groupby('B').head(2)
Out[139]:
   A  B  C
0  0  a  0
1  1  a  1
2  2  b  2
3  3  b  3
6  6  c  6
7  7  c  7
```

### 2.16.7 Dispatching to instance methods

When doing an aggregation or transformation, you might just want to call an instance method on each data group. This is pretty easy to do by passing lambda functions:

```
In [140]: grouped = df.groupby('A')
In [141]: grouped.agg(
    ...:     lambda x: x.std())
Out[141]:
   C       D
A  bar  0.181231  1.366330
     foo  0.912265  0.884785
```

But, it’s rather verbose and can be untidy if you need to pass additional arguments. Using a bit of metaprogramming cleverness, GroupBy now has the ability to “dispatch” method calls to the groups:

```
In [142]: grouped.std()
Out[142]:
   C       D
A  bar  0.181231  1.366330
     foo  0.912265  0.884785
```

What is actually happening here is that a function wrapper is being generated. When invoked, it takes any passed arguments and invokes the function with any arguments on each group (in the above example, the \texttt{std} function). The results are then combined together much in the style of \texttt{agg} and \texttt{transform} (it actually uses \texttt{apply} to infer the gluing, documented next). This enables some operations to be carried out rather succinctly:

```
In [143]: tsdf = pd.DataFrame(np.random.randn(1000, 3),
                        index=pd.date_range('1/1/2000', periods=1000),
                        columns=['A', 'B', 'C'])
```

```
In [144]: tsdf.iloc[:2] = np.nan
In [145]: grouped = tsdf.groupby(lambda x: x.year)
In [146]: grouped.fillna(method='pad')
Out[146]:
   A  B  C
0  0  a  0
1  1  a  1
2  2  b  2
3  3  b  3
6  6  c  6
7  7  c  7
```

(continues on next page)
In this example, we chopped the collection of time series into yearly chunks then independently called `fillna` on the groups.

The `nlargest` and `nsmallest` methods work on `Series` style groupbys:

```python
In [147]: s = pd.Series([9, 8, 7, 5, 19, 1, 4.2, 3.3])
In [148]: g = pd.Series(list('abababab'))
In [149]: gb = s.groupby(g)
In [150]: gb.nlargest(3)
Out[150]:
   a  4  19.0
    0  9.0
    2  7.0
   b  1  8.0
    3  5.0
    7  3.3
dtype: float64
In [151]: gb.nsmallest(3)
Out[151]:
   a  6  4.2
    2  7.0
    0  9.0
   b  5  1.0
    7  3.3
    3  5.0
dtype: float64
```

### 2.16.8 Flexible apply

Some operations on the grouped data might not fit into either the aggregate or transform categories. Or, you may simply want `GroupBy` to infer how to combine the results. For these, use the `apply` function, which can be substituted for both `aggregate` and `transform` in many standard use cases. However, `apply` can handle some exceptional use cases, for example:

```python
In [152]: df
Out[152]:
A  B  C  D
--- --- --- ---
   A  B  C  D
```
pandas: powerful Python data analysis toolkit, Release 1.1.5

In [153]: grouped = df.groupby('A')

    # could also just call .describe()
In [154]: grouped['C'].apply(lambda x: x.describe())

    Out[154]:

A
bar count 3.000000
    mean 0.130980
    std 0.181231
    min -0.077118
    25% 0.069390
    ...
    foo min -1.143704
    25% -0.862495
    50% -0.575247
    75% -0.408530
    max 1.193555
Name: C, Length: 16, dtype: float64

The dimension of the returned result can also change:

In [155]: grouped = df.groupby('A')['C']

In [156]: def f(group):
    ....:     return pd.DataFrame({'original': group,
    ....:                              'demeaned': group - group.mean()})
    ....:

In [157]: grouped.apply(f)

    Out[157]:

original  demeaned
0 -0.575247 -0.215962
1 0.254161 0.123181
2 -1.143704 -0.784420
3 0.215897 0.084917
4 1.193555 1.552839
5 -0.077118 -0.208098
6 -0.408530 -0.049245
7 -0.862495 -0.053211

apply on a Series can operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a DataFrame:

In [158]: def f(x):
    ....:     return pd.Series([x, x ** 2], index=['x', 'x^2'])
    ....:

2.16. Group by: split-apply-combine
In [159]: s = pd.Series(np.random.rand(5))

In [160]: s
Out[160]:
   0   0.321438
   1   0.493496
   2   0.139505
   3   0.910103
   4   0.194158
dtype: float64

In [161]: s.apply(f)
Out[161]:
   x   x^2
 0  0.321438  0.103323
 1  0.493496  0.243538
 2  0.139505  0.019462
 3  0.910103  0.828287
 4  0.194158  0.037697

Note: apply can act as a reducer, transformer, or filter function, depending on exactly what is passed to it. So depending on the path taken, and exactly what you are grouping. Thus the grouped columns(s) may be included in the output as well as set the indices.

2.16.9 Numba Accelerated Routines

New in version 1.1.

If Numba is installed as an optional dependency, the transform and aggregate methods support engine='numba' and engine_kwargs arguments. The engine_kwargs argument is a dictionary of keyword arguments that will be passed into the numba.jit decorator. These keyword arguments will be applied to the passed function. Currently only nogil, nopython, and parallel are supported, and their default values are set to False, True and False respectively.

The function signature must start with values, index exactly as the data belonging to each group will be passed into values, and the group index will be passed into index.

Warning: When using engine='numba', there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Note: In terms of performance, the first time a function is run using the Numba engine will be slow as Numba will have some function compilation overhead. However, the compiled functions are cached, and subsequent calls will be fast. In general, the Numba engine is performant with a larger amount of data points (e.g. 1+ million).
In [3]: df = pd.DataFrame(data, columns=[0, 1])

In [4]: def f_numba(values, index):
   ...:     total = 0
   ...:     for i, value in enumerate(values):
   ...:         if i % 2:
   ...:             total += value + 5
   ...:         else:
   ...:             total += value * 2
   ...:     return total
   ...

In [5]: def f_cython(values):
   ...:     total = 0
   ...:     for i, value in enumerate(values):
   ...:         if i % 2:
   ...:             total += value + 5
   ...:         else:
   ...:             total += value * 2
   ...:     return total
   ...

In [6]: groupby = df.groupby(0)
# Run the first time, compilation time will affect performance
In [7]: %timeit -r 1 -n 1 groupby.aggregate(f_numba, engine='numba')  # noqa: E225
2.14 s ± 0 ns per loop (mean ± std. dev. of 1 run, 1 loop each)
# Function is cached and performance will improve
In [8]: %timeit groupby.aggregate(f_numba, engine='numba')
4.93 ms ± 32.3 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

In [9]: %timeit groupby.aggregate(f_cython, engine='cython')
18.6 ms ± 84.8 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

2.16.10 Other useful features

Automatic exclusion of “nuisance” columns

Again consider the example DataFrame we’ve been looking at:

Suppose we wish to compute the standard deviation grouped by the A column. There is a slight problem, namely that we don’t care about the data in column B. We refer to this as a “nuisance” column. If the passed aggregation function can’t be applied to some columns, the troublesome columns will be (silently) dropped. Thus, this does not pose any problems:
In [163]: df.groupby('A').std()
Out[163]:
     C    D
A
bar  0.181231  1.366330
foo  0.912265  0.884785

Note that df.groupby('A').colname.std(). is more efficient than df.groupby('A').std().

Note: Any object column, also if it contains numerical values such as Decimal objects, is considered as a “nuisance” columns. They are excluded from aggregate functions automatically in groupby.

If you do wish to include decimal or object columns in an aggregation with other non-nuisance data types, you must do so explicitly.

In [164]: from decimal import Decimal
In [165]: df_dec = pd.DataFrame(
    .....:     {'id': [1, 2, 1, 2],
    .....:       'int_column': [1, 2, 3, 4],
    .....:       'dec_column': [Decimal('0.50'), Decimal('0.15'),
    .....:                            Decimal('0.25'), Decimal('0.40')]
    .....:   }
    .....:)

# Decimal columns can be sum'd explicitly by themselves...
In [166]: df_dec.groupby(['id'])[['dec_column']].sum()
Out[166]:
          dec_column
id
1  0.75
2  0.55

# ...but cannot be combined with standard data types or they will be excluded
In [167]: df_dec.groupby(['id'])[['int_column', 'dec_column']].sum()
Out[167]:
           int_column
id
1  4
2  6

# Use .agg function to aggregate over standard and "nuisance" data types
# at the same time
In [168]: df_dec.groupby(['id']).agg({'int_column': 'sum', 'dec_column': 'sum'})
Out[168]:
            int_column  dec_column
id
1  4  0.75
2  6  0.55
Handling of (un)observed Categorical values

When using a `Categorical` grouper (as a single grouper, or as part of multiple groupers), the `observed` keyword controls whether to return a cartesian product of all possible groupers values (`observed=False`) or only those that are observed groupers (`observed=True`).

Show all values:

```python
In [169]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'], categories=['a', 'b'], observed=False)).count()
Out[169]:
a    3
b    0
dtype: int64
```

Show only the observed values:

```python
In [170]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'], categories=['a', 'b'], observed=True)).count()
Out[170]:
a    3
dtype: int64
```

The returned `dtype` of the grouped will *always* include all of the categories that were grouped.

```python
In [171]: s = pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'], categories=['a', 'b'], observed=False)).count()

In [172]: s.index.dtype
Out[172]: CategoricalDType(categories=['a', 'b'], ordered=False)
```

**NA and NaT group handling**

If there are any NaN or NaT values in the grouping key, these will be automatically excluded. In other words, there will never be an “NA group” or “NaT group”. This was not the case in older versions of pandas, but users were generally discarding the NA group anyway (and supporting it was an implementation headache).

**Grouping with ordered factors**

Categorical variables represented as instance of pandas’s `Categorical` class can be used as group keys. If so, the order of the levels will be preserved:

```python
In [173]: data = pd.Series(np.random.randn(100))
In [174]: factor = pd.qcut(data, [0, .25, .5, .75, 1.])
In [175]: data.groupby(factor).mean()
Out[175]:
(-2.645, -0.523]  -1.362896
    (continued on next page)```
Grouping with a grouper specification

You may need to specify a bit more data to properly group. You can use the `pd.Grouper` to provide this local control.

```
In [176]: import datetime

In [177]: df = pd.DataFrame({'Branch': 'A A A A A A A B'.split(),
                   'Buyer': 'Carl Mark Carl Carl Joe Joe Joe Carl'.split(),
                   'Quantity': [1, 3, 5, 1, 8, 1, 9, 3],
                   'Date': [datetime.datetime(2013, 1, 1, 13, 0),
                             datetime.datetime(2013, 1, 1, 13, 5),
                             datetime.datetime(2013, 10, 1, 20, 0),
                             datetime.datetime(2013, 10, 2, 10, 0),
                             datetime.datetime(2013, 10, 1, 20, 0),
                             datetime.datetime(2013, 12, 2, 12, 0),
                             datetime.datetime(2013, 12, 2, 14, 0)]})

In [178]: df
Out[178]:
   Branch  Buyer   Quantity   Date
0       A   Carl        1  2013-01-01 13:00:00
1       A   Mark        3  2013-01-01 13:05:00
2       A   Carl        5  2013-10-01 20:00:00
3       A   Carl        1  2013-10-02 10:00:00
4       A   Joe         8  2013-10-01 20:00:00
5       A   Joe         1  2013-10-02 10:00:00
6       A   Joe         9  2013-12-02 12:00:00
7       B   Carl        3  2013-12-02 14:00:00
```

Group by a specific column with the desired frequency. This is like resampling.

```
In [179]: df.groupby([pd.Grouper(freq='1M', key='Date'), 'Buyer']).sum()
Out[179]:
          Quantity
Date  Buyer
2013-01-31   Carl   1
           Mark   3
2013-10-31   Carl   6
           Joe   9
2013-12-31   Carl   3
           Joe   9
```

You have an ambiguous specification in that you have a named index and a column that could be potential groupers.
In [180]: df = df.set_index('Date')
In [181]: df['Date'] = df.index + pd.offsets.MonthEnd(2)
In [182]: df.groupby([pd.Grouper(freq='6M', key='Date'), 'Buyer']).sum()
Out[182]:

<table>
<thead>
<tr>
<th>Date</th>
<th>Buyer</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-02-28</td>
<td>Carl</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Mark</td>
<td>3</td>
</tr>
<tr>
<td>2014-02-28</td>
<td>Carl</td>
<td>9</td>
</tr>
<tr>
<td></td>
<td>Joe</td>
<td>18</td>
</tr>
</tbody>
</table>

In [183]: df.groupby([pd.Grouper(freq='6M', level='Date'), 'Buyer']).sum()
Out[183]:

<table>
<thead>
<tr>
<th>Date</th>
<th>Buyer</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-31</td>
<td>Carl</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Mark</td>
<td>3</td>
</tr>
<tr>
<td>2014-01-31</td>
<td>Carl</td>
<td>9</td>
</tr>
<tr>
<td></td>
<td>Joe</td>
<td>18</td>
</tr>
</tbody>
</table>

**Taking the first rows of each group**

Just like for a DataFrame or Series you can call head and tail on a groupby:

In [184]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=['A', 'B'])
In [185]: df
Out[185]:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
</tr>
</tbody>
</table>

In [186]: g = df.groupby('A')
In [187]: g.head(1)
Out[187]:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
</tr>
</tbody>
</table>

In [188]: g.tail(1)
Out[188]:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
</tr>
</tbody>
</table>
Taking the nth row of each group

To select from a DataFrame or Series the nth item, use `nth()`. This is a reduction method, and will return a single row (or no row) per group if you pass an int for n:

```python
In [189]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])
In [190]: g = df.groupby('A')
In [191]: g.nth(0)
Out[191]:
   B
A  
  1  NaN
  5  6.0
In [192]: g.nth(-1)
Out[192]:
   B
A  
  1   4.0
  5   6.0
In [193]: g.nth(1)
Out[193]:
   B
A  
  1   4.0

If you want to select the nth not-null item, use the `dropna` kwarg. For a DataFrame this should be either 'any' or 'all' just like you would pass to dropna:

```python
# nth(0) is the same as g.first()
In [194]: g.nth(0, dropna='any')
Out[194]:
   B
A  
  1   4.0
  5   6.0
In [195]: g.first()
Out[195]:
   B
A  
  1   4.0
  5   6.0

# nth(-1) is the same as g.last()
In [196]: g.nth(-1, dropna='any') # NaNs denote group exhausted when using dropna
Out[196]:
   B
A  
  1   4.0
  5   6.0
In [197]: g.last()
Out[197]:
   B
```

(continues on next page)
As with other methods, passing `as_index=False`, will achieve a filtration, which returns the grouped row.

```python
In [199]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])
In [200]: g = df.groupby('A', as_index=False)
In [201]: g.nth(0)
Out[201]:
   A  B
0  1  NaN
2  5  6.0
```

You can also select multiple rows from each group by specifying multiple nth values as a list of ints.

```python
In [203]: business_dates = pd.date_range(start='4/1/2014', end='6/30/2014', freq='B')
In [204]: df = pd.DataFrame(1, index=business_dates, columns=['a', 'b'])
# get the first, 4th, and last date index for each month
In [205]: df.groupby([df.index.year, df.index.month]).nth([0, 3, -1])
Out[205]:
       a  b
2014 4  1 1
     4  1 1
     5  1 1
     6  1 1
     6  1 1
     6  1 1
2015 4  1 1
     4  1 1
     5  1 1
     5  1 1
     6  1 1
     6  1 1
```

2.16. Group by: split-apply-combine
Enumerate group items

To see the order in which each row appears within its group, use the \texttt{cumcount} method:

\begin{Verbatim}
In [206]: dfg = pd.DataFrame(list('aabba'), columns=['A'])

In [207]: dfg
Out[207]:
     A
0   a
1   a
2   a
3   b
4   b
5   a

In [208]: dfg.groupby('A').cumcount()
Out[208]:
     0  0  1
  1   1  2
  2   2  3
  3   3  0
  4   1  1
  5   3  0
dtype: int64

In [209]: dfg.groupby('A').cumcount(ascending=\texttt{False})
Out[209]:
     0  3  2
  1   2  1
  2   3  1
  3   4  0
  4   1  0
  5   3  0
dtype: int64
\end{Verbatim}

Enumerate groups

To see the ordering of the groups (as opposed to the order of rows within a group given by \texttt{cumcount}) you can use \texttt{ngroup()}.

Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the groupby object, not the order they are first observed.

\begin{Verbatim}
In [210]: dfg = pd.DataFrame(list('aabba'), columns=['A'])

In [211]: dfg
Out[211]:
     A
0   a
1   a
2   a
3   b
4   b
5   a
\end{Verbatim}
In [212]: dfg.groupby('A').ngroup()
Out[212]:
0 0
1 0
2 0
3 1
4 1
5 0
dtype: int64

In [213]: dfg.groupby('A').ngroup(ascending=False)
Out[213]:
0 1
1 1
2 1
3 0
4 0
5 1
dtype: int64

Plotting

Groupby also works with some plotting methods. For example, suppose we suspect that some features in a DataFrame may differ by group, in this case, the values in column 1 where the group is “B” are 3 higher on average.

In [214]: np.random.seed(1234)
In [215]: df = pd.DataFrame(np.random.randn(50, 2))
In [216]: df['g'] = np.random.choice(['A', 'B'], size=50)
In [217]: df.loc[df['g'] == 'B', 1] += 3

We can easily visualize this with a boxplot:

In [218]: df.groupby('g').boxplot()
The result of calling `boxplot` is a dictionary whose keys are the values of our grouping column \texttt{g} ("A" and "B"). The values of the resulting dictionary can be controlled by the `return_type` keyword of `boxplot`. See the visualization documentation for more.

**Warning:** For historical reasons, `df.groupby("g").boxplot()` is not equivalent to `df.boxplot(by="g").` See here for an explanation.

**Piping function calls**

Similar to the functionality provided by `DataFrame` and `Series`, functions that take GroupBy objects can be chained together using a `pipe` method to allow for a cleaner, more readable syntax. To read about `.pipe` in general terms, see here.

Combining `.groupby` and `.pipe` is often useful when you need to reuse GroupBy objects.

As an example, imagine having a DataFrame with columns for stores, products, revenue and quantity sold. We'd like to do a groupwise calculation of prices (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable. First we set the data:

```python
In [219]: n = 1000
In [220]: df = pd.DataFrame({'Store': np.random.choice(['Store_1', 'Store_2'], n),
                        'Product': np.random.choice(['Product_1', 'Product_2'], n),
                        'Revenue': np.random.uniform(0, 100, n),
                        'Quantity': np.random.randint(1, 100, n)})
```
.....:
.....: 'Product': np.random.choice(['Product_1', 'Product_2'], n),
.....: 'Revenue': (np.random.random(n) * 50 + 10).round(2),
.....: 'Quantity': np.random.randint(1, 10, size=n))

In [221]: df.head(2)
Out[221]:
  Store  Product  Revenue  Quantity
0  Store_2  Product_1   26.12       1
1  Store_2  Product_1   28.86       1

Now, to find prices per store/product, we can simply do:

In [222]: (df.groupby(['Store', 'Product'])
       .pipe(lambda grp: grp.Revenue.sum() / grp.Quantity.sum())
       .unstack().round(2))

Out[222]:
          Product  Product_1  Product_2
Store
Store_1  6.82        7.05
Store_2  6.30        6.64

Piping can also be expressive when you want to deliver a grouped object to some arbitrary function, for example:

In [223]: def mean(groupby):
       ...:     return groupby.mean()

In [224]: df.groupby(['Store', 'Product']).pipe(mean)
Out[224]:
                  Revenue  Quantity
Store Product
Store_1 Product_1  34.622727  5.075758
                  Product_2  35.482815  5.029630
Store_2 Product_1  32.972837  5.237589
                  Product_2  34.684360  5.224000

where `mean` takes a GroupBy object and finds the mean of the Revenue and Quantity columns respectively for each Store-Product combination. The `mean` function can be any function that takes in a GroupBy object; the `.pipe` will pass the GroupBy object as a parameter into the function you specify.

## 2.16.11 Examples

### Regrouping by factor

Regroup columns of a DataFrame according to their sum, and sum the aggregated ones.

In [225]: df = pd.DataFrame({'a': [1, 0, 0], 'b': [0, 1, 0],
       ...:     'c': [1, 0, 0], 'd': [2, 3, 4]})

In [226]: df
Out[226]:

(continues on next page)
Multi-column factorization

By using \texttt{ngroup()}, we can extract information about the groups in a way similar to \texttt{factorize()} (as described further in the \textit{reshaping API}) but which applies naturally to multiple columns of mixed type and different sources. This can be useful as an intermediate categorical-like step in processing, when the relationships between the group rows are more important than their content, or as input to an algorithm which only accepts the integer encoding. (For more information about support in pandas for full categorical data, see the \textit{Categorical introduction} and the \textit{API documentation}.)

\begin{verbatim}
In [228]: dfg = pd.DataFrame({"A": [1, 1, 2, 3, 2], "B": list("aaaba"))
In [229]: dfg
Out[229]:
   A B
0  1 a
1  1 a
2  2 a
3  3 b
4  2 a

In [230]: dfg.groupby(["A", "B"]).ngroup()
Out[230]:
0  0
1  0
2  1
3  2
4  1
dtype: int64

In [231]: dfg.groupby(["A", [0, 0, 0, 1, 1]]).ngroup()
Out[231]:
0  0
1  0
2  1
3  3
4  2
dtype: int64
\end{verbatim}
Groupby by indexer to ‘resample’ data

Resampling produces new hypothetical samples (resamples) from already existing observed data or from a model that generates data. These new samples are similar to the pre-existing samples.

In order to resample to work on indices that are non-datetimelike, the following procedure can be utilized.

In the following examples, `df.index // 5` returns a binary array which is used to determine what gets selected for the groupby operation.

Note: The below example shows how we can downsample by consolidation of samples into fewer samples. Here by using `df.index // 5`, we are aggregating the samples in bins. By applying `std()` function, we aggregate the information contained in many samples into a small subset of values which is their standard deviation thereby reducing the number of samples.

```
In [232]: df = pd.DataFrame(np.random.randn(10, 2))

In [233]: df
Out[233]:
       0       1
0  0.793893  0.321153
1  0.342250  1.618906
2 -0.975807  1.918201
3 -0.810847 -1.405919
4 -1.977759  0.461659
5  0.730057 -1.316938
6  0.751328  0.528290
7 -0.257759 -1.081009
8 -0.505895 -1.701948
9 -1.006349  0.020208

In [234]: df.index // 5
Out[234]: Int64Index([0, 0, 0, 0, 0, 1, 1, 1, 1, 1], dtype='int64')

In [235]: df.groupby(df.index // 5).std()
Out[235]:
       0       1
0  0.823647  1.312912
1  0.760109  0.942941
```

Returning a Series to propagate names

Group DataFrame columns, compute a set of metrics and return a named Series. The Series name is used as the name for the column index. This is especially useful in conjunction with reshaping operations such as stacking in which the column index name will be used as the name of the inserted column:

```
In [236]: def compute_metrics(x):
   ....:     result = {'b_sum': x['b'].sum(), 'c_mean': x['c'].mean()}
   ....:     return pd.Series(result, name='metrics')

In [237]: df = pd.DataFrame({
   ....:     'a': [0, 0, 0, 0, 1, 1, 1, 1, 2, 2, 2, 2],
   ....:     'b': [0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1],
   ....:     'c': [1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0],
   ....:     'd': [0, 0, 0, 1, 0, 0, 0, 1, 0, 0, 0, 1]})

In [238]: compute_metrics(df)
Out[238]:
       metrics
0      {'b_sum': 1.0, 'c_mean': 0.5}
1      {'b_sum': 1.0, 'c_mean': 0.5}
```

(continues on next page)
In [238]: result = df.groupby('a').apply(compute_metrics)

In [239]: result
Out[239]:
metrics b_sum  c_mean
a
0  2.0  0.5
1  2.0  0.5
2  2.0  0.5

In [240]: result.stack()
Out[240]:
a metrics
0 b_sum 2.0
  c_mean 0.5
1 b_sum 2.0
  c_mean 0.5
2 b_sum 2.0
  c_mean 0.5
dtype: float64

2.17 Time series / date functionality

pandas contains extensive capabilities and features for working with time series data for all domains. Using the NumPy datetime64 and timedelta64 dtypes, pandas has consolidated a large number of features from other Python libraries like scikits.timeseries as well as created a tremendous amount of new functionality for manipulating time series data.

For example, pandas supports:

Parsing time series information from various sources and formats

```python
In [1]: import datetime
In [2]: dti = pd.to_datetime(['1/1/2018', np.datetime64('2018-01-01'),
                        datetime.datetime(2018, 1, 1))
...:
In [3]: dti
                      dtype='datetime64[ns]', freq=None)
```

Generate sequences of fixed-frequency dates and time spans

```python
In [4]: dti = pd.date_range('2018-01-01', periods=3, freq='H')
In [5]: dti
Out[5]: DatetimeIndex(['2018-01-01 00:00:00', '2018-01-01 01:00:00',
                      '2018-01-01 02:00:00'],
                     dtype='datetime64[ns]', freq='H')
```

Manipulating and converting date times with timezone information
In [6]: dti = dti.tz_localize('UTC')

In [7]: dti
Out[7]:
DatetimeIndex(['2018-01-01 00:00:00+00:00', '2018-01-01 01:00:00+00:00',
               '2018-01-01 02:00:00+00:00'],
dtype='datetime64[ns, UTC]', freq='H')

In [8]: dti.tz_convert('US/Pacific')
Out[8]:
DatetimeIndex(['2017-12-31 16:00:00-08:00', '2017-12-31 17:00:00-08:00',
                '2017-12-31 18:00:00-08:00'],
dtype='datetime64[ns, US/Pacific]', freq='H')

Resampling or converting a time series to a particular frequency

In [9]: idx = pd.date_range('2018-01-01', periods=5, freq='H')
In [10]: ts = pd.Series(range(len(idx)), index=idx)
In [11]: ts
Out[11]:
2018-01-01 00:00:00    0
2018-01-01 01:00:00    1
2018-01-01 02:00:00    2
2018-01-01 03:00:00    3
2018-01-01 04:00:00    4
Freq: H, dtype: int64

In [12]: ts.resample('2H').mean()
Out[12]:
2018-01-01 00:00:00    0.5
2018-01-01 02:00:00    2.5
2018-01-01 04:00:00    4.0
Freq: 2H, dtype: float64

Performing date and time arithmetic with absolute or relative time increments

In [13]: friday = pd.Timestamp('2018-01-05')
In [14]: friday.day_name()
Out[14]: 'Friday'

# Add 1 day
In [15]: saturday = friday + pd.Timedelta('1 day')
In [16]: saturday.day_name()
Out[16]: 'Saturday'

# Add 1 business day (Friday --> Monday)
In [17]: monday = friday + pd.offsets.BDay()
In [18]: monday.day_name()
Out[18]: 'Monday'

pandas provides a relatively compact and self-contained set of tools for performing the above tasks and more.

2.17. Time series / date functionality
2.17.1 Overview

pandas captures 4 general time related concepts:

1. **Date times**: A specific date and time with timezone support. Similar to `datetime.datetime` from the standard library.
2. **Time deltas**: An absolute time duration. Similar to `datetime.timedelta` from the standard library.
3. **Time spans**: A span of time defined by a point in time and its associated frequency.
4. **Date offsets**: A relative time duration that respects calendar arithmetic. Similar to `dateutil.relativedelta.relativedelta` from the `dateutil` package.

<table>
<thead>
<tr>
<th>Concept</th>
<th>Scalar Class</th>
<th>Array Class</th>
<th>pandas Data Type</th>
<th>Primary Creation Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date times</td>
<td>Timestamp</td>
<td>DatetimeIndex</td>
<td>datetime64[ns] or datetime64[ns, tz]</td>
<td>to_datetime or date_range or date_range</td>
</tr>
<tr>
<td>Time deltas</td>
<td>Timedelta</td>
<td>TimedeltaIndex</td>
<td>timedelta64[ns]</td>
<td>to_timedelta or timedelta_range</td>
</tr>
<tr>
<td>Time spans</td>

<td>period[freq]</td>
<td>Period or period_range</td>
</tr>
<tr>
<td>Date offsets</td>
<td>DateOffset</td>
<td>None</td>
<td>None</td>
<td>DateOffset</td>
</tr>
</tbody>
</table>

For time series data, it’s conventional to represent the time component in the index of a `Series` or `DataFrame` so manipulations can be performed with respect to the time element.

```python
In [19]: pd.Series(range(3), index=pd.date_range('2000', freq='D', periods=3))
Out[19]:
2000-01-01 0
2000-01-02 1
2000-01-03 2
Freq: D, dtype: int64
```

However, `Series` and `DataFrame` can directly also support the time component as data itself.

```python
In [20]: pd.Series(pd.date_range('2000', freq='D', periods=3))
Out[20]:
0  2000-01-01
1  2000-01-02
2  2000-01-03
dtype: datetime64[ns]
```

`Series` and `DataFrame` have extended data type support and functionality for `datetime`, `timedelta` and `Period` data when passed into those constructors. `DateOffset` data however will be stored as `object` data.

```python
In [21]: pd.Series(pd.period_range('1/1/2011', freq='M', periods=3))
Out[21]:
0  2011-01
1  2011-02
2  2011-03
dtype: period[M]
```

```python
In [22]: pd.Series([pd.DateOffset(1), pd.DateOffset(2)])
Out[22]:
0 <DateOffset>
```

(continues on next page)
Lastly, pandas represents null date times, time deltas, and time spans as `NaT` which is useful for representing missing or null date like values and behaves similar as `np.nan` does for float data.

```
In [24]: pd.Timestamp(pd.NaT)
Out[24]: NaT

In [25]: pd.Timedelta(pd.NaT)
Out[25]: NaT

In [26]: pd.Period(pd.NaT)
Out[26]: NaT

# Equality acts as np.nan would
In [27]: pd.NaT == pd.NaT
Out[27]: False
```

2.17.2 Timestamps vs. time spans

Timestamped data is the most basic type of time series data that associates values with points in time. For pandas objects it means using the points in time.

```
In [28]: pd.Timestamp(datetime.datetime(2012, 5, 1))
Out[28]: Timestamp('2012-05-01 00:00:00')

In [29]: pd.Timestamp('2012-05-01')
Out[29]: Timestamp('2012-05-01 00:00:00')

In [30]: pd.Timestamp(2012, 5, 1)
Out[30]: Timestamp('2012-05-01 00:00:00')
```

However, in many cases it is more natural to associate things like change variables with a time span instead. The span represented by `Period` can be specified explicitly, or inferred from datetime string format.

For example:

```
In [31]: pd.Period('2011-01')
Out[31]: Period('2011-01', 'M')

In [32]: pd.Period('2012-05', freq='D')
Out[32]: Period('2012-05-01', 'D')
```

`Timestamp` and `Period` can serve as an index. Lists of `Timestamp` and `Period` are automatically coerced to `DatetimeIndex` and `PeriodIndex` respectively.
pandas: powerful Python data analysis toolkit, Release 1.1.5

In [33]: dates = [pd.Timestamp('2012-05-01'),
               ....:      pd.Timestamp('2012-05-02'),
               ....:      pd.Timestamp('2012-05-03')]

In [34]: ts = pd.Series(np.random.randn(3), dates)

In [35]: type(ts.index)
Out[35]: pandas.core.indexes.datetimes.DatetimeIndex

In [36]: ts.index
Out[36]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]', freq=None)

In [37]: ts
Out[37]:
2012-05-01  0.469112
2012-05-02 -0.282863
2012-05-03 -1.509059
dtype: float64

In [38]: periods = [pd.Period('2012-01'),
               pd.Period('2012-02'),
               pd.Period('2012-03')]

In [39]: ts = pd.Series(np.random.randn(3), periods)

In [40]: type(ts.index)
Out[40]: pandas.core.indexes.period.PeriodIndex

In [41]: ts.index
Out[41]: PeriodIndex(['2012-01', '2012-02', '2012-03'], dtype='period[M]', freq='M')

In [42]: ts
Out[42]:
2012-01  -1.135632
2012-02   1.212112
2012-03  -0.173215
Freq: M, dtype: float64

pandas allows you to capture both representations and convert between them. Under the hood, pandas represents
timestamps using instances of Timestamp and sequences of timestamps using instances of DatetimeIndex. For
regular time spans, pandas uses Period objects for scalar values and PeriodIndex for sequences of spans. Better
support for irregular intervals with arbitrary start and end points are forth-coming in future releases.

2.17.3 Converting to timestamps

To convert a Series or list-like object of date-like objects e.g. strings, epochs, or a mixture, you can use the
to_datetime function. When passed a Series, this returns a Series (with the same index), while a list-like is
converted to a DatetimeIndex:

In [43]: pd.to_datetime(pd.Series(['Jul 31, 2009', '2010-01-10', None]))
Out[43]:
0  2009-07-31
1  2010-01-10
2    NaT
dtype: datetime64[ns]

(continues on next page)
If you use dates which start with the day first (i.e. European style), you can pass the **dayfirst** flag:

```
In [45]: pd.to_datetime(['04-01-2012 10:00'], dayfirst=True)
Out[45]: DatetimeIndex(['2012-01-04 10:00:00'], dtype='datetime64[ns]', freq=None)
```

```
In [46]: pd.to_datetime(['14-01-2012', '01-14-2012'], dayfirst=True)
Out[46]: DatetimeIndex(['2012-01-14', '2012-01-14'], dtype='datetime64[ns]', freq=None)
```

**Warning**: You see in the above example that **dayfirst** isn’t strict, so if a date can’t be parsed with the day being first it will be parsed as if **dayfirst** were False.

If you pass a single string to **to_datetime**, it returns a single **Timestamp**. **Timestamp** can also accept string input, but it doesn’t accept string parsing options like **dayfirst** or **format**, so use **to_datetime** if these are required.

```
In [47]: pd.to_datetime('2010/11/12')
Out[47]: Timestamp('2010-11-12 00:00:00')
```

```
In [48]: pd.Timestamp('2010/11/12')
Out[48]: Timestamp('2010-11-12 00:00:00')
```

You can also use the **DatetimeIndex** constructor directly:

```
In [49]: pd.DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'])
Out[49]: DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'], dtype='datetime64[ns]', freq=None)
```

```
In [50]: pd.DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'], freq='infer')
Out[50]: DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'], dtype='datetime64[ns]', freq='2D')
```

**Providing a format argument**

In addition to the required datetime string, a **format** argument can be passed to ensure specific parsing. This could also potentially speed up the conversion considerably.

```
In [51]: pd.to_datetime('2010/11/12', format='%Y/%m/%d')
Out[51]: Timestamp('2010-11-12 00:00:00')
```

```
In [52]: pd.to_datetime('12-11-2010 00:00', format='%d-%m-%Y %H:%M')
Out[52]: Timestamp('2010-11-12 00:00:00')
```

For more information on the choices available when specifying the **format** option, see the Python **datetime** documentation.

2.17. Time series / date functionality
Assembling datetime from multiple DataFrame columns

You can also pass a DataFrame of integer or string columns to assemble into a Series of Timestamps.

```python
In [53]: df = pd.DataFrame({'year': [2015, 2016],
                      ....:                     'month': [2, 3],
                      ....:                     'day': [4, 5],
                      ....:                     'hour': [2, 3]})

In [54]: pd.to_datetime(df)
Out[54]:
0   2015-02-04 02:00:00
1   2016-03-05 03:00:00
dtype: datetime64[ns]
```

You can pass only the columns that you need to assemble.

```python
In [55]: pd.to_datetime(df[['year', 'month', 'day']])
Out[55]:
0   2015-02-04
1   2016-03-05
 dtype: datetime64[ns]
```

`pd.to_datetime` looks for standard designations of the datetime component in the column names, including:

- **required**: year, month, day
- **optional**: hour, minute, second, millisecond, microsecond, nanosecond

Invalid data

The default behavior, `errors='raise'`, is to raise when unparsable:

```python
In [2]: pd.to_datetime(['2009/07/31', 'asd'], errors='raise')
ValueError: Unknown string format
```

Pass `errors='ignore'` to return the original input when unparsable:

```python
In [56]: pd.to_datetime(['2009/07/31', 'asd'], errors='ignore')
Out[56]: Index(['2009/07/31', 'asd'], dtype='object')
```

Pass `errors='coerce'` to convert unparsable data to NaT (not a time):

```python
In [57]: pd.to_datetime(['2009/07/31', 'asd'], errors='coerce')
Out[57]: DatetimeIndex(['2009-07-31', NaT], dtype='datetime64[ns]', freq=None)
```
Epoch timestamps

pandas supports converting integer or float epoch times to Timestamp and DatetimeIndex. The default unit is nanoseconds, since that is how Timestamp objects are stored internally. However, epochs are often stored in another unit which can be specified. These are computed from the starting point specified by the origin parameter.

```python
In [58]: pd.to_datetime([1349720105, 1349806505, 1349892905, 1349979305, 1350065705], unit='s')
Out[58]:
DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05', '2012-10-10 18:15:05', '2012-10-11 18:15:05', '2012-10-12 18:15:05'], dtype='datetime64[ns]', freq=None)

In [59]: pd.to_datetime([1349720105100, 1349720105200, 1349720105300, 1349720105400, 1349720105500], unit='ms')
Out[59]:
DatetimeIndex(['2012-10-08 18:15:05.100000', '2012-10-08 18:15:05.200000', '2012-10-08 18:15:05.300000', '2012-10-08 18:15:05.400000', '2012-10-08 18:15:05.500000'], dtype='datetime64[ns]', freq=None)
```

Note: The unit parameter does not use the same strings as the format parameter that was discussed above). The available units are listed on the documentation for pandas.to_datetime().

Constructing a Timestamp or DatetimeIndex with an epoch timestamp with the tz argument specified will currently localize the epoch timestamps to UTC first then convert the result to the specified time zone. However, this behavior is deprecated, and if you have epochs in wall time in another timezone, it is recommended to read the epochs as timezone-naive timestamps and then localize to the appropriate timezone:

```python
In [60]: pd.Timestamp(1262347200000000000).tz_localize('US/Pacific')
Out[60]:
Timestamp('2010-01-01 12:00:00-0800', tz='US/Pacific')

In [61]: pd.DatetimeIndex([1262347200000000000]).tz_localize('US/Pacific')
Out[61]:
DatetimeIndex(['2010-01-01 12:00:00-08:00'], dtype='datetime64[ns, US/Pacific]', freq=None)
```

Note: Epoch times will be rounded to the nearest nanosecond.

Warning: Conversion of float epoch times can lead to inaccurate and unexpected results. Python floats have about 15 digits precision in decimal. Rounding during conversion from float to high precision Timestamp is unavoidable. The only way to achieve exact precision is to use a fixed-width types (e.g. an int64).

```python
In [62]: pd.to_datetime([1490195805.433, 1490195805.433502912], unit='s')
Out[62]:
DatetimeIndex(['2017-03-22 15:16:45.433000088', '2017-03-22 15:16:45.433502913'], dtype='datetime64[ns]', freq=None)

In [63]: pd.to_datetime(1490195805433502912, unit='ns')
Out[63]:
Timestamp('2017-03-22 15:16:45.433502912')
```
See also:

*Using the origin Parameter*

### From timestamps to epoch

To invert the operation from above, namely, to convert from a `Timestamp` to a ‘unix’ epoch:

```
In [64]: stamps = pd.date_range('2012-10-08 18:15:05', periods=4, freq='D')
In [65]: stamps
Out[65]:
DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05',
              '2012-10-10 18:15:05', '2012-10-11 18:15:05'],
   dtype='datetime64[ns]', freq='D')
```

We subtract the epoch (midnight at January 1, 1970 UTC) and then floor divide by the “unit” (1 second).

```
In [66]: (stamps - pd.Timestamp("1970-01-01")) // pd.Timedelta('1s')
Out[66]:
Int64Index([1349720105, 1349806505, 1349892905, 1349979305], dtype='int64')
```

### Using the origin Parameter

Using the `origin` parameter, one can specify an alternative starting point for creation of a `DatetimeIndex`. For example, to use 1960-01-01 as the starting date:

```
In [67]: pd.to_datetime([1, 2, 3], unit='D', origin=pd.Timestamp('1960-01-01'))
Out[67]:
DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'],
               dtype='datetime64[ns]', freq=None)
```

The default is set at `origin='unix'`, which defaults to `1970-01-01 00:00:00`. Commonly called ‘unix epoch’ or POSIX time.

```
In [68]: pd.to_datetime([1, 2, 3], unit='D')
Out[68]:
DatetimeIndex(['1970-01-02', '1970-01-03', '1970-01-04'],
               dtype='datetime64[ns]', freq=None)
```

### 2.17.4 Generating ranges of timestamps

To generate an index with timestamps, you can use either the `DatetimeIndex` or `Index` constructor and pass in a list of datetime objects:

```
In [69]: dates = [datetime.datetime(2012, 5, 1),
           ....:   datetime.datetime(2012, 5, 2),
           ....:   datetime.datetime(2012, 5, 3)]

# Note the frequency information
In [70]: index = pd.DatetimeIndex(dates)
In [71]: index
Out[71]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'],
                       dtype='datetime64[ns]', freq=None)
```
In practice this becomes very cumbersome because we often need a very long index with a large number of timestamps. If we need timestamps on a regular frequency, we can use the `date_range()` and `bdate_range()` functions to create a DatetimeIndex. The default frequency for `date_range` is a calendar day while the default for `bdate_range` is a business day:

```python
In [74]: start = datetime.datetime(2011, 1, 1)
In [75]: end = datetime.datetime(2012, 1, 1)
In [76]: index = pd.date_range(start, end)
In [77]: index
                    '2011-01-09', '2011-01-10', ...
                    '2011-12-23', '2011-12-24', '2011-12-25', '2011-12-26',
                    '2011-12-27', '2011-12-28', '2011-12-29', '2011-12-30',
                    '2011-12-31', '2012-01-01'],
                   dtype='datetime64[ns]', length=366, freq='D')
```

```python
In [78]: index = pd.bdate_range(start, end)
In [79]: index
                    '2011-01-13', '2011-01-14', ...
                    '2011-12-19', '2011-12-20', '2011-12-21', '2011-12-22',
                    '2011-12-23', '2011-12-26', '2011-12-27', '2011-12-28',
                    '2011-12-29', '2011-12-30'],
                   dtype='datetime64[ns]', length=260, freq='B')
```

Convenience functions like `date_range` and `bdate_range` can utilize a variety of frequency aliases:

```python
In [80]: pd.date_range(start, periods=1000, freq='M')
                      '2011-09-30', '2011-10-31', ...
                      '2093-07-31', '2093-08-31', '2093-09-30', '2093-10-31',
                      '2093-11-30', '2094-01-31', '2094-02-28',
                      '2094-03-31', '2094-04-30'],
                     dtype='datetime64[ns]', length=1000, freq='M')
```

```python
In [81]: pd.bdate_range(start, periods=250, freq='BQS')
```

(continues on next page)
date_range and bdate_range make it easy to generate a range of dates using various combinations of parameters like start, end, periods, and freq. The start and end dates are strictly inclusive, so dates outside of those specified will not be generated:

In [82]: pd.date_range(start, end, freq='BM')
Out[82]:
           dtype='datetime64[ns]', freq='BM')

In [83]: pd.date_range(start, end, freq='W')
Out[83]:
               '2011-08-14', '2011-08-21', '2011-08-28', '2011-09-04',
               '2011-12-04', '2011-12-11', '2011-12-18', '2011-12-25',
               '2012-01-01'],
           dtype='datetime64[ns]', freq='W-SUN')

In [84]: pd.bdate_range(end=end, periods=20)
Out[84]:
DatetimeIndex(['2011-12-05', '2011-12-06', '2011-12-07', '2011-12-08',
               '2011-12-09', '2011-12-12', '2011-12-13', '2011-12-14',
               '2011-12-15', '2011-12-16', '2011-12-19', '2011-12-20',
               '2011-12-21', '2011-12-22', '2011-12-23', '2011-12-26',
               '2011-12-27', '2011-12-28', '2011-12-29', '2011-12-30'],
           dtype='datetime64[ns]', freq='B')

In [85]: pd.bdate_range(start=start, periods=20)
Out[85]:
           dtype='datetime64[ns]', freq='B')
Specifying `start`, `end`, and `periods` will generate a range of evenly spaced dates from `start` to `end` inclusively, with `periods` number of elements in the resulting `DatetimeIndex`:

```python
In [86]: pd.date_range('2018-01-01', '2018-01-05', periods=5)
Out[86]:
               '2018-01-05'], dtype='datetime64[ns]', freq=None)

In [87]: pd.date_range('2018-01-01', '2018-01-05', periods=10)
Out[87]:
DatetimeIndex(['2018-01-01 00:00:00', '2018-01-01 10:40:00',
               '2018-01-01 21:20:00', '2018-01-02 08:00:00',
               '2018-01-02 18:40:00', '2018-01-03 05:20:00',
               '2018-01-03 16:00:00', '2018-01-04 02:40:00',
               '2018-01-04 13:20:00', '2018-01-05 00:00:00'],
              dtype='datetime64[ns]', freq=None)
```

**Custom frequency ranges**

`bdate_range` can also generate a range of custom frequency dates by using the `weekmask` and `holidays` parameters. These parameters will only be used if a custom frequency string is passed.

```python
In [88]: weekmask = 'Mon Wed Fri'

In [89]: holidays = [datetime.datetime(2011, 1, 5), datetime.datetime(2011, 3, 14)]

In [90]: pd.bdate_range(start, end, freq='C', weekmask=weekmask, holidays=holidays)
Out[90]:
               '2011-01-24', '2011-01-26',
               ... '2011-12-09', '2011-12-12', '2011-12-14', '2011-12-16',
               '2011-12-19', '2011-12-21', '2011-12-23', '2011-12-26',
               '2011-12-28', '2011-12-30'],
              dtype='datetime64[ns]', length=154, freq='C')

In [91]: pd.bdate_range(start, end, freq='CBMS', weekmask=weekmask)
Out[91]:
DatetimeIndex(['2011-01-03', '2011-02-02', '2011-03-02', '2011-04-01',
               '2011-09-02', '2011-10-03', '2011-11-02', '2011-12-02'],
              dtype='datetime64[ns]', freq='CBMS')
```

See also:

*Custom business days*
2.17.5 Timestamp limitations

Since pandas represents timestamps in nanosecond resolution, the time span that can be represented using a 64-bit integer is limited to approximately 584 years:

```python
In [92]: pd.Timestamp.min
Out[92]: Timestamp('1677-09-21 00:12:43.145225')
In [93]: pd.Timestamp.max
Out[93]: Timestamp('2262-04-11 23:47:16.854775807')
```

See also:

*Representing out-of-bounds spans*

2.17.6 Indexing

One of the main uses for `DatetimeIndex` is as an index for pandas objects. The `DatetimeIndex` class contains many time series related optimizations:

- A large range of dates for various offsets are pre-computed and cached under the hood in order to make generating subsequent date ranges very fast (just have to grab a slice).
- Fast shifting using the `shift` method on pandas objects.
- Unioning of overlapping `DatetimeIndex` objects with the same frequency is very fast (important for fast data alignment).
- Quick access to date fields via properties such as `year`, `month`, etc.
- Regularization functions like `snap` and very fast `asof` logic.

`DatetimeIndex` objects have all the basic functionality of regular `Index` objects, and a smorgasbord of advanced time series specific methods for easy frequency processing.

See also:

*Reindexing methods*

**Note:** While pandas does not force you to have a sorted date index, some of these methods may have unexpected or incorrect behavior if the dates are unsorted.

`DatetimeIndex` can be used like a regular index and offers all of its intelligent functionality like selection, slicing, etc.

```python
In [94]: rng = pd.date_range(start, end, freq='BM')
In [95]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
In [96]: ts.index
                     dtype='datetime64[ns]', freq='BM')
In [97]: ts[:5].index
Out[97]:

(continues on next page)
Partial string indexing

Dates and strings that parse to timestamps can be passed as indexing parameters:

```
In [99]: ts['1/31/2011']
Out[99]: 0.11920871129693428

In [100]: ts[datetime.datetime(2011, 12, 25):]
Out[100]:
2011-12-30 0.56702
Freq: BM, dtype: float64

In [101]: ts['10/31/2011':'12/31/2011']
Out[101]:
2011-10-31 0.271860  
2011-11-30 -0.424972  
2011-12-30 0.567020  
Freq: BM, dtype: float64
```

To provide convenience for accessing longer time series, you can also pass in the year or year and month as strings:

```
In [102]: ts['2011']
Out[102]:
2011-01-31 0.119209  
2011-02-28 -1.044236  
2011-03-31 -0.861849  
2011-04-29 -2.104569  
2011-05-31 -0.494929  
2011-06-30 1.071804  
2011-07-29 0.721555  
2011-08-31 -0.706771  
2011-09-30 -1.039575  
2011-10-31 0.271860  
2011-11-30 -0.424972  
2011-12-30 0.567020  
Freq: BM, dtype: float64

In [103]: ts['2011-6']
Out[103]:
2011-06-30 1.071804  
Freq: BM, dtype: float64
```

This type of slicing will work on a DataFrame with a DatetimeIndex as well. Since the partial string selection is a form of label slicing, the endpoints will be included. This would include matching times on an included date:
In 

```python
In [104]: dft = pd.DataFrame(np.random.randn(100000, 1), columns=['A'],
                      index=pd.date_range('20130101', periods=100000, freq='T'))

In [105]: dft
Out[105]:
    A
2013-01-01 00:00:00  0.276232
2013-01-01 00:01:00 -1.087401
2013-01-01 00:02:00  -0.673690
2013-01-01 00:03:00  0.113648
2013-01-01 00:04:00  -1.478427
... ... ...
2013-03-11 10:35:00  -0.747967
2013-03-11 10:36:00  -0.034523
2013-03-11 10:37:00  -0.201754
2013-03-11 10:38:00  -1.509067
2013-03-11 10:39:00  -1.693043
[100000 rows x 1 columns]
```

This starts on the very first time in the month, and includes the last date and time for the month:

In 

```python
In [106]: dft['2013']
Out[106]:
    A
2013-01-01 00:00:00  0.276232
2013-01-01 00:01:00 -1.087401
2013-01-01 00:02:00  -0.673690
2013-01-01 00:03:00  0.113648
2013-01-01 00:04:00  -1.478427
... ... ...
2013-02-28 23:55:00  0.850929
2013-02-28 23:56:00  0.976712
2013-02-28 23:57:00  -2.693884
2013-02-28 23:58:00  -1.575535
2013-02-28 23:59:00  -1.573517
[84960 rows x 1 columns]
```
This specifies a stop time that includes all of the times on the last day:

```
In [108]: dft['2013-1':'2013-2-28']
Out[108]:
    A
2013-01-01 00:00:00  0.276232
2013-01-01 00:01:00  -1.087401
2013-01-01 00:02:00   0.673690
2013-01-01 00:03:00   0.113648
2013-01-01 00:04:00  -1.478427
...  ...
2013-02-28 23:55:00   0.850929
2013-02-28 23:56:00   0.976712
2013-02-28 23:57:00  -2.693884
2013-02-28 23:58:00  -1.575535
2013-02-28 23:59:00  -1.573517
[84960 rows x 1 columns]
```

This specifies an exact stop time (and is not the same as the above):

```
In [109]: dft['2013-1':'2013-2-28 00:00:00']
Out[109]:
    A
2013-01-01 00:00:00  0.276232
2013-01-01 00:01:00  -1.087401
2013-01-01 00:02:00   0.673690
2013-01-01 00:03:00   0.113648
2013-01-01 00:04:00  -1.478427
...  ...
2013-02-27 23:56:00   1.197749
2013-02-27 23:57:00   0.720521
2013-02-27 23:58:00  -0.072718
2013-02-27 23:59:00  -0.681192
2013-02-28 00:00:00  -0.557501
[83521 rows x 1 columns]
```

We are stopping on the included end-point as it is part of the index:

```
In [110]: dft['2013-1-15':'2013-1-15 12:30:00']
Out[110]:
    A
2013-01-15 00:00:00 -0.984810
2013-01-15 00:01:00   0.941451

[751 rows x 1 columns]
```

DatetimeIndex partial string indexing also works on a DataFrame with a MultiIndex:

2.17. Time series / date functionality
In [111]: dft2 = pd.DataFrame(np.random.randn(20, 1),
                           columns=['A'],
                           index=pd.MultiIndex.from_product(
                            [pd.date_range('20130101', periods=10, freq='12H'),
                             ['a', 'b']]))

In [112]: dft2
Out[112]:
     A
2013-01-01 00:00:00 a -0.298694  
             b  0.823553  
2013-01-01 12:00:00 a  0.943285  
             b -1.479399  
2013-01-02 00:00:00 a -1.643342  
                   ...  
2013-01-04 12:00:00 b  0.069036  
2013-01-05 00:00:00 a  0.122297  
             b  1.422060  
2013-01-05 12:00:00 a  0.370079  
             b  1.016331  
[20 rows x 1 columns]

In [113]: dft2.loc['2013-01-05']
Out[113]:
     A
2013-01-05 00:00:00 a  0.122297  
             b  1.422060  
2013-01-05 12:00:00 a  0.370079  
             b  1.016331

In [114]: idx = pd.IndexSlice

In [115]: dft2 = dft2.swaplevel(0, 1).sort_index()

In [116]: dft2.loc[idx[:, '2013-01-05'], :]
Out[116]:
     A
a 2013-01-05 00:00:00 0.122297  
2013-01-05 12:00:00 0.370079  
2013-01-05 12:00:00 0.370079  

New in version 0.25.0.
Slicing with string indexing also honors UTC offset.

In [117]: df = pd.DataFrame([0], index=pd.DatetimeIndex(['2019-01-01'], tz='US/Pacific'))

In [118]: df
Out[118]:
     D
2019-01-01 00:00:00-08:00 0

In [119]: df['2019-01-01 12:00:00+04:00':'2019-01-01 13:00:00+04:00']
Out[119]:

(continues on next page)
Slice vs. exact match

Changed in version 0.20.0.

The same string used as an indexing parameter can be treated either as a slice or as an exact match depending on the resolution of the index. If the string is less accurate than the index, it will be treated as a slice, otherwise as an exact match.

Consider a Series object with a minute resolution index:

```
In [120]: series_minute = pd.Series([1, 2, 3],
    ....:     pd.DatetimeIndex(['2011-12-31 23:59:00',
    ....:                  '2012-01-01 00:00:00',
    ....:                  '2012-01-01 00:02:00']))

In [121]: series_minute.index.resolution
Out[121]: 'minute'
```

A timestamp string less accurate than a minute gives a Series object.

```
In [122]: series_minute['2011-12-31 23']
Out[122]:
2011-12-31 23:59:00    1
dtype: int64
```

A timestamp string with minute resolution (or more accurate), gives a scalar instead, i.e. it is not casted to a slice.

```
In [123]: series_minute['2011-12-31 23:59']
Out[123]: 1

In [124]: series_minute['2011-12-31 23:59:00']
Out[124]: 1
```

If index resolution is second, then the minute-accurate timestamp gives a Series.

```
In [125]: series_second = pd.Series([1, 2, 3],
    ....:     pd.DatetimeIndex(['2011-12-31 23:59:59',
    ....:                  '2012-01-01 00:00:00',
    ....:                  '2012-01-01 00:00:01']))

In [126]: series_second.index.resolution
Out[126]: 'second'

In [127]: series_second['2011-12-31 23:59']
Out[127]:
2011-12-31 23:59:59    1
dtype: int64
```

If the timestamp string is treated as a slice, it can be used to index DataFrame with [] as well.
In [128]: dft_minute = pd.DataFrame({"a": [1, 2, 3], "b": [4, 5, 6]},
                               index=series_minute.index)

In [129]: dft_minute['2011-12-31 23']
Out[129]:
          a  b
2011-12-31 23:59:00 1  4

Warning: However, if the string is treated as an exact match, the selection in DataFrame's [] will be column-wise and not row-wise, see Indexing Basics. For example dft_minute['2011-12-31 23:59'] will raise KeyError as '2012-12-31 23:59' has the same resolution as the index and there is no column with such name:

To always have unambiguous selection, whether the row is treated as a slice or a single selection, use .loc.

In [130]: dft_minute.loc['2011-12-31 23:59']
Out[130]:
          a  b
2011-12-31 23:59:00 1  4

Note also that DatetimeIndex resolution cannot be less precise than day.

In [131]: series_monthly = pd.Series([1, 2, 3],
                               pd.DatetimeIndex(['2011-12', '2012-01', '2012-02']))

In [132]: series_monthly.index.resolution
Out[132]: 'day'

In [133]: series_monthly['2011-12']  # returns Series
Out[133]:
2011-12-01  1
dtype: int64

Exact indexing

As discussed in previous section, indexing a DatetimeIndex with a partial string depends on the “accuracy” of the period, in other words how specific the interval is in relation to the resolution of the index. In contrast, indexing with Timestamp or datetime objects is exact, because the objects have exact meaning. These also follow the semantics of including both endpoints.

These Timestamp and datetime objects have exact hours, minutes, and seconds, even though they were not explicitly specified (they are 0).

In [134]: dft[datetime.datetime(2013, 1, 1):datetime.datetime(2013, 2, 28)]
Out[134]:
          A
2013-01-01 00:00:00 0.276232
2013-01-01 00:01:00 -1.087401

         2013-02-28 10:11:00  0.085288
         2013-02-28 10:12:00  0.950146
[83521 rows x 1 columns]
```

Truncating & fancy indexing

A `truncate()` convenience function is provided that is similar to slicing. Note that `truncate` assumes a 0 value for any unspecified date component in a `DatetimeIndex` in contrast to slicing which returns any partially matching dates:

```python
In [136]: rng2 = pd.date_range('2011-01-01', '2012-01-01', freq='W')
In [137]: ts2 = pd.Series(np.random.randn(len(rng2)), index=rng2)
In [138]: ts2.truncate(before='2011-11', after='2011-12')
```

```
Out[138]:
         2011-11-06   0.437823
         2011-11-13  -0.293083
         2011-11-20  -0.059881
         2011-11-27   1.252450
Freq: W-SUN, dtype: float64
```

```python
In [139]: ts2['2011-11':'2011-12']
```

```
Out[139]:
         2011-11-06   0.437823
         2011-11-13  -0.293083
         2011-11-20  -0.059881
         2011-11-27   1.252450
```

(continues on next page)
2011-12-04  0.046611
2011-12-11  0.059478
2011-12-18  -0.286539
2011-12-25  0.841669
Freq: W-SUN, dtype: float64

Even complicated fancy indexing that breaks the DatetimeIndex frequency regularity will result in a DatetimeIndex, although frequency is lost:

```
In [140]: ts2[[0, 2, 6]].index
Out[140]: DatetimeIndex(['2011-01-02', '2011-01-16', '2011-02-13'], dtype=
˓→'datetime64[ns]', freq=None)
```

### 2.17.7 Time/date components

There are several time/date properties that one can access from Timestamp or a collection of timestamps like a DatetimeIndex.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>year</td>
<td>The year of the datetime</td>
</tr>
<tr>
<td>month</td>
<td>The month of the datetime</td>
</tr>
<tr>
<td>day</td>
<td>The days of the datetime</td>
</tr>
<tr>
<td>hour</td>
<td>The hour of the datetime</td>
</tr>
<tr>
<td>minute</td>
<td>The minutes of the datetime</td>
</tr>
<tr>
<td>second</td>
<td>The seconds of the datetime</td>
</tr>
<tr>
<td>microsecond</td>
<td>The microseconds of the datetime</td>
</tr>
<tr>
<td>nanosecond</td>
<td>The nanoseconds of the datetime</td>
</tr>
<tr>
<td>date</td>
<td>Returns datetime.date (does not contain timezone information)</td>
</tr>
<tr>
<td>time</td>
<td>Returns datetime.time (does not contain timezone information)</td>
</tr>
<tr>
<td>timetz</td>
<td>Returns datetime.time as local time with timezone information</td>
</tr>
<tr>
<td>dayofyear</td>
<td>The ordinal day of year</td>
</tr>
<tr>
<td>weekofyear</td>
<td>The week ordinal of the year</td>
</tr>
<tr>
<td>week</td>
<td>The week ordinal of the year</td>
</tr>
<tr>
<td>dayofweek</td>
<td>The number of the day of the week with Monday=0, Sunday=6</td>
</tr>
<tr>
<td>weekday</td>
<td>The number of the day of the week with Monday=0, Sunday=6</td>
</tr>
<tr>
<td>quarter</td>
<td>Quarter of the date: Jan-Mar = 1, Apr-Jun = 2, etc.</td>
</tr>
<tr>
<td>days_in_month</td>
<td>The number of days in the month of the datetime</td>
</tr>
<tr>
<td>is_month_start</td>
<td>Logical indicating if first day of month (defined by frequency)</td>
</tr>
<tr>
<td>is_month_end</td>
<td>Logical indicating if last day of month (defined by frequency)</td>
</tr>
<tr>
<td>is_quarter_start</td>
<td>Logical indicating if first day of quarter (defined by frequency)</td>
</tr>
<tr>
<td>is_quarter_end</td>
<td>Logical indicating if last day of quarter (defined by frequency)</td>
</tr>
<tr>
<td>is_year_start</td>
<td>Logical indicating if first day of year (defined by frequency)</td>
</tr>
<tr>
<td>is_year_end</td>
<td>Logical indicating if last day of year (defined by frequency)</td>
</tr>
<tr>
<td>is_leap_year</td>
<td>Logical indicating if the date belongs to a leap year</td>
</tr>
</tbody>
</table>

Furthermore, if you have a Series with datetimelike values, then you can access these properties via the `.dt` accessor, as detailed in the section on `.dt accessors.`

New in version 1.1.0.

You may obtain the year, week and day components of the ISO year from the ISO 8601 standard:
In [141]: idx = pd.date_range(start='2019-12-29', freq='D', periods=4)

In [142]: idx.isocalendar()
Out[142]:
   year  week  day
2019-12-29  2019   52   7
2019-12-30  2020    1   1
2019-12-31  2020    1   2
2020-01-01  2020    1   3

In [143]: idx.to_series().dt.isocalendar()
Out[143]:
   year  week  day
2019-12-29  2019   52   7
2019-12-30  2020    1   1
2019-12-31  2020    1   2
2020-01-01  2020    1   3

2.17.8 DateOffset objects

In the preceding examples, frequency strings (e.g. 'D') were used to specify a frequency that defined:

- how the date times in DatetimeIndex were spaced when using date_range()
- the frequency of a Period or PeriodIndex

These frequency strings map to a DateOffset object and its subclasses. A DateOffset is similar to a Timedelta that represents a duration of time but follows specific calendar duration rules. For example, a Timedelta day will always increment datetimes by 24 hours, while a DateOffset day will increment datetimes to the same time the next day whether a day represents 23, 24 or 25 hours due to daylight savings time. However, all DateOffset subclasses that are an hour or smaller (Hour, Minute, Second, Milli, Micro, Nano) behave like Timedelta and respect absolute time.

The basic DateOffset acts similar to dateutil.relativedelta (relativedelta documentation) that shifts a date time by the corresponding calendar duration specified. The arithmetic operator (+) or the apply method can be used to perform the shift.

# This particular day contains a day light savings time transition
In [144]: ts = pd.Timestamp('2016-10-30 00:00:00', tz='Europe/Helsinki')

# Respects absolute time
In [145]: ts + pd.Timedelta(days=1)
Out[145]: Timestamp('2016-10-30 23:00:00+0200', tz='Europe/Helsinki')

# Respects calendar time
In [146]: ts + pd.DateOffset(days=1)
Out[146]: Timestamp('2016-10-31 00:00:00+0200', tz='Europe/Helsinki')

In [147]: friday = pd.Timestamp('2018-01-05')

In [148]: friday.day_name()
Out[148]: 'Friday'

# Add 2 business days (Friday --> Tuesday)
In [149]: two_business_days = 2 * pd.offsets.BDay()
Most `DateOffsets` have associated frequencies strings, or offset aliases, that can be passed into `freq` keyword arguments. The available date offsets and associated frequency strings can be found below:

<table>
<thead>
<tr>
<th>Date Offset</th>
<th>Frequency String</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DateOffset</code></td>
<td><code>None</code></td>
<td>Generic offset class, defaults to 1 calendar day</td>
</tr>
<tr>
<td><code>BDay</code> or <code>BusinessDay</code></td>
<td>'B'</td>
<td>Business day (weekday)</td>
</tr>
<tr>
<td><code>CDay</code> or <code>CustomBusinessDay</code></td>
<td>'C'</td>
<td>Custom business day</td>
</tr>
<tr>
<td><code>Week</code></td>
<td>'W'</td>
<td>One week, optionally anchored on a day of the week</td>
</tr>
<tr>
<td><code>WeekOfMonth</code></td>
<td>'WOM'</td>
<td>The x-th day of the y-th week of each month</td>
</tr>
<tr>
<td><code>LastWeekOfMonth</code></td>
<td>'LWOM'</td>
<td>The x-th day of the last week of each month</td>
</tr>
<tr>

<td>one nanosecond</td>
</tr>
</tbody>
</table>

DateOffsets additionally have rollforward() and rollback() methods for moving a date forward or backward respectively to a valid offset date relative to the offset. For example, business offsets will roll dates that land on the weekends (Saturday and Sunday) forward to Monday since business offsets operate on the weekdays.

```
In [133]: ts = pd.Timestamp('2018-01-06 00:00:00')

In [134]: ts.day_name()
Out[134]: 'Saturday'

# BusinessHour's valid offset dates are Monday through Friday
In [135]: offset = pd.offsets.BusinessHour(start='09:00')

# Bring the date to the closest offset date (Monday)
In [136]: offset.rollforward(ts)
Out[136]: Timestamp('2018-01-08 09:00:00')

# Date is brought to the closest offset date first and then the hour is added
In [137]: ts + offset
Out[137]: Timestamp('2018-01-08 10:00:00')
```

These operations preserve time (hour, minute, etc) information by default. To reset time to midnight, use normalize() before or after applying the operation (depending on whether you want the time information included in the operation).

```
In [138]: ts = pd.Timestamp('2014-01-01 09:00')

In [139]: day = pd.offsets.Day()

In [140]: day.apply(ts)
Out[140]: Timestamp('2014-01-02 09:00:00')

In [141]: day.apply(ts).normalize()
Out[141]: Timestamp('2014-01-02 00:00:00')

In [142]: ts = pd.Timestamp('2014-01-01 22:00')

In [143]: hour = pd.offsets.Hour()

In [144]: hour.apply(ts)
Out[144]: Timestamp('2014-01-01 23:00:00')

In [145]: hour.apply(ts).normalize()
Out[145]: Timestamp('2014-01-01 00:00:00')
```

(continues on next page)
In [166]: hour.apply(pd.Timestamp("2014-01-01 23:30")).normalize()
Out[166]: Timestamp('2014-01-02 00:00:00')

Parametric offsets

Some of the offsets can be “parameterized” when created to result in different behaviors. For example, the Week offset for generating weekly data accepts a weekday parameter which results in the generated dates always lying on a particular day of the week:

In [167]: d = datetime.datetime(2008, 8, 18, 9, 0)
In [168]: d
Out[168]: datetime.datetime(2008, 8, 18, 9, 0)
In [169]: d + pd.offsets.Week()
Out[169]: Timestamp('2008-08-25 09:00:00')
In [170]: d + pd.offsets.Week(weekday=4)
Out[170]: Timestamp('2008-08-22 09:00:00')
In [171]: (d + pd.offsets.Week(weekday=4)).weekday()
Out[171]: 4
In [172]: d - pd.offsets.Week()
Out[172]: Timestamp('2008-08-11 09:00:00')

The normalize option will be effective for addition and subtraction.

In [173]: d + pd.offsets.Week(normalize=True)
Out[173]: Timestamp('2008-08-25 00:00:00')
In [174]: d - pd.offsets.Week(normalize=True)
Out[174]: Timestamp('2008-08-11 00:00:00')

Another example is parameterizing YearEnd with the specific ending month:

In [175]: d + pd.offsets.YearEnd()
Out[175]: Timestamp('2008-12-31 09:00:00')
In [176]: d + pd.offsets.YearEnd(month=6)
Out[176]: Timestamp('2009-06-30 09:00:00')

Using offsets with Series/DatetimeIndex

Offsets can be used with either a Series or DatetimeIndex to apply the offset to each element.

In [177]: rng = pd.date_range('2012-01-01', '2012-01-03')
In [178]: s = pd.Series(rng)
In [179]: rng
Out[179]: DatetimeIndex(['2012-01-01', '2012-01-02', '2012-01-03'], dtype='datetime64[ns]', freq='D')
In [180]: rng + pd.DateOffset(months=2)
Out[180]: DatetimeIndex(['2012-03-01', '2012-03-02', '2012-03-03'], dtype='datetime64[ns]', freq=None)

In [181]: s + pd.DateOffset(months=2)
Out[181]:
0 2012-03-01
1 2012-03-02
2 2012-03-03
dtype: datetime64[ns]

In [182]: s - pd.DateOffset(months=2)
Out[182]:
0 2011-11-01
1 2011-11-02
2 2011-11-03
dtype: datetime64[ns]

If the offset class maps directly to a Timedelta (Day, Hour, Minute, Second, Micro, Milli, Nano) it can be used exactly like a Timedelta - see the Timedelta section for more examples.

In [183]: s - pd.offsets.Day(2)
Out[183]:
0 2011-12-30
1 2011-12-31
2 2012-01-01
dtype: datetime64[ns]

In [184]: td = s - pd.Series(pd.date_range('2011-12-29', '2011-12-31'))

In [185]: td
Out[185]:
0 3 days
1 3 days
2 3 days
dtype: timedelta64[ns]

In [186]: td + pd.offsets.Minute(15)
Out[186]:
0 3 days 00:15:00
1 3 days 00:15:00
2 3 days 00:15:00
dtype: timedelta64[ns]

Note that some offsets (such as BQuarterEnd) do not have a vectorized implementation. They can still be used but may calculate significantly slower and will show a PerformanceWarning

In [187]: rng + pd.offsets.BQuarterEnd()
Out[187]: DatetimeIndex(['2012-03-30', '2012-03-30', '2012-03-30'], dtype='datetime64[ns]', freq=None)
Custom business days

The CDay or CustomBusinessDay class provides a parametric BusinessDay class which can be used to create customized business day calendars which account for local holidays and local weekend conventions.

As an interesting example, let’s look at Egypt where a Friday-Saturday weekend is observed.

```
In [188]: weekmask_egypt = 'Sun Mon Tue Wed Thu'

# They also observe International Workers' Day so let's
# add that for a couple of years
In [189]: holidays = ['2012-05-01',
                   datetime.datetime(2013, 5, 1),
                   np.datetime64('2014-05-01')]

In [190]: bday_egypt = pd.offsets.CustomBusinessDay(holidays=holidays,
                                                   weekmask=weekmask_egypt)

In [191]: dt = datetime.datetime(2013, 4, 30)

In [192]: dt + 2 * bday_egypt
Out[192]: Timestamp('2013-05-05 00:00:00')

Let's map to the weekday names:

```
In [193]: dts = pd.date_range(dt, periods=5, freq=bday_egypt)
In [194]: pd.Series(dts.weekday, dts).map(pd.Series('Mon Tue Wed Thu Fri Sat Sun'.split()))
Out[194]:
2013-04-30 Tue
2013-05-02 Thu
2013-05-05 Sun
2013-05-06 Mon
2013-05-07 Tue
Freq: C, dtype: object
```

Holiday calendars can be used to provide the list of holidays. See the holiday calendar section for more information.

```
In [195]: from pandas.tseries.holiday import USFederalHolidayCalendar
In [196]: bday_us = pd.offsets.CustomBusinessDay(calendar=USFederalHolidayCalendar())
# Friday before MLK Day
In [197]: dt = datetime.datetime(2014, 1, 17)
# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [198]: dt + bday_us
Out[198]: Timestamp('2014-01-21 00:00:00')
```

Monthly offsets that respect a certain holiday calendar can be defined in the usual way.

```
In [199]: bmth_us = pd.offsets.CustomBusinessMonthBegin(calendar=USFederalHolidayCalendar())
(continues on next page)
In [200]: dt = datetime.datetime(2013, 12, 17)

In [201]: dt + bmth_us
Out[201]: Timestamp('2014-01-02 00:00:00')

# Define date index with custom offset
In [202]: pd.date_range(start='20100101', end='20120101', freq=bmth_us)
Out[202]:
DatetimeIndex(['2010-01-04', '2010-02-01', '2010-03-01', '2010-04-01',
               '2010-05-03', '2010-06-01', '2010-07-01', '2010-08-02',
               '2010-09-01', '2010-10-01', '2010-11-01', '2010-12-01',
               '2011-01-03', '2011-02-01', '2011-03-01', '2011-04-01',
               '2011-09-01', '2011-10-03', '2011-11-01', '2011-12-01'],
dtype='datetime64[ns]', freq='CBMS')

Note: The frequency string ‘C’ is used to indicate that a CustomBusinessDay DateOffset is used, it is important to note that since CustomBusinessDay is a parameterised type, instances of CustomBusinessDay may differ and this is not detectable from the ‘C’ frequency string. The user therefore needs to ensure that the ‘C’ frequency string is used consistently within the user’s application.

Business hour

The BusinessHour class provides a business hour representation on BusinessDay, allowing to use specific start and end times.

By default, BusinessHour uses 9:00 - 17:00 as business hours. Adding BusinessHour will increment Timestamp by hourly frequency. If target Timestamp is out of business hours, move to the next business hour then increment it. If the result exceeds the business hours end, the remaining hours are added to the next business day.

In [203]: bh = pd.offsets.BusinessHour()

In [204]: bh
Out[204]: <BusinessHour: BH=09:00-17:00>

# 2014-08-01 is Friday
In [205]: pd.Timestamp('2014-08-01 10:00').weekday()
Out[205]: 4

In [206]: pd.Timestamp('2014-08-01 10:00') + bh
Out[206]: Timestamp('2014-08-01 11:00:00')

# Below example is the same as: pd.Timestamp('2014-08-01 09:00') + bh
In [207]: pd.Timestamp('2014-08-01 08:00') + bh
Out[207]: Timestamp('2014-08-01 10:00:00')

# If the results is on the end time, move to the next business day
In [208]: pd.Timestamp('2014-08-01 16:00') + bh
Out[208]: Timestamp('2014-08-04 09:00:00')

# Remainings are added to the next day
In [209]: pd.Timestamp('2014-08-01 16:30') + bh
Out[209]: Timestamp('2014-08-04 09:30:00')

# Adding 2 business hours
In [210]: pd.Timestamp('2014-08-01 10:00') + pd.offsets.BusinessHour(2)
Out[210]: Timestamp('2014-08-01 12:00:00')

# Subtracting 3 business hours
In [211]: pd.Timestamp('2014-08-01 10:00') + pd.offsets.BusinessHour(-3)
Out[211]: Timestamp('2014-07-31 15:00:00')

You can also specify start and end time by keywords. The argument must be a str with an hour:minute representation or a datetime.time instance. Specifying seconds, microseconds and nanoseconds as business hour results in ValueError.

In [212]: bh = pd.offsets.BusinessHour(start='11:00', end=datetime.time(20, 0))
In [213]: bh
Out[213]: <BusinessHour: BH=11:00-20:00>
In [214]: pd.Timestamp('2014-08-01 13:00') + bh
Out[214]: Timestamp('2014-08-01 14:00:00')
In [215]: pd.Timestamp('2014-08-01 09:00') + bh
Out[215]: Timestamp('2014-08-01 12:00:00')
In [216]: pd.Timestamp('2014-08-01 18:00') + bh
Out[216]: Timestamp('2014-08-01 19:00:00')

Passing start time later than end represents midnight business hour. In this case, business hour exceeds midnight and overlap to the next day. Valid business hours are distinguished by whether it started from valid BusinessDay.

In [217]: bh = pd.offsets.BusinessHour(start='17:00', end='09:00')
In [218]: bh
Out[218]: <BusinessHour: BH=17:00-09:00>
In [219]: pd.Timestamp('2014-08-01 17:00') + bh
Out[219]: Timestamp('2014-08-01 18:00:00')
In [220]: pd.Timestamp('2014-08-01 23:00') + bh
Out[220]: Timestamp('2014-08-02 00:00:00')

# Although 2014-08-02 is Saturday, # it is valid because it starts from 08-01 (Friday).
In [221]: pd.Timestamp('2014-08-02 04:00') + bh
Out[221]: Timestamp('2014-08-02 05:00:00')

# Although 2014-08-04 is Monday, # it is out of business hours because it starts from 08-03 (Sunday).
In [222]: pd.Timestamp('2014-08-04 04:00') + bh
Out[222]: Timestamp('2014-08-04 18:00:00')

Applying BusinessHour.rollforward and rollback to out of business hours results in the next business hour start or previous day’s end. Different from other offsets, BusinessHour.rollforward may output different results from apply by definition.
This is because one day’s business hour end is equal to next day’s business hour start. For example, under the default business hours (9:00 - 17:00), there is no gap (0 minutes) between 2014-08-01 17:00 and 2014-08-04 09:00.

```python
# This adjusts a Timestamp to business hour edge
In [223]: pd.offsets.BusinessHour().rollback(pd.Timestamp('2014-08-01 17:00'))
Out[223]: Timestamp('2014-08-01 17:00:00')

In [224]: pd.offsets.BusinessHour().rollforward(pd.Timestamp('2014-08-02 15:00'))
Out[224]: Timestamp('2014-08-04 09:00:00')

# It is the same as BusinessHour().apply(pd.Timestamp('2014-08-01 17:00')).
# And it is the same as BusinessHour().apply(pd.Timestamp('2014-08-04 09:00'))
In [225]: pd.offsets.BusinessHour().apply(pd.Timestamp('2014-08-02 15:00'))
Out[225]: Timestamp('2014-08-04 10:00:00')

# BusinessDay results (for reference)
In [226]: pd.offsets.BusinessHour().rollforward(pd.Timestamp('2014-08-02'))
Out[226]: Timestamp('2014-08-04 09:00:00')

# It is the same as BusinessDay().apply(pd.Timestamp('2014-08-01'))
# The result is the same as rollworward because BusinessDay never overlap.
In [227]: pd.offsets.BusinessHour().apply(pd.Timestamp('2014-08-02'))
Out[227]: Timestamp('2014-08-04 10:00:00')
```

BusinessHour regards Saturday and Sunday as holidays. To use arbitrary holidays, you can use CustomBusinessHour offset, as explained in the following subsection.

**Custom business hour**

The CustomBusinessHour is a mixture of BusinessHour and CustomBusinessDay which allows you to specify arbitrary holidays. CustomBusinessHour works as the same as BusinessHour except that it skips specified custom holidays.

```python
In [228]: from pandas.tseries.holiday import USFederalHolidayCalendar

In [229]: bhour_us = pd.offsets.CustomBusinessHour(calendar=USFederalHolidayCalendar())

# Friday before MLK Day
In [230]: dt = datetime.datetime(2014, 1, 17, 15)

In [231]: dt + bhour_us
Out[231]: Timestamp('2014-01-17 16:00:00')

# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [232]: dt + bhour_us * 2
Out[232]: Timestamp('2014-01-21 09:00:00')
```

You can use keyword arguments supported by either BusinessHour and CustomBusinessDay.

```python
In [233]: bhour_mon = pd.offsets.CustomBusinessHour(start='10:00',
......:   weekmask='Tue Wed Thu Fri')
......:

# Monday is skipped because it's a holiday, business hour starts from 10:00
```

(continues on next page)
Offset aliases

A number of string aliases are given to useful common time series frequencies. We will refer to these aliases as offset aliases.

<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>business day frequency</td>
</tr>
<tr>
<td>C</td>
<td>custom business day frequency</td>
</tr>
<tr>
<td>D</td>
<td>calendar day frequency</td>
</tr>
<tr>
<td>W</td>
<td>weekly frequency</td>
</tr>
<tr>
<td>M</td>
<td>month end frequency</td>
</tr>
<tr>
<td>SM</td>
<td>semi-month end frequency (15th and end of month)</td>
</tr>
<tr>
<td>BM</td>
<td>business month end frequency</td>
</tr>
<tr>
<td>CBM</td>
<td>custom business month end frequency</td>
</tr>
<tr>
<td>MS</td>
<td>month start frequency</td>
</tr>
<tr>
<td>SMS</td>
<td>semi-month start frequency (1st and 15th)</td>
</tr>
<tr>
<td>BMS</td>
<td>business month start frequency</td>
</tr>
<tr>
<td>CBMS</td>
<td>custom business month start frequency</td>
</tr>
<tr>
<td>Q</td>
<td>quarter end frequency</td>
</tr>
<tr>
<td>BQ</td>
<td>business quarter end frequency</td>
</tr>
<tr>
<td>QS</td>
<td>quarter start frequency</td>
</tr>
<tr>
<td>BQS</td>
<td>business quarter start frequency</td>
</tr>
<tr>
<td>A, Y</td>
<td>year end frequency</td>
</tr>
<tr>
<td>BA, BY</td>
<td>business year end frequency</td>
</tr>
<tr>
<td>AS, YS</td>
<td>year start frequency</td>
</tr>
<tr>
<td>BAS, BYS</td>
<td>business year start frequency</td>
</tr>
<tr>
<td>BH</td>
<td>business hour frequency</td>
</tr>
<tr>
<td>H</td>
<td>hourly frequency</td>
</tr>
<tr>
<td>T, min</td>
<td>minutely frequency</td>
</tr>
<tr>
<td>S</td>
<td>secondly frequency</td>
</tr>
<tr>
<td>L, ms</td>
<td>milliseconds</td>
</tr>
<tr>
<td>U, us</td>
<td>microseconds</td>
</tr>
<tr>
<td>N</td>
<td>nanoseconds</td>
</tr>
</tbody>
</table>

Combining aliases

As we have seen previously, the alias and the offset instance are fungible in most functions:

```
In [235]: pd.date_range(start, periods=5, freq='B')
Out[235]:
dtype='datetime64[ns]', freq='B')
```

```
In [236]: pd.date_range(start, periods=5, freq=pd.offsets.BDay())
Out[236]:
dtype='datetime64[ns]', freq='B')
```
You can combine together day and intraday offsets:

```python
def pd.date_range(start, periods=10, freq='2h20min')
Out [237]:
DateTimeIndex(['2011-01-01 00:00:00', '2011-01-01 02:20:00',
'2011-01-01 04:40:00', '2011-01-01 07:00:00',
'2011-01-01 09:20:00', '2011-01-01 11:40:00',
'2011-01-01 14:00:00', '2011-01-01 16:20:00',
'2011-01-01 18:40:00', '2011-01-01 21:00:00'],
dtype='datetime64[ns]', freq='140T')
```

```python
def pd.date_range(start, periods=10, freq='1D10U')
Out [238]:
DateTimeIndex(['2011-01-01 00:00:00', '2011-01-02 00:00:00.000010',
'2011-01-03 00:00:00.000020', '2011-01-04 00:00:00.000030',
'2011-01-05 00:00:00.000040', '2011-01-06 00:00:00.000050',
'2011-01-07 00:00:00.000060', '2011-01-08 00:00:00.000070',
'2011-01-09 00:00:00.000080', '2011-01-10 00:00:00.000090'],
dtype='datetime64[ns]', freq='86400000010U')
```

### Anchored offsets

For some frequencies you can specify an anchoring suffix:

<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>W-SUN</td>
<td>weekly frequency (Sundays). Same as 'W'</td>
</tr>
<tr>
<td>W-MON</td>
<td>weekly frequency (Mondays)</td>
</tr>
<tr>
<td>W-TUE</td>
<td>weekly frequency (Tuesdays)</td>
</tr>
<tr>
<td>W-WED</td>
<td>weekly frequency (Wednesdays)</td>
</tr>
<tr>
<td>W-THU</td>
<td>weekly frequency (Thursdays)</td>
</tr>
<tr>
<td>W-FRI</td>
<td>weekly frequency (Fridays)</td>
</tr>
<tr>
<td>W-SAT</td>
<td>weekly frequency (Saturdays)</td>
</tr>
<tr>
<td>(B)Q(S)-DEC</td>
<td>quarterly frequency, year ends in December. Same as 'Q'</td>
</tr>
<tr>
<td>(B)Q(S)-JAN</td>
<td>quarterly frequency, year ends in January</td>
</tr>
<tr>
<td>(B)Q(S)-FEB</td>
<td>quarterly frequency, year ends in February</td>
</tr>
<tr>
<td>(B)Q(S)-MAR</td>
<td>quarterly frequency, year ends in March</td>
</tr>
<tr>
<td>(B)Q(S)-APR</td>
<td>quarterly frequency, year ends in April</td>
</tr>
<tr>
<td>(B)Q(S)-MAY</td>
<td>quarterly frequency, year ends in May</td>
</tr>
<tr>
<td>(B)Q(S)-JUN</td>
<td>quarterly frequency, year ends in June</td>
</tr>
<tr>
<td>(B)Q(S)-JUL</td>
<td>quarterly frequency, year ends in July</td>
</tr>
</tbody>
</table>
Table 4 – continued from previous page

<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(B)Q(S)-AUG</td>
<td>quarterly frequency, year ends in August</td>
</tr>
<tr>
<td>(B)Q(S)-SEP</td>
<td>quarterly frequency, year ends in September</td>
</tr>
<tr>
<td>(B)Q(S)-OCT</td>
<td>quarterly frequency, year ends in October</td>
</tr>
<tr>
<td>(B)Q(S)-NOV</td>
<td>quarterly frequency, year ends in November</td>
</tr>
<tr>
<td>(B)A(S)-DEC</td>
<td>annual frequency, anchored end of December. Same as ‘A’</td>
</tr>
<tr>
<td>(B)A(S)-JAN</td>
<td>annual frequency, anchored end of January</td>
</tr>
<tr>
<td>(B)A(S)-FEB</td>
<td>annual frequency, anchored end of February</td>
</tr>
<tr>
<td>(B)A(S)-MAR</td>
<td>annual frequency, anchored end of March</td>
</tr>
<tr>
<td>(B)A(S)-APR</td>
<td>annual frequency, anchored end of April</td>
</tr>
<tr>
<td>(B)A(S)-MAY</td>
<td>annual frequency, anchored end of May</td>
</tr>
<tr>
<td>(B)A(S)-JUN</td>
<td>annual frequency, anchored end of June</td>
</tr>
<tr>
<td>(B)A(S)-JUL</td>
<td>annual frequency, anchored end of July</td>
</tr>
<tr>
<td>(B)A(S)-AUG</td>
<td>annual frequency, anchored end of August</td>
</tr>
<tr>
<td>(B)A(S)-SEP</td>
<td>annual frequency, anchored end of September</td>
</tr>
<tr>
<td>(B)A(S)-OCT</td>
<td>annual frequency, anchored end of October</td>
</tr>
<tr>
<td>(B)A(S)-NOV</td>
<td>annual frequency, anchored end of November</td>
</tr>
</tbody>
</table>

These can be used as arguments to `date_range`, `bdate_range`, constructors for `DatetimeIndex`, as well as various other timeseries-related functions in pandas.

** Anchored offset semantics

For those offsets that are anchored to the start or end of specific frequency (`MonthEnd`, `MonthBegin`, `WeekEnd`, etc), the following rules apply to rolling forward and backwards.

When $n$ is not 0, if the given date is not on an anchor point, it snapped to the next(previous) anchor point, and moved $|n| - 1$ additional steps forwards or backwards.

```
In [239]: pd.Timestamp('2014-01-02') + pd.offsets.MonthBegin(n=1)
Out[239]: Timestamp('2014-02-01 00:00:00')
```

```
In [240]: pd.Timestamp('2014-01-02') + pd.offsets.MonthEnd(n=1)
Out[240]: Timestamp('2014-01-31 00:00:00')
```

```
In [241]: pd.Timestamp('2014-01-02') - pd.offsets.MonthBegin(n=1)
```
If the given date is on an anchor point, it is moved $|n|$ points forwards or backwards.

For the case when $n=0$, the date is not moved if on an anchor point, otherwise it is rolled forward to the next anchor point.
Holidays / holiday calendars

Holidays and calendars provide a simple way to define holiday rules to be used with `CustomBusinessDay` or in other analysis that requires a predefined set of holidays. The `AbstractHolidayCalendar` class provides all the necessary methods to return a list of holidays and only rules need to be defined in a specific holiday calendar class. Furthermore, the `start_date` and `end_date` class attributes determine over what date range holidays are generated. These should be overwritten on the `AbstractHolidayCalendar` class to have the range apply to all calendar subclasses. `USFederalHolidayCalendar` is the only calendar that exists and primarily serves as an example for developing other calendars.

For holidays that occur on fixed dates (e.g., US Memorial Day or July 4th) an observance rule determines when that holiday is observed if it falls on a weekend or some other non-observed day. Defined observance rules are:

<table>
<thead>
<tr>
<th>Rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nearest_workday</td>
<td>move Saturday to Friday and Sunday to Monday</td>
</tr>
<tr>
<td>sunday_to_monday</td>
<td>move Sunday to following Monday</td>
</tr>
<tr>
<td>next_monday_or_tuesday</td>
<td>Saturday to Monday and Sunday/Monday to Tuesday</td>
</tr>
<tr>
<td>previous_friday</td>
<td>move Saturday and Sunday to previous Friday</td>
</tr>
<tr>
<td>next_monday</td>
<td>move Saturday and Sunday to following Monday</td>
</tr>
</tbody>
</table>

An example of how holidays and holiday calendars are defined:

```python
In [255]: from pandas.tseries.holiday import Holiday, USMemorialDay,
....: AbstractHolidayCalendar, nearest_workday, MO
....:

In [256]: class ExampleCalendar(AbstractHolidayCalendar):
    .....:     rules = [
    .....:         USMemorialDay,
    .....:         Holiday('July 4th', month=7, day=4, observance=nearest_workday),
    .....:         Holiday('Columbus Day', month=10, day=1,
    .....:             offset=pd.DateOffset(weekday=MO(2)))
    .....:

In [257]: cal = ExampleCalendar()

In [258]: cal.holidays(datetime.datetime(2012, 1, 1), datetime.datetime(2012, 12, 31))
Out[258]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype='datetime64[ns]', freq=None)

```

```python
>>> weekday=MO(2) is same as 2 * Week(weekday=2)
```

Using this calendar, creating an index or doing offset arithmetic skips weekends and holidays (i.e., Memorial Day/July 4th). For example, the below defines a custom business day offset using the `ExampleCalendar`. Like any other offset, it can be used to create a `DatetimeIndex` or added to `datetime` or `Timestamp` objects.

```python
In [259]: pd.date_range(start='7/1/2012', end='7/10/2012',
                      freq=pd.offsets.CDay(calendar=cal)).to_pydatetime()
Out[259]: array([datetime.datetime(2012, 7, 2, 0, 0),
                   datetime.datetime(2012, 7, 3, 0, 0),
                   datetime.datetime(2012, 7, 5, 0, 0),
                   datetime.datetime(2012, 7, 6, 0, 0),
                   datetime.datetime(2012, 7, 9, 0, 0),
                   datetime.datetime(2012, 7, 10, 0, 0)], dtype=object)
```
offset = pd.offsets.CustomBusinessDay(calendar=cal)

datetime.datetime(2012, 5, 25) + offset

datetime.datetime(2012, 7, 3) + offset

datetime.datetime(2012, 7, 3) + 2 * offset

datetime.datetime(2012, 7, 6) + offset

Ranges are defined by the start_date and end_date class attributes of AbstractHolidayCalendar. The
defaults are shown below.

In [265]: AbstractHolidayCalendar.start_date
Out[265]: Timestamp('1970-01-01 00:00:00')

In [266]: AbstractHolidayCalendar.end_date
Out[266]: Timestamp('2200-12-31 00:00:00')

These dates can be overwritten by setting the attributes as datetime/Timestamp/string.

In [267]: AbstractHolidayCalendar.start_date = datetime.datetime(2012, 1, 1)

In [268]: AbstractHolidayCalendar.end_date = datetime.datetime(2012, 12, 31)

In [269]: cal.holidays()
Out[269]: DatetimeIndex(["2012-05-28", "2012-07-04", "2012-10-08"], dtype=
˓→'datetime64[ns]', freq=None)

Every calendar class is accessible by name using the get_calendar function which returns a holiday class instance. Any imported calendar class will automatically be available by this function. Also, HolidayCalendarFactory provides an easy interface to create calendars that are combinations of calendars or calendars with additional rules.

In [270]: from pandas.tseries.holiday import get_calendar, HolidayCalendarFactory,
        USLaborDay
       
In [271]: cal = get_calendar('ExampleCalendar')

In [272]: cal.rules
Out[272]: [Holiday: Memorial Day (month=5, day=31, offset=<DateOffset: weekday=MO(-1)>),
       Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at 0x7fbf80603790>),
       Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=MO(+2)>)]

In [273]: new_cal = HolidayCalendarFactory('NewExampleCalendar', cal, USLaborDay)

In [274]: new_cal.rules
Out[274]: [Holiday: Labor Day (month=9, day=1, offset=<DateOffset: weekday=MO(+1)>),
       (continues on next page)
2.17.9 Time series-related instance methods

Shifting / lagging

One may want to *shift* or *lag* the values in a time series back and forward in time. The method for this is `shift()`, which is available on all of the pandas objects.

```python
In [275]: ts = pd.Series(range(len(rng)), index=rng)
In [276]: ts = ts[:5]
In [277]: ts.shift(1)
Out[277]:
2012-01-01  NaN
2012-01-02  0.0
2012-01-03  1.0
Freq: D, dtype: float64
```

The `shift` method accepts an `freq` argument which can accept a `DateOffset` class or other `timedelta`-like object or also an *offset alias*.

When `freq` is specified, `shift` method changes all the dates in the index rather than changing the alignment of the data and the index:

```python
In [278]: ts.shift(5, freq='D')
Out[278]:
2012-01-06  0
2012-01-07  1
2012-01-08  2
Freq: D, dtype: int64

In [279]: ts.shift(5, freq=pd.offsets.BDay())
Out[279]:
2012-01-06  0
2012-01-09  1
2012-01-10  2
dtype: int64

In [280]: ts.shift(5, freq='BM')
Out[280]:
2012-05-31  0
2012-05-31  1
2012-05-31  2
dtype: int64
```

Note that with when `freq` is specified, the leading entry is no longer NaN because the data is not being realigned.
Frequency conversion

The primary function for changing frequencies is the \texttt{asfreq()} method. For a \texttt{DatetimeIndex}, this is basically just a thin, but convenient wrapper around \texttt{reindex()} which generates a \texttt{date_range} and calls \texttt{reindex}.

\begin{verbatim}
In [281]: dr = pd.date_range('1/1/2010', periods=3, freq=3 * pd.offsets.BDay())
In [282]: ts = pd.Series(np.random.randn(3), index=dr)
In [283]: ts
Out[283]:
2010-01-01  1.494522
2010-01-06 -0.778425
2010-01-11 -0.253355
Freq: 3B, dtype: float64
In [284]: ts.asfreq(pd.offsets.BDay())
Out[284]:
2010-01-01  1.494522
2010-01-04  NaN
2010-01-05  NaN
2010-01-06 -0.778425
2010-01-07  NaN
2010-01-08  NaN
2010-01-11 -0.253355
Freq: B, dtype: float64
\end{verbatim}

\texttt{asfreq} provides a further convenience so you can specify an interpolation method for any gaps that may appear after the frequency conversion.

\begin{verbatim}
In [285]: ts.asfreq(pd.offsets.BDay(), method='pad')
Out[285]:
2010-01-01  1.494522
2010-01-04  1.494522
2010-01-05  1.494522
2010-01-06 -0.778425
2010-01-07 -0.778425
2010-01-08 -0.778425
2010-01-11 -0.253355
Freq: B, dtype: float64
\end{verbatim}

\textbf{Filling forward / backward}

Related to \texttt{asfreq} and \texttt{reindex} is \texttt{fillna()}, which is documented in the \textit{missing data section}.

\textbf{Converting to Python datetimes}

\texttt{DatetimeIndex} can be converted to an array of Python native \texttt{datetime.datetime} objects using the \texttt{to_pydatetime} method.
2.17.10 Resampling

Pandas has a simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications.

`resample()` is a time-based groupby, followed by a reduction method on each of its groups. See some cookbook examples for some advanced strategies.

The `resample()` method can be used directly from DataFrameGroupBy objects, see the groupby docs.

**Note:** `.resample()` is similar to using a `rolling()` operation with a time-based offset, see a discussion here.

**Basics**

```python
In [286]: rng = pd.date_range('1/1/2012', periods=100, freq='S')
In [287]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)
In [288]: ts.resample('5Min').sum()
Out[288]:
2012-01-01  25103
Freq: 5T, dtype: int64
```

The `resample` function is very flexible and allows you to specify many different parameters to control the frequency conversion and resampling operation.

Any function available via dispatching is available as a method of the returned object, including `sum`, `mean`, `std`, `sem`, `max`, `min`, `median`, `first`, `last`, `ohlc`:

```python
In [289]: ts.resample('5Min').mean()
Out[289]:
2012-01-01  251.03
Freq: 5T, dtype: float64
In [290]: ts.resample('5Min').ohlc()
Out[290]:
open   high  low  close
2012-01-01  308   460   9  205
In [291]: ts.resample('5Min').max()
Out[291]:
2012-01-01  460
Freq: 5T, dtype: int64
```

For downsampling, `closed` can be set to ‘left’ or ‘right’ to specify which end of the interval is closed:

```python
In [292]: ts.resample('5Min', closed='right').mean()
Out[292]:
2011-12-31 23:55:00  308.000000
2012-01-01 00:00:00  250.454545
Freq: 5T, dtype: float64
In [293]: ts.resample('5Min', closed='left').mean()
```

(continues on next page)
Parameters like `label` are used to manipulate the resulting labels. `label` specifies whether the result is labeled with the beginning or the end of the interval.

```
In [294]: ts.resample('5Min').mean()  # by default label='left'
Out[294]:
2012-01-01  251.03
Freq: 5T, dtype: float64

In [295]: ts.resample('5Min', label='left').mean()
Out[295]:
2012-01-01  251.03
Freq: 5T, dtype: float64
```

**Warning:** The default values for `label` and `closed` is `left` for all frequency offsets except for `M`, `A`, `Q`, `BM`, `BA`, `BQ`, and `W` which all have a default of `right`.

This might unintentionally lead to looking ahead, where the value for a later time is pulled back to a previous time as in the following example with the `BusinessDay` frequency:

```
In [296]: s = pd.date_range('2000-01-01', '2000-01-05').to_series()
In [297]: s.iloc[2] = pd.NaT
In [298]: s.dt.day_name()
Out[298]:
2000-01-01 Saturday
2000-01-02 Sunday
2000-01-03 NaN
2000-01-04 Tuesday
2000-01-05 Wednesday
Freq: D, dtype: object

# default: label='left', closed='left'
In [299]: s.resample('B').last().dt.day_name()
Out[299]:
1999-12-31 Sunday
2000-01-03 NaN
2000-01-04 Tuesday
2000-01-05 Wednesday
Freq: B, dtype: object
```

Notice how the value for Sunday got pulled back to the previous Friday. To get the behavior where the value for Sunday is pushed to Monday, use instead

```
In [300]: s.resample('B', label='right', closed='right').last().dt.day_name()
Out[300]:
2000-01-03 Sunday
2000-01-04 Tuesday
2000-01-05 Wednesday
Freq: B, dtype: object
```

The `axis` parameter can be set to 0 or 1 and allows you to resample the specified axis for a `DataFrame`. 

2.17. Time series / date functionality

---

**Note:** This documentation is from a specific version of Pandas, and the code examples might not work in newer or older versions of the library. It is recommended to use the latest version of Pandas for the most accurate and up-to-date functionalities.
kind can be set to ‘timestamp’ or ‘period’ to convert the resulting index to/from timestamp and time span representations. By default resample retains the input representation.

convention can be set to ‘start’ or ‘end’ when resampling period data (detail below). It specifies how low frequency periods are converted to higher frequency periods.

**Upsampling**

For upsampling, you can specify a way to upsample and the limit parameter to interpolate over the gaps that are created:

```python
# from secondly to every 250 milliseconds
In [301]: ts[:2].resample('250L').asfreq()
Out[301]:
2012-01-01 00:00:00.000   308.0
2012-01-01 00:00:00.250     NaN
2012-01-01 00:00:00.500     NaN
2012-01-01 00:00:00.750     NaN
2012-01-01 00:00:01.000    204.0
Freq: 250L, dtype: float64

In [302]: ts[:2].resample('250L').ffill()
Out[302]:
2012-01-01 00:00:00.000   308
2012-01-01 00:00:00.250   308
2012-01-01 00:00:00.500   308
2012-01-01 00:00:00.750   308
2012-01-01 00:00:01.000   204
Freq: 250L, dtype: int64

In [303]: ts[:2].resample('250L').ffill(limit=2)
Out[303]:
2012-01-01 00:00:00.000   308.0
2012-01-01 00:00:00.250   308.0
2012-01-01 00:00:00.500   308.0
2012-01-01 00:00:00.750     NaN
2012-01-01 00:00:01.000    204.0
Freq: 250L, dtype: float64
```

**Sparse resampling**

Sparse timeseries are the ones where you have a lot fewer points relative to the amount of time you are looking to resample. Naively upsampling a sparse series can potentially generate lots of intermediate values. When you don’t want to use a method to fill these values, e.g. fill_method is None, then intermediate values will be filled with NaN.

Since resample is a time-based groupby, the following is a method to efficiently resample only the groups that are not all NaN.

```python
In [304]: rng = pd.date_range('2014-1-1', periods=100, freq='D') + pd.Timedelta('1s')
In [305]: ts = pd.Series(range(100), index=rng)
```

If we want to resample to the full range of the series:
We can instead only resample those groups where we have points as follows:

```python
In [307]: from functools import partial
In [308]: from pandas.tseries.frequencies import to_offset
In [309]: def round(t, freq):
   ....:     freq = to_offset(freq)
   ....:     return pd.Timestamp((t.value // freq.delta.value) * freq.delta.value)
   ....:
In [310]: ts.groupby(partial(round, freq='3T')).sum()
```

```
Out[310]:
2014-01-01  0
2014-01-02  1
2014-01-03  2
2014-01-04  3
2014-01-05  4
   ..
2014-04-06 95
2014-04-07 96
2014-04-08 97
2014-04-09 98
2014-04-10 99
Length: 100, dtype: int64
```

### Aggregation

Similar to the `aggregating API`, `groupby API`, and the `window functions API`, a Resampler can be selectively resampled.

Resampling a DataFrame, the default will be to act on all columns with the same function.

```python
In [311]: df = pd.DataFrame(np.random.randn(1000, 3),
   index=pd.date_range('1/1/2012', freq='S', periods=1000),
   columns=['A', 'B', 'C'])
In [312]: r = df.resample('3T')
In [313]: r.mean()
```
We can select a specific column or columns using standard getitem.

```
In [314]: r['A'].mean()
Out[314]:
2012-01-01 00:00:00  -0.033823
2012-01-01 00:03:00   0.056909
2012-01-01 00:06:00  -0.058837
2012-01-01 00:09:00   0.063123
2012-01-01 00:12:00   0.186340
2012-01-01 00:15:00  -0.085954
Freq: 3T, Name: A, dtype: float64
```

```
In [315]: r[['A', 'B']].mean()
Out[315]:
   A     B
2012-01-01 00:00:00  -0.033823 -0.121514
2012-01-01 00:03:00   0.056909  0.146731
2012-01-01 00:06:00  -0.058837  0.047046
2012-01-01 00:09:00   0.063123 -0.026158
2012-01-01 00:12:00   0.186340 -0.003144
2012-01-01 00:15:00  -0.085954 -0.016287
```

You can pass a list or dict of functions to do aggregation with, outputting a DataFrame:

```
In [316]: r['A'].agg([np.sum, np.mean, np.std])
Out[316]:
                   sum    mean   std
2012-01-01 00:00:00  -6.088060 -0.033823 1.043263
2012-01-01 00:03:00  10.243678  0.056909 1.058534
2012-01-01 00:06:00 -10.590584 -0.058837 0.949264
2012-01-01 00:09:00  26.411633  0.063123 1.028096
2012-01-01 00:12:00  33.541257  0.186340 0.884586
2012-01-01 00:15:00 - 8.595393 -0.085954 1.035476
```

On a resampled DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [317]: r.agg([np.sum, np.mean])
Out[317]:
   A         B         C
   sum    mean  sum   mean  sum   mean
2012-01-01 00:00:00 -6.088060 -0.033823 -21.872530 -0.121514 -14.660515 -0.081447
2012-01-01 00:03:00 10.243678  0.056909  26.411633  0.146731  -4.377642 -0.024320
2012-01-01 00:06:00 10.470584 -0.558837  8.468289  0.047046  -9.363825 -0.052021
2012-01-01 00:09:00  7.150047  0.063123  -3.085260 -0.026158  13.455529  0.074752
2012-01-01 00:12:00 33.541257  0.186340  -0.565895 -0.003144 13.455529  0.074752
2012-01-01 00:15:00 -8.595393 -0.085954  -1.628689 -0.016287  -5.004580 -0.050046
```
By passing a dict to `aggregate` you can apply a different aggregation to the columns of a `DataFrame`:

```
In [318]: r.agg({'A': np.sum,
           'B': lambda x: np.std(x, ddof=1)})
```

```
Out[318]:

                      A       B
2012-01-01 00:00:00 -6.088060 1.001294
2012-01-01 00:03:00 10.243678 1.074597
2012-01-01 00:06:00 -10.590584 0.987309
2012-01-01 00:09:00 11.362228 0.944953
2012-01-01 00:12:00 33.541257 1.095025
2012-01-01 00:15:00 -8.595393 1.035312
```

The function names can also be strings. In order for a string to be valid it must be implemented on the resampled object:

```
In [319]: r.agg({'A': 'sum', 'B': 'std'})
```

```
Out[319]:

                      A       B
2012-01-01 00:00:00 -6.088060 1.001294
2012-01-01 00:03:00 10.243678 1.074597
2012-01-01 00:06:00 -10.590584 0.987309
2012-01-01 00:09:00 11.362228 0.944953
2012-01-01 00:12:00 33.541257 1.095025
2012-01-01 00:15:00 -8.595393 1.035312
```

Furthermore, you can also specify multiple aggregation functions for each column separately.

```
In [320]: r.agg({'A': ['sum', 'std'], 'B': ['mean', 'std']})
```

```
Out[320]:

                      A     B
                  sum  std mean std
2012-01-01 00:00:00 -6.088060 1.043263 -0.121514 1.001294
2012-01-01 00:03:00 10.243678 1.058534 0.146731 1.074597

```

If a `DataFrame` does not have a datetimelike index, but instead you want to resample based on datetimelike column in the frame, it can passed to the `on` keyword.

```
In [321]: df = pd.DataFrame({'date': pd.date_range('2015-01-01', freq='W', periods=5),
                     'a': np.arange(5),
                     index=pd.MultiIndex.from_arrays([
                       [1, 2, 3, 4, 5],
                       pd.date_range('2015-01-01', freq='W', periods=5)],
                     names=['v', 'd']))
```

```
In [322]: df
```

```
     date    a
1  2015-01-04  0
2  2015-01-11  1
3  2015-01-18  2
```

(continues on next page)
Similarly, if you instead want to resample by a datetimelike level of `MultiIndex`, its name or location can be passed to the `level` keyword.

```python
In [324]: df.resample('M', level='d').sum()
Out[324]:
   d
   2015-01-31  6
   2015-02-28  4
```

Iterating through groups

With the `Resampler` object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

```python
In [325]: small = pd.Series(
   ....:     range(6),
   ....:     index=pd.to_datetime(
   ....:         ['2017-01-01T00:00:00',
   ....:         '2017-01-01T00:30:00',
   ....:         '2017-01-01T00:31:00',
   ....:         '2017-01-01T01:00:00',
   ....:         '2017-01-01T03:00:00',
   ....:         '2017-01-01T03:05:00']))

In [326]: resampled = small.resample('H')

In [327]: for name, group in resampled:
   ....:     print("Group: ", name)
   ....:     print("-
```

```
Group: 2017-01-01 00:00:00
-----------------------
2017-01-01 00:00:00 0
2017-01-01 00:30:00 1
2017-01-01 00:31:00 2
dtype: int64
```

```
Group: 2017-01-01 01:00:00
-----------------------
2017-01-01 01:00:00 3
dtype: int64
```

(continues on next page)
Group: 2017-01-01 02:00:00
Series([], dtype: int64)

Group: 2017-01-01 03:00:00
---------------------------
2017-01-01 03:00:00 4
2017-01-01 03:05:00 5
dtype: int64

See Iterating through groups or Resampler.__iter__ for more.

**Use origin or offset to adjust the start of the bins**

New in version 1.1.0.

The bins of the grouping are adjusted based on the beginning of the day of the time series starting point. This works well with frequencies that are multiples of a day (like 30D) or that divide a day evenly (like 90s or 1min). This can create inconsistencies with some frequencies that do not meet this criteria. To change this behavior you can specify a fixed Timestamp with the argument origin.

For example:

```python
In [328]: start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
In [329]: middle = '2000-10-02 00:00:00'
In [330]: rng = pd.date_range(start, end, freq='7min')
In [331]: ts = pd.Series(np.arange(len(rng)) * 3, index=rng)

In [332]: ts
Out[332]:
2000-10-01 23:30:00    0
2000-10-01 23:37:00    3
2000-10-01 23:44:00    6
2000-10-01 23:51:00    9
2000-10-01 23:58:00   12
2000-10-02 00:05:00   15
2000-10-02 00:12:00   18
2000-10-02 00:19:00   21
2000-10-02 00:26:00   24
Freq: 7T, dtype: int64
```

Here we can see that, when using origin with its default value ('start_day'), the result after '2000-10-02 00:00:00' are not identical depending on the start of time series:

```python
In [333]: ts.resample('17min', origin='start_day').sum()
Out[333]:
2000-10-01 23:14:00    0
2000-10-01 23:31:00    9
2000-10-01 23:48:00   21
2000-10-02 00:05:00   54
2000-10-02 00:22:00   24
Freq: 17T, dtype: int64
```

(continues on next page)
In [334]: ts[middle:end].resample('17min', origin='start_day').sum()
Out[334]:
2000-10-02 00:00:00   33
2000-10-02 00:17:00   45
Freq: 17T, dtype: int64

Here we can see that, when setting origin to 'epoch', the result after '2000-10-02 00:00:00' are identical depending on the start of time series:

In [335]: ts.resample('17min', origin='epoch').sum()
Out[335]:
2000-10-01 23:18:00   0
2000-10-01 23:35:00   18
2000-10-01 23:52:00   27
2000-10-02 00:09:00   39
2000-10-02 00:26:00   24
Freq: 17T, dtype: int64

In [336]: ts[middle:end].resample('17min', origin='epoch').sum()
Out[336]:
2000-10-02 00:04:00   54
2000-10-02 00:21:00   24
Freq: 17T, dtype: int64

If needed you can use a custom timestamp for origin:

In [337]: ts.resample('17min', origin='2001-01-01').sum()
Out[337]:
2000-10-01 23:30:00    9
2000-10-01 23:47:00   21
2000-10-02 00:04:00   54
2000-10-02 00:21:00   24
Freq: 17T, dtype: int64

In [338]: ts[middle:end].resample('17min', origin=pd.Timestamp('2001-01-01')).sum()
Out[338]:
2000-10-02 00:04:00   54
2000-10-02 00:21:00   24
Freq: 17T, dtype: int64

If needed you can just adjust the bins with an offset Timedelta that would be added to the default origin. Those two examples are equivalent for this time series:

In [339]: ts.resample('17min', origin='start').sum()
Out[339]:
2000-10-01 23:30:00    9
2000-10-01 23:47:00   21
2000-10-02 00:04:00   54
2000-10-02 00:21:00   24
Freq: 17T, dtype: int64

In [340]: ts.resample('17min', offset='23h30min').sum()
Out[340]:
2000-10-01 23:30:00    9
2000-10-01 23:47:00   21
(continues on next page)
Note the use of 'start' for origin on the last example. In that case, origin will be set to the first value of the timeseries.

### 2.17.11 Time span representation

Regular intervals of time are represented by Period objects in pandas while sequences of Period objects are collected in a PeriodIndex, which can be created with the convenience function period_range.

**Period**

A Period represents a span of time (e.g., a day, a month, a quarter, etc). You can specify the span via freq keyword using a frequency alias like below. Because freq represents a span of Period, it cannot be negative like “-3D”.

```python
In [341]: pd.Period('2012', freq='A-DEC')
Out[341]: Period('2012', 'A-DEC')

In [342]: pd.Period('2012-1-1', freq='D')
Out[342]: Period('2012-01-01', 'D')

In [343]: pd.Period('2012-1-1 19:00', freq='H')
Out[343]: Period('2012-01-01 19:00', 'H')

In [344]: pd.Period('2012-1-1 19:00', freq='5H')
Out[344]: Period('2012-01-01 19:00', '5H')
```

Adding and subtracting integers from periods shifts the period by its own frequency. Arithmetic is not allowed between Period with different freq (span).

```python
In [345]: p = pd.Period('2012', freq='A-DEC')

In [346]: p + 1
Out[346]: Period('2013', 'A-DEC')

In [347]: p - 3
Out[347]: Period('2009', 'A-DEC')

In [348]: p = pd.Period('2012-01', freq='2M')

In [349]: p + 2
Out[349]: Period('2012-05', '2M')

In [350]: p - 1
Out[350]: Period('2011-11', '2M')

In [351]: p == pd.Period('2012-01', freq='3M')
---------------------------------------------------------------------------
IncompatibleFrequency
Traceback (most recent call last)
  in <module>
    p == pd.Period('2012-01', freq='3M')
```

(continues on next page)
If Period freq is daily or higher (D, H, T, S, L, U, N), offsets and timedelta-like can be added if the result can have the same freq. Otherwise, ValueError will be raised.

```python
In [352]: p = pd.Period('2014-07-01 09:00', freq='H')

In [353]: p + pd.offsets.Hour(2)
Out[353]: Period('2014-07-01 11:00', 'H')

In [354]: p + datetime.timedelta(minutes=120)
Out[354]: Period('2014-07-01 11:00', 'H')

In [355]: p + np.timedelta64(7200, 's')
Out[355]: Period('2014-07-01 11:00', 'H')

In [1]: p + pd.offsets.Minute(5)
Traceback...
ValueError: Input has different freq from Period(freq=H)
```

If Period has other frequencies, only the same offsets can be added. Otherwise, ValueError will be raised.

```python
In [356]: p = pd.Period('2014-07', freq='M')

In [357]: p + pd.offsets.MonthEnd(3)
Out[357]: Period('2014-10', 'M')

In [1]: p + pd.offsets.MonthBegin(3)
Traceback...
ValueError: Input has different freq from Period(freq=M)
```

Taking the difference of Period instances with the same frequency will return the number of frequency units between them:

```python
Out[358]: <10 * YearEnds: month=12>
```

**PeriodIndex and period_range**

Regular sequences of Period objects can be collected in a PeriodIndex, which can be constructed using the period_range convenience function:

```python
In [359]: prng = pd.period_range('1/1/2011', '1/1/2012', freq='M')

In [360]: prng
   ...], freq='M', name='M', length=12)
```

(continues on next page)
The `PeriodIndex` constructor can also be used directly:

```
In [361]: pd.PeriodIndex(['2011-1', '2011-2', '2011-3'], freq='M')
Out[361]: PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]', freq='M')
```

Passing multiplied frequency outputs a sequence of `Period` which has multiplied span.

```
In [362]: pd.period_range(start='2014-01', freq='3M', periods=4)
```

If `start` or `end` are `Period` objects, they will be used as anchor endpoints for a `PeriodIndex` with frequency matching that of the `PeriodIndex` constructor.

```
In [363]: pd.period_range(start=pd.Period('2017Q1', freq='Q'),
                       end=pd.Period('2017Q2', freq='Q'), freq='M')
Out[363]: PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'], dtype='period[M]', freq='M')
```

Just like `DatetimeIndex`, a `PeriodIndex` can also be used to index pandas objects:

```
In [364]: ps = pd.Series(np.random.randn(len(prng)), prng)
In [365]: ps
Out[365]:
2011-01 -2.916901
2011-02  0.514474
2011-03  1.346470
2011-04  0.816397
2011-05  2.258648
2011-06  0.494789
2011-07  0.301239
2011-08  0.464776
2011-09 -1.393581
2011-10  0.056780
2011-11  0.197035
2011-12  2.261385
2012-01 -0.329583
Freq: M, dtype: float64
```

`PeriodIndex` supports addition and subtraction with the same rule as `Period`.

```
In [366]: idx = pd.period_range('2014-07-01 09:00', periods=5, freq='H')
In [367]: idx
Out[367]:
PeriodIndex(['2014-07-01 09:00', '2014-07-01 10:00', '2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00'], dtype='period[H]', freq='H')
In [368]: idx + pd.offsets.Hour(2)
Out[368]:
```

(continues on next page)
PeriodIndex has its own dtype named period, refer to Period Dtypes.

Period dtypes

PeriodIndex has a custom period dtype. This is a pandas extension dtype similar to the *timezone aware dtype* (datetime64[ns, tz]).

The period dtype holds the freq attribute and is represented with period[freq] like period[D] or period[M], using *frequency strings*.

The period dtype can be used in .astype(...). It allows one to change the freq of a PeriodIndex like .asfreq() and convert a DatetimeIndex to PeriodIndex like to_period():

```python
# change monthly freq to daily freq
In [375]: pi = pd.period_range('2016-01-01', periods=3, freq='M')
Out[375]: PeriodIndex(['2016-01', '2016-02', '2016-03'], dtype='period[M]', freq='M')

# convert to DatetimeIndex
In [376]: pi.astype('datetime64[ns]')
Out[376]: DatetimeIndex(['2016-01-01', '2016-02-01', '2016-03-01'], dtype='datetime64[ns]', freq='MS')

# convert to PeriodIndex
In [377]: dti = pd.date_range('2011-01-01', freq='M', periods=3)
Out[377]: DatetimeIndex(['2011-01-01', '2011-02-01', '2011-03-01'], dtype='datetime64[ns]', freq='M')

In [378]: dti
Out[378]: DatetimeIndex(['2011-01-01', '2011-02-01', '2011-03-01'], dtype='datetime64[ns]', freq='M')

In [379]: dti.astype('period[M]')
Out[379]: PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]', freq='M')
```
PeriodIndex partial string indexing

PeriodIndex now supports partial string slicing with non-monotonic indexes.

New in version 1.1.0.

You can pass in dates and strings to Series and DataFrame with PeriodIndex, in the same manner as DatetimeIndex. For details, refer to DatetimeIndex Partial String Indexing.

In [380]: ps['2011-01']
Out[380]: -2.9169013294054507

In [381]: ps[datetime.datetime(2011, 12, 25):]
Out[381]:
2011-12 2.261385
2012-01 -0.329583
Freq: M, dtype: float64

In [382]: ps['10/31/2011':'12/31/2011']
Out[382]:
2011-10 0.056780
2011-11 0.197035
2011-12 2.261385
Freq: M, dtype: float64

Passing a string representing a lower frequency than PeriodIndex returns partial sliced data.

In [383]: ps['2011']
Out[383]:
2011-01 -2.916901
2011-02 0.514474
2011-03 1.346470
2011-04 0.816397
2011-05 2.258648
2011-06 0.494789
2011-07 0.301239
2011-08 0.464776
2011-09 -1.393581
2011-10 0.056780
2011-11 0.197035
2011-12 2.261385
Freq: M, dtype: float64

In [384]: dfp = pd.DataFrame(np.random.randn(600, 1),
                     columns=['A'],
                     index=pd.period_range('2013-01-01 9:00',
                                           periods=600,
                                           freq='T'))

In [385]: dfp
Out[385]:
               A
2013-01-01 09:00 -0.538468
2013-01-01 09:01 -1.365819
2013-01-01 09:02 -0.969051
2013-01-01 09:03 -0.331152
2013-01-01 09:04 -0.245334
(continues on next page)
As with DatetimeIndex, the endpoints will be included in the result. The example below slices data starting from 10:00 to 11:59.

```
In [387]: dfp['2013-01-01 10H':'2013-01-01 11H']
Out[387]:
   A
2013-01-01 10:00 -0.308975
2013-01-01 10:01  0.542520
2013-01-01 10:02  1.061068
2013-01-01 10:03  0.754005
2013-01-01 10:04  0.352933
... ...                                                    
2013-01-01 11:55 -0.865621
2013-01-01 11:56 -1.167818
2013-01-01 11:57 -2.081748
2013-01-01 11:58 -0.527146
2013-01-01 11:59  0.802298
[120 rows x 1 columns]
```
Frequency conversion and resampling with PeriodIndex

The frequency of Period and PeriodIndex can be converted via the asfreq method. Let’s start with the fiscal year 2011, ending in December:

**In [388]:** p = pd.Period('2011', freq='A-DEC')

**In [389]:** p

**Out[389]:** Period('2011', 'A-DEC')

We can convert it to a monthly frequency. Using the how parameter, we can specify whether to return the starting or ending month:

**In [390]:** p.asfreq('M', how='start')

**Out[390]:** Period('2011-01', 'M')

**In [391]:** p.asfreq('M', how='end')

**Out[391]:** Period('2011-12', 'M')

The shorthands ‘s’ and ‘e’ are provided for convenience:

**In [392]:** p.asfreq('M', 's')

**Out[392]:** Period('2011-01', 'M')

**In [393]:** p.asfreq('M', 'e')

**Out[393]:** Period('2011-12', 'M')

Converting to a “super-period” (e.g., annual frequency is a super-period of quarterly frequency) automatically returns the super-period that includes the input period:

**In [394]:** p = pd.Period('2011-12', freq='M')

**In [395]:** p.asfreq('A-NOV')

**Out[395]:** Period('2012', 'A-NOV')

Note that since we converted to an annual frequency that ends the year in November, the monthly period of December 2011 is actually in the 2012 A-NOV period.

Period conversions with anchored frequencies are particularly useful for working with various quarterly data common to economics, business, and other fields. Many organizations define quarters relative to the month in which their fiscal year starts and ends. Thus, first quarter of 2011 could start in 2010 or a few months into 2011. Via anchored frequencies, pandas works for all quarterly frequencies Q-JAN through Q-DEC.

Q-DEC define regular calendar quarters:

**In [396]:** p = pd.Period('2012Q1', freq='Q-DEC')

**In [397]:** p.asfreq('D', 's')

**Out[397]:** Period('2012-01-01', 'D')

**In [398]:** p.asfreq('D', 'e')

**Out[398]:** Period('2012-03-31', 'D')

Q-MAR defines fiscal year end in March:

**In [399]:** p = pd.Period('2011Q4', freq='Q-MAR')

**In [400]:** p.asfreq('D', 's')

(continues on next page)
2.17.12 Converting between representations

Timestamped data can be converted to PeriodIndex-ed data using `to_period` and vice-versa using `to_timestamp`:

```python
In [402]: rng = pd.date_range('1/1/2012', periods=5, freq='M')
In [403]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
In [404]: ts
Out[404]:
2012-01-31  1.931253
2012-02-29 -0.184594
2012-03-31  0.249656
2012-04-30 -0.978151
2012-05-31 -0.873389
Freq: M, dtype: float64
In [405]: ps = ts.to_period()
In [406]: ps
Out[406]:
2012-01  1.931253
2012-02 -0.184594
2012-03  0.249656
2012-04 -0.978151
2012-05 -0.873389
Freq: M, dtype: float64
In [407]: ps.to_timestamp()
Out[407]:
2012-01-01  1.931253
2012-02-01 -0.184594
2012-03-01  0.249656
2012-04-01 -0.978151
2012-05-01 -0.873389
Freq: MS, dtype: float64
```

Remember that ‘s’ and ‘e’ can be used to return the timestamps at the start or end of the period:

```python
In [408]: ps.to_timestamp('D', how='s')
Out[408]:
2012-01-01  1.931253
2012-02-01 -0.184594
2012-03-01  0.249656
2012-04-01 -0.978151
2012-05-01 -0.873389
Freq: MS, dtype: float64
```

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following
example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```
In [409]: prng = pd.period_range('1990Q1', '2000Q4', freq='Q-NOV')
In [410]: ts = pd.Series(np.random.randn(len(prng)), prng)
In [411]: ts.index = (prng.asfreq('M', 'e') + 1).asfreq('H', 's') + 9
In [412]: ts.head()
Out[412]:
1990-03-01 09:00 -0.109291
1990-06-01 09:00 -0.637235
1990-09-01 09:00 -1.735925
1990-12-01 09:00 2.096946
1991-03-01 09:00 -1.039926
Freq: H, dtype: float64
```

### 2.17.13 Representing out-of-bounds spans

If you have data that is outside of the Timestamp bounds, see [Timestamp limitations](#), then you can use a `PeriodIndex` and/or `Series` of Periods to do computations.

```
In [413]: span = pd.period_range('1215-01-01', '1381-01-01', freq='D')
In [414]: span
Out[414]:
PeriodIndex(['1215-01-01', '1215-01-02', '1215-01-03', '1215-01-04',
            '1215-01-05', '1215-01-06', '1215-01-07', '1215-01-08',
            '1215-01-09', '1215-01-10', ...
            '1380-12-23', '1380-12-24', '1380-12-25', '1380-12-26',
            '1380-12-27', '1380-12-28', '1380-12-29', '1380-12-30',
            '1380-12-31', '1381-01-01'],
    dtype='period[D]', length=60632, freq='D')
```

To convert from an `int64` based YYYYMMDD representation.

```
In [415]: s = pd.Series([20121231, 20141130, 99991231])
In [416]: s
Out[416]:
0  20121231
1  20141130
2  99991231
dtype: int64
In [417]: def conv(x):
      .....:     return pd.Period(year=x // 10000, month=x // 100 % 100,
      .....:                      day=x % 100, freq='D')
      .....:
In [418]: s.apply(conv)
Out[418]:
0  2012-12-31
1  2014-11-30
```

(continues on next page)
2.17.14 Time zone handling

pandas provides rich support for working with timestamps in different time zones using the \texttt{pytz} and \texttt{dateutil} libraries or class: \texttt{datetime.timezone} objects from the standard library.

Working with time zones

By default, pandas objects are time zone unaware:

```python
In [422]: rng = pd.date_range('3/6/2012 00:00', periods=15, freq='D')
In [423]: rng.tz
Out[423]: None
```

To localize these dates to a time zone (assign a particular time zone to a naive date), you can use the \texttt{tz_localize} method or the \texttt{tz} keyword argument in \texttt{date_range()}, \texttt{Timestamp}, or \texttt{DatetimeIndex}. You can either pass \texttt{pytz} or \texttt{dateutil} time zone objects or Olson time zone database strings. Olson time zone strings will return \texttt{pytz} time zone objects by default. To return \texttt{dateutil} time zone objects, append \texttt{dateutil/} before the string.

- In \texttt{pytz} you can find a list of common (and less common) time zones using \texttt{from pytz import common_timezones, all_timezones}.
- \texttt{dateutil} uses the OS time zones so there isn’t a fixed list available. For common zones, the names are the same as \texttt{pytz}.

```python
In [424]: import dateutil
   ...:
# pytz
In [425]: rng_pytz = pd.date_range('3/6/2012 00:00', periods=3, freq='D',
   ...:       tz='Europe/London')
In [426]: rng_pytz.tz
Out[426]: DstTzInfo 'Europe/London' LMT-1 day, 23:59:00 STD
# dateutil
In [427]: rng_dateutil = pd.date_range('3/6/2012 00:00', periods=3, freq='D')
In [428]: rng_dateutil = rng_dateutil.tz_localize('dateutil/Europe/London')
```

(continues on next page)
In [429]: rng_dateutil.tz
Out[429]: tzfile('/usr/share/zoneinfo/Europe/London')

# dateutil - utc special case
In [430]: rng_utc = pd.date_range('3/6/2012 00:00', periods=3, freq='D',
.....:          tz=dateutil.tz.tzutc())
.....:
In [431]: rng_utc.tz
Out[431]: tzutc()

New in version 0.25.0.

In [432]: rng_utc = pd.date_range('3/6/2012 00:00', periods=3, freq='D',
.....:          tz=datetime.timezone.utc)
.....:
In [433]: rng_utc.tz
Out[433]: datetime.timezone.utc

Note that the UTC time zone is a special case in dateutil and should be constructed explicitly as an instance of
dateutil.tz.tzutc. You can also construct other time zones objects explicitly first.

In [434]: import pytz
# pytz
In [435]: tz_pytz = pytz.timezone('Europe/London')
In [436]: rng_pytz = pd.date_range('3/6/2012 00:00', periods=3, freq='D')
In [437]: rng_pytz = rng_pytz.tz_localize(tz_pytz)
In [438]: rng_pytz.tz == tz_pytz
Out[438]: True

# dateutil
In [439]: tz_dateutil = dateutil.tz.gettz('Europe/London')
In [440]: rng_dateutil = pd.date_range('3/6/2012 00:00', periods=3, freq='D',
.....:          tz=tz_dateutil)
.....:
In [441]: rng_dateutil.tz == tz_dateutil
Out[441]: True

To convert a time zone aware pandas object from one time zone to another, you can use the tz_convert method.

In [442]: rng_pytz.tz_convert('US/Eastern')
Out[442]: DatetimeIndex(['2012-03-05 19:00:00-05:00', '2012-03-06 19:00:00-05:00',
   '2012-03-07 19:00:00-05:00'],
   dtype='datetime64[ns, US/Eastern]', freq=None)

Note: When using pytz time zones, DatetimeIndex will construct a different time zone object than a
Timestamp for the same time zone input. A DatetimeIndex can hold a collection of Timestamp objects
that may have different UTC offsets and cannot be succinctly represented by one `pytz` time zone instance while one `Timestamp` represents one point in time with a specific UTC offset.

````python
In [443]: dti = pd.date_range('2019-01-01', periods=3, freq='D', tz='US/Pacific')
In [444]: dti.tz
Out[444]: <DstTzInfo 'US/Pacific' LMT-1 day, 16:07:00 STD>
In [445]: ts = pd.Timestamp('2019-01-01', tz='US/Pacific')
In [446]: ts.tz
Out[446]: <DstTzInfo 'US/Pacific' PST-1 day, 16:00:00 STD>
````

**Warning:** Be wary of conversions between libraries. For some time zones, `pytz` and `dateutil` have different definitions of the zone. This is more of a problem for unusual time zones than for 'standard' zones like US/Eastern.

**Warning:** Be aware that a time zone definition across versions of time zone libraries may not be considered equal. This may cause problems when working with stored data that is localized using one version and operated on with a different version. See [here](#) for how to handle such a situation.

**Warning:** For `pytz` time zones, it is incorrect to pass a time zone object directly into the `datetime.datetime` constructor (e.g., `datetime.datetime(2011, 1, 1, tz=pytz.timezone('US/Eastern'))`). Instead, the datetime needs to be localized using the `localize` method on the `pytz` time zone object.

**Warning:** If you are using dates beyond 2038-01-18, due to current deficiencies in the underlying libraries caused by the year 2038 problem, daylight saving time (DST) adjustments to timezone aware dates will not be applied. If and when the underlying libraries are fixed, the DST transitions will be applied. It should be noted though, that time zone data for far future time zones are likely to be inaccurate, as they are simple extrapolations of the current set of (regularly revised) rules.

For example, for two dates that are in British Summer Time (and so would normally be GMT+1), both the following asserts evaluate as true:

````python
In [447]: d_2037 = '2037-03-31T010101'
In [448]: d_2038 = '2038-03-31T010101'
In [449]: DST = 'Europe/London'
In [450]: assert pd.Timestamp(d_2037, tz=DST) != pd.Timestamp(d_2037, tz='GMT')
In [451]: assert pd.Timestamp(d_2038, tz=DST) == pd.Timestamp(d_2038, tz='GMT')
````

Under the hood, all timestamps are stored in UTC. Values from a time zone aware `DatetimeIndex` or `Timestamp` will have their fields (day, hour, minute, etc.) localized to the time zone. However, timestamps with the same UTC value are still considered to be equal even if they are in different time zones:
In [452]: rng_eastern = rng_utc.tz_convert('US/Eastern')

In [453]: rng_berlin = rng_utc.tz_convert('Europe/Berlin')

In [454]: rng_eastern[2]
Out[454]: Timestamp('2012-03-07 19:00:00-0500', tz='US/Eastern', freq='D')

In [455]: rng_berlin[2]
Out[455]: Timestamp('2012-03-08 01:00:00+0100', tz='Europe/Berlin', freq='D')

Out[456]: True

Operations between *Series* in different time zones will yield UTC *Series*, aligning the data on the UTC times-tamps:

In [457]: ts_utc = pd.Series(range(3), pd.date_range('20130101', periods=3, tz='UTC'))

In [458]: eastern = ts_utc.tz_convert('US/Eastern')

In [459]: berlin = ts_utc.tz_convert('Europe/Berlin')

In [460]: result = eastern + berlin

In [461]: result
Out[461]:
2013-01-01 00:00:00+00:00    0
2013-01-02 00:00:00+00:00    2
2013-01-03 00:00:00+00:00    4
Freq: D, dtype: int64

In [462]: result.index
Out[462]:
DatetimeIndex(['2013-01-01 00:00:00', '2013-01-02 00:00:00', '2013-01-03 00:00:00'],
dtype='datetime64[ns, UTC]', freq='D')

To remove time zone information, use `tz_localize(None)` or `tz_convert(None)`. `tz_localize(None)` will remove the time zone yielding the local time representation. `tz_convert(None)` will remove the time zone after converting to UTC time.

In [463]: didx = pd.date_range(start='2014-08-01 09:00', freq='H',
.....: periods=3, tz='US/Eastern')
.....:

In [464]: didx
Out[464]:
DatetimeIndex(['2014-08-01 09:00:00-04:00', '2014-08-01 10:00:00-04:00',
               '2014-08-01 11:00:00-04:00'],
dtype='datetime64[ns, US/Eastern]', freq='H')

In [465]: didx.tz_localize(None)
Out[465]:
DatetimeIndex(['2014-08-01 09:00:00', '2014-08-01 10:00:00',
               '2014-08-01 11:00:00'],
dtype='datetime64[ns]', freq=None)

(continues on next page)
Fold

New in version 1.1.0.

For ambiguous times, pandas supports explicitly specifying the keyword-only fold argument. Due to daylight saving time, one wall clock time can occur twice when shifting from summer to winter time; fold describes whether the datetime-like corresponds to the first (0) or the second time (1) the wall clock hits the ambiguous time. Fold is supported only for constructing from naive `datetime.datetime` (see `datetime` documentation for details) or from `Timestamp` or for constructing from components (see below). Only `dateutil` timezones are supported (see `dateutil` documentation for `dateutil` methods that deal with ambiguous datetimes) as `pytz` timezones do not support fold (see `pytz` documentation for details on how `pytz` deals with ambiguous datetimes). To localize an ambiguous datetime with `pytz`, please use `Timestamp.tz_localize()`. In general, we recommend to rely on `Timestamp.tz_localize()` when localizing ambiguous datetimes if you need direct control over how they are handled.

Ambiguous times when localizing

tz_localize may not be able to determine the UTC offset of a timestamp because daylight savings time (DST) in a local time zone causes some times to occur twice within one day (“clocks fall back”). The following options are available:

- 'raise': Raises a `pytz.AmbiguousTimeError` (the default behavior)
- 'infer': Attempt to determine the correct offset base on the monotonicity of the timestamps
- 'NaT': Replaces ambiguous times with NaT
- bool: True represents a DST time, False represents non-DST time. An array-like of bool values is supported for a sequence of times.
In [470]: rng_hourly = pd.DatetimeIndex(['11/06/2011 00:00', '11/06/2011 01:00', '11/06/2011 02:00'])

This will fail as there are ambiguous times ('11/06/2011 01:00')

In [2]: rng_hourly.tz_localize('US/Eastern')
AmbiguousTimeError: Cannot infer dst time from Timestamp('2011-11-06 01:00:00'), try...

Handle these ambiguous times by specifying the following.

In [471]: rng_hourly.tz_localize('US/Eastern', ambiguous='infer')
Out[471]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', '2011-11-06 01:00:00-04:00', '2011-11-06 01:00:00-05:00', '2011-11-06 02:00:00-05:00'],
dtype='datetime64[ns, US/Eastern]', freq=None)

In [472]: rng_hourly.tz_localize('US/Eastern', ambiguous='NaT')
Out[472]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', 'NaT', 'NaT', '2011-11-06 02:00:00-05:00'],
dtype='datetime64[ns, US/Eastern]', freq=None)

In [473]: rng_hourly.tz_localize('US/Eastern', ambiguous=[True, True, False, False])
Out[473]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', '2011-11-06 01:00:00-04:00', '2011-11-06 01:00:00-05:00', '2011-11-06 02:00:00-05:00'],
dtype='datetime64[ns, US/Eastern]', freq=None)

Nonexistent times when localizing

A DST transition may also shift the local time ahead by 1 hour creating nonexistent local times (“clocks spring forward”). The behavior of localizing timeseries with nonexistent times can be controlled by the nonexistent argument. The following options are available:

- 'raise': Raises a pytz.NonExistentTimeError (the default behavior)
- 'NaT': Replaces nonexistent times with NaT
- 'shift_forward': Shifts nonexistent times forward to the closest real time
- 'shift_backward': Shifts nonexistent times backward to the closest real time
- timedelta object: Shifts nonexistent times by the timedelta duration

In [474]: dti = pd.date_range(start='2015-03-29 02:30:00', periods=3, freq='H')
# 2:30 is a nonexistent time

Localization of nonexistent times will raise an error by default.

In [2]: dti.tz_localize('Europe/Warsaw')
NonExistentTimeError: 2015-03-29 02:30:00

Transform nonexistent times to NaT or shift the times.
In [475]: dti
Out[475]:
DatetimeIndex(['2015-03-29 02:30:00', '2015-03-29 03:30:00',
               '2015-03-29 04:30:00'],
               dtype='datetime64[ns]', freq='H')

In [476]: dti.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
Out[476]:
DatetimeIndex(['2015-03-29 03:00:00+02:00', '2015-03-29 03:30:00+02:00',
               '2015-03-29 04:30:00+02:00'],
               dtype='datetime64[ns, Europe/Warsaw]', freq=None)

In [477]: dti.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
Out[477]:
DatetimeIndex(['2015-03-29 01:59:59.999999999+01:00',
               '2015-03-29 03:30:00+02:00',
               '2015-03-29 04:30:00+02:00'],
               dtype='datetime64[ns, Europe/Warsaw]', freq=None)

In [478]: dti.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta(1, unit='H'))
Out[478]:
DatetimeIndex(['2015-03-29 03:30:00+02:00', '2015-03-29 03:30:00+02:00',
               '2015-03-29 04:30:00+02:00'],
               dtype='datetime64[ns, Europe/Warsaw]', freq=None)

In [479]: dti.tz_localize('Europe/Warsaw', nonexistent='NaT')
Out[479]:
DatetimeIndex(['NaT', '2015-03-29 03:30:00+02:00',
               '2015-03-29 04:30:00+02:00'],
               dtype='datetime64[ns, Europe/Warsaw]', freq=None)

Time zone series operations

A `Series` with time zone **naive** values is represented with a dtype of `datetime64[ns]`.

In [480]: s_naive = pd.Series(pd.date_range('20130101', periods=3))
In [481]: s_naive
Out[481]:
0   2013-01-01
1   2013-01-02
2   2013-01-03
dtype: datetime64[ns]

A `Series` with a time zone **aware** values is represented with a dtype of `datetime64[ns, tz]` where **tz** is the time zone.

In [482]: s_aware = pd.Series(pd.date_range('20130101', periods=3, tz='US/Eastern'))
In [483]: s_aware
Out[483]:
0   2013-01-01 00:00:00-05:00
1   2013-01-02 00:00:00-05:00
2   2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]

Both of these `Series` time zone information can be manipulated via the `.dt` accessor, see *the dt accessor section*. 
For example, to localize and convert a naive stamp to time zone aware.

```python
In [484]: s_naive.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out[484]:
0  2012-12-31 19:00:00-05:00
1  2013-01-01 19:00:00-05:00
2  2013-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

Time zone information can also be manipulated using the `astype` method. This method can localize and convert time zone naive timestamps or convert time zone aware timestamps.

```python
# localize and convert a naive time zone
In [485]: s_naive.astype('datetime64[ns, US/Eastern]')
Out[485]:
0  2012-12-31 19:00:00-05:00
1  2013-01-01 19:00:00-05:00
2  2013-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]

# make an aware tz naive
In [486]: s_aware.astype('datetime64[ns]')
Out[486]:
0  2013-01-01 05:00:00
1  2013-01-02 05:00:00
2  2013-01-03 05:00:00
dtype: datetime64[ns]

# convert to a new time zone
In [487]: s_aware.astype('datetime64[ns, CET]')
Out[487]:
0  2013-01-01 06:00:00+01:00
1  2013-01-02 06:00:00+01:00
2  2013-01-03 06:00:00+01:00
dtype: datetime64[ns, CET]
```

**Note:** Using `Series.to_numpy()` on a `Series`, returns a NumPy array of the data. NumPy does not currently support time zones (even though it is printing in the local time zone!), therefore an object array of Timestamps is returned for time zone aware data:

```python
In [488]: s_naive.to_numpy()
Out[488]:
array([Timestamp('2013-01-01T00:00:00.000000000', tz='US/Eastern', freq='D'),
       Timestamp('2013-01-02T00:00:00.000000000', tz='US/Eastern', freq='D'),
       Timestamp('2013-01-03T00:00:00.000000000', tz='US/Eastern', freq='D')],
dtype=object)
```

By converting to an object array of Timestamps, it preserves the time zone information. For example, when converting back to a Series:

```python
In [489]: pd.Series(s_aware.to_numpy())
Out[489]:
(continues on next page)
```
However, if you want an actual NumPy `datetime64[ns]` array (with the values converted to UTC) instead of an array of objects, you can specify the `dtype` argument:

```
In [491]: s_aware.to_numpy(dtype='datetime64[ns]')
Out[491]:
array(['2013-01-01T05:00:00.000000000', '2013-01-02T05:00:00.000000000',
       '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')
```

## 2.18 Time deltas

Timedeltas are differences in times, expressed in difference units, e.g. days, hours, minutes, seconds. They can be both positive and negative.

`Timedelta` is a subclass of `datetime.timedelta`, and behaves in a similar manner, but allows compatibility with `np.timedelta64` types as well as a host of custom representation, parsing, and attributes.

### 2.18.1 Parsing

You can construct a `Timedelta` scalar through various arguments:

```
In [1]: import datetime

# strings
In [2]: pd.Timedelta('1 days')
Out[2]: Timedelta('1 days 00:00:00')

In [3]: pd.Timedelta('1 days 00:00:00')
Out[3]: Timedelta('1 days 00:00:00')

In [4]: pd.Timedelta('1 days 2 hours')
Out[4]: Timedelta('1 days 02:00:00')

In [5]: pd.Timedelta('-1 days 2 min 3us')
Out[5]: Timedelta('-2 days +23:57:59.999997')

# like datetime.timedelta
# note: these MUST be specified as keyword arguments
In [6]: pd.Timedelta(days=1, seconds=1)
Out[6]: Timedelta('1 days 00:00:01')

# integers with a unit
In [7]: pd.Timedelta(1, unit='d')
Out[7]: Timedelta('1 days 00:00:00')

# from a datetime.timedelta/np.timedelta64
In [8]: pd.Timedelta(datetime.timedelta(days=1, seconds=1))
Out[8]: Timedelta('1 days 00:00:01')
```

(continues on next page)
In [9]: pd.Timedelta(np.timedelta64(1, 'ms'))
Out[9]: Timedelta('0 days 00:00:00.001000')

# negative Timedeltas have this string repr
# to be more consistent with datetime.timedelta conventions
In [10]: pd.Timedelta('-1us')
Out[10]: Timedelta('-1 days +23:59:59.999999')

# a NaT
In [11]: pd.Timedelta('nan')
Out[11]: NaT

In [12]: pd.Timedelta('nat')
Out[12]: NaT

# ISO 8601 Duration strings
In [13]: pd.Timedelta('P0DT0H1M0S')
Out[13]: Timedelta('0 days 00:01:00')

In [14]: pd.Timedelta('P0DT0H0M0.000000123S')
Out[14]: Timedelta('0 days 00:00:00.000000123')

New in version 0.23.0: Added constructor for ISO 8601 Duration strings

DateOffsets (Day, Hour, Minute, Second, Milli, Micro, Nano) can also be used in construction.

In [15]: pd.Timedelta(pd.offsets.Second(2))
Out[15]: Timedelta('0 days 00:00:02')

Further, operations among the scalars yield another scalar Timedelta.

In [16]: pd.Timedelta(pd.offsets.Day(2)) + pd.Timedelta(pd.offsets.Second(2)) +
.....:    pd.Timedelta('00:00:00.000123')
.....:
Out[16]: Timedelta('2 days 00:00:02.000123')

to_timedelta

Using the top-level pd.to_timedelta, you can convert a scalar, array, list, or Series from a recognized timedelta format/value into a Timedelta type. It will construct Series if the input is a Series, a scalar if the input is scalar-like, otherwise it will output a TimedeltaIndex.

You can parse a single string to a Timedelta:

In [17]: pd.to_timedelta('1 days 06:05:01.00003')
Out[17]: Timedelta('1 days 06:05:01.000030')

In [18]: pd.to_timedelta('15.5us')
Out[18]: Timedelta('0 days 00:00:00.000015500')

or a list/array of strings:

In [19]: pd.to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
Out[19]: TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015500', NaT],
    dtype='timedelta64[ns]', freq=None)
The `unit` keyword argument specifies the unit of the Timedelta:

```python
In [20]: pd.to_timedelta(np.arange(5), unit='s')
Out[20]:
TimedeltaIndex(['0 days 00:00:00', '0 days 00:00:01', '0 days 00:00:02',
               '0 days 00:00:03', '0 days 00:00:04'],
               dtype='timedelta64[ns]', freq=None)
```

```python
In [21]: pd.to_timedelta(np.arange(5), unit='d')
Out[21]:
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq=None)
```

**Timedelta limitations**

Pandas represents Timedeltas in nanosecond resolution using 64 bit integers. As such, the 64 bit integer limits determine the Timedelta limits.

```python
In [22]: pd.Timedelta.min
Out[22]:
Timedelta('-106752 days +00:12:43.145224193')
```

```python
In [23]: pd.Timedelta.max
Out[23]:
Timedelta('106751 days 23:47:16.854775807')
```

### 2.18.2 Operations

You can operate on Series/DataFrames and construct `timedelta64[ns]` Series through subtraction operations on `datetime64[ns]` Series, or Timestamps.

```python
In [24]: s = pd.Series(pd.date_range('2012-1-1', periods=3, freq='D'))
In [25]: td = pd.Series([pd.Timedelta(days=i) for i in range(3)])
In [26]: df = pd.DataFrame({'A': s, 'B': td})
In [27]: df
Out[27]:
     A     B
 0 2012-01-01 0 days
 1 2012-01-02 1 days
 2 2012-01-03 2 days

In [28]: df['C'] = df['A'] + df['B']
In [29]: df
Out[29]:
     A     B     C
 0 2012-01-01 0 days 2012-01-01
 1 2012-01-02 1 days 2012-01-03
 2 2012-01-03 2 days 2012-01-05

In [30]: df.dtypes
Out[30]:
A  datetime64[ns]
B  timedelta64[ns]
C  datetime64[ns]
```

(continues on next page)
Operations with scalars from a `timedelta64[ns]` series:

```python
In [36]: y = s - s[0]
```

```python
In [37]: y
Out[37]:
0     0 days
1     1 days
2     2 days
dtype: timedelta64[ns]
```

Series of timedeltas with NaT values are supported:

```python
In [38]: y = s - s.shift()
```

```python
In [39]: y
Out[39]:
0     NaT
1     1 days
2     1 days
```
Elements can be set to NaT using np.nan analogously to datetimes:

```
In [40]: y[1] = np.nan
In [41]: y
Out[41]:
0   NaT
1   NaT
2   1 days
dtype: timedelta64[ns]
```

Operands can also appear in a reversed order (a singular object operated with a Series):

```
In [42]: s.max() - s
Out[42]:
0   2 days
1   1 days
2   0 days
dtype: timedelta64[ns]
In [43]: datetime.datetime(2011, 1, 1, 3, 5) - s
Out[43]:
0  -365 days +03:05:00
1  -366 days +03:05:00
2  -367 days +03:05:00
dtype: timedelta64[ns]
In [44]: datetime.timedelta(minutes=5) + s
Out[44]:
0  2012-01-01 00:05:00
1  2012-01-02 00:05:00
2  2012-01-03 00:05:00
dtype: datetime64[ns]
```

min, max and the corresponding idxmin, idxmax operations are supported on frames:

```
In [45]: A = s - pd.Timestamp('20120101') - pd.Timedelta('00:05:05')
In [46]: B = s - pd.Series(pd.date_range('2012-1-2', periods=3, freq='D'))
In [47]: df = pd.DataFrame({'A': A, 'B': B})
In [48]: df
Out[48]:
    A   B
0 -1 days 23:54:55 -1 days
1  0 days 23:54:55 -1 days
2  1 days 23:54:55 -1 days
In [49]: df.min()
Out[49]:
A  -1 days 23:54:55
B  -1 days 00:00:00
dtype: timedelta64[ns]
```

(continues on next page)
In [50]: df.min(axis=1)
Out[50]:
   0 -1 days
   1 -1 days
   2 -1 days
dtype: timedelta64[ns]

In [51]: df.idxmin()
Out[51]:
   A 0
   B 0
dtype: int64

In [52]: df.idxmax()
Out[52]:
   A 2
   B 0
dtype: int64

min, max, idxmin, idxmax operations are supported on Series as well. A scalar result will be a Timedelta.

In [53]: df.min().max()
Out[53]: Timedelta('-1 days +23:54:55')

In [54]: df.min(axis=1).min()
Out[54]: Timedelta('-1 days +00:00:00')

In [55]: df.min().idxmax()
Out[55]: 'A'

In [56]: df.min(axis=1).idxmin()
Out[56]: 0

You can fillna on timedeltas, passing a timedelta to get a particular value.

In [57]: y.fillna(pd.Timedelta(0))
Out[57]:
   0 0 days
   1 0 days
   2 1 days
dtype: timedelta64[ns]

In [58]: y.fillna(pd.Timedelta(10, unit='s'))
Out[58]:
   0 0 days 00:00:10
   1 0 days 00:00:10
   2 1 days 00:00:00
dtype: timedelta64[ns]

In [59]: y.fillna(pd.Timedelta('-1 days, 00:00:05'))
Out[59]:
   0 -1 days +00:00:05
   1 -1 days +00:00:05
   2 1 days 00:00:00
dtype: timedelta64[ns]

You can also negate, multiply and use abs on Timedeltas:

2.18. Time deltas
In [60]: tdl = pd.Timedelta('−1 days 2 hours 3 seconds')

In [61]: tdl
Out[61]: Timedelta('−2 days +21:59:57')

In [62]: −1 * tdl
Out[62]: Timedelta('1 days 02:00:03')

In [63]: − tdl
Out[63]: Timedelta('1 days 02:00:03')

In [64]: abs(tdl)
Out[64]: Timedelta('1 days 02:00:03')

2.18.3 Reductions

Numeric reduction operation for timedelta64[ns] will return Timedelta objects. As usual NaT are skipped during evaluation.

In [65]: y2 = pd.Series(pd.to_timedelta([‘−1 days +00:00:05’, ’nat’, 
     ....:     ‘−1 days +00:00:05’, ’1 days’]))

In [66]: y2
Out[66]:
0  −1 days +00:00:05
1    NaT
2  −1 days +00:00:05
3    1 days 00:00:00
dtype: timedelta64[ns]

In [67]: y2.mean()
Out[67]: Timedelta(‘−1 days +16:00:03.333333334’)

In [68]: y2.median()
Out[68]: Timedelta(‘−1 days +00:00:05’)

In [69]: y2.quantile(.1)
Out[69]: Timedelta(‘−1 days +00:00:05’)

In [70]: y2.sum()
Out[70]: Timedelta(‘−1 days +00:00:10’)

2.18.4 Frequency conversion

Timedelta Series, TimedeltaIndex, and Timedelta scalars can be converted to other ‘frequencies’ by dividing by another timedelta, or by astyping to a specific timedelta type. These operations yield Series and propagate NaT -> nan. Note that division by the NumPy scalar is true division, while astyping is equivalent of floor division.

In [71]: december = pd.Series(pd.date_range(‘20121201’, periods=4))

In [72]: january = pd.Series(pd.date_range(‘20130101’, periods=4))

In [73]: td = january − december

(continues on next page)
In [74]: td[2] += datetime.timedelta(minutes=5, seconds=3)

In [75]: td[3] = np.nan

In [76]: td
Out[76]:
       0  31 days 00:00:00
       1  31 days 00:00:00
       2  31 days 00:05:03
       3    NaT
       dtype: timedelta64[ns]

# to days
In [77]: td / np.timedelta64(1, 'D')
Out[77]:
        0 31.000000
        1 31.000000
        2 31.003507
        3    NaN
        dtype: float64

In [78]: td.astype('timedelta64[D]')
Out[78]:
        0  31.0
        1  31.0
        2  31.0
        3    NaN
        dtype: float64

# to seconds
In [79]: td / np.timedelta64(1, 's')
Out[79]:
        0 2678400.0
        1 2678400.0
        2 2678703.0
        3    NaN
        dtype: float64

In [80]: td.astype('timedelta64[s]')
Out[80]:
        0 2678400.0
        1 2678400.0
        2 2678703.0
        3    NaN
        dtype: float64

# to months (these are constant months)
In [81]: td / np.timedelta64(1, 'M')
Out[81]:
        0 1.018501
        1 1.018501
        2 1.018617
        3    NaN
        dtype: float64

Dividing or multiplying a timedelta64[ns] Series by an integer or integer Series yields another
timedelta64[ns] dtypes Series.

```
In [82]: td * -1
Out[82]:
    0  -31 days +00:00:00
    1  -31 days +00:00:00
    2  -32 days +23:54:57
    3     NaT
    dtype: timedelta64[ns]

In [83]: td * pd.Series([1, 2, 3, 4])
Out[83]:
    0   31 days 00:00:00
    1   62 days 00:00:00
    2   93 days 00:15:09
    3      NaT
    dtype: timedelta64[ns]
```

Rounded division (floor-division) of a timedelta64[ns] Series by a scalar Timedelta gives a series of integers.

```
In [84]: td // pd.Timedelta(days=3, hours=4)
Out[84]:
    0    9.0
    1    9.0
    2    9.0
    3  NaN
    dtype: float64

In [85]: pd.Timedelta(days=3, hours=4) // td
Out[85]:
    0    0.0
    1    0.0
    2    0.0
    3   NaN
    dtype: float64
```

The mod (%) and divmod operations are defined for Timedelta when operating with another timedelta-like or with a numeric argument.

```
In [86]: pd.Timedelta(hours=37) % datetime.timedelta(hours=2)
Out[86]: Timedelta('0 days 01:00:00')

# divmod against a timedelta-like returns a pair (int, Timedelta)
In [87]: divmod(datetime.timedelta(hours=2), pd.Timedelta(minutes=11))
Out[87]: (10, Timedelta('0 days 00:10:00'))

# divmod against a numeric returns a pair (Timedelta, Timedelta)
In [88]: divmod(pd.Timedelta(hours=25), 86400000000000)
Out[88]: (Timedelta('0 days 00:00:00.000000001'), Timedelta('0 days 01:00:00'))
```
2.18.5 Attributes

You can access various components of the Timedelta or TimedeltaIndex directly using the attributes days, seconds, microseconds, nanoseconds. These are identical to the values returned by datetime.timedelta. in that, for example, the .seconds attribute represents the number of seconds >= 0 and < 1 day. These are signed according to whether the Timedelta is signed.

These operations can also be directly accessed via the .dt property of the Series as well.

**Note:** Note that the attributes are NOT the displayed values of the Timedelta. Use .components to retrieve the displayed values.

For a Series:

```
In [89]: td.dt.days
Out[89]:
0   31.0
1   31.0
2   31.0
3   NaN
   dtype: float64

In [90]: td.dt.seconds
Out[90]:
0    0.0
1    0.0
2  303.0
3   NaN
   dtype: float64
```

You can access the value of the fields for a scalar Timedelta directly.

```
In [91]: tds = pd.Timedelta('31 days 5 min 3 sec')

In [92]: tds.days
Out[92]: 31

In [93]: tds.seconds
Out[93]: 303

In [94]: (-tds).seconds
Out[94]: 86097
```

You can use the .components property to access a reduced form of the timedelta. This returns a DataFrame indexed similarly to the Series. These are the displayed values of the Timedelta.

```
In [95]: td.dt.components
Out[95]:
   days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0   31.0    0.0      0.0    0.0          0.0          0.0          0.0
1   31.0    0.0      0.0    0.0          0.0          0.0          0.0
2   31.0    0.0      5.0    3.0          0.0          0.0          0.0
3   NaN    NaN      NaN    NaN          NaN          NaN          NaN

In [96]: td.dt.components.seconds
Out[96]:
```

(continues on next page)
You can convert a Timedelta to an ISO 8601 Duration string with the .isoformat method:

```
In [97]: pd.Timedelta(days=6, minutes=50, seconds=3,
       ....: milliseconds=10, microseconds=10,  
       ....: nanosecond=12).isoformat()
       ....:
Out[97]: 'P6DT0H50M3.010010012S'
```

### 2.18.6 TimedeltaIndex

To generate an index with time delta, you can use either the `TimedeltaIndex` or the `timedelta_range()` constructor. Using `TimedeltaIndex` you can pass string-like, Timedelta, timedelta, or np.timedelta64 objects. Passing np.nan/pd.NaT/nat will represent missing values.

```
In [98]: pd.TimedeltaIndex(['1 days', '1 days, 00:00:05', np.timedelta64(2, 'D'),  
       ....: datetime.timedelta(days=2, seconds=2))
       ....:
Out[98]: TimedeltaIndex(['1 days 00:00:00', '1 days 00:00:05', '2 days 00:00:00',  
       '2 days 00:00:02'],
       'timedelta64[ns]', freq=None)
```

The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation:

```
In [99]: pd.TimedeltaIndex(['0 days', '10 days', '20 days'], freq='infer')
Out[99]: TimedeltaIndex(['0 days', '10 days', '20 days'], dtype='timedelta64[ns]',  
       →freq='10D')
```

**Generating ranges of time deltas**

Similar to `date_range()`, you can construct regular ranges of a TimedeltaIndex using `timedelta_range()`. The default frequency for `timedelta_range` is calendar day:

```
In [100]: pd.timedelta_range(start='1 days', periods=5)
Out[100]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'], dtype=  
       →'timedelta64[ns]', freq='D')
```

Various combinations of `start`, `end`, and `periods` can be used with `timedelta_range`:

```
In [101]: pd.timedelta_range(start='1 days', end='5 days')
Out[101]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'], dtype=  
       →'timedelta64[ns]', freq='D')
```
```
In [102]: pd.timedelta_range(end='10 days', periods=4)
Out[102]: TimedeltaIndex(['7 days', '8 days', '9 days', '10 days'], dtype=  
       →'timedelta64[ns]', freq='D')
```
The `freq` parameter can passed a variety of frequency aliases:

```
In [103]: pd.timedelta_range(start='1 days', end='2 days', freq='30T')
Out[103]:
TimedeltaIndex(['1 days 00:00:00', '1 days 00:30:00', '1 days 01:00:00',
 '1 days 01:30:00', '1 days 02:00:00', '1 days 02:30:00',
 '1 days 03:00:00', '1 days 03:30:00', '1 days 04:00:00',
 '1 days 04:30:00', '1 days 05:00:00', '1 days 05:30:00',
 '1 days 06:00:00', '1 days 06:30:00', '1 days 07:00:00',
 '1 days 07:30:00', '1 days 08:00:00', '1 days 08:30:00',
 '1 days 09:00:00', '1 days 09:30:00', '1 days 10:00:00',
 '1 days 10:30:00', '1 days 11:00:00', '1 days 11:30:00',
 '1 days 12:00:00', '1 days 12:30:00', '1 days 13:00:00',
 '1 days 13:30:00', '1 days 14:00:00', '1 days 14:30:00',
 '1 days 15:00:00', '1 days 15:30:00', '1 days 16:00:00',
 '1 days 16:30:00', '1 days 17:00:00', '1 days 17:30:00',
 '1 days 18:00:00', '1 days 18:30:00', '1 days 19:00:00',
 '1 days 19:30:00', '1 days 20:00:00', '1 days 20:30:00',
 '1 days 21:00:00', '1 days 21:30:00', '1 days 22:00:00',
 '1 days 22:30:00', '1 days 23:00:00', '1 days 23:30:00',
 '2 days 00:00:00'],
dtype='timedelta64[ns]', freq='30T')
```

```
In [104]: pd.timedelta_range(start='1 days', periods=5, freq='2D5H')
Out[104]:
TimedeltaIndex(['1 days 00:00:00', '3 days 05:00:00', '5 days 10:00:00',
 '7 days 15:00:00', '9 days 20:00:00'],
dtype='timedelta64[ns]', freq='53H')
```

New in version 0.23.0.

Specifying `start`, `end`, and `periods` will generate a range of evenly spaced timedeltas from `start` to `end` inclusively, with `periods` number of elements in the resulting TimedeltaIndex:

```
In [105]: pd.timedelta_range('0 days', '4 days', periods=5)
Out[105]:
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq=None)
```

```
In [106]: pd.timedelta_range('0 days', '4 days', periods=10)
Out[106]:
TimedeltaIndex(['0 days 00:00:00', '0 days 10:40:00', '0 days 21:20:00',
 '1 days 08:00:00', '1 days 18:40:00', '2 days 05:20:00',
 '2 days 16:00:00', '3 days 02:40:00', '3 days 13:20:00',
 '4 days 00:00:00'],
dtype='timedelta64[ns]', freq=None)
```

**Using the TimedeltaIndex**

Similarly to other of the datetime-like indices, DatetimeIndex and PeriodIndex, you can use TimedeltaIndex as the index of pandas objects.

```
In [107]: s = pd.Series(np.arange(100),
       index=pd.timedelta_range('1 days', periods=100, freq='h'))
```

```
In [108]: s
Out[108]:
```
Selections work similarly, with coercion on string-likes and slices:

```python
In [109]: s['1 day':'2 day']
Out[109]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
   ..
2 days 19:00:00    43
2 days 20:00:00    44
2 days 21:00:00    45
2 days 22:00:00    46
2 days 23:00:00    47
Freq: H, Length: 48, dtype: int64
```

```python
In [110]: s['1 day 01:00:00']
Out[110]:
1
```

```python
In [111]: s[pd.Timedelta('1 day 1h')]
Out[111]:
```

Furthermore you can use partial string selection and the range will be inferred:

```python
In [112]: s['1 day':'1 day 5 hours']
Out[112]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
1 days 05:00:00    5
Freq: H, dtype: int64
```
Operations

Finally, the combination of `TimedeltaIndex` with `DatetimeIndex` allow certain combination operations that are NaT preserving:

```python
In [113]: tdi = pd.TimedeltaIndex(['1 days', pd.NaT, '2 days'])
In [114]: tdi.to_list()
Out[114]: [Timedelta('1 days 00:00:00'), NaT, Timedelta('2 days 00:00:00')]
In [115]: dti = pd.date_range('20130101', periods=3)
In [116]: dti.to_list()
Out[116]: [Timestamp('2013-01-01 00:00:00', freq='D'),
          Timestamp('2013-01-02 00:00:00', freq='D'),
          Timestamp('2013-01-03 00:00:00', freq='D')]
In [117]: (dti + tdi).to_list()
Out[117]: [Timestamp('2013-01-02 00:00:00'), NaT, Timestamp('2013-01-05 00:00:00')]
In [118]: (dti - tdi).to_list()
Out[118]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2013-01-01 00:00:00')]
```

Conversions

Similarly to frequency conversion on a `Series` above, you can convert these indices to yield another `Index`.

```python
In [119]: tdi / np.timedelta64(1, 's')
Out[119]: Float64Index([86400.0, nan, 172800.0], dtype='float64')
In [120]: tdi.astype('timedelta64[s]')
Out[120]: Float64Index([86400.0, nan, 172800.0], dtype='float64')
```

Scalars type ops work as well. These can potentially return a `different` type of index.

```python
# adding or timedelta and date -> datelike
In [121]: tdi + pd.Timestamp('20130101')
Out[121]: DatetimeIndex(['2013-01-02', 'NaT', '2013-01-03'], dtype='datetime64[ns]',
          freq=None)

# subtraction of a date and a timedelta -> datelike
# note that trying to subtract a date from a Timedelta will raise an exception
In [122]: (pd.Timestamp('2013-01-02 00:00:00') - tdi).to_list()
Out[122]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2012-12-30 00:00:00')]

# timedelta + timedelta -> timedelta
In [123]: tdi + pd.Timedelta('10 days')
Out[123]: TimedeltaIndex(['11 days', NaT, '12 days'], dtype='timedelta64[ns]',
          freq=None)

# division can result in a Timedelta if the divisor is an integer
In [124]: tdi / 2
Out[124]: TimedeltaIndex(['0 days 12:00:00', NaT, '1 days 00:00:00'], dtype=
          'timedelta64[ns]', freq=None)
```

(continues on next page)
2.18.7 Resampling

Similar to timeseries resampling, we can resample with a TimedeltaIndex.

In [126]: s.resample('D').mean()
Out[126]:
1 days 11.5
2 days 35.5
3 days 59.5
4 days 83.5
5 days 97.5
Freq: D, dtype: float64

2.19 Styling

This document is written as a Jupyter Notebook, and can be viewed or downloaded here.

You can apply conditional formatting, the visual styling of a DataFrame depending on the data within, by using the DataFrame.style property. This is a property that returns a Styler object, which has useful methods for formatting and displaying DataFrames.

The styling is accomplished using CSS. You write “style functions” that take scalars, DataFrames or Series, and return like-indexed DataFrames or Series with CSS "attribute: value" pairs for the values. These functions can be incrementally passed to the Styler which collects the styles before rendering.

2.19.1 Building styles

Pass your style functions into one of the following methods:

- Styler.applymap: elementwise
- Styler.apply: column-/row-/table-wise

Both of those methods take a function (and some other keyword arguments) and applies your function to the DataFrame in a certain way. Styler.applymap works through the DataFrame elementwise. Styler.apply passes each column or row into your DataFrame one-at-a-time or the entire table at once, depending on the axis keyword argument. For columnwise use axis=0, rowwise use axis=1, and for the entire table at once use axis=None.

For Styler.applymap your function should take a scalar and return a single string with the CSS attribute-value pair.

For Styler.apply your function should take a Series or DataFrame (depending on the axis parameter), and return a Series or DataFrame with an identical shape where each value is a string with a CSS attribute-value pair.

Let’s see some examples.

[2]: import pandas as pd
import numpy as np
np.random.seed(24)
df = pd.DataFrame({'A': np.linspace(1, 10, 10)})
df = pd.concat([df, pd.DataFrame(np.random.randn(10, 4), columns=list('BCDE'))],
               axis=1)
df.iloc[3, 3] = np.nan
df.iloc[0, 2] = np.nan

Here’s a boring example of rendering a DataFrame, without any (visible) styles:

```python
[3]: df.style
[3]: <pandas.io.formats.style.Styler at 0x7f3375730eb0>
```

**Note:** The DataFrame.style attribute is a property that returns a Styler object. Styler has a _repr_html_ method defined on it so they are rendered automatically. If you want the actual HTML back for further processing or for writing to file call the .render() method which returns a string.

The above output looks very similar to the standard DataFrame HTML representation. But we’ve done some work behind the scenes to attach CSS classes to each cell. We can view these by calling the .render method.

```python
[4]: df.style.highlight_null().render().split('n')[:10]
```

The row0_col12 is the identifier for that particular cell. We’ve also prepended each row/column identifier with a UUID unique to each DataFrame so that the style from one doesn’t collide with the styling from another within the same notebook or page (you can set the uuid if you’d like to tie together the styling of two DataFrames).

When writing style functions, you take care of producing the CSS attribute / value pairs you want. Pandas matches those up with the CSS classes that identify each cell.

Let’s write a simple style function that will color negative numbers red and positive numbers black.

```python
[5]: def color_negative_red(val):
   ""
   Takes a scalar and returns a string with
   the css property 'color: red' for negative
   strings, black otherwise.
   ""
```

(continues on next page)
In this case, the cell’s style depends only on its own value. That means we should use the `Styler.applymap` method which works elementwise.

```
[6]: s = df.style.applymap(color_negative_red)
   s
[6]: <pandas.io.formats.style.Styler at 0x7f333e0d8d60>
```

Notice the similarity with the standard `df.applymap`, which operates on DataFrames elementwise. We want you to be able to reuse your existing knowledge of how to interact with DataFrames.

Notice also that our function returned a string containing the CSS attribute and value, separated by a colon just like in a `<style>` tag. This will be a common theme.

Finally, the input shapes matched. `Styler.applymap` calls the function on each scalar input, and the function returns a scalar output.

Now suppose you wanted to highlight the maximum value in each column. We can’t use `.applymap` anymore since that operated elementwise. Instead, we’ll turn to `.apply` which operates columnwise (or rowwise using the `axis` keyword). Later on we’ll see that something like `highlight_max` is already defined on `Styler` so you wouldn’t need to write this yourself.

```
[7]: def highlight_max(s):
   ...:     '''highlight the maximum in a Series yellow.'''
   ...:     is_max = s == s.max()
   ...:     return ['background-color: yellow' if v else '' for v in is_max]

[8]: df.style.apply(highlight_max)
[8]: <pandas.io.formats.style.Styler at 0x7f333e185fd0>
```

In this case the input is a Series, one column at a time. Notice that the output shape of `highlight_max` matches the input shape, an array with `len(s)` items.

We encourage you to use method chains to build up a style piecewise, before finally rendering at the end of the chain.

```
[9]: df.style.
   applymap(color_negative_red).\n   apply(highlight_max)
[9]: <pandas.io.formats.style.Styler at 0x7f333e055d00>
```

Above we used `Styler.apply` to pass in each column one at a time.

Debugging Tip: If you’re having trouble writing your style function, try just passing it into `DataFrame.apply`. Internally, `Styler.apply` uses `DataFrame.apply` so the result should be the same.

What if you wanted to highlight just the maximum value in the entire table? Use `.apply(function, axis=None)` to indicate that your function wants the entire table, not one column or row at a time. Let’s try that next.

We’ll rewrite our `highlight_max` to handle either Series (from `.apply(axis=0 or 1)`) or DataFrames (from `.apply(axis=None)`). We’ll also allow the color to be adjustable, to demonstrate that `.apply`, and `.applymap` pass along keyword arguments.
def highlight_max(data, color='yellow'):
    '''
    highlight the maximum in a Series or DataFrame
    '''
    attr = 'background-color: {}'.format(color)
    if data.ndim == 1:  # Series from .apply(axis=0) or axis=1
        is_max = data == data.max()
        return [attr if v else '' for v in is_max]
    else:  # from .apply(axis=None)
        is_max = data == data.max().max()
        return pd.DataFrame(np.where(is_max, attr, ''),
                            index=data.index, columns=data.columns)

When using Styler.apply(func, axis=None), the function must return a DataFrame with the same index and column labels.

def highlight_max, color='darkorange', axis=None
<
pandas.io.formats.style.Styler at 0x7f333e059940>

Building Styles Summary

Style functions should return strings with one or more CSS attribute: value delimited by semicolons. Use

• Styler.applymap(func) for elementwise styles
• Styler.apply(func, axis=0) for columnwise styles
• Styler.apply(func, axis=1) for rowwise styles
• Styler.apply(func, axis=None) for tablewise styles

And crucially the input and output shapes of func must match. If x is the input then func(x).shape == x.shape.

2.19.2 Finer control: slicing

Both Styler.apply, and Styler.applymap accept a subset keyword. This allows you to apply styles to specific rows or columns, without having to code that logic into your style function.

The value passed to subset behaves similar to slicing a DataFrame.

• A scalar is treated as a column label
• A list (or series or numpy array)
• A tuple is treated as (row_indexer, column_indexer)

Consider using pd.IndexSlice to construct the tuple for the last one.

def highlight_max, subset=['B', 'C', 'D'])
<
pandas.io.formats.style.Styler at 0x7f333e059880>

For row and column slicing, any valid indexer to .loc will work.

def applymap(color_negative_red,
             subset=pd.IndexSlice[2:5, ['B', 'D']])

2.19. Styling
Only label-based slicing is supported right now, not positional.

If your style function uses a subset or axis keyword argument, consider wrapping your function in a functools.partial, partialing out that keyword.

```python
my_func2 = functools.partial(my_func, subset=42)
```

### 2.19.3 Finer Control: Display Values

We distinguish the display value from the actual value in Styler. To control the display value, the text is printed in each cell, use Styler.format. Cells can be formatted according to a format spec string or a callable that takes a single value and returns a string.

```python
df.style.format("{:.2%}")
```

Use a dictionary to format specific columns.

```python
df.style.format({"B": "{:0<4.0f}", 'D': '{:+.2f}'})
```

Or pass in a callable (or dictionary of callables) for more flexible handling.

```python
df.style.format({"B": lambda x: "±{:.2f}".format(abs(x))})
```

You can format the text displayed for missing values by na_rep.

```python
df.style.format("{:.2%}", na_rep="-")
```

These formatting techniques can be used in combination with styling.

```python
df.style.highlight_max().format(None, na_rep="-")
```

### 2.19.4 Built-in styles

Finally, we expect certain styling functions to be common enough that we’ve included a few “built-in” to the Styler, so you don’t have to write them yourself.

```python
df.style.highlight_null(null_color='red')
```

You can create “heatmaps” with the background_gradient method. These require matplotlib, and we’ll use Seaborn to get a nice colormap.
```python
import seaborn as sns

cm = sns.light_palette("green", as_cmap=True)
s = df.style.background_gradient(cmap=cm)
s
```

Styler.background_gradient takes the keyword arguments low and high. Roughly speaking these extend the range of your data by low and high percent so that when we convert the colors, the colormap’s entire range isn’t used. This is useful so that you can actually read the text still.

```python
# Uses the full color range
df.loc[:4].style.background_gradient(cmap='viridis')
```

```python
# Compress the color range
df.loc[:4]
    .style
    .background_gradient(cmap='viridis', low=.5, high=0)
    .highlight_null('red'))
```

There’s also .highlight_min and .highlight_max.

```python
df.style.highlight_max(axis=0)
```

Use Styler.set_properties when the style doesn’t actually depend on the values.

```python
df.style.set_properties(**{'background-color': 'black',
                           'color': 'lawngreen',
                           'border-color': 'white'})
```

### Bar charts

You can include “bar charts” in your DataFrame.

```python
df.style.bar(subset=['A', 'B'], color='#d65f5f')
```

New in version 0.20.0 is the ability to customize further the bar chart: You can now have the df.style.bar be centered on zero or midpoint value (in addition to the already existing way of having the min value at the left side of the cell), and you can pass a list of [color_negative, color_positive].

Here’s how you can change the above with the new align='mid' option:

```python
df.style.bar(subset=['A', 'B'], align='mid', color=['#d65f5f', '#5fba7d'])
```

The following example aims to give a highlight of the behavior of the new align options:
import pandas as pd
from IPython.display import HTML

# Test series
test1 = pd.Series([-100,-60,-30,-20], name='All Negative')
test2 = pd.Series([10,20,50,100], name='All Positive')
test3 = pd.Series([-10,-5,0,90], name='Both Pos and Neg')

head = ""
<table>
  <thead>
    <th>Align</th>
    <th>All Negative</th>
    <th>All Positive</th>
    <th>Both Neg and Pos</th>
  </thead>
  <tbody>
    ""

aligns = ['left','zero','mid']
for align in aligns:
    row = "<tr><th>".format(align)
    for series in [test1,test2,test3]:
        s = series.copy()
        s.name=''
        row += "<td>".format(s.to_frame().style.bar(align=align,
                                  color=['#d65f5f', '#5fba7d'],
                                  width=100).render())
    row += '</tr>
    head += row

head+= ""
</tbody>
</table>"

HTML(head)

2.19.5 Sharing styles

Say you have a lovely style built up for a DataFrame, and now you want to apply the same style to a second DataFrame. Export the style with df1.style.export, and import it on the second DataFrame with df1.style.set

df2 = -df
style1 = df.style.applymap(color_negative_red)
style1

<pandas.io.formats.style.Styler at 0x7f333b6719d0>

style2 = df2.style
style2.use(style1.export())
style2
Notice that you’re able to share the styles even though they’re data aware. The styles are re-evaluated on the new DataFrame they’ve been used upon.

2.19.6 Other Options

You’ve seen a few methods for data-driven styling. Styler also provides a few other options for styles that don’t depend on the data.

- precision
- captions
- table-wide styles
- missing values representation
- hiding the index or columns

Each of these can be specified in two ways:

- A keyword argument to Styler.__init__
- A call to one of the .set_ or .hide_methods, e.g. .set_caption or .hide_columns

The best method to use depends on the context. Use the Styler constructor when building many styled DataFrames that should all share the same properties. For interactive use, the .set_ and .hide_methods are more convenient.

**Precision**

You can control the precision of floats using pandas’ regular `display.precision` option.

```python
[30]: with pd.option_context('display.precision', 2):
    html = (df.style
             .applymap(color_negative_red)
             .apply(highlight_max))

[30]: <pandas.io.formats.style.Styler at 0x7f333b698d90>
```

Or through a set_precision method.

```python
[31]: df.style\
    .applymap(color_negative_red)\
    .apply(highlight_max)\
    .set_precision(2)

[31]: <pandas.io.formats.style.Styler at 0x7f333b698880>
```

Setting the precision only affects the printed number; the full-precision values are always passed to your style functions. You can always use `df.round(2).style` if you’d prefer to round from the start.
Captions

Regular table captions can be added in a few ways.

```python
[32]: df.style.set_caption('Colormaps, with a caption.')
    .background_gradient(cmap=cm)

[32]: <pandas.io.formats.style.Styler at 0x7f333b6983a0>
```

Table styles

The next option you have are “table styles”. These are styles that apply to the table as a whole, but don’t look at the data. Certain sytlings, including pseudo-selectors like :hover can only be used this way.

```python
[33]: from IPython.display import HTML
def hover(hover_color="#ffff99"):
    return dict(selector="tr:hover",
                props=[("background-color", "%s" % hover_color)])

styles = [
    hover(),
    dict(selector="th", props=[("font-size", "150%"),
                             ("text-align", "center")]),
    dict(selector="caption", props=[("caption-side", "bottom")])
]
html = (df.style.set_table_styles(styles)
        .set_caption("Hover to highlight."))
html

[33]: <pandas.io.formats.style.Styler at 0x7f333b624d00>
```

table_styles should be a list of dictionaries. Each dictionary should have the selector and props keys. The value for selector should be a valid CSS selector. Recall that all the styles are already attached to an id, unique to each Styler. This selector is in addition to that id. The value for props should be a list of tuples of ('attribute', 'value').

```python
[33]: table_styles are extremely flexible, but not as fun to type out by hand. We hope to collect some useful ones either in pandas, or preferable in a new package that builds on top the tools here.
```

Missing values

You can control the default missing values representation for the entire table through set_na_rep method.

```python
[34]: (df.style
    .set_na_rep("FAIL")
    .format(\n        None, na_rep="PASS", subset=["D")
    .highlight_null("yellow"))
```

```python
[34]: <pandas.io.formats.style.Styler at 0x7f333b6228b0>
```
### Hiding the Index or Columns

The index can be hidden from rendering by calling `Styler.hide_index`. Columns can be hidden from rendering by calling `Styler.hide_columns` and passing in the name of a column, or a slice of columns.

```python
[35]: df.style.hide_index()
```

```python
[35]: <pandas.io.formats.style.Styler at 0x7f333b698be0>
```

```python
[36]: df.style.hide_columns(['C','D'])
```

```python
[36]: <pandas.io.formats.style.Styler at 0x7f333b671b80>
```

### CSS classes

Certain CSS classes are attached to cells.

- Index and Column names include `index_name` and `level<k>` where `k` is its level in a MultiIndex
- Index label cells include
  - `row_heading`
  - `row<n>` where `n` is the numeric position of the row
  - `level<k>` where `k` is the level in a MultiIndex
- Column label cells include
  - `col_heading`
  - `col<n>` where `n` is the numeric position of the column
  - `level<k>` where `k` is the level in a MultiIndex
- Blank cells include `blank`
- Data cells include `data`

### Limitations

- DataFrame only (use `Series.to_frame().style`)
- The index and columns must be unique
- No large repr, and performance isn’t great; this is intended for summary DataFrames
- You can only style the `values`, not the index or columns
- You can only apply styles, you can’t insert new HTML entities

Some of these will be addressed in the future.
Terms

- Style function: a function that's passed into `Styler.apply` or `Styler.applymap` and returns values like 'css attribute: value'
- Builtin style functions: style functions that are methods on `Styler`
- Table style: a dictionary with the two keys `selector` and `props`. `selector` is the CSS selector that `props` will apply to. `props` is a list of `(attribute, value)` tuples. A list of table styles passed into `Styler`.

2.19.7 Fun stuff

Here are a few interesting examples.

`Styler` interacts pretty well with widgets. If you're viewing this online instead of running the notebook yourself, you're missing out on interactively adjusting the color palette.

```python
from IPython.html import widgets

@widgets.interact
def f(h_neg=(0, 359, 1), h_pos=(0, 359), s=(0., 99.9), l=(0., 99.9)):
    return df.style.background_gradient(cmap=sns.palettes.diverging_palette(h_neg=h_neg, h_pos=h_pos, s=s, l=l, as_cmap=True))
```

```python
def magnify():
    return [dict(selector="th",
               props=[("font-size", "4pt")]),
            dict(selector="td",
               props=[('padding', "0em 0em")],
            dict(selector="th:hover",
               props=[("font-size", "12pt")]),
            dict(selector="tr:hover td:hover",
               props=[('max-width', '200px'),
                      ('font-size', '12pt')])
]
```

```python
np.random.seed(25)
cmap = cmap=sns.diverging_palette(5, 250, as_cmap=True)
bigdf = pd.DataFrame(np.random.randn(20, 25)).cumsum()
bigdf.style.background_gradient(cmap, axis=1)\ .set_properties(**{'max-width': '80px', 'font-size': '1pt'})\ .set_caption("Hover to magnify")\ .set_precision(2)\ .set_table_styles(magnify())
```

```python
< pandas.io.formats.style.Styler at 0x7f333e038070 >
```
2.19.8 Export to Excel

New in version 0.20.0

Experimental: This is a new feature and still under development. We’ll be adding features and possibly making breaking changes in future releases. We’d love to hear your feedback.

Some support is available for exporting styled DataFrames to Excel worksheets using the OpenPyXL or XlsxWriter engines. CSS2.2 properties handled include:

- background-color
- border-style, border-width, border-color and their {top, right, bottom, left variants}
- color
- font-family
- font-style
- font-weight
- text-align
- text-decoration
- vertical-align
- white-space: nowrap
- Only CSS2 named colors and hex colors of the form #rgb or #rrggbb are currently supported.
- The following pseudo CSS properties are also available to set excel specific style properties:
  - number-format

```python
[40]: df.style.\n    applymap(color_negative_red).\n    apply(highlight_max).\n    to_excel('styled.xlsx', engine='openpyxl')
```

A screenshot of the output:
2.19.9 Extensibility

The core of pandas is, and will remain, its “high-performance, easy-to-use data structures”. With that in mind, we hope that `DataFrame.style` accomplishes two goals

- Provide an API that is pleasing to use interactively and is “good enough” for many tasks
- Provide the foundations for dedicated libraries to build on

If you build a great library on top of this, let us know and we’ll link to it.

Subclassing

If the default template doesn’t quite suit your needs, you can subclass `Styler` and extend or override the template. We’ll show an example of extending the default template to insert a custom header before each table.

```python
from jinja2 import Environment, ChoiceLoader, FileSystemLoader
from IPython.display import HTML
from pandas.io.formats.style import Styler

We’ll use the following template:

```text
{% extends "html.tpl" %}
{% block table %}
<h1>{{ table_title|default("My Table") }}</h1>
{{ super() }}
{% endblock table %}
```

Now that we’ve created a template, we need to set up a subclass of `Styler` that knows about it.

```python
class MyStyler(Styler):
    env = Environment(
        loader=ChoiceLoader([
            FileSystemLoader("templates"), # contains ours
            Styler.loader, # the default
        ])
    )
    template = env.get_template("myhtml.tpl")
```

Notice that we include the original loader in our environment’s loader. That’s because we extend the original template, so the Jinja environment needs to be able to find it.

Now we can use that custom styler. It’s `__init__` takes a DataFrame.

```bash
MyStyler(df)
```

Our custom template accepts a `table_title` keyword. We can provide the value in the `.render` method.

```python
HTML(MyStyler(df).render(table_title="Extending Example"))
```

For convenience, we provide the `Styler.from_custom_template` method that does the same as the custom subclass.
pandas: powerful Python data analysis toolkit, Release 1.1.5

[46]: EasyStyler = Styler.from_custom_template("templates", "myhtml.tpl")
    EasyStyler(df)

[46]: <pandas.io.formats.style.Styler.from_custom_template.<locals>.MyStyler at 0x7f333b698c40>

Here’s the template structure:

[47]: with open("templates/template_structure.html") as f:
    structure = f.read()

    HTML(structure)

[47]: <IPython.core.display.HTML object>

See the template in the GitHub repo for more details.

2.20 Options and settings

2.20.1 Overview

pandas has an options system that lets you customize some aspects of its behaviour, display-related options being those the user is most likely to adjust.

Options have a full “dotted-style”, case-insensitive name (e.g. display.max_rows). You can get/set options directly as attributes of the top-level options attribute:

```python
In [1]: import pandas as pd

In [2]: pd.options.display.max_rows
Out[2]: 15

In [3]: pd.options.display.max_rows = 999

In [4]: pd.options.display.max_rows
Out[4]: 999
```

The API is composed of 5 relevant functions, available directly from the pandas namespace:

- `get_option()` / `set_option()` - get/set the value of a single option.
- `reset_option()` - reset one or more options to their default value.
- `describe_option()` - print the descriptions of one or more options.
- `option_context()` - execute a codeblock with a set of options that revert to prior settings after execution.

Note: Developers can check out pandas/core/config.py for more information.

All of the functions above accept a regexp pattern (re.search style) as an argument, and so passing in a substring will work - as long as it is unambiguous:

```python
In [5]: pd.get_option("display.max_rows")
Out[5]: 999

In [6]: pd.set_option("display.max_rows", 101)

In [7]: pd.get_option("display.max_rows")
```

(continues on next page)
The following will **not work** because it matches multiple option names, e.g. `display.max_colwidth`, `display.max_rows`, `display.max_columns`:

```python
In [10]: try:
....:     pd.get_option("column")
....: except KeyError as e:
....:     print(e)
....:
'Pattern matched multiple keys'
```

**Note:** Using this form of shorthand may cause your code to break if new options with similar names are added in future versions.

You can get a list of available options and their descriptions with `describe_option`. When called with no argument `describe_option` will print out the descriptions for all available options.

### 2.20.2 Getting and setting options

As described above, `get_option()` and `set_option()` are available from the pandas namespace. To change an option, call `set_option('option_regex', new_value)`.

```python
In [11]: pd.get_option('mode.sim_interactive')
Out[11]: False

In [12]: pd.set_option('mode.sim_interactive', True)

In [13]: pd.get_option('mode.sim_interactive')
Out[13]: True
```

**Note:** The option ‘mode.sim_interactive’ is mostly used for debugging purposes.

All options also have a default value, and you can use `reset_option` to do just that:

```python
In [14]: pd.get_option("display.max_rows")
Out[14]: 60

In [15]: pd.set_option("display.max_rows", 999)

In [16]: pd.get_option("display.max_rows")
Out[16]: 999

In [17]: pd.reset_option("display.max_rows")

In [18]: pd.get_option("display.max_rows")
Out[18]: 60
```

It's also possible to reset multiple options at once (using a regex):
option_context context manager has been exposed through the top-level API, allowing you to execute code with given option values. Option values are restored automatically when you exit the with block:

```python
In [20]: with pd.option_context("display.max_rows", 10, "display.max_columns", 5):
    ....:     print(pd.get_option("display.max_rows"))
    ....:     print(pd.get_option("display.max_columns"))
    ....:
10
5
```

```python
In [21]: print(pd.get_option("display.max_rows"))
60
```

```python
In [22]: print(pd.get_option("display.max_columns"))
0
```

### 2.20.3 Setting startup options in Python/IPython environment

Using startup scripts for the Python/IPython environment to import pandas and set options makes working with pandas more efficient. To do this, create a .py or .ipy script in the startup directory of the desired profile. An example where the startup folder is in a default ipython profile can be found at:

`$IPYTHONDIR/profile_default/startup`

More information can be found in the ipython documentation. An example startup script for pandas is displayed below:

```python
import pandas as pd
pd.set_option('display.max_rows', 999)
pd.set_option('precision', 5)
```

### 2.20.4 Frequently used options

The following is a walk-through of the more frequently used display options.

`display.max_rows` and `display.max_columns` sets the maximum number of rows and columns displayed when a frame is pretty-printed. Truncated lines are replaced by an ellipsis.

```python
In [23]: df = pd.DataFrame(np.random.randn(7, 2))
In [24]: pd.set_option('max_rows', 7)
In [25]: df
```

(continues on next page)
In [26]: pd.set_option('max_rows', 5)

In [27]: df
Out[27]:
   0   1
0  0.469112 -0.282863
1 -1.509059 -1.135632
..   ...   ...
5 -0.494929  1.071804
6  0.721555 -0.706771
[7 rows x 2 columns]

In [28]: pd.reset_option('max_rows')

Once the display.max_rows is exceeded, the display.min_rows options determines how many rows are shown in the truncated repr.

In [29]: pd.set_option('max_rows', 8)

In [30]: pd.set_option('min_rows', 4)

# below max_rows -> all rows shown
In [31]: df = pd.DataFrame(np.random.randn(7, 2))

In [32]: df
Out[32]:
   0   1
0 -1.039575  0.271860
1 -0.424972  0.567020
2  0.276232 -1.087401
3 -0.673690  0.113648
4 -1.478427  0.524988
5  0.404705  0.577046
6 -1.715002 -1.039268

# above max_rows -> only min_rows (4) rows shown
In [33]: df = pd.DataFrame(np.random.randn(9, 2))

In [34]: df
Out[34]:
   0   1
0 -1.039575  0.271860
1 -0.424972  0.567020
2  0.276232 -1.087401
3 -0.673690  0.113648
4 -1.478427  0.524988
5  0.404705  0.577046
6 -1.715002 -1.039268
7 -0.370647 -1.157892
8 -1.344312  0.844885
9  0.276662 -0.472035
[9 rows x 2 columns]

In [35]: pd.reset_option('max_rows')

In [36]: pd.reset_option('min_rows')

display.expand_frame_repr allows for the representation of dataframes to stretch across pages, wrapped over the full column vs row-wise.
```python
In [37]: df = pd.DataFrame(np.random.randn(5, 10))

In [38]: pd.set_option('expand_frame_repr', True)

In [39]: df
Out[39]:
   0  1  2  3  4  5  6  7
0 -0.006154 -0.923061 0.895717 0.805244 -1.206412 2.565646 1.431256 1.340309
   -170299 -0.226169
1  0.410835  0.813850 0.132003 -0.827317 -0.187678 1.130127 -1.436737
   -413681  1.607920

   -959726  1.110336
4 -0.619976  0.149748 -0.732339  0.687738  0.176444  0.403310 -0.154951
   -179861 -1.369849

In [40]: pd.set_option('expand_frame_repr', False)

In [41]: df
Out[41]:
   0  1  2  3  4  5  6  7
0 -0.006154 -0.923061 0.895717 0.805244 -1.206412 2.565646 1.431256 1.340309
   -170299 -0.226169
1  0.410835  0.813850 0.132003 -0.827317 -0.187678 1.130127 -1.436737
   -413681  1.607920
2  1.024180  0.569605 0.875906 -2.211372  0.974466 -2.006747  1.130127
   -545952 -1.219217
3 -1.226825  0.769804 -1.281247 -0.727707 -0.121306  0.974466 -0.078638
   -959726  1.110336
4 -0.619976  0.149748 -0.732339  0.687738  0.176444  0.403310 -0.154951
   -179861 -1.369849

In [42]: pd.reset_option('expand_frame_repr')

display.large_repr lets you select whether to display dataframes that exceed max_columns or max_rows
as a truncated frame, or as a summary.

In [43]: df = pd.DataFrame(np.random.randn(10, 10))

In [44]: pd.set_option('max_rows', 5)

In [45]: pd.set_option('large_repr', 'truncate')

In [46]: df
Out[46]:

   -413681  1.607920
```

2.20. Options and settings
### display.max_colwidth

The `display.max_colwidth` setter sets the maximum width of columns. Cells of this length or longer will be truncated with an ellipsis.

```python
In [51]: df = pd.DataFrame(np.array([['foo', 'bar', 'bim', 'uncomfortably long string'], ['horse', 'cow', 'banana', 'apple']]))
In [52]: pd.set_option('max_colwidth', 40)
```

```
  0 1 2 3
0 foo bar bim uncomfortably long string
1 horse cow banana apple
```

```python
In [53]: df
Out[53]:
```
```
0 1 2 3
0 foo bar bim uncomfortably long string
1 horse cow banana apple
```

```python
In [54]: pd.set_option('max_colwidth', 6)
```

```
  0 1 2
0 foo bar bim un...
1 horse cow ba...
```

```python
In [55]: df
Out[55]:
```
```
0 1 2
0 foo bar bim un...
1 horse cow ba...
```
display.max_info_columns sets a threshold for when by-column info will be given.

```python
In [57]: df = pd.DataFrame(np.random.randn(10, 10))
In [58]: pd.set_option('max_info_columns', 11)
In [59]: df.info()
```

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10 entries, 0 to 9
Data columns (total 10 columns):
   #   Column  Non-Null Count  Dtype
      ---  --------  -----------  ----
       0    0       10 non-null  float64
       1    1       10 non-null  float64
       2    2       10 non-null  float64
       3    3       10 non-null  float64
       4    4       10 non-null  float64
       5    5       10 non-null  float64
       6    6       10 non-null  float64
       7    7       10 non-null  float64
       8    8       10 non-null  float64
       9    9       10 non-null  float64
dtypes: float64(10)
memory usage: 928.0 bytes
```

```python
In [60]: pd.set_option('max_info_columns', 5)
In [61]: df.info()
```

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10 entries, 0 to 9
Columns: 10 entries, 0 to 9
dtypes: float64(10)
memory usage: 928.0 bytes
```

```python
In [62]: pd.reset_option('max_info_columns')
```

display.max_info_rows: df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions then specified. Note that you can specify the option df.info(null_counts=True) to override on showing a particular frame.

```python
In [63]: df = pd.DataFrame(np.random.choice([0, 1, np.nan], size=(10, 10)))
In [64]: df
```

```
Out[64]:
     0  1  2  3  4  5  6  7  8  9
0  0.0 NaN NaN NaN  0.0 NaN  0.0 NaN  1.0
1  1.0  1.0  1.0  1.0 NaN  0.0  0.0 NaN
2  0.0 NaN  1.0  0.0  0.0 NaN NaN  0.0
3  NaN NaN NaN  0.0  1.0  1.0 NaN NaN
4  0.0 NaN NaN NaN NaN  0.0 NaN  1.0
5  0.0  1.0  1.0  1.0  1.0 NaN NaN  0.0
6  1.0  0.0 NaN NaN  1.0  1.0  0.0 NaN NaN
```
display.precision sets the output display precision in terms of decimal places. This is only a suggestion.

In [70]: df = pd.DataFrame(np.random.randn(5, 5))

In [71]: pd.set_option('precision', 7)

In [72]: df
Out[72]:
   0  1  2  3  4
0  0  1  2  3  4
display.chop_threshold sets at what level pandas rounds to zero when it displays a Series of DataFrame. This setting does not change the precision at which the number is stored.

```python
In [75]: df = pd.DataFrame(np.random.randn(6, 6))
In [76]: pd.set_option('chop_threshold', 0)
In [77]: df
```

```
Out[77]:
          0  1  2  3  4  5
0  1.2884 0.2946 -1.1658 0.8470 -0.6856 0.6091

3 -1.0133 1.9209 -0.3882 -2.3144 0.6655 0.4026
4  0.3996 -1.7660 0.8504 0.3881 0.9923 0.7441
5 -0.7398 -1.0549 -0.1796 0.6396 1.5850 1.9067
```

```python
In [78]: pd.set_option('chop_threshold', .5)
In [79]: df
```

```
Out[79]:
          0  1  2  3  4  5
0  1.2884 0.0000 -1.1658 0.8470 -0.6856 0.6091
1  0.0000 0.6256 0.0000 0.0000 1.1039 -1.0875
2  1.9980 0.0000 0.0000 0.8863 -1.3507 -0.8863
3 -1.0133 1.9209 0.0000 -2.3144 0.6655 0.4026
4  0.3996 -1.7660 0.8504 0.0000 0.9923 0.7441
5 -0.7398 -1.0549 0.0000 0.6396 1.5850 1.9067
```

```python
In [80]: pd.reset_option('chop_threshold')
```

display.colheader_justify controls the justification of the headers. The options are ‘right’, and ‘left’.

```python
In [81]: df = pd.DataFrame(np.array([np.random.randn(6),
                              np.random.randint(1, 9, 6) * .1,
                              np.zeros(6)]).T,
                      columns=['A', 'B', 'C'], dtype='float')
```

(continues on next page)
2.20.5 Available options

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>display.chop_threshold</td>
<td>None</td>
<td>If set to a float value, all float values smaller then the given threshold will be displayed as exactly 0.</td>
</tr>
<tr>
<td>display.colheader_justify</td>
<td>right</td>
<td>Controls the justification of column headers. used by DataFrameFormatter.</td>
</tr>
<tr>
<td>display.column_space</td>
<td>12</td>
<td>No description available.</td>
</tr>
<tr>
<td>display.date_dayfirst</td>
<td>False</td>
<td>When True, prints and parses dates with the day first, eg 20/01/2005</td>
</tr>
<tr>
<td>display.date_yearfirst</td>
<td>False</td>
<td>When True, prints and parses dates with the year first, eg 2005/01/20</td>
</tr>
<tr>
<td>display.encoding</td>
<td>UTF-8</td>
<td>Defaults to the detected encoding of the console. Specifies the encoding to be used.</td>
</tr>
<tr>
<td>display.expand_frame_repr</td>
<td>True</td>
<td>Whether to print out the full DataFrame repr for wide DataFrames across multiple pages.</td>
</tr>
<tr>
<td>display.float_format</td>
<td>None</td>
<td>The callable should accept a floating point number and return a string with the desired format of the number.</td>
</tr>
<tr>
<td>display.large_repr</td>
<td>truncate</td>
<td>For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can be truncated.</td>
</tr>
<tr>
<td>display.latex.escape</td>
<td>True</td>
<td>Escapes special characters in DataFrames, when using the to_latex method.</td>
</tr>
<tr>
<td>display.latex.longtable</td>
<td>False</td>
<td>Specifies if the to_latex method of a DataFrame uses the longtable format.</td>
</tr>
<tr>
<td>display.latex.multicolumn</td>
<td>True</td>
<td>Combines columns when using a MultiIndex.</td>
</tr>
<tr>
<td>display.latex.multicolumn_format</td>
<td>T</td>
<td>Alignment of multicolumn labels.</td>
</tr>
<tr>
<td>display.latex.multirow</td>
<td>False</td>
<td>Combines rows when using a MultiIndex. Centered instead of top-aligned, separated by vertical lines.</td>
</tr>
<tr>
<td>display.max_columns</td>
<td>0 or 20</td>
<td>max_rows and max_columns are used in <strong>repr</strong>() methods to decide if to_string() or info() is used.</td>
</tr>
<tr>
<td>display.max_colwidth</td>
<td>50</td>
<td>The maximum width in characters of a column in the repr of a pandas data structure.</td>
</tr>
<tr>
<td>display.max_info_columns</td>
<td>100</td>
<td>max_info_columns is used in DataFrame.info method to decide if per column information is shown.</td>
</tr>
<tr>
<td>display.max_info_rows</td>
<td>1690785</td>
<td>df.info() will usually show null-counts for each column. For large frames this can be very slow.</td>
</tr>
<tr>
<td>display.max_rows</td>
<td>60</td>
<td>The maximum number of rows pandas should output when printing output.</td>
</tr>
<tr>
<td>display.min_rows</td>
<td>10</td>
<td>The numbers of rows to show in a truncated repr (when max_rows is exceeded).</td>
</tr>
<tr>
<td>display.max_seq_items</td>
<td>100</td>
<td>When pretty-printing a long sequence, no more then max_seq_items will be printed.</td>
</tr>
</tbody>
</table>
### 2.20.6 Number formatting

Pandas also allows you to set how numbers are displayed in the console. This option is not set through the `set_options` API.

Use the `set_eng_float_format` function to alter the floating-point formatting of pandas objects to produce a particular format.

For instance:

```python
In [87]: import numpy as np

In [88]: pd.set_eng_float_format(accuracy=3, use_eng_prefix=True)

In [89]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [90]: s / 1.e3
Out[90]:
   a     303.638u
   b    -721.084u
   c    -622.696u
   d     648.250u
   e    -1.945m

In [91]: s / 1.e6
Out[91]:
   a  303.638n
```

(continues on next page)
To round floats on a case-by-case basis, you can also use `round()` and `round()`.

### 2.20.7 Unicode formatting

**Warning:** Enabling this option will affect the performance for printing of DataFrame and Series (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters whose width corresponds to two Latin characters. If a DataFrame or Series contains these characters, the default output mode may not align them properly.

**Note:** Screen captures are attached for each output to show the actual results.

```python
In [92]: df = pd.DataFrame({'': ['UK', ''], '': ['Alice', '']})

In [93]: df
Out[93]:
0  UK  Alice
1
```

Enabling `display.unicode.east_asian_width` allows pandas to check each character’s “East Asian Width” property. These characters can be aligned properly by setting this option to `True`. However, this will result in longer render times than the standard `len` function.

```python
In [94]: pd.set_option('display.unicode.east_asian_width', True)

In [95]: df
Out[95]:
0  UK  Alice
1
```

In addition, Unicode characters whose width is “Ambiguous” can either be 1 or 2 characters wide depending on the terminal setting or encoding. The option `display.unicode.ambiguous_as_wide` can be used to handle the ambiguity.

```python
>>> df = pd.DataFrame({'名前, 国籍': ['UK', '日本'], '名前': ['Alice', 'しのぶ']})

>>> df
    名前 国籍
0   Alice  UK
1   しのぶ  日本
```
By default, an “Ambiguous” character’s width, such as “¡” (inverted exclamation) in the example below, is taken to be 1.

```python
In [96]: df = pd.DataFrame({'a': ['xxx', '¡¡'], 'b': ['yyy', '¡¡']})

In [97]: df
Out[97]:
   a     b
0  xxx   yyy
1  ¡¡    ¡¡

Enabling `display.unicode.ambiguous_as_wide` makes pandas interpret these characters’ widths to be 2. (Note that this option will only be effective when `display.unicode.east_asian_width` is enabled.) However, setting this option incorrectly for your terminal will cause these characters to be aligned incorrectly:

```python
In [98]: pd.set_option('display.unicode.ambiguous_as_wide', True)

In [99]: df
Out[99]:
   a     b
0  xxx   yyy
1  ¡¡    ¡¡

```python
>>> pd.set_option('display.unicode.ambiguous_as_wide', True)

```python
>>> df
   a     b
0  xxx   yyy
1  ¡¡    ¡¡

2.20.8 Table schema display

`DataFrame` and `Series` will publish a Table Schema representation by default. False by default, this can be enabled globally with the `display.html.table_schema` option:

```python
In [100]: pd.set_option('display.html.table_schema', True)

```

Only 'display.max_rows' are serialized and published.

2.21 Enhancing performance

In this part of the tutorial, we will investigate how to speed up certain functions operating on pandas `DataFrames` using three different techniques: Cython, Numba and `pandas.eval()`. We will see a speed improvement of ~200 when we use Cython and Numba on a test function operating row-wise on the `DataFrame`. Using `pandas.eval()` we will speed up a sum by an order of ~2.

Note: In addition to following the steps in this tutorial, users interested in enhancing performance are highly encouraged to install the recommended dependencies for pandas. These dependencies are often not installed by default, but
will offer speed improvements if present.

## 2.21.1 Cython (writing C extensions for pandas)

For many use cases writing pandas in pure Python and NumPy is sufficient. In some computationally heavy applications however, it can be possible to achieve sizable speed-ups by offloading work to Cython.

This tutorial assumes you have refactored as much as possible in Python, for example by trying to remove for-loops and making use of NumPy vectorization. It’s always worth optimising in Python first.

This tutorial walks through a “typical” process of cythonizing a slow computation. We use an example from the Cython documentation but in the context of pandas. Our final cythonized solution is around 100 times faster than the pure Python solution.

### Pure Python

We have a DataFrame to which we want to apply a function row-wise.

```python
In [1]: df = pd.DataFrame({'a': np.random.randn(1000),
            'b': np.random.randn(1000),
            'N': np.random.randint(100, 1000, (1000)),
            'x': 'x'})
```

```python
In [2]: df
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>N</th>
<th>x</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.469112</td>
<td>-0.218470</td>
<td>585</td>
<td>x</td>
</tr>
<tr>
<td>-0.282863</td>
<td>-0.061645</td>
<td>841</td>
<td>x</td>
</tr>
<tr>
<td>-1.509059</td>
<td>-0.723780</td>
<td>251</td>
<td>x</td>
</tr>
<tr>
<td>-1.135632</td>
<td>0.551225</td>
<td>972</td>
<td>x</td>
</tr>
<tr>
<td>1.212112</td>
<td>-0.497767</td>
<td>181</td>
<td>x</td>
</tr>
</tbody>
</table>

[1000 rows x 4 columns]

Here’s the function in pure Python:

```python
In [3]: def f(x):
    ...:     return x * (x - 1)
    ...:
```

```python
In [4]: def integrate_f(a, b, N):
    ...:     s = 0
    ...:     dx = (b - a) / N
    ...:     for i in range(N):
    ...:         s += f(a + i * dx)
    ...:     return s * dx
    ...:
```

We achieve our result by using `apply` (row-wise):
But clearly this isn’t fast enough for us. Let’s take a look and see where the time is spent during this operation (limited to the most time consuming four calls) using the `prun` ipython magic function:

```python
In [5]: %prun -l 4 df.apply(lambda x: integrate_f(x['a'], x['b'], x['N']), axis=1) #
622830 function calls (622809 primitive calls) in 0.181 seconds
Ordered by: internal time
List reduced from 214 to 4 due to restriction <4>
ncalls  tottime  percall  cumtime  percall filename:lineno(function)
1000    0.104    0.000    0.149    0.000 <ipython-input-4-c2a74e076cf0>:1(integrate_f)
552423   0.044    0.000    0.044    0.000 <ipython-input-3-c138bdd570e3>:1(f)
3000    0.005    0.000    0.023    0.000 series.py:868(__getitem__)
3000    0.003    0.000    0.016    0.000 series.py:973(__get_value)
```

By far the majority of time is spend inside either `integrate_f` or `f`, hence we’ll concentrate our efforts cythonizing these two functions.

### Plain Cython

First we’re going to need to import the Cython magic function to ipython:

```python
In [6]: %load_ext Cython
```

Now, let’s simply copy our functions over to Cython as is (the suffix is here to distinguish between function versions):

```python
In [7]: %cython
...: def f_plain(x):
...:     return x * (x - 1)
...: def integrate_f_plain(a, b, N):
...:     s = 0
...:     dx = (b - a) / N
...:     for i in range(N):
...:         s += f_plain(a + i * dx)
...:     return s * dx
...:
```

**Note:** If you’re having trouble pasting the above into your ipython, you may need to be using bleeding edge ipython for paste to play well with cell magics.

```python
In [4]: %timeit df.apply(lambda x: integrate_f_plain(x['a'], x['b'], x['N']), axis=1)
10 loops, best of 3: 85.5 ms per loop
```

Already this has shaved a third off, not too bad for a simple copy and paste.
Adding type

We get another huge improvement simply by providing type information:

```
In [8]: %%cython
cdef double f_typed(double x) except? -2:
   ...:   return x * (x - 1)
cdef double integrate_f_typed(double a, double b, int N):
   ...:   cdef int i
   ...:   cdef double s, dx
   ...:   s = 0
   ...:   dx = (b - a) / N
   ...:   for i in range(N):
   ...:     s += f_typed(a + i * dx)
   ...:   return s * dx
```

```
In [4]: %timeit df.apply(lambda x: integrate_f_typed(x['a'], x['b'], x['N']), axis=1)
10 loops, best of 3: 20.3 ms per loop
```

Now, we’re talking! It’s now over ten times faster than the original python implementation, and we haven’t *really* modified the code. Let’s have another look at what’s eating up time:

```
In [9]: %prun -l 4 df.apply(lambda x: integrate_f_typed(x['a'], x['b'], x['N']),
   →axis=1)
70396 function calls (70375 primitive calls) in 0.031 seconds
Ordered by: internal time
List reduced from 208 to 4 due to restriction <4>
ncalls  tottime  percall  cumtime  percall filename:lineno(function)
3000   0.004    0.000    0.020    0.000 series.py:868(__getitem__)
3000   0.003    0.000    0.014    0.000 series.py:973(__get_value)
3000   0.002    0.000    0.006    0.000 base.py:2854(get_loc)
3000   0.002    0.000    0.004    0.000 base.py:4979(__maybe_cast_indexer)
```

Using ndarray

It’s calling series… a lot! It’s creating a Series from each row, and get-ting from both the index and the series (three times for each row). Function calls are expensive in Python, so maybe we could minimize these by cythonizing the apply part.

**Note:** We are now passing ndarrays into the Cython function, fortunately Cython plays very nicely with NumPy.

```
In [10]: %%cython
cimport numpy as np
import numpy as np

cdef double f_typed(double x) except? -2:
   ...:   return x * (x - 1)
cdef double integrate_f_typed(double a, double b, int N):
   ...:   cdef int i
   ...:   cdef double s, dx
   ...:   s = 0
   ...:   dx = (b - a) / N
```
....:     for i in range(N):
....:         s += f_typed(a + i * dx)
....:     return s * dx
....: cpdef np.ndarray[double] apply_integrate_f(np.ndarray col_a, np.ndarray col_b,
....:     np.ndarray col_N):
....:     assert (col_a.dtype == np.float
....:             and col_b.dtype == np.float and col_N.dtype == np.int)
....:     cdef Py_ssize_t i, n = len(col_N)
....:     assert (len(col_a) == len(col_b) == n)
....:     cdef np.ndarray[double] res = np.empty(n)
....:     for i in range(len(col_a)):
....:         res[i] = integrate_f_typed(col_a[i], col_b[i], col_N[i])
....:     return res
....:
The implementation is simple, it creates an array of zeros and loops over the rows, applying our integrate_f_typed, and putting this in the zeros array.

Warning: You can not pass a Series directly as a ndarray typed parameter to a Cython function. Instead pass the actual ndarray using the Series.to_numpy(). The reason is that the Cython definition is specific to an ndarray and not the passed Series.

So, do not do this:

```python
apply_integrate_f(df['a'], df['b'], df['N'])
```

But rather, use Series.to_numpy() to get the underlying ndarray:

```python
apply_integrate_f(df['a'].to_numpy(),
                  df['b'].to_numpy(),
                  df['N'].to_numpy())
```

Note: Loops like this would be extremely slow in Python, but in Cython looping over NumPy arrays is fast.

```
In [4]: %timeit apply_integrate_f(df['a'].to_numpy(),
                               df['b'].to_numpy(),
                               df['N'].to_numpy())
```

1000 loops, best of 3: 1.25 ms per loop

We’ve gotten another big improvement. Let’s check again where the time is spent:

```python
In [11]: %prun -l 4 apply_integrate_f(df['a'].to_numpy(),
                              df['b'].to_numpy(),
                              df['N'].to_numpy())
```

218 function calls in 0.001 seconds

Ordered by: internal time
List reduced from 59 to 4 due to restriction <4>

```
ncalls  tottime  percall  cumtime  percall  filename:lineno(function)
1    0.001    0.001    0.001    0.001 {built-in method _cython_magic_
   ..6881e8aa4e75f7c54d4f9fe93591f6a.apply_integrate_f}
```
As one might expect, the majority of the time is now spent in `apply_integrate_f`, so if we wanted to make anymore efficiencies we must continue to concentrate our efforts here.

**More advanced techniques**

There is still hope for improvement. Here’s an example of using some more advanced Cython techniques:

```python
In [12]: %cython
cimport cython
cimport numpy as np
import numpy as np
cdef double f_typed(double x) except? -2:
   return x * (x - 1)
cdef double integrate_f_typed(double a, double b, int N):
   cdef int i
   cdef double s, dx
   s = 0
   dx = (b - a) / N
   for i in range(N):
      s += f_typed(a + i * dx)
   return s * dx
@cython.boundscheck(False)
@cython.wraparound(False)
cdef np.ndarray[double] apply_integrate_f_wrap(np.ndarray[double] col_a,
                                           np.ndarray[double] col_b,
                                           np.ndarray[int] col_N):
   cdef int i, n = len(col_N)
   assert len(col_a) == len(col_b) == n
   cdef np.ndarray[double] res = np.empty(n)
   for i in range(n):
      res[i] = integrate_f_typed(col_a[i], col_b[i], col_N[i])
   return res
```

```python
In [4]: %timeit apply_integrate_f_wrap(df['a'].to_numpy(),
                                 df['b'].to_numpy(),
                                 df['N'].to_numpy())
1000 loops, best of 3: 987 us per loop
```

Even faster, with the caveat that a bug in our Cython code (an off-by-one error, for example) might cause a segfault because memory access isn’t checked. For more about `boundscheck` and `wraparound`, see the Cython docs on compiler directives.
2.21.2 Using Numba

A recent alternative to statically compiling Cython code, is to use a dynamic jit-compiler, Numba.

Numba gives you the power to speed up your applications with high performance functions written directly in Python. With a few annotations, array-oriented and math-heavy Python code can be just-in-time compiled to native machine instructions, similar in performance to C, C++ and Fortran, without having to switch languages or Python interpreters.

Numba works by generating optimized machine code using the LLVM compiler infrastructure at import time, runtime, or statically (using the included pycc tool). Numba supports compilation of Python to run on either CPU or GPU hardware, and is designed to integrate with the Python scientific software stack.

**Note:** You will need to install Numba. This is easy with conda, by using: `conda install numba`, see *installing using miniconda*.

**Note:** As of Numba version 0.20, pandas objects cannot be passed directly to Numba-compiled functions. Instead, one must pass the NumPy array underlying the pandas object to the Numba-compiled function as demonstrated below.

**Jit**

We demonstrate how to use Numba to just-in-time compile our code. We simply take the plain Python code from above and annotate with the `@jit` decorator.

```python
import numba

@numba.jit
def f_plain(x):
    return x * (x - 1)

@numba.jit
def integrate_f_numba(a, b, N):
    s = 0
    dx = (b - a) / N
    for i in range(N):
        s += f_plain(a + i * dx)
    return s * dx

@numba.jit
def apply_integrate_f_numba(col_a, col_b, col_N):
    n = len(col_N)
    result = np.empty(n, dtype='float64')
    assert len(col_a) == len(col_b) == n
    for i in range(n):
        result[i] = integrate_f_numba(col_a[i], col_b[i], col_N[i])
    return result

def compute_numba(df):
    result = apply_integrate_f_numba(df['a'].to_numpy(),
                                      df['b'].to_numpy(),
                                      (continues on next page)
```
Note that we directly pass NumPy arrays to the Numba function. `compute_numba` is just a wrapper that provides a nicer interface by passing/returning pandas objects.

```python
In [4]: %timeit compute_numba(df)
1000 loops, best of 3: 798 us per loop
```

In this example, using Numba was faster than Cython.

### Vectorize

Numba can also be used to write vectorized functions that do not require the user to explicitly loop over the observations of a vector; a vectorized function will be applied to each row automatically. Consider the following toy example of doubling each observation:

```python
import numba

def double_every_value_nonumba(x):
    return x * 2

@numba.vectorize
def double_every_value_withnumba(x):
    return x * 2

# Custom function without numba
In [5]: %timeit df['col1_doubled'] = df['a'].apply(double_every_value_nonumba)  # noqa E501
1000 loops, best of 3: 797 us per loop

# Standard implementation (faster than a custom function)
In [6]: %timeit df['col1_doubled'] = df['a'] * 2
1000 loops, best of 3: 233 us per loop

# Custom function with numba
In [7]: %timeit df['col1_doubled'] = double_every_value_withnumba(df['a'].to_numpy())
1000 loops, best of 3: 145 us per loop
```

### Caveats

**Note:** Numba will execute on any function, but can only accelerate certain classes of functions.

Numba is best at accelerating functions that apply numerical functions to NumPy arrays. When passed a function that only uses operations it knows how to accelerate, it will execute in `nopython` mode.

If Numba is passed a function that includes something it doesn’t know how to work with – a category that currently includes sets, lists, dictionaries, or string functions – it will revert to `object` mode. In `object` mode, Numba will execute but your code will not speed up significantly. If you would prefer that Numba throw an error if it cannot...
compile a function in a way that speeds up your code, pass Numba the argument `nopython=True` (e.g. `@numba.jit(nopython=True)`). For more on troubleshooting Numba modes, see the Numba troubleshooting page. Read more in the Numba docs.

### 2.21.3 Expression evaluation via `eval()`

The top-level function `pandas.eval()` implements expression evaluation of `Series` and `DataFrame` objects.

**Note:** To benefit from using `eval()` you need to install `numexpr`. See the recommended dependencies section for more details.

The point of using `eval()` for expression evaluation rather than plain Python is two-fold: 1) large `DataFrame` objects are evaluated more efficiently and 2) large arithmetic and boolean expressions are evaluated all at once by the underlying engine (by default `numexpr` is used for evaluation).

**Note:** You should not use `eval()` for simple expressions or for expressions involving small DataFrames. In fact, `eval()` is many orders of magnitude slower for smaller expressions/objects than plain ol’ Python. A good rule of thumb is to only use `eval()` when you have a `DataFrame` with more than 10,000 rows.

`eval()` supports all arithmetic expressions supported by the engine in addition to some extensions available only in pandas.

**Note:** The larger the frame and the larger the expression the more speedup you will see from using `eval()`.

#### Supported syntax

These operations are supported by `pandas.eval()`:

- Arithmetic operations except for the left shift (<<) and right shift (>>) operators, e.g., `df + 2 * pi / s ** 4 % 42 - the_golden_ratio`
- Comparison operations, including chained comparisons, e.g., `2 < df < df2`
- Boolean operations, e.g., `df < df2 and df3 < df4 or not df_bool`
- List and tuple literals, e.g., `[1, 2] or (1, 2)`
- Attribute access, e.g., `df.a`
- Subscript expressions, e.g., `df[0]`
- Simple variable evaluation, e.g., `pd.eval('df')` (this is not very useful)
- Math functions: `sin`, `cos`, `exp`, `log`, `expm1`, `log1p`, `sqrt`, `sinh`, `cosh`, `tanh`, `arcsin`, `arccos`, `arctan`, `arccosh`, `arcsinh`, `arctanh`, `abs`, `arctan2` and `log10`.

This Python syntax is **not** allowed:

- Expressions
  - Function calls other than math functions.
  - `is/is not` operations
  - `if` expressions
- lambda expressions
- list/set/dict comprehensions
- Literal dict and set expressions
- yield expressions
- Generator expressions
- Boolean expressions consisting of only scalar values

• Statements
  - Neither simple nor compound statements are allowed. This includes things like for, while, and if.

**eval() examples**

*pandas.eval()* works well with expressions containing large arrays.

First let’s create a few decent-sized arrays to play with:

```python
In [13]: nrows, ncols = 20000, 100
In [14]: df1, df2, df3, df4 = [pd.DataFrame(np.random.randn(nrows, ncols)) for _ in range(4)]
```

Now let’s compare adding them together using plain ol’ Python versus *eval()*:

```python
In [15]: %timeit df1 + df2 + df3 + df4
13.2 ms ± 44.1 us per loop (mean ± std. dev. of 7 runs, 100 loops each)
In [16]: %timeit pd.eval('df1 + df2 + df3 + df4')
6.92 ms ± 19.8 us per loop (mean ± std. dev. of 7 runs, 100 loops each)
```

Now let’s do the same thing but with comparisons:

```python
In [17]: %timeit (df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)
8.25 ms ± 38.7 us per loop (mean ± std. dev. of 7 runs, 100 loops each)
In [18]: %timeit pd.eval('(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)')
9.52 ms ± 69.9 us per loop (mean ± std. dev. of 7 runs, 100 loops each)
```

*eval()* also works with unaligned pandas objects:

```python
In [19]: s = pd.Series(np.random.randn(50))
In [20]: %timeit df1 + df2 + df3 + df4 + s
16.4 ms ± 78.9 us per loop (mean ± std. dev. of 7 runs, 10 loops each)
In [21]: %timeit pd.eval('df1 + df2 + df3 + df4 + s')
7.48 ms ± 27.7 us per loop (mean ± std. dev. of 7 runs, 100 loops each)
```

**Note:** Operations such as

```
1 and 2  # would parse to 1 & 2, but should evaluate to 2
3 or 4  # would parse to 3 | 4, but should evaluate to 3
~1  # this is okay, but slower when using eval
```
should be performed in Python. An exception will be raised if you try to perform any boolean/bitwise operations with scalar operands that are not of type `bool` or `np.bool_`. Again, you should perform these kinds of operations in plain Python.

### The DataFrame.eval method

In addition to the top level `pandas.eval()` function you can also evaluate an expression in the “context” of a `DataFrame`.

```python
In [22]: df = pd.DataFrame(np.random.randn(5, 2), columns=['a', 'b'])
In [23]: df.eval('a + b')
Out[23]:
      0       1
0  0.5407  0.2467
1 -0.2467  0.8678
2  1.6256 -1.3449
3 -1.1349  0.0277
4  0.0277 -1.0278
```

Any expression that is a valid `pandas.eval()` expression is also a valid `DataFrame.eval()` expression, with the added benefit that you don’t have to prefix the name of the `DataFrame` to the column(s) you’re interested in evaluating.

In addition, you can perform assignment of columns within an expression. This allows for formulaic evaluation. The assignment target can be a new column name or an existing column name, and it must be a valid Python identifier.

The `inplace` keyword determines whether this assignment will performed on the original `DataFrame` or return a copy with the new column.

```python
In [24]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
In [25]: df.eval('c = a + b', inplace=True)
In [26]: df.eval('d = a + b + c', inplace=True)
In [27]: df.eval('a = 1', inplace=True)
In [28]: df
Out[28]:
     a  b  c  d
0  1  5   5 10
1  1  6   7 14
2  1  7   9 18
3  1  8  11 22
4  1  9  13 26
```

When `inplace` is set to `False`, the default, a copy of the `DataFrame` with the new or modified columns is returned and the original frame is unchanged.

```python
In [29]: df
Out[29]:
     a  b  c  d
0  1  5   5 10
1  1  6   7 14
2  1  7   9 18
```

(continues on next page)
```python
In [30]: df.eval('e = a - c', inplace=False)
Out[30]:
   a  b  c   d   e
0  1  5  5  10  -4
1  1  6  7  14  -6
2  1  7  9  18  -8
3  1  8 11  22 -10
4  1  9 13  26 -12
```

As a convenience, multiple assignments can be performed by using a multi-line string.

```python
In [32]: df.eval(""
   .... c = a + b
   .... d = a + b + c
   .... a = 1",
       inplace=False)
   
Out[32]:
   a  b  c  d
0  1  5  6  12
1  1  6  7  14
2  1  7  8  16
3  1  8  9  18
4  1  9 10  20
```

The equivalent in standard Python would be

```python
In [33]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
In [34]: df['c'] = df['a'] + df['b']
In [35]: df['d'] = df['a'] + df['b'] + df['c']
In [36]: df['a'] = 1
In [37]: df
Out[37]:
   a  b  c  d
0  1  5  6  12
1  1  6  7  14
2  1  7  8  16
3  1  8  9  18
4  1  9 10  20
```

The `query` method has an `inplace` keyword which determines whether the query modifies the original frame.
In [38]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))

In [39]: df.query('a > 2')
Out[39]:
   a  b
0  3  3
1  4  4

In [40]: df.query('a > 2', inplace=True)

In [41]: df
Out[41]:
   a  b
0  3  3
1  4  4

Local variables

You must explicitly reference any local variable that you want to use in an expression by placing the @ character in front of the name. For example,

In [42]: df = pd.DataFrame(np.random.randn(5, 2), columns=list('ab'))

In [43]: newcol = np.random.randn(len(df))

In [44]: df.eval('b + @newcol')
Out[44]:
   0   1   2   3   4
0 -0.173926 2.493083 -0.881831 -0.691045 1.334703
dtype: float64

In [45]: df.query('b < @newcol')
Out[45]:
   a  b
0 0.863987 -0.115998
2 -2.621419 -1.297879

If you don’t prefix the local variable with @, pandas will raise an exception telling you the variable is undefined.

When using DataFrame.eval() and DataFrame.query(), this allows you to have a local variable and a DataFrame column with the same name in an expression.

In [46]: a = np.random.randn()

In [47]: df.query('@a < a')
Out[47]:
   a  b
0 0.863987 -0.115998

In [48]: df.loc[a < df['a']]  # same as the previous expression
Out[48]:
   a  b
0 0.863987 -0.115998

2.21. Enhancing performance
With `pandas.eval()` you cannot use the @ prefix at all, because it isn’t defined in that context. `pandas` will let you know this if you try to use @ in a top-level call to `pandas.eval()`. For example,

```
In [49]: a, b = 1, 2
In [50]: pd.eval('@a + b')
Traceback (most recent call last):
  File "/opt/conda/envs/pandas/lib/python3.8/site-packages/IPython/core/万户\interactiveshell.py", line 3418, in run_code
    exec(code_obj, self.user_global_ns, self.user_ns)
  File "<ipython-input-50-af17947a194f>", line 1, in <module>
    pd.eval('@a + b')
  File "/pandas/pandas/core/computation/eval.py", line 330, in eval
    _check_for_locals(expr, level, parser)
  File "/pandas/pandas/core/computation/eval.py", line 158, in _check_for_locals
    raise SyntaxError(msg)
  File "<string>", line unknown
SyntaxError: The '@' prefix is not allowed in top-level eval calls. Please refer to your variables by name without the '@' prefix.
```

In this case, you should simply refer to the variables like you would in standard Python.

```
In [51]: pd.eval('a + b')
Out[51]: 3
```

`pandas.eval() parsers`

There are two different parsers and two different engines you can use as the backend.

The default 'pandas' parser allows a more intuitive syntax for expressing query-like operations (comparisons, conjunctions and disjunctions). In particular, the precedence of the & and | operators is made equal to the precedence of the corresponding boolean operations and or.

For example, the above conjunction can be written without parentheses. Alternatively, you can use the 'python' parser to enforce strict Python semantics.

```
In [52]: expr = '(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)'
In [53]: x = pd.eval(expr, parser='python')
In [54]: expr_no_parens = 'df1 > 0 & df2 > 0 & df3 > 0 & df4 > 0'
In [55]: y = pd.eval(expr_no_parens, parser='pandas')
In [56]: np.all(x == y)
Out[56]: True
```

The same expression can be “anded” together with the word and as well:

```
In [57]: expr = '(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)'
In [58]: x = pd.eval(expr, parser='python')
```
In [59]: expr_with_ands = 'df1 > 0 and df2 > 0 and df3 > 0 and df4 > 0'
In [60]: y = pd.eval(expr_with_ands, parser='pandas')
In [61]: np.all(x == y)
Out[61]: True

The and and or operators here have the same precedence that they would in vanilla Python.

**pandas.eval() backends**

There’s also the option to make eval() operate identical to plain ol’ Python.

**Note:** Using the 'python' engine is generally not useful, except for testing other evaluation engines against it. You will achieve no performance benefits using eval() with engine='python' and in fact may incur a performance hit.

You can see this by using pandas.eval() with the 'python' engine. It is a bit slower (not by much) than evaluating the same expression in Python.

In [62]: %timeit df1 + df2 + df3 + df4
   13.1 ms +- 23.8 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [63]: %timeit pd.eval('df1 + df2 + df3 + df4', engine='python')
   14 ms +- 67 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

**pandas.eval() performance**

eval() is intended to speed up certain kinds of operations. In particular, those operations involving complex expressions with large DataFrame/Series objects should see a significant performance benefit. Here is a plot showing the running time of pandas.eval() as function of the size of the frame involved in the computation. The two lines are two different engines.
Note: Operations with smallish objects (around 15k-20k rows) are faster using plain Python:

This plot was created using a DataFrame with 3 columns each containing floating point values generated using numpy.random.randn().
Technical minutia regarding expression evaluation

Expressions that would result in an object dtype or involve datetime operations (because of NaT) must be evaluated in Python space. The main reason for this behavior is to maintain backwards compatibility with versions of NumPy < 1.7. In those versions of NumPy a call to `ndarray.astype(str)` will truncate any strings that are more than 60 characters in length. Second, we can’t pass object arrays to `numexpr` thus string comparisons must be evaluated in Python space.

The upshot is that this only applies to object-dtype expressions. So, if you have an expression— for example

```python
In [64]: df = pd.DataFrame({'strings': np.repeat(list('cba'), 3),
   ....:                      'nums': np.repeat(range(3), 3)})
   ....:   ....:
In [65]: df
Out[65]:
   strings  nums
0        c    0
1        c    0
2        c    0
3        b    1
4        b    1
5        b    1
6        a    2
7        a    2
8        a    2
```

the numeric part of the comparison (`nums == 1`) will be evaluated by `numexpr`.

In general, `DataFrame.query()` / `pandas.eval()` will evaluate the subexpressions that can be evaluated by `numexpr` and those that must be evaluated in Python space transparently to the user. This is done by inferring the result type of an expression from its arguments and operators.

### 2.22 Scaling to large datasets

Pandas provides data structures for in-memory analytics, which makes using pandas to analyze datasets that are larger than memory datasets somewhat tricky. Even datasets that are a sizable fraction of memory become unwieldy, as some pandas operations need to make intermediate copies.

This document provides a few recommendations for scaling your analysis to larger datasets. It’s a complement to Enhancing performance, which focuses on speeding up analysis for datasets that fit in memory.

But first, it’s worth considering not using pandas. Pandas isn’t the right tool for all situations. If you’re working with very large datasets and a tool like PostgreSQL fits your needs, then you should probably be using that. Assuming you want or need the expressiveness and power of pandas, let’s carry on.

```python
In[1]: import pandas as pd
In[2]: import numpy as np
```

2.22. Scaling to large datasets
### 2.22.1 Load less data

Suppose our raw dataset on disk has many columns:

<table>
<thead>
<tr>
<th>id_0</th>
<th>name_0</th>
<th>x_0</th>
<th>y_0</th>
<th>id_1</th>
<th>name_1</th>
<th>x_1</th>
<th>y_1</th>
<th>timestamp</th>
<th>id_0</th>
<th>name_0</th>
<th>x_0</th>
<th>y_0</th>
<th>id_1</th>
<th>name_1</th>
<th>x_1</th>
<th>y_1</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

To load the columns we want, we have two options. Option 1 loads in all the data and then filters to what we need.

```python
In [3]: columns = ['id_0', 'name_0', 'x_0', 'y_0']

In [4]: pd.read_parquet("timeseries_wide.parquet")[columns]
```

```sql
Out [4]:
```

### Option 2 only loads the columns we request.

```python
In [5]: pd.read_parquet("timeseries_wide.parquet", columns=columns)
```

```sql
Out [5]:
```
If we were to measure the memory usage of the two calls, we’d see that specifying `columns` uses about 1/10th the memory in this case.

With `pandas.read_csv()`, you can specify `usecols` to limit the columns read into memory. Not all file formats that can be read by pandas provide an option to read a subset of columns.

### 2.22.2 Use efficient datatypes

The default pandas data types are not the most memory efficient. This is especially true for text data columns with relatively few unique values (commonly referred to as “low-cardinality” data). By using more efficient data types, you can store larger datasets in memory.

```
In [6]: ts = pd.read_parquet("timeseries.parquet")
In [7]: ts
Out[7]:
     id   name   x     y
timestamp
2000-01-01 00:00:00 1029   Michael  0.278837  0.247932
2000-01-01 00:00:30 1010  Patricia  0.077144  0.490260
2000-01-01 00:01:00 1001   Victor  0.214525  0.258635
2000-01-01 00:01:30 1018    Alice -0.646866  0.822104
2000-01-01 00:02:00 991     Dan  0.902389  0.466665
...       ...   ...    ...  ...
2000-12-30 23:58:00 992   Sarah  0.721155  0.944118
2000-12-30 23:58:30 1007  Ursula  0.409277  0.133227
2000-12-30 23:59:00 1009  Hannah -0.452802  0.184318
2000-12-30 23:59:30 978    Kevin -0.904728 -0.179146
2000-12-31 00:00:00 973  Ingrid -0.370763 -0.794667
[1051201 rows x 4 columns]
```

Now, let’s inspect the data types and memory usage to see where we should focus our attention.

```
In [8]: ts.dtypes
Out[8]:
    id     int64
  name   object
     x    float64
(continues on next page)
The `name` column is taking up much more memory than any other. It has just a few unique values, so it’s a good candidate for converting to a `Categorical`. With a Categorical, we store each unique name once and use space-efficient integers to know which specific name is used in each row.

```python
In [10]: ts2 = ts.copy()
In [11]: ts2['name'] = ts2['name'].astype('category')
In [12]: ts2.memory_usage(deep=True)
```

We can go a bit further and downcast the numeric columns to their smallest types using `pandas.to_numeric()`.

```python
In [13]: ts2['id'] = pd.to_numeric(ts2['id'], downcast='unsigned')
In [14]: ts2[['x', 'y']] = ts2[['x', 'y']].apply(pd.to_numeric, downcast='float')
In [15]: ts2.dtypes
```

```python
In [16]: ts2.memory_usage(deep=True)
```

```python
In [17]: reduction = (ts2.memory_usage(deep=True).sum() / ts.memory_usage(deep=True).sum())
.....:
```
In all, we’ve reduced the in-memory footprint of this dataset to 1/5 of its original size.

See \textit{Categorical data} for more on \textit{Categorical} and \textit{dtypes} for an overview of all of pandas’ dtypes.

### 2.22.3 Use chunking

Some workloads can be achieved with chunking: splitting a large problem like \textit{“convert this directory of CSVs to parquet”} into a bunch of small problems (\textit{“convert this individual CSV file into a Parquet file. Now repeat that for each file in this directory.”}). As long as each chunk fits in memory, you can work with datasets that are much larger than memory.

\textbf{Note:} Chunking works well when the operation you’re performing requires zero or minimal coordination between chunks. For more complicated workflows, you’re better off \textit{using another library}.

Suppose we have an even larger \textit{“logical dataset”} on disk that’s a directory of parquet files. Each file in the directory represents a different year of the entire dataset.

Now we’ll implement an out-of-core \texttt{value_counts}. The peak memory usage of this workflow is the single largest chunk, plus a small series storing the unique value counts up to this point. As long as each individual file fits in memory, this will work for arbitrary-sized datasets.

```python
In [19]: %%time
.....: files = pathlib.Path("data/timeseries/").glob("ts*.parquet")
.....: counts = pd.Series(dtype=int)
.....: for path in files:
.....:     df = pd.read_parquet(path)
.....:     counts = counts.add(df['name'].value_counts(), fill_value=0)
.....:     counts.astype(int)
.....:
CPU times: user 842 ms, sys: 80.9 ms, total: 923 ms
Wall time: 686 ms
Out[19]:
Alice    229802
Bob      229211
```
Some readers, like `pandas.read_csv()`, offer parameters to control the `chunksize` when reading a single file. Manually chunking is an OK option for workflows that don’t require too sophisticated of operations. Some operations, like `groupby`, are much harder to do chunkwise. In these cases, you may be better switching to a different library that implements these out-of-core algorithms for you.

### 2.22.4 Use other libraries

Pandas is just one library offering a DataFrame API. Because of its popularity, pandas’ API has become something of a standard that other libraries implement. The pandas documentation maintains a list of libraries implementing a DataFrame API in our ecosystem page.

For example, Dask, a parallel computing library, has `dask.dataframe`, a pandas-like API for working with larger than memory datasets in parallel. Dask can use multiple threads or processes on a single machine, or a cluster of machines to process data in parallel.

We’ll import `dask.dataframe` and notice that the API feels similar to pandas. We can use Dask’s `read_parquet` function, but provide a globstring of files to read in.

```python
In [20]: import dask.dataframe as dd
In [21]: ddf = dd.read_parquet("data/timeseries/ts*.parquet", engine="pyarrow")
In [22]: ddf
```

```text
Out[22]:
Dask DataFrame Structure:
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>x</th>
<th>y</th>
</tr>
</thead>
<tbody>
<tr>
<td>npartitions=12</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>int64</td>
<td>object</td>
<td>float64</td>
<td>float64</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>Dask Name: read-parquet, 12 tasks</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Inspecting the `ddf` object, we see a few things:

- There are familiar attributes like `.columns` and `.dtypes`
- There are familiar methods like `.groupby`, `.sum`, etc.
- There are new attributes like `.npartitions` and `.divisions`

The partitions and divisions are how Dask parallelizes computation. A Dask DataFrame is made up of many Pandas DataFrames. A single method call on a Dask DataFrame ends up making many pandas method calls, and Dask knows how to coordinate everything to get the result.
One major difference: the `dask.dataframe` API is lazy. If you look at the repr above, you’ll notice that the values aren’t actually printed out; just the column names and dtypes. That’s because Dask hasn’t actually read the data yet. Rather than executing immediately, doing operations build up a task graph.

Each of these calls is instant because the result isn’t being computed yet. We’re just building up a list of computation to do when someone needs the result. Dask knows that the return type of a `pandas.Series.value_counts` is a pandas Series with a certain dtype and a certain name. So the Dask version returns a Dask Series with the same dtype and the same name.

To get the actual result you can call `.compute()`.
In [29]: %time ddf['name'].value_counts().compute()
CPU times: user 926 ms, sys: 118 ms, total: 1.04 s
Wall time: 729 ms
Out[29]:
Laura 230906
Ingrid 230838
Kevin 230698
Dan 230621
Frank 230595
... 
Ray 229603
Xavier 229553
Charlie 229303
Bob 229211
Yvonne 228766
Name: name, Length: 26, dtype: int64

At that point, you get back the same thing you’d get with pandas, in this case a concrete pandas Series with the count of each name.

Calling `.compute` causes the full task graph to be executed. This includes reading the data, selecting the columns, and doing the `value_counts`. The execution is done in parallel where possible, and Dask tries to keep the overall memory footprint small. You can work with datasets that are much larger than memory, as long as each partition (a regular pandas DataFrame) fits in memory.

By default, `dask.dataframe` operations use a threadpool to do operations in parallel. We can also connect to a cluster to distribute the work on many machines. In this case we’ll connect to a local “cluster” made up of several processes on this single machine.

```
>>> from dask.distributed import Client, LocalCluster

>>> cluster = LocalCluster()

>>> client = Client(cluster)

>>> client
<Client: 'tcp://127.0.0.1:53349' processes=4 threads=8, memory=17.18 GB>
```

Once this `client` is created, all of Dask’s computation will take place on the cluster (which is just processes in this case).

Dask implements the most used parts of the pandas API. For example, we can do a familiar groupby aggregation.

```
In [30]: %time ddf.groupby('name')[['x', 'y']].mean().compute().head()
CPU times: user 1.7 s, sys: 226 ms, total: 1.92 s
Wall time: 1.01 s
Out[30]:
     x      y
name
Alice 0.000086 -0.001170
Bob -0.000843 -0.000799
Charlie 0.000564 -0.000038
Dan  0.000584  0.000818
Edith -0.000116 -0.000044
```

The grouping and aggregation is done out-of-core and in parallel.

When Dask knows the divisions of a dataset, certain optimizations are possible. When reading parquet datasets written by dask, the divisions will be known automatically. In this case, since we created the parquet files manually, we need to supply the divisions manually.
In [31]: N = 12
In [32]: starts = [f'20\{i+1\}:02d-01-01' for i in range(N)]
In [33]: ends = [f'20\{i+1\}:02d-12-13' for i in range(N)]
In [34]: divisions = tuple(pd.to_datetime(starts)) + (pd.Timestamp(ends[-1]),)
In [35]: ddf.divisions = divisions
In [36]: ddf
Out[36]:
Dask DataFrame Structure:
   id  name  x    y
npartitions=12
2000-01-01 int64 object float64 float64
2001-01-01  ...  ...  ...  ...
...  ...  ...  ...
2011-01-01  ...  ...  ...  ...
2011-12-13  ...  ...  ...  ...
Dask Name: read-parquet, 12 tasks

Now we can do things like fast random access with .loc.

In [37]: ddf.loc['2002-01-01 12:01':'2002-01-01 12:05'].compute()
Out[37]:
   id  name   x    y
timestamp
2002-01-01 12:01:00  983  Laura  0.243985 -0.079392
2002-01-01 12:02:00  1001 Laura  -0.523119 -0.226026
2002-01-01 12:03:00  1059 Oliver  0.612886  0.405680
2002-01-01 12:04:00  993  Kevin  0.451977  0.332947
2002-01-01 12:05:00  1014 Yvonne -0.948681  0.361748

Dask knows to just look in the 3rd partition for selecting values in 2002. It doesn’t need to look at any other data.

Many workflows involve a large amount of data and processing it in a way that reduces the size to something that fits in memory. In this case, we’ll resample to daily frequency and take the mean. Once we’ve taken the mean, we know the results will fit in memory, so we can safely call compute without running out of memory. At that point it’s just a regular pandas object.

In [38]: ddf[['x', 'y']].resample("1D").mean().cumsum().compute().plot()
These Dask examples have all be done using multiple processes on a single machine. Dask can be deployed on a cluster to scale up to even larger datasets.

You see more dask examples at https://examples.dask.org.

2.23 Sparse data structures

Pandas provides data structures for efficiently storing sparse data. These are not necessarily sparse in the typical “mostly 0”. Rather, you can view these objects as being “compressed” where any data matching a specific value (NaN / missing value, though any value can be chosen, including 0) is omitted. The compressed values are not actually stored in the array.

```
In [1]: arr = np.random.randn(10)
In [2]: arr[2:-2] = np.nan
In [3]: ts = pd.Series(pd.arrays.SparseArray(arr))
In [4]: ts
Out[4]:
   0   0.469112
   1  -0.282863
   2    NaN
```

(continues on next page)
Notice the dtype, Sparse[float64, nan]. The nan means that elements in the array that are nan aren’t actually stored, only the non-nan elements are. Those non-nan elements have a float64 dtype.

The sparse objects exist for memory efficiency reasons. Suppose you had a large, mostly NA DataFrame:

```
In [5]: df = pd.DataFrame(np.random.randn(10000, 4))
In [6]: df.iloc[:9998] = np.nan
In [7]: sdf = df.astype(pd.SparseDtype("float", np.nan))
In [8]: sdf.head()
Out[8]:
   0  1  2  3
0  NaN NaN NaN NaN
1  NaN NaN NaN NaN
2  NaN NaN NaN NaN
3  NaN NaN NaN NaN
4  NaN NaN NaN NaN

In [9]: sdf.dtypes
Out[9]:
0  Sparse[float64, nan]
1  Sparse[float64, nan]
2  Sparse[float64, nan]
3  Sparse[float64, nan]
dtype: object

In [10]: sdf.sparse.density
Out[10]: 0.0002
```

As you can see, the density (% of values that have not been “compressed”) is extremely low. This sparse object takes up much less memory on disk (pickled) and in the Python interpreter.

```
In [11]: 'dense: {:.2f} bytes'.format(df.memory_usage().sum() / 1e3)
Out[11]: 'dense: 320.13 bytes'

In [12]: 'sparse: {:.2f} bytes'.format(sdf.memory_usage().sum() / 1e3)
Out[12]: 'sparse: 0.22 bytes'
```

Functionally, their behavior should be nearly identical to their dense counterparts.
2.23.1 SparseArray

`arrays.SparseArray` is an `ExtensionArray` for storing an array of sparse values (see `dtypes` for more on extension arrays). It is a 1-dimensional ndarray-like object storing only values distinct from the `fill_value`:

```python
In [13]: arr = np.random.randn(10)
In [14]: arr[2:5] = np.nan
In [15]: arr[7:8] = np.nan
In [16]: sparr = pd.arrays.SparseArray(arr)
In [17]: sparr
```

```
Out[17]:
[-1.9556635297215477, -1.6588664275960427, nan, nan, nan, 1.1589328886422277, 0.14529711373305043, nan, 0.6060271905134522, 1.3342113401317768]
Fill: nan
IntIndex
Indices: array([0, 1, 5, 6, 8, 9], dtype=int32)
```

A sparse array can be converted to a regular (dense) ndarray with `numpy.asarray()`:

```python
In [18]: np.asarray(sparr)
```

```
Out[18]:
array([-1.9557, -1.6589, nan, nan, nan, 1.1589, 0.1453, nan, 0.606 , 1.3342])
```

2.23.2 SparseDtype

The `SparseArray.dtype` property stores two pieces of information:

1. The dtype of the non-sparse values
2. The scalar fill value

```python
In [19]: sparr.dtype
```

```
Out[19]: Sparse[uint8, nan]
```

A `SparseDtype` may be constructed by passing each of these:

```python
In [20]: pd.SparseDtype(np.dtype('datetime64[ns]'))
```

```
Out[20]: Sparse[datetime64[ns], NaT]
```

The default fill value for a given NumPy dtype is the “missing” value for that dtype, though it may be overridden:

```python
In [21]: pd.SparseDtype(np.dtype('datetime64[ns]'),
....: fill_value=pd.Timestamp('2017-01-01'))
```

```
Out[21]: Sparse[datetime64[ns], Timestamp('2017-01-01 00:00:00')]
```

Finally, the string alias `Sparse[dtype]` may be used to specify a sparse dtype in many places:

```python
In [22]: pd.array([[1, 0, 0, 2], dtype='Sparse[int]')
```

```
Out[22]:
[1, 0, 0, 2]
```
2.23.3 Sparse accessor

New in version 0.24.0.

Pandas provides a `.sparse` accessor, similar to `.str` for string data, `.cat` for categorical data, and `.dt` for datetime-like data. This namespace provides attributes and methods that are specific to sparse data.

```python
In [23]: s = pd.Series([0, 0, 1, 2], dtype="Sparse[int"]")
In [24]: s.sparse.density
Out[24]: 0.5
In [25]: s.sparse.fill_value
Out[25]: 0
```

This accessor is available only on data with `SparseDtype`, and on the `Series` class itself for creating a Series with sparse data from a scipy COO matrix with.

New in version 0.25.0.

A `.sparse` accessor has been added for `DataFrame` as well. See `Sparse accessor` for more.

2.23.4 Sparse calculation

You can apply NumPy `ufuncs` to `SparseArray` and get a `SparseArray` as a result.

```python
In [26]: arr = pd.arrays.SparseArray([1., np.nan, np.nan, -2., np.nan])
In [27]: np.abs(arr)
Out[27]: [1.0, nan, nan, 2.0, nan]
Fill: nan
IntIndex
Indices: array([0, 3], dtype=int32)
```

The `ufunc` is also applied to `fill_value`. This is needed to get the correct dense result.

```python
In [28]: arr = pd.arrays.SparseArray([1., -1, -1, -2., -1], fill_value=-1)
In [29]: np.abs(arr)
Out[29]: [1.0, 1, 1, 2.0, 1]
Fill: 1
IntIndex
Indices: array([0, 3], dtype=int32)
```

```python
In [30]: np.abs(arr).to_dense()
Out[30]: array([1., 1., 1., 2., 1.])
```
2.23.5 Migrating

Note: SparseSeries and SparseDataFrame were removed in pandas 1.0.0. This migration guide is present to aid in migrating from previous versions.

In older versions of pandas, the SparseSeries and SparseDataFrame classes (documented below) were the preferred way to work with sparse data. With the advent of extension arrays, these subclasses are no longer needed. Their purpose is better served by using a regular Series or DataFrame with sparse values instead.

Note: There’s no performance or memory penalty to using a Series or DataFrame with sparse values, rather than a SparseSeries or SparseDataFrame.

This section provides some guidance on migrating your code to the new style. As a reminder, you can use the python warnings module to control warnings. But we recommend modifying your code, rather than ignoring the warning.

Construction

From an array-like, use the regular Series or DataFrame constructors with SparseArray values.

```
# Previous way
>>> pd.SparseDataFrame({'A': [0, 1]})
```

```
# New way
In [31]: pd.DataFrame({'A': pd.arrays.SparseArray([0, 1])})
Out[31]:
   A
0  0
1  1
```

From a SciPy sparse matrix, use DataFrame.sparse.from_spmatrix().

```
# Previous way
>>> from scipy import sparse
>>> mat = sparse.eye(3)
>>> df = pd.SparseDataFrame(mat, columns=['A', 'B', 'C'])
```

```
# New way
In [32]: from scipy import sparse
In [33]: mat = sparse.eye(3)
In [34]: df = pd.DataFrame.sparse.from_spmatrix(mat, columns=['A', 'B', 'C'])
In [35]: df.dtypes
Out[35]:
   A  Sparse[<class 'float64'>, 0]
   B  Sparse[<class 'float64'>, 0]
   C  Sparse[<class 'float64'>, 0]
 dtype: object
```

Conversion

From sparse to dense, use the .sparse accessors
In [36]: df.sparse.to_dense()
Out[36]:
      A  B  C
0  1.0  0.0  0.0
1  0.0  1.0  0.0
2  0.0  0.0  1.0

In [37]: df.sparse.to_coo()
Out[37]:
<3x3 sparse matrix of type '<class 'numpy.float64'>'
    with 3 stored elements in COOrdinate format>

From dense to sparse, use DataFrame.astype() with a SparseDtype.

In [38]: dense = pd.DataFrame({"A": [1, 0, 0, 1]})
In [39]: dtype = pd.SparseDtype(int, fill_value=0)
In [40]: dense.astype(dtype)
Out[40]:
   A
0  1
1  0
2  0
3  1

Sparse Properties

Sparse-specific properties, like density, are available on the .sparse accessor.

In [41]: df.sparse.density
Out[41]: 0.3333333333333333

General differences

In a SparseDataFrame, all columns were sparse. A DataFrame can have a mixture of sparse and dense columns. As a consequence, assigning new columns to a DataFrame with sparse values will not automatically convert the input to be sparse.

# Previous Way
>>> df = pd.SparseDataFrame({"A": [0, 1]})
>>> df["B"] = [0, 0]  # implicitly becomes Sparse
>>> df["B"].dtype
Sparse[int64, nan]

Instead, you’ll need to ensure that the values being assigned are sparse

In [42]: df = pd.DataFrame({"A": pd.arrays.SparseArray([0, 1])})
In [43]: df["B"] = [0, 0]  # remains dense
In [44]: df["B"].dtype
Out[44]: dtype('int64')
In [45]: df["B"] = pd.arrays.SparseArray([0, 0])
In [46]: df["B"].dtype
Out[46]: Sparse[int64, 0]

2.23. Sparse data structures
The `SparseDataFrame.default_kind` and `SparseDataFrame.default_fill_value` attributes have no replacement.

2.23.6 Interaction with scipy.sparse

Use `DataFrame.sparse.from_spmatrix()` to create a `DataFrame` with sparse values from a sparse matrix. New in version 0.25.0.

```python
In [47]: from scipy.sparse import csr_matrix

In [48]: arr = np.random.random(size=(1000, 5))

In [49]: arr[arr < .9] = 0

In [50]: sp_arr = csr_matrix(arr)

In [51]: sp_arr
Out[51]:
<1000x5 sparse matrix of type '<class 'numpy.float64'>'
 with 517 stored elements in Compressed Sparse Row format>

In [52]: sdf = pd.DataFrame.sparse.from_spmatrix(sp_arr)

In [53]: sdf.head()
Out[53]:
        0    1    2    3    4
0  0.956380  0.0  0.0  0.0  0.0
1  0.000000  0.0  0.0  0.0  0.0
2  0.000000  0.0  0.0  0.0  0.0
3  0.000000  0.0  0.0  0.0  0.0
4  0.999552  0.0  0.0  0.956153  0.0

In [54]: sdf.dtypes
Out[54]:
0    Sparse[float64, 0]
1    Sparse[float64, 0]
2    Sparse[float64, 0]
3    Sparse[float64, 0]
4    Sparse[float64, 0]
dtype: object
```

All sparse formats are supported, but matrices that are not in `COOrdinate` format will be converted, copying data as needed. To convert back to sparse SciPy matrix in COO format, you can use the `DataFrame.sparse.to_coo()` method:

```python
In [55]: sdf.sparse.to_coo()
Out[55]:
<1000x5 sparse matrix of type '<class 'numpy.float64'>'
 with 517 stored elements in COOrdinate format>
```

`Series.sparse.to_coo` is implemented for transforming a `Series` with sparse values indexed by a `MultiIndex` to a `scipy.sparse.coo_matrix`.

The method requires a `MultiIndex` with two or more levels.
In [56]: s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])

In [57]: s.index = pd.MultiIndex.from_tuples([(1, 2, 'a', 0),
                                             (1, 2, 'a', 1),
                                             (1, 1, 'b', 0),
                                             (1, 1, 'b', 1),
                                             (2, 1, 'b', 0),
                                             (2, 1, 'b', 1)],
                                             names=['A', 'B', 'C', 'D'])

In [58]: s
Out[58]:
    A B C D
0  1 2 a 0  3.0
     1  NaN
1  1  b 0  1.0
     2  3.0
2  2  b 0  NaN
     1  NaN
dtype: float64

In [59]: ss = s.astype('Sparse')

In [60]: ss
Out[60]:
    A B C D
0  1 2 a 0  3.0
     1  NaN
1  1  b 0  1.0
     2  3.0
2  2  b 0  NaN
     1  NaN
dtype: Sparse[Float64, nan]

In the example below, we transform the Series to a sparse representation of a 2-d array by specifying that the first and second MultiIndex levels define labels for the rows and the third and fourth levels define labels for the columns. We also specify that the column and row labels should be sorted in the final sparse representation.

In [61]: A, rows, columns = ss.sparse.to_coo(row_levels=['A', 'B'],
                                           column_levels=['C', 'D'],
                                           sort_labels=True)

In [62]: A
Out[62]:
<3x4 sparse matrix of type 'class 'numpy.float64''
    with 3 stored elements in COOrdinate format>

In [63]: A.todense()
Out[63]:
matrix([[0., 0., 1., 3.],
        [3., 0., 0., 0.],
        [0., 0., 0., 0.]])

In [64]: rows
Out[64]: [(1, 1), (1, 2), (2, 1)]

(continues on next page)
In [65]: columns
Out[65]: [('a', 0), ('a', 1), ('b', 0), ('b', 1)]

Specifying different row and column labels (and not sorting them) yields a different sparse matrix:

In [66]: A, rows, columns = ss.sparse.to_coo(row_levels=['A', 'B', 'C'], 
       column_levels=['D'], 
       sort_labels=False)

In [67]: A
Out[67]:
<3x2 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>

In [68]: A.todense()
Out[68]:
matrix([[3., 0.],
        [1., 3.],
        [0., 0.]])

In [69]: rows
Out[69]: [(1, 2, 'a'), (1, 1, 'b'), (2, 1, 'b')]

In [70]: columns
Out[70]: [0, 1]

A convenience method Series.sparse.from_coo() is implemented for creating a Series with sparse values from a scipy.sparse.coo_matrix.

In [71]: from scipy import sparse

In [72]: A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])), 
                              shape=(3, 4))

In [73]: A
Out[73]:
<3x4 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>

In [74]: A.todense()
Out[74]:
matrix([[3., 0., 1., 2.],
        [0., 0., 0., 0.],
        [0., 0., 0., 0.]])

The default behaviour (with dense_index=False) simply returns a Series containing only the non-null entries.

In [75]: ss = pd.Series.sparse.from_coo(A)

In [76]: ss
Out[76]:
0  2  1.0
3  2.0
Specifying `dense_index=True` will result in an index that is the Cartesian product of the row and columns coordinates of the matrix. Note that this will consume a significant amount of memory (relative to `dense_index=False`) if the sparse matrix is large (and sparse) enough.

```python
In [77]: ss_dense = pd.Series.sparse.from_coo(A, dense_index=True)
In [78]: ss_dense
Out[78]:
0 0  NaN
1  NaN
2 1.0
3 2.0
1 0  3.0
1  NaN
2  NaN
3  NaN
2 0  NaN
1  NaN
2  NaN
3  NaN
dtype: Sparse[Float64, nan]
```

## 2.24 Frequently Asked Questions (FAQ)

### 2.24.1 DataFrame memory usage

The memory usage of a DataFrame (including the index) is shown when calling the `info()`. A configuration option, `display.memory_usage` (see the list of options), specifies if the DataFrame’s memory usage will be displayed when invoking the `df.info()` method.

For example, the memory usage of the DataFrame below is shown when calling `info()`:

```python
In [1]: dtypes = ['int64', 'float64', 'datetime64[ns]', 'timedelta64[ns]',
            'complex128', 'object', 'bool']

In [2]: n = 5000

In [3]: data = {t: np.random.randint(100, size=n).astype(t) for t in dtypes}

In [4]: df = pd.DataFrame(data)

In [5]: df['categorical'] = df['object'].astype('category')

In [6]: df.info()
<...>
```

(continues on next page)
The + symbol indicates that the true memory usage could be higher, because pandas does not count the memory used by values in columns with `dtype=object`.

Passing `memory_usage='deep'` will enable a more accurate memory usage report, accounting for the full usage of the contained objects. This is optional as it can be expensive to do this deeper introspection.

```
In [7]: df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
   # Column     Non-Null Count   Dtype
     ---         --------------   ------
0   int64      5000 non-null   int64
1   float64    5000 non-null   float64
2   datetime64[ns]  5000 non-null   datetime64[ns]
3   timedelta64[ns]  5000 non-null   timedelta64[ns]
4   complex128  5000 non-null   complex128
5   object     5000 non-null   object
6   bool       5000 non-null   bool
7   categorical 5000 non-null  category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1),
       object(1), timedelta64[ns](1)
memory usage: 289.1+ KB
```

By default the display option is set to `True` but can be explicitly overridden by passing the `memory_usage` argument when invoking `df.info()`.

The memory usage of each column can be found by calling the `memory_usage()` method. This returns a Series with an index represented by column names and memory usage of each column shown in bytes. For the `DataFrame` above, the memory usage of each column and the total memory usage can be found with the `memory_usage` method:

```
In [8]: df.memory_usage()
Out[8]:
Index       128
int64      40000
float64    40000
datetime64[ns]  40000
timedelta64[ns]  40000
complex128  80000
object      40000
bool        5000
categorical 10920
dtype: int64
# total memory usage of dataframe
```

(continues on next page)
In [9]: df.memory_usage().sum()
Out[9]: 296048

By default the memory usage of the DataFrame’s index is shown in the returned Series, the memory usage of the index can be suppressed by passing the index=False argument:

In [10]: df.memory_usage(index=False)
Out[10]:
int64 40000
float64 40000
datetime64[ns] 40000
timedelta64[ns] 40000
complex128 80000
object 40000
bool 5000
categorical 10920
dtype: int64

The memory usage displayed by the info() method utilizes the memory_usage() method to determine the memory usage of a DataFrame while also formatting the output in human-readable units (base-2 representation; i.e. 1KB = 1024 bytes).

See also Categorical Memory Usage.

2.24.2 Using if/truth statements with pandas

pandas follows the NumPy convention of raising an error when you try to convert something to a bool. This happens in an if-statement or when using the boolean operations: and, or, and not. It is not clear what the result of the following code should be:

```python
>>> if pd.Series([False, True, False]):
...       pass
```

Should it be True because it’s not zero-length, or False because there are False values? It is unclear, so instead, pandas raises a ValueError:

```python
>>> if pd.Series([False, True, False]):
...       print("I was true")
Traceback
...       ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

You need to explicitly choose what you want to do with the DataFrame, e.g. use any(), all() or empty(). Alternatively, you might want to compare if the pandas object is None:

```python
>>> if pd.Series([False, True, False]) is not None:
...       print("I was not None")
I was not None
```

Below is how to check if any of the values are True:

```python
>>> if pd.Series([False, True, False]).any():
...       print("I am any")
I am any
```

To evaluate single-element pandas objects in a boolean context, use the method bool():

2.24. Frequently Asked Questions (FAQ)
Bitwise boolean

Bitwise boolean operators like `==` and `!=` return a boolean `Series`, which is almost always what you want anyways.

```python
>>> s = pd.Series(range(5))
>>> s == 4
0    False
1    False
2    False
3    False
4     True
dtype: bool
```

See `boolean comparisons` for more examples.

Using the `in` operator

Using the Python `in` operator on a `Series` tests for membership in the index, not membership among the values.

```python
In [15]: s = pd.Series(range(5), index=list('abcde'))
In [16]: 2 in s
Out[16]: False
In [17]: 'b' in s
Out[17]: True
```

If this behavior is surprising, keep in mind that using `in` on a Python dictionary tests keys, not values, and `Series` are dict-like. To test for membership in the values, use the method `isin()`:

```python
In [18]: s.isin([2])
Out[18]:
   a  False
   b  False
   c   True
   d  False
   e  False
dtype: bool
In [19]: s.isin([2]).any()
Out[19]: True
```

For `DataFrames`, likewise, `in` applies to the column axis, testing for membership in the list of column names.
2.24.3 NaN, Integer NA values and NA type promotions

Choice of NA representation

For lack of NA (missing) support from the ground up in NumPy and Python in general, we were given the difficult choice between either:

- A masked array solution: an array of data and an array of boolean values indicating whether a value is there or is missing.
- Using a special sentinel value, bit pattern, or set of sentinel values to denote NA across the dtypes.

For many reasons we chose the latter. After years of production use it has proven, at least in my opinion, to be the best decision given the state of affairs in NumPy and Python in general. The special value NaN (Not-A-Number) is used everywhere as the NA value, and there are API functions `isna` and `notna` which can be used across the dtypes to detect NA values.

However, it comes with it a couple of trade-offs which I most certainly have not ignored.

Support for integer NA

In the absence of high performance NA support being built into NumPy from the ground up, the primary casualty is the ability to represent NAs in integer arrays. For example:

```
In [20]: s = pd.Series([1, 2, 3, 4, 5], index=list('abcde'))

In [21]: s
Out [21]:
     a  1
     b  2
     c  3
     d  4
     e  5
dtype: int64

In [22]: s.dtype
Out [22]: dtype('int64')

In [23]: s2 = s.reindex(['a', 'b', 'c', 'f', 'u'])

In [24]: s2
Out [24]:
     a  1.0
     b  2.0
     c  3.0
     f  NaN
     u  NaN
dtype: float64

In [25]: s2.dtype
Out [25]: dtype('float64')
```

This trade-off is made largely for memory and performance reasons, and also so that the resulting Series continues to be “numeric”.

If you need to represent integers with possibly missing values, use one of the nullable-integer extension dtypes provided by pandas.

2.24. Frequently Asked Questions (FAQ)
• `Int8Dtype`
• `Int16Dtype`
• `Int32Dtype`
• `Int64Dtype`

```
In [26]: s_int = pd.Series([1, 2, 3, 4, 5], index=list('abcde'),
                     dtype=pd.Int64Dtype())
....:
....:

In [27]: s_int
Out[27]:
a 1  
b 2  
c 3  
d 4  
e 5  
dtype: Int64

In [28]: s_int.dtype
Out[28]: Int64Dtype()

In [29]: s2_int = s_int.reindex(['a', 'b', 'c', 'f', 'u'])

In [30]: s2_int
Out[30]:
a 1  
b 2  
c 3  
f <NA> 
u <NA>
dtype: Int64

In [31]: s2_int.dtype
Out[31]: Int64Dtype()
```

See *Nullable integer data type* for more.

### NA type promotions

When introducing NAs into an existing `Series` or `DataFrame` via `reindex()` or some other means, boolean and integer types will be promoted to a different `dtype` in order to store the NAs. The promotions are summarized in this table:

<table>
<thead>
<tr>
<th>Typeclass</th>
<th>Promotion dtype for storing NAs</th>
</tr>
</thead>
<tbody>
<tr>
<td>floating</td>
<td>no change</td>
</tr>
<tr>
<td>object</td>
<td>no change</td>
</tr>
<tr>
<td>integer</td>
<td>cast to <code>float64</code></td>
</tr>
<tr>
<td>boolean</td>
<td>cast to <code>object</code></td>
</tr>
</tbody>
</table>

While this may seem like a heavy trade-off, I have found very few cases where this is an issue in practice i.e. storing values greater than $2^{**53}$. Some explanation for the motivation is in the next section.
Why not make NumPy like R?

Many people have suggested that NumPy should simply emulate the NA support present in the more domain-specific statistical programming language R. Part of the reason is the NumPy type hierarchy:

<table>
<thead>
<tr>
<th>Typeclass</th>
<th>Dtypes</th>
</tr>
</thead>
<tbody>
<tr>
<td>numpy.floating</td>
<td>float16, float32, float64, float128</td>
</tr>
<tr>
<td>numpy.integer</td>
<td>int8, int16, int32, int64</td>
</tr>
<tr>
<td>numpy.unsignedinteger</td>
<td>uint8, uint16, uint32, uint64</td>
</tr>
<tr>
<td>numpy.object_</td>
<td>object_</td>
</tr>
<tr>
<td>numpy.bool_</td>
<td>bool_</td>
</tr>
<tr>
<td>numpy.character</td>
<td>string_, unicode_</td>
</tr>
</tbody>
</table>

The R language, by contrast, only has a handful of built-in data types: integer, numeric (floating-point), character, and boolean. NA types are implemented by reserving special bit patterns for each type to be used as the missing value. While doing this with the full NumPy type hierarchy would be possible, it would be a more substantial trade-off (especially for the 8- and 16-bit data types) and implementation undertaking.

An alternate approach is that of using masked arrays. A masked array is an array of data with an associated boolean mask denoting whether each value should be considered NA or not. I am personally not in love with this approach as I feel that overall it places a fairly heavy burden on the user and the library implementer. Additionally, it exacts a fairly high performance cost when working with numerical data compared with the simple approach of using NaN. Thus, I have chosen the Pythonic “practicality beats purity” approach and traded integer NA capability for a much simpler approach of using a special value in float and object arrays to denote NA, and promoting integer arrays to floating when NAs must be introduced.

### 2.24.4 Differences with NumPy

For `Series` and `DataFrame` objects, `var()` normalizes by N–1 to produce unbiased estimates of the sample variance, while NumPy’s `var` normalizes by N, which measures the variance of the sample. Note that `cov()` normalizes by N–1 in both pandas and NumPy.

### 2.24.5 Thread-safety

As of pandas 0.11, pandas is not 100% thread safe. The known issues relate to the `copy()` method. If you are doing a lot of copying of `DataFrame` objects shared among threads, we recommend holding locks inside the threads where the data copying occurs.

See this link for more information.

### 2.24.6 Byte-ordering issues

Occasionally you may have to deal with data that were created on a machine with a different byte order than the one on which you are running Python. A common symptom of this issue is an error like:

```
Traceback
...  
ValueError: Big-endian buffer not supported on little-endian compiler
```

To deal with this issue you should convert the underlying NumPy array to the native system byte order before passing it to `Series` or `DataFrame` constructors using something similar to the following:
In [32]: x = np.array(list(range(10)), '>i4')  # big endian
In [33]: newx = x.byteswap().newbyteorder()  # force native byteorder
In [34]: s = pd.Series(newx)

See the NumPy documentation on byte order for more details.

## 2.25 Cookbook

This is a repository for short and sweet examples and links for useful pandas recipes. We encourage users to add to this documentation.

Adding interesting links and/or inline examples to this section is a great First Pull Request.

Simplified, condensed, new-user friendly, in-line examples have been inserted where possible to augment the StackOverflow and GitHub links. Many of the links contain expanded information, above what the in-line examples offer.

Pandas (pd) and Numpy (np) are the only two abbreviated imported modules. The rest are kept explicitly imported for newer users.

These examples are written for Python 3. Minor tweaks might be necessary for earlier python versions.

### 2.25.1 Idioms

These are some neat pandas idioms

- if-then/if-then-else on one column, and assignment to another one or more columns:

```python
In [1]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
                  ...: 'BBB': [10, 20, 30, 40],
                  ...: 'CCC': [100, 50, -30, -50]})

In [2]: df
Out[2]:
       AAA  BBB  CCC
0     4    10   100
1     5    20    50
2     6    30   -30
3     7    40   -50

if-then...
```

An if-then on one column

```python
In [3]: df.loc[df.AAA >= 5, 'BBB'] = -1
In [4]: df
Out[4]:
       AAA  BBB  CCC
0     4    10   100
1     5   -1    50
```

(continues on next page)
An if-then with assignment to 2 columns:

```python
In [5]: df.loc[df.AAA >= 5, ['BBB', 'CCC']] = 555
```

```python
In [6]: df
Out[6]:
   AAA  BBB  CCC
0    4   10  100
1    5   555  555
2    6   555  555
3    7   555  555
```

Add another line with different logic, to do the -else

```python
In [7]: df.loc[df.AAA < 5, ['BBB', 'CCC']] = 2000
```

```python
In [8]: df
Out[8]:
   AAA  BBB  CCC
0    4  2000  2000
1    5   555  555
2    6   555  555
3    7   555  555
```

Or use pandas where after you've set up a mask

```python
In [9]: df_mask = pd.DataFrame({'AAA': [True] * 4,
                             'BBB': [False] * 4,
                             'CCC': [True, False] * 2})
```

```python
In [10]: df.where(df_mask, -1000)
Out[10]:
   AAA  BBB  CCC
0    4 -1000  2000
1    5 -1000 -1000
2    6 -1000  555
3    7 -1000 -1000
```

If-then-else using numpy’s where()

```python
In [11]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
                        'BBB': [10, 20, 30, 40],
                        'CCC': [100, 50, -30, -50]})
```

```python
In [12]: df
Out[12]:
   AAA  BBB  CCC
0    4   10  100
1    5   20   50
2    6   30  -30
3    7   40  -50
```
Splitting

Split a frame with a boolean criterion

Building criteria

Select with multi-column criteria
[26x619]Out[21]:
0 4
1 5
Name: AAA, dtype: int64

...or (without assignment returns a Series)

In [22]: df.loc[(df['BBB'] > 25) | (df['CCC'] >= -40), 'AAA']
Out[22]:
0 4
1 5
2 6
3 7
Name: AAA, dtype: int64

...or (with assignment modifies the DataFrame.)

In [23]: df.loc[(df['BBB'] > 25) | (df['CCC'] >= 75), 'AAA'] = 0.1
In [24]: df
Out[24]:
   AAA  BBB  CCC
0  0.1  10  100
1  5.0  20   50
2  0.1  30 -30
3  0.1  40 -50

Select rows with data closest to certain value using argsort

In [25]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
                     'BBB': [10, 20, 30, 40],
                     'CCC': [100, 50, -30, -50]})
In [26]: df
Out[26]:
   AAA  BBB  CCC
0  4.0  10  100
1  5.0  20   50
2  6.0  30 -30
3  7.0  40 -50
In [27]: aValue = 43.0
In [28]: df.loc[(df.CCC - aValue).abs().argsort()]
Out[28]:
   AAA  BBB  CCC
1  5.0  20   50
0  4.0  10  100
2  6.0  30 -30
3  7.0  40 -50

2.25. Cookbook
Dynamically reduce a list of criteria using a binary operators

```
In [29]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
                        'BBB': [10, 20, 30, 40],
                        'CCC': [100, 50, -30, -50]})

In [30]: df
Out[30]:
AAA  BBB  CCC
---  ---  ---
0  4   10  100
1  5   20   50
2  6   30  -30
3  7   40  -50

In [31]: Crit1 = df.AAA <= 5.5
In [32]: Crit2 = df.BBB == 10.0
In [33]: Crit3 = df.CCC > -40.0

One could hard code:

```
In [34]: AllCrit = Crit1 & Crit2 & Crit3
```

...Or it can be done with a list of dynamically built criteria

```
In [35]: import functools
In [36]: CritList = [Crit1, Crit2, Crit3]
In [37]: AllCrit = functools.reduce(lambda x, y: x & y, CritList)
In [38]: df[AllCrit]
Out[38]:
AAA  BBB  CCC
---  ---  ---
0  4   10  100
```

### 2.25.2 Selection

**Dataframes**

The `indexing` docs.

Using both row labels and value conditionals

```
In [39]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
                        'BBB': [10, 20, 30, 40],
                        'CCC': [100, 50, -30, -50]})

In [40]: df
Out[40]:
AAA  BBB  CCC
---  ---  ---
0  4   10  100
1  5   20   50
```

(continues on next page)
2 6 30 -30
3 7 40 -50

In [41]: df[(df.AAA <= 6) & (df.index.isin([0, 2, 4]))]
Out[41]:
      AAA  BBB  CCC
0     4    10   100
2     6     30   -30

Use loc for label-oriented slicing and iloc positional slicing

In [42]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
   ....:                    'BBB': [10, 20, 30, 40],
   ....:                    'CCC': [100, 50, -30, -50],
   ....:                    index=['foo', 'bar', 'boo', 'kar'])

There are 2 explicit slicing methods, with a third general case
1. Positional-oriented (Python slicing style : exclusive of end)
2. Label-oriented (Non-Python slicing style : inclusive of end)
3. General (Either slicing style : depends on if the slice contains labels or positions)

In [43]: df.loc['bar':'kar']  # Label
Out[43]:
      AAA  BBB  CCC
bar    5    20   50
boo    6    30   -30
kar    7    40   -50

# Generic
In [44]: df[0:3]
Out[44]:
     AAA  BBB  CCC
foo    4    10   100
bar    5    20   50
boo    6    30   -30

In [45]: df['bar':'kar']
Out[45]:
     AAA  BBB  CCC
bar    5    20   50
boo    6    30   -30
kar    7    40   -50

Ambiguity arises when an index consists of integers with a non-zero start or non-unit increment.

In [46]: data = {'AAA': [4, 5, 6, 7],
   ....:             'BBB': [10, 20, 30, 40],
   ....:             'CCC': [100, 50, -30, -50]}
   ....:
In [47]: df2 = pd.DataFrame(data=data, index=[1, 2, 3, 4])  # Note index starts at 1.
In [48]: df2.iloc[1:3]  # Position-oriented
Out[48]:
   (continues on next page)
In [49]: df2.loc[1:3]  # label-oriented
Out[49]:
             AAA  BBB  CCC
    1       4     10    100
    2       5     20     50
    3       6     30    -30

Using inverse operator (~) to take the complement of a mask

In [50]: df = pd.DataFrame({'AAA': [4, 5, 6, 7],
                         'BBB': [10, 20, 30, 40],
                         'CCC': [100, 50, -30, -50]})

In [51]: df
Out[51]:
             AAA  BBB  CCC
    0       4     10    100
    1       5     20     50
    2       6     30    -30
    3       7     40    -50

In [52]: df[~((df.AAA <= 6) & (df.index.isin([0, 2, 4])))]
Out[52]:
             AAA  BBB  CCC
    1       5     20     50
    3       7     40    -50

New columns

Efficiently and dynamically creating new columns using applymap

In [53]: df = pd.DataFrame({'AAA': [1, 2, 1, 3],
                         'BBB': [1, 1, 2, 2],
                         'CCC': [2, 1, 3, 1]})

In [54]: df
Out[54]:
             AAA  BBB  CCC
    0       1     1     2
    1       2     1     1
    2       1     2     3
    3       3     2     1

In [55]: source_cols = df.columns  # or some subset would work too

In [56]: new_cols = [str(x) + "_cat" for x in source_cols]

In [57]: categories = {1: 'Alpha', 2: 'Beta', 3: 'Charlie'}

(continues on next page)
Keep other columns when using `min()` with `groupby`

```python
In [60]: df = pd.DataFrame({'AAA': [1, 1, 1, 2, 2, 2, 3, 3],
                      'BBB': [2, 1, 3, 4, 5, 1, 2, 3]})

In [61]: df
Out[61]:
   AAA  BBB
0   1   2
1   1   1
2   1   3
3   2   4
4   2   5
5   2   1
6   3   2
7   3   3
```

Method 1: `idxmin()` to get the index of the minimums

```python
In [62]: df.loc[df.groupby("AAA")["BBB"].idxmin()]
Out[62]:
   AAA  BBB
0   1   1
1   2   1
6   3   2
```

Method 2: sort then take first of each

```python
In [63]: df.sort_values(by="BBB").groupby("AAA", as_index=False).first()
Out[63]:
   AAA  BBB
0   1   1
1   2   1
2   3   2
```

Notice the same results, with the exception of the index.
2.25.3 Multiindexing

The *multindexing* docs.

Creating a MultiIndex from a labeled frame

```python
In [64]: df = pd.DataFrame({'row': [0, 1, 2],
                    ....:             'One_X': [1.1, 1.1, 1.1],
                    ....:             'One_Y': [1.2, 1.2, 1.2],
                    ....:             'Two_X': [1.11, 1.11, 1.11],
                    ....:             'Two_Y': [1.22, 1.22, 1.22])

In [65]: df
```

```
Out[65]:
row One_X One_Y Two_X Two_Y
0 0 1.1 1.2 1.11 1.22
1 1 1.1 1.2 1.11 1.22
2 2 1.1 1.2 1.11 1.22
```

# As Labelled Index

```python
In [66]: df = df.set_index('row')

In [67]: df
```

```
Out[67]:
One_X One_Y Two_X Two_Y
row
0 1.1 1.2 1.11 1.22
1 1.1 1.2 1.11 1.22
2 1.1 1.2 1.11 1.22
```

# With Hierarchical Columns

```python
In [68]: df.columns = pd.MultiIndex.from_tuples([tuple(c.split('_')) for c in df.columns])

In [69]: df
```

```
Out[69]:
One Two
X Y X Y
row
0 1.1 1.2 1.11 1.22
1 1.1 1.2 1.11 1.22
2 1.1 1.2 1.11 1.22
```

# Now stack & Reset

```python
In [70]: df = df.stack(0).reset_index(1)

In [71]: df
```

```
Out[71]:
level_1 X Y
row
0 One 1.10 1.20
0 Two 1.11 1.22
1 One 1.10 1.20
1 Two 1.11 1.22
2 One 1.10 1.20
2 Two 1.11 1.22
```

(continues on next page)
And fix the labels (Notice the label 'level_1' got added automatically)

```python
In [72]: df.columns = ['Sample', 'All_X', 'All_Y']
```

```python
In [73]: df
Out[73]:
   Sample  All_X  All_Y
  0   One    1.10  1.20
  0   Two    1.11  1.22
  1   One    1.10  1.20
  1   Two    1.11  1.22
  2   One    1.10  1.20
  2   Two    1.11  1.22
```

Arithmetic

Performing arithmetic with a MultiIndex that needs broadcasting

```python
In [74]: cols = pd.MultiIndex.from_tuples([(x, y) for x in ['A', 'B', 'C'] for y in ['O', 'I']])
In [75]: df = pd.DataFrame(np.random.randn(2, 6), index=['n', 'm'], columns=cols)
In [76]: df
Out[76]:
     A     B     C
   O I    O I    O I
n  0.469112 -0.282863 -1.509059 -1.135632 1.212112 -0.173215
m  0.119209 -1.044236 -0.861849 -2.104569 -0.494929 1.071804
```

Slicing

Slicing a MultiIndex with `xs`

```python
In [79]: coords = [('AA', 'one'), ('AA', 'six'), ('BB', 'one'), ('BB', 'two'), ('BB', 'six')]
In [80]: index = pd.MultiIndex.from_tuples(coords)
In [81]: df = pd.DataFrame([11, 22, 33, 44, 55], index, ['MyData'])
In [82]: df
```

(continues on next page)
To take the cross section of the 1st level and 1st axis the index:

```python
# Note : level and axis are optional, and default to zero
In [83]: df.xs('BB', level=0, axis=0)
Out[83]:
   MyData
   one 33
   two 44
   six 55
```

... and now the 2nd level of the 1st axis.

```python
In [84]: df.xs('six', level=1, axis=0)
Out[84]:
   MyData
   AA 22
   BB 55
```

Slicing a MultiIndex with xs, method #2

```python
In [85]: import itertools
In [86]: index = list(itertools.product(['Ada', 'Quinn', 'Violet'],
       ['Comp', 'Math', 'Sci']))
In [87]: headr = list(itertools.product(['Exams', 'Labs'], ['I', 'II']))
In [88]: indx = pd.MultiIndex.from_tuples(index, names=['Student', 'Course'])
In [89]: cols = pd.MultiIndex.from_tuples(headr) # Notice these are un-named
In [90]: data = [[70 + x + y + (x * y) % 3 for x in range(4)] for y in range(9)]
In [91]: df = pd.DataFrame(data, indx, cols)
In [92]: df
Out[92]:
     Exams  Labs
   I   II   I   II
Student Course
Ada Comp  70  71  72  73
    Math  71  73  75  74
    Sci   72  75  75  75
Quinn Comp  73  74  75  76
    Math  74  76  78  77
    Sci   75  78  78  78
Violet Comp  76  77  78  79
    Math  77  79  81  80
```

(continues on next page)
In [93]: All = slice(None)

In [94]: df.loc['Violet']
Out[94]:

<table>
<thead>
<tr>
<th></th>
<th>Exams</th>
<th>Labs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Course</td>
<td></td>

</table>

Setting portions of a MultiIndex with `xs`
Sorting

Sort by specific column or an ordered list of columns, with a MultiIndex

```
In [99]: df.sort_values(by=('Labs', 'II'), ascending=False)
Out[99]:
            Exams  Labs
   Student  Course I   II  I   II
         Violet  Sci    81   81    78   81
             Math    79   80    77   79
            Comp    76   78    77   79
        Quinn  Sci    78   78    75   78
             Math    76   77    74   76
            Comp    73   76    73   76
         Ada  Sci    75   78    72   75
             Math    73   76    71   74
            Comp    70   72    70   73
```

Partial selection, the need for sortedness;

Levels

Prepending a level to a multiindex

Flatten Hierarchical columns

2.25.4 Missing data

The missing data docs.

Fill forward a reversed timeseries

```
In [100]: df = pd.DataFrame(np.random.randn(6, 1),
   index=pd.date_range('2013-08-01', periods=6, freq='B'),
   columns=list('A'))
   ....:
In [101]: df.loc[df.index[3], 'A'] = np.nan
In [102]: df.reindex(df.index[::-1]).ffill()
Out[102]:
   A
2013-08-08  0.567020
2013-08-07  0.424972
2013-08-06  0.424972
2013-08-07  0.424972
2013-08-08  0.567020
```

(continues on next page)
cumsum reset at NaN values

Replace

Using replace with backrefs

2.25.5 Grouping

The grouping docs.

Basic grouping with apply

Unlike agg, apply’s callable is passed a sub-DataFrame which gives you access to all the columns

```python
In [104]: df = pd.DataFrame({'animal': 'cat dog cat fish dog cat cat'.split(),
                      'size': list('SSMMMLL'),
                      'weight': [8, 10, 11, 1, 20, 12, 12],
                      'adult': [False] * 5 + [True] * 2})

In [105]: df
Out[105]:
   animal size weight  adult
0     cat    S      8  False
1    dog    S     10  False
2     cat    M     11  False
3     fish    M      1  False
4    dog    M     20  False
5     cat    L     12   True
6     cat    L     12   True

# List the size of the animals with the highest weight.
In [106]: df.groupby('animal').apply(lambda subf: subf['size'][subf['weight'].idxmax()])
Out[106]:
   animal
   cat    L
   dog    M
   fish    M
dtype: object
```

Using get_group

```python
In [107]: gb = df.groupby(['animal'])

In [108]: gb.get_group('cat')
Out[108]:
   animal size weight  adult
0     cat    S      8  False
1     cat    M     11  False
```
Apply to different items in a group

```
In [109]: def GrowUp(x):
    ....:     avg_weight = sum(x[x['size'] == 'S'].weight * 1.5)
    ....:     avg_weight += sum(x[x['size'] == 'M'].weight * 1.25)
    ....:     avg_weight += sum(x[x['size'] == 'L'].weight)
    ....:     avg_weight /= len(x)
    ....:     return pd.Series(['L', avg_weight, True],
    ....:                        index=['size', 'weight', 'adult'])

In [110]: expected_df = gb.apply(GrowUp)
```

```
In [111]: expected_df
Out[111]:
    size weight  adult
animal     
  cat   L    12.4375    True
  dog   L    20.0000    True
  fish  L    1.2500    True
```

Expanding apply

```
In [112]: S = pd.Series([i / 100.0 for i in range(1, 11)])

In [113]: def cum_ret(x, y):
    ....:     return x * (1 + y)
    ....: 

In [114]: def red(x):
    ....:     return functools.reduce(cum_ret, x, 1.0)
    ....: 

In [115]: S.expanding().apply(red, raw=True)
Out[115]:
    0     1.010000
    1     1.030200
    2     1.061106
    3     1.103550
    4     1.158728
    5     1.228251
    6     1.314229
    7     1.419367
    8     1.547110
    9     1.701821
    dtype: float64
```

Replacing some values with mean of the rest of a group

```
In [116]: df = pd.DataFrame({'A': [1, 1, 2, 2], 'B': [1, -1, 1, 2]})

In [117]: gb = df.groupby('A')
```

```
In [118]: def replace(g):
    ....:

(continues on next page)
mask = g < 0

return g.where(mask, g[~mask].mean())

In [119]: gb.transform(replace)
Out[119]:
   B
0  1.0
1 -1.0
2  1.5
3  1.5

Sort groups by aggregated data

In [120]: df = pd.DataFrame({'code': ['foo', 'bar', 'baz'] * 2,
                         'data': [0.16, -0.21, 0.33, 0.45, -0.59, 0.62],
                         'flag': [False, True] * 3})

In [121]: code_groups = df.groupby('code')
In [122]: agg_n_sort_order = code_groups[['data']].transform(sum).sort_values(by='data')
In [123]: sorted_df = df.loc[agg_n_sort_order.index]
In [124]: sorted_df
Out[124]:
   code  data  flag
0  foo  0.16  False
1  bar -0.21   True
2  baz  0.33  False
3  baz  0.62   True

Create multiple aggregated columns

In [125]: rng = pd.date_range(start='2014-10-07', periods=10, freq='2min')
In [126]: ts = pd.Series(data=list(range(10)), index=rng)
In [127]: def MyCust(x):
   ...:     if len(x) > 2:
   ...:         return x[1] * 1.234
   ...:     return pd.NaT
   ...
In [128]: mhc = {'Mean': np.mean, 'Max': np.max, 'Custom': MyCust}
In [129]: ts.resample('5min').apply(mhc)
Out[129]:
   Mean       2014-10-07 00:00:00  1
             2014-10-07 00:05:00  3.5
             2014-10-07 00:10:00   6
             2014-10-07 00:15:00  8.5
   Max       2014-10-07 00:00:00  2
(continues on next page)

Freq: 2T, dtype: int64

Create a value counts column and reassign back to the DataFrame

In [131]: df = pd.DataFrame({'Color': 'Red Red Red Blue'.split(),
                         'Value': [100, 150, 50, 50]})

In [132]: df
Out[132]:
   Color Value
0   Red  100
1   Red  150
2   Red   50
3  Blue   50

In [133]: df['Counts'] = df.groupby(['Color']).transform(len)

In [134]: df
Out[134]:
   Color Value Counts
0   Red  100      3
1   Red  150      3
2   Red   50      3
3  Blue   50      1

Shift groups of the values in a column based on the index

In [135]: df = pd.DataFrame({'line_race': [10, 10, 8, 10, 10, 8],
                         'beyer': [99, 102, 103, 103, 88, 100],
                         'index': ['Last Gunfighter', 'Last Gunfighter', 'Last Gunfighter', 'Paynter', 'Paynter', 'Paynter']})

In [136]: df
pandas: powerful Python data analysis toolkit, Release 1.1.5

Out[136]:

<table>
<thead>
<tr>
<th>line_race</th>
<th>beyer</th>
</tr>
</thead>
<tbody>

2.25.6 Timeseries

Between times
Using indexer between time
Constructing a datetime range that excludes weekends and includes only certain times
Vectorized Lookup
Aggregation and plotting time series
Turn a matrix with hours in columns and days in rows into a continuous row sequence in the form of a time series.
How to rearrange a Python pandas DataFrame?

Dealing with duplicates when reindexing a timeseries to a specified frequency
Calculate the first day of the month for each entry in a DatetimeIndex

```python
In [175]: dates = pd.date_range('2000-01-01', periods=5)
In [176]: dates.to_period(freq='M').to_timestamp()
Out[176]:
               '2000-01-01'], dtype='datetime64[ns]', freq=None)
```

Resampling

The Resample docs.
Using Grouper instead of TimeGrouper for time grouping of values
Time grouping with some missing values
Valid frequency arguments to Grouper Timeseries
Grouping using a MultiIndex
Using TimeGrouper and another grouping to create subgroups, then apply a custom function
Resampling with custom periods
Resample intraday frame without adding new days
Resample minute data
Resample with groupby

2.25.7 Merge

The Concat docs. The Join docs.
Append two dataframes with overlapping index (emulate R rbind)

```python
In [177]: rng = pd.date_range('2000-01-01', periods=6)
In [178]: df1 = pd.DataFrame(np.random.randn(6, 3), index=rng, columns=['A', 'B', 'C
In [179]: df2 = df1.copy()
```
Depending on df construction, ignore_index may be needed

```
In [180]: df = df1.append(df2, ignore_index=True)
```

```
In [181]: df
Out[181]:
   A   B    C
0 -0.870117 -0.479265 -0.790855

```

How to set the index and join

KDB like asof join

Join with a criteria based on the values

Using searchsorted to merge based on values inside a range
2.25.8 Plotting

The Plotting docs.
Make Matplotlib look like R
Setting x-axis major and minor labels
Plotting multiple charts in an ipython notebook
Creating a multi-line plot
Plotting a heatmap
Annotate a time-series plot
Annotate a time-series plot #2
Generate Embedded plots in excel files using Pandas, Vincent and xlsxwriter
Boxplot for each quartile of a stratifying variable

```python
In [186]: df = pd.DataFrame(
    ....:     {'stratifying_var': np.random.uniform(0, 100, 20),
    ....:      'price': np.random.normal(100, 5, 20)})
    ....:

In [187]: df['quartiles'] = pd.qcut(
    ....:     df['stratifying_var'],
    ....:     4,
    ....:     labels=['0-25%', '25-50%', '50-75%', '75-100%'])
    ....:

In [188]: df.boxplot(column='price', by='quartiles')
Out[188]: <AxesSubplot:title={'center':'price'}, xlabel='quartiles'>
2.25.9 Data in/out

Performance comparison of SQL vs HDF5

CSV

The CSV docs

read_csv in action

appending to a csv

Reading a csv chunk-by-chunk

Reading only certain rows of a csv chunk-by-chunk

Reading the first few lines of a frame

Reading a file that is compressed but not by gzip/bz2 (the native compressed formats which read_csv understands). This example shows a WinZipped file, but is a general application of opening the file within a context manager and using that handle to read. See here

Inferring dtypes from a file

Dealing with bad lines
Dealing with bad lines II

Reading CSV with Unix timestamps and converting to local timezone

Write a multi-row index CSV without writing duplicates

**Reading multiple files to create a single DataFrame**

The best way to combine multiple files into a single DataFrame is to read the individual frames one by one, put all of the individual frames into a list, and then combine the frames in the list using `pd.concat()`:

```python
In [189]: for i in range(3):
   .....:     data = pd.DataFrame(np.random.randn(10, 4))
   .....:     data.to_csv('file_{i}.csv'.format(i))
   .....:
In [190]: files = ['file_0.csv', 'file_1.csv', 'file_2.csv']
In [191]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

You can use the same approach to read all files matching a pattern. Here is an example using `glob`:

```python
In [192]: import glob
In [193]: import os
In [194]: files = glob.glob('file_*.csv')
In [195]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

Finally, this strategy will work with the other `pd.read_*(...)` functions described in the `io docs`.

**Parsing date components in multi-columns**

Parsing date components in multi-columns is faster with a format:

```python
In [196]: i = pd.date_range('20000101', periods=10000)
In [197]: df = pd.DataFrame({'year': i.year, 'month': i.month, 'day': i.day})
In [198]: df.head()
Out[198]:
   year  month  day
0     2000     1     1
1     2000     1     2
2     2000     1     3
3     2000     1     4
4     2000     1     5
In [199]: %timeit pd.to_datetime(df.year * 10000 + df.month * 100 + df.day, format='%Y-%m-%d')
   .....:     ds = df.apply(lambda x: "%04d%02d%02d" % (x['year'], x['month'], x['day']), axis=1)
   .....:     ds.head()
   .....:     %timeit pd.to_datetime(ds)
```

(continues on next page)
Skip row between header and data

```python
In [200]: data = ";;;;
......: ;;;;
......: ;;;;
......: ;;;;
......: ;;;;
......: ;;;;
......: ;;;;
......: ;;;;
......: date;Param1;Param2;Param4;Param5
......: ;m°;°C;m°;m
......: ;;;;
......: 01.01.1990 00:00;1;1;2;3
......: 01.01.1990 01:00;5;3;4;5
......: 01.01.1990 02:00;9;5;6;7
......: 01.01.1990 03:00;13;7;8;9
......: 01.01.1990 04:00;17;9;10;11
......: 01.01.1990 05:00;21;11;12;13
......: 
......:
```

Option 1: pass rows explicitly to skip rows

```python
In [201]: from io import StringIO

In [202]: pd.read_csv(StringIO(data), sep=';', skiprows=[11, 12],
......: index_col=0, parse_dates=True, header=10)
```

```
Out[202]:
                  Param1  Param2  Param4  Param5  date
year   month   hour  minute
1990-01-01  00:00:00      1        1        2        3
1990-01-01  01:00:00      5        3        4        5
1990-01-01  02:00:00      9        5        6        7
1990-01-01  03:00:00     13        7        8        9
1990-01-01  04:00:00     17        9       10       11
1990-01-01  05:00:00     21       11       12       13
```

Option 2: read column names and then data

```
In [203]: pd.read_csv(StringIO(data), sep=';', header=10, nrows=10).columns
Out[203]: Index(['date', 'Param1', 'Param2', 'Param4', 'Param5'], dtype='object')

In [204]: columns = pd.read_csv(StringIO(data), sep=';', header=10, nrows=10).columns
In [205]: pd.read_csv(StringIO(data), sep=';', index_col=0, 
                      header=12, parse_dates=True, names=columns) 
```

<table>

Avoiding inconsistencies when writing to a store from multiple processes/threads

De-duplicating a large store by chunks, essentially a recursive reduction operation. Shows a function for taking in data from csv file and creating a store by chunks, with date parsing as well. See here

Creating a store chunk-by-chunk from a csv file

Appending to a store, while creating a unique index
Large Data work flows
Reading in a sequence of files, then providing a global unique index to a store while appending
Groupby on a HDFStore with low group density
Groupby on a HDFStore with high group density
Hierarchical queries on a HDFStore
Counting with a HDFStore
Troubleshoot HDFStore exceptions
Setting min_itemsize with strings
Using ptrepack to create a completely-sorted-index on a store

In [206]: df = pd.DataFrame(np.random.randn(8, 3))
In [207]: store = pd.HDFStore('test.h5')
In [208]: store.put('df', df)
# you can store an arbitrary Python object via pickle
In [209]: store.get_storer('df').attrs.my_attribute = {'A': 10}
In [210]: store.get_storer('df').attrs.my_attribute
Out[210]: {'A': 10}

You can create or load a HDFStore in-memory by passing the driver parameter to PyTables. Changes are only written to disk when the HDFStore is closed.

In [211]: store = pd.HDFStore('test.h5', 'w', diver='H5FD_CORE')
In [212]: df = pd.DataFrame(np.random.randn(8, 3))
In [213]: store['test'] = df
# only after closing the store, data is written to disk:
In [214]: store.close()
```c
int main(int argc, const char *argv[]) {
    size_t n = 10;
    Data d[n];

    for (int i = 0; i < n; ++i) {
        d[i].count = i;
        d[i].avg = i + 1.0;
        d[i].scale = (float) i + 2.0f;
    }

    FILE *file = fopen("binary.dat", "wb");
    fwrite(&d, sizeof(Data), n, file);
    fclose(file);
    return 0;
}
```

the following Python code will read the binary file `binary.dat` into a pandas DataFrame, where each element of the struct corresponds to a column in the frame:

```python
def read_binary(file):
    dt = np.dtype([('count', 'i4'), ('avg', 'f8'), ('scale', 'f4')])
    df = pd.read_csv(file, dtype=dt)
    return df
```

```python
names = ['count', 'avg', 'scale']

# note that the offsets are larger than the size of the type because of
# struct padding
offsets = 0, 8, 16
formats = 'i4', 'f8', 'f4'
dt = np.dtype({'names': names, 'offsets': offsets, 'formats': formats},
              align=True)
df = pd.DataFrame(np.fromfile('binary.dat', dt))
```

**Note:** The offsets of the structure elements may be different depending on the architecture of the machine on which the file was created. Using a raw binary file format like this for general data storage is not recommended, as it is not cross platform. We recommended either HDF5 or parquet, both of which are supported by pandas’ IO facilities.

### 2.25.10 Computation

Numerical integration (sample-based) of a time series

#### Correlation

Often it’s useful to obtain the lower (or upper) triangular form of a correlation matrix calculated from DataFrame.

```py
In [215]: df = pd.DataFrame(np.random.random(size=(100, 5)))
In [216]: corr_mat = df.corr()
In [217]: mask = np.tril(np.ones_like(corr_mat, dtype=np.bool), k=-1)
```
The method argument within DataFrame.corr can accept a callable in addition to the named correlation types. Here we compute the distance correlation matrix for a DataFrame object.

```python
In [218]: def distcorr(x, y):
    ...:    n = len(x)
    ...:    a = np.zeros(shape=(n, n))
    ...:    b = np.zeros(shape=(n, n))
    ...:    for i in range(n):
    ...:        for j in range(i + 1, n):
    ...:            a[i, j] = abs(x[i] - x[j])
    ...:            b[i, j] = abs(y[i] - y[j])
    ...:    a += a.T
    ...:    b += b.T
    ...:    a_bar = np.vstack([np.nanmean(a, axis=0)] * n)
    ...:    b_bar = np.vstack([np.nanmean(b, axis=0)] * n)
    ...:    A = a - a_bar - a_bar.T + np.full(shape=(n, n), fill_value=a_bar.mean())
    ...:    B = b - b_bar - b_bar.T + np.full(shape=(n, n), fill_value=b_bar.mean())
    ...:    cov_ab = np.sqrt(np.nansum(A * B)) / n
    ...:    std_a = np.sqrt(np.sqrt(np.nansum(A**2)) / n)
    ...:    std_b = np.sqrt(np.sqrt(np.nansum(B**2)) / n)
    ...:    return cov_ab / std_a / std_b

In [220]: df = pd.DataFrame(np.random.normal(size=(100, 3)))
In [221]: df.corr(method=distcorr)
```

2.25.11 Timedeltas

The Timedeltas docs.

Using timedeltas

```python
In [222]: import datetime
In [223]: s = pd.Series(pd.date_range('2012-1-1', periods=3, freq='D'))
In [224]: s - s.max()
```

(continues on next page)
Adding and subtracting deltas and dates

```
In [230]: deltas = pd.Series([datetime.timedelta(days=i) for i in range(3)])
In [231]: df = pd.DataFrame({'A': s, 'B': deltas})
In [232]: df
Out[232]:
      A           B
0 2012-01-01  0 days
1 2012-01-02  1 days
2 2012-01-03  2 days
In [233]: df['New Dates'] = df['A'] + df['B']
In [234]: df['Delta'] = df['A'] - df['New Dates']
In [235]: df
```

Another example

Values can be set to NaT using np.nan, similar to datetime

```
In [237]: y = s - s.shift()

In [238]:
y
Out[238]:
0  NaT
1  1 days
2  1 days
dtype: timedelta64[ns]

In [239]: y[1] = np.nan

In [240]: y
Out[240]:
0  NaT
1  NaT
2  1 days
dtype: timedelta64[ns]
```

### 2.25.12 Creating example data

To create a dataframe from every combination of some given values, like R’s `expand.grid()` function, we can create a dict where the keys are column names and the values are lists of the data values:

```
In [241]: def expand_grid(data_dict):
    ...:     rows = itertools.product(*data_dict.values())
    ...:     return pd.DataFrame.from_records(rows, columns=data_dict.keys())
    ...:

In [242]: df = expand_grid({'height': [60, 70],
    ...:                 'weight': [100, 140, 180],
    ...:                 'sex': ['Male', 'Female']})

In [243]: df
Out[243]:
height  weight  sex
0  60  100  Male
1  60  100  Female
```

(continues on next page)

</table>
This page gives an overview of all public pandas objects, functions and methods. All classes and functions exposed in pandas.* namespace are public.

Some subpackages are public which include pandas.errors, pandas.plotting, and pandas.testing. Public functions in pandas.io and pandas.tseries submodules are mentioned in the documentation. pandas.api.types subpackage holds some public functions related to data types in pandas.

**Warning:** The pandas.core, pandas.compat, and pandas.util top-level modules are PRIVATE. Stable functionality in such modules is not guaranteed.

### 3.1 Input/output

#### 3.1.1 Pickling

```python
read_pickle(filepath_or_buffer[, compression])
```

Load pickled pandas object (or any object) from file.

**Warning:** Loading pickled data received from untrusted sources can be unsafe. See here.

**Parameters**

- `filepath_or_buffer` [str, path object or file-like object] File path, URL, or buffer where the pickled object will be loaded from.

  Changed in version 1.0.0: Accept URL. URL is not limited to S3 and GCS.

- `compression` ['infer', 'gzip', 'bz2', 'zip', 'xz', None], default ‘infer’

  If ‘infer’ and ‘path_or_url’ is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’ (otherwise no compression) If ‘infer’ and ‘path_or_url’ is not path-like, then use None (= no decompression).

**Returns**
unpickled [same type as object stored in file]

See also:

- **DataFrame.to_pickle** Pickle (serialize) DataFrame object to file.
- **Series.to_pickle** Pickle (serialize) Series object to file.
- **read_hdf** Read HDF5 file into a DataFrame.
- **read_sql** Read SQL query or database table into a DataFrame.
- **read_parquet** Load a parquet object, returning a DataFrame.

**Notes**

read_pickle is only guaranteed to be backwards compatible to pandas 0.20.3.

**Examples**

```python
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0   0   5
1   1   6
2   2   7
3   3   8
4   4   9

>>> pd.to_pickle(original_df, ".\dummy.pkl")

>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0   0   5
1   1   6
2   2   7
3   3   8
4   4   9

>>> import os
>>> os.remove("./dummy.pkl")
```

float_precision=None)
Read general delimited file into DataFrame.
Also supports optionally iterating or breaking of the file into chunks.
Additional help can be found in the online docs for IO Tools.
Parameters
filepath_or_buffer [str, path object or file-like object] Any valid string path is acceptable. The
string could be a URL. Valid URL schemes include http, ftp, s3, gs, and file. For file URLs,
a host is expected. A local file could be: file://localhost/path/to/table.csv.
If you want to pass in a path object, pandas accepts any os.PathLike.
By file-like object, we refer to objects with a read() method, such as a file handler (e.g.
via builtin open function) or StringIO.
sep [str, default ‘\t’ (tab-stop)] Delimiter to use. If sep is None, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used
and automatically detect the separator by Python’s builtin sniffer tool, csv.Sniffer. In
addition, separators longer than 1 character and different from '\s+' will be interpreted as
regular expressions and will also force the use of the Python parsing engine. Note that regex
delimiters are prone to ignoring quoted data. Regex example: '\r\t'.
delimiter [str, default None] Alias for sep.
header [int, list of int, default ‘infer’] Row number(s) to use as the column names, and the
start of the data. Default behavior is to infer the column names: if no names are passed the
behavior is identical to header=0 and column names are inferred from the first line of the
file, if column names are passed explicitly then the behavior is identical to header=None.
Explicitly pass header=0 to be able to replace existing names. The header can be a list of
integers that specify row locations for a multi-index on the columns e.g. [0,1,3]. Intervening
rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this
parameter ignores commented lines and empty lines if skip_blank_lines=True, so
header=0 denotes the first line of data rather than the first line of the file.
names [array-like, optional] List of column names to use. If the file contains a header row, then
you should explicitly pass header=0 to override the column names. Duplicates in this list
are not allowed.
index_col [int, str, sequence of int / str, or False, default None] Column(s) to use as the row
labels of the DataFrame, either given as string name or column index. If a sequence of int
/ str is given, a MultiIndex is used.

3.1. Input/output

921


Note: `index_col=False` can be used to force pandas to not use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

**usecols** [list-like or callable, optional] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in *names* or inferred from the document header row(s). For example, a valid list-like *usecols* parameter would be `[0, 1, 2]` or `['foo', 'bar', 'baz']`. Element order is ignored, so *usecols*=`[0, 1]` is the same as `[1, 0]`. To instantiate a DataFrame from data with element order preserved use `pd.read_csv(data, usecols=('foo', 'bar'))[[('foo', 'bar')]]` for columns in `['foo', 'bar']` order or `pd.read_csv(data, usecols=('foo', 'bar'))[[('bar', 'foo')]]` for `['bar', 'foo']` order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True. An example of a valid callable argument would be `lambda x: x.upper() in ['AAA', 'BBB', 'DDD']`. Using this parameter results in much faster parsing time and lower memory usage.

**squeeze** [bool, default False] If the parsed data only contains one column then return a Series.

**prefix** [str, optional] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1, …

**mangle_dupe_cols** [bool, default True] Duplicate columns will be specified as ‘X’, ‘X.1’, … ‘X.N’, rather than ‘X’…‘X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

**dtype** [Type name or dict of column -> type, optional] Data type for data or columns. E.g. `{‘a’: np.float64, ‘b’: np.int32, ‘c’: ‘Int64’}` Use *str* or *object* together with suitable *na_values* settings to preserve and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

**engine** [{'c', 'python'}, optional] Parser engine to use. The C engine is faster while the python engine is currently more feature-complete.

**converters** [dict, optional] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

**true_values** [list, optional] Values to consider as True.

**false_values** [list, optional] Values to consider as False.

**skipinitialspace** [bool, default False] Skip spaces after delimiter.

**skiprows** [list-like, int or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

**skipfooter** [int, default 0] Number of lines at bottom of file to skip (Unsupported with engine='c').

**nrows** [int, optional] Number of rows of file to read. Useful for reading pieces of large files.

**na_values** [scalar, str, list-like, or dict, optional] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘’, ‘#N/A’, ‘#N/A N/A’, ‘#NA’, ‘-1.#IND’, ‘-1.#QNAN’, ‘-NaN’, ‘-nan’, ‘1.#IND’, ‘1.#QNAN’, ‘<NA>’, ‘N/A’, ‘NA’, ‘NULL’, ‘NaN’, ‘n/a’, ‘nan’, ‘null’.

**keep_default_na** [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether *na_values* is passed in, the behavior is as follows:
• If `keep_default_na` is True, and `na_values` are specified, `na_values` is appended to the default NaN values used for parsing.

• If `keep_default_na` is True, and `na_values` are not specified, only the default NaN values are used for parsing.

• If `keep_default_na` is False, and `na_values` are specified, only the NaN values specified `na_values` are used for parsing.

• If `keep_default_na` is False, and `na_values` are not specified, no strings will be parsed as NaN.

Note that if `na_filter` is passed in as False, the `keep_default_na` and `na_values` parameters will be ignored.

`na_filter` [bool, default True] Detect missing value markers (empty strings and the value of `na_values`). In data without any NAs, passing `na_filter=False` can improve the performance of reading a large file.

`verbose` [bool, default False] Indicate number of NA values placed in non-numeric columns.

`skip_blank_lines` [bool, default True] If True, skip over blank lines rather than interpreting as NaN values.

`parse_dates` [bool or list of int or names or list of lists or dict, default False] The behavior is as follows:

• boolean. If True -> try parsing the index.

• list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.

• list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.

• dict, e.g. `{‘foo’ : [1, 3]}` -> parse columns 1, 3 as date and call result ‘foo’

If a column or index cannot be represented as an array of datetimes, say because of an unparsable value or a mixture of timezones, the column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`. To parse an index or column with a mixture of timezones, specify `date_parser` to be a partially-applied `pandas.to_datetime()` with `utc=True`. See Parsing a CSV with mixed timezones for more.

Note: A fast-path exists for iso8601-formatted dates.

`infer_datetime_format` [bool, default False] If True and `parse_dates` is enabled, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

`keep_date_col` [bool, default False] If True and `parse_dates` specifies combining multiple columns then keep the original columns.

`date_parser` [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

`dayfirst` [bool, default False] DD/MM format dates, international and European format.
cache_dates [bool, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

iterator [bool, default False] Return TextFileReader object for iteration or getting chunks with get_chunk().

chunksize [int, optional] Return TextFileReader object for iteration. See the IO Tools docs for more information on iterator and chunksize.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’ and filepath_or_buffer is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’ (otherwise no decompression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

thousands [str, optional] Thousands separator.

decimal [str, default ‘.’] Character to recognize as decimal point (e.g. use ‘,’ for European data).

lineterminator [str (length 1), optional] Character to break file into lines. Only valid with C parser.

quotechar [str (length 1), optional] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

quoting [int or csv.QUOTE_* instance, default 0] Control field quoting behavior per csv.QUOTE_* constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

doublequote [bool, default True] When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements INSIDE a field as a single quotechar element.

escapechar [str (length 1), optional] One-character string used to escape other characters.

comment [str, optional] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as skip_blank_lines=True), fully commented lines are ignored by the parameter header but not by skiprows. For example, if comment=’#’, parsing #empty\na,b,c\n1,2,3 with header=0 will result in ‘a,b,c’ being treated as the header.

encoding [str, optional] Encoding to use for UTF when reading/writing (ex. ‘utf-8’). List of Python standard encodings.

dialect [str or csv.Dialect, optional] If provided, this parameter will override values (default or not) for the following parameters: delimiter, doublequote, escapechar, skipinitialspace, quotechar, and quoting. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

error_bad_lines [bool, default True] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will be dropped from the DataFrame that is returned.

warn_bad_lines [bool, default True] If error_bad_lines is False, and warn_bad_lines is True, a warning for each “bad line” will be output.
**delim_whitespace** [bool, default False] Specifies whether or not whitespace (e.g. ' ' or '
') will be used as the sep. Equivalent to setting `sep='\s+'`. If this option is set to True, nothing should be passed in for the `delimiter` parameter.

**low_memory** [bool, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the `dtype` parameter. Note that the entire file is read into a single DataFrame regardless, use the `chunksize` or `iterator` parameter to return the data in chunks. (Only valid with C parser).

**memory_map** [bool, default False] If a filepath is provided for `filepath_or_buffer`, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

**float_precision** [str, optional] Specifies which converter the C engine should use for floating-point values. The options are `None` for the ordinary converter, `high` for the high-precision converter, and `round_trip` for the round-trip converter.

**Returns**

- **DataFrame or TextParser** A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

**See also:**

- `DataFrame.to_csv` Write DataFrame to a comma-separated values (csv) file.
- `read_csv` Read a comma-separated values (csv) file into DataFrame.
- `read_fwf` Read a table of fixed-width formatted lines into DataFrame.

**Examples**

```python
>>> pd.read_table('data.csv')
```

### `pandas.read_csv`

`pandas.read_csv` is a function that reads a comma-separated values (csv) file into a DataFrame. It also supports optionally iterating or breaking the file into chunks. Additional help can be found in the online docs for IO Tools.

**Parameters**

- `filepath_or_buffer` (str) The file to be read.
- `sep` (str) The separator character. Default is a comma (',').
- `delimiter` (str) The delimiter character. Default is the empty string ("").
- `header` (int or str or None) The row to use as the column names. Default is 'infer'.
- `names` (list of str or None) The column names. Default is None.
- `index_col` (int or str or list of int or str or None) The column or columns to be parsed as index. Default is None.
- `usecols` (list of int or str or None) The columns to use. Default is None.
- `squeeze` (bool) Squeeze the resulting DataFrame. Default is False.
- `prefix` (str or None) Prefix to add to column names. Default is None.
- `mangle_dupe_cols` (bool) Mangle duplicate column names. Default is True.
- `dtype` (str or dict or None) The data type to infer or specify. Default is None.
- `engine` (str or None) The engine to use for the C parser. Default is None.
- `converters` (dict or None) The converters to use for the C parser. Default is None.
- `true_values` (list or str or None) The acceptable values for True. Default is None.
- `false_values` (list or str or None) The acceptable values for False. Default is None.
- `skipinitialspace` (bool) Skip whitespace at the beginning of each line. Default is False.
- `skiprows` (int or list or None) The rows to skip. Default is None.
- `skipfooter` (int) The number of rows at the end to skip. Default is 0.
- `nrows` (int) The number of rows to read. Default is None.
- `na_values` (dict or list or None) The acceptable values for NaN. Default is None.
- `keep_default_na` (bool) Keep the default NaN value. Default is True.
- `na_filter` (bool) Filter out rows with non-finite values. Default is True.
- `verbose` (bool) Print progress messages. Default is False.
- `skip_blank_lines` (bool) Ignore blank lines in the file. Default is True.
- `parse_dates` (bool) Parse dates. Default is False.
- `infer_datetime_format` (bool) Infer datetime format. Default is False.
- `keep_date_col` (bool) Keep the date column. Default is False.
- `date_parser` (func) The function to use for parsing dates. Default is None.
- `dayfirst` (bool) Parse day first. Default is False.
- `cache_dates` (bool) Cache parsed dates. Default is True.
- `iterator` (bool) Iterate over the file. Default is False.
- `chunksize` (int or None) The chunk size. Default is None.
- `compression` (str or None) The compression to use. Default is 'infer'.
- `thousands` (str or None) The thousands separator. Default is None.
- `decimal` (str or None) The decimal separator. Default is None.
- `lineterminator` (str or None) The line terminator. Default is None.
- `quotechar` (str or None) The quote character. Default is None.
- `quoting` (int) The type of quoting. Default is 0.
- `doublequote` (bool) Double quote strings. Default is True.
- `escapechar` (str or None) The escape character. Default is None.
- `comment` (str or None) The comment character. Default is None.
- `encoding` (str or None) The encoding to use. Default is None.
- `dialect` (str or None) The CSV dialect. Default is None.
- `error_bad_lines` (bool) Ignore bad lines. Default is True.
- `warn_bad_lines` (bool) Warn about bad lines. Default is True.
- `delim_whitespace` (bool) Use whitespace as delimiters. Default is False.
- `low_memory` (bool) Use low memory mode. Default is True.
- `memory_map` (bool) Map the file onto memory. Default is False.
- `float_precision` (str or None) The float precision. Default is None.
filepath_or_buffer [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, gs, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.csv.

If you want to pass in a path object, pandas accepts any os.PathLike.

By file-like object, we refer to objects with a read() method, such as a file handler (e.g. via builtin open function) or StringIO.

sep [str, default ‘,’] Delimiter to use. If sep is None, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python’s builtin sniffer tool, csv.Sniffer. In addition, separators longer than 1 character and different from '\s+' will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: '\r\t'.

delimiter [str, default None] Alias for sep.

header [int, list of int, default ‘infer’] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to header=0 and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to header=None. Explicitly pass header=0 to be able to replace existing names. The header can be a list of integers that specify row locations for a multi-index on the columns e.g. [0,1,3]. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if skip_blank_lines=True, so header=0 denotes the first line of data rather than the first line of the file.

names [array-like, optional] List of column names to use. If the file contains a header row, then you should explicitly pass header=0 to override the column names. Duplicates in this list are not allowed.

index_col [int, str, sequence of int / str, or False, default None] Column(s) to use as the row labels of the DataFrame, either given as string name or column index. If a sequence of int / str is given, a MultiIndex is used.

Note: index_col=False can be used to force pandas to not use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

usecols [list-like or callable, optional] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in names or inferred from the document header row(s). For example, a valid list-like usecols parameter would be [0, 1, 2] or ['foo', 'bar', 'baz']. Element order is ignored, so usecols=[0, 1] is the same as [1, 0]. To instantiate a DataFrame from data with element order preserved use pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']] for columns in ['foo', 'bar'] order or pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']] for ['bar', 'foo'] order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True. An example of a valid callable argument would be lambda x: x.upper() in ['AAA', 'BBB', 'DDD']. Using this parameter results in much faster parsing time and lower memory usage.

squeeze [bool, default False] If the parsed data only contains one column then return a Series.

prefix [str, optional] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1, …

mangle_dupe_cols [bool, default True] Duplicate columns will be specified as ‘X’, ‘X.1’, … ‘X.N’, rather than ‘X’… ‘X’. Passing in False will cause data to be overwritten if there
are duplicate names in the columns.

**dtype** [Type name or dict of column -> type, optional] Data type for data or columns. E.g. `{ ‘a’: np.float64, ‘b’: np.int32, ‘c’: ‘Int64’ } Use `str` or `object` together with suitable `na_values` settings to preserve and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

**engine** [('c', 'python'), optional] Parser engine to use. The C engine is faster while the python engine is currently more feature-complete.

**converters** [dict, optional] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

**true_values** [list, optional] Values to consider as True.

**false_values** [list, optional] Values to consider as False.

**skipinitialspace** [bool, default False] Skip spaces after delimiter.

**skiprows** [list-like, int or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

**skipfooter** [int, default 0] Number of lines at bottom of file to skip (Unsupported with engine='c').

**nrows** [int, optional] Number of rows of file to read. Useful for reading pieces of large files.

**na_values** [scalar, str, list-like, or dict, optional] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: '', '#N/A', '#N/A N/A', '#NA', '-1.#IND', '-1.#QNAN', '-NaN', '-nan', '1.#IND', '1.#QNAN', '<NA>', 'N/A', 'NA', 'NULL', 'NaN', 'n/a', 'nan', 'null'.

**keep_default_na** [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether `na_values` is passed in, the behavior is as follows:

- If `keep_default_na` is True, and `na_values` are specified, `na_values` is appended to the default NaN values used for parsing.
- If `keep_default_na` is True, and `na_values` are not specified, only the default NaN values are used for parsing.
- If `keep_default_na` is False, and `na_values` are specified, only the NaN values specified `na_values` are used for parsing.
- If `keep_default_na` is False, and `na_values` are not specified, no strings will be parsed as NaN.

Note that if `na_filter` is passed in as False, the `keep_default_na` and `na_values` parameters will be ignored.

**na_filter** [bool, default True] Detect missing value markers (empty strings and the value of `na_values`). In data without any NAs, passing `na_filter=False` can improve the performance of reading a large file.

**verbose** [bool, default False] Indicate number of NA values placed in non-numeric columns.

**skip_blank_lines** [bool, default True] If True, skip over blank lines rather than interpreting as NaN values.
**parse_dates** [bool or list of int or names or list of lists or dict, default False] The behavior is as follows:

- boolean. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. {'foo': [1, 3]} -> parse columns 1, 3 as date and call result 'foo'

If a column or index cannot be represented as an array of datetimes, say because of an unparsable value or a mixture of timezones, the column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`. To parse an index or column with a mixture of timezones, specify `date_parser` to be a partially-applied `pandas.to_datetime()` with `utc=True`. See Parsing a CSV with mixed timezones for more.

Note: A fast-path exists for iso8601-formatted dates.

**infer_datetime_format** [bool, default False] If True and `parse_dates` is enabled, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

**keep_date_col** [bool, default False] If True and `parse_dates` specifies combining multiple columns then keep the original columns.

**date_parser** [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

**dayfirst** [bool, default False] DD/MM format dates, international and European format.

**cache_dates** [bool, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

**iterator** [bool, default False] Return TextFileReader object for iteration or getting chunks with `get_chunk()`.

**chunksize** [int, optional] Return TextFileReader object for iteration. See the IO Tools docs for more information on `iterator` and `chunksize`.

**compression** [{'infer', 'gzip', 'bz2', 'zip', 'xz', None}, default 'infer'] For on-the-fly decompression of on-disk data. If 'infer' and `filepath_or_buffer` is path-like, then detect compression from the following extensions: `.gz`, `.bz2`, `.zip`, or `.xz` (otherwise no decompression). If using 'zip', the ZIP file must contain only one data file to be read in. Set to None for no decompression.

**thousands** [str, optional] Thousands separator.

**decimal** [str, default '.'] Character to recognize as decimal point (e.g. use ',' for European data).

**lineterminator** [str (length 1), optional] Character to break file into lines. Only valid with C parser.
quotechar [str (length 1), optional] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

quoting [int or csv.QUOTE_* instance, default 0] Control field quoting behavior per csv.QUOTE_* constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

doublequote [bool, default True] When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements INSIDE a field as a single quotechar element.

escapechar [str (length 1), optional] One-character string used to escape other characters.

comment [str, optional] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as skip_blank_lines=True), fully commented lines are ignored by the parameter header but not by skiprows. For example, if comment='#', parsing #empty
a,b,c
1,2,3 with header=0 will result in 'a,b,c' being treated as the header.

encoding [str, optional] Encoding to use for UTF when reading/writing (ex. ‘utf-8’). List of Python standard encodings.

dialect [str or csv.Dialect, optional] If provided, this parameter will override values (default or not) for the following parameters: delimiter, doublequote, escapechar, skipinitialspace, quotechar, and quoting. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

error_bad_lines [bool, default True] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will dropped from the DataFrame that is returned.

warn_bad_lines [bool, default True] If error_bad_lines is False, and warn_bad_lines is True, a warning for each “bad line” will be output.

delim_whitespace [bool, default False] Specifies whether or not whitespace (e.g. ' ' or ') will be used as the sep. Equivalent to setting sep='\s+'. If this option is set to True, nothing should be passed in for the delimiter parameter.

low_memory [bool, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the dtype parameter. Note that the entire file is read into a single DataFrame regardless, use the chunksize or iterator parameter to return the data in chunks. (Only valid with C parser).

memory_map [bool, default False] If a filepath is provided for filepath_or_buffer, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

float_precision [str, optional] Specifies which converter the C engine should use for floating-point values. The options are None for the ordinary converter, high for the high-precision converter, and round_trip for the round-trip converter.

Returns

DataFrame or TextParser A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

DataFrame.to_csv Write DataFrame to a comma-separated values (csv) file.
**read_csv**  Read a comma-separated values (csv) file into DataFrame.

**read_fwf**  Read a table of fixed-width formatted lines into DataFrame.

**Examples**

```python
>>> pd.read_csv('data.csv')
```

**pandas.read_fwf**

```python
pandas.read_fwf(filepath_or_buffer, colspecs='infer', widths=None, infer_nrows=100, **kwds)
```

Read a table of fixed-width formatted lines into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for IO Tools.

**Parameters**

- **filepath_or_buffer** [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.csv.

  If you want to pass in a path object, pandas accepts any os.PathLike.

  By file-like object, we refer to objects with a read() method, such as a file handler (e.g. via builtin open function) or StringIO.

- **colspecs** [list of tuple (int, int) or ‘infer’. optional] A list of tuples giving the extents of the fixed-width fields of each line as half-open intervals (i.e., [from, to[ ). String value ‘infer’ can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data which are not being skipped via skiprows (default=’infer’).

- **widths** [list of int, optional] A list of field widths which can be used instead of ‘colspecs’ if the intervals are contiguous.

- **infer_nrows** [int, default 100] The number of rows to consider when letting the parser determine the colspecs.

  New in version 0.24.0.

- ****kwds [optional] Optional keyword arguments can be passed to TextFileReader.

**Returns**

- **DataFrame or TextParser** A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

**See also:**

- **DataFrame.to_csv** Write DataFrame to a comma-separated values (csv) file.

- **read_csv** Read a comma-separated values (csv) file into DataFrame.
Examples

```python
>>> pd.read_fwf('data.csv')
```

### 3.1.3 Clipboard

`read_clipboard([sep])` Read text from clipboard and pass to read_csv.

**pandas.read_clipboard**

`pandas.read_clipboard(sep='\s+', **kwargs)`

Read text from clipboard and pass to read_csv.

**Parameters**

- `sep` [str, default \s+] A string or regex delimiter. The default of \s+ denotes one or more whitespace characters.
- `**kwargs` See read_csv for the full argument list.

**Returns**

- `DataFrame` A parsed DataFrame object.

### 3.1.4 Excel

`read_excel(io[, sheet_name, header, names, ...])` Read an Excel file into a pandas DataFrame.

**ExcelFile.parse([sheet_name, header, names, ...])**

Parse specified sheet(s) into a DataFrame.

**pandas.read_excel**

`pandas.read_excel(io, sheet_name=0, header=0, names=None, index_col=None, usecols=None, squeeze=False, dtype=None, engine=None, converters=None, true_values=None, false_values=None, skiprows=None, nrows=None, na_values=None, keep_default_na=True, na_filter=True, verbose=False, parse_dates=False, date_parser=None, thousands=None, comment=None, skipfooter=0, convert_float=True, mangle_dupe_cols=True)`

Read an Excel file into a pandas DataFrame.

Supports xls, xlsx, xslm, xslb, odf, ods and odt file extensions read from a local filesystem or URL. Supports an option to read a single sheet or a list of sheets.

**Parameters**

- `io` [str, bytes, ExcelFile, xlrd.Book, path object, or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: file:///localhost/path/to/table.xlsx.

  If you want to pass in a path object, pandas accepts any os.PathLike.
By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via built-in `open` function) or `StringIO`.

**sheet_name** [str, int, list, or None, default 0] Strings are used for sheet names. Integers are used in zero-indexed sheet positions. Lists of strings/integers are used to request multiple sheets. Specify None to get all sheets.

Available cases:
- Defaults to 0: 1st sheet as a `DataFrame`
- 1: 2nd sheet as a `DataFrame`
- "Sheet1": Load sheet with name “Sheet1”
- [0, 1, "Sheet5"]: Load first, second and sheet named “Sheet5” as a dict of `DataFrame`
- None: All sheets.

**header** [int, list of int, default 0] Row (0-indexed) to use for the column labels of the parsed DataFrame. If a list of integers is passed those row positions will be combined into a `MultiIndex`. Use None if there is no header.

**names** [array-like, default None] List of column names to use. If file contains no header row, then you should explicitly pass header=None.

**index_col** [int, list of int, default None] Column (0-indexed) to use as the row labels of the DataFrame. Pass None if there is no such column. If a list is passed, those columns will be combined into a `MultiIndex`. If a subset of data is selected with `usecols`, `index_col` is based on the subset.

**usecols** [int, str, list-like, or callable default None]
- If None, then parse all columns.
- If str, then indicates comma separated list of Excel column letters and column ranges (e.g. “A:E” or “A,C,E:F”). Ranges are inclusive of both sides.
- If list of int, then indicates list of column numbers to be parsed.
- If list of string, then indicates list of column names to be parsed.
  - New in version 0.24.0.
- If callable, then evaluate each column name against it and parse the column if the callable returns True.
  - New in version 0.24.0.

Returns a subset of the columns according to behavior above.

**squeeze** [bool, default False] If the parsed data only contains one column then return a Series.

**dtype** [Type name or dict of column -> type, default None] Data type for data or columns. E.g. `{’a’: np.float64, ‘b’: np.int32}` Use `object` to preserve data as stored in Excel and not interpret `dtype`. If converters are specified, they will be applied INSTEAD of `dtype` conversion.

**engine** [str, default None] If io is not a buffer or path, this must be set to identify io. Supported engines: “xlrd”, “openpyxl”, “odf”, “pyxlsb”, default “xlrd”. Engine compatibility:
- “xlrd” supports most old/new Excel file formats.
- “openpyxl” supports newer Excel file formats.
- “odf” supports OpenDocument file formats (.odf, .ods, .odt).
- “pyxlsb” supports Binary Excel files.
converters [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels, values are functions that take one input argument, the Excel cell content, and return the transformed content.

true_values [list, default None] Values to consider as True.

false_values [list, default None] Values to consider as False.

skiprows [list-like] Rows to skip at the beginning (0-indexed).

nrows [int, default None] Number of rows to parse.

New in version 0.23.0.

na_values [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘‘’, ‘#N/A’, ‘#N/A N/A’, ‘#NA’, ‘-1.#IND’, ‘-1.#QNAN’, ‘-NaN’, ‘-nan’, ‘1.#IND’, ‘1.#QNAN’, ‘<NA>’, ‘N/A’, ‘NA’, ‘NULL’, ‘NaN’, ‘n/a’, ‘nan’, ‘null’.

keep_default_na [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether na_values is passed in, the behavior is as follows:

• If keep_default_na is True, and na_values are specified, na_values is appended to the default NaN values used for parsing.

• If keep_default_na is True, and na_values are not specified, only the default NaN values are used for parsing.

• If keep_default_na is False, and na_values are specified, only the NaN values specified na_values are used for parsing.

• If keep_default_na is False, and na_values are not specified, no strings will be parsed as NaN.

Note that if na_filter is passed in as False, the keep_default_na and na_values parameters will be ignored.

na_filter [bool, default True] Detect missing value markers (empty strings and the value of na_values). In data without any NAs, passing na_filter=False can improve the performance of reading a large file.

verbose [bool, default False] Indicate number of NA values placed in non-numeric columns.

parse_dates [bool, list-like, or dict, default False] The behavior is as follows:

• bool. If True -> try parsing the index.

• list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.

• list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.

• dict, e.g. {'foo' : [1, 3]} -> parse columns 1, 3 as date and call result ‘foo’

If a column or index contains an unparseable date, the entire column or index will be returned unaltered as an object data type. If you don’t want to parse some cells as date just change their type in Excel to “Text”. For non-standard datetime parsing, use pd.to_datetime after pd.read_excel.

Note: A fast-path exists for iso8601-formatted dates.

date_parser [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses dateutil.parser.parser to do the conversion. Pandas will try to call date_parser in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by parse_dates) as arguments;
2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

**thousands** [str, default None] Thousands separator for parsing string columns to numeric. Note that this parameter is only necessary for columns stored as TEXT in Excel, any numeric columns will automatically be parsed, regardless of display format.

**comment** [str, default None] Comments out remainder of line. Pass a character or characters to this argument to indicate comments in the input file. Any data between the comment string and the end of the current line is ignored.

**skipfooter** [int, default 0] Rows at the end to skip (0-indexed).

**convert_float** [bool, default True] Convert integral floats to int (i.e., 1.0 -> 1). If False, all numeric data will be read in as floats: Excel stores all numbers as floats internally.

**mangle_dupe_cols** [bool, default True] Duplicate columns will be specified as ‘X’, ‘X.1’, ‘X.2’, ..., rather than ‘X’...’X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

**Returns**

- **DataFrame or dict of DataFrames** DataFrame from the passed in Excel file. See notes in `sheet_name` argument for more information on when a dict of DataFrames is returned.

**See also:**

- `DataFrame.to_excel` Write DataFrame to an Excel file.
- `DataFrame.to_csv` Write DataFrame to a comma-separated values (csv) file.
- `read_csv` Read a comma-separated values (csv) file into DataFrame.
- `read_fwf` Read a table of fixed-width formatted lines into DataFrame.

**Examples**

The file can be read using the file name as string or an open file object:

```
>>> pd.read_excel('tmp.xlsx', index_col=0)
Name  Value
0  string1  1
1  string2  2
2  #Comment  3
```

```
>>> pd.read_excel(open('tmp.xlsx', 'rb'),
                 ...                   sheet_name='Sheet3')
   Name  Value
 0   string1  1
 1   string2  2
 2  #Comment  3
```

Index and header can be specified via the `index_col` and `header` arguments:

```
>>> pd.read_excel('tmp.xlsx', index_col=None, header=None)
            0  1  2
   NaN  Name  Value
 0  0.0  string1  1
```

(continues on next page)
Column types are inferred but can be explicitly specified

```python
>>> pd.read_excel('tmp.xlsx', index_col=0,
...                dtype={'Name': str, 'Value': float})
Name   Value
0  string1  1.0
1  string2  2.0
2   #Comment  3.0
```

True, False, and NA values, and thousands separators have defaults, but can be explicitly specified, too. Supply the values you would like as strings or lists of strings!

```python
>>> pd.read_excel('tmp.xlsx', index_col=0,
...                na_values=['string1', 'string2'])
Name   Value
0  NaN    1.0
1  NaN    2.0
2   #Comment  3.0
```

Comment lines in the excel input file can be skipped using the `comment` kwarg

```python
>>> pd.read_excel('tmp.xlsx', index_col=0, comment='#')
Name   Value
0  string1  1.0
1  string2  2.0
2  None    NaN
```

**pandas.ExcelFile.parse**

`pandas.ExcelFile.parse` method parses specified sheet(s) into a DataFrame.

```
pandas.ExcelFile.parse(sheet_name=0, header=0, names=None, index_col=None, usecols=None, squeeze=False, converters=None, true_values=None, false_values=None, skiprows=None, nrows=None, na_values=None, parse_dates=False, date_parser=None, thousands=None, comment=None, skipfooter=0, convert_float=True, mangle_dupe_cols=True, **kwds)
```

Parse specified sheet(s) into a DataFrame.

Equivalent to `read_excel(ExcelFile, ...)`. See the `read_excel` docstring for more info on accepted parameters.

**Returns**

- **DataFrame or dict of DataFrames**: DataFrame from the passed in Excel file.

**ExcelWriter**

`ExcelWriter(path[, engine])` class for writing DataFrame objects into excel sheets.
pandas: powerful Python data analysis toolkit, Release 1.1.5

pandas.ExcelWriter

class pandas.ExcelWriter (path, engine=None, **kwargs)
Class for writing DataFrame objects into excel sheets.

Default is to use xlwt for xls, openpyxl for xlsx, odf for ods. See DataFrame.to_excel for typical usage.

Parameters

  path [str] Path to xls or xlsx or ods file.
  engine [str (optional)] Engine to use for writing. If None, defaults to io.excel.<extension>.writer. NOTE: can only be passed as a keyword argument.
  date_format [str, default None] Format string for dates written into Excel files (e.g. ‘YYYY-MM-DD’).
  datetime_format [str, default None] Format string for datetime objects written into Excel files.
    (e.g. ‘YYYY-MM-DD HH:MM:SS’).
  mode [{‘w’, ‘a’}, default ‘w’] File mode to use (write or append).

New in version 0.24.0.

Notes

None of the methods and properties are considered public.

For compatibility with CSV writers, ExcelWriter serializes lists and dicts to strings before writing.

Examples

Default usage:

```python
>>> with ExcelWriter('path_to_file.xlsx') as writer:
...    df.to_excel(writer)
```

To write to separate sheets in a single file:

```python
>>> with ExcelWriter('path_to_file.xlsx') as writer:
...    df1.to_excel(writer, sheet_name='Sheet1')
...    df2.to_excel(writer, sheet_name='Sheet2')
```

You can set the date format or datetime format:

```python
>>> with ExcelWriter('path_to_file.xlsx',
    date_format='YYYY-MM-DD',
    datetime_format='YYYY-MM-DD HH:MM:SS') as writer:
...    df.to_excel(writer)
```

You can also append to an existing Excel file:

```python
>>> with ExcelWriter('path_to_file.xlsx', mode='a') as writer:
...    df.to_excel(writer, sheet_name='Sheet3')
```
3.1.5 JSON

**read_json((path_or_buf, orient, typ, dtype, ...))** Convert a JSON string to pandas object.

**json_normalize(data[, record_path, meta, ...])** Normalize semi-structured JSON data into a flat table.

### pandas.read_json

**pandas.read_json** (path_or_buf=None, orient=None, typ='frame', dtype=None, convert_axes=None, convert_dates=True, keep_default_dates=True, numpy=False, precise_float=False, date_unit=None, encoding=None, lines=False, chunksize=None, compression='infer', nrows=None)

Convert a JSON string to pandas object.

**Parameters**

- **path_or_buf** [a valid JSON str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.json.

  If you want to pass in a path object, pandas accepts any os.PathLike.

  By file-like object, we refer to objects with a read() method, such as a file handler (e.g. via builtin open function) or StringIO.

- **orient** [str] Indication of expected JSON string format. Compatible JSON strings can be produced by to_json() with a corresponding orient value. The set of possible orients is:
  - 'split': dict like {index -> [index], columns -> [columns], data -> [values]}
  - 'records': list like [{column -> value}, ... , {column -> value}]
  - 'index': dict like {index -> {column -> value}}
  - 'columns': dict like {column -> {index -> value}}
  - 'values': just the values array

  The allowed and default values depend on the value of the typ parameter.

  - when typ == 'series',
    - allowed orients are {'split', 'records', 'index'}
    - default is 'index'
- The Series index must be unique for orient 'index'.
- The DataFrame index must be unique for orients 'index' and 'columns'.
- The DataFrame columns must be unique for orients 'index', 'columns', and 'records'.

New in version 0.23.0: ‘table’ as an allowed value for the orient argument

typ ([‘frame’, ‘series’], default ‘frame’) The type of object to recover.
dtype [bool or dict, default None] If True, infer dtypes; if a dict of column to dtype, then use those; if False, then don’t infer dtypes at all, applies only to the data.

For all orient values except 'table', default is True.

Changed in version 0.25.0: Not applicable for orient='table'.

convert_axes [bool, default None] Try to convert the axes to the proper dtypes.

For all orient values except 'table', default is True.

Changed in version 0.25.0: Not applicable for orient='table'.

convert_dates [bool or list of str, default True] If True then default datelike columns may be converted (depending on keep_default_dates). If False, no dates will be converted. If a list of column names, then those columns will be converted and default datelike columns may also be converted (depending on keep_default_dates).

keep_default_dates [bool, default True] If parsing dates (convert_dates is not False), then try to parse the default datelike columns. A column label is datelike if

- it ends with '._at',
- it ends with '._time',
- it begins with 'timestamp',
- it is 'modified', or
- it is 'date'.

numpy [bool, default False] Direct decoding to numpy arrays. Supports numeric data only, but non-numeric column and index labels are supported. Note also that the JSON ordering MUST be the same for each term if numpy=True.

Deprecated since version 1.0.0.

precise_float [bool, default False] Set to enable usage of higher precision (strtod) function when decoding string to double values. Default (False) is to use fast but less precise builtin functionality.

date_unit [str, default None] The timestamp unit to detect if converting dates. The default behaviour is to try and detect the correct precision, but if this is not desired then pass one of ‘s’, ‘ms’, ‘us’ or ‘ns’ to force parsing only seconds, milliseconds, microseconds or nanoseconds respectively.

encoding [str, default is ‘utf-8’] The encoding to use to decode py3 bytes.

lines [bool, default False] Read the file as a json object per line.
chunksize [int, optional] Return JsonReader object for iteration. See the line-delimited json docs for more information on chunksize. This can only be passed if lines=True. If this is None, the file will be read into memory all at once.

compression [\{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None\}, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’, then use gzip, bz2, zip or xz if path_or_buf is a string ending in ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’, respectively, and no decompression otherwise. If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.
	nrows [int, optional] The number of lines from the line-delimited jsonfile that has to be read. This can only be passed if lines=True. If this is None, all the rows will be returned.

New in version 1.1.

Returns

Series or DataFrame The type returned depends on the value of typ.

See also:

DataFrame.to_json Convert a DataFrame to a JSON string.

Series.to_json Convert a Series to a JSON string.

Notes

Specific to orient='table', if a DataFrame with a literal Index name of index gets written with to_json(), the subsequent read operation will incorrectly set the Index name to None. This is because index is also used by DataFrame.to_json() to denote a missing Index name, and the subsequent read_json() operation cannot distinguish between the two. The same limitation is encountered with a MultiIndex and any names beginning with 'level_'.

Examples

>>> df = pd.DataFrame([['a', 'b'], ['c', 'd']],
...                   index=['row 1', 'row 2'],
...                   columns=['col 1', 'col 2'])

Encoding/decoding a Dataframe using 'split' formatted JSON:

>>> df.to_json(orient='split')
'"columns": ["col 1", "col 2"],
  "index": ["row 1", "row 2"],
  "data": [["a", "b"], ["c", "d"]]
' >>> pd.read_json(_, orient='split')
col 1 col 2
row 1 a b
row 2 c d

Encoding/decoding a Dataframe using 'index' formatted JSON:

>>> df.to_json(orient='index')
'"row 1": {"col 1": "a", "col 2": "b"},
"row 2": {"col 1": "c", "col 2": "d"}
' >>> pd.read_json(_, orient='index')
col 1 col 2
(continues on next page)
Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```python
>>> df.to_json(orient='records')
'[{"col 1":"a","col 2":"b"},{"col 1":"c","col 2":"d"}]

>>> pd.read_json(_, orient='records')
col 1  col 2
0    a    b
1    c    d
```

Encoding with Table Schema

```python
>>> df.to_json(orient='table')
"{"schema": {"fields": [{"name": "index", "type": "string"}],
{"name": "col 1", "type": "string"},
{"name": "col 2", "type": "string"}],
"primaryKey": "index",
"pandas_version": "0.20.0"},
"data": [{"index": "row 1", "col 1": "a", "col 2": "b"},
{"index": "row 2", "col 1": "c", "col 2": "d"}]}
```

**pandas.json_normalize**

`pandas.json_normalize(data, record_path=None, meta=None, meta_prefix=None, record_prefix=None, errors='raise', sep='.', max_level=None)`

Normalize semi-structured JSON data into a flat table.

**Parameters**

- `data` [dict or list of dicts] Unserialized JSON objects.
- `record_path` [str or list of str, default None] Path in each object to list of records. If not passed, data will be assumed to be an array of records.
- `meta` [list of paths (str or list of str), default None] Fields to use as metadata for each record in resulting table.
- `meta_prefix` [str, default None] If True, prefix records with dotted (?) path, e.g. foo.bar.field if meta is [‘foo’, ‘bar’].
- `record_prefix` [str, default None] If True, prefix records with dotted (?) path, e.g. foo.bar.field if path to records is [‘foo’, ‘bar’].
- `errors` [‘raise’, ‘ignore’], default ‘raise’ Configures error handling.
  - ‘ignore’ : will ignore KeyError if keys listed in meta are not always present.
  - ‘raise’ : will raise KeyError if keys listed in meta are not always present.
- `sep` [str, default ’.’] Nested records will generate names separated by sep. e.g., for sep=’.’,
{‘foo’: {‘bar’: 0}} -> foo.bar.
- `max_level` [int, default None] Max number of levels(depth of dict) to normalize. if None, normalizes all levels.

New in version 0.25.0.
Returns

frame [DataFrame]

Normalize semi-structured JSON data into a flat table.

Examples

```python
>>> data = [{'id': 1, 'name': {'first': 'Coleen', 'last': 'Volk'}},
          {'id': 2, 'name': 'Faye Raker'}

>>> pandas.json_normalize(data)
   id    name       name.family  name.first  name.given  name.last
0  1.0  NaN         NaN          NaN         NaN        NaN
1 NaN  Regner      NaN          Nan         Mose       NaN
2  2.0  Faye Raker NaN          NaN         NaN        NaN

>>> data = [{'id': 1, 'name': 'Cole Volk', 'fitness': {'height': 130, 'weight': 60}},
          {'id': 2, 'name': 'Faye Raker', 'fitness': {'height': 130, 'weight': 60}}

>>> json_normalize(data, max_level=0)
   fitness       id  name
0  {'height': 130, 'weight': 60}  1.0  Cole Volk
1  {'height': 130, 'weight': 60}  NaN  Mose Raker
2  {'height': 130, 'weight': 60}  2.0  Faye Raker

Normalizes nested data up to level 1.

```python
>>> data = [{'id': 1, 'name': 'Cole Volk', 'fitness': {'height': 130, 'weight': 60}},
          {'id': 2, 'name': 'Faye Raker', 'fitness': {'height': 130, 'weight': 60}}

>>> json_normalize(data, max_level=1)
   fitness.height  fitness.weight  id  name
0           130             60  1.0  Cole Volk
1            NaN             NaN  NaN  Mose Raker
2            NaN             NaN  2.0  Faye Raker
```

```python
>>> data = [{'state': 'Florida', 'shortname': 'FL',
          'info': {'governor': 'Rick Scott'},
          'counties': [{'name': 'Dade', 'population': 12345},
                       {'name': 'Broward', 'population': 40000},
                       {'name': 'Palm Beach', 'population': 60000}]},
          {'state': 'Ohio', 'shortname': 'OH',
          'info': {'governor': 'John Kasich'},
          'counties': [{'name': 'Summit', 'population': 1234},
                       {'name': 'Cuyahoga', 'population': 1337}]
```

(continues on next page)
>>> result = json_normalize(data, 'counties', 
...                         [['state', 'shortname'],
...                          ['info', 'governor']])

>>> result

<table>
<thead>
<tr>
<th>name</th>
<th>population</th>
<th>state</th>
<th>shortname</th>
<th>info.governor</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dade</td>
<td>12345</td>
<td>Florida</td>
<td>FL</td>
<td>Rick Scott</td>
</tr>
<tr>
<td>Broward</td>
<td>40000</td>
<td>Florida</td>
<td>FL</td>
<td>Rick Scott</td>
</tr>
<tr>
<td>Palm Beach</td>
<td>60000</td>
<td>Florida</td>
<td>FL</td>
<td>Rick Scott</td>
</tr>
<tr>
<td>Summit</td>
<td>1234</td>
<td>Ohio</td>
<td>OH</td>
<td>John Kasich</td>
</tr>
<tr>
<td>Cuyahoga</td>
<td>1337</td>
<td>Ohio</td>

<td>John Kasich</td>
</tr>
</tbody>
</table>

>>> data = {'A': [1, 2]}

>>> json_normalize(data, 'A', record_prefix='Prefix.')

<table>
<thead>
<tr>
<th>Prefix.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 1</td>
</tr>
<tr>
<td>1 2</td>
</tr>
</tbody>
</table>

Returns normalized data with columns prefixed with the given string.

---

**build_table_schema**

Create a Table schema from data.

---

**pandas.io.json.build_table_schema**

Create a Table schema from data.

**Parameters**

- **data** [Series, DataFrame]
- **index** [bool, default True] Whether to include data.index in the schema.
- **primary_key** [bool or None, default True] Column names to designate as the primary key. The default None will set 'primaryKey' to the index level or levels if the index is unique.
- **version** [bool, default True] Whether to include a field pandas_version with the version of pandas that generated the schema.

**Returns**

- **schema** [dict]

**Notes**

See Table Schema for conversion types. Timedeltas as converted to ISO8601 duration format with 9 decimal places after the seconds field for nanosecond precision.

Categoricals are converted to the any dtype, and use the enum field constraint to list the allowed values. The ordered attribute is included in an ordered field.
Examples

```python
>>> df = pd.DataFrame(
...     {'A': [1, 2, 3],
...      'B': ['a', 'b', 'c'],
...      'C': pd.date_range('2016-01-01', freq='d', periods=3),
...    }, index=pd.Index(range(3), name='idx'))
>>> build_table_schema(df)
{'fields': [{'name': 'idx', 'type': 'integer'},
            {'name': 'A', 'type': 'integer'},
            {'name': 'B', 'type': 'string'},
            {'name': 'C', 'type': 'datetime'}],
   'pandas_version': '0.20.0',
   'primaryKey': ['idx']}
```

3.1.6 HTML

```python
pandas.read_html
```

Read HTML tables into a list of DataFrame objects.

Parameters

- `io` [str, path object or file-like object] A URL, a file-like object, or a raw string containing HTML. Note that lxml only accepts the http, ftp and file url protocols. If you have a URL that starts with 'https' you might try removing the 's'.
- `match` [str or compiled regular expression, optional] The set of tables containing text matching this regex or string will be returned. Unless the HTML is extremely simple you will probably need to pass a non-empty string here. Defaults to '.+' (match any non-empty string). The default value will return all tables contained on a page. This value is converted to a regular expression so that there is consistent behavior between Beautiful Soup and lxml.
- `flavor` [str, optional] The parsing engine to use. 'bs4' and 'html5lib' are synonymous with each other, they are both there for backwards compatibility. The default of `None` tries to use lxml to parse and if that fails it falls back on bs4 + html5lib.
- `header` [int or list-like, optional] The row (or list of rows for a `MultiIndex`) to use to make the columns headers.
- `index_col` [int or list-like, optional] The column (or list of columns) to use to create the index.
- `skiprows` [int, list-like or slice, optional] Number of rows to skip after parsing the column integer. 0-based. If a sequence of integers or a slice is given, will skip the rows indexed by that sequence. Note that a single element sequence means ‘skip the nth row’ whereas an integer means ‘skip n rows’.
- `attrs` [dict, optional] This is a dictionary of attributes that you can pass to use to identify the table in the HTML. These are not checked for validity before being passed to lxml or BeautifulSoup.

3.1. Input/output 943
Soup. However, these attributes must be valid HTML table attributes to work correctly. For
example,

```python
attrs = {'id': 'table'}
```

is a valid attribute dictionary because the ‘id’ HTML tag attribute is a valid HTML attribute
for any HTML tag as per this document.

```python
attrs = {'asdf': 'table'}
```

is not a valid attribute dictionary because ‘asdf’ is not a valid HTML attribute even if it is a
valid XML attribute. Valid HTML 4.01 table attributes can be found here. A working draft
of the HTML 5 spec can be found here. It contains the latest information on table attributes
for the modern web.

**parse_dates** [bool, optional] See `read_csv()` for more details.

**thousands** [str, optional] Separator to use to parse thousands. Defaults to ‘,’.

**encoding** [str, optional] The encoding used to decode the web page. Defaults to `None`. `None`
preserves the previous encoding behavior, which depends on the underlying parser library
(e.g., the parser library will try to use the encoding provided by the document).

**decimal** [str, default ‘.’] Character to recognize as decimal point (e.g. use ‘,’ for European data).

**converters** [dict, default None] Dict of functions for converting values in certain columns. Keys
can either be integers or column labels, values are functions that take one input argument,
the cell (not column) content, and return the transformed content.

**na_values** [iterable, default None] Custom NA values.

**keep_default_na** [bool, default True] If na_values are specified and keep_default_na is False
the default NaN values are overridden, otherwise they’re appended to.

**displayed_only** [bool, default True] Whether elements with “display: none” should be parsed.

**Returns**

ds A list of DataFrames.

**See also:**

- `read_csv()` Read a comma-separated values (csv) file into DataFrame.

**Notes**

Before using this function you should read the [gotchas about the HTML parsing libraries](#).

Expect to do some cleanup after you call this function. For example, you might need to manually assign column
names if the column names are converted to NaN when you pass the `header=0` argument. We try to assume as
little as possible about the structure of the table and push the idiosyncrasies of the HTML contained in the table
to the user.

This function searches for `<table>` elements and only for `<tr>` and `<th>` rows and `<td>` elements within
each `<tr>` or `<th>` element in the table. `<td>` stands for “table data”. This function attempts to properly
handle colspan and rowspan attributes. If the function has a `<thead>` argument, it is used to construct
the header, otherwise the function attempts to find the header within the body (by putting rows with only `<th>`
elements into the header).

Similar to `read_csv()` the `header` argument is applied after `skiprows` is applied.
This function will *always* return a list of `DataFrame` or it will fail, e.g., it will *not* return an empty list.

**Examples**

See the *read_html documentation in the IO section of the docs* for some examples of reading in HTML tables.

### 3.1.7 HDFStore: PyTables (HDF5)

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>read_hdf(path_or_buf[, key, mode, errors, ...])</code></td>
<td>Read from the store, close it if we opened it.</td>
</tr>
<tr>
<td><code>HDFStore.put(key, value[, format, index, ...])</code></td>
<td>Store object in HDFStore.</td>
</tr>
<tr>
<td><code>HDFStore.append(key, value[, format, axes, ...])</code></td>
<td>Append to Table in file.</td>
</tr>
<tr>
<td><code>HDFStore.get(key)</code></td>
<td>Retrieve pandas object stored in file.</td>
</tr>
<tr>
<td><code>HDFStore.select(key[, where, start, stop, ...])</code></td>
<td>Retrieve pandas object stored in file, optionally based on where criteria.</td>
</tr>
<tr>
<td><code>HDFStore.info()</code></td>
<td>Print detailed information on the store.</td>
</tr>
<tr>
<td><code>HDFStore.keys([include])</code></td>
<td>Return a list of keys corresponding to objects stored in HDFStore.</td>
</tr>
<tr>
<td><code>HDFStore.groups()</code></td>
<td>Return a list of all the top-level nodes.</td>
</tr>
<tr>
<td><code>HDFStore.walk([where])</code></td>
<td>Walk the pytables group hierarchy for pandas objects.</td>
</tr>
</tbody>
</table>

`pandas.read_hdf`

`pandas.read_hdf(path_or_buf, key=None, mode='r', errors='strict', where=None, start=None, stop=None, columns=None, iterator=False, chunksize=None, **kwargs)`

Read from the store, close it if we opened it.

Retrieve pandas object stored in file, optionally based on where criteria.

**Warning:** Pandas uses PyTables for reading and writing HDF5 files, which allows serializing object-dtype data with pickle when using the “fixed” format. Loading pickled data received from untrusted sources can be unsafe.

See: https://docs.python.org/3/library/pickle.html for more.

**Parameters**

- **path_or_buf** [str, path object, pandas.HDFStore or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file:///localhost/path/to/table.h5`.

  If you want to pass in a path object, pandas accepts any `os.PathLike`.

  Alternatively, pandas accepts an open `pandas.HDFStore` object.

  By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via `builtins.open` function) or `StringIO`.

- **key** [object, optional] The group identifier in the store. Can be omitted if the HDF file contains a single pandas object.

- **mode** [{‘r’, ‘r+’, ‘a’}, default ‘r’] Mode to use when opening the file. Ignored if path_or_buf is a `pandas.HDFStore`. Default is ‘r’.
errors [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for open() for a full list of options.

where [list, optional] A list of Term (or convertible) objects.

start [int, optional] Row number to start selection.

stop [int, optional] Row number to stop selection.

columns [list, optional] A list of columns names to return.

iterator [bool, optional] Return an iterator object.

chunksize [int, optional] Number of rows to include in an iteration when using an iterator.

**kwargs Additional keyword arguments passed to HDFStore.

Returns

item [object] The selected object. Return type depends on the object stored.

See also:

**DataFrame.to_hdf** Write a HDF file from a DataFrame.

**HDFStore** Low-level access to HDF files.

Examples

```python
>>> df = pd.DataFrame([[1, 1.0, 'a']], columns=['x', 'y', 'z'])
>>> df.to_hdf('./store.h5', 'data')
>>> reread = pd.read_hdf('./store.h5')
```

**pandas.HDFStore.put**

HDFStore.put(key, value, format=None, index=True, append=False, complib=None, complevel=None, min_itemsize=None, nan_rep=None, data_columns=None, encoding=None, errors='strict', track_times=True)

Store object in HDFStore.

Parameters

key [str]

value [{Series, DataFrame}]

format ['fixed(f)|table(t)', default is 'fixed'] Format to use when storing object in HDFStore. Value can be one of:

'fixed' Fixed format. Fast writing/reading. Not-appendable, nor searchable.

'table' Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.

append [bool, default False] This will force Table format, append the input data to the existing.

data_columns [list, default None] List of columns to create as data columns, or True to use all columns. See here.

encoding [str, default None] Provide an encoding for strings.
**dropna** [bool, default False, do not write an ALL nan row to] The store settable by the option `io.hdf.dropna_table`.

**track_times** [bool, default True] Parameter is propagated to `create_table` method of `PyTables`. If set to False it enables to have the same h5 files (same hashes) independent on creation time.

New in version 1.1.0.

### pandas.HDFStore.append

HDFStore.**append**(key, value, format=None, axes=None, index=True, append=True, complib=None, complevel=None, columns=None, min_itemsize=None, nan_rep=None, chunksize=None, expectedrows=None, dropna=None, data_columns=None, encoding=None, errors='strict')

Append to Table in file. Node must already exist and be Table format.

**Parameters**

- **key** [str]
- **value** [{Series, DataFrame}]
- **format** ['table' is the default] Format to use when storing object in HDFStore. Value can be one of:
  - 'table' Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
- **append** [bool, default True] Append the input data to the existing.
- **data_columns** [list of columns, or True, default None] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See here.
- **min_itemsize** [dict of columns that specify minimum str sizes]
- **nan_rep** [str to use as str nan representation]
- **chunksize** [size to chunk the writing]
- **expectedrows** [expected TOTAL row size of this table]
- **encoding** [default None, provide an encoding for str]
- **dropna** [bool, default False] Do not write an ALL nan row to the store settable by the option `io.hdf.dropna_table`.

**Notes**

Does not check if data being appended overlaps with existing data in the table, so be careful

---

**3.1. Input/output**
pandas.HDFStore.get

HDFStore.get(key)
Retrieve pandas object stored in file.

Parameters
key [str]

Returns
object Same type as object stored in file.

pandas.HDFStore.select

HDFStore.select(key, where=None, start=None, stop=None, columns=None, iterator=False, chunksize=None, auto_close=False)
Retrieve pandas object stored in file, optionally based on where criteria.

Warning: Pandas uses PyTables for reading and writing HDF5 files, which allows serializing object-dtype
data with pickle when using the “fixed” format. Loading pickled data received from untrusted sources can
be unsafe.
See: https://docs.python.org/3/library/pickle.html for more.

Parameters
key [str] Object being retrieved from file.
where [list, default None] List of Term (or convertible) objects, optional.
start [int, default None] Row number to start selection.
stop [int, default None] Row number to stop selection.
columns [list, default None] A list of columns that if not None, will limit the return columns.
iterator [bool, default False] Returns an iterator.
chunksize [int, default None] Number or rows to include in iteration, return an iterator.
auto_close [bool, default False] Should automatically close the store when finished.

Returns
object Retrieved object from file.

pandas.HDFStore.info

HDFStore.info()
Print detailed information on the store.

Returns
str
pandas.HDFStore.keys

HDFStore.keys(include='pandas')

Return a list of keys corresponding to objects stored in HDFStore.

Parameters

include [str, default ‘pandas’] When kind equals ‘pandas’ return pandas objects When kind equals ‘native’ return native HDF5 Table objects

New in version 1.1.0.

Returns

list List of ABSOLUTE path-names (e.g. have the leading ‘/’).

Raises

raises ValueError if kind has an illegal value

pandas.HDFStore.groups

HDFStore.groups()

Return a list of all the top-level nodes.

Each node returned is not a pandas storage object.

Returns

list List of objects.

pandas.HDFStore.walk

HDFStore.walk(where='/')

Walk the pytables group hierarchy for pandas objects.

This generator will yield the group path, subgroups and pandas object names for each group.

Any non-pandas PyTables objects that are not a group will be ignored.

The where group itself is listed first (preorder), then each of its child groups (following an alphanumerical order) is also traversed, following the same procedure.

New in version 0.24.0.

Parameters

where [str, default ‘/’] Group where to start walking.

Yields

path [str] Full path to a group (without trailing ‘/’).

groups [list] Names (strings) of the groups contained in path.

leaves [list] Names (strings) of the pandas objects contained in path.
3.1.8 Feather

read_feather(path[, columns, use_threads])  
Load a feather-format object from the file path.

pandas.read_feather

pandas.read_feather(path, columns=None, use_threads=True)  
Load a feather-format object from the file path.

Parameters

- **path** [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: file:///localhost/path/to/table.feather.
  
  If you want to pass in a path object, pandas accepts any os.PathLike.
  
  By file-like object, we refer to objects with a read() method, such as a file handler (e.g. via builtin open function) or StringIO.
  
- **columns** [sequence, default None] If not provided, all columns are read.
  
  New in version 0.24.0.

- **use_threads** [bool, default True]  
  
  Whether to parallelize reading using multiple threads.
  
  New in version 0.24.0.

Returns

- **type of object stored in file**

3.1.9 Parquet

read_parquet(path[, engine, columns])  
Load a parquet object from the file path, returning a DataFrame.

pandas.read_parquet

pandas.read_parquet(path, engine='auto', columns=None, **kwargs)  
Load a parquet object from the file path, returning a DataFrame.

Parameters

- **path** [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: file:///localhost/path/to/table.parquet. A file URL can also be a path to a directory that contains multiple partitioned parquet files. Both pyarrow and fastparquet support paths to directories as well as file URLs. A directory path could be: file:///localhost/path/to/tables or s3://bucket/partition_dir.
  
  If you want to pass in a path object, pandas accepts any os.PathLike.
By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via built-in `open` function) or `StringIO`.

**engine** [‘auto’, ‘pyarrow’, ‘fastparquet’], default ‘auto’] Parquet library to use. If ‘auto’, then the option `io.parquet.engine` is used. The default `io.parquet.engine` behavior is to try ‘pyarrow’, falling back to ‘fastparquet’ if ‘pyarrow’ is unavailable.

**columns** [list, default=None] If not None, only these columns will be read from the file.

**kwargs** Any additional kwargs are passed to the engine.

### 3.1.10 ORC

```python
read_orc(path[, columns])
```

Load an ORC object from the file path, returning a DataFrame.

**pandas.read_orc**

```python
pandas.read_orc(path, columns=None, **kwargs)
```

Load an ORC object from the file path, returning a DataFrame.

New in version 1.0.0.

**Parameters**

- **path** [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file:///localhost/path/to/table.orc`.

  If you want to pass in a path object, pandas accepts any `os.PathLike`.

  By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via built-in `open` function) or `StringIO`.

- **columns** [list, default=None] If not None, only these columns will be read from the file.

  **kwargs** Any additional kwargs are passed to pyarrow.

### 3.1.11 SAS

```python
read_sas(filepath_or_buffer[, format, ...])
```

Read SAS files stored as either XPORT or SAS7BDAT format files.
pandas: powerful Python data analysis toolkit, Release 1.1.5

**pandas.read_sas**

```python
pandas.read_sas(filepath_or_buffer, format=None, index=None, encoding=None, chunksize=None, iterator=False)
```

Read SAS files stored as either XPORT or SAS7BDAT format files.

**Parameters**

- `filepath_or_buffer [str, path object or file-like object]` Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.sas`.

  If you want to pass in a path object, pandas accepts any `os.PathLike`.

  By file-like object, we refer to objects with a `read()` method, such as a file handler (e.g. via builtin `open` function) or `StringIO`.

- `format [str {'xport', 'sas7bdat'} or None]` If None, file format is inferred from file extension. If ‘xport’ or ‘sas7bdat’, uses the corresponding format.

- `index [identifier of index column, defaults to None]` Identifier of column that should be used as index of the DataFrame.

- `encoding [str, default is None]` Encoding for text data. If None, text data are stored as raw bytes.

- `chunksize [int]` Read file `chunksize` lines at a time, returns iterator.

- `iterator [bool, defaults to False]` If True, returns an iterator for reading the file incrementally.

**Returns**

- DataFrame if iterator=False and chunksize=None, else SAS7BDATReader or XportReader

**3.1.12 SPSS**

```python
read_spss(path[, usecols, convert_categoricals])
```

Load an SPSS file from the file path, returning a DataFrame.

New in version 0.25.0.

**Parameters**

- `path [str or Path]` File path.

- `usecols [list-like, optional]` Return a subset of the columns. If None, return all columns.

- `convert_categoricals [bool, default is True]` Convert categorical columns into `pd.Categorical`.

**Returns**

- DataFrame
3.1.13 SQL

`pandas.read_sql_table` table_name, con[, schema, ...]

Read SQL database table into a DataFrame.

Given a table name and a SQLAlchemy connectable, returns a DataFrame. This function does not support DBAPI connections.

**Parameters**

- `table_name` [str] Name of SQL table in database.
- `con` [SQLAlchemy connectable or str] A database URI could be provided as as str. SQLite DBAPI connection mode not supported.
- `schema` [str, default None] Name of SQL schema in database to query (if database flavor supports this). Uses default schema if None (default).
- `index_col` [str or list of str, optional, default: None] Column(s) to set as index(MultiIndex).
- `coerce_float` [bool, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Can result in loss of Precision.
- `parse_dates` [list or dict, default None]
  - List of column names to parse as dates.
  - Dict of {column_name: format string} where format string is strftime compatible in case of parsing string times or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
  - Dict of {column_name: arg dict}, where the arg dict corresponds to the keyword arguments of pandas.to_datetime() Especially useful with databases without native Datetime support, such as SQLite.
- `columns` [list, default None] List of column names to select from SQL table.
- `chunksize` [int, default None] If specified, returns an iterator where chunksize is the number of rows to include in each chunk.

**Returns**

DataFrame or Iterator[DataFrame] A SQL table is returned as two-dimensional data structure with labeled axes.

**See also:**

- `pandas.read_sql_query` Read SQL query into a DataFrame.
- `pandas.read_sql` Read SQL query or database table into a DataFrame.
Notes

Any datetime values with time zone information will be converted to UTC.

Examples

```python
>>> pd.read_sql_table('table_name', 'postgres:///db_name')
```

`pandas.read_sql_query`

`pandas.read_sql_query` *(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None, chunksize=None)*

Read SQL query into a DataFrame.

Returns a DataFrame corresponding to the result set of the query string. Optionally provide an `index_col` parameter to use one of the columns as the index, otherwise default integer index will be used.

Parameters

- **sql** [str SQL query or SQLAlchemy Selectable (select or text object)] SQL query to be executed.
- **con** [SQLAlchemy connectable, str, or sqlite3 connection] Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported.
- **index_col** [str or list of str, optional, default: None] Column(s) to set as index(MultiIndex).
- **coerce_float** [bool, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Useful for SQL result sets.
- **params** [list, tuple or dict, optional, default: None] List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249’s paramstyle, is supported. Eg. for psycopg2, uses %(name)s so use params={'name' : ‘value’}.
- **parse_dates** [list or dict, default: None] List of column names to parse as dates.
  - Dict of {column_name: format string} where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
  - Dict of {column_name: arg dict}, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()` Especially useful with databases without native Datetime support, such as SQLite.
- **chunksize** [int, default None] If specified, return an iterator where chunksize is the number of rows to include in each chunk.

Returns

DataFrame or Iterator[DataFrame]

See also:

- `read_sql_table` Read SQL database table into a DataFrame.
- `read_sql` Read SQL query or database table into a DataFrame.
Notes

Any datetime values with time zone information parsed via the `parse_dates` parameter will be converted to UTC.

**pandas.read_sql**

```python
pandas.read_sql(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None, columns=None, chunksize=None)
```

Read SQL query or database table into a DataFrame.

This function is a convenience wrapper around `pandas.read_sql_table` and `pandas.read_sql_query` (for backward compatibility). It will delegate to the specific function depending on the provided input. A SQL query will be routed to `read_sql_query`, while a database table name will be routed to `read_sql_table`. Note that the delegated function might have more specific notes about their functionality not listed here.

**Parameters**

- `sql` [str or SQLAlchemy Selectable (select or text object)] SQL query to be executed or a table name.
- `con` [SQLAlchemy connectable, str, or sqlite3 connection] Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable. See here.
- `index_col` [str or list of str, optional, default: None] Column(s) to set as index(MultiIndex).
- `coerce_float` [bool, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets.
- `params` [list, tuple or dict, optional, default: None] List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249's paramstyle, is supported. Eg. for psycopg2, uses %(name)s so use params={'name': 'value'}.
- `parse_dates` [list or dict, default: None]
  - List of column names to parse as dates.
  - Dict of `{column_name: format string}` where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
  - Dict of `{column_name: arg dict}`, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()` Especially useful with databases without native Datetime support, such as SQLite.
- `columns` [list, default: None] List of column names to select from SQL table (only used when reading a table).
- `chunksize` [int, default None] If specified, return an iterator where `chunksize` is the number of rows to include in each chunk.

**Returns**

DataFrame or Iterator[DataFrame]

See also:

- `read_sql_table` Read SQL database table into a DataFrame.
**read_sql_query**  Read SQL query into a DataFrame.

### 3.1.14 Google BigQuery

**read_gbq**(query[, project_id, index_col, . . .])  Load data from Google BigQuery.

**pandas.read_gbq**

pandas.read_gbq(query, project_id=None, index_col=None, col_order=None, reauth=False, auth_local_webserver=False, dialect=None, location=None, configuration=None, credentials=None, use_bqstorage_api=None, max_results=None, private_key=None, verbose=None, progress_bar_type=None)

Load data from Google BigQuery.

This function requires the pandas-gbq package.

See the How to authenticate with Google BigQuery guide for authentication instructions.

**Parameters**

- **query**  [str] SQL-Like Query to return data values.
- **project_id**  [str, optional] Google BigQuery Account project ID. Optional when available from the environment.
- **index_col**  [str, optional] Name of result column to use for index in results DataFrame.
- **col_order**  [list(str), optional] List of BigQuery column names in the desired order for results DataFrame.
- **reauth**  [bool, default False] Force Google BigQuery to re-authenticate the user. This is useful if multiple accounts are used.
- **auth_local_webserver**  [bool, default False] Use the local webserver flow instead of the console flow when getting user credentials.
  
  *New in version 0.2.0 of pandas-gbq.*

- **dialect**  [str, default ‘legacy’] Note: The default value is changing to ‘standard’ in a future version. SQL syntax dialect to use. Value can be one of:
  
  - **’legacy’** Use BigQuery’s legacy SQL dialect. For more information see BigQuery Legacy SQL Reference.
  
  - **’standard’** Use BigQuery’s standard SQL, which is compliant with the SQL 2011 standard. For more information see BigQuery Standard SQL Reference.

  *Changed in version 0.24.0.*

- **location**  [str, optional] Location where the query job should run. See the BigQuery locations documentation for a list of available locations. The location must match that of any datasets used in the query.
  
  *New in version 0.5.0 of pandas-gbq.*

- **configuration**  [dict, optional] Query config parameters for job processing. For example:

  ```python
  configuration = {'query': {'useQueryCache': False}}
  ```
For more information see BigQuery REST API Reference.

**credentials** [google.auth.credentials.Credentials, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine google.auth.compute_engine.Credentials or Service Account google.oauth2.service_account.Credentials directly.

*New in version 0.8.0 of pandas-gbq.*

New in version 0.24.0.

**use_bqstorage_api** [bool, default False] Use the BigQuery Storage API to download query results quickly, but at an increased cost. To use this API, first enable it in the Cloud Console. You must also have the bigquery.readsessions.create permission on the project you are billing queries to.

This feature requires version 0.10.0 or later of the pandas-gbq package. It also requires the google-cloud-bigquery-storage and fastavro packages.

*New in version 0.25.0.*

**max_results** [int, optional] If set, limit the maximum number of rows to fetch from the query results.

*New in version 0.12.0 of pandas-gbq.*

New in version 1.1.0.

**progress_bar_type** [Optional, str] If set, use the tqdm library to display a progress bar while the data downloads. Install the tqdm package to use this feature.

Possible values of progress_bar_type include:

- **None** No progress bar.
- **tqdm** Use the tqdm.tqdm() function to print a progress bar to sys.stderr.
- **tqdm_notebook** Use the tqdm.tqdm_notebook() function to display a progress bar as a Jupyter notebook widget.
- **tqdm_gui** Use the tqdm.tqdm_gui() function to display a progress bar as a graphical dialog box.

Note that this feature requires version 0.12.0 or later of the pandas-gbq package. And it requires the tqdm package. Slightly different than pandas-gbq, here the default is None.

New in version 1.0.0.

**Returns**

- **df**: DataFrame DataFrame representing results of query.

**See also:**

- **pandas_gbq.read_gbq** This function in the pandas-gbq library.
- **DataFrame.to_gbq** Write a DataFrame to Google BigQuery.
3.1.15 STATA

```
read_stata(filepath_or_buffer[, ...])  Read Stata file into DataFrame.
```

**pandas.read_stata**

```
pandas.read_stata(filepath_or_buffer, convert_dates=True, convert_categoricals=True, index_col=None, convert_missing=False, preserve_dtypes=True, columns=None, order_categoricals=True, chunksize=None, iterator=False)
```

Read Stata file into DataFrame.

**Parameters**

- **filepath_or_buffer** [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.dta.
  
  If you want to pass in a path object, pandas accepts any os.PathLike.
  
  By file-like object, we refer to objects with a read() method, such as a file handler (e.g. via builtin open function) or StringIO.

- **convert_dates** [bool, default True] Convert date variables to DataFrame time values.

- **convert_categoricals** [bool, default True] Read value labels and convert columns to Categorical/Factor variables.

- **index_col** [str, optional] Column to set as index.

- **convert_missing** [bool, default False] Flag indicating whether to convert missing values to their Stata representations. If False, missing values are replaced with nan. If True, columns containing missing values are returned with object data types and missing values are represented by StataMissingValue objects.

- **preserve_dtypes** [bool, default True] Preserve Stata datatypes. If False, numeric data are upcast to pandas default types for foreign data (float64 or int64).

- **columns** [list or None] Columns to retain. Columns will be returned in the given order. None returns all columns.

- **order_categoricals** [bool, default True] Flag indicating whether converted categorical data are ordered.

- **chunksize** [int, default None] Return StataReader object for iterations, returns chunks with given number of lines.

- **iterator** [bool, default False] Return StataReader object.

**Returns**

- **DataFrame or StataReader**

**See also:**

- **io.stata.StataReader** Low-level reader for Stata data files.

- **DataFrame.to_stata** Export Stata data files.
Notes

Categorical variables read through an iterator may not have the same categories and dtype. This occurs when a variable stored in a DTA file is associated to an incomplete set of value labels that only label a strict subset of the values.

Examples

Read a Stata dta file:

>>> df = pd.read_stata('filename.dta')

Read a Stata dta file in 10,000 line chunks:

>>> itr = pd.read_stata('filename.dta', chunksize=10000)
>>> for chunk in itr:
...   do_something(chunk)

pandas.io.stata.StataReader.data_label

property StataReader.data_label
Return data label of Stata file.

pandas.io.stata.StataReader.value_labels

StataReader.value_labels()
Return a dict, associating each variable name a dict, associating each value its corresponding label.

pandas.io.stata.StataReader.variable_labels

StataReader.variable_labels()
Return variable labels as a dict, associating each variable name with corresponding label.
### 3.2 General functions

#### 3.2.1 Data manipulations

- **melt**(frame[, id_vars, value_vars, var_name, ...])  
  Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

- **pivot**(data[, index, columns, values])  
  Return reshaped DataFrame organized by given index / column values.

- **pivot_table**(data[, values, index, columns, ...])  
  Create a spreadsheet-style pivot table as a DataFrame.

- **crosstab**(index, columns[, values, rownames, ...])  
  Compute a simple cross tabulation of two (or more) factors.

- **cut**(x, bins[, right, labels, retbins, ...])  
  Bin values into discrete intervals.

- **qcut**(x, q[, labels, retbins, precision, ...])  
  Quantile-based discretization function.

- **merge**(left, right[, how, on, left_on, ...])  
  Merge DataFrame or named Series objects with a database-style join.

- **merge_ordered**(left, right[, on, left_on, ...])  
  Perform merge with optional filling/interpolation.

- **merge_asof**(left, right[, on, left_on, ...])  
  Perform an asof merge.

- **concat**(objs[, axis, join, ignore_index, ...])  
  Concatenate pandas objects along a particular axis with optional set logic along the other axes.

- **get_dummies**(data[, prefix, prefix_sep, ...])  
  Convert categorical variable into dummy/indicator variables.

- **factorize**(values[, sort, na_sentinel, size_hint])  
  Encode the object as an enumerated type or categorical variable.

- **unique**(values)  
  Hash table-based unique.

- **wide_to_long**(df, stubnames, i, j[, sep, suffix])  
  Wide panel to long format.

### pandas.melt

**pandas.melt**(frame, id_vars=None, value_vars=None, var_name=None, value_name='value', col_level=None, ignore_index=True)  
Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (id_vars), while all other columns, considered measured variables (value_vars), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’.

**Parameters**

- **id_vars** [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.

- **value_vars** [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as id_vars.

- **var_name** [scalar] Name to use for the ‘variable’ column. If None it uses frame.columns.name or ‘variable’.

- **value_name** [scalar, default ‘value’] Name to use for the ‘value’ column.

- **col_level** [int or str, optional] If columns are a MultiIndex then use this level to melt.
ignore_index  [bool, default True] If True, original index is ignored. If False, the original index is retained. Index labels will be repeated as necessary.

New in version 1.1.0.

Returns

DataFrame  Un pivoted DataFrame.

See also:

     DataFrame.melt    Identical method.
     pivot_table      Create a spreadsheet-style pivot table as a DataFrame.
     DataFrame.pivot  Return reshaped DataFrame organized by given index / column values.
     DataFrame.explode Explode a DataFrame from list-like columns to long format.

Examples

```python
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
                      'B': {0: 1, 1: 3, 2: 5},
                      'C': {0: 2, 1: 4, 2: 6}})

>>> df
   A  B  C
0  a  1  2
1  b  3  4
2  c  5  6

>>> pd.melt(df, id_vars=['A'], value_vars=['B'])
    variable  value
0         A    1
1         B    3
2         B    5

>>> pd.melt(df, id_vars=['A'], value_vars=['B', 'C'])
    variable  value
0         A    1
1         B    3
2         B    5
3         A    2
4         B    4
5         C    6

The names of ‘variable’ and ‘value’ columns can be customized:

```python
>>> pd.melt(df, id_vars=['A'], value_vars=['B', 'C'],
          var_name='myVarname', value_name='myValname')
    myVarname  myValname
0         A    1
1         B    3
2         B    5
```

Original index values can be kept around:
```python
>>> pd.melt(df, id_vars=['A'], value_vars=['B', 'C'], ignore_index=False)
   A  variable  value
0  a        B    1
1  b        B    3
2  c        B    5
0  a        C    2
1  b        C    4
2  c        C    6
```

If you have multi-index columns:

```python
>>> df.columns = ['list('ABC'), list('DEF')]  
>>> df
   A  B  C  D  E  F
0  a  1  2  3  4  5
1  b  3  4  5  6  7
2  c  5  6  7  8  9
```

```python
>>> pd.melt(df, col_level=0, id_vars=['A'], value_vars=['B'])
   A  variable  value
0  a        B    1
1  b        B    3
2  c        B    5
```

```python
>>> pd.melt(df, id_vars=[('A', 'D')], value_vars=[('B', 'E')])
   (A, D)  variable_0  variable_1  value
0  a      B        E      1
1  b      B        E      3
2  c      B        E      5
```

---

### pandas.pivot

**pandas.pivot** *(data, index=None, columns=None, values=None)*

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified *index / columns* to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the *User Guide* for more on reshaping.

**Parameters**

- **data** [DataFrame]
- **index** [str or object or a list of str, optional] Column to use to make new frame’s index. If None, uses existing index.
  
  Changed in version 1.1.0: Also accept list of index names.

- **columns** [str or object or a list of str] Column to use to make new frame’s columns.

  Changed in version 1.1.0: Also accept list of columns names.

- **values** [str, object or a list of the previous, optional] Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.

  Changed in version 0.23.0: Also accept list of column names.
Returns

**DataFrame** Returns reshaped DataFrame.

**Raises**

**ValueError:** When there are any *index, columns* combinations with multiple values.

*DataFrame.pivot_table* when you need to aggregate.

**See also:**

*DataFrame.pivot_table* Generalization of pivot that can handle duplicate values for one index/column pair.

*DataFrame.unstack* Pivot based on the index values instead of a column.

**Notes**

For finer-tuned control, see hierarchical indexing documentation along with the related stack/unstack methods.

**Examples**

```python
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two', 'two'],
                    ...            'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
                    ...            'baz': [1, 2, 3, 4, 5, 6],
                    ...            'zoo': ['x', 'y', 'z', 'q', 'w', 't']})
>>> df
   foo   bar  baz  zoo
0  one   A    1   x
1  one   B    2   y
2  one   C    3   z
3  two   A    4   q
4  two   B    5   w
5  two   C    6   t

>>> df.pivot(index='foo', columns='bar', values='baz')
   bar  A  B  C
foo
one  1  2  3
two  4  5  6

>>> df.pivot(index='foo', columns='bar')['baz']
   bar  A  B  C
foo
one  1  2  3
two  4  5  6

>>> df.pivot(index='foo', columns='bar', values=['baz', 'zoo'])
   baz  zoo
bar A  B  C A  B  C
foo
one  1  2  3 x  y  z
two  4  5  6 q  w  t
```

You could also assign a list of column names or a list of index names.
>>> df = pd.DataFrame({
...     "lev1": [1, 1, 2, 2, 2],
...     "lev2": [1, 1, 2, 1, 2],
...     "lev3": [1, 2, 1, 2, 1],
...     "lev4": [1, 2, 3, 4, 5],
...     "values": [0, 1, 2, 3, 4, 5]
... })

<table>
<thead>
<tr>
<th>lev1</th>
<th>lev2</th>
<th>lev3</th>
<th>lev4</th>
<th>values</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>2</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>2</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>1</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>1</td>
<td>1</td>
<td>5</td>
</tr>
<tr>
<td>5</td>
<td>2</td>
<td>2</td>
<td>2</td>
<td>6</td>
</tr>
</tbody>
</table>

>>> df.pivot(index="lev1", columns=["lev2", "lev3"], values="values")

<table>
<thead>
<tr>
<th>lev2</th>
<th>lev3</th>
<th>lev1</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0.0</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>1.0</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>4.0</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>3.0</td>
</tr>
</tbody>
</table>

A ValueError is raised if there are any duplicates.

>>> df = pd.DataFrame({"foo": ["one", "one", "two", "two"],
...     "bar": ["A", "A", "B", "C"],
...     "baz": [1, 2, 3, 4]})

<table>
<thead>
<tr>
<th>foo</th>
<th>bar</th>
<th>baz</th>
</tr>
</thead>
<tbody>
<tr>
<td>one</td>
<td>A</td>
<td>1</td>
</tr>
<tr>
<td>one</td>
<td>A</td>
<td>2</td>
</tr>
<tr>
<td>two</td>
<td>B</td>
<td>3</td>
</tr>
<tr>
<td>two</td>
<td>C</td>
<td>4</td>
</tr>
</tbody>
</table>

Notice that the first two rows are the same for our index and columns arguments.

>>> df.pivot(index='foo', columns='bar', values='baz')

Traceback (most recent call last):
 ...
ValueError: Index contains duplicate entries, cannot reshape
pandas.pivot_table

**pandas.pivot_table**(data, values=None, index=None, columns=None, aggfunc='mean', fill_value=None, margins=False, dropna=True, margins_name='All', observed=False)

Create a spreadsheet-style pivot table as a DataFrame.

The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

**Parameters**

- **data** [DataFrame]  
- **values** [column to aggregate, optional]  
- **index** [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.  
- **columns** [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.  
- **aggfunc** [function, list of functions, dict, default numpy.mean] If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions.  
- **fill_value** [scalar, default None] Value to replace missing values with (in the resulting pivot table, after aggregation).  
- **margins** [bool, default False] Add all row / columns (e.g. for subtotal / grand totals).  
- **dropna** [bool, default True] Do not include columns whose entries are all NaN.  
- **margins_name** [str, default ‘All’] Name of the row / column that will contain the totals when margins is True.  
- **observed** [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

*Changed in version 0.25.0.*

**Returns**

- **DataFrame** An Excel style pivot table.

**See also:**

- **DataFrame.pivot** Pivot without aggregation that can handle non-numeric data.
Examples

```python
>>> df = pd.DataFrame({
    "A": ['foo', 'foo', 'foo', 'foo', 'foo',
          'bar', 'bar', 'bar', 'bar'],
    "B": ['one', 'one', 'one', 'two', 'two',
          'one', 'one', 'two', 'two'],
    "C": ['small', 'large', 'large', 'small',
          'small', 'large', 'small', 'small',
          'large'],
    "D": [1, 2, 2, 3, 3, 4, 5, 6, 7],
    "E": [2, 4, 5, 5, 6, 6, 8, 9, 9]
})
```

```python
>>> df
```

```
   A  B  C  D  E
0 foo one small 1 2
1 foo one large 2 4
2 foo one large 2 5
3 foo two small 3 5
4 foo two small 3 6
5 bar one large 4 6
6 bar one small 5 8
7 bar two small 6 9
8 bar two large 7 9
```

This first example aggregates values by taking the sum.

```python
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
                          columns=['C'], aggfunc=np.sum)
```

```
   C     large  small
   A    B
bar one 4.0  5.0
      two 7.0  6.0
foo one 4.0  1.0
      two NaN  6.0
```

We can also fill missing values using the `fill_value` parameter.

```python
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
                          columns=['C'], aggfunc=np.sum, fill_value=0)
```

```
   C     large  small
   A    B
bar one 4  5
      two 7  6
foo one 4  1
      two 0  6
```

The next example aggregates by taking the mean across multiple columns.

```python
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
                          aggfunc={'D': np.mean,
                                   'E': np.mean})
```

```
   D     E
   A    C
bar large 5.500000 7.500000
      small 5.500000 8.500000
```

(continues on next page)
We can also calculate multiple types of aggregations for any given value column.

```python
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                        aggfunc={'D': np.mean,
...                                'E': [min, max, np.mean]})
>>> table

<table>
<thead>
<tr>
<th></th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>mean</td>
<td>max</td>
</tr>
<tr>
<td>A</td>
<td></td>
<td></td>
</tr>
<tr>
<td>bar</td>
<td>5.5</td>
<td>9.0</td>
</tr>
<tr>
<td>small</td>
<td>5.5</td>
<td>9.0</td>
</tr>
<tr>
<td>foo</td>
<td>2.0</td>
<td>5.0</td>
</tr>
<tr>
<td>small</td>
<td>2.3</td>
<td>6.0</td>
</tr>
</tbody>
</table>
```

pandas.crosstab

```python
pandas.crosstab(index, columns, values=None, rownames=None, colnames=None, aggfunc=None, margins=False, margins_name='All', dropna=True, normalize=False)
```

Compute a simple cross tabulation of two (or more) factors. By default computes a frequency table of the factors unless an array of values and an aggregation function are passed.

**Parameters**

- `index` [array-like, Series, or list of arrays/Series] Values to group by in the rows.
- `columns` [array-like, Series, or list of arrays/Series] Values to group by in the columns.
- `values` [array-like, optional] Array of values to aggregate according to the factors. Requires `aggfunc` to be specified.
- `rownames` [sequence, default None] If passed, must match number of row arrays passed.
- `colnames` [sequence, default None] If passed, must match number of column arrays passed.
- `aggfunc` [function, optional] If specified, requires `values` to be specified as well.
- `margins` [bool, default False] Add row/column margins (subtotals).
- `margins_name` [str, default ‘All’] Name of the row/column that will contain the totals when margins is True.
- `dropna` [bool, default True] Do not include columns whose entries are all NaN.
- `normalize` [bool, {'all', 'index', 'columns'}, or {0,1}, default False] Normalize by dividing all values by the sum of values.
  - If passed ‘all’ or True, will normalize over all values.
  - If passed ‘index’ will normalize over each row.
  - If passed ‘columns’ will normalize over each column.
  - If margins is True, will also normalize margin values.

**Returns**

- `DataFrame` Cross tabulation of the data.

See also:
**DataFrame.pivot**  Reshape data based on column values.

**pivot_table**  Create a pivot table as a DataFrame.

**Notes**

Any Series passed will have their name attributes used unless row or column names for the cross-tabulation are specified.

Any input passed containing Categorical data will have all of its categories included in the cross-tabulation, even if the actual data does not contain any instances of a particular category.

In the event that there aren’t overlapping indexes an empty DataFrame will be returned.

**Examples**

```python
>>> a = np.array(['foo', 'foo', 'foo', 'foo', 'bar', 'bar',
... 'bar', 'foo', 'foo', 'foo'], dtype=object)
>>> b = np.array(['one', 'one', 'one', 'two', 'one', 'one',
... 'two', 'two', 'two', 'one'], dtype=object)
>>> c = np.array(['dull', 'dull', 'shiny', 'dull', 'dull', 'shiny',
... 'shiny', 'dull', 'shiny', 'shiny'], dtype=object)
>>> pd.crosstab(a, [b, c], rownames=['a'], colnames=['b', 'c'])

<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
</tr>
</thead>
<tbody>
<tr>
<td>dull</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>shiny</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>bar</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>foo</td>
<td>2</td>
<td>2</td>
</tr>
</tbody>
</table>
```

Here ‘c’ and ‘f’ are not represented in the data and will not be shown in the output because dropna is True by default. Set dropna=False to preserve categories with no data.

```python
>>> foo = pd.Categorical(['a', 'b'], categories=['a', 'b', 'c'])
>>> bar = pd.Categorical(['d', 'e'], categories=['d', 'e', 'f'])
>>> pd.crosstab(foo, bar)

col_0 d e f
row_0
a   1  0  0
b   0  1  0
c   0  0  0
```
pandas.cut

```python
def pandas.cut(x, bins, right=True, labels=None, retbins=False, precision=3, include_lowest=False, duplicates='raise', ordered=True)
```

Bin values into discrete intervals.

Use `cut` when you need to segment and sort data values into bins. This function is also useful for going from a continuous variable to a categorical variable. For example, `cut` could convert ages to groups of age ranges. Supports binning into an equal number of bins, or a pre-specified array of bins.

**Parameters**

- **x** [array-like] The input array to be binned. Must be 1-dimensional.
- **bins** [int, sequence of scalars, or IntervalIndex] The criteria to bin by.
  - int : Defines the number of equal-width bins in the range of `x`. The range of `x` is extended by .1% on each side to include the minimum and maximum values of `x`.
  - sequence of scalars : Defines the bin edges allowing for non-uniform width. No extension of the range of `x` is done.
  - IntervalIndex : Defines the exact bins to be used. Note that IntervalIndex for `bins` must be non-overlapping.
- **right** [bool, default True] Indicates whether `bins` includes the rightmost edge or not. If `right == True` (the default), then the `bins [1, 2, 3, 4]` indicate (1,2], (2,3], (3,4]. This argument is ignored when `bins` is an IntervalIndex.
- **labels** [array or False, default None] Specifies the labels for the returned bins. Must be the same length as the resulting bins. If False, returns only integer indicators of the bins. This affects the type of the output container (see below). This argument is ignored when `bins` is an IntervalIndex. If True, raises an error. When `ordered=False`, labels must be provided.
- **retbins** [bool, default False] Whether to return the bins or not. Useful when bins is provided as a scalar.
- **precision** [int, default 3] The precision at which to store and display the bins labels.
- **include_lowest** [bool, default False] Whether the first interval should be left-inclusive or not.
- **duplicates** [(default ‘raise’, ‘drop’), optional] If bin edges are not unique, raise ValueError or drop non-uniques.
  
  New in version 0.23.0.
- **ordered** [bool, default True] Whether the labels are ordered or not. Applies to returned types Categorical and Series (with Categorical dtype). If True, the resulting categorical will be ordered. If False, the resulting categorical will be unordered (labels must be provided).
  
  New in version 1.1.0.

**Returns**

- **out** [Categorical, Series, or ndarray] An array-like object representing the respective bin for each value of `x`. The type depends on the value of `labels`.
  - True (default) : returns a Series for Series `x` or a Categorical for all other inputs. The values stored within are Interval dtype.
  - sequence of scalars : returns a Series for Series `x` or a Categorical for all other inputs. The values stored within are whatever the type in the sequence is.
  - False : returns an ndarray of integers.
bins [numpy.ndarray or IntervalIndex.] The computed or specified bins. Only returned when retbins=True. For scalar or sequence bins, this is an ndarray with the computed bins. If set duplicates=drop, bins will drop non-unique bin. For an IntervalIndex bins, this is equal to bins.

See also:

gcut Discretize variable into equal-sized buckets based on rank or based on sample quantiles.

Categorical Array type for storing data that come from a fixed set of values.

Series One-dimensional array with axis labels (including time series).

IntervalIndex Immutable Index implementing an ordered, sliceable set.

Notes

Any NA values will be NA in the result. Out of bounds values will be NA in the resulting Series or Categorical object.

Examples

Discretize into three equal-sized bins.

```python
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3)
...[(0.994, 3.0], (3.0, 5.0], (3.0, 5.0], (3.0, 5.0], (3.0, 5.0], ...
Categories (3, interval[float64]): [(0.994, 3.0) < (3.0, 5.0) ...

>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3, retbins=True)
...[(0.994, 3.0], (3.0, 5.0], (3.0, 5.0], (3.0, 5.0], (3.0, 5.0], ...
Categories (3, interval[float64]): [(0.994, 3.0) < (3.0, 5.0) ...
array([0.994, 3. , 5. , 7. , 5. , 7. ])
```

Discovers the same bins, but assign them specific labels. Notice that the returned Categorical’s categories are labels and is ordered.

```python
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3, labels=['bad', 'medium', 'good'])
['bad', 'good', 'medium', 'medium', 'good', 'bad']
Categories (3, object): ['bad' < 'medium' < 'good']
```

ordered=False will result in unordered categories when labels are passed. This parameter can be used to allow non-unique labels:

```python
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3, labels=['B', 'A', 'B'], ordered=False)
['B', 'B', 'A', 'B', 'B', 'B']
Categories (2, object): ['A', 'B']
```

labels=False implies you just want the bins back.

```python
>>> pd.cut([0, 1, 1, 2], bins=4, labels=False)
array([0, 1, 1, 3])
```

Passing a Series as an input returns a Series with categorical dtype:
>>> s = pd.Series(np.array([2, 4, 6, 8, 10]),
...       index=['a', 'b', 'c', 'd', 'e'])
>>> pd.cut(s, 3)
...  a (1.992, 4.667]
  b (1.992, 4.667]
  c (4.667, 7.333]
  d (7.333, 10.0]
  e (7.333, 10.0]
dtype: category
Categories (3, interval[float64]): [(1.992, 4.667] < (4.667, ... 

Passing a Series as an input returns a Series with mapping value. It is used to map numerically to intervals based on bins.

>>> s = pd.Series(np.array([2, 4, 6, 8, 10]),
...       index=['a', 'b', 'c', 'd', 'e'])
>>> pd.cut(s, [0, 2, 4, 6, 8, 10], labels=False, retbins=True, right=False)
...
  (a 1.0 
  b 2.0 
  c 3.0 
  d 4.0 
  e NaN 
dtype: float64,
array([ 0, 2, 4, 6, 8, 10]))

Use drop optional when bins is not unique

>>> pd.cut(s, [0, 2, 4, 6, 10, 10], labels=False, retbins=True, right=False, duplicates='drop')
...
  (a 1.0 
  b 2.0 
  c 3.0 
  d 3.0 
  e NaN 
dtype: float64,
array([ 0, 2, 4, 6, 10]))

Passing an IntervalIndex for bins results in those categories exactly. Notice that values not covered by the IntervalIndex are set to NaN. 0 is to the left of the first bin (which is closed on the right), and 1.5 falls between two bins.

>>> bins = pd.IntervalIndex.from_tuples([(0, 1), (2, 3), (4, 5)])
>>> pd.cut([0, 0.5, 1.5, 2.5, 4.5], bins)
[NaN, (0.0, 1.0], NaN, (2.0, 3.0], (4.0, 5.0]
Categories (3, interval[int64]): [(0, 1] < (2, 3] < (4, 5]]
pandas.qcut

pandas.qcut (x, q, labels=None, retbins=False, precision=3, duplicates='raise')

Quantile-based discretization function.

Discretize variable into equal-sized buckets based on rank or based on sample quantiles. For example 1000 values for 10 quantiles would produce a Categorical object indicating quantile membership for each data point.

Parameters

- x [1d ndarray or Series] Number of quantiles. 10 for deciles, 4 for quartiles, etc. Alternately array of quantiles, e.g. [0, .25, .5, .75, 1.] for quartiles.
- q [int or list-like of float] Number of quantiles. 10 for deciles, 4 for quartiles, etc. Alternately array of quantiles, e.g. [0, .25, .5, .75, 1.] for quartiles.
- labels [array or False, default None] Used as labels for the resulting bins. Must be of the same length as the resulting bins. If False, return only integer indicators of the bins. If True, raises an error.
- retbins [bool, optional] Whether to return the (bins, labels) or not. Can be useful if bins is given as a scalar.
- precision [int, optional] The precision at which to store and display the bins labels.
- duplicates [(default ‘raise’, ‘drop’), optional] If bin edges are not unique, raise ValueError or drop non-uniques.

Returns

- out [Categorical or Series or array of integers if labels is False] The return type (Categorical or Series) depends on the input: a Series of type category if input is a Series else Categorical. Bins are represented as categories when categorical data is returned.
- bins [ndarray of floats] Returned only if retbins is True.

Notes

Out of bounds values will be NA in the resulting Categorical object

Examples

```python
>>> pd.qcut(range(5), 4)
...
[(-0.001, 1.0], (-0.001, 1.0], (1.0, 2.0], (2.0, 3.0], (3.0, 4.0]
Categories (4, interval[float64]): [(-0.001, 1.0] < (1.0, 2.0] ...
```

```python
>>> pd.qcut(range(5), 3, labels=["good", "medium", "bad"]
...
[good, good, medium, bad, bad]
Categories (3, object): [good < medium < bad]
```

```python
>>> pd.qcut(range(5), 4, labels=False)
array([0, 0, 1, 2, 3])
```
pandas.merge

pandas.merge(left, right, how='inner', on=None, left_on=None, right_on=None, left_index=False, right_index=False, sort=False, suffixes=('_x', '_y'), copy=True, indicator=False, validate=None)

Merge DataFrame or named Series objects with a database-style join.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes will be ignored. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on.

Parameters

left [DataFrame]  
right [DataFrame or named Series] Object to merge with.

how [{‘left’, ‘right’, ‘outer’, ‘inner’}, default ‘inner’] Type of merge to be performed.
  • left: use only keys from left frame, similar to a SQL left outer join; preserve key order.
  • right: use only keys from right frame, similar to a SQL right outer join; preserve key order.
  • outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
  • inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.

on [label or list] Column or index level names to join on. These must be found in both DataFrames. If on is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

left_on [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

right_on [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

left_index [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

right_index [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as left_index.

sort [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword).

suffixes [list-like, default is (“_x”, “_y”)] A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in left and right respectively. Pass a value of None instead of a string to indicate that the column name from left or right should be left as-is, with no suffix. At least one of the values must not be None.

copy [bool, default True] If False, avoid copy if possible.

indicator [bool or str, default False] If True, adds a column to the output DataFrame called “_merge” with information on the source of each row. The column can be given a different name by providing a string argument. The column will have a Categorical type with the value of “left_only” for observations whose merge key only appears in the left DataFrame,
“right_only” for observations whose merge key only appears in the right DataFrame, and “both” if the observation’s merge key is found in both DataFrames.

**validate** [str, optional] If specified, checks if merge is of specified type.
- “one_to_one” or “1:1”: check if merge keys are unique in both left and right datasets.
- “one_to_many” or “1:m”: check if merge keys are unique in left dataset.
- “many_to_one” or “m:1”: check if merge keys are unique in right dataset.
- “many_to_many” or “m:m”: allowed, but does not result in checks.

**Returns**

**DataFrame** A DataFrame of the two merged objects.

**See also:**

*merge_ordered* Merge with optional filling/interpolation.

*merge_asof* Merge on nearest keys.

*DataFrame.join* Similar method using indices.

**Notes**

Support for specifying index levels as the *on*, *left_on*, and *right_on* parameters was added in version 0.23.0

Support for merging named Series objects was added in version 0.24.0

**Examples**

```python
>>> df1 = pd.DataFrame({'lkey': ['foo', 'bar', 'baz', 'foo'],
...                     'value': [1, 2, 3, 5]})
>>> df2 = pd.DataFrame({'rkey': ['foo', 'bar', 'baz', 'foo'],
...                     'value': [5, 6, 7, 8]})
>>> df1
lkey  value
0    foo      1
1    bar      2
2    baz      3
3    foo      5
>>> df2
rkey  value
0    foo      5
1    bar      6
2    baz      7
3    foo      8
```

Merge df1 and df2 on the lkey and rkey columns. The value columns have the default suffixes, _x and _y, appended.

```python
>>> df1.merge(df2, left_on='lkey', right_on='rkey')
lkey value_x rkey value_y
0    foo      1    foo      5
1    foo      1    foo      8
2    foo      5    foo      5
3    foo      5    foo      8
```

(continues on next page)
Merge DataFrames df1 and df2 with specified left and right suffixes appended to any overlapping columns.

```python
>>> df1.merge(df2, left_on='lkey', right_on='rkey',
... suffixes=('_left', '_right'))
```

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>lkey</td>
<td>value_left</td>
<td>rkey</td>
</tr>
<tr>
<td>0</td>
<td>foo</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>foo</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>foo</td>
<td>5</td>
</tr>
<tr>
<td>3</td>
<td>foo</td>
<td>5</td>
</tr>
<tr>
<td>4</td>
<td>bar</td>
<td>2</td>
</tr>
<tr>
<td>5</td>
<td>baz</td>
<td>3</td>
</tr>
</tbody>
</table>

Merge DataFrames df1 and df2, but raise an exception if the DataFrames have any overlapping columns.

```python
>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=(False, False))
```

Traceback (most recent call last):
... ValueError: columns overlap but no suffix specified: Index(["value"], dtype='object')

### pandas.merge_ordered

`pandas.merge_ordered(left, right, on=None, left_on=None, right_on=None, left_by=None, right_by=None, fill_method=None, suffixes=('x', 'y'), how='outer')`

Perform merge with optional filling/interpolation.

Designed for ordered data like time series data. Optionally perform group-wise merge (see examples).

**Parameters**

- **left** [DataFrame]
- **right** [DataFrame]
- **on** [label or list] Field names to join on. Must be found in both DataFrames.
- **left_on** [label or list, or array-like] Field names to join on in left DataFrame. Can be a vector or list of vectors of the length of the DataFrame to use a particular vector as the join key instead of columns.
- **right_on** [label or list, or array-like] Field names to join on in right DataFrame or vector/list of vectors per left_on docs.
- **left_by** [column name or list of column names] Group left DataFrame by group columns and merge piece by piece with right DataFrame.
- **right_by** [column name or list of column names] Group right DataFrame by group columns and merge piece by piece with left DataFrame.
- **fill_method** ["ffill", None], default None] Interpolation method for data.
- **suffixes** [list-like, default is ("_x", "_y")]] A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in left and right respectively. Pass a value of None instead of a string to indicate that the column name from left or right should be left as-is, with no suffix. At least one of the values must not be None.

Changed in version 0.25.0.
**how**  
- left: use only keys from left frame (SQL: left outer join)  
- right: use only keys from right frame (SQL: right outer join)  
- outer: use union of keys from both frames (SQL: full outer join)  
- inner: use intersection of keys from both frames (SQL: inner join).

**Returns**

**DataFrame**  
The merged DataFrame output type will be the same as ‘left’, if it is a subclass of DataFrame.

**See also:**

**merge**  
Merge with a database-style join.

**merge_asof**  
Merge on nearest keys.

**Examples**

```python
>>> df1 = pd.DataFrame({
    ...
    "key": ["a", "c", "e", "a", "c", "e"],
    ...
    "lvalue": [1, 2, 3, 1, 2, 3],
    ...
    "group": ["a", "a", "a", "b", "b", "b"]
    ...
})
>>> df1
   key  lvalue  group
0    a      1      a
1    c      2      a
2    e      3      a
3    a      1      b
4    c      2      b
5    e      3      b

>>> df2 = pd.DataFrame({"key": ["b", "c", "d"], "rvalue": [1, 2, 3]})
>>> df2
   key  rvalue
0    b      1
1    c      2
2    d      3

>>> merge_ordered(df1, df2, fill_method="ffill", left_by="group")
   key  lvalue  group  rvalue
0    a      1      a     NaN
1    b      1      a     1.0
2    c      2      a     2.0
3    d      2      a     3.0
4    e      3      a     3.0
5    a      1      b     NaN
6    b      1      b     1.0
7    c      2      b     2.0
8    d      2      b     3.0
9    e      3      b     3.0
```
pandas: powerful Python data analysis toolkit, Release 1.1.5

**pandas.merge_asof**

```python
pandas.merge_asof(left, right, on=None, left_on=None, right_on=None, left_index=False, right_index=False, by=None, left_by=None, right_by=None, suffixes=('_x', '_y'), tolerance=None, allow_exact_matches=True, direction='backward')
```

Perform an asof merge.

This is similar to a left-join except that we match on nearest key rather than equal keys. Both DataFrames must be sorted by the key.

For each row in the left DataFrame:

- A “backward” search selects the last row in the right DataFrame whose ‘on’ key is less than or equal to the left’s key.
- A “forward” search selects the first row in the right DataFrame whose ‘on’ key is greater than or equal to the left’s key.
- A “nearest” search selects the row in the right DataFrame whose ‘on’ key is closest in absolute distance to the left’s key.

The default is “backward” and is compatible in versions below 0.20.0. The direction parameter was added in version 0.20.0 and introduces “forward” and “nearest”.

Optionally match on equivalent keys with ‘by’ before searching with ‘on’.

**Parameters**

- **left** [DataFrame]
- **right** [DataFrame]
- **on** [label] Field name to join on. Must be found in both DataFrames. The data MUST be ordered. Furthermore this must be a numeric column, such as datetimelike, integer, or float. On or left_on/right_on must be given.
- **left_on** [label] Field name to join on in left DataFrame.
- **right_on** [label] Field name to join on in right DataFrame.
- **left_index** [bool] Use the index of the left DataFrame as the join key.
- **right_index** [bool] Use the index of the right DataFrame as the join key.
- **by** [column name or list of column names] Match on these columns before performing merge operation.
- **left_by** [column name] Field names to match on in the left DataFrame.
- **right_by** [column name] Field names to match on in the right DataFrame.
- **suffixes** [2-length sequence (tuple, list, …)] Suffix to apply to overlapping column names in the left and right side, respectively.
- **tolerance** [int or Timedelta, optional, default None] Select asof tolerance within this range; must be compatible with the merge index.
- **allow_exact_matches** [bool, default True]
  - If True, allow matching with the same ‘on’ value (i.e. less-than-or-equal-to / greater-than-or-equal-to)
  - If False, don’t match the same ‘on’ value (i.e., strictly less-than / strictly greater-than).
- **direction** [‘backward’ (default), ‘forward’, or ‘nearest’] Whether to search for prior, subsequent, or closest matches.
Returns

merged [DataFrame]

See also:

merge Merge with a database-style join.
merge_ordered Merge with optional filling/interpolation.

Examples

```python
>>> left = pd.DataFrame({"a": [1, 5, 10], "left_val": ["a", "b", "c"]})
>>> left
     a  left_val
0   1     a
1   5     b
2  10     c

>>> right = pd.DataFrame({"a": [1, 2, 3, 6, 7], "right_val": [1, 2, 3, 6, 7]})
>>> right
     a  right_val
0   1       1
1   2       2
2   3       3
3   6       6
4   7       7

>>> pd.merge_asof(left, right, on="a")
     a  left_val  right_val
0   1     a       1
1   5     b       3
2  10     c       NaN

>>> pd.merge_asof(left, right, on="a", allow_exact_matches=False)
     a  left_val  right_val
0   1     a       NaN
1   5     b       3.0
2  10     c       7.0

>>> pd.merge_asof(left, right, on="a", direction="forward")
     a  left_val  right_val
0   1     a       1.0
1   5     b       6.0
2  10     c       NaN

>>> pd.merge_asof(left, right, on="a", direction="nearest")
     a  left_val  right_val
0   1     a       1
1   5     b       6
2  10     c       7
```

We can use indexed DataFrames as well.
>>> left = pd.DataFrame({'left_val': ['a', 'b', 'c'], index=[1, 5, 10])
  left_val
 1    a
 5    b
 10   c

>>> right = pd.DataFrame({'right_val': [1, 2, 3, 6, 7], index=[1, 2, 3, 6, 7])
  right_val
 1      1
 2      2
 3      3
 6      6
 7      7

>>> pd.merge_asof(left, right, left_index=True, right_index=True)
  left_val  right_val
 1        a      1
 5        b      3
 10       c      7

Here is a real-world times-series example

>>> quotes = pd.DataFrame({
    ... 'time': [pd.Timestamp('2016-05-25 13:30:00.023'),
               pd.Timestamp('2016-05-25 13:30:00.023'),
               pd.Timestamp('2016-05-25 13:30:00.030'),
               pd.Timestamp('2016-05-25 13:30:00.041'),
               pd.Timestamp('2016-05-25 13:30:00.048'),
               pd.Timestamp('2016-05-25 13:30:00.049'),
               pd.Timestamp('2016-05-25 13:30:00.072'),
               pd.Timestamp('2016-05-25 13:30:00.075')],
    ... 'ticker': ['GOOG',
                 'MSFT',
                 'MSFT',
                 'MSFT',
                 'GOOG',
                 'AAPL',
                 'GOOG',
                 'MSFT'],
    ... 'bid': [720.50, 51.95, 51.97, 51.99, 720.50, 97.99, 720.50, 52.01],
    ... 'ask': [720.93, 51.96, 51.98, 52.00, 720.93, 98.01, 720.88, 52.03]
    ... },
    ... 'time'='time',
    ... 'ticker'='ticker',
    ... 'bid'='bid',
    ... 'ask'='ask'}

        pd.Timestamp("2016-05-25 13:30:00.038"),
        pd.Timestamp("2016-05-25 13:30:00.048"),
        pd.Timestamp("2016-05-25 13:30:00.048"),
    ],
    "ticker": ["MSFT", "MSFT", "GOOG", "GOOG", "AAPL"],
    "price": [51.95, 51.95, 720.77, 720.92, 98.0],
    "quantity": [75, 155, 100, 100, 100]
},
...
)

By default we are taking the asof of the quotes

```python
>>> pd.merge_asof(trades, quotes, on="time", by="ticker")
```

We only asof within 2ms between the quote time and the trade time

```python
>>> pd.merge_asof(trades, quotes, on="time", by="ticker", tolerance=pd.Timedelta("2ms"))
```

We only asof within 10ms between the quote time and the trade time and we exclude exact matches on time. However prior data will propagate forward

```python
>>> pd.merge_asof(trades, quotes, on="time", by="ticker",)
```
```python
... tolerance=pd.Timedelta("10ms"),
... allow_exact_matches=False
...)
```

</table>

**pandas.concat**

```python
pandas.concat(objs, axis=0, join='outer', ignore_index=False, keys=None, levels=None, names=None, verify_integrity=False, sort=False, copy=True)
```

Concatenate pandas objects along a particular axis with optional set logic along the other axes.

Can also add a layer of hierarchical indexing on the concatenation axis, which may be useful if the labels are the same (or overlapping) on the passed axis number.

**Parameters**

- `objs` [a sequence or mapping of Series or DataFrame objects] If a mapping is passed, the sorted keys will be used as the `keys` argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a ValueError will be raised.

- `axis` [{0/'index', 1/'columns'}, default 0] The axis to concatenate along.

- `join` [{‘inner’, ‘outer’}, default ‘outer’] How to handle indexes on other axis (or axes).

- `ignore_index` [bool, default False] If True, do not use the index values along the concatenation axis. The resulting axis will be labeled 0, ..., n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.

- `keys` [sequence, default None] If multiple levels passed, should contain tuples. Construct hierarchical index using the passed keys as the outermost level.

- `levels` [list of sequences, default None] Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys.

- `names` [list, default None] Names for the levels in the resulting hierarchical index.

- `verify_integrity` [bool, default False] Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.

- `sort` [bool, default False] Sort non-concatenation axis if it is not already aligned when `join` is ‘outer’. This has no effect when `join='inner'`, which already preserves the order of the non-concatenation axis.

New in version 0.23.0.

Changed in version 1.0.0: Changed to not sort by default.

- `copy` [bool, default True] If False, do not copy data unnecessarily.

**Returns**
object, type of objs  When concatenating all Series along the index (axis=0), a Series is returned. When_objs contains at least one DataFrame, a DataFrame is returned. When concatenating along the columns (axis=1), a DataFrame is returned.

See also:

Series.append  Concatenate Series.

Dataframe.append  Concatenate DataFrames.

Dataframe.join  Join DataFrames using indexes.

Dataframe.merge  Merge DataFrames by indexes or columns.

Notes

The keys, levels, and names arguments are all optional.

A walkthrough of how this method fits in with other tools for combining pandas objects can be found here.

Examples

Combine two Series.

```python
>>> s1 = pd.Series(['a', 'b'])
>>> s2 = pd.Series(['c', 'd'])
>>> pd.concat([s1, s2])
0    a
1    b
0    c
1    d
dtype: object
```

Clear the existing index and reset it in the result by setting the ignore_index option to True.

```python
>>> pd.concat([s1, s2], ignore_index=True)
0    a
1    b
2    c
3    d
dtype: object
```

Add a hierarchical index at the outermost level of the data with the keys option.

```python
>>> pd.concat([s1, s2], keys=['s1', 's2'])
s1     0    a
     1    b
     2    c
s2     0    c
     1    d
dtype: object
```

Label the index keys you create with the names option.

```python
>>> pd.concat([s1, s2], keys=['s1', 's2'],
...           names=['Series name', 'Row ID'])
Series name  Row ID
s1     0    a
```

(continues on next page)
Combine two DataFrame objects with identical columns.

```python
>>> df1 = pd.DataFrame([[1, 'a'], [2, 'b']],
                      columns=['letter', 'number'])
>>> df1
   letter  number
0      a     1
1      b     2
```

```python
>>> df2 = pd.DataFrame([[3, 'c'], [4, 'd']],
                      columns=['letter', 'number'])
>>> df2
   letter  number
0      c     3
1      d     4
```

```python
>>> pd.concat([df1, df2])
   letter  number
0      a     1
1      b     2
0      c     3
1      d     4
```

Combine DataFrame objects with overlapping columns and return everything. Columns outside the intersection will be filled with NaN values.

```python
>>> df3 = pd.DataFrame([[3, 'c', 'cat'], [4, 'd', 'dog']],
                      columns=['letter', 'number', 'animal'])
>>> df3
   letter  number  animal
0      c       3      cat
1      d       4      dog
```

```python
>>> pd.concat([df1, df3], sort=False)
   letter  number  animal
0      a       1  NaN
1      b       2  NaN
0      c       3      cat
1      d       4      dog
```

Combine DataFrame objects with overlapping columns and return only those that are shared by passing inner to the join keyword argument.

```python
>>> pd.concat([df1, df3], join="inner")
   letter  number  animal
0      a       1  NaN
1      b       2  NaN
0      c       3      cat
1      d       4      dog
```

Combine DataFrame objects horizontally along the x axis by passing in axis=1.

```python
>>> df4 = pd.DataFrame([[1, 'bird', 'polly'], [2, 'monkey', 'george']],
                      columns=['animal', 'name'])
>>> df4
   animal     name
0   bird  polly
1  monkey george
```

(continues on next page)
Prevent the result from including duplicate index values with the `verify_integrity` option.

```python
>>> df5 = pd.DataFrame([1], index=['a'])
>>> df6 = pd.DataFrame([2], index=['a'])
>>> pd.concat([df5, df6], verify_integrity=True)
Traceback (most recent call last):
  ...  
ValueError: Indexes have overlapping values: ['a']
```

### pandas.get_dummies

`pandas.get_dummies` converts categorical variable into dummy/indicator variables.

**Parameters**

- **data** [array-like, Series, or DataFrame] Data of which to get dummy indicators.
- **prefix** [str, list of str, or dict of str, default None] String to append DataFrame column names. Pass a list with length equal to the number of columns when calling get_dummies on a DataFrame. Alternatively, `prefix` can be a dictionary mapping column names to prefixes.
- **prefix_sep** [str, default '_'] If appending prefix, separator/delimiter to use. Or pass a list or dictionary as with `prefix`.
- **dummy_na** [bool, default False] Add a column to indicate NaNs, if False NaNs are ignored.
- **columns** [list-like, default None] Column names in the DataFrame to be encoded. If `columns` is None then all the columns with `object` or `category` dtype will be converted.
- **sparse** [bool, default False] Whether the dummy-encoded columns should be backed by a `SparseArray` (True) or a regular NumPy array (False).
- **drop_first** [bool, default False] Whether to get k-1 dummies out of k categorical levels by removing the first level.
- **dtype** [dtype, default np.uint8] Data type for new columns. Only a single dtype is allowed.

**Returns**

- **DataFrame** Dummy-coded data.

**See also:**

`Series.str.get_dummies` Convert Series to dummy codes.
Examples

```python
>>> s = pd.Series(list('abca'))

```
```python
>>> pd.get_dummies(s)
   a  b  c
0  1  0  0
1  0  1  0
2  0  0  1
3  1  0  0
```
```python
>>> sl = ['a', 'b', np.nan]

```
```python
>>> pd.get_dummies(sl)
   a  b
0  1  0
1  0  1
2  0  0
```
```python
>>> pd.get_dummies(sl, dummy_na=True)
   a  b  NaN
0  1  0  0
1  0  1  0
2  0  0  1
```
```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['b', 'a', 'c'], ... 'C': [1, 2, 3]})

```
```python
>>> pd.get_dummies(df, prefix=['col1', 'col2'])
   C  col1_a  col1_b  col2_a  col2_b  col2_c
0  1      1       0       1       0
1  2      0       1       1       0
2  3      1       0       0       1
```
```python
>>> pd.get_dummies(pd.Series(list('abca')))  
   a  b  c
0  1  0  0
1  0  1  0
2  0  0  1
3  1  0  0
4  1  0  0
```
```python
>>> pd.get_dummies(pd.Series(list('abca')), drop_first=True)
   b  c
0  0  0
1  1  0
2  0  1
3  0  0
4  0  0
```
```python
>>> pd.get_dummies(pd.Series(list('abc')), dtype=float)
   a  b  c
0 1.0 0.0 0.0
```

pandas.factorize

pandas.factorize(values, sort=False, na_sentinel=-1, size_hint=None)

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. factorize is available as both a top-level function pandas.factorize(), and as a method Series.factorize() and Index.factorize().

Parameters

values [sequence] A 1-D sequence. Sequences that aren’t pandas objects are coerced to ndarrays before factorization.

sort [bool, default False] Sort uniques and shuffle codes to maintain the relationship.

na_sentinel [int or None, default -1] Value to mark “not found”. If None, will not drop the NaN from the uniques of the values.

Changed in version 1.1.2.

size_hint [int, optional] Hint to the hashtable sizer.

Returns

codes [ndarray] An integer ndarray that’s an indexer into uniques. uniques.take(codes) will have the same values as values.

uniques [ndarray, Index, or Categorical] The unique valid values. When values is Categorical, uniques is a Categorical. When values is some other pandas object, an Index is returned. Otherwise, a 1-D ndarray is returned.

Note: Even if there’s a missing value in values, uniques will not contain an entry for it.

See also:

cut Discretize continuous-valued array.
unique Find the unique value in an array.

Examples

These examples all show factorize as a top-level method like pd.factorize(values). The results are identical for methods like Series.factorize().

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> codes
array([0, 0, 1, 2, 0]...)
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With sort=True, the uniques will be sorted, and codes will be shuffled so that the relationship is maintained.
```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in `codes` with `na_sentinel` (-1 by default). Note that missing values are never included in `uniques`.

```python
>>> codes, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
array([ 0, -1, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we’ve only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of `uniques` will differ. For Categoricals, a `Categorical` is returned.

```python
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
array([0, 0, 1])
>>> uniques
['a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```python
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

If NaN is in the values, and we want to include NaN in the uniques of the values, it can be achieved by setting `na_sentinel=None`.

```python
>>> values = np.array([1, 2, 1, np.nan])
>>> codes, uniques = pd.factorize(values)  # default: na_sentinel=-1
array([0, 1, 0, -1])
>>> uniques
array([1., 2.])
```

```python
>>> codes, uniques = pd.factorize(values, na_sentinel=None)
array([0, 1, 0, 2])
>>> uniques
array([1., 2., nan])
```
pandas: powerful Python data analysis toolkit, Release 1.1.5

pandas.unique

pandas.unique(values)
Hash table-based unique. Uniques are returned in order of appearance. This does NOT sort.

Significantly faster than numpy.unique. Includes NA values.

Parameters

values [1d array-like]

Returns

numpy.ndarray or ExtensionArray  The return can be:

• Index : when the input is an Index
• Categorical : when the input is a Categorical dtype
• ndarray : when the input is a Series/ndarray

Return numpy.ndarray or ExtensionArray.

See also:

Index.unique  Return unique values from an Index.

Series.unique  Return unique values of Series object.

Examples

```python
>>> pd.unique(pd.Series([2, 1, 3, 3]))
array([2, 1, 3])

>>> pd.unique(pd.Series([2] + [1] * 5))
array([2, 1])

>>> pd.unique(pd.Series([pd.Timestamp('20160101'), ... pd.Timestamp('20160101')]))
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')

>>> pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'), ... pd.Timestamp('20160101', tz='US/Eastern')]))
array([Timestamp('2016-01-01 00:00:00-05:00', tz='US/Eastern')], dtype=object)

>>> pd.unique(pd.Index([pd.Timestamp('20160101', tz='US/Eastern'), ... pd.Timestamp('20160101', tz='US/Eastern')]))
DatetimeIndex(['2016-01-01 00:00:00-05:00'], ...
               dtype='datetime64[ns, US/Eastern]', freq=None)

>>> pd.unique(list('baabc'))
array(['b', 'a', 'c'], dtype=object)
```

An unordered Categorical will return categories in the order of appearance.

```python
>>> pd.unique(pd.Series(pd.Categorical(list('baabc'))))
[b, a, c]  Categories (3, object): [b, a, c]
```
An ordered Categorical preserves the category ordering.

```python
>>> pd.unique(pd.Series(pd.Categorical(list('baabc'),
...                           categories=list('abc'))),
...           ordered=True))
[b, a, c]
Categories (3, object): [a < b < c]
```

An array of tuples

```python
>>> pd.unique([('a', 'b'), ('b', 'a'), ('a', 'c'), ('b', 'a')])
array([(b, b), (b, a), (a, c)], dtype=object)
```

### pandas.wide_to_long

`pandas.wide_to_long(df, stubnames, i, j, sep='', suffix='\d+')`

Wide panel to long format. Less flexible but more user-friendly than melt.

With stubnames `[A, B]`, this function expects to find one or more group of columns with format A-suffix1, A-suffix2... B-suffix1, B-suffix2... You specify what you want to call this suffix in the resulting long format with `j` (for example `j='year'`)

Each row of these wide variables are assumed to be uniquely identified by `i` (can be a single column name or a list of column names)

All remaining variables in the data frame are left intact.

**Parameters**

- **df** [DataFrame] The wide-format DataFrame.
- **stubnames** [str or list-like] The stub name(s). The wide format variables are assumed to start with the stub names.
- **i** [str or list-like] Column(s) to use as id variable(s).
- **j** [str] The name of the sub-observation variable. What you wish to name your suffix in the long format.
- **sep** [str, default ‘’] A character indicating the separation of the variable names in the wide format, to be stripped from the names in the long format. For example, if your column names are A-suffix1, A-suffix2, you can strip the hyphen by specifying `sep='-'`.
- **suffix** [str, default ‘\d+’] A regular expression capturing the wanted suffixes. ‘\d+’ captures numeric suffixes. Suffixes with no numbers could be specified with the negated character class ‘\D+’. You can also further disambiguate suffixes, for example, if your wide variables are of the form A-one, B-two,..., and you have an unrelated column A-rating, you can ignore the last one by specifying `suffix='(?one\|two)'`.

**Returns**

- **DataFrame** A DataFrame that contains each stub name as a variable, with new index (i, j).

3.2. General functions
Notes

All extra variables are left untouched. This simply uses pandas.melt under the hood, but is hard-coded to “do the right thing” in a typical case.

Examples

```python
>>> np.random.seed(123)
>>> df = pd.DataFrame({
...     "A1970": {0: "a", 1: "b", 2: "c"},
...     "A1980": {0: "d", 1: "e", 2: "f"},
...     "B1970": {0: 2.5, 1: 1.2, 2: .7},
...     "B1980": {0: 3.2, 1: 1.3, 2: .1},
...     "X": dict(zip(range(3), np.random.randn(3)))
... })
>>> df["id"] = df.index
>>> df
0     a     d     2.5    3.2 -1.085631  0
1     b     e     1.2    1.3  0.997345  1
2     c     f     0.7   0.1  0.282978  2

>>> pd.wide_to_long(df, ["A", "B"], i="id", j="year")
   X  A  B
id year
0  1970 -1.085631 a  2.5
1  1970  0.997345 b  1.2
2  1970  0.282978 c  0.7
0  1980 -1.085631 d  3.2
1  1980  0.997345 e  1.3
2  1980  0.282978 f  0.1
```

With multiple id columns

```python
>>> df = pd.DataFrame(
...     {"famid": [1, 1, 1, 2, 2, 2, 3, 3, 3],
...     "birth": [1, 2, 3, 1, 2, 3, 1, 2, 3],
...     "ht1": [2.8, 2.9, 2.2, 1.8, 1.9, 2.2, 2.3, 2.1],
...     "ht2": [3.4, 3.8, 2.9, 3.2, 2.8, 2.4, 3.3, 3.4, 2.9]}
... )
>>> df
   famid  birth   ht1   ht2
0     1      1  2.8    3.4
1     1      2  2.9    3.8
2     2      3  2.2    2.9
3     2      1  2.0    3.2
4     2      2  1.8    2.8
5     2      3  1.9    2.4
6     3      1  2.2    3.3
7     3      2  2.3    3.4
8     3      3  2.1    2.9
```

```python
>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age')
>>> l
   famid  birth   age
1     1      1  2.8
```

(continues on next page)
Going from long back to wide just takes some creative use of `unstack`

```python
g = l.unstack()
g.columns = g.columns.map('{0[0]}{0[1]}'.format)
g.reset_index()
```

<table>
<thead>
<tr>
<th>famid</th>
<th>birth</th>
<th>ht1</th>
<th>ht2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>2.8</td>
<td>3.4</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>2.9</td>
<td>3.8</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>2.2</td>
<td>2.9</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>2.0</td>
<td>3.2</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>1.8</td>
<td>2.8</td>
</tr>
<tr>
<td>5</td>
<td>2</td>
<td>1.9</td>
<td>2.4</td>
</tr>
<tr>
<td>6</td>
<td>3</td>
<td>2.2</td>
<td>3.3</td>
</tr>
<tr>
<td>7</td>
<td>3</td>
<td>2.3</td>
<td>3.4</td>
</tr>
<tr>
<td>8</td>
<td>3</td>
<td>2.1</td>
<td>2.9</td>
</tr>
</tbody>
</table>

Less wieldy column names are also handled

```python
np.random.seed(0)
df = pd.DataFrame({'A(weekly)-2010': np.random.rand(3), ...
  'A(weekly)-2011': np.random.rand(3), ...
  'B(weekly)-2010': np.random.rand(3), ...
  'B(weekly)-2011': np.random.rand(3), ...
  'X': np.random.randint(3, size=3)})
df['id'] = df.index
df
```

<table>
<thead>
<tr>
<th>id</th>
<th>X</th>
<th>A(weekly)-2010</th>
<th>A(weekly)-2011</th>
<th>B(weekly)-2010</th>
<th>B(weekly)-2011</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0.548814</td>
<td>0.544883</td>
<td>0.437587</td>
<td>0.383442</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0.715189</td>
<td>0.423655</td>
<td>0.891773</td>
<td>0.791725</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>0.602763</td>
<td>0.645894</td>
<td>0.963663</td>
<td>0.528895</td>
</tr>
</tbody>
</table>

```python
pd.wide_to_long(df, ['A(weekly)', 'B(weekly)'], i='id', ...
  j='year', sep='-', )
```

<table>
<thead>
<tr>
<th>id</th>
<th>year</th>
<th>X</th>
<th>A(weekly)</th>
<th>B(weekly)</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>1</td>
<td>2010</td>
<td>1</td>
<td>0.715189</td>
<td>0.891773</td>
</tr>
</tbody>
</table>

(continues on next page)
If we have many columns, we could also use a regex to find our stubnames and pass that list on to `wide_to_long`:

```python
stubnames = sorted(set([match[0] for match in df.columns.str.findall(r'[A-B]\(.*\)').values if match != []])

list(stubnames)
['A(weekly)', 'B(weekly)']
```

All of the above examples have integers as suffixes. It is possible to have non-integers as suffixes:

```python
df = pd.DataFrame({
    'famid': [1, 1, 1, 2, 2, 2, 3, 3, 3],
    'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],
    'ht_one': [2.8, 2.9, 2.2, 2.0, 1.8, 1.9, 2.2, 2.3, 2.1],
    'ht_two': [3.4, 3.8, 3.2, 2.8, 2.4, 3.3, 3.4, 2.9]
})
```

```python
l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age', sep='_', suffix='\w+')
```

```plaintext
<table>
<thead>

<td>Detect non-missing values for an array-like object.</td>
</tr>
</tbody>
</table>

**pandas.isna**

The function `pandas.isna(obj)` detects missing values for an array-like object.

- **Parameters**
  - `obj` [scalar or array-like] Object to check for null or missing values.

- **Returns**
  - `bool or array-like of bool` For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

**See also:**
- `notna` Boolean inverse of pandas.isna.
- `Series.isna` Detect missing values in a Series.
- `DataFrame.isna` Detect missing values in a DataFrame.
- `Index.isna` Detect missing values in an Index.

**Examples**

Scalar arguments (including strings) result in a scalar boolean.

```python
>>> pd.isna('dog')
False
```

```python
>>> pd.isna(pd.NA)
True
```

```python
>>> pd.isna(np.nan)
True
```

Arrays result in an ndarray of booleans.
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan, 3.],
       [ 4., 5., nan]])
>>> pd.isna(array)
array([[False, True, False],
       [False, False, True]])

For indexes, an ndarray of booleans is returned.

>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None, '2017-07-08'])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.isna(index)
array([False, False, True, False])

For Series and DataFrame, the same type is returned, containing booleans.

>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
     0  1  2
0    ant  bee  cat
1    dog  None  fly
>>> pd.isna(df)
     0  1  2
0  False False False
1  False  True False
>>> pd.isna(df[1])
0  False
1  True
Name: 1, dtype: bool

**pandas.isnull**

**pandas.isnull(obj)**
Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

**Parameters**

- **obj** [scalar or array-like] Object to check for null or missing values.

**Returns**

- **bool or array-like of bool** For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

**See also:**

- **notna** Boolean inverse of pandas.isna.
- **Series.isna** Detect missing values in a Series.
- **DataFrame.isna** Detect missing values in a DataFrame.
**Index.isna** Detect missing values in an Index.

### Examples

Scalar arguments (including strings) result in a scalar boolean.

```python
>>> pd.isna('dog')
False
```

```python
>>> pd.isna(pd.NA)
True
```

```python
>>> pd.isna(np.nan)
True
```

Ndarrays result in an ndarray of booleans.

```python
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> pd.isna(array)
array([[False, True, False],
       [False, False, True]])
```

For indexes, an ndarray of booleans is returned.

```python
>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None, ...
                             '2017-07-08'])
>>> pd.isna(index)
array([False, False, True, False])
```

For Series and DataFrame, the same type is returned, containing booleans.

```python
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> pd.isna(df)
0    False  False  False
1    False  True   False
Name: 1, dtype: bool
```

```python
>>> pd.isna(df[1])
0    False
1    True
Name: 1, dtype: bool
```
pandas: powerful Python data analysis toolkit, Release 1.1.5

pandas.notna

**pandas.notna**(obj)

Detect non-missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

**Parameters**

- **obj** [array-like or object value] Object to check for not null or non-missing values.

**Returns**

- **bool or array-like of bool** For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

**See also:**

- **isna** Boolean inverse of pandas.notna.
- **Series.notna** Detect valid values in a Series.
- **DataFrame.notna** Detect valid values in a DataFrame.
- **Index.notna** Detect valid values in an Index.

**Examples**

Scalar arguments (including strings) result in a scalar boolean.

```python
>>> pd.notna('dog')
True
```

```python
>>> pd.notna(pd.NA)
False
```

```python
>>> pd.notna(np.nan)
False
```

Ndarrays result in an ndarray of booleans.

```python
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan, 3.],
       [ 4., 5., nan]])
>>> pd.notna(array)
array([[ True, False, True],
       [ True, True, False]])
```

For indexes, an ndarray of booleans is returned.

```python
>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None,
                             ...                           '2017-07-08'])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.notna(index)
array([ True, True, False, True])
```
For Series and DataFrame, the same type is returned, containing booleans.

```python
>>> df = pd.DataFrame([[ant, 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
  0  1  2
0 ant bee cat
1 dog None fly
>>> pd.notna(df)
   0   1   2
0  True True True
1  True False True
```

```python
>>> pd.notna(df[1])
0  True
1  False
Name: 1, dtype: bool
```

**pandas.notnull**

`pandas.notnull(obj)`

Detect non-missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

**Parameters**

- `obj` [array-like or object value] Object to check for not null or non-missing values.

**Returns**

- bool or array-like of bool For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

**See also:**

- `isna` Boolean inverse of pandas.notna.
- `Series.notna` Detect valid values in a Series.
- `DataFrame.notna` Detect valid values in a DataFrame.
- `Index.notna` Detect valid values in an Index.

**Examples**

Scalar arguments (including strings) result in a scalar boolean.

```python
>>> pd.notna('dog')
True
```

```python
>>> pd.notna(pd.NA)
False
```

```python
>>> pd.notna(np.nan)
False
```

ndarrays result in an ndarray of booleans.
```python
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])

>>> pd.notna(array)
array([[ True, False,  True],
       [ True,  True, False]])
```

For indexes, an ndarray of booleans is returned.

```python
>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
"2017-07-08"])
```

```python
>>> pd.notna(index)
array([ True, True, False, True])
```

For Series and DataFrame, the same type is returned, containing booleans.

```python
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> pd.notna(df)
   0  1  2
0  True  True  True
1  True  False  True

>>> pd.notna(df[1])
0   True
1   False
Name: 1, dtype: bool
```

### 3.2.3 Top-level conversions

**to_numeric**(arg[, errors, downcast]) Convert argument to a numeric type.

**pandas.to_numeric**(arg, errors='raise', downcast=None)
Convert argument to a numeric type.

The default return dtype is float64 or int64 depending on the data supplied. Use the downcast parameter to obtain other dtypes.

Please note that precision loss may occur if really large numbers are passed in. Due to the internal limitations of ndarray, if numbers smaller than -9223372036854775808 (np.iinfo(np.int64).min) or larger than 18446744073709551615 (np.iinfo(np.uint64).max) are passed in, it is very likely they will be converted to float so that they can stored in an ndarray. These warnings apply similarly to Series since it internally leverages ndarray.

**Parameters**
arg [scalar, list, tuple, 1-d array, or Series] Argument to be converted.

errors [{‘ignore’, ‘raise’, ‘coerce’}, default ‘raise’]
- If ‘raise’, then invalid parsing will raise an exception.
- If ‘coerce’, then invalid parsing will be set as NaN.
- If ‘ignore’, then invalid parsing will return the input.

downcast [{‘integer’, ‘signed’, ‘unsigned’, ‘float’}, default None] If not None, and if the data
has been successfully cast to a numerical dtype (or if the data was numeric to begin with),
downcast that resulting data to the smallest numerical dtype possible according to the fol-
lowing rules:
- ‘integer’ or ‘signed’: smallest signed int dtype (min.: np.int8)
- ‘unsigned’: smallest unsigned int dtype (min.: np.uint8)
- ‘float’: smallest float dtype (min.: np.float32)

As this behaviour is separate from the core conversion to numeric values, any errors raised
during the downcasting will be surfaced regardless of the value of the ‘errors’ input.

In addition, downcasting will only occur if the size of the resulting data’s dtype is strictly
larger than the dtype it is to be cast to, so if none of the dtypes checked satisfy that specifi-
cation, no downcasting will be performed on the data.

Returns

ret Numeric if parsing succeeded. Return type depends on input. Series if Series, otherwise
ndarray.

See also:

DataFrame.astype Cast argument to a specified dtype.
to_datetime Convert argument to datetime.
to_timedelta Convert argument to timedelta.
numpy.ndarray.astype Cast a numpy array to a specified type.

DataFrame.convert_dtypes Convert dtypes.

Examples

Take separate series and convert to numeric, coercing when told to

```python
>>> s = pd.Series(['1.0', '2', -3])
>>> pd.to_numeric(s)
0    1.0
1    2.0
2   -3.0
dtype: float64
>>> pd.to_numeric(s, downcast='float')
0    1.0
1    2.0
2   -3.0
dtype: float32
>>> pd.to_numeric(s, downcast='signed')
0    1
```

(continues on next page)
1  2
2 -3
dtype: int8
>>> s = pd.Series(['apple', '1.0', '2', -3])
>>> pd.to_numeric(s, errors='ignore')
0  apple
1   1.0
2     2
3    -3
dtype: object
>>> pd.to_numeric(s, errors='coerce')
0   NaN
1   1.0
2   2.0
3  -3.0
dtype: float64

3.2.4 Top-level dealing with datetimelike

to_datetime(arg[, errors, dayfirst, ...])  Convert argument to datetime.
to_timedelta(arg[, unit, errors])  Convert argument to timedelta.
date_range([start, end, periods, freq, tz, ...])  Return a fixed frequency DatetimeIndex.
bdate_range([start, end, periods, freq, tz, ...])  Return a fixed frequency DatetimeIndex, with business day as the default frequency.
period_range([start, end, periods, freq, name])  Return a fixed frequency PeriodIndex.
timedelta_range([start, end, periods, freq, ...])  Return a fixed frequency TimedeltaIndex, with day as the default frequency.
infer_freq(index[, warn])  Infer the most likely frequency given the input index.

pandas.to_datetime

pandas.to_datetime( arg, errors=’raise’, dayfirst=False, yearfirst=False, utc=None, format=None, exact=True, unit=None, infer_datetime_format=False, origin=’unix’, cache=True )  Convert argument to datetime.

Parameters

arg [int, float, str, datetime, list, tuple, 1-d array, Series, DataFrame/dict-like] The object to convert to a datetime.

errors [[‘ignore’, ‘raise’, ‘coerce’], default ‘raise’]
  If ‘raise’, then invalid parsing will raise an exception.
  If ‘coerce’, then invalid parsing will be set as NaT.
  If ‘ignore’, then invalid parsing will return the input.

dayfirst [bool, default False] Specify a date parse order if arg is str or its list-likes. If True, parses dates with the day first, eg 10/11/12 is parsed as 2012-11-10. Warning: dayfirst=True is not strict, but will prefer to parse with day first (this is a known bug, based on dateutil behavior).

yearfirst [bool, default False] Specify a date parse order if arg is str or its list-likes.
• If True parses dates with the year first, eg 10/11/12 is parsed as 2010-11-12.

• If both dayfirst and yearfirst are True, yearfirst is preceded (same as dateutil).

Warning: yearfirst=True is not strict, but will prefer to parse with year first (this is a known bug, based on dateutil behavior).

utc [bool, default None] Return UTC DatetimeIndex if True (converting any tz-aware datetime.datetime objects as well).

format [str, default None] The strftime to parse time, eg “%d/%m/%Y”, note that “%f” will parse all the way up to nanoseconds. See strftime documentation for more information on choices: https://docs.python.org/3/library/datetime.html#strftime-and-strptime-behavior.

exact [bool, True by default] Behaves as: - If True, require an exact format match. - If False, allow the format to match anywhere in the target string.

unit [str, default ‘ns’] The unit of the arg (D,s,ms,us,ns) denote the unit, which is an integer or float number. This will be based off the origin. Example, with unit=’ms’ and origin=’unix’ (the default), this would calculate the number of milliseconds to the unix epoch start.

infer_datetime_format [bool, default False] If True and no format is given, attempt to infer the format of the datetime strings based on the first non-NaN element, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by ~5-10x.

origin [scalar, default ‘unix’] Define the reference date. The numeric values would be parsed as number of units (defined by unit) since this reference date.

• If ‘unix’ (or POSIX) time; origin is set to 1970-01-01.

• If ‘julian’, unit must be ‘D’, and origin is set to beginning of Julian Calendar. Julian day number 0 is assigned to the day starting at noon on January 1, 4713 BC.

• If Timestamp convertible, origin is set to Timestamp identified by origin.

cache [bool, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets. The cache is only used when there are at least 50 values. The presence of out-of-bounds values will render the cache unusable and may slow down parsing.

New in version 0.23.0.

Changed in version 0.25.0: - changed default value from False to True.

Returns
datetime If parsing succeeded. Return type depends on input:

• list-like: DatetimeIndex
• Series: Series of datetime64 dtype
• scalar: Timestamp

In case when it is not possible to return designated types (e.g. when any element of input is before Timestamp.min or after Timestamp.max) return will have datetime.datetime type (or corresponding array/Series).

See also:

Dataframe.astype Cast argument to a specified dtype.
to_timedelta Convert argument to timedelta.
**convert_dtypes**  Convert dtypes.

**Examples**

Assembling a datetime from multiple columns of a DataFrame. The keys can be common abbreviations like ['year', 'month', 'day', 'minute', 'second', 'ms', 'us', 'ns']) or plurals of the same.

```python
>>> df = pd.DataFrame({'year': [2015, 2016],
                      'month': [2, 3],
                      'day': [4, 5]})
>>> pd.to_datetime(df)
0 2015-02-04
1 2016-03-05
dtype: datetime64[ns]
```

If a date does not meet the timestamp limitations, passing errors='ignore' will return the original input instead of raising any exception.

Passing errors='coerce' will force an out-of-bounds date to NaT, in addition to forcing non-dates (or non-parseable dates) to NaT.

```python
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='ignore')
datetime.datetime(1300, 1, 1, 0, 0)
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='coerce')
NaT
```

Passing infer_datetime_format=True can often-times speedup a parsing if its not an ISO8601 format exactly, but in a regular format.

```python
>>> s.head()
0 3/11/2000
1 3/12/2000
2 3/13/2000
3 3/11/2000
4 3/12/2000
dtype: object
```

```python
>>> %timeit pd.to_datetime(s, infer_datetime_format=True)
100 loops, best of 3: 10.4 ms per loop
>>> %timeit pd.to_datetime(s, infer_datetime_format=False)
1 loop, best of 3: 471 ms per loop
```

Using a unix epoch time

```python
>>> pd.to_datetime(1490195805, unit='s')
Timestamp('2017-03-22 15:16:45')
>>> pd.to_datetime(1490195805433502912, unit='ns')
Timestamp('2017-03-22 15:16:45.433502912')
```

**Warning:** For float arg, precision rounding might happen. To prevent unexpected behavior use a fixed-width exact type.

Using a non-unix epoch origin
pandas.to_datetime

pandas.to_datetime(arg, unit=None, errors='raise')

Convert argument to datetime.

Timedeltas are absolute differences in times, expressed in difference units (e.g. days, hours, minutes, seconds). This method converts an argument from a recognized timedelta format / value into a Timedelta type.

Parameters

arg [str, timedelta, list-like or Series] The data to be converted to timedelta.

unit [str, optional] Denotes the unit of the arg for numeric arg. Defaults to "ns".

Possible values:
- ‘W’
- ‘D’ / ‘days’ / ‘day’
- ‘hours’ / ‘hour’ / ‘hr’ / ‘h’
- ‘m’ / ‘minute’ / ‘min’ / ‘minutes’ / ‘T’
- ‘S’ / ‘seconds’ / ‘sec’ / ‘second’
- ‘ms’ / ‘milliseconds’ / ‘millisecond’ / ‘milli’ / ‘millis’ / ‘L’
- ‘us’ / ‘microseconds’ / ‘microsecond’ / ‘micro’ / ‘micros’ / ‘U’
- ‘ns’ / ‘nanoseconds’ / ‘nano’ / ‘nanos’ / ‘nanosecond’ / ‘N’

Changed in version 1.1.0: Must not be specified when arg context strings and errors= "raise".

errors [‘ignore’, ‘raise’, ‘coerce’], default ‘raise’]

- If ‘raise’, then invalid parsing will raise an exception.
- If ‘coerce’, then invalid parsing will be set as NaT.
- If ‘ignore’, then invalid parsing will return the input.

Returns
timedelta64 or numpy.array of timedelta64 Output type returned if parsing succeeded.

See also:

Dataframe.astype Cast argument to a specified dtype.
to_datetime Convert argument to datetime.
convert_dtypes Convert dtypes.
Examples

Parsing a single string to a Timedelta:

```python
>>> pd.to_timedelta('1 days 06:05:01.00003')
Timedelta('1 days 06:05:01.000030')
>>> pd.to_timedelta('15.5us')
Timedelta('0 days 00:00:00.000015500')
```

Parsing a list or array of strings:

```python
>>> pd.to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015500', NaT],
    dtype='timedelta64[ns]', freq=None)
```

Converting numbers by specifying the `unit` keyword argument:

```python
>>> pd.to_timedelta(np.arange(5), unit='s')
TimedeltaIndex(['0 days 00:00:00', '0 days 00:00:01', '0 days 00:00:02',
    '0 days 00:00:03', '0 days 00:00:04'],
    dtype='timedelta64[ns]', freq=None)
>>> pd.to_timedelta(np.arange(5), unit='d')
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
    dtype='timedelta64[ns]', freq=None)
```

date_range

date_range(start=None, end=None, periods=None, freq=None, tz=None, normalize=False, name=None, closed=None, **kwargs)

Return a fixed frequency DatetimeIndex.

Parameters
- **start** [str or datetime-like, optional] Left bound for generating dates.
- **end** [str or datetime-like, optional] Right bound for generating dates.
- **periods** [int, optional] Number of periods to generate.
- **freq** [str or DateOffset, default ‘D’] Frequency strings can have multiples, e.g. ‘5H’. See [here](#) for a list of frequency aliases.
- **tz** [str or tzinfo, optional] Time zone name for returning localized DatetimeIndex, for example ‘Asia/Hong_Kong’. By default, the resulting DatetimeIndex is timezone-naive.
- **normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.
- **name** [str, default None] Name of the resulting DatetimeIndex.
- **closed** [None, ‘left’, ‘right’], optional] Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None, the default).

**kwargs For compatibility. Has no effect on the result.

Returns
- **rng** [DatetimeIndex]

See also:
**DatetimeIndex** An immutable container for datetimes.

**timedelta_range** Return a fixed frequency TimedeltaIndex.

**period_range** Return a fixed frequency PeriodIndex.

**interval_range** Return a fixed frequency IntervalIndex.

**Notes**

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting `DatetimeIndex` will have `periods` linearly spaced elements between `start` and `end` (closed on both sides).

To learn more about the frequency strings, please see [this link](#).

**Examples**

**Specifying the values**

The next four examples generate the same `DatetimeIndex`, but vary the combination of `start`, `end` and `periods`.

Specify `start` and `end`, with the default daily frequency.

```python
>>> pd.date_range(start='1/1/2018', end='1/08/2018')
dtype='datetime64[ns]', freq='D')
```

Specify `start` and `periods`, the number of periods (days).

```python
>>> pd.date_range(start='1/1/2018', periods=8)
dtype='datetime64[ns]', freq='D')
```

Specify `end` and `periods`, the number of periods (days).

```python
>>> pd.date_range(end='1/1/2018', periods=8)
DatetimeIndex(['2017-12-25', '2017-12-26', '2017-12-27', '2017-12-28', '2017-12-29', '2017-12-30', '2017-12-31', '2018-01-01'],
dtype='datetime64[ns]', freq='D')
```

Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```python
>>> pd.date_range(start='2018-04-24', end='2018-04-27', periods=3)
DatetimeIndex(['2018-04-24 00:00:00', '2018-04-25 12:00:00', '2018-04-27 00:00:00'],
dtype='datetime64[ns]', freq=None)
```

**Other Parameters**

Changed the `freq` (frequency) to 'M' (month end frequency).

```python
>>> pd.date_range(start='1/1/2018', periods=5, freq='M')
dtype='datetime64[ns]', freq='M')
```
Multiples are allowed

```python
>>> pd.date_range(start='1/1/2018', periods=5, freq='3M')
               '2019-01-31'],
               dtype='datetime64[ns]', freq='3M')
```

`freq` can also be specified as an Offset object.

```python
>>> pd.date_range(start='1/1/2018', periods=5, freq=pd.offsets.MonthEnd(3))
               '2019-01-31'],
               dtype='datetime64[ns]', freq='3M')
```

Specify `tz` to set the timezone.

```python
>>> pd.date_range(start='1/1/2018', periods=5, tz='Asia/Tokyo')
DatetimeIndex(['2018-01-01 00:00:00+09:00', '2018-01-02 00:00:00+09:00',
               '2018-01-03 00:00:00+09:00', '2018-01-04 00:00:00+09:00',
               '2018-01-05 00:00:00+09:00'],
               dtype='datetime64[ns, Asia/Tokyo]', freq='D')
```

closed controls whether to include `start` and `end` that are on the boundary. The default includes boundary points on either end.

```python
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed=None)
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03', '2017-01-04'],
               dtype='datetime64[ns]', freq='D')
```

Use `closed='left'` to exclude `end` if it falls on the boundary.

```python
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed='left')
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03'],
               dtype='datetime64[ns]', freq='D')
```

Use `closed='right'` to exclude `start` if it falls on the boundary.

```python
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed='right')
DatetimeIndex(['2017-01-02', '2017-01-03', '2017-01-04'],
               dtype='datetime64[ns]', freq='D')
```

### pandas.bdate_range

`pandas.bdate_range(start=None, end=None, periods=None, freq='B', tz=None, normalize=True, name=None, weekmask=None, holidays=None, closed=None, **kwargs)`

Return a fixed frequency DatetimeIndex, with business day as the default frequency.

**Parameters**

- **start** [str or datetime-like, default None] Left bound for generating dates.
- **end** [str or datetime-like, default None] Right bound for generating dates.
- **periods** [int, default None] Number of periods to generate.
- **freq** [str or DateOffset, default ‘B’ (business daily)] Frequency strings can have multiples, e.g. ‘5H’. 

tz [str or None] Time zone name for returning localized DatetimeIndex, for example Asia/Beijing.

normalize [bool, default False] Normalize start/end dates to midnight before generating date range.

name [str, default None] Name of the resulting DatetimeIndex.

weekmask [str or None, default None] Weekmask of valid business days, passed to numpy.busdaycalendar, only used when custom frequency strings are passed. The default value None is equivalent to ‘Mon Tue Wed Thu Fri’.

holidays [list-like or None, default None] Dates to exclude from the set of valid business days, passed to numpy.busdaycalendar, only used when custom frequency strings are passed.

closed [str, default None] Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None).

**kwargs For compatibility. Has no effect on the result.

Returns

DatetimeIndex

Notes

Of the four parameters: start, end, periods, and freq, exactly three must be specified. Specifying freq is a requirement for bdate_range. Use date_range if specifying freq is not desired.

To learn more about the frequency strings, please see this link.

Examples

Note how the two weekend days are skipped in the result.

```python
>>> pd.bdate_range(start='1/1/2018', end='1/08/2018')
```

**pandas.period_range**

pandas.period_range (start=’None’, end=’None’, periods=’None’, freq=’None’, name=’None’)  
Return a fixed frequency PeriodIndex.

The day (calendar) is the default frequency.

Parameters

start [str or period-like, default None] Left bound for generating periods.

date_range

ead [str or period-like, default None] Right bound for generating periods.

periods [int, default None] Number of periods to generate.

freq [str or DateOffset, optional] Frequency alias. By default the freq is taken from start or end if those are Period objects. Otherwise, the default is "D" for daily frequency.

name [str, default None] Name of the resulting PeriodIndex.
Returns

PeriodIndex

Notes

Of the three parameters: start, end, and periods, exactly two must be specified.

To learn more about the frequency strings, please see this link.

Examples

```python
>>> pd.period_range(start='2017-01-01', end='2018-01-01', freq='M')
PeriodIndex(['2017-01', '2017-02', '2017-03', '2017-04', '2017-05', '2017-06',
             '2017-07', '2017-08', '2017-09', '2017-10', '2017-11', '2017-12',
             '2018-01'],
            dtype='period[M]', freq='M')
```

If start or end are Period objects, they will be used as anchor endpoints for a PeriodIndex with frequency matching that of the period_range constructor.

```python
>>> pd.period_range(start=pd.Period('2017Q1', freq='Q'),
                   end=pd.Period('2017Q2', freq='Q'), freq='M')
PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'],
            dtype='period[M]', freq='M')
```

pandas.timedelta_range

pandas.timedelta_range(start=None, end=None, periods=None, freq=None, name=None, closed=None)

Return a fixed frequency TimedeltaIndex, with day as the default frequency.

Parameters

- **start** [str or timedelta-like, default None] Left bound for generating timedeltas.
- **end** [str or timedelta-like, default None] Right bound for generating timedeltas.
- **periods** [int, default None] Number of periods to generate.
- **freq** [str or DateOffset, default ‘D’] Frequency strings can have multiples, e.g. ‘5H’.
- **name** [str, default None] Name of the resulting TimedeltaIndex.
- **closed** [str, default None] Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None).

Returns

- **rng** [TimedeltaIndex]
Notes

Of the four parameters start, end, periods, and freq, exactly three must be specified. If freq is omitted, the resulting TimedeltaIndex will have periods linearly spaced elements between start and end (closed on both sides).

To learn more about the frequency strings, please see this link.

Examples

```python
>>> pd.timedelta_range(start='1 day', periods=4)
TimedeltaIndex(['1 days', '2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq='D')
```

The closed parameter specifies which endpoint is included. The default behavior is to include both endpoints.

```python
>>> pd.timedelta_range(start='1 day', periods=4, closed='right')
TimedeltaIndex(['2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq='D')
```

The freq parameter specifies the frequency of the TimedeltaIndex. Only fixed frequencies can be passed, non-fixed frequencies such as 'M' (month end) will raise.

```python
>>> pd.timedelta_range(start='1 day', end='2 days', freq='6H')
TimedeltaIndex(['1 days 00:00:00', '1 days 06:00:00', '1 days 12:00:00',
                 '1 days 18:00:00', '2 days 00:00:00'],
               dtype='timedelta64[ns]', freq='6H')
```

Specify start, end, and periods; the frequency is generated automatically (linearly spaced).

```python
>>> pd.timedelta_range(start='1 day', end='5 days', periods=4)
TimedeltaIndex(['1 days 00:00:00', '2 days 08:00:00', '3 days 16:00:00',
                 '5 days 00:00:00'],
               dtype='timedelta64[ns]', freq=None)
```

pandas.infer_freq

```python
pandas.infer_freq(index, warn=True)
```

Infer the most likely frequency given the input index. If the frequency is uncertain, a warning will be printed.

Parameters

- `index` [DatetimeIndex or TimedeltaIndex] If passed a Series will use the values of the series (NOT THE INDEX).
- `warn` [bool, default True]

Returns

- str or None None if no discernible frequency.

Raises

- TypeError If the index is not datetime-like.
- ValueError If there are fewer than three values.
3.2.5 Top-level dealing with intervals

`interval_range`([start, end, periods, freq, ...]) Return a fixed frequency IntervalIndex.

`pandas.interval_range`

`pandas.interval_range(start=None, end=None, periods=None, freq=None, name=None, closed='right')`

Return a fixed frequency IntervalIndex.

**Parameters**

- **start** [numeric or datetime-like, default None] Left bound for generating intervals.
- **end** [numeric or datetime-like, default None] Right bound for generating intervals.
- **periods** [int, default None] Number of periods to generate.
- **freq** [numeric, str, or DateOffset, default None] The length of each interval. Must be consistent with the type of start and end, e.g. 2 for numeric, or ‘5H’ for datetime-like. Default is 1 for numeric and ‘D’ for datetime-like.
- **name** [str, default None] Name of the resulting IntervalIndex.
- **closed** [‘left’, ‘right’, ‘both’, ‘neither’], default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.

**Returns**

IntervalIndex

**See also:**

`IntervalIndex` An Index of intervals that are all closed on the same side.

**Notes**

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting `IntervalIndex` will have `periods` linearly spaced elements between `start` and `end`, inclusively.

To learn more about datetime-like frequency strings, please see this link.

**Examples**

Numeric `start` and `end` is supported.

```python
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]], closed='right', dtype='interval[int64]')
```

Additionally, datetime-like input is also supported.

```python
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'), end=pd.Timestamp('2017-01-04'))
IntervalIndex([(2017-01-01, 2017-01-02], (2017-01-02, 2017-01-03], (2017-01-03, 2017-01-04])
```
The freq parameter specifies the frequency between the left and right endpoints of the individual intervals within the IntervalIndex. For numeric start and end, the frequency must also be numeric.

```python
>>> pd.interval_range(start=0, periods=4, freq=1.5)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]],
closed='right', dtype='interval[datetime64[ns]]')
```

Similarly, for datetime-like start and end, the frequency must be convertible to a DateOffset.

```python
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
... periods=3, freq='MS')
IntervalIndex([(2017-01-01, 2017-02-01], (2017-02-01, 2017-03-01],
(2017-03-01, 2017-04-01]],
closed='right', dtype='interval[datetime64[ns]]')
```

Specify start, end, and periods; the frequency is generated automatically (linearly spaced).

```python
>>> pd.interval_range(start=0, end=6, periods=4)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]],
closed='right',
dtype='interval[float64]')
```

The closed parameter specifies which endpoints of the individual intervals within the IntervalIndex are closed.

```python
>>> pd.interval_range(end=5, periods=4, closed='both')
IntervalIndex([[1, 2], [2, 3], [3, 4], [4, 5]],
closed='both', dtype='interval[int64]')
```

### 3.2.6 Top-level evaluation

`eval(expr[, parser, engine, truediv, ...])` Evaluate a Python expression as a string using various backends.

```python
def eval(expr, parser='pandas', engine=None, truediv=<object object>,
        local_dict=None, global_dict=None, resolvers=(), level=0, target=None,
        inplace=False):
```

Evaluate a Python expression as a string using various backends.

The following arithmetic operations are supported: +, -, *, /, **, %, // (python engine only) along with the following boolean operations: | (or), & (and), and ~ (not). Additionally, the 'pandas' parser allows the use of and, or, and not with the same semantics as the corresponding bitwise operators. Series and DataFrame objects are supported and behave as they would with plain ol’ Python evaluation.

**Parameters**

- **expr** [str] The expression to evaluate. This string cannot contain any Python statements, only Python expressions.
- **parser** [{‘pandas’, ‘python’}, default ‘pandas’] The parser to use to construct the syntax tree
from the expression. The default of 'pandas' parses code slightly different than standard Python. Alternatively, you can parse an expression using the 'python' parser to retain strict Python semantics. See the enhancing performance documentation for more details.

**engine** ['python', 'numexpr'], default 'numexpr' The engine used to evaluate the expression. Supported engines are

- None: tries to use numexpr, falls back to python
- 'numexpr': This default engine evaluates pandas objects using numexpr for large speed ups in complex expressions with large frames.
- 'python': Performs operations as if you had eval'd in top level python. This engine is generally not that useful.

More backends may be available in the future.

**truediv** [bool, optional] Whether to use true division, like in Python >= 3. deprecated:: 1.0.0

**local_dict** [dict or None, optional] A dictionary of local variables, taken from locals() by default.

**global_dict** [dict or None, optional] A dictionary of global variables, taken from globals() by default.

**resolvers** [list of dict-like or None, optional] A list of objects implementing the __getitem__ special method that you can use to inject an additional collection of namespaces to use for variable lookup. For example, this is used in the query() method to inject the DataFrame.index and DataFrame.columns variables that refer to their respective DataFrame instance attributes.

**level** [int, optional] The number of prior stack frames to traverse and add to the current scope. Most users will not need to change this parameter.

**target** [object, optional, default None] This is the target object for assignment. It is used when there is variable assignment in the expression. If so, then target must support item assignment with string keys, and if a copy is being returned, it must also support .copy() method.

**inplace** [bool, default False] If target is provided, and the expression mutates target, whether to modify target inplace. Otherwise, return a copy of target with the mutation.

**Returns**

- ndarray, numeric scalar, DataFrame, Series

**Raises**

**ValueError** There are many instances where such an error can be raised:

- target=None, but the expression is multiline.

- The expression is multiline, but not all them have item assignment. An example of such an arrangement is this:
  
  ```
  a = b + 1 a + 2
  ```

  Here, there are expressions on different lines, making it multiline, but the last line has no variable assigned to the output of \(a + 2\).

- inplace=True, but the expression is missing item assignment.

- Item assignment is provided, but the target does not support string item assignment.

- Item assignment is provided and inplace=False, but the target does not support the .copy() method.
See also:

**DataFrame.query**  Evaluates a boolean expression to query the columns of a frame.

**DataFrame.eval**  Evaluate a string describing operations on DataFrame columns.

**Notes**

The dtype of any objects involved in an arithmetic \% operation are recursively cast to float64.

See the _enhancing performance_ documentation for more details.

**Examples**

```python
def = pd.DataFrame({"animal": ["dog", "pig"], "age": [10, 20]})
def
animal  age
0  dog  10
1  pig  20
```

We can add a new column using pd.eval:

```python
def.eval("double_age = df.age * 2", target=df)
animal  age  double_age
0  dog  10   20
1  pig  20   40
```

### 3.2.7 Hashing

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pandas.util.hash_array(vals[, encoding, hash_key, ...])</td>
<td>Given a 1d array, return an array of deterministic integers.</td>
</tr>
<tr>
<td>pandas.util.hash_pandas_object(obj[, index, ...])</td>
<td>Return a data hash of the Index/Series/DataFrame.</td>
</tr>
</tbody>
</table>

**pandas.util.hash_array**

Given a 1d array, return an array of deterministic integers.

**Parameters**

- **vals**  [ndarray, Categorical]
- **encoding**  [str, default 'utf8']  Encoding for data & key when strings.
- **hash_key**  [str, default _default_hash_key]  Hash_key for string key to encode.
- **categorize**  [bool, default True]  Whether to first categorize object arrays before hashing. This is more efficient when the array contains duplicate values.

**Returns**

1d uint64 numpy array of hash values, same length as the vals
**pandas: powerful Python data analysis toolkit, Release 1.1.5**

### pandas.util.hash_pandas_object

`pandas.util.hash_pandas_object(obj, index=True, encoding='utf8', hash_key='0123456789123456', categorize=True)`

Return a data hash of the Index/Series/DataFrame.

**Parameters**

- `index` [bool, default True] Include the index in the hash (if Series/DataFrame).
- `encoding` [str, default ‘utf8’] Encoding for data & key when strings.
- `hash_key` [str, default _default_hash_key] Hash_key for string key to encode.
- `categorize` [bool, default True] Whether to first categorize object arrays before hashing. This is more efficient when the array contains duplicate values.

**Returns**

Series of uint64, same length as the object

#### 3.2.8 Testing

`test([extra_args])`

### pandas.test

`pandas.test(extra_args=None)`

### 3.3 Series

#### 3.3.1 Constructor

`Series([data, index, dtype, name, copy, ...])` One-dimensional ndarray with axis labels (including time series).

### pandas.Series

**class pandas.Series(data=None, index=None, dtype=None, name=None, copy=False, fast-path=False)**

One-dimensional ndarray with axis labels (including time series).

Labels need not be unique but must be a hashable type. The object supports both integer- and label-based indexing and provides a host of methods for performing operations involving the index. Statistical methods from ndarray have been overridden to automatically exclude missing data (currently represented as NaN).

Operations between Series (+, -, /, *) align values based on their associated index values— they need not be the same length. The result index will be the sorted union of the two indexes.

**Parameters**

- `data` [array-like, Iterable, dict, or scalar value] Contains data stored in Series.
Changed in version 0.23.0: If data is a dict, argument order is maintained for Python 3.6 and later.

**index** [array-like or Index (1d)] Values must be hashable and have the same length as *data*. Non-unique index values are allowed. Will default to RangelIndex (0, 1, 2, . . . , n) if not provided. If both a dict and index sequence are used, the index will override the keys found in the dict.

**dtype** [str, numpy.dtype, or ExtensionDtype, optional] Data type for the output Series. If not specified, this will be inferred from *data*. See the *user guide* for more usages.

**name** [str, optional] The name to give to the Series.

**copy** [bool, default False] Copy input data.

### Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>T</td>
<td>Return the transpose, which is by definition self.</td>
</tr>
<tr>
<td>array</td>
<td>The ExtensionArray of the data backing this Series or Index.</td>
</tr>
<tr>
<td>at</td>
<td>Access a single value for a row/column label pair.</td>
</tr>
<tr>
<td>attrs</td>
<td>Dictionary of global attributes on this object.</td>
</tr>
<tr>
<td>axes</td>
<td>Return a list of the row axis labels.</td>
</tr>
<tr>
<td>dtype</td>
<td>Return the dtypes object of the underlying data.</td>

<tr>
<td>dtytypes</td>
<td>Return the dtypes object of the underlying data.</td>
</tr>
<tr>
<td>hasnans</td>
<td>Return if I have any nans; enables various perf speedups.</td>
</tr>
<tr>
<td>iat</td>
<td>Access a single value for a row/column pair by integer position.</td>
</tr>
<tr>
<td>iloc</td>
<td>Purely integer-location based indexing for selection by position.</td>
</tr>
<tr>
<td>index</td>
<td>The index (axis labels) of the Series.</td>
</tr>
<tr>
<td>is_monotonic</td>
<td>Return boolean if values in the object are monotonic_increasing.</td>
</tr>
<tr>
<td>is_monotonic_decreasing</td>
<td>Return boolean if values in the object are monotonic_decreasing.</td>
</tr>
<tr>
<td>is_monotonic_increasing</td>
<td>Alias for is_monotonic.</td>
</tr>
<tr>
<td>is_unique</td>
<td>Return boolean if values in the object are unique.</td>
</tr>
<tr>
<td>loc</td>
<td>Access a group of rows and columns by label(s) or a boolean array.</td>
</tr>
<tr>
<td>name</td>
<td>Return the name of the Series.</td>
</tr>
<tr>
<td>nbytes</td>
<td>Return the number of bytes in the underlying data.</td>
</tr>
<tr>
<td>ndim</td>
<td>Number of dimensions of the underlying data, by definition 1.</td>
</tr>
<tr>
<td>shape</td>
<td>Return a tuple of the shape of the underlying data.</td>
</tr>
<tr>
<td>size</td>
<td>Return the number of elements in the underlying data.</td>
</tr>
<tr>
<td>values</td>
<td>Return Series as ndarray or ndarray-like depending on the dtype.</td>
</tr>
</tbody>
</table>

3.3. Series  1015
pandas.Series.T

**property Series.T**

Return the transpose, which is by definition self.

pandas.Series.array

**property Series.array**

The ExtensionArray of the data backing this Series or Index.

New in version 0.24.0.

**Returns**

**ExtensionArray** An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around `numpy.ndarray`.

`.array` differs `.values` which may require converting the data to a different form.

**See also:**

*Index.to_numpy* Similar method that always returns a NumPy array.

*Series.to_numpy* Similar method that always returns a NumPy array.

**Notes**

This table lays out the different array types for each extension dtype within pandas.

<table>
<thead>
<tr>
<th>dtype</th>
<th>array type</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>Categorical</td>
</tr>
<tr>
<td>period</td>
<td>PeriodArray</td>
</tr>
<tr>
<td>interval</td>
<td>IntervalArray</td>
</tr>
<tr>
<td>IntegerNA</td>
<td>IntegerArray</td>
</tr>
<tr>
<td>string</td>
<td>StringArray</td>
</tr>
<tr>
<td>boolean</td>
<td>BooleanArray</td>
</tr>
<tr>
<td>datetime64[ns, tz]</td>
<td>DatetimeArray</td>
</tr>
</tbody>
</table>

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes `.array` will be a `arrays.NumpyExtensionArray` wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use `Series.to_numpy()` instead.
Examples

For regular NumPy types like int, and float, a PandasArray is returned.

```python
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

For extension types, like Categorical, the actual ExtensionArray is returned

```python
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
['a', 'b', 'a']
Categories (2, object): ['a', 'b']
```

**pandas.Series.at**

**property Series.at**
Access a single value for a row/column label pair.

Similar to **loc**, in that both provide label-based lookups. Use **at** if you only need to get or set a single value in a DataFrame or Series.

**Raises**

**KeyError** If ‘label’ does not exist in DataFrame.

**See also:**

**DataFrame.iat** Access a single value for a row/column pair by integer position.

**DataFrame.loc** Access a group of rows and columns by label(s).

**Series.at** Access a single value using a label.

**Examples**

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                   index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
   A  B  C
4  0  2  3
5  0  4  1
6 10 20 30
```

Get value at specified row/column pair

```python
>>> df.at[4, 'B']
2
```

Set value at specified row/column pair

```python
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```
Get value within a Series

```python
>>> df.loc[5].at['B']
4
```

**pandas.Series.attrs**

**property** Series.attrs

Dictionary of global attributes on this object.

**Warning:** attrs is experimental and may change without warning.

**pandas.Series.axes**

**property** Series.axes

Return a list of the row axis labels.

**pandas.Series.dtype**

**property** Series.dtype

Return the dtype object of the underlying data.

**pandas.Series.dtypes**

**property** Series.dtypes

Return the dtype object of the underlying data.

**pandas.Series.hasnans**

**property** Series.hasnans

Return if I have any nans; enables various perf speedups.

**pandas.Series.iat**

**property** Series.iat

Access a single value for a row/column pair by integer position.

Similar to `iloc`, in that both provide integer-based lookups. Use `iat` if you only need to get or set a single value in a DataFrame or Series.

**Raises**

**IndexError** When integer position is out of bounds.

**See also:**

- `DataFrame.at` Access a single value for a row/column label pair.
- `DataFrame.loc` Access a group of rows and columns by label(s).
**Dataframe.iloc** Access a group of rows and columns by integer position(s).

**Examples**

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
                    columns=['A', 'B', 'C'])
>>> df
   A  B  C
0  0  2  3
1  0  4  1
2 10 20 30
```

Get value at specified row/column pair

```
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair

```
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series

```
>>> df.loc[0].iat[1]
2
```

**pandas.Series.iloc**

*property Series.iloc*

Purely integer-location based indexing for selection by position.

.iloc[ ] is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. [4, 3, 0].
- A slice object with ints, e.g. 1:7.
- A boolean array.
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don’t have a reference to the calling object, but would like to base your selection on some value.

.iloc[ ] will raise IndexError if a requested indexer is out-of-bounds, except slice indexers which allow out-of-bounds indexing (this conforms with python/numpy slice semantics).

See more at *Selection by Position.*

See also:

**DataFrame.iat** Fast integer location scalar accessor.
DataFrame.loc Purely label-location based indexer for selection by label.
Series.iloc Purely integer-location based indexing for selection by position.

Examples

```python
>>> mydict = [{"a": 1, "b": 2, "c": 3, "d": 4},
... {"a": 100, "b": 200, "c": 300, "d": 400},
... {"a": 1000, "b": 2000, "c": 3000, "d": 4000 }]

>>> df = pd.DataFrame(mydict)

>>> df
   a  b  c  d
0  1  2  3  4
1 100 200 300 400
2 1000 2000 3000 4000
```

Indexing just the rows

With a scalar integer.

```python
>>> type(df.iloc[0])
<class 'pandas.core.series.Series'>
>>> df.iloc[0]
    a    b    c    d
0  1.0  2.0  3.0  4.0
```

With a list of integers.

```python
>>> df.iloc[[0]]
   a  b  c  d
0  1  2  3  4
```

With a slice object.

```python
>>> df.iloc[:3]
   a  b  c  d
0  1  2  3  4
1 100 200 300 400
2 1000 2000 3000 4000
```

With a boolean mask the same length as the index.

```python
>>> df.iloc[[True, False, True]]
   a  b  c  d
0  1  2  3  4
2 1000 2000 3000 4000
```
With a callable, useful in method chains. The \texttt{x} passed to the \texttt{lambda} is the DataFrame being sliced. This selects the rows whose index label even.

```python
>>> df.iloc[lambda x: x.index % 2 == 0]
a b c d
0 1 2 3 4
2 1000 2000 3000 4000
```

**Indexing both axes**

You can mix the indexer types for the index and columns. Use \texttt{:} to select the entire axis.

With scalar integers.

```python
>>> df.iloc[0, 1]
2
```

With lists of integers.

```python
>>> df.iloc[[0, 2], [1, 3]]
b  d
0  2  4
2 2000 4000
```

With \texttt{slice} objects.

```python
>>> df.iloc[1:3, 0:3]
a b c
1 100 200 300
2 1000 2000 3000
```

With a boolean array whose length matches the columns.

```python
>>> df.iloc[:, [True, False, True, False]]
a  c
0 1 3
1 100 300
2 1000 3000
```

With a callable function that expects the Series or DataFrame.

```python
>>> df.iloc[:, lambda df: [0, 2]]
a  c
0 1 3
1 100 300
2 1000 3000
```

**pandas.Series.index**

\texttt{Series.index: pandas.core.indexes.base.Index}

The index (axis labels) of the Series.
pandas.Series.is_monotonic

property Series.is_monotonic
Return boolean if values in the object are monotonic_increasing.

Returns
bool

pandas.Series.is_monotonic_decreasing

property Series.is_monotonic_decreasing
Return boolean if values in the object are monotonic_decreasing.

Returns
bool

pandas.Series.is_monotonic_increasing

property Series.is_monotonic_increasing
Alias for is_monotonic.

pandas.Series.is_unique

property Series.is_unique
Return boolean if values in the object are unique.

Returns
bool

pandas.Series.loc

property Series.loc
Access a group of rows and columns by label(s) or a boolean array.

.loc[] is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

• A single label, e.g. 5 or 'a', (note that 5 is interpreted as a label of the index, and never as an integer position along the index).
• A list or array of labels, e.g. ['a', 'b', 'c'].
• A slice object with labels, e.g. 'a':'f'.

Warning: Note that contrary to usual python slices, both the start and the stop are included

• A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
• A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above)
See more at *Selection by Label*

**Raises**

- **KeyError** If any items are not found.

See also:

- **DataFrame.at** Access a single value for a row/column label pair.
- **DataFrame.iloc** Access group of rows and columns by integer position(s).
- **DataFrame.xs** Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.
- **Series.loc** Access group of values using labels.

**Examples**

**Getting values**

```python
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                   index=['cobra', 'viper', 'sidewinder'],
...                   columns=['max_speed', 'shield'])
>>> df
   max_speed  shield
     cobra    1     2
     viper    4     5
    sidewinder  7     8

Single label. Note this returns the row as a Series.

>>> df.loc['viper']
max_speed    4
shield       5
Name: viper, dtype: int64

List of labels. Note using [[]] returns a DataFrame.

```python
>>> df.loc[['viper', 'sidewinder']]
   max_speed  shield
     viper     4     5
    sidewinder  7     8
```  

Single label for row and column

```python
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```python
>>> df.loc['cobra':'viper', 'max_speed']
cobra    1
viper    4
Name: max_speed, dtype: int64
```

Boolean list with the same length as the row axis
Conditional that returns a boolean Series

```python
>>> df.loc[[False, False, True]]
                   max_speed   shield
    sidewinder       7       8
```

Conditional that returns a boolean Series with column labels specified

```python
>>> df.loc[df['shield'] > 6, ['max_speed']]  
                   max_speed
    sidewinder       7
```

Callable that returns a boolean Series

```python
>>> df.loc[lambda df: df['shield'] == 8]  
                   max_speed   shield
                 sidewinder       7       8
```

Setting values

Set value for all items matching the list of labels

```python
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
                   max_speed   shield
     cobra          1       2
     viper         4       50
    sidewinder     7       50
```

Set value for an entire row

```python
>>> df.loc['cobra'] = 10
>>> df
                   max_speed   shield
     cobra         10      10
     viper         4       50
    sidewinder     7       50
```

Set value for an entire column

```python
>>> df.loc[:, 'max_speed'] = 30  
>>> df
                      max_speed   shield
     cobra           30      10
     viper           30      50
    sidewinder     30      50
```

Set value for rows matching callable condition

```python
>>> df.loc[df['shield'] > 35] = 0
>>> df
                   max_speed   shield
     cobra           30      10
```

(continues on next page)
Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```python
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                    index=[7, 8, 9], columns=['max_speed', 'shield'])
>>>
>>> df
          max_speed  shield
    7       1       2
    8       4       5
    9       7       8
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```python
>>> df.loc[7:9]
          max_speed  shield
    7       1       2
    8       4       5
    9       7       8
```

Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```python
tuples = [
    ('cobra', 'mark i'), ('cobra', 'mark ii'),
    ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
    ('viper', 'mark ii'), ('viper', 'mark iii')
]

index = pd.MultiIndex.from_tuples(tuples)
values = [[12, 2], [0, 4], [10, 20],
          [1, 4], [7, 1], [16, 36]]

df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
```

```python
>>> df
          max_speed  shield
cobra  mark i    12     2
       mark ii     0     4
sidewinder  mark i    10    20
       mark ii     1     4
viper  mark ii     7     1
       mark iii   16    36
```

Single label. Note this returns a DataFrame with a single index.

```python
>>> df.loc['cobra']
          max_speed  shield
       mark i    12     2
       mark ii     0     4
```

Single index tuple. Note this returns a Series.

```python
>>> df.loc[('cobra', 'mark ii')]
          max_speed
          0
```

(continues on next page)
Single label for row and column. Similar to passing in a tuple, this returns a Series.

```python
>>> df.loc['cobra', 'mark i']
max_speed    12
shield        2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using `[]` returns a DataFrame.

```python
>>> df.loc[('cobra', 'mark ii')]
    max_speed  shield
cobra  mark ii    0     4
```

Single tuple for the index with a single label for the column

```python
>>> df.loc[('cobra', 'mark i'), 'shield']
2
```

Slice from index tuple to single label

```python
>>> df.loc[('cobra', 'mark i'):'viper']
    max_speed  shield
   cobra  mark i     12     2
          mark ii      0     4
   sidewinder  mark i    10    20
          mark ii      1     4
   viper  mark ii      7     1
          mark iii   16   36
```

Slice from index tuple to index tuple

```python
>>> df.loc[('cobra', 'mark i'):'viper', 'mark ii']
    max_speed  shield
   cobra  mark i     12     2
          mark ii      0     4
   sidewinder  mark i    10    20
          mark ii      1     4
   viper  mark ii      7     1
          mark iii   16   36
```

**pandas.Series.name**

**property** `Series.name`

Return the name of the Series.

The name of a Series becomes its index or column name if it is used to form a DataFrame. It is also used whenever displaying the Series using the interpreter.

**Returns**

- `label (hashable object)` The name of the Series, also the column name if part of a DataFrame.

**See also:**
**Series.rename**  Sets the Series name when given a scalar input.

**Index.name**  Corresponding Index property.

### Examples

The Series name can be set initially when calling the constructor.

```python
>>> s = pd.Series([1, 2, 3], dtype=np.int64, name='Numbers')
>>> s
0    1
1    2
2    3
Name: Numbers, dtype: int64
>>> s.name = "Integers"
>>> s
0    1
1    2
2    3
Name: Integers, dtype: int64
```

The name of a Series within a DataFrame is its column name.

```python
>>> df = pd.DataFrame([[1, 2], [3, 4], [5, 6]],
                    columns=['Odd Numbers', 'Even Numbers'])
>>> df
   Odd Numbers  Even Numbers
0       1         2
1       3         4
2       5         6
>>> df["Even Numbers"].name
'Even Numbers'
```

**pandas.Series.nbytes**

**property Series.nbytes**  
Return the number of bytes in the underlying data.

**pandas.Series.ndim**

**property Series.ndim**  
Number of dimensions of the underlying data, by definition 1.

**pandas.Series.shape**

**property Series.shape**  
Return a tuple of the shape of the underlying data.
pandas.Series.size

**property Series.size**

Return the number of elements in the underlying data.

pandas.Series.values

**property Series.values**

Return Series as ndarray or ndarray-like depending on the dtype.

**Warning:** We recommend using `Series.array` or `Series.to_numpy()`, depending on whether you need a reference to the underlying data or a NumPy array.

Returns

numpy.ndarray or ndarray-like

See also:

* **Series.array** Reference to the underlying data.
* **Series.to_numpy** A NumPy array representing the underlying data.

**Examples**

```python
>>> pd.Series([1, 2, 3]).values
array([1, 2, 3])
```

```python
>>> pd.Series(list('aabc')).values
array(['a', 'a', 'b', 'c'], dtype=object)
```

```python
>>> pd.Series(list('aabc')).astype('category').values
['a', 'a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Timezone aware datetime data is converted to UTC:

```python
>>> pd.Series(pd.date_range('20130101', periods=3, tz='US/Eastern')).values
array(['2013-01-01T05:00:00.000000000',
      '2013-01-02T05:00:00.000000000',
      '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')
```

empty

### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>abs()</td>
<td>Return a Series/DataFrame with absolute numeric value of each element.</td>
</tr>
<tr>
<td>add(other[, level, fill_value, axis])</td>
<td>Return Addition of series and other, element-wise (binary operator add).</td>
</tr>
<tr>
<td>add_prefix(prefix)</td>
<td>Prefix labels with string prefix.</td>
</tr>
<tr>
<td>add_suffix(suffix)</td>
<td>Suffix labels with string suffix.</td>
</tr>
<tr>
<td>agg([func, axis])</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>aggregate([func, axis])</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>align(other[, join, axis, level, copy, ...])</td>
<td>Align two objects on their axes with the specified join method.</td>
</tr>
<tr>
<td>all([axis, bool_only, skipna, level])</td>
<td>Return whether all elements are True, potentially over an axis.</td>
</tr>
<tr>
<td>any([axis, bool_only, skipna, level])</td>
<td>Return whether any element is True, potentially over an axis.</td>
</tr>
<tr>
<td>append(to_append[, ignore_index, ...])</td>
<td>Concatenate two or more Series.</td>
</tr>
<tr>
<td>apply(func[, convert_dtype, args])</td>
<td>Invoke function on values of Series.</td>
</tr>
<tr>
<td>argmax([axis, skipna])</td>
<td>Return int position of the largest value in the Series.</td>
</tr>
<tr>
<td>argmin([axis, skipna])</td>
<td>Return int position of the smallest value in the Series.</td>
</tr>
<tr>
<td>argsort([axis, kind, order])</td>
<td>Return the integer indices that would sort the Series values.</td>
</tr>
<tr>
<td>asfreq(freq[, method, how, normalize, ...])</td>
<td>Convert TimeSeries to specified frequency.</td>
</tr>
<tr>
<td>asof(where[, subset])</td>
<td>Return the last row(s) without any NaNs before where.</td>
</tr>
<tr>
<td>astype(dtype[, copy, errors])</td>
<td>Cast a pandas object to a specified dtype dtype.</td>
</tr>
<tr>
<td>at_time(time[, asof, axis])</td>
<td>Select values at particular time of day (e.g., 9:30AM).</td>
</tr>
<tr>
<td>autocorr([lag])</td>
<td>Compute the lag-N autocorrelation.</td>
</tr>
<tr>
<td>backfill([axis, inplace, limit, downcast])</td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='bfill'.</td>
</tr>
<tr>
<td>between(left, right[, inclusive])</td>
<td>Return boolean Series equivalent to left &lt;= series &lt;= right.</td>
</tr>
<tr>
<td>between_time(start_time, end_time[, ...])</td>
<td>Select values between particular times of the day (e.g., 9:00-9:30 AM).</td>
</tr>
<tr>
<td>bfill([axis, inplace, limit, downcast])</td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='bfill'.</td>
</tr>
<tr>
<td>bool()</td>
<td>Return the bool of a single element Series or DataFrame.</td>
</tr>
<tr>
<td>cat</td>
<td>alias of pandas.core.arrays.categorical.CategoricalAccessor</td>
</tr>
<tr>
<td>clip([lower, upper, axis, inplace])</td>
<td>Trim values at input threshold(s).</td>
</tr>
<tr>
<td>combine(other, func[, fill_value])</td>
<td>Combine the Series with a Series or scalar according to func.</td>
</tr>
<tr>
<td>combine_first(other)</td>
<td>Combine Series values, choosing the calling Series’s values first.</td>
</tr>
<tr>
<td>compare(other[, align_axis, keep_shape, ...])</td>
<td>Compare to another Series and show the differences.</td>
</tr>
<tr>
<td>convert_dtypes([infer_objects, ...])</td>
<td>Convert columns to best possible dtypes using dtypes supporting pd.NA.</td>
</tr>
</tbody>

Table 29 – continued from previous page

- **to_hdf**(path_or_buf, key[, mode, complevel, ...]) Write the contained data to an HDF5 file using HDFStore.
- **to_json**(path_or_buf, orient, date_format, ...) Convert the object to a JSON string.
- **to_latex**(buf, columns, col_space, header, ...) Render object to a LaTeX tabular, longtable, or nested table/tabular.
- **to_list**() Return a list of the values.
- **to_markdown**(buf, mode, index) Print Series in Markdown-friendly format.
- **to_numpy**(dtype, copy, na_value) A NumPy ndarray representing the values in this Series or Index.
- **to_period**(freq, copy) Convert Series from DatetimeIndex to PeriodIndex.
- **to_pickle**(path[, compression, protocol]) Pickle (serialize) object to file.
- **to_sql**(name, con[, schema, if_exists, ...]) Write records stored in a DataFrame to a SQL database.
- **to_string**(buf, na_rep, float_format, ...) Render a string representation of the Series.
- **to_timestamp**(freq, how, copy) Cast to DatetimeIndex of Timestamps, at beginning of period.
- **to_xarray**() Return an xarray object from the pandas object.
- **tolist**() Return a list of the values.
- **transform**(func[, axis]) Call func on self producing a Series with transformed values.
- **transpose**(*args, **kwargs) Return the transpose, which is by definition self.
- **truediv**(other[, level, fill_value, axis]) Return Floating division of series and other, element-wise (binary operator truediv).
- **truncate**(before, after, axis, copy) Truncate a Series or DataFrame before and after some index value.
- **tshift**(periods, freq, axis) (DEPRECATED) Shift the time index, using the index’s frequency if available.
- **tz_convert**(tz[, axis, level, copy]) Convert tz-aware axis to target time zone.
- **tz_localize**(tz[, axis, level, copy, ...]) Localize tz-naive index of a Series or DataFrame to target time zone.
- **unique**() Return unique values of Series object.
- **unstack**(level, fill_value) Unstack, also known as pivot, Series with MultiIndex to produce DataFrame.
- **update**(other) Modify Series in place using values from passed Series.
- **value_counts**(normalize, sort, ascending, ...) Return a Series containing counts of unique values.
- **var**(axis, skipna, level, ddof, numeric_only) Return unbiased variance over requested axis.
- **view**(dtype) Create a new view of the Series.
- **where**(cond[, other, inplace, axis, level, ...]) Replace values where the condition is False.
- **xs**(key[, axis, level, drop_level]) Return cross-section from the Series/DataFrame.

**pandas.Series.abs**

**Series.abs**()

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

**Returns**

- abs Series/DataFrame containing the absolute value of each element.

**See also:**
**numpy.abs**

Calculate the absolute value element-wise.

**Notes**

For complex inputs, \(1.2 + 1j\), the absolute value is \(\sqrt{a^2 + b^2}\).

**Examples**

Absolute numeric values in a Series.

```python
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1    2.00
2    3.33
3    4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```python
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```python
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0   1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using argsort (from StackOverflow).

```python
>>> df = pd.DataFrame({
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
...     'c': [100, 50, -30, -50]
... })
>>> df
   a  b  c
0  4  10  100
1  5  20   50
2  6  30  -30
3  7  40  -50

>>> df.loc[(df.c - 43).abs().argsort()]
        a  b  c
0  5.00  20  50
1  4.00  10  100
2  6.00  30  -30
3  7.00  40  -50
```
**pandas.Series.add**

Series.add(other, level=None, fill_value=None, axis=0)

Return Addition of series and other, element-wise (binary operator add).

Equivalent to series + other, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

Series The result of the operation.

**See also:**

Series.radd Reverse of the Addition operator, see Python documentation for more details.

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.add(b, fill_value=0)
a 2.0
b 1.0
c 1.0
d 1.0
e NaN
dtype: float64
```
pandas.Series.add_prefix

Series.add_prefix(prefix)
Prefix labels with string prefix.
For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

Parameters
prefix [str] The string to add before each label.

Returns
Series or DataFrame New Series or DataFrame with updated labels.

See also:
Series.add_suffix Suffix row labels with string suffix.
DataFrame.add_suffix Suffix column labels with string suffix.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64

>>> s.add_prefix('item_')
       item_0  1
item_1   2
item_2   3
item_3   4
dtype: int64
```

```python
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6

>>> df.add_prefix('col_')
       col_A  col_B
0    1     3
1    2     4
2    3     5
3    4     6
```
pandas.Series.add_suffix

Series.add_suffix(suffix)

SUFFIX labels with string suffix.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

Parameters

suffix [str] The string to add after each label.

Returns

Series or DataFrame New Series or DataFrame with updated labels.

See also:

dataframes.add_prefix Prefix row labels with string prefix.

Series.add_prefix Prefix row labels with string prefix.

DataFrame.add_suffix Prefix column labels with string prefix.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64

>>> s.add_suffix('_item')
0_item    1
1_item    2
2_item    3
3_item    4
dtype: int64

>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6

>>> df.add_suffix('_col')
   A_col  B_col
0  1   3
1  2   4
2  3   5
3  4   6
```
pandas.Series.agg

`Series.agg(func=None, axis=0, *args, **kwargs)`

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

**Parameters**

- **func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.
  
  Accepted combinations are:
  
  - function
  - string function name
  - list of functions and/or function names, e.g. `[np.sum, 'mean']`
  - dict of axis labels -> functions, function names or list of such.

- **axis** [{0 or ‘index’}] Parameter needed for compatibility with DataFrame.

- **args** Positional arguments to pass to `func`.

- **kwargs** Keyword arguments to pass to `func`.

**Returns**

- scalar, Series or DataFrame The return can be:
  
  - scalar : when Series.agg is called with single function
  - Series : when DataFrame.agg is called with a single function
  - DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

**See also:**

- `Series.apply` Invoke function on a Series.

- `Series.transform` Transform function producing a Series with like indexes.

**Notes**

`agg` is an alias for `aggregate`. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0  1
1  2
2  3
3  4
dtype: int64
```
>>> s.agg('min')
1

>>> s.agg(['min', 'max'])
min    1
max    4
dtype: int64

pandas.Series.aggregate

**Series.aggregate** *(func=None, axis=0, *args, **kwargs)*
Aggregate using one or more operations over the specified axis.
New in version 0.20.0.

**Parameters**

- **func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.
  Accepted combinations are:
  - function
  - string function name
  - list of functions and/or function names, e.g. [np.sum, 'mean']
  - dict of axis labels -> functions, function names or list of such.

- **axis** [[0 or 'index']] Parameter needed for compatibility with DataFrame.

- **args** Positional arguments to pass to *func*.

- **kwargs** Keyword arguments to pass to *func*.

**Returns**

- scalar, Series or DataFrame  The return can be:
  - scalar : when Series.agg is called with single function
  - Series : when DataFrame.agg is called with a single function
  - DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

**See also:**

- **Series.apply** Invoke function on a Series.
- **Series.transform** Transform function producing a Series with like indexes.
Notes

`agg` is an alias for `aggregate`. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64

>>> s.agg('min')
1

>>> s.agg(['min', 'max'])
min  1
max  4
dtype: int64
```

```
pandas.Series.align

Series.align(other, join='outer', axis=None, level=None, copy=True, fill_value=None, method=None, limit=None, fill_axis=0, broadcast_axis=None)
```

Align two objects on their axes with the specified join method.

Join method is specified for each axis Index.

Parameters

- `other` [DataFrame or Series]
- `join` [{‘outer’, ‘inner’, ‘left’, ‘right’}, default ‘outer’]
- `axis` [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None).
- `level` [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level.
- `copy` [bool, default True] Always returns new objects. If copy=False and no reindexing is required then original objects are returned.
- `fill_value` [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.
  - pad / ffill: propagate last valid observation forward to next valid.
  - backfill / bfill: use NEXT valid observation to fill gap.
limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

fill_axis [{0 or ‘index’}, default 0] Filling axis, method and limit.

broadcast_axis [{0 or ‘index’}, default None] Broadcast values along this axis, if aligning two objects of different dimensions.

Returns

(left, right) [(Series, type of other)] Aligned objects.

pandas.Series.all

Series.all (axis=0, bool_only=None, skipna=True, level=None, **kwargs)
Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

Parameters

axis [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Indicate which axis or axes should be reduced.
• 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
• 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
• None : reduce all axes, return a scalar.

bool_only [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

skipna [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**kwargs [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series If level is specified, then, Series is returned; otherwise, scalar is returned.

See also:

Series.all Return True if all elements are True.

DataFrame.any Return True if one (or more) elements are True.
Examples

Series

```python
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([]).all()
True
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

DataFrames

Create a dataframe from a dictionary.

```python
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
   col1 col2
0   True  True
1   True  False
```

Default behaviour checks if column-wise values all return True.

```python
>>> df.all()
col1    True
col2     False
dtype: bool
```

Specify `axis='columns'` to check if row-wise values all return True.

```python
>>> df.all(axis='columns')
0   True
1   False
dtype: bool
```

Or `axis=None` for whether every value is True.

```python
>>> df.all(axis=None)
False
```

pandas.Series.any

Series.any (axis=0, bool_only=None, skipna=True, level=None, **kwargs)

Return whether any element is True, potentially over an axis.

Returns False unless there at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

Parameters

- `axis` ([0 or ‘index’, 1 or ‘columns’, None], default 0) Indicate which axis or axes should be reduced.
  - 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
• 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
• None : reduce all axes, return a scalar.

bool_only [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

skipna [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**kwargs [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

 scalar or Series  If level is specified, then, Series is returned; otherwise, scalar is returned.

See also:

numpy.any  Numpy version of this method.
Series.any  Return whether any element is True.
Series.all  Return whether all elements are True.
DataFrame.any  Return whether any element is True over requested axis.
DataFrame.all  Return whether all elements are True over requested axis.

Examples

Series

For Series input, the output is a scalar indicating whether any element is True.

```python
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([]).any()
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True
```

DataFrame

Whether each column contains at least one True element (the default).

```python
>>> df = pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
>>> df
   A  B  C
0  1  0  0
1  2  2  0
```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})

>>> df
A  B
0  True 1
1  False 2

>>> df.any(axis='columns')
0   True
1   True
dtype: bool

Aggregating over the entire DataFrame with `axis=None`.

>>> df.any(axis=None)
True

`any` for an empty DataFrame is an empty Series.

>>> pd.DataFrame([]).any()
Series([], dtype: bool)

**pandas.Series.append**

`Series.append(to_append, ignore_index=False, verify_integrity=False)`
Concatenate two or more Series.

**Parameters**

- `to_append` [Series or list/tuple of Series] Series to append with self.
- `ignore_index` [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.
- `verify_integrity` [bool, default False] If True, raise Exception on creating index with duplicates.

**Returns**

- `Series` Concatenated Series.
See also:

`concat` General function to concatenate DataFrame or Series objects.

Notes

Iteratively appending to a Series can be more computationally intensive than a single concatenate. A better solution is to append values to a list and then concatenate the list with the original Series all at once.

Examples

```python
>>> s1 = pd.Series([1, 2, 3])
>>> s2 = pd.Series([4, 5, 6])
>>> s3 = pd.Series([4, 5, 6], index=[3, 4, 5])
>>> s1.append(s2)
0    1
1    2
2    3
0    4
1    5
2    6
dtype: int64

>>> s1.append(s3)
0    1
1    2
2    3
3    4
4    5
5    6
dtype: int64
With `ignore_index` set to True:

```python
>>> s1.append(s2, ignore_index=True)
0    1
1    2
2    3
3    4
4    5
5    6
dtype: int64
```

With `verify_integrity` set to True:

```python
>>> s1.append(s2, verify_integrity=True)
Traceback (most recent call last):
...
ValueError: Indexes have overlapping values: [0, 1, 2]
```
### pandas.Series.apply

Series.apply (func, convert_dtype=True, args=(), **kwds)

Invoke function on values of Series.

Can be ufunc (a NumPy function that applies to the entire Series) or a Python function that only works on single values.

**Parameters**

- **func**: [function] Python function or NumPy ufunc to apply.
- **convert_dtype**: [bool, default True] Try to find better dtype for elementwise function results. If False, leave as dtype=object.
- **args**: [tuple] Positional arguments passed to func after the series value.
- **kwds**: Additional keyword arguments passed to func.

**Returns**

Series or DataFrame If func returns a Series object the result will be a DataFrame.

See also:

- **Series.map** For element-wise operations.
- **Series.agg** Only perform aggregating type operations.
- **Series.transform** Only perform transforming type operations.

### Examples

Create a series with typical summer temperatures for each city.

```python
>>> s = pd.Series([20, 21, 12],
                 index=['London', 'New York', 'Helsinki'])
>>> s
London    20
New York  21
Helsinki  12
```

Square the values by defining a function and passing it as an argument to apply().

```python
>>> def square(x):
...     return x ** 2
... >>> s.apply(square)
London    400
New York  441
Helsinki  144
```

Square the values by passing an anonymous function as an argument to apply().

```python
>>> s.apply(lambda x: x ** 2)
London    400
New York  441
Helsinki  144
```
Define a custom function that needs additional positional arguments and pass these additional arguments using the `args` keyword.

```python
>>> def subtract_custom_value(x, custom_value):
...    return x - custom_value

>>> s.apply(subtract_custom_value, args=(5,))
London    15
New York  16
Helsinki  7
dtype: int64
```

Define a custom function that takes keyword arguments and pass these arguments to `apply`.

```python
>>> def add_custom_values(x, **kwargs):
...    for month in kwargs:
...        x += kwargs[month]
...    return x

>>> s.apply(add_custom_values, june=30, july=20, august=25)
London    95
New York  96
Helsinki  87
dtype: int64
```

Use a function from the Numpy library.

```python
>>> s.apply(np.log)
London    2.995732
New York  3.044522
Helsinki  2.484907
dtype: float64
```

**pandas.Series.argmax**

`Series.argmax(axis=None, skipna=True, *args, **kwargs)`

Return int position of the largest value in the Series. If the maximum is achieved in multiple locations, the first row position is returned.

**Parameters**

- `axis` ([None]) Dummy argument for consistency with Series.
- `skipna` [bool, default True] Exclude NA/null values when showing the result.
- `*args, **kwargs` Additional arguments and keywords for compatibility with NumPy.

**Returns**

- `int` Row position of the maximum value.

**See also:**

- `Series.argmax` Return position of the maximum value.
- `Series.argmin` Return position of the minimum value.
- `numpy.ndarray.argmax` Equivalent method for numpy arrays.
**Series.idxmax** Return index label of the maximum values.

**Series.idxmin** Return index label of the minimum values.

**Examples**

Consider dataset containing cereal calories

```python
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0, ...
                      'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
>>> s
Corn Flakes    100.0
Almond Delight 110.0
Cinnamon Toast Crunch 120.0
Cocoa Puff      110.0
dtype: float64
```

```python
>>> s.argmax()
2
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.

**pandas.Series.argmin**

`Series.argmin(axis=None, skipna=True, *args, **kwargs)`

Return int position of the smallest value in the Series.

- **Parameters**
  - `axis` [{None}] Dummy argument for consistency with Series.
  - `skipna` [bool, default True] Exclude NA/null values when showing the result.
  - `*args, **kwargs` Additional arguments and keywords for compatibility with NumPy.

- **Returns**
  - `int` Row position of the minimum value.

**See also:**

- `Series.argmin` Return position of the minimum value.
- `Series.argmax` Return position of the maximum value.
- `numpy.ndarray.argmin` Equivalent method for numpy arrays.
- `Series.idxmax` Return index label of the maximum values.
- `Series.idxmin` Return index label of the minimum values.
Examples

Consider dataset containing cereal calories

```python
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,
...                  'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
>>> s
Corn Flakes    100.0
Almond Delight 110.0
Cinnamon Toast Crunch    120.0
Cocoa Puff 110.0
dtype: float64

>>> s.argmax()
2
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.

pandas.Series.argsort

Series.argsort (axis=0, kind='quicksort', order=None)

Return the integer indices that would sort the Series values.

Override ndarray.argsort. Argsorts the value, omitting NA/null values, and places the result in the same locations as the non-NA values.

Parameters

- **axis** [0 or “index”] Has no effect but is accepted for compatibility with numpy.
- **kind** [‘mergesort’, ‘quicksort’, ‘heapsort’], default ‘quicksort’ Choice of sorting algorithm. See np.sort for more information. ‘mergesort’ is the only stable algorithm.
- **order** [None] Has no effect but is accepted for compatibility with numpy.

Returns

Series Positions of values within the sort order with -1 indicating nan values.

See also:

numpy.ndarray.argsort Returns the indices that would sort this array.

pandas.Series.asfreq

Series.asfreq (freq, method=None, how=None, normalize=False, fill_value=None)

Convert TimeSeries to specified frequency.

Optionally provide filling method to pad/backfill missing values.

Returns the original data conformed to a new index with the specified frequency. resample is more appropriate if an operation, such as summarization, is necessary to represent the data at the new frequency.

Parameters

- **freq** [DateOffset or str] Frequency DateOffset or string.
method: A dictionary containing one of the following:
- 'backfill' or 'bfill': method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):
  - 'pad' or 'ffill': propagate last valid observation forward to next valid
  - 'backfill' or 'bfill': use NEXT valid observation to fill.
how: A list containing one of the following:
- 'start': start of the new index
- 'end': end of the new index

normalize: A boolean indicating whether to reset output index to midnight.
fill_value: A scalar indicating the value to use for missing values, applied during upampling.

Returns: Same type as caller. Object converted to the specified frequency.

See also: reindex

Notes
To learn more about the frequency strings, please see this link.

Examples
Start by creating a series with 4 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s':series})
```

Upsample the series into 30 second bins.

```python
>>> df.asfreq(freq='30S')
```

Upsample again, providing a fill value.

```python
>>> df.asfreq(freq='30S', fill_value=9.0)
```
Upsample again, providing a method.

```python
>>> df.asfreq(freq='30S', method='bfill')
```

```
2000-01-01 00:00:00 0.0
2000-01-01 00:00:30 NaN
2000-01-01 00:01:00 NaN
2000-01-01 00:01:30 2.0
2000-01-01 00:02:00 2.0
2000-01-01 00:02:30 3.0
2000-01-01 00:03:00 3.0
```

**pandas.Series.asof**

`pandas.Series.asof(where, subset=None)`

Return the last row(s) without any NaNs before `where`.

The last row (for each element in `where`, if list) without any NaN is taken. In case of a `DataFrame`, the last row without NaN considering only the subset of columns (if not `None`).

If there is no good value, NaN is returned for a Series or a Series of NaN values for a DataFrame.

**Parameters**

- `where` [date or array-like of dates] Date(s) before which the last row(s) are returned.
- `subset` [str or array-like of str, default `None`] For DataFrame, if not `None`, only use these columns to check for NaNs.

**Returns**

- scalar, Series, or DataFrame The return can be:
  - scalar : when `self` is a Series and `where` is a scalar
  - Series: when `self` is a Series and `where` is an array-like, or when `self` is a DataFrame and `where` is a scalar
  - DataFrame : when `self` is a DataFrame and `where` is an array-like

Return scalar, Series, or DataFrame.

**See also:**

- `merge_asof` Perform an asof merge. Similar to left join.
Notes

Dates are assumed to be sorted. Raises if this is not the case.

Examples

A Series and a scalar where.

```python
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10    1.0
20    2.0
30   NaN
40    4.0
dtype: float64

>>> s.asof(20)
2.0
```

For a sequence where, a Series is returned. The first value is NaN, because the first element of where is before the first index value.

```python
>>> s.asof([5, 20])
5   NaN
20  2.0
dtype: float64
```

Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

```python
>>> s.asof(30)
2.0
```

Take all columns into consideration

```python
>>> df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
...                     'b': [None, None, None, None, 500]},
...                   index=pd.DatetimeIndex(['2018-02-27 09:01:00',
...                                       '2018-02-27 09:02:00',
...                                       '2018-02-27 09:03:00',
...                                       '2018-02-27 09:04:00',
...                                       '2018-02-27 09:05:00']))

>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                            '2018-02-27 09:04:30']))
   a     b
2018-02-27 09:03:30 NaN  NaN
2018-02-27 09:04:30 NaN  NaN
```

Take a single column into consideration

```python
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                            '2018-02-27 09:04:30']),
...         subset=['a'])
   a     b
2018-02-27 09:03:30 30.0  NaN
2018-02-27 09:04:30 40.0  NaN
```
pandas.Series.astype

`Series.astype(dtype, copy=True, errors='raise')`  
Cast a pandas object to a specified dtype `dtype`.

**Parameters**

- `dtype` [data type, or dict of column name -> data type] Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use `{col: dtype, ...}`, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame’s columns to column-specific types.

- `copy` [bool, default True] Return a copy when `copy=True` (be very careful setting `copy=False` as changes to values then may propagate to other pandas objects).

- `errors` [{'raise', 'ignore'}, default 'raise'] Control raising of exceptions on invalid data for provided dtype.
  - `raise`: allow exceptions to be raised
  - `ignore`: suppress exceptions. On error return original object.

**Returns**

- `casted` [same type as caller]

See also:

- `to_datetime` Convert argument to datetime.
- `to_timedelta` Convert argument to timedelta.
- `to_numeric` Convert argument to a numeric type.
- `numpy.ndarray.astype` Cast a numpy array to a specified type.

**Examples**

Create a DataFrame:

```python
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df.dtypes
  col1    int64
  col2    int64
dtype: object
```

Cast all columns to int32:

```python
>>> df.astype('int32').dtypes
  col1    int32
  col2    int32
dtype: object
```

Cast col1 to int32 using a dictionary:

```python
>>> df.astype({"col1": 'int32'}).dtypes
  col1    int32
  col2    int64
dtype: object
```
Create a series:

```python
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0 1
1 2
dtype: int32
>>> ser.astype('int64')
0 1
1 2
dtype: int64
```

Convert to categorical type:

```python
>>> ser.astype('category')
0 1
1 2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```python
>>> cat_dtype = pd.api.types.CategoricalDtype(
...    categories=[2, 1], ordered=True)
>>> ser.astype(cat_dtype)
0 1
1 2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```python
>>> s1 = pd.Series([1, 2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1 # note that s1[0] has changed too
0 10
1 2
dtype: int64
```

Create a series of dates:

```python
>>> ser_date = pd.Series(pd.date_range('20200101', periods=3))
>>> ser_date
0 2020-01-01
1 2020-01-02
2 2020-01-03
dtype: datetime64[ns]
```

Datetimes are localized to UTC first before converting to the specified timezone:

```python
>>> ser_date.astype('datetime64[ns, US/Eastern]')
0 2019-12-31 19:00:00-05:00
1 2020-01-01 19:00:00-05:00
2 2020-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```
pandas.Series.at_time

Series.at_time(time, asof=False, axis=None)
Select values at particular time of day (e.g., 9:30AM).

Parameters
- time [datetime.time or str]
- axis [{0 or 'index', 1 or 'columns'}, default 0] New in version 0.24.0.

Returns
- Series or DataFrame

Raises
- TypeError If the index is not a DatetimeIndex

See also:
- between_time Select values between particular times of the day.
- first Select initial periods of time series based on a date offset.
- last Select final periods of time series based on a date offset.
- DatetimeIndex.indexer_at_time Get just the index locations for values at particular time of the day.

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
   A
0  2018-04-09 00:00:00  1
1  2018-04-09 12:00:00  2
2  2018-04-10 00:00:00  3
3  2018-04-10 12:00:00  4

>>> ts.at_time('12:00')
   A
0  2018-04-09 12:00:00  2
1  2018-04-10 12:00:00  4
```

pandas.Series.autocorr

Series.autocorr(lag=1)
Compute the lag-N autocorrelation.

This method computes the Pearson correlation between the Series and its shifted self.

Parameters
- lag [int, default 1] Number of lags to apply before performing autocorrelation.

Returns
- float The Pearson correlation between self and self.shift(lag).
See also:

- **Series.corr** Compute the correlation between two Series.
- **Series.shift** Shift index by desired number of periods.
- **DataFrame.corr** Compute pairwise correlation of columns.
- **DataFrame.corrwith** Compute pairwise correlation between rows or columns of two DataFrame objects.

**Notes**

If the Pearson correlation is not well defined return ‘NaN’.

**Examples**

```python
>>> s = pd.Series([0.25, 0.5, 0.2, -0.05])
>>> s.autocorr()
0.10355...
>>> s.autocorr(lag=2)
-0.99999...
```

If the Pearson correlation is not well defined, then ‘NaN’ is returned.

```python
>>> s = pd.Series([1, 0, 0, 0])
>>> s.autocorr()
nan
```

**pandas.Series.backfill**

- **backfill**(axis=None, inplace=False, limit=None, downcast=None)
  Synonym for **DataFrame.fillna()** with method='bfill'.

**Returns**

- {klass} or None Object with missing values filled or None if inplace=True.

**pandas.Series.between**

- **between**(left, right, inclusive=True)
  Return boolean Series equivalent to left <= series <= right.

  This function returns a boolean vector containing True wherever the corresponding Series element is between the boundary values left and right. NA values are treated as False.

**Parameters**

- **left** [scalar or list-like] Left boundary.
- **right** [scalar or list-like] Right boundary.
- **inclusive** [bool, default True] Include boundaries.

**Returns**

- Series Series representing whether each element is between left and right (inclusive).
See also:

- **Series.gt** Greater than of series and other.
- **Series.lt** Less than of series and other.

Notes

This function is equivalent to \((left <= \text{ser}) \& (\text{ser} <= right)\)

Examples

```python
>>> s = pd.Series([2, 0, 4, 8, np.nan])
Boundary values are included by default:

```python
gt
0   True
1   False
2   True
3   False
4   False
dtype: bool
```  

With `inclusive` set to `False` boundary values are excluded:

```python
>>> s.between(1, 4, inclusive=False)
0   True
1   False
2   False
3   False
4   False
dtype: bool
```  

`left` and `right` can be any scalar value:

```python
>>> s = pd.Series(['Alice', 'Bob', 'Carol', 'Eve'])
>>> s.between('Anna', 'Daniel')
0   False
1   True
2   True
3   False
dtype: bool
```  

**pandas.Series.between_time**

- **Series.between_time** \((\text{start\_time}, \text{end\_time}, \text{include\_start}=True, \text{include\_end}=True, \text{axis}=None)\)
  
Select values between particular times of the day (e.g., 9:00-9:30 AM).

  
By setting `start_time` to be later than `end_time`, you can get the times that are *not* between the two times.

  
**Parameters**

- **start_time** [datetime.time or str] Initial time as a time filter limit.
end_time  [datetime.time or str] End time as a time filter limit.
include_start  [bool, default True] Whether the start time needs to be included in the result.
include_end  [bool, default True] Whether the end time needs to be included in the result.
axis  [{0 or ‘index’, 1 or ‘columns’}, default 0] Determine range time on index or columns value.

    New in version 0.24.0.

Returns

Series or DataFrame  Data from the original object filtered to the specified dates range.

Raises

TypeError  If the index is not a DatetimeIndex

See also:

    at_time  Select values at a particular time of the day.
    first    Select initial periods of time series based on a date offset.
    last     Select final periods of time series based on a date offset.
    DatetimeIndex.indexer_between_time Get just the index locations for values between particular times of the day.

Examples

>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
         A
2018-04-09 00:00:00  1
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3
2018-04-12 01:00:00  4

>>> ts.between_time('0:15', '0:45')
         A
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3

You get the times that are not between two times by setting start_time later than end_time:

>>> ts.between_time('0:45', '0:15')
         A
2018-04-09 00:00:00  1
2018-04-12 01:00:00  4

3.3. Series  1059
pandas.Series.bfill

```python
Series.bfill(axis=None, inplace=False, limit=None, downcast=None)
```

Synonym for `DataFrame.fillna()` with method='bfill'.

Returns

{klass} or None  Object with missing values filled or None if `inplace=True`.

pandas.Series.bool

```python
Series.bool()
```

Return the bool of a single element Series or DataFrame.

This must be a boolean scalar value, either True or False. It will raise a ValueError if the Series or DataFrame does not have exactly 1 element, or that element is not boolean (integer values 0 and 1 will also raise an exception).

Returns

bool  The value in the Series or DataFrame.

See also:

* Series.astype  Change the data type of a Series, including to boolean.
* DataFrame.astype  Change the data type of a DataFrame, including to boolean.
* numpy.bool_  NumPy boolean data type, used by pandas for boolean values.

**Examples**

The method will only work for single element objects with a boolean value:

```python
>>> pd.Series([True]).bool()
True
>>> pd.Series([False]).bool()
False
```

```python
>>> pd.DataFrame({'col': [True]}).bool()
True
>>> pd.DataFrame({'col': [False]}).bool()
False
```

pandas.Series.cat

```python
Series.cat()
```

Accessor object for categorical properties of the Series values.

Be aware that assigning to `categories` is an inplace operation, while all methods return new categorical data per default (but can be called with `inplace=True`).

**Parameters**

* data  [Series or CategoricalIndex]
Examples

```python
>>> s = pd.Series(list("abbccc")).astype("category")
>>> s
0   a
1   b
2   b
3   c
4   c
5   c
dtype: category
Categories (3, object): ['a', 'b', 'c']

>>> s.cat.categories
Index(['a', 'b', 'c'], dtype='object')

>>> s.cat.rename_categories(list("cba"))
0   c
1   b
2   b
3   a
4   a
5   a
dtype: category
Categories (3, object): ['c', 'b', 'a']

>>> s.cat.reorder_categories(list("cba"))
0   a
1   b
2   b
3   c
4   c
5   c
dtype: category
Categories (3, object): ['c', 'b', 'a']

>>> s.cat.add_categories(["d", "e"])
0   a
1   b
2   b
3   c
4   c
5   c
dtype: category
Categories (5, object): ['a', 'b', 'c', 'd', 'e']

>>> s.cat.remove_categories(["a", "c"])
0   NaN
1   b
2   b
3   NaN
4   NaN
5   NaN
dtype: category
Categories (1, object): ['b']
```
>>> s1 = s.cat.add_categories(["d", "e"])
>>> s1.cat.remove_unused_categories()
0  a
1  b
2  b
3  c
4  c
5  c
dtype: category
Categories (3, object): ['a', 'b', 'c']

>>> s.cat.set_categories(list("abcde"))
0  a
1  b
2  b
3  c
4  c
5  c
dtype: category
Categories (5, object): ['a', 'b', 'c', 'd', 'e']

>>> s.cat.as_ordered()
0  a
1  b
2  b
3  c
4  c
5  c
dtype: category
Categories (3, object): ['a' < 'b' < 'c']

>>> s.cat.as_unordered()
0  a
1  b
2  b
3  c
4  c
5  c
dtype: category
Categories (3, object): ['a', 'b', 'c']

pandas.Series.clip

Series.clip(lower=None, upper=None, axis=None, inplace=False, *args, **kwargs)
Trim values at input threshold(s).
Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and
in the latter case the clipping is performed element-wise in the specified axis.

Parameters

lower [float or array_like, default None] Minimum threshold value. All values below this
threshold will be set to it.

upper [float or array_like, default None] Maximum threshold value. All values above this
threshold will be set to it.
axis [int or str axis name, optional] Align object with lower and upper along the given axis.

inplace [bool, default False] Whether to perform the operation in place on the data.

*args, **kwargs Additional keywords have no effect but might be accepted for compatibility with numpy.

**Returns**

Series or DataFrame Same type as calling object with the values outside the clip boundaries replaced.

See also:

Series.clip Trim values at input threshold in series.

DataFrame.clip Trim values at input threshold in dataframe.

numpy.clip Clip (limit) the values in an array.

**Examples**

```python
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
    col_0   col_1
0      9     -2
1     -3     -7
2      0      6
3     -1      8
4      5     -5
```

Clips per column using lower and upper thresholds:

```python
>>> df.clip(-4, 6)
  col_0  col_1
0    6     -2
1   -3     -4
2    0      6
3   -1      6
4    5     -4
```

Clips using specific lower and upper thresholds per column element:

```python
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0    2
1   -4
2   -1
3    6
4    3
dtype: int64

>>> df.clip(t, t + 4, axis=0)
  col_0  col_1
0    6      2
1   -3     -4
```
pandas.Series.combine

Series\_combine\_\(other,\_func,\_fill\_value=None\)  
Combine the Series with a Series or scalar according to \(func\).

Combine the Series and \(other\) using \(func\) to perform elementwise selection for combined Series. \(fill\_value\) is assumed when value is missing at some index from one of the two objects being combined.

**Parameters**
- \(other\) [Series or scalar] The value(s) to be combined with the Series.
- \(func\) [function] Function that takes two scalars as inputs and returns an element.
- \(fill\_value\) [scalar, optional] The value to assume when an index is missing from one Series or the other. The default specifies to use the appropriate NaN value for the underlying dtype of the Series.

**Returns**
Series The result of combining the Series with the other object.

**See also:**
- Series\_combine\_first Combine Series values, choosing the calling Series’ values first.

**Examples**

Consider 2 Datasets s1 and s2 containing highest clocked speeds of different birds.

```python
>>> s1 = pd.Series({'falcon': 330.0, 'eagle': 160.0})
>>> s1
falcon 330.0
eagle 160.0
dtype: float64

>>> s2 = pd.Series({'falcon': 345.0, 'eagle': 200.0, 'duck': 30.0})
>>> s2
falcon 345.0
eagle 200.0
duck 30.0
dtype: float64
```

Now, to combine the two datasets and view the highest speeds of the birds across the two datasets

```python
>>> s1.combine(s2, max)
duck NaN
eagle 200.0
falcon 345.0
dtype: float64
```

In the previous example, the resulting value for duck is missing, because the maximum of a NaN and a float is a NaN. So, in the example, we set \(fill\_value\)=0, so the maximum value returned will be the value from some dataset.
pandas.Series.combine_first

Series.combine_first(other)
Combine Series values, choosing the calling Series’s values first.

Parameters
other [Series] The value(s) to be combined with the Series.

Returns
Series The result of combining the Series with the other object.

See also:
Series.combine Perform elementwise operation on two Series using a given function.

Notes
Result index will be the union of the two indexes.

Examples

```python
>>> s1 = pd.Series([1, np.nan])
>>> s2 = pd.Series([3, 4])
>>> s1.combine_first(s2)
0   1.0
1   4.0
dtype: float64
```

pandas.Series.compare

Series.compare(other, align_axis=1, keep_shape=False, keep_equal=False)
Compare to another Series and show the differences.
New in version 1.1.0.

Parameters
other [Series] Object to compare with.
align_axis [{0 or ‘index’, 1 or ‘columns’}, default 1] Determine which axis to align the comparison on.
- 0, or ‘index’ [Resulting differences are stacked vertically] with rows drawn alternately from self and other.
- 1, or ‘columns’ [Resulting differences are aligned horizontally] with columns drawn alternately from self and other.
keep_shape [bool, default False] If true, all rows and columns are kept. Otherwise, only the ones with different values are kept.

keep_equal [bool, default False] If true, the result keeps values that are equal. Otherwise, equal values are shown as NaNs.

Returns

Series or DataFrame If axis is 0 or ‘index’ the result will be a Series. The resulting index will be a MultiIndex with ‘self’ and ‘other’ stacked alternately at the inner level.

If axis is 1 or ‘columns’ the result will be a DataFrame. It will have two columns namely ‘self’ and ‘other’.

See also:

DataFrame.compare Compare with another DataFrame and show differences.

Notes

Matching NaNs will not appear as a difference.

Examples

```python
>>> s1 = pd.Series(['a', 'b', 'c', 'd', 'e'])
>>> s2 = pd.Series(['a', 'a', 'c', 'b', 'e'])
```

Align the differences on columns

```python
>>> s1.compare(s2)
  self    other
1   b     a
3   d     b
```

Stack the differences on indices

```python
>>> s1.compare(s2, align_axis=0)
  self    other
1     b
  other  a
3     d
  other  b
dtype: object
```

Keep all original rows

```python
>>> s1.compare(s2, keep_shape=True)
  self    other
0   NaN   NaN
1     b     a
2   NaN   NaN
3     d     b
4   NaN   NaN
```

Keep all original rows and also all original values
```python
>>> s1.compare(s2, keep_shape=True, keep_equal=True)
  self  other
0    a    a
1    b    a
2    c    c
3    d    b
4    e    e
```

**pandas.Series.convert_dtypes**

Series.convert_dtypes(infer_objects=True, convert_string=True, convert_integer=True, convert_boolean=True)

Convert columns to best possible dtypes using dtypes supporting pd.NA.

New in version 1.0.0.

**Parameters**

- **infer_objects** [bool, default True] Whether object dtypes should be converted to the best possible types.
- **convert_string** [bool, default True] Whether object dtypes should be converted to StringDtype().
- **convert_integer** [bool, default True] Whether, if possible, conversion can be done to integer extension types.
- **convert_boolean** [bool, default True] Whether object dtypes should be converted to BooleanDtype().

**Returns**

Series or DataFrame Copy of input object with new dtype.

**See also:**

- infer_objects Infer dtypes of objects.
- to_datetime Convert argument to datetime.
- to_timedelta Convert argument to timedelta.
- to_numeric Convert argument to a numeric type.

**Notes**

By default, `convert_dtypes` will attempt to convert a Series (or each Series in a DataFrame) to dtypes that support pd.NA. By using the options `convert_string`, `convert_integer`, and `convert_boolean`, it is possible to turn off individual conversions to StringDtype, the integer extension types or BooleanDtype, respectively.

For object-dtyped columns, if `infer_objects` is True, use the inference rules as during normal Series/DataFrame construction. Then, if possible, convert to StringDtype, BooleanDtype or an appropriate integer extension type, otherwise leave as object.

If the dtype is integer, convert to an appropriate integer extension type.

If the dtype is numeric, and consists of all integers, convert to an appropriate integer extension type.
In the future, as new dtypes are added that support `pd.NA`, the results of this method will change to support those new dtypes.

**Examples**

```python
df = pd.DataFrame({
    "a": pd.Series([1, 2, 3], dtype=np.dtype("int32")),
    "b": pd.Series(["x", "y", "z"], dtype=np.dtype("O")),
    "c": pd.Series([True, False, np.nan], dtype=np.dtype("O")),
    "d": pd.Series(["h", "i", np.nan], dtype=np.dtype("O")),
    "e": pd.Series([10, np.nan, 20], dtype=np.dtype("float")),
    "f": pd.Series([np.nan, 100.5, 200], dtype=np.dtype("float")),
})
```

Start with a DataFrame with default dtypes.

```python
df
a b c d e f
0 1 x  True  h  10.0  NaN
1 2 y False  i  NaN  100.5
2 3 z  NaN  NaN  20.0  200.0
```

```python
df.dtypes
a int32
b object
c object
d object
e float64
f float64
dtype: object
```

Convert the DataFrame to use best possible dtypes.

```python
dfn = df.convert_dtypes()
dfn
a b c d e f
0 1 x  True  h  10.0  NaN
1 2 y False  i  <NA>  100.5
2 3 z  <NA>  <NA>  20  200.0
```

```python
dfn.dtypes
a  Int32
b    string
c   boolean
d    string
e  Int64
f  float64
dtype: object
```

Start with a Series of strings and missing data represented by `np.nan`.

```python
s = pd.Series(["a", "b", np.nan])
s
```

(continues on next page)
Obtain a Series with dtype StringDtype.

```
>>> s.convert_dtypes()
0    a
1    b
2   <NA>
dtype: string
```

### pandas.Series.copy

**Series.copy** *(deep=True)*

Make a copy of this object’s indices and data.

When `deep=True` (default), a new object will be created with a copy of the calling object’s data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When `deep=False`, a new object will be created without copying the calling object’s data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

**Parameters**

- **deep** [bool, default True] Make a deep copy, including a copy of the data and the indices. With `deep=False` neither the indices nor the data are copied.

**Returns**

- **copy** [Series or DataFrame] Object type matches caller.

**Notes**

When `deep=True`, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to `copy.deepcopy` in the Standard Library, which recursively copies object data (see examples below).

While Index objects are copied when `deep=True`, the underlying numpy array is not copied for performance reasons. Since Index is immutable, the underlying data can be safely shared and a copy is not needed.
Examples

```python
>>> s = pd.Series([1, 2], index=[“a”, “b”])
>>> s
a 1
b 2
dtype: int64

>>> s_copy = s.copy()
>>> s_copy
a 1
b 2
dtype: int64

Shallow copy versus default (deep) copy:

```python
>>> s = pd.Series([1, 2], index=[“a”, “b”])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)

Shallow copy shares data and index with original.

```python
>>> s is shallow
False
>>> s.values is shallow.values and s.index is shallow.index
True

Deep copy has own copy of data and index.

```python
>>> s is deep
False
>>> s.values is deep.values or s.index is deep.index
False

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```python
>>> s[0] = 3
>>> shallow[1] = 4
>>> s
a 3
b 4
dtype: int64
>>> shallow
a 3
b 4
dtype: int64
>>> deep
a 1
b 2
dtype: int64

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```python
>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
```
pandas.Series.corr

Series.corr (other, method='pearson', min_periods=None)
Compute correlation with other Series, excluding missing values.

Parameters

other [Series] Series with which to compute the correlation.

method [(‘pearson’, ‘kendall’, ‘spearman’) or callable] Method used to compute correlation:
• pearson : Standard correlation coefficient
• kendall : Kendall Tau correlation coefficient
• spearman : Spearman rank correlation
• callable: Callable with input two 1d ndarrays and returning a float.

New in version 0.24.0: Note that the returned matrix from corr will have 1 along the diagonals and will be symmetric regardless of the callable’s behavior.

min_periods [int, optional] Minimum number of observations needed to have a valid result.

Returns

float Correlation with other.

See also:

DataFrame.corr Compute pairwise correlation between columns.

DataFrame.corrwith Compute pairwise correlation with another DataFrame or Series.

Examples

```python
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v
>>> s1 = pd.Series([.2, .0, .6, .2])
>>> s2 = pd.Series([.3, .6, .0, .1])
>>> s1.corr(s2, method=histogram_intersection)
0.3
```
pandas.Series.count

Series.count(level=None)
Return number of non-NA/null observations in the Series.

Parameters

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count
along a particular level, collapsing into a smaller Series.

Returns

int or Series (if level specified) Number of non-null values in the Series.

See also:

DataFrame.count Count non-NA cells for each column or row.

Examples

```python
>>> s = pd.Series([0.0, 1.0, np.nan])
>>> s.count()
2
```

pandas.Series.cov

Series.cov(other, min_periods=None, ddof=1)
Compute covariance with Series, excluding missing values.

Parameters

other [Series] Series with which to compute the covariance.

min_periods [int, optional] Minimum number of observations needed to have a valid
result.

ddof [int, default 1] Delta degrees of freedom. The divisor used in calculations is \( N -
ddof \), where \( N \) represents the number of elements.

New in version 1.1.0.

Returns

float Covariance between Series and other normalized by N-1 (unbiased estimator).

See also:

DataFrame.cov Compute pairwise covariance of columns.
Examples

```python
>>> s1 = pd.Series([0.90010907, 0.13484424, 0.62036035])
>>> s2 = pd.Series([0.12528585, 0.26962463, 0.51111198])
>>> s1.cov(s2)
-0.01685762652715874
```

**pandas.Series.cummax**

`Series.cummax(axis=None, skipna=True, *args, **kwargs)`

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

**Parameters**

- `axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.
- `skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- `*args, **kwargs` Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- `scalar or Series` Return cumulative maximum of scalar or Series.

**See also:**

- `core.window.Expanding.max` Similar functionality but ignores NaN values.
- `Series.max` Return the maximum over Series axis.
- `Series.cummax` Return cumulative maximum over Series axis.
- `Series.cummin` Return cumulative minimum over Series axis.
- `Series.cumsum` Return cumulative sum over Series axis.
- `Series.cumprod` Return cumulative product over Series axis.

**Examples**

**Series**

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0   2.0
1   NaN
2   5.0
3  -1.0
4   0.0
dtype: float64
```

By default, NA values are ignored.
To include NA values in the operation, use `skipna=False`

```
>>> s.cummax(skipna=False)
    0    2.0
    1  NaN
    2  NaN
    3  NaN
    4  NaN
dtype: float64
```

```
DataFrame

>>> df = pd.DataFrame([[2.0, 1.0],
                      ...                     [3.0, np.nan],
                      ...                     [1.0, 0.0]],
                      ...                     columns=list('AB'))

>>> df
     A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummax()
     A    B
0  2.0  1.0
1  3.0  NaN
2  3.0  1.0
```

To iterate over columns and find the maximum in each row, use `axis=1`

```
>>> df.cummax(axis=1)
     A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0
```
pandas.Series.cummin

Series.cummin(axis=None, skipna=True, *args, **kwargs)
Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

Parameters

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

*args, **kwargs Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series Return cumulative minimum of scalar or Series.

See also:
core.window.Expanding.min Similar functionality but ignores NaN values.
Series.min Return the minimum over Series axis.
Series.cummax Return cumulative maximum over Series axis.
Series.cummin Return cumulative minimum over Series axis.
Series.cumsum Return cumulative sum over Series axis.
Series.cumprod Return cumulative product over Series axis.

Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0  2.0
1  NaN
2  5.0
3 -1.0
4  0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cummin()
0  2.0
1  NaN
2  2.0
3 -1.0
4 -1.0
dtype: float64
```

To include NA values in the operation, use skipna=False
```
>>> s.cummin(skipna=False)
0  2.0
1  NaN
2  NaN
3  NaN
4  NaN
dtype: float64
```

**DataFrame**

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                   columns=list('AB'))
```

By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummin()
   A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```
>>> df.cummin(axis=1)
   A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

**pandas.Series.cumprod**

```
Series.cumprod(axis=None, skipna=True, *args, **kwargs)
```

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

**Parameters**

- `axis` [[0 or ‘index’, 1 or ‘columns’], default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.
- `skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- `*args, **kwargs` Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- `scalar or Series` Return cumulative product of scalar or Series.
See also:

**core.window.Expanding.prod** Similar functionality but ignores NaN values.

**Series.prod** Return the product over Series axis.

**Series.cummax** Return cumulative maximum over Series axis.

**Series.cummin** Return cumulative minimum over Series axis.

**Series.cumsum** Return cumulative sum over Series axis.

**Series.cumprod** Return cumulative product over Series axis.

### Examples

**Series**

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
```

```python
>>> s
```

```
0   2.0
1   NaN
2   5.0
3  -1.0
4   0.0
```

```
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cumprod()
```

```
0   2.0
1   NaN
2   10.0
3  -10.0
4   -0.0
```

```
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cumprod(skipna=False)
```

```
0   2.0
1   NaN
2   NaN
3   NaN
4   NaN
```

```
dtype: float64
```

**DataFrame**

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                   columns=list('AB'))
```

```python
>>> df
```

```
   A  B
0  2.0 1.0
1  3.0 NaN
2  1.0 0.0
```

```
By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
def.cumprod()
    A   B
 0  2.0  1.0
 1  6.0  NaN
 2  6.0  0.0
```

To iterate over columns and find the product in each row, use `axis=1`

```python
def.cumprod(axis=1)
    A   B
 0  2.0  2.0
 1  3.0  NaN
 2  1.0  0.0
```

**pandas.Series.cumsum**

Series.cumsum(axis=None, skipna=True, *args, **kwargs)

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

**Parameters**

- **axis** [[0 or 'index', 1 or 'columns'], default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

- ***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- **scalar or Series** Return cumulative sum of scalar or Series.

**See also:**

core.window.Expanding.sum  Similar functionality but ignores NaN values.

Series.sum  Return the sum over Series axis.

Series.cummax  Return cumulative maximum over Series axis.

Series.cummin  Return cumulative minimum over Series axis.

Series.cumsum  Return cumulative sum over Series axis.

Series.cumprod  Return cumulative product over Series axis.
Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1   NaN
2     5.0
3    -1.0
4     0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cumsum()
0    2.0
1   NaN
2     7.0
3     6.0
4     6.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cumsum(skipna=False)
0    2.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64
```

DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cumsum()
   A  B
0  2.0  1.0
1  5.0  NaN
2  6.0  1.0
```

To iterate over columns and find the sum in each row, use `axis=1`

```python
>>> df.cumsum(axis=1)
```

(continues on next page)
pandas.Series.describe

Series.describe(percentiles=None, include=None, exclude=None, datetime_is_numeric=False)

Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset’s distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

percentiles [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

include ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for Series. Here are the options:

• ‘all’ : All columns of the input will be included in the output.

• A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit numpy.number. To limit it instead to object columns submit the numpy.object data type. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To select pandas categorical columns, use 'category'

• None (default) : The result will include all numeric columns.

exclude [list-like of dtypes or None (default), optional,] A black list of data types to omit from the result. Ignored for Series. Here are the options:

• A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit numpy.number. To exclude object columns submit the data type numpy.object. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To exclude pandas categorical columns, use 'category'

• None (default) : The result will exclude nothing.

datetime_is_numeric [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

New in version 1.1.0.

Returns

Series or DataFrame Summary statistics of the Series or Dataframe provided.

See also:

DataFrame.count Count number of non-NA/null observations.

DataFrame.max Maximum of the values in the object.
**DataFrame.min**  Minimum of the values in the object.

**DataFrame.mean**  Mean of the values.

**DataFrame.std**  Standard deviation of the observations.

**DataFrame.select_dtypes**  Subset of a DataFrame including/excluding columns based on their dtype.

**Notes**

For numeric data, the result’s index will include count, mean, std, min, max as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result’s index will include count, unique, top, and freq. The top is the most common value. The freq is the most common value’s frequency. Timestamps also include the first and last items.

If multiple object values have the highest count, then the count and top results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a DataFrame, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If include='all' is provided as an option, the result will include a union of attributes of each type.

The include and exclude parameters can be used to limit which columns in a DataFrame are analyzed for the output. The parameters are ignored when analyzing a Series.

**Examples**

Describing a numeric Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count    3.0
mean     2.0
std      1.0
min      1.0
25%      1.5
50%      2.0
75%      2.5
max      3.0
dtype: float64
```

Describing a categorical Series.

```python
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count    4
unique   3
top      a
freq     2
dtype: object
```

Describing a timestamp Series.
```python
>>> s = pd.Series([
... np.datetime64("2000-01-01"),
... np.datetime64("2010-01-01"),
... np.datetime64("2010-01-01")
... ])  
>>> s.describe(datetime_is_numeric=True)
    count     3
     mean   2006-09-01 08:00:00
      min   2000-01-01 00:00:00
     25%  2004-12-31 12:00:00
     50%   2010-01-01 00:00:00
     75%   2010-01-01 00:00:00
      max   2010-01-01 00:00:00
    dtype: object
```

Describing a DataFrame. By default only numeric fields are returned.

```python
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d','e','f']),
...                     'numeric': [1, 2, 3],
...                     'object': ['a', 'b', 'c']
...                     })
>>> df.describe()
    numeric
       count  3.0
       mean   2.0
       std    1.0
       min   1.0
      25%   1.5
      50%   2.0
      75%   2.5
       max   3.0
```

Describing all columns of a DataFrame regardless of data type.

```python
>>> df.describe(include='all')
     categorical numeric    object
       count      3       3.0       3
      unique       3    NaN       3
       top        f  NaN       a
      freq       1  NaN       1
      mean   NaN   2.0  NaN
       std   NaN   1.0  NaN
      min   NaN   1.0  NaN
     25%   NaN   1.5  NaN
     50%   NaN   2.0  NaN
     75%   NaN   2.5  NaN
      max   NaN   3.0  NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```python
>>> df.numeric.describe()
    count  3.0
       mean   2.0
       std    1.0
       min   1.0
      25%   1.5
      50%   2.0
```

(continues on next page)
Including only numeric columns in a DataFrame description.

```python
>>> df.describe(include=[np.number])
   numeric
Count    3
Mean     2.0
Std      1.0
Min      1.0
25%      1.5
50%      2.0
75%      2.5
Max      3.0
```

Including only string columns in a DataFrame description.

```python
>>> df.describe(include=[object])
   object
Count    3
Unique   3
Top      a
Freq     1
```

Including only categorical columns from a DataFrame description.

```python
>>> df.describe(include=['category'])
   categorical
Count    3
Unique   3
Top      f
Freq     1
```

Excluding numeric columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.number])
   categorical  object
Count     3     3
Unique    3     3
Top       f     a
Freq      1     1
```

Excluding object columns from a DataFrame description.

```python
>>> df.describe(exclude=[object])
   categorical  numeric
Count     3     3.0
Unique    3     NaN
Top       f     NaN
Freq      1     NaN
Mean      NaN    2.0
Std       NaN    1.0
Min       NaN    1.0
25%       NaN    1.5
```

(continues on next page)
pandas.Series.diff

Series.diff(periods=1)
First discrete difference of element.
Calculates the difference of a Series element compared with another element in the Series (default is element in previous row).

Parameters

periods [int, default 1] Periods to shift for calculating difference, accepts negative values.

Returns

Series First differences of the Series.

See also:

Series.pct_change Percent change over given number of periods.
Series.shift Shift index by desired number of periods with an optional time freq.
DataFrame.diff First discrete difference of object.

Notes

For boolean dtypes, this uses operator.xor() rather than operator.sub(). The result is calculated according to current dtype in Series, however dtype of the result is always float64.

Examples

Difference with previous row

```python
>>> s = pd.Series([1, 1, 2, 3, 5, 8])
>>> s.diff()
0    NaN
1    0.0
2    1.0
3    1.0
4    2.0
5    3.0
dtype: float64
```

Difference with 3rd previous row

```python
>>> s.diff(periods=3)
0    NaN
1    NaN
2    NaN
3    2.0
4    4.0
```

(continues on next page)
Difference with following row

```python
>>> s.diff(periods=-1)
0    0.0
1   -1.0
2   -1.0
3   -2.0
4   -3.0
5    NaN
dtype: float64
```

Overflow in input dtype

```python
>>> s = pd.Series([1, 0], dtype=np.uint8)
>>> s.diff()
0    NaN
1  255.0
dtype: float64
```

### pandas.Series.div

Series.div(other, level=None, fill_value=None, axis=0)

Return Floating division of series and other, element-wise (binary operator truediv).

Equivalent to series / other, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

- **Series** The result of the operation.

**See also:**

- Series.rtruediv Reverse of the Floating division operator, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
```  
```python
>>> a.divide(b, fill_value=0)
a 1.0
b inf
c inf
d 0.0
e NaN
dtype: float64
```  

**pandas.Series.divide**

`Series.divide(other, level=None, fill_value=None, axis=0)`  
Return Floating division of series and other, element-wise (binary operator `truediv`).  
Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- `other` [Series or scalar value]
- `fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- `level` [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

- `Series` The result of the operation.

**See also:**

- `Series.rtruediv` Reverse of the Floating division operator, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d  NaN
dtype: float64

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b  NaN
d    1.0
e  NaN
dtype: float64

>>> a.divide(b, fill_value=0)
a    1.0
b    NaN
c    NaN
d    0.0
e  NaN
dtype: float64
```

```
pandas.Series.divmod

Series.divmod(other, level=None, fill_value=None, axis=0)

Return Integer division and modulo of series and other, element-wise (binary operator divmod).
Equivalent to series divmod other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

- other [Series or scalar value]
- fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

- 2-Tuple of Series The result of the operation.

See also:

- Series.rdivmod Reverse of the Integer division and modulo operator, see Python documentation for more details.
```
**pandas.Series.dot**

`Series.dot(other)`

Compute the dot product between the Series and the columns of other.

This method computes the dot product between the Series and another one, or the Series and each columns of a DataFrame, or the Series and each columns of an array.

It can also be called using `self @ other` in Python >= 3.5.

**Parameters**

- **other**  [Series, DataFrame or array-like] The other object to compute the dot product with its columns.

**Returns**

- **scalar, Series or numpy.ndarray** Return the dot product of the Series and other if other is a Series, the Series of the dot product of Series and each rows of other if other is a DataFrame or a numpy.ndarray between the Series and each columns of the numpy array.

**See also:**

- `DataFrame.dot`  Compute the matrix product with the DataFrame.
- `Series.mul`  Multiplication of series and other, element-wise.

**Notes**

The Series and other has to share the same index if other is a Series or a DataFrame.

**Examples**

```python
>>> s = pd.Series([0, 1, 2, 3])
>>> other = pd.Series([-1, 2, -3, 4])
>>> s.dot(other)
8
>>> s @ other
8
>>> df = pd.DataFrame([[0, 1], [-2, 3], [4, -5], [6, 7]])
>>> s.dot(df)
0    24
1    14
dtype: int64
>>> arr = np.array([[0, 1], [-2, 3], [4, -5], [6, 7]])
>>> s.dot(arr)
array([24, 14])
```
pandas.Series.drop

Series.drop(labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise')

Return Series with specified index labels removed.

Remove elements of a Series based on specifying the index labels. When using a multi-index, labels on
different levels can be removed by specifying the level.

Parameters

- **labels** [single label or list-like] Index labels to drop.
- **axis** [0, default 0] Redundant for application on Series.
- **index** [single label or list-like] Redundant for application on Series, but ‘index’ can be
  used instead of ‘labels’.
- **columns** [single label or list-like] No change is made to the Series; use ‘index’ or ‘labels’
  instead.
- **level** [int or level name, optional] For MultiIndex, level for which the labels will be re-
  moved.
- **inplace** [bool, default False] If True, do operation inplace and return None.
- **errors** ['ignore', 'raise'], default ‘raise’] If ‘ignore’, suppress error and only existing
  labels are dropped.

Returns

- **Series** Series with specified index labels removed.

Raises

- **KeyError** If none of the labels are found in the index.

See also:

- **Series.reindex** Return only specified index labels of Series.
- **Series.dropna** Return series without null values.
- **Series.drop_duplicates** Return Series with duplicate values removed.
- **DataFrame.drop** Drop specified labels from rows or columns.

Examples

```python
>>> s = pd.Series(data=np.arange(3), index=['A', 'B', 'C'])
>>> s
A  0
B  1
C  2
dtype: int64

Drop labels B en C
```

```python
>>> s.drop(labels=['B', 'C'])
A  0
dtype: int64
```
Drop 2nd level label in MultiIndex Series

```python
>>> midx = pd.MultiIndex(levels=[['lama', 'cow', 'falcon'],
... ['speed', 'weight', 'length']],
... codes=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
... [0, 1, 2, 0, 1, 2, 0, 1, 2]])
>>> s = pd.Series([45, 200, 1.2, 30, 250, 1.5, 320, 1, 0.3],
... index=midx)
>>> s
lama  speed   45.0
      weight  200.0
      length  1.2
cow   speed   30.0
      weight  250.0
      length  1.5
falcon speed  320.0
      weight  1.0
      length  0.3
dtype: float64

>>> s.drop(labels='weight', level=1)
lama  speed   45.0
      length  1.2
cow   speed   30.0
      length  1.5
falcon speed  320.0
      length  0.3
dtype: float64
```

**pandas.Series.drop_duplicates**

Series.drop_duplicates (keep='first', inplace=False)
Return Series with duplicate values removed.

**Parameters**

- keep [{'first', 'last', False}, default ‘first’] Method to handle dropping duplicates:
  - ‘first’ : Drop duplicates except for the first occurrence.
  - ‘last’ : Drop duplicates except for the last occurrence.
  - False : Drop all duplicates.

- inplace [bool, default False] If True, performs operation inplace and returns None.

**Returns**

Series Series with duplicates dropped.

**See also:**

- Index.drop_duplicates Equivalent method on Index.
- DataFrame.drop_duplicates Equivalent method on DataFrame.
- Series.duplicated Related method on Series, indicating duplicate Series values.
Examples

Generate a Series with duplicated entries.

```python
>>> s = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'],
                 name='animal')
>>> s
0   lama
1    cow
2   lama
3  beetle
4    lama
5   hippo
Name: animal, dtype: object
```

With the ‘keep’ parameter, the selection behaviour of duplicated values can be changed. The value ‘first’ keeps the first occurrence for each set of duplicated entries. The default value of keep is ‘first’.

```python
>>> s.drop_duplicates()  
0   lama
1    cow
2   lama
3  beetle
4    lama
5   hippo
Name: animal, dtype: object
```

The value ‘last’ for parameter ‘keep’ keeps the last occurrence for each set of duplicated entries.

```python
>>> s.drop_duplicates(keep='last')
1    cow
3  beetle
4    lama
5   hippo
Name: animal, dtype: object
```

The value False for parameter ‘keep’ discards all sets of duplicated entries. Setting the value of ‘inplace’ to True performs the operation inplace and returns None.

```python
>>> s.drop_duplicates(keep=False, inplace=True)
>>> s
1    cow
3  beetle
5   hippo
Name: animal, dtype: object
```

**pandas.Series.droplevel**

Series.droplevel(*level*, axis=0)

Return DataFrame with requested index / column level(s) removed.

New in version 0.24.0.

**Parameters**

- **level** [int, str, or list-like] If a string is given, must be the name of a level If list-like, elements must be names or positional indexes of levels.

- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis along which the level(s) is removed:
• 0 or ‘index’: remove level(s) in column.
• 1 or ‘columns’: remove level(s) in row.

Returns

DataFrame DataFrame with requested index / column level(s) removed.

Examples

```python
>>> df = pd.DataFrame([...
... [1, 2, 3, 4],
... [5, 6, 7, 8],
... [9, 10, 11, 12]
... ]).set_index([0, 1]).rename_axis(['a', 'b'])

>>> df.columns = pd.MultiIndex.from_tuples([...
... ('c', 'e'), ('d', 'f')
... ], names=['level_1', 'level_2'])

>>> df
level_1  c  d
level_2  e  f
a  b
  1  2  3  4
  5  6  7  8
  9 10 11 12

>>> df.droplevel('a')
level_1  c  d
level_2  e  f
b
  2  3  4
  6  7  8
 10 11 12

>>> df.droplevel('level_2', axis=1)
level_1  c  d
a  b
  1  2  3  4
  5  6  7  8
  9 10 11 12
```

pandas.Series.dropna

Series.dropna (axis=0, inplace=False, how=None)  
Return a new Series with missing values removed.

See the User Guide for more on which values are considered missing, and how to work with missing data.

Parameters

axis [[0 or ‘index’], default 0] There is only one axis to drop values from.
inplace [bool, default False] If True, do operation inplace and return None.
Returns

Series Series with NA entries dropped from it.

See also:

Series.isna Indicate missing values.
Series.notna Indicate existing (non-missing) values.
Series.fillna Replace missing values.
DataFrame.dropna Drop rows or columns which contain NA values.
Index.dropna Drop missing indices.

Examples

```python
>>> ser = pd.Series([1., 2., np.nan])
>>> ser
0  1.0
1  2.0
2  NaN
dtype: float64

Drop NA values from a Series.

>>> ser.dropna()
0  1.0
1  2.0
dtype: float64

Keep the Series with valid entries in the same variable.

>>> ser.dropna(inplace=True)
>>> ser
0  1.0
1  2.0
dtype: float64

Empty strings are not considered NA values. None is considered an NA value.

>>> ser = pd.Series([np.NaN, 2, pd.NaT, '', None, 'I stay'])
>>> ser
0   NaN
1     2
2    NaT
3
4   None
5   I stay
dtype: object

>>> ser.dropna()
1     2
3
5   I stay
dtype: object
```
pandas.Series.dt

Series.dt()

Accessor object for datetimelike properties of the Series values.

Examples

```python
>>> seconds_series = pd.Series(pd.date_range("2000-01-01", periods=3, freq="s"))
>>> seconds_series
t0 2000-01-01 00:00:00
1 2000-01-01 00:00:01
2 2000-01-01 00:00:02
dtype: datetime64[ns]
>>> seconds_series.dt.second
0 0
1 1
2 2
dtype: int64
```

```python
>>> hours_series = pd.Series(pd.date_range("2000-01-01", periods=3, freq="h"))
>>> hours_series
t0 2000-01-01 00:00:00
1 2000-01-01 01:00:00
2 2000-01-01 02:00:00
dtype: datetime64[ns]
>>> hours_series.dt.hour
0 0
1 1
2 2
dtype: int64
```

```python
>>> quarters_series = pd.Series(pd.date_range("2000-01-01", periods=3, freq="q"))
>>> quarters_series
t0 2000-03-31
1 2000-06-30
2 2000-09-30
dtype: datetime64[ns]
>>> quarters_series.dt.quarter
0 1
1 2
2 3
dtype: int64
```

Returns a Series indexed like the original Series. Raises TypeError if the Series does not contain datetimelike values.
**pandas.Series.duplicated**

Series.duplicated(keep='first')

Indicate duplicate Series values.

Duplicated values are indicated as True values in the resulting Series. Either all duplicates, all except the first or all except the last occurrence of duplicates can be indicated.

**Parameters**

keep [{‘first’, ‘last’, False}, default ‘first’] Method to handle dropping duplicates:

- ‘first’ : Mark duplicates as True except for the first occurrence.
- ‘last’ : Mark duplicates as True except for the last occurrence.
- False : Mark all duplicates as True.

**Returns**

Series Series indicating whether each value has occurred in the preceding values.

**See also:**

Index.duplicated Equivalent method on pandas.Index.

DataFrame.duplicated Equivalent method on pandas.DataFrame.

Series.drop_duplicates Remove duplicate values from Series.

**Examples**

By default, for each set of duplicated values, the first occurrence is set on False and all others on True:

```python
>>> animals = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> animals.duplicated()
0    False
1     False
2     True
3     False
4     True
dtype: bool
```

which is equivalent to

```python
>>> animals.duplicated(keep='first')
0    False
1     False
2     True
3     False
4     True
dtype: bool
```

By using ‘last’, the last occurrence of each set of duplicated values is set on False and all others on True:

```python
>>> animals.duplicated(keep='last')
0     True
1    False
2     True
3     False
```

(continues on next page)
4 False
dtype: bool

By setting keep on False, all duplicates are True:

```
>>> animals.duplicated(keep=False)
  0 True
  1 False
  2 True
  3 False
  4 True
dtype: bool
```

pandas.Series.eq

Series.eq(other, level=None, fill_value=None, axis=0)
Return Equal to of series and other, element-wise (binary operator eq).
Equivalent to series == other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters
- **other** (Series or scalar value)
- **fill_value** (None or float value, default None (NaN)) Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** (int or name) Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns
- **Series** The result of the operation.

Examples
```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0
b  1.0
c  1.0
d  NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b  NaN
c  1.0
e  NaN
dtype: float64
>>> a.eq(b, fill_value=0)
a  True
```
pandas.Series.equals

Series.equals(other)
Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the
same shape and elements. NaNs in the same location are considered equal. The column headers do not
need to have the same type, but the elements within the columns must be the same dtype.

Parameters

other [Series or DataFrame] The other Series or DataFrame to be compared with the first.

Returns

bool True if all elements are the same in both objects, False otherwise.

See also:

Series.eq Compare two Series objects of the same length and return a Series where each element is
True if the element in each Series is equal, False otherwise.

DataFrame.eq Compare two DataFrame objects of the same shape and return a DataFrame where
each element is True if the respective element in each DataFrame is equal, False otherwise.

testing.assert_series_equal Raises an AssertionError if left and right are not equal. Provides
an easy interface to ignore inequality in dtypes, indexes and precision among others.

testing.assert_frame_equal Like assert_series_equal, but targets DataFrames.

numpy.array_equal Return True if two arrays have the same shape and elements, False otherwise.

Notes

This function requires that the elements have the same dtype as their respective elements in the other
Series or DataFrame. However, the column labels do not need to have the same type, as long as they are
still considered equal.

Examples

```python
>>> df = pd.DataFrame({1: [10], 2: [20]})
>>> df
  1  2
0 10 20
```

DataFrames df and exactly_equal have the same types and values for their elements and column labels,
which will return True.
>>> exactly_equal = pd.DataFrame({1: [10], 2: [20]})
>>> exactly_equal
   1  2
0 10 20
>>> df.equals(exactly_equal)
True

DataFrames df and different_column_type have the same element types and values, but have different types for the column labels, which will still return True.

>>> different_column_type = pd.DataFrame({1.0: [10], 2.0: [20]})
>>> different_column_type
   1.0  2.0
0    10   20
>>> df.equals(different_column_type)
True

DataFrames df and different_data_type have different types for the same values for their elements, and will return False even though their column labels are the same values and types.

>>> different_data_type = pd.DataFrame({1: [10.0], 2: [20.0]})
>>> different_data_type
   1    2
0 10.0 20.0
>>> df.equals(different_data_type)
False

pandas.Series.ewm

Series.ewm(com=None, span=None, halflife=None, alpha=None, min_periods=0, adjust=True, ignore_na=False, axis=0, times=None)
Provide exponential weighted (EW) functions.
Available EW functions: mean(), var(), std(), corr(), cov().
Exactly one parameter: com, span, halflife, or alpha must be provided.

Parameters

- **com** [float, optional] Specify decay in terms of center of mass, \( \alpha = 1/(1 + \text{com}) \), for \( \text{com} \geq 0 \).
- **span** [float, optional] Specify decay in terms of span, \( \alpha = 2/(\text{span} + 1) \), for \( \text{span} \geq 1 \).
- **halflife** [float, str, timedelta, optional] Specify decay in terms of half-life, \( \alpha = 1 - \exp(-\ln(2)/\text{halflife}) \), for \( \text{halflife} > 0 \).
  
  If times is specified, the time unit (str or timedelta) over which an observation decays to half its value. Only applicable to mean() and halflife value will not apply to the other functions.
  
  New in version 1.1.0.
- **alpha** [float, optional] Specify smoothing factor \( \alpha \) directly, \( 0 < \alpha \leq 1 \).
- **min_periods** [int, default 0] Minimum number of observations in window required to have a value (otherwise result is NA).
- **adjust** [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average).
• When `adjust=True` (default), the EW function is calculated using weights \( w_i = (1 - \alpha)^i \). For example, the EW moving average of the series \([x_0, x_1, \ldots, x_t]\) would be:

\[
y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \ldots + (1 - \alpha)^t x_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + \ldots + (1 - \alpha)^t}
\]

• When `adjust=False`, the exponentially weighted function is calculated recursively:

\[
y_0 = x_0 \\
y_t = (1 - \alpha)y_{t-1} + \alpha x_t,
\]

`ignore_na` [bool, default False] Ignore missing values when calculating weights; specify `True` to reproduce pre-0.15.0 behavior.

• When `ignore_na=False` (default), weights are based on absolute positions. For example, the weights of \( x_0 \) and \( x_2 \) used in calculating the final weighted average of \([x_0, None, x_2]\) are \((1 - \alpha)^2\) and 1 if `adjust=True`, and \((1 - \alpha)^2\) and \(\alpha\) if `adjust=False`.

• When `ignore_na=True` (reproducing pre-0.15.0 behavior), weights are based on relative positions. For example, the weights of \( x_0 \) and \( x_2 \) used in calculating the final weighted average of \([x_0, None, x_2]\) are \(1 - \alpha\) and 1 if `adjust=True`, and \(1 - \alpha\) and \(\alpha\) if `adjust=False`.

`axis` [{0, 1}, default 0] The axis to use. The value 0 identifies the rows, and 1 identifies the columns.

`times` [str, np.ndarray, Series, default None] New in version 1.1.0.

Times corresponding to the observations. Must be monotonically increasing and `datetime64[ns]` dtype.

If str, the name of the column in the DataFrame representing the times.

If 1-D array like, a sequence with the same shape as the observations.

Only applicable to `mean()`.

Returns

DataFrame A Window sub-classed for the particular operation.

See also:

`rolling` Provides rolling window calculations.

`expanding` Provides expanding transformations.

Notes

More details can be found at: Exponentially weighted windows.
Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0
1  1
2  2
3  NaN
4  4

>>> df.ewm(com=0.5).mean()
   B
0 0.000000
1 0.750000
2 1.615385
3 1.615385
4 3.670213

Specifying times with a timedelta halflife when computing mean.

```python
>>> times = ['2020-01-01', '2020-01-03', '2020-01-10', '2020-01-15', '2020-01-17', ]
>>> df.ewm(halflife='4 days', times=pd.DatetimeIndex(times)).mean()
   B
0 0.000000
1 0.585786
2 1.523889
3 1.523889
4 3.233686
```

pandas.Series.expanding

Series.expanding(min_periods=1, center=None, axis=0)
Provide expanding transformations.

Parameters

- **min_periods** [int, default 1] Minimum number of observations in window required to have a value (otherwise result is NA).
- **center** [bool, default False] Set the labels at the center of the window.
- **axis** [int or str, default 0]

Returns

a Window sub-classed for the particular operation

See also:

- **rolling** Provides rolling window calculations.
- **ewm** Provides exponential weighted functions.
Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

Examples

```python
>>> df = pd.DataFrame({"B": [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0

>>> df.expanding(2).sum()
   B
0  NaN
1  1.0
2  3.0
3  3.0
4  7.0
```

`pandas.Series.explode`

Series.explode(\texttt{ignore\_index}=\texttt{False})  
Transform each element of a list-like to a row.

New in version 0.25.0.

Parameters

- `ignore_index` [bool, default False] If True, the resulting index will be labeled 0, 1, ..., n - 1.

New in version 1.1.0.

Returns

- `Series` Exploded lists to rows; index will be duplicated for these rows.

See also:

- `Series.str.split` Split string values on specified separator.
- `Series.unstack` Unstack, a.k.a. pivot, Series with MultiIndex to produce DataFrame.
- `DataFrame.melt` Unpivot a DataFrame from wide format to long format.
- `DataFrame.explode` Explode a DataFrame from list-like columns to long format.
Notes

This routine will explode list-likes including lists, tuples, Series, and np.ndarray. The result dtype of the subset rows will be object. Scalars will be returned unchanged. Empty list-likes will result in a np.nan for that row.

Examples

```python
>>> s = pd.Series([[1, 2, 3], 'foo', [], [3, 4]])
>>> s
0    [1, 2, 3]
1        foo
2        []
3    [3, 4]
dtype: object

>>> s.explode()
0  1
0  2
0  3
1    foo
2   NaN
3  3
3  4
dtype: object
```

**pandas.Series.factorize**

`Series.factorize(sort=False, na_sentinel=-1)`

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. `factorize` is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

Parameters

- `sort` [bool, default False] Sort uniques and shuffle codes to maintain the relationship.
- `na_sentinel` [int or None, default -1] Value to mark “not found”. If None, will not drop the NaN from the uniques of the values.

Changed in version 1.1.2.

Returns

- `codes` [ndarray] An integer ndarray that’s an indexer into uniques. `uniques.take(codes)` will have the same values as `values`.
- `uniques` [ndarray, Index, or Categorical] The unique valid values. When `values` is Categorical, `uniques` is a Categorical. When `values` is some other pandas object, an `Index` is returned. Otherwise, a 1-D ndarray is returned.

**Note:** Even if there’s a missing value in `values`, `uniques` will not contain an entry for it.
See also:

cut Discretize continuous-valued array.
unique Find the unique value in an array.

Examples

These examples all show factorize as a top-level method like pd.factorize(values). The results are identical for methods like Series.factorize().

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> codes
array([0, 0, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With sort=True, the uniques will be sorted, and codes will be shuffled so that the relationship is maintained.

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> codes
array([1, 1, 0, 2, 1])
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in codes with na_sentinel (-1 by default). Note that missing values are never included in uniques.

```python
>>> codes, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> codes
array([ 0, -1, 1, 2, 0])
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we’ve only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of uniques will differ. For Categoricals, a Categorical is returned.

```python
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])
>>> uniques
['a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Notice that 'b' is in uniques.categories, despite not being present in cat.values.

For all other pandas objects, an Index of the appropriate type is returned.

```python
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```
If NaN is in the values, and we want to include NaN in the uniques of the values, it can be achieved by setting `na_sentinel=None`.

```python
>>> values = np.array([1, 2, 1, np.nan])
>>> codes, uniques = pd.factorize(values)  # default: `na_sentinel=-1`
>>> codes
array([ 0, 1, 0, -1])
>>> uniques
array([1., 2.])
```

```python
>>> codes, uniques = pd.factorize(values, na_sentinel=None)
>>> codes
array([0, 1, 0, 2])
>>> uniques
array([ 1., 2., nan])
```

**pandas.Series.ffill**

Series.ffill *(axis=None, inplace=False, limit=None, downcast=None)*

Synonym for `DataFrame.fillna()` with `method='ffill'`.

**Returns**

{klass} or None  Object with missing values filled or None if `inplace=True`.

**pandas.Series.fillna**

Series.fillna *(value=None, method=None, axis=None, inplace=False, limit=None, downcast=None)*

Fill NA/NaN values using the specified method.

**Parameters**

- **value** [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

- **axis** [{0 or ‘index’}] Axis along which to fill missing values.

- **inplace** [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

- **limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

- **downcast** [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

**Returns**
Series or None  Object with missing values filled or None if inplace=True.

See also:

*interpolate*  Fill NaN values using interpolation.

*reindex*  Conform object to new index.

*asfreq*  Convert TimeSeries to specified frequency.

Examples

```python
>>> df = pd.DataFrame(
[[np.nan, 2, np.nan, 0],
  3, 4, np.nan, 1],
[[np.nan, np.nan, np.nan, 5],
  [np.nan, 3, np.nan, 4]],
columns=list('ABCD'))
```

Replace all NaN elements with 0s.

```python
>>> df.fillna(0)
```

We can also propagate non-null values forward or backward.

```python
>>> df.fillna(method='ffill')
```

Replace all NaN elements in column ‘A’, ‘B’, ‘C’, and ‘D’, with 0, 1, 2, and 3 respectively.

```python
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
```

Only replace the first NaN element.

```python
>>> df.fillna(value=values, limit=1)
```
pandas.Series.filter

Series.filter (items=None, like=None, regex=None, axis=None)
Subset the dataframe rows or columns according to the specified index labels.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

Parameters

items [list-like] Keep labels from axis which are in items.
like [str] Keep labels from axis for which "like in label == True".
regex [str (regular expression)] Keep labels from axis for which re.search(regex, label) == True.
axis [{0 or ‘index’, 1 or ‘columns’, None}, default None] The axis to filter on, expressed either as an index (int) or axis name (str). By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame.

Returns

same type as input object

See also:

DataFrame.loc Access a group of rows and columns by label(s) or a boolean array.

Notes

The items, like, and regex parameters are enforced to be mutually exclusive.
axis defaults to the info axis that is used when indexing with [].

Examples

```python
>>> df = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6]]),
                      index=['mouse', 'rabbit'],
                      columns=['one', 'two', 'three'])
>>> df
   one  two  three
mouse  1    2    3
rabbit 4    5    6

>>> # select columns by name
>>> df.filter(items=['one', 'three'])
   one  three
mouse  1    3
rabbit 4    6
```
>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
    one  three
mouse 1 3
rabbit 4 6

>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
    one  two  three
rabbit 4 5 6

pandas.Series.first

Series.<code>first</code> (<code>offset</code>)
Select initial periods of time series data based on a date offset.

When having a DataFrame with dates as index, this function can select the first few rows based on a date offset.

Parameters

- <code>offset</code> [str, DateOffset or dateutil.relativedelta] The offset length of the data that will be selected. For instance, ‘1M’ will display all the rows having their index within the first month.

Returns

- Series or DataFrame  A subset of the caller.

Raises

- TypeError  If the index is not a DatetimeIndex

See also:

- last  Select final periods of time series based on a date offset.
- at_time  Select values at a particular time of the day.
- between_time  Select values between particular times of the day.

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
    A
2018-04-09 1
2018-04-11 2
2018-04-13 3
2018-04-15 4
```

Get the rows for the first 3 days:
Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

**pandas.Series.first_valid_index**

Series.first_valid_index()
Return index for first non-NA/null value.

**Returns**
- scalar [type of index]

**Notes**
If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

**pandas.Series.floordiv**

Series.floordiv(other, level=None, fill_value=None, axis=0)
Return Integer division of series and other, element-wise (binary operator floordiv).
Equivalent to series // other, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**
- other [Series or scalar value]
- fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**
- Series The result of the operation.

**See also:**
- Series.rfloordiv Reverse of the Integer division operator, see Python documentation for more details.
### Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64

>>> a.floordiv(b, fill_value=0)
a 1.0
b NaN
c NaN
d 0.0
e NaN
dtype: float64
```

#### pandas.Series.ge

The **ge** method returns greater than or equal to of series and other, element-wise (binary operator `ge`).

Equivalent to `series >= other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- `other` [Series or scalar value]

- `fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

- `level` [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

- `Series` The result of the operation.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
e    1.0
dtype: float64
>>> b = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
>>> b
a    0.0
b    1.0
c    2.0
d    NaN
f    1.0
dtype: float64
>>> a.ge(b, fill_value=0)
a    True
b    True
c   False
d   False
e    True
f   False
dtype: bool
```

**pandas.Series.get**

`Series.get(key, default=None)`

Get item from object for given key (ex: DataFrame column). Returns default value if not found.

**Parameters**

- `key` [object]

**Returns**

- `value` [same type as items contained in object]

**pandas.Series.groupby**

`Series.groupby(by=None, axis=0, level=None, as_index=True, sort=True, group_keys=True, squeeze=<object object>, observed=False, dropna=True)`

Group Series using a mapper or by a Series of columns.

A groupby operation involves some combination of splitting the object, applying a function, and combining the results. This can be used to group large amounts of data and compute operations on these groups.

**Parameters**

- `by` [mapping, function, label, or list of labels] Used to determine the groups for the groupby. If `by` is a function, it’s called on each value of the object’s index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the
groups (the Series’ values are first aligned; see .align() method). If an ndarray is
passed, the values are used as-is to determine the groups. A label or list of labels may
be passed to group by the columns in self. Notice that a tuple is interpreted as a
(single) key.

axis [[0 or ‘index’, 1 or ‘columns’], default 0] Split along rows (0) or columns (1).
level [int, level name, or sequence of such, default None] If the axis is a MultiIndex
(hierarchical), group by a particular level or levels.

as_index [bool, default True] For aggregated output, return object with group labels as
the index. Only relevant for DataFrame input. as_index=False is effectively “SQL-
style” grouped output.

sort [bool, default True] Sort group keys. Get better performance by turning this off.
Note this does not influence the order of observations within each group. Groupby
preserves the order of rows within each group.

group_keys [bool, default True] When calling apply, add group keys to index to identify
pieces.

squeeze [bool, default False] Reduce the dimensionality of the return type if possible,
otherwise return a consistent type.

Deprecated since version 1.1.0.

observed [bool, default False] This only applies if any of the groupers are Categoricals.
If True: only show observed values for categorical groupers. If False: show all values
for categorical groupers.

New in version 0.23.0.

dropna [bool, default True] If True, and if group keys contain NA values, NA values
together with row/column will be dropped. If False, NA values will also be treated as
the key in groups

New in version 1.1.0.

Returns

SeriesGroupBy Returns a groupby object that contains information about the groups.

See also:

resample Convenience method for frequency conversion and resampling of time series.

Notes

See the user guide for more.
Examples

```python
>>> ser = pd.Series([390., 350., 30., 20.],
...                   index=['Falcon', 'Falcon', 'Parrot', 'Parrot'], name="Max Speed")
>>> ser
Falcon  390.0
Falcon  350.0
Parrot  30.0
Parrot  20.0
Name: Max Speed, dtype: float64
>>> ser.groupby(["a", "b", "a", "b"]).mean()
a 210.0
b 185.0
Name: Max Speed, dtype: float64
>>> ser.groupby(level=0).mean()
Falcon 370.0
Parrot 25.0
Name: Max Speed, dtype: float64
>>> ser.groupby(ser > 100).mean()
Max Speed
False  25.0
True 370.0
Name: Max Speed, dtype: float64
```

Grouping by Indexes

We can groupby different levels of a hierarchical index using the `level` parameter:

```python
>>> arrays = [['Falcon', 'Falcon', 'Parrot', 'Parrot'],
...            ['Captive', 'Wild', 'Captive', 'Wild']]
>>> index = pd.MultiIndex.from_arrays(arrays, names=('Animal', 'Type'))
>>> ser = pd.Series([390., 350., 30., 20.], index=index, name="Max Speed")
>>> ser
Animal  Type
Falcon Captive 390.0
        Wild  350.0
Parrot Captive 30.0
        Wild  20.0
Name: Max Speed, dtype: float64
>>> ser.groupby(level=0).mean()
Animal
Falcon 370.0
Parrot 25.0
Name: Max Speed, dtype: float64
>>> ser.groupby(level="Type").mean()
Type
Captive 210.0
Wild 185.0
Name: Max Speed, dtype: float64
```

We can also choose to include NA in group keys or not by defining `dropna` parameter, the default setting is `True`:

```python
>>> ser = pd.Series([1, 2, 3, 3], index=['a', 'a', 'b', np.nan])
>>> ser.groupby(level=0).sum()
a 3
(continues on next page)```
>>> ser.groupby(level=0, dropna=False).sum()
            a    b  NaN
       dtype: int64

>>> arrays = ['Falcon', 'Falcon', 'Parrot', 'Parrot']
>>> ser = pd.Series([390., 350., 30., 20.], index=arrays, name="Max Speed")
>>> ser.groupby(['a', 'b', 'a', np.nan]).mean()
       a    b  NaN
Name: Max Speed, dtype: float64

>>> ser.groupby(['a', 'b', 'a', np.nan], dropna=False).mean()
       a    b  NaN
Name: Max Speed, dtype: float64

pandas.Series.gt

Series.gt (other, level=None, fill_value=None, axis=0)
Return Greater than of series and other, element-wise (binary operator gt).
Equivalent to series > other, but with support to substitute a fill_value for missing data in either
one of the inputs.

Parameters
- other [Series or scalar value]
- fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values,
  and any new element needed for successful Series alignment, with this value before
  computation. If data in both corresponding Series locations is missing the result of
  filling (at that location) will be missing.
- level [int or name] Broadcast across a level, matching Index values on the passed Multi-
  Index level.

Returns
- Series The result of the operation.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
>>> a
a    1.0
b    1.0
c    1.0
d   NaN
e    1.0
dtype: float64
```

```python
>>> b = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
>>> b
a    0.0
b    1.0
c    2.0
d   NaN
f    1.0
dtype: float64
```

```python
>>> a.gt(b, fill_value=0)
a   True
b  False
c  False
d  False
e   True
f  False
dtype: bool
```

**pandas.Series.head**

`Series.head(n=5)`

Return the first `n` rows.

This function returns the first `n` rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

For negative values of `n`, this function returns all rows except the last `n` rows, equivalent to `df[:-n]`.

**Parameters**

- `n` [int, default 5] Number of rows to select.

**Returns**

- `same type as caller` The first `n` rows of the caller object.

See also:

- `DataFrame.tail` Returns the last `n` rows.
Examples

```python
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
... 'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
animal      0    alligator
         1      bee
         2  falcon
         3    lion
         4  monkey
         5  parrot
         6  shark
         7  whale
         8  zebra
         View the first 5 lines
>>> df.head()
animal
0    alligator
1      bee
2  falcon
3    lion
4  monkey

Viewing the first $n$ lines (three in this case)

```python
>>> df.head(3)
animal
0    alligator
1      bee
2  falcon

For negative values of $n$

```python
>>> df.head(-3)
animal
0    alligator
1      bee
2  falcon
3    lion
4  monkey
5  parrot

```

**pandas.Series.hist**

`.hist(by=None, ax=None, grid=True, xlabels=None, xrot=None, ylabels=None, yrot=None, figsize=None, backend=None, legend=False, **kwargs)`

Draw histogram of the input series using matplotlib.

**Parameters**

- **by** [object, optional] If passed, then used to form histograms for separate groups.
- **ax** [matplotlib axis object] If not passed, uses gca().
- **grid** [bool, default True] Whether to show axis grid lines.
**xlabelsize**  [int, default None] If specified changes the x-axis label size.

**xrot**  [float, default None] Rotation of x axis labels.

**ylabelsize**  [int, default None] If specified changes the y-axis label size.

**yrot**  [float, default None] Rotation of y axis labels.

**figsize**  [tuple, default None] Figure size in inches by default.

**bins**  [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

**backend**  [str, default None] Backend to use instead of the backend specified in the option plotting.backend. For instance, ‘matplotlib’. Alternatively, to specify the plotting.backend for the whole session, set pd.options.plotting.backend.

New in version 1.0.0.

**legend**  [bool, default False] Whether to show the legend.

New in version 1.1.0.

**kwargs** To be passed to the actual plotting function.

**Returns**

```
matplotlib.AxesSubplot  A histogram plot.
```

**See also:**

```
matplotlib.axes.Axes.hist  Plot a histogram using matplotlib.
```

### pandas.Series.idxmax

**Series.idxmax**(axis=0, skipna=True, *args, **kwargs)

Return the row label of the maximum value.

If multiple values equal the maximum, the first row label with that value is returned.

**Parameters**

axis  [int, default 0] For compatibility with DataFrame.idxmax. Redundant for application on Series.

skipna  [bool, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.

*args, **kwargs Additional arguments and keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

Index  Label of the maximum value.

**Raises**

ValueError  If the Series is empty.

**See also:**
**numpy.argmax**  Return indices of the maximum values along the given axis.

**DataFrame.idxmax**  Return index of first occurrence of maximum over requested axis.

**Series.idxmin**  Return index *label* of the first occurrence of minimum of values.

**Notes**

This method is the Series version of *ndarray.argmax*. This method returns the label of the maximum, while *ndarray.argmax* returns the position. To get the position, use `series.values.argmax()`.

**Examples**

```python
>>> s = pd.Series(data=[1, None, 4, 3, 4],
                 index=['A', 'B', 'C', 'D', 'E'])
>>> s
A   1.0
B  NaN
C   4.0
D   3.0
E   4.0
dtype: float64
```

```python
>>> s.idxmax()
'C'
```

If *skipna* is False and there is an NA value in the data, the function returns `nan`.

```python
>>> s.idxmax(skipna=False)
 nan
```

**pandas.Series.idxmin**

**Series.idxmin**(axis=0, skipna=True, *args, **kwargs)

Return the row label of the minimum value.

If multiple values equal the minimum, the first row label with that value is returned.

**Parameters**

- **axis**  [int, default 0]  For compatibility with `DataFrame.idxmin`. Redundant for application on Series.
- **skipna**  [bool, default True]  Exclude NA/null values. If the entire Series is NA, the result will be NA.
- **args, **kwargs**  Additional arguments and keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- **Index**  Label of the minimum value.

**Raises**

- **ValueError**  If the Series is empty.

**See also:**

3.3. Series
numpy.argmin Return indices of the minimum values along the given axis.

DataFrame.idxmin Return index of first occurrence of minimum over requested axis.

Series.idxmax Return index label of the first occurrence of maximum of values.

Notes

This method is the Series version of ndarray.argmin. This method returns the label of the minimum, while ndarray.argmin returns the position. To get the position, use series.values.argmin().

Examples

```python
>>> s = pd.Series(data=[1, None, 4, 1],
...                index=['A', 'B', 'C', 'D'])
>>> s
A 1.0
B NaN
C 4.0
D 1.0
dtype: float64

>>> s.idxmin()
'A'
```

If skipna is False and there is an NA value in the data, the function returns nan.

```python
>>> s.idxmin(skipna=False)
nan
```

pandas.Series.infer_objects

Series.infer_objects() Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

Returns

converted [same type as input object]

See also:

to_datetime Convert argument to datetime.
to_timedelta Convert argument to timedelta.
to_numeric Convert argument to numeric type.
convert_dtypes Convert argument to best possible dtype.
Examples

```python
>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
   A
0  1
1  2
2  3
```

```python
>>> df.dtypes
A  object
dtype: object
```

```python
>>> df.infer_objects().dtypes
A  int64
dtype: object
```

**pandas.Series.interpolate**

`Series.interpolate(method='linear', axis=0, limit=None, inplace=False, limit_direction=None, limit_area=None, downcast=None, **kwargs)`

Please note that only `method='linear'` is supported for DataFrame/Series with a MultiIndex.

**Parameters**

- **method** [str, default ‘linear’] Interpolation technique to use. One of:
  - ‘linear’: Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
  - ‘time’: Works on daily and higher resolution data to interpolate given length of interval.
  - ‘index’, ‘values’: use the actual numerical values of the index.
  - ‘pad’: Fill in NaNs using existing values.
  - ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘spline’, ‘barycentric’, ‘polynomial’: Passed to `scipy.interpolate.interp1d`. These methods use the numerical values of the index. Both ‘polynomial’ and ‘spline’ require that you also specify an `order` (int), e.g. `df.interpolate(method='polynomial', order=5)`.
  - ‘from_derivatives’: Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces ‘piecewise_polynomial’ interpolation method in scipy 0.18.

- **axis** [{0 or ‘index’, 1 or ‘columns’, None}, default None] Axis to interpolate along.

- **limit** [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

- **inplace** [bool, default False] Update the data in place if possible.

- **limit_direction** [{‘forward’, ‘backward’, ‘both’}, Optional] Consecutive NaNs will be filled in this direction.

If limit is specified:
• If ‘method’ is ‘pad’ or ‘ffill’, ‘limit_direction’ must be ‘forward’.
• If ‘method’ is ‘backfill’ or ‘bfill’, ‘limit_direction’ must be ‘backwards’.

**If ‘limit’ is not specified:**
• If ‘method’ is ‘backfill’ or ‘bfill’, the default is ‘backward’
• else the default is ‘forward’

Changed in version 1.1.0: raises ValueError if limit_direction is ‘forward’ or ‘both’ and method is ‘backfill’ or ‘bfill’. raises ValueError if limit_direction is ‘backward’ or ‘both’ and method is ‘pad’ or ‘ffill’.

limit_area {{{None, ‘inside’, ‘outside’}}}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.
• None: No fill restriction.
• ‘inside’: Only fill NaNs surrounded by valid values (interpolate).
• ‘outside’: Only fill NaNs outside valid values (extrapolate).

New in version 0.23.0.

downcast [optional, ‘infer’ or None, defaults to None] Downcast dtypes if possible.

**kwargs Keyword arguments to pass on to the interpolating function.

**Returns**

Series or DataFrame Returns the same object type as the caller, interpolated at some or all NaN values.

See also:

fillna Fill missing values using different methods.

scipy.interpolate.Akima1DInterpolator Piecewise cubic polynomials (Akima interpolator).

scipy.interpolate.BPoly.from_derivatives Piecewise polynomial in the Bernstein basis.

scipy.interpolate.interpld Interpolate a 1-D function.

scipy.interpolate.KroghInterpolator Interpolate polynomial (Krogh interpolator).

scipy.interpolate.PchipInterpolator PCHIP 1-d monotonic cubic interpolation.

scipy.interpolate.CubicSpline Cubic spline data interpolator.

**Notes**
The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the SciPy documentation and SciPy tutorial.
Examples

Filling in NaN in a *Series* via linear interpolation.

```python
def s = pd.Series([0, 1, np.nan, 3])
>>> s
0 0.0
1 1.0
2 NaN
3 3.0
dtype: float64
>>> s.interpolate()
0 0.0
1 1.0
2 2.0
3 3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.

```python
def s = pd.Series([np.nan, "single_one", np.nan,
... "fill_two_more", np.nan, np.nan, np.nan,
... 4.71, np.nan])
>>> s
0 NaN
1 single_one
2 NaN
3 fill_two_more
4 NaN
5 NaN
6 NaN
7 4.71
8 NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0 NaN
1 single_one
2 single_one
3 fill_two_more
4 fill_two_more
5 fill_two_more
6 NaN
7 4.71
8 4.71
dtype: object
```

Filling in NaN in a Series via polynomial interpolation or splines: Both 'polynomial' and 'spline' methods require that you also specify an order (int).

```python
def s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0 0.000000
1 2.000000
2 4.666667
3 8.000000
dtype: float64
```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.
Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it to use for interpolation.

```python
>>> df = pd.DataFrame([
    (0.0, np.nan, -1.0, 1.0),
    (np.nan, 2.0, np.nan, np.nan),
    (2.0, 3.0, np.nan, 9.0),
    (np.nan, 4.0, -4.0, 16.0),
], columns=list('abcd'))
>>> df
    a      b      c     d
0  0.0    NaN    -1.0  1.0
1  NaN    2.0    NaN   NaN
2  2.0    3.0    NaN   9.0
3  NaN    4.0   -4.0  16.0
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
    a      b      c     d
0  0.0    NaN    -1.0  1.0
1  1.0    2.0   -2.0  5.0
2  2.0    3.0   -3.0  9.0
3  2.0    4.0   -4.0  16.0
```

Using polynomial interpolation.

```python
>>> df['d'].interpolate(method='polynomial', order=2)
0    1.0
1    4.0
2    9.0
3   16.0
Name: d, dtype: float64
```

### pandas.Series.isin

`Series.isin(values)`

Whether elements in Series are contained in `values`.

Return a boolean Series showing whether each element in the Series matches an element in the passed sequence of `values` exactly.

**Parameters**

- `values` [set or list-like] The sequence of values to test. Passing in a single string will raise a `TypeError`. Instead, turn a single string into a list of one element.

**Returns**

- `Series` Series of booleans indicating if each element is in `values`.

**Raises**

- `TypeError` When `values` is a string.

**See also:**

- `DataFrame.isin` Equivalent method on DataFrame.
pandas.Series.isna

Series.isna()

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy.Nan, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

Returns

Series  Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:

Series.isnull  Alias of isna.

Series.notna  Boolean inverse of isna.

Series.dropna  Omit axes labels with missing values.

isna  Top-level isna.
Examples

Show which entries in a DataFrame are NA.

```python
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                     'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                       pd.Timestamp('1940-04-25')],
...                     'name': ['Alfred', 'Batman', ''],
...                     'toy': [None, 'Batmobile', 'Joker'])

>>> df
          age   born     name    toy
0      5.0  NaT    Alfred       None
1      6.0  1939-05-27  Batman  Batmobile
2     NaN  1940-04-25       Joker

>>> df.isna()
          age   born     name    toy
0     False  True    False   True
1     False  False    False   False
2      True  False    False   False
```

Show which entries in a Series are NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2    NaN
dtype: float64

>>> ser.isna()
0  False
1  False
2   True
dtype: bool
```

*pandas.Series.isnull*

Series.isnull()

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy.NaN, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

Returns

Series Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:

Series.isnull Alias of isna.

Series.notna Boolean inverse of isna.
**Series.dropna** Omit axes labels with missing values.

**isna** Top-level isna.

### Examples

Show which entries in a DataFrame are NA.

```python
def = pd.DataFrame({'age': [5, 6, np.NaN],
                              pd.Timestamp('1940-04-25')],
                    'name': ['Alfred', 'Batman', ''],
                    'toy': [None, 'Batmobile', 'Joker']})
```

```python
def
    age  born  name  toy
0    5.0    NaT  Alfred  None
1   6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25  Joker
```

```python
def.isna()
    age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2  True  False  False  False
```

Show which entries in a Series are NA.

```python
ser = pd.Series([5, 6, np.NaN])
```

```python
ser
    0   5.0
    1   6.0
    2  NaN
dtype: float64
```

```python
ser.isna()
    0  False
    1  False
    2  True
dtype: bool
```

### pandas.Series.item

**Series.item()**

Return the first element of the underlying data as a python scalar.

- **Returns**
  - scalar The first element of %(klass)s.

- **Raises**
  - ValueError If the data is not length-1.
pandas.Series.items

**Series.items()**

Lazily iterate over (index, value) tuples.

This method returns an iterable tuple (index, value). This is convenient if you want to create a lazy iterator.

**Returns**

iterable  Iterable of tuples containing the (index, value) pairs from a Series.

**See also:**

*DataFrame.items*  Iterate over (column name, Series) pairs.

*DataFrame.iterrows*  Iterate over DataFrame rows as (index, Series) pairs.

**Examples**

```python
>>> s = pd.Series(['A', 'B', 'C'])
>>> for index, value in s.items:
...     print(f"Index : {index}, Value : {value}")
Index : 0, Value : A
Index : 1, Value : B
Index : 2, Value : C
```

pandas.Series.iteritems

**Series.iteritems()**

Lazily iterate over (index, value) tuples.

This method returns an iterable tuple (index, value). This is convenient if you want to create a lazy iterator.

**Returns**

iterable  Iterable of tuples containing the (index, value) pairs from a Series.

**See also:**

*DataFrame.items*  Iterate over (column name, Series) pairs.

*DataFrame.iterrows*  Iterate over DataFrame rows as (index, Series) pairs.

**Examples**

```python
>>> s = pd.Series(['A', 'B', 'C'])
>>> for index, value in s.items:
...     print(f"Index : {index}, Value : {value}")
Index : 0, Value : A
Index : 1, Value : B
Index : 2, Value : C
```
pandas.Series.keys

Series.keys()
Return alias for index.

Returns
- Index Index of the Series.

pandas.Series.kurt

Series.kurt(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters
- axis {[index (0)]} Axis for the function to be applied on.
- skipna [bool, default True] Exclude NA/null values when computing the result.
- level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs Additional keyword arguments to be passed to the function.

Returns
- scalar or Series (if level specified)

pandas.Series.kurtosis

Series.kurtosis(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters
- axis {[index (0)]} Axis for the function to be applied on.
- skipna [bool, default True] Exclude NA/null values when computing the result.
- level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs Additional keyword arguments to be passed to the function.

Returns
- scalar or Series (if level specified)
**pandas.Series.last**

Series' last(offset)

Select final periods of time series data based on a date offset.

When having a DataFrame with dates as index, this function can select the last few rows based on a date offset.

**Parameters**

offset [str, DateOffset, dateutil.relativedelta] The offset length of the data that will be selected. For instance, ‘3D’ will display all the rows having their index within the last 3 days.

**Returns**

Series or DataFrame A subset of the caller.

** Raises**

TypeError If the index is not a DatetimeIndex

**See also:**

first Select initial periods of time series based on a date offset.

at_time Select values at a particular time of the day.

between_time Select values between particular times of the day.

**Examples**

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
     A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4

Get the rows for the last 3 days:

```python
>>> ts.last('3D')
     A
2018-04-13  3
2018-04-15  4
```

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.
pandas.Series.last_valid_index

Series.last_valid_index()
Return index for last non-NA/null value.

Returns

scalar [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.Series.le

Series.le(other, level=None, fill_value=None, axis=0)
Return Less than or equal to of series and other, element-wise (binary operator le).
Equivalent to series <= other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]
fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
e    1.0
dtype: float64
>>> b = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
>>> b
a    0.0
b    1.0
c    2.0
d    NaN
f    1.0
dtype: float64
>>> a.le(b, fill_value=0)
```

(continues on next page)
pandas.Series.lt

Series.lt (other, level=None, fill_value=None, axis=0)

Return Less than of series and other, element-wise (binary operator lt).

Equivalent to series < other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

Examples

```python
g = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
g   a 1.0
    b 1.0
    c 1.0
    d NaN
    e 1.0
dtype: float64
g = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
g   a 0.0
    b 1.0
    c 2.0
    d NaN
    f 1.0
dtype: float64
g.lt(b, fill_value=0)
g   a False
    b False
    c True
    d False
```
pandas.Series.mad

Series.mad (axis=None, skipna=None, level=None)
Return the mean absolute deviation of the values for the requested axis.

Parameters

axis [[index (0)]] Axis for the function to be applied on.
skipna [bool, default None] Exclude NA/null values when computing the result.
level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count
along a particular level, collapsing into a scalar.

Returns
scalar or Series (if level specified)

pandas.Series.map

Series.map (arg, na_action=None)
Map values of Series according to input correspondence.

Used for substituting each value in a Series with another value, that may be derived from a function, a
dict or a Series.

Parameters

na_action [{None, ‘ignore’}, default None] If ‘ignore’, propagate NaN values, without
passing them to the mapping correspondence.

Returns
Series Same index as caller.

See also:

Series.apply For applying more complex functions on a Series.
DataFrame.apply Apply a function row-/column-wise.
DataFrame.applymap Apply a function elementwise on a whole DataFrame.
Notes

When `arg` is a dictionary, values in Series that are not in the dictionary (as keys) are converted to NaN. However, if the dictionary is a dict subclass that defines `__missing__` (i.e. provides a method for default values), then this default is used rather than NaN.

Examples

```python
gg = s = pd.Series(['cat', 'dog', np.nan, 'rabbit'])
>>> s
0   cat
1   dog
2  NaN
3  rabbit
dtype: object

map accepts a dict or a Series. Values that are not found in the dict are converted to NaN, unless the dict has a default value (e.g. defaultdict):

```python
>>> s.map({'cat': 'kitten', 'dog': 'puppy'})
0   kitten
1   puppy
2  NaN
3  NaN
```
dtype: object

It also accepts a function:

```python
>>> s.map('I am a {}'.format)
0   I am a cat
1   I am a dog
2   I am a NaN
3   I am a rabbit
```
dtype: object

To avoid applying the function to missing values (and keep them as NaN) `na_action='ignore'` can be used:

```python
>>> s.map('I am a {}'.format, na_action='ignore')
0   I am a cat
1   I am a dog
2  NaN
3   I am a rabbit
```
dtype: object
pandas.Series.mask

Series.mask(cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False)

Replace values where the condition is True.

Parameters

cond [bool Series/DataFrame, array-like, or callable] Where cond is False, keep the original value. Where True, replace with corresponding value from other. If cond is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

other [scalar, Series/DataFrame, or callable] Entries where cond is True are replaced with corresponding value from other. If other is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.

• ‘raise’: allow exceptions to be raised.
• ‘ignore’: suppress exceptions. On error return original object.

try_cast [bool, default False] Try to cast the result back to the input type (if possible).

Returns

Same type as caller

See also:

DataFrame.where() Return an object of same shape as self.

Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if cond is False the element is used; otherwise the corresponding element from the DataFrame other is used.

The signature for DataFrame.where() differs from numpy.where(). Roughly df1.where(m, df2) is equivalent to np.where(m, df1, df2).

For further details and examples see the mask documentation in indexing.
Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1     1.0
2     2.0
3     3.0
4     4.0
dtype: float64

>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64

>>> s.where(s > 1, 10)
0    10.0
1     1.0
2     2.0
3     3.0
4     4.0
dtype: int64

>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9

>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0  -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9

>>> df.where(m, -df) == np.where(m, df, -df)
   A  B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True

>>> df.where(m, -df) == df.mask(~m, -df)
   A  B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```
**pandas.Series.max**

Series.max(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return the maximum of the values for the requested axis.

If you want the index of the maximum, use idxmax. This is the equivalent of the numpy.ndarray method argmax.

**Parameters**

- **axis** ([index (0)]) Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs** Additional keyword arguments to be passed to the function.

**Returns**

scalar or Series (if level specified)

**See also:**

- Series.sum
- Series.min
- Series.max
- Series.idxmin
- Series.idxmax

**DataFrame.sum** Return the sum over the requested axis.

**DataFrame.min** Return the minimum over the requested axis.

**DataFrame.max** Return the maximum over the requested axis.

**DataFrame.idxmin** Return the index of the minimum over the requested axis.

**DataFrame.idxmax** Return the index of the maximum over the requested axis.

**Examples**

```python
>>> idx = pd.MultiIndex.from_arrays([...
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded animal
warm dog 4
falcon 2
cold fish 0
spider 8
Name: legs, dtype: int64
```
Max using level names, as well as indices.

```
>>> s.max()
8

>>> s.max(level='blooded')
blooded
warm  4
cold  8
Name: legs, dtype: int64

>>> s.max(level=0)
blooded
warm  4
cold  8
Name: legs, dtype: int64
```

**pandas.Series.mean**

Series.mean(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return the mean of the values for the requested axis.

**Parameters**

- `axis` ([index (0)]) Axis for the function to be applied on.
- `skipna` [bool, default True] Exclude NA/null values when computing the result.
- `level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- `numeric_only` [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- `**kwargs` Additional keyword arguments to be passed to the function.

**Returns**

- scalar or Series (if level specified)

**pandas.Series.median**

Series.median(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return the median of the values for the requested axis.

**Parameters**

- `axis` ([index (0)]) Axis for the function to be applied on.
- `skipna` [bool, default True] Exclude NA/null values when computing the result.
- `level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- `numeric_only` [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
**kwargs  Additional keyword arguments to be passed to the function.

**Returns**

scalar or Series (if level specified)

pandas.Series.memory_usage

Series.memory_usage (index=True, deep=False)

Return the memory usage of the Series.

The memory usage can optionally include the contribution of the index and of elements of object dtype.

**Parameters**

index  [bool, default True] Specifies whether to include the memory usage of the Series index.

depth  [bool, default False] If True, introspect the data deeply by interrogating object dtypes for system-level memory consumption, and include it in the returned value.

**Returns**

int  Bytes of memory consumed.

**See also:**
	numpy.ndarray.nbytes  Total bytes consumed by the elements of the array.

DataFrame.memory_usage  Bytes consumed by a DataFrame.

**Examples**

```python
>>> s = pd.Series(range(3))
>>> s.memory_usage()
152

Not including the index gives the size of the rest of the data, which is necessarily smaller:

```python
>>> s.memory_usage(index=False)
24
```

The memory footprint of object values is ignored by default:

```python
>>> s = pd.Series(["a", "b"])
>>> s.values
array(["a", "b"], dtype=object)
>>> s.memory_usage()
144
>>> s.memory_usage(deep=True)
260
```
pandas.Series.min

Series.min(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return the minimum of the values for the requested axis.

If you want the *index* of the minimum, use idxmin. This is the equivalent of the numpy.ndarray method argmin.

**Parameters**

- **axis** ([index (0)]) Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Additional keyword arguments to be passed to the function.**

**Returns**

- scalar or Series (if level specified)

**See also:**

- Series.sum Return the sum.
- Series.min Return the minimum.
- Series.max Return the maximum.
- Series.idxmin Return the index of the minimum.
- Series.idxmax Return the index of the maximum.
- DataFrame.sum Return the sum over the requested axis.
- DataFrame.min Return the minimum over the requested axis.
- DataFrame.max Return the maximum over the requested axis.
- DataFrame.idxmin Return the index of the minimum over the requested axis.
- DataFrame.idxmax Return the index of the maximum over the requested axis.

**Examples**

```python
gp = pd.DataFrame(
    [4, 2, 0, 8], name='legs', index=idx)
gp
```
>>> s.min()
0

Min using level names, as well as indices.

>>> s.min(level='blooded')
blooded
<table>
<thead>
<tr>
<th>warm</th>
<th>cold</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>Name: legs, dtype: int64</td>
<td></td>
</tr>
</tbody>
</table>

>>> s.min(level=0)
blooded
<table>
<thead>
<tr>
<th>warm</th>
<th>cold</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>Name: legs, dtype: int64</td>
<td></td>
</tr>
</tbody>
</table>

pandas.Series.mod

Series.mod(other, level=None, fill_value=None, axis=0)

Return Modulo of series and other, element-wise (binary operator mod).

Equivalent to series % other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.rmod Reverse of the Modulo operator, see Python documentation for more details.

Examples

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
3.3. Series  1139
pandas: powerful Python data analysis toolkit, Release 1.1.5

(continued from previous page)

```
a  1.0
d  1.0
e  NaN
dtype: float64
```

```
a.mod(b, fill_value=0)
a  0.0
b  NaN
c  NaN
d  0.0
e  NaN
dtype: float64
```

**pandas.Series.mode**

Series .mode (dropna=True)

Return the mode(s) of the dataset.

Always returns Series even if only one value is returned.

**Parameters**

- **dropna** [bool, default True] Don’t consider counts of NaN/NaT.

  New in version 0.24.0.

**Returns**

- **Series** Modes of the Series in sorted order.

**pandas.Series.mul**

Series .mul (other, level=None, fill_value=None, axis=0)

Return Multiplication of series and other, element-wise (binary operator mul).

Equivalent to series * other, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]

- **fill_value** [None or float value, default None] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

- **level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

- **Series** The result of the operation.

**See also:**

- **Series.rmul** Reverse of the Multiplication operator, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.multiply(b, fill_value=0)
a 1.0
b 0.0
c 0.0
d 0.0
e NaN
dtype: float64
```

**pandas.Series.multiply**

`Series.multiply(other, level=None, fill_value=None, axis=0)`

Return Multiplication of series and other, element-wise (binary operator `mul`). Equivalent to `series * other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- `other` [Series or scalar value]
- `fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- `level` [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

`Series` The result of the operation.

**See also:**

- `Series.rmul` Reverse of the Multiplication operator, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0
b  1.0
c  1.0
d  NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b  NaN
d  1.0
e  NaN
dtype: float64
>>> a.multiply(b, fill_value=0)
a  1.0
b  0.0
c  0.0
d  0.0
e  NaN
dtype: float64
```

**pandas.Series.ne**

`Series.ne(other, level=None, fill_value=None, axis=0)`

Return Not equal to of series and other, element-wise (binary operator `ne`).

Equivalent to `series != other`, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- `other` [Series or scalar value]
- `fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- `level` [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

- `Series` The result of the operation.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.ne(b, fill_value=0)
```
```
a False
b True
c True
d True
e True
dtype: bool
```

pandas.Series.nlargest

Series.nlargest \((n=5, \text{keep}='\text{first}')\)
Return the largest \(n\) elements.

**Parameters**

- **n** [int, default 5] Return this many descending sorted values.
- **keep** [{‘first’, ‘last’, ‘all’}, default ‘first’] When there are duplicate values that cannot all fit in a Series of \(n\) elements:
  - **first** [return the first \(n\) occurrences in order] of appearance.
  - **last** [return the last \(n\) occurrences in reverse] order of appearance.
  - **all** [keep all occurrences. This can result in a Series of] size larger than \(n\).

**Returns**

- **Series** The \(n\) largest values in the Series, sorted in decreasing order.

See also:

- **Series.nsmallest** Get the \(n\) smallest elements.
- **Series.sort_values** Sort Series by values.
- **Series.head** Return the first \(n\) rows.
Notes

Faster than `.sort_values(ascending=False).head(n)` for small \( n \) relative to the size of the Series object.

Examples

```python
countries_population = {
    "Italy": 59000000, "France": 65000000,
    "Malta": 4340000, "Maldives": 434000,
    "Brunei": 434000, "Iceland": 337000,
    "Nauru": 11300, "Tuvalu": 11300,
    "Anguilla": 11300, "Montserrat": 5200
}

s = pd.Series(countries_population)

>>> s
Italy 59000000
France 65000000
Malta 4340000
Maldives 434000
Brunei 434000
Iceland 337000
Nauru 11300
Tuvalu 11300
Anguilla 11300
Montserrat 5200
dtype: int64

The \( n \) largest elements where \( n=5 \) by default.

```python
s.nlargest()
```  
France 65000000
Italy 59000000
Malta 4340000
Maldives 434000
Brunei 434000
dtype: int64

The \( n \) largest elements where \( n=3 \). Default `keep` value is ‘first’ so Malta will be kept.

```python
s.nlargest(3)
```  
France 65000000
Italy 59000000
Malta 4340000
dtype: int64

The \( n \) largest elements where \( n=3 \) and keeping the last duplicates. Brunei will be kept since it is the last with value 434000 based on the index order.

```python
s.nlargest(3, keep='last')
```  
France 65000000
Italy 59000000
Brunei 4340000
dtype: int64

The \( n \) largest elements where \( n=3 \) with all duplicates kept. Note that the returned Series has five elements due to the three duplicates.
>>> s.nlargest(3, keep='all')
France    65000000
Italy     59000000
Malta     4340000
Maldives  4340000
Brunei    4340000
dtype: int64

pandas.Series.notna

Series.notna()

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

Returns

Series Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:

Series.notnull Alias of notna.
Series.isna Boolean inverse of notna.
Series.dropna Omit axes labels with missing values.
notna Top-level notna.

Examples

Show which entries in a DataFrame are not NA.

>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                         pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})

>>> df
   age   born      name   toy
0  5.0    NaT  Alfred  None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN  1940-04-25     Joker

>>> df.notna()
   age   born      name   toy
0  True   False   True   False
1  True   True    True    True
2 False   True    True    True

Show which entries in a Series are not NA.
```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0  5.0
1  6.0
2  NaN
dtype: float64

>>> ser.notna()
0   True
1   True
2   False
dtype: bool
```

**pandas.Series.notnull**

*Series.notnull()*

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

**Returns**

*Series*  
Mask of bool values for each element in Series that indicates whether an element is not an NA value.

**See also:**

*Series.notnull*  
Alias of notna.

*Series.isna*  
Boolean inverse of notna.

*Series.dropna*  
Omit axes labels with missing values.

*notna*  
Top-level notna.

**Examples**

Show which entries in a DataFrame are not NA.

```python
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
                               pd.Timestamp('1940-04-25')],
                      'name': ['Alfred', 'Batman', ''],
                      'toy': [None, 'Batmobile', 'Joker']})

>>> df
   age  born       name  toy
0  5.0  NaT    Alfred   None
1  6.0 1939-05-27  Batman  Batmobile
2  NaN 1940-04-25  Joker

>>> df.notna()
   age  born       name  toy
0  True  NaN  True  False
1  True  True   True  True
2 False  True  True  False
```
Show which entries in a Series are not NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0   5.0
1   6.0
2   NaN
dtype: float64
```

```python
>>> ser.notna()
0   True
1   True
2   False
dtype: bool
```

**pandas.Series.nsmallest**

Series.\texttt{nsmallest}\texttt{(n=5, keep='first')}  
Return the smallest \(n\) elements.

**Parameters**

- **n** [int, default 5] Return this many ascending sorted values.
- **keep** [‘first’, ‘last’, ‘all’], default ‘first’ When there are duplicate values that cannot all fit in a Series of \(n\) elements:
  - **first** [return the first \(n\) occurrences in order] of appearance.
  - **last** [return the last \(n\) occurrences in reverse] order of appearance.
  - **all** [keep all occurrences. This can result in a Series of] size larger than \(n\).

**Returns**

- **Series** The \(n\) smallest values in the Series, sorted in increasing order.

**See also:**

- **Series.nlargest** Get the \(n\) largest elements.
- **Series.sort_values** Sort Series by values.
- **Series.head** Return the first \(n\) rows.
Notes

Faster than `.sort_values().head(n)` for small $n$ relative to the size of the Series object.

Examples

```python
>>> countries_population = {
    "Italy": 59000000,  "France": 65000000,
    "Brunei": 4340000,   "Malta": 4340000,
    "Maldives": 434000,  "Iceland": 337000,
    "Nauru": 11300,      "Tuvalu": 11300,
    "Anguilla": 11300,   "Montserrat": 5200
}
>>> s = pd.Series(countries_population)
```

```python
>>> s
Italy     59000000
France    65000000
Brunei    4340000
Malta     4340000
Maldives  4340000
Iceland   337000
Nauru     11300
Tuvalu    11300
Anguilla  11300
Montserrat 5200
dtype: int64
```

The $n$ smallest elements where $n=5$ by default.

```python
>>> s.nsmallest()
Montserrat   5200
Nauru        11300
Tuvalu       11300
Anguilla     11300
Iceland      337000
dtype: int64
```

The $n$ smallest elements where $n=3$. Default `keep` value is ‘first’ so Nauru and Tuvalu will be kept.

```python
>>> s.nsmallest(3)
Montserrat   5200
Nauru        11300
Tuvalu       11300
dtype: int64
```

The $n$ smallest elements where $n=3$ and keeping the last duplicates. Anguilla and Tuvalu will be kept since they are the last with value 11300 based on the index order.

```python
>>> s.nsmallest(3, keep='last')
Montserrat   5200
Anguilla     11300
Tuvalu       11300
dtype: int64
```

The $n$ smallest elements where $n=3$ with all duplicates kept. Note that the returned Series has four elements due to the three duplicates.
```python
>>> s.nsmallest(3, keep='all')
Montserrat  5200
Nauru       11300
Tuvalu     11300
Anguilla   11300
dtype: int64
```

### pandas.Series.nunique

**Series.nunique** *(dropna=True)*

- Return number of unique elements in the object.
- Excludes NA values by default.

**Parameters**

- `dropna` [bool, default True] Don’t include NaN in the count.

**Returns**

- `int`

**See also:**

- `DataFrame.nunique` Method nunique for DataFrame.
- `Series.count` Count non-NA/null observations in the Series.

**Examples**

```python
>>> s = pd.Series([1, 3, 5, 7, 7])
>>> s
0  1
1  3
2  5
3  7
4  7
dtype: int64

>>> s.nunique()
4
```

### pandas.Series.pad

**Series.pad** *(axis=None, inplace=False, limit=None, downcast=None)*

- Synonym for DataFrame.fillna() with method='ffill'.

**Returns**

- `{klass} or None` Object with missing values filled or None if inplace=True.
**pandas.Series.pct_change**

*pandas.Series.pct_change*(*periods=1, fill_method='pad', limit=None, freq=None, **kwargs*)

Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

**Parameters**

- **periods** [int, default 1] Periods to shift for forming percent change.
- **fill_method** [str, default 'pad'] How to handle NAs before computing percent changes.
- **limit** [int, default None] The number of consecutive NAs to fill before stopping.
- **freq** [DateOffset, timedelta, or str, optional] Increment to use from time series API (e.g. ‘M’ or BDay()).
- **kwargs** Additional keyword arguments are passed into *DataFrame.shift* or *Series.shift*.

**Returns**

- **chg** [Series or DataFrame] The same type as the calling object.

See also:

- *Series.diff* Compute the difference of two elements in a Series.
- *DataFrame.diff* Compute the difference of two elements in a DataFrame.
- *Series.shift* Shift the index by some number of periods.
- *DataFrame.shift* Shift the index by some number of periods.

**Examples**

**Series**

```python
>>> s = pd.Series([90, 91, 85])
>>> s
0  90
1  91
2  85
dtype: int64
```

```python
>>> s.pct_change()
0    NaN
1  0.011111
2 -0.065934
dtype: float64
```

```python
>>> s.pct_change(periods=2)
0    NaN
1    NaN
2 -0.055556
dtype: float64
```

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.
```python
>>> s = pd.Series([90, 91, None, 85])
>>> s
0   90.0
1   91.0
2   NaN
3   85.0
dtype: float64

>>> s.pct_change(fill_method='ffill')
0     NaN
1  0.011111
2  0.000000
3 -0.065934
dtype: float64
```

**DataFrame**

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```python
>>> df = pd.DataFrame({
...     'FR': [4.0405, 4.0963, 4.3149],
...     'GR': [1.7246, 1.7482, 1.8519],
...     'IT': [804.74, 810.01, 860.13],
...     'index': ['1980-01-01', '1980-02-01', '1980-03-01']}
>>> df
   FR    GR    IT
1980-01-01 4.0405 1.7246 804.74
1980-02-01 4.0963 1.7482 810.01
1980-03-01 4.3149 1.8519 860.13

>>> df.pct_change()
   FR    GR    IT
1980-01-01 NaN  NaN  NaN
1980-02-01 0.013810 0.013684 0.006549
1980-03-01 0.053365 0.059318 0.061876
```

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

```python
>>> df = pd.DataFrame({
...     '2016': [1769950, 30586265],
...     '2015': [1500923, 40912316],
...     '2014': [1371819, 41403351],
...     'index': ['GOOG', 'APPL']}
>>> df
   2016  2015  2014
GOOG  1769950 1500923 1371819
APPL  30586265 40912316 41403351

>>> df.pct_change(axis='columns')
   2016  2015  2014
GOOG  NaN -0.151997 -0.086016
APPL  NaN  0.337604  0.012002
```

3.3. Series
**pandas.Series.pipe**

Series.pipe(func, *args, **kwargs)
Apply func(self, *args, **kwargs).

**Parameters**

- **func** [function] Function to apply to the Series/DataFrame. args, and kwargs are passed into func. Alternatively a (callable, data_keyword) tuple where data_keyword is a string indicating the keyword of callable that expects the Series/DataFrame.
- **args** [iterable, optional] Positional arguments passed into func.
- **kwargs** [mapping, optional] A dictionary of keyword arguments passed into func.

**Returns**

- **object** [the return type of func.]

**See also:**

- **DataFrame.apply** Apply a function along input axis of DataFrame.
- **DataFrame.applymap** Apply a function elementwise on a whole DataFrame.
- **Series.map** Apply a mapping correspondence on a Series.

**Notes**

Use .pipe when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```
>>> func(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```
>>> (df.pipe(h)
...  .pipe(g, arg1=a)
...  .pipe(func, arg2=b, arg3=c)
...)
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose f takes its data as arg2:

```
>>> (df.pipe(h)
...  .pipe(g, arg1=a)
...  .pipe((func, 'arg2'), arg1=a, arg3=c)
...)
```
pandas.Series.plot

Series.plot(*args, **kwargs)
Make plots of Series or DataFrame.

Uses the backend specified by the option plotting.backend. By default, matplotlib is used.

Parameters

data [Series or DataFrame] The object for which the method is called.
x [label or position, default None] Only used if data is a DataFrame.
y [label, position or list of label, positions, default None] Allows plotting of one column versus another. Only used if data is a DataFrame.

kind [str] The kind of plot to produce:
- ‘line’: line plot (default)
- ‘bar’: vertical bar plot
- ‘barh’: horizontal bar plot
- ‘hist’: histogram
- ‘box’: boxplot
- ‘kde’: Kernel Density Estimation plot
- ‘density’: same as ‘kde’
- ‘area’: area plot
- ‘pie’: pie plot
- ‘scatter’: scatter plot
- ‘hexbin’: hexbin plot.

ax [matplotlib axes object, default None] An axes of the current figure.
subplots [bool, default False] Make separate subplots for each column.
sharex [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in; Be aware, that passing in both an ax and sharex=True will alter all x axis labels for all axis in a figure.
sharey [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.
layout [tuple, optional] (rows, columns) for the layout of subplots.
figsize [a tuple (width, height) in inches] Size of a figure object.
use_index [bool, default True] Use index as ticks for x axis.
title [str or list] Title to use for the plot. If a string is passed, print the string at the top of the figure. If a list is passed and subplots is True, print each item in the list above the corresponding subplot.
grid [bool, default None (matlab style default)] Axis grid lines.
legend [bool or {‘reverse’}] Place legend on axis subplots.
style [list or dict] The matplotlib line style per column.
logx [bool or ‘sym’, default False] Use log scaling or symlog scaling on x axis. .. versionchanged:: 0.25.0
logy [bool or ‘sym’ default False] Use log scaling or symlog scaling on y axis. .. versionchanged:: 0.25.0
loglog [bool or ‘sym’, default False] Use log scaling or symlog scaling on both x and y axes. .. versionchanged:: 0.25.0
xticks [sequence] Values to use for the xticks.
yticks [sequence] Values to use for the yticks.
xlim [2-tuple/list] Set the x limits of the current axes.
ylim [2-tuple/list] Set the y limits of the current axes.
xlabel [label, optional] Name to use for the xlabel on x-axis. Default uses index name as xlabel.
       New in version 1.1.0.
ylabel [label, optional] Name to use for the ylabel on y-axis. Default will show no ylabel.
       New in version 1.1.0.
rot [int, default None] Rotation for ticks (xticks for vertical, yticks for horizontal plots).
fontsize [int, default None] Font size for xticks and yticks.
colormap [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.
colorbar [bool, optional] If True, plot colorbar (only relevant for ‘scatter’ and ‘hexbin’ plots).
position [float] Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center).
table [bool, Series or DataFrame, default False] If True, draw a table using the data in the DataFrame and the data will be transposed to meet matplotlib’s default layout. If a Series or DataFrame is passed, use passed data to draw a table.
yerr [DataFrame, Series, array-like, dict and str] See Plotting with Error Bars for detail.
xerr [DataFrame, Series, array-like, dict and str] Equivalent to yerr.
stacked [bool, default False in line and bar plots, and True in area plot] If True, create stacked plot.
sort_columns [bool, default False] Sort column names to determine plot ordering.
secondary_y [bool or sequence, default False] Whether to plot on the secondary y-axis if a list/tuple, which columns to plot on secondary y-axis.
mark_right [bool, default True] When using a secondary_y axis, automatically mark the column labels with “(right)” in the legend.
include_bool [bool, default is False] If True, boolean values can be plotted.
backend [str, default None] Backend to use instead of the backend specified in the option plotting.backend. For instance, ‘matplotlib’. Alternatively, to specify the plotting.backend for the whole session, set pd.options.plotting.backend.
       New in version 1.0.0.
**kwargs Options to pass to matplotlib plotting method.

Returns

matplotlib.axes.Axes or numpy.ndarray of them If the backend is not the default matplotlib one, the return value will be the object returned by the backend.

Notes

- See matplotlib documentation online for more on this subject
- If kind = ‘bar’ or ‘barh’, you can specify relative alignments for bar plot layout by position keyword. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

**pandas.Series.pop**

Series.pop(item)

Return item and drops from series. Raise KeyError if not found.

Parameters

item [label] Index of the element that needs to be removed.

Returns

Value that is popped from series.

Examples

```python
>>> ser = pd.Series([1, 2, 3])
```

```python
>>> ser.pop(0)
1
```

```python
>>> ser
1  2
2  3
```

```
dtype: int64
```

**pandas.Series.pow**

Series.pow(other, level=None, fill_value=None, axis=0)

Return Exponential power of series and other, element-wise (binary operator pow).

Equivalent to series ** other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
level [int or name] Broadcast across a level, matching Index values on the passed Multi-
Index level.

Returns

Series The result of the operation.

See also:

Series.rpow Reverse of the Exponential power operator, see Python documentation for more details.

Examples

```python
g >>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
g >>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
g >>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
g >>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
g >>> a.pow(b, fill_value=0)
a 1.0
b 1.0
c 1.0
d 0.0
e NaN
dtype: float64
```

pandas.Series.prod

Series.prod(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)
Return the product of the values for the requested axis.

Parameters

- **axis** [[index (0)]] Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count
  along a particular level, collapsing into a scalar.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None,
  will attempt to use everything, then use only numeric data. Not implemented for
  Series.
- **min_count** [int, default 0] The required number of valid values to perform the operation.
  If fewer than min_count non-NA values are present the result will be NA.
New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**kwargs Additional keyword arguments to be passed to the function.

**Examples**

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```python
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0
```

```python
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

**pandas.Series.product**

`Series.product`(*axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs*)

Return the product of the values for the requested axis.

**Parameters**

- `axis` [{index (0)}] Axis for the function to be applied on.
- `skipna` [bool, default True] Exclude NA/null values when computing the result.
- `level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- `numeric_only` [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- `min_count` [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**kwargs Additional keyword arguments to be passed to the function.

**Returns**

scalar or Series (if level specified)
Examples

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```python
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

**pandas.Series.quantile**

`Series.quantile` (*q=0.5, interpolation='linear')

Return value at the given quantile.

**Parameters**

- `q` [float or array-like, default 0.5 (50% quantile)] The quantile(s) to compute, which can lie in range: 0 <= q <= 1.
- `interpolation` ['linear', 'lower', 'higher', 'midpoint', 'nearest'] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points `i` and `j`:
  - linear: `i + (j - i) * fraction`, where `fraction` is the fractional part of the index surrounded by `i` and `j`.
  - lower: `i`.
  - higher: `j`.
  - nearest: `i` or `j` whichever is nearest.
  - midpoint: `(i + j) / 2`.

**Returns**

- float or Series If `q` is an array, a Series will be returned where the index is `q` and the values are the quantiles, otherwise a float will be returned.

**See also:**

- `core.window.Rolling.quantile` Calculate the rolling quantile.
- `numpy.percentile` Returns the q-th percentile(s) of the array elements.
Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.quantile(.5)
2.5
>>> s.quantile([.25, .5, .75])
0.25  1.75
0.50  2.50
0.75  3.25
dtype: float64
```

pandas.Series.radd

Series.radd(other, level=None, fill_value=None, axis=0)

Return Addition of series and other, element-wise (binary operator radd).

Equivalent to other + series, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.add Element-wise Addition, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0
b  1.0
c  1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b NaN
c  1.0
e NaN
dtype: float64
>>> a.add(b, fill_value=0)
```

(continues on next page)
pandas.Series.rank

Series.rank (axis=0, method='average', numeric_only=None, na_option='keep', ascending=True, pct=False)

Compute numerical data ranks (1 through n) along axis.

By default, equal values are assigned a rank that is the average of the ranks of those values.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] Index to direct ranking.

method [{‘average’, ‘min’, ‘max’, ‘first’, ‘dense’}, default ‘average’] How to rank the group of records that have the same value (i.e. ties):
  • average: average rank of the group
  • min: lowest rank in the group
  • max: highest rank in the group
  • first: ranks assigned in order they appear in the array
  • dense: like ‘min’, but rank always increases by 1 between groups.

numeric_only [bool, optional] For DataFrame objects, rank only numeric columns if set to True.

na_option [{‘keep’, ‘top’, ‘bottom’}, default ‘keep’] How to rank NaN values:
  • keep: assign NaN rank to NaN values
  • top: assign smallest rank to NaN values if ascending
  • bottom: assign highest rank to NaN values if ascending.

ascending [bool, default True] Whether or not the elements should be ranked in ascending order.

pct [bool, default False] Whether or not to display the returned rankings in percentile form.

Returns

same type as caller Return a Series or DataFrame with data ranks as values.

See also:

core.groupby.GroupBy.rank Rank of values within each group.
Examples

```python
>>> df = pd.DataFrame(data={'Animal': ['cat', 'penguin', 'dog',
... 'spider', 'snake'],
... 'Number_legs': [4, 2, 4, 8, np.nan]})
>>> df
   Animal  Number_legs
0       cat          4.0
1  penguin         2.0
2       dog          4.0
3     spider         8.0
4      snake         NaN
```

The following example shows how the method behaves with the above parameters:

- **default_rank**: this is the default behaviour obtained without using any parameter.
- **max_rank**: setting `method = 'max'` the records that have the same values are ranked using the highest rank (e.g.: since ‘cat’ and ‘dog’ are both in the 2nd and 3rd position, rank 3 is assigned.)
- **NA_bottom**: choosing `na_option = 'bottom'`, if there are records with NaN values they are placed at the bottom of the ranking.
- **pct_rank**: when setting `pct = True`, the ranking is expressed as percentile rank.

```python
>>> df['default_rank'] = df['Number_legs'].rank()
>>> df['max_rank'] = df['Number_legs'].rank(method='max')
>>> df['NA_bottom'] = df['Number_legs'].rank(na_option='bottom')
>>> df['pct_rank'] = df['Number_legs'].rank(pct=True)
>>> df
   Animal  Number_legs  default_rank  max_rank  NA_bottom  pct_rank
0       cat          4.0           2.5       3.0        2.5   0.625
1  penguin         2.0           1.0       1.0        1.0   0.250
2       dog          4.0           2.5       3.0        2.5   0.625
3     spider         8.0           4.0       4.0        4.0   1.000
4      snake         NaN           NaN       NaN        NaN  NaN
```

**pandas.Series.ravel**

```python
Series.ravel(order='C')
```

Return the flattened underlying data as an ndarray.

**Returns**

- **numpy.ndarray or ndarray-like**: Flattened data of the Series.

**See also:**

- `numpy.ndarray.ravel`: Return a flattened array.
pandas.Series.rdiv

Series.rdiv(other, level=None, fill_value=None, axis=0)

Return Floating division of series and other, element-wise (binary operator \texttt{rtruediv}).

Equivalent to \texttt{other / series}, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

Series The result of the operation.

**See also:**

\texttt{Series.truediv} Element-wise Floating division, see Python documentation for more details.

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.divide(b, fill_value=0)
da 1.0
b inf
c inf
d 0.0
e NaN
dtype: float64
```
**pandas.Series.rdivmod**

Series.rdivmod(other, level=None, fill_value=None, axis=0)

Return integer division and modulo of series and other, element-wise (binary operator rdivmod).

Equivalent to other divmod series, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

2-Tuple of Series The result of the operation.

**See also:**

Series.divmod Element-wise integer division and modulo, see Python documentation for more details.

**pandas.Series.reindex**

Series.reindex(index=None, **kwargs)

Conform Series to new index with optional filling logic.

Places NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

**Parameters**

- **index** [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data.
- **method** [{None, ‘backfill’/’bfill’, ‘pad’/’ffill’, ‘nearest’}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.
  - None (default): don’t fill gaps
  - pad / ffill: Propagate last valid observation forward to next valid.
  - backfill / bfill: Use next valid observation to fill gap.
  - nearest: Use nearest valid observations to fill gap.
- **copy** [bool, default True] Return a new object, even if the passed indexes are the same.
- **level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.
- **fill_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.
limit [int, default None] Maximum number of consecutive elements to forward or backward fill.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation \( \text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance} \).

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

Returns

Series with changed index.

See also:

Dataframe.set_index Set row labels.
Dataframe.reset_index Remove row labels or move them to new columns.
Dataframe.reindex_like Change to same indices as other Dataframe.

Examples

DataFrame.reindex supports two calling conventions

- (index=index_labels, columns=column_labels, ...)
- (labels, axis={'index', 'columns'}, ...)

We highly recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({'http_status': [200, 200, 404, 404, 301],
...                     'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]},
...                    index=index)
>>> df
          http_status response_time
Firefox     200.00        0.040
Chrome      200.00        0.020
Safari      404.00        0.070
IE10        404.00        0.080
Konqueror   301.00        1.000
```

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```
>>> new_index = ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10',
...               'Chrome']
>>> df.reindex(new_index)
          http_status response_time
Safari    404.00        0.070
Iceweasel NaN           NaN
Comodo Dragon NaN         NaN
IE10      404.00        0.080
Chrome    200.00        0.020
```
We can fill in the missing values by passing a value to the keyword `fill_value`. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword `method` to fill the NaN values.

```python
>>> df.reindex(new_index, fill_value=0)
   http_status  response_time
Safari       404       0.07
Iceweasel    0         0.00
Comodo Dragon 0         0.00
IE10         404       0.08
Chrome       200       0.02
```

```python
>>> df.reindex(new_index, fill_value='missing')
   http_status  response_time
Safari       404       0.07
Iceweasel    missing  missing
Comodo Dragon missing  missing
IE10         404       0.08
Chrome       200       0.02
```

We can also reindex the columns.

```python
>>> df.reindex(columns=['http_status', 'user_agent'])
   http_status  user_agent
Firefox       200   NaN
Chrome        200   NaN
Safari        404   NaN
IE10          404   NaN
Konqueror     301   NaN
```

Or we can use “axis-style” keyword arguments

```python
>>> df.reindex(['http_status', 'user_agent'], axis="columns")
   http_status  user_agent
Firefox       200   NaN
Chrome        200   NaN
Safari        404   NaN
IE10          404   NaN
Konqueror     301   NaN
```

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

```python
>>> date_index = pd.date_range('1/1/2010', periods=6, freq='D')
>>> df2 = pd.DataFrame({"prices": [100, 101, np.nan, 100, 89, 88]},
...                     index=date_index)
>>> df2
    prices
2010-01-01  100.0
2010-01-02  101.0
2010-01-03   NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
```

Suppose we decide to expand the dataframe to cover a wider date range.
```python
>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')
>>> df2.reindex(date_index2)
   prices
2009-12-29   NaN
2009-12-30   NaN
2009-12-31   NaN
2010-01-01  100.0
2010-01-02  101.0
2010-01-03   NaN
2010-01-04  100.0
2010-01-05  89.0
2010-01-06  88.0
2010-01-07   NaN
```

The index entries that did not have a value in the original data frame (for example, ‘2009-12-29’) are by default filled with NaN. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the NaN values, pass bfill as an argument to the method keyword.

```python
>>> df2.reindex(date_index2, method='bfill')
   prices
2009-12-29  100.0
2009-12-30  100.0
2009-12-31  100.0
2010-01-01  100.0
2010-01-02  101.0
2010-01-03   NaN
2010-01-04  100.0
2010-01-05  89.0
2010-01-06  88.0
2010-01-07   NaN
```

Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the fillna() method.

See the user guide for more.

**pandas.Series.reindex_like**

`Series.reindex_like(other, method=None, copy=True, limit=None, tolerance=None)`

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

**Parameters**

- **other** [Object of the same data type] Its row and column indices are used to define the new indices of this object.
- **method** [[None, ‘backfill’/’bfill’, ‘pad’/’ffill’, ‘nearest’]] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.
• None (default): don’t fill gaps
• pad / ffill: propagate last valid observation forward to next valid
• backfill / bfill: use next valid observation to fill gap
• nearest: use nearest valid observations to fill gap.

**copy** [bool, default True] Return a new object, even if the passed indexes are the same.

**limit** [int, default None] Maximum number of consecutive labels to fill for inexact matches.

**tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation

\[
\text{abs(index[indexer] - target)} \leq \text{tolerance}
\]

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

**Returns**

* Series or DataFrame* Same type as caller, but with changed indices on each axis.

**See also:**

*DataFrame.set_index* Set row labels.
*DataFrame.reset_index* Remove row labels or move them to new columns.
*DataFrame.reindex* Change to new indices or expand indices.

**Notes**

Same as calling .reindex(index=other.index, columns=other.columns,...).

**Examples**

```python
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
... [31, 87.8, 'high'],
... [22, 71.6, 'medium'],
... [35, 95, 'medium']],
... columns=['temp_celsius', 'temp_fahrenheit',
... 'windspeed'],
... index=pd.date_range(start='2014-02-12',
... end='2014-02-15', freq='D'))
```

```python
>>> df1
   temp_celsius  temp_fahrenheit  windspeed
2014-02-12     24.3             75.7    high
2014-02-13     31.0             87.8    high
2014-02-14     22.0             71.6  medium
2014-02-15     35.0             95.0  medium
```
```python
>>> df2 = pd.DataFrame([[28, 'low'],
...                     [30, 'low'],
...                     [35.1, 'medium']],
...                     columns=['temp_celsius', 'windspeed'],
...                     index=pd.DatetimeIndex(['2014-02-12', '2014-02-13',
...                     '2014-02-15']))
```

```
>>> df2
```

```
  temp_celsius windspeed
2014-02-12  28.0      low
2014-02-13  30.0      low
2014-02-15  35.1    medium
```

```python
>>> df2.reindex_like(df1)
```

```
  temp_celsius  temp_fahrenheit windspeed
2014-02-12  28.0        NaN      low
2014-02-13  30.0        NaN      low
2014-02-14   NaN        NaN     NaN
2014-02-15  35.1        NaN    medium
```

### pandas.Series.rename

**Series.rename**

```
Series.rename(index=None, *, axis=None, copy=True, inplace=False, level=None, errors='ignore')
```

Alter Series index labels or name.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don’t throw an error.

Alternatively, change `Series.name` with a scalar value.

See the user guide for more.

**Parameters**

- **axis** [{0 or “index”}] Unused. Accepted for compatibility with DataFrame method only.
- **index** [scalar, hashable sequence, dict-like or function, optional] Functions or dict-like are transformations to apply to the index. Scalar or hashable sequence-like will alter the `Series.name` attribute.
- ****kwargs Additional keyword arguments passed to the function. Only the “inplace” keyword is used.

**Returns**

- **Series** Series with index labels or name altered.

**See also:**

- **DataFrame.rename** Corresponding DataFrame method.
- **Series.rename_axis** Set the name of the axis.
Examples

```python
girl = pd.Series([1, 2, 3])
girl
0    1  
1    2  
2    3  
dtype: int64
girl.rename("my_name")  # scalar, changes Series.name
0    1  
1    2  
2    3  
Name: my_name, dtype: int64
girl.rename(lambda x: x ** 2)  # function, changes labels
0    1  
1    2  
4    3  
dtype: int64
girl.rename({1: 3, 2: 5})  # mapping, changes labels
0    1  
3    2  
5    3  
dtype: int64
```

**pandas.Series.rename_axis**

`Series.rename_axis(mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False)`

Set the name of the axis for the index or columns.

**Parameters**

- `mapper` [scalar, list-like, optional] Value to set the axis name attribute.
- `index, columns` [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis’ values. Note that the column parameter is not allowed if the object is a Series. This parameter only apply for DataFrame type objects.

Use either `mapper` and `axis` to specify the axis to target with `mapper`, or `index` and/or `columns`.

Changed in version 0.24.0.

- `axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to rename.
- `copy` [bool, default True] Also copy underlying data.
- `inplace` [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

**Returns**

- `Series, DataFrame, or None` The same type as the caller or None if inplace is True.

**See also:**

- `Series.rename` Alter Series index labels or name.
- `DataFrame.rename` Alter DataFrame index labels or name.
**Index.rename** Set new names on index.

### Notes

**DataFrame.rename_axis** supports two calling conventions

- `(index=index_mapper, columns=columns_mapper, ...)`
- `(mapper, axis={'index', 'columns'}, ...)`

The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter `copy` is ignored.

The second calling convention will modify the names of the the corresponding index if mapper is a list or a scalar. However, if mapper is dict-like or a function, it will use the deprecated behavior of modifying the axis `labels`.

We **highly** recommend using keyword arguments to clarify your intent.

### Examples

**Series**

```python
>>> s = pd.Series(['dog', 'cat', 'monkey'])
>>> s
0    dog
1     cat
2   monkey
dtype: object
>>> s.rename_axis('animal')
animal
0   dog
1  cat
2 monkey
dtype: object
```

**DataFrame**

```python
>>> df = pd.DataFrame({'num_legs': [4, 4, 2],
...                     'num_arms': [0, 0, 2]})
...                     ['dog', 'cat', 'monkey'])
>>> df
   num_legs  num_arms
dog    4      0
cat    4      0
monkey 2      2
>>> df = df.rename_axis('animal')
>>> df
   num_legs  num_arms
animal
   dog    4      0
   cat    4      0
   monkey 2      2
>>> df = df.rename_axis('limbs', axis='columns')
>>> df
   limbs   num_legs  num_arms
animal
   dog    4      0
   cat    4      0
   monkey 2      2
```

(continues on next page)
MultiIndex

```python
>>> df.index = pd.MultiIndex.from_product([[mammal],
... [dog, cat, monkey]],
... names=['type', 'name'])

>>> df
limbs   num_legs   num_arms  
type   name       
mammal dog  4        0        
         cat  4        0        
         monkey 2        2

>>> df.rename_axis(index={'type': 'class'})
limbs   num_legs   num_arms  
class   name       
mammal dog  4        0        
          cat  4        0        
          monkey 2        2

>>> df.rename_axis(columns=str.upper)
LIMBS   num_legs   num_arms  
type   name       
mammal dog  4        0        
          cat  4        0        
          monkey 2        2
```

**pandas.Series.reorder_levels**

Series.reorder_levels(order)

Rearrange index levels using input order.

May not drop or duplicate levels.

Parameters

- **order** [list of int representing new level order] Reference level by number or key.

Returns

- type of caller (new object)
pandas.Series.repeat

Series.repeat(repeats, axis=None)

Repeat elements of a Series.

Returns a new Series where each element of the current Series is repeated consecutively a given number of times.

Parameters

- repeats [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Series.
- axis [None] Must be None. Has no effect but is accepted for compatibility with numpy.

Returns

Series Newly created Series with repeated elements.

See also:

Index.repeat Equivalent function for Index.
numpy.repeat Similar method for numpy.ndarray.

Examples

```python
g = pd.Series(['a', 'b', 'c'])
g
0 a
1 b
2 c
dtype: object
g.repeat(2)
0 a
0 a
1 b
1 b
2 c
2 c
dtype: object
g.repeat([1, 2, 3])
0 a
1 b
1 b
2 c
2 c
2 c
dtype: object```
pandas.Series.replace

`Series.replace(to_replace=None, value=None, inplace=False, limit=None, regex=False, method='pad')`

Replace values given in `to_replace` with `value`.

Values of the Series are replaced with other values dynamically. This differs from updating with `.loc` or `.iloc`, which require you to specify a location to update with some value.

**Parameters**

- **to_replace** [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.
  - numeric, str or regex:
    - numeric: numeric values equal to `to_replace` will be replaced with `value`
    - str: string exactly matching `to_replace` will be replaced with `value`
    - regex: regexs matching `to_replace` will be replaced with `value`
  - list of str, regex, or numeric:
    - First, if `to_replace` and `value` are both lists, they **must** be the same length.
    - Second, if `regex=True` then all of the strings in both lists will be interpreted as regexs otherwise they will match directly. This doesn’t matter much for `value` since there are only a few possible substitution regexes you can use.
    - str, regex and numeric rules apply as above.
  - dict:
    - Dicts can be used to specify different replacement values for different existing values. For example, `{'a': 'b', 'y': 'z'}` replaces the value ‘a’ with ‘b’ and ‘y’ with ‘z’. To use a dict in this way the `value` parameter should be `None`.
    - For a DataFrame a dict can specify that different values should be replaced in different columns. For example, `{'a': 1, 'b': 'z'}` looks for the value 1 in column ‘a’ and the value ‘z’ in column ‘b’ and replaces these values with whatever is specified in `value`. The `value` parameter should not be `None` in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.
    - For a DataFrame nested dictionaries, e.g., `{'a': {'b': np.nan}}`, are read as follows: look in column ‘a’ for the value ‘b’ and replace it with NaN. The `value` parameter should be `None` to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) **cannot** be regular expressions.
  - None:
    - This means that the `regex` argument must be a string, compiled regular expression, or list, dict, ndarray or Series of such elements. If `value` is also `None` then this **must** be a nested dictionary or Series.

See the examples section for examples of each of these.

- **value** [scalar, dict, list, str, regex, default None] Value to replace any values matching `to_replace` with. For a DataFrame a dict of values can be used to specify which
value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

* inplace [bool, default False] If True, in place. Note: this will modify any other views on this object (e.g. a column from a DataFrame). Returns the caller if this is True.

* limit [int, default None] Maximum size gap to forward or backward fill.

* regex [bool or same types as `to_replace`, default False] Whether to interpret `to_replace` and/or `value` as regular expressions. If this is True then `to_replace` must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case `to_replace` must be None.

* method [null, ‘pad’, ‘ffill’, ‘bfill’, None] The method to use when for replacement, when `to_replace` is a scalar, list or tuple and `value` is None.

    Changed in version 0.23.0: Added to DataFrame.

Returns

* Series Object after replacement.

Raises

* `AssertionError`

    • If `regex` is not a bool and `to_replace` is not None.

* `TypeError`

    • If `to_replace` is not a scalar, array-like, dict, or None

    • If `to_replace` is a dict and `value` is not a list, dict, ndarray, or Series

    • If `to_replace` is None and `regex` is not compilable into a regular expression or is a list, dict, ndarray, or Series.

    • When replacing multiple bool or datetime64 objects and the arguments to `to_replace` does not match the type of the value being replaced

* `ValueError`

    • If a list or an ndarray is passed to `to_replace` and `value` but they are not the same length.

See also:

* `Series.fillna` Fill NA values.

* `Series.where` Replace values based on boolean condition.

* `Series.str.replace` Simple string replacement.

Notes

• Regex substitution is performed under the hood with `re.sub`. The rules for substitution for `re.sub` are the same.

• Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers are strings, then you can do this.
• This method has a lot of options. You are encouraged to experiment and play with this method to gain intuition about how it works.

• When dict is used as the to_replace value, it is like key(s) in the dict are the to_replace part and value(s) in the dict are the value parameter.

Examples

Scalar `to_replace` and `value`

```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0    5
1    1
2    2
3    3
4    4
dtype: int64

>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
                      'B': [5, 6, 7, 8, 9],
                      'C': ['a', 'b', 'c', 'd', 'e']})
>>> df.replace(0, 5)
   A  B   C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e

List-like `to_replace`

```python
>>> df.replace([0, 1, 2, 3], 4)
   A  B   C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e

>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B   C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e
```

```python
>>> s.replace([1, 2], method='bfill')
0    0
1    3
2    3
3    3
4    4
dtype: int64
```

dict-like `to_replace`
pandas: powerful Python data analysis toolkit, Release 1.1.5

>>> df.replace({0: 10, 1: 100})
   A  B  C
0  10  5  a
1  100  6  b
2   2  7  c
3   3  8  d
4   4  9  e

>>> df.replace({'A': 0, 'B': 5}, 100)
   A  B  C
0  100  100  a
1    1    6  b
2    2    7  c
3    3    8  d
4    4    9  e

>>> df.replace({'A': {0: 100, 4: 400}})
   A  B  C
0  100  5  a
1    1    6  b
2    2    7  c
3    3    8  d
4  400    9  e

Regular expression `to_replace`

>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
...                    'B': ['abc', 'bar', 'xyz']})

>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
   A  B
0 new abc
1 foo new
2 bait xyz

>>> df.replace({'A': r'^ba.\$'}, {'A': 'new'}, regex=True)
   A  B
0 new abc
1 xyz new
2 bait xyz

>>> df.replace(regex=r'^ba.\$', value='new')
   A  B
0 new abc
1 foo new
2 bait xyz

>>> df.replace(regex={r'^ba.\$': 'new', 'foo': 'xyz'})
   A  B
0 new abc
1 xyz new
2 bait xyz

>>> df.replace(regex=[r'^ba.\$', 'foo'], value='new')
   A  B
0 new abc

(continues on next page)
Note that when replacing multiple bool or datetime64 objects, the data types in the to_replace parameter must match the data type of the value being replaced:

```python
>>> df = pd.DataFrame({'A': [True, False, True],
                    ... 'B': [False, True, False]})
>>> df.replace({'a string': 'new value', True: False})  # raises
Traceback (most recent call last):
... TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'
```

This raises a TypeError because one of the dict keys is not of the correct type for replacement.

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the to_replace parameter:

```python
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
When one uses a dict as the to_replace value, it is like the value(s) in the dict are equal to the value parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None):

```python
>>> s.replace({'a': None})
0  10
1  None
2  None
3  b
4  None
dtype: object
```

When `value=None` and `to_replace` is a scalar, list or tuple, `replace` uses the method parameter (default ‘pad’) to do the replacement. So this is why the ‘a’ values are being replaced by 10 in rows 1 and 2 and ‘b’ in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad'):

```python
>>> s.replace('a', None)
0  10
1  10
2  10
3  b
4  b
dtype: object
```

### pandas.Series.resample

**pandas.Series.resample**

Parameters

Series `resample` (rule, axis=0, closed=None, label=None, convention='start', kind=None, offset=None, base=None, on=None, level=None, origin='start_day', offset=None)

Resample time-series data.

Convenience method for frequency conversion and resampling of time series. Object must have a datetime-like index (DatetimeIndex, PeriodIndex, or TimedeltaIndex), or pass datetime-like values to the on or level keyword.
rule [DateOffset, Timedelta or str] The offset string or object representing target conversion.

axis {[0 or ‘index’, 1 or ‘columns’], default 0] Which axis to use for up- or down-sampling. For Series this will default to 0, i.e. along the rows. Must be DatetimeIndex, TimedeltaIndex or PeriodIndex.

convention {[‘start’, ‘end’, ‘s’, ‘e’], default ‘start’] For PeriodIndex only, controls whether to use the start or end of rule.

kind {[‘timestamp’, ‘period’], optional, default None] Pass ‘timestamp’ to convert the resulting index to a DateTimeIndex or ‘period’ to convert it to a PeriodIndex. By default the input representation is retained.

loffset [timedelta, default None] Adjust the resampled time labels.

    Deprecated since version 1.1.0: You should add the loffset to the df.index after the resample. See below.

base [int, default 0] For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0.

    Deprecated since version 1.1.0: The new arguments that you should use are ‘offset’ or ‘origin’.

on [str, optional] For a DataFrame, column to use instead of index for resampling. Column must be datetime-like.

level [str or int, optional] For a MultiIndex, level (name or number) to use for resampling. level must be datetime-like.

origin {[‘epoch’, ‘start’, ‘start_day’], Timestamp or str, default ‘start_day’} The timestamp on which to adjust the grouping. The timezone of origin must match the timezone of the index. If a timestamp is not used, these values are also supported:

    • ‘epoch’: origin is 1970-01-01
    • ‘start’: origin is the first value of the timeseries
    • ‘start_day’: origin is the first day at midnight of the timeseries

    New in version 1.1.0.

offset [Timedelta or str, default is None] An offset timedelta added to the origin.

    New in version 1.1.0.

Returns

Resampler object

See also:

groupby Group by mapping, function, label, or list of labels.

Series.resample Resample a Series.
**DataFrame.resample** Resample a DataFrame.

**Notes**

See the user guide for more.

To learn more about the offset strings, please see this link.

**Examples**

Start by creating a series with 9 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
2000-01-01 00:00:00    0
2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
2000-01-01 00:08:00    8
Freq: T, dtype: int64
```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```python
>>> series.resample('3T').sum()
2000-01-01 00:00:00    3
2000-01-01 00:03:00   12
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket `2000-01-01 00:03:00` contains the value 3, but the summed value in the resampled bucket with the label `2000-01-01 00:03:00` does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```python
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00    3
2000-01-01 00:06:00   12
2000-01-01 00:09:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```python
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00    0
2000-01-01 00:03:00     6
2000-01-01 00:06:00    15
2000-01-01 00:09:00    15
Freq: 3T, dtype: int64
```
Upsample the series into 30 second bins.

```python
>>> series.resample('30S').asfreq()[0:5]  # Select first 5 rows
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  NaN
2000-01-01 00:01:00  1.0
2000-01-01 00:01:30  NaN
2000-01-01 00:02:00  2.0
Freq: 30S, dtype: float64
```

Upsample the series into 30 second bins and fill the NaN values using the `pad` method.

```python
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00   0
2000-01-01 00:00:30   0
2000-01-01 00:01:00   1
2000-01-01 00:01:30   1
2000-01-01 00:02:00   2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the `bfill` method.

```python
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00   0
2000-01-01 00:00:30   1
2000-01-01 00:01:00   1
2000-01-01 00:01:30   2
2000-01-01 00:02:00   2
Freq: 30S, dtype: int64
```

Pass a custom function via `apply`

```python
>>> def custom_resampler(array_like):
...     return np.sum(array_like) + 5
...
>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00   8
2000-01-01 00:03:00  17
2000-01-01 00:06:00  26
Freq: 3T, dtype: int64
```

For a Series with a PeriodIndex, the keyword `convention` can be used to control whether to use the start or end of `rule`.

Resample a year by quarter using `start` `convention`. Values are assigned to the first quarter of the period.

```python
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
... freq='A',
... periods=2))
>>> s
2012  1
2013  2
Freq: A-DEC, dtype: int64
>>> s.resample('Q', convention='start').asfreq()
2012Q1  1.0
2012Q2  NaN
2012Q3  NaN
2012Q4  NaN
(continues on next page)```
Resample quarters by month using ‘end’ convention. Values are assigned to the last month of the period.

```python
>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01', freq='Q', periods=4))
```

For DataFrame objects, the keyword `on` can be used to specify the column instead of the index for resampling.

```python
>>> d = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
            'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df = pd.DataFrame(d)
```

For a DataFrame with MultiIndex, the keyword `level` can be used to specify on which level the resampling needs to take place.

```python
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018', freq='W')
```

```python
>>> df.resample('M', on='week_starting').mean()
```

```
For a DataFrame with MultiIndex, the keyword level can be used to specify on which level the resampling needs to take place.
```
```python
>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...            'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df2 = pd.DataFrame(d2,
...                     index=pd.MultiIndex.from_product([[days,
...                                                          'morning',
...                                                          'afternoon']]))
>>> df2
       price  volume
2000-01-01 morning  10    50
    afternoon  11    60
2000-01-02 morning  9     40
    afternoon  13   100
2000-01-03 morning 14     50
    afternoon 18   100
2000-01-04 morning 17     40
    afternoon 19    50
>>> df2.resample('D', level=0).sum()
       price  volume
2000-01-01  21   110
2000-01-02  22   140
2000-01-03  32   150
2000-01-04  36    90

If you want to adjust the start of the bins based on a fixed timestamp:

```python
>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
>>> ts
2000-10-01 23:30:00     0
2000-10-01 23:37:00     3
2000-10-01 23:44:00     6
2000-10-01 23:51:00     9
2000-10-01 23:58:00    12
2000-10-02 00:05:00    15
2000-10-02 00:12:00    18
2000-10-02 00:19:00    21
2000-10-02 00:26:00    24
Freq: 7T, dtype: int64

>>> ts.resample('17min').sum()
2000-10-01 23:14:00     0
2000-10-01 23:31:00     9
2000-10-01 23:48:00    21
2000-10-02 00:05:00    54
2000-10-02 00:22:00    24
Freq: 17T, dtype: int64

>>> ts.resample('17min', origin='epoch').sum()
2000-10-01 23:18:00     0
2000-10-01 23:35:00    18
2000-10-01 23:52:00    27
2000-10-02 00:09:00    39
2000-10-02 00:26:00    24
Freq: 17T, dtype: int64
```
If you want to adjust the start of the bins with an offset Timedelta, the two following lines are equivalent:

```python
>>> ts.resample('17min', origin='start').sum()
2000-10-01 23:30:00 9
2000-10-01 23:47:00 21
2000-10-02 00:04:00 54
2000-10-02 00:21:00 24
Freq: 17T, dtype: int64
```

To replace the use of the deprecated `base` argument, you can now use `offset`, in this example it is equivalent to have `base=2`:

```python
>>> ts.resample('17min', offset='2min').sum()
2000-10-01 23:16:00 0
2000-10-01 23:33:00 9
2000-10-01 23:50:00 36
2000-10-02 00:07:00 39
2000-10-02 00:24:00 24
Freq: 17T, dtype: int64
```

To replace the use of the deprecated `loffset` argument:

```python
>>> from pandas.tseries.frequencies import to_offset
>>> loffset = '19min'
>>> ts_out = ts.resample('17min').sum()
>>> ts_out.index = ts_out.index + to_offset(loffset)
>>> ts_out
2000-10-01 23:33:00 0
2000-10-01 23:50:00 9
2000-10-02 00:07:00 21
2000-10-02 00:24:00 54
2000-10-02 00:41:00 24
Freq: 17T, dtype: int64
```
**pandas.Series.reset_index**

Series.reset_index(level=None, drop=False, name=None, inplace=False)

Generate a new DataFrame or Series with the index reset.

This is useful when the index needs to be treated as a column, or when the index is meaningless and needs to be reset to the default before another operation.

**Parameters**

- **level** [int, str, tuple, or list, default optional] For a Series with a MultiIndex, only remove the specified levels from the index. Removes all levels by default.
- **drop** [bool, default False] Just reset the index, without inserting it as a column in the new DataFrame.
- **name** [object, optional] The name to use for the column containing the original Series values. Uses self.name by default. This argument is ignored when drop is True.
- **inplace** [bool, default False] Modify the Series in place (do not create a new object).

**Returns**

Series or DataFrame When drop is False (the default), a DataFrame is returned. The newly created columns will come first in the DataFrame, followed by the original Series values. When drop is True, a Series is returned. In either case, if inplace=True, no value is returned.

**See also:**

DataFrame.reset_index Analogous function for DataFrame.

**Examples**

```python
generate a DataFrame with default index.

```> s = pd.Series([1, 2, 3, 4], name='foo', ... index=pd.Index(['a', 'b', 'c', 'd'], name='idx'))

```> s.reset_index()
   idx  foo
0   a   1
1   b   2
2   c   3
3   d   4

To specify the name of the new column use name.

```> s.reset_index(name='values')
   idx   values
0   a    1
1   b    2
2   c    3
3   d    4

To generate a new Series with the default set drop to True.

```> s.reset_index(name='values', drop=True)
   values
0    1
1    2
2    3
3    4```
To update the Series in place, without generating a new one set `inplace` to True. Note that it also requires `drop=True`.

```python
>>> s.reset_index(inplace=True, drop=True)
>>> s
0 1
1 2
2 3
3 4
Name: foo, dtype: int64
```

The `level` parameter is interesting for Series with a multi-level index.

```python
>>> arrays = [np.array(['bar', 'bar', 'baz', 'baz']),
            np.array(['one', 'two', 'one', 'two'])]
>>> s2 = pd.Series(
                    range(4), name='foo',
                    index=pd.MultiIndex.from_arrays(arrays,
                                                      names=['a', 'b']))
```

To remove a specific level from the Index, use `level`.

```python
>>> s2.reset_index(level='a')
a foo
  b
one bar 0
two bar 1
one baz 2
two baz 3
```

If `level` is not set, all levels are removed from the Index.

```python
>>> s2.reset_index()
a b foo
  0 bar one 0
  1 bar two 1
  2 baz one 2
  3 baz two 3
```

### pandas.Series.rfloordiv

Series `rfloordiv` *(other, level=None, fill_value=None, axis=0)*

Return Integer division of series and other, element-wise (binary operator `rfloordiv`).

Equivalent to `other // series`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- `other` [Series or scalar value]
fill_value  [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level  [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series  The result of the operation.

See also:

Series.floordiv  Element-wise Integer division, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0  
b  1.0  
c  1.0  
d  NaN  
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0  
b  NaN  
d  1.0  
e  NaN  
dtype: float64
>>> a.floordiv(b, fill_value=0)
a  1.0  
b  NaN  
c  NaN  
d  0.0  
e  NaN  
dtype: float64
```

pandas.Series.rmod

Series.rmod (other, level=None, fill_value=None, axis=0)

Return Modulo of series and other, element-wise (binary operator rmod).

Equivalent to other % series, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other  [Series or scalar value]

fill_value  [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
level  [int or name] Broadcast across a level, matching Index values on the passed Multi-
Index level.

Returns

Series  The result of the operation.

See also:

Series.mod  Element-wise Modulo, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a   1.0
b   1.0
c   1.0
d   NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a   1.0
b   NaN
d   1.0
e   NaN
dtype: float64
>>> a.mod(b, fill_value=0)
a   0.0
b   NaN
c   NaN
d   0.0
e   NaN
dtype: float64
```

pandas.Series.rmul

Series.rmul(other, level=None, fill_value=None, axis=0)

Return Multiplication of series and other, element-wise (binary operator rmul).

Equivalent to other * series, but with support to substitute a fill_value for missing data in either
one of the inputs.

Parameters

other  [Series or scalar value]

fill_value  [None or float value, default None (NaN)] Fill existing missing (NaN) values,
and any new element needed for successful Series alignment, with this value before
computation. If data in both corresponding Series locations is missing the result of
filling (at that location) will be missing.

level  [int or name] Broadcast across a level, matching Index values on the passed Multi-
Index level.

Returns

Series  The result of the operation.
See also:

*Series.mul* Element-wise Multiplication, see Python documentation for more details.

**Examples**

```python
g>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
g>>> a  
 a    1.0  
b    1.0  
c    1.0  
d    NaN  
dtype: float64
g>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
g>>> b  
a    1.0  
b    NaN  
d    1.0  
e    NaN  
dtype: float64
g>>> a.multiply(b, fill_value=0)  
a    1.0  
b    0.0  
c    0.0  
d    0.0  
e    NaN  
dtype: float64
```

**pandas.Series.rolling**

*Series.rolling*(window, min_periods=None, center=False, win_type=None, on=None, axis=0, closed=None)

Provide rolling window calculations.

**Parameters**

- **window** [int, offset, or BaseIndexer subclass] Size of the moving window. This is the number of observations used for calculating the statistic. Each window will be a fixed size. If its an offset then this will be the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes. If a BaseIndexer subclass is passed, calculates the window boundaries based on the defined get_window_bounds method. Additional rolling keyword arguments, namely min_periods, center, and closed will be passed to get_window_bounds.

- **min_periods** [int, default None] Minimum number of observations in window required to have a value (otherwise result is NA). For a window that is specified by an offset, min_periods will default to 1. Otherwise, min_periods will default to the size of the window.

- **center** [bool, default False] Set the labels at the center of the window.

- **win_type** [str, default None] Provide a window type. If None, all points are evenly weighted. See the notes below for further information.
on [str, optional] For a DataFrame, a datetime-like column or MultiIndex level on which to calculate the rolling window, rather than the DataFrame’s index. Provided integer column is ignored and excluded from result since an integer index is not used to calculate the rolling window.

axis [int or str, default 0]

closed [str, default None] Make the interval closed on the ‘right’, ‘left’, ‘both’ or ‘neither’ endpoints. For offset-based windows, it defaults to ‘right’. For fixed windows, defaults to ‘both’. Remaining cases not implemented for fixed windows.

Returns

a Window or Rolling sub-classed for the particular operation

See also:

expanding Provides expanding transformations.
ewm Provides exponential weighted functions.

Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting center=True.

To learn more about the offsets & frequency strings, please see this link.

The recognized win_types are:

- boxcar
- triang
- blackman
- hamming
- bartlett
- parzen
- bohman
- blackmanharris
- nuttall
- barthann
- kaiser (needs parameter: beta)
- gaussian (needs parameter: std)
- general_gaussian (needs parameters: power, width)
- slepian (needs parameter: width)
- exponential (needs parameter: tau), center is set to None.

If win_type=None all points are evenly weighted. To learn more about different window types see scipy.signal window functions.

Certain window types require additional parameters to be passed. Please see the third example below on how to add the additional parameters.
Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

Rolling sum with a window length of 2, using the ‘triang’ window type.

```python
>>> df.rolling(2, win_type='triang').sum()
   B
0  NaN
1  0.5
2  1.5
3  NaN
4  NaN
```

Rolling sum with a window length of 2, using the ‘gaussian’ window type (note how we need to specify std).

```python
>>> df.rolling(2, win_type='gaussian').sum(std=3)
   B
0  NaN
1  0.986207
2  2.958621
3  NaN
4  NaN
```

Rolling sum with a window length of 2, min_periods defaults to the window length.

```python
>>> df.rolling(2).sum()
   B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN
```

Same as above, but explicitly set the min_periods

```python
>>> df.rolling(2, min_periods=1).sum()
   B
0  0.0
1  1.0
2  3.0
3  2.0
4  4.0
```

Same as above, but with forward-looking windows

```python
>>> indexer = pd.api.indexers.FixedForwardWindowIndexer(window_size=2)
>>> df.rolling(window=indexer, min_periods=1).sum()
   B
```
(continues on next page)
A ragged (meaning not-a-regular frequency), time-indexed DataFrame

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4],
                     'index': [pd.Timestamp('20130101 09:00:00'),
                              pd.Timestamp('20130101 09:00:02'),
                              pd.Timestamp('20130101 09:00:03'),
                              pd.Timestamp('20130101 09:00:05'),
                              pd.Timestamp('20130101 09:00:06')])
```

Contrasting to an integer rolling window, this will roll a variable length window corresponding to the time period. The default for min_periods is 1.

```python
>>> df.rolling('2s').sum()
```

```
B
2013-01-01 09:00:00 0.0
2013-01-01 09:00:02 1.0
2013-01-01 09:00:03 3.0
2013-01-01 09:00:05 NaN
2013-01-01 09:00:06 4.0
```

### pandas.Series.round

**Series.round** *(decimals=0, *args, **kwargs)*

Round each value in a Series to the given number of decimals.

**Parameters**

- **decimals** [int, default 0] Number of decimal places to round to. If decimals is negative, it specifies the number of positions to the left of the decimal point.

- ***args, **kwargs** Additional arguments and keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- **Series** Rounded values of the Series.

**See also:**

- **numpy.around** Round values of an np.array.
- **DataFrame.round** Round values of a DataFrame.
Examples

```python
>>> s = pd.Series([0.1, 1.3, 2.7])
>>> s.round()
0  0.0
1  1.0
2  3.0
dtype: float64
```

**pandas.Series.rpow**

`Series.rpow(other, level=None, fill_value=None, axis=0)`

Return Exponential power of series and other, element-wise (binary operator rpow).

Equivalent to `other ** series`, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- `other` [Series or scalar value]
- `fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- `level` [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

`Series` The result of the operation.

**See also:**

`Series.pow` Element-wise Exponential power, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0
b  1.0
c  1.0
d  NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b  NaN
d  1.0
e  NaN
dtype: float64
>>> a.pow(b, fill_value=0)
a  1.0
b  1.0
(continues on next page)```
pandas.Series.rsub

Series.rsub(other, level=None, fill_value=None, axis=0)

Return Subtraction of series and other, element-wise (binary operator rsub).

Equivalent to other - series, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

- other [Series or scalar value]
- fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.sub Element-wise Subtraction, see Python documentation for more details.

Examples

```python
cpy a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
cpy a
a  1.0
 b  1.0
 c  1.0
 d  NaN
dtype: float64

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
cpy b
a  1.0
 b  NaN
 d  1.0
 e  NaN
dtype: float64

>>> a.subtract(b, fill_value=0)
 a  0.0
 b  1.0
 c  1.0
 d -1.0
 e  NaN
dtype: float64
```
### pandas.Series.rtruediv

Series.rtruediv(other, level=None, fill_value=None, axis=0)

Return Floating division of series and other, element-wise (binary operator rtruediv).

Equivalent to other / series, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

Series The result of the operation.

**See also:**

Series.truediv Element-wise Floating division, see Python documentation for more details.

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d   NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b  NaN
d    1.0
e   NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b  inf
c  inf
d  0.0
e   NaN
dtype: float64
```
pandas.Series.sample

Series.sample(n=None, frac=None, replace=False, weights=None, random_state=None, axis=None)

Return a random sample of items from an axis of object.

You can use random_state for reproducibility.

Parameters

- **n** [int, optional] Number of items from axis to return. Cannot be used with frac. Default = 1 if frac = None.
- **frac** [float, optional] Fraction of axis items to return. Cannot be used with n.
- **replace** [bool, default False] Allow or disallow sampling of the same row more than once.
- **weights** [str or ndarray-like, optional] Default ‘None’ results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when axis = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.
- **random_state** [int, array-like, BitGenerator, np.random.RandomState, optional] If int, array-like, or BitGenerator (NumPy>=1.17), seed for random number generator If np.random.RandomState, use as numpy RandomState object.

Changed in version 1.1.0: array-like and BitGenerator (for NumPy>=1.17) object now passed to np.random.RandomState() as seed

- **axis** [{0 or ‘index’, 1 or ‘columns’, None}, default None] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames).

Returns

- **Series** or **DataFrame** A new object of same type as caller containing n items randomly sampled from the caller object.

See also:

- **DataFrameGroupBy.sample** Generates random samples from each group of a DataFrame object.
- **SeriesGroupBy.sample** Generates random samples from each group of a Series object.
- **numpy.random.choice** Generates a random sample from a given 1-D numpy array.

Notes

If frac > 1, replacement should be set to True.
Examples

```python
>>> df = pd.DataFrame({'num_legs': [2, 4, 8, 0],
...                    'num_wings': [2, 0, 0, 0],
...                    'num_specimen_seen': [10, 2, 1, 8]},
...                   index=['falcon', 'dog', 'spider', 'fish'])
```

```
num_legs  num_wings  num_specimen_seen
falcon     2          2              10
dog        4          0              2
spider     8          0              1
fish       0          0              8
```

Extract 3 random elements from the Series `df['num_legs']`: Note that we use `random_state` to ensure the reproducibility of the examples.

```python
>>> df['num_legs'].sample(n=3, random_state=1)
```

```
fish  0
spider  8
falcon  2
Name: num_legs, dtype: int64
```

A random 50% sample of the DataFrame with replacement:

```python
>>> df.sample(frac=0.5, replace=True, random_state=1)
```

```
num_legs  num_wings  num_specimen_seen
dog       4          0              2
fish      0          0              8
```

An upsample sample of the DataFrame with replacement: Note that `replace` parameter has to be `True` for `frac` parameter > 1.

```python
>>> df.sample(frac=2, replace=True, random_state=1)
```

```
num_legs  num_wings  num_specimen_seen
dog       4          0              2
fish      0          0              8
falcon    2          2              10
falcon    2          2              10
fish      0          0              8
dog       4          0              2
fish      0          0              8
dog       4          0              2
```

Using a DataFrame column as weights. Rows with larger value in the `num_specimen_seen` column are more likely to be sampled.

```python
>>> df.sample(n=2, weights='num_specimen_seen', random_state=1)
```

```
num_legs  num_wings  num_specimen_seen
falcon    2          2              10
fish      0          0              8
```

pandas.Series.searchsorted

Series.searchsorted(value, side='left', sorter=None)

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted Series self such that, if the corresponding elements in value were inserted before the indices, the order of self would be preserved.

Note: The Series must be monotonically sorted, otherwise wrong locations will likely be returned. Pandas does not check this for you.

Parameters

value [array_like] Values to insert into self.

side [{‘left’, ‘right’}, optional] If ‘left’, the index of the first suitable location found is given. If ‘right’, return the last such index. If there is no suitable index, return either 0 or N (where N is the length of self).

sorter [1-D array_like, optional] Optional array of integer indices that sort self into ascending order. They are typically the result of np.argsort.

Returns

int or array of int A scalar or array of insertion points with the same shape as value.

Changed in version 0.24.0: If value is a scalar, an int is now always returned. Previously, scalar inputs returned an 1-item array for Series and Categorical.

See also:

sort_values Sort by the values along either axis.

numpy.searchsorted Similar method from NumPy.

Notes

Binary search is used to find the required insertion points.

Examples

```python
>>> ser = pd.Series([1, 2, 3])
>>> ser
0    1
1    2
2    3
dtype: int64

>>> ser.searchsorted(4)
3

>>> ser.searchsorted([0, 4])
array([0, 3])
```
>>> ser.searchsorted([1, 3], side='left')
array([0, 2])

>>> ser.searchsorted([1, 3], side='right')
array([1, 3])

>>> ser = pd.Categorical(
...    ['apple', 'bread', 'bread', 'cheese', 'milk'], ordered=True
...)

>>> ser
['apple', 'bread', 'bread', 'cheese', 'milk']
Categories (4, object): ['apple' < 'bread' < 'cheese' < 'milk']

>>> ser.searchsorted('bread')
1

>>> ser.searchsorted(['bread'], side='right')
array([3])

If the values are not monotonically sorted, wrong locations may be returned:

>>> ser = pd.Series([2, 1, 3])

>>> ser
0 2
1 1
2 3
dtype: int64

>>> ser.searchsorted(1)
0  # wrong result, correct would be 1

pandas.Series.sem

Series.sem(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)
Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

Parameters

    axis [index (0)]
    skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
    level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
    ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
    numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns
scalar or Series (if level specified)

**pandas.Series.set_axis**

```
Series.set_axis(labels, axis=0, inplace=False)
```

Assign desired index to given axis.

Indexes for row labels can be changed by assigning a list-like or Index.

**Parameters**

- `labels` [list-like, Index] The values for the new index.
- `axis` [{0 or ‘index’}, default 0] The axis to update. The value 0 identifies the rows.
- `inplace` [bool, default False] Whether to return a new Series instance.

**Returns**

- `renamed` [Series or None] An object of type Series if inplace=False, None otherwise.

**See also:**

*Series.rename_axis* Alter the name of the index.

**Examples**

```python
>>> s = pd.Series([1, 2, 3])
>>> s
0 1
1 2
2 3
dtype: int64

>>> s.set_axis(['a', 'b', 'c'], axis=0)
a 1
b 2
c 3
dtype: int64
```

**pandas.Series.shift**

```
Series.shift(periods=1, freq=None, axis=0, fill_value=None)
```

Shift index by desired number of periods with an optional time `freq`.

When `freq` is not passed, shift the index without realigning the data. If `freq` is passed (in this case, the index must be date or datetime, or it will raise a `NotImplementedError`), the index will be increased using the periods and the `freq`. `freq` can be inferred when specified as “infer” as long as either `freq` or `inferred_freq` attribute is set in the index.

**Parameters**

- `periods` [int] Number of periods to shift. Can be positive or negative.
- `freq` [DateOffset, tseries.offsets, timedelta, or str, optional] Offset to use from the tseries module or time rule (e.g. ‘EOM’). If `freq` is specified then the index values are shifted but the data is not realigned. That is, use `freq` if you would like to extend the index.
when shifting and preserve the original data. If `freq` is specified as “infer” then it will be inferred from the `freq` or `inferred_freq` attributes of the index. If neither of those attributes exist, a ValueError is thrown.

**axis** [0 or ‘index’, 1 or ‘columns’, None], default None Shift direction.

**fill_value** [object, optional] The scalar value to use for newly introduced missing values. the default depends on the `dtype` of `self`. For numeric data, `np.nan` is used. For datetime, timedelta, or period data, etc. `NaT` is used. For extension dtypes, `self.dtype.na_value` is used.

Changed in version 1.1.0.

**Returns**

`Series` Copy of input object, shifted.

**See also:**

`Index.shift` Shift values of Index.

`DatetimeIndex.shift` Shift values of DatetimeIndex.

`PeriodIndex.shift` Shift values of PeriodIndex.

`tshift` Shift the time index, using the index’s frequency if available.

**Examples**

```python
>>> df = pd.DataFrame({'Col1': [10, 20, 15, 30, 45],
...                     'Col2': [13, 23, 18, 33, 48],
...                     'Col3': [17, 27, 22, 37, 52]},
...                    index=pd.date_range('2020-01-01', '2020-01-05'))
>>> df
      Col1  Col2  Col3
2020-01-01   10    13    17
2020-01-02   20    23    27
2020-01-03   15    18    22
2020-01-04   30    33    37
2020-01-05   45    48    52

>>> df.shift(periods=3)
      Col1   Col2   Col3
2020-01-01   NaN   NaN   NaN
2020-01-02   NaN   NaN   NaN
2020-01-03   NaN   NaN   NaN
2020-01-04  10.0  13.0  17.0
2020-01-05  20.0  23.0  27.0

>>> df.shift(periods=1, axis='columns')
      Col1  Col2  Col3
2020-01-01   NaN  10.0  13.0
2020-01-02   NaN  20.0  23.0
2020-01-03   NaN  15.0  18.0
2020-01-04   NaN  30.0  33.0
2020-01-05   NaN  45.0  48.0
```
```
>>> df.shift(periods=3, fill_value=0)
   Col1  Col2  Col3
2020-01-01   0    0    0
2020-01-02   0    0    0
2020-01-03   0    0    0
2020-01-04  10   13   17
2020-01-05  20   23   27

>>> df.shift(periods=3, freq="D")
   Col1  Col2  Col3
2020-01-04  10   13   17
2020-01-05  20   23   27
2020-01-06  15   18   22
2020-01-07  30   33   37
2020-01-08  45   48   52

>>> df.shift(periods=3, freq="infer")
   Col1  Col2  Col3
2020-01-04  10   13   17
2020-01-05  20   23   27
2020-01-06  15   18   22
2020-01-07  30   33   37
2020-01-08  45   48   52
```

**pandas.Series.skew**

`Series.skew(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return unbiased skew over requested axis.

Normalized by N-1.

**Parameters**

axis [{index (0)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs Additional keyword arguments to be passed to the function.

**Returns**

scalar or Series (if level specified)
**pandas.Series.slice_shift**

Series.slice_shift(periods=1, axis=0)

Equivalent to shift without copying data.

The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

**Parameters**

- **periods** [int] Number of periods to move, can be positive or negative.

**Returns**

- **shifted** [same type as caller]

**Notes**

While the slice_shift is faster than shift, you may pay for it later during alignment.

**pandas.Series.sort_index**

Series.sort_index(axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na_position='last', sort_remaining=True, ignore_index=False, key=None)

Sort Series by index labels.

Returns a new Series sorted by label if inplace argument is False, otherwise updates the original series and returns None.

**Parameters**

- **axis** [int, default 0] Axis to direct sorting. This can only be 0 for Series.
- **level** [int, optional] If not None, sort on values in specified index level(s).
- **ascending** [bool or list of bools, default True] Sort ascending vs. descending. When the index is a MultiIndex the sort direction can be controlled for each level individually.
- **inplace** [bool, default False] If True, perform operation in-place.
- **kind** [{‘quicksort’, ‘mergesort’, ‘heapsort’}, default ‘quicksort’] Choice of sorting algorithm. See also numpy.sort() for more information. ‘mergesort’ is the only stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.
- **na_position** [{‘first’, ‘last’}, default ‘last’] If ‘first’ puts NaNs at the beginning, ‘last’ puts NaNs at the end. Not implemented for MultiIndex.
- **sort_remaining** [bool, default True] If True and sorting by level and index is multilevel, sort by other levels too (in order) after sorting by specified level.
- **ignore_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

- **key** [callable, optional] If not None, apply the key function to the index values before sorting. This is similar to the key argument in the builtin sorted() function, with the notable difference that this key function should be vectorized. It should expect an Index and return an Index of the same shape.

New in version 1.1.0.
Returns

Series  The original Series sorted by the labels.

See also:

Dataframe.sort_index  Sort DataFrame by the index.
Dataframe.sort_values  Sort DataFrame by the value.
Series.sort_values  Sort Series by the value.

Examples

```python
>>> s = pd.Series(['a', 'b', 'c', 'd'], index=[3, 2, 1, 4])
>>> s.sort_index()
1   c
2   b
3   a
4   d
dtype: object
```

Sort Descending

```python
>>> s.sort_index(ascending=False)
4   d
3   a
2   b
1   c
dtype: object
```

Sort Inplace

```python
>>> s.sort_index(inplace=True)
>>> s
1   c
2   b
3   a
4   d
dtype: object
```

By default NaNs are put at the end, but use `na_position` to place them at the beginning

```python
>>> s = pd.Series(['a', 'b', 'c', 'd'], index=[3, 2, 1, np.nan])
>>> s.sort_index(na_position='first')
NaN   d
1.0   c
2.0   b
3.0   a
dtype: object
```

Specify index level to sort

```python
>>> arrays = [np.array(['qux', 'qux', 'foo', 'foo',
...                      'baz', 'baz', 'bar', 'bar']),
...           np.array(['two', 'one', 'two', 'one',
...                      'two', 'one', 'two', 'one'])]
>>> s = pd.Series([1, 2, 3, 4, 5, 6, 7, 8], index=arrays)
```
pandas: powerful Python data analysis toolkit, Release 1.1.5

(continued from previous page)

```python
>>> s.sort_index(level=1)
bar one 8
baz one 6
foo one 4
qux one 2
bar two 7
baz two 5
foo two 3
qux two 1
dtype: int64
Does not sort by remaining levels when sorting by levels

```python
>>> s.sort_index(level=1, sort_remaining=False)
qux one 2
foo one 4
baz one 6
bar one 8
qux two 1
foo two 3
baz two 5
bar two 7
dtype: int64

```python
Apply a key function before sorting

```python
>>> s = pd.Series([1, 2, 3, 4], index=['A', 'b', 'C', 'd'])
>>> s.sort_index(key=lambda x : x.str.lower())
A 1
b 2
C 3
d 4
dtype: int64

```

**pandas.Series.sort_values**

Series.sort_values(axis=0, ascending=True, inplace=False, kind='quicksort',
na_position='last', ignore_index=False, key=None)
Sort by the values.
Sort a Series in ascending or descending order by some criterion.

**Parameters**

- **axis** [(0 or ‘index’), default 0] Axis to direct sorting. The value ‘index’ is accepted for compatibility with DataFrame.sort_values.
- **ascending** [bool, default True] If True, sort values in ascending order, otherwise descending.
- **inplace** [bool, default False] If True, perform operation in-place.
- **kind** [['quicksort', ‘mergesort’ or ‘heapsort’], default ‘quicksort’] Choice of sorting algorithm. See also numpy.sort() for more information. ‘mergesort’ is the only stable algorithm.
- **na_position** [['first’ or ‘last’], default ‘last’] Argument ‘first’ puts NaNs at the beginning, ‘last’ puts NaNs at the end.
ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

key [callable, optional] If not None, apply the key function to the series values before sorting. This is similar to the key argument in the builtin sorted() function, with the notable difference that this key function should be vectorized. It should expect a Series and return an array-like.

New in version 1.1.0.

Returns

Series Series ordered by values.

See also:

Series.sort_index Sort by the Series indices.

DataFrame.sort_values Sort DataFrame by the values along either axis.

DataFrame.sort_index Sort DataFrame by indices.

Examples

```python
gs = pd.Series([np.nan, 1, 3, 10, 5])
gs
0 NaN
1 1.0
2 3.0
3 10.0
4 5.0
dtype: float64

Sort values ascending order (default behaviour)

>>> gs.sort_values(ascending=True)
1 1.0
2 3.0
4 5.0
3 10.0
0 NaN
dtype: float64

Sort values descending order

>>> gs.sort_values(ascending=False)
3 10.0
4 5.0
2 3.0
1 1.0
0 NaN
dtype: float64

Sort values inplace
```
>>> s.sort_values(ascending=False, inplace=True)

Sort values putting NAs first

>>> s.sort_values(na_position='first')

Sort a series of strings

>>> s = pd.Series(['z', 'b', 'd', 'a', 'c'])

Sort using a key function. Your key function will be given the Series of values and should return an array-like.

>>> s = pd.Series(['a', 'B', 'c', 'D', 'e'])

NumPy ufuncs work well here. For example, we can sort by the sin of the value
>>> s = pd.Series([-4, -2, 0, 2, 4])
>>> s.sort_values(key=np.sin)
   0   1  
1  2 -2  
4  4  0  
2  2 -4  
3  2  4  
dtype: int64

More complicated user-defined functions can be used, as long as they expect a Series and return an array-like

>>> s.sort_values(key=lambda x: (np.tan(x.cumsum())))
   0  4  1  3  2  
0 -4  2  4 -2  
4  4  4  2  0  
dtype: int64

**pandas.Series.sparse**

Series.sparse()

Accessor for SparseSparse from other sparse matrix data types.

**pandas.Series.squeeze**

Series.squeeze(axis=None)

Squeeze 1 dimensional axis objects into scalars.

Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.

This method is most useful when you don’t know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call squeeze to ensure you have a Series.

Parameters

axis [{0 or ‘index’, 1 or ‘columns’, None}, default None] A specific axis to squeeze. By default, all length-1 axes are squeezed.

Returns

DataFrame, Series, or scalar The projection after squeezing axis or all the axes.

See also:

Series.iloc Integer-location based indexing for selecting scalars.

DataFrame.iloc Integer-location based indexing for selecting Series.

Series.to_frame Inverse of DataFrame.squeeze for a single-column DataFrame.

3.3. Series
**Examples**

```python
>>> primes = pd.Series([2, 3, 5, 7])
```

Slicing might produce a Series with a single value:

```python
>>> even_primes = primes[primes % 2 == 0]
>>> even_primes
0    2
dtype: int64
>>> even_primes.squeeze()
2
```

Squeezing objects with more than one value in every axis does nothing:

```python
>>> odd_primes = primes[primes % 2 == 1]
>>> odd_primes
1    3
2    5
3    7
dtype: int64
>>> odd_primes.squeeze()
1    3
2    5
3    7
dtype: int64
```

Squeezing is even more effective when used with DataFrames.

```python
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
>>> df
   a b
0  1  2
1  3  4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```python
>>> df_a = df[['a']]
>>> df_a
   a
0  1
1  3
```

So the columns can be squeezed down, resulting in a Series:

```python
>>> df_a.squeeze('columns')
0  1
1  3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```python
>>> df_0a = df.loc[df.index < 1, ['a']]
>>> df_0a
```

(continues on next page)
Squeezing the rows produces a single scalar Series:

```python
>>> df_0a.squeeze('rows')
a  1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```python
>>> df_0a.squeeze()
1
```

**pandas.Series.std**

`Series.std` *(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)*

Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument.

**Parameters**

- **axis** ([index (0)])
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

scalar or Series (if level specified)

**pandas.Series.str**

`Series.str()`

Vectorized string functions for Series and Index.

NAs stay NA unless handled otherwise by a particular method. Patterned after Python’s string methods, with some inspiration from R’s stringr package.
Examples

```python
>>> s = pd.Series(["A_Str_Series"])  
>>> s
0   A_Str_Series
dtype: object

>>> s.str.split("_")
0   [A, Str, Series]
dtype: object

>>> s.str.replace("_", "")
0   AStrSeries
dtype: object
```

**pandas.Series.sub**

Series.\texttt{sub}(other, level=None, fill_value=None, axis=0)

Return Subtraction of series and other, element-wise (binary operator \texttt{sub}).

Equivalent to \texttt{series - other}, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

Series The result of the operation.

**See also:**

Series.\texttt{rsub} Reverse of the Subtraction operator, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])  
>>> a
a   1.0  
b   1.0  
c   1.0  
d   NaN  
dtype: float64

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])  
>>> b
a   1.0  
```

(continues on next page)
Series.subtract

Series.subtract(other, level=None, fill_value=None, axis=0)
Return Subtraction of series and other, element-wise (binary operator sub).
Equivalent to series - other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]
fill_value [None or float value, default None (NaN)]. Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
level [int or name]. Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.rsub Reverse of the Subtraction operator, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0
type: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
type: float64
```
pandas.Series.sum

Series.sum(\texttt{axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs})

Return the sum of the values for the requested axis.

This is equivalent to the method \texttt{numpy.sum}.

Parameters

\begin{itemize}
  \item \texttt{axis} \quad \{[\text{index (0)}]\} Axis for the function to be applied on.
  \item \texttt{skipna} \quad \{bool, default True\} Exclude NA/null values when computing the result.
  \item \texttt{level} \quad \{int or level name, default None\} If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
  \item \texttt{numeric_only} \quad \{bool, default None\} Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
  \item \texttt{min_count} \quad \{int, default 0\} The required number of valid values to perform the operation. If fewer than \texttt{min_count} non-NA values are present the result will be NA.
\end{itemize}

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

**\texttt{kwargs}** Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

See also:

\begin{itemize}
  \item \texttt{Series.sum} Return the sum.
  \item \texttt{Series.min} Return the minimum.
  \item \texttt{Series.max} Return the maximum.
  \item \texttt{Series.idxmin} Return the index of the minimum.
  \item \texttt{Series.idxmax} Return the index of the maximum.
  \item \texttt{DataFrame.sum} Return the sum over the requested axis.
  \item \texttt{DataFrame.min} Return the minimum over the requested axis.
  \item \texttt{DataFrame.max} Return the maximum over the requested axis.
  \item \texttt{DataFrame.idxmin} Return the index of the minimum over the requested axis.
  \item \texttt{DataFrame.idxmax} Return the index of the maximum over the requested axis.
\end{itemize}
Examples

```python
>>> idx = pd.MultiIndex.from_arrays([  
...     ['warm', 'warm', 'cold', 'cold'],  
...     ['dog', 'falcon', 'fish', 'spider']  
... ], names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal  
  warm  dog  4
  falcon  2
  cold  fish  0
  spider  8
Name: legs, dtype: int64

>>> s.sum()
14
```

Sum using level names, as well as indices.

```python
>>> s.sum(level='blooded')
blooded  
  warm  6
  cold  8
Name: legs, dtype: int64

>>> s.sum(level=0)
blooded  
  warm  6
  cold  8
Name: legs, dtype: int64
```

By default, the sum of an empty or all-NA Series is 0.

```python
>>> pd.Series([]).sum()  # min_count=0 is the default
0.0
```

This can be controlled with the `min_count` parameter. For example, if you’d like the sum of an empty series to be NaN, pass `min_count=1`.

```python
>>> pd.Series([]).sum(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).sum()
0.0

>>> pd.Series([np.nan]).sum(min_count=1)
nan
```
pandas.Series.swapaxes

Series.swapaxes(axis1, axis2, copy=True)
Interchange axes and swap values axes appropriately.

Returns

y [same as input]

pandas.Series.swaplevel

Series.swaplevel(i=-2, j=-1, copy=True)
Swap levels i and j in a MultiIndex.
Default is to swap the two innermost levels of the index.

Parameters

i, j [int, str] Level of the indices to be swapped. Can pass level name as string.
copy [bool, default True] Whether to copy underlying data.

Returns

Series Series with levels swapped in MultiIndex.

pandas.Series.tail

Series.tail(n=5)
Return the last n rows.
This function returns last n rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.
For negative values of n, this function returns all rows except the first n rows, equivalent to df[n:].

Parameters

n [int, default 5] Number of rows to select.

Returns

type of caller The last n rows of the caller object.

See also:

Dataframe.head The first n rows of the caller object.

Examples

```python
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                           'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0  alligator
1     bee
2  falcon
3    lion
```
Viewing the last 5 lines

```python
>>> df.tail()
animal
4 monkey
5 parrot
6 shark
7 whale
8 zebra
```

Viewing the last $n$ lines (three in this case)

```python
>>> df.tail(3)
animal
6 shark
7 whale
8 zebra
```

For negative values of $n$

```python
>>> df.tail(-3)
animal
3 lion
4 monkey
5 parrot
6 shark
7 whale
8 zebra
```

**pandas.Series.take**

`Series.take(indices, axis=0, is_copy=None, **kwargs)`

Return the elements in the given positional indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

**Parameters**

- `indices` [array-like] An array of ints indicating which positions to take.
- `axis` [{0 or ‘index’, 1 or ‘columns’, None}, default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.
- `is_copy` [bool] Before pandas 1.0, `is_copy=False` can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, `take` always returns a copy, and the keyword is therefore deprecated. Deprecated since version 1.0.0.
- `**kwargs` For compatibility with `numpy.take()`. Has no effect on the output.
Returns

taken [same type as caller] An array-like containing the elements taken from the object.

See also:

Dataframe.loc Select a subset of a Dataframe by labels.

Dataframe.iloc Select a subset of a Dataframe by positions.

Numpy.take Take elements from an array along an axis.

Examples

```
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                     ('parrot', 'bird', 24.0),
...                     ('lion', 'mammal', 80.5),
...                     ('monkey', 'mammal', np.nan)],
...                     columns=['name', 'class', 'max_speed'],
...                     index=[0, 2, 3, 1])
>>> df
       name   class     max_speed
0   falcon   bird       389.0
2   parrot   bird        24.0
3    lion  mammal       80.5
1   monkey  mammal         NaN

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

>>> df.take([0, 3])
     name   class     max_speed
0   falcon   bird       389.0
1   monkey  mammal         NaN

Take elements at indices 1 and 2 along the axis 1 (column selection).

>>> df.take([1, 2], axis=1)
     class     max_speed
0   bird       389.0
2   bird        24.0
3  mammal       80.5
1  mammal         NaN

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

>>> df.take([-1, -2])
     name   class     max_speed
1   monkey  mammal         NaN
3    lion  mammal        80.5
```
pandas.Series.to_clipboard

Series.to_clipboard(excel=True, sep=None, **kwargs)
Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

Parameters

- **excel** [bool, default True] Produce output in a csv format for easy pasting into excel.
  - True, use the provided separator for csv pasting.
  - False, write a string representation of the object to the clipboard.
- **sep** [str, default ' \t '] Field delimiter.
- **kwargs** These parameters will be passed to DataFrame.to_csv.

See also:

DataFrame.to_csv Write a DataFrame to a comma-separated values (csv) file.
read_clipboard Read text from clipboard and pass to read_table.

Notes

Requirements for your platform.

- Linux : xclip, or xsel (with PyQt4 modules)
- Windows : none
- OS X : none

Examples

Copy the contents of a DataFrame to the clipboard.

```python
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
```

```python
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the index by passing the keyword `index` and setting it to false.

```python
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```
### pandas.Series.to_csv

**Series.to_csv**

```python
Series.to_csv(path_or_buf=None, sep=’,’, na_rep=’’, float_format=None, columns=None, header=True, index=True, index_label=None, mode=’w’, encoding=None, compression=’infer’, quoting=None, quotechar=’”’, line_terminator=None, chunksize=None, date_format=None, doublequote=True, escapechar=None, decimal=’.’, errors=’strict’)
```

Write object to a comma-separated values (csv) file.

*Changed in version 0.24.0*: The order of arguments for Series was changed.

#### Parameters

- **path_or_buf** [str or file handle, default None] File path or object, if None is provided the result is returned as a string. If a file object is passed it should be opened with `newline=’’`, disabling universal newlines.

  *Changed in version 0.24.0*: Was previously named “path” for Series.

- **sep** [str, default ‘’] String of length 1. Field delimiter for the output file.

- **na_rep** [str, default ‘’] Missing data representation.

- **float_format** [str, default None] Format string for floating point numbers.

- **columns** [sequence, optional] Columns to write.

- **header** [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

  *Changed in version 0.24.0*: Previously defaulted to False for Series.

- **index** [bool, default True] Write row names (index).

- **index_label** [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and `header` and `index` are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use `index_label=False` for easier importing in R.

- **mode** [str] Python write mode, default ‘w’.

- **encoding** [str, optional] A string representing the encoding to use in the output file, defaults to ‘utf-8’.

- **compression** [str or dict, default ‘infer’] If str, represents compression mode. If dict, value at ‘method’ is the compression mode. Compression mode may be any of the following possible values: {‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}. If compression mode is ‘infer’ and `path_or_buf` is path-like, then detect compression mode from the following extensions: .gz, .bz2, .zip or .xz. (otherwise no compression). If dict given and mode is one of {‘zip’, ‘gzip’, ‘bz2’}, or inferred as one of the above, other entries passed as additional compression options.

  *Changed in version 1.0.0*: May now be a dict with key ‘method’ as compression mode and other entries as additional compression options if compression mode is ‘zip’.

  *Changed in version 1.1.0*: Passing compression options as keys in dict is supported for compression modes ‘gzip’ and ‘bz2’ as well as ‘zip’.

- **quoting** [optional constant from csv module] Defaults to csv.QUOTE_MINIMAL. If you have set a `float_format` then floats are converted to strings and thus csv.QUOTE_NONNUMERIC will treat them as non-numeric.

- **quotechar** [str, default ‘”’] String of length 1. Character used to quote fields.
line_terminator [str, optional] The newline character or character sequence to use in the
output file. Defaults to os.linesep, which depends on the OS in which this method is
called (‘n’ for linux, ‘m’ for Windows, i.e.).

Changed in version 0.24.0.

chunksize [int or None] Rows to write at a time.

date_format [str, default None] Format string for datetime objects.

doublequote [bool, default True] Control quoting of quotechar inside a field.

escapechar [str, default None] String of length 1. Character used to escape sep and
quotechar when appropriate.

decimal [str, default ‘.’] Character recognized as decimal separator. E.g. use ‘,’ for
European data.

doublequote [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled.
See the errors argument for open() for a full list of options.

New in version 1.1.0.

Returns

None or str If path_or_buf is None, returns the resulting csv format as a string. Other-
wise returns None.

See also:

read_csv Load a CSV file into a DataFrame.
to_excel Write DataFrame to an Excel file.

Examples

```python
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                    'mask': ['red', 'purple'],
...                    'weapon': ['sai', 'bo staff']})
>>> df.to_csv(index=False)
'name,mask,weapon
Raphael,red,sai
Donatello,purple,bo staff'
Create ‘out.zip’ containing ‘out.csv’

>>> compression_opts = dict(method='zip',
...                            archive_name='out.csv')
>>> df.to_csv('out.zip', index=False,
...           compression=compression_opts)
```

pandas.Series.to_dict

Series.to_dict(into=<class 'dict'>)
Convert Series to {label -> value} dict or dict-like object.

Parameters

into [class, default dict] The collections.abc.Mapping subclass to use as the return object.
Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.
Returns

collections.abc.Mapping  Key-value representation of Series.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_dict()
{0: 1, 1: 2, 2: 3, 3: 4}
>>> from collections import OrderedDict, defaultdict
>>> s.to_dict(OrderedDict)
OrderedDict([(0, 1), (1, 2), (2, 3), (3, 4)])
>>> dd = defaultdict(list)
>>> s.to_dict(dd)
defaultdict(<class 'list'>, {0: 1, 1: 2, 2: 3, 3: 4})
```

**pandas.Series.to_excel**

Series.to_excel(excel_writer, sheet_name='Sheet1', na_rep='', float_format=None, columns=None, header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf', verbose=True, freeze_panes=None)

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an ExcelWriter object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique sheet_name. With all data written to the file it is necessary to save the changes. Note that creating an ExcelWriter object with a file name that already exists will result in the contents of the existing file being erased.

Parameters

- **excel_writer** [str or ExcelWriter object] File path or existing ExcelWriter.
- **sheet_name** [str, default ‘Sheet1’] Name of sheet which will contain DataFrame.
- **na_rep** [str, default ‘’] Missing data representation.
- **float_format** [str, optional] Format string for floating point numbers. For example `float_format="%.2f"` will format 0.1234 to 0.12.
- **columns** [sequence or list of str, optional] Columns to write.
- **header** [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.
- **index** [bool, default True] Write row names (index).
- **index_label** [str or sequence, optional] Column label for index column(s) if desired. If not specified, and header and index are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- **startrow** [int, default 0] Upper left cell row to dump data frame.
- **startcol** [int, default 0] Upper left cell column to dump data frame.
**engine** [str, optional] Write engine to use, ‘openpyxl’ or ‘xlsxwriter’. You can also set this via the options io.excel.xlsx.writer, io.excel.xlsl.writer, and io.excel.xlsm.writer.

**merge_cells** [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.

**encoding** [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.

**inf_rep** [str, default ‘inf’] Representation for infinity (there is no native representation for infinity in Excel).

**verbose** [bool, default True] Display more information in the error logs.

**freeze_panes** [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

See also:

- **to_csv** Write DataFrame to a comma-separated values (csv) file.
- **ExcelWriter** Class for writing DataFrame objects into excel sheets.
- **read_excel** Read an Excel file into a pandas DataFrame.
- **read_csv** Read a comma-separated values (csv) file into DataFrame.

**Notes**

For compatibility with to_csv(), to_excel serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible write further data without rewriting the whole workbook.

**Examples**

Create, write to and save a workbook:

```python
>>> df1 = pd.DataFrame([['a', 'b'], ['c', 'd']],
                   index=['row 1', 'row 2'],
                   columns=['col 1', 'col 2'])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```python
>>> df1.to_excel("output.xlsx",
               sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:

```python
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

ExcelWriter can also be used to append to an existing Excel file:
To set the library that is used to write the Excel file, you can pass the `engine` keyword (the default engine is automatically chosen depending on the file extension):

```python
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```

### pandas.Series.to_frame

**Series.to_frame(name=None)**

Convert Series to DataFrame.

**Parameters**

- **name** [object, default None] The passed name should substitute for the series name (if it has one).

**Returns**

- **DataFrame** DataFrame representation of Series.

**Examples**

```python
>>> s = pd.Series(["a", "b", "c"],
                 name="vals")
>>> s.to_frame()
vals
0  a
1  b
2  c
```

### pandas.Series.to_hdf

**Series.to_hdf(path_or_buf, key, mode=’a’, complevel=None, complib=None, append=False, format=None, index=True, min_itemsize=None, nan_rep=None, dropna=None, data_columns=None, errors='strict', encoding='UTF-8')**

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different a key.

For more information see the user guide.

**Parameters**

- **path_or_buf** [str or pandas.HDFStore] File path or HDFStore object.
- **key** [str] Identifier for the group in the store.
- **mode** [[‘a’, ‘w’, ‘r+’], default ‘a’] Mode to open file:
• ‘w’: write, a new file is created (an existing file with the same name would be deleted).
• ‘a’: append, an existing file is opened for reading and writing, and if the file does not exist it is created.
• ‘r+’: similar to ‘a’, but the file must already exist.

**complevel** [{0-9}, optional] Specifies a compression level for data. A value of 0 disables compression.

**complib** [{'zlib', 'lz4', 'bzip2', 'blosc'}, default ‘zlib’] Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: ‘blosc:blosclz’): {'blosc:blosclz', 'blosc:lz4', 'blosclz4hc', 'blosc:snappy', 'blosc:zlib', 'blosc:zstd’}. Specifying a compression library which is not available issues a ValueError.

**append** [bool, default False] For Table formats, append the input data to the existing.

**format** [{‘fixed’, ‘table’, None}, default ‘fixed’] Possible values:
• ‘table’: Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
• If None, pd.get_option(‘io.hdf.default_format’) is checked, followed by fallback to “fixed”

**errors** [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for open() for a full list of options.

**encoding** [str, default “UTF-8”]

**min_itemsize** [dict or int, optional] Map column names to minimum string sizes for columns.

**nan_rep** [Any, optional] How to represent null values as str. Not allowed with append=True.

**data_columns** [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See Query via data columns. Applicable only to format=’table’.

See also:

**DataFrame.read_hdf** Read from HDF file.

**DataFrame.to_parquet** Write a DataFrame to the binary parquet format.

**DataFrame.to_sql** Write to a sql table.

**DataFrame.to_feather** Write out feather-format for DataFrames.

**DataFrame.to_csv** Write out to a csv file.
Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
                   index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')

We can add another object to the same file:

```python
ts = pd.Series([1, 2, 3, 4])
ts.to_hdf('data.h5', key='ts')
```      

Reading from HDF file:

```python
>>> pd.read_hdf('data.h5', 'df')
A  B
a 1 4
b 2 5
c 3 6
>>> pd.read_hdf('data.h5', 'ts')
0 1
1 2
2 3
3 4
dtype: int64
```

Deleting file with data:

```python
>>> import os

>>> os.remove('data.h5')
```

**pandas.Series.to_json**

`Series.to_json(path_or_buf=None, orient=None, date_format=None, double_precision=10, force_ascii=True, date_unit='ms', default_handler=None, lines=False, compression='infer', index=True, indent=None)`

Convert the object to a JSON string.

Note NaN's and None will be converted to null and datetime objects will be converted to UNIX timestamps.

**Parameters**

- **path_or_buf** [str or file handle, optional] File path or object. If not specified, the result is returned as a string.

- **orient** [str] Indication of expected JSON string format.
  - **Series**:
    - default is ‘index’
    - allowed values are: {‘split’, ‘records’, ‘index’, ‘table’}.
  - **DataFrame**:
    - default is ‘columns’
    - allowed values are: {‘split’, ‘records’, ‘index’, ‘columns’, ‘values’, ‘table’}.
  - The format of the JSON string:
pandas: powerful Python data analysis toolkit, Release 1.1.5

- ‘split’ : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
- ‘records’ : list like [{column -> value}, . . . , {column -> value}]
- ‘index’ : dict like {index -> {column -> value}}
- ‘columns’ : dict like {column -> {index -> value}}
- ‘values’ : just the values array
- ‘table’ : dict like {'schema': {schema}, 'data': {data}}

Describing the data, where data component is like orient='records'.

Changed in version 0.20.0.

date_format [{None, 'epoch', 'iso'}] Type of date conversion. ‘epoch’ = epoch milliseconds, ‘iso’ = ISO8601. The default depends on the orient. For orient='table', the default is ‘iso’. For all other orients, the default is ‘epoch’.

double_precision [int, default 10] The number of decimal places to use when encoding floating point values.

force_ascii [bool, default True] Force encoded string to be ASCII.

date_unit [str, default ‘ms’ (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’, ‘ns’ for second, millisecond, microsecond, and nanosecond respectively.

default_handler [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

lines [bool, default False] If ‘orient’ is ‘records’ write out line delimited json format. Will throw ValueError if incorrect ‘orient’ since others are not list like.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

Changed in version 0.24.0: ‘infer’ option added and set to default

index [bool, default True] Whether to include the index values in the JSON string. Not including the index (index=False) is only supported when orient is ‘split’ or ‘table’.

New in version 0.23.0.

indent [int, optional] Length of whitespace used to indent each record.

New in version 1.0.0.

Returns

None or str If path_or_buf is None, returns the resulting json format as a string. Otherwise returns None.

See also:

read_json Convert a JSON string to pandas object.
Notes

The behavior of `indent=0` varies from the stdlib, which does not indent the output but does insert newlines. Currently, `indent=0` and the default `indent=None` are equivalent in pandas, though this may change in a future release.

Examples

```python
>>> import json

>>> df = pd.DataFrame(
...     [["a", "b"], ["c", "d"],
...      index=["row 1", "row 2"],
...      columns=["col 1", "col 2"]
...  )

>>> result = df.to_json(orient="split")

>>> parsed = json.loads(result)

>>> json.dumps(parsed, indent=4)

{
  "columns": [
    "col 1",
    "col 2"
  ],
  "index": [
    "row 1",
    "row 2"
  ],
  "data": [
    [
      "a",
      "b"
    ],
    [
      "c",
      "d"
    ]
  ]
}
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```python
>>> result = df.to_json(orient="records")

>>> parsed = json.loads(result)

>>> json.dumps(parsed, indent=4)

[ {
  "col 1": "a",
  "col 2": "b"
},
{
  "col 1": "c",
  "col 2": "d"
} ]
```
Encoding/decoding a Dataframe using 'index' formatted JSON:

```python
>>> result = df.to_json(orient="index")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "row 1": {
        "col 1": "a",
        "col 2": "b"
    },
    "row 2": {
        "col 1": "c",
        "col 2": "d"
    }
}
```

Encoding/decoding a Dataframe using 'columns' formatted JSON:

```python
>>> result = df.to_json(orient="columns")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "col 1": {
        "row 1": "a",
        "row 2": "c"
    },
    "col 2": {
        "row 1": "b",
        "row 2": "d"
    }
}
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```python
>>> result = df.to_json(orient="values")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[
    ["a",
     "b"],
    ["c",
     "d"
]
```

Encoding with Table Schema:

```python
>>> result = df.to_json(orient="table")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "schema": {
        "fields": [
            {
                "name": "index",
```
pandas.Series.to_latex

Series.to_latex(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, bold_rows=False, column_format=None, longtable=None, escape=None, encoding=None, decimal='.', multicolumn=None, multicolumn_format=None, multirow=None, caption=None, label=None)

Render object to a LaTeX tabular, longtable, or nested table/tabular.

Requires \usepackage{booktabs}. The output can be copy/pasted into a main LaTeX document or read from an external file with \input{table.tex}.

Changed in version 0.20.2: Added to Series.

Changed in version 1.0.0: Added caption and label arguments.

Parameters

- **buf** [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.
- **columns** [list of label, optional] The subset of columns to write. Writes all columns by default.
- **col_space** [int, optional] The minimum width of each column.
- **header** [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.
index [bool, default True] Write row names (index).

na_rep [str, default ‘NaN’] Missing data representation.

formatters [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.

float_format [one-parameter function or str, optional, default None] Formatter for floating point numbers. For example float_format="%.2f" and float_format="{:0.2f}".format will both result in 0.1234 being formatted as 0.12.

sparsify [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.

index_names [bool, default True] Prints the names of the indexes.

bold_rows [bool, default False] Make the row labels bold in the output.

column_format [str, optional] The columns format as specified in LaTeX table format e.g. ‘rc’ for 3 columns. By default, ‘l’ will be used for all columns except columns of numbers, which default to ‘r’.

longtable [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a usepackage{longtable} to your LaTeX preamble.

escape [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to ‘utf-8’.

decimal [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

multicolumn [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.

multicolumn_format [str, default ‘l’] The alignment for multicolumns, similar to column_format. The default will be read from the config module.

multirow [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a usepackage{multirow} to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

caption [str, optional] The LaTeX caption to be placed inside \caption{} in the output.

label [str, optional] The LaTeX label to be placed inside \label{} in the output. This is used with \ref{} in the main .tex file.

Returns

str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:
Dataframe.to_string  Render a DataFrame to a console-friendly tabular output.

Dataframe.to_html  Render a DataFrame as an HTML table.

Examples

```python
def = pd.DataFrame({'name': ['Raphael', 'Donatello'],
        'mask': ['red', 'purple'],
        'weapon': ['sai', 'bo staff']})

print(df.to_latex(index=False))

\begin{tabular}{lll}
\toprule
name & mask & weapon \\
\midrule
Raphael & red & sai \\
Donatello & purple & bo staff \\
\bottomrule
\end{tabular}
```

Pandas.Series.to_list

Series.to_list()  Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:

numpy.ndarray.tolist  Return the array as an n-dim-levels deep nested list of Python scalars.

Pandas.Series.to_markdown

Series.to_markdown(buf=None, mode=None, index=True, **kwargs)  Print Series in Markdown-friendly format.

New in version 1.0.0.

Parameters

buf  [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

mode  [str, optional] Mode in which file is opened.

index  [bool, optional, default True] Add index (row) labels.

New in version 1.1.0.

**kwargs  These parameters will be passed to tabulate.

Returns

str  Series in Markdown-friendly format.
Examples

```python
>>> s = pd.Series(["elk", "pig", "dog", "quetzal"], name="animal")
>>> print(s.to_markdown())
<table>
<thead>
<tr>
<th align="right"></th>
<th align="left">animal</th>
</tr>
</thead>
<tbody>
<tr>
<td align="right">0</td>
<td align="left">elk</td>
</tr>
<tr>
<td align="right">1</td>
<td align="left">pig</td>
</tr>
<tr>
<td align="right">2</td>
<td align="left">dog</td>
</tr>
<tr>
<td align="right">3</td>
<td align="left">quetzal</td>
</tr>
</tbody>
</table>
```

Output markdown with a tabulate option.

```python
>>> print(s.to_markdown(tablefmt="grid"))
+----+----------+
|    | animal   |
|----+----------+
| 0  | elk      |
|----+----------+
| 1  | pig      |
|----+----------+
| 2  | dog      |
|----+----------+
| 3  | quetzal  |
+----+----------+
```

`pandas.Series.to_numpy`

`Series.to_numpy (dtype=None, copy=False, na_value=<object object>, **kwargs)`

A NumPy ndarray representing the values in this Series or Index.

New in version 0.24.0.

Parameters

- **dtype** [str or numpy.dtype, optional] The dtype to pass to `numpy.asarray()`.
- **copy** [bool, default False] Whether to ensure that the returned value is not a view on another array. Note that `copy=False` does not ensure that `to_numpy()` is no-copy. Rather, `copy=True` ensure that a copy is made, even if not strictly necessary.
- **na_value** [Any, optional] The value to use for missing values. The default value depends on `dtype` and the type of the array.

New in version 1.0.0.

- ****kwars** Additional keywords passed through to the `to_numpy` method of the underlying array (for extension arrays).

New in version 1.0.0.

Returns

`numpy.ndarray`

See also:

- `Series.array` Get the actual data stored within.
**Index.array**  Get the actual data stored within.

**DataFrame.to_numpy**  Similar method for DataFrame.

**Notes**

The returned array will be the same up to equality (values equal in `self` will be equal in the returned array; likewise for values that are not equal). When `self` contains an ExtensionArray, the dtype may be different. For example, for a category-dtype Series, `to_numpy()` will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming `copy=False`). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, `to_numpy()` *may* require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, `Series.array` should be used instead.

This table lays out the different dtypes and default return types of `to_numpy()` for various dtypes within pandas.

<table>
<thead>
<tr>
<th>dtype</th>
<th>array type</th>
</tr>
</thead>
<tbody>
<tr>
<td>category[T]</td>
<td>ndarray[T] (same dtype as input)</td>
</tr>
<tr>
<td>period</td>
<td>ndarray[object] (Periods)</td>
</tr>
<tr>
<td>interval</td>
<td>ndarray[object] (Intervals)</td>
</tr>
<tr>
<td>IntegerNA</td>
<td>ndarray[object]</td>
</tr>
<tr>
<td>datetime64[ns]</td>
<td>datetime64[ns]</td>
</tr>
<tr>
<td>datetime64[ns,tz]</td>
<td>ndarray[object] (Timestamps)</td>
</tr>
</tbody>
</table>

**Examples**

```python
g = pd.Series(pd.Categorical(['a', 'b', 'a']))
g.to_numpy()
array(['a', 'b', 'a'], dtype=object)
```

Specify the `dtype` to control how datetime-aware data is represented. Use `dtype=object` to return an ndarray of pandas `Timestamp` objects, each with the correct `tz`.

```python
g = pd.Series(pd.date_range('2000', periods=2, tz='CET'))
g.to_numpy(dtype=object)
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
       dtype=object)
```

Or `dtype='datetime64[ns]'` to return an ndarray of native datetime64 values. The values are converted to UTC and the timezone info is dropped.

```python
g.to_numpy(dtype='datetime64[ns]')
...  
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00...'],
       dtype='datetime64[ns]')
```
pandas.Series.to_period

Series.to_period(freq=None, copy=True)
Convert Series from DatetimeIndex to PeriodIndex.

Parameters

freq [str, default None] Frequency associated with the PeriodIndex.

copy [bool, default True] Whether or not to return a copy.

Returns

Series Series with index converted to PeriodIndex.

pandas.Series.to_pickle

Series.to_pickle(path, compression='infer', protocol=5)
Pickle (serialize) object to file.

Parameters

path [str] File path where the pickled object will be stored.

protocol [int] Int which indicates which protocol should be used by the pickler, default HIGHEST_PROTOCOL (see [1] paragraph 12.1.2). The possible values are 0, 1, 2, 3, 4. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST_PROTOCOL.

See also:

read_pickle Load pickled pandas object (or any object) from file.

DataFrame.to_hdf Write DataFrame to an HDF5 file.

DataFrame.to_sql Write DataFrame to a SQL database.

DataFrame.to_parquet Write a DataFrame to the binary parquet format.

Examples

```python
>>> original_df = pd.DataFrame({'foo': range(5), 'bar': range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> original_df.to_pickle('./dummy.pkl')

>>> unpickled_df = pd.read_pickle('./dummy.pkl')
>>> unpickled_df
   foo  bar
   0    5
   1    6
   2    7
   3    8
   4    9
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.1.5

(continued from previous page)

```python
>>> import os
>>> os.remove("./dummy.pkl")
```

**pandas.Series.to_sql**

Series.to_sql(name, con, schema=None, if_exists='fail', index=True, index_label=None, chunksize=None, dtype=None, method=None)

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [1] are supported. Tables can be newly created, appended to, or overwritten.

**Parameters**

- **name** [str] Name of SQL table.
- **con** [sqlalchemy.engine.(Engine or Connection) or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable See here.
- **schema** [str, optional] Specify the schema (if database flavor supports this). If None, use default schema.
- **if_exists** [{'fail', 'replace', 'append'}, default 'fail'] How to behave if the table already exists.
  - fail: Raise a ValueError.
  - replace: Drop the table before inserting new values.
  - append: Insert new values to the existing table.
- **index** [bool, default True] Write DataFrame index as a column. Uses index_label as the column name in the table.
- **index_label** [str or sequence, default None] Column label for index column(s). If None is given (default) and index is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- **chunksize** [int, optional] Specify the number of rows in each batch to be written at a time. By default, all rows will be written at once.
- **dtype** [dict or scalar, optional] Specifying the datatype for columns. If a dictionary is used, the keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode. If a scalar is provided, it will be applied to all columns.
- **method** [[None, ‘multi’, callable], optional] Controls the SQL insertion clause used:
  - None : Uses standard SQL INSERT clause (one per row).
  - ‘multi’: Pass multiple values in a single INSERT clause.
• callable with signature `(pd_table, conn, keys, data_iter)`.

Details and a sample callable implementation can be found in the section `insert method`.

New in version 0.24.0.

Raises

`ValueError` When the table already exists and `if_exists` is ‘fail’ (the default).

See also:

`read_sql` Read a DataFrame from a table.

Notes

Timezone aware datetime columns will be written as `Timestamp with timezone` type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

New in version 0.24.0.

References

[1], [2]

Examples

Create an in-memory SQLite database.

```python
>>> from sqlalchemy import create_engine

>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```python
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
   name
0  User 1
1  User 2
2  User 3

>>> df.to_sql('users', con=engine)
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

An `sqlalchemy.engine.Connection` can also be passed to `con`: >>> with engine.begin() as connection: ... df1 = pd.DataFrame({'name': ['User 4', 'User 5']}) ... df1.to_sql('users', con=connection, if_exists='append')

This is allowed to support operations that require that the same DBAPI connection is used for the entire operation.
Overwrite the table with just df2.

```python
>>> df2.to_sql('users', con=engine, if_exists='replace',
... index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 6'), (1, 'User 7')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```python
>>> df = pd.DataFrame({"A": [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0
```

```python
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
... dtype={"A": Integer()})
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

**pandas.Series.to_string**

Series.to_string(buf=None, na_rep='NaN', float_format=None, header=True, index=True,
length=False, dtype=False, name=False, max_rows=None, min_rows=None)

Render a string representation of the Series.

**Parameters**

- `buf` [StringIO-like, optional] Buffer to write to.
- `float_format` [one-parameter function, optional] Formatter function to apply to columns’ elements if they are floats, default None.
- `header` [bool, default True] Add the Series header (index name).
- `index` [bool, optional] Add index (row) labels, default True.
- `length` [bool, default False] Add the Series length.
- `dtype` [bool, default False] Add the Series dtype.
- `name` [bool, default False] Add the Series name if not None.
- `max_rows` [int, optional] Maximum number of rows to show before truncating. If None, show all.
min_rows [int, optional] The number of rows to display in a truncated repr (when number of rows is above max_rows).

Returns

str or None String representation of Series if buf=None, otherwise None.

pandas.Series.to_timestamp

Series.to_timestamp (freq=None, how='start', copy=True) Cast to DatetimeIndex of Timestamps, at beginning of period.

Parameters

freq [str, default frequency of PeriodIndex] Desired frequency.

how ['s', 'e', 'start', 'end'] Convention for converting period to timestamp; start of period vs. end.

copy [bool, default True] Whether or not to return a copy.

Returns

Series with DatetimeIndex

pandas.Series.to_xarray

Series.to_xarray () Return an xarray object from the pandas object.

Returns

xarray.DataArray or xarray.Dataset Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

See also:

Dataframe.to_hdf Write DataFrame to an HDF5 file.

Dataframe.to_parquet Write a DataFrame to the binary parquet format.

Notes

See the xarray docs

Examples

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0, 2),
...     ('parrot', 'bird', 24.0, 2),
...     ('lion', 'mammal', 80.5, 4),
...     ('monkey', 'mammal', np.nan, 4)],
...     columns=['name', 'class', 'max_speed',
...     'num_legs'])
```

(continues on next page)
1 parrot bird 24.0 2
2 lion mammal 80.5 4
3 monkey mammal NaN 4

```python
>>> df.to_xarray()
<xarray.Dataset>
Dimensions: (index: 4)
Coordinates:
* index (index) int64 0 1 2 3
Data variables:
    name (index) object 'falcon' 'parrot' 'lion' 'monkey'
    class (index) object 'bird' 'bird' 'mammal' 'mammal'
    max_speed (index) float64 389.0 24.0 80.5 nan
    num_legs (index) int64 2 2 4 4

>>> df['max_speed'].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389., 24., 80.5, nan])
Coordinates:
* index (index) int64 0 1 2 3

>>> dates = pd.to_datetime(['2018-01-01', '2018-01-01', ... '2018-01-02', '2018-01-02'])
>>> df_multiindex = pd.DataFrame({'date': dates, ... 'animal': ['falcon', 'parrot', ... 'falcon', 'parrot'], ... 'speed': [350, 18, 361, 15]})
>>> df_multiindex.set_index(['date', 'animal'])

>>> df_multiindex
speed
date    animal
2018-01-01  falcon   350
          parrot     18
2018-01-02  falcon   361
          parrot     15

>>> df_multiindex.to_xarray()
<xarray.Dataset>
Dimensions: (animal: 2, date: 2)
Coordinates:
* date (date) datetime64[ns] 2018-01-01 2018-01-02
* animal (animal) object 'falcon' 'parrot'
Data variables:
    speed  (date, animal) int64 350 18 361 15
pandas.Series.tolist

Series.tolist()  
Return a list of the values.  
These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)  

Returns  
list  
See also:  

numpy.ndarray.tolist  Return the array as an andim-levels deep nested list of Python scalars.

pandas.Series.transform

Series.transform(func, axis=0, *args, **kwargs)  
Call func on self producing a Series with transformed values.  
Produced Series will have same axis length as self.  

Parameters  

func  [function, str, list or dict] Function to use for transforming the data. If a function, must either work when passed a Series or when passed to Series.apply.  
Accepted combinations are:  
• function  
• string function name  
• list of functions and/or function names, e.g. [np.exp, 'sqrt']  
• dict of axis labels -> functions, function names or list of such.  

axis  [[0 or 'index']] Parameter needed for compatibility with DataFrame.  

*args  Positional arguments to pass to func.  

**kwargs  Keyword arguments to pass to func.  

Returns  
Series  A Series that must have the same length as self.  

Raises  

ValueError  [If the returned Series has a different length than self.]  

See also:  

Series.agg  Only perform aggregating type operations.  

Series.apply  Invoke function on a Series.
Examples

```python
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
   A  B
0  0  1
1  1  2
2  2  3

>>> df.transform(lambda x: x + 1)
   A  B
0  1  2
1  2  3
2  3  4
```

Even though the resulting Series must have the same length as the input Series, it is possible to provide several input functions:

```python
>>> s = pd.Series(range(3))
>>> s
0  0
1  1
2  2
dtype: int64

>>> s.transform([np.sqrt, np.exp])
          sqrt        exp
   0  0.000000  1.000000
   1  1.000000  2.718282
   2  1.414214  7.389056
```

**pandas.Series.transpose**

Series.transpose(*args, **kwargs)

Return the transpose, which is by definition self.

Returns

%(klass)s

**pandas.Series.truediv**

Series.truediv(other, level=None, fill_value=None, axis=0)

Return Floating division of series and other, element-wise (binary operator truediv).

Equivalent to series / other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.
Returns

Series  The result of the operation.

See also:

Series.rtruediv  Reverse of the Floating division operator, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a 1.0
b inf
c inf
d 0.0
e NaN
dtype: float64
```

pandas.Series.truncate

Series.truncate(before=None, after=None, axis=None, copy=True)

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

Parameters

- **before** [date, str, int] Truncate all rows before this index value.
- **after** [date, str, int] Truncate all rows after this index value.
- **axis** [[0 or ‘index’, 1 or ‘columns’], optional] Axis to truncate. Truncates the index (rows) by default.
- **copy** [bool, default is True] Return a copy of the truncated section.

Returns

- **type of caller**  The truncated Series or DataFrame.

See also:

DataFrame.loc  Select a subset of a DataFrame by label.
**DataFrame.iloc** Select a subset of a DataFrame by position.

**Notes**

If the index being truncated contains only datetime values, `before` and `after` may be specified as strings instead of Timestamps.

**Examples**

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
...                    'B': ['f', 'g', 'h', 'i', 'j'],
...                    'C': ['k', 'l', 'm', 'n', 'o']},
...                   index=[1, 2, 3, 4, 5])
>>> df
   A  B  C
1  a  f  k
2  b  g  l
3  c  h  m
4  d  i  n
5  e  j  o
```

```python
>>> df.truncate(before=2, after=4)
   A  B  C
2  b  g  l
3  c  h  m
4  d  i  n
```

The columns of a DataFrame can be truncated.

```python
>>> df.truncate(before="A", after="B", axis="columns")
   A  B
1  a  f
2  b  g
3  c  h
4  d  i
5  e  j
```

For Series, only rows can be truncated.

```python
>>> df['A'].truncate(before=2, after=4)
2  b
3  c
4  d
Name: A, dtype: object
```

The index values in `truncate` can be datetimes or string dates.

```python
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
---
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
A
2016-01-31 23:59:56 1
2016-01-31 23:59:57 1
2016-01-31 23:59:58 1
```

(continues on next page)
Because the index is a DatetimeIndex containing only dates, we can specify `before` and `after` as strings. They will be coerced to Timestamps before truncation.

```
>>> df.truncate('2016-01-05', '2016-01-10').tail()
A
2016-01-09 23:59:56 1
2016-01-09 23:59:57 1
2016-01-09 23:59:58 1
2016-01-09 23:59:59 1
2016-01-10 00:00:00 1
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
A
2016-01-10 23:59:55 1
2016-01-10 23:59:56 1
2016-01-10 23:59:57 1
2016-01-10 23:59:58 1
2016-01-10 23:59:59 1
```

### pandas.Series.tshift

`Series.tshift(periods=1, freq=None, axis=0)`

Shift the time index, using the index’s frequency if available.

Deprecated since version 1.1.0: Use `shift` instead.

**Parameters**

- `periods` [int] Number of periods to move, can be positive or negative.
- `freq` [DateOffset, timedelta, or str, default None] Increment to use from the tseries module or time rule expressed as a string (e.g. ‘EOM’).
- `axis` [0 or ‘index’, 1 or ‘columns’, None, default 0] Corresponds to the axis that contains the Index.

**Returns**

- `shifted` [Series/DataFrame]
Notes

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown.

**pandas.Series.tz_convert**

```python
Series.tz_convert (tz, axis=0, level=None, copy=True)
```

Convert tz-aware axis to target time zone.

**Parameters**

- `tz` [str or tzinfo object]
- `axis` [the axis to convert]
- `level` [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None.
- `copy` [bool, default True] Also make a copy of the underlying data.

**Returns**

- `{klass}` Object with time zone converted axis.

**Raises**

- `TypeError` If the axis is tz-naive.

**pandas.Series.tz_localize**

```python
Series.tz_localize (tz, axis=0, level=None, copy=True, ambiguous='raise', nonexistent='raise')
```

Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use `Series.dt.tz_localize()`.

**Parameters**

- `tz` [str or tzinfo]
- `axis` [the axis to localize]
- `level` [int, str, default None] If axis ia a MultiIndex, localize a specific level. Otherwise must be None.
- `copy` [bool, default True] Also make a copy of the underlying data.
- `ambiguous` ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the `ambiguous` parameter dictates how ambiguous times should be handled.
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.
nonexistent [str, default ‘raise’] A nonexistent time does not exist in a particular time-zone where clocks moved forward due to DST. Valid values are:

- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

Series or DataFrame  Same type as the input.

Raises

TypeError  If the TimeSeries is tz-aware and tz is not None.

Examples

Localize local times:

```python
>>> s = pd.Series([1],
...                index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00  1
```

dtype: int64

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```python
>>> s = pd.Series(range(7),
...                index=pd.DatetimeIndex(['2018-10-28 01:30:00',
...                                          '2018-10-28 02:00:00',
...                                          '2018-10-28 02:30:00',
...                                          '2018-10-28 02:00:00',
...                                          '2018-10-28 02:30:00',
...                                          '2018-10-28 03:00:00',
...                                          '2018-10-28 03:30:00']))
```

```python
>>> s.tz_localize('CET', ambiguous='infer')
2018-10-28 01:30:00+02:00  0
2018-10-28 02:00:00+02:00  1
2018-10-28 02:30:00+02:00  2
2018-10-28 02:00:00+01:00  3
2018-10-28 02:30:00+01:00  4
2018-10-28 03:00:00+01:00  5
2018-10-28 03:30:00+01:00  6
```

dtype: int64

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly

```python
>>> s = pd.Series(range(7),
...                index=pd.DatetimeIndex(['2018-10-28 01:30:00',
...                                          '2018-10-28 02:00:00',
...                                          '2018-10-28 02:30:00',
...                                          '2018-10-28 02:00:00',
...                                          '2018-10-28 02:30:00',
...                                          '2018-10-28 03:00:00',
...                                          '2018-10-28 03:30:00']))
```

```python
>>> s.tz_localize('CET', ambiguous=['infer',
...                                           'infer',
...                                           'infer',
...                                           'infer',
...                                           'infer',
...                                           'infer',
...                                           'infer'])
2018-10-28 01:30:00+02:00  0
2018-10-28 02:00:00+02:00  1
2018-10-28 02:30:00+02:00  2
2018-10-28 02:00:00+01:00  3
2018-10-28 02:30:00+01:00  4
2018-10-28 03:00:00+01:00  5
2018-10-28 03:30:00+01:00  6
```

dtype: int64

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly

3.3. Series

1245
>>> s = pd.Series(range(3),
...     index=pd.DatetimeIndex(['2018-10-28 01:20:00',
...     '2018-10-28 02:36:00',
...     '2018-10-28 03:46:00']))
>>> s.tz_localize('CET', ambiguous=np.array([True, True, False]))
2018-10-28 01:20:00+02:00 0
2018-10-28 02:36:00+02:00 1
2018-10-28 03:46:00+01:00 2
dtype: int64

If the DST transition causes nonexistent times, you can shift these dates forward or backward with a timedelta object or 'shift_forward' or 'shift_backward'.

>>> s = pd.Series(range(2),
...     index=pd.DatetimeIndex(['2015-03-29 02:30:00',
...     '2015-03-29 03:30:00']))
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
2015-03-29 03:00:00+02:00 0
2015-03-29 03:30:00+02:00 1
dtype: int64
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
2015-03-29 01:59:59.999999999+01:00 0
2015-03-29 03:30:00+02:00 1
dtype: int64
>>> s.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
2015-03-29 03:30:00+02:00 0
2015-03-29 03:30:00+02:00 1
dtype: int64

pandas.Series.unique

Series.unique()
Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

Returns

   ndarray or ExtensionArray  The unique values returned as a NumPy array.  See Notes.

See also:

unique  Top-level unique method for any 1-d array-like object.

Index.unique  Return Index with unique values from an Index object.
Notes

Returns the unique values as a NumPy array. In case of an extension-array backed Series, a new `ExtensionArray` of that type with just the unique values is returned. This includes

- Categorical
- Period
- Datetime with Timezone
- Interval
- Sparse
- IntegerNA

See Examples section.

Examples

```python
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])

>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')

>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern') ... for _ in range(3)]).unique()
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]

An unordered Categorical will return categories in the order of appearance.

```python
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
['b', 'a', 'c']
Categories (3, object): ['b', 'a', 'c']
```  

An ordered Categorical preserves the category ordering.

```python
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'), ... ordered=True)).unique()
['b', 'a', 'c']
Categories (3, object): ['a' < 'b' < 'c']
```  

`pandas.Series.unstack`

`Series.unstack(level=-1, fill_value=None)`

Unstack, also known as pivot, Series with MultiIndex to produce DataFrame.

Parameters

- **level** [int, str, or list of these, default last level] Level(s) to unstack, can pass level name.
- **fill_value** [scalar value, default None] Value to use when replacing NaN values.

Returns
DataFrame  Unstacked Series.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4],
    index=pd.MultiIndex.from_product([['one', 'two'], ['a', 'b']]))

>>> s
one a 1
   b 2
two a 3
   b 4
dtype: int64

>>> s.unstack(level=-1)
   a  b
one 1  2
two 3  4

>>> s.unstack(level=0)
   one  two
   a  1  3
   b  2  4
```

pandas.Series.update

Series.update(other)
Modify Series in place using values from passed Series.
Uses non-NA values from passed Series to make updates. Aligns on index.

Parameters
- other [Series, or object coercible into Series]

Examples

```python
>>> s = pd.Series([1, 2, 3])

>>> s.update(pd.Series([4, 5, 6]))

>>> s
0 4
1 5
2 6
dtype: int64

>>> s = pd.Series(['a', 'b', 'c'])

>>> s.update(pd.Series(['d', 'e'], index=[0, 2]))

>>> s
0 d
1 b
2 e
dtype: object
```
```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6, 7, 8]))
>>> s
0    4
1    5
2    6
dtype: int64
```

If `other` contains NaNs the corresponding values are not updated in the original Series.

```
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, np.nan, 6]))
>>> s
0    4
1    2
2    6
dtype: int64
```

`other` can also be a non-Series object type that is coercible into a Series

```
>>> s = pd.Series([1, 2, 3])
>>> s.update([4, np.nan, 6])
>>> s
0    4
1    2
2    6
dtype: int64
```

```
>>> s = pd.Series([1, 2, 3])
>>> s.update({1: 9})
>>> s
0    1
1    9
2    3
dtype: int64
```

**pandas.Series.value_counts**

Series.value_counts(normalize=False, sort=True, ascending=False, bins=None, dropna=True)

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

**Parameters**

- `normalize` [bool, default False] If True then the object returned will contain the relative frequencies of the unique values.
- `sort` [bool, default True] Sort by frequencies.
- `ascending` [bool, default False] Sort in ascending order.
- `bins` [int, optional] Rather than count values, group them into half-open bins, a convenience for pd.cut, only works with numeric data.
- `dropna` [bool, default True] Don’t include counts of NaN.
Returns

Series

See also:

*Series.count* Number of non-NA elements in a Series.

*DataFrame.count* Number of non-NA elements in a DataFrame.

*DataFrame.value_counts* Equivalent method on DataFrames.

Examples

```python
>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0    2
4.0    1
2.0    1
1.0    1
dtype: int64
```

With `normalize` set to `True`, returns the relative frequency by dividing all values by the sum of values.

```python
>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0    0.4
4.0    0.2
2.0    0.2
1.0    0.2
dtype: float64
```

**bins**

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.

```python
>>> s.value_counts(bins=3)
(2.0, 3.0]    2
(0.996, 2.0]   2
(3.0, 4.0]    1
dtype: int64
```

**dropna**

With `dropna` set to `False` we can also see NaN index values.

```python
>>> s.value_counts(dropna=False)
3.0    2
NaN    1
4.0    1
2.0    1
1.0    1
dtype: int64
```
pandas.Series.var

Series.var(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)
Return unbiased variance over requested axis.
Normalized by N-1 by default. This can be changed using the ddof argument

Parameters

axis [[index (0)]]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns
scalar or Series (if level specified)

pandas.Series.view

Series.view(dtype=None)
Create a new view of the Series.
This function will return a new Series with a view of the same underlying values in memory, optionally reinterpreted with a new data type. The new data type must preserve the same size in bytes as to not cause index misalignment.

Parameters

dtype [data type] Data type object or one of their string representations.

Returns

Series A new Series object as a view of the same data in memory.

See also:

numpy.ndarray.view Equivalent numpy function to create a new view of the same data in memory.

Notes

Series are instantiated with dtype=float64 by default. While numpy.ndarray.view() will return a view with the same data type as the original array, Series.view() (without specified dtype) will try using float64 and may fail if the original data type size in bytes is not the same.
Examples

```python
>>> s = pd.Series([-2, -1, 0, 1, 2], dtype='int8')
>>> s
0 -2
1 -1
2  0
3  1
4  2
dtype: int8
```

The 8 bit signed integer representation of -1 is `0b11111111`, but the same bytes represent 255 if read as an 8 bit unsigned integer:

```python
>>> us = s.view('uint8')
>>> us
0 254
1 255
2  0
3  1
4  2
dtype: uint8
```

The views share the same underlying values:

```python
>>> us[0] = 128
>>> s
0 -128
1  -1
2   0
3   1
4   2
dtype: int8
```

**pandas.Series.where**

`Series.where(cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False)`

Replace values where the condition is False.

**Parameters**

- **cond** [bool Series/DataFrame, array-like, or callable] Where `cond` is True, keep the original value. Where False, replace with corresponding value from `other`. If `cond` is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

- **other** [scalar, Series/DataFrame, or callable] Entries where `cond` is False are replaced with corresponding value from `other`. If other is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

- **inplace** [bool, default False] Whether to perform the operation in place on the data.

- **axis** [int, default None] Alignment axis if needed.

- **level** [int, default None] Alignment level if needed.
**errors** [str, {'raise', 'ignore'}, default ‘raise’] Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.

- ‘raise’ : allow exceptions to be raised.
- ‘ignore’ : suppress exceptions. On error return original object.

**try_cast** [bool, default False] Try to cast the result back to the input type (if possible).

**Returns**

Same type as caller

**See also:**

*DataFrame.mask()* Return an object of same shape as self.

**Notes**

The where method is an application of the if-then idiom. For each element in the calling DataFrame, if *cond* is True the element is used; otherwise the corresponding element from the DataFrame *other* is used.

The signature for *DataFrame.where()* differs from *numpy.where()*.

```
>>> df1.where(m, df2)
```

is equivalent to

```
np.where(m, df1, df2)
```

For further details and examples see the where documentation in *indexing*.

**Examples**

```
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

```
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```
>>> s.where(s > 1, 10)
0    10
1    10
2    2
3    3
4    4
dtype: int64
```
```python
df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
df
A  B
0 0 1
1 2 3
2 4 5
3 6 7
4 8 9
m = df % 3 == 0
df.where(m, -df)
A  B
0 0 -1
1 -2 3
2 -4 -5
3 6 -7
4 -8 9
df.where(m, -df) == np.where(m, df, -df)
A  B
0 True True
1 True True
2 True True
3 True True
4 True True
df.where(m, -df) == df.mask(~m, -df)
A  B
0 True True
1 True True
2 True True
3 True True
4 True True
```

**pandas.Series.xs**

`Series.xs(key, axis=0, level=None, drop_level=True)`  
Return cross-section from the Series/DataFrame.

This method takes a `key` argument to select data at a particular level of a MultiIndex.

**Parameters**

- **key** [label or tuple of label] Label contained in the index, or partially in a MultiIndex.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis to retrieve cross-section on.
- **level** [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.
- **drop_level** [bool, default True] If False, returns object with same levels as self.

**Returns**

Series or DataFrame  Cross-section from the original Series or DataFrame corresponding to the selected index levels.

**See also:**

DataFrame.loc  Access a group of rows and columns by label(s) or a boolean array.
**Dataframe.iloc** Purely integer-location based indexing for selection by position.

**Notes**

*xs* can not be used to set values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of *xs* functionality, see *MultiIndex Slicers*.

**Examples**

```python
>>> d = {'num_legs': [4, 4, 2, 2],
...     'num_wings': [0, 0, 2, 2],
...     'class': ['mammal', 'mammal', 'mammal', 'bird'],
...     'animal': ['cat', 'dog', 'bat', 'penguin'],
...     'locomotion': ['walks', 'walks', 'flies', 'walks']}
>>> df = pd.DataFrame(data=d)
>>> df = df.set_index(['class', 'animal', 'locomotion'])
>>> df
   num_legs  num_wings
class animal locomotion
  mammal  cat walks  4  0
          dog walks  4  0
          bat flies  2  2
  bird    penguin walks  2  2
```

Get values at specified index

```python
>>> df.xs('mammal')
   num_legs  num_wings
animal locomotion
  cat walks  4  0
  dog walks  4  0
  bat flies  2  2
```

Get values at several indexes

```python
>>> df.xs(('mammal', 'dog'))
   num_legs  num_wings
locomotion
  walks  4  0
```

Get values at specified index and level

```python
>>> df.xs('cat', level=1)
   num_legs  num_wings
class locomotion
  mammal walks  4  0
```

Get values at several indexes and levels

```python
>>> df.xs(('bird', 'walks'),
...        level=[0, 'locomotion'])
   num_legs  num_wings
animal
  penguin  2  2
```
Get values at specified column and axis

```python
>>> df.xs('num_wings', axis=1)
class  animal  locomotion
mammal cat walks 0
dog walks 0
bat flies  2
bird penguin walks 2
Name: num_wings, dtype: int64
```

### 3.3.2 Attributes

#### Axes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.index</code></td>
<td>The index (axis labels) of the Series.</td>
</tr>
<tr>
<td><code>Series.array</code></td>
<td>The ExtensionArray of the data backing this Series or Index.</td>
</tr>
<tr>
<td><code>Series.values</code></td>
<td>Return Series as ndarray or ndarray-like depending on the dtype.</td>
</tr>
<tr>
<td><code>Series.dtype</code></td>
<td>Return the dtype object of the underlying data.</td>
</tr>
<tr>
<td><code>Series.shape</code></td>
<td>Return a tuple of the shape of the underlying data.</td>
</tr>
<tr>
<td><code>Series.nbytes</code></td>
<td>Return the number of bytes in the underlying data.</td>
</tr>
<tr>
<td><code>Series.ndim</code></td>
<td>Number of dimensions of the underlying data, by definition 1.</td>
</tr>
<tr>
<td><code>Series.size</code></td>
<td>Return the number of elements in the underlying data.</td>
</tr>
<tr>
<td><code>Series.T</code></td>
<td>Return the transpose, which is by definition self.</td>
</tr>
<tr>
<td><code>Series.memory_usage([index, deep])</code></td>
<td>Return the memory usage of the Series.</td>
</tr>
<tr>
<td><code>Series.hasnans</code></td>
<td>Return if I have any nans; enables various perf speedups.</td>
</tr>
<tr>
<td><code>Series.empty</code></td>
<td>Indicator whether DataFrame is empty.</td>
</tr>
<tr>
<td><code>Series.dtypes</code></td>
<td>Return the dtype object of the underlying data.</td>
</tr>
<tr>
<td><code>Series.name</code></td>
<td>Return the name of the Series.</td>
</tr>
</tbody>
</table>

#### `pandas.Series.empty`

**property Series.empty**

Indicator whether DataFrame is empty.

- **Returns**
  - `bool` If DataFrame is empty, return True, if not return False.

**See also:**

- `Series.dropna` Return series without null values.
- `DataFrame.dropna` Return DataFrame with labels on given axis omitted where (all or any) data are missing.
Notes

If DataFrame contains only NaNs, it is still not considered empty. See the example below.

Examples

An example of an actual empty DataFrame. Notice the index is empty:

```python
>>> df_empty = pd.DataFrame({'A' : []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []
>>> df_empty.empty
True
```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```python
>>> df = pd.DataFrame({'A' : [np.nan]})
>>> df
   A
0 NaN
>>> df.empty
False
>>> df.dropna().empty
True
```

3.3.3 Conversion

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.astype</code></td>
<td>Cast a pandas object to a specified dtype <code>dtype</code>.</td>
</tr>
<tr>
<td><code>Series.convert_dtypes</code></td>
<td>Convert columns to best possible dtypes using dtypes supporting <code>pd.NA</code>.</td>
</tr>
<tr>
<td><code>Series.infer_objects</code></td>
<td>Attempt to infer better dtypes for object columns.</td>
</tr>
<tr>
<td><code>Series.copy</code></td>
<td>Make a copy of this object's indices and data.</td>
</tr>
<tr>
<td><code>Series.bool</code></td>
<td>Return the bool of a single element Series or DataFrame.</td>
</tr>
<tr>
<td><code>Series.to_numpy</code></td>
<td>A NumPy ndarray representing the values in this Series or Index.</td>
</tr>
<tr>
<td><code>Series.to_period</code></td>
<td>Convert Series from DatetimeIndex to PeriodIndex.</td>
</tr>
<tr>
<td><code>Series.to_timestamp</code></td>
<td>Cast to DatetimeIndex of Timestamps, at <code>beginning</code> of period.</td>
</tr>
<tr>
<td><code>Series.to_list</code></td>
<td>Return a list of the values.</td>
</tr>
<tr>
<td><code>Series.__array__</code></td>
<td>Return the values as a NumPy array.</td>
</tr>
</tbody>
</table>
pandas.Series.__array__

Series.__array__(dtype=None)
Return the values as a NumPy array.

Users should not call this directly. Rather, it is invoked by numpy.array() and numpy.asarray().

Parameters

dtype [str or numpy.dtype, optional] The dtype to use for the resulting NumPy array. By
default, the dtype is inferred from the data.

Returns

numpy.ndarray The values in the series converted to a numpy.ndarray with the specified dtype.

See also:

array Create a new array from data.
Series.array Zero-copy view to the array backing the Series.
Series.to_numpy Series method for similar behavior.

Examples

```python
>>> ser = pd.Series([1, 2, 3])
>>> np.asarray(ser)
array([1, 2, 3])
```

For timezone-aware data, the timezones may be retained with dtype='object'

```python
>>> tzser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> np.asarray(tzser, dtype="object")
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
      Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
```

Or the values may be localized to UTC and the tzinfo discarded with dtype='datetime64[ns]'

```python
>>> np.asarray(tzser, dtype="datetime64[ns]")
array(['1999-12-31T23:00:00.000000000', ...],
      dtype='datetime64[ns]')
```

3.3.4 Indexing, iteration

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.get(key[, default])</td>
<td>Get item from object for given key (ex: DataFrame column).</td>
</tr>
<tr>
<td>Series.at</td>
<td>Access a single value for a row/column label pair.</td>
</tr>
<tr>
<td>Series.iat</td>
<td>Access a single value for a row/column pair by integer position.</td>
</tr>
<tr>
<td>Series.loc</td>
<td>Access a group of rows and columns by label(s) or a boolean array.</td>
</tr>
<tr>
<td>Series.iloc</td>
<td>Purely integer-location based indexing for selection by position.</td>
</tr>
<tr>
<td>Series.<strong>iter</strong>()</td>
<td>Return an iterator of the values.</td>
</tr>
</tbody>
</table>
Table 33 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.items()</code></td>
<td>Lazily iterate over (index, value) tuples.</td>
</tr>
<tr>
<td><code>Series.iteritems()</code></td>
<td>Lazily iterate over (index, value) tuples.</td>
</tr>
<tr>
<td><code>Series.keys()</code></td>
<td>Return alias for index.</td>
</tr>
<tr>
<td><code>Series.pop(item)</code></td>
<td>Return item and drops from series.</td>
</tr>
<tr>
<td><code>Series.item()</code></td>
<td>Return the first element of the underlying data as a python scalar.</td>
</tr>
<tr>
<td><code>Series.xs(key[, axis, level, drop_level])</code></td>
<td>Return cross-section from the Series/DataFrame.</td>
</tr>
</tbody>
</table>

**pandas.Series.__iter__**

Series.__iter__()  

Return an iterator of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

**Returns**  

iterator

For more information on .at, .iat, .loc, and .iloc, see the indexing documentation.

### 3.3.5 Binary operator functions

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.add(other[, level, fill_value, axis])</code></td>
<td>Return Addition of series and other, element-wise (binary operator add).</td>
</tr>
<tr>
<td><code>Series.sub(other[, level, fill_value, axis])</code></td>
<td>Return Subtraction of series and other, element-wise (binary operator sub).</td>
</tr>
<tr>
<td><code>Series.mul(other[, level, fill_value, axis])</code></td>
<td>Return Multiplication of series and other, element-wise (binary operator mul).</td>
</tr>
<tr>
<td><code>Series.div(other[, level, fill_value, axis])</code></td>
<td>Return Floating division of series and other, element-wise (binary operator truediv).</td>
</tr>
<tr>
<td><code>Series.truediv(other[, level, fill_value, axis])</code></td>
<td>Return Floating division of series and other, element-wise (binary operator truediv).</td>
</tr>
<tr>
<td><code>Series.floordiv(other[, level, fill_value, axis])</code></td>
<td>Return Integer division of series and other, element-wise (binary operator floordiv).</td>
</tr>
<tr>
<td><code>Series.mod(other[, level, fill_value, axis])</code></td>
<td>Return Modulo of series and other, element-wise (binary operator mod).</td>
</tr>
<tr>
<td><code>Series.pow(other[, level, fill_value, axis])</code></td>
<td>Return Exponential power of series and other, element-wise (binary operator pow).</td>
</tr>
<tr>
<td><code>Series.radd(other[, level, fill_value, axis])</code></td>
<td>Return Addition of series and other, element-wise (binary operator radd).</td>
</tr>
<tr>
<td><code>Series.rsub(other[, level, fill_value, axis])</code></td>
<td>Return Subtraction of series and other, element-wise (binary operator rsub).</td>
</tr>
<tr>
<td><code>Series.rmul(other[, level, fill_value, axis])</code></td>
<td>Return Multiplication of series and other, element-wise (binary operator rsub).</td>
</tr>
<tr>
<td><code>Series.rdiv(other[, level, fill_value, axis])</code></td>
<td>Return Floating division of series and other, element-wise (binary operator rtruediv).</td>
</tr>
<tr>
<td><code>Series.rtruediv(other[, level, fill_value, axis])</code></td>
<td>Return Floating division of series and other, element-wise (binary operator rtruediv).</td>
</tr>
</tbody>
</table>

continues on next page
Table 34 – continued from previous page

<table>
<thead>
<tr>
<th>Function call</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.rfloordiv(other[, level, fill_value, ...])</code></td>
<td>Return Integer division of series and other, element-wise (binary operator <code>rfloordiv</code>).</td>
</tr>
<tr>
<td><code>Series.rmod(other[, level, fill_value, axis])</code></td>
<td>Return Modulo of series and other, element-wise (binary operator <code>rmod</code>).</td>
</tr>
<tr>
<td><code>Series.rpow(other[, level, fill_value, axis])</code></td>
<td>Return Exponential power of series and other, element-wise (binary operator <code>rpow</code>).</td>
</tr>
<tr>
<td><code>Series.combine(other, func[, fill_value])</code></td>
<td>Combine the Series with a Series or scalar according to <code>func</code>.</td>
</tr>
<tr>
<td><code>Series.combine_first(other)</code></td>
<td>Combine Series values, choosing the calling Series’s values first.</td>
</tr>
<tr>
<td><code>Series.round([decimals])</code></td>
<td>Round each value in a Series to the given number of decimals.</td>
</tr>
<tr>
<td><code>Series.lt(other[, level, fill_value, axis])</code></td>
<td>Return Less than of series and other, element-wise (binary operator <code>lt</code>).</td>
</tr>
<tr>
<td><code>Series.gt(other[, level, fill_value, axis])</code></td>
<td>Return Greater than of series and other, element-wise (binary operator <code>gt</code>).</td>
</tr>
<tr>
<td><code>Series.le(other[, level, fill_value, axis])</code></td>
<td>Return Less than or equal to of series and other, element-wise (binary operator <code>le</code>).</td>
</tr>
<tr>
<td><code>Series.ge(other[, level, fill_value, axis])</code></td>
<td>Return Greater than or equal to of series and other, element-wise (binary operator <code>ge</code>).</td>
</tr>
<tr>
<td><code>Series.ne(other[, level, fill_value, axis])</code></td>
<td>Return Not equal to of series and other, element-wise (binary operator <code>ne</code>).</td>
</tr>
<tr>
<td><code>Series.eq(other[, level, fill_value, axis])</code></td>
<td>Return Equal to of series and other, element-wise (binary operator <code>eq</code>).</td>
</tr>
<tr>
<td><code>Series.product([axis, skipna, level, ...])</code></td>
<td>Return the product of the values for the requested axis.</td>
</tr>
<tr>
<td><code>Series.dot(other)</code></td>
<td>Compute the dot product between the Series and the columns of other.</td>
</tr>
</tbody>
</table>

3.3.6 Function application, GroupBy & window

<table>
<thead>
<tr>
<th>Function call</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.apply(func[, convert_dtypes, args])</code></td>
<td>Invoke function on values of Series.</td>
</tr>
<tr>
<td><code>Series.agg([func, axis])</code></td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td><code>Series.aggregate([func, axis])</code></td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td><code>Series.transform(func[, axis])</code></td>
<td>Call <code>func</code> on self producing a Series with transformed values.</td>
</tr>
<tr>
<td><code>Series.map(arg[, na_action])</code></td>
<td>Map values of Series according to input correspondence.</td>
</tr>
<tr>
<td><code>Series.groupby([by, axis, level, as_index, ...])</code></td>
<td>Group Series using a mapper or by a Series of columns.</td>
</tr>
<tr>
<td><code>Series.rolling(window[, min_periods, ...])</code></td>
<td>Provide rolling window calculations.</td>
</tr>
<tr>
<td><code>Series.expanding([min_periods, center, axis])</code></td>
<td>Provide expanding transformations.</td>
</tr>
<tr>
<td><code>Series.ewm([com, span, halflife, alpha, ...])</code></td>
<td>Provide exponential weighted (EW) functions.</td>
</tr>
</tbody>
</table>
| `Series.pipe(func, *args, **kwargs)` | Apply `func(self, *args, **kwargs)`.
### 3.3.7 Computations / descriptive stats

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.abs()</td>
<td>Return a Series/DataFrame with absolute numeric value of each element.</td>
</tr>
<tr>
<td>Series.all(...)</td>
<td>Return whether all elements are True, potentially over an axis.</td>
</tr>
<tr>
<td>Series.any(...)</td>
<td>Return whether any element is True, potentially over an axis.</td>
</tr>
<tr>
<td>Series.autocorr(...)</td>
<td>Compute the lag-N autocorrelation.</td>
</tr>
<tr>
<td>Series.between(...)</td>
<td>Return boolean Series equivalent to left &lt;= series &lt;= right.</td>
</tr>
<tr>
<td>Series.clip(...)</td>
<td>Trim values at input threshold(s).</td>
</tr>
<tr>
<td>Series.corr(...)</td>
<td>Compute correlation with other Series, excluding missing values.</td>
</tr>
<tr>
<td>Series.count(...)</td>
<td>Return number of non-NA/null observations in the Series.</td>
</tr>
<tr>
<td>Series.cov(...)</td>
<td>Compute covariance with Series, excluding missing values.</td>
</tr>
<tr>
<td>Series.cummax(...)</td>
<td>Return cumulative maximum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td>Series.cummin(...)</td>
<td>Return cumulative minimum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td>Series.cumprod(...)</td>
<td>Return cumulative product over a DataFrame or Series axis.</td>
</tr>
<tr>
<td>Series.cumsum(...)</td>
<td>Return cumulative sum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td>Series.describe(...)</td>
<td>Generate descriptive statistics.</td>
</tr>
<tr>
<td>Series.diff(...)</td>
<td>First discrete difference of element.</td>
</tr>
<tr>
<td>Series.factorize(...)</td>
<td>Encode the object as an enumerated type or categorical variable.</td>
</tr>
<tr>
<td>Series.kurt(...)</td>
<td>Return unbiased kurtosis over requested axis.</td>
</tr>
<tr>
<td>Series.mad(...)</td>
<td>Return the mean absolute deviation of the values for the requested axis.</td>
</tr>
<tr>
<td>Series.max(...)</td>
<td>Return the maximum of the values for the requested axis.</td>
</tr>
<tr>
<td>Series.median(...)</td>
<td>Return the median of the values for the requested axis.</td>
</tr>
<tr>
<td>Series.min(...)</td>
<td>Return the minimum of the values for the requested axis.</td>
</tr>
<tr>
<td>Series.mode(...)</td>
<td>Return the mode(s) of the dataset.</td>
</tr>
<tr>
<td>Series.nlargest(...)</td>
<td>Return the largest ( n ) elements.</td>
</tr>
<tr>
<td>Series.nsmallest(...)</td>
<td>Return the smallest ( n ) elements.</td>
</tr>
<tr>
<td>Series.pct_change(...)</td>
<td>Percentage change between the current and a prior element.</td>
</tr>
<tr>
<td>Series.prod(...)</td>
<td>Return the product of the values for the requested axis.</td>
</tr>
<tr>
<td>Series.quantile(...)</td>
<td>Return value at the given quantile.</td>
</tr>
<tr>
<td>Series.rank(...)</td>
<td>Compute numerical data ranks (1 through ( n )) along axis.</td>
</tr>
<tr>
<td>Series.sem(...)</td>
<td>Return unbiased standard error of the mean over requested axis.</td>
</tr>
<tr>
<td>Series.skew(...)</td>
<td>Return unbiased skew over requested axis.</td>
</tr>
<tr>
<td>Series.std(...)</td>
<td>Return sample standard deviation over requested axis.</td>
</tr>
<tr>
<td>Series.sum(...)</td>
<td>Return the sum of the values for the requested axis.</td>
</tr>
<tr>
<td>Series.var(...)</td>
<td>Return unbiased variance over requested axis.</td>
</tr>
</tbody>
</table>

### 3.3.8 Reindexing / selection / label manipulation

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.align(other[, join, axis, level, ...])</td>
<td>Align two objects on their axes with the specified join method.</td>
</tr>
<tr>
<td>Series.drop([labels, axis, index, columns, ...])</td>
<td>Return Series with specified index labels removed.</td>
</tr>
<tr>
<td>Series.droplevel(level[, axis])</td>
<td>Return DataFrame with requested index / column level(s) removed.</td>
</tr>
<tr>
<td>Series.drop_duplicates([keep, inplace])</td>
<td>Return Series with duplicate values removed.</td>
</tr>
<tr>
<td>Series.duplicated([keep])</td>
<td>Indicate duplicate Series values.</td>
</tr>
<tr>
<td>Series.equals(other)</td>
<td>Test whether two objects contain the same elements.</td>
</tr>
<tr>
<td>Series.first(offset)</td>
<td>Select initial periods of time series data based on a date offset.</td>
</tr>
<tr>
<td>Series.head([n])</td>
<td>Return the first n rows.</td>
</tr>
<tr>
<td>Series.idxmax([axis, skipna])</td>
<td>Return the row label of the maximum value.</td>
</tr>
<tr>
<td>Series.idxmin([axis, skipna])</td>
<td>Return the row label of the minimum value.</td>
</tr>
<tr>
<td>Series.isin(values)</td>
<td>Whether elements in Series are contained in values.</td>
</tr>
<tr>
<td>Series.last(offset)</td>
<td>Select final periods of time series data based on a date offset.</td>
</tr>
<tr>
<td>Series.reindex(index)</td>
<td>Conform Series to new index with optional filling logic.</td>
</tr>
<tr>
<td>Series.reindex_like(other[, method, copy, ...])</td>
<td>Return an object with matching indices as other object.</td>
</tr>
<tr>
<td>Series.rename([index, axis, copy, inplace])</td>
<td>Alter Series index labels or name.</td>
</tr>
<tr>
<td>Series.rename_axis({mapper, index, columns, ...})</td>
<td>Set the name of the axis for the index or columns.</td>
</tr>
<tr>
<td>Series.reset_index([level, drop, name, inplace])</td>
<td>Generate a new DataFrame or Series with the index reset.</td>
</tr>
<tr>
<td>Series.sample([n, frac, replace, weights, ...])</td>
<td>Return a random sample of items from an axis of object.</td>
</tr>
<tr>
<td>Series.set_axis(labels[, axis, inplace])</td>
<td>Assign desired index to given axis.</td>
</tr>
<tr>
<td>Series.take(indices[, axis, is_copy])</td>
<td>Return the elements in the given positional indices along an axis.</td>
</tr>
<tr>
<td>Series.tail([n])</td>
<td>Return the last n rows.</td>
</tr>
<tr>
<td>Series.truncate([before, after, axis, copy])</td>
<td>Truncate a Series or DataFrame before and after some index value.</td>
</tr>
<tr>
<td>Series.where(cond[, other, inplace, axis, ...])</td>
<td>Replace values where the condition is False.</td>
</tr>
<tr>
<td>Series.mask(cond[, other, inplace, axis, ...])</td>
<td>Replace values where the condition is True.</td>
</tr>
<tr>
<td>Series.add_prefix(prefix)</td>
<td>Prefix labels with string prefix.</td>
</tr>
<tr>
<td>Series.add_suffix(suffix)</td>
<td>Suffix labels with string suffix.</td>
</tr>
<tr>
<td>Series.filter([items, like, regex, axis])</td>
<td>Subset the dataframe rows or columns according to the specified index labels.</td>
</tr>
</tbody>
</table>
### 3.3.9 Missing data handling

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.backfill()</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='bfill'.</td>
</tr>
<tr>
<td><code>Series.bfill()</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='bfill'.</td>
</tr>
<tr>
<td><code>Series.dropna()</code></td>
<td>Return a new Series with missing values removed.</td>
</tr>
<tr>
<td><code>Series.ffill()</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='ffill'.</td>
</tr>
<tr>
<td><code>Series.fillna()</code></td>
<td>Fill NA/NaN values using the specified method.</td>
</tr>
<tr>
<td><code>Series.interpolate()</code></td>
<td>Please note that only method='linear' is supported for DataFrame/Series with a MultiIndex.</td>
</tr>
<tr>
<td><code>Series.isna()</code></td>
<td>Detect missing values.</td>
</tr>
<tr>
<td><code>Series.isnull()</code></td>
<td>Detect missing values.</td>
</tr>
<tr>
<td><code>Series.notna()</code></td>
<td>Detect existing (non-missing) values.</td>
</tr>
<tr>
<td><code>Series.notnull()</code></td>
<td>Detect existing (non-missing) values.</td>
</tr>
<tr>
<td><code>Series.pad()</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='ffill'.</td>
</tr>
<tr>
<td><code>Series.replace()</code></td>
<td>Replace values given in <code>to_replace</code> with <code>value</code>.</td>
</tr>
</tbody>
</table>

### 3.3.10 Reshaping, sorting

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.argsort()</code></td>
<td>Return the integer indices that would sort the Series values.</td>
</tr>
<tr>
<td><code>Series.argmin()</code></td>
<td>Return int position of the smallest value in the Series.</td>
</tr>
<tr>
<td><code>Series.argmax()</code></td>
<td>Return int position of the largest value in the Series.</td>
</tr>
<tr>
<td><code>Series.reorder_levels()</code></td>
<td>Rearrange index levels using input order.</td>
</tr>
<tr>
<td><code>Series.sort_values()</code></td>
<td>Sort by the values.</td>
</tr>
<tr>
<td><code>Series.sort_index()</code></td>
<td>Sort Series by index labels.</td>
</tr>
<tr>
<td><code>Series.swaplevel()</code></td>
<td>Swap levels i and j in a MultiIndex.</td>
</tr>
<tr>
<td><code>Series.unstack()</code></td>
<td>Unstack, also known as pivot, Series with MultiIndex to produce DataFrame.</td>
</tr>
<tr>
<td><code>Series.explode()</code></td>
<td>Transform each element of a list-like to a row.</td>
</tr>
<tr>
<td><code>Series.searchsorted()</code></td>
<td>Find indices where elements should be inserted to maintain order.</td>
</tr>
<tr>
<td><code>Series.ravel()</code></td>
<td>Return the flattened underlying data as an ndarray.</td>
</tr>
<tr>
<td><code>Series.repeat()</code></td>
<td>Repeat elements of a Series.</td>
</tr>
<tr>
<td><code>Series.squeeze()</code></td>
<td>Squeeze 1 dimensional axis objects into scalars.</td>
</tr>
<tr>
<td><code>Series.view()</code></td>
<td>Create a new view of the Series.</td>
</tr>
</tbody>
</table>
3.3.11 Combining / comparing / joining / merging

- `Series.append(to_append[, ignore_index, ...])`: Concatenate two or more Series.
- `Series.compare(other[, align_axis, ...])`: Compare to another Series and show the differences.
- `Series.replace([to_replace, value, inplace, ...])`: Replace values given in `to_replace` with `value`.
- `Series.update(other)`: Modify Series in place using values from passed Series.

3.3.12 Time Series-related

- `Series.asfreq(freq[, method, how, ...])`: Convert TimeSeries to specified frequency.
- `Series.asof(where[, subset])`: Return the last row(s) without any NaNs before `where`.
- `Series.shift([periods, freq, axis, fill_value])`: Shift index by desired number of periods with an optional `freq`.
- `Series.first_valid_index()`: Return index for first non-NA/null value.
- `Series.last_valid_index()`: Return index for last non-NA/null value.
- `Series.resample(rule[, axis, closed, label, ...])`: Resample time-series data.
- `Series.tz_convert(tz[, axis, level, copy])`: Convert tz-aware axis to target time zone.
- `Series.tz_localize(tz[, axis, level, copy, ...])`: Localize tz-naive index of a Series or DataFrame to target time zone.
- `Series.at_time(time[, asof, axis])`: Select values at particular time of day (e.g., 9:30AM).
- `Series.between_time(start_time, end_time[, ...])`: Select values between particular times of the day (e.g., 9:00-9:30 AM).
- `Series.tshift([periods, freq, axis])`: (DEPRECATED) Shift the time index, using the index’s frequency if available.
- `Series.slice_shift([periods, axis])`: Equivalent to `shift` without copying data.

3.3.13 Accessors

Pandas provides dtype-specific methods under various accessors. These are separate namespaces within `Series` that only apply to specific data types.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Accessor</th>
</tr>
</thead>
<tbody>
<tr>
<td>Datetime, Timedelta, Period</td>
<td><code>dt</code></td>
</tr>
<tr>
<td>String</td>
<td><code>str</code></td>
</tr>
<tr>
<td>Categorical</td>
<td><code>cat</code></td>
</tr>
<tr>
<td>Sparse</td>
<td><code>sparse</code></td>
</tr>
</tbody>
</table>
Datetimelike properties

Series.dt can be used to access the values of the series as datetimelike and return several properties. These can be accessed like Series.dt.<property>.

### Datetime properties

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.dt.date</td>
<td>Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).</td>
</tr>
<tr>
<td>Series.dt.time</td>
<td>Returns numpy array of datetime.time.</td>
</tr>
<tr>
<td>Series.dt.timetz</td>
<td>Returns numpy array of datetime.time also containing timezone information.</td>
</tr>
<tr>
<td>Series.dt.year</td>
<td>The year of the datetime.</td>
</tr>
<tr>
<td>Series.dt.month</td>
<td>The month as January=1, December=12.</td>
</tr>
<tr>
<td>Series.dt.day</td>
<td>The day of the datetime.</td>
</tr>
<tr>
<td>Series.dt.hour</td>
<td>The hours of the datetime.</td>
</tr>
<tr>
<td>Series.dt.minute</td>
<td>The minutes of the datetime.</td>
</tr>
<tr>
<td>Series.dt.second</td>
<td>The seconds of the datetime.</td>
</tr>
<tr>
<td>Series.dt.microsecond</td>
<td>The microseconds of the datetime.</td>
</tr>
<tr>
<td>Series.dt.nanosecond</td>
<td>The nanoseconds of the datetime.</td>
</tr>
<tr>
<td>Series.dt.week</td>
<td>(DEPRECATED) The week ordinal of the year.</td>
</tr>
<tr>
<td>Series.dt.weekofyear</td>
<td>(DEPRECATED) The week ordinal of the year.</td>
</tr>
<tr>
<td>Series.dt.dayofweek</td>
<td>The day of the week with Monday=0, Sunday=6.</td>
</tr>
<tr>
<td>Series.dt.weekday</td>
<td>The day of the week with Monday=0, Sunday=6.</td>
</tr>
<tr>
<td>Series.dt.dayofyear</td>
<td>The ordinal day of the year.</td>
</tr>
<tr>
<td>Series.dt.quarter</td>
<td>The quarter of the date.</td>
</tr>
<tr>
<td>Series.dt.is_month_start</td>
<td>Indicates whether the date is the first day of the month.</td>
</tr>
<tr>
<td>Series.dt.is_month_end</td>
<td>Indicates whether the date is the last day of the month.</td>
</tr>
<tr>
<td>Series.dt.is_quarter_start</td>
<td>Indicator for whether the date is the first day of a quarter.</td>
</tr>
<tr>
<td>Series.dt.is_quarter_end</td>
<td>Indicator for whether the date is the last day of a quarter.</td>
</tr>
<tr>
<td>Series.dt.is_year_start</td>
<td>Indicate whether the date is the first day of a year.</td>
</tr>
<tr>
<td>Series.dt.is_year_end</td>
<td>Indicate whether the date is the last day of the year.</td>
</tr>
<tr>
<td>Series.dt.is_leap_year</td>
<td>Boolean indicator if the date belongs to a leap year.</td>
</tr>
<tr>
<td>Series.dt.days_in_month</td>
<td>The number of days in the month.</td>
</tr>
<tr>
<td>Series.dt.tz</td>
<td>Return timezone, if any.</td>
</tr>
<tr>
<td>Series.dt.freq</td>
<td>Return the frequency object for this PeriodArray.</td>
</tr>
</tbody>
</table>
pandas.Series.dt.date

Series.dt.date

Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).

pandas.Series.dt.time

Series.dt.time

Returns numpy array of datetime.time. The time part of the Timestamps.

pandas.Series.dt.timetz

Series.dt.timetz

Returns numpy array of datetime.time also containing timezone information. The time part of the Timestamps.

pandas.Series.dt.year

Series.dt.year

The year of the datetime.

Examples

```python
>>> datetime_series = pd.Series(  
...     pd.date_range("2000-01-01", periods=3, freq="Y")  
... )
>>> datetime_series
0  2000-12-31
1  2001-12-31
2  2002-12-31
dtype: datetime64[ns]
>>> datetime_series.dt.year
0  2000
1  2001
2  2002
dtype: int64
```

pandas.Series.dt.month

Series.dt.month

The month as January=1, December=12.
Examples

```python
>>> datetime_series = pd.Series(
...    pd.date_range("2000-01-01", periods=3, freq="M")
... )
>>> datetime_series
0   2000-01-31
1   2000-02-29
2   2000-03-31
dtype: datetime64[ns]
>>> datetime_series.dt.month
0    1
1    2
2    3
dtype: int64
```

`pandas.Series.dt.day`

Series.dt.day

The day of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...    pd.date_range("2000-01-01", periods=3, freq="D")
... )
>>> datetime_series
0   2000-01-01
1   2000-01-02
2   2000-01-03
dtype: datetime64[ns]
>>> datetime_series.dt.day
0    1
1    2
2    3
dtype: int64
```
pandas.Series.dt.hour

Series.dt.hour
The hours of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...    pd.date_range("2000-01-01", periods=3, freq="h")
...)
>>> datetime_series
0 2000-01-01 00:00:00
1 2000-01-01 01:00:00
2 2000-01-01 02:00:00
dtype: datetime64[ns]
>>> datetime_series.dt.hour
0 0
1 1
2 2
dtype: int64
```

pandas.Series.dt.minute

Series.dt.minute
The minutes of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...    pd.date_range("2000-01-01", periods=3, freq="T")
...)
>>> datetime_series
0 2000-01-01 00:00:00
1 2000-01-01 00:01:00
2 2000-01-01 00:02:00
dtype: datetime64[ns]
>>> datetime_series.dt.minute
0 0
1 1
2 2
dtype: int64
```
pandas.Series.dt.second

Series.dt.second
The seconds of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="s")
... )
>>> datetime_series
0 2000-01-01 00:00:00
1 2000-01-01 00:00:01
2 2000-01-01 00:00:02
dtype: datetime64[ns]
>>> datetime_series.dt.second
0 0
1 1
2 2
dtype: int64
```

pandas.Series.dt.microsecond

Series.dt.microsecond
The microseconds of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="us")
... )
>>> datetime_series
0 2000-01-01 00:00:00.000000
1 2000-01-01 00:00:00.000001
2 2000-01-01 00:00:00.000002
dtype: datetime64[ns]
>>> datetime_series.dt.microsecond
0 0
1 1
2 2
dtype: int64
```
pandas.Series.dt.nanosecond

Series.dt.nanosecond
The nanoseconds of the datetime.

Examples

```python
code
>>> datetime_series = pd.Series(
    ...
    pd.date_range("2000-01-01", periods=3, freq="ns")
    ...
)
>>> datetime_series
0   2000-01-01 00:00:00.000000000
1   2000-01-01 00:00:00.000000001
2   2000-01-01 00:00:00.000000002
dtype: datetime64[ns]
>>> datetime_series.dt.nanosecond
0    0
1    1
2    2
```
```
```

pandas.Series.dt.week

Series.dt.week
The week ordinal of the year.

Depreciated since version 1.1.0.
Series.dt.weekofyear and Series.dt.week have been deprecated. Please use Series.dt.isocalendar().week instead.

pandas.Series.dt.weekofyear

Series.dt.weekofyear
The week ordinal of the year.

Depreciated since version 1.1.0.
Series.dt.weekofyear and Series.dt.week have been deprecated. Please use Series.dt.isocalendar().week instead.

pandas.Series.dt.dayofweek

Series.dt.dayofweek
The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the dt accessor) or DatetimeIndex.

Returns

- **Series or Index** Containing integers indicating the day number.

See also:

- `Series.dt.dayofweek` Alias.
- `Series.dt.weekday` Alias.
Series.dt.day_name

Returns the name of the day of the week.

Examples

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31  5
2017-01-01  6
2017-01-02  0
2017-01-03  1
2017-01-04  2
2017-01-05  3
2017-01-06  4
2017-01-07  5
2017-01-08  6
Freq: D, dtype: int64
```

pandas.Series.dt.weekday

Series.dt.weekday

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the dt accessor) or DatetimeIndex.

Returns

Series or Index  Containing integers indicating the day number.

See also:

Series.dt.dayofweek  Alias.
Series.dt.weekday  Alias.
Series.dt.day_name  Returns the name of the day of the week.

Examples

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31  5
2017-01-01  6
2017-01-02  0
2017-01-03  1
2017-01-04  2
2017-01-05  3
2017-01-06  4
2017-01-07  5
2017-01-08  6
Freq: D, dtype: int64
```
pandas.Series.dt.dayofyear

Series.dt.dayofyear
The ordinal day of the year.

pandas.Series.dt.quarter

Series.dt.quarter
The quarter of the date.

pandas.Series.dt.is_month_start

Series.dt.is_month_start
Indicates whether the date is the first day of the month.

Returns

Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

is_month_start Return a boolean indicating whether the date is the first day of the month.
is_month_end Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0 2018-02-27
1 2018-02-28
2 2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0 False
1 False
2 True
dtype: bool
>>> s.dt.is_month_end
0 False
1 True
2 False
dtype: bool
```

```python
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```
pandas.Series.dt.is_month_end

Series.dt.is_month_end
Indicates whether the date is the last day of the month.

Returns

Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

See also:

is_month_start Return a boolean indicating whether the date is the first day of the month.
is_month_end Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0 2018-02-27
1 2018-02-28
2 2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0 False
1 False
2 True
dtype: bool
>>> s.dt.is_month_end
0 False
1 True
2 False
dtype: bool
```

```python
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```

pandas.Series.dt.is_quarter_start

Series.dt.is_quarter_start
Indicator for whether the date is the first day of a quarter.

Returns

is_quarter_start [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

quarter Return the quarter of the date.
is_quarter_end Similar property for indicating the quarter start.
Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```python
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30", 
    ... periods=4))})
>>> df.assign(quarter=df.dates.dt.quarter, 
    ... is_quarter_start=df.dates.dt.is_quarter_start)
```
```
<table>
<thead>
<tr>
<th>dates</th>
<th>quarter</th>
<th>is_quarter_start</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017-03-30</td>
<td>1</td>
<td>False</td>
</tr>
<tr>
<td>2017-03-31</td>
<td>1</td>
<td>False</td>
</tr>
<tr>
<td>2017-04-01</td>
<td>2</td>
<td>True</td>
</tr>
<tr>
<td>2017-04-02</td>
<td>2</td>
<td>False</td>
</tr>
</tbody>
</table>
```

```python
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
```
```
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
    dtype='datetime64[ns]', freq='D')
```

```python
>>> idx.is_quarter_start
array([False, False,  True, False])
```

### pandas.Series.dt.is_quarter_end

Series.dt.is_quarter_end

Indicator for whether the date is the last day of a quarter.

**Returns**

is_quarter_end [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

*quarter* Return the quarter of the date.

*is_quarter_start* Similar property indicating the quarter start.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```python
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30", 
    ... periods=4))})
>>> df.assign(quarter=df.dates.dt.quarter, 
    ... is_quarter_end=df.dates.dt.is_quarter_end)
```
```
<table>
<thead>
<tr>
<th>dates</th>
<th>quarter</th>
<th>is_quarter_end</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017-03-30</td>
<td>1</td>
<td>False</td>
</tr>
<tr>
<td>2017-03-31</td>
<td>1</td>
<td>True</td>
</tr>
<tr>
<td>2017-04-01</td>
<td>2</td>
<td>False</td>
</tr>
<tr>
<td>2017-04-02</td>
<td>2</td>
<td>False</td>
</tr>
</tbody>
</table>
```

```python
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
```
```
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
    dtype='datetime64[ns]', freq='D')
```
pandas.Series.dt.is_year_start

Series.dt.is_year_start
Indicate whether the date is the first day of a year.

Returns

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

is_year_end Similar property indicating the last day of the year.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
datetime64[ns]
0 2017-12-30
1 2017-12-31
2 2018-01-01
dtype: datetime64[ns]

>>> dates.dt.is_year_start
0 False
1 False
2 True
dtype: bool
```

```python
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
dtype='datetime64[ns]', freq='D')

>>> idx.is_year_start
array([False, False, True])
```

pandas.Series.dt.is_year_end

Series.dt.is_year_end
Indicate whether the date is the last day of the year.

Returns

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

is_year_start Similar property indicating the start of the year.
Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0  2017-12-30
1  2017-12-31
2  2018-01-01
dtype: datetime64[ns]
```

```python
>>> dates.dt.is_year_end
0   False
1    True
2   False
dtype: bool
```

```python
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
dtype='datetime64[ns]', freq='D')
```

```python
>>> idx.is_year_end
array([False,  True, False])
```

pandas.Series.dt.is_leap_year

Series.dt.is_leap_year

Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

Returns

Series or ndarray  Booleans indicating if dates belong to a leap year.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
dtype='datetime64[ns]', freq='A-DEC')
```

```python
>>> idx.is_leap_year
array([ True, False, False])
```

```python
>>> dates_series = pd.Series(idx)
>>> dates_series
0  2012-12-31
1  2013-12-31
2  2014-12-31
dtype: datetime64[ns]
```

```python
>>> dates_series.dt.is_leap_year
(continues on next page)
```
0  True
1  False
2  False
dtype: bool

pandas.Series.dt.daysinmonth

Series.dt.

The number of days in the month.

pandas.Series.dt.days_in_month

Series.dt.

The number of days in the month.

pandas.Series.dt.tz

Series.dt.

Return timezone, if any.

Returns

datetime.tzinfo, pytz.tzinfo.BaseTZInfo, dateutil.tz.tzfile, or None  Returns  None

when the array is tz-naive.

pandas.Series.dt.freq

Series.dt.

Datetime methods

Series.dt.to_period(*args, **kwargs)  Cast to PeriodArray/Index at a particular frequency.
Series.dt.to_pydatetime()  Return the data as an array of native Python datetime objects.
Series.dt.tz_localize(*args, **kwargs)  Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.
Series.dt.tz_convert(*args, **kwargs)  Convert tz-aware Datetime Array/Index from one time zone to another.
Series.dt.normalize(*args, **kwargs)  Convert times to midnight.
Series.dt.strftime(*args, **kwargs)  Convert to Index using specified date_format.
Series.dt.round(*args, **kwargs)  Perform round operation on the data to the specified freq.
Series.dt.floor(*args, **kwargs)  Perform floor operation on the data to the specified freq.
Series.dt.ceil(*args, **kwargs)  Perform ceil operation on the data to the specified freq.
Series.dt.month_name(*args, **kwargs)  Return the month names of the DateTimeIndex with specified locale.

continues on next page
Table 43 – continued from previous page

| pandas.Series.dt.day_name(*args, **kwargs) | Return the day names of the DateTimeIndex with specified locale. |

pandas.Series.dt.to_period

Series.dt.to_period(*args, **kwargs)
Cast to PeriodArray/Index at a particular frequency.
Converts DatetimeArray/Index to PeriodArray/Index.

Parameters

freq [str or Offset, optional] One of pandas’ offset strings or an Offset object. Will be inferred by default.

Returns

PeriodArray/Index

Raises

ValueError When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

See also:

PeriodIndex Immutable ndarray holding ordinal values.
DatetimeIndex.to_pydatetime Return DatetimeIndex as object.

Examples

```python
>>> df = pd.DataFrame({'y': [1, 2, 3]},
                   index=pd.to_datetime(['2000-03-31 00:00:00',
                                         '2000-05-31 00:00:00',
                                         '2000-08-31 00:00:00']))
>>> df.index.to_period('M')
PeriodIndex(['2000-03', '2000-05', '2000-08'],
            dtype='period[M]', freq='M')
```

Infer the daily frequency

```python
>>> idx = pd.date_range('2017-01-01', periods=2)
>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
            dtype='period[D]', freq='D')
```

pandas.Series.dt.to_pydatetime

Series.dt.to_pydatetime()
Return the data as an array of native Python datetime objects.
Timezone information is retained if present.

Warning: Python’s datetime uses microsecond resolution, which is lower than pandas (nanosecond). The values are truncated.
**Returns**

`numpy.ndarray` Object dtype array containing native Python datetime objects.

See also:

`datetime.datetime` Standard library value for a datetime.

**Examples**

```python
>>> s = pd.Series(pd.date_range('20180310', periods=2))
>>> s
0 2018-03-10
1 2018-03-11
dtype: datetime64[ns]
```

```python
>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 11, 0, 0)], dtype=object)
```

Pandas’ nanosecond precision is truncated to microseconds.

```python
>>> s = pd.Series(pd.date_range('20180310', periods=2, freq='ns'))
>>> s
0 2018-03-10 00:00:00.000000000
1 2018-03-10 00:00:00.000000001
dtype: datetime64[ns]
```

```python
>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 10, 0, 0)], dtype=object)
```

**pandas.Series.dt.tz_localize**

Series.dt.tz_localize(*args, **kwargs)  
Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone. Time zone localization helps to switch from time zone aware to time zone unaware objects.

**Parameters**

- **tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone to convert timestamps to. Passing `None` will remove the time zone information preserving local time.

- **ambiguous** ['infer', 'NaT', bool array, default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the `ambiguous` parameter dictates how ambiguous times should be handled.
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-array where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

**nonexistent** ['shift_forward', 'shift_backward', ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

• ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
• ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
• ‘NaT’ will return NaT where there are nonexistent times
• timedelta objects will shift nonexistent times by the timedelta
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

**Same type as self** Array/Index converted to the specified time zone.

**Raises**

**TypeError** If the Datetime Array/Index is tz-aware and tz is not None.

See also:

**DatetimeIndex.tz_convert** Convert tz-aware DatetimeIndex from one time zone to another.

**Examples**

```python
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(["2018-03-01 09:00:00", '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'], dtype='datetime64[ns]', freq='D')

Localyze DatetimeIndex in US/Eastern time zone:

```python
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
>>> tz_aware
DatetimeIndex(["2018-03-01 09:00:00-05:00", '2018-03-02 09:00:00-05:00',
              '2018-03-03 09:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)

With the tz=None, we can remove the time zone information while keeping the local time (not converted to UTC):

```python
>>> tz_aware.tz_localize(None)
DatetimeIndex(["2018-03-01 09:00:00", '2018-03-02 09:00:00',
              '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq=None)

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```python
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:30:00',
                                 ...
                                 '2018-10-28 02:00:00',
                                 ...
                                 '2018-10-28 02:30:00',
                                 ...
                                 '2018-10-28 03:00:00'])
```
In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly

```python
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:20:00',
    ... '2018-10-28 02:36:00',
    ... '2018-10-28 03:46:00']))
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
0 2018-10-28 01:20:00+02:00
1 2018-10-28 02:36:00+02:00
2 2018-10-28 03:46:00+01:00
dtype: datetime64[ns, CET]
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a timedelta object or 'shift_forward' or 'shift_backwards'.

```python
>>> s = pd.to_datetime(pd.Series(['2015-03-29 02:30:00',
    ... '2015-03-29 03:30:00']))
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
0 2015-03-29 03:00:00+02:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```

```python
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
0 2015-03-29 01:59:59.999999999+01:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```

```python
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
0 2015-03-29 03:30:00+02:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```
**pandas.Series.dt.tz_convert**

```
Series.dt.`tz_convert`(*args, **kwargs)
```

Convert tz-aware Datetime Array/Index from one time zone to another.

**Parameters**

- `tz` [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A `tz` of None will convert to UTC and remove the timezone information.

**Returns**

Array or Index

**Raises**

TypeError If Datetime Array/Index is tz-naive.

**See also:**

- `DatetimeIndex.tz` A timezone that has a variable offset from UTC.
- `DatetimeIndex.tz_localize` Localize tz-naive DatetimeIndex to a given time zone, or remove timezone from a tz-aware DatetimeIndex.

**Examples**

With the `tz` parameter, we can change the DatetimeIndex to other time zones:

```python
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                     freq='H', periods=3, tz='Europe/Berlin')

>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')

>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
               '2014-08-01 03:00:00-05:00',
               '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the `tz=None`, we can remove the timezone (after converting to UTC if necessary):

```python
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                     freq='H', periods=3, tz='Europe/Berlin')

>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')

>>> dti.tz_convert(None)
DatetimeIndex(['2014-08-01 07:00:00',
               '2014-08-01 08:00:00',
               '2014-08-01 09:00:00'],
              dtype='datetime64[ns, None]', freq='H')
```

(continues on next page)
pandas.Series.dt.normalize

Series.dt.normalize(*args, **kwargs)
Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the
time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the .dt accessor, and directly on Datetime
Array/Index.

Returns

DatetimeArray, DatetimeIndex or Series The same type as the original data. Series will
have the same name and index. DatetimeIndex will have the same name.

See also:

floor Floor the datetimes to the specified freq.
ceil Ceil the datetimes to the specified freq.
round Round the datetimes to the specified freq.

Examples

```python
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
...     periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
               '2014-08-01 11:00:00+05:30',
               '2014-08-01 12:00:00+05:30'],
               dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30'],
               dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

pandas.Series.dt.strftime

Series.dt.strftime(*args, **kwargs)
Convert to Index using specified date_format.

Return an Index of formatted strings specified by date_format, which supports the same string format as the
python standard library. Details of the string format can be found in python string format doc.

Parameters

date_format [str] Date format string (e.g. “%Y-%m-%d”).

Returns

ndarray NumPy ndarray of formatted strings.

See also:
to_datetime Convert the given argument to datetime.  
`DatetimeIndex.normalize` Return DatetimeIndex with times to midnight.  
`DatetimeIndex.round` Round the DatetimeIndex to the specified freq.  
`DatetimeIndex.floor` Floor the DatetimeIndex to the specified freq.

Examples

```python
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
                      ...                  periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM', 'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

`pandas.Series.dt.round`

Series.dt.round(*args, **kwargs) Perform round operation on the data to the specified freq.  

Parameters

freq [str or Offset] The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

ambiguous ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:

• ‘infer’ will attempt to infer fall dst-transition hours based on order
• bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
• ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', ‘NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

• ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
• ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
• ‘NaT’ will return NaT where there are nonexistent times
• timedelta objects will shift nonexistent times by the timedelta
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises
ValueError if the `freq` cannot be converted.

**Examples**

**DatetimeIndex**

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'], dtype='datetime64[ns]', freq='T')

>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'], dtype='datetime64[ns]', freq=None)
```

**Series**

```python
>>> pd.Series(rng).dt.round("H")
0    2018-01-01 12:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

**pandas.Series.dt.floor**

`Series.dt.floor(*args, **kwargs)`

Perform floor operation on the data to the specified `freq`.

**Parameters**

- freq [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

- ambiguous ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

  New in version 0.24.0.

- nonexistent ['shift_forward', 'shift_backward', ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST:
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta

3.3. Series
• ‘raise’ will raise a NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00', '2018-01-01 12:01:00'],
                dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00', '2018-01-01 12:00:00'],
                dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.floor("H")
0   2018-01-01 11:00:00
1   2018-01-01 12:00:00
2   2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.Series.dt.ceil

Series.dt.ceil(*args, **kwargs)

Perform ceil operation on the data to the specified freq.

Parameters

freq [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

ambiguous ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:

• ‘infer’ will attempt to infer fall dst-transition hours based on order
• bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
• ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.
nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

**Returns**

- DatetimeIndex, TimedeltaIndex, or Series  Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**

ValueError if the freq cannot be converted.

**Examples**

**DatetimeIndex**

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
```

```python
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

**Series**

```python
>>> pd.Series(rng).dt.ceil("H")
0  2018-01-01 12:00:00
1  2018-01-01 12:00:00
2  2018-01-01 13:00:00
dtype: datetime64[ns]
```

**pandas.Series.dt.month_name**

Series.dt.month_name(*args, **kwargs)

Return the month names of the DateTimeIndex with specified locale.

New in version 0.23.0.

**Parameters**

- locale [str, optional] Locale determining the language in which to return the month name.
  Default is English locale.

**Returns**
Index

Index of month names.

Examples

```python
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
               dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```

pandas.Series.dt.month_name

Series.dt.month_name(*args, **kwargs)

Return the month names of the DateTimeIndex with specified locale.

New in version 0.23.0.

Parameters

- `locale` [str, optional] Locale determining the language in which to return the month name. Default is English locale.

Returns

- `Index` Index of month names.

Examples

```python
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
               dtype='datetime64[ns]', freq='D')
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

Period properties

- `Series.dt.qyear`
- `Series.dt.start_time`
- `Series.dt.end_time`
pandas.Series.dt.qyear

Series.dt.qyear

pandas.Series.dt.start_time

Series.dt.start_time

pandas.Series.dt.end_time

Series.dt.end_time

Timedelta properties

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.dt.days</td>
<td>Number of days for each element.</td>
</tr>
<tr>
<td>Series.dt.seconds</td>
<td>Number of seconds (&gt;= 0 and less than 1 day) for each element.</td>
</tr>
<tr>
<td>Series.dt.microseconds</td>
<td>Number of microseconds (&gt;= 0 and less than 1 second) for each element.</td>
</tr>

<td>Number of nanoseconds (&gt;= 0 and less than 1 microsecond) for each element.</td>
</tr>
<tr>
<td>Series.dt.components</td>
<td>Return a DataFrame of the components of the Timedeltas.</td>
</tr>
</tbody>
</table>

pandas.Series.dt.days

Series.dt.days
Number of days for each element.

pandas.Series.dt.seconds

Series.dt.seconds
Number of seconds (>= 0 and less than 1 day) for each element.

pandas.Series.dt.microseconds

Series.dt.microseconds
Number of microseconds (>= 0 and less than 1 second) for each element.
**pandas.Series.dt.nanoseconds**

Series.dt.nanoseconds

Number of nanoseconds (>= 0 and less than 1 microsecond) for each element.

**pandas.Series.dt.components**

Series.dt.components

Return a Dataframe of the components of the Timedeltas.

Returns

DataFrame

**Examples**

```python
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='s'))
>>> s
0 0 days 00:00:00
1 0 days 00:00:01
2 0 days 00:00:02
3 0 days 00:00:03
4 0 days 00:00:04
dtype: timedelta64[ns]
```

```python
>>> s.dt.components
days hours minutes seconds milliseconds micros seconds nanoseconds
0 0 0 0 0 0 0 0
1 0 0 0 1 0 0 0
2 0 0 0 2 0 0 0
3 0 0 0 3 0 0 0
4 0 0 0 4 0 0 0
```

**Timedelta methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.dt.to_pytimedelta()</td>
<td>Return an array of native <code>datetime.timedelta</code> objects.</td>
</tr>
<tr>
<td>Series.dt.total_seconds(*args, **kwargs)</td>
<td>Return total duration of each element expressed in seconds.</td>
</tr>
</tbody>
</table>

**pandas.Series.dt.to_pytimedelta**

Series.dt.to_pytimedelta()

Return an array of native `datetime.timedelta` objects.

Python’s standard `datetime` library uses a different representation timedelta’s. This method converts a Series of pandas Timedeltas to `datetime.timedelta` format with the same length as the original Series.

Returns

numpy.ndarray Array of 1D containing data with `datetime.timedelta` type.

See also:

`datetime.timedelta`
Examples

```python
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit="d"))
>>> s
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]
```

```python
>>> s.dt.to_pytimedelta()
array([datetime.timedelta(0), datetime.timedelta(days=1),
       datetime.timedelta(days=2), datetime.timedelta(days=3),
       datetime.timedelta(days=4)], dtype=object)
```

**pandas.Series.dt.total_seconds**

Series.dt.total_seconds (*args, **kwargs)

Return total duration of each element expressed in seconds.

This method is available directly on TimedeltaArray, TimedeltaIndex and on Series containing timedelta values under the .dt namespace.

**Returns**

seconds [[ndarray, Float64Index, Series]] When the calling object is a TimedeltaArray, the return type is ndarray. When the calling object is a TimedeltaIndex, the return type is a Float64Index. When the calling object is a Series, the return type is Series of type float64 whose index is the same as the original.

**See also:**

datetime.timedelta.total_seconds Standard library version of this method.

TimedeltaIndex.components Return a DataFrame with components of each Timedelta.

Examples

Series

```python
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]
```

```python
>>> s.dt.total_seconds()
0     0.0
1    86400.0
2   172800.0
3   259200.0
4   345600.0
dtype: float64
```
TimedeltaIndex

```python
>>> idx = pd.to_timedelta(np.arange(5), unit='d')
>>> idx
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq=None)
```

```python
>>> idx.total_seconds()
Float64Index([0.0, 86400.0, 172800.0, 259200.0, 345600.0],
              dtype='float64')
```

String handling

`Series.str` can be used to access the values of the series as strings and apply several methods to it. These can be accessed like `Series.str.<function/property>`.

<table>

</tbody>
</table>
**pandas.Series.str.capitalize**

`Series.str.capitalize()`  
Convert strings in the Series/Index to be capitalized.  
Equivalent to `str.capitalize()`.  

**Returns**  
Series or Index of object  

**See also:**  
- `Series.str.lower`  
- `Series.str.upper`  
- `Series.str.title`  
- `Series.str.capitalize`  
- `Series.str.swapcase`  
- `Series.str.casefold`  

**Examples**

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0    lower
1    CAPITALS
2    this is a sentence
3    SwApCaSe
dtype: object

>>> s.str.lower()
0    lower
1    capitals
2    this is a sentence
3    swapcase
dtype: object

>>> s.str.upper()
0    LOWER
1    CAPITALS
2    THIS IS A SENTENCE
3    SWAPCASE
dtype: object

>>> s.str.title()
0    Lower
1    Capitals
2    This Is A Sentence
3    Swapcase
dtype: object

>>> s.str.capitalize()
0    Lower
1    Capitals
2    This is a sentence
3    Swapcase
dtype: object
```
```python
>>> s.str.swapcase()
0    LOWER
1   capitals
2  THIS IS A SENTENCE
3    sWaPcAsE
dtype: object
```

### pandas.Series.str.casefold

Series.str.casefold()

Convert strings in the Series/Index to be casefolded.

New in version 0.25.0.

Equivalent to `str.casefold()`.

Returns

Series or Index of object

See also:

- **Series.str.lower** Converts all characters to lowercase.
- **Series.str.upper** Converts all characters to uppercase.
- **Series.str.title** Converts first character of each word to uppercase and remaining to lowercase.
- **Series.str.capitalize** Converts first character to uppercase and remaining to lowercase.
- **Series.str.swapcase** Converts uppercase to lowercase and lowercase to uppercase.
- **Series.str.casefold** Removes all case distinctions in the string.

### Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])

>>> s
0    lower
1    CAPITALS
2  this is a sentence
3    SwApCaSe
dtype: object

>>> s.str.lower()
0    lower
1    capitals
2  this is a sentence
3    swapcase
dtype: object

>>> s.str.upper()
0    LOWER
1    CAPITALS
2  THIS IS A SENTENCE
3    SWAPCASE
dtype: object

>>> s.str.title()
0    Lower
```

(continues on next page)
1 Capitals
2 This Is A Sentence
3 Swapcase
dtype: object

```python
>>> s.str.capitalize()
0 Lower
1 Capitals
2 This is a sentence
3 Swapcase
dtype: object
```

```python
>>> s.str.swapcase()
0 LOWER
1 capitals
2 THIS IS A SENTENCE
3 sWaPcAsE
dtype: object
```

**pandas.Series.str.cat**

`Series.str.cat(others=None, sep=None, na_rep=None, join='left')`

Concatenate strings in the Series/Index with given separator.

If `others` is specified, this function concatenates the Series/Index and elements of `others` element-wise. If `others` is not passed, then all values in the Series/Index are concatenated into a single string with a given `sep`.

**Parameters**

- **others** [Series, Index, DataFrame, np.ndarray or list-like] Series, Index, DataFrame, np.ndarray (one- or two-dimensional) and other list-likes of strings must have the same length as the calling Series/Index, with the exception of indexed objects (i.e. Series/Index/DataFrame) if `join` is not None.

  If `others` is a list-like that contains a combination of Series, Index or np.ndarray (1-dim), then all elements will be unpacked and must satisfy the above criteria individually.

  If `others` is None, the method returns the concatenation of all strings in the calling Series/Index.

- **sep** [str, default ‘’] The separator between the different elements/columns. By default the empty string ‘’ is used.

- **na_rep** [str or None, default None] Representation that is inserted for all missing values:

  - If `na_rep` is None, and `others` is None, missing values in the Series/Index are omitted from the result.
  
  - If `na_rep` is None, and `others` is not None, a row containing a missing value in any of the columns (before concatenation) will have a missing value in the result.

- **join** [[‘left’, ‘right’, ‘outer’, ‘inner’], default ‘left’] Determines the join-style between the calling Series/Index and any Series/Index/DataFrame in `others` (objects without an index need to match the length of the calling Series/Index). To disable alignment, use `.values` on any Series/Index/DataFrame in `others`.

New in version 0.23.0.

Changed in version 1.0.0: Changed default of `join` from None to ‘left’.
Returns

str, Series or Index  If others is None, str is returned, otherwise a Series/Index (same type as caller) of objects is returned.

See also:
split  Split each string in the Series/Index.
join  Join lists contained as elements in the Series/Index.

Examples

When not passing others, all values are concatenated into a single string:

```python
>>> s = pd.Series(['a', 'b', np.nan, 'd'])
>>> s.str.cat(sep=' ')
'a b d'
```

By default, NA values in the Series are ignored. Using na_rep, they can be given a representation:

```python
>>> s.str.cat(sep=' ', na_rep='?')
'a b ? d'
```

If others is specified, corresponding values are concatenated with the separator. Result will be a Series of strings.

```python
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',' )
0 a,A
1 b,B
2 NaN
3 d,D
dtype: object
```

Missing values will remain missing in the result, but can again be represented using na_rep:

```python
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',' , na_rep='-')
0 a,A
1 b,B
2 -,C
3 d,D
dtype: object
```

If sep is not specified, the values are concatenated without separation.

```python
>>> s.str.cat(['A', 'B', 'C', 'D'], na_rep='-')
0 aA
1 bB
2 -,C
3 dD
dtype: object
```

Series with different indexes can be aligned before concatenation. The join-keyword works as in other methods.

```python
>>> t = pd.Series(['d', 'a', 'e', 'c'], index=[3, 0, 4, 2])
>>> s.str.cat(t, join='left', na_rep='-')
0 aa
1 b-
2 -c
3 dd
dtype: object
```

(continues on next page)
For more examples, see here.

**pandas.Series.str.center**

`Series.str.center(width, fillchar='')`

Pad left and right side of strings in the Series/Index.

Equivalent to `str.center()`.

**Parameters**

- `width` [int] Minimum width of resulting string; additional characters will be filled with `fillchar`.
- `fillchar` [str] Additional character for filling, default is whitespace.

**Returns**

- `filled` [Series/Index of objects]

**pandas.Series.str.contains**

`Series.str.contains(pat, case=True, flags=0, na=nan, regex=True)`

Test if pattern or regex is contained within a string of a Series or Index.

Return boolean Series or Index based on whether a given pattern or regex is contained within a string of a Series or Index.

**Parameters**

- `pat` [str] Character sequence or regular expression.
- `case` [bool, default True] If True, case sensitive.
