DatetimeArray, DatetimeIndex or Series  The same type as the original data. Series will
have the same name and index. DatetimeIndex will have the same name.

See also:
floor  Floor the datetimes to the specified freq.
ceil   Ceil the datetimes to the specified freq.
round  Round the datetimes to the specified freq.

Examples

```python
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
                      periods=3, tz='Asia/Calcutta')
```

```python
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
                '2014-08-01 11:00:00+05:30',
                '2014-08-01 12:00:00+05:30'],
               dtype='datetime64[ns, Asia/Calcutta]', freq='H')
```

```python
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
                '2014-08-01 00:00:00+05:30',
                '2014-08-01 00:00:00+05:30'],
               dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

pandas.Series.dt.strftime

Series.dt.strftime(*args, **kwargs)
Convert to Index using specified date_format.

Return an Index of formatted strings specified by date_format, which supports the same string format as the
python standard library. Details of the string format can be found in python string format doc.

Parameters

date_format  [str] Date format string (e.g. “%Y-%m-%d”).

Returns

ndarray  NumPy ndarray of formatted strings.

See also:
to_datetime Convert the given argument to datetime.

DatetimeIndex.normalize Return DatetimeIndex with times to midnight.

DatetimeIndex.round Round the DatetimeIndex to the specified freq.

DatetimeIndex.floor Floor the DatetimeIndex to the specified freq.

Examples

```python
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...     periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
    'March 10, 2018, 09:00:02 AM'],
    dtype='object')
```

pandas.Series.dt.round

`Series.dt.round(*args, **kwargs)`

Perform round operation on the data to the specified `freq`.

Parameters

- `freq` [str or Offset] The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See `frequency aliases` for a list of possible `freq` values.

- `ambiguous` ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

- `nonexistent` ['shift_forward’, ‘shift_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

- DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises
ValueError if the freq cannot be converted.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00', '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
```

```python
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00', '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.round("H")
0 2018-01-01 12:00:00
1 2018-01-01 12:00:00
2 2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.Series.dt.floor

Series.dt.floor(*args, **kwargs)

Perform floor operation on the data to the specified freq.

Parameters

freq [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

ambiguous ['infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:

• ‘infer’ will attempt to infer fall dst-transition hours based on order
• bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
• ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

nonexistent ['shift_forward’, ‘shift_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

• ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
• ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
• ‘NaT’ will return NaT where there are nonexistent times
• timedelta objects will shift nonexistent times by the timedelta
pandas: powerful Python data analysis toolkit, Release 1.1.1

- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series  Index of the same type for a DatetimeIndex or
TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'], dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'], dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.floor("H")
0  2018-01-01 11:00:00
1  2018-01-01 12:00:00
2  2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.Series.dt.ceil

Series.dt.ceil(*args, **kwargs)

Perform ceil operation on the data to the specified freq.

Parameters

freq [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like
‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq
values.

ambiguous ['infer', bool-ndarray, 'NaT', default ‘raise’] Only relevant for DatetimeIndex:
- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time
  (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.
nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- 'shift_forward' will shift the nonexistent time forward to the closest existing time
- 'shift_backward' will shift the nonexistent time backward to the closest existing time
- 'NaT' will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- 'raise' will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
```

```python
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 13:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.ceil("H")
0  2018-01-01 12:00:00
1  2018-01-01 12:00:00
2  2018-01-01 13:00:00
dtype: datetime64[ns]
```

pandas.Series.dt.month_name

Series.dt.month_name(*args, **kwargs)

Return the month names of the DateTimeIndex with specified locale.

New in version 0.23.0.

Parameters

- locale [str, optional] Locale determining the language in which to return the month name. Default is English locale.

Returns
Index  Index of month names.

Examples

```python
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
   dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```

**pandas.Series.dt.day_name**

Series.dt.day_name(*args, **kwargs)

Return the day names of the DateTimeIndex with specified locale.

New in version 0.23.0.

Parameters

locale  [str, optional] Locale determining the language in which to return the day name. Default is English locale.

Returns

Index  Index of day names.

Examples

```python
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
   dtype='datetime64[ns]', freq='D')
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

4      0       0         0         4              0             0             0

Timedelta methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.dt.to_pytimedelta()</td>
<td>Return an array of native datetime.timedelta objects.</td>
</tr>
<tr>
<td>Series.dt.total_seconds(*args, **kwargs)</td>
<td>Return total duration of each element expressed in seconds.</td>
</tr>
</tbody>
</table>

pandas.Series.dt.to_pytimedelta

Series.dt.to_pytimedelta()
Return an array of native datetime.timedelta objects.

Python’s standard datetime library uses a different representation timedelta’s. This method converts a Series of pandas Timedeltas to datetime.timedelta format with the same length as the original Series.

Returns
numpy.ndarray Array of 1D containing data with datetime.timedelta type.

See also:
datetime.timedelta

3.3. Series
Examples

```python
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit="d"))
>>> s
0 0 days
1 1 days
2 2 days
3 3 days
4 4 days
dtype: timedelta64[ns]

>>> s.dt.to_pytimedelta()
array([datetime.timedelta(0), datetime.timedelta(days=1),
       datetime.timedelta(days=2), datetime.timedelta(days=3),
       datetime.timedelta(days=4)], dtype=object)
```

**pandas.Series.dt.total_seconds**

Series.dt.total_seconds(*args, **kwargs)

Return total duration of each element expressed in seconds.

This method is available directly on TimedeltaArray, TimedeltaIndex and on Series containing timedelta values under the .dt namespace.

**Returns**

seconds [[ndarray, Float64Index, Series]] When the calling object is a TimedeltaArray, the return type is ndarray. When the calling object is a TimedeltaIndex, the return type is a Float64Index. When the calling object is a Series, the return type is Series of type float64 whose index is the same as the original.

See also:

datetime.timedelta.total_seconds Standard library version of this method.
TimedeltaIndex.components Return a DataFrame with components of each Timedelta.

Examples

Series

```python
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
0 0 days
1 1 days
2 2 days
3 3 days
4 4 days
dtype: timedelta64[ns]

>>> s.dt.total_seconds()
0 0.0
1 86400.0
2 172800.0
3 259200.0
4 345600.0
dtype: float64
```
TimedeltaIndex

```python
>>> idx = pd.to_timedelta(np.arange(5), unit='d')
>>> idx
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq=None)

>>> idx.total_seconds()
Float64Index([0.0, 86400.0, 172800.0, 259200.0, 345600.0],
              dtype='float64')
```

String handling

Series.str can be used to access the values of the series as strings and apply several methods to it. These can be accessed like `Series.str.<function/property>.

```python
Series.str.capitalize(*args, **kwars) Convert strings in the Series/Index to be capitalized.
Series.str.casefold(*args, **kwars) Convert strings in the Series/Index to be casefolded.
Series.str.cat(*args, **kwars) Concatenate strings in the Series/Index with given separator.
Series.str.center(*args, **kwars) Pad left and right side of strings in the Series/Index.
Series.str.contains(*args, **kwars) Test if pattern or regex is contained within a string of a Series or Index.
Series.str.count(*args, **kwars) Count occurrences of pattern in each string of the Series/Index.
Series.str.decode(encoding[, errors]) Decode character string in the Series/Index using indicated encoding.
Series.str.encode(*args, **kwargs) Encode character string in the Series/Index using indicated encoding.
Series.str.endswith(*args, **kwargs) Test if the end of each string element matches a pattern.
Series.str.extract(*args, **kwargs) Extract capture groups in the regex pat as columns in a DataFrame.
Series.str.extractall(*args, **kwargs) Extract capture groups in the regex pat as columns in DataFrame.
Series.str.find(*args, **kwargs) Return lowest indexes in each strings in the Series/Index.
Series.str.findall(*args, **kwargs) Find all occurrences of pattern or regular expression in the Series/Index.
Series.str.get(i) Extract element from each component at specified position.
Series.str.index(*args, **kwargs) Return lowest indexes in each string in Series/Index.
Series.str.join(*args, **kwargs) Join lists contained as elements in the Series/Index with passed delimiter.
Series.str.len(*args, **kwargs) Compute the length of each element in the Series/Index.
Series.str.ljust(*args, **kwargs) Pad right side of strings in the Series/Index.
Series.str.lower(*args, **kwargs) Convert strings in the Series/Index to lowercase.
Series.str.lstrip(*args, **kwargs) Remove leading characters.
Series.str.match(*args, **kwargs) Determine if each string starts with a match of a regular expression.
Series.str.normalize(*args, **kwargs) Return the Unicode normal form for the strings in the Series/Index.
```
<table>

<tr>
<td><code>Series.str.isdecimal(*args, **kwargs)</code></td>
<td>Check whether all characters in each string are decimal.</td>
</tr>
<tr>
<td><code>Series.str.get_dummies(*args, **kwargs)</code></td>
<td>Return DataFrame of dummy/indicator variables for Series.</td>
</tr>
</tbody>
</table>
pandas.Series.str.capitalize

Series.str.capitalize(*args, **kwargs)
Convert strings in the Series/Index to be capitalized.

Equivalent to str.capitalize().

Returns
Series or Index of object

See also:
Series.str.lower  Converts all characters to lowercase.
Series.str.upper  Converts all characters to uppercase.
Series.str.title  Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize  Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase  Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold  Removes all case distinctions in the string.

Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])

>>> s
0    lower
1  CAPITALS
2    this is a sentence
3       SwApCaSe
dtype: object

>>> s.str.lower()
0    lower
1  capitals
2    this is a sentence
3       swapcase
dtype: object

>>> s.str.upper()
0   LOWER
1  CAPITALS
2  THIS IS A SENTENCE
3     SWAPCASE
dtype: object

>>> s.str.title()
0   Lower
1  Capitals
2  This Is A Sentence
3       Swapcase
dtype: object

>>> s.str.capitalize()
0   Lower
1  Capitals
2  This is a sentence
3       Swapcase
dtype: object
```
pandas.Series.str.swapcase

Series.str.swapcase()  
Convert uppercase to lowercase and lowercase to uppercase.

Series or Index of object

Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0   lower
1  CAPITALS
2  this is a sentence
3     SwApCaSe
dtype: object

>>> s.str.swapcase()
0    LOWER
1  capitals
2  THIS IS A SENTENCE
3     sWaFCaSE
dtype: object
```

pandas.Series.str.casefold

Series.str.casefold(*args, **kwargs)
  
Convert strings in the Series/Index to be casefolded.

New in version 0.25.0.

Equivalent to str.casefold().

Returns
  
Series or Index of object

See also:

Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold Removes all case distinctions in the string.

Examples

```python
>>> s.str.swapcase()
0    LOWER
1  capitals
2  THIS IS A SENTENCE
3     sWaFCaSE

>>> s.str.lower()
0   lower
1  capitals
2  this is a sentence
3     swapcase
dtype: object

>>> s.str.upper()
0    LOWER
1  CAPITALS
2  THIS IS A SENTENCE
3     SWAPCASE
dtype: object

>>> s.str.title()
0    Lower
(continues on next page)```
1 Capitals
2 This Is A Sentence
3 Swapcase
dtype: object

```python
>>> s.str.capitalize()
0 Lower
1 Capitals
2 This is a sentence
3 Swapcase
dtype: object
```

```python
>>> s.str.swapcase()
0 LOWER
1 capitals
2 THIS IS A SENTENCE
3 sWaPcAsE
dtype: object
```

**pandas.Series.str.cat**

`Series.str.cat(*args, **kwargs)`
Concatenate strings in the Series/Index with given separator.

If `others` is specified, this function concatenates the Series/Index and elements of `others` element-wise. If `others` is not passed, then all values in the Series/Index are concatenated into a single string with a given `sep`.

**Parameters**

- **others** [Series, Index, DataFrame, np.ndarray or list-like] Series, Index, DataFrame, np.ndarray (one- or two-dimensional) and other list-likes of strings must have the same length as the calling Series/Index, with the exception of indexed objects (i.e. Series/Index/DataFrame) if `join` is not None.

  If `others` is a list-like that contains a combination of Series, Index or np.ndarray (1-dim), then all elements will be unpacked and must satisfy the above criteria individually.

  If `others` is None, the method returns the concatenation of all strings in the calling Series/Index.

- **sep** [str, default ''] The separator between the different elements/columns. By default the empty string '' is used.

- **na_rep** [str or None, default None] Representation that is inserted for all missing values:
  - If `na_rep` is None, and `others` is None, missing values in the Series/Index are omitted from the result.
  - If `na_rep` is None, and `others` is not None, a row containing a missing value in any of the columns (before concatenation) will have a missing value in the result.

- **join** [‘left’, ‘right’, ‘outer’, ‘inner’], default ‘left’] Determines the join-style between the calling Series/Index and any Series/Index/DataFrame in `others` (objects without an index need to match the length of the calling Series/Index). To disable alignment, use `.values` on any Series/Index/DataFrame in `others`.

  New in version 0.23.0.

  Changed in version 1.0.0: Changed default of `join` from None to ‘left’.

```
```
Returns

*str, Series or Index*  If `others` is None, `str` is returned, otherwise a `Series/Index` (same type as caller) of objects is returned.

See also:

- **split** Split each string in the Series/Index.
- **join** Join lists contained as elements in the Series/Index.

Examples

When not passing `others`, all values are concatenated into a single string:

```python
>>> s = pd.Series(['a', 'b', np.nan, 'd'])
>>> s.str.cat(sep=' ')
'a b d'
```

By default, NA values in the Series are ignored. Using `na_rep`, they can be given a representation:

```python
>>> s.str.cat(sep=' ', na_rep='?')
'a b ? d'
```

If `others` is specified, corresponding values are concatenated with the separator. Result will be a Series of strings.

```python
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=','
0 a,A
1 b,B
2 NaN
3 d,D
dtype: object
```

Missing values will remain missing in the result, but can again be represented using `na_rep`

```python
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=' ', na_rep='--')
0 aA
1 bB
2 --C
3 dD
dtype: object
```

If `sep` is not specified, the values are concatenated without separation.

```python
>>> s.str.cat(['A', 'B', 'C', 'D'], na_rep='--')
0 aA
1 bB
2 --C
3 dD
dtype: object
```

Series with different indexes can be aligned before concatenation. The `join`-keyword works as in other methods.

```python
>>> t = pd.Series(['d', 'a', 'e', 'c'], index=[3, 0, 4, 2])
>>> s.str.cat(t, join='left', na_rep='--')
0 aa
1 b--
2 --c
3 dd
```

(continues on next page)
```python
dtype: object
>>> s.str.cat(t, join='outer', na_rep='-')
0   aa
1   b-
2   -c
3   dd
4   -e
dtype: object

>>> s.str.cat(t, join='inner', na_rep='-')
0   aa
2   -c
3   dd
dtype: object

>>> s.str.cat(t, join='right', na_rep='-')
3   dd
0   aa
4   -e
2   -c
dtype: object
```

For more examples, see [here](#).

### pandas.Series.str.center

**Series.str.center(*args, **kwargs)**

Pad left and right side of strings in the Series/Index.

Equivalent to `str.center()`.

**Parameters**

- `width` [int] Minimum width of resulting string; additional characters will be filled with `fillchar`.
- `fillchar` [str] Additional character for filling, default is whitespace.

**Returns**

- `filled` [Series/Index of objects.]

### pandas.Series.str.contains

**Series.str.contains(*args, **kwargs)**

Test if pattern or regex is contained within a string of a Series or Index.

Return boolean Series or Index based on whether a given pattern or regex is contained within a string of a Series or Index.

**Parameters**

- `pat` [str] Character sequence or regular expression.
- `case` [bool, default True] If True, case sensitive.
- `flags` [int, default 0 (no flags)] Flags to pass through to the re module, e.g. re.IGNORECASE.
- `na` [default NaN] Fill value for missing values.
regex [bool, default True] If True, assumes the pat is a regular expression.

If False, treats the pat as a literal string.

Returns

Series or Index of boolean values A Series or Index of boolean values indicating whether
the given pattern is contained within the string of each element of the Series or Index.

See also:

match Analogous, but stricter, relying on re.match instead of re.search.
Series.str.startswith Test if the start of each string element matches a pattern.
Series.str.endswith Same as startswith, but tests the end of string.

Examples

Returning a Series of booleans using only a literal pattern.

```python
>>> s1 = pd.Series(['Mouse', 'dog', 'house and parrot', '23', np.NaN])
>>> s1.str.contains('og', regex=False)
0    False
1     True
2    False
3    False
4    NaN
dtype: object
```

Returning an Index of booleans using only a literal pattern.

```python
>>> ind = pd.Index(['Mouse', 'dog', 'house and parrot', '23.0', np.NaN])
>>> ind.str.contains('23', regex=False)
Index([False, False, False, True, nan], dtype='object')
```

Specifying case sensitivity using case.

```python
>>> s1.str.contains('oG', case=True, regex=True)
0    False
1    False
2    False
3    False
4    NaN
dtype: object
```

Specifying na to be False instead of NaN replaces NaN values with False. If Series or Index does not contain NaN values the resultant dtype will be bool, otherwise, an object dtype.

```python
>>> s1.str.contains('og', na=False, regex=True)
0    False
1     True
2    False
3    False
4    False
dtype: bool
```

Returning ‘house’ or ‘dog’ when either expression occurs in a string.
>>> s1.str.contains('house|dog', regex=True)
0    False
1     True
2     True
3    False
4    NaN
dtype: object

Ignoring case sensitivity using flags with regex.

>>> import re

>>> s1.str.contains('PARROT', flags=re.IGNORECASE, regex=True)
0    False
1    False
2     True
3    False
4    NaN
dtype: object

Returning any digit using regular expression.

>>> s1.str.contains('\d', regex=True)
0    False
1    False
2    False
3     True
4    NaN
dtype: object

Ensure pat is a not a literal pattern when regex is set to True. Note in the following example one might expect only s2[1] and s2[3] to return True. However, '\.0' as a regex matches any character followed by a 0.

>>> s2 = pd.Series(['40', '40.0', '41', '41.0', '35'])
>>> s2.str.contains('.0', regex=True)
0     True
1     True
2    False
3     True
4    False
dtype: bool

**pandas.Series.str.count**

Series.str.count(*args, **kwargs)

Count occurrences of pattern in each string of the Series/Index.

This function is used to count the number of times a particular regex pattern is repeated in each of the string elements of the Series.

- **Parameters**
  - pat [str] Valid regular expression.
  - flags [int, default 0, meaning no flags] Flags for the re module. For a complete list, see here.
  - **kwargs** For compatibility with other string methods. Not used.

- **Returns**
Series or Index  Same type as the calling object containing the integer counts.

See also:
- re  Standard library module for regular expressions.
- str.count  Standard library version, without regular expression support.

Notes
Some characters need to be escaped when passing in pat. eg. ‘$’ has a special meaning in regex and must be escaped when finding this literal character.

Examples

```python
>>> s = pd.Series(['A', 'B', 'Aaba', 'Baca', np.nan, 'CABA', 'cat'])
>>> s.str.count('a')
0    0.0
1    0.0
2    2.0
3    2.0
4    NaN
5    0.0
6    1.0
dtype: float64
```

Escape ' $ ' to find the literal dollar sign.

```python
>>> s = pd.Series(['$', 'B', 'Aab$', '$$ca', 'C$B$', 'cat'])
>>> s.str.count('\$')
0    1
1    0
2    1
3    2
4    2
5    0
dtype: int64
```

This is also available on Index

```python
>>> pd.Index(['A', 'A', 'Aaba', 'cat']).str.count('a')
Int64Index([0, 0, 2, 1], dtype='int64')
```

pandas.Series.str.decode

Series.str.decode(encoding, errors='strict')
Decode character string in the Series/Index using indicated encoding.

Equivalent to str.decode() in python2 and bytes.decode() in python3.

Parameters
- encoding  [str]
- errors  [str, optional]

Returns
Series or Index
pandas.Series.str.encode

Series.str.encode(*args, **kwargs)
Encode character string in the Series/Index using indicated encoding.

Equivalent to str.encode().

Parameters
- encoding [str]
- errors [str, optional]

Returns
- encoded [Series/Index of objects]

pandas.Series.str.endswith

Series.str.endswith(*args, **kwargs)
Test if the end of each string element matches a pattern.

Equivalent to str.endswith().

Parameters
- pat [str] Character sequence. Regular expressions are not accepted.
- na [object, default NaN] Object shown if element tested is not a string.

Returns
- Series or Index of bool A Series of booleans indicating whether the given pattern matches
the end of each string element.

See also:
- str.endswith Python standard library string method.
- Series.str.startswith Same as endswith, but tests the start of string.
- Series.str.contains Tests if string element contains a pattern.

Examples

```python
>>> s = pd.Series(['bat', 'bear', 'caT', np.nan])
>>> s
0  bat
1  bear
2  caT
3  NaN
dtype: object

>>> s.str.endswith('t')
0   True
1  False
2  False
3   NaN
dtype: object
```

Specifying `na` to be `False` instead of `NaN`. 
>>> s.str.endswith('t', na=False)
0    True  
1      False
2     False
3     False
dtype: bool

**pandas.Series.str.extract**

Series.str.extract(*args, **kwargs)

Extract capture groups in the regex pat as columns in a DataFrame.

For each subject string in the Series, extract groups from the first match of regular expression pat.

**Parameters**

- **pat** [str] Regular expression pattern with capturing groups.
- **flags** [int, default 0 (no flags)] Flags from the re module, e.g. re.IGNORECASE, that modify regular expression matching for things like case, spaces, etc. For more details, see re.
- **expand** [bool, default True] If True, return DataFrame with one column per capture group. If False, return a Series/Index if there is one capture group or DataFrame if there are multiple capture groups.

**Returns**

- **DataFrame or Series or Index** A DataFrame with one row for each subject string, and one column for each group. Any capture group names in regular expression pat will be used for column names; otherwise capture group numbers will be used. The dtype of each result column is always object, even when no match is found. If expand=False and pat has only one capture group, then return a Series (if subject is a Series) or Index (if subject is an Index).

**See also:**

extractall Returns all matches (not just the first match).

**Examples**

A pattern with two groups will return a DataFrame with two columns. Non-matches will be NaN.

```python
>>> s = pd.Series(['a1', 'b2', 'c3'])
>>> s.str.extract(r'([ab])(\d)')
   0  1
0 a 1
1 b 2
2 NaN NaN
```

A pattern may contain optional groups.

```python
>>> s.str.extract(r'([ab])?(\d)')
   0  1
0 a 1
1 b 2
2 NaN NaN
```

Named groups will become column names in the result.
A pattern with one group will return a DataFrame with one column if expand=True.

```
>>> s.str.extract(r'(?P<letter>[ab])(?P<digit>\d)')
   letter digit
0    a     1
1    b     2
2  NaN   NaN
```

A pattern with one group will return a Series if expand=False.

```
>>> s.str.extract(r'([ab])(\d)', expand=False)
0  1
1  2
2  NaN
dtype: object
```

**pandas.Series.str.extractall**

Series.str.extractall(*args, **kwargs)

Extract capture groups in the regex pat as columns in DataFrame.

For each subject string in the Series, extract groups from all matches of regular expression pat. When each subject string in the Series has exactly one match, extractall(pat).xs(0, level='match') is the same as extract(pat).

**Parameters**

- **pat** [str] Regular expression pattern with capturing groups.
- **flags** [int, default 0 (no flags)] A re module flag, for example re.IGNORECASE. These allow to modify regular expression matching for things like case, spaces, etc. Multiple flags can be combined with the bitwise OR operator, for example re.IGNORECASE | re.MULTILINE.

**Returns**

DataFrame A DataFrame with one row for each match, and one column for each group. Its rows have a MultiIndex with first levels that come from the subject Series. The last level is named 'match' and indexes the matches in each item of the Series. Any capture group names in regular expression pat will be used for column names; otherwise capture group numbers will be used.

**See also:**

- extract Returns first match only (not all matches).
Examples

A pattern with one group will return a DataFrame with one column. Indices with no matches will not appear in the result.

```python
>>> s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"])
>>> s.str.extractall(r"\[ab\](\d)")
match
0     A 0
1     1  2
B 0  1
```

Capture group names are used for column names of the result.

```python
>>> s.str.extractall(r"\[ab\](?P<digit>\d)")
digit
match
0    A 0
1    1  2
B 0  1
```

A pattern with two groups will return a DataFrame with two columns.

```python
>>> s.str.extractall(r"(?P<letter>[ab])(?P<digit>\d)")
letter digit
match
A 0    a  1
1      a  2
B 0    b  1
```

Optional groups that do not match are NaN in the result.

```python
>>> s.str.extractall(r"(?P<letter>[ab])?(?P<digit>\d)")
letter digit
match
A 0    a  1
1      a  2
B 0    b  1
C 0  NaN  1
```

`pandas.Series.str.find`

`Series.str.find(*args, **kwargs)`

Return lowest indexes in each strings in the Series/Index.

Each of returned indexes corresponds to the position where the substring is fully contained between [start:end]. Return -1 on failure. Equivalent to standard `str.find()`.

Parameters

- `sub` [str] Substring being searched.
- `start` [int] Left edge index.
- `end` [int] Right edge index.

Returns
Series or Index of int.

See also:

**rfind** Return highest indexes in each strings.

### pandas.Series.str.findall

**pandas.Series.str.findall**(*args, **kwargs*)

Find all occurrences of pattern or regular expression in the Series/Index.

Equivalent to applying `re.findall()` to all the elements in the Series/Index.

**Parameters**

- `pat` [str] Pattern or regular expression.
- `flags` [int, default 0] Flags from `re` module, e.g. `re.IGNORECASE` (default is 0, which means no flags).

**Returns**

*Series/Index of lists of strings* All non-overlapping matches of pattern or regular expression in each string of this Series/Index.

See also:

- `count` Count occurrences of pattern or regular expression in each string of the Series/Index.
- `extractall` For each string in the Series, extract groups from all matches of regular expression and return a DataFrame with one row for each match and one column for each group.
- `re.findall` The equivalent `re` function to all non-overlapping matches of pattern or regular expression in string, as a list of strings.

### Examples

```python
>>> s = pd.Series(['Lion', 'Monkey', 'Rabbit'])

The search for the pattern ‘Monkey’ returns one match:

```python
gbgeg
s.str.findall('Monkey')
```

```
0    []
1   ['Monkey']
2    []
dtype: object
```

On the other hand, the search for the pattern ‘MONKEY’ doesn’t return any match:

```python
gbgeg
s.str.findall('MONKEY')
```

```
0    []
1    []
2    []
dtype: object
```

Flags can be added to the pattern or regular expression. For instance, to find the pattern ‘MONKEY’ ignoring the case:

```python
>>> import re
>>> s.str.findall('MONKEY', flags=re.IGNORECASE)
```

```
0    []
```
When the pattern matches more than one string in the Series, all matches are returned:

```python
>>> s.str.findall('on')
0    [on]
1    [on]
2     []
dtype: object
```

Regular expressions are supported too. For instance, the search for all the strings ending with the word ‘on’ is shown next:

```python
>>> s.str.findall('on$')
0    [on]
1     []
2     []
dtype: object
```

If the pattern is found more than once in the same string, then a list of multiple strings is returned:

```python
>>> s.str.findall('b')
0     []
1     []
2    [b, b]
dtype: object
```

### pandas.Series.str.get

**Series.str.get(i)**

Extract element from each component at specified position.

Extract element from lists, tuples, or strings in each element in the Series/Index.

**Parameters**

- **i** [int] Position of element to extract.

**Returns**

Series or Index

**Examples**

```python
>>> s = pd.Series(['String',
...                 (1, 2, 3),
...                 ['a', 'b', 'c'],
...                 123,
...                 -456,
...                 {1: 'Hello', 2: 'World'}])
>>> s
0    String
1    (1, 2, 3)
2    [a, b, c]
3    123
4    -456
5    {1: 'Hello', 2: 'World'}
```

```python
(continues on next page)```
```
2       [a, b, c]
3          123
4          -456
5    {1: 'Hello', '2': 'World'}
dtype: object
```

```
>>> s.str.get(1)
0   t
1   2
2   b
3  NaN
4  NaN
5  Hello
dtype: object
```

```
>>> s.str.get(-1)
0   g
1   3
2   c
3  NaN
4  NaN
5   None
dtype: object
```

```
pandas.Series.str.index
```

Series.str.index(*args, **kwargs)

Return lowest indexes in each string in Series/Index.

Each of the returned indexes corresponds to the position where the substring is fully contained between [start:end]. This is the same as str.find except instead of returning -1, it raises a ValueError when the substring is not found. Equivalent to standard str.index.

Parameters

- **sub** [str] Substring being searched.
- **start** [int] Left edge index.
- **end** [int] Right edge index.

Returns

Series or Index of object

See also:

- **rindex** Return highest indexes in each strings.
**pandas.Series.str.join**

Series.str.join(*args, **kwargs)

Join lists contained as elements in the Series/Index with passed delimiter.

If the elements of a Series are lists themselves, join the content of these lists using the delimiter passed to the function. This function is an equivalent to `str.join()`.

**Parameters**

- `sep` [str] Delimiter to use between list entries.

**Returns**

- **Series/Index:** object The list entries concatenated by intervening occurrences of the delimiter.

**Raises**

- `AttributeError` If the supplied Series contains neither strings nor lists.

**See also:**

- `str.join` Standard library version of this method.
- `Series.str.split` Split strings around given separator/delimiter.

**Notes**

If any of the list items is not a string object, the result of the join will be `NaN`.

**Examples**

Example with a list that contains non-string elements.

```python
>>> s = pd.Series([['lion', 'elephant', 'zebra'],
                 ... [1.1, 2.2, 3.3],
                 ... ['cat', np.nan, 'dog'],
                 ... ['cow', 4.5, 'goat'],
                 ... ['duck', ['swan', 'fish'], 'guppy']])
```

Join all lists using a `-`. The lists containing object(s) of types other than str will produce a NaN.

```python
>>> s.str.join('-')
0    lion-elephant-zebra
1     NaN
2     NaN
3     NaN
4     NaN
dtype: object
```
pandas.Series.str.len

Series.str.len(*args, **kwargs)
Compute the length of each element in the Series/Index.

The element may be a sequence (such as a string, tuple or list) or a collection (such as a dictionary).

Returns

Series or Index of int A Series or Index of integer values indicating the length of each element in the Series or Index.

See also:

str.len Python built-in function returning the length of an object.
Series.size Returns the length of the Series.

Examples

Returns the length (number of characters) in a string. Returns the number of entries for dictionaries, lists or tuples.

```python
>>> s = pd.Series(['dog', '', 5, ('foo': 'bar'), [2, 3, 5, 7], ('one', 'two', 'three')])
>>> s
0   dog
1    
2    5
3   {'foo': 'bar'}
4  [2, 3, 5, 7]
5   (one, two, three)
dtype: object
>>> s.str.len()
0  3.0
1  0.0
2  NaN
3  1.0
4  4.0
5  3.0
dtype: float64
```

pandas.Series.str.ljust

Series.str.ljust(*args, **kwargs)
Pad right side of strings in the Series/Index.

Equivalent to str.ljust().

Parameters

- **width** [int] Minimum width of resulting string; additional characters will be filled with fillchar.
- **fillchar** [str] Additional character for filling, default is whitespace.

Returns
Series.str.lower

Series.str.lower(*args, **kwargs)

Convert strings in the Series/Index to lowercase.

Equivalent to str.lower().

Returns

Series or Index of object

See also:

Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold Removes all case distinctions in the string.

Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0     lower
1    CAPITALS
2   this is a sentence
3   SwApCaSe
dtype: object

>>> s.str.lower()  #Converts all characters to lowercase.
0     lower
1    capitals
2   this is a sentence
3   swapcase
dtype: object

>>> s.str.upper()  #Converts all characters to uppercase.
0      LOWER
1    CAPITALS
2  THIS IS A SENTENCE
3   SWAPCASE
dtype: object

>>> s.str.title()  #Converts first character of each word to uppercase and remaining to lowercase.
0     Lower
1    Capitals
2   This Is A Sentence
3   Swapcase
dtype: object

>>> s.str.capitalize()  #Converts first character to uppercase and remaining to lowercase.
0     Lower
1    Capitals
```
```python
>>> s = pd.Series(['1. Ant.', '2. Bee!
', '3. Cat?	', np.nan])
>>> s
0   1. Ant.
1  2. Bee!
2   3. Cat?
3     NaN
dtype: object
```

```python
>>> s.str.strip()
0   1. Ant.
1  2. Bee!
2   3. Cat?
3     NaN
dtype: object
```

```python
>>> s = pd.Series(['1. Ant.', '2. Bee!
', '3. Cat?	', np.nan])
>>> s
0   1. Ant.
1  2. Bee!
2   3. Cat?
3     NaN
dtype: object
```

```python
>>> s.str.lstrip('123.')
0   Ant.
1  Bee!
2   Cat?
3     NaN
dtype: object
```

```python
>>> s = pd.Series(['1. Ant.', '2. Bee!
', '3. Cat?	', np.nan])
>>> s
0   1. Ant.
1  2. Bee!
2   3. Cat?
3     NaN
dtype: object
```

```python
>>> s.str.lstrip('I23.')
0   Ant.
1  Bee!
```

---

**pandas.Series.str.lstrip**

`Series.str.lstrip(*args, **kwargs)`

Remove leading characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left side. Equivalent to `str.lstrip()`.

**Parameters**

- `to_strip` [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

**Returns**

Series or Index of object

**See also:**

- `Series.str.strip` Remove leading and trailing characters in Series/Index.
- `Series.str.lstrip` Remove leading characters in Series/Index.
- `Series.str.rstrip` Remove trailing characters in Series/Index.

**Examples**

```python
>>> s = pd.Series(['1. Ant. ', '2. Bee!
', '3. Cat?	', np.nan])
>>> s
0   1. Ant. 
1   2. Bee!
2   3. Cat?
3     NaN
dtype: object
```

```python
>>> s.str.strip()
0   1. Ant. 
1   2. Bee!
2   3. Cat?
3     NaN
dtype: object
```

```python
>>> s = pd.Series(['1. Ant. ', '2. Bee!
', '3. Cat?	', np.nan])
>>> s
0   1. Ant. 
1   2. Bee!
2   3. Cat?
3     NaN
dtype: object
```

```python
>>> s.str.lstrip('123.')
0   Ant. 
1   Bee!
2   Cat?
3     NaN
dtype: object
```

---

3.3. Series 1311
pandas.Series.str.match

Series.str.match(*args, **kwargs)

Determine if each string starts with a match of a regular expression.

Parameters:

- **pat** [str] Character sequence or regular expression.
- **case** [bool, default True] If True, case sensitive.
- **flags** [int, default 0 (no flags)] Regex module flags, e.g. re.IGNORECASE.
- **na** [default NaN] Fill value for missing values.

Returns:

Series/array of boolean values

See also:

fullmatch  Stricter matching that requires the entire string to match.
contains   Analogous, but less strict, relying on re.search instead of re.match.
extract    Extract matched groups.

pandas.Series.str.normalize

Series.str.normalize(*args, **kwargs)

Return the Unicode normal form for the strings in the Series/Index.

For more information on the forms, see the unicodedata.normalize().

Parameters:

Returns:

normalized [Series/Index of objects]
pandas.Series.str.pad

Series.str.pad(*args, **kwargs)

Pad strings in the Series/Index up to width.

Parameters

- **width** [int] Minimum width of resulting string; additional characters will be filled with character defined in fillchar.
- **side** [{'left', 'right', 'both'}, default 'left'] Side from which to fill resulting string.
- **fillchar** [str, default ' '] Additional character for filling, default is whitespace.

Returns

Series or Index of object  Returns Series or Index with minimum number of char in object.

See also:

- **Series.str.rjust** Fills the left side of strings with an arbitrary character. Equivalent to Series.str.pad(side='left').
- **Series.str.ljust** Fills the right side of strings with an arbitrary character. Equivalent to Series.str.pad(side='right').
- **Series.str.center** Fills both sides of strings with an arbitrary character. Equivalent to Series.str.pad(side='both').
- **Series.str.zfill** Pad strings in the Series/Index by prepending '0' character. Equivalent to Series.str.pad(side='left', fillchar='0').

Examples

```python
>>> s = pd.Series(['caribou', 'tiger'])
>>> s
0  caribou
1   tiger
dtype: object

>>> s.str.pad(width=10)
0  caribou
1   tiger
dtype: object

>>> s.str.pad(width=10, side='right', fillchar='-')
0  caribou---
1 ---tiger---
dtype: object

>>> s.str.pad(width=10, side='both', fillchar='-')
0  -caribou--
1   --tiger---
dtype: object
```
pandas.Series.str.partition

Series.str.partition(*args, **kwargs)
Split the string at the first occurrence of sep.

This method splits the string at the first occurrence of sep, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing the string itself, followed by two empty strings.

Parameters

- sep [str, default whitespace] String to split on.
- expand [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality. If False, return Series/Index.

Returns

DataFrame/MultiIndex or Series/Index of objects

See also:

- rpartition Split the string at the last occurrence of sep.
- Series.str.split Split strings around given separators.
- str.partition Standard library version.

Examples

```python
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0   Linda van der Berg
1   George Pitt-Rivers
dtype: object

>>> s.str.partition()
   0   1   2
0  Linda  van der Berg
1  George Pitt-Rivers

To partition by the last space instead of the first one:

```python
>>> s.str.rpartition()
   0   1   2
0  Linda  van der Berg
1  George Pitt-Rivers
```

To partition by something different than a space:

```python
>>> s.str.partition('-')
   0   1   2
0  Linda  van der Berg
1  George Pitt - Rivers
```

To return a Series containing tuples instead of a DataFrame:

```python
>>> s.str.partition('-', expand=False)
   0   1   2
0 (Linda van der Berg, , )
1 (George Pitt, -, Rivers)
dtype: object
```
Also available on indices:

```python
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```python
>>> idx.str.partition()
MultiIndex([('X', ' ', '123'), ('Y', ' ', '999')],
           )
```

Or an index with tuples with `expand=False`:

```python
>>> idx.str.partition(expand=False)
Index([('X', ' ', '123'), ('Y', ' ', '999')], dtype='object')
```

**pandas.Series.str.repeat**

`Series.str.repeat(*args, **kwargs)`

Duplicate each string in the Series or Index.

**Parameters**

- `repeats` [int or sequence of int] Same value for all (int) or different value per (sequence).

**Returns**

- `Series or Index of object` Series or Index of repeated string objects specified by input parameter repeats.

**Examples**

```python
>>> s = pd.Series(['a', 'b', 'c'])
>>> s
0    a
1    b
2    c
dtype: object

Single int repeats string in Series

```python
>>> s.str.repeat(repeats=2)
0   aa
1   bb
2   cc
dtype: object
```

Sequence of int repeats corresponding string in Series

```python
>>> s.str.repeat(repeats=[1, 2, 3])
0    a
1   bb
2  ccc
dtype: object
```
pandas.Series.str.replace

Series.str.replace(*args, **kwargs)
Replace each occurrence of pattern/regex in the Series/Index.

Equivalent to str.replace() or re.sub(), depending on the regex value.

**Parameters**

- **pat** [str or compiled regex] String can be a character sequence or regular expression.
- **repl** [str or callable] Replacement string or a callable. The callable is passed the regex match object and must return a replacement string to be used. See re.sub().
- **n** [int, default -1 (all)] Number of replacements to make from start.
- **case** [bool, default None] Determines if replace is case sensitive:
  - If True, case sensitive (the default if pat is a string)
  - Set to False for case insensitive
  - Cannot be set if pat is a compiled regex.
- **flags** [int, default 0 (no flags)] Regex module flags, e.g. re.IGNORECASE. Cannot be set if pat is a compiled regex.
- **regex** [bool, default True] Determines if assumes the passed-in pattern is a regular expression:
  - If True, assumes the passed-in pattern is a regular expression.
  - If False, treats the pattern as a literal string
  - Cannot be set to False if pat is a compiled regex or repl is a callable.

New in version 0.23.0.

**Returns**

Series or Index of object A copy of the object with all matching occurrences of pat replaced by repl.

**Raises**

- **ValueError**
  - if regex is False and repl is a callable or pat is a compiled regex
  - if pat is a compiled regex and case or flags is set

**Notes**

When pat is a compiled regex, all flags should be included in the compiled regex. Use of case, flags, or regex=False with a compiled regex will raise an error.
Examples

When `pat` is a string and `regex` is True (the default), the given `pat` is compiled as a regex. When `repl` is a string, it replaces matching regex patterns as with `re.sub()`. NaN value(s) in the Series are left as is:

```python
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f.', 'ba', regex=True)
0 bao
1 baz
2 NaN
dtype: object
```

When `pat` is a string and `regex` is False, every `pat` is replaced with `repl` as with `str.replace()`:

```python
>>> pd.Series(['f.o', 'fuz', np.nan]).str.replace('f.', 'ba', regex=False)
0 bao
1 fuz
2 NaN
dtype: object
```

When `repl` is a callable, it is called on every `pat` using `re.sub()`. The callable should expect one positional argument (a regex object) and return a string.

To get the idea:

```python
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f', repr)
0 <re.Match object; span=(0, 1), match='f'>oo
1 <re.Match object; span=(0, 1), match='f'>uz
2 NaN
dtype: object
```

Reverse every lowercase alphabetic word:

```python
>>> repl = lambda m: m.group(0)[::-1]
>>> pd.Series(['foo 123', 'bar baz', np.nan]).str.replace(r'[a-z]+', repl)
0 oof 123
1 rab zab
2 NaN
dtype: object
```

Using regex groups (extract second group and swap case):

```python
>>> pat = r"(?P<one>[a-zA-Z]) (?P<two>[a-zA-Z]) (?P<three>[a-zA-Z])"
>>> repl = lambda m: m.group('two').swapcase()
>>> pd.Series(['One Two Three', 'Foo Bar Baz']).str.replace(pat, repl)
0 tWO
1 bAR
dtype: object
```

Using a compiled regex with flags

```python
>>> import re
>>> regex_pat = re.compile(r'FUZ', flags=re.IGNORECASE)
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace(regex_pat, 'bar')
0 foo
1 bar
2 NaN
dtype: object
```
pandas.Series.str.rfind

Series.str.rfind(*args, **kwargs)
Return highest indexes in each strings in the Series/Index.
Each of returned indexes corresponds to the position where the substring is fully contained between [start:end].
Return -1 on failure. Equivalent to standard str.rfind().

Parameters
- sub [str] Substring being searched.
- start [int] Left edge index.
- end [int] Right edge index.

Returns
Series or Index of int.

See also:
find Return lowest indexes in each strings.

pandas.Series.str.rindex

Series.str.rindex(*args, **kwargs)
Return highest indexes in each string in Series/Index.
Each of the returned indexes corresponds to the position where the substring is fully contained between [start:end]. This is the same as str.rfind except instead of returning -1, it raises a ValueError when the substring is not found. Equivalent to standard str.rindex.

Parameters
- sub [str] Substring being searched.
- start [int] Left edge index.
- end [int] Right edge index.

Returns
Series or Index of object

See also:
index Return lowest indexes in each strings.

pandas.Series.str.rjust

Series.str.rjust(*args, **kwargs)
Pad left side of strings in the Series/Index.
Equivalent to str.rjust().

Parameters
- width [int] Minimum width of resulting string; additional characters will be filled with fillchar.

fillchar [str] Additional character for filling, default is whitespace.

Returns
filled [Series/Index of objects.]
**pandas.Series.str.rpartition**

Series.str.rpartition(*args, **kwargs)

Split the string at the last occurrence of `sep`.

This method splits the string at the last occurrence of `sep`, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing two empty strings, followed by the string itself.

**Parameters**

- `sep` [str, default whitespace] String to split on.
- `expand` [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality. If False, return Series/Index.

**Returns**

DataFrame/MultiIndex or Series/Index of objects

See also:

- `partition` Split the string at the first occurrence of `sep`.
- `Series.str.split` Split strings around given separators.
- `str.partition` Standard library version.

**Examples**

```python
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0   Linda van der Berg
1   George Pitt-Rivers
dtype: object

>>> s.str.partition()
   0    1    2
0  Linda  van  Berg
1  George Pitt-Rivers

To partition by the last space instead of the first one:

```python
>>> s.str.rpartition()
   0   1   2
0  Linda   van   Berg
1  George  Pitt-Rivers
```  

To partition by something different than a space:

```python
>>> s.str.partition('-')
   0   1   2
0  Linda van der Berg
1  George  Pitt-Rivers
```

To return a Series containing tuples instead of a DataFrame:

```python
>>> s.str.partition('-', expand=False)
   0       1       2
0 (Linda van der Berg, , )
1 (George Pitt, -, Rivers)
```

```
3.3. Series 1319
```
Also available on indices:

```python
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```python
>>> idx.str.partition()
MultiIndex([(X', ' ', '123'),
            ('Y', ' ', '999')],
           )
```

Or an index with tuples with `expand=False`:

```python
>>> idx.str.partition(expand=False)
Index([(X', ' ', '123'), (Y', ' ', '999')], dtype='object')
```

### pandas.Series.str.rstrip

Series.str.rstrip(*args, **kwargs)

Remove trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from right side. Equivalent to `str.rstrip()`.

**Parameters**

- `to_strip` [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

**Returns**

Series or Index of object

**See also:**

- `Series.str.strip` Remove leading and trailing characters in Series/Index.
- `Series.str.lstrip` Remove leading characters in Series/Index.
- `Series.str.rstrip` Remove trailing characters in Series/Index.

**Examples**

```python
>>> s = pd.Series(['1. Ant. ', '2. Bee!
', '3. Cat?\t', np.nan])
>>> s
0     1. Ant.
1     2. Bee!
2     3. Cat?
3         NaN
dtype: object

>>> s.str.strip()
0     1. Ant.
1     2. Bee!
2     3. Cat?
3         NaN
dtype: object
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

>>> s.str.lstrip('123.')</div><div class="highlight"><span class="n">0</span>  Ant.
1  Bee!
2  Cat?
3  NaN
<code class="highlighted">dtype</code>: <span class="n">object</span><br/></div>

>>> s.str.rstrip('.!? 
\t')
0  1. Ant
1  2. Bee
2  3. Cat
3  NaN<code class="highlighted"><br/></code><br/>

>>> s.str.strip('123.!? 
\t')
0  Ant
1  Bee
2  Cat
3  NaN<code class="highlighted"><br/></code><br/>

**pandas.Series.str.slice**

Series.str.slice(<code class="highlighted">start=None, stop=None, step=None</code>)

Slice substrings from each element in the Series or Index.

**Parameters**

- **start** [int, optional] Start position for slice operation.
- **stop** [int, optional] Stop position for slice operation.
- **step** [int, optional] Step size for slice operation.

**Returns**

Series or Index of object Series or Index from sliced substring from original string object.

**See also:**

- **Series.str.slice_replace** Replace a slice with a string.
- **Series.str.get** Return element at position. Equivalent to `Series.str.slice(start=i, stop=i+1)` with `i` being the position.

**Examples**

```python
>>> s = pd.Series(['koala', 'fox', 'chameleon'])
```

```python
>>> s
0  koala
1  fox
2  chameleon
<code class="highlighted"></code><br/>
dtype: <span class="n">object</span><br/>
```

```python
>>> s.str.slice(start=1)
0  oala
1  ox
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.1.1

(continued from previous page)

2  hameleon
dtype: object

>>> s.str.slice(start=-1)
 0  a
 1  x
 2  n
dtype: object

>>> s.str.slice(stop=2)
 0  ko
 1  fo
 2  ch
dtype: object

>>> s.str.slice(step=2)
 0  kaa
 1  fx
 2  caeen
dtype: object

>>> s.str.slice(start=0, stop=5, step=3)
 0  kl
 1  f
 2  cm
dtype: object

equivalent behaviour to:

>>> s.str[0:5:3]
 0  kl
 1  f
 2  cm
dtype: object

pandas.Series.str.slice_replace

Series.str.slice_replace(*args, **kwargs)
Replace a positional slice of a string with another value.

Parameters

- **start** [int, optional] Left index position to use for the slice. If not specified (None), the slice is unbounded on the left, i.e. slice from the start of the string.
- **stop** [int, optional] Right index position to use for the slice. If not specified (None), the slice is unbounded on the right, i.e. slice until the end of the string.
- **repl** [str, optional] String for replacement. If not specified (None), the sliced region is replaced with an empty string.

Returns

Series or Index Same type as the original object.

See also:

Series.str.slice Just slicing without replacement.
Examples

```python
>>> s = pd.Series(['a', 'ab', 'abc', 'abdc', 'abcde'])
>>> s
0    a
1   ab
2   abc
3  abdc
4  abcde
dtype: object
```

Specify just `start`, meaning replace `start` until the end of the string with `repl`.

```python
>>> s.str.slice_replace(start=1, repl='X')
0    aX
1   aX
2   aX
3   aX
4   aX
dtype: object
```

Specify just `stop`, meaning the start of the string to `stop` is replaced with `repl`, and the rest of the string is included.

```python
>>> s.str.slice_replace(stop=2, repl='X')
0   X
1   Xc
2   Xdc
3   Xdc
4   Xdc
dtype: object
```

Specify `start` and `stop`, meaning the slice from `start` to `stop` is replaced with `repl`. Everything before or after `start` and `stop` is included as is.

```python
>>> s.str.slice_replace(start=1, stop=3, repl='X')
0    aX
1   aX
2   aX
3   aXc
4   aXdc
dtype: object
```

**pandas.Series.str.split**

`Series.str.split(*args, **kwargs)`

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the beginning, at the specified delimiter string. Equivalent to `str.split()`.

**Parameters**

- `pat` [str, optional] String or regular expression to split on. If not specified, split on whitespace.
- `n` [int, default -1 (all)] Limit number of splits in output. None, 0 and -1 will be interpreted as return all splits.
expand [bool, default False] Expand the split strings into separate columns.

- If True, return DataFrame/MultiIndex expanding dimensionality.
- If False, return Series/Index, containing lists of strings.

Returns

Series, Index, DataFrame or MultiIndex  Type matches caller unless expand=True (see Notes).

See also:

Series.str.split  Split strings around given separator/delimiter.
Series.str.rsplit  Splits string around given separator/delimiter, starting from the right.
Series.str.join  Join lists contained as elements in the Series/Index with passed delimiter.
str.split  Standard library version for split.
str.rsplit  Standard library version for rsplit.

Notes

The handling of the $n$ keyword depends on the number of found splits:

- If found splits > $n$, make first $n$ splits only
- If found splits <= $n$, make all splits
- If for a certain row the number of found splits < $n$, append None for padding up to $n$ if expand=True

If using expand=True, Series and Index callers return DataFrame and MultiIndex objects, respectively.

Examples

```python
>>> s = pd.Series(
...     [
...         "this is a regular sentence",
...         "https://docs.python.org/3/tutorial/index.html",
...         np.nan
...     ]
... )
>>> s
0  this is a regular sentence
1  https://docs.python.org/3/tutorial/index.html
2      NaN
dtype: object

In the default setting, the string is split by whitespace.

```python
>>> s.str.split()
0  [this, is, a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2      NaN
dtype: object
```

Without the $n$ parameter, the outputs of rsplit and split are identical.

```python
>>> s.str.rsplit()
0  [this, is, a, regular, sentence]
1  [https://docs.python.org/3/tutorial/index.html]
2      NaN
dtype: object
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

The n parameter can be used to limit the number of splits on the delimiter. The outputs of split and rsplit are
different.
>>> s.str.split(n=2)
0
[this, is, a regular sentence]
1
[https://docs.python.org/3/tutorial/index.html]
2
NaN
dtype: object
>>> s.str.rsplit(n=2)
0
[this is a, regular, sentence]
1
[https://docs.python.org/3/tutorial/index.html]
2
NaN
dtype: object

The pat parameter can be used to split by other characters.
>>> s.str.split(pat="/")
0
[this is a regular sentence]
1
[https:, , docs.python.org, 3, tutorial, index...
2
NaN
dtype: object

When using expand=True, the split elements will expand out into separate columns. If NaN is present, it is
propagated throughout the columns during the split.
>>> s.str.split(expand=True)
0
1
2

3.3. Series

1325


pandas.Series.str.rsplit

Series.str.rsplit (*args, **kwargs)

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the end, at the specified delimiter string. Equivalent to str.rsplited().

Parameters

- **pat** [str, optional] String or regular expression to split on. If not specified, split on whitespace.
- **n** [int, default -1 (all)] Limit number of splits in output. None, 0 and -1 will be interpreted as return all splits.
- **expand** [bool, default False] Expand the split strings into separate columns.
  - If True, return DataFrame/MultiIndex expanding dimensionality.
  - If False, return Series/Index, containing lists of strings.

Returns

Series, Index, DataFrame or MultiIndex Type matches caller unless expand=True (see Notes).

See also:

- Series.str.split Split strings around given separator/delimiter.
- Series.str.rsplit Splits string around given separator/delimiter, starting from the right.
- Series.str.join Join lists contained as elements in the Series/Index with passed delimiter.
- str.split Standard library version for split.
- str.rsplit Standard library version for rsplit.

Notes

The handling of the n keyword depends on the number of found splits:
- If found splits > n, make first n splits only
- If found splits <= n, make all splits
- If for a certain row the number of found splits < n, append None for padding up to n if expand=True

If using expand=True, Series and Index callers return DataFrame and MultiIndex objects, respectively.

Examples

```python
>>> s = pd.Series(
...     [  
...         "this is a regular sentence",
...         "https://docs.python.org/3/tutorial/index.html",
...         np.nan
...     ]
... )
```

```python
>>> s
0 this is a regular sentence  
1 https://docs.python.org/3/tutorial/index.html  
2         NaN
```

dtype: object

In the default setting, the string is split by whitespace.
Without the \textit{n} parameter, the outputs of \textit{rsplit} and \textit{split} are identical.

The \textit{n} parameter can be used to limit the number of splits on the delimiter. The outputs of \textit{split} and \textit{rsplit} are different.

The \textit{pat} parameter can be used to split by other characters.

When using \texttt{expand=True}, the split elements will expand out into separate columns. If NaN is present, it is propagated throughout the columns during the split.

For slightly more complex use cases like splitting the html document name from a url, a combination of parameter settings can be used.

Remember to escape special characters when explicitly using regular expressions.
>>> s = pd.Series(["1+1=2"])  
>>> s  
0 1+1=2  
dtype: object  
>>> s.str.split(r"\+|=", expand=True)  
0 1 2  
1 1 2

### pandas.Series.str.startswith

Series.str.startswith(*args, **kwargs)  
Test if the start of each string element matches a pattern.

Equivalent to str.startswith().

Parameters

- **pat** [str] Character sequence. Regular expressions are not accepted.
- **na** [object, default NaN] Object shown if element tested is not a string.

Returns

Series or Index of bool A Series of booleans indicating whether the given pattern matches the start of each string element.

See also:

- [str.startswith](https://docs.python.org/3/library/stdtypes.html#str.startswith) Python standard library string method.

#### Examples

```python
>>> s = pd.Series(["bat", 'Bear', 'cat', np.nan])
```

```python
>>> s  
0 bat  
1 Bear  
2 cat  
3 NaN  
dtype: object
```

```python
>>> s.str.startswith('b')  
0 True  
1 False  
2 False  
3 NaN  
dtype: object
```

Specifying `na` to be `False` instead of `NaN`.

```python
>>> s.str.startswith('b', na=False)  
0 True  
1 False  
2 False  
3 False  
dtype: bool
```
**pandas.Series.str.strip**

```python
def str.strip(*args, **kwargs)
```

Remove leading and trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left and right sides. Equivalent to `str.strip()`.

**Parameters**

- `to_strip` [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

**Returns**

Series or Index of object

**See also:**

- `Series.str.strip` Remove leading and trailing characters in Series/Index.
- `Series.str.lstrip` Remove leading characters in Series/Index.
- `Series.str.rstrip` Remove trailing characters in Series/Index.

**Examples**

```python
>>> s = pd.Series(['1. Ant. ', '2. Bee!
', '3. Cat?	', np.nan])
>>> s
0    1. Ant.
1    2. Bee!
2    3. Cat?
3     NaN
dtype: object

>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3     NaN
dtype: object

>>> s.str.lstrip('123.')
0    Ant.
1    Bee!
2    Cat?
3     NaN
dtype: object

>>> s.str.rstrip('.!?\n\t')
0    1. Ant
1    2. Bee
2    3. Cat
3     NaN
dtype: object

>>> s.str.strip('123.?!\n\t')
0    Ant
(continues on next page)
pandas.Series.str.swapcase

Series.str.swapcase(*args, **kwargs)
Convert strings in the Series/Index to be swapcased.

Equivalent to str.swapcase().

Returns
Series or Index of object

See also:
Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold Removes all case distinctions in the string.

Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0        lower
1    CAPITALS
2  this is a sentence
3     SwApCaSe
dtype: object

>>> s.str.lower()
0        lower
1    capitals
2  this is a sentence
3     swapcase
dtype: object

>>> s.str.upper()
0     LOWER
1    CAPITALS
2  THIS IS A SENTENCE
3       SWAPCASE
dtype: object

>>> s.str.title()
0     Lower
1   Capitals
2  This Is A Sentence
3         Swapcase
dtype: object
```
pandas.Series.str.title

Series.str.title(*args, **kwargs)

Convert strings in the Series/Index to titlecase.

Equivalent to str.title().

Returns

Series or Index of object

See also:

Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold Removes all case distinctions in the string.

Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0    lower
1  CAPITALS
2  this is a sentence
3    SwApCaSe
dtype: object
```

```python
>>> s.str.lower()  
0    lower
1  capitals
2  this is a sentence
3    swapcase
dtype: object
```

```python
>>> s.str.upper()  
0    LOWER
1  CAPITALS
2  THIS IS A SENTENCE
```

(continues on next page)
3    SWAPCASE
   dtype: object

>>> s.str.title()
0       Lower
1      Capitals
2  This Is A Sentence
3      Swapcase
   dtype: object

>>> s.str.capitalize()
0       Lower
1      Capitals
2  This is a sentence
3      Swapcase
   dtype: object

>>> s.str.swapcase()
0       LOWER
1   capitals
2  THIS IS A SENTENCE
3   sWaPcAsE
   dtype: object

pandas.Series.str.translate

Series.str.translate(*args, **kwargs)
Map all characters in the string through the given mapping table.

Equivalent to standard str.translate().

Parameters
    table [dict] Table is a mapping of Unicode ordinals to Unicode ordinals, strings, or None. Unmapped characters are left untouched. Characters mapped to None are deleted. str.maketrans() is a helper function for making translation tables.

Returns
    Series or Index

pandas.Series.str.upper

Series.str.upper(*args, **kwargs)
Convert strings in the Series/Index to uppercase.

Equivalent to str.upper().

Returns
    Series or Index of object

See also:
    Series.str.lower Converts all characters to lowercase.
    Series.str.upper Converts all characters to uppercase.
    Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
**Series.str.capitalize** Converts first character to uppercase and remaining to lowercase.
**Series.str.swapcase** Converts uppercase to lowercase and lowercase to uppercase.
**Series.str.casefold** Removes all case distinctions in the string.

### Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0  lower
1  CAPITALS
2  this is a sentence
3  SwApCaSe
dtype: object

>>> s.str.lower()  
0  lower
1  capitals
2  this is a sentence
3  swapcase
dtype: object

>>> s.str.upper()  
0  LOWER
1  CAPITALS
2  THIS IS A SENTENCE
3  SWAPCASE
dtype: object

>>> s.str.title()  
0  Lower
1  Capitals
2  This Is A Sentence
3  Swapcase
dtype: object

>>> s.str.capitalize()  
0  Lower
1  Capitals
2  This is a sentence
3  Swapcase
dtype: object

>>> s.str.swapcase()  
0  LOWER
1  capitals
2  THIS IS A SENTENCE
3  sWaPcAsE
dtype: object
```
pandas.Series.str.wrap

Series.str.wrap(*args, **kwargs)
Wrap strings in Series/Index at specified line width.
This method has the same keyword parameters and defaults as textwrap.TextWrapper.

Parameters

width [int] Maximum line width.
expand_tabs [bool, optional] If True, tab characters will be expanded to spaces (default: True).
replace_whitespace [bool, optional] If True, each whitespace character (as defined by string.whitespace) remaining after tab expansion will be replaced by a single space (default: True).
drop_whitespace [bool, optional] If True, whitespace that, after wrapping, happens to end up at the beginning or end of a line is dropped (default: True).
break_long_words [bool, optional] If True, then words longer than width will be broken in order to ensure that no lines are longer than width. If it is false, long words will not be broken, and some lines may be longer than width (default: True).
break_on_hyphens [bool, optional] If True, wrapping will occur preferably on whitespace and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set break_long_words to false if you want truly inseparable words (default: True).

Returns

Series or Index

Notes

Internally, this method uses a textwrap.TextWrapper instance with default settings. To achieve behavior matching R’s stringr library str_wrap function, use the arguments:

- expand_tabs = False
- replace_whitespace = True
- drop_whitespace = True
- break_long_words = False
- break_on_hyphens = False

Examples

```python
>>> s = pd.Series(['line to be wrapped', 'another line to be wrapped'])
>>> s.str.wrap(12)
0    line to be\n     wrapped
1    another line\n     to be\n     wrapped
dtype: object
```
### pandas.Series.str.zfill

**Series.str.zfill(*args, **kwargs)**

Pad strings in the Series/Index by prepending ‘0’ characters.

Strings in the Series/Index are padded with ‘0’ characters on the left of the string to reach a total string length `width`. Strings in the Series/Index with length greater or equal to `width` are unchanged.

**Parameters**

- `width` [int] Minimum length of resulting string; strings with length less than `width` be prepended with ‘0’ characters.

**Returns**

Series/Index of objects.

**See also:**

- `Series.str.rjust` Fills the left side of strings with an arbitrary character.
- `Series.str.ljust` Fills the right side of strings with an arbitrary character.
- `Series.str.pad` Fills the specified sides of strings with an arbitrary character.
- `Series.str.center` Fills both sides of strings with an arbitrary character.

**Notes**

Differs from `str.zfill()` which has special handling for ‘+/−’ in the string.

**Examples**

```python
>>> s = pd.Series(['-1', '1', '1000', 10, np.nan])
>>> s
0   -1
1    1
2  1000
3    10
4   NaN
dtype: object
```

Note that 10 and NaN are not strings, therefore they are converted to NaN. The minus sign in ‘−1’ is treated as a regular character and the zero is added to the left of it (`str.zfill()` would have moved it to the left). 1000 remains unchanged as it is longer than `width`.

```python
>>> s.str.zfill(3)
0   0-1
1   001
2  1000
3   NaN
4   NaN
dtype: object
```
pandas.Series.str.isalnum

Series.str.isalnum(*args, **kwargs)
Check whether all characters in each string are alphanumeric.
This is equivalent to running the Python string method str.isalnum() for each element of the Series/Index. If a string has zero characters, False is returned for that check.

Returns
Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:
Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0   True
1  False
2  False
3  False
dtype: bool

>>> s1.str.isnumeric()
0  False
1  False
2   True
3  False
dtype: bool

>>> s1.str.isalnum()
0   True
1   True
2   True
3  False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
```
(continues on next page)
More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
1    True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\r\n ', ''])
```  

```python
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```  

```python
>>> s5.str.islower()
0    True
1    False
```

(continues on next page)
The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0    False
1      True
2    False
3    False
dtype: bool
```

**pandas.Series.str.isalpha**

`Series.str.isalpha(*args, **kwargs)`

Check whether all characters in each string are alphabetic.

This is equivalent to running the Python string method `str.isalpha()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- `Series.str.isalpha` Check whether all characters are alphabetic.
- `Series.str.isnumeric` Check whether all characters are numeric.
- `Series.str.isalnum` Check whether all characters are alphanumeric.
- `Series.str.isdigit` Check whether all characters are digits.
- `Series.str.isdecimal` Check whether all characters are decimal.
- `Series.str.isspace` Check whether all characters are whitespace.
- `Series.str.islower` Check whether all characters are lowercase.
- `Series.str.isupper` Check whether all characters are uppercase.
- `Series.str.istitle` Check whether all characters are titlecase.
Examples

Checks for Alphabetic and Numeric Characters

```python
g1 = pd.Series(['one', 'one1', '1', ''])
```

```python
>>> g1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```python
>>> g1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```python
>>> g1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
g2 = pd.Series(['A B', '1.5', '3,000'])
```

```python
>>> g2.str.isalnum()
0  False
1  False
2  False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
g3 = pd.Series(['23', '3', '', ''])
```

The `g3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> g3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The `g3.str.isdigit` method is the same as `g3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> g3.str.isdigit()
0    True
```

(continues on next page)
The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\r\n ', ''])
>>> s4.str.isspace()
daatype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
daype: bool
```

```python
>>> s5.str.isupper()
daype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
daype: bool
```
pandas.Series.str.isdigit

Series.str.isdigit(*args, **kwargs)
Check whether all characters in each string are digits.

This is equivalent to running the Python string method `str.isdigit()` for each element of the Series/Index. If a string has zero characters, False is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool

>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
(continues on next page)
More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
s3 = pd.Series(['23', '³', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
s3.str.isdecimal()
```

0    True
1    False
2    False
3    False
dtype: bool

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
s3.str.isdigit()
```

0    True
1    True
2    False
3    False
dtype: bool

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
s3.str.isnumeric()
```

0    True
1    True
2    True
3    False
dtype: bool

Checks for Whitespace

```python
s4 = pd.Series([' ', '	\r\n', ''])
```

```python
s4.str.isspace()
```

0    True
1    True
2    False
dtype: bool

Checks for Character Case

```python
s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
```

```python
s5.str.islower()
```

0    True
1    False
The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

### pandas.Series.str.isspace

**Series.str.isspace(***args, **kwargs**

Check whether all characters in each string are whitespace.

This is equivalent to running the Python string method `str.isspace()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- `Series.str.isalpha` Check whether all characters are alphabetic.
- `Series.str.isnumeric` Check whether all characters are numeric.
- `Series.str.isalnum` Check whether all characters are alphanumeric.
- `Series.str.isdigit` Check whether all characters are digits.
- `Series.str.isdecimal` Check whether all characters are decimal.
- `Series.str.isspace` Check whether all characters are whitespace.
- `Series.str.islower` Check whether all characters are lowercase.
- `Series.str.isupper` Check whether all characters are uppercase.
- `Series.str.istitle` Check whether all characters are titlecase.
Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0   True
1  False
2  False
3  False
dtype: bool

>>> s1.str.isnumeric()
0   False
1  False
2   True
3  False
dtype: bool

>>> s1.str.isalnum()
0   True
1   True
2   True
3  False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
0  False
1  False
2  False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '²', '', ''])

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0   True
1  False
2  False
3  False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0   True
```

(continues on next page)
The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])

>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool

>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0    False
1    True
2    False
3    False
dtype: bool
```
**pandas.Series.str.islower**

Series.str.islower(*args, **kwargs)

Check whether all characters in each string are lowercase.

This is equivalent to running the Python string method `str.islower()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

Series or Index of bool  
Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- `Series.str.isalpha` Check whether all characters are alphabetic.
- `Series.str.isnumeric` Check whether all characters are numeric.
- `Series.str.isalnum` Check whether all characters are alphanumeric.
- `Series.str.isdigit` Check whether all characters are digits.
- `Series.str.isdecimal` Check whether all characters are decimal.
- `Series.str.isspace` Check whether all characters are whitespace.
- `Series.str.islower` Check whether all characters are lowercase.
- `Series.str.isupper` Check whether all characters are uppercase.
- `Series.str.istitle` Check whether all characters are titlecase.

**Examples**

**Checks for Alphabetic and Numeric Characters**

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0   True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2   True
3   False
dtype: bool

>>> s1.str.isalnum()
0   True
1   True
2   True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
0   False
1   False
2   False
```

(continues on next page)
More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
1    True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
0    True
1    False
```

(continues on next page)
2    False
3    False
dtype: bool

```python
>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0    False
1    True
2    False
3    False
dtype: bool
```

### pandas.Series.str.isupper

`Series.str.isupper(*args, **kwargs)`

Check whether all characters in each string are uppercase.

This is equivalent to running the Python string method `str.isupper()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

Series or Index of bool  Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- `Series.str.isalpha`  Check whether all characters are alphabetic.
- `Series.str.isnumeric`  Check whether all characters are numeric.
- `Series.str.isalnum`  Check whether all characters are alphanumeric.
- `Series.str.isdigit`  Check whether all characters are digits.
- `Series.str.isdecimal`  Check whether all characters are decimal.
- `Series.str.isspace`  Check whether all characters are whitespace.
- `Series.str.islower`  Check whether all characters are lowercase.
- `Series.str.isupper`  Check whether all characters are uppercase.
- `Series.str.istitle`  Check whether all characters are titlecase.
Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0    True
1    False
2    False
3    False
dtype: bool

>>> s1.str.isnumeric()
0    False
1    False
2    True
3    False
dtype: bool

>>> s1.str.isalnum()
0    True
1    True
2    True
3    False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumerical check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
0    False
1    False
2    False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])

The s3.str.isdecimal method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool
```

The s.str.isdigit method is the same as s3.str.isdecimal but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
```
The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

### Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

### Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```python
>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0    False
1    True
2    False
3    False
dtype: bool
```
pandas.Series.str.istitle

Series.str.istitle(*args, **kwargs)
Check whether all characters in each string are titlecase.

This is equivalent to running the Python string method str.istitle() for each element of the Series/Index. If a string has zero characters, False is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.

Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0   True
1  False
2  False
3  False
   dtype: bool

>>> s1.str.isnumeric()
0  False
1  False
2   True
3  False
   dtype: bool

>>> s1.str.isalnum()
0   True
1   True
2   True
3  False
   dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()

>>> s5.str.islower()
0    True
1    False
```

(continues on next page)
s5.str.isupper()
0 False
1 False
2 True
3 False
dtype: bool

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be any sequence of non-numeric characters separated by whitespace characters.

s5.str.istitle()
0 False
1 True
2 False
3 False
dtype: bool

**pandas.Series.str.isnumeric**

`Series.str.isnumeric(*args, **kwargs)`

Check whether all characters in each string are numeric.

This is equivalent to running the Python string method `str.isnumeric()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- `Series.str.isalpha`: Check whether all characters are alphabetic.
- `Series.str.isnumeric`: Check whether all characters are numeric.
- `Series.str.isalnum`: Check whether all characters are alphanumeric.
- `Series.str.isdigit`: Check whether all characters are digits.
- `Series.str.isdecimal`: Check whether all characters are decimal.
- `Series.str.isspace`: Check whether all characters are whitespace.
- `Series.str.islower`: Check whether all characters are lowercase.
- `Series.str.isupper`: Check whether all characters are uppercase.
- `Series.str.istitle`: Check whether all characters are titlecase.
Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool

>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

```python
>>> s5.str.istitle()
0   False
1    True
2   False
3   False
dtype: bool
```

### pandas.Series.str.get_dummies

`Series.str.get_dummies(*args, **kwargs)`

Return DataFrame of dummy/indicator variables for Series.

Each string in Series is split by sep and returned as a DataFrame of dummy/indicator variables.

**Parameters**

- `sep` [str, default “|”] String to split on.

**Returns**

DataFrame Dummy variables corresponding to values of the Series.

**See also:**

- `get_dummies` Convert categorical variable into dummy/indicator variables.

**Examples**

```python
>>> pd.Series(['a|b', 'a', 'a|c']).str.get_dummies()
   a  b  c
0  1  1  0
1  1  0  0
2  1  0  1

>>> pd.Series(['a|b', np.nan, 'a|c']).str.get_dummies()
   a  b  c
0  1  1  0
1  0  0  0
2  1  0  1
```
Categorical accessor

Categorical-dtype specific methods and attributes are available under the `Series.cat` accessor.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.cat.categories</code></td>
<td>The categories of this categorical.</td>
</tr>
<tr>
<td><code>Series.cat.ordered</code></td>
<td>Whether the categories have an ordered relationship.</td>
</tr>
<tr>
<td><code>Series.cat.codes</code></td>
<td>Return Series of codes as well as the index.</td>
</tr>
</tbody>
</table>

**pandas.Series.cat.categories**

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to `categories` is an inplace operation!

**Raises**

- `ValueError` If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

**See also:**

- `rename_categories` Rename categories.
- `reorder_categories` Reorder categories.
- `add_categories` Add new categories.
- `remove_categories` Remove the specified categories.
- `remove_unused_categories` Remove categories which are not used.
- `set_categories` Set the categories to the specified ones.

**pandas.Series.cat.ordered**

Whether the categories have an ordered relationship.

**pandas.Series.cat.codes**

Return Series of codes as well as the index.

<table>
<thead>

</tr>
</tbody>
</table>

**pandas.Series.cat.rename_categories**

Series.cat.rename_categories(*args, **kwargs)

Rename categories.

Parameters

  new_categories [list-like, dict-like or callable] New categories which will replace old categories.
    - list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
    - dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.
    - callable : a callable that is called on all items in the old categories and whose return values comprise the new categories.

  inplace [bool, default False] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

Returns

  cat [Categorical or None] With inplace=False, the new categorical is returned. With inplace=True, there is no return value.

Raises

  ValueError If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

See also:

  reorder_categories Reorder categories.
  add_categories Add new categories.
  remove_categories Remove the specified categories.
  remove_unused_categories Remove categories which are not used.
  set_categories Set the categories to the specified ones.

Examples

```python
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like new_categories, extra keys are ignored and categories not in the dictionary are passed through

```python
>>> c.rename_categories({'a': 'A', 'c': 'C'})
['A', 'A', 'b']
Categories (2, object): ['A', 'b']
```
You may also provide a callable to create the new categories

```python
>>> c.rename_categories(lambda x: x.upper())
['A', 'A', 'B']
Categories (2, object): ['A', 'B']
```

### pandas.Series.cat.reorder_categories

`Series.cat.reorder_categories(*args, **kwargs)`

Reorder categories as specified in new_categories.

- **new_categories** need to include all old categories and no new category items.

**Parameters**

- **new_categories** [Index-like] The categories in new order.
- **ordered** [bool, optional] Whether or not the categorical is treated as a ordered categorical.
  If not given, do not change the ordered information.
- **inplace** [bool, default False] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

**Returns**

- **cat** [Categorical with reordered categories or None if inplace.]

**Raises**

- **ValueError** If the new categories do not contain all old category items or any new ones.

See also:

- **rename_categories** Rename categories.
- **add_categories** Add new categories.
- **remove_categories** Remove the specified categories.
- **remove_unused_categories** Remove categories which are not used.
- **set_categories** Set the categories to the specified ones.

### pandas.Series.cat.add_categories

`Series.cat.add_categories(*args, **kwargs)`

Add new categories.

- **new_categories** will be included at the last/highest place in the categories and will be unused directly after this call.

**Parameters**

- **new_categories** [category or list-like of category] The new categories to be included.
- **inplace** [bool, default False] Whether or not to add the categories inplace or return a copy of this categorical with added categories.

**Returns**

- **cat** [Categorical with new categories added or None if inplace.]

**Raises**

- **ValueError** If the new categories include old categories or do not validate as categories.

See also:
rename_categories Rename categories.
reorder_categories Reorder categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

pandas.Series.cat.remove_categories

Series.cat.remove_categories(*args, **kwargs)
Remove the specified categories.

removals must be included in the old categories. Values which were in the removed categories will be set to NaN.

Parameters

removals [category or list of categories] The categories which should be removed.
inplace [bool, default False] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

Returns

cat [Categorical with removed categories or None if inplace.]

Raises

ValueError If the removals are not contained in the categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

pandas.Series.cat.remove_unused_categories

Series.cat.remove_unused_categories(*args, **kwargs)
Remove categories which are not used.

Parameters

inplace [bool, default False] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

Returns

cat [Categorical with unused categories dropped or None if inplace.]

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
set_categories Set the categories to the specified ones.
pandas.Series.cat.set_categories

Series.cat.set_categories(*args, **kwargs)
Set the categories to the specified new_categories.

new_categories can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If rename==True, the categories will simple be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this methods does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes, which does not considers a S1 string equal to a single char python string.

Parameters

- new_categories [Index-like] The categories in new order.
- ordered [bool, default False] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.
- rename [bool, default False] Whether or not the new_categories should be considered as a rename of the old categories or as reordered categories.
- inplace [bool, default False] Whether or not to reorder the categories in-place or return a copy of this categorical with reordered categories.

Returns

Categorical with reordered categories or None if inplace.

Raises

ValueError If new_categories does not validate as categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.

pandas.Series.cat.as_ordered

Series.cat.as_ordered(*args, **kwargs)
Set the Categorical to be ordered.

Parameters

- inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to True.

Returns

Categorical Ordered Categorical.
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.Series.cat.as_unordered

Series.cat.as_unordered(*args, **kwargs)
Set the Categorical to be unordered.

Parameters
inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to False.

Returns
Categorical Unordered Categorical.

Sparse accessor

Sparse-dtype specific methods and attributes are provided under the Series.sparse accessor.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.sparse.npoints</td>
<td>The number of non-fill_value points.</td>
</tr>
<tr>
<td>Series.sparse.density</td>
<td>The percent of non-fill_value points, as decimal.</td>
</tr>
<tr>
<td>Series.sparse.fill_value</td>
<td>Elements in data that are fill_value are not stored.</td>
</tr>
<tr>
<td>Series.sparse.sp_values</td>
<td>An ndarray containing the non-fill_value values.</td>
</tr>
</tbody>
</table>

pandas.Series.sparse.npoints

Series.sparse.npoints
The number of non-fill_value points.

Examples

```python
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.npoints
3
```

pandas.Series.sparse.density

Series.sparse.density
The percent of non-fill_value points, as decimal.

Examples

```python
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.density
0.6
```
**pandas.Series.sparse.fill_value**

Series.sparse.fill_value

Elements in data that are fill_value are not stored.

For memory savings, this should be the most common value in the array.

**pandas.Series.sparse.sp_values**

Series.sparse.sp_values

An ndarray containing the non-fill_value values.

**Examples**

```python
>>> s = SparseArray([0, 0, 1, 0, 2], fill_value=0)
>>> s.sp_values
array([1, 2])
```

**Series.sparse.from_coo(A, dense_index=False)**

Create a Series with sparse values from a scipy.sparse.coo_matrix.

**Parameters**

- **A** [scipy.sparse.coo_matrix]
- **dense_index** [bool, default False] If False (default), the SparseSeries index consists of only the coords of the non-null entries of the original coo_matrix. If True, the SparseSeries index consists of the full sorted (row, col) coordinates of the coo_matrix.

**Returns**

- **s** [Series] A Series with sparse values.

**Examples**

```python
>>> from scipy import sparse

>>> A = sparse.coo_matrix(
...     ([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])), shape=(3, 4)
... )
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'>
with 3 stored elements in COOrdinate format>
```
```python
>>> A.todense()
matrix([[0., 0., 1., 2.],
        [3., 0., 0., 0.],
        [0., 0., 0., 0.]])
```

```python
>>> ss = pd.Series.sparse.from_coo(A)
>>> ss
0  2  1.0
  3  2.0
1  0  3.0
dtype: Sparse[float64, nan]
```

### `pandas.Series.sparse.to_coo`

`Series.sparse.to_coo(row_levels=0, column_levels=1, sort_labels=False)`

Create a scipy.sparse.coo_matrix from a Series with MultiIndex.

Use `row_levels` and `column_levels` to determine the row and column coordinates respectively. `row_levels` and `column_levels` are the names (labels) or numbers of the levels. `{row_levels, column_levels}` must be a partition of the MultiIndex level names (or numbers).

**Parameters**

- `row_levels` [tuple/list]
- `column_levels` [tuple/list]
- `sort_labels` [bool, default False] Sort the row and column labels before forming the sparse matrix.

**Returns**

- `y` [scipy.sparse.coo_matrix]
- `rows` [list (row labels)]
- `columns` [list (column labels)]

**Examples**

```python
>>> s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
>>> s.index = pd.MultiIndex.from_tuples(...
...   [ ...
...     (1, 2, "a", 0),
...     (1, 2, "a", 1),
...     (1, 1, "b", 0),
...     (1, 1, "b", 1),
...     (2, 1, "b", 0),
...     (2, 1, "b", 1)
...   ],
...   names=["A", "B", "C", "D"],
... )
>>> s
A  B  C  D
1  2  a  0  3.0
   1  NaN
   1  b  0  1.0
(continues on next page)
```
1 3.0
2 1 b 0 NaN
   1 NaN
dtype: float64

>>> ss = s.astype("Sparse")
>>> ss
A   B   C   D
1  2 a  0  3.0
   1   NaN
1 b  0  1.0
   1   NaN
2  1 b  0  NaN
   1   NaN
dtype: Sparse[float64, nan]

>>> A, rows, columns = ss.sparse.to_coo(
...   row_levels=["A", "B"], column_levels=["C", "D"], sort_labels=True
...)

>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>

>>> A.todense()
matrix([[0., 0., 1., 3.],
        [3., 0., 0., 0.],
        [0., 0., 0., 0.]])

>>> rows
[(1, 1), (1, 2), (2, 1)]

>>> columns
[('a', 0), ('a', 1), ('b', 0), ('b', 1)]

**Metadata**

*Series.attrs* is a dictionary for storing global metadata for this Series.

**Warning:** *Series.attrs* is considered experimental and may change without warning.

*Series.attrs* Dictionary of global attributes on this object.
3.3.14 Plotting

Series.plot is both a callable method and a namespace attribute for specific plotting methods of the form Series.plot.<kind>.

Series.plot(kind, ax, figsize, . . .) Series plotting accessor and method

Series.plot.area(x, y) Draw a stacked area plot.
Series.plot.bar(x, y) Vertical bar plot.
Series.plot.barch(x, y) Make a horizontal bar plot.
Series.plot.box(by) Make a box plot of the DataFrame columns.
Series.plot.density(bw_method, ind) Generate Kernel Density Estimate plot using Gaussian kernels.
Series.plot.hist(by, bins) Draw one histogram of the DataFrame’s columns.
Series.plot.kde(bw_method, ind) Generate Kernel Density Estimate plot using Gaussian kernels.
Series.plot.line(x, y) Plot Series or DataFrame as lines.
Series.plot.pie(**kwargs) Generate a pie plot.

pandas.Series.plot.area

Series.plot.area(x=None, y=None, **kwargs)
  Draw a stacked area plot.

  An area plot displays quantitative data visually. This function wraps the matplotlib area function.

  Parameters
  
  x [label or position, optional] Coordinates for the X axis. By default uses the index.
  y [label or position, optional] Column to plot. By default uses all columns.
  stacked [bool, default True] Area plots are stacked by default. Set to False to create a unstacked plot.
  **kwargs Additional keyword arguments are documented in DataFrame.plot().

  Returns
  
  matplotlib.axes.Axes or numpy.ndarray Area plot, or array of area plots if subplots is True.

  See also:
  
  DataFrame.plot Make plots of DataFrame using matplotlib / pylab.

Examples

Draw an area plot based on basic business metrics:

>>> df = pd.DataFrame({'
...     'sales': [3, 2, 3, 9, 10, 6],
...     'signups': [5, 5, 6, 12, 14, 13],
...     'visits': [20, 42, 28, 62, 81, 50],
... }, index=pd.date_range(start='2018/01/01', end='2018/07/01',
...     freq='M'))

>>> ax = df.plot.area()
Area plots are stacked by default. To produce an unstacked plot, pass `stacked=False`:

```python
>>> ax = df.plot.area(stacked=False)
```

Draw an area plot for a single column:

```python
>>> ax = df.plot.area(y='sales')
```

Draw with a different `x`:

```python
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3],
...     'visits': [20, 42, 28],
...     'day': [1, 2, 3],
... })
>>> ax = df.plot.area(x='day')
```
3.3. Series
pandas.Series.plot.bar

Series.plot.bar(x=None, y=None, **kwargs)

Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

x [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

y [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.

color [str, array_like, or dict, optional] The color for each of the DataFrame's columns. Possible values are:

- A single color string referred to by name, RGB or RGBA code, for instance 'red' or '#a98d19'.
- A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column's bar will be filled in green or yellow, alternatively.
- A dict of the form {column name: [color], so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {'a': 'green', 'b': 'red'} will color bars for column a in green and bars for column b in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

DataFrame.plot.barh Horizontal bar plot.
DataFrame.plot Make plots of a DataFrame.
matplotlib.pyplot.bar Make a bar plot with matplotlib.

Examples

Basic plot.

```python
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',...
  'rabbit', 'giraffe', 'coyote', 'horse']
```

(continues on next page)
>>> df = pd.DataFrame({'speed': speed,
...                    'lifespan': lifespan}, index=index)

>>> ax = df.plot.bar(rot=0)

Plot stacked bar charts for the DataFrame

>>> ax = df.plot.bar(stacked=True)

Instead of nesting, the figure can be split by column with subplots=True. In this case, a numpy.ndarray of matplotlib.axes.Axes are returned.

>>> axes = df.plot.bar(rot=0, subplots=True)

If you don’t like the default colours, you can specify how you’d like each column to be colored.

```python
def plot_bar(subplots=True, color=None):
    ax = df.plot.bar(subplots=subplots, color=color)
    legend(loc=2)
```

Plot a single column.
pandas.Series.plot.bar

Series.plot.barh(x=None, y=None, **kwargs)

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

- x [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- y [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- color [str, array_like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:
• A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.

• A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column’s bar will be filled in green or yellow, alternatively.

• A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {'a': 'green', 'b': 'red'} will color bars for column a in green and bars for column b in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

DataFrame.plot.bar Vertical bar plot.

DataFrame.plot Make plots of DataFrame using matplotlib.

matplotlib.axes.Axes.bar Plot a vertical bar plot using matplotlib.

Examples

Basic example

>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')

Plot a whole DataFrame to a horizontal bar plot

>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant', ...
         'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed, ...
         'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
pandas: powerful Python data analysis toolkit, Release 1.1.1

3.3. Series

3.3. Series

3.3. Series
Plot DataFrame versus the desired column

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...    'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...    'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(x='lifespan')
```
pandas.Series.plot.box

Series.plot.box(by=None, **kwargs)

Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to 1.5*IQR (IQR = Q3 - Q1) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia’s entry for boxplot.

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

Parameters

- **by** [str or sequence] Column in the DataFrame to group by.
- **kwargs** Additional keywords are documented in DataFrame.plot().

Returns

- matplotlib.axes.Axes or numpy.ndarray of them

See also:

- DataFrame.boxplot Another method to draw a box plot.
- Series.plot.box Draw a box plot from a Series object.
- matplotlib.pyplot.boxplot Draw a box plot in matplotlib.

Examples

Draw a box plot from a DataFrame with four columns of randomly generated data.

```python
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```

pandas.Series.plot.density

Series.plot.density(bw_method=None, ind=None, **kwargs)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

- **bw_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See scipy.stats.gaussian_kde for more information.
- **ind** [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.
- **kwargs** Additional keyword arguments are documented in pandas.%(this-datatype)s.plot().
Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

scipy.stats.gaussian_kde Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

![Graph of estimated density function]

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the ind parameter determines the evaluation points for the plot of the estimated PDF:
For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame(
...   {'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...    'y': [4, 4, 4.5, 5, 5.5, 6, 6]},
...)
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)

>>> ax = df.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```
3.3. Series
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.Series.plot.hist

Series.plot.hist(by=None, bins=10, **kwargs)

Draw one histogram of the DataFrame’s columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one matplotlib.axes.Axes. This is useful when the DataFrame’s Series are in a similar scale.

Parameters

by [str or sequence, optional] Column in the DataFrame to group by.
bins [int, default 10] Number of histogram bins to be used.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

class:matplotlib.AxesSubplot Return a histogram plot.

See also:

DataFrame.hist Draw histograms per DataFrame’s Series.
Series.hist Draw a histogram with Series’ data.

Examples

When we draw a dice 6000 times, we expect to get each value around 1000 times. But when we draw two dices and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```python
>>> df = pd.DataFrame(...
...     np.random.randint(1, 7, 6000),
...     columns = ['one'])
>>> df['two'] = df['one'] + np.random.randint(1, 7, 6000)
>>> ax = df.plot.hist(bins=12, alpha=0.5)
```

pandas.Series.plot.kde

Series.plot.kde(bw_method=None, ind=None, **kwargs)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See scipy.stats.gaussian_kde for more information.

ind [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.

**kwargs Additional keyword arguments are documented in pandas.%(this-datatype)s.plot().

Returns

1398 Chapter 3. API reference
matplotlib.axes.Axes or numpy.ndarray of them

See also:

scipy.stats.gaussian_kde Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:
3.3. Series
For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)

>>> ax = df.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5])
```
**pandas.Series.plot.line**

Series.plot.line(x=None, y=None, **kwargs)

Plot Series or DataFrame as lines.

This function is useful to plot lines using DataFrame’s values as coordinates.

**Parameters**

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- **color** [str, array_like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:
  - A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
  - A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column’s line will be filled in green or yellow, alternatively.
  - A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called `a` and `b`, then passing {'a': 'green', 'b': 'red'} will color lines for column `a` in green and lines for column `b` in red.

New in version 1.1.0.

**kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

**Returns**

- `matplotlib.axes.Axes` or `np.ndarray` of them An ndarray is returned with one `matplotlib.axes.Axes` per column when subplots=True.

See also:

- `matplotlib.pyplot.plot` Plot y versus x as lines and/or markers.

**Examples**

```python
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
```

The following example shows the populations for some animals over the years.

```python
>>> df = pd.DataFrame(
...     {'pig': [20, 18, 489, 675, 1776],
...      'horse': [4, 25, 281, 600, 1900],
```

```python
>>> lines = df.plot.line()  # An example with subplots, so an array of axes is returned.
```

```python
>>> axes = df.plot.line(subplots=True)
```

```python
>>> type(axes)
<class 'numpy.ndarray'>
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

Let’s repeat the same example, but specifying colors for each column (in this case, for each animal).
>>> axes = df.plot.line(
...
subplots=True, color={"pig": "pink", "horse": "#742802"}
... )

The following example shows the relationship between both populations.
>>> lines = df.plot.line(x='pig', y='horse')

pandas.Series.plot.pie
Series.plot.pie(**kwargs)
Generate a pie plot.
A pie plot is a proportional representation of the numerical data in a column. This function wraps
matplotlib.pyplot.pie() for the specified column.
If no column reference is passed and
subplots=True a pie plot is drawn for each numerical column independently.
Parameters
y [int or label, optional] Label or position of the column to plot.
subplots=True argument must be passed.

If not provided,

**kwargs Keyword arguments to pass on to DataFrame.plot().

1412

Chapter 3. API reference


Returns

`matplotlib.axes.Axes` or `np.ndarray` of them

A NumPy array is returned when `subplots` is True.

See also:

* `Series.plot.pie` Generate a pie plot for a Series.
* `DataFrame.plot` Make plots of a DataFrame.

Examples

In the example below we have a DataFrame with the information about planet’s mass and radius. We pass the ‘mass’ column to the pie function to get a pie plot.

```
>>> df = pd.DataFrame({'mass': [0.330, 4.87, 5.97],
...    'radius': [2439.7, 6051.8, 6378.1]},
...    index=['Mercury', 'Venus', 'Earth'])
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
```

```
>>> plot = df.plot.pie(subplots=True, figsize=(11, 6))
```
```python
Series.hist(by, ax, grid, xlabelsize, ...) Draw histogram of the input series using matplotlib.
```

### 3.3.15 Serialization / IO / conversion

```python
Series.to_pickle(path[, compression, protocol]) Pickle (serialize) object to file.
Series.to_csv(path_or_buf, sep, na_rep, ...) Write object to a comma-separated values (csv) file.
Series.to_dict(into) Convert Series to {label -> value} dict or dict-like object.
Series.to_excel(excel_writer[, sheet_name, ...]) Write object to an Excel sheet.
Series.to_frame(name) Convert Series to DataFrame.
Series.to_xarray() Return an xarray object from the pandas object.
Series.to_hdf(path_or_buf, key[, mode, ...]) Write the contained data to an HDF5 file using HDFStore.
Series.to_sql(name, con[, schema, ...]) Write records stored in a DataFrame to a SQL database.
Series.to_json(path_or_buf, orient, ...) Convert the object to a JSON string.
Series.to_string([buf, na_rep, orient, ...]) Render a string representation of the Series.
Series.to_clipboard([excel, sep]) Copy object to the system clipboard.
Series.to_latex(buf, columns, col_space, ...) Render object to a LaTeX tabular, longtable, or nested table/tabular.
Series.to_markdown([buf, mode, index]) Print Series in Markdown-friendly format.
```

### 3.4 DataFrame

#### 3.4.1 Constructor

```python
DataFrame([data, index, columns, dtype, copy]) Two-dimensional, size-mutable, potentially heterogeneous tabular data.
```
columns [Index or array-like] Column labels to use for resulting frame. Will default to
RangelIndex (0, 1, 2, ..., n) if no column labels are provided.
dtype [dtype, default None] Data type to force. Only a single dtype is allowed. If None,
infer.
copy [bool, default False] Copy data from inputs. Only affects DataFrame / 2d ndarray input.

See also:
DataFrame.from_records Constructor from tuples, also record arrays.
DataFrame.from_dict From dicts of Series, arrays, or dicts.
read_csv Read a comma-separated values (csv) file into DataFrame.
read_table Read general delimited file into DataFrame.
read_clipboard Read text from clipboard into DataFrame.

Examples

Constructing DataFrame from a dictionary.

```python
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df
   col1  col2
0     1     3
1     2     4
```
Notice that the inferred dtype is int64.

```python
>>> df.dtypes
col1    int64
col2    int64
dtype: object
```
To enforce a single dtype:

```python
>>> df = pd.DataFrame(data=d, dtype=np.int8)
>>> df.dtypes
   col1   int8
   col2   int8
dtype: object
```

Constructing DataFrame from numpy ndarray:

```python
>>> df2 = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]),
   columns=['a', 'b', 'c'])
```
```python
   a b c
0 1 2 3
1 4 5 6
2 7 8 9
```
Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>at</code></td>
<td>Access a single value for a row/column label pair.</td>
</tr>
<tr>
<td><code>attrs</code></td>
<td>Dictionary of global attributes on this object.</td>
</tr>

<tr>
<td><code>index</code></td>
<td>The index (row labels) of the DataFrame.</td>
</tr>
<tr>
<td><code>loc</code></td>
<td>Access a group of rows and columns by label(s) or a boolean array.</td>
</tr>
<tr>
<td><code>ndim</code></td>
<td>Return an int representing the number of axes / array dimensions.</td>
</tr>
<tr>
<td><code>shape</code></td>
<td>Return a tuple representing the dimensionality of the DataFrame.</td>
</tr>
<tr>
<td><code>size</code></td>
<td>Return an int representing the number of elements in this object.</td>
</tr>
<tr>
<td><code>style</code></td>
<td>Returns a Styler object.</td>
</tr>
<tr>
<td><code>values</code></td>
<td>Return a Numpy representation of the DataFrame.</td>
</tr>
</tbody>
</table>

pandas.DataFrame.at

**property** DataFrame.at
Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

**Raises**

`KeyError` If ‘label’ does not exist in DataFrame.

**See also:**

- `DataFrame.iat` Access a single value for a row/column pair by integer position.
- `DataFrame.loc` Access a group of rows and columns by label(s).
- `Series.at` Access a single value using a label.
Examples

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
                   index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
   A  B  C
4  0  2  3
5  0  4  1
6 10 20 30

Get value at specified row/column pair

```python
>>> df.at[4, 'B']
2
```n

Set value at specified row/column pair

```python
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```n

Get value within a Series

```python
>>> df.loc[5].at['B']
4
```n

**pandas.DataFrame.attrs**

**property** pandas.DataFrame.attrs

Dictionary of global attributes on this object.

**Warning:** attrs is experimental and may change without warning.

**pandas.DataFrame.axes**

**property** pandas.DataFrame.axes

Return a list representing the axes of the DataFrame.

It has the row axis labels and column axis labels as the only members. They are returned in that order.

**Examples**

```python
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.axes
[RangeIndex(start=0, stop=2, step=1), Index(['col1', 'col2'],
     dtype='object')]
```
pandas.DataFrame.columns

DataFrame.columns: Index
The column labels of the DataFrame.

pandas.DataFrame.dtypes

property DataFrame.dtypes
Return the dtypes in the DataFrame.

This returns a Series with the data type of each column. The result’s index is the original DataFrame’s columns. Columns with mixed types are stored with the object dtype. See the User Guide for more.

Returns
pandas.Series The data type of each column.

Examples

```python
def = pd.DataFrame({'float': [1.0],
...    'int': [1],
...    'datetime': [pd.Timestamp('20180310')],
...    'string': ['foo'])
def.dtypes
float       float64
int         int64
datetime    datetime64[ns]
string      object
dtype: object
```

pandas.DataFrame.empty

property DataFrame.empty
Indicator whether DataFrame is empty.

True if DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

Returns
bool If DataFrame is empty, return True, if not return False.

See also:

Series.dropna Return series without null values.
DataFrame.dropna Return DataFrame with labels on given axis omitted where (all or any) data are missing.
Notes

If DataFrame contains only NaNs, it is still not considered empty. See the example below.

Examples

An example of an actual empty DataFrame. Notice the index is empty:

```python
>>> df_empty = pd.DataFrame({'A': []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []
>>> df_empty.empty
True
```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```python
>>> df = pd.DataFrame({'A': [np.nan]})
>>> df
   A
0  NaN
>>> df.empty
False
>>> df.dropna().empty
True
```

**pandas.DataFrame.iat**

**property** `DataFrame.iat`

Access a single value for a row/column pair by integer position.

Similar to `iloc`, in that both provide integer-based lookups. Use `iat` if you only need to get or set a single value in a DataFrame or Series.

**Raises**

- `IndexError` When integer position is out of bounds.

**See also:**

- `DataFrame.at` Access a single value for a row/column label pair.
- `DataFrame.loc` Access a group of rows and columns by label(s).
- `DataFrame.iloc` Access a group of rows and columns by integer position(s).
Examples

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
                      columns=['A', 'B', 'C'])
>>> df
   A  B  C
0  0  2  3
1  0  4  1
2 10 20 30
```

Get value at specified row/column pair

```python
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair

```python
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series

```python
>>> df.loc[0].iat[1]
2
```

**pandas.DataFrame.iloc**

**property** `DataFrame.iloc`

Purely integer-location based indexing for selection by position.

`.iloc[]` is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. [4, 3, 0].
- A slice object with ints, e.g. 1:7.
- A boolean array.
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don’t have a reference to the calling object, but would like to base your selection on some value.

`.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except `slice` indexers which allow out-of-bounds indexing (this conforms with python/numpy `slice` semantics).

See more at `Selection by Position`.

See also:

- `DataFrame.iat` Fast integer location scalar accessor.
- `DataFrame.loc` Purely label-location based indexer for selection by label.
- `Series.iloc` Purely integer-location based indexing for selection by position.
### Examples

```python
>>> mydict = [{'a': 1, 'b': 2, 'c': 3, 'd': 4},
            {'a': 100, 'b': 200, 'c': 300, 'd': 400},
            {'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000}]

>>> df = pd.DataFrame(mydict)

>>> df
     a  b  c  d
0   1  2  3  4
1 100 200 300 400
2 1000 2000 3000 4000

### Indexing just the rows

With a scalar integer.

```python
>>> type(df.iloc[0])
<class 'pandas.core.series.Series'>

>>> df.iloc[0]
a 1
b 2
c 3
d 4
Name: 0, dtype: int64
```

With a list of integers.

```python
>>> df.iloc[[0]]
     a  b  c  d
0   1  2  3  4

>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>
```

```python
>>> df.iloc[[0, 1]]
     a  b  c  d
0   1  2  3  4
1 100 200 300 400
```

With a slice object.

```python
>>> df.iloc[:3]
     a  b  c  d
0   1  2  3  4
1 100 200 300 400
2 1000 2000 3000 4000
```

With a boolean mask the same length as the index.

```python
>>> df.iloc[[True, False, True]]
     a  b  c  d
0   1  2  3  4
2 1000 2000 3000 4000
```

With a callable, useful in method chains. The x passed to the lambda is the DataFrame being sliced.

This selects the rows whose index label even.

```python
```
```python
>>> df.iloc[lambda x: x.index % 2 == 0]
a  b  c  d
0  1  2  3  4
2 1000 2000 3000 4000
```

### Indexing both axes

You can mix the indexer types for the index and columns. Use : to select the entire axis.

With scalar integers.

```python
>>> df.iloc[0, 1]
2
```

With lists of integers.

```python
>>> df.iloc[[0, 2], [1, 3]]
   b  d
0  2  4
2 2000 4000
```

With `slice` objects.

```python
>>> df.iloc[1:3, 0:3]
a  b  c
1 100 200 300
2 1000 2000 3000
```

With a boolean array whose length matches the columns.

```python
>>> df.iloc[:, [True, False, True, False]]
a  c
0 1 3
1 100 300
2 1000 3000
```

With a callable function that expects the Series or DataFrame.

```python
>>> df.iloc[:, lambda df: [0, 2]]
a  c
0 1 3
1 100 300
2 1000 3000
```

---

**pandas.DataFrame.index**

Dataframe.index: Index

The index (row labels) of the DataFrame.
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.DataFrame.loc

**property** DataFrame.loc

Access a group of rows and columns by label(s) or a boolean array.

`.loc[]` is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a *label* of the index, and **never** as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a':'f'.

**Warning:** Note that contrary to usual python slices, **both** the start and the stop are included.

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above).

See more at *Selection by Label*

**Raises**

**KeyError**  If any items are not found.

See also:

**DataFrame.at**  Access a single value for a row/column label pair.

**DataFrame.iloc**  Access group of rows and columns by integer position(s).

**DataFrame.xs**  Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.

**Series.loc**  Access group of values using labels.

**Examples**

**Getting values**

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
                    index=['cobra', 'viper', 'sidewinder'],
                    columns=['max_speed', 'shield'])
>>> df
      max_speed  shield
    cobra       1       2
    viper       4       5
    sidewinder  7       8
```

Single label. Note this returns the row as a Series.

```
>>> df.loc['viper']
max_speed    4
shield       5
Name: viper, dtype: int64
```
List of labels. Note using `[]` returns a DataFrame.

```
>>> df.loc[['viper', 'sidewinder']]
   max_speed  shield
viper       4       5
sidewinder  7       8
```

Single label for row and column

```
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc['cobra':'viper', 'max_speed']
cobra   1
viper   4
Name: max_speed, dtype: int64
```

Boolean list with the same length as the row axis

```
>>> df.loc[[False, False, True]]
   max_speed  shield
sidewinder  7       8
```

Conditional that returns a boolean Series

```
>>> df.loc[df['shield'] > 6]
   max_speed  shield
sidewinder  7       8
```

Conditional that returns a boolean Series with column labels specified

```
>>> df.loc[df['shield'] > 6, ['max_speed']]
   max_speed
sidewinder  7
```

Callable that returns a boolean Series

```
>>> df.loc[lambda df: df['shield'] == 8]
   max_speed  shield
sidewinder  7       8
```

Setting values

Set value for all items matching the list of labels

```
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
   max_speed  shield
  cobra      1       2
  viper      4       50
  sidewinder 7       50
```

Set value for an entire row
```python
>>> df.loc['cobra'] = 10
>>> df
  max_speed  shield
cobra    10      10
viper     4      50
sidewinder  7      50

Set value for an entire column

>>> df.loc[:, 'max_speed'] = 30
>>> df
  max_speed  shield
cobra    30      10
viper    30      50
sidewinder    30     50

Set value for rows matching callable condition

>>> df.loc[df['shield'] > 35] = 0
>>> df
  max_speed  shield
cobra    30      10
viper     0      0
sidewinder    0      0

Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
                   index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
  max_speed  shield
7          1      2
8          4      5
9          7      8

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

>>> df.loc[7:9]
  max_speed  shield
7          1      2
8          4      5
9          7      8

Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

>>> tuples = [
...     ('cobra', 'mark i'), ('cobra', 'mark ii'),
...     ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
...     ('viper', 'mark ii'), ('viper', 'mark iii')
... ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
...           [1, 4], [7, 1], [16, 36]]
(continues on next page)
>>>
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
>>> df

<table>
<thead>
<tr>
<th></th>
<th>max_speed</th>
<th>shield</th>
</tr>
</thead>
<tbody>
<tr>
<td>cobra</td>
<td>mark i</td>
<td>12</td>
</tr>
<tr>
<td></td>
<td>mark ii</td>
<td>0</td>
</tr>
<tr>
<td>sidewinder</td>
<td>mark i</td>
<td>10</td>
</tr>
<tr>
<td></td>
<td>mark ii</td>
<td>1</td>
</tr>
<tr>
<td>viper</td>
<td>mark ii</td>
<td>7</td>
</tr>
<tr>
<td></td>
<td>mark iii</td>
<td>16</td>
</tr>
</tbody>
</table>

Single label. Note this returns a DataFrame with a single index.

```python
>>> df.loc['cobra']

<table>
<thead>
<tr>
<th></th>
<th>max_speed</th>
<th>shield</th>
</tr>
</thead>
<tbody>
<tr>
<td>mark i</td>
<td>12</td>
<td>2</td>
</tr>
<tr>
<td>mark ii</td>
<td>0</td>
<td>4</td>
</tr>
</tbody>
</table>
```

Single index tuple. Note this returns a Series.

```python
>>> df.loc[('cobra', 'mark ii')]

max_speed 0
shield 4
Name: (cobra, mark ii), dtype: int64
```

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```python
>>> df.loc['cobra', 'mark i']

max_speed 12
shield 2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using [[]] returns a DataFrame.

```python
>>> df.loc[['cobra', 'mark ii']]

<table>
<thead>
<tr>
<th></th>
<th>max_speed</th>
<th>shield</th>
</tr>
</thead>
<tbody>
<tr>
<td>cobra</td>
<td>mark ii</td>
<td>0</td>
</tr>
</tbody>
</table>
```

Single tuple for the index with a single label for the column

```python
>>> df.loc[['cobra', 'mark i'], 'shield']

2
```

Slice from index tuple to single label

```python
>>> df.loc[['cobra', 'mark i']:'viper']

<table>
<thead>
<tr>
<th></th>
<th>max_speed</th>
<th>shield</th>
</tr>
</thead>
<tbody>
<tr>
<td>cobra</td>
<td>mark i</td>
<td>12</td>
</tr>
<tr>
<td></td>
<td>mark ii</td>
<td>0</td>
</tr>
<tr>
<td>sidewinder</td>
<td>mark i</td>
<td>10</td>
</tr>
<tr>
<td></td>
<td>mark ii</td>
<td>1</td>
</tr>
<tr>
<td>viper</td>
<td>mark ii</td>
<td>7</td>
</tr>
<tr>
<td></td>
<td>mark iii</td>
<td>16</td>
</tr>
</tbody>
</table>
```

Slice from index tuple to index tuple
pandas: powerful Python data analysis toolkit, Release 1.1.1

```python
>>> df.loc[('cobra', 'mark i'):('viper', 'mark ii')]
   max_speed  shield
  cobra     mark i   12   2
        mark ii    0   4
sidewinder mark i  10  20
        mark ii   1   4
  viper     mark ii  7   1
```

**pandas.DataFrame.ndim**

**property DataFrame.ndim**

Return an int representing the number of axes / array dimensions.

Return 1 if Series. Otherwise return 2 if DataFrame.

See also:

*ndarray.ndim* Number of array dimensions.

**Examples**

```python
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.ndim
1

>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.ndim
2
```

**pandas.DataFrame.shape**

**property DataFrame.shape**

Return a tuple representing the dimensionality of the DataFrame.

See also:

*ndarray.shape*

**Examples**

```python
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.shape
(2, 2)

>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4],
... 'col3': [5, 6]})
>>> df.shape
(2, 3)
```
pandas.DataFrame.size

**property** DataFrame.size

Return an int representing the number of elements in this object.

Return the number of rows if Series. Otherwise return the number of rows times number of columns if DataFrame.

See also:

ndarray.size Number of elements in the array.

**Examples**

```python
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.size
3

>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.size
4
```

pandas.DataFrame.style

**property** DataFrame.style

Returns a Styler object.

Contains methods for building a styled HTML representation of the DataFrame.

See also:

io.formats.style.Styler Helps style a DataFrame or Series according to the data with HTML and CSS.

pandas.DataFrame.values

**property** DataFrame.values

Return a Numpy representation of the DataFrame.

**Warning:** We recommend using DataFrame.to_numpy() instead.

Only the values in the DataFrame will be returned, the axes labels will be removed.

**Returns**

- **numpy.ndarray** The values of the DataFrame.

See also:

DataFrame.to_numpy Recommended alternative to this method.

DataFrame.index Retrieve the index labels.

DataFrame.columns Retrieving the column names.
Notes

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcast to int32. By numpy.find_common_type() convention, mixing int64 and uint64 will result in a float64 dtype.

Examples

A DataFrame where all columns are the same type (e.g., int64) results in an array of the same type.

```python
>>> df = pd.DataFrame({'age': [3, 29],
...                    'height': [94, 170],
...                    'weight': [31, 115]})

>>> df
   age  height  weight
0    3      94      31
1   29     170     115

>>> df.dtypes
age     int64
height   int64
weight   int64
dtype: object

>>> df.values
array([[ 3, 94, 31],
       [29, 170, 115]])
```

A DataFrame with mixed type columns (e.g., str/object, int64, float32) results in an ndarray of the broadest type that accommodates these mixed types (e.g., object).

```python
>>> df2 = pd.DataFrame([('parrot', 24.0, 'second'),
...                      ('lion', 80.5, 1),
...                      ('monkey', np.nan, None)],
...                     columns=('name', 'max_speed', 'rank'))

>>> df2.dtypes
name    object
max_speed     float64
rank      object
dtype: object

>>> df2.values
array([[parrot', 24.0, 'second'],
       ['lion', 80.5, 1],
       ['monkey', nan, None]], dtype=object)
```

| `xs(key[, axis, level, drop_level])` | Return cross-section from the Series/DataFrame. |

**pandas.DataFrame.abs**

**DataFrame.abs()**

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

**Returns**

- **abs** Series/DataFrame containing the absolute value of each element.

**See also:**

- **numpy.absolute** Calculate the absolute value element-wise.

**Notes**

For complex inputs, \(1.2 + 1j\), the absolute value is \(\sqrt{a^2 + b^2}\).

**Examples**

Absolute numeric values in a Series.

```python
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0   1.10
1   2.00
2   3.33
3   4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```python
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0  1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```python
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0  1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using argsort (from StackOverflow).

```python
>>> df = pd.DataFrame(
...     {'a': [4, 5, 6, 7],
...      'b': [10, 20, 30, 40],
...      'c': [100, 50, -30, -50]
...     }
... )
```

(continues on next page)
>>> df
   a  b  c
0  4 10 100
1  5  20  50
2  6  30 -30
3  7  40 -50

>>> df.loc[(df.c - 43).abs().argsort()]
   a  b  c
1  5  20  50
0  4  10 100
2  6  30 -30
3  7  40 -50

**pandas.DataFrame.add**

`DataFrame.add(other, axis='columns', level=None, fill_value=None)`

Get Addition of dataframe and other, element-wise (binary operator `add`).

Equivalent to `dataframe + other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `radd`.

Among flexible wrappers (`add, sub, mul, div, mod, pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- `fill_value` [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

- `DataFrame` Result of the arithmetic operation.

**See also:**

- `DataFrame.add` Add DataFrames.
- `DataFrame.sub` Subtract DataFrames.
- `DataFrame.mul` Multiply DataFrames.
- `DataFrame.div` Divide DataFrames (float division).
- `DataFrame.truediv` Divide DataFrames (float division).
- `DataFrame.floordiv` Divide DataFrames (integer division).
- `DataFrame.mod` Calculate modulo (remainder after division).
- `DataFrame.pow` Calculate exponential power.
### Notes

Mismatched indices will be unioned together.

### Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
                      'degrees': [360, 180, 360],
                      'index': ['circle', 'triangle', 'rectangle']})
>>> df
  angles  degrees
circle     0      360
triangle    3      180
rectangle   4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
  angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

```python
>>> df.add(1)
  angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
  angles  degrees
circle   0.0     36.0
triangle 0.3     18.0
rectangle 0.4    36.0
```

```python
>>> df.rdiv(10)
  angles  degrees
circle  inf     0.027778
triangle 3.33333 0.055556
rectangle 2.50000 0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
  angles  degrees
circle   -1      358
triangle    2      178
rectangle   3      358
```

```python
>>> df.sub([1, 2], axis='columns')
  angles  degrees
circle   -1      358
triangle    2      178
rectangle   3      358
```
Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                    index=['circle', 'triangle', 'rectangle'])
```

```
>>> df + other
angles  degrees
circle  0.0    NaN
triangle 9.0    NaN
rectangle 16.0   NaN
```

```
>>> df.mul(other, fill_value=0)
angles  degrees
circle  0.0
triangle 9.0
rectangle 16.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720]},
                               index=['A', 'A', 'A', 'B', 'B', 'B'],
                               ['circle', 'triangle', 'rectangle',
                               'square', 'pentagon', 'hexagon'])
```

```
>>> df_multindex
angles  degrees
A circle 0.0 360
triangle 3.0 180
rectangle 4.0 360
B square 4.0 360
pentagon 5.0 540
hexagon 6.0 720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
angles  degrees
A circle NaN 1.0
triangle 1.0 1.0
rectangle 1.0 1.0
B square 0.0 0.0
pentagon 0.0 0.0
hexagon 0.0 0.0
```
pandas.DataFrame.add_prefix

DataFrame.add_prefix(prefix)
Prefix labels with string prefix.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

Parameters

prefix [str] The string to add before each label.

Returns

Series or DataFrame New Series or DataFrame with updated labels.

See also:

Series.add_suffix Suffix row labels with string suffix.
DataFrame.add_suffix Suffix column labels with string suffix.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64

>>> s.add_prefix('item_')
item_0 1
item_1 2
item_2 3
item_3 4
dtype: int64

>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6

>>> df.add_prefix('col_')
   col_A  col_B
0      1      3
1      2      4
2      3      5
3      4      6
```
**pandas.DataFrame.add_suffix**

```python
dataframe.add_suffix(suffix)
```

Suffix labels with string `suffix`.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

**Parameters**

- `suffix` [str] The string to add after each label.

**Returns**

- `Series` or `DataFrame` New Series or DataFrame with updated labels.

**See also:**

- `Series.add_prefix` Prefix row labels with string `prefix`.
- `DataFrame.add_prefix` Prefix column labels with string `prefix`.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```python
>>> s.add_suffix('_item')
0_item    1
1_item    2
2_item    3
3_item    4
dtype: int64
```

```python
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6
```

```python
>>> df.add_suffix('_col')
   A_col  B_col
0      1      3
1      2      4
2      3      5
3      4      6
```
DataFrame.agg (func=None, axis=0, *args, **kwargs)
Aggregate using one or more operations over the specified axis.
New in version 0.20.0.

Parameters

- **func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply. Accepted combinations are:
  - function
  - string function name
  - list of functions and/or function names, e.g. [np.sum, 'mean']
  - dict of axis labels -> functions, function names or list of such.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] If 0 or ‘index’: apply function to each column. If 1 or ‘columns’: apply function to each row.
- **args** Positional arguments to pass to **func**.
- **kwargs** Keyword arguments to pass to **func**.

Returns

scalar, Series or DataFrame  The return can be:
  - scalar : when Series.agg is called with single function
  - Series : when DataFrame.agg is called with a single function
  - DataFrame : when DataFrame.agg is called with several functions

The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from 
numpy aggregation functions (mean, median, prod, sum, std, var), where the default is to compute the aggregation of the flattened 
array, e.g., numpy.mean(arr_2d) as opposed to 
numpy.mean(arr_2d, axis=0).

agg is an alias for aggregate. Use the alias.

See also:

- **DataFrame.apply** Perform any type of operations.
- **DataFrame.transform** Perform transformation type operations.
- core.groupby.GroupBy Perform operations over groups.
- core.resample.Resampler Perform operations over resampled bins.
- core.window.Rolling Perform operations over rolling window.
- core.window.Expanding Perform operations over expanding window.
**Notes**

`agg` is an alias for `aggregate`. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

**Examples**

```python
df = pd.DataFrame([[1, 2, 3],
                   [4, 5, 6],
                   [7, 8, 9],
                   [np.nan, np.nan, np.nan]],
                  columns=['A', 'B', 'C'])
```

Aggregate these functions over the rows.

```python
df.agg(['sum', 'min'])
```

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>sum</td>
<td>12.0</td>
<td>15.0</td>
<td>18.0</td>
</tr>
<tr>
<td>min</td>
<td>1.0</td>
<td>2.0</td>
<td>3.0</td>
</tr>
</tbody>
</table>

Different aggregations per column.

```python
df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
```

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>max</td>
<td>NaN 8.0</td>
</tr>
<tr>
<td>min</td>
<td>1.0 2.0</td>
</tr>
<tr>
<td>sum</td>
<td>12.0 NaN</td>
</tr>
</tbody>
</table>

Aggregate over the columns.

```python
df.agg("mean", axis="columns")
```

| 0  | 2.0 |
| 1  | 5.0 |
| 2  | 8.0 |
| 3  | NaN |

dtype: float64

**pandas.DataFrame.aggregate**

`DataFrame.aggregate` *(func=None, axis=0, *args, **kwargs)*

Aggregate using one or more operations over the specified axis.

New in version 0.20.0.

**Parameters**

- **func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

  Accepted combinations are:
  - function
• string function name
• list of functions and/or function names, e.g. [np.sum, 'mean']
• dict of axis labels -> functions, function names or list of such.

**axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] If 0 or ‘index’: apply function to each column. If 1 or ‘columns’: apply function to each row.

*args Positional arguments to pass to **func**.

**kwargs Keyword arguments to pass to **func**.

Returns

**scalar, Series or DataFrame** The return can be:
  • scalar : when Series.agg is called with single function
  • Series : when DataFrame.agg is called with a single function
  • DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from

**numpy aggregation functions** (**mean**, **median**, **prod**, **sum**, **std**, **var**), where the default is to compute the aggregation of the flattened array, e.g., **numpy.mean(arr_2d)** as opposed to **numpy.mean(arr_2d, axis=0)**.

**agg** is an alias for **aggregate**. Use the alias.

See also:

**DataFrame.agg** Perform any type of operations.

**DataFrame.transform** Perform transformation type operations.

**core.groupby.GroupBy** Perform operations over groups.

**core.resample.Resampler** Perform operations over resampled bins.

**core.window.Rolling** Perform operations over rolling window.

**core.window.Expanding** Perform operations over expanding window.

**core.window.ExponentialMovingWindow** Perform operation over exponential weighted window.
Notes

`agg` is an alias for `aggregate`. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> df = pd.DataFrame([[1, 2, 3],
...                     [4, 5, 6],
...                     [7, 8, 9],
...                     [np.nan, np.nan, np.nan]],
...                     columns=['A', 'B', 'C'])

Aggregate these functions over the rows.

```python
>>> df.agg(['sum', 'min'])
```

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>sum</td>
<td>12.0</td>
<td>15.0</td>
<td>18.0</td>
</tr>
<tr>
<td>min</td>
<td>1.0</td>
<td>2.0</td>
<td>3.0</td>
</tr>
</tbody>
</table>

Different aggregations per column.

```python
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
```

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>max</td>
<td>NaN</td>
<td>8.0</td>
</tr>
<tr>
<td>min</td>
<td>1.0</td>
<td>2.0</td>
</tr>
<tr>
<td>sum</td>
<td>12.0</td>
<td>NaN</td>
</tr>
</tbody>
</table>

Aggregate over the columns.

```python
>>> df.agg("mean", axis="columns")
```

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2.0</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>5.0</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>8.0</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>NaN</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

dtype: float64

`pandas.DataFrame.align`

DataFrame.align(other, join='outer', axis=None, level=None, copy=True, fill_value=None, method=None, limit=None, fill_axis=0, broadcast_axis=None)

Align two objects on their axes with the specified join method.

Join method is specified for each axis Index.

Parameters

- **other** [DataFrame or Series]
- **join** [{‘outer’, ‘inner’, ‘left’, ‘right’}, default ‘outer’]
- **axis** [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None).
- **level** [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level.
copy [bool, default True] Always returns new objects. If copy=False and no reindexing is required then original objects are returned.

fill_value [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.

  • pad / ffill: propagate last valid observation forward to next valid.
  • backfill / bfill: use NEXT valid observation to fill gap.

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

fill_axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Filling axis, method and limit.

broadcast_axis [{0 or ‘index’, 1 or ‘columns’}, default None] Broadcast values along this axis, if aligning two objects of different dimensions.

Returns
(left, right) [(DataFrame, type of other)] Aligned objects.

pandas.DataFrame.all

DataFrame.all (axis=0, bool_only=None, skipna=True, level=None, **kwargs)
Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

Parameters

axis [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Indicate which axis or axes should be reduced.
  • 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
  • 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
  • None : reduce all axes, return a scalar.

bool_only [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

skipna [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**kwargs [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns
Series or DataFrame If level is specified, then, DataFrame is returned; otherwise, Series is returned.

See also:

Series.all Return True if all elements are True.

DataFrame.any Return True if one (or more) elements are True.

Examples

Series

```python
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([]).all()
True
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

DataFrames

Create a dataframe from a dictionary.

```python
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
   col1  col2
0    True  True
1    True  False
```

Default behaviour checks if column-wise values all return True.

```python
>>> df.all()
   col1  col2
0   True  True
dtype: bool
```

Specify axis='columns' to check if row-wise values all return True.

```python
>>> df.all(axis='columns')
0  True
1  False
dtype: bool
```

Or axis=None for whether every value is True.

```python
>>> df.all(axis=None)
False
```
DataFrame.any (axis=0, bool_only=None, skipna=True, level=None, **kwargs)

Return whether any element is True, potentially over an axis.

Returns False unless there at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

Parameters

axis [[0 or ‘index’, 1 or ‘columns’, None], default 0] Indicate which axis or axes should be reduced.

• 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
• 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
• None : reduce all axes, return a scalar.

bool_only [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

skipna [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**kwargs [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame If level is specified, then, DataFrame is returned; otherwise, Series is returned.

See also:

numpy.any Numpy version of this method.
Series.any Return whether any element is True.
Series.all Return whether all elements are True.
DataFrame.any Return whether any element is True over requested axis.
DataFrame.all Return whether all elements are True over requested axis.

Examples

Series

For Series input, the output is a scalar indicating whether any element is True.

```python
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([]).any()
```

(continues on next page)
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True

**DataFrame**

Whether each column contains at least one True element (the default).

```python
>>> df = pd.DataFrame({'A': [1, 2], 'B': [0, 2], 'C': [0, 0]})
>>> df
   A  B  C
0  1  0  0
1  2  2  0
```

```python
>>> df.any()
A   True
B  True
C  False
dtype: bool
```

Aggregating over the columns.

```python
>>> df = pd.DataFrame({'A': [True, False], 'B': [1, 2]})
>>> df
   A  B
0  True 1
1  False 2
```

```python
>>> df.any(axis='columns')
0   True
1   True
dtype: bool
```

```python
>>> df = pd.DataFrame({'A': [True, False], 'B': [1, 0]})
>>> df
   A  B
0  True 1
1  False 0
```

```python
>>> df.any(axis='columns')
0   True
1  False
dtype: bool
```

Aggregating over the entire DataFrame with `axis=None`.

```python
>>> df.any(axis=None)
True
```

`any` for an empty DataFrame is an empty Series.

```python
>>> pd.DataFrame([]).any()
Series([], dtype: bool)
```
pandas.DataFrame.append

DataFrame.append(other, ignore_index=False, verify_integrity=False, sort=False)

Append rows of other to the end of caller, returning a new object.

Columns in other that are not in the caller are added as new columns.

Parameters

other [DataFrame or Series/dict-like object, or list of these] The data to append.
ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n-1.
verify_integrity [bool, default False] If True, raise ValueError on creating index with duplicates.
sort [bool, default False] Sort columns if the columns of self and other are not aligned.

New in version 0.23.0.
Changed in version 1.0.0: Changed to not sort by default.

Returns

DataFrame

See also:

concat General function to concatenate DataFrame or Series objects.

Notes

If a list of dict/series is passed and the keys are all contained in the DataFrame’s index, the order of the columns in the resulting DataFrame will be unchanged.

Iteratively appending rows to a DataFrame can be more computationally intensive than a single concatenate. A better solution is to append those rows to a list and then concatenate the list with the original DataFrame all at once.

Examples

```python
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=list('AB'))
```
```
  A  B
0 1 2
1 3 4
```
```python
>>> df2 = pd.DataFrame([[5, 6], [7, 8]], columns=list('AB'))
```
```python
>>> df.append(df2)
```
```
  A  B
0 1 2
1 3 4
0 5 6
1 7 8
```

With ignore_index set to True:
The following, while not recommended methods for generating DataFrames, show two ways to generate a DataFrame from multiple data sources.

Less efficient:

```python
>>> df = pd.DataFrame(columns=['A'])
>>> for i in range(5):
...   df = df.append({'A': i}, ignore_index=True)

>>> df
A
0 0
1 1
2 2
3 3
4 4
```

More efficient:

```python
>>> pd.concat([pd.DataFrame([i], columns=['A']) for i in range(5)], ignore_index=True)

   A
0 0
1 1
2 2
3 3
4 4
```

---

**pandas.DataFrame.apply**

DataFrame.apply(func, axis=0, raw=False, result_type=None, args=(), **kwds)

Apply a function along an axis of the DataFrame.

Objects passed to the function are Series objects whose index is either the DataFrame’s index (axis=0) or the DataFrame’s columns (axis=1). By default (result_type=None), the final return type is inferred from the return type of the applied function. Otherwise, it depends on the result_type argument.

**Parameters**

- **func** [function] Function to apply to each column or row.
- **axis** [[0 or ‘index’, 1 or ‘columns’], default 0] Axis along which the function is applied:
  - 0 or ‘index’: apply function to each column.
  - 1 or ‘columns’: apply function to each row.
- **raw** [bool, default False] Determines if row or column is passed as a Series or ndarray object:
  - False: passes each row or column as a Series to the function.
• True: the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

result_type [[‘expand’, ‘reduce’, ‘broadcast’, None], default None] These only act when axis=1 (columns):
  • ‘expand’: list-like results will be turned into columns.
  • ‘reduce’: returns a Series if possible rather than expanding list-like results. This is the opposite of ‘expand’.
  • ‘broadcast’: results will be broadcast to the original shape of the DataFrame, the original index and columns will be retained.

The default behaviour (None) depends on the return value of the applied function: list-like results will be returned as a Series of those. However if the apply function returns a Series these are expanded to columns.

New in version 0.23.0.

args [tuple] Positional arguments to pass to func in addition to the array/series.

**kwds Additional keyword arguments to pass as keywords arguments to func.

Returns

Series or DataFrame Result of applying func along the given axis of the DataFrame.

See also:

DataFrame.applymap For elementwise operations.

DataFrame.aggregate Only perform aggregating type operations.

DataFrame.transform Only perform transforming type operations.

Examples

```python
>>> df = pd.DataFrame([[4, 9]] * 3, columns=['A', 'B'])
>>> df
   A  B
0  4  9
1  4  9
2  4  9

Using a numpy universal function (in this case the same as np.sqrt(df)):

```python
>>> df.apply(np.sqrt)
   A  B
0  2.0  3.0
1  2.0  3.0
2  2.0  3.0
```

Using a reducing function on either axis

```python
>>> df.apply(np.sum, axis=0)
   A   B
0  12  27
dtype: int64
```
>>> df.apply(np.sum, axis=1)
0  13
1  13
2  13
dtype: int64

Returning a list-like will result in a Series

>>> df.apply(lambda x: [1, 2], axis=1)
0  [1, 2]
1  [1, 2]
2  [1, 2]
dtype: object

Passing result_type='expand' will expand list-like results to columns of a Dataframe

>>> df.apply(lambda x: [1, 2], axis=1, result_type='expand')
       0  1
0   1  2
1   1  2
2   1  2

Returning a Series inside the function is similar to passing result_type='expand'. The resulting column names will be the Series index.

>>> df.apply(lambda x: pd.Series([1, 2], index=['foo', 'bar']), axis=1)
     foo  bar
0   1   2
1   1   2
2   1   2

Passing result_type='broadcast' will ensure the same shape result, whether list-like or scalar is returned by the function, and broadcast it along the axis. The resulting column names will be the originals.

>>> df.apply(lambda x: [1, 2], axis=1, result_type='broadcast')
       A  B
0   1   2
1   1   2
2   1   2

**pandas.DataFrame.applymap**

Dataframe.applymap(func)

Apply a function to a Dataframe elementwise.

This method applies a function that accepts and returns a scalar to every element of a Dataframe.

**Parameters**

- **func** [callable] Python function, returns a single value from a single value.

**Returns**

- **DataFrame** Transformed DataFrame.

**See also:**

- **DataFrame.apply** Apply a function along input axis of DataFrame.
Examples

```python
>>> df = pd.DataFrame([[1, 2.12], [3.356, 4.567]])
>>> df
  0 1
0 1.000 2.120
1 3.356 4.567
```

```python
>>> df.applymap(lambda x: len(str(x)))
  0 1
0 3 4
1 5 5
```

Note that a vectorized version of `func` often exists, which will be much faster. You could square each number elementwise.

```python
>>> df.applymap(lambda x: x**2)
  0 1
0 1.000000 4.494400
1 11.262736 20.857489
```

But it’s better to avoid applymap in that case.

```python
>>> df ** 2
  0 1
0 1.000000 4.494400
1 11.262736 20.857489
```

**pandas.DataFrame.asfreq**

`DataFrame.asfreq(freq, method=None, how=None, normalize=False, fill_value=None)`

Convert TimeSeries to specified frequency.

Optionally provide filling method to pad/backfill missing values.

Returns the original data conformed to a new index with the specified frequency. `resample` is more appropriate if an operation, such as summarization, is necessary to represent the data at the new frequency.

**Parameters**

- `freq` [DateOffset or str] Frequency DateOffset or string.
- `method` [{'backfill'/'bfill', 'pad'/'ffill'}, default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):
  - ‘pad’ / ‘ffill’: propagate last valid observation forward to next valid
  - ‘backfill’ / ‘bfill’: use NEXT valid observation to fill.
- `how` [{'start', 'end'}, default end] For PeriodIndex only (see `PeriodIndex.asfreq`).
- `normalize` [bool, default False] Whether to reset output index to midnight.
- `fill_value` [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

**Returns**

- `Same type as caller` Object converted to the specified frequency.
See also:

**reindex** Conform DataFrame to new index with optional filling logic.

Notes

To learn more about the frequency strings, please see this link.

Examples

Start by creating a series with 4 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s':series})
>>> df
   s
0 0.0
1 NaN
2 2.0
3 3.0
```

Upsample the series into 30 second bins.

```python
>>> df.asfreq(freq='30S')
   s
0 0.0
1 NaN
2 NaN
3 2.0
4 NaN
5 9.0
6 9.0
7 3.0
```

Upsample again, providing a fill value.

```python
>>> df.asfreq(freq='30S', fill_value=9.0)
   s
0 0.0
1 9.0
2 NaN
3 9.0
4 2.0
5 9.0
6 3.0
```

Upsample again, providing a method.

```python
>>> df.asfreq(freq='30S', method='bfill')
   s
0 0.0
1 NaN
2 NaN
3 2.0
4 2.0
```

(continues on next page)
pandas.DataFrame.asof

DataFrame.asof(where, subset=None)
Return the last row(s) without any NaNs before where.
The last row (for each element in where, if list) without any NaN is taken. In case of a DataFrame, the last row without NaN considering only the subset of columns (if not None)
If there is no good value, NaN is returned for a Series or a Series of NaN values for a DataFrame

Parameters
where [date or array-like of dates] Date(s) before which the last row(s) are returned.
subset [str or array-like of str, default None] For DataFrame, if not None, only use these columns to check for NaNs.

Returns
scalar, Series, or DataFrame The return can be:
• scalar : when self is a Series and where is a scalar
• Series: when self is a Series and where is an array-like, or when self is a DataFrame and where is a scalar
• DataFrame : when self is a DataFrame and where is an array-like

Return scalar, Series, or DataFrame.

See also:
merge_asof Perform an asof merge. Similar to left join.

Notes
Dates are assumed to be sorted. Raises if this is not the case.

Examples
A Series and a scalar where.
```python
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10  1.0
20  2.0
30  NaN
40  4.0
dtype: float64

>>> s.asof(20)
2.0
```
For a sequence `where`, a Series is returned. The first value is NaN, because the first element of `where` is before the first index value.

```python
>>> s.asof([5, 20])
5   NaN
20  2.0
dtype: float64
```

Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

```python
>>> s.asof(30)
2.0
```

Take all columns into consideration

```python
>>> df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
...                     'b': [None, None, None, None, 500],
...                     'c': [1.0, 1.5, 2.0, 2.5, 3.0]},
...                    index=pd.DatetimeIndex(['2018-02-27 09:01:00',
...                                              '2018-02-27 09:02:00',
...                                              '2018-02-27 09:03:00',
...                                              '2018-02-27 09:04:00',
...                                              '2018-02-27 09:05:00']))
```

```python
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                             '2018-02-27 09:04:30'])),
...                    subset=['a'])
```

```python
a b
2018-02-27 09:03:30 30.0 NaN
2018-02-27 09:04:30 40.0 NaN
```

**pandas.DataFrame.assign**

**DataFrame.assign(**kwargs**)**

Assign new columns to a DataFrame.

Returns a new object with all original columns in addition to new ones. Existing columns that are reassigned will be overwritten.

**Parameters**

**kwargs** [dict of {str: callable or Series}] The column names are keywords. If the values are callable, they are computed on the DataFrame and assigned to the new columns. The callable must not change input DataFrame (though pandas doesn’t check it). If the values are not callable, (e.g. a Series, scalar, or array), they are simply assigned.

**Returns**

**DataFrame** A new DataFrame with the new columns in addition to all the existing columns.
Notes

Assigning multiple columns within the same assign is possible. Later items in `**kwargs` may refer to newly created or modified columns in `df`; items are computed and assigned into `df` in order.

Changed in version 0.23.0: Keyword argument order is maintained.

Examples

```python
>>> df = pd.DataFrame({'temp_c': [17.0, 25.0]},
                    index=['Portland', 'Berkeley'])
```

```text
temp_c
Portland 17.0
Berkeley 25.0
```

Where the value is a callable, evaluated on `df`:

```python
>>> df.assign(temp_f=lambda x: x.temp_c * 9 / 5 + 32)
```

```text
temp_c temp_f
Portland 17.0 62.6
Berkeley 25.0 77.0
```

Alternatively, the same behavior can be achieved by directly referencing an existing Series or sequence:

```python
>>> df.assign(temp_f=df['temp_c'] * 9 / 5 + 32)
```

```text
temp_c temp_f
Portland 17.0 62.6
Berkeley 25.0 77.0
```

You can create multiple columns within the same assign where one of the columns depends on another one defined within the same assign:

```python
>>> df.assign(temp_f=lambda x: x['temp_c'] * 9 / 5 + 32, 
               temp_k=lambda x: (x['temp_f'] + 459.67) * 5 / 9)
```

```text
temp_c temp_f temp_k
Portland 17.0 62.6 290.15
Berkeley 25.0 77.0 298.15
```

### pandas.DataFrame.astype

DataFrame `.astype(dtype, copy=True, errors='raise')`

Cast a pandas object to a specified `dtype` `dtype`.

**Parameters**

- `dtype` [data type, or dict of column name -> data type] Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use `{col: dtype, ...}`, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame's columns to column-specific types.

- `copy` [bool, default True] Return a copy when `copy=True` (be very careful setting `copy=False` as changes to values then may propagate to other pandas objects).

- `errors` [‘raise’, ‘ignore’], default ‘raise’] Control raising of exceptions on invalid data for provided `dtype`.  

3.4. DataFrame
• **raise**: allow exceptions to be raised
• **ignore**: suppress exceptions. On error return original object.

**Returns**

**casted** [same type as caller]

**See also:**

to\_datetime Convert argument to datetime.
to\_timedelta Convert argument to timedelta.
to\_numeric Convert argument to a numeric type.
numpy\_ndarray\_astype Cast a numpy array to a specified type.

**Examples**

Create a DataFrame:

```python
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df.dtypes
col1    int64
col2    int64
dtype: object
```

Cast all columns to int32:

```python
>>> df.astype('int32').dtypes
col1    int32
col2    int32
dtype: object
```

Cast col1 to int32 using a dictionary:

```python
>>> df.astype({'col1': 'int32'}).dtypes
col1    int32
col2    int64
dtype: object
```

Create a series:

```python
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0    1
1    2
dtype: int32
>>> ser.astype('int64')
0    1
1    2
dtype: int64
```

Convert to categorical type:
Convert to ordered categorical type with custom ordering:

```python
>>> cat_dtype = pd.api.types.CategoricalDtype(
...     categories=[2, 1], ordered=True)
```  
```python
>>> ser.astype(cat_dtype)
0 1
1 2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```python
>>> s1 = pd.Series([1, 2])
```  
```python
>>> s2 = s1.astype('int64', copy=False)
```  
```python
>>> s2[0] = 10
```  
```python
0 10
1 2
dtype: int64
```

Create a series of dates:

```python
>>> ser_date = pd.Series(pd.date_range('20200101', periods=3))
```  
```python
>>> ser_date
0 2020-01-01
1 2020-01-02
2 2020-01-03
dtype: datetime64[ns]
```

Datetimes are localized to UTC first before converting to the specified timezone:

```python
>>> ser_date.astype('datetime64[ns, US/Eastern]')
0 2019-12-31 19:00:00-05:00
1 2020-01-01 19:00:00-05:00
2 2020-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

### pandas.DataFrame.at_time

DataFrame.**at_time**(time, asof=False, axis=None)

Select values at particular time of day (e.g., 9:30AM).

**Parameters**

- **time** [datetime.time or str]
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] New in version 0.24.0.

**Returns**

- Series or DataFrame
Raises

TypeError  If the index is not a `DatetimeIndex`

See also:

between_time  Select values between particular times of the day.
first  Select initial periods of time series based on a date offset.
last  Select final periods of time series based on a date offset.

`DatetimeIndex.indexer_at_time`  Get just the index locations for values at particular time of the day.

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
   A
2018-04-09 00:00:00 1
2018-04-09 12:00:00 2
2018-04-10 00:00:00 3
2018-04-10 12:00:00 4

>>> ts.at_time('12:00')
   A
2018-04-09 12:00:00 2
2018-04-10 12:00:00 4
```

`pandas.DataFrame.backfill`

`DataFrame.backfill`  Synonym for `DataFrame.fillna()` with method='bfill'.

Parameters

[klass] or None  Object with missing values filled or None if inplace=True.

`pandas.DataFrame.between_time`

`DataFrame.between_time`  Select values between particular times of the day (e.g., 9:00-9:30 AM).

Parameters

start_time  [datetime.time or str] Initial time as a time filter limit.
end_time  [datetime.time or str] End time as a time filter limit.
include_start  [bool, default True] Whether the start time needs to be included in the result.
include_end [bool, default True] Whether the end time needs to be included in the result.

axis [[0 or ‘index’, 1 or ‘columns’], default 0] Determine range time on index or columns value.

New in version 0.24.0.

Returns

Series or DataFrame Data from the original object filtered to the specified dates range.

Raises

TypeError If the index is not a DatetimeIndex

See also:

at_time Select values at a particular time of the day.

first Select initial periods of time series based on a date offset.

last Select final periods of time series based on a date offset.

DatetimeIndex.indexer_between_time Get just the index locations for values between particular times of the day.

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
          A
2018-04-09 00:00:00  1
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3
2018-04-12 01:00:00  4

>>> ts.between_time('0:15', '0:45')
          A
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3

You get the times that are not between two times by setting start_time later than end_time:

```
pandas.DataFrame.bfill

DataFrame.bfill (axis=None, inplace=False, limit=None, downcast=None)
Synonym for DataFrame.fillna() with method='bfill'.

Returns

{klass} or None  Object with missing values filled or None if inplace=True.

pandas.DataFrame.bool

DataFrame.bool()

Return the bool of a single element Series or DataFrame.

This must be a boolean scalar value, either True or False. It will raise a ValueError if the Series or DataFrame does not have exactly 1 element, or that element is not boolean (integer values 0 and 1 will also raise an exception).

Returns

bool  The value in the Series or DataFrame.

See also:

Series.astype Change the data type of a Series, including to boolean.
DataFrame.astype Change the data type of a DataFrame, including to boolean.
numpy.bool_ NumPy boolean data type, used by pandas for boolean values.

Examples

The method will only work for single element objects with a boolean value:

```python
>>> pd.Series([True]).bool()
True

>>> pd.Series([False]).bool()
False
```

```python
>>> pd.DataFrame({'col': [True]}).bool()
True

>>> pd.DataFrame({'col': [False]}).bool()
False
```

pandas.DataFrame.boxplot

DataFrame.boxplot (column=None, by=None, ax=None, fontsize=None, rot=0, grid=True, figsize=None, layout=None, return_type=None, backend=None, **kwargs)

Make a box plot from DataFrame columns.

Make a box-and-whisker plot from DataFrame columns, optionally grouped by some other columns. A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. By default, they extend no more than 1.5 * IQR (IQR = Q3 - Q1) from the edges of the box, ending at the farthest data point within that interval. Outliers are plotted as separate dots.
For further details see Wikipedia’s entry for `boxplot`.

**Parameters**

- **column** [str or list of str, optional] Column name or list of names, or vector. Can be any valid input to `pandas.DataFrame.groupby()`.
- **by** [str or array-like, optional] Column in the DataFrame to `pandas.DataFrame.groupby()`. One box-plot will be done per value of columns in `by`.
- **ax** [object of class matplotlib.axes.Axes, optional] The matplotlib axes to be used by `boxplot`.
- **fontsize** [float or str] Tick label font size in points or as a string (e.g., `large`).
- **rot** [int or float, default 0] The rotation angle of labels (in degrees) with respect to the screen coordinate system.
- **grid** [bool, default True] Setting this to True will show the grid.
- **figsize** [A tuple (width, height) in inches] The size of the figure to create in matplotlib.
- **layout** [tuple (rows, columns), optional] For example, (3, 5) will display the subplots using 3 columns and 5 rows, starting from the top-left.
- **return_type** [{'axes', 'dict', 'both'} or None, default 'axes'] The kind of object to return. The default is `axes`.
  - 'axes' returns the matplotlib axes the boxplot is drawn on.
  - 'dict' returns a dictionary whose values are the matplotlib Lines of the boxplot.
  - 'both' returns a namedtuple with the axes and dict.
  - when grouping with `by`, a Series mapping columns to `return_type` is returned.
    
    If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned.

- **backend** [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, `matplotlib`. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.
  
  New in version 1.0.0.

- ****kwargs All other plotting keyword arguments to be passed to `matplotlib.pyplot.boxplot()`.

**Returns**

- **result** See Notes.

**See also:**

- `Series.plot.hist` Make a histogram.
- `matplotlib.pyplot.boxplot` Matplotlib equivalent plot.
Notes

The return type depends on the return_type parameter:

- 'axes': object of class matplotlib.axes.Axes
- 'dict': dict of matplotlib.lines.Line2D objects
- 'both': a namedtuple with structure (ax, lines)

For data grouped with by, return a Series of the above or a numpy array:

- Series
- array (for return_type = None)

Use return_type='dict' when you want to tweak the appearance of the lines after plotting. In this case a dict containing the Lines making up the boxes, caps, fliers, medians, and whiskers is returned.

Examples

Boxplots can be created for every column in the dataframe by df.boxplot() or indicating the columns to be used:

```python
>>> np.random.seed(1234)
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                   columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
```

Boxplots of variables distributions grouped by the values of a third variable can be created using the option by. For instance:

```python
>>> df = pd.DataFrame(np.random.randn(10, 2),
...                   columns=['Col1', 'Col2'])
...                      'B', 'B', 'B', 'B', 'B'])
>>> boxplot = df.boxplot(by='X')
```

A list of strings (i.e. ['X', 'Y']) can be passed to boxplot in order to group the data by combination of the variables in the x-axis:

```python
>>> df = pd.DataFrame(np.random.randn(10, 3),
...                   columns=['Col1', 'Col2', 'Col3'])
...                      'B', 'B', 'B', 'B', 'B'])
>>> df['Y'] = pd.Series(['A', 'B', 'A', 'B', 'A',
...                      'B', 'A', 'B', 'A', 'B'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```

The layout of boxplot can be adjusted giving a tuple to layout:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       layout=(2, 1))
```

Additional formatting can be done to the boxplot, like suppressing the grid (grid=False), rotating the labels in the x-axis (i.e. rot=45) or changing the fontsize (i.e. fontsize=15):

```python
>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)
```
3.4. DataFrame
The parameter `return_type` can be used to select the type of element returned by `boxplot`. When `return_type='axes'` is selected, the matplotlib axes on which the boxplot is drawn are returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
>>> type(boxplot)
<class 'matplotlib.axes._subplots.AxesSubplot'>
```

When grouping with `by`, a Series mapping columns to `return_type` is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       return_type='axes')
>>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
...                       return_type=None)
>>> type(boxplot)
<class 'numpy.ndarray'>
```

### pandas.DataFrame.clip

DataFrame.clip(lower=None, upper=None, axis=None, inplace=False, *args, **kwargs)

Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

**Parameters**

- `lower` [float or array_like, default None] Minimum threshold value. All values below this threshold will be set to it.
- `upper` [float or array_like, default None] Maximum threshold value. All values above this threshold will be set to it.
- `axis` [int or str axis name, optional] Align object with lower and upper along the given axis.
- `inplace` [bool, default False] Whether to perform the operation in place on the data.
- `*args, **kwargs` Additional keywords have no effect but might be accepted for compatibility with numpy.

**Returns**

Series or DataFrame Same type as calling object with the values outside the clip boundaries replaced.

**See also:**

- `Series.clip` Trim values at input threshold in series.
- `DataFrame.clip` Trim values at input threshold in dataframe.
- `numpy.clip` Clip (limit) the values in an array.
Examples

```python
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0 col_1
0     9   -2
1    -3   -7
2     0    6
3    -1    8
4     5   -5
Clips per column using lower and upper thresholds:

```  
```python
>>> df.clip(-4, 6)
   col_0 col_1
0     6   -2
1    -3   -4
2     0    6
3    -1    6
4     5   -4
```

Clips using specific lower and upper thresholds per column element:

```python
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0    2
1   -4
2   -1
3    6
4    3
dtype: int64
```  
```python
>>> df.clip(t, t + 4, axis=0)
   col_0 col_1
0     6    2
1    -3   -4
2     0    3
3     6    8
4     5    3
```

pandas.DataFrame.combine

DataFrame.combine(other, func, fill_value=None, overwrite=True)
Perform column-wise combine with another DataFrame.

Combines a DataFrame with other DataFrame using func to element-wise combine columns. The row and column indexes of the resulting DataFrame will be the union of the two.

Parameters

other [DataFrame] The DataFrame to merge column-wise.

func [function] Function that takes two series as inputs and return a Series or a scalar.
Used to merge the two dataframes column by columns.

fill_value [scalar value, default None] The value to fill NaNs with prior to passing any column to the merge func.
overwrite [bool, default True] If True, columns in self that do not exist in other will be overwritten with NaNs.

Returns

DataFrame Combination of the provided DataFrames.

See also:

DataFrame.combine_first Combine two DataFrame objects and default to non-null values in frame calling the method.

Examples

Combine using a simple function that chooses the smaller column.

```python
def take_smaller(s1, s2):
    return s1 if s1.sum() < s2.sum() else s2

>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, take_smaller)
A  B
0  3
1  3
```

Example using a true element-wise combine function.

```python
>>> df1 = pd.DataFrame({'A': [5, 0], 'B': [2, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, np.minimum)
A  B
0  1  2
1  0  3
```

Using fill_value fills Nones prior to passing the column to the merge function.

```python
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
A  B
0  0  -5.0
1  0  4.0
```

However, if the same element in both dataframes is None, that None is preserved

```python
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [None, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
A  B
0  0  -5.0
1  0  3.0
```

Example that demonstrates the use of overwrite and behavior when the axis differ between the dataframes.

```python
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [-10, 1], }, index=[1, 2])
>>> df1.combine(df2, take_smaller)
A  B  C
0  4  3
1  4  1
```

(continues on next page)
```python
>>> df1 = pd.DataFrame({'A': [0, 1, 2], 'B': [3, 3, 3], 'C': [1, 1, 1]}, index=[0, 1, 2])

0  NaN NaN NaN
1  NaN 3.0 -10.0
2  NaN 3.0  1.0
```

```python
>>> df1.combine(df2, take_smaller, overwrite=False)
    A     B     C
0  0.0   NaN  NaN
1  0.0   3.0  -10.0
2  NaN   3.0   1.0
```

Demonstrating the preference of the passed in dataframe.

```python
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [1, 1]}, index=[1, 2])
>>> df2.combine(df1, take_smaller)
    A     B     C
0  0.0   NaN  NaN
1  0.0   3.0  NaN
2  NaN   3.0  NaN
```

```python
>>> df2.combine(df1, take_smaller, overwrite=False)
    A     B     C
0  0.0   NaN  NaN
1  0.0   3.0  1.0
2  NaN   3.0  1.0
```

**pandas.DataFrame.combine_first**

`DataFrame.combine_first(other)`

Update null elements with value in the same location in `other`.

Combine two DataFrame objects by filling null values in one DataFrame with non-null values from other DataFrame. The row and column indexes of the resulting DataFrame will be the union of the two.

**Parameters**

- `other` [DataFrame] Provided DataFrame to use to fill null values.

**Returns**

- `DataFrame`

**See also:**

- `DataFrame.combine` Perform series-wise operation on two DataFrames using a given function.
Examples

```python
>>> df1 = pd.DataFrame({'A': [None, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine_first(df2)
          A   B
0       1.0  3.0
1       0.0  4.0
```

Null values still persist if the location of that null value does not exist in `other`

```python
>>> df1 = pd.DataFrame({'A': [None, 0], 'B': [4, None]})
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [1, 1]}, index=[1, 2])
>>> df1.combine_first(df2)
          A  B  C
0   NaN  4.0  NaN
1  0.0  3.0  1.0
2   NaN  3.0  1.0
```

**pandas.DataFrame.compare**

DataFrame.compare(other, align_axis=1, keep_shape=False, keep_equal=False)

Compare to another DataFrame and show the differences.

New in version 1.1.0.

**Parameters**

- `other` [DataFrame] Object to compare with.
- `align_axis` [{0 or ‘index’, 1 or ‘columns’}, default 1] Determine which axis to align the comparison on.
  - 0, or ‘index’ [Resulting differences are stacked vertically] with rows drawn alternately from self and other.
  - 1, or ‘columns’ [Resulting differences are aligned horizontally] with columns drawn alternately from self and other.
- `keep_shape` [bool, default False] If true, all rows and columns are kept. Otherwise, only the ones with different values are kept.
- `keep_equal` [bool, default False] If true, the result keeps values that are equal. Otherwise, equal values are shown as NaNs.

**Returns**

DataFrame DataFrame that shows the differences stacked side by side.

The resulting index will be a MultiIndex with ‘self’ and ‘other’ stacked alternately at the inner level.

**See also:**

Series.compare Compare with another Series and show differences.
Notes

Matching NaNs will not appear as a difference.

Examples

```python
>>> df = pd.DataFrame(
...     {
...         "col1": ["a", "a", "b", "b", "a"],
...         "col2": [1.0, 2.0, 3.0, np.nan, 5.0],
...         "col3": [1.0, 2.0, 3.0, 4.0, 5.0]
...     },
...     columns=["col1", "col2", "col3"],
... )
>>> df
    col1 col2  col3
0     a   1.0  1.0
1     a   2.0  2.0
2     b   3.0  3.0
3     b NaN  4.0
4     a   5.0  5.0

>>> df2 = df.copy()
>>> df2.loc[0, 'col1'] = 'c'
>>> df2.loc[2, 'col3'] = 4.0
>>> df2
    col1  col2  col3
0     c   1.0  1.0
1     a   2.0  2.0
2     b   3.0  4.0
3     b  NaN  4.0
4     a   5.0  5.0

Align the differences on columns

```python
```python
>>> df.compare(df2)
    col1   col3
self other self other
0     a   c  NaN  NaN
2   NaN  NaN  3.0  4.0
```  

Stack the differences on rows

```python
>>> df.compare(df2, align_axis=0)
    col1   col3
  self other self other
0    a  NaN  NaN  NaN
2   NaN  NaN  3.0  4.0
```  

Keep the equal values

```python
>>> df.compare(df2, keep_equal=True)
    col1   col3
self other self other
0    a  NaN  NaN  NaN
2   NaN  NaN  3.0  4.0
```
Keep all original rows and columns

```python
>>> df.compare(df2, keep_shape=True)
col1    col2    col3
self other self other self other
0   a    c   NaN   NaN   NaN   NaN
1   NaN   NaN   NaN   NaN   NaN   NaN
2   NaN   NaN   NaN   NaN   3.0   4.0
3   NaN   NaN   NaN   NaN   NaN   NaN
4   NaN   NaN   NaN   NaN   NaN   NaN
```

Keep all original rows and columns and also all original values

```python
>>> df.compare(df2, keep_shape=True, keep_equal=True)
col1    col2    col3
self other self other self other
0   a    c   1.0   1.0   1.0   1.0
1   a    a   2.0   2.0   2.0   2.0
2   b    b   3.0   3.0   3.0   4.0
3   b    b   NaN   NaN   4.0   4.0
4   a    a   5.0   5.0   5.0   5.0
```

#### pandas.DataFrame.convert_dtypes

Convert columns to best possible dtypes using dtypes supporting `pd.NA`.

New in version 1.0.0.

**Parameters**

- **infer_objects** [bool, default True] Whether object dtypes should be converted to the best possible types.
- **convert_string** [bool, default True] Whether object dtypes should be converted to `StringDtype()`.
- **convert_integer** [bool, default True] Whether, if possible, conversion can be done to integer extension types.
- **convert_boolean** [bool, default True] Whether object dtypes should be converted to `BooleanDtypes()`.

**Returns**

- **Series** or **DataFrame** Copy of input object with new dtype.

See also:

- **infer_objects** Infer dtypes of objects.
- **to_datetime** Convert argument to datetime.
- **to_timedelta** Convert argument to timedelta.
to_numeric Convert argument to a numeric type.

Notes

By default, convert_dtypes will attempt to convert a Series (or each Series in a DataFrame) to dtypes that support pd.NA. By using the options convert_string, convert_integer, and convert_boolean, it is possible to turn off individual conversions to StringDtype, the integer extension types or BooleanDtype, respectively.

For object-dtyped columns, if infer_objects is True, use the inference rules as during normal Series/DataFrame construction. Then, if possible, convert to StringDtype, BooleanDtype or an appropriate integer extension type, otherwise leave as object.

If the dtype is integer, convert to an appropriate integer extension type.

If the dtype is numeric, and consists of all integers, convert to an appropriate integer extension type.

In the future, as new dtypes are added that support pd.NA, the results of this method will change to support those new dtypes.

Examples

```python
>>> df = pd.DataFrame(
...     {
...         "a": pd.Series([1, 2, 3], dtype=np.dtype("int32")),
...         "b": pd.Series(["x", "y", "z"], dtype=np.dtype("O")),
...         "c": pd.Series([True, False, np.nan], dtype=np.dtype("O")),
...         "d": pd.Series(["h", "i", np.nan], dtype=np.dtype("O")),
...         "e": pd.Series([10, np.nan, 20], dtype=np.dtype("float")),
...         "f": pd.Series([np.nan, 100.5, 200], dtype=np.dtype("float")),
...     }
... )

Start with a DataFrame with default dtypes.

```python
def
```

```python
>> df
   a  b  c  d  e  f
0  1  x  True  h  10.0  NaN
1  2  y  False  i  NaN  100.5
2  3  z  NaN  NaN  20.0  200.0
```

```python
>>> df.dtypes
a    int32
b    object
c    object
d    object
e    float64
f    float64
dtype: object
```

Convert the DataFrame to use best possible dtypes.

```python
>>> dfn = df.convert_dtypes()
```

```python
>>> dfn
   a  b  c  d  e  f
0  1  x  True  h   10  NaN
```

(continues on next page)
Start with a Series of strings and missing data represented by np.nan.

```python
>>> s = pd.Series(['a', 'b', np.nan])
>>> s
0    a
1    b
2  NaN
dtype: object
```

Obtain a Series with dtype StringDtype.

```python
>>> s.convert_dtypes()
0    a
1    b
2  <NA>
dtype: string
```

**pandas.DataFrame.copy**

DataFrame.copy (**deep=True**)  
Make a copy of this object’s indices and data.  

*When deep=True (default), a new object will be created with a copy of the calling object’s data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below). When deep=False, a new object will be created without copying the calling object’s data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).*

**Parameters**

- **deep** [bool, default True] Make a deep copy, including a copy of the data and the indices. With deep=False neither the indices nor the data are copied.

**Returns**

- **copy** [Series or DataFrame] Object type matches caller.
Notes

When `deep=True`, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to `copy.deepcopy` in the Standard Library, which recursively copies object data (see examples below).

While `Index` objects are copied when `deep=True`, the underlying numpy array is not copied for performance reasons. Since `Index` is immutable, the underlying data can be safely shared and a copy is not needed.

Examples

```python
default_copy = s.copy()
default_copy
```

Shallow copy versus default (deep) copy:

```python
shallow_copy = s.copy()
shallow_copy
```

Shallow copy shares data and index with original.

```python
shallow.values is shallow.values and shallow.index is shallow.index
```

Deep copy has own copy of data and index.

```python
shallow.values is deep.values or shallow.index is deep.index
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```python
shallow[1] = 4
shallow
```

(continues on next page)
Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```python
>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
>>> s
0  [10, 2]  
1  [3, 4]  
dtype: object
>>> deep
0  [10, 2]  
1  [3, 4]  
dtype: object
```

**pandas.DataFrame.corr**

Dataframe.
corr**(method='pearson', min_periods=1)**

Compute pairwise correlation of columns, excluding NA/null values.

**Parameters**

- **method** ['pearson', 'kendall', 'spearman'] or callable] Method of correlation:
  - pearson : standard correlation coefficient
  - kendall : Kendall Tau correlation coefficient
  - spearman : Spearman rank correlation
  - callable: callable with input two 1d ndarrays and returning a float. Note that the returned matrix from corr will have 1 along the diagonals and will be symmetric regardless of the callable's behavior.

- **min_periods** [int, optional] Minimum number of observations required per pair of columns to have a valid result. Currently only available for Pearson and Spearman correlation.

**Returns**

- **DataFrame** Correlation matrix.

**See also:**

- **DataFrame.corrwith** Compute pairwise correlation with another DataFrame or Series.
- **Series.corr** Compute the correlation between two Series.
Examples

```python
>>> def histogram_intersection(a, b):
    ...
    v = np.minimum(a, b).sum().round(decimals=1)
    ...
    return v

>>> df = pd.DataFrame([(.2, .3), (.0, .6), (.6, .0), (.2, .1)],
    ...
    columns=['dogs', 'cats'])

>>> df.corr(method=histogram_intersection)
     dogs  cats
dogs  1.0  0.3
cats  0.3  1.0
```

**pandas.DataFrame.corrwith**

DataFrame.corrwith(other, axis=0, drop=False, method='pearson')

Compute pairwise correlation.

Pairwise correlation is computed between rows or columns of DataFrame with rows or columns of Series or DataFrame. DataFrames are first aligned along both axes before computing the correlations.

**Parameters**

- **other**  [DataFrame, Series] Object with which to compute correlations.
- **axis**  [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to use. 0 or ‘index’ to compute column-wise, 1 or ‘columns’ for row-wise.
- **drop**  [bool, default False] Drop missing indices from result.
- **method**  [{‘pearson’, ‘kendall’, ‘spearman’} or callable] Method of correlation:
  - pearson : standard correlation coefficient
  - kendall : Kendall Tau correlation coefficient
  - spearman : Spearman rank correlation
  - callable: callable with input two 1d ndarrays and returning a float.

New in version 0.24.0.

**Returns**

- **Series**  Pairwise correlations.

**See also:**

- DataFrame.corr  Compute pairwise correlation of columns.

**pandas.DataFrame.count**

DataFrame.count(axis=0, level=None, numeric_only=False)

Count non-NA cells for each column or row.

The values None, NaN, NaT, and optionally numpy.inf (depending on pandas.options.mode.use_inf_as_na) are considered NA.

**Parameters**
axis [{0 or 'index', 1 or 'columns'}, default 0] If 0 or 'index' counts are generated for each column. If 1 or 'columns' counts are generated for each row.

level [int or str, optional] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame. A str specifies the level name.

numeric_only [bool, default False] Include only float, int or boolean data.

Returns

Series or DataFrame For each column/row the number of non-NA/null entries. If level is specified returns a DataFrame.

See also:

Series.count Number of non-NA elements in a Series.

DataFrame.shape Number of DataFrame rows and columns (including NA elements).

DataFrame.isna Boolean same-sized DataFrame showing places of NA elements.

Examples

Constructing DataFrame from a dictionary:

```python
>>> df = pd.DataFrame({'Person': ['John', 'Myla', 'Lewis', 'John', 'Myla'],
...                    'Age': [24., np.nan, 21., 33., 26.],
...                    'Single': [False, True, True, True, False]})
```

Notice the uncounted NA values:

```python
>>> df.count()
Person    5
Age       4
Single    5
dtype: int64
```

Counts for each row:

```python
>>> df.count(axis='columns')
0   3
1   2
2   3
3   3
4   3
dtype: int64
```

Counts for one level of a MultiIndex:
```python
>>> df.set_index(["Person", "Single"]).count(level="Person")
  Age
Person  
  John   2
  Lewis  1
  Myla   1
```

**pandas.DataFrame.cov**

`DataFrame.cov(min_periods=None, ddof=1)`

Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the covariance matrix of the columns of the DataFrame.

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as NaN.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

**Parameters**

- `min_periods` [int, optional] Minimum number of observations required per pair of columns to have a valid result.
- `ddof` [int, default 1] Delta degrees of freedom. The divisor used in calculations is \(N - ddof\), where \(N\) represents the number of elements.

**Returns**

- `DataFrame` The covariance matrix of the series of the DataFrame.

**See also:**

- `Series.cov` Compute covariance with another Series.
- `core.window.ExponentialMovingWindow.cov` Exponential weighted sample covariance.
- `core.window.Expanding.cov` Expanding sample covariance.
- `core.window.Rolling.cov` Rolling sample covariance.

**Notes**

Returns the covariance matrix of the DataFrame’s time series. The covariance is normalized by N-ddof.

For DataFrames that have Series that are missing data (assuming that data is missing at random) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.
Examples

```python
>>> df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
...    columns=['dogs', 'cats'])
>>> df.cov()
dogs  cats
dogs  0.666667 -1.000000
cats -1.000000  1.666667

>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
...    columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()
a   b   c   d   e
a  0.998438 -0.020161 0.059277 -0.008943 0.014144
b -0.020161 1.059352 -0.008543 -0.024738 0.009826
c  0.059277 -0.008543 1.010670 -0.001486 -0.000271
d -0.008943 -0.024738 -0.001486 0.921297 -0.013692
e  0.014144 0.009826 -0.000271 -0.013692 0.977795
```

Minimum number of periods

This method also supports an optional `min_periods` keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```python
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
...    columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)
a   b   c
a  0.316741 NaN -0.150812
b  NaN 1.248003 0.191417
c -0.150812 0.191417 0.895202
```

**pandas.DataFrame.cummax**

DataFrame.cummax(\(\text{axis}=None, \text{skipna}=\text{True}, \text{args}, \text{kwargs}\))

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

**Parameters**

- **axis** \([0 \text{ or ‘index’}, 1 \text{ or ‘columns’}], \text{default 0} \) The index or the name of the axis. 0 is equivalent to None or ‘index’.

- **skipna** \([\text{bool, default True}] \) Exclude NA/null values. If an entire row/column is NA, the result will be NA.

- **args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

Series or DataFrame Return cumulative maximum of Series or DataFrame.

See also:
core.window.Expanding.max  Similar functionality but ignores NaN values.

DataFrame.max  Return the maximum over DataFrame axis.

DataFrame.cummax  Return cumulative maximum over DataFrame axis.

DataFrame.cummin  Return cumulative minimum over DataFrame axis.

DataFrame.cumsum  Return cumulative sum over DataFrame axis.

DataFrame.cumprod  Return cumulative product over DataFrame axis.

Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4     0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cummax()
0    2.0
1    NaN
2    5.0
3    5.0
4    5.0
dtype: float64
```

To include NA values in the operation, use skipna=False

```python
>>> s.cummax(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to axis=None or axis='index'.

3.4. DataFrame
pandas: powerful Python data analysis toolkit, Release 1.1.1

```python
>>> df.cummax()
   A   B
0  2.0  1.0
1  3.0  NaN
2  3.0  1.0

To iterate over columns and find the maximum in each row, use `axis=1`

```python
>>> df.cummax(axis=1)
   A   B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0
```

pandas.DataFrame.cummin

DataFrame.cummin(axis=None, skipna=True, *args, **kwargs)
Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

*args, **kwargs Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame Return cumulative minimum of Series or DataFrame.

See also:

core.window.Expanding.min Similar functionality but ignores NaN values.
DataFrame.min Return the minimum over DataFrame axis.
DataFrame.cummax Return cumulative maximum over DataFrame axis.
DataFrame.cummin Return cumulative minimum over DataFrame axis.
DataFrame.cumsum Return cumulative sum over DataFrame axis.
DataFrame.cumprod Return cumulative product over DataFrame axis.
Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1   NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cummin()
0    2.0
1   NaN
2    2.0
3   -1.0
4   -1.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cummin(skipna=False)
0    2.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64
```

DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0], ...
...                      [3.0, np.nan], ...
...                      [1.0, 0.0]], ...
...                     columns=list('AB'))
>>> df
   A  B
0  2.0  1.0
1  3.0   NaN
2  1.0   0.0
```

By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cummin()
   A  B
0  2.0  1.0
1  2.0   NaN
2  1.0   0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```python
>>> df.cummin(axis=1)
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.DataFrame.cumprod

DataFrame.cumprod(axis=None, skipna=True, args, kwargs)

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

Parameters

- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

Series or DataFrame Return cumulative product of Series or DataFrame.

See also:

core.window.Expanding.prod Similar functionality but ignores NaN values.

DataFrame.prod Return the product over DataFrame axis.

DataFrame.cummax Return cumulative maximum over DataFrame axis.

DataFrame.cummin Return cumulative minimum over DataFrame axis.

DataFrame.cumsum Return cumulative sum over DataFrame axis.

DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

```py
>>> s = pd.Series([2, np.nan, 5, -1, 0])
```

By default, NA values are ignored.
```python
>>> s.cumprod()
0   2.0
1   NaN
2  10.0
3 -10.0
4   0.0
dtype: float64

To include NA values in the operation, use `skipna=False`

```python
>>> s.cumprod(skipna=False)
0   2.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64
```

### DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0],
                      [3.0, np.nan],
                      [1.0, 0.0]],
                    columns=list('AB'))
```

```python
>>> df
df
A   B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cumprod()
df
A   B
0  2.0  1.0
1  6.0  NaN
2  6.0  0.0
```

To iterate over columns and find the product in each row, use `axis=1`

```python
>>> df.cumprod(axis=1)
df
A   B
0  2.0  2.0
1  3.0  NaN
2  1.0  0.0
```
**pandas.DataFrame.cumsum**

DataFrame.cumsum(axis=None, skipna=True, *args, **kwargs)

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

**Parameters**

- **axis** [[0 or 'index', 1 or 'columns'], default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **args, **kwargs Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

Series or DataFrame Return cumulative sum of Series or DataFrame.

See also:

core.window.Expanding.sum Similar functionality but ignores NaN values.

DataFrame.sum Return the sum over DataFrame axis.

DataFrame.cummax Return cumulative maximum over DataFrame axis.

DataFrame.cummin Return cumulative minimum over DataFrame axis.

DataFrame.cumsum Return cumulative sum over DataFrame axis.

DataFrame.cumprod Return cumulative product over DataFrame axis.

**Examples**

**Series**

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
```

```python
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cumsum()
0   2.0
1   NaN
2    7.0
3    6.0
4    6.0
dtype: float64
```

To include NA values in the operation, use skipna=False
```python
>>> s.cumsum(skipna=False)
0  2.0
1  NaN
2  NaN
3  NaN
4  NaN
dtype: float64
```

**DataFrame**

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                    [3.0, np.nan],
...                    [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cumsum()
   A  B
0  2.0  3.0
1  5.0  NaN
2  6.0  1.0
```

To iterate over columns and find the sum in each row, use `axis=1`

```python
>>> df.cumsum(axis=1)
   A  B
0  2.0  3.0
1  3.0  NaN
2  1.0  1.0
```

**pandas.DataFrame.describe**

`DataFrame.describe(percentiles=None, include=None, exclude=None, date-time_is_numeric=False)`

Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset’s distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

**Parameters**

- `percentiles` [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is `[.25, .5, .75]`, which returns the 25th, 50th, and 75th percentiles.

- `include` ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for `Series`. Here are the options:
• ‘all’ : All columns of the input will be included in the output.
• A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use 'category'
• None (default) : The result will include all numeric columns.

`exclude` [list-like of dtypes or None (default), optional] A black list of data types to omit from the result. Ignored for `Series`. Here are the options:

• A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To exclude pandas categorical columns, use 'category'
• None (default) : The result will exclude nothing.

`datetime_is_numeric` [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

New in version 1.1.0.

Returns

`Series` or `DataFrame` Summary statistics of the Series or Dataframe provided.

See also:

`DataFrame.count` Count number of non-NA/null observations.
`DataFrame.max` Maximum of the values in the object.
`DataFrame.min` Minimum of the values in the object.
`DataFrame.mean` Mean of the values.
`DataFrame.std` Standard deviation of the observations.
`DataFrame.select_dtypes` Subset of a DataFrame including/excluding columns based on their dtype.

Notes

For numeric data, the result’s index will include `count`, `mean`, `std`, `min`, `max` as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result’s index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value’s frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a `DataFrame`, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns,
the default is to return an analysis of both the object and categorical columns. If include='all' is provided as an option, the result will include a union of attributes of each type.

The include and exclude parameters can be used to limit which columns in a DataFrame are analyzed for the output. The parameters are ignored when analyzing a Series.

Examples

Describing a numeric Series.

```python
g = pd.Series([1, 2, 3])
g.describe()
```

Describing a categorical Series.

```python
g = pd.Series(['a', 'a', 'b', 'c'])
g.describe()
```

Describing a timestamp Series.

```python
g = pd.Series([np.datetime64("2000-01-01"),
               np.datetime64("2010-01-01"),
               np.datetime64("2010-01-01")])
g.describe(datetime_is_numeric=True)
```

Describing a DataFrame. By default only numeric fields are returned.

```python
df = pd.DataFrame({'categorical': pd.Categorical(['d', 'e', 'f']),
                   'numeric': [1, 2, 3],
                   'object': ['a', 'b', 'c']})
df.describe()
```
count  3.0
mean  2.0
std   1.0
min   1.0
25%   1.5
50%   2.0
75%   2.5
max   3.0

Describing all columns of a DataFrame regardless of data type.

```python
>>> df.describe(include='all')
```

```
categorical          numeric          object
count                  3             3.0             3
unique                 3             NaN             3
top                    f             NaN             a
freq                   1             NaN             1
mean                   NaN           2.0             NaN
std                    NaN           1.0             NaN
min                    NaN           1.0             NaN
25%                    NaN           1.5             NaN
50%                    NaN           2.0             NaN
75%                    NaN           2.5             NaN
max                    NaN           3.0             NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```python
>>> df.numeric.describe()
```

```
count  3.0
mean   2.0
std    1.0
min    1.0
25%    1.5
50%    2.0
75%    2.5
max    3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a DataFrame description.

```python
>>> df.describe(include=[np.number])
```

```
numeric
count  3.0
mean   2.0
std    1.0
min    1.0
25%    1.5
50%    2.0
75%    2.5
max    3.0
```

Including only string columns in a DataFrame description.

```python
>>> df.describe(include=[object])
```

```
object
count  3
```
Including only categorical columns from a DataFrame description.

```python
>>> df.describe(include=['category'])
categorical
    count  3
    unique 3
top   f
freq  1
```

Excluding numeric columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.number])
categorical  object
    count  3  3
    unique 3  3
top   f  a
freq  1  1
```

Excluding object columns from a DataFrame description.

```python
>>> df.describe(exclude=[object])
categorical  numeric
    count  3  3.0
    unique 3  NaN
top   f  NaN
freq  1  NaN
mean  NaN  2.0
std   NaN  1.0
min  NaN  1.0
25%  NaN  1.5
50%  NaN  2.0
75%  NaN  2.5
max  NaN  3.0
```

**pandas.DataFrame.diff**

`DataFrame.diff(periods=1, axis=0)`

First discrete difference of element.

Calculates the difference of a Dataframe element compared with another element in the Dataframe (default is element in previous row).

**Parameters**

- **periods** [int, default 1] Periods to shift for calculating difference, accepts negative values.
- **axis** [[0 or ‘index’, 1 or ‘columns’], default 0] Take difference over rows (0) or columns (1).

**Returns**

- **Dataframe** First differences of the Series.
See also:

**Dataframe.pct_change** Percent change over given number of periods.

**Dataframe.shift** Shift index by desired number of periods with an optional time freq.

**Series.diff** First discrete difference of object.

Notes

For boolean dtypes, this uses `operator.xor()` rather than `operator.sub()`. The result is calculated according to current dtype in Dataframe, however dtype of the result is always float64.

Examples

Difference with previous row

```python
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
                  'b': [1, 1, 2, 3, 5, 8],
                  'c': [1, 4, 9, 16, 25, 36]})
>>> df
   a  b  c
0  1  1  1
1  2  1  4
2  3  2  9
3  4  3 16
4  5  5 25
5  6  8 36
>>> df.diff()
    a    b    c
0 NaN  NaN  NaN
1  1.0  0.0  3.0
2  1.0  1.0  5.0
3  1.0  1.0  7.0
4  1.0  2.0  9.0
5  1.0  3.0 11.0
```

Difference with previous column

```python
>>> df.diff(axis=1)
    a    b    c
0  NaN  0.0  0.0
1  NaN -1.0  3.0
2  NaN -1.0  7.0
3  NaN -1.0 13.0
4  NaN  0.0 20.0
5  NaN  2.0 28.0
```

Difference with 3rd previous row

```python
>>> df.diff(periods=3)
    a    b    c
0  NaN  NaN  NaN
1  NaN  NaN  NaN
2  NaN  NaN  NaN
(continues on next page)
```
Difference with following row

```python
>>> df.diff(periods=-1)
    a     b     c
0  3.0  2.0  15.0
1  3.0  4.0  21.0
2  3.0  6.0  27.0
3  3.0  8.0  33.0
4  3.0 10.0  39.0
```

Overflow in input dtype

```python
>>> df = pd.DataFrame({'a': [1, 0]}, dtype=np.uint8)
>>> df.diff()
    a
0  NaN
1  255.0
```

### pandas.DataFrame.div

DataFrame.div(other, axis='columns', level=None, fill_value=None)

Get Floating division of dataframe and other, element-wise (binary operator `truediv`).

Equivalent to `dataframe / other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `rtruediv`.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [(0 or ‘index’, 1 or ‘columns’)] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

- **DataFrame** Result of the arithmetic operation.

**See also:**

- `DataFrame.add` Add DataFrames.
- `DataFrame.sub` Subtract DataFrames.
DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
    angles  degrees
circle     0       360
triangle   3       180
rectangle  4       360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
    angles  degrees
circle     1       361
triangle   4       181
rectangle  5       361
```

```python
>>> df.add(1)
    angles  degrees
circle     1       361
triangle   4       181
rectangle  5       361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
    angles  degrees
circle     0.0      36.0
triangle   0.3      18.0
rectangle  0.4      36.0
```

```python
>>> df.rdiv(10)
    angles  degrees
circle     inf      0.027778
triangle  3.333333  0.055556
rectangle 2.500000  0.027778
```

Subtract a list and Series by axis with operator version.
>>> df = [1, 2]
angles  degrees
circle  -1     358
triangle 2      178
rectangle 3      358

>>> df.sub([1, 2], axis='columns')
angles  degrees
circle  -1     358
triangle 2      178
rectangle 3      358

>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
         axis='index')
angles  degrees
circle  -1     359
triangle 2      179
rectangle 3      359

Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])

>>> df * other
angles  degrees
circle  0      NaN
triangle 9      NaN
rectangle 16     NaN

>>> df.mul(other, fill_value=0)
angles  degrees
circle  0      0.0
triangle 9      0.0
rectangle 16     0.0

Divide by a MultiIndex by level.

>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                              'degrees': [360, 180, 360, 360, 540, 720],
                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
                                     ['circle', 'triangle', 'rectangle',
                                      'square', 'pentagon', 'hexagon']])

>>> df_multindex
A angles  degrees
circle  0      360
triangle 3      180
rectangle 4      360
B square 4      360
pentagon 5      540
hexagon 6      720

3.4. DataFrame
```python
>>> df.div(df_multindex, level=1, fill_value=0)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>A circle</td>
<td>NaN</td>
</tr>
<tr>
<td>triangle</td>
<td>1.0</td>
</tr>
<tr>
<td>rectangle</td>
<td>1.0</td>
</tr>
<tr>
<td>B square</td>
<td>0.0</td>
</tr>
<tr>
<td>pentagon</td>
<td>0.0</td>
</tr>
<tr>
<td>hexagon</td>
<td>0.0</td>
</tr>
</tbody>
</table>

**pandas.DataFrame.divide**

DataFrame.divide(other, axis='columns', level=None, fill_value=None)

Get Floating division of dataframe and other, element-wise (binary operator truediv).

Equivalent to dataframe / other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rtruediv.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [[0 or 'index', 1 or 'columns']] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame Result of the arithmetic operation.

**See also:**

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
... 'degrees': [360, 180, 360]},
... index=['circle', 'triangle', 'rectangle'])
>>> df
           angles  degrees
    circle        0      360
    triangle      3      180
    rectangle     4      360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
           angles  degrees
    circle       1      361
    triangle      4      181
    rectangle     5      361
```

```python
>>> df.add(1)
           angles  degrees
    circle       1      361
    triangle      4      181
    rectangle     5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
           angles  degrees
    circle    0.0     36.0
    triangle  0.3     18.0
    rectangle 0.4     36.0
```

```python
>>> df.rdiv(10)
           angles  degrees
    circle    inf   0.027778
    triangle  3.333333  0.055556
    rectangle 2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
           angles  degrees
    circle     -1      358
    triangle     2      178
    rectangle     3      358
```

```python
>>> df.sub([1, 2], axis='columns')
           angles  degrees
    circle     -1      358
    triangle     2      178
    rectangle     3      358
```
Multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
...                      index=['circle', 'triangle', 'rectangle'])
>>> df * other
```

```
angles  degrees
circle  0   NaN
triangle 9   NaN
rectangle 16  NaN
```

```
>>> df.mul(other, fill_value=0)
```

```
angles  degrees
circle  0   0.0
triangle 9   0.0
rectangle 16  0.0
```

Divide by a MultiIndex by level.

```
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                               'degrees': [360, 180, 360, 360, 540, 720]},
...                               index=['A', 'A', 'A', 'B', 'B', 'B'],
...                               ['circle', 'triangle', 'rectangle',
...                            'square', 'pentagon', 'hexagon'])
>>> df_multindex
```

```
   angles  degrees
   A circle  0  360
  triangle  3  180
     rectangle 4  360
   B square  4  360
    pentagon 5  540
  hexagon  6  720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
```

```
   angles  degrees
   A circle  NaN  1.0
  triangle  1.0  1.0
     rectangle 1.0  1.0
   B square  0.0  0.0
    pentagon 0.0  0.0
  hexagon  0.0  0.0
```
pandas.DataFrame.dot

**DataFrame.dot**(other)
Compute the matrix multiplication between the DataFrame and other.

This method computes the matrix product between the DataFrame and the values of an other Series, DataFrame or a numpy array.

It can also be called using self @ other in Python >= 3.5.

**Parameters**

other [Series, DataFrame or array-like] The other object to compute the matrix product with.

**Returns**

Series or DataFrame If other is a Series, return the matrix product between self and other as a Series. If other is a DataFrame or a numpy.array, return the matrix product of self and other in a DataFrame of a np.array.

**See also:**

*Series.dot* Similar method for Series.

**Notes**

The dimensions of DataFrame and other must be compatible in order to compute the matrix multiplication. In addition, the column names of DataFrame and the index of other must contain the same values, as they will be aligned prior to the multiplication.

The dot method for Series computes the inner product, instead of the matrix product here.

**Examples**

Here we multiply a DataFrame with a Series.

```python
>>> df = pd.DataFrame([[0, 1, -2, -1], [1, 1, 1, 1]])
>>> s = pd.Series([1, 1, 2, 1])
>>> df.dot(s)
0   -4
1    5
dtype: int64
```

Here we multiply a DataFrame with another DataFrame.

```python
>>> other = pd.DataFrame([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(other)
   0  1
0  1  4
1  2  2
```

Note that the dot method give the same result as @

```python
>>> df @ other
   0  1
0  1  4
1  2  2
```
The dot method works also if other is an np.array.

```python
>>> arr = np.array([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(arr)
 0  1
 0  1  4
 1  2  2
```

Note how shuffling of the objects does not change the result.

```python
>>> s2 = s.reindex([1, 0, 2, 3])
>>> df.dot(s2)
 0  -4
 1   5
dtype: int64
```

### pandas.DataFrame.drop

DataFrame's `.drop` method can be used to remove rows or columns by specifying label names and corresponding axis, or by specifying directly index or column names. When using a multi-index, labels on different levels can be removed by specifying the level.

**Parameters**

- **labels** [single label or list-like] Index or column labels to drop.
- **axis** [{0 or 'index', 1 or 'columns'}, default 0] Whether to drop labels from the index (0 or ‘index’) or columns (1 or ‘columns’).
- **index** [single label or list-like] Alternative to specifying axis (labels, axis=0 is equivalent to index=labels).
- **columns** [single label or list-like] Alternative to specifying axis (labels, axis=1 is equivalent to columns=labels).
- **level** [int or level name, optional] For MultiIndex, level from which the labels will be removed.
- **inplace** [bool, default False] If False, return a copy. Otherwise, do operation inplace and return None.
- **errors** [{‘ignore’, ‘raise’}, default ‘raise’] If ‘ignore’, suppress error and only existing labels are dropped.

**Returns**

DataFrame DataFrame without the removed index or column labels.

**Raises**

- **KeyError** If any of the labels is not found in the selected axis.

See also:

- `DataFrame.loc` Label-location based indexer for selection by label.
**DataFrame.dropna** Return DataFrame with labels on given axis omitted where (all or any) data are missing.

**DataFrame.drop_duplicates** Return DataFrame with duplicate rows removed, optionally only considering certain columns.

**Series.drop** Return Series with specified index labels removed.

### Examples

```python
def = pd.DataFrame(np.arange(12).reshape(3, 4),
                   columns=['A', 'B', 'C', 'D'])
def
```

```
A  B  C  D
0  0  1  2  3
1  4  5  6  7
2  8  9 10 11
```

Drop columns

```python
def.drop(['B', 'C'], axis=1)
def.drop(columns=['B', 'C'])
```

```
A  D
0  0  3
1  4  7
2  8 11
```

Drop a row by index

```python
def.drop([0, 1])
```

```
A  B  C  D
2  8  9 10 11
```

Drop columns and/or rows of MultiIndex DataFrame

```python
midx = pd.MultiIndex(levels=[['lama', 'cow', 'falcon'],
                            ['speed', 'weight', 'length']],
                     codes=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
                            [0, 1, 2, 0, 1, 2, 0, 1, 2]])
def = pd.DataFrame(index=midx, columns=['big', 'small'],
                   data=[[45, 30], [200, 100], [1.5, 1], [30, 20],
                         [250, 150], [1.5, 0.8], [320, 250],
                         [1, 0.8], [0.3, 0.2]])
def
```

```
<table>
<thead>
<tr>
<th></th>
<th>big</th>
<th>small</th>
</tr>
</thead>
<tbody>
<tr>
<td>lama</td>
<td>speed</td>
<td>45.0</td>
</tr>
<tr>
<td></td>
<td>weight</td>
<td>200.0</td>
</tr>
<tr>
<td></td>
<td>length</td>
<td>1.5</td>
</tr>
<tr>
<td>cow</td>
<td>speed</td>
<td>30.0</td>
</tr>
<tr>
<td></td>
<td>weight</td>
<td>250.0</td>
</tr>
<tr>
<td></td>
<td>length</td>
<td>1.5</td>
</tr>
<tr>
<td>falcon</td>
<td>speed</td>
<td>320.0</td>
</tr>
</tbody>
</table>
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.1.1

(pandas: powerful Python data analysis toolkit, Release 1.1.1)

weight 1.0 0.8
length 0.3 0.2

```python
>>> df.drop(index='cow', columns='small')
big
lama speed 45.0
weight 200.0
length 1.5
falcon speed 320.0
weight 1.0
length 0.3
```

```python
>>> df.drop(index='length', level=1)
big small
lama speed 45.0 30.0
weight 200.0 100.0
cow speed 30.0 20.0
weight 250.0 150.0
falcon speed 320.0 250.0
weight 1.0 0.8
```

**pandas.DataFrame.drop_duplicates**

**Dataframe**.drop_duplicates(subset=None, keep='first', inplace=False, ignore_index=False)

Return DataFrame with duplicate rows removed.

Considering certain columns is optional. Indexes, including time indexes are ignored.

**Parameters**

- **subset** [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns.
- **keep** [{‘first’, ‘last’, False}, default ‘first’] Determines which duplicates (if any) to keep. - first : Drop duplicates except for the first occurrence. - last : Drop duplicates except for the last occurrence. - False : Drop all duplicates.
- **inplace** [bool, default False] Whether to drop duplicates in place or to return a copy.
- **ignore_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

**Returns**

- **DataFrame** DataFrame with duplicates removed or None if inplace=True.

**See also:**

- **DataFrame.value_counts** Count unique combinations of columns.
Examples

Consider dataset containing ramen rating.

```python
>>> df = pd.DataFrame({
...     'brand': ['Yum Yum', 'Yum Yum', 'Indomie', 'Indomie', 'Indomie'],
...     'style': ['cup', 'cup', 'cup', 'pack', 'pack'],
...     'rating': [4, 4, 3.5, 15, 5]
... })
>>> df
   brand style rating
0   Yum Yum   cup   4.0
1   Yum Yum   cup   4.0
2   Indomie   cup   3.5
3   Indomie   pack  15.0
4   Indomie   pack   5.0
```

By default, it removes duplicate rows based on all columns.

```python
>>> df.drop_duplicates()
   brand style rating
0   Yum Yum   cup   4.0
2   Indomie   cup   3.5
3   Indomie   pack  15.0
4   Indomie   pack   5.0
```

To remove duplicates on specific column(s), use `subset`.

```python
>>> df.drop_duplicates(subset=['brand'])
   brand style rating
0   Yum Yum   cup   4.0
2   Indomie   cup   3.5
```

To remove duplicates and keep last occurrences, use `keep`.

```python
>>> df.drop_duplicates(subset=['brand', 'style'], keep='last')
   brand style rating
1   Yum Yum   cup   4.0
2   Indomie   cup   3.5
4   Indomie   pack   5.0
```

`pandas.DataFrame.droplevel`  
`DataFrame.droplevel(level, axis=0)`  
Return DataFrame with requested index / column level(s) removed.

New in version 0.24.0.

Parameters

- `level` [int, str, or list-like] If a string is given, must be the name of a level. If list-like, elements must be names or positional indexes of levels.
- `axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis along which the level(s) is removed:
  - 0 or ‘index’: remove level(s) in column.
  - 1 or ‘columns’: remove level(s) in row.
Returns

DataFrame DataFrame with requested index / column level(s) removed.

Examples

```python
>>> df = pd.DataFrame([... [1, 2, 3, 4], ... [5, 6, 7, 8], ... [9, 10, 11, 12] ... ]).set_index([0, 1]).rename_axis(["a", "b"])
```

```python
>>> df.columns = pd.MultiIndex.from_tuples([... ("c", "e"), ("d", "f") ... ], names=["level_1", "level_2"])
```

```python
>>> df
level_1   c   d
level_2   e   f
  a   b
1  2   3   4
5  6   7   8
9 10  11  12
```

```python
>>> df.droplevel('a')
level_1   c   d
level_2   e   f
  b
2   3   4
6   7   8
10  11  12
```

```python
>>> df.droplevel('level_2', axis=1)
level_1   c   d
level_2   e   f
  a   b
1  2   3   4
5  6   7   8
9 10  11  12
```

pandas.DataFrame.dropna

DataFrame.dropna(axis=0, how='any', thresh=None, subset=None, inplace=False)
Remove missing values.

See the User Guide for more on which values are considered missing, and how to work with missing data.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] Determine if rows or columns which contain missing values are removed.

- 0, or ‘index’ : Drop rows which contain missing values.
- 1, or ‘columns’ : Drop columns which contain missing value.
Changed in version 1.0.0: Pass tuple or list to drop on multiple axes. Only a single axis is allowed.

- **how** [{‘any’, ‘all’}, default ‘any’] Determine if row or column is removed from DataFrame, when we have at least one NA or all NA.
  - ‘any’: If any NA values are present, drop that row or column.
  - ‘all’: If all values are NA, drop that row or column.

- **thresh** [int, optional] Require that many non-NA values.

- **subset** [array-like, optional] Labels along other axis to consider, e.g. if you are dropping rows these would be a list of columns to include.

- **inplace** [bool, default False] If True, do operation in-place and return None.

**Returns**

- **DataFrame** DataFrame with NA entries dropped from it.

**See also:**

- **DataFrame.isna** Indicate missing values.
- **DataFrame.notna** Indicate existing (non-missing) values.
- **DataFrame.fillna** Replace missing values.
- **Series.dropna** Drop missing values.
- **Index.dropna** Drop missing indices.

**Examples**

```python
>>> df = pd.DataFrame({"name": ['Alfred', 'Batman', 'Catwoman'],
...                      "toy": [np.nan, 'Batmobile', 'Bullwhip'],
...                      "born": [pd.NaT, pd.Timestamp("1940-04-25"), pd.NaT]})
```

Drop the rows where at least one element is missing.

```bash
>>> df.dropna()
name     toy      born
1  Batman  Batmobile 1940-04-25
```

Drop the columns where at least one element is missing.

```bash
>>> df.dropna(axis='columns')
name
0  Alfred
1  Batman
2  Catwoman
```

Drop the rows where all elements are missing.

```bash
>>> df.dropna(axis='columns')
name
0  Alfred
1  Batman
2  Catwoman
```
```python
>>> df.dropna(how='all')
   name    toy    born
0  Alfred      NaN    NaT
1  Batman  Batmobile  1940-04-25
2  Catwoman     Bullwhip    NaT
Keep only the rows with at least 2 non-NA values.
```  
```python
>>> df.dropna(thresh=2)
   name    toy    born
1  Batman  Batmobile  1940-04-25
2  Catwoman     Bullwhip    NaT
Define in which columns to look for missing values.
```  
```python
>>> df.dropna(subset=['name', 'born'])
   name    toy    born
1  Batman  Batmobile  1940-04-25
Keep the DataFrame with valid entries in the same variable.
```  
```python
>>> df.dropna(inplace=True)
```

**pandas.DataFrame.duplicated**

DataFrame.duplicated(subset=None, keep='first')

Return boolean Series denoting duplicate rows.

Considering certain columns is optional.

**Parameters**

- **subset** [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns.
- **keep** [‘first’, ‘last’, False], default ‘first’ Determines which duplicates (if any) to mark.
  
  - first: Mark duplicates as True except for the first occurrence.
  - last: Mark duplicates as True except for the last occurrence.
  - False: Mark all duplicates as True.

**Returns**

Series Boolean series for each duplicated rows.

**See also:**

* Index.duplicated Equivalent method on index.
* Series.duplicated Equivalent method on Series.
* Series.drop_duplicates Remove duplicate values from Series.
* DataFrame.drop_duplicates Remove duplicate values from DataFrame.
Examples

Consider dataset containing ramen rating.

```python
>>> df = pd.DataFrame({
...     'brand': ['Yum Yum', 'Yum Yum', 'Indomie', 'Indomie', 'Indomie'],
...     'style': ['cup', 'cup', 'cup', 'pack', 'pack'],
...     'rating': [4, 4, 3.5, 15, 5]
... })
```

```python
>>> df
     brand  style rating
0     Yum     cup   4.0
1     Yum     cup   4.0
2   Indomie   cup   3.5
3   Indomie   pack  15.0
4   Indomie   pack   5.0
```

By default, for each set of duplicated values, the first occurrence is set on False and all others on True.

```python
>>> df.duplicated()
0    False
1     True
2    False
3     False
4     False
dtype: bool
```

By using `last`, the last occurrence of each set of duplicated values is set on False and all others on True.

```python
>>> df.duplicated(keep='last')
0   True
1  False
2  False
3  False
4  False
dtype: bool
```

By setting `keep` on False, all duplicates are True.

```python
>>> df.duplicated(keep=False)
0  True
1  True
2  False
3  False
4  False
dtype: bool
```

To find duplicates on specific column(s), use `subset`.

```python
>>> df.duplicated(subset=['brand'])
0  False
1   True
2  False
3   True
4   True
dtype: bool
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.DataFrame.eq

DataFrame.eq(other, axis='columns', level=None)
Get Equal to of dataframe and other, element-wise (binary operator eq).
Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.
Equivalent to ==, =!, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').
level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.
DataFrame.ne Compare DataFrames for inequality elementwise.
DataFrame.le Compare DataFrames for less than inequality or equality elementwise.
DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.
DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.
DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes
Mismatched indices will be unioned together. NaN values are considered different (i.e. NaN != NaN).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                   'revenue': [100, 250, 300]},
...                   index=['A', 'B', 'C'])
>>> df
   cost  revenue
A  250    100
B  150    250
C  100    300
```

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
   cost  revenue
A  False    True
B  False    False
C  True     False
```
When `other` is a `Series`, the columns of a DataFrame are aligned with the index of `other` and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
    cost  revenue
  A   True    True
  B   True    False
  C   False    True
```

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
    cost  revenue
  A   True    False
  B   True    True
  C   True    True
  D   True    True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```python
>>> df == [250, 100]
    cost  revenue
  A   True    True
  B   False    False
  C   False    False
```

Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
    cost  revenue
  A   True    False
  B   False    True
  C   True    False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                        index=['A', 'B', 'C', 'D'])
>>> df.gt(other)
    cost  revenue
  A     True   False
  B     True    True
  C     True    True
  D     True    True
```

(continues on next page)
A False False
B False False
C False True
D False False

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
                               'revenue': [100, 250, 300, 200, 175, 225],
                               'index': [['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
                                         ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
   cost  revenue
Q1 A    250     100
      B    150     250
      C     100     300
Q2 A    150     200
      B    300     175
      C    220     225
```

```python
>>> df.le(df_multindex, level=1)
   cost  revenue
Q1 A   True   True
      B   True   True
      C   True   True
Q2 A  False   True
      B   True   False
      C   True   False
```

### pandas.DataFrame.equals

**DataFrame.equals**(other)

Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the same shape and elements. NaNs in the same location are considered equal. The column headers do not need to have the same type, but the elements within the columns must be the same dtype.

**Parameters**

- **other** [Series or DataFrame] The other Series or DataFrame to be compared with the first.

**Returns**

- **bool** True if all elements are the same in both objects, False otherwise.

**See also:**

- **Series.eq** Compare two Series objects of the same length and return a Series where each element is True if the element in each Series is equal, False otherwise.

- **DataFrame.eq** Compare two DataFrame objects of the same shape and return a DataFrame where each element is True if the respective element in each DataFrame is equal, False otherwise.

- **testing.assert_series_equal** Raises an AssertionError if left and right are not equal. Provides an easy interface to ignore inequality in dtypes, indexes and precision among others.
**testing.assert_frame_equal**  Like assert_series_equal, but targets DataFrames.

**numpy.array_equal**  Return True if two arrays have the same shape and elements, False otherwise.

**Notes**

This function requires that the elements have the same dtype as their respective elements in the other Series or DataFrame. However, the column labels do not need to have the same type, as long as they are still considered equal.

**Examples**

```python
>>> df = pd.DataFrame({1: [10], 2: [20]})
>>> df
   1  2
0 10 20

DataFrames df and exactly_equal have the same types and values for their elements and column labels, which will return True.

```python
>>> exactly_equal = pd.DataFrame({1: [10], 2: [20]})
>>> exactly_equal
   1  2
0 10 20
>>> df.equals(exactly_equal)
True
```

DataFrames df and different_column_type have the same element types and values, but have different types for the column labels, which will still return True.

```python
>>> different_column_type = pd.DataFrame({1.0: [10], 2.0: [20]})
>>> different_column_type
   1.0  2.0
0  10  20
>>> df.equals(different_column_type)
True
```

DataFrames df and different_data_type have different types for the same values for their elements, and will return False even though their column labels are the same values and types.

```python
>>> different_data_type = pd.DataFrame({1: [10.0], 2: [20.0]})
>>> different_data_type
   1   2
0 10.0 20.0
>>> df.equals(different_data_type)
False
```
pandas.DataFrame.eval

pandas.DataFrame.eval(expr, inplace=False, **kwargs)
Evaluate a string describing operations on DataFrame columns.

Operates on columns only, not specific rows or elements. This allows eval to run arbitrary code, which can make you vulnerable to code injection if you pass user input to this function.

Parameters

expr [str] The expression string to evaluate.

inplace [bool, default False] If the expression contains an assignment, whether to perform the operation inplace and mutate the existing DataFrame. Otherwise, a new DataFrame is returned.

**kwargs See the documentation for eval() for complete details on the keyword arguments accepted by query().

Returns

ndarray, scalar, or pandas object The result of the evaluation.

See also:

DataFrame.query Evaluates a boolean expression to query the columns of a frame.

DataFrame.assign Can evaluate an expression or function to create new values for a column.

eval Evaluate a Python expression as a string using various backends.

Notes

For more details see the API documentation for eval(). For detailed examples see enhancing performance with eval.

Examples

```python
>>> df = pd.DataFrame({'A': range(1, 6), 'B': range(10, 0, -2)})
>>> df
   A  B
0  1 10
1  2  8
2  3  6
3  4  4
4  5  2
>>> df.eval('A + B')
   0  11
  1  10
  2  9
  3  8
  4  7
dtype: int64
```

Assignment is allowed though by default the original DataFrame is not modified.
>>> df.eval('C = A + B')
    A  B  C
0  1  10  11
1  2  8  10
2  3  6  9
3  4  4  8
4  5  2  7

Use `inplace=True` to modify the original DataFrame.

>>> df.eval('C = A + B', inplace=True)
>>> df
    A  B  C
0  1  10  11
1  2  8  10
2  3  6  9
3  4  4  8
4  5  2  7

Multiple columns can be assigned to using multi-line expressions:

>>> df.eval('''
... C = A + B
... D = A - B
... '''
... )
    A  B  C  D
0  1  10  11 -9
1  2  8  10 -6
2  3  6  9 -3
3  4  4  8  0
4  5  2  7  3

**pandas.DataFrame.ewm**

DataFrame.ewm (com=None, span=None, halflife=None, alpha=None, min_periods=0, adjust=True, ignore_na=False, axis=0, times=None)

Provide exponential weighted (EW) functions.

Available EW functions: mean(), var(), std(), corr(), cov().

Exactly one parameter: com, span, halflife, or alpha must be provided.

**Parameters**

- **com** [float, optional] Specify decay in terms of center of mass, $\alpha = 1/(1 + \text{com})$, for $\text{com} \geq 0$.
- **span** [float, optional] Specify decay in terms of span, $\alpha = 2/(\text{span}+1)$, for $\text{span} \geq 1$. 

---

3.4. DataFrame
halflife [float, str, timedelta, optional] Specify decay in terms of half-life, \( \alpha = 1 - \exp\left(-\ln(2)/\text{halflife}\right) \), for \( \text{halflife} > 0 \).

If times is specified, the time unit (str or timedelta) over which an observation decays to half its value. Only applicable to \textit{mean()} and halflife value will not apply to the other functions.

New in version 1.1.0.

alpha [float, optional] Specify smoothing factor \( \alpha \) directly, \( 0 < \alpha \leq 1 \).

min_periods [int, default 0] Minimum number of observations in window required to have a value (otherwise result is NA).

adjust [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average).

- When adjust=True (default), the EW function is calculated using weights \( w_i = (1 - \alpha)^i \). For example, the EW moving average of the series \([x_0, x_1, ..., x_t]\) would be:

\[
y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + ... + (1 - \alpha)^tx_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + ... + (1 - \alpha)^t}
\]

- When adjust=False, the exponentially weighted function is calculated recursively:

\[
y_0 = x_0 \\
y_t = (1 - \alpha)y_{t-1} + \alpha x_t,
\]

ignore_na [bool, default False] Ignore missing values when calculating weights; specify True to reproduce pre-0.15.0 behavior.

- When ignore_na=False (default), weights are based on absolute positions. For example, the weights of \( x_0 \) and \( x_2 \) used in calculating the final weighted average of \([x_0, None, x_2]\) are \((1 - \alpha)^2\) and \(1\) if adjust=True, and \((1 - \alpha)^2\) and \(\alpha\) if adjust=False.

- When ignore_na=True (reproducing pre-0.15.0 behavior), weights are based on relative positions. For example, the weights of \( x_0 \) and \( x_2 \) used in calculating the final weighted average of \([x_0, None, x_2]\) are \(1 - \alpha\) and \(1\) if adjust=True, and \(1 - \alpha\) and \(\alpha\) if adjust=False.

axis [{0, 1}, default 0] The axis to use. The value 0 identifies the rows, and 1 identifies the columns.

times [str, np.ndarray, Series, default None] New in version 1.1.0.

Times corresponding to the observations. Must be monotonically increasing and datetime64[ns] dtype.

If str, the name of the column in the DataFrame representing the times.

If 1-D array like, a sequence with the same shape as the observations.

Only applicable to \textit{mean()}.

Returns

\textit{DataFrame} A Window sub-classed for the particular operation.

See also:

\begin{verbatim}
pandas: powerful Python data analysis toolkit, Release 1.1.1
\end{verbatim}
**rolling** Provides rolling window calculations.

**expanding** Provides expanding transformations.

**Notes**

More details can be found at: *Exponentially weighted windows*.

**Examples**

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
      B
0     0
1     1
2     2
3   NaN
4     4

>>> df.ewm(com=0.5).mean()
      B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213

Specifying times with a timedelta halflife when computing mean.

```python
>>> times = ['2020-01-01', '2020-01-03', '2020-01-10', '2020-01-15', '2020-01-17']
>>> df.ewm(halflife='4 days', times=pd.DatetimeIndex(times)).mean()
      B
0  0.000000
1  0.585786
2  1.523889
3  1.523889
4  3.233686
```

**pandas.DataFrame.expanding**

Dataframe.**expanding** *min_periods=1, center=None, axis=0*

Provide expanding transformations.

**Parameters**

- `min_periods [int, default 1]` Minimum number of observations in window required to have a value (otherwise result is NA).
- `center [bool, default False]` Set the labels at the center of the window.
- `axis [int or str, default 0]`

**Returns**

- a Window sub-classed for the particular operation
See also:

- **rolling**  Provides rolling window calculations.
- **ewm**  Provides exponential weighted functions.

**Notes**

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

**Examples**

```python
gf = pd.DataFrame({"B": [0, 1, 2, np.nan, 4]})
gf

0    0.0
1    1.0
2    2.0
3   NaN
4    4.0

gf.expanding(2).sum()

0  NaN
1  1.0
2  3.0
3  3.0
4  7.0
```

**pandas.DataFrame.explode**

DataFrame.explode(column, ignore_index=False)

Transform each element of a list-like to a row, replicating index values.

New in version 0.25.0.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>column</strong></td>
</tr>
<tr>
<td><strong>ignore_index</strong></td>
</tr>
</tbody>
</table>

New in version 1.1.0.

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DataFrame</strong></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Raises</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ValueError</strong></td>
</tr>
</tbody>
</table>

See also:
**DataFrame.unstack** Pivot a level of the (necessarily hierarchical) index labels.

**DataFrame.melt** Unpivot a DataFrame from wide format to long format.

**Series.explode** Explode a DataFrame from list-like columns to long format.

**Notes**

This routine will explode list-likes including lists, tuples, Series, and np.ndarray. The result dtype of the subset rows will be object. Scalars will be returned unchanged. Empty list-likes will result in a np.nan for that row.

**Examples**

```python
>>> df = pd.DataFrame({'A': [[1, 2, 3], 'foo', [], [3, 4]], 'B': 1})
>>> df
   A    B
0 [1, 2, 3] 1
1   foo  1
2     []  1
3 [3, 4]  1
```

```python
>>> df.explode('A')
   A    B
0  1    1
0  2    1
0  3    1
1  foo  1
2   NaN  1
3  3    1
3  4    1
```

**pandas.DataFrame.ffill**

**DataFrame.ffill** *(axis=None, inplace=False, limit=None, downcast=None)*

Synonym for **DataFrame.fillna()** with method='ffill'.

**Returns**

{klass} or None Object with missing values filled or None if inplace=True.

**pandas.DataFrame.fillna**

**DataFrame.fillna** *(value=None, method=None, axis=None, inplace=False, limit=None, downcast=None)*

Fill NA/NaN values using the specified method.

**Parameters**

value [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

axis  [{0 or ‘index’, 1 or ‘columns’}] Axis along which to fill missing values.

inplace  [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

limit  [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

downcast  [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns

DataFrame or None  Object with missing values filled or None if inplace=True.

See also:

interpolate  Fill NaN values using interpolation.

reindex  Conform object to new index.

asfreq  Convert TimeSeries to specified frequency.

Examples

```python
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                     [3, 4, np.nan, 1],
...                     [np.nan, np.nan, np.nan, 5],
...                     [np.nan, 3, np.nan, 4]],
...                    columns=list('ABCD'))
>>> df
     A  B   C  D
0   NaN 2.0  NaN 0
1   3.0 4.0  NaN 1
2   NaN  NaN  NaN 5
3   NaN  3.0  NaN 4
```

Replace all NaN elements with 0s.

```python
>>> df.fillna(0)
     A  B   C  D
0  0.0 2.0  0.0 0
1  3.0 4.0  0.0 1
2  0.0 0.0  0.0 5
3  0.0 3.0  0.0 4
```

We can also propagate non-null values forward or backward.

```python
>>> df.fillna(method='ffill')
     A  B   C  D
0   NaN 2.0  NaN 0
1   3.0 4.0  NaN 1
2   0.0 0.0  0.0 5
3   0.0 3.0  0.0 4
```
Replace all NaN elements in column ‘A’, ‘B’, ‘C’, and ‘D’, with 0, 1, 2, and 3 respectively.

```python
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
       A   B   C   D
0  0.0  2.0  2.0  0.0
1  3.0  4.0  2.0  1.0
2  0.0  1.0  2.0  5.0
3  0.0  3.0  2.0  4.0
```

Only replace the first NaN element.

```python
>>> df.fillna(value=values, limit=1)
       A   B   C   D
0  0.0  2.0  2.0  0.0
1  3.0  4.0  NaN  1.0
2  NaN  1.0  NaN  5.0
3  NaN  3.0  NaN  4.0
```

### pandas.DataFrame.filter

**DataFrame.filter**(items=None, like=None, regex=None, axis=None)  
Subset the dataframe rows or columns according to the specified index labels.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

**Parameters**

- **items** [list-like] Keep labels from axis which are in items.
- **like** [str] Keep labels from axis for which “like in label == True”.
- **regex** [str (regular expression)] Keep labels from axis for which re.search(regex, label) == True.
- **axis** [[0 or ‘index’, 1 or ‘columns’, None], default None] The axis to filter on, expressed either as an index (int) or axis name (str). By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame.

**Returns**

same type as input object

**See also:**

- **DataFrame.loc** Access a group of rows and columns by label(s) or a boolean array.
Notes

The items, like, and regex parameters are enforced to be mutually exclusive.

axis defaults to the info axis that is used when indexing with [].

Examples

```python
>>> df = pd.DataFrame(np.array(((1, 2, 3), (4, 5, 6))),
...                    index=['mouse', 'rabbit'],
...                    columns=['one', 'two', 'three'])
>>> df
   one  two  three
mouse  1    2    3
rabbit 4    5    6

>>> # select columns by name
>>> df.filter(items=['one', 'three'])
   one  three
mouse   1    3
rabbit   4    6

>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
   one  three
mouse   1    3
rabbit   4    6

>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
   one  two  three
rabbit 4    5    6
```

pandas.DataFrame.first

DataFrame.first(offset)

Select initial periods of time series data based on a date offset.

When having a DataFrame with dates as index, this function can select the first few rows based on a date offset.

Parameters

offset [str, DateOffset or dateutil.relativedelta] The offset length of the data that will be selected. For instance, ‘1M’ will display all the rows having their index within the first month.

Returns

Series or DataFrame A subset of the caller.

Raises

TypeError If the index is not a DatetimeIndex.
last Select final periods of time series based on a date offset.

at_time Select values at a particular time of the day.

between_time Select values between particular times of the day.

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
      A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4

Get the rows for the first 3 days:

```python
>>> ts.first('3D')
      A
2018-04-09  1
2018-04-11  2
```

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.

pandas.DataFrame.first_valid_index

DataFrame.first_valid_index() Return index for first non-NA/null value.

Returns

scalar [type of index]

Notes

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.DataFrame.floordiv

DataFrame.floordiv(other, axis='columns', level=None, fill_value=None) Get Integer division of dataframe and other, element-wise (binary operator `floordiv`). Equivalent to `dataframe // other`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, `rfloordiv`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis  [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.

level  [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value  [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame  Result of the arithmetic operation.

See also:

DataFrame.add  Add DataFrames.
DataFrame.sub  Subtract DataFrames.
DataFrame.mul  Multiply DataFrames.
DataFrame.div  Divide DataFrames (float division).
DataFrame.truediv  Divide DataFrames (float division).
DataFrame.floordiv  Divide DataFrames (integer division).
DataFrame.mod  Calculate modulo (remainder after division).
DataFrame.pow  Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle    0      360
triangle   3      180
rectangle  4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```
divide by constant with reverse version.

```python
>>> df.div(10)
angles degrees
circle 0.0 36.0
triangle 0.3 18.0
rectangle 0.4 36.0
```

subtract a list and series by axis with operator version.

```python
>>> df - [1, 2]
angles degrees
circle -1 358
triangle 2 178
rectangle 3 358
```

multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({'angles': [0, 3, 4]},
                     index=['circle', 'triangle', 'rectangle'])
>>> df * other
angles degrees
circle 0 NaN
triangle 9 NaN
rectangle 16 NaN
```
Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                             'degrees': [360, 180, 360, 360, 540, 720],
...                             'index': ['A', 'A', 'A', 'B', 'B', 'B'],
...                             'circle', 'triangle', 'rectangle',
...                             'square', 'pentagon', 'hexagon']})
>>> df_multindex
  angles  degrees
   A  circle    0    360
     triangle   3    180
     rectangle  4    360
   B    square   4    360
     pentagon   5    540
     hexagon   6    720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
  angles  degrees
   A  circle  NaN     1.0
     triangle  1.0     1.0
     rectangle  1.0     1.0
   B    square  0.0     0.0
     pentagon  0.0     0.0
     hexagon  0.0     0.0
```

`pandas.DataFrame.from_dict`

classmethod `DataFrame.from_dict`(data, orient='columns', dtype=None, columns=None)  
Construct DataFrame from dict of array-like or dicts.  
Creates DataFrame object from dictionary by columns or by index allowing dtype specification.

Parameters

data [dict] Of the form {field : array-like} or {field : dict}.
orient ['columns', 'index'], default 'columns' The “orientation” of the data. If the keys of the passed dict should be the columns of the resulting DataFrame, pass ‘columns’ (default). Otherwise if the keys should be rows, pass ‘index’.
dtype [dtype, default None] Data type to force, otherwise infer.
columns [list, default None] Column labels to use when orient='index'. Raises a ValueError if used with orient='columns'.

Returns

DataFrame

See also:
DataFrame.from_records DataFrame from structured ndarray, sequence of tuples or dicts, or DataFrame.

DataFrame DataFrame object creation using constructor.

Examples

By default the keys of the dict become the DataFrame columns:

```python
>>> data = {'col_1': [3, 2, 1, 0], 'col_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data)
       col_1 col_2
    0    3    a
    1    2    b
    2    1    c
    3    0    d
```

Specify orient='index' to create the DataFrame using dictionary keys as rows:

```python
>>> data = {'row_1': [3, 2, 1, 0], 'row_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data, orient='index')
      0  1  2  3
row_1 3  2  1  0
row_2 a  b  c  d
```

When using the ‘index’ orientation, the column names can be specified manually:

```python
>>> pd.DataFrame.from_dict(data, orient='index',
...                        columns=['A', 'B', 'C', 'D'])
   A  B  C  D
row_1 3  2  1  0
row_2 a  b  c  d
```

pandas.DataFrame.from_records

classmethod DataFrame.from_records(data, index=None, exclude=None, columns=None, coerce_float=False, nrows=None)

Convert structured or record ndarray to DataFrame.

Creates a DataFrame object from a structured ndarray, sequence of tuples or dicts, or DataFrame.

Parameters

- **data**: [structured ndarray, sequence of tuples or dicts, or DataFrame] Structured input data.
- **index**: [str, list of fields, array-like] Field of array to use as the index, alternately a specific set of input labels to use.
- **exclude**: [sequence, default None] Columns or fields to exclude.
- **columns**: [sequence, default None] Column names to use. If the passed data do not have names associated with them, this argument provides names for the columns. Otherwise this argument indicates the order of the columns in the result (any names not found in the data will become all-NA columns).
- **coerce_float**: [bool, default False] Attempt to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets.
nrows [int, default None] Number of rows to read if data is an iterator.

Returns

DataFrame

See also:

DataFrame.from_dict DataFrame from dict of array-like or dicts.

DataFrame DataFrame object creation using constructor.

Examples

Data can be provided as a structured ndarray:

```python
>>> data = np.array([(3, 'a'), (2, 'b'), (1, 'c'), (0, 'd')],
                   dtype=[('col_1', 'i4'), ('col_2', 'U1')])
```

```text
>> pd.DataFrame.from_records(data)
col_1   col_2
0   3   a
1   2   b
2   1   c
3   0   d
```

Data can be provided as a list of dicts:

```python
>>> data = [{'col_1': 3, 'col_2': 'a'},
          {'col_1': 2, 'col_2': 'b'},
          {'col_1': 1, 'col_2': 'c'},
          {'col_1': 0, 'col_2': 'd'}]
```

```text
>> pd.DataFrame.from_records(data)
col_1   col_2
0   3   a
1   2   b
2   1   c
3   0   d
```

Data can be provided as a list of tuples with corresponding columns:

```python
>>> data = [(3, 'a'), (2, 'b'), (1, 'c'), (0, 'd')]
```

```text
>> pd.DataFrame.from_records(data, columns=['col_1', 'col_2'])
col_1   col_2
0   3   a
1   2   b
2   1   c
3   0   d
```
DataFrame.ge

DataFrame.ge(other, axis='columns', level=None)
Get Greater than or equal to of dataframe and other, element-wise (binary operator ge).

Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.
Equivalent to ==, !=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').
level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.
DataFrame.ne Compare DataFrames for inequality elementwise.
DataFrame.le Compare DataFrames for less than inequality or equality elementwise.
DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.
DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.
DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. NaN values are considered different (i.e. NaN != NaN).

Examples

```
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300

Comparison with a scalar, using either the operator or method:
```
```
>>> df == 100
   cost  revenue
A  False     True
```
(continues on next page)
When other is a Series, the columns of a DataFrame are aligned with the index of other and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
   cost  revenue
A   True     True
B   True     False
C  False     True
```

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
   cost  revenue
A   True     False
B   True     True
C  True     True
D  True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in other:

```python
>>> df == [250, 100]
   cost  revenue
A   True     True
B  False     False
C  False     False
```

Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
   cost  revenue
A  False     False
B   True     True
C  True     False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                        index=['A', 'B', 'C', 'D'])
>>> other
revenue
A     300
B     250
C     100
D     150

>>> df.gt(other)
   cost  revenue
```

(continues on next page)
Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
... 'revenue': [100, 250, 300, 200, 175, 225],
... 'index': [ ['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
... [ 'A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
  cost  revenue
Q1  A    250       100
    B    150       250
    C    100       300
Q2  A    150       200
    B    300       175
    C    220       225

>>> df.le(df_multindex, level=1)
  cost  revenue
Q1  A    True      True
    B    True      True
    C    True      True
Q2  A    False     True
    B    True      False
    C    True      False
```

**pandas.DataFrame.get**

`DataFrame.get(key, default=None)`

Get item from object for given key (ex: DataFrame column).

Returns default value if not found.

**Parameters**

- `key` [object]

**Returns**

- `value` [same type as items contained in object]

**pandas.DataFrame.groupby**

`DataFrame.groupby(by=None, axis=0, level=None, as_index=True, sort=True, group_keys=True, squeeze=<object object>, observed=False, dropna=True)`

Group DataFrame using a mapper or by a Series of columns.

A groupby operation involves some combination of splitting the object, applying a function, and combining the results. This can be used to group large amounts of data and compute operations on these groups.

**Parameters**
by [mapping, function, label, or list of labels] Used to determine the groups for the
groupby. If by is a function, it’s called on each value of the object’s index. If a
dict or Series is passed, the Series or dict VALUES will be used to determine the
groups (the Series’ values are first aligned; see .align() method). If an ndarray
is passed, the values are used as-is to determine the groups. A label or list of labels
may be passed to group by the columns in self. Notice that a tuple is interpreted
as a (single) key.

axis [[0 or ‘index’, 1 or ‘columns’], default 0] Split along rows (0) or columns (1).

level [int, level name, or sequence of such, default None] If the axis is a MultiIndex
(hierarchical), group by a particular level or levels.

as_index [bool, default True] For aggregated output, return object with group labels
as the index. Only relevant for DataFrame input. as_index=False is effectively
“SQL-style” grouped output.

sort [bool, default True] Sort group keys. Get better performance by turning this off.
Note this does not influence the order of observations within each group. Groupby
preserves the order of rows within each group.

group_keys [bool, default True] When calling apply, add group keys to index to iden-
tify pieces.

squeeze [bool, default False] Reduce the dimensionality of the return type if possible,
otherwise return a consistent type.
Deprecation since version 1.1.0.

observed [bool, default False] This only applies if any of the groupers are Categoricals.
If True: only show observed values for categorical groupers. If False: show all
values for categorical groupers.
New in version 0.23.0.

dropna [bool, default True] If True, and if group keys contain NA values, NA values
together with row/column will be dropped. If False, NA values will also be treated
as the key in groups
New in version 1.1.0.

Returns

DataFrameGroupBy Returns a groupby object that contains information about the
groups.

See also:

resample Convenience method for frequency conversion and resampling of time series.

Notes

See the user guide for more.
Examples

```python
groupby (["Animal"]).mean()
Animal
Falcon 375.0
Parrot 25.0
```

Hierarchical Indexes

We can groupby different levels of a hierarchical index using the `level` parameter:

```python
groupby (level=0).mean()
Animal
Falcon 370.0
Parrot 25.0
```

We can also choose to include NA in group keys or not by setting `dropna` parameter, the default setting is `True`:

```python
groupby (by="b").sum()
a c b
1.0 2 3
2.0 2 5
```
```python
>>> df.groupby(by=["b"], dropna=False).sum()
    a  c
  b  1.0  2  3
   2.0  2  5
    NaN  1  4
```

```python
>>> l = ["a", 12, 12], [None, 12.3, 33.], ["b", 12.3, 123], ["a", 1, 1]
>>> df = pd.DataFrame(l, columns=["a", "b", "c"])
```

```python
>>> df.groupby(by="a").sum()
    b  c
  a  13.0  13.0
  b  12.3  123.0
```

```python
>>> df.groupby(by="a", dropna=False).sum()
    b  c
  a  13.0  13.0
  b  12.3  123.0
    NaN  12.3  33.0
```

### pandas.DataFrame.gt

DataFrame.gt( other, axis='columns', level=None)

Get Greater than of dataframe and other, element-wise (binary operator gt).

Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.

Equivalent to ==, !=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default ‘columns’] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’).
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

DataFrame of bool Result of the comparison.

**See also:**

- **DataFrame.eq** Compare DataFrames for equality elementwise.
- **DataFrame.ne** Compare DataFrames for inequality elementwise.
- **DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.
- **DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.
- **DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.
**DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.

**Notes**

Mismatched indices will be unioned together. *NaN* values are considered different (i.e. *NaN* != *NaN*).

**Examples**

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                   index=['A', 'B', 'C'])
>>> df
       cost  revenue
    A      250     100
    B      150     250
    C      100     300

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
       cost  revenue
    A   False     True
    B   False    False
    C    True    False
```

```python
>>> df.eq(100)
       cost  revenue
    A   False     True
    B   False    False
    C    True    False
```

When `other` is a `Series`, the columns of a DataFrame are aligned with the index of `other` and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
       cost  revenue
    A    True     True
    B    True    False
    C   False     True
```

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
       cost  revenue
    A    True    False
    B    True     True
    C    True     True
    D    True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```python
>>> df == [250, 100]
       cost  revenue
    A    True     True
```

(continues on next page)
Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
   cost  revenue
A  True   False
B  False  True
C  True   False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                       index=['A', 'B', 'C', 'D'])
>>> other
          revenue
A      300
B      250
C      100
D      150
```

```python
>>> df.gt(other)
   cost  revenue
A  False  False
B  False  False
C  False  True
D  False  False
```

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
                               'revenue': [100, 250, 300, 200, 175, 225],
                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
                                      ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
   cost  revenue
Q1 A  250    100
   B  150    250
   C  100    300
Q2 A  150    200
   B  300    175
   C  220    225
```

```python
>>> df.le(df_multindex, level=1)
   cost  revenue
Q1 A  True   True
   B  True   True
   C  True   True
Q2 A  False  True
   B  True   False
   C  True   False
```
**pandas.DataFrame.head**

DataFrame.head(n=5)

Return the first $n$ rows.

This function returns the first $n$ rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

For negative values of $n$, this function returns all rows except the last $n$ rows, equivalent to $\text{df}[:-n]$.

**Parameters**

- **n** [int, default 5] Number of rows to select.

**Returns**

- **same type as caller** The first $n$ rows of the caller object.

**See also:**

*DataFrame.tail* Returns the last $n$ rows.

**Examples**

```python
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion', ...
                     'monkey', 'parrot', 'shark', 'whale', 'zebra']})

Viewing the first 5 lines

```python
>>> df.head()
   animal
0  alligator
1     bee
2   falcon
3     lion
4   monkey
5  parrot
6    shark
7   whale
8  zebra
```

Viewing the first $n$ lines (three in this case)

```python
>>> df.head(3)
   animal
0  alligator
1     bee
2   falcon
```

For negative values of $n
```python
>>> df.head(-3)
   animal
 0  alligator
 1      bee
 2    falcon
 3     lion
 4  monkey
 5  parrot
```

**pandas.DataFrame.hist**

DataFrame.hist(column=None, by=None, grid=True, xlabelsize=None, xrot=None, ylabelsize=None, yrot=None, ax=None, sharex=False, sharey=False, figsize=None, layout=None, bins=10, backend=None, legend=False, **kwargs)

Make a histogram of the DataFrame’s.

A **histogram** is a representation of the distribution of data. This function calls `matplotlib.pyplot.hist()`, on each series in the DataFrame, resulting in one histogram per column.

**Parameters**

- **data** [DataFrame] The pandas object holding the data.
- **column** [str or sequence] If passed, will be used to limit data to a subset of columns.
- **by** [object, optional] If passed, then used to form histograms for separate groups.
- **grid** [bool, default True] Whether to show axis grid lines.
- **xlabelsize** [int, default None] If specified changes the x-axis label size.
- **xrot** [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.
- **ylabelsize** [int, default None] If specified changes the y-axis label size.
- **yrot** [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.
- **ax** [Matplotlib axes object, default None] The axes to plot the histogram on.
- **sharex** [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.
- **sharey** [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.
- **figsize** [tuple] The size in inches of the figure to create. Uses the value in `matplotlib.rcParams` by default.
- **layout** [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.
- **bins** [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.
- **backend** [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, ‘matplotlib’. Alternatively, to
specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

**legend** [bool, default False] Whether to show the legend.

New in version 1.1.0.

**kwargs** All other plotting keyword arguments to be passed to `matplotlib.pyplot.hist()`.

Returns

- `matplotlib.AxesSubplot` or `numpy.ndarray` of them

See also:

- `matplotlib.pylot.hist` Plot a histogram using matplotlib.

**Examples**

This example draws a histogram based on the length and width of some animals, displayed in three bins

```python
>>> df = pd.DataFrame({
...    'length': [1.5, 0.5, 1.2, 0.9, 3],
...    'width': [0.7, 0.2, 0.15, 0.2, 1.1]
...    }, index=['pig', 'rabbit', 'duck', 'chicken', 'horse'])

>>> hist = df.hist(bins=3)
```

### `pandas.DataFrame.idxmax`

`DataFrame.idxmax(axis=0, skipna=True)`

Return index of first occurrence of maximum over requested axis.

NA/null values are excluded.

**Parameters**

- **axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**Returns**

- **Series** Indexes of maxima along the specified axis.

**Raises**

- **ValueError**

  - If the row/column is empty

**See also:**

- `Series.idxmax` Return index of the maximum element.
Notes

This method is the DataFrame version of `ndarray.argmax`.

Examples

Consider a dataset containing food consumption in Argentina.

```python
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
...                   'co2_emissions': [37.2, 19.66, 1712]})
...                   index=['Pork', 'Wheat Products', 'Beef'])

>>> df
consumption  co2_emissions
Pork         10.51        37.20
Wheat Products 103.11      19.66
Beef          55.48       1712.00

By default, it returns the index for the maximum value in each column.

```python
>>> df.idxmax()
consumption    Wheat Products
co2_emissions  Beef
```

To return the index for the maximum value in each row, use `axis="columns"`.

```python
>>> df.idxmax(axis="columns")
Pork       co2_emissions
Wheat Products consumption
Beef       co2_emissions
```

`pandas.DataFrame.idxmin`

`DataFrame.idxmin(axis=0, skipna=True)`

Return index of first occurrence of minimum over requested axis.

NA/null values are excluded.

Parameters

- `axis` [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.
- `skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

- `Series` Indexes of minima along the specified axis.

Raises

- `ValueError`
  - If the row/column is empty
See also:

*Series.idxmin* Return index of the minimum element.

**Notes**

This method is the DataFrame version of *ndarray.argmin*.

**Examples**

Consider a dataset containing food consumption in Argentina.

```python
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
...                     'co2_emissions': [37.2, 19.66, 1712]},
...                    index=['Pork', 'Wheat Products', 'Beef'])
```

```
>>> df
consumption   co2_emissions
Pork          10.51   37.20
Wheat Products 103.11  19.66
Beef          55.48  1712.00
```

By default, it returns the index for the minimum value in each column.

```python
>>> df.idxmin()
consumption    Pork
co2_emissions  Wheat Products
dtype: object
```

To return the index for the minimum value in each row, use *axis="columns"*.

```python
>>> df.idxmin(axis="columns")
Pork consumtion
Wheat Products co2_emissions
Beef           consumption
dtype: object
```

---

**pandas.DataFrame.infer_objects**

*DataFrame.infer_objects()*

Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

**Returns**

converted [same type as input object]

**See also:**

*to_datetime* Convert argument to datetime.

*to_timedelta* Convert argument to timedelta.

*to_numeric* Convert argument to numeric type.
**convert_dtypes** Convert argument to best possible dtype.

### Examples

```python
>>> df = pd.DataFrame({'A': ['a', 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
   A
0  1
1  2
2  3
```

```python
>>> df.dtypes
A    object
dtype: object
```

```python
>>> df.infer_objects().dtypes
A    int64
dtype: object
```

#### pandas.DataFrame.info

**DataFrame.info** *(verbose=None, buf=None, max_cols=None, memory_usage=None, null_counts=None)*

Print a concise summary of a DataFrame.

This method prints information about a DataFrame including the index dtype and columns, non-null values and memory usage.

**Parameters**

- **data** [DataFrame] DataFrame to print information about.
- **verbose** [bool, optional] Whether to print the full summary. By default, the setting in pandas.options.display.max_info_columns is followed.
- **buf** [writable buffer, defaults to sys.stdout] Where to send the output. By default, the output is printed to sys.stdout. Pass a writable buffer if you need to further process the output.
- **max_cols** [int, optional] When to switch from the verbose to the truncated output. If the DataFrame has more than max_cols columns, the truncated output is used. By default, the setting in pandas.options.display.max_info_columns is used.
- **memory_usage** [bool, str, optional] Specifies whether total memory usage of the DataFrame elements (including the index) should be displayed. By default, this follows the pandas.options.display.memory_usage setting.

True always show memory usage. False never shows memory usage. A value of ‘deep’ is equivalent to “True with deep introspection”. Memory usage is shown in human-readable units (base-2 representation). Without deep introspection a memory estimation is made based in column dtype and number of rows assuming values consume the same memory amount for corresponding dtypes. With deep memory introspection, a real memory usage calculation is performed at the cost of computational resources.
null_counts [bool, optional] Whether to show the non-null counts. By default, this is shown only if the DataFrame is smaller than pandas.options.display.max_info_rows and pandas.options.display.max_info_columns. A value of True always shows the counts, and False never shows the counts.

Returns

None This method prints a summary of a DataFrame and returns None.

See also:

DataFrame.describe Generate descriptive statistics of DataFrame columns.

DataFrame.memory_usage Memory usage of DataFrame columns.

Examples

>>> int_values = [1, 2, 3, 4, 5]
>>> text_values = ['alpha', 'beta', 'gamma', 'delta', 'epsilon']
>>> float_values = [0.0, 0.25, 0.5, 0.75, 1.0]
>>> df = pd.DataFrame({'int_col': int_values, 'text_col': text_values, ...
"float_col": float_values})
>>> df
   int_col  text_col  float_col
0     1     alpha    0.00
1     2      beta    0.25
2     3    gamma    0.50
3     4     delta    0.75
4     5   epsilon    1.00

Prints information of all columns:

>>> df.info(verbose=True)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Data columns (total 3 columns):
   # Column    Non-Null Count  Dtype
   ---        -------------- -----
0  int_col    5 non-null     int64
1  text_col   5 non-null     object
2  float_col  5 non-null     float64
dtypes: float64(1), int64(1), object(1)
memory usage: 248.0+ bytes

Prints a summary of columns count and its dtypes but not per column information:

>>> df.info(verbose=False)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Columns: 3 entries, int_col to float_col
dtypes: float64(1), int64(1), object(1)
memory usage: 248.0+ bytes

Pipe output of DataFrame.info to buffer instead of sys.stdout, get buffer content and writes to a text file:
The `memory_usage` parameter allows deep introspection mode, specially useful for big DataFrames and fine-tune memory optimization:

```python
>>> random_strings_array = np.random.choice(['a', 'b', 'c'], 10 ** 6)
>>> df = pd.DataFrame(
    ... 'column_1': np.random.choice(['a', 'b', 'c'], 10 ** 6),
    ... 'column_2': np.random.choice(['a', 'b', 'c'], 10 ** 6),
    ... 'column_3': np.random.choice(['a', 'b', 'c'], 10 ** 6)
    ...
)
>>> df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
# Column    Non-Null Count   Dtype
--- ------ -------------- ----- 
0 column_1  1000000 non-null object
1 column_2  1000000 non-null object
2 column_3  1000000 non-null object
dtypes: object(3)
memory usage: 22.9+ MB

>>> df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
# Column    Non-Null Count   Dtype
--- ------ -------------- ----- 
0 column_1  1000000 non-null object
1 column_2  1000000 non-null object
2 column_3  1000000 non-null object
dtypes: object(3)
memory usage: 188.8 MB
```

### `DataFrame.insert`

DataFrame.insert(loc, column, value, allow_duplicates=False)

Insert column into DataFrame at specified location.

Raises a ValueError if column is already contained in the DataFrame, unless allow_duplicates is set to True.

**Parameters**

- **loc** [int] Insertion index. Must verify 0 <= loc <= len(columns).
- **column** [str, number, or hashable object] Label of the inserted column.
- **value** [int, Series, or array-like]
allow_duplicates [bool, optional]

pandas.DataFrame.interpolate

Dataframe.interpolate(method='linear', axis=0, limit=None, inplace=False, limit_direction=None, limit_area=None, downcast=None, **kwargs)

Please note that only method='linear' is supported for DataFrame/Series with a MultiIndex.

Parameters

method [str, default ‘linear’] Interpolation technique to use. One of:

• ‘linear’: Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
• ‘time’: Works on daily and higher resolution data to interpolate given length of interval.
• ‘index’, ‘values’: use the actual numerical values of the index.
• ‘pad’: Fill in NaNs using existing values.
• ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘spline’, ‘barycentric’, ‘polynomial’. Passed to scipy.interpolate.interp1d. These methods use the numerical values of the index. Both ‘polynomial’ and ‘spline’ require that you also specify an order (int), e.g. df.interpolate(method='polynomial', order=5).
• ‘from_derivatives’: Refers to scipy.interpolate.BPoly.from_derivatives which replaces ‘piecewise_polynomial’ interpolation method in scipy 0.18.

axis [{0 or ‘index’, 1 or ‘columns’, None}, default None] Axis to interpolate along.

limit [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

inplace [bool, default False] Update the data in place if possible.

limit_direction [{‘forward’, ‘backward’, ‘both’}], Optional] Consecutive NaNs will be filled in this direction.

If limit is specified:

• If ‘method’ is ‘pad’ or ‘ffill’, ‘limit_direction’ must be ‘forward’.
• If ‘method’ is ‘backfill’ or ‘bfill’, ‘limit_direction’ must be ‘backwards’.

If ‘limit’ is not specified:

• If ‘method’ is ‘backfill’ or ‘bfill’, the default is ‘backward’
• else the default is ‘forward’

Changed in version 1.1.0: raises ValueError if limit_direction is ‘forward’ or ‘both’ and method is ‘backfill’ or ‘bfill’, raises ValueError if limit_direction is ‘backward’ or ‘both’ and method is ‘pad’ or ‘ffill’.

limit_area [{None, ‘inside’, ‘outside’}], default None] If limit is specified, consecutive NaNs will be filled with this restriction.

• None: No fill restriction.
• ‘inside’: Only fill NaNs surrounded by valid values (interpolate).
• ‘outside’: Only fill NaNs outside valid values (extrapolate).

New in version 0.23.0.

downcast  [optional, ‘infer’ or None, defaults to None] Downcast dtypes if possible.

**kwargs  Keyword arguments to pass on to the interpolating function.

Returns

Series or DataFrame  Returns the same object type as the caller, interpolated at some or all NaN values.

See also:

fillna  Fill missing values using different methods.

scipy.interpolate.Akima1DInterpolator  Piecewise cubic polynomials (Akima interpolator).

scipy.interpolate.BPoly.from_derivatives  Piecewise polynomial in the Bernstein basis.

scipy.interpolate.interp1d  Interpolate a 1-D function.

scipy.interpolate.KroghInterpolator  Interpolate polynomial (Krogh interpolator).

scipy.interpolate.PchipInterpolator  PCHIP 1-d monotonic cubic interpolation.

scipy.interpolate.CubicSpline  Cubic spline data interpolator.

Notes

The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the SciPy documentation and SciPy tutorial.

Examples

Filling in NaN in a Series via linear interpolation.

```python
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0  0.0
1  1.0
2  NaN
3  3.0
dtype: float64

>>> s.interpolate()
0  0.0
1  1.0
2  2.0
3  3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.
Filling in NaN in a Series via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an order (int).

```
>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0     0.000000
1     2.000000
2     4.666667
3     8.000000
dtype: float64
```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it to use for interpolation.

```
>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
...                     (np.nan, 2.0, np.nan, np.nan),
...                     (2.0, 3.0, np.nan, 9.0),
...                     (np.nan, 4.0, -4.0, 16.0)],
...                    columns=list('abcd'))
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
0   NaN  -1.0   1.0
1  2.0     NaN     NaN
2  3.0     NaN    9.0
3  4.0    -4.0   16.0
```
Using polynomial interpolation.

```python
In [1]: df['d'].interpolate(method='polynomial', order=2)
Out[1]:
   0  1.0
   1  4.0
   2  9.0
   3 16.0
```

### pandas.DataFrame.isin

DataFrame.isin(values)

Whether each element in the DataFrame is contained in values.

**Parameters**

- `values` [iterable, Series, DataFrame or dict] The result will only be true at a location if all the labels match. If `values` is a Series, that’s the index. If `values` is a dict, the keys must be the column names, which must match. If `values` is a DataFrame, then both the index and column labels must match.

**Returns**

Dataframe Dataframe of booleans showing whether each element in the DataFrame is contained in values.

**See also:**

- DataFrame.eq Equality test for DataFrame.
- Series.isin Equivalent method on Series.
- Series.str.contains Test if pattern or regex is contained within a string of a Series or Index.

**Examples**

```python
In [2]: df = pd.DataFrame({'num_legs': [2, 4], 'num_wings': [2, 0]},
                    index=['falcon', 'dog'])
In [3]: df
   num_legs num_wings
  falcon    2        2
  dog       4        0

In [4]: df.isin([0, 2])
   num_legs num_wings
  falcon  True     True
  dog    False     True
```

When `values` is a list check whether every value in the DataFrame is present in the list (which animals have 0 or 2 legs or wings)

When `values` is a dict, we can pass values to check for each column separately:
pandas: powerful Python data analysis toolkit, Release 1.1.1

```python
>>> df.isin({'num_wings': [0, 3]})
  num_legs num_wings
falcon  False  False
dog  False  True
```

When `values` is a Series or DataFrame the index and column must match. Note that ‘falcon’ does not match based on the number of legs in df2.

```python
>>> other = pd.DataFrame({'num_legs': [8, 2], 'num_wings': [0, 2]},
                      index=['spider', 'falcon'])
>>> df.isin(other)
  num_legs num_wings
falcon  True  True
dog  False  False
```

### pandas.DataFrame.isna

DataFrame.isna()

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or `numpy.NaN`, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

**Returns**

DataFrame Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

**See also:**

- `DataFrame.isnull` Alias of isna.
- `DataFrame.notna` Boolean inverse of isna.
- `DataFrame.dropna` Omit axes labels with missing values.
- `isna` Top-level isna.

#### Examples

Show which entries in a DataFrame are NA.

```python
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                     'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                     'name': ['Alfred', 'Batman', ''],
...                     'toy': [None, 'Batmobile', 'Joker']})
>>> df
   age  born     name  toy
0  5.0  NaT  Alfred  None
1 6.0 1939-05-27  Batman Batmobile
2  NaT 1940-04-25  Joker
```
Show which entries in a Series are NA.

```
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0   5.0
1   6.0
2   NaN
dtype: float64
```

```
>>> ser.isna()
0  False
1  False
2   True
dtype: bool
```

**pandas.DataFrame.isnull**

DataFrame.isnull()  
Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy.nan, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

**Returns**

- DataFrame: Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

**See also:**

- DataFrame.isnull: Alias of isna.
- DataFrame.notna: Boolean inverse of isna.
- DataFrame.dropna: Omit axes labels with missing values.
- isna: Top-level isna.

**Examples**

Show which entries in a DataFrame are NA.

```
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                     'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                              pd.Timestamp('1940-04-25')],
...                     'name': ['Alfred', 'Batman', ''],
...                     'toy': [None, 'Batmobile', 'Joker']})
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.1.1

```python
>>> df.isna()
   age   born  name  toy
0  False  True  False  True
1  False  False  False  False
2   True  False  False  False
```

Show which entries in a Series are NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0  5.0
1  6.0
2  NaN
dtype: float64

>>> ser.isna()
0  False
1  False
2   True
dtype: bool
```

pandas.DataFrame.items

DataFrame.items()

Iterate over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

Yields

- **label** [object] The column names for the DataFrame being iterated over.
- **content** [Series] The column entries belonging to each label, as a Series.

See also:

- **DataFrame.iterrows** Iterate over DataFrame rows as (index, Series) pairs.
- **DataFrame.itertuples** Iterate over DataFrame rows as namedtuples of the values.

Examples

```python
>>> df = pd.DataFrame({'species': ['bear', 'bear', 'marsupial'],
...                    'population': [1864, 22000, 80000],
...                    'index': ['panda', 'polar', 'koala']})
>>> df
      species population
panda  bear     1864
polar bear    22000
```

(continues on next page)
koala marsupial 80000
>>> for label, content in df.items():
...     print(f'label: {label!r}')
...     print(f'content: {content!r}', sep='\n')
...     label: species
     content:
panda bear
polar bear
koala marsupial
Name: species, dtype: object
label: population
content:
panda 1864
polar 22000
koala 80000
Name: population, dtype: int64

pandas.DataFrame.items

DataFrame.items() Iterate over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

Yields

label [object] The column names for the DataFrame being iterated over.
content [Series] The column entries belonging to each label, as a Series.

See also:

DataFrame.iterrows Iterate over DataFrame rows as (index, Series) pairs.
DataFrame.itertuples Iterate over DataFrame rows as namedtuples of the values.

Examples

>>> df = pd.DataFrame({'species': ['bear', 'bear', 'marsupial'],
...                     'population': [1864, 22000, 80000]},
...                     index=['panda', 'polar', 'koala'])
>>> df
    species      population
panda    bear          1864
polar    bear          22000
koala    marsupial     80000

>>> for label, content in df.items():
...     print(f'label: {label!r}')
...     print(f'content: {content!r}', sep='\n')
...     label: species
     content:
panda    bear
polar    bear
(continues on next page)
pandas.DataFrame.iterrows

DataFrame.iterrows()
Iterate over DataFrame rows as (index, Series) pairs.

Yields

index [label or tuple of label] The index of the row. A tuple for a MultiIndex.
data [Series] The data of the row as a Series.
it [generator] A generator that iterates over the rows of the frame.

See also:

DataFrame.itertuples Iterate over DataFrame rows as namedtuples of the values.
DataFrame.items Iterate over (column name, Series) pairs.

Notes

1. Because iterrows returns a Series for each row, it does not preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```python
>>> df = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])
>>> row = next(df.iterrows())[1]
>>> row
int 1.0
float 1.5
Name: 0, dtype: float64
>>> print(row['int'].dtype)
float64
>>> print(df['int'].dtype)
int64
```

To preserve dtypes while iterating over the rows, it is better to use itertuples() which returns namedtuples of the values and which is generally faster than iterrows.

2. You should never modify something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect.
pandas.DataFrame.itertuples

DataFrame.itertuples (index=True, name='Pandas')
Iterate over DataFrame rows as namedtuples.

Parameters

- **index** [bool, default True] If True, return the index as the first element of the tuple.
- **name** [str or None, default “Pandas”] The name of the returned namedtuples or None to return regular tuples.

Returns

- **iterator** An object to iterate over namedtuples for each row in the DataFrame with the first field possibly being the index and following fields being the column values.

See also:

- **DataFrame.iterrows** Iterate over DataFrame rows as (index, Series) pairs.
- **DataFrame.items** Iterate over (column name, Series) pairs.

Notes

The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. On python versions < 3.7 regular tuples are returned for DataFrames with a large number of columns (>254).

Examples

```python
>>> df = pd.DataFrame({'num_legs': [4, 2], 'num_wings': [0, 2]},
                   index=['dog', 'hawk'])
>>> df
   num_legs  num_wings
dog       4          0
hawk      2          2
```

```python
>>> for row in df.itertuples():
...    print(row)
...Pandas(Index='dog', num_legs=4, num_wings=0)
Pandas(Index='hawk', num_legs=2, num_wings=2)
```

By setting the `index` parameter to False we can remove the index as the first element of the tuple:

```python
>>> for row in df.itertuples(index=False):
...    print(row)
...Pandas(num_legs=4, num_wings=0)
Pandas(num_legs=2, num_wings=2)
```

With the `name` parameter set we set a custom name for the yielded namedtuples:

```python
>>> for row in df.itertuples(name='Animal'):
...    print(row)
...```

(continues on next page)
pandas.DataFrame.join

DataFrame.join(other, on=None, how='left', lsuffix='', rsuffix='', sort=False)

Join columns of another DataFrame.

Join columns with other DataFrame either on index or on a key column. Efficiently join multiple DataFrame objects by index at once by passing a list.

Parameters

- **other** [DataFrame, Series, or list of DataFrame] Index should be similar to one of the columns in this one. If a Series is passed, its name attribute must be set, and that will be used as the column name in the resulting joined DataFrame.

- **on** [str, list of str, or array-like, optional] Column or index level name(s) in the caller to join on the index in other, otherwise joins index-on-index. If multiple values given, the other DataFrame must have a MultiIndex. Can pass an array as the join key if it is not already contained in the calling DataFrame. Like an Excel VLOOKUP operation.

- **how** [{‘left’, ‘right’, ‘outer’, ‘inner’}, default ‘left’] How to handle the operation of the two objects.

  - left: use calling frame’s index (or column if on is specified)
  - right: use other’s index.
  - outer: form union of calling frame’s index (or column if on is specified) with other’s index, and sort it lexicographically.
  - inner: form intersection of calling frame’s index (or column if on is specified) with other’s index, preserving the order of the calling’s one.

- **lsuffix** [str, default ‘’] Suffix to use from left frame’s overlapping columns.

- **rsuffix** [str, default ‘’] Suffix to use from right frame’s overlapping columns.

- **sort** [bool, default False] Order result DataFrame lexicographically by the join key. If False, the order of the join key depends on the join type (how keyword).

Returns

DataFrame A dataframe containing columns from both the caller and other.

See also:

- **DataFrame.merge** For column(s)-on-column(s) operations.
Notes

Parameters `on`, `lsuffix`, and `rsuffix` are not supported when passing a list of `DataFrame` objects.
Support for specifying index levels as the `on` parameter was added in version 0.23.0.

Examples

```python
>>> df = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3', 'K4', 'K5'],
                    'A': ['A0', 'A1', 'A2', 'A3', 'A4', 'A5']})
>>> df
   key  A
0   K0  A0
1   K1  A1
2   K2  A2
3   K3  A3
4   K4  A4
5   K5  A5

>>> other = pd.DataFrame({'key': ['K0', 'K1', 'K2'],
                         'B': ['B0', 'B1', 'B2']})
>>> other
   key  B
0   K0  B0
1   K1  B1
2   K2  B2

Join DataFrames using their indexes.

```python
>>> df.join(other, lsuffix='_caller', rsuffix='_other')
   key_caller  A  key_other  B
0    K0    A0    K0  B0
1    K1    A1    K1  B1
2    K2    A2    K2  B2
3    K3    A3  NaN  NaN
4    K4    A4  NaN  NaN
5    K5    A5  NaN  NaN
```

If we want to join using the key columns, we need to set key to be the index in both `df` and `other`. The joined DataFrame will have key as its index.

```python
>>> df.set_index('key').join(other.set_index('key'))
      A  B
key
K0  A0  B0
K1  A1  B1
K2  A2  B2
K3  A3  NaN
K4  A4  NaN
K5  A5  NaN
```

Another option to join using the key columns is to use the `on` parameter. DataFrame.join always uses `other`'s index but we can use any column in `df`. This method preserves the original DataFrame's index in the result.

```python
>>> df.join(other, on='key')
      A  B
key
K0  A0  B0
K1  A1  B1
K2  A2  B2
K3  A3  NaN
K4  A4  NaN
K5  A5  NaN
```
>>> df.join(other.set_index('key'), on='key')
key  A  B
0  K0  A0  B0
1  K1  A1  B1
2  K2  A2  B2
3  K3  A3  NaN
4  K4  A4  NaN
5  K5  A5  NaN

pandas.DataFrame.keys

DataFrame.keys()

Get the ‘info axis’ (see Indexing for more).

This is index for Series, columns for DataFrame.

Returns

Index  Info axis.

pandas.DataFrame.kurt

DataFrame.kurt(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis  [[index (0), columns (1)]] Axis for the function to be applied on.

skipna  [bool, default True] Exclude NA/null values when computing the result.

level  [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only  [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs  Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.kurtosis

DataFrame.kurtosis(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

Parameters

axis  [[index (0), columns (1)]] Axis for the function to be applied on.

skipna  [bool, default True] Exclude NA/null values when computing the result.
**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs** Additional keyword arguments to be passed to the function.

**Returns**

Series or DataFrame (if level specified)

---

**pandas.DataFrame.last**

**DataFrame.last**(offset)

Select final periods of time series data based on a date offset.

When having a DataFrame with dates as index, this function can select the last few rows based on a date offset.

**Parameters**

offset [str, DateOffset, dateutil.relativedelta] The offset length of the data that will be selected. For instance, ‘3D’ will display all the rows having their index within the last 3 days.

**Returns**

Series or DataFrame A subset of the caller.

**Raises**

TypeError If the index is not a DatetimeIndex

**See also:**

first Select initial periods of time series based on a date offset.
at_time Select values at a particular time of the day.
between_time Select values between particular times of the day.

**Examples**

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
A
2018-04-09 1
2018-04-11 2
2018-04-13 3
2018-04-15 4

Get the rows for the last 3 days:

```python
>>> ts.last('3D')
A
2018-04-13 3
2018-04-15 4
```
Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

**pandas.DataFrame.last_valid_index**

Dataframe.last_valid_index()  
Return index for last non-NA/null value.

**Returns**

scalar [type of index]

**Notes**

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

**pandas.DataFrame.le**

Dataframe.le(other, axis='columns', level=None)  
Get Less than or equal to of dataframe and other, element-wise (binary operator le).

Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.

Equivalent to ==, !=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

**Parameters**

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or ‘index’, 1 or ‘columns’}, default ‘columns’] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’).

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

DataFrame of bool  Result of the comparison.

See also:

- DataFrame.eq  Compare DataFrames for equality elementwise.
- DataFrame.ne  Compare DataFrames for inequality elementwise.
- DataFrame.le  Compare DataFrames for less than inequality or equality elementwise.
- DataFrame.lt  Compare DataFrames for strictly less than inequality elementwise.
- DataFrame.ge  Compare DataFrames for greater than inequality or equality elementwise.
- DataFrame.gt  Compare DataFrames for strictly greater than inequality elementwise.
Notes

Mismatched indices will be unioned together. NaN values are considered different (i.e. NaN != NaN).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
                    'revenue': [100, 250, 300]},
                    index=['A', 'B', 'C'])
>>> df
   cost revenue
A   250    100
B   150    250
C   100    300

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
   cost  revenue
A  False  True
B  False  False
C  True  False
```

```python
>>> df.eq(100)
   cost  revenue
A  False  True
B  False  False
C  True  False
```

When `other` is a `Series`, the columns of a DataFrame are aligned with the index of `other` and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
   cost  revenue
A  True  True
B  True  False
C  False  True
```

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
   cost  revenue
A  True  False
B  True  True
C  True  True
D  True  True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```python
>>> df == [250, 100]
   cost  revenue
A  True  True
B  False  False
C  False  False
```

Use the method to control the axis:
>>> df.eq([250, 250, 100], axis='index')
    cost  revenue
   A    True   False
   B   False    True
   C    True   False

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                       index=['A', 'B', 'C', 'D'])
>>> other
     revenue
    A    300
    B    250
    C    100
    D    150
```

```python
>>> df.gt(other)
    cost  revenue
   A   False   False
   B   False   False
   C   False    True
   D   False   False
```

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
                               'revenue': [100, 250, 300, 200, 175, 225],
                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
                                      ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
     cost  revenue
    Q1   A    250    100
          B    150    250
          C    100    300
    Q2   A    150    200
          B    300    175
          C    220    225
```

```python
>>> df.le(df_multindex, level=1)
    cost  revenue
   Q1   A    True    True
       B    True    True
       C    True    True
   Q2   A   False    True
       B    True   False
       C    True   False
```
### pandas.DataFrame.lookup

**DataFrame.lookup**(row_labels, col_labels)

Label-based “fancy indexing” function for DataFrame.

Given equal-length arrays of row and column labels, return an array of the values corresponding to each (row, col) pair.

**Parameters**

- row_labels [sequence] The row labels to use for lookup.
- col_labels [sequence] The column labels to use for lookup.

**Returns**

- numpy.ndarray The found values.

### pandas.DataFrame.lt

**DataFrame.lt**(other, axis='columns', level=None)

Get Less than of dataframe and other, element-wise (binary operator lt).

Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.

Equivalent to ==, !=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

**Parameters**

- other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- axis [{0 or ‘index’, 1 or ‘columns’}, default ‘columns’] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’).
- level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

- DataFrame of bool Result of the comparison.

**See also:**

- **DataFrame.eq** Compare DataFrames for equality elementwise.
- **DataFrame.ne** Compare DataFrames for inequality elementwise.
- **DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.
- **DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.
- **DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.
- **DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.
Notes

Mismatched indices will be unioned together. NaN values are considered different (i.e. NaN != NaN).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],  
                     'revenue': [100, 250, 300]},  
                     index=['A', 'B', 'C'])

>>> df
   cost  revenue
A  250     100
B  150     250
C  100     300

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
   cost  revenue
A   False    True
B   False    False
C    True    False
```  

```python
>>> df.eq(100)
   cost  revenue
A   False    True
B   False    False
C    True    False
```  

When `other` is a `Series`, the columns of a DataFrame are aligned with the index of `other` and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
   cost  revenue
A   True    True
B   True    False
C  False    True

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
   cost  revenue
A   True    False
B   True    True
C  True     True
D   True    True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```python
>>> df == [250, 100]
   cost  revenue
A   True    True
B  False    False
C  False    False
```

Use the method to control the axis:
```python
>>> df.eq([250, 250, 100], axis='index')
   cost  revenue
  A    True   False
  B   False    True
  C    True   False

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                        index=['A', 'B', 'C', 'D'])
>>> other
     revenue
  A      300
  B      250
  C      100
  D      150

```python
>>> df.gt(other)
   cost  revenue
  A  False  False
  B  False  False
  C  False    True
  D  False  False

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
                               'revenue': [100, 250, 300, 200, 175, 225],
                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
                                      ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
     cost  revenue
  Q1 A   250    100
    B  150    250
    C  100    300
  Q2 A   150    200
    B  300    175
    C  220    225

```python
>>> df.le(df_multindex, level=1)
   cost  revenue
  Q1 A   True    True
    B   True    True
    C   True    True
  Q2 A  False    True
    B   True  False
    C   True  False
```
**pandas.DataFrame.mad**

DataFrame.mad(axis=None, skipna=None, level=None)

Return the mean absolute deviation of the values for the requested axis.

**Parameters**

- **axis** [{index (0), columns (1)}] Axis for the function to be applied on.
- **skipna** [bool, default None] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**Returns**

Series or DataFrame (if level specified)

**pandas.DataFrame.mask**

DataFrame.mask(cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False)

Replace values where the condition is True.

**Parameters**

- **cond** [bool Series/DataFrame, array-like, or callable] Where cond is False, keep the original value. Where True, replace with corresponding value from other. If cond is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn’t check it).
- **other** [scalar, Series/DataFrame, or callable] Entries where cond is True are replaced with corresponding value from other. If other is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn’t check it).
- **inplace** [bool, default False] Whether to perform the operation in place on the data.
- **axis** [int, default None] Alignment axis if needed.
- **level** [int, default None] Alignment level if needed.
- **errors** [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.
  - ‘raise’: allow exceptions to be raised.
  - ‘ignore’: suppress exceptions. On error return original object.
- **try_cast** [bool, default False] Try to cast the result back to the input type (if possible).

**Returns**

Same type as caller

**See also:**

DataFrame.where() Return an object of same shape as self.
Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if \texttt{cond} is \texttt{False} the element is used; otherwise the corresponding element from the DataFrame \texttt{other} is used.

The signature for \texttt{DataFrame.where()} differs from \texttt{numpy.where()}. Roughly \texttt{df1.where(m, df2)} is equivalent to \texttt{np.where(m, df1, df2)}.

For further details and examples see the \texttt{mask} documentation in \texttt{indexing}.

Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0 NaN
1 1.0
2 2.0
3 3.0
4 4.0
dtype: float64
```

```python
>>> s.mask(s > 0)
0 0.0
1 NaN
2 NaN
3 NaN
4 NaN
dtype: float64
```

```python
>>> s.where(s > 1, 10)
0 10
1 10
2 2
3 3
4 4
dtype: int64
```

```python
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
        A   B
0      0   1
1      2   3
2      4   5
3      6   7
4      8   9
```

```python
>>> m = df % 3 == 0
>>> df.where(m, -df)
        A   B
0     -1   1
1      2  -3
2     -4  -5
3      6  -7
4     -8   9
```

```python
>>> df.where(m, -df) == np.where(m, df, -df)
```

(continues on next page)
**`pandas.DataFrame.max`**

`DataFrame.max` *(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)*

Return the maximum of the values for the requested axis.

If you want the index of the maximum, use `idxmax`. This is the equivalent of the `numpy.ndarray` method `argmax`.

**Parameters**

- **axis** [index (0), columns (1)] Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- ****kwargs** Additional keyword arguments to be passed to the function.

**Returns**

Series or DataFrame (if level specified)

**See also:**

- `Series.sum` Return the sum.
- `Series.min` Return the minimum.
- `Series.max` Return the maximum.
- `Series.idxmin` Return the index of the minimum.
- `Series.idxmax` Return the index of the maximum.
- `DataFrame.sum` Return the sum over the requested axis.
- `DataFrame.min` Return the minimum over the requested axis.
- `DataFrame.max` Return the maximum over the requested axis.
- `DataFrame.idxmin` Return the index of the minimum over the requested axis.
- `DataFrame.idxmax` Return the index of the maximum over the requested axis.
Examples

```python
>>> idx = pd.MultiIndex.from_arrays([['warm', 'warm', 'cold', 'cold'],
...                         ['dog', 'falcon', 'fish', 'spider'],
...                         names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded    animal
  warm    dog  4
   falcon  2
  cold    fish  0
   spider  8
Name: legs, dtype: int64

>>> s.max()
8

Max using level names, as well as indices.

>>> s.max(level='blooded')
blooded
  warm  4
  cold  8
Name: legs, dtype: int64

>>> s.max(level=0)
blooded
  warm  4
  cold  8
Name: legs, dtype: int64

pandas.DataFrame.mean

DataFrame.mean (axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
Return the mean of the values for the requested axis.

Parameters

axis         [{index (0), columns (1)}] Axis for the function to be applied on.
skipna       [bool, default True] Exclude NA/null values when computing the result.
level         [int or level name, default None] If the axis is a MultiIndex (hierarchical), count
              along a particular level, collapsing into a Series.
numeric_only  [bool, default None] Include only float, int, boolean columns. If None,
              will attempt to use everything, then use only numeric data. Not implemented for
              Series.
**kwargs Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)
pandas.DataFrame.median

DataFrame.median (axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return the median of the values for the requested axis.

Parameters

axis [{index (0), columns (1)}] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.DataFrame.melt

DataFrame.melt (id_vars=None, value_vars=None, var_name=None, value_name='value', col_level=None, ignore_index=True)

Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (id_vars), while all other columns, considered measured variables (value_vars), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’.

New in version 0.20.0.

Parameters

id_vars [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.

value_vars [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as id_vars.

var_name [scalar] Name to use for the ‘variable’ column. If None it uses frame.columns.name or ‘variable’.

value_name [scalar, default ‘value’] Name to use for the ‘value’ column.

col_level [int or str, optional] If columns are a MultiIndex then use this level to melt.

ignore_index [bool, default True] If True, original index is ignored. If False, the original index is retained. Index labels will be repeated as necessary.

New in version 1.1.0.

Returns

DataFrame Unpivoted DataFrame.

See also:

melt Identical method.

pivot_table Create a spreadsheet-style pivot table as a DataFrame.
**DataFrame.pivot** Return reshaped DataFrame organized by given index / column values.

**DataFrame.explode** Explode a DataFrame from list-like columns to long format.

### Examples

```python
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
                      'B': {0: 1, 1: 3, 2: 5},
                      'C': {0: 2, 1: 4, 2: 6}})
```

```plaintext
A   B   C  
0   a   1   2  
1   b   3   4  
2   c   5   6  
```

```python
>>> df.melt(id_vars=['A'], value_vars=['B'])
```

```plaintext
A  variable  value
0   a         B  1  
1   b         B  3  
2   c         B  5  
```

```python
>>> df.melt(id_vars=['A'], value_vars=['B', 'C'])
```

```plaintext
A  variable  value
0   a         B  1  
1   b         B  3  
2   c         B  5  
3   a         C  2  
4   b         C  4  
5   c         C  6  
```

The names of ‘variable’ and ‘value’ columns can be customized:

```python
>>> df.melt(id_vars=['A'], value_vars=['B', 'C'], var_name='myVarname', value_name='myValname')
```

```plaintext
A  myVarname  myValname
0   a         B  1  
1   b         B  3  
2   c         B  5  
```

Original index values can be kept around:

```python
>>> df.melt(id_vars=['A'], value_vars=['B', 'C'], ignore_index=False)
```

```plaintext
A  variable  value
0   a         B  1  
1   b         B  3  
2   c         B  5  
0   a         C  2  
1   b         C  4  
2   c         C  6  
```

If you have multi-index columns:

```python
>>> df.columns = [list('ABC'), list('DEF')]
```

```plaintext
A   B   C     
D   E   F
```

(continues on next page)
pandas.DataFrame.memory_usage

DataFrame memory_usage(index=True, deep=False)

Return the memory usage of each column in bytes.

The memory usage can optionally include the contribution of the index and elements of object dtype.

This value is displayed in DataFrame.info by default. This can be suppressed by setting pandas.options.display.memory_usage to False.

Parameters

- **index** [bool, default True] Specifies whether to include the memory usage of the DataFrame's index in returned Series. If index=True, the memory usage of the index is the first item in the output.

- **deep** [bool, default False] If True, introspect the data deeply by interrogating object dtypes for system-level memory consumption, and include it in the returned values.

Returns

Series A Series whose index is the original column names and whose values is the memory usage of each column in bytes.

See also:

- **numpy.ndarray.nbytes** Total bytes consumed by the elements of an ndarray.

- **Series.memory_usage** Bytes consumed by a Series.

- **Categorical** Memory-efficient array for string values with many repeated values.

- **DataFrame.info** Concise summary of a DataFrame.
Examples

```python
>>> dtypes = ['int64', 'float64', 'complex128', 'object', 'bool']
>>> data = dict([(t, np.ones(shape=5000).astype(t))
...               for t in dtypes])
>>> df = pd.DataFrame(data)
>>> df.head()
           int64  float64  complex128  object  bool
0         1.0     1.00 1.000000+0.000000j   1.0  True
1         1.0     1.00 1.000000+0.000000j   1.0  True
2         1.0     1.00 1.000000+0.000000j   1.0  True
3         1.0     1.00 1.000000+0.000000j   1.0  True
4         1.0     1.00 1.000000+0.000000j   1.0  True

>>> df.memory_usage()
Index 128
int64 40000
float64 40000
complex128 80000
object 40000
bool 5000
dtype: int64

>>> df.memory_usage(index=False)
int64 40000
float64 40000
complex128 80000
object 40000
bool 5000
dtype: int64

The memory footprint of object dtype columns is ignored by default:

>>> df.memory_usage(deep=True)
Index 128
int64 40000
float64 40000
complex128 80000
object 160000
bool 5000
dtype: int64

Use a Categorical for efficient storage of an object-dtype column with many repeated values.

>>> df['object'].astype('category').memory_usage(deep=True)
5216
```
pandas.DataFrame.merge

DataFrame.merge(right, how='inner', on=None, left_on=None, right_on=None, left_index=False, right_index=False, sort=False, suffixes='_x', '_y', copy=True, indicator=False, validate=None)

Merge DataFrame or named Series objects with a database-style join.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes will be ignored. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on.

Parameters

right [DataFrame or named Series] Object to merge with.

how [{'left', 'right', 'outer', 'inner'}, default 'inner'] Type of merge to be performed.

• left: use only keys from left frame, similar to a SQL left outer join; preserve key order.
• right: use only keys from right frame, similar to a SQL right outer join; preserve key order.
• outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
• inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.

on [label or list] Column or index level names to join on. These must be found in both DataFrames. If on is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

left_on [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

right_on [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

left_index [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

right_index [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as left_index.

sort [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword).

suffixes [list-like, default is ("_x", "_y")]) A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in left and right respectively. Pass a value of None instead of a string to indicate that the column name from left or right should be left as-is, with no suffix. At least one of the values must not be None.

copy [bool, default True] If False, avoid copy if possible.

indicator [bool or str, default False] If True, adds a column to the output DataFrame called “_merge” with information on the source of each row. The column can be given a different name by providing a string argument. The column will have a
Categorical type with the value of “left_only” for observations whose merge key only appears in the left DataFrame, “right_only” for observations whose merge key only appears in the right DataFrame, and “both” if the observation’s merge key is found in both DataFrames.

**validate** [str, optional] If specified, checks if merge is of specified type.
- “one_to_one” or “1:1”: check if merge keys are unique in both left and right datasets.
- “one_to_many” or “1:m”: check if merge keys are unique in left dataset.
- “many_to_one” or “m:1”: check if merge keys are unique in right dataset.
- “many_to_many” or “m:m”: allowed, but does not result in checks.

**Returns**

**DataFrame** A DataFrame of the two merged objects.

**See also:**

- **merge_ordered** Merge with optional filling/interpolation.
- **merge_asof** Merge on nearest keys.
- **DataFrame.join** Similar method using indices.

**Notes**

Support for specifying index levels as the `on, left_on, and right_on` parameters was added in version 0.23.0
Support for merging named Series objects was added in version 0.24.0

**Examples**

```python
>>> df1 = pd.DataFrame({'lkey': ['foo', 'bar', 'baz', 'foo'],
                      'value': [1, 2, 3, 5])
>>> df2 = pd.DataFrame({'rkey': ['foo', 'bar', 'baz', 'foo'],
                      'value': [5, 6, 7, 8])
```

Merge `df1` and `df2` on the `lkey` and `rkey` columns. The value columns have the default suffixes, `_x` and `_y`, appended.

```python
>>> df1.merge(df2, left_on='lkey', right_on='rkey')
lkey  value_x  rkey  value_y
0   foo       1  foo       5
1   bar       2  bar       6
2   baz       3  baz       7
3   foo       5  foo       8
```

(continues on next page)
Merge DataFrames df1 and df2 with specified left and right suffixes appended to any overlapping columns.

```python
>>> df1.merge(df2, left_on='lkey', right_on='rkey',
... suffixes=('left', 'right'))
```

<table>
<thead>
<tr>
<th>lkey</th>
<th>value_left</th>
<th>rkey</th>
<th>value_right</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>foo</td>
<td>1</td>
<td>foo 5</td>
</tr>
<tr>
<td>1</td>
<td>foo</td>
<td>1</td>
<td>foo 8</td>
</tr>
<tr>
<td>2</td>
<td>foo</td>
<td>5</td>
<td>foo 5</td>
</tr>
<tr>
<td>3</td>
<td>foo</td>
<td>5</td>
<td>foo 8</td>
</tr>
<tr>
<td>4</td>
<td>bar</td>
<td>2</td>
<td>bar 6</td>
</tr>
<tr>
<td>5</td>
<td>baz</td>
<td>3</td>
<td>baz 7</td>
</tr>
</tbody>
</table>

Merge DataFrames df1 and df2, but raise an exception if the DataFrames have any overlapping columns.

```python
>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=(False, False))
```

Traceback (most recent call last):
... 
ValueError: columns overlap but no suffix specified:
Index(['value'], dtype='object')

**pandas.DataFrame.min**

DataFrame.min *(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)*

Return the minimum of the values for the requested axis.

If you want the index of the minimum, use idxmin. This is the equivalent of the numpy.ndarray method argmin.

**Parameters**

- **axis** *(index (0), columns (1))| Axis for the function to be applied on.*
- **skipna** *[bool, default True] Exclude NA/null values when computing the result.*
- **level** *[int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.*
- **numeric_only** *[bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.*

**Returns**

Series or DataFrame (if level specified)

**See also:**

- **Series.sum** Return the sum.
- **Series.min** Return the minimum.
**Series.max**  Return the maximum.

**Series.idxmin**  Return the index of the minimum.

**Series.idxmax**  Return the index of the maximum.

**DataFrame.sum**  Return the sum over the requested axis.

**DataFrame.min**  Return the minimum over the requested axis.

**DataFrame.max**  Return the maximum over the requested axis.

**DataFrame.idxmin**  Return the index of the minimum over the requested axis.

**DataFrame.idxmax**  Return the index of the maximum over the requested axis.

### Examples

```python
>>> idx = pd.MultiIndex.from_arrays([
    ... ['warm', 'warm', 'cold', 'cold'],
    ... ['dog', 'falcon', 'fish', 'spider'],
    ... names=['blooded', 'animal'])

>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)

>>> s
blooded  animal
  warm   dog  4
       falcon  2
  cold   fish  0
       spider  8
Name: legs, dtype: int64

>>> s.min()
0

Min using level names, as well as indices.

>>> s.min(level='blooded')
blooded
  warm   2
  cold   0
Name: legs, dtype: int64

>>> s.min(level=0)
blooded
  warm   2
  cold   0
Name: legs, dtype: int64
```
pandas.DataFrame.mod

DataFrame.mod(other, axis='columns', level=None, fill_value=None)

Get Modulo of dataframe and other, element-wise (binary operator mod).

Equivalent to dataframe % other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rmod.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

- **DataFrame.add** Add DataFrames.
- **DataFrame.sub** Subtract DataFrames.
- **DataFrame.mul** Multiply DataFrames.
- **DataFrame.div** Divide DataFrames (float division).
- **DataFrame.truediv** Divide DataFrames (float division).
- **DataFrame.floordiv** Divide DataFrames (integer division).
- **DataFrame.mod** Calculate modulo (remainder after division).
- **DataFrame.pow** Calculate exponential power.

Notes

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
```

```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0</td>
</tr>
<tr>
<td>triangle</td>
<td>3</td>
</tr>
<tr>
<td>rectangle</td>
<td>4</td>
</tr>
</tbody>
</table>
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```

```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
</tbody>
</table>
```

```python
>>> df.add(1)
```

```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
</tbody>
</table>
```

Divide by constant with reverse version.

```python
>>> df.div(10)
```

```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0</td>
</tr>
<tr>
<td>triangle</td>
<td>0.3</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.4</td>
</tr>
</tbody>
</table>
```

```python
>>> df.rdiv(10)
```

```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>inf</td>
</tr>
<tr>
<td>triangle</td>
<td>0.027778</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.027778</td>
</tr>
</tbody>
</table>
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
```

```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>
```

```python
>>> df.sub([1, 2], axis='columns')
```

```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
          axis='index')
```

(continues on next page)
Multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({'angles': [0, 3, 4]},
                     index=['circle', 'triangle', 'rectangle'])
```

```python
other
```

```
angles
circle 0
triangle 3
rectangle 4
```

```python
df * other
```

```
angles degrees
circle 0 NaN
triangle 9 NaN
rectangle 16 NaN
```

```python
df.mul(other, fill_value=0)
```

```
angles degrees
circle 0 0.0
triangle 9 0.0
rectangle 16 0.0
```

Divide by a MultiIndex by level.

```python
df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6], 'degrees': [360, 180, 360, 360, 540, 720]},
                            index=['A', 'A', 'A', 'B', 'B', 'B',
                                   'circle', 'triangle', 'rectangle',
                                   'square', 'pentagon', 'hexagon'])
```

```python
df_multindex
```

```
angles degrees
A circle 0 360
triangle 3 180
rectangle 4 360
B square 4 360
pentagon 5 540
hexagon 6 720
```

```python
df.div(df_multindex, level=1, fill_value=0)
```

```
angles degrees
A circle NaN 1.0
triangle 1.0 1.0
rectangle 1.0 1.0
B square 0.0 0.0
pentagon 0.0 0.0
hexagon 0.0 0.0
```
pandas.DataFrame.mode

DataFrame.mode (axis=0, numeric_only=False, dropna=True)
Get the mode(s) of each element along the selected axis.

The mode of a set of values is the value that appears most often. It can be multiple values.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to iterate over while searching for the mode:
- 0 or 'index' : get mode of each column
- 1 or 'columns' : get mode of each row.
numeric_only [bool, default False] If True, only apply to numeric columns.
dropna [bool, default True] Don’t consider counts of NaN/NaT.

New in version 0.24.0.

Returns

DataFrame The modes of each column or row.

See also:

Series.mode Return the highest frequency value in a Series.
Series.value_counts Return the counts of values in a Series.

Examples

```python
def = pd.DataFrame([('bird', 2, 2),
                     ('mammal', 4, np.nan),
                     ('arthropod', 8, 0),
                     ('bird', 2, np.nan)],
                    index=('falcon', 'horse', 'spider', 'ostrich'),
                    columns=('species', 'legs', 'wings'))
def.mode()
```

By default, missing values are not considered, and the mode of wings are both 0 and 2. The second row of species and legs contains NaN, because they have only one mode, but the DataFrame has two rows.

```python
def.mode(dropna=False)
```

Setting dropna=False NaN values are considered and they can be the mode (like for wings).
Setting `numeric_only=True`, only the mode of numeric columns is computed, and columns of other types are ignored.

```python
>>> df.mode(numeric_only=True)
   legs  wings
 0  2.0  0.0
 1  NaN  2.0
```

To compute the mode over columns and not rows, use the `axis` parameter:

```python
>>> df.mode(axis='columns', numeric_only=True)
     0  1
  falcon  2.0 NaN
  horse   4.0 NaN
  spider  0.0  8.0
 ostrich  2.0 NaN
```

**pandas.DataFrame.mul**

DataFrame.mul(other, axis='columns', level=None, fill_value=None)

Get Multiplication of dataframe and other, element-wise (binary operator mul).

Equivalent to `dataframe * other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `rmul`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame Result of the arithmetic operation.

**See also:**

- `DataFrame.add` Add DataFrames.
- `DataFrame.sub` Subtract DataFrames.
- `DataFrame.mul` Multiply DataFrames.
- `DataFrame.div` Divide DataFrames (float division).
- `DataFrame.truediv` Divide DataFrames (float division).
- `DataFrame.floordiv` Divide DataFrames (integer division).
- `DataFrame.mod` Calculate modulo (remainder after division).
**DataFrame.pow** Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

**Examples**

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```

```plaintext
angles  degrees
circle  1  361
triangle 4  181
rectangle 5  361
```

```python
>>> df.add(1)
```

```plaintext
angles  degrees
circle  1  361
triangle 4  181
rectangle 5  361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
```

```plaintext
angles  degrees
circle  0.0 36.0
triangle 0.3 18.0
rectangle 0.4 36.0
```

```python
>>> df.rdiv(10)
```

```plaintext
angles  degrees
circle   inf  0.027778
triangle 3.333333  0.055556
rectangle 2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
```

```plaintext
angles  degrees
circle   -1 358
triangle  2  178
rectangle 3  358
```
```python
>>> df.sub([1, 2], axis='columns')
   angles  degrees
circle   -1     358
triangle   2     178
rectangle   3     358

>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
         axis='index')
   angles  degrees
circle   -1     359
triangle   2     179
rectangle   3     359

Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4],
                       'degrees': [360, 180, 360],
                       index=['circle', 'triangle', 'rectangle'])

```python
>>> df * other
   angles  degrees
circle    0      NaN
triangle   9      NaN
rectangle 16      NaN

```python
>>> df.mul(other, fill_value=0)
   angles  degrees
circle    0      0.0
triangle   9      0.0
rectangle 16      0.0

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               index=['A', 'A', 'A', 'B', 'B', 'B'],
                               columns=['circle', 'triangle', 'rectangle',
                                        'square', 'pentagon', 'hexagon'])

>>> df_multindex
   angles  degrees
A circle   0     360
triangle   3     180
rectangle  4     360
B square   4     360
pentagon   5     540
hexagon    6     720

>>> df.div(df_multindex, level=1, fill_value=0)
   angles  degrees
A circle  NaN      1.0
triangle  1.0      1.0
rectangle 1.0      1.0
```
(continues on next page)
pandas.DataFrame.multiply

DataFrame.multiply(other, axis='columns', level=None, fill_value=None)
Get Multiplication of dataframe and other, element-wise (binary operator mul).
Equivalent to dataframe * other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rmul.
Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters
- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [[0 or 'index', 1 or 'columns']] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns
- **DataFrame** Result of the arithmetic operation.

See also:
- DataFrame.add Add DataFrames.
- DataFrame.sub Subtract DataFrames.
- DataFrame.mul Multiply DataFrames.
- DataFrame.div Divide DataFrames (float division).
- DataFrame.truediv Divide DataFrames (float division).
- DataFrame.floordiv Divide DataFrames (integer division).
- DataFrame.mod Calculate modulo (remainder after division).
- DataFrame.pow Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                   'degrees': [360, 180, 360],
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
         angles  degrees
    circle     0       360
   triangle    3       180
  rectangle    4       360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
         angles  degrees
    circle     1       361
   triangle    4       181
  rectangle    5       361

```python
>>> df.add(1)
         angles  degrees
    circle     1       361
   triangle    4       181
  rectangle    5       361

Divide by constant with reverse version.

```python
>>> df.div(10)
         angles  degrees
    circle   0.0     36.0
   triangle  0.3     18.0
  rectangle  0.4     36.0

```python
>>> df.rdiv(10)
         angles  degrees
    circle  inf     0.027778
   triangle  3.333333  0.055556
  rectangle  2.500000  0.027778

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
         angles  degrees
    circle   -1     358
   triangle    2     178
  rectangle    3     358

>>> df.sub([1, 2], axis='columns')
         angles  degrees
    circle   -1     358
   triangle    2     178
  rectangle    3     358
```
Multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({'angles': [0, 3, 4]},
                     index=['circle', 'triangle', 'rectangle'])
other
```

```plaintext
angles
circle 0
triangle 3
rectangle 4
```

```python
df + other
```

```plaintext
angles degrees
circle 0 NaN
triangle 9 NaN
rectangle 16 NaN
```

```python
df.mul(other, fill_value=0)
```

```plaintext
angles degrees
circle 0 0.0
triangle 9 0.0
rectangle 16 0.0
```

Divide by a MultiIndex by level.

```python
df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                              'degrees': [360, 180, 360, 360, 540, 720]},
                              index=[['A', 'A', 'A', 'B', 'B', 'B'],
                                     ['circle', 'triangle', 'rectangle',
                                    'square', 'pentagon', 'hexagon']])
```

```python
df_multindex
```

```plaintext
angles degrees
A circle 0 360
triangle 3 180
rectangle 4 360
B square 4 360
pentagon 5 540
hexagon 6 720
```

```python
df.div(df_multindex, level=1, fill_value=0)
```

```plaintext
angles degrees
A circle NaN 1.0
triangle 1.0 1.0
rectangle 1.0 1.0
B square 0.0 0.0
pentagon 0.0 0.0
hexagon 0.0 0.0
```
pandas.DataFrame.ne

DataFrame.ne (other, axis='columns', level=None)
Get Not equal to of dataframe and other, element-wise (binary operator ne).

Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.
Equivalent to ==, !=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis [[0 or `index`, 1 or `columns`], default `columns`] Whether to compare by the index (0 or `index`) or columns (1 or `columns`).
level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.
DataFrame.ne Compare DataFrames for inequality elementwise.
DataFrame.le Compare DataFrames for less than inequality or equality elementwise.
DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.
DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.
DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. NaN values are considered different (i.e. NaN != NaN).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                    'revenue': [100, 250, 300]},
...                   index=['A', 'B', 'C'])
>>> df
     cost  revenue
    A  250     100
    B  150     250
    C  100     300
```

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
     cost  revenue
    A   False    True
    B    True    False
    C    True    True
```
When `other` is a `Series`, the columns of a DataFrame are aligned with the index of `other` and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
cost  revenue
A     True   True
B     True   False
C     False  True
```

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
cost  revenue
A     True   False
B     True   True
C     True   True
D     True   True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```python
>>> df == [250, 100]
cost  revenue
A     True   True
B     False  False
C     False  False
```

Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
cost  revenue
A     True   False
B     False  True
C     True   False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150],
                        ...
                        index=['A', 'B', 'C', 'D'])
>>> other
revenue
A  300
B  250
C  100
D  150
```

```python
>>> df.gt(other)
cost  revenue
(continues on next page)
```
Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                            'revenue': [100, 250, 300, 200, 175, 225],
...                            index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                  ['A', 'B', 'C', 'A', 'B', 'C']])
```

```python
>>> df_multindex
   cost  revenue
Q1 A   250     100
   B   150     250
   C   100     300
Q2 A   150     200
   B   300     175
   C   220     225
```

```python
>>> df.le(df_multindex, level=1)
   cost  revenue
Q1 A   True    True
   B   True    True
   C   True    True
Q2 A   False   True
   B   True    False
   C   True    False
```

### `pandas.DataFrame.nlargest`

Dataframe.nlargest(n, columns, keep='first')

Return the first n rows ordered by columns in descending order.

Return the first n rows with the largest values in columns, in descending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to df.sort_values(columns, ascending=False).head(n), but more performant.

**Parameters**

- **n** [int] Number of rows to return.
- **columns** [label or list of labels] Column label(s) to order by.
- **keep** [{‘first’, ‘last’, ‘all’}, default ‘first’] Where there are duplicate values:
  - **first** : prioritize the first occurrence(s)
  - **last** : prioritize the last occurrence(s)
  - **all** [do not drop any duplicates, even it means] selecting more than n items.

**Returns**

- **DataFrame** The first n rows ordered by the given columns in descending order.
See also:

*DataFrame.nsmallest* Return the first $n$ rows ordered by columns in ascending order.

*DataFrame.sort_values* Sort DataFrame by the values.

*DataFrame.head* Return the first $n$ rows without re-ordering.

Notes

This function cannot be used with all column types. For example, when specifying columns with *object* or *category* dtypes, *TypeError* is raised.

Examples

```python
>>> df = pd.DataFrame({'population': [59000000, 65000000, 4340000, 4340000, 337000, 11300], 'GDP': [1937894, 2583560, 12011, 4520, 12128, 17036, 182, 38, 311], 'alpha-2': ['IT', 'FR', 'MT', 'MV', 'BN', 'IS', 'NR', 'TV', 'AI']}, index=['Italy', 'France', 'Malta', 'Maldives', 'Brunei', 'Iceland', 'Nauru', 'Tuvalu', 'Anguilla'])
>>> df
    population  GDP  alpha-2
Italy  59000000  1937894  IT
France  65000000  2583560  FR
Malta  4340000   12011  MT
Maldives  434000  4520  MV
Brunei  434000   12128  BN
Iceland  337000  17036  IS
Nauru  11300    182  NR
Tuvalu  11300    38  TV
Anguilla  11300  311  AI
```

In the following example, we will use `nlargest` to select the three rows having the largest values in column “population”.

```python
>>> df.nlargest(3, 'population')
    population  GDP  alpha-2
France  65000000  2583560  FR
Italy  59000000  1937894  IT
Malta  4340000   12011  MT
```

When using `keep='last'`, ties are resolved in reverse order:

```python
>>> df.nlargest(3, 'population', keep='last')
    population  GDP  alpha-2
France  65000000  2583560  FR
Italy  59000000  1937894  IT
Brunei  4340000   12128  BN
```

When using `keep='all'`, all duplicate items are maintained:
To order by the largest values in column “population” and then “GDP”, we can specify multiple columns like in the next example.

```python
>>> df.nlargest(3, ['population', 'GDP'])
   population     GDP alpha-2
France 65000000 2583560   FR
Italy  59000000 1937894   IT
Brunei 434000   12128   BN
```

### pandas.DataFrame.notna

DataFrame.notna()  
Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

Returns  
- **DataFrame** Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

- **DataFrame.notnull** Alias of notna.
- **DataFrame.isna** Boolean inverse of notna.
- **DataFrame.dropna** Omit axes labels with missing values.

**notna** Top-level notna.

#### Examples

Show which entries in a DataFrame are not NA.

```python
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
                     ...
                              pd.Timestamp('1940-04-25')],
                     ...
                     'name': ['Alfred', 'Batman', ''],
                     ...
                     'toy': [None, 'Batmobile', 'Joker']})
```

```python
>>> df
  age  born   name  toy
0  5.0  NaT     Alfred  None
1  6.0  1939-05-27 Batman  Batmobile
2  NaN  1940-04-25        Joker
```
Show which entries in a Series are not NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2  NaN
dtype: float64
>>> ser.notna()
0   True
1   True
2  False
dtype: bool
```

**pandas.DataFrame.notnull**

`DataFrame.notnull()`

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

Returns

- **DataFrame** Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See Also:

- **DataFrame.notnull** Alias of notna.
- **DataFrame.isna** Boolean inverse of notna.
- **DataFrame.dropna** Omit axes labels with missing values.
- **notna** Top-level notna.

Examples

Show which entries in a DataFrame are not NA.

```python
>>> df = pd.DataFrame({'age': [5, 6, np.NaN],
...                    'born': [pd.NaT, pd.Timestamp('1939-05-27'),
...                             pd.Timestamp('1940-04-25')],
...                    'name': ['Alfred', 'Batman', ''],
...                    'toy': [None, 'Batmobile', 'Joker']})
>>> df
```

(continues on next page)
```python
>>> df.notna()
age born name toy
0 True False True False
1 True True True True
2 False True True True
```

Show which entries in a Series are not NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0    5.0
1    6.0
2     NaN
dtype: float64

>>> ser.notna()
0 True
1 True
2 False
dtype: bool
```

**pandas.DataFrame.nsmallest**

`DataFrame.nsmallest(n, columns, keep='first')`

Return the first `n` rows ordered by `columns` in ascending order.

Return the first `n` rows with the smallest values in `columns`, in ascending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to `df.sort_values(columns, ascending=True).head(n)`, but more performant.

**Parameters**

- `n` [int] Number of items to retrieve.
- `columns` [list or str] Column name or names to order by.
- `keep` [{‘first’, ‘last’, ‘all’}, default ‘first’] Where there are duplicate values:
  - `first`: take the first occurrence.
  - `last`: take the last occurrence.
  - `all`: do not drop any duplicates, even it means selecting more than `n` items.

New in version 0.24.0.

**Returns**

- `DataFrame`

**See also:**
**DataFrame.nlargest**  Return the first $n$ rows ordered by columns in descending order.

**DataFrame.sort_values**  Sort DataFrame by the values.

**DataFrame.head**  Return the first $n$ rows without re-ordering.

**Examples**

```python
>>> df = pd.DataFrame({'population': [59000000, 65000000, 4340000, 4340000, 337000, 337000, 11300, 11300, 11300, 11300], 'GDP': [1937894, 2583560, 12011, 4520, 12128, 17036, 182, 38, 38, 311], 'alpha-2': ['IT', 'FR', 'MT', 'MV', 'BN', 'IS', 'NR', 'TV', 'AI']}, index=['Italy', 'France', 'Malta', 'Maldives', 'Brunei', 'Iceland', 'Nauru', 'Tuvalu', 'Anguilla'])

In the following example, we will use `nsmallest` to select the three rows having the smallest values in column “population”.

```python
>>> df.nsmallest(3, 'population')
   population  GDP  alpha-2
Tuvalu      11300  38   TV
Anguilla    11300  311  AI
Iceland    337000 17036 IS
```

When using `keep='last'`, ties are resolved in reverse order:

```python
>>> df.nsmallest(3, 'population', keep='last')
   population  GDP  alpha-2
Anguilla    11300  311  AI
Tuvalu      11300  38   TV
Nauru       337000 182  NR
```

When using `keep='all'`, all duplicate items are maintained:

```python
>>> df.nsmallest(3, 'population', keep='all')
   population  GDP  alpha-2
Tuvalu      11300  38   TV
Anguilla    11300  311  AI
Iceland    337000 17036 IS
Nauru       337000 182  NR
```

To order by the smallest values in column “population” and then “GDP”, we can specify multiple columns like in the next example.
```python
>>> df.nsmallest(3, ['population', 'GDP'])
     population  GDP  alpha-2
Tuvalu     11300  38   TV
Anguilla   11300  311  AI
Nauru     337000 182  NR
```

**pandas.DataFrame.nunique**

DataFrame.nunique(*axis=0, dropna=True*)

Count distinct observations over requested axis.

Return Series with number of distinct observations. Can ignore NaN values.

**Parameters**

- **axis** [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.
- **dropna** [bool, default True] Don’t include NaN in the counts.

**Returns**

Series

**See also:**

- Series.nunique Method nunique for Series.
- DataFrame.count Count non-NA cells for each column or row.

**Examples**

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [1, 1, 1]})
>>> df.nunique()
A     3
B     1
dtype: int64
```

```python
>>> df.nunique(axis=1)
0  1
1  2
2  2
dtype: int64
```

**pandas.DataFrame.pad**

DataFrame.pad(*axis=None, inplace=False, limit=None, downcast=None*)

Synonym for DataFrame.fillna() with method='ffill'.

**Returns**

{klass} or None Object with missing values filled or None if inplace=True.
pandas.DataFrame.pct_change

DataFrame\.pct_change(periods=1, fill_method='pad', limit=None, freq=None, **kwargs)

Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

**Parameters**

- **periods**: [int, default 1] Periods to shift for forming percent change.
- **fill_method**: [str, default ‘pad’] How to handle NAs before computing percent changes.
- **limit**: [int, default None] The number of consecutive NAs to fill before stopping.
- **freq**: [DateOffset, timedelta, or str, optional] Increment to use from time series API (e.g. ‘M’ or BDay()).
- **kwargs**: Additional keyword arguments are passed into DataFrame.shift or Series.shift.

**Returns**

chg [Series or DataFrame] The same type as the calling object.

See also:

- **Series.diff** Compute the difference of two elements in a Series.
- **DataFrame.diff** Compute the difference of two elements in a DataFrame.
- **Series.shift** Shift the index by some number of periods.
- **DataFrame.shift** Shift the index by some number of periods.

**Examples**

**Series**

```python
>>> s = pd.Series([90, 91, 85])
>>> s
0  90
1  91
2  85
dtype: int64

>>> s.pct_change()
0   NaN
1  0.011111
2 -0.065934
dtype: float64

>>> s.pct_change(periods=2)
0   NaN
1   NaN
2 -0.055556
dtype: float64
```

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

---

3.4. DataFrame
% >>> s = pd.Series([90, 91, None, 85])
% >>> s
% 0    90.0
% 1    91.0
% 2     NaN
% 3    85.0
% dtype: float64
% >>> s.pct_change(fill_method='ffill')
% 0   NaN
% 1  0.011111
% 2  0.000000
% 3 -0.065934
% dtype: float64

**DataFrame**

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

% >>> df = pd.DataFrame({
% ... 'FR': [4.0405, 4.0963, 4.3149],
% ... 'GR': [1.7246, 1.7482, 1.8519],
% ... 'IT': [804.74, 810.01, 860.13]},
% ... index=['1980-01-01', '1980-02-01', '1980-03-01'])
% >>> df
%            FR    GR     IT
% 1980-01-01  4.0405  1.7246  804.74
% 1980-02-01  4.0963  1.7482  810.01
% 1980-03-01  4.3149  1.8519  860.13
% >>> df.pct_change()
%            FR    GR     IT
% 1980-01-01  NaN  NaN   NaN
% 1980-02-01  0.013810  0.013684  0.006549
% 1980-03-01  0.053365  0.059318  0.061876

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

% >>> df = pd.DataFrame({
% ... '2016': [1769950, 30586265],
% ... '2015': [1500923, 40912316],
% ... '2014': [1371819, 41403351]},
% ... index=['GOOG', 'APPL'])
% >>> df
%            GOOG      APPL
% 2016   1769950  30586265
% 2015   1500923  40912316
% 2014   1371819  41403351
% >>> df.pct_change(axis='columns')
%            GOOG     APPL
% 2016  NaN -0.151997
% 2015  NaN  0.337604
% 2014  NaN  0.012002
**DataFrame.pipe**

DataFrame.pipe(func, *args, **kwargs)

Apply func(self, *args, **kwargs).

**Parameters**

- **func** [function] Function to apply to the Series/DataFrame. args, and kwargs are passed into func. Alternatively a (callable, data_keyword) tuple where data_keyword is a string indicating the keyword of callable that expects the Series/DataFrame.

- **args** [iterable, optional] Positional arguments passed into func.

- **kwargs** [mapping, optional] A dictionary of keyword arguments passed into func.

**Returns**

- **object** [the return type of func.]

**See also:**

- **DataFrame.apply** Apply a function along input axis of DataFrame.
- **DataFrame.applymap** Apply a function elementwise on a whole DataFrame.
- **Series.map** Apply a mapping correspondence on a Series.

**Notes**

Use .pipe when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```python
def g(df):
    return df['A']

def h(df):
    return df.where(df['A'] > 0)

def func(arg1, arg2, arg3):
    return arg1 + arg2 + arg3
```

You can write

```python
>>> (df.pipe(h)
...     .pipe(g, arg1=10)
...     .pipe(func, arg2=20, arg3=30)
... )
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose f takes its data as arg2:

```python
>>> (df.pipe(h)
...     .pipe(g, arg1=10)
...     .pipe(f, (func, 'arg2'), arg1=10, arg3=30)
... )
```
pandas.DataFrame.pivot

DataFrame.pivot(index=None, columns=None, values=None)

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified index / columns to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the User Guide for more on reshaping.

Parameters

index [str or object or a list of str, optional] Column to use to make new frame’s index.
If None, uses existing index.
Changed in version 1.1.0: Also accept list of index names.

columns [str or object or a list of str] Column to use to make new frame’s columns.
Changed in version 1.1.0: Also accept list of columns names.

values [str, object or a list of the previous, optional] Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.
Changed in version 0.23.0: Also accept list of column names.

Returns

DataFrame Returns reshaped DataFrame.

Raises

ValueError: When there are any index, columns combinations with multiple values.
DataFrame.pivot_table when you need to aggregate.

See also:

DataFrame.pivot_table Generalization of pivot that can handle duplicate values for one index/column pair.

DataFrame.unstack Pivot based on the index values instead of a column.

Notes

For finer-tuned control, see hierarchical indexing documentation along with the related stack/unstack methods.

Examples

```python
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two', ...
...     'two'],
...     'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
...     'baz': [1, 2, 3, 4, 5, 6],
...     'zoo': ['x', 'y', 'z', 'q', 'w', 't']})
```

```python
0 one A 1 x
1 one B 2 y
2 one C 3 z
```
(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.1.1

3 two A  4    q
4 two B  5    w
5 two C  6    t

>>> df.pivot(index='foo', columns='bar', values='baz')
bar   A B C
foo
one  1 2 3
two  4 5 6

>>> df.pivot(index='foo', columns='bar')['baz']
bar   A B C
foo
one  1 2 3
two  4 5 6

>>> df.pivot(index='foo', columns='bar', values=['baz', 'zoo'])
baz zoo
bar   A B C A B C
foo
one  1 2 3 x y z
two  4 5 6 q w t

You could also assign a list of column names or a list of index names.

>>> df = pd.DataFrame({'
...     "lev1": [1, 1, 1, 2, 2, 2],
...     "lev2": [1, 1, 2, 1, 1, 2],
...     "lev3": [1, 2, 1, 2, 1, 2],
...     "lev4": [1, 2, 3, 4, 5, 6],
...     "values": [0, 1, 2, 3, 4, 5])

>>> df
lev1  lev2  lev3  lev4  values
0 1 1 1 1 1 0
1 1 1 2 2 1
2 1 2 1 3 2
3 2 1 2 4 3
4 2 1 1 5 4
5 2 2 2 6 5

>>> df.pivot(index="lev1", columns=["lev2", "lev3"],values="values")
lev2  lev3
lev1
1   0.0 1.0 2.0 NaN
2   4.0 3.0 NaN 5.0

>>> df.pivot(index="lev1", "lev2", columns="lev3",values="values")
lev3  lev1  lev2
1   1 0.0 1.0
    2 2.0 NaN
2   1 4.0 3.0
    2 NaN 5.0

A ValueError is raised if there are any duplicates.
```
>>> df = pd.DataFrame({"foo": ['one', 'one', 'two', 'two'],
... "bar": ['A', 'A', 'B', 'C'],
... "baz": [1, 2, 3, 4]})

>>> df
  foo bar baz
0  one A  1
1  one A  2
2  two B  3
3  two C  4
```

Notice that the first two rows are the same for our `index` and `columns` arguments.

```
>>> df.pivot(index='foo', columns='bar', values='baz')
Traceback (most recent call last):
...
ValueError: Index contains duplicate entries, cannot reshape
```

`pandas.DataFrame.pivot_table`

`DataFrame.pivot_table`(*values=None, index=None, columns=None, aggfunc='mean', fill_value=None, margins=False, dropna=True, margins_name='All', observed=False*)

Create a spreadsheet-style pivot table as a DataFrame.

The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

**Parameters**

- **values** [column to aggregate, optional]
- **index** [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.
- **columns** [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.
- **aggfunc** [function, list of functions, dict, default `numpy.mean`] If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions.
- **fill_value** [scalar, default `None`] Value to replace missing values with (in the resulting pivot table, after aggregation).
- **margins** [bool, default `False`] Add all row / columns (e.g. for subtotal / grand totals).
- **dropna** [bool, default `True`] Do not include columns whose entries are all NaN.
- **margins_name** [str, default ‘All’] Name of the row / column that will contain the totals when margins is `True`.
- **observed** [bool, default `False`] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.
Changed in version 0.25.0.

Returns

DataFrame An Excel style pivot table.

See also:

DataFrame.pivot Pivot without aggregation that can handle non-numeric data.

Examples

```python
>>> df = pd.DataFrame(
    {"A": ["foo", "foo", "foo", "foo", "foo", "bar", "bar", "bar", "bar"],
     "B": ["one", "one", "one", "two", "two", "one", "two", "two"],
     "C": ["small", "large", "large", "small", "small", "large", "small", "large"],
     "D": [1, 2, 2, 3, 3, 4, 5, 6, 7],
     "E": [2, 4, 5, 5, 6, 6, 8, 9, 9]})
```

This first example aggregates values by taking the sum.

```python
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
                         columns=['C'], aggfunc=np.sum)
```

We can also fill missing values using the `fill_value` parameter.

```python
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
                         columns=['C'], aggfunc=np.sum, fill_value=0)
```

The next example aggregates by taking the mean across multiple columns.
```python
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                        aggfunc={'D': np.mean,
...                                'E': np.mean})
>>> table

D   E
A  C
---  ---
bar large 5.500000 7.500000
     small 5.500000 8.500000
foo large 2.000000 4.500000
     small 2.333333 4.333333

We can also calculate multiple types of aggregations for any given value column.

```n
code-block:: python

```py
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                        aggfunc={'D': np.mean,
...                                'E': [min, max, np.mean]})
>>> table

D    E
mean  max  mean  min
A  C
---  ---  ---  ---
bar large  5.500000  9.0  7.500000  6.0
     small  5.500000  9.0  8.500000  8.0
foo large  2.000000  5.0  4.500000  4.0
     small  2.333333  6.0  4.333333  2.0
```

**pandas.DataFrame.plot**

Dataframe.plot(*args, **kwargs)

Make plots of Series or DataFrame.

Uses the backend specified by the option plottingbackend. By default, matplotlib is used.

**Parameters**

- `data` [Series or DataFrame] The object for which the method is called.
- `x` [label or position, default None] Only used if data is a DataFrame.
- `y` [label, position or list of label, positions, default None] Allows plotting of one column versus another. Only used if data is a DataFrame.
- `kind` [str] The kind of plot to produce:
  - ‘line’: line plot (default)
  - ‘bar’: vertical bar plot
  - ‘barh’: horizontal bar plot
  - ‘hist’: histogram
  - ‘box’: boxplot
  - ‘kde’: Kernel Density Estimation plot
  - ‘density’: same as ‘kde’
  - ‘area’: area plot
  - ‘pie’: pie plot
  - ‘scatter’: scatter plot
• ‘hexbin’: hexbin plot.

**ax** [matplotlib axes object, default None] An axes of the current figure.

**subplots** [bool, default False] Make separate subplots for each column.

**sharex** [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in; Be aware, that passing in both an ax and sharex=True will alter all x axis labels for all axis in a figure.

**sharey** [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.

**layout** [tuple, optional] (rows, columns) for the layout of subplots.

**figsize** [a tuple (width, height) in inches] Size of a figure object.

**use_index** [bool, default True] Use index as ticks for x axis.

**title** [str or list] Title to use for the plot. If a string is passed, print the string at the top of the figure. If a list is passed and subplots is True, print each item in the list above the corresponding subplot.

**grid** [bool, default None (matlab style default)] Axis grid lines.

**legend** [bool or {‘reverse’}] Place legend on axis subplots.

**style** [list or dict] The matplotlib line style per column.

**logx** [bool or ‘sym’, default False] Use log scaling or symlog scaling on x axis. .. versionchanged:: 0.25.0

**logy** [bool or ‘sym’ default False] Use log scaling or symlog scaling on y axis. .. versionchanged:: 0.25.0

**loglog** [bool or ‘sym’, default False] Use log scaling or symlog scaling on both x and y axes. .. versionchanged:: 0.25.0

**xticks** [sequence] Values to use for the xticks.

**yticks** [sequence] Values to use for the yticks.

**xlim** [2-tuple/list] Set the x limits of the current axes.

**ylim** [2-tuple/list] Set the y limits of the current axes.

**xlabel** [label, optional] Name to use for the xlabel on x-axis. Default uses index name as xlabel.

New in version 1.1.0.

**ylabel** [label, optional] Name to use for the ylabel on y-axis. Default will show no ylabel.

New in version 1.1.0.

**rot** [int, default None] Rotation for ticks (xticks for vertical, yticks for horizontal plots).

**fontsize** [int, default None] Font size for xticks and yticks.

**colormap** [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

**colorbar** [bool, optional] If True, plot colorbar (only relevant for ‘scatter’ and ‘hexbin’ plots).
position [float] Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center).

table [bool, Series or DataFrame, default False] If True, draw a table using the data in the DataFrame and the data will be transposed to meet matplotlib’s default layout. If a Series or DataFrame is passed, use passed data to draw a table.

eyerr [DataFrame, Series, array-like, dict and str] See Plotting with Error Bars for detail.

xerr [DataFrame, Series, array-like, dict and str] Equivalent to yerr.

stacked [bool, default False in line and bar plots, and True in area plot] If True, create stacked plot.

sort_columns [bool, default False] Sort column names to determine plot ordering.

secondary_y [bool or sequence, default False] Whether to plot on the secondary y-axis if a list/tuple, which columns to plot on secondary y-axis.

mark_right [bool, default True] When using a secondary_y axis, automatically mark the column labels with “(right)” in the legend.

include_bool [bool, default is False] If True, boolean values can be plotted.

backend [str, default None] Backend to use instead of the backend specified in the option plotting.backend. For instance, ‘matplotlib’. Alternatively, to specify the plotting.backend for the whole session, set pd.options.plotting.backend. New in version 1.0.0.

**kwargs Options to pass to matplotlib plotting method.

Returns

matplotlib.axes.Axes or numpy.ndarray of them If the backend is not the default matplotlib one, the return value will be the object returned by the backend.

Notes

• See matplotlib documentation online for more on this subject

• If kind = ‘bar’ or ‘barh’, you can specify relative alignments for bar plot layout by position keyword. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

pandas.DataFrame.pop

DataFrame.pop(item)

Return item and drop from frame. Raise KeyError if not found.

Parameters

item [label] Label of column to be popped.

Returns

Series
Examples

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                    columns=('name', 'class', 'max_speed'))
```

```python
>>> df
    name   class  max_speed
0  falcon  bird     389.0
1  parrot  bird      24.0
2    lion  mammal    80.5
3   monkey  mammal     NaN
```

```python
>>> df.pop('class')
0    bird
1    bird
2  mammal
3  mammal
Name: class, dtype: object
```

```python
>>> df
    name  max_speed
0  falcon     389.0
1  parrot     24.0
2    lion     80.5
3   monkey     NaN
```

pandas.DataFrame.pow

DataFrame.pow(other, axis='columns', level=None, fill_value=None)

Get Exponential power of dataframe and other, element-wise (binary operator pow).

Equivalent to dataframe ** other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rpow.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

- **axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

- **DataFrame** Result of the arithmetic operation.
See also:

- `DataFrame.add` Add DataFrames.
- `DataFrame.sub` Subtract DataFrames.
- `DataFrame.mul` Multiply DataFrames.
- `DataFrame.div` Divide DataFrames (float division).
- `DataFrame.truediv` Divide DataFrames (float division).
- `DataFrame.floordiv` Divide DataFrames (integer division).
- `DataFrame.mod` Calculate modulo (remainder after division).
- `DataFrame.pow` Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle     0      360
triangle   3      180
rectangle  4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle     1      361
triangle   4      181
rectangle  5      361
```

```python
>>> df.add(1)
   angles  degrees
circle     1      361
triangle   4      181
rectangle  5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle    0.0    36.0
triangle  0.3    18.0
rectangle 0.4    36.0
```
Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
angles  degrees
circle   -1   358
triangle  2    178
rectangle 3    358
```

```python
>>> df.sub([1, 2], axis='columns')
angles  degrees
circle   -1   358
triangle  2    178
rectangle 3    358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
angles  degrees
circle   -1   359
triangle  2    179
rectangle 3    359
```

Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])
```

```python
>>> df * other
angles  degrees
circle   0    NaN
triangle  9    NaN
rectangle 16   NaN
```

```python
>>> df.mul(other, fill_value=0)
angles  degrees
circle   0    0.0
triangle  9    0.0
rectangle 16   0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               'index': ['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon']})
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.1.1

```
>>> df_multindex
angles  degrees
A  circle  0  360
triangle  3  180
rectangle  4  360
B  square  4  360
pentagon  5  540
hexagon  6  720
```

```
>>> df.div(df_multindex, level=1, fill_value=0)
angles  degrees
A  circle  NaN  1.0
triangle  1.0  1.0
rectangle  1.0  1.0
B  square  0.0  0.0
pentagon  0.0  0.0
hexagon  0.0  0.0
```

**pandas.DataFrame.prod**

Dataframe `.prod` (axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)

Return the product of the values for the requested axis.

**Parameters**

- **axis** ([index (0), columns (1)]) Axis for the function to be applied on.
- **skipna** (bool, default True) Exclude NA/null values when computing the result.
- **level** (int or level name, default None) If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **numeric_only** (bool, default None) Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **min_count** (int, default 0) The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

- **kwargs** Additional keyword arguments to be passed to the function.

**Returns**

- Series or DataFrame (if level specified)
**Examples**

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```python
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0

>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

---

**pandas.DataFrame.product**

`DataFrame.product` *(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)*

Return the product of the values for the requested axis.

**Parameters**

- `axis` [{index (0), columns (1)}] Axis for the function to be applied on.
- `skipna` [bool, default True] Exclude NA/null values when computing the result.
- `level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- `numeric_only` [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- `min_count` [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.

- `**kwargs` Additional keyword arguments to be passed to the function.

**Returns**

- Series or DataFrame (if level specified)
Examples

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([]).prod()
1.0
```

This can be controlled with the `min_count` parameter

```python
>>> pd.Series([]).prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0
```
```python
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

pandas.DataFrame.quantile

DataFrame.quantile(q=0.5, axis=0, numeric_only=True, interpolation='linear')

Return values at the given quantile over requested axis.

**Parameters**

- **q** [float or array-like, default 0.5 (50% quantile)] Value between 0 <= q <= 1, the quantile(s) to compute.
- **axis** [[0, 1, ‘index’, ‘columns’], default 0] Equals 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.
- **numeric_only** [bool, default True] If False, the quantile of datetime and timedelta data will be computed as well.
- **interpolation** [{‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’}] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points \( i \) and \( j \):
  - linear: \( i + (j - i) \times \text{fraction} \), where \( \text{fraction} \) is the fractional part of the index surrounded by \( i \) and \( j \).
  - lower: \( i \).
  - higher: \( j \).
  - nearest: \( i \) or \( j \) whichever is nearest.
  - midpoint: \( (i + j) / 2 \).

**Returns**

Series or DataFrame

If \( q \) is an array, a DataFrame will be returned where the index is \( q \), the columns are the columns of self, and the values are the quantiles.

If \( q \) is a float, a Series will be returned where the index is the columns of self and the values are the quantiles.
See also:

**core.window.Rolling.quantile** Rolling quantile.

**numpy.percentile** Numpy function to compute the percentile.

**Examples**

```python
>>> df = pd.DataFrame(np.array([[1, 1], [2, 10], [3, 100], [4, 100]]),
                    columns=['a', 'b'])

>>> df.quantile(.1)
   a  1.3
   b  3.7
Name: 0.1, dtype: float64

>>> df.quantile([.1, .5])
   a  b
 0.1 1.3 3.7
 0.5 2.5 55.0
```

Specifying `numeric_only=False` will also compute the quantile of datetime and timedelta data.

```python
>>> df = pd.DataFrame({'A': [1, 2],
                     'B': [pd.Timestamp('2010'),
                           pd.Timestamp('2011')],
                     'C': [pd.Timedelta('1 days'),
                           pd.Timedelta('2 days')]})

>>> df.quantile(0.5, numeric_only=False)
   A  1.5
   B 2010-07-02 12:00:00
   C  1 days 12:00:00
Name: 0.5, dtype: object
```

**pandas.DataFrame.query**

`DataFrame.query(expr, inplace=False, **kwargs)`

Query the columns of a DataFrame with a boolean expression.

**Parameters**

- `expr` [str] The query string to evaluate.

  You can refer to variables in the environment by prefixing them with an `@` character like `@a + b`.

  You can refer to column names that contain spaces or operators by surrounding them in backticks. This way you can also escape names that start with a digit, or those that are a Python keyword. Basically when it is not valid Python identifier. See notes down for more details.

  For example, if one of your columns is called `a a` and you want to sum it with `b`, your query should be `@a + b`.

New in version 0.25.0: Backtick quoting introduced.

New in version 1.0.0: Expanding functionality of backtick quoting for more than only spaces.
inplace [bool] Whether the query should modify the data in place or return a modified copy.

**kwargs See the documentation for `eval()` for complete details on the keyword arguments accepted by `DataFrame.query()`.

**Returns**

*DataFrame* DataFrame resulting from the provided query expression.

**See also:**

*eval* Evaluate a string describing operations on DataFrame columns.

*DataFrame.eval* Evaluate a string describing operations on DataFrame columns.

**Notes**

The result of the evaluation of this expression is first passed to `DataFrame.loc` and if that fails because of a multidimensional key (e.g., a DataFrame) then the result will be passed to `DataFrame.__getitem__()`.

This method uses the top-level `eval()` function to evaluate the passed query.

The `query()` method uses a slightly modified Python syntax by default. For example, the & and | (bitwise) operators have the precedence of their boolean cousins, **and** and **or**. This is syntactically valid Python, however the semantics are different.

You can change the semantics of the expression by passing the keyword argument `parser='python'`. This enforces the same semantics as evaluation in Python space. Likewise, you can pass `engine='python'` to evaluate an expression using Python itself as a backend. This is not recommended as it is inefficient compared to using `numexpr` as the engine.

The `DataFrame.index` and `DataFrame.columns` attributes of the `DataFrame` instance are placed in the query namespace by default, which allows you to treat both the index and columns of the frame as a column in the frame. The identifier `index` is used for the frame index; you can also use the name of the index to identify it in a query. Please note that Python keywords may not be used as identifiers.

For further details and examples see the `query` documentation in `indexing`.

**Backtick quoted variables**

Backtick quoted variables are parsed as literal Python code and are converted internally to a Python valid identifier. This can lead to the following problems.

During parsing a number of disallowed characters inside the backtick quoted string are replaced by strings that are allowed as a Python identifier. These characters include all operators in Python, the space character, the question mark, the exclamation mark, the dollar sign, and the euro sign. For other characters that fall outside the ASCII range (U+0001..U+007F) and those that are not further specified in PEP 3131, the query parser will raise an error. This excludes whitespace different than the space character, but also the hashtag (as it is used for comments) and the backtick itself (backtick can also not be escaped).

In a special case, quotes that make a pair around a backtick can confuse the parser. For example, `it's > `that's` will raise an error, as it forms a quoted string ('s > `that`) with a backtick inside.

See also the Python documentation about lexical analysis (https://docs.python.org/3/reference/lexical_analysis.html) in combination with the source code in `pandas.core.computation.parsing`. 

1618 Chapter 3. API reference
Examples

```python
>>> df = pd.DataFrame({'A': range(1, 6),
                    'B': range(10, 0, -2),
                    'C C': range(10, 5, -1)})

>>> df
   A  B  C C
0  1  10 10
1  2  8  9
2  3  6  8
3  4  4  7
4  5  2  6

>>> df.query('A > B')
   A  B  C C
4  5  2  6
```

The previous expression is equivalent to

```python
>>> df[df.A > df.B]
   A  B  C C
4  5  2  6
```

For columns with spaces in their name, you can use backtick quoting.

```python
>>> df.query('B == `C C``')
   A  B  C C
0  1  10 10
```

The previous expression is equivalent to

```python
>>> df[df.B == df['C C']]  
   A  B  C C
0  1  10 10
```

---

**pandas.DataFrame.radd**

DataFrame .radd (other, axis='columns', level=None, fill_value=None)

Get Addition of dataframe and other, element-wise (binary operator radd).
Equivalent to other + dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, add.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before
computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

**DataFrame** Result of the arithmetic operation.

See also:

*DataFrame.add* Add DataFrames.

*DataFrame.sub* Subtract DataFrames.

*DataFrame.mul* Multiply DataFrames.

*DataFrame.div* Divide DataFrames (float division).

*DataFrame.truediv* Divide DataFrames (float division).

*DataFrame.floordiv* Divide DataFrames (integer division).

*DataFrame.mod* Calculate modulo (remainder after division).

*DataFrame.pow* Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
angles  degrees
circle     0      360
triangle   3      180
rectangle  4      360

Add a scalar with operator version which return the same results.

```python
>>> df + 1

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
</tbody>
</table>
```

```python
>>> df.add(1)

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
</tbody>
</table>
```
Divide by a MultiIndex by level.

3.4. DataFrame
pandas.DataFrame.rank

DataFrame.rank(axis=0, method='average', numeric_only=None, na_option='keep', ascending=True, pct=False)

Compute numerical data ranks (1 through n) along axis.
By default, equal values are assigned a rank that is the average of the ranks of those values.

Parameters

- **axis** ([0 or ‘index’, 1 or ‘columns’], default 0) Index to direct ranking.
- **method** ([‘average’, ‘min’, ‘max’, ‘first’, ‘dense’], default ‘average’) How to rank the group of records that have the same value (i.e. ties):
  - average: average rank of the group
  - min: lowest rank in the group
  - max: highest rank in the group
  - first: ranks assigned in order they appear in the array
  - dense: like ‘min’, but rank always increases by 1 between groups.
- **numeric_only** [bool, optional] For DataFrame objects, rank only numeric columns if set to True.
- **na_option** ([‘keep’, ‘top’, ‘bottom’], default ‘keep’) How to rank NaN values:
  - keep: assign NaN rank to NaN values
  - top: assign smallest rank to NaN values if ascending
  - bottom: assign highest rank to NaN values if ascending.
- **ascending** [bool, default True] Whether or not the elements should be ranked in ascending order.
**pct** [bool, default False] Whether or not to display the returned rankings in percentile form.

**Returns**

**same type as caller** Return a Series or DataFrame with data ranks as values.

**See also:**

**core.groupby.GroupBy.rank** Rank of values within each group.

**Examples**

```python
def = pd.DataFrame(data={'Animal': ['cat', 'penguin', 'dog', 'spider', 'snake'],
                         'Number_legs': [4, 2, 4, 8, np.nan]})
```

The following example shows how the method behaves with the above parameters:

- **default_rank**: this is the default behaviour obtained without using any parameter.
- **max_rank**: setting `method = 'max'` the records that have the same values are ranked using the highest rank (e.g.: since ‘cat’ and ‘dog’ are both in the 2nd and 3rd position, rank 3 is assigned.)
- **NA_bottom**: choosing `na_option = 'bottom'`, if there are records with NaN values they are placed at the bottom of the ranking.
- **pct_rank**: when setting `pct = True`, the ranking is expressed as percentile rank.

```python
def['default_rank'] = df['Number_legs'].rank()
def['max_rank'] = df['Number_legs'].rank(method='max')
def['NA_bottom'] = df['Number_legs'].rank(na_option='bottom')
def['pct_rank'] = df['Number_legs'].rank(pct=True)
```

```plaintext
Animal   Number_legs  default_rank  max_rank  NA_bottom  pct_rank
        0     cat        4.0          2.5        3.0      2.5  0.625
        1    penguin    2.0          1.0        1.0      1.0  0.250
        2      dog      4.0          2.5        3.0      2.5  0.625
        3    spider     8.0          4.0        4.0      4.0  1.000
        4     snake     NaN         NaN        NaN      NaN  NaN
```
**pandas.DataFrame.rdiv**

`DataFrame.rdiv(other, axis='columns', level=None, fill_value=None)`

Get Floating division of dataframe and other, element-wise (binary operator `rtruediv`).

Equivalent to `other / dataframe`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, `truediv`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- `fill_value` [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

*Dataframe* Result of the arithmetic operation.

**See also:**

- `DataFrame.add` Add DataFrames.
- `DataFrame.sub` Subtract DataFrames.
- `DataFrame.mul` Multiply DataFrames.
- `DataFrame.div` Divide DataFrames (float division).
- `DataFrame.truediv` Divide DataFrames (float division).
- `DataFrame.floordiv` Divide DataFrames (integer division).
- `DataFrame.mod` Calculate modulo (remainder after division).
- `DataFrame.pow` Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
    angles  degrees
circle     0       360
triangle    3       180
rectangle   4       360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
    angles  degrees
circle     1       361
triangle    4       181
rectangle   5       361
``` 

```python
>>> df.add(1)
    angles  degrees
circle     1       361
triangle    4       181
rectangle   5       361
``` 

Divide by constant with reverse version.

```python
>>> df.div(10)
    angles  degrees
circle     0.0      36.0
triangle    0.3      18.0
rectangle   0.4      36.0
``` 

```python
>>> df.rdiv(10)
    angles  degrees
circle     inf      0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
``` 

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
    angles  degrees
circle     -1      358
triangle     2      178
rectangle    3      358
``` 

```python
>>> df.sub([1, 2], axis='columns')
    angles  degrees
circle     -1      358
triangle     2      178
rectangle    3      358
``` 

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
    angles  degrees
circle     -1      358
triangle     2      178
rectangle    3      358
``` 

(continues on next page)
Multiply a DataFrame of different shape with operator version.

```
other = pd.DataFrame({'angles': [0, 3, 4],
                     'index':['circle', 'triangle', 'rectangle'])
other
```
```
angles
circle 0
triangle 3
rectangle 4
```
```
other = pd.DataFrame({'angles': [0, 3, 4],
                     'index':['circle', 'triangle', 'rectangle'])
other
```
```
angles
circle 0
triangle 3
rectangle 4
```
```
other
```
```
angles

```
```
df.multindex, level=1, fill_value=0)
```
```
angles degrees
A circle NaN 1.0
triangle 1.0 1.0
rectangle 1.0 1.0
B square 0.0 0.0
pentagon 0.0 0.0
hexagon 0.0 0.0
```
```
df.multindex, level=1, fill_value=0)
```
```
angles degrees
A circle NaN 1.0
triangle 1.0 1.0
rectangle 1.0 1.0
B square 0.0 0.0
pentagon 0.0 0.0
hexagon 0.0 0.0
```
```
df.multindex, level=1, fill_value=0)
```
```
angles degrees
A circle NaN 1.0
triangle 1.0 1.0
rectangle 1.0 1.0
B square 0.0 0.0
pentagon 0.0 0.0
hexagon 0.0 0.0
```
DataFrame.reindex

DataFrame.reindex(**kwargs)
Conform Series/DataFrame to new index with optional filling logic.

Places NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

Parameters

keywords for axes [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data.

method [{None, ‘backfill’/’bfill’ , ‘pad’/’ffill’, ‘nearest’}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.
  • None (default): don’t fill gaps
  • pad / ffill: Propagate last valid observation forward to next valid.
  • backfill / bfill: Use next valid observation to fill gap.
  • nearest: Use nearest valid observations to fill gap.

copy [bool, default True] Return a new object, even if the passed indexes are the same.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.

limit [int, default None] Maximum number of consecutive elements to forward or backward fill.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation abs(index[indexer] - target) <= tolerance.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

Returns

Series/DataFrame with changed index.

See also:

DataFrame.set_index Set row labels.

DataFrame.reset_index Remove row labels or move them to new columns.

DataFrame.reindex_like Change to same indices as other DataFrame.
Examples

**DataFrame.reindex** supports two calling conventions

- `(index=index_labels, columns=column_labels, ...)`
- `(labels, axis={'index', 'columns'}, ...)`

We highly recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({'http_status': [200, 200, 404, 404, 301],
                     'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]},
                     index=index)
>>> df
http_status response_time
Firefox 200 0.04
Chrome 200 0.02
Safari 404 0.07
IE10 404 0.08
Konqueror 301 1.00
```

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```
>>> new_index = ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10',
               'Chrome']
>>> df.reindex(new_index)
http_status response_time
Safari 404 0.07
Iceweasel NaN NaN
Comodo Dragon NaN NaN
IE10 404 0.08
Chrome 200 0.02
```

We can fill in the missing values by passing a value to the keyword `fill_value`. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword `method` to fill the NaN values.

```
>>> df.reindex(new_index, fill_value=0)
http_status response_time
Safari 404 0.07
Iceweasel 0 0.00
Comodo Dragon 0 0.00
IE10 404 0.08
Chrome 200 0.02
```

```
>>> df.reindex(new_index, fill_value='missing')
http_status response_time
Safari 404 0.07
Iceweasel missing missing
Comodo Dragon missing missing
IE10 404 0.08
Chrome 200 0.02
```

We can also reindex the columns.
Or we can use “axis-style” keyword arguments

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

Suppose we decide to expand the dataframe to cover a wider date range.

The index entries that did not have a value in the original data frame (for example, ‘2009-12-29’) are by default filled with NaN. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the NaN values, pass `bfill` as an argument to the method keyword.
Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method.

See the user guide for more.

**pandas.DataFrame.reindex_like**

`DataFrame.reindex_like` *(other, method=None, copy=True, limit=None, tolerance=None)*

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

**Parameters**

- **other** [Object of the same data type] Its row and column indices are used to define the new indices of this object.

- **method** [{None, ‘backfill’/’bfill’, ‘pad’/’ffill’, ‘nearest’}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.
  - None (default): don’t fill gaps
  - pad / ffill: propagate last valid observation forward to next valid
  - backfill / bfill: use next valid observation to fill gap
  - nearest: use nearest valid observations to fill gap.

- **copy** [bool, default True] Return a new object, even if the passed indexes are the same.

- **limit** [int, default None] Maximum number of consecutive labels to fill for inexact matches.

- **tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation \( \text{abs(index[indexer] - target) <= tolerance} \).
  - Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

**Returns**
**Series or DataFrame** Same type as caller, but with changed indices on each axis.

*See also:*

**DataFrame.set_index** Set row labels.

**DataFrame.reset_index** Remove row labels or move them to new columns.

**DataFrame.reindex** Change to new indices or expand indices.

**Notes**

Same as calling `.reindex(index=other.index, columns=other.columns,...)`.

**Examples**

```python
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
                      [31, 87.8, 'high'],
                      [22, 71.6, 'medium'],
                      [35, 95, 'medium']],
                     columns=['temp_celsius', 'temp_fahrenheit', 'windspeed'],
                     index=pd.date_range(start='2014-02-12',
                                         end='2014-02-15', freq='D'))

>>> df1
       temp_celsius  temp_fahrenheit  windspeed
2014-02-12     24.3              75.7     high
2014-02-13     31.0              87.8     high
2014-02-14     22.0              71.6    medium
2014-02-15     35.0              95.0    medium
```

```python
>>> df2 = pd.DataFrame([[28, 'low'],
                      [30, 'low'],
                      [35.1, 'medium']],
                     columns=['temp_celsius', 'windspeed'],
                     index=pd.DatetimeIndex(['2014-02-12', '2014-02-13',
                                              '2014-02-15']))

>>> df2
       temp_celsius  windspeed
2014-02-12     28.0     low
2014-02-13     30.0     low
2014-02-15     35.1    medium
```

```python
>>> df2.reindex_like(df1)
       temp_celsius  temp_fahrenheit  windspeed
2014-02-12     28.0            NaN     low
2014-02-13     30.0            NaN     low
2014-02-14       NaN            NaN     NaN
2014-02-15     35.1            NaN    medium
```
pandas.DataFrame.rename

DataFrame.rename(**kwargs)
Alter axes labels.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don’t throw an error.

See the user guide for more.

Parameters

mapper [dict-like or function] Dict-like or functions transformations to apply to that axis’ values. Use either mapper and axis to specify the axis to target with mapper, or index and columns.

index [dict-like or function] Alternative to specifying axis (mapper, axis=0 is equivalent to index=mapper).

columns [dict-like or function] Alternative to specifying axis (mapper, axis=1 is equivalent to columns=mapper).

axis [[0 or ‘index’, 1 or ‘columns’], default 0] Axis to target with mapper. Can be either the axis name (‘index’, ‘columns’) or number (0, 1). The default is ‘index’.

copy [bool, default True] Also copy underlying data.

inplace [bool, default False] Whether to return a new DataFrame. If True then value of copy is ignored.

level [int or level name, default None] In case of a MultiIndex, only rename labels in the specified level.

errors [{‘ignore’, ‘raise’}, default ‘ignore’] If ‘raise’, raise a KeyError when a dict-like mapper, index, or columns contains labels that are not present in the Index being transformed. If ‘ignore’, existing keys will be renamed and extra keys will be ignored.

Returns

DataFrame DataFrame with the renamed axis labels.

Raises

KeyError If any of the labels is not found in the selected axis and “errors=’raise’”.

See also:

DataFrame.rename_axis Set the name of the axis.

Examples

DataFrame.rename supports two calling conventions

• (index=index_mapper, columns=columns_mapper, ...)
• (mapper, axis=['index', 'columns'], ...)

We highly recommend using keyword arguments to clarify your intent.

Rename columns using a mapping:
```python
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
>>> df.rename(columns={"A": "a", "B": "c"})
    a  c
0  1  4
1  2  5
2  3  6

Rename index using a mapping:
```n
```python
>>> df.rename(index={0: "x", 1: "y", 2: "z"})
    A  B
x  1  4
y  2  5
z  3  6

Cast index labels to a different type:
```n
```python
>>> df.index
RangeIndex(start=0, stop=3, step=1)
>>> df.rename(index=str).index
Index(["0", "1", "2"], dtype='object')

Using axis-style parameters
```n
```python
>>> df.rename(str.lower, axis='columns')
    a  b
0  1  4
1  2  5
2  3  6

>>> df.rename({1: 2, 2: 4}, axis='index')
    A  B
0  1  4
2  2  5
4  3  6
```

**pandas.DataFrame.rename_axis**

**DataFrame.rename_axis(**kwargs**)**

Set the name of the axis for the index or columns.

**Parameters**

mapper [scalar, list-like, optional] Value to set the axis name attribute.

index, columns [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis’ values. Note that the columns parameter is not allowed if the object is a Series. This parameter only apply for DataFrame type objects.

Use either mapper and axis to specify the axis to target with mapper, or index and/or columns.

3.4. DataFrame
Changed in version 0.24.0.

axis [[0 or ‘index’, 1 or ‘columns’], default 0] The axis to rename.

copy [bool, default True] Also copy underlying data.

inplace [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

Returns

Series, DataFrame, or None The same type as the caller or None if inplace is True.

See also:

Series.rename Alter Series index labels or name.

DataFrame.rename Alter DataFrame index labels or name.

Index.rename Set new names on index.

Notes

DataFrame.rename_axis supports two calling conventions

* (index=index_mapper, columns=columns_mapper, ...)
* (mapper, axis={'index', 'columns'}, ...)

The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter copy is ignored.

The second calling convention will modify the names of the the corresponding index if mapper is a list or a scalar. However, if mapper is dict-like or a function, it will use the deprecated behavior of modifying the axis labels.

We highly recommend using keyword arguments to clarify your intent.

Examples

Series

```python
>>> s = pd.Series(['dog', 'cat', 'monkey'])
>>> s
0   dog
1   cat
2  monkey
dtype: object
>>> s.rename_axis('animal')
animal
0   dog
1   cat
2  monkey
dtype: object
```

DataFrame
```python
>>> df = pd.DataFrame({"num_legs": [4, 4, 2], "num_arms": [0, 0, 2]},
                    index=["dog", "cat", "monkey"])
>>> df
   num_legs num_arms
dog      4        0
cat      4        0
monkey   2        2
>>> df = df.rename_axis("animal")
>>> df
   num_legs num_arms
animal
dog   4   0
cat   4   0
monkey   2   2
>>> df.rename_axis(index={'type': 'class'})
   num_legs num_arms
class
type
mammal
dog   4   0
cat   4   0
monkey   2   2
>>> df.rename_axis(columns=str.upper)
   LIMBS num_legs num_arms
type
name
mammal
dog   4   0
cat   4   0
monkey   2   2
```

**MultiIndex**

```python
>>> df.index = pd.MultiIndex.from_product([['mammal'], ['dog', 'cat', 'monkey']], names=['type', 'name'])
>>> df
   limbs num_legs num_arms
   type name
mammal
dog   4   0
cat   4   0
monkey   2   2
>>> df.rename_axis('class')
   num_legs num_arms
   type
   class
mammal
dog   4   0
cat   4   0
monkey   2   2
>>> df.rename_axis('str.upper')
   LIMBS num_legs num_arms
   type
   name
mammal
dog   4   0
cat   4   0
monkey   2   2
```
pandas.DataFrame.reorder_levels

DataFrame.reorder_levels(order, axis=0)
Rearrange index levels using input order. May not drop or duplicate levels.

Parameters

order [list of int or list of str] List representing new level order. Reference level by number (position) or by key (label).
axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Where to reorder levels.

Returns
DataFrame

pandas.DataFrame.replace

DataFrame.replace(to_replace=None, value=None, inplace=False, limit=None, regex=False, method='pad')
Replace values given in to_replace with value.
Values of the DataFrame are replaced with other values dynamically. This differs from updating with .loc or .iloc, which require you to specify a location to update with some value.

Parameters

to_replace [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.
• numeric, str or regex:
  – numeric: numeric values equal to to_replace will be replaced with value
  – str: string exactly matching to_replace will be replaced with value
  – regex: regexs matching to_replace will be replaced with value
• list of str, regex, or numeric:
  – First, if to_replace and value are both lists, they must be the same length.
  – Second, if regex=True then all of the strings in both lists will be interpreted as regexs otherwise they will match directly. This doesn’t matter much for value since there are only a few possible substitution regexes you can use.
  – str, regex and numeric rules apply as above.
• dict:
  – Dicts can be used to specify different replacement values for different existing values. For example, {'a': 'b', 'y': 'z'} replaces the value ‘a’ with ‘b’ and ‘y’ with ‘z’. To use a dict in this way the value parameter should be None.
  – For a DataFrame a dict can specify that different values should be replaced in different columns. For example, {'a': 1, 'b': 'z'} looks for the value 1 in column ‘a’ and the value ‘z’ in column ‘b’ and replaces these values with whatever is specified in value. The value parameter should not be None in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.
For a DataFrame nested dictionaries, e.g., `{'a': {'b': np.nan}}`, are read as follows: look in column ‘a’ for the value ‘b’ and replace it with NaN. The value parameter should be None to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) cannot be regular expressions.

- None:
  - This means that the regex argument must be a string, compiled regular expression, or list, dict, ndarray or Series of such elements. If value is also None then this must be a nested dictionary or Series.

See the examples section for examples of each of these.

Parameter &Description &Notes
--- &--- &---
value &[scalar, dict, list, str, regex, default None] Value to replace any values matching to_replace with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

inplace &[bool, default False] If True, in place. Note: this will modify any other views on this object (e.g. a column from a DataFrame). Returns the caller if this is True.

limit &[int, default None] Maximum size gap to forward or backward fill.

regex &[bool or same types as to_replace, default False] Whether to interpret to_replace and/or value as regular expressions. If this is True then to_replace must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case to_replace must be None.

method &[{'pad', 'ffill', 'bfill', None}] The method to use when for replacement, when to_replace is a scalar, list or tuple and value is None.

Returns

DataFrame Object after replacement.

Raises

AssertionError
- If regex is not a bool and to_replace is not None.

TypeError
- If to_replace is not a scalar, array-like, dict, or None
- If to_replace is a dict and value is not a list, dict, ndarray, or Series
- If to_replace is None and regex is not compilable into a regular expression or is a list, dict, ndarray, or Series.
- When replacing multiple bool or datetime64 objects and the arguments to to_replace does not match the type of the value being replaced

ValueError
- If a list or an ndarray is passed to to_replace and value but they are not the same length.

See also:

Dataframe.fillna Fill NA values.
DataFrame.where Replace values based on boolean condition.

Series.str.replace Simple string replacement.

Notes

• Regex substitution is performed under the hood with re.sub. The rules for substitution for re.sub are the same.

• Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers are strings, then you can do this.

• This method has a lot of options. You are encouraged to experiment and play with this method to gain intuition about how it works.

• When dict is used as the to_replace value, it is like key(s) in the dict are the to_replace part and value(s) in the dict are the value parameter.

Examples

Scalar `to_replace` and `value`

```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0  5  
1  1  
2  2  
3  3  
4  4  
dtype: int64
```

```python
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
...                    'B': [5, 6, 7, 8, 9],
...                    'C': ['a', 'b', 'c', 'd', 'e']})
>>> df.replace(0, 5)
   A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

List-like `to_replace`

```python
>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

```python
>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e
```

```python
>>> s.replace([1, 2], method='bfill')
0  0
1  3
2  3
3  3
4  4
dtype: int64
```

**dict-like `to_replace`**

```python
>>> df.replace({0: 10, 1: 100})
   A  B  C
0 10  5  a
1 100  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```

```python
>>> df.replace({'A': 0, 'B': 5}, 100)
   A  B  C
0  100 100 a
1   1  6  b
2   2  7  c
3   3  8  d
4   4  9  e
```

```python
>>> df.replace({'A': {0: 100, 4: 400}})
   A  B  C
0 100  5  a
1   1  6  b
2   2  7  c
3   3  8  d
4  400  9  e
```

**Regular expression `to_replace`**

```python
>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
                    'B': ['abc', 'bar', 'xyz']})
```

```python
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
   A  B
0 new abc
1 foo new
2 bait xyz
```

```python
>>> df.replace({'A': r'^ba.$'}, {'A': 'new'}, regex=True)
   A  B
0 new abc
```

(continues on next page)
1 foo bar
2 bait xyz

```python
>>> df.replace(regex=r'^ba.$', value='new')
   A   B
0  new abc
1  foo new
2  bait xyz
```

```python
>>> df.replace(regex={r'^ba.$': 'new', 'foo': 'xyz'})
   A   B
0  new abc
1  xyz new
2  bait xyz
```

```python
>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
   A   B
0  new abc
1  new new
2  bait xyz
```

Note that when replacing multiple bool or datetime64 objects, the data types in the `to_replace` parameter must match the data type of the value being replaced:

```python
>>> df = pd.DataFrame({'A': [True, False, True],
...                    'B': [False, True, False]})
>>> df.replace({'a string': 'new value', True: False})  # raises
Traceback (most recent call last):
  ...  
TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'
```

This raises a `TypeError` because one of the dict keys is not of the correct type for replacement.

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the `to_replace` parameter:

```python
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
```

When one uses a dict as the `to_replace` value, it is like the value(s) in the dict are equal to the `value` parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None):

```python
>>> s.replace({'a': None})
0  10
1  None
2  None
3   b
4  None
dtype: object
```

When `value=None` and `to_replace` is a scalar, list or tuple, `replace` uses the method parameter (default ‘pad’) to do the replacement. So this is why the ‘a’ values are being replaced by 10 in rows 1 and 2 and ‘b’ in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace=['a'], value=None, method='pad'):`
```python
>>> s.replace('a', None)
0     10
1     10
2     10
3      b
4      b
dtype: object
```

**pandas.DataFrame.resample**

**DataFrame.resample**(rule, axis=0, closed=None, label=None, convention='start', kind=None, loffset=None, base=None, on=None, level=None, origin='start_day', offset=None)

Resample time-series data.

Convenience method for frequency conversion and resampling of time series. Object must have a datetime-like index (`DatetimeIndex`, `PeriodIndex`, or `TimedeltaIndex`), or pass datetime-like values to the `on` or `level` keyword.

**Parameters**

- **rule** [DateOffset, Timedelta or str] The offset string or object representing target conversion.
- **axis** [{0 or 'index', 1 or 'columns'}, default 0] Which axis to use for up- or down-sampling. For Series this will default to 0, i.e. along the rows. Must be `DateTimeIndex`, `TimedeltaIndex` or `PeriodIndex`.
- **label** [{‘right’, ‘left’}, default None] Which bin edge label to label bucket with. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.
- **convention** [{‘start’, ‘end’, ‘s’, ‘e’}, default ‘start’] For `PeriodIndex` only, controls whether to use the start or end of `rule`.
- **kind** [{‘timestamp’, ‘period’}, optional, default None] Pass ‘timestamp’ to convert the resulting index to a `DateTimeIndex` or ‘period’ to convert it to a `PeriodIndex`. By default the input representation is retained.
- **loffset** [timedelta, default None] Adjust the resampled time labels.

Deprecated since version 1.1.0: You should add the loffset to the `df.index` after the resample. See below.

- **base** [int, default 0] For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0.

    Deprecated since version 1.1.0: The new arguments that you should use are ‘offset’ or ‘origin’.

- **on** [str, optional] For a DataFrame, column to use instead of index for resampling. Column must be datetime-like.
- **level** [str or int, optional] For a MultiIndex, level (name or number) to use for resampling. `level` must be datetime-like.
origin [{‘epoch’, ‘start’, ‘start_day’}, Timestamp or str, default ‘start_day’] The times-
tamp on which to adjust the grouping. The timezone of origin must match the
timezone of the index. If a timestamp is not used, these values are also supported:

- ‘epoch’: origin is 1970-01-01
- ‘start’: origin is the first value of the timeseries
- ‘start_day’: origin is the first day at midnight of the timeseries

New in version 1.1.0.

offset [Timedelta or str, default is None] An offset timedelta added to the origin.

New in version 1.1.0.

Returns
Resampler object

See also:

groupby Group by mapping, function, label, or list of labels.
Series.resample Resample a Series.
DataFrame.resample Resample a DataFrame.

Notes
See the user guide for more.
To learn more about the offset strings, please see this link.

Examples
Start by creating a series with 9 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```python
>>> series.resample('3T').sum()
```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket 2000-01-01 00:03:00 contains the value 3, but the summed value in the resampled bucket with the label 2000-01-01 00:03:00 does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```python
>>> series.resample('3T', label='right').sum()
2000-01-01 00:00:00   3
2000-01-01 00:03:00   12
2000-01-01 00:06:00   21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```python
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00   0
2000-01-01 00:03:00   6
2000-01-01 00:06:00  15
2000-01-01 00:09:00  15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.

```python
>>> series.resample('30S').asfreq()[0:5]  # Select first 5 rows
2000-01-01 00:00:00   0.0
2000-01-01 00:00:30   NaN
2000-01-01 00:01:00   1.0
2000-01-01 00:01:30   NaN
2000-01-01 00:02:00   2.0
Freq: 30S, dtype: float64
```

Upsample the series into 30 second bins and fill the NaN values using the pad method.

```python
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00   0
2000-01-01 00:00:30   0
2000-01-01 00:01:00   1
2000-01-01 00:01:30   1
2000-01-01 00:02:00   2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the bfill method.

```python
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00   0
2000-01-01 00:00:30   1
2000-01-01 00:01:00   1
2000-01-01 00:01:30   2
2000-01-01 00:02:00   2
Freq: 30S, dtype: int64
```

Pass a custom function via apply

```python
>>> def custom_resampler(array_like):
...     return np.sum(array_like) + 5
...
```
For a Series with a PeriodIndex, the keyword convention can be used to control whether to use the start or end of rule.

Resample a year by quarter using 'start' convention. Values are assigned to the first quarter of the period.

```python
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01', freq='A', periods=2))
>>> s
2012 1
2013 2
Freq: A-DEC, dtype: int64

>>> s.resample('Q', convention='start').asfreq()
2012Q1 1.0
2012Q2 NaN
2012Q3 NaN
2012Q4 NaN
2013Q1 2.0
2013Q2 NaN
2013Q3 NaN
2013Q4 NaN
Freq: Q-DEC, dtype: float64
```

Resample quarters by month using 'end' convention. Values are assigned to the last month of the period.

```python
>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01', freq='Q', periods=4))
>>> q
2018Q1 1
2018Q2 2
2018Q3 3
2018Q4 4
Freq: Q-DEC, dtype: int64

>>> q.resample('M', convention='end').asfreq()
2018-03 1.0
2018-04 NaN
2018-05 NaN
2018-06 2.0
2018-07 NaN
2018-08 NaN
2018-09 3.0
2018-10 NaN
2018-11 NaN
2018-12 4.0
Freq: M, dtype: float64
```

For DataFrame objects, the keyword on can be used to specify the column instead of the index for resampling.
>>> d = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...    'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018',
...    periods=8,
...    freq='W')
>>> df

<table>
<thead>
<tr>
<th>price</th>
<th>volume</th>
<th>week_starting</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>50</td>
<td>2018-01-07</td>
</tr>
<tr>
<td>11</td>
<td>60</td>
<td>2018-01-14</td>
</tr>
<tr>
<td>9</td>
<td>40</td>
<td>2018-01-21</td>
</tr>
<tr>
<td>13</td>
<td>100</td>
<td>2018-01-28</td>
</tr>
<tr>
<td>14</td>
<td>50</td>
<td>2018-02-04</td>
</tr>
<tr>
<td>18</td>
<td>100</td>
<td>2018-02-11</td>
</tr>
<tr>
<td>17</td>
<td>40</td>
<td>2018-02-18</td>
</tr>
<tr>
<td>19</td>
<td>50</td>
<td>2018-02-25</td>
</tr>
</tbody>
</table>

>>> df.resample('M', on='week_starting').mean()

<table>
<thead>
<tr>
<th>week_starting</th>
<th>price</th>
<th>volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>2018-01-31</td>
<td>10.75</td>
<td>62.5</td>
</tr>
<tr>
<td>2018-02-28</td>
<td>17.00</td>
<td>60.0</td>
</tr>
</tbody>
</table>

For a DataFrame with MultiIndex, the keyword `level` can be used to specify on which level the resampling needs to take place.

>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = dict({'price': [10, 11, 9, 13, 14, 18, 17, 19],
...    'volume': [50, 60, 40, 100, 50, 100, 40, 50]})
>>> df2 = pd.DataFrame(d2, index=pd.MultiIndex.from_product([[days],
...    ['morning', 'afternoon']])
>>> df2

<table>
<thead>
<tr>
<th>price</th>
<th>volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01 morning</td>
<td>10</td>
</tr>
<tr>
<td>afternoon</td>
<td>11</td>
</tr>
<tr>
<td>2000-01-02 morning</td>
<td>9</td>
</tr>
<tr>
<td>afternoon</td>
<td>13</td>
</tr>
<tr>
<td>2000-01-03 morning</td>
<td>14</td>
</tr>
<tr>
<td>afternoon</td>
<td>18</td>
</tr>
<tr>
<td>2000-01-04 morning</td>
<td>17</td>
</tr>
<tr>
<td>afternoon</td>
<td>19</td>
</tr>
</tbody>
</table>

>>> df2.resample('D', level=0).sum()

<table>
<thead>
<tr>
<th>week_starting</th>
<th>price</th>
<th>volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>21</td>
<td>110</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>22</td>
<td>140</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>32</td>
<td>150</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>36</td>
<td>90</td>
</tr>
</tbody>
</table>

If you want to adjust the start of the bins based on a fixed timestamp:

>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
>>> ts

(continues on next page)
If you want to adjust the start of the bins with an `offset` Timedelta, the two following lines are equivalent:

```python
>>> ts.resample('17min', origin='start').sum()
2000-10-01 23:30:00  9
2000-10-01 23:47:00  21
2000-10-02 00:04:00  54
2000-10-02 00:21:00  24
Freq: 17T, dtype: int64
```
```
>>> ts.resample('17min', offset='23h30min').sum()
2000-10-01 23:30:00  9
2000-10-01 23:47:00  21
2000-10-02 00:04:00  54
2000-10-02 00:21:00  24
Freq: 17T, dtype: int64
```

To replace the use of the deprecated `base` argument, you can now use `offset`, in this example it is equivalent to have `base=2`:

```python
>>> ts.resample('17min', offset='2min').sum()
2000-10-01 23:16:00  0
2000-10-01 23:33:00  9
```

To replace the use of the deprecated `loffset` argument:

```python
>>> from pandas.tseries.frequencies import to_offset
>>> loffset = '19min'
>>> ts_out = ts.resample('17min').sum()
>>> ts_out.index = ts_out.index + to_offset(loffset)
```

```
2000-10-01 23:33:00   0
2000-10-01 23:50:00   9
2000-10-02 00:07:00  21
2000-10-02 00:24:00  54
2000-10-02 00:41:00  24
Freq: 17T, dtype: int64
```

**pandas.DataFrame.reset_index**

DataFrame.reset_index (level=None, drop=False, inplace=False, col_level=0, col_fill='')

Reset the index, or a level of it.

Reset the index of the DataFrame, and use the default one instead. If the DataFrame has a MultiIndex, this method can remove one or more levels.

**Parameters**

- **level** [int, str, tuple, or list, default None] Only remove the given levels from the index. Removes all levels by default.
- **drop** [bool, default False] Do not try to insert index into dataframe columns. This resets the index to the default integer index.
- **inplace** [bool, default False] Modify the DataFrame in place (do not create a new object).
- **col_level** [int or str, default 0] If the columns have multiple levels, determines which level the labels are inserted into. By default it is inserted into the first level.
- **col_fill** [object, default ‘’] If the columns have multiple levels, determines how the other levels are named. If None then the index name is repeated.

**Returns**

- **DataFrame or None** DataFrame with the new index or None if inplace=True.

**See also:**

- **DataFrame.set_index** Opposite of reset_index.
- **DataFrame.reindex** Change to new indices or expand indices.
- **DataFrame.reindex_like** Change to same indices as other DataFrame.
Examples

```python
>>> df = pd.DataFrame([('bird', 389.0),
...                     ('bird', 24.0),
...                     ('mammal', 80.5),
...                     ('mammal', np.nan),
...                     index=['falcon', 'parrot', 'lion', 'monkey'],
...                     columns=('class', 'max_speed'))
>>> df
    class max_speed
falcon bird    389.0
parrot bird    24.0
lion mammal    80.5
monkey mammal  NaN

When we reset the index, the old index is added as a column, and a new sequential index is used:

```python
>>> df.reset_index()
    index class max_speed
       0  falcon bird    389.0
       1  parrot bird    24.0
       2    lion mammal    80.5
       3 monkey mammal   NaN
```

We can use the `drop` parameter to avoid the old index being added as a column:

```python
>>> df.reset_index(drop=True)
    class max_speed
       0  bird    389.0
       1  bird    24.0
       2  mammal    80.5
       3  mammal    NaN

You can also use `reset_index` with `MultiIndex`.

```python
>>> index = pd.MultiIndex.from_tuples([('bird', 'falcon'),
...                                     ('bird', 'parrot'),
...                                     ('mammal', 'lion'),
...                                     ('mammal', 'monkey')],
...                                     names=['class', 'name'])
>>> columns = pd.MultiIndex.from_tuples([('speed', 'max'),
...                                        ('species', 'type')])
>>> df = pd.DataFrame([(389.0, 'fly'),
...                     ( 24.0, 'fly'),
...                     ( 80.5, 'run'),
...                     (np.nan, 'jump')],
...                     index=index,
...                     columns=columns)
>>> df
    speed species
    max type
      class name
    bird falcon 389.0   fly
    parrot 24.0   fly
    mammal lion 80.5   run
    monkey NaN  NaN
```

If the index has multiple levels, we can reset a subset of them:
If we are not dropping the index, by default, it is placed in the top level. We can place it in another level:

```
>>> df.reset_index(level='class', col_level=1)
```

When the index is inserted under another level, we can specify under which one with the parameter `col_fill`:

```
>>> df.reset_index(level='class', col_level=1, col_fill='species')
```

If we specify a nonexistent level for `col_fill`, it is created:

```
>>> df.reset_index(level='class', col_level=1, col_fill='genus')
```

---

**pandas.DataFrame.rfloordiv**

Dataframe `.rfloordiv` (other, axis='columns', level=None, fill_value=None)

Get integer division of dataframe and other, element-wise (binary operator `rfloordiv`).

Equivalent to `other // dataframe`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, `floordiv`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’)
or columns (1 or ‘columns’). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any
new element needed for successful DataFrame alignment, with this value before
computation. If data in both corresponding DataFrame locations is missing the
result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
     angles  degrees
circle      0      360
triangle    3      180
rectangle   4      360

Add a scalar with operator version which return the same results.

```
divide by constant with reverse version.

```
>>> df.div(10)
   angles  degrees
circle     0.0   36.0
triangle   0.3   18.0
rectangle  0.4   36.0
```

```
>>> df.rdiv(10)
   angles  degrees
circle    inf   0.027778
triangle  3.333333  0.055556
rectangle 2.500000  0.027778
```

subtract a list and series by axis with operator version.

```
>>> df - [1, 2]
   angles  degrees
circle   -1   358
triangle   2   178
rectangle  3   358
```

```
>>> df.sub([1, 2], axis='columns')
   angles  degrees
circle   -1   358
triangle   2   178
rectangle  3   358
```

```
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
         axis='index')
   angles  degrees
circle   -1   359
triangle   2   179
rectangle  3   359
```

multiply a DataFrame of different shape with operator version.

```
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])
>>> other
   angles
circle   0
triangle   3
rectangle   4
```

```
>>> df * other
   angles  degrees
circle     0   NaN
triangle    9   NaN
rectangle  16   NaN
```
>>> df.mul(other, fill_value=0)
   angles  degrees
   circle    0       0
   triangle   9       0
   rectangle 16       0

Divide by a MultiIndex by level.

>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               'index': [['A', 'A', 'A', 'B', 'B', 'B'],
                                         ['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon']]})

>>> df_multindex
   angles  degrees
   A circle 0         360
        triangle 3       180
        rectangle 4       360
   B square 4         360
        pentagon 5        540
        hexagon 6        720

>>> df.div(df_multindex, level=1, fill_value=0)
   angles  degrees
   A circle NaN       1.0
        triangle 1.0    1.0
        rectangle 1.0    1.0
   B square 0.0       0.0
        pentagon 0.0    0.0
        hexagon 0.0    0.0

pandas.DataFrame.rmod

DataFrame.rmod(other, axis='columns', level=None, fill_value=None)

Get Modulo of dataframe and other, element-wise (binary operator rmod).

Equivalent to other % dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, mod.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other  [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis  [(0 or 'index', 1 or 'columns')] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
level  [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
fill_value  [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns
**DataFrame**  Result of the arithmetic operation.

**See also:**

- *DataFrame.add*  Add DataFrames.
- *DataFrame.sub*  Subtract DataFrames.
- *DataFrame.mul*  Multiply DataFrames.
- *DataFrame.div*  Divide DataFrames (float division).
- *DataFrame.truediv*  Divide DataFrames (float division).
- *DataFrame.floordiv*  Divide DataFrames (integer division).
- *DataFrame.mod*  Calculate modulo (remainder after division).
- *DataFrame.pow*  Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

**Examples**

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle     0      360
triangle    3      180
rectangle   4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
    angles  degrees
  circle    1      361
  triangle   4      181
  rectangle  5      361
```

```python
>>> df.add(1)
    angles  degrees
  circle    1      361
  triangle   4      181
  rectangle  5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
    angles  degrees
  circle    0.0     36.0
  triangle  0.3      18.0
  rectangle 0.4     36.0
```

3.4. *DataFrame*  1653
Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
angles  degrees  
circle -1    358
triangle  2     178
rectangle 3     358
```

```python
>>> df.sub([1, 2], axis='columns')
angles  degrees  
circle -1    358
triangle  2     178
rectangle 3     358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
angles  degrees  
circle -1    359
triangle  2     179
rectangle 3     359
```

Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]}, index=['circle', 'triangle', 'rectangle'])
```

```python
>>> df * other
angles  degrees  
circle  0.0   NaN
triangle 9.0   NaN
rectangle 16.0  NaN
```

```python
>>> df.mul(other, fill_value=0)
angles  degrees  
circle  0.0   0.0
triangle 9.0   0.0
rectangle 16.0  0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6], 'degrees': [360, 180, 360, 360, 540, 720]}, index=['A', 'A', 'A', 'B', 'B', 'B'], columns=['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon'])
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

(continued from previous page)

```python
>>> df_multindex = pandas.DataFrame({
    'angles': [0, 3, 4, 5, 6],
    'degrees': [360, 180, 360, 540, 720]
    }, index=['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon'])
```

```python
>>> df = df_multindex
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
```

```
angles  degrees
A circle   NaN   1.0
triangle  1.0   1.0
rectangle 1.0   1.0
B square  0.0   0.0
pentagon  0.0   0.0
hexagon  0.0   0.0
```

**pandas.DataFrame.rmul**

DataFrame.rmul (other, axis='columns', level=None, fill_value=None)

Get Multiplication of dataframe and other, element-wise (binary operator rmul).

Equivalent to other * dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, mul.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame Result of the arithmetic operation.

**See also:**

- DataFrame.add Add DataFrames.
- DataFrame.sub Subtract DataFrames.
- DataFrame.mul Multiply DataFrames.
- DataFrame.div Divide DataFrames (float division).
- DataFrame.truediv Divide DataFrames (float division).
**DataFrame.floordiv**  Divide DataFrames (integer division).

**DataFrame.mod**  Calculate modulo (remainder after division).

**DataFrame.pow**  Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

### Examples

```python
gf = pd.DataFrame({'angles': [0, 3, 4],
                   'degrees': [360, 180, 360]},
                   index=['circle', 'triangle', 'rectangle'])

gf
angles  degrees
---  ------
circle   0  360
triangle  3  180
rectangle 4  360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
angles  degrees
---  ------
circle   1  361
triangle  4  181
rectangle 5  361
```

```python
>>> df.add(1)
angles  degrees
---  ------
circle   1  361
triangle  4  181
rectangle 5  361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
angles  degrees
---  ------
circle  0.0  36.0
triangle 0.3  18.0
rectangle 0.4  36.0
```

```python
>>> df.rdiv(10)
angles  degrees
---  ------
circle inf 0.027778
triangle 3.333333 0.055556
rectangle 2.500000 0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
angles  degrees
---  ------
circle  -1  358
triangle   2  178
rectangle   3  358
```
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                      index=['circle', 'triangle', 'rectangle'])
```

```plaintext
>>>
```

```python
>>> df * other
>>>
```

```plaintext
    angles degrees
  circle    0      NaN
  triangle  9      NaN
  rectangle 16      NaN
```

```python
>>> df.mul(other, fill_value=0)
>>>
```

```plaintext
    angles degrees
  circle    0       0.0
  triangle  9       0.0
  rectangle 16      0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 720],
                               index=['A', 'A', 'A', 'B', 'B', 'B'],
                               ...
                               })
```

```plaintext
>>>
```

```python
>>> df_multindex
>>>
```

```plaintext
   angles degrees
A circle    0      360
triangle  3      180
rectangle  4      360
B square  4      360
pentagon  5      540
hexagon  6      720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
>>>
```

```plaintext
   angles degrees
A circle    NaN      1.0
triangle  1.0      1.0
rectangle  1.0      1.0
```

pandas.DataFrame.rolling

DataFrame.rolling(window, min_periods=None, center=False, win_type=None, on=None, axis=0, closed=None)

Provide rolling window calculations.

Parameters

- **window** [int, offset, or BaseIndexer subclass] Size of the moving window. This is the number of observations used for calculating the statistic. Each window will be a fixed size.

  If its an offset then this will be the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes.

  If a BaseIndexer subclass is passed, calculates the window boundaries based on the defined `get_window_bounds` method. Additional rolling keyword arguments, namely `min_periods`, `center`, and `closed` will be passed to `get_window_bounds`.

- **min_periods** [int, default None] Minimum number of observations in window required to have a value (otherwise result is NA). For a window that is specified by an offset, `min_periods` will default to 1. Otherwise, `min_periods` will default to the size of the window.

- **center** [bool, default False] Set the labels at the center of the window.

- **win_type** [str, default None] Provide a window type. If `None`, all points are evenly weighted. See the notes below for further information.

- **on** [str, optional] For a DataFrame, a datetime-like column or MultiIndex level on which to calculate the rolling window, rather than the DataFrame’s index. Provided integer column is ignored and excluded from result since an integer index is not used to calculate the rolling window.

- **axis** [int or str, default 0]

- **closed** [str, default None] Make the interval closed on the ‘right’, ‘left’, ‘both’ or ‘neither’ endpoints. For offset-based windows, it defaults to ‘right’. For fixed windows, defaults to ‘both’. Remaining cases not implemented for fixed windows.

Returns

A Window or Rolling sub-classed for the particular operation

See also:

- **expanding** Provides expanding transformations.
- **ewm** Provides exponential weighted functions.
Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

To learn more about the offsets & frequency strings, please see this link.

The recognized `win_types` are:

- `boxcar`
- `triang`
- `blackman`
- `hamming`
- `bartlett`
- `parzen`
- `bohman`
- `blackmanharris`
- `nuttall`
- `barthann`
- `kaiser` (needs parameter: `beta`)
- `gaussian` (needs parameter: `std`)
- `general_gaussian` (needs parameters: `power`, `width`)
- `slepian` (needs parameter: `width`)
- `exponential` (needs parameter: `tau`), center is set to `None`.

If `win_type=None` all points are evenly weighted. To learn more about different window types see `scipy.signal window functions`.

Certain window types require additional parameters to be passed. Please see the third example below on how to add the additional parameters.

Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

Rolling sum with a window length of 2, using the ‘triang’ window type.

```python
>>> df.rolling(2, win_type='triang').sum()
   B
0  NaN
1  0.5
2  1.5
```

Rolling sum with a window length of 2, using the ‘gaussian’ window type (note how we need to specify std).

```python
>>> df.rolling(2, win_type='gaussian').sum(std=3)
B
0  NaN
1  0.986207
2  2.958621
3  NaN
4  NaN
```

Rolling sum with a window length of 2, min_periods defaults to the window length.

```python
>>> df.rolling(2).sum()
B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN
```

Same as above, but explicitly set the min_periods

```python
>>> df.rolling(2, min_periods=1).sum()
B
0  0.0
1  1.0
2  3.0
3  2.0
4  4.0
```

Same as above, but with forward-looking windows

```python
>>> indexer = pd.api.indexers.FixedForwardWindowIndexer(window_size=2)
>>> df.rolling(window=indexer, min_periods=1).sum()
B
0  1.0
1  3.0
2  2.0
3  4.0
4  4.0
```

A ragged (meaning not-a-regular frequency), time-indexed DataFrame

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
...                   index = [pd.Timestamp('20130101 09:00:00'),
...                     pd.Timestamp('20130101 09:00:02'),
...                     pd.Timestamp('20130101 09:00:03'),
...                     pd.Timestamp('20130101 09:00:05'),
...                     pd.Timestamp('20130101 09:00:06')])
>>> df
     B
0  0.0
1  1.0
2  3.0
3  2.0
4  4.0
```

(continues on next page)
Contrasting to an integer rolling window, this will roll a variable length window corresponding to the time period. The default for min_periods is 1.

```python
>>> df.rolling('2s').sum()
```

```
B
2013-01-01 09:00:00 0.0  
2013-01-01 09:00:02 1.0  
2013-01-01 09:00:03 2.0  
2013-01-01 09:00:05 NaN  
2013-01-01 09:00:06 4.0  
```

**pandas.DataFrame.round**

DataFrame.round(decimals=0, *args, **kwargs)

Round a DataFrame to a variable number of decimal places.

**Parameters**

- **decimals** [int, dict, Series] Number of decimal places to round each column to. If an int is given, round each column to the same number of places. Otherwise dict and Series round to variable numbers of places. Column names should be in the keys if decimals is a dict-like, or in the index if decimals is a Series. Any columns not included in decimals will be left as is. Elements of decimals which are not columns of the input will be ignored.
- **args** Additional keywords have no effect but might be accepted for compatibility with numpy.
- **kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

**Returns**

DataFrame A DataFrame with the affected columns rounded to the specified number of decimal places.

**See also:**

- **numpy.around** Round a numpy array to the given number of decimals.
- **Series.round** Round a Series to the given number of decimals.
Examples

```python
>>> df = pd.DataFrame([(0.21, 0.32), (0.01, 0.67), (0.66, 0.03), (0.21, 0.18)],
... columns=['dogs', 'cats'])
>>> df
dogs  cats
0  0.21  0.32
1  0.01  0.67
2  0.66  0.03
3  0.21  0.18
By providing an integer each column is rounded to the same number of decimal places
>>> df.round(1)
dogs  cats
0  0.2  0.3
1  0.0  0.7
2  0.7  0.0
3  0.2  0.2
With a dict, the number of places for specific columns can be specified with the column names as key and the number of decimal places as value
>>> df.round({'dogs': 1, 'cats': 0})
dogs  cats
0  0.2  0.0
1  0.0  1.0
2  0.7  0.0
3  0.2  0.0
Using a Series, the number of places for specific columns can be specified with the column names as index and the number of decimal places as value
>>> decimals = pd.Series([0, 1], index=['cats', 'dogs'])
>>> df.round(decimals)
dogs  cats
0  0.2  0.0
1  0.0  1.0
2  0.7  0.0
3  0.2  0.0
```

pandas.DataFrame.rpow

DataFrame.rpow(other, axis='columns', level=None, fill_value=None)

Get Exponential power of dataframe and other, element-wise (binary operator rpow).

Equivalent to other ** dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, pow.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, //, %, **.

Parameters

- other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

- axis [(0 or ‘index’, 1 or ‘columns’)] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
**level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

**DataFrame** Result of the arithmetic operation.

**See also:**

- `DataFrame.add` Add DataFrames.
- `DataFrame.sub` Subtract DataFrames.
- `DataFrame.mul` Multiply DataFrames.
- `DataFrame.div` Divide DataFrames (float division).
- `DataFrame.truediv` Divide DataFrames (float division).
- `DataFrame.floordiv` Divide DataFrames (integer division).
- `DataFrame.mod` Calculate modulo (remainder after division).
- `DataFrame.pow` Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

**Examples**

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle     0      360
triangle   3      180
rectangle  4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle   1      361
triangle 4      181
rectangle 5      361
```

```python
>>> df.add(1)
   angles  degrees
circle   1      361
triangle 4      181
rectangle 5      361
```
Divide by constant with reverse version.

```python
>>> df.div(10)
angles   degrees
 circle   0.0    36.0
 triangle 0.3    18.0
 rectangle 0.4    36.0
```

```python
>>> df.rdiv(10)
angles   degrees
 circle   inf    0.027778
 triangle 3.333333 0.055556
 rectangle 2.500000 0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
angles   degrees
 circle  -1    358
 triangle 2    178
 rectangle 3    358
```

```python
>>> df.sub([1, 2], axis='columns')
angles   degrees
 circle  -1    358
 triangle 2    178
 rectangle 3    358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
angles   degrees
 circle  -1    359
 triangle 2    179
 rectangle 3    359
```

Multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({'angles': [0, 3, 4],
                      index=['circle', 'triangle', 'rectangle'])
```

```python
>>> df * other
angles   degrees
 circle  0.0    NaN
 triangle 9.0    NaN
 rectangle 16.0   NaN
```

```python
>>> df.mul(other, fill_value=0)
angles   degrees
 circle  0.0    0.0
 triangle 0.0    0.0
 rectangle 0.0    0.0
```
Divide by a MultiIndex by level.

```python
def_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                             'degrees': [360, 180, 360, 360, 540, 720],
                             'index': ['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon']})
```

```python
>>> df_multindex
angles  degrees
A circle  0   360
triangle  3   180
rectangle 4   360
B square  4   360
pentagon  5   540
hexagon  6   720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
```

```
angles  degrees
A circle  NaN  1.0
triangle  1.0  1.0
rectangle 1.0  1.0
B square  0.0  0.0
pentagon  0.0  0.0
hexagon  0.0  0.0
```

**pandas.DataFrame.rsub**

Dataframe.rsub(\(\text{other, axis='columns', level=None, fill\_value=None}\))

Get Subtraction of dataframe and other, element-wise (binary operator \(\text{rsub}\)).

Equivalent to \(\text{other} - \text{dataframe}\), but with support to substitute a fill\_value for missing data in one of the inputs. With reverse version, \(\text{sub}\).

Among flexible wrappers (\(\text{add, sub, mul, div, mod, pow}\)) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- \(\text{other}\) [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- \(\text{axis}\) [0 or ‘index’, 1 or ‘columns’] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- \(\text{level}\) [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- \(\text{fill\_value}\) [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

Dataframe Result of the arithmetic operation.

**See also:**

- **DataFrame.add** Add DataFrames.
- **DataFrame.sub** Subtract DataFrames.
DataFrame.mul  Multiply DataFrames.
DataFrame.div  Divide DataFrames (float division).
DataFrame.truediv  Divide DataFrames (float division).
DataFrame.floordiv  Divide DataFrames (integer division).
DataFrame.mod  Calculate modulo (remainder after division).
DataFrame.pow  Calculate exponential power.

Notes
Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
```

```text
angles  degrees
circle  0  360
triangle  3  180
rectangle  4  360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```

```text
angles  degrees
circle  1  361
triangle  4  181
rectangle  5  361
```

```python
>>> df.add(1)
```

```text
angles  degrees
circle  1  361
triangle  4  181
rectangle  5  361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
```

```text
angles  degrees
circle  0.0  36.0
triangle  0.3  18.0
rectangle  0.4  36.0
```

```python
>>> df.rdiv(10)
```

```text
angles  degrees
circle  inf  0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.
```python
>>> df = [1, 2]
   angles  degrees
circle   -1   358
triangle   2   178
circle   3   358

>>> df.sub([1, 2], axis='columns')
   angles  degrees
circle   -1   358
triangle   2   178
circle   3   358

>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
   angles  degrees
circle   -1   359
triangle   2   179
circle   3   359

Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4]}, index=['circle', 'triangle', 'rectangle'])

>>> df * other
   angles  degrees
circle   0  NaN
triangle   9  NaN
rectangle 16  NaN

>>> df.mul(other, fill_value=0)
   angles  degrees
circle   0   0.0
triangle   9   0.0
rectangle 16   0.0

Divide by a MultiIndex by level.

>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
   'degrees': [360, 180, 360, 360, 540, 720],
   index=[['A', 'A', 'A', 'B', 'B', 'B'],
          ['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon']])

>>> df_multindex
   angles  degrees
    A circle   0  360
      triangle   3  180
         rectangle   4  360
    B square   4  360
       pentagon   5  540
          hexagon   6  720
```

3.4. DataFrame
pandas: powerful Python data analysis toolkit, Release 1.1.1

```python
>>> df.div(df_multindex, level=1, fill_value=0)

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>NaN</td>
</tr>
<tr>
<td>triangle</td>
<td>1.0</td>
</tr>
<tr>
<td>rectangle</td>
<td>1.0</td>
</tr>
<tr>
<td>B</td>
<td>0.0</td>
</tr>
<tr>
<td>square</td>
<td>0.0</td>
</tr>
<tr>
<td>pentagon</td>
<td>0.0</td>
</tr>
<tr>
<td>hexagon</td>
<td>0.0</td>
</tr>
</tbody>
</table>
```

**pandas.DataFrame.rtruediv**

`DataFrame.rtruediv(other, axis='columns', level=None, fill_value=None)`

Get Floating division of dataframe and other, element-wise (binary operator `rtruediv`).

Equivalent to `other / dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `truediv`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- `fill_value` [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

`DataFrame` Result of the arithmetic operation.

**See also:**

- `DataFrame.add` Add DataFrames.
- `DataFrame.sub` Subtract DataFrames.
- `DataFrame.mul` Multiply DataFrames.
- `DataFrame.div` Divide DataFrames (float division).
- `DataFrame.truediv` Divide DataFrames (float division).
- `DataFrame.floordiv` Divide DataFrames (integer division).
- `DataFrame.mod` Calculate modulo (remainder after division).
- `DataFrame.pow` Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle    0       360
triangle   3       180
rectangle  4       360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle    1       361
triangle   4       181
rectangle  5       361
```

```python
>>> df.add(1)
   angles  degrees
circle    1       361
triangle   4       181
rectangle  5       361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle  0.0       36.0
triangle 0.3       18.0
rectangle 0.4       36.0
```

```python
>>> df.rdiv(10)
   angles  degrees
circle  inf      0.027778
triangle  3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
   angles  degrees
circle   -1       358
triangle    2       178
rectangle   3       358
```

```python
>>> df.sub([1, 2], axis='columns')
   angles  degrees
circle   -1       358
triangle    2       178
rectangle   3       358
```
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])
>>> other
angles
circle 0
triangle 3
rectangle 4
```

```python
>>> df + other
   angles  degrees
circle   0      NaN
triangle 9      NaN
rectangle 16     NaN
```

```python
>>> df.mul(other, fill_value=0)
   angles  degrees
circle   0       0.0
triangle 9       0.0
rectangle 16     0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               'index': [['A', 'A', 'A', 'B', 'B', 'B'],
                                         ['circle', 'triangle', 'rectangle',
                                          'square', 'pentagon', 'hexagon']])
>>> df_multindex
    angles  degrees
A circle 0       360
triangle 3       180
rectangle 4      360
B square 4       360
pentagon 5       540
hexagon 6       720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
   angles  degrees
A circle   NaN       1.0
triangle  1.0       1.0
rectangle 1.0       1.0
B square   0.0       0.0
pentagon   0.0       0.0
hexagon   0.0       0.0
```
DataFrame.sample

DataFrame.sample(n=None, frac=None, replace=False, weights=None, random_state=None, axis=None)

Return a random sample of items from an axis of object.

You can use random_state for reproducibility.

Parameters

- **n** [int, optional] Number of items from axis to return. Cannot be used with frac. Default = 1 if frac = None.
- **frac** [float, optional] Fraction of axis items to return. Cannot be used with n.
- **replace** [bool, default False] Allow or disallow sampling of the same row more than once.
- **weights** [str or ndarray-like, optional] Default ‘None’ results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when axis = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.
- **random_state** [int, array-like, BitGenerator, np.random.RandomState, optional] If int, array-like, or BitGenerator (NumPy>=1.17), seed for random number generator If np.random.RandomState, use as numpy RandomState object.

Changed in version 1.1.0: array-like and BitGenerator (for NumPy>=1.17) object now passed to np.random.RandomState() as seed

- **axis** [[0 or ‘index’, 1 or ‘columns’, None], default None] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames).

Returns

- **Series or DataFrame** A new object of same type as caller containing n items randomly sampled from the caller object.

See also:

- **DataFrameGroupBy.sample** Generates random samples from each group of a DataFrame object.
- **SeriesGroupBy.sample** Generates random samples from each group of a Series object.
- **numpy.random.choice** Generates a random sample from a given 1-D numpy array.
Notes

If \( \text{frac} > 1 \), replacement should be set to True.

Examples

```python
>>> df = pd.DataFrame({
    'num_legs': [2, 4, 8, 0],
    'num_wings': [2, 0, 0, 0],
    'num_specimen_seen': [10, 2, 1, 8],
}, index=['falcon', 'dog', 'spider', 'fish'])

>>> df
  num_legs num_wings num_specimen_seen
falcon     2         2            10
dog        4         0             2
spider     8         0             1
fish       0         0             8

Extract 3 random elements from the Series df['num_legs']: Note that we use random_state to ensure the reproducibility of the examples.

```python
>>> df['num_legs'].sample(n=3, random_state=1)
fish
spider
falcon
Name: num_legs, dtype: int64
```

A random 50% sample of the DataFrame with replacement:

```python
>>> df.sample(frac=0.5, replace=True, random_state=1)
  num_legs num_wings num_specimen_seen
dog        4         0             2
fish       0         0             8

An upsample sample of the DataFrame with replacement: Note that replace parameter has to be True for frac parameter > 1.

```python
>>> df.sample(frac=2, replace=True, random_state=1)
  num_legs num_wings num_specimen_seen
dog        4         0             2
fish       0         0             8
falcon     2         2             10
falcon     2         2             10
fish       0         0             8
dog        4         0             2
fish       0         0             8
dog        4         0             2

Using a DataFrame column as weights. Rows with larger value in the num_specimen_seen column are more likely to be sampled.

```python
>>> df.sample(n=2, weights='num_specimen_seen', random_state=1)
  num_legs num_wings num_specimen_seen
falcon     2         2             10
fish       0         0             8
```
**pandas.DataFrame.select_dtypes**

`DataFrame.select_dtypes(include=None, exclude=None)`

Return a subset of the DataFrame’s columns based on the column dtypes.

**Parameters**

- `include, exclude` [scalar or list-like] A selection of dtypes or strings to be included/excluded. At least one of these parameters must be supplied.

**Returns**

- `DataFrame` The subset of the frame including the dtypes in `include` and excluding the dtypes in `exclude`.

**Raises**

- `ValueError` • If both of `include` and `exclude` are empty
  • If `include` and `exclude` have overlapping elements
  • If any kind of string dtype is passed in.

**See also:**

- `DataFrame.dtypes` Return Series with the data type of each column.

**Notes**

- To select all numeric types, use `np.number` or `'number'`
- To select strings you must use the `object` dtype, but note that this will return all `object` dtype columns
- See the numpy dtype hierarchy
- To select datetimes, use `np.datetime64`, `'datetime'` or `'datetime64'`
- To select timedeltas, use `np.timedelta64`, `'timedelta'` or `'timedelta64'`
- To select Pandas categorical dtypes, use `'category'`
- To select Pandas datetimetz dtypes, use `'datetimetz'` (new in 0.20.0) or `'datetime64[ns, tz]'`

**Examples**

```python
>>> df = pd.DataFrame({'a': [1, 2] * 3,
...                    'b': [True, False] * 3,
...                    'c': [1.0, 2.0] * 3})
>>> df
      a   b   c
0  1.0  True  1.0
1  2.0   False  2.0
2  1.0  True  1.0
3  2.0   False  2.0
4  1.0  True  1.0
5  2.0   False  2.0
```
```python
>>> df.select_dtypes(include='bool')
   b
0  True
1  False
2  True
3  False
4  True
5  False

>>> df.select_dtypes(include=['float64'])
   c
0  1.0
1  2.0
2  1.0
3  2.0
4  1.0
5  2.0

>>> df.select_dtypes(exclude=['int64'])
   b   c
0  True  1.0
1  False 2.0
2  True  1.0
3  False 2.0
4  True  1.0
5  False 2.0
```

**pandas.DataFrame.sem**

`DataFrame.sem(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)`

Return unbiased standard error of the mean over requested axis. Normalized by N-1 by default. This can be changed using the ddof argument.

**Parameters**

- **axis** [{index (0), columns (1)}]
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

Series or DataFrame (if level specified)
DataFrame.set_axis

DataFrame.set_axis(labels, axis=0, inplace=False)
Assign desired index to given axis.
Indexes for column or row labels can be changed by assigning a list-like or Index.

Parameters

labels [list-like, Index] The values for the new index.
axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to update. The value 0 identifies the rows, and 1 identifies the columns.
inplace [bool, default False] Whether to return a new DataFrame instance.

Returns

renamed [DataFrame or None] An object of type DataFrame if inplace=False, None otherwise.

See also:

DataFrame.rename_axis Alter the name of the index or columns.

Examples

```python
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
```
Change the row labels.
```python
>>> df.set_axis(['a', 'b', 'c'], axis='index')
```
```
   A  B
  a 1 4
  b 2 5
  c 3 6
```
Change the column labels.
```python
>>> df.set_axis(['I', 'II'], axis='columns')
```
```
   I  II
  0 1 4
  1 2 5
  2 3 6
```
Now, update the labels inplace.
```python
>>> df.set_axis(['i', 'ii'], axis='columns', inplace=True)
```
```python
   i  ii
  0 1 4
  1 2 5
  2 3 6
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.DataFrame.set_index

DataFrame.set_index (keys, drop=True, append=False, inplace=False, verify_integrity=False)
Set the DataFrame index using existing columns.
Set the DataFrame index (row labels) using one or more existing columns or arrays (of the correct length). The index can replace the existing index or expand on it.

Parameters
- keys [label or array-like or list of labels_arrays] This parameter can be either a single column key, a single array of the same length as the calling DataFrame, or a list containing an arbitrary combination of column keys and arrays. Here, “array” encompasses Series, Index, np.ndarray, and instances of Iterator.
- drop [bool, default True] Delete columns to be used as the new index.
- append [bool, default False] Whether to append columns to existing index.
- verify_integrity [bool, default False] Check the new index for duplicates. Otherwise defer the check until necessary. Setting to False will improve the performance of this method.

Returns
- DataFrame Changed row labels.

See also:
- DataFrame.reset_index Opposite of set_index.
- DataFrame.reindex Change to new indices or expand indices.
- DataFrame.reindex_like Change to same indices as other DataFrame.

Examples

```python
>>> df = pd.DataFrame({'month': [1, 4, 7, 10],
... 'year': [2012, 2014, 2013, 2014],
... 'sale': [55, 40, 84, 31]})
```
```
month year sale
0 1 2012 55
1 4 2014 40
2 7 2013 84
3 10 2014 31
```
Set the index to become the ‘month’ column:

```python
>>> df.set_index('month')
```
```
year sale
month
1 2012 55
4 2014 40
7 2013 84
10 2014 31
```
Create a MultiIndex using columns ‘year’ and ‘month’:

```python
>>> df.set_index(['year', 'month'])
   sale
year  month
2012   1  55
2014   4  40
2013   7  84
2014  10  31
```

Create a MultiIndex using an Index and a column:

```python
>>> df.set_index([pd.Index([1, 2, 3, 4]), 'year'])
   sale
month
year
1  2012   1  55
2  2014   4  40
3  2013   7  84
4  2014  10  31
```

Create a MultiIndex using two Series:

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> df.set_index([s, s**2])
   sale
month  year
1  1  2012   55
2  4  2014   40
3  9  2013   84
4 16  2014   31
```

**pandas.DataFrame.shift**

DataFrame.shift (periods=1, freq=None, axis=0, fill_value=None)

Shift index by desired number of periods with an optional time freq.

When freq is not passed, shift the index without realigning the data. If freq is passed (in this case, the index must be date or datetime, or it will raise a `NotImplementedError`), the index will be increased using the periods and the freq. freq can be inferred when specified as “infer” as long as either freq or inferred_freq attribute is set in the index.

**Parameters**

- **periods** [int] Number of periods to shift. Can be positive or negative.
- **freq** [DateOffset, tseries.offsets, timedelta, or str, optional] Offset to use from the tseries module or time rule (e.g. ‘EOM’). If freq is specified then the index values are shifted but the data is not realigned. That is, use freq if you would like to extend the index when shifting and preserve the original data. If freq is specified as “infer” then it will be inferred from the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown
- **axis** [{0 or ‘index’, 1 or ‘columns’, None}, default None] Shift direction.
- **fill_value** [object, optional] The scalar value to use for newly introduced missing values. the default depends on the dtype of self. For numeric data, np.nan is used. For datetime, timedelta, or period data, etc. NaT is used. For extension dtypes, self.dtype.na_value is used.
Changed in version 1.1.0.

Returns

DataFrame  Copy of input object, shifted.

See also:

Index.shift  Shift values of Index.
DateTimeIndex.shift  Shift values of DatetimeIndex.
PeriodIndex.shift  Shift values of PeriodIndex.
tshift  Shift the time index, using the index’s frequency if available.

Examples

```python
>>> df = pd.DataFrame({"Col1": [10, 20, 15, 30, 45],
...                     "Col2": [13, 23, 18, 33, 48],
...                     "Col3": [17, 27, 22, 37, 52]},
...                    index=pd.date_range("2020-01-01", "2020-01-05")
)

>>> df
  Col1  Col2  Col3
2020-01-01  10   13   17
2020-01-02  20   23   27
2020-01-03  15   18   22
2020-01-04  30   33   37
2020-01-05  45   48   52

>>> df.shift(periods=3)
  Col1  Col2  Col3
2020-01-01  NaN  NaN  NaN
2020-01-02  NaN  NaN  NaN
2020-01-03  NaN  NaN  NaN
2020-01-04  10.0  13.0  17.0

### pandas.DataFrame.skew

DataFrame.skew(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return unbiased skew over requested axis.

Normalized by N-1.

**Parameters**

- **axis** ([index (0), columns (1)]{index (0), columns (1)}) Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs Additional keyword arguments to be passed to the function.

**Returns**

Series or DataFrame (if level specified)

### pandas.DataFrame.slice_shift

DataFrame.slice_shift(periods=1, axis=0)

Equivalent to shift without copying data.

The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

**Parameters**

- **periods** [int] Number of periods to move, can be positive or negative.

**Returns**

- **shifted** [same type as caller]
Notes

While the `slice_shift` is faster than `shift`, you may pay for it later during alignment.

### pandas.DataFrame.sort_index

`DataFrame.sort_index(axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na_position='last', sort_remaining=True, ignore_index=False, key=None)`

Sort object by labels (along an axis).

Returns a new DataFrame sorted by label if `inplace` argument is `False`, otherwise updates the original DataFrame and returns None.

**Parameters**

- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis along which to sort. The value 0 identifies the rows, and 1 identifies the columns.
- **level** [int or level name or list of ints or list of level names] If not None, sort on values in specified index level(s).
- **ascending** [bool or list of bools, default True] Sort ascending vs. descending. When the index is a MultiIndex the sort direction can be controlled for each level individually.
- **inplace** [bool, default False] If True, perform operation in-place.
- **kind** [{‘quicksort’, ‘mergesort’, ‘heapsort’}, default ‘quicksort’] Choice of sorting algorithm. See also `ndarray.np.sort` for more information. `mergesort` is the only stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.
- **na_position** [{‘first’, ‘last’}, default ‘last’] Puts NaNs at the beginning if `first`; `last` puts NaNs at the end. Not implemented for MultiIndex.
- **sort_remaining** [bool, default True] If True and sorting by level and index is multi-level, sort by other levels too (in order) after sorting by specified level.
- **ignore_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, …, n - 1.

New in version 1.0.0.

- **key** [callable, optional] If not None, apply the key function to the index values before sorting. This is similar to the `key` argument in the built-in `sorted()` function, with the notable difference that this `key` function should be `vectorized`. It should expect an Index and return an Index of the same shape. For MultiIndex inputs, the key is applied per level.

New in version 1.1.0.

**Returns**

`DataFrame` The original DataFrame sorted by the labels.

**See also:**

- `Series.sort_index` Sort Series by the index.
- `DataFrame.sort_values` Sort DataFrame by the value.
- `Series.sort_values` Sort Series by the value.
pandas: powerful Python data analysis toolkit, Release 1.1.1

Examples
>>> df = pd.DataFrame([1, 2, 3, 4, 5], index=[100, 29, 234, 1, 150],
...
columns=['A'])
>>> df.sort_index()
A
1
4
29
2
100 1
150 5
234 3

By default, it sorts in ascending order, to sort in descending order, use ascending=False
>>> df.sort_index(ascending=False)
A
234 3
150 5
100 1
29
2
1
4

A key function can be specified which is applied to the index before sorting. For a MultiIndex this is
applied to each level separately.
>>> df = pd.DataFrame({"a": [1, 2, 3, 4]}, index=['A', 'b', 'C', 'd'])
>>> df.sort_index(key=lambda x: x.str.lower())
a
A 1
b 2
C 3
d 4

pandas.DataFrame.sort_values
DataFrame.sort_values(by, axis=0, ascending=True, inplace=False,
na_position='last', ignore_index=False, key=None)
Sort by the values along either axis.

kind='quicksort',

Parameters
by [str or list of str] Name or list of names to sort by.
• if axis is 0 or ‘index’ then by may contain index levels and/or column labels.
• if axis is 1 or ‘columns’ then by may contain column levels and/or index labels.
Changed in version 0.23.0: Allow specifying index or column level names.
axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis to be sorted.
ascending [bool or list of bool, default True] Sort ascending vs. descending. Specify
list for multiple sort orders. If this is a list of bools, must match the length of the
by.
inplace [bool, default False] If True, perform operation in-place.
kind [{‘quicksort’, ‘mergesort’, ‘heapsort’}, default ‘quicksort’] Choice of sorting algorithm. See also ndarray.np.sort for more information. mergesort is the only

3.4. DataFrame

1681


stable algorithm. For DataFrames, this option is only applied when sorting on a single column or label.

**na_position** [{‘first’, ‘last’}, default ‘last’] Puts NaNs at the beginning if first; last puts NaNs at the end.

**ignore_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

**key** [callable, optional] Apply the key function to the values before sorting. This is similar to the key argument in the builtin sorted() function, with the notable difference that this key function should be vectorized. It should expect a Series and return a Series with the same shape as the input. It will be applied to each column in by independently.

New in version 1.1.0.

**Returns**

- **DataFrame or None** DataFrame with sorted values if inplace=False, None otherwise.

**See also:**

- **DataFrame.sort_index** Sort a DataFrame by the index.
- **Series.sort_values** Similar method for a Series.

**Examples**

```python
>>> df = pd.DataFrame(
...     {'col1': ['A', 'A', 'B', np.nan, 'D', 'C'],
...      'col2': [2, 1, 9, 8, 7, 4],
...      'col3': [0, 1, 9, 4, 2, 3],
...      'col4': ['a', 'B', 'c', 'D', 'e', 'F']
...     })
>>> df
   col1 col2 col3 col4
0    A   2   0   a
1    A   1   1   B
2    B   9   9   c
3  NaN   8   4   D
4    D   7   2   e
5    C   4   3   F
```

Sort by col1

```python
>>> df.sort_values(by=['col1'])
   col1  col2  col3  col4
0    A   2    0    a
1    A   1    1    B
2    B   9    9    c
3  NaN   8    4    D
4    D   7    2    e
5    C   4    3    F
```

Sort by multiple columns

```python
>>> df.sort_values(by=['col1', 'col2'])
   col1  col2  col3  col4
0    A   2    0    a
1    A   1    1    B
2    B   9    9    c
3  NaN   8    4    D
4    D   7    2    e
5    C   4    3    F
```
```python
>>> df.sort_values(by=['col1', 'col2'])
col1  col2  col3  col4
0   A     2   0   a
1   A     1   1   B
2   B     9   9   c
3   C     4   3   F
4   D     7   2   e
5  NaN    8   4   D

Sort Descending

```python
>>> df.sort_values(by='col1', ascending=False)
col1  col2  col3  col4
0   A     2   0   a
1   A     1   1   B
2   B     9   9   c
3   C     4   3   F
4   D     7   2   e
5  NaN    8   4   D

Putting NAs first

```python
>>> df.sort_values(by='col1', ascending=False, na_position='first')
col1  col2  col3  col4
0   A     2   0   a
1   A     1   1   B
2   B     9   9   c
3  NaN    8   4   D
4   D     7   2   e
5   C     4   3   F

Sorting with a key function

```python
>>> df.sort_values(by='col4', key=lambda col: col.str.lower())
col1  col2  col3  col4
0   A     2   0   a
1   A     1   1   B
2   B     9   9   c
3  NaN    8   4   D
4   D     7   2   e
5   C     4   3   F
```
**pandas.DataFrame.sparse**

DataFrame.sparse()

DataFrame accessor for sparse data.
New in version 0.25.0.

**pandas.DataFrame.squeeze**

DataFrame.squeeze(axis=None)

Squeeze 1 dimensional axis objects into scalars.
Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.

This method is most useful when you don’t know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call `squeeze` to ensure you have a Series.

**Parameters**

- **axis** ([0 or ‘index’, 1 or ‘columns’, None], default None) A specific axis to squeeze. By default, all length-1 axes are squeezed.

**Returns**

- [DataFrame, Series, or scalar] The projection after squeezing `axis` or all the axes.

**See also:**

- `Series.iloc` Integer-location based indexing for selecting scalars.
- `DataFrame.iloc` Integer-location based indexing for selecting Series.
- `Series.to_frame` Inverse of `DataFrame.squeeze` for a single-column DataFrame.

**Examples**

```python
>>> primes = pd.Series([2, 3, 5, 7])

Slicing might produce a Series with a single value:

```python
>>> even_primes = primes[primes % 2 == 0]
```{.ipy}

```python
>>> even_primes
0 2
dtype: int64
```{.ipy}

```python
>>> even_primes.squeeze()
2
```{.ipy}

Squeezing objects with more than one value in every axis does nothing:

```python
>>> odd_primes = primes[primes % 2 == 1]
```{.ipy}

```python
>>> odd_primes
0 3
1 5
2 7
dtype: int64
```{.ipy}
Squeezing is even more effective when used with DataFrames.

```python
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
>>> df
   a  b
0  1  2
1  3  4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```python
>>> df_a = df[['a']]
>>> df_a
   a
0  1
1  3
```

So the columns can be squeezed down, resulting in a Series:

```python
>>> df_a.squeeze('columns')
0  1
1  3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```python
>>> df_0a = df.loc[df.index < 1, ['a']]
>>> df_0a
   a
0  1
```

Squeezing the rows produces a single scalar Series:

```python
>>> df_0a.squeeze('rows')
a  1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```python
>>> df_0a.squeeze()
1
```
pandas.DataFrame.stack

`DataFrame.stack(level=-1, dropna=True)`

Stack the prescribed level(s) from columns to index.

Return a reshaped DataFrame or Series having a multi-level index with one or more new inner-most levels compared to the current DataFrame. The new inner-most levels are created by pivoting the columns of the current dataframe:

- if the columns have a single level, the output is a Series;
- if the columns have multiple levels, the new index level(s) is (are) taken from the prescribed level(s) and the output is a DataFrame.

**Parameters**

- `level` [int, str, list, default -1] Level(s) to stack from the column axis onto the index axis, defined as one index or label, or a list of indices or labels.
- `dropna` [bool, default True] Whether to drop rows in the resulting Frame/Series with missing values. Stacking a column level onto the index axis can create combinations of index and column values that are missing from the original dataframe. See Examples section.

**Returns**

- `DataFrame or Series` Stacked dataframe or series.

See also:

- `DataFrame.unstack` Unstack prescribed level(s) from index axis onto column axis.
- `DataFrame.pivot` Reshape dataframe from long format to wide format.
- `DataFrame.pivot_table` Create a spreadsheet-style pivot table as a DataFrame.

**Notes**

The function is named by analogy with a collection of books being reorganized from being side by side on a horizontal position (the columns of the dataframe) to being stacked vertically on top of each other (in the index of the dataframe).

**Examples**

**Single level columns**

```python
>>> df_single_level_cols = pd.DataFrame([[0, 1], [2, 3]],
                           index=['cat', 'dog'],
                           columns=['weight', 'height'])
```

Stacking a dataframe with a single level column axis returns a Series:

```python
>>> df_single_level_cols
              weight  height
          cat  0      1
          dog  2      3
```

```python
>>> df_single_level_cols.stack()  
```

(continues on next page)
Multi level columns: simple case

```python
>>> multicoll = pd.MultiIndex.from_tuples([('weight', 'kg'),
                                          ('height', 'm')])
>>> df_multi_level_cols2 = pd.DataFrame([[1.0, 2.0], [3.0, 4.0]],
                                       index=['cat', 'dog'],
                                       columns=multicoll)
```

Stacking a dataframe with a multi-level column axis:

```python
>>> df_multi_level_cols1
weight
kg pounds
cat 1 2
dog 2 4
```

```python
>>> df_multi_level_cols1.stack()
height weight
cat kg NaN 1.0
m 2.0 NaN
dog kg NaN 3.0
m 4.0 NaN
```

Missing values

```python
>>> multicoll2 = pd.MultiIndex.from_tuples([('weight', 'kg'),
                                          ('height', 'm'))
>>> df_multi_level_cols2 = pd.DataFrame([[1.0, 2.0], [3.0, 4.0]],
                                       index=['cat', 'dog'],
                                       columns=multicoll2)
```

It is common to have missing values when stacking a dataframe with multi-level columns, as the stacked dataframe typically has more values than the original dataframe. Missing values are filled with NaNs:

```python
>>> df_multi_level_cols2
weight height
kg m
cat 1.0 2.0
dog 3.0 4.0
```

```python
>>> df_multi_level_cols2.stack()
height weight
cat kg NaN 1.0
m 2.0 NaN
dog kg NaN 3.0
m 4.0 NaN
```

Prescribing the level(s) to be stacked

The first parameter controls which level or levels are stacked:

```python
>>> df_multi_level_cols2.stack(0)
kg m
```
cat height NaN 2.0  
weight 1.0 NaN  
dog height NaN 4.0  
weight 3.0 NaN  

>>> df_multi_level_cols2.stack([0, 1])  
cat height m 2.0  
weight kg 1.0  
dog height m 4.0  
weight kg 3.0  
dtype: float64

Dropping missing values

>>> df_multi_level_cols3 = pd.DataFrame([[None, 1.0], [2.0, 3.0]],  
index=['cat', 'dog'],  
columns=multicol2)

Note that rows where all values are missing are dropped by default but this behaviour can be controlled via the dropna keyword parameter:

>>> df_multi_level_cols3  
weight height  
kg m  
cat NaN 1.0  
dog 2.0 3.0  

>>> df_multi_level_cols3.stack(dropna=False)  
height weight  
kg NaN NaN  
m NaN 1.0  
dog kg NaN 2.0  
m NaN 3.0  

>>> df_multi_level_cols3.stack(dropna=True)  
height weight  
kg NaN NaN  
m NaN 1.0  
dog kg NaN 2.0  
m NaN 3.0

pandas.DataFrame.std

DataFrame.std((axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs))

Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

Parameters

axis      [[index (0), columns (1)]]

skipna   [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level    [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

ddof     [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.
**numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**
Series or DataFrame (if level specified)

**pandas.DataFrame.sub**

DataFrame.sub (other, axis='columns', level=None, fill_value=None)  
Get Subtraction of dataframe and other, element-wise (binary operator sub).

Equivalent to dataframe - other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rsub.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [[0 or ‘index’, 1 or ‘columns’]] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame Result of the arithmetic operation.

**See also:**

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360],
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle    0      360
triangle   3      180
rectangle  4      360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```  
```python
>>> df.add(1)
   angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle   0.0     36.0
triangle 0.3     18.0
rectangle 0.4    36.0
```  
```python
>>> df.rdiv(10)
   angles  degrees
circle   inf    0.027778
triangle 3.333333 0.055556
rectangle 2.500000 0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
   angles  degrees
circle   -1     358
triangle   2     178
rectangle  3     358
```  
```python
>>> df.sub([1, 2], axis='columns')
   angles  degrees
circle   -1     358
triangle   2     178
rectangle  3     358
```
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({
    'angles': [0, 3, 4],
    'degrees': [360, 360, 540, 720]
},
index=['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon'])
>>> df_multindex
  angles  degrees
A circle    0      360
triangle    3      360
rectangle   4      360
B square    4      360
pentagon    5      540
hexagon     6      720

>>> df_multindex.div(df_multindex, level=1, fill_value=0)
  angles  degrees
A circle      NaN      1.0
triangle     1.0      1.0
rectangle   1.0      1.0
B square     0.0      0.0
pentagon    0.0      0.0
hexagon     0.0      0.0
```

Divide by a MultiIndex by level.

```python
>>> df = df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>

>>> df
  angles  degrees
circle    -1      359
triangle    2      179
rectangle   3      359

>>> df * other
  angles  degrees
circle    0      NaN
triangle    9      NaN
rectangle  16      NaN

>>> df.mul(other, fill_value=0)
  angles  degrees
circle    0      0.0
triangle    9      0.0
rectangle  16      0.0
```

```python
>>> df_multindex.div(df_multindex, level=1, fill_value=0)
  angles  degrees
A circle      NaN      1.0
triangle     1.0      1.0
rectangle   1.0      1.0
B square     0.0      0.0
pentagon    0.0      0.0
hexagon     0.0      0.0
```
pandas.DataFrame.subtract

**DataFrame.subtract**(other, axis='columns', level=None, fill_value=None)

Get Subtraction of dataframe and other, element-wise (binary operator `sub`).

Equivalent to `dataframe - other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `rsub`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

**DataFrame** Result of the arithmetic operation.

**See also:**

- `DataFrame.add` Add DataFrames.
- `DataFrame.sub` Subtract DataFrames.
- `DataFrame.mul` Multiply DataFrames.
- `DataFrame.div` Divide DataFrames (float division).
- `DataFrame.truediv` Divide DataFrames (float division).
- `DataFrame.floordiv` Divide DataFrames (integer division).
- `DataFrame.mod` Calculate modulo (remainder after division).
- `DataFrame.pow` Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df

    angles  degrees
circle     0      360
triangle   3      180
rectangle  4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1

    angles  degrees
circle     1      361
triangle   4      181
rectangle  5      361
```

```python
>>> df.add(1)

    angles  degrees
circle     1      361
triangle   4      181
rectangle  5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)

    angles  degrees
circle   0.0     36.0
triangle 0.3     18.0
rectangle 0.4    36.0
```

```python
>>> df.rdiv(10)

    angles   degrees
circle  inf    0.027778
triangle 3.333333  0.055556
rectangle 2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]

    angles  degrees
circle   -1      358
triangle   2      178
rectangle  3      358
```

```python
>>> df.sub([1, 2], axis='columns')

    angles  degrees
circle   -1      358
triangle   2      178
rectangle  3      358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')

    angles  degrees
```

(continues on next page)
Multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({'angles': [0, 3, 4],
                     'index': ['circle', 'triangle', 'rectangle'])
other
```

```
angles
circle 0
triangle 3
rectangle 4
```

```python
df * other
```

```
angles  degrees
circle    0 NaN
triangle   9 NaN
rectangle 16 NaN
```

```python
df.mul(other, fill_value=0)
```

```
angles  degrees
circle    0  0.0
triangle   9  0.0
rectangle 16  0.0
```

Divide by a MultiIndex by level.

```python
df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                             'degrees': [360, 180, 360, 360, 540, 720],
                             'index': ['A', 'A', 'A', 'B', 'B', 'B'],
                             ['circle', 'triangle', 'rectangle',
                              'square', 'pentagon', 'hexagon'])
```

```python
df_multindex
```

```
angles  degrees
A circle  0  360
triangle  3  180
rectangle 4  360
B square  4  360
pentagon  5  540
hexagon  6  720
```

```python
df.div(df_multindex, level=1, fill_value=0)
```

```
angles  degrees
A circle NaN  1.0
triangle  1.0  1.0
rectangle 1.0  1.0
B square  0.0  0.0
pentagon  0.0  0.0
hexagon  0.0  0.0
```
DataFrame\.sum\(\text{axis}=\text{None}, \text{skipna}=\text{None}, \text{level}=\text{None}, \text{numeric_only}=\text{None}, \text{min_count}=0, **\text{kwargs}\)\\
Return the sum of the values for the requested axis.\\
This is equivalent to the method \text{numpy}.sum.\\

**Parameters**\\
\begin{itemize}\\
\item \textbf{axis} [[index (0), columns (1)]] Axis for the function to be applied on.\\
\item \textbf{skipna} [bool, default True] Exclude NA/null values when computing the result.\\
\item \textbf{level} [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.\\
\item \textbf{numeric_only} [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.\\
\item \textbf{min_count} [int, default 0] The required number of valid values to perform the operation. If fewer than \text{min_count} non-NA values are present the result will be NA.\\
\end{itemize}\\
New in version 0.22.0: Added with the default being 0. This means the sum of an all-NA or empty Series is 0, and the product of an all-NA or empty Series is 1.\\

**\textbf{kwargs}** Additional keyword arguments to be passed to the function.\\

**Returns**\\
Series or DataFrame (if level specified)\\

**See also:**\\
\begin{itemize}\\
\item \textit{Series}.sum Return the sum.\\
\item \textit{Series}.min Return the minimum.\\
\item \textit{Series}.max Return the maximum.\\
\item \textit{Series}.idxmin Return the index of the minimum.\\
\item \textit{Series}.idxmax Return the index of the maximum.\\
\item \textit{DataFrame}.sum Return the sum over the requested axis.\\
\item \textit{DataFrame}.min Return the minimum over the requested axis.\\
\item \textit{DataFrame}.max Return the maximum over the requested axis.\\
\item \textit{DataFrame}.idxmin Return the index of the minimum over the requested axis.\\
\item \textit{DataFrame}.idxmax Return the index of the maximum over the requested axis.\\
\end{itemize}
Examples

```python
>>> idx = pd.MultiIndex.from_arrays([['warm', 'warm', 'cold', 'cold'], ...
... ['dog', 'falcon', 'fish', 'spider']], ...
... names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
 blooded  animal
  warm  dog  4
         falcon 2
  cold  fish  0
         spider 8
Name: legs, dtype: int64

>>> s.sum()
14

Sum using level names, as well as indices.

```python
>>> s.sum(level='blooded')
 blooded
  warm  6
  cold  8
Name: legs, dtype: int64

>>> s.sum(level=0)
 blooded
  warm  6
  cold  8
Name: legs, dtype: int64
```

By default, the sum of an empty or all-NA Series is 0.

```python
>>> pd.Series([]).sum()  # min_count=0 is the default
0.0
```

This can be controlled with the `min_count` parameter. For example, if you’d like the sum of an empty series to be NaN, pass `min_count=1`.

```python
>>> pd.Series([]).sum(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).sum()
0.0

>>> pd.Series([np.nan]).sum(min_count=1)
nan
```
**pandas.DataFrame.swapaxes**

DataFrame.swapaxes(axis1, axis2, copy=True)

Interchange axes and swap values axes appropriately.

Returns

y [same as input]

**pandas.DataFrame.swaplevel**

DataFrame.swaplevel(i=-2, j=-1, axis=0)

Swap levels i and j in a MultiIndex on a particular axis.

Parameters

i, j [int or str] Levels of the indices to be swapped. Can pass level name as string.

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to swap levels on. 0 or ‘index’
for row-wise, 1 or ‘columns’ for column-wise.

Returns

DataFrame

**pandas.DataFrame.tail**

DataFrame.tail(n=5)

Return the last n rows.

This function returns last n rows from the object based on position. It is useful for quickly verifying data,
for example, after sorting or appending rows.

For negative values of n, this function returns all rows except the first n rows, equivalent to df[n:].

Parameters

n [int, default 5] Number of rows to select.

Returns

type of caller The last n rows of the caller object.

See also:

DataFrame.head The first n rows of the caller object.

**Examples**

```python
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                            'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
animal
0  alligator
1      bee
2     falcon
3      lion
4  monkey
```

(continues on next page)
5 parrot
6 shark
7 whale
8 zebra

Viewing the last 5 lines

```python
>>> df.tail()
   animal
4  monkey
5  parrot
6    shark
7  whale
8  zebra
```

Viewing the last $n$ lines (three in this case)

```python
>>> df.tail(3)
   animal
6    shark
7  whale
8  zebra
```

For negative values of $n$

```python
>>> df.tail(-3)
   animal
3    lion
4  monkey
5  parrot
6    shark
7  whale
8  zebra
```

pandas.DataFrame.take

Dataframe.take(indices, axis=0, is_copy=None, **kwargs)

Return the elements in the given positional indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

**Parameters**

- **indices** [array-like] An array of ints indicating which positions to take.
- **axis** [[0 or ‘index’, 1 or ‘columns’, None], default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.
- **is_copy** [bool] Before pandas 1.0, is_copy=False can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, take always returns a copy, and the keyword is therefore deprecated. Deprecated since version 1.0.0.

**Returns**

For compatibility with numpy.take(). Has no effect on the output.
taken [same type as caller] An array-like containing the elements taken from the object.

See also:

DataFrame.loc Select a subset of a DataFrame by labels.

DataFrame.iloc Select a subset of a DataFrame by positions.

numpy.take Take elements from an array along an axis.

Examples

```python
def df = pd.DataFrame({'falcon': 'bird', 389.0},
... ('parrot', 'bird', 24.0),
... ('lion', 'mammal', 80.5),
... ('monkey', 'mammal', np.nan),
... columns=['name', 'class', 'max_speed'],
... index=[0, 2, 3, 1])
def take([0, 3])
    name class max_speed
0 falcon bird 389.0
2 parrot bird 24.0
3 lion mammal 80.5
1 monkey mammal NaN
def.take([1, 2], axis=1)
class max_speed
0  bird 389.0
2  bird 24.0
3 mammal 80.5
1 mammal NaN
def.take([-1, -2])
      name   class  max_speed
1      monkey mammal  NaN
3      lion     mammal  80.5
```

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.
**pandas.DataFrame.to_clipboard**

`DataFrame.to_clipboard(excel=True, sep=None, **kwargs)`

Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

**Parameters**

- **excel** [bool, default True] Produce output in a csv format for easy pasting into excel.
  - True, use the provided separator for csv pasting.
  - False, write a string representation of the object to the clipboard.
- **sep** [str, default ' \t '] Field delimiter.
- **kwargs** These parameters will be passed to DataFrame.to_csv.

**See also:**

- `DataFrame.to_csv` Write a DataFrame to a comma-separated values (csv) file.
- `read_clipboard` Read text from clipboard and pass to read_table.

**Notes**

Requirements for your platform.

- Linux: xclip, or xsel (with PyQt4 modules)
- Windows: none
- OS X: none

**Examples**

Copy the contents of a DataFrame to the clipboard.

```python
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
```

```python
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the index by passing the keyword `index` and setting it to false.

```python
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.DataFrame.to_csv
DataFrame.to_csv(path_or_buf=None, sep=',', na_rep='', float_format=None, columns=None,
header=True, index=True, index_label=None, mode='w', encoding=None,
compression='infer', quoting=None, quotechar='"', line_terminator=None,
chunksize=None, date_format=None, doublequote=True, escapechar=None,
decimal='.', errors='strict')
Write object to a comma-separated values (csv) file.
Changed in version 0.24.0: The order of arguments for Series was changed.
Parameters
path_or_buf [str or file handle, default None] File path or object, if None is provided
the result is returned as a string. If a file object is passed it should be opened with
newline=”, disabling universal newlines.
Changed in version 0.24.0: Was previously named “path” for Series.
sep [str, default ‘,’] String of length 1. Field delimiter for the output file.
na_rep [str, default ‘’] Missing data representation.
float_format [str, default None] Format string for floating point numbers.
columns [sequence, optional] Columns to write.
header [bool or list of str, default True] Write out the column names. If a list of strings
is given it is assumed to be aliases for the column names.
Changed in version 0.24.0: Previously defaulted to False for Series.
index [bool, default True] Write row names (index).
index_label [str or sequence, or False, default None] Column label for index column(s)
if desired. If None is given, and header and index are True, then the index names
are used. A sequence should be given if the object uses MultiIndex. If False do not
print fields for index names. Use index_label=False for easier importing in R.
mode [str] Python write mode, default ‘w’.
encoding [str, optional] A string representing the encoding to use in the output file,
defaults to ‘utf-8’.
compression [str or dict, default ‘infer’] If str, represents compression mode. If dict,
value at ‘method’ is the compression mode. Compression mode may be any of the
following possible values: {‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}. If compression mode is ‘infer’ and path_or_buf is path-like, then detect compression mode
from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’ or ‘.xz’. (otherwise no compression). If dict given and mode is one of {‘zip’, ‘gzip’, ‘bz2’}, or inferred as one of
the above, other entries passed as additional compression options.
Changed in version 1.0.0: May now be a dict with key ‘method’ as compression
mode and other entries as additional compression options if compression mode is
‘zip’.
Changed in version 1.1.0: Passing compression options as keys in dict is supported
for compression modes ‘gzip’ and ‘bz2’ as well as ‘zip’.
quoting [optional constant from csv module] Defaults to csv.QUOTE_MINIMAL.
If you have set a float_format then floats are converted to strings and thus
csv.QUOTE_NONNUMERIC will treat them as non-numeric.

3.4. DataFrame

1701


quotechar [str, default ‘”’] String of length 1. Character used to quote fields.

line_terminator [str, optional] The newline character or character sequence to use in
the output file. Defaults to os.linesep, which depends on the OS in which this
method is called (‘n’ for linux, ‘rn’ for Windows, i.e.).

Changed in version 0.24.0.

chunksize [int or None] Rows to write at a time.

date_format [str, default None] Format string for datetime objects.

doublequote [bool, default True] Control quoting of quotechar inside a field.

escapechar [str, default None] String of length 1. Character used to escape sep and
quotechar when appropriate.

decimal [str, default ‘.’] Character recognized as decimal separator. E.g. use ‘,’ for
European data.

doubleslashter [str, default ‘strict’] Specifies how encoding and decoding errors are to be han-
dled. See the errors argument for open() for a full list of options.

New in version 1.1.0.

Returns

None or str If path_or_buf is None, returns the resulting csv format as a string. Otherwise returns None.

See also:

read_csv Load a CSV file into a DataFrame.

to_excel Write DataFrame to an Excel file.

Examples

```python
>>> df = pd.DataFrame({
    'name': ['Raphael', 'Donatello'],
    'mask': ['red', 'purple'],
    'weapon': ['sai', 'bo staff']
})

>>> df.to_csv(index=False)
'name,mask,weapon
Raphael,red,sai
Donatello,purple,bo staff
'

Create ‘out.zip’ containing ‘out.csv’

```python
>>> compression_opts = dict(method='zip',
... archive_name='out.csv')

>>> df.to_csv('out.zip', index=False,
... compression=compression_opts)
```
pandas.DataFrame.to_dict

DataFrame.to_dict (orient='dict', into=<class 'dict'>)  
Convert the DataFrame to a dictionary.

The type of the key-value pairs can be customized with the parameters (see below).

Parameters

- **orient** [str {'dict', 'list', 'series', 'split', 'records', 'index'}] Determines the type of the values of the dictionary.
  - 'dict' (default): dict like {column -> {index -> value}}
  - 'list': dict like {column -> [values]}
  - 'series': dict like {column -> Series(values)}
  - 'split': dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
  - 'records': list like [{column -> value}, ..., {column -> value}]
  - 'index': dict like {index -> {column -> value}}

Abbreviations are allowed. *s* indicates *series* and *sp* indicates *split*.

- **into** [class, default dict] The collections.abc.Mapping subclass used for all Mappings in the return value. Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

Returns

- **dict, list or collections.abc.Mapping** Return a collections.abc.Mapping object representing the DataFrame. The resulting transformation depends on the *orient* parameter.

See also:

- **DataFrame.from_dict** Create a DataFrame from a dictionary.
- **DataFrame.to_json** Convert a DataFrame to JSON format.

Examples

```python
>>> df = pd.DataFrame({'col1': [1, 2],
...                    'col2': [0.5, 0.75]},
...                   index=['row1', 'row2'])
>>> df
   col1  col2
row1   1   0.5
row2   2   0.75
>>> df.to_dict()
{'col1': {'row1': 1, 'row2': 2}, 'col2': {'row1': 0.5, 'row2': 0.75}}
```

You can specify the return orientation.

```python
>>> df.to_dict('series')
{'col1': row1 1
  row2 2
Name: col1, dtype: int64,
```

(continues on next page)
>>> df.to_dict('split')
{'index': ['row1', 'row2'], 'columns': ['col1', 'col2'],
'data': [[1, 0.5], [2, 0.75]]}

>>> df.to_dict('records')
[['col1': 1, 'col2': 0.5], ['col1': 2, 'col2': 0.75]]

>>> df.to_dict('index')
{'row1': {'col1': 1, 'col2': 0.5}, 'row2': {'col1': 2, 'col2': 0.75}}

You can also specify the mapping type.

>>> from collections import OrderedDict, defaultdict

>>> df.to_dict('records', into=OrderedDict)
OrderedDict([('col1', OrderedDict([('row1', 1), ('row2', 2)])),
('col2', OrderedDict([('row1', 0.5), ('row2', 0.75)]))])

If you want a defaultdict, you need to initialize it:

>>> dd = defaultdict(list)

>>> df.to_dict('records', into=dd)
[defaultdict(<class 'list'>, {'col1': 1, 'col2': 0.5}),
defaultdict(<class 'list'>, {'col1': 2, 'col2': 0.75})]

```
pandas.DataFrame.to_excel
```

DataFrame.to_excel(excel_writer, sheet_name='Sheet1', na_rep='', float_format=None, columns=None, header=True, index_label=None, startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf', verbose=True, freeze_panes=None)

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an ExcelWriter object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique sheet_name. With all data written to the file it is necessary to save the changes. Note that creating an ExcelWriter object with a file name that already exists will result in the contents of the existing file being erased.

Parameters

- **excel_writer** [str or ExcelWriter object] File path or existing ExcelWriter.
- **sheet_name** [str, default 'Sheet1'] Name of sheet which will contain DataFrame.
- **na_rep** [str, default `''`] Missing data representation.
- **float_format** [str, optional] Format string for floating point numbers. For example float_format="%.2f" will format 0.1234 to 0.12.
- **columns** [sequence or list of str, optional] Columns to write.
header [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

index_label [str or sequence, optional] Column label for index column(s) if desired. If not specified, and header and index are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

startrow [int, default 0] Upper left cell row to dump data frame.

startcol [int, default 0] Upper left cell column to dump data frame.

merge_cells [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.

encoding [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.

inf_rep [str, default ‘inf’] Representation for infinity (there is no native representation for infinity in Excel).

verbose [bool, default True] Display more information in the error logs.

freeze_panes [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

See also:

to_csv Write DataFrame to a comma-separated values (csv) file.

ExcelWriter Class for writing DataFrame objects into excel sheets.

read_excel Read an Excel file into a pandas DataFrame.

read_csv Read a comma-separated values (csv) file into DataFrame.

Notes

For compatibility with to_csv(), to_excel serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible write further data without rewriting the whole workbook.

Examples

Create, write to and save a workbook:

```python
>>> df1 = pd.DataFrame([[\'a\', \'b\'], [\'c\', \'d\']],
                        index=['row 1', 'row 2'],
                        columns=['col 1', 'col 2'])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```python
>>> df1.to_excel("output.xlsx",
                sheet_name='Sheet_name_1')
```
If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:

```python
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...    df1.to_excel(writer, sheet_name='Sheet_name_1')
...    df2.to_excel(writer, sheet_name='Sheet_name_2')
```

ExcelWriter can also be used to append to an existing Excel file:

```python
>>> with pd.ExcelWriter('output.xlsx', mode='a') as writer:
...    df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the `engine` keyword (the default engine is automatically chosen depending on the file extension):

```python
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```

### pandas.DataFrame.to_feather

DataFrame.to_feather(**kwargs)

Write a DataFrame to the binary Feather format.

**Parameters**

- **path** [str] String file path.
- **kwargs** Additional keywords passed to pyarrow.feather.write_feather(). Starting with pyarrow 0.17, this includes the `compression`, `compression_level`, `chunksize` and `version` keywords.

New in version 1.1.0.

### pandas.DataFrame.to_gbq

DataFrame.to_gbq(destination_table, project_id=None, chunksize=None, reauth=False, if_exists='fail', auth_local_webserver=False, table_schema=None, location=None, progress_bar=True, credentials=None)

Write a DataFrame to a Google BigQuery table.

This function requires the pandas-gbq package.

See the [How to authenticate with Google BigQuery](https://pandas.pydata.org/pandas-docs/stable/guide/database.html#how-to-authenticate-with-google-bigquery) guide for authentication instructions.

**Parameters**

- **destination_table** [str] Name of table to be written, in the form dataset.tablename.
- **project_id** [str, optional] Google BigQuery Account project ID. Optional when available from the environment.
- **chunksize** [int, optional] Number of rows to be inserted in each chunk from the dataframe. Set to `None` to load the whole dataframe at once.
- **reauth** [bool, default False] Force Google BigQuery to re-authenticate the user. This is useful if multiple accounts are used.
if_exists [str, default ‘fail’] Behavior when the destination table exists. Value can be one of:

'fail' If table exists raise pandas_gbq.gbq.TableCreationError.
'replace' If table exists, drop it, recreate it, and insert data.
'append' If table exists, insert data. Create if does not exist.

auth_local_webserver [bool, default False] Use the local webserver flow instead of the console flow when getting user credentials.

New in version 0.2.0 of pandas-gbq.

table_schema [list of dicts, optional] List of BigQuery table fields to which according DataFrame columns conform to, e.g. [{'name': 'col1', 'type': 'STRING'}, ...]. If schema is not provided, it will be generated according to dtypes of DataFrame columns. See BigQuery API documentation on available names of a field.

New in version 0.3.1 of pandas-gbq.

location [str, optional] Location where the load job should run. See the BigQuery locations documentation for a list of available locations. The location must match that of the target dataset.

New in version 0.5.0 of pandas-gbq.

progress_bar [bool, default True] Use the library tqdm to show the progress bar for the upload, chunk by chunk.

New in version 0.5.0 of pandas-gbq.

credentials [google.auth.credentials.Credentials, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine google.auth.compute_engine.Credentials or Service Account google.oauth2.service_account.Credentials directly.

New in version 0.8.0 of pandas-gbq.

New in version 0.24.0.

See also:

pandas_gbq.to_gbq This function in the pandas-gbq library.
read_gbq Read a DataFrame from Google BigQuery.

pandas.DataFrame.to_hdf

DataFrame.to_hdf(path_or_buf, key, mode='a', complevel=None, complib=None, append=False, format=None, index=True, min_itemsize=None, nan_rep=None, dropna=None, data_columns=None, errors='strict', encoding='UTF-8')

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different a key.
For more information see the user guide.

Parameters

path_or_buf [str or pandas.HDFStore] File path or HDFStore object.

key [str] Identifier for the group in the store.

mode [{'a', 'w', 'r+'}, default 'a'] Mode to open file:
  • ‘w’: write, a new file is created (an existing file with the same name would be deleted).
  • ‘a’: append, an existing file is opened for reading and writing, and if the file does not exist it is created.
  • ‘r+’: similar to ‘a’, but the file must already exist.

complevel [{0-9}, optional] Specifies a compression level for data. A value of 0 disables compression.

complib [{'zlib', 'lzo', 'bzip2', 'blosc'}, default 'zlib'] Specifies the compression library to be used. As of v0.20.2 these additional compressors for Blosc are supported (default if no compressor specified: 'blosc:blosclz'): {'blosc:blosclz', 'blosc:lz4', 'blosc:lz4hc', 'blosc:snappy', 'blosc:zlib', 'blosc:zstd'}. Specifying a compression library which is not available issues a ValueError.

append [bool, default False] For Table formats, append the input data to the existing.

format [{'fixed', 'table', None}, default ‘fixed’] Possible values:
  • ‘table’: Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
  • If None, pd.get_option('io.hdf.default_format') is checked, followed by fallback to “fixed”

errors [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for open() for a full list of options.

encoding [str, default “UTF-8”]

min_itemsize [dict or int, optional] Map column names to minimum string sizes for columns.

data_columns [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See Query via data columns. Applicable only to format=‘table’.

See also:

DataFrame.read_hdf Read from HDF file.

DataFrame.to_parquet Write a DataFrame to the binary parquet format.

DataFrame.to_sql Write to a sql table.

DataFrame.to_feather Write out feather-format for DataFrames.
**DataFrame.to_csv**  Write out to a csv file.

**Examples**

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
                    index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')

We can add another object to the same file:

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```python
>>> pd.read_hdf('data.h5', 'df')
   A  B
a 1  4
b 2  5
c 3  6
```

```python
>>> pd.read_hdf('data.h5', 's')
0   1
1   2
2   3
3   4
dtype: int64
```

Deleting file with data:

```python
>>> import os
>>> os.remove('data.h5')
```

**pandas.DataFrame.to_html**

DataFrame.to_html(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, justify=None, max_rows=None, max_cols=None, show_dimensions=False, decimal='.', bold_rows=True, classes=None, escape=True, notebook=False, border=None, table_id=None, render_links=False, encoding=None)

Render a DataFrame as an HTML table.

**Parameters**

- **buf** [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

- **columns** [sequence, optional, default None] The subset of columns to write. Writes all columns by default.

- **col_space** [str or int, list or dict of int or str, optional] The minimum width of each column in CSS length units. An int is assumed to be px units.

  New in version 0.25.0: Ability to use str.

- **header** [bool, optional] Whether to print column labels, default True.
index [bool, optional, default True] Whether to print index (row) labels.

na_rep [str, optional, default ‘NaN’] String representation of NAN to use.

formatters [list, tuple or dict of one-param. functions, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List/tuple must be of length equal to the number of columns.

float_format [one-parameter function, optional, default None] Formatter function to apply to columns’ elements if they are floats. The result of this function must be a unicode string.

sparsify [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.

index_names [bool, optional, default True] Prints the names of the indexes.

justify [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by set_option), ‘right’ out of the box. Valid values are

- left
- right
- center
- justify
- justify-all
- start
- end
- inherit
- match-parent
- initial
- unset.

max_rows [int, optional] Maximum number of rows to display in the console.

min_rows [int, optional] The number of rows to display in the console in a truncated repr (when number of rows is above max_rows).

max_cols [int, optional] Maximum number of columns to display in the console.

show_dimensions [bool, default False] Display DataFrame dimensions (number of rows by number of columns).

decimal [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

bold_rows [bool, default True] Make the row labels bold in the output.

classes [str or list or tuple, default None] CSS class(es) to apply to the resulting html table.

escape [bool, default True] Convert the characters <, >, and & to HTML-safe sequences.

notebook [{True, False}, default False] Whether the generated HTML is for IPython Notebook.
border [int] A border=border attribute is included in the opening <table> tag. Default pd.options.display.html.border.

encoding [str, default “utf-8”] Set character encoding.

New in version 1.0.

table_id [str, optional] A css id is included in the opening <table> tag if specified.

New in version 0.23.0.

render_links [bool, default False] Convert URLs to HTML links.

New in version 0.24.0.

Returns

str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:

to_string Convert DataFrame to a string.

pandas.DataFrame.to_json

DataFrame.to_json(path_or_buf=None, orient=None, date_format=None, double_precision=10, force_ascii=True, date_unit='ms', default_handler=None, lines=False, compression='infer', index=True, indent=None)

Convert the object to a JSON string.

Note NaN’s and None will be converted to null and datetime objects will be converted to UNIX timestamps.

Parameters

path_or_buf [str or file handle, optional] File path or object. If not specified, the result is returned as a string.

orient [str] Indication of expected JSON string format.

• Series:
  – default is ‘index’
  – allowed values are: {'split','records','index','table'}.

• DataFrame:
  – default is ‘columns’
  – allowed values are: {'split', ‘records’, ‘index’, ‘columns’, ‘values’, ‘table’}.

• The format of the JSON string:
  – ‘split’ : dict like {‘index’ -> [index], ‘columns’ -> [columns], ‘data’ -> [values]}
  – ‘records’ : list like [[column -> value], . . . , [column -> value]]
  – ‘index’ : dict like {index -> [column -> value]}
  – ‘columns’ : dict like {column -> [column -> value]}
  – ‘values’ : just the values array
Describing the data, where data component is like 
orient='records'.

Changed in version 0.20.0.

date_format [{None, ‘epoch’, ‘iso’}] Type of date conversion. ‘epoch’ = epoch milliseconds, ‘iso’ = ISO8601. The default depends on the orient. For orient='table', the default is ‘iso’. For all other orients, the default is ‘epoch’.

double_precision [int, default 10] The number of decimal places to use when encoding floating point values.

force_ascii [bool, default True] Force encoded string to be ASCII.

date_unit [str, default ‘ms’ (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’, ‘ns’ for second, millisecond, microsecond, and nanosecond respectively.

default_handler [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

lines [bool, default False] If ‘orient’ is ‘records’ write out line delimited json format. Will throw ValueError if incorrect ‘orient’ since others are not list like.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

index [bool, default True] Whether to include the index values in the JSON string. Not including the index (index=False) is only supported when orient is ‘split’ or ‘table’.

indent [int, optional] Length of whitespace used to indent each record.

Returns

None or str If path_or_buf is None, returns the resulting json format as a string. Otherwise returns None.

See also:

read_json Convert a JSON string to pandas object.
Notes

The behavior of `indent=0` varies from the stdlib, which does not indent the output but does insert newlines. Currently, `indent=0` and the default `indent=None` are equivalent in pandas, though this may change in a future release.

Examples

```python
>>> import json
>>> df = pd.DataFrame(
...     [["a", "b"], ["c", "d"]],
...     index=["row 1", "row 2"],
...     columns=["col 1", "col 2"],
... )

>>> result = df.to_json(orient="split")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "columns": [
        "col 1",
        "col 2"
    ],
    "index": [
        "row 1",
        "row 2"
    ],
    "data": [
        ["a",
         "b"],
        ["c",
         "d"
    ]
}
```

Encoding/decoding a Dataframe using `records` formatted JSON. Note that index labels are not preserved with this encoding.

```python
>>> result = df.to_json(orient="records")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[
    {
        "col 1": "a",
        "col 2": "b"
    },
    {
        "col 1": "c",
        "col 2": "d"
    }
]
```
Encoding/decoding a Dataframe using 'index' formatted JSON:

```python
>>> result = df.to_json(orient="index")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
  "row 1": {
    "col 1": "a",
    "col 2": "b"
  },
  "row 2": {
    "col 1": "c",
    "col 2": "d"
  }
}
```

Encoding/decoding a Dataframe using 'columns' formatted JSON:

```python
>>> result = df.to_json(orient="columns")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
  "col 1": {
    "row 1": "a",
    "row 2": "c"
  },
  "col 2": {
    "row 1": "b",
    "row 2": "d"
  }
}
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```python
>>> result = df.to_json(orient="values")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[
  ["a", "b"],
  ["c", "d"]
]
```

Encoding with Table Schema:

```python
>>> result = df.to_json(orient="table")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
  "schema": {
    "fields": [
    {
      "name": "index",
      ...
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

(continued from previous page)

```json
{
    "type": "string",
    "name": "col 1",
    "type": "string"
},
{
    "name": "col 2",
    "type": "string"
},
"primaryKey": [
    "index"
],
"pandas_version": "0.20.0"
},
"data": [
    {
        "index": "row 1",
        "col 1": "a",
        "col 2": "b"
    },
    {
        "index": "row 2",
        "col 1": "c",
        "col 2": "d"
    }
]
}
```

### pandas.DataFrame.to_latex

**DataFrame.to_latex** *(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparse=None, index_names=True, bold_rows=False, column_format=None, longtable=None, escape=None, encoding=None, decimal='.', multicolumn=None, multicolumn_format=None, multirow=None, caption=None, label=None)*

Render object to a LaTeX tabular, longtable, or nested table/tabular.

Requires \usepackage{booktabs}. The output can be copy/pasted into a main LaTeX document or read from an external file with \input{table.tex}.

Changed in version 0.20.2: Added to Series.

Changed in version 1.0.0: Added caption and label arguments.

**Parameters**

- **buf** [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.
- **columns** [list of label, optional] The subset of columns to write. Writes all columns by default.
- **col_space** [int, optional] The minimum width of each column.
header [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

na_rep [str, default ‘NaN’] Missing data representation.

formatters [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.

float_format [one-parameter function or str, optional, default None] Formatter for floating point numbers. For example float_format="%.2f" and float_format="{:0.2f}" will both result in 0.1234 being formatted as 0.12.

sparsify [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.

index_names [bool, default True] Prints the names of the indexes.

bold_rows [bool, default False] Make the row labels bold in the output.

column_format [str, optional] The columns format as specified in LaTeX table format e.g. ‘rcl’ for 3 columns. By default, ‘l’ will be used for all columns except columns of numbers, which default to ‘r’.

longtable [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a usepackage{longtable} to your LaTeX preamble.

escape [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to ‘utf-8’.

decimal [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

multicolumn [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.

multicolumn_format [str, default ‘l’] The alignment for multicolumns, similar to column_format. The default will be read from the config module.

multirow [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a usepackage{multirow} to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

caption [str, optional] The LaTeX caption to be placed inside \caption{} in the output.

New in version 1.0.0.

label [str, optional] The LaTeX label to be placed inside \label{} in the output. This is used with \ref{} in the main .tex file.

New in version 1.0.0.

Returns
str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:

DataFrame.to_string Render a DataFrame to a console-friendly tabular output.

DataFrame.to_html Render a DataFrame as an HTML table.

Examples

```python
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
                    'mask': ['red', 'purple'],
                    'weapon': ['sai', 'bo staff']})
>>> print(df.to_latex(index=False))
\begin{tabular}{lll}
\toprule
name & mask & weapon \\
\midrule
Raphael & red & sai \\
Donatello & purple & bo staff \\
\bottomrule
\end{tabular}
```

pandas.DataFrame.to_markdown

DataFrame.to_markdown (buf=None, mode=None, index=True, **kwargs)
Print DataFrame in Markdown-friendly format.

New in version 1.0.0.

Parameters

- **buf** [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.
- **mode** [str, optional] Mode in which file is opened.
- **index** [bool, optional, default True] Add index (row) labels.

New in version 1.1.0.

**kwargs These parameters will be passed to tabulate.

Returns

- **str** DataFrame in Markdown-friendly format.

Examples

```python
>>> s = pd.Series(['elk', 'pig', 'dog', 'quetzal'], name="animal")
>>> print(s.to_markdown())
<table>
<thead>
<tr>
<th></th>
<th>animal</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>elk</td>
</tr>
<tr>
<td>1</td>
<td>pig</td>
</tr>
<tr>
<td>2</td>
<td>dog</td>
</tr>
<tr>
<td>3</td>
<td>quetzal</td>
</tr>
</tbody>
</table>
```
Output markdown with a tabulate option.

```python
>>> print(s.to_markdown(tablefmt="grid"))
+----+----------+
| 0  | elk      |
| 1  | pig      |
| 2  | dog      |
| 3  | quetzal  |
+----+----------+
```

**pandas.DataFrame.to_numpy**

**DataFrame.to_numpy** *(dtype=None, copy=False, na_value=<object object>)*

Convert the DataFrame to a NumPy array.

New in version 0.24.0.

By default, the dtype of the returned array will be the common NumPy dtype of all types in the DataFrame. For example, if the dtypes are `float16` and `float32`, the results dtype will be `float32`. This may require copying data and coercing values, which may be expensive.

**Parameters**

- **dtype** [str or numpy.dtype, optional] The dtype to pass to numpy.asarray().
- **copy** [bool, default False] Whether to ensure that the returned value is not a view on another array. Note that copy=False does not ensure that to_numpy() is no-copy. Rather, copy=True ensure that a copy is made, even if not strictly necessary.
- **na_value** [Any, optional] The value to use for missing values. The default value depends on dtype and the dtypes of the DataFrame columns.

New in version 1.1.0.

**Returns**

numpy.ndarray

**See also:**

**Series.to_numpy** Similar method for Series.

**Examples**

```python
>>> pd.DataFrame({"A": [1, 2], "B": [3, 4]}).to_numpy()
array([[1, 2],
       [3, 4]])
```

With heterogeneous data, the lowest common type will have to be used.
For a mix of numeric and non-numeric types, the output array will have object dtype.

```python
>>> df['C'] = pd.date_range('2000', periods=2)
```
DataFrame.to_csv  Write a csv file.

DataFrame.to_sql  Write to a sql table.

DataFrame.to_hdf  Write to hdf.

Notes

This function requires either the fastparquet or pyarrow library.

Examples

```python
>>> df = pd.DataFrame(data={'col1': [1, 2], 'col2': [3, 4]})
>>> df.to_parquet('df.parquet.gzip',
...    compression='gzip')
>>> pd.read_parquet('df.parquet.gzip')
  col1  col2
0    1    3
1    2    4
```

If you want to get a buffer to the parquet content you can use a io.BytesIO object, as long as you don’t use partition_cols, which creates multiple files.

```python
>>> import io

>>> f = io.BytesIO()

>>> df.to_parquet(f)

>>> f.seek(0)

>>> content = f.read()
```

pandas.DataFrame.to_period

DataFrame.to_period(freq=None, axis=0, copy=True)

Convert DataFrame from DatetimeIndex to PeriodIndex.

Convert DataFrame from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).

Parameters

- freq [str, default] Frequency of the PeriodIndex.
- axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to convert (the index by default).
- copy [bool, default True] If False then underlying input data is not copied.

Returns

DataFrame with PeriodIndex
pandas.DataFrame.to_pickle

DataFrame.to_pickle(path, compression='infer', protocol=5)
Pickle (serialize) object to file.

Parameters

    path [str] File path where the pickled object will be stored.

    protocol [int] Int which indicates which protocol should be used by the pickler, default HIGHEST_PROTOCOL (see [1] paragraph 12.1.2). The possible values are 0, 1, 2, 3, 4. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST_PROTOCOL.

See also:

    read_pickle Load pickled pandas object (or any object) from file.

    DataFrame.to_hdf Write DataFrame to an HDF5 file.

    DataFrame.to_sql Write DataFrame to a SQL database.

    DataFrame.to_parquet Write a DataFrame to the binary parquet format.

Examples

```python
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0  0   5
1  1   6
2  2   7
3  3   8
4  4   9

>>> original_df.to_pickle("./dummy.pkl")

>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0  0   5
1  1   6
2  2   7
3  3   8
4  4   9

>>> import os
>>> os.remove("./dummy.pkl")
```
pandas.DataFrame.to_records

DataFrame.to_records (index=True, column_dtypes=None, index_dtypes=None)

Convert DataFrame to a NumPy record array.

Index will be included as the first field of the record array if requested.

Parameters

- **index** [bool, default True] Include index in resulting record array, stored in ‘index’ field or using the index label, if set.

- **column_dtypes** [str, type, dict, default None] New in version 0.24.0.
  
  If a string or type, the data type to store all columns. If a dictionary, a mapping of column names and indices (zero-indexed) to specific data types.

- **index_dtypes** [str, type, dict, default None] New in version 0.24.0.

  If a string or type, the data type to store all index levels. If a dictionary, a mapping of index level names and indices (zero-indexed) to specific data types.

  This mapping is applied only if index=True.

Returns

- **numpy.recarray** NumPy ndarray with the DataFrame labels as fields and each row of the DataFrame as entries.

See also:

- **DataFrame.from_records** Convert structured or record ndarray to DataFrame.

- **numpy.recarray** An ndarray that allows field access using attributes, analogous to typed columns in a spreadsheet.

Examples

```python
>>> df = pd.DataFrame({'A': [1, 2], 'B': [0.5, 0.75]},
    ...            index=['a', 'b'])
>>> df
   A  B
a 1  0.5
b 2  0.75
>>> df.to_records()
rec.array([(a', 1, 0.5), (b', 2, 0.75)],
          dtype=[('index', 'O'), (A', '<i8'), (B', '<f8')])
```

If the DataFrame index has no label then the recarray field name is set to ‘index’. If the index has a label then this is used as the field name:

```python
>>> df.index = df.index.rename("I")
>>> df.to_records()
rec.array([(a', 1, 0.5), (b', 2, 0.75)],
          dtype=[('I', 'O'), (A', '<i8'), (B', '<f8')])
```

The index can be excluded from the record array:

```python
>>> df.index = df.index.rename("I")
>>> df.to_records()
rec.array([(a', 1, 0.5), (b', 2, 0.75)],
          dtype=[('I', 'O'), (A', '<i8'), (B', '<f8')])
```
Data types can be specified for the columns:

```python
cols = {'A': 'int32'}
df.to_records(column_dtypes=cols)
```

As well as for the index:

```python
idx = df.index.str.len().max()
df.to_records(index_dtypes=f'<{idx}S')
```

### pandas.DataFrame.to_sql

DataFrame.to_sql(name, con, schema=None, if_exists='fail', index=True, index_label=None, chunksize=None, dtype=None, method=None)

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [1] are supported. Tables can be newly created, appended to, or overwritten.

**Parameters**

- **name** [str] Name of SQL table.
- **con** [sqlalchemy.engine.(Engine or Connection) or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable See here.
- **schema** [str, optional] Specify the schema (if database flavor supports this). If None, use default schema.
- **if_exists** ['fail', 'replace', 'append', 'fail'] How to behave if the table already exists.
  - fail: Raise a ValueError.
  - replace: Drop the table before inserting new values.
  - append: Insert new values to the existing table.
- **index** [bool, default True] Write DataFrame index as a column. Uses index_label as the column name in the table.
- **index_label** [str or sequence, default None] Column label for index column(s). If None is given (default) and index is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
chunksize [int, optional] Specify the number of rows in each batch to be written at a
time. By default, all rows will be written at once.

dtype [dict or scalar, optional] Specifying the datatype for columns. If a dict-
ionary is used, the keys should be the column names and the values should be the
SQLAlchemy types or strings for the sqlite3 legacy mode. If a scalar is provided,
it will be applied to all columns.

method [{None, ‘multi’, callable}, optional] Controls the SQL insertion clause used:
  • None : Uses standard SQL INSERT clause (one per row).
  • ‘multi’: Pass multiple values in a single INSERT clause.
  • callable with signature (pd_table, conn, keys, data_iter).

Details and a sample callable implementation can be found in the section insert
method.

New in version 0.24.0.

Raises

ValueError When the table already exists and if_exists is ‘fail’ (the default).

See also:

read_sql Read a DataFrame from a table.

Notes

Timezone aware datetime columns will be written as Timestamp with timezone type with
SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware
timestamps local to the original timezone.

New in version 0.24.0.

References

[1], [2]

Examples

Create an in-memory SQLite database.

```python
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```python
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
    name
0  User 1
1  User 2
2  User 3
```
An `sqlalchemy.engine.Connection` can also be passed to to `con`: >>> with engine.begin() as connection: ... df1 = pd.DataFrame({'name': ['User 4', 'User 5']}) ... df1.to_sql('users', con=connection, if_exists='append')

This is allowed to support operations that require that the same DBAPI connection is used for the entire operation.

Overwrite the table with just `df2`.

```python
>>> df2.to_sql('users', con=engine, if_exists='replace', ... index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 6'), (1, 'User 7')]
```

Specify the `dtype` (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```python
>>> df = pd.DataFrame({"A": [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0

>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False, ... dtype={"A": Integer()})
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

### pandas.DataFrame.to_stata

DataFrame.to_stata(**kwargs)

Export DataFrame object to Stata dta format.

Writes the DataFrame to a Stata dataset file. “dta” files contain a Stata dataset.

**Parameters**

- `path` [str, buffer or path object] String, path object (pathlib.Path or py._path.local.LocalPath) or object implementing a binary write() function. If using a buffer then the buffer will not be automatically closed after the file data has been written.
Changed in version 1.0.0.

Previously this was “fname”

**convert_dates**  [dict] Dictionary mapping columns containing datetime types to stata internal format to use when writing the dates. Options are ‘tc’, ‘td’, ‘tm’, ‘tw’, ‘th’, ‘tq’, ‘ty’. Column can be either an integer or a name. Datetime columns that do not have a conversion type specified will be converted to ‘tc’. Raises **NotImplementedError** if a datetime column has timezone information.

**write_index**  [bool] Write the index to Stata dataset.

**byteorder**  [str] Can be “>”, “<”, “little”, or “big”. default is sys.byteorder.

**time_stamp**  [datetime] A datetime to use as file creation date. Default is the current time.

**data_label**  [str, optional] A label for the data set. Must be 80 characters or smaller.

**variable_labels**  [dict] Dictionary containing columns as keys and variable labels as values. Each label must be 80 characters or smaller.

**version**  [{114, 117, 118, 119, None}, default 114] Version to use in the output dta file. Set to None to let pandas decide between 118 or 119 formats depending on the number of columns in the frame. Version 114 can be read by Stata 10 and later. Version 117 can be read by Stata 13 or later. Version 118 is supported in Stata 14 and later. Version 119 is supported in Stata 15 and later. Version 114 limits string variables to 244 characters or fewer while versions 117 and later allow strings with lengths up to 2,000,000 characters. Versions 118 and 119 support Unicode characters, and version 119 supports more than 32,767 variables.

New in version 0.23.0.

Changed in version 1.0.0: Added support for formats 118 and 119.

**convert_strl**  [list, optional] List of column names to convert to string columns to Stata StrL format. Only available if version is 117. Storing strings in the StrL format can produce smaller dta files if strings have more than 8 characters and values are repeated.

New in version 0.23.0.

**compression**  [str or dict, default ‘infer’] For on-the-fly compression of the output dta. If string, specifies compression mode. If dict, value at key ‘method’ specifies compression mode. Compression mode must be one of {‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}. If compression mode is ‘infer’ and **fname** is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’ (otherwise no compression). If dict and compression mode is one of {‘zip’, ‘gzip’, ‘bz2’}, or inferred as one of the above, other entries passed as additional compression options.

New in version 1.1.0.

**Raises**

**NotImplementedError**

* If datetimes contain timezone information
* Column dtype is not representable in Stata

**ValueError**
• Columns listed in convert_dates are neither datetime64[ns] or datetime
• Column listed in convert_dates is not in DataFrame
• Categorical label contains more than 32,000 characters

See also:

read_stata Import Stata data files.
io.stata.StataWriter Low-level writer for Stata data files.
io.stata.StataWriter117 Low-level writer for version 117 files.

Examples

```python
>>> df = pd.DataFrame({'animal': ['falcon', 'parrot', 'falcon', ...
        'parrot'],
        ...
        'speed': [350, 18, 361, 15]})
>>> df.to_stata('animals.dta')
```

pandas.DataFrame.to_string

DataFrame.to_string(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, justify=None, max_rows=None, min_rows=None, max_cols=None, show_dimensions=False, decimal='.', line_width=None, max_colwidth=None, encoding=None)

Render a DataFrame to a console-friendly tabular output.

Parameters

buf [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.
columns [sequence, optional, default None] The subset of columns to write. Writes all columns by default.
col_space [int, list or dict of int, optional] The minimum width of each column.
header [bool or sequence, optional] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.
index [bool, optional, default True] Whether to print index (row) labels.
na_rep [str, optional, default ‘NaN’] String representation of NAN to use.
formatters [list, tuple or dict of one-param. functions, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List/tuple must be of length equal to the number of columns.
float_format [one-parameter function, optional, default None] Formatter function to apply to columns’ elements if they are floats. The result of this function must be a unicode string.
sparsify [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.
index_names [bool, optional, default True] Prints the names of the indexes.

**justifies**  [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by set_option), 'right' out of the box. Valid values are

- left
- right
- center
- justify
- justify-all
- start
- end
- inherit
- match-parent
- initial
- unset.

**max_rows**  [int, optional] Maximum number of rows to display in the console.

**min_rows**  [int, optional] The number of rows to display in the console in a truncated repr (when number of rows is above max_rows).

**max_cols**  [int, optional] Maximum number of columns to display in the console.

**show_dimensions**  [bool, default False] Display DataFrame dimensions (number of rows by number of columns).

**decimal**  [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

**line_width**  [int, optional] Width to wrap a line in characters.

**max_colwidth**  [int, optional] Max width to truncate each column in characters. By default, no limit.

New in version 1.0.0.

**encoding**  [str, default “utf-8”] Set character encoding.

New in version 1.0.

Returns

- **str or None** If buf is None, returns the result as a string. Otherwise returns None.

See also:

- **to_html** Convert DataFrame to HTML.
### Examples

```python
>>> d = {'col1': [1, 2, 3], 'col2': [4, 5, 6]}
>>> df = pd.DataFrame(d)
>>> print(df.to_string())
   col1  col2
0     1     4
1     2     5
2     3     6
```

#### pandas.DataFrame.to_timestamp

DataFrame.to_timestamp(freq=None, how='start', axis=0, copy=True)

Cast to DatetimeIndex of timestamps, at beginning of period.

**Parameters**

- `freq` [str, default frequency of PeriodIndex] Desired frequency.
- `how` [{‘s’, ‘e’, ‘start’, ‘end’}] Convention for converting period to timestamp; start of period vs. end.
- `axis` [0 or ‘index’, 1 or ‘columns’], default 0] The axis to convert (the index by default).
- `copy` [bool, default True] If False then underlying input data is not copied.

**Returns**

DataFrame with DatetimeIndex

#### pandas.DataFrame.to_xarray

DataFrame.to_xarray()

Return an xarray object from the pandas object.

**Returns**

xarray.DataArray or xarray.Dataset Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

**See also:**

- **DataFrame.to_hdf** Write DataFrame to an HDF5 file.
- **DataFrame.to_parquet** Write a DataFrame to the binary parquet format.
Notes

See the `xarray` docs

Examples

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0, 2),
...                    ('parrot', 'bird', 24.0, 2),
...                    ('lion', 'mammal', 80.5, 4),
...                    ('monkey', 'mammal', np.nan, 4)],
...                    columns=['name', 'class', 'max_speed', 'num_legs'])
```
```
name  class  max_speed  num_legs
0  falcon  bird      389.0     2
1  parrot  bird      24.0     2
2  lion    mammal    80.5     4
3  monkey  mammal    NaN     4
```

```python
>>> df.to_xarray()
<xarray.Dataset
  Dimensions:    (index: 4)
  Coordinates:
    * index (index) int64 0 1 2 3
  Data variables:
    name (index) object 'falcon' 'parrot' 'lion' 'monkey'
    class (index) object 'bird' 'bird' 'mammal' 'mammal'
    max_speed (index) float64 389.0 24.0 80.5 nan
    num_legs (index) int64 2 2 4 4
```

```python
>>> df['max_speed'].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389., 24., 80.5, nan])
Coordinates:
    * index (index) int64 0 1 2 3
```

```python
dates = pd.to_datetime(['2018-01-01', '2018-01-01',
                        '2018-01-02', '2018-01-02'])
```
```
>>> df_multiindex = pd.DataFrame({'date': dates,
                                 'animal': ['falcon', 'parrot', 'falcon', 'parrot'],
                                 'speed': [350, 18, 361, 15]})
```
```
>>> df_multiindex = df_multiindex.set_index(['date', 'animal'])
```
```
>>> df_multiindex
date  animal  speed
2018-01-01  falcon  350
2018-01-01  parrot  18
2018-01-02  falcon  361
2018-01-02  parrot  15
```
```
>>> df_multiindex.to_xarray()
<xarray.Dataset
  Dimensions:    (index: 4)
  Coordinates:
    * index (index) int64 0 1 2 3
  Data variables:
    speed (index) float64 350 18 361 15
```
```
(continues on next page)
Dimensions: (animal: 2, date: 2)
Coordinates:
* date (date) datetime64[ns] 2018-01-01 2018-01-02
* animal (animal) object 'falcon' 'parrot'
Data variables:
  speed (date, animal) int64 350 18 361 15

pandas.DataFrame.transform

DataFrame.transform(func, axis=0, *args, **kwargs)
Call func on self producing a DataFrame with transformed values.
Produced DataFrame will have same axis length as self.

Parameters

  func [function, str, list or dict] Function to use for transforming the data. If a function,
  must either work when passed a DataFrame or when passed to DataFrame.apply.
  Accepted combinations are:
  • function
  • string function name
  • list of functions and/or function names, e.g. [np.exp, 'sqrt']
  • dict of axis labels -> functions, function names or list of such.

  axis [{0 or 'index', 1 or 'columns'}, default 0] If 0 or ‘index’: apply function to each
  column. If 1 or ‘columns’: apply function to each row.

  *args Positional arguments to pass to func.

  **kwargs Keyword arguments to pass to func.

Returns

  DataFrame A DataFrame that must have the same length as self.

 Raises

  ValueError [If the returned DataFrame has a different length than self.]

See also:

  DataFrame.agg Only perform aggregating type operations.
  DataFrame.apply Invoke function on a DataFrame.
Examples

```python
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
      A  B
0      0  1
1      1  2
2      2  3
>>> df.transform(lambda x: x + 1)
      A  B
0      1  2
1      2  3
2      3  4
```

Even though the resulting DataFrame must have the same length as the input DataFrame, it is possible to provide several input functions:

```python
>>> s = pd.Series(range(3))
>>> s
0 0
1 1
2 2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
     sqrt     exp
0 0.000000 1.000000
1 1.000000 2.718282
2 1.414214 7.389056
```

**pandas.DataFrame.transpose**

DataFrame.transpose(*args, copy=False)

Transpose index and columns.

Reflect the DataFrame over its main diagonal by writing rows as columns and vice-versa. The property $T$ is an accessor to the method `transpose()`.

**Parameters**

*args [tuple, optional] Accepted for compatibility with NumPy.

**copy** [bool, default False] Whether to copy the data after transposing, even for DataFrames with a single dtype.

Note that a copy is always required for mixed dtype DataFrames, or for DataFrames with any extension types.

**Returns**

DataFrame The transposed DataFrame.

**See also:**

numpy.transpose Permutes the dimensions of a given array.
Notes

Transposing a DataFrame with mixed dtypes will result in a homogeneous DataFrame with the object dtype. In such a case, a copy of the data is always made.

Examples

Square DataFrame with homogeneous dtype

```python
>>> d1 = {'col1': [1, 2], 'col2': [3, 4]}
>>> df1 = pd.DataFrame(data=d1)
>>> df1
   col1  col2
0    1    3
1    2    4

>>> df1_transposed = df1.T # or df1.transpose()
>>> df1_transposed
   0  1
  col1  1  2
  col2  3  4
```

When the dtype is homogeneous in the original DataFrame, we get a transposed DataFrame with the same dtype:

```python
>>> df1.dtypes
col1    int64
col2    int64
dtype: object
>>> df1_transposed.dtypes
0    int64
1    int64
dtype: object
```

Non-square DataFrame with mixed dtypes

```python
>>> d2 = {'name': ['Alice', 'Bob'],
...       'score': [9.5, 8],
...       'employed': [False, True],
...       'kids': [0, 0]}
>>> df2 = pd.DataFrame(data=d2)
>>> df2
   name  score  employed  kids
0  Alice   9.5       False   0
1     Bob   8.0        True   0

>>> df2_transposed = df2.T # or df2.transpose()
>>> df2_transposed
   0  1
  name  Alice  Bob
  score   9.5   8
  employed  False  True
  kids      0      0
```

When the DataFrame has mixed dtypes, we get a transposed DataFrame with the object dtype:
pandas: powerful Python data analysis toolkit, Release 1.1.1

```python
>>> df2.dtypes
name    object
score  float64
employed  bool
kids    int64
dtype: object

>>> df2_transposed.dtypes
0    object
1    object
dtype: object
```

**pandas.DataFrame.truediv**

Dataframe.truediv(other, axis='columns', level=None, fill_value=None)

Get floating division of dataframe and other, element-wise (binary operator truediv).

Equivalent to dataframe / other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rtruediv.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.

DataFrame.sub Subtract DataFrames.

DataFrame.mul Multiply DataFrames.

DataFrame.div Divide DataFrames (float division).

DataFrame.truediv Divide DataFrames (float division).

DataFrame.floordiv Divide DataFrames (integer division).

DataFrame.mod Calculate modulo (remainder after division).

DataFrame.pow Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
    angles  degrees
  circle    0      360
   triangle  3      180
  rectangle  4      360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
    angles  degrees
  circle    1      361
   triangle  4      181
  rectangle  5      361
``` 

```python
>>> df.add(1)
    angles  degrees
  circle    1      361
   triangle  4      181
  rectangle  5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
    angles  degrees
  circle    0.0     36.0
   triangle  0.3     18.0
  rectangle  0.4     36.0
```

```python
>>> df.rdiv(10)
    angles  degrees
  circle    inf     0.027778
   triangle  3.333333  0.055556
  rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
    angles  degrees
  circle    -1      358
   triangle   2      178
  rectangle   3      358
```

```python
>>> df.sub([1, 2], axis='columns')
    angles  degrees
  circle    -1      358
   triangle   2      178
  rectangle   3      358
```
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])
>>> other
angles
circle 0
triangle 3
rectangle 4

>>> df * other
angles degrees
circle 0 NaN
triangle 9 NaN
rectangle 16 NaN

>>> df.mul(other, fill_value=0)
angles degrees
circle 0.0
triangle 0.0
rectangle 0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720]},
                              index=['A', 'A', 'A', 'B', 'B', 'B'],
                              columns=['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon'])
>>> df_multindex
angles degrees
A circle 0 360
triangle 3 180
rectangle 4 360
B square 4 360
pentagon 5 540
hexagon 6 720

>>> df.div(df_multindex, level=0, fill_value=0)
angles degrees
A circle NaN 1.0
triangle 1.0 1.0
rectangle 1.0 1.0
B square 0.0 0.0
pentagon 0.0 0.0
hexagon 0.0 0.0
```
pandas.DataFrame.truncate

DataFrame.truncate(before=None, after=None, axis=None, copy=True)
Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

Parameters

- **before** [date, str, int] Truncate all rows before this index value.
- **after** [date, str, int] Truncate all rows after this index value.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, optional] Axis to truncate. Truncates the index (rows) by default.
- **copy** [bool, default is True.] Return a copy of the truncated section.

Returns

- type of caller The truncated Series or DataFrame.

See also:

- **DataFrame.loc** Select a subset of a DataFrame by label.
- **DataFrame.iloc** Select a subset of a DataFrame by position.

Notes

If the index being truncated contains only datetime values, before and after may be specified as strings instead of Timestamps.

Examples

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
                    'B': ['f', 'g', 'h', 'i', 'j'],
                    'C': ['k', 'l', 'm', 'n', 'o']},
                    index=[1, 2, 3, 4, 5])
>>> df
   A  B  C
1  a  f  k
2  b  g  l
3  c  h  m
4  d  i  n
5  e  j  o
```

```python
>>> df.truncate(before=2, after=4)
   A  B  C
2  b  g  l
3  c  h  m
4  d  i  n
```

The columns of a DataFrame can be truncated.
For Series, only rows can be truncated.

```
>>> df['A'].truncate(before=2, after=4)  
2   b  
3   c  
4   d  
Name: A, dtype: object
```

The index values in `truncate` can be datetimes or string dates.

```
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()  
      A
2016-01-31 23:59:56 1
2016-01-31 23:59:57 1
2016-01-31 23:59:58 1
2016-01-31 23:59:59 1
2016-02-01 00:00:00 1
```

```
>>> df.truncate(before=pd.Timestamp('2016-01-05'),
...             after=pd.Timestamp('2016-01-10')).tail()  
      A
2016-01-09 23:59:56 1
2016-01-09 23:59:57 1
2016-01-09 23:59:58 1
2016-01-09 23:59:59 1
2016-01-10 00:00:00 1
```

Because the index is a DatetimeIndex containing only dates, we can specify `before` and `after` as strings. They will be coerced to Timestamps before truncation.

```
>>> df.truncate('2016-01-05', '2016-01-10').tail()  
      A
2016-01-09 23:59:56 1
2016-01-09 23:59:57 1
2016-01-09 23:59:58 1
2016-01-09 23:59:59 1
2016-01-10 00:00:00 1
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```
>>> df.loc['2016-01-05':'2016-01-10', :].tail()  
      A
2016-01-10 23:59:55 1
2016-01-10 23:59:56 1
2016-01-10 23:59:57 1
(continues on next page)
pandas.DataFrame.tshift

DataFrame.tshift (periods=1, freq=None, axis=0)
Shift the time index, using the index’s frequency if available.
Deprecated since version 1.1.0: Use shift instead.

Parameters

periods [int] Number of periods to move, can be positive or negative.

freq [DateOffset, timedelta, or str, default None] Increment to use from the tseries module or time rule expressed as a string (e.g. ‘EOM’).

axis [[0 or ‘index’, 1 or ‘columns’, None], default 0] Corresponds to the axis that contains the Index.

Returns

shifted [Series/DataFrame]

Notes

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown

pandas.DataFrame.tz_convert

DataFrame.tz_convert (tz, axis=0, level=None, copy=True)
Convert tz-aware axis to target time zone.

Parameters

tz [str or tzinfo object]
axis [the axis to convert]
level [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None.

copy [bool, default True] Also make a copy of the underlying data.

Returns

{klass} Object with time zone converted axis.

Raises

TypeError If the axis is tz-naive.
pandas.DataFrame.tz_localize

```python
DataFrame.tz_localize(tz, axis=0, level=None, copy=True, ambiguous='raise', nonexistent='raise')
```

Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use `Series.dt.tz_localize()`.

**Parameters**

- `tz` [str or tzinfo]
- `axis` [the axis to localize]
- `level` [int, str, default None] If axis ia a MultiIndex, localize a specific level. Otherwise must be None.
- `copy` [bool, default True] Also make a copy of the underlying data.
- `ambiguous` ['infer', bool-ndarray, `NaT`, default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the `ambiguous` parameter dictates how ambiguous times should be handled.
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.
- `nonexistent` [str, default 'raise'] A nonexistent time does not exist in a particular time-zone where clocks moved forward due to DST. Valid values are:
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

**Returns**

- Series or DataFrame Same type as the input.

**Raises**

- TypeError If the TimeSeries is tz-aware and tz is not None.
Examples

Localize local times:

```python
>>> s = pd.Series([1],
                 index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00 1
dtype: int64
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```python
>>> s = pd.Series(range(7),
                 index=pd.DatetimeIndex(['2018-10-28 01:30:00',
                                         '2018-10-28 02:00:00',
                                         '2018-10-28 02:30:00',
                                         '2018-10-28 02:00:00',
                                         '2018-10-28 02:30:00',
                                         '2018-10-28 03:00:00',
                                         '2018-10-28 03:30:00']))
>>> s.tz_localize('CET', ambiguous='infer')
2018-10-28 01:30:00+02:00 0
2018-10-28 02:00:00+02:00 1
2018-10-28 02:30:00+02:00 2
2018-10-28 02:00:00+01:00 3
2018-10-28 02:30:00+01:00 4
2018-10-28 03:00:00+01:00 5
2018-10-28 03:30:00+01:00 6
dtype: int64
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly

```python
>>> s = pd.Series(range(3),
                 index=pd.DatetimeIndex(['2018-10-28 01:20:00',
                                         '2018-10-28 02:36:00',
                                         '2018-10-28 03:46:00']))
>>> s.tz_localize('CET', ambiguous=np.array([True, True, False]))
```

If the DST transition causes nonexistent times, you can shift these dates forward or backward with a timedelta object or ‘shift_forward’ or ‘shift_backward’.

```python
>>> s = pd.Series(range(2),
                 index=pd.DatetimeIndex(['2015-03-29 02:30:00',
                                         '2015-03-29 03:30:00']))
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
>>> s.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
```

(continues on next page)
pandas.DataFrame.unstack

DataFrame.unstack(level=-1, fill_value=None)

Pivot a level of the (necessarily hierarchical) index labels.

Returns a DataFrame having a new level of column labels whose inner-most level consists of the pivoted index labels.

If the index is not a MultiIndex, the output will be a Series (the analogue of stack when the columns are not a MultiIndex).

Parameters

level [int, str, or list of these, default -1 (last level)] Level(s) of index to unstack, can pass level name.

fill_value [int, str or dict] Replace NaN with this value if the unstack produces missing values.

Returns

Series or DataFrame

See also:

DataFrame.pivot  Pivot a table based on column values.

DataFrame.stack  Pivot a level of the column labels (inverse operation from unstack).

Examples

```python
>>> index = pd.MultiIndex.from_tuples([("one", 'a'), ('one', 'b'), ...
        ('two', 'a'), ('two', 'b')])
>>> s = pd.Series(np.arange(1.0, 5.0), index=index)
>>> s
one a 1.0
   b 2.0
two a 3.0
   b 4.0
dtype: float64

>>> s.unstack(level=-1)
a  b
one 1.0 2.0
two 3.0 4.0

>>> s.unstack(level=0)
one two
a 1.0 3.0
   b 2.0 4.0
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

```python
>>> df = s.unstack(level=0)
>>> df.unstack()
one  a  1.0
   b  2.0
two  a  3.0
   b  4.0
dtype: float64
```

**pandas.DataFrame.update**

DataFrame.update(other, join='left', overwrite=True, filter_func=None, errors='ignore')

Modify in place using non-NA values from another DataFrame.

Aligns on indices. There is no return value.

**Parameters**

- **other** [DataFrame, or object coercible into a DataFrame] Should have at least one matching index/column label with the original DataFrame. If a Series is passed, its name attribute must be set, and that will be used as the column name to align with the original DataFrame.

- **join** [‘left’] Only left join is implemented, keeping the index and columns of the original object.

- **overwrite** [bool, default True] How to handle non-NA values for overlapping keys:
  - True: overwrite original DataFrame’s values with values from other.
  - False: only update values that are NA in the original DataFrame.

- **filter_func** [callable(1d-array) -> bool 1d-array, optional] Can choose to replace values other than NA. Return True for values that should be updated.

- **errors** [‘raise’, ‘ignore’] If ‘raise’, will raise a ValueError if the DataFrame and other both contain non-NA data in the same place.

  Changed in version 0.24.0: Changed from raise_conflict=False|True to errors='ignore'|’raise’.

**Returns**

None [method directly changes calling object]

**Raises**

- **ValueError**
  - When errors=’raise’ and there’s overlapping non-NA data.
  - When errors is not either ‘ignore’ or ‘raise’

- **NotImplementedError**
  - If join != ‘left’

**See also:**

dict.update Similar method for dictionaries.

DataFrame.merge For column(s)-on-columns(s) operations.
Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3],
... 'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, 5, 6],
... 'C': [7, 8, 9]})
>>> df.update(new_df)
```

```
  A  B
0  1  4
1  2  5
2  3  6
```

The DataFrame’s length does not increase as a result of the update, only values at matching index/column labels are updated.

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
... 'B': ['x', 'y', 'z']})
>>> new_df = pd.DataFrame({'B': ['d', 'e', 'f', 'g', 'h', 'i']})
>>> df.update(new_df)
```

```
  A  B
0 a  d
1 b  e
2 c  f
```

For Series, it’s name attribute must be set.

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
... 'B': ['x', 'y', 'z']})
>>> new_column = pd.Series(['d', 'e'], name='B', index=[0, 2])
>>> df.update(new_column)
```

```
  A  B
0 a  d
1 b  y
2 c  e
```

If other contains NaNs the corresponding values are not updated in the original dataframe.

```python
>>> df = pd.DataFrame({'A': [1, 2, 3],
... 'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, np.nan, 6]})
>>> df.update(new_df)
```

```
  A  B
0 1  4.0
1 2 500.0
2 3 6.0
```
pandas.DataFrame.value_counts

DataFrame.value_counts (subset=None, normalize=False, sort=True, ascending=False)

Return a Series containing counts of unique rows in the DataFrame.

New in version 1.1.0.

Parameters

- **subset** [list-like, optional] Columns to use when counting unique combinations.
- **normalize** [bool, default False] Return proportions rather than frequencies.
- **sort** [bool, default True] Sort by frequencies.
- **ascending** [bool, default False] Sort in ascending order.

Returns

Series

See also:

Series.value_counts Equivalent method on Series.

Notes

The returned Series will have a MultiIndex with one level per input column. By default, rows that contain any NA values are omitted from the result. By default, the resulting Series will be in descending order so that the first element is the most frequently-occurring row.

Examples

```python
>>> df = pd.DataFrame({'num_legs': [2, 4, 4, 6],
... 'num_wings': [2, 0, 0, 0]},
... index=['falcon', 'dog', 'cat', 'ant'])
>>> df
  num_legs num_wings  
falcon    2        2  
dog       4        0  
cat       4        0  
ant       6        0

>>> df.value_counts()
  num_legs num_wings
4        0        2
6        0        1
2        2        1
dtype: int64

>>> df.value_counts(sort=False)
  num_legs num_wings
2        2        1
4        0        2
6        0        1
dtype: int64
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

```python
>>> df.value_counts(ascending=True)
num_legs  num_wings
2         2
6         1
4         0
4         2
dtype: int64

>>> df.value_counts(normalize=True)
num_legs  num_wings
4         0  0.50
6         0  0.25
2         2  0.25
dtype: float64
```

**pandas.DataFrame.var**

DataFrame.var (axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

**Parameters**

- **axis** [{index (0), columns (1)}]
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

Series or DataFrame (if level specified)

**pandas.DataFrame.where**

DataFrame.where (cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=False)

Replace values where the condition is False.

**Parameters**

- **cond** [bool Series/DataFrame, array-like, or callable] Where cond is True, keep the original value. Where False, replace with corresponding value from other. If cond is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn’t check it).
- **other** [scalar, Series/DataFrame, or callable] Entries where cond is False are replaced with corresponding value from other. If other is callable, it is computed on the
Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

**inplace** [bool, default False] Whether to perform the operation in place on the data.

**axis** [int, default None] Alignment axis if needed.

**level** [int, default None] Alignment level if needed.

**errors** [str, {'raise', ‘ignore’}, default ‘raise’] Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.

- ‘raise’: allow exceptions to be raised.
- ‘ignore’: suppress exceptions. On error return original object.

**try_cast** [bool, default False] Try to cast the result back to the input type (if possible).

Returns

Same type as caller

See also:

*DataFrame.mask()* Return an object of same shape as self.

Notes

The where method is an application of the if-then idiom. For each element in the calling DataFrame, if *cond* is True the element is used; otherwise the corresponding element from the DataFrame *other* is used.

The signature for *DataFrame.where()* differs from *numpy.where()*.

Roughly *df1.where(m, df2)* is equivalent to *np.where(m, df1, df2)*.

For further details and examples see the *where* documentation in *indexing*.

Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64

>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```
```python
>>> s.where(s > 1, 10)
0    10
1    10
2     2
3     3
4     4
dtype: int64
```

```python
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
```

```python
>>> df.where(m, -df) == df.mask(~m, -df)
```

```python
pandas.DataFrame.xs
```

DataFrame.xs (key, axis=0, level=None, drop_level=True)

Return cross-section from the Series/DataFrame.

This method takes a `key` argument to select data at a particular level of a MultiIndex.

**Parameters**

- **key** [label or tuple of label] Label contained in the index, or partially in a MultiIndex.
- **axis** [{0 or 'index', 1 or 'columns'}, default 0] Axis to retrieve cross-section on.
- **level** [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.
- **drop_level** [bool, default True] If False, returns object with same levels as self.
Returns

Series or DataFrame: Cross-section from the original Series or DataFrame corresponding to the selected index levels.

See also:

DataFrame.loc: Access a group of rows and columns by label(s) or a boolean array.

DataFrame.iloc: Purely integer-location based indexing for selection by position.

Notes

xs can not be used to set values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of xs functionality, see MultiIndex Slicers.

Examples

```python
>>> d = {'num_legs': [4, 4, 2, 2],
...       'num_wings': [0, 0, 2, 2],
...       'class': ['mammal', 'mammal', 'mammal', 'bird'],
...       'animal': ['cat', 'dog', 'bat', 'penguin'],
...       'locomotion': ['walks', 'walks', 'flies', 'walks']}
>>> df = pd.DataFrame(data=d)
>>> df = df.set_index(['class', 'animal', 'locomotion'])
>>> df
   num_legs  num_wings
animal locomotion
mammal  cat walks  4  0
        dog walks  4  0
        bat flies  2  2
bird    penguin walks  2  2

Get values at specified index

```python
>>> df.xs('mammal')
   num_legs  num_wings
animal locomotion
cat   walks  4  0
dog   walks  4  0
bat   flies  2  2

Get values at several indexes

```python
>>> df.xs(('mammal', 'dog'))
   locomotion
num_legs  num_wings
walks  4  0

Get values at specified index and level

```python
>>> df.xs('cat', level=1)
   num_legs  num_wings
class locomotion
mammal  walks  4  0
```
Get values at several indexes and levels

```python
>>> df.xs(('bird', 'walks'),
...       level=[0, 'locomotion'])
     num_legs num_wings
animal    2         2
penguin    2         2
```

Get values at specified column and axis

```python
>>> df.xs('num_wings', axis=1)
   class       animal  locomotion
  mammal       cat    walks  0
      dog    walks  0
      bat    flies  2
  bird  penguin   walks  2
Name: num_wings, dtype: int64
```

### 3.4.2 Attributes and underlying data

#### Axes

- **DataFrame.index**: The index (row labels) of the DataFrame.
- **DataFrame.columns**: The column labels of the DataFrame.

- **DataFrame.dtypes**: Return the dtypes in the DataFrame.
- **DataFrame.info([verbose, buf, max_cols,...])**: Print a concise summary of a DataFrame.
- **DataFrame.select_dtypes([include, exclude])**: Return a subset of the DataFrame's columns based on the column dtypes.
- **DataFrame.values**: Return a Numpy representation of the DataFrame.
- **DataFrame.axes**: Return a list representing the axes of the DataFrame.
- **DataFrame.ndim**: Return an int representing the number of axes / array dimensions.
- **DataFrame.size**: Return an int representing the number of elements in this object.
- **DataFrame.shape**: Return a tuple representing the dimensionality of the DataFrame.
- **DataFrame.memory_usage([index, deep])**: Return the memory usage of each column in bytes.
- **DataFrame.empty**: Indicator whether DataFrame is empty.

### 3.4.3 Conversion

- **DataFrame.astype(dtype[, copy, errors])**: Cast a pandas object to a specified dtype `dtype`.
- **DataFrame.convert_dtypes([infer_objects, ...])**: Convert columns to best possible dtypes using dtypes supporting `pd.NA`.
- **DataFrame.infer_objects()**: Attempt to infer better dtypes for object columns.
- **DataFrame.copy([deep])**: Make a copy of this object's indices and data.
- **DataFrame.bool()**: Return the bool of a single element Series or DataFrame.
3.4.4 Indexing, iteration

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame.head</td>
<td>Return the first ( n ) rows.</td>
</tr>
<tr>
<td>DataFrame.at</td>
<td>Access a single value for a row/column label pair.</td>
</tr>
<tr>
<td>DataFrame.iat</td>
<td>Access a single value for a row/column pair by integer position.</td>
</tr>
<tr>
<td>DataFrame.loc</td>
<td>Access a group of rows and columns by label(s) or a boolean array.</td>
</tr>
<tr>
<td>DataFrame.iloc</td>
<td>Purely integer-location based indexing for selection by position.</td>
</tr>
<tr>
<td>DataFrame.insert</td>
<td>Insert column into DataFrame at specified location.</td>
</tr>
<tr>
<td>DataFrame.<strong>iter</strong></td>
<td>Iterate over info axis.</td>
</tr>
<tr>
<td>DataFrame.items</td>
<td>Iterate over (column name, Series) pairs.</td>
</tr>
<tr>
<td>DataFrame.iteritems</td>
<td>Iterate over (column name, Series) pairs.</td>
</tr>
<tr>
<td>DataFrame.keys</td>
<td>Get the “info axis” (see Indexing for more).</td>
</tr>
<tr>
<td>DataFrame.iterrows</td>
<td>Iterate over DataFrame rows as (index, Series) pairs.</td>
</tr>
<tr>
<td>DataFrame.iteritems</td>
<td>Iterate over DataFrame rows as namedtuples.</td>
</tr>
<tr>
<td>DataFrame.lookup</td>
<td>Label-based “fancy indexing” function for DataFrame.</td>
</tr>
<tr>
<td>DataFrame.pop</td>
<td>Return item and drop from frame.</td>
</tr>
<tr>
<td>DataFrame.tail</td>
<td>Return the last ( n ) rows.</td>
</tr>
<tr>
<td>DataFrame.xs</td>
<td>Return cross-section from the Series/DataFrame.</td>
</tr>
<tr>
<td>DataFrame.get</td>
<td>Get item from object for given key (ex: DataFrame column).</td>
</tr>
<tr>
<td>DataFrame.isin</td>
<td>Whether each element in the DataFrame is contained in values.</td>
</tr>
<tr>
<td>DataFrame.where</td>
<td>Replace values where the condition is False.</td>
</tr>
<tr>
<td>DataFrame.mask</td>
<td>Replace values where the condition is True.</td>
</tr>
<tr>
<td>DataFrame.query</td>
<td>Query the columns of a DataFrame with a boolean expression.</td>
</tr>
</tbody>
</table>

pandas.DataFrame.__iter__

DataFrame.__iter__()

Iterate over info axis.

Returns

iterator  Info axis as iterator.

For more information on .at, .iat, .loc, and .iloc, see the indexing documentation.

3.4.5 Binary operator functions

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame.add</td>
<td>Get Addition of dataframe and other, element-wise (binary operator add).</td>
</tr>
<tr>
<td>DataFrame.sub</td>
<td>Get Subtraction of dataframe and other, element-wise (binary operator sub).</td>
</tr>
<tr>
<td>DataFrame.mul</td>
<td>Get Multiplication of dataframe and other, element-wise (binary operator mul).</td>
</tr>
<tr>
<td>DataFrame.div</td>
<td>Get Floating division of dataframe and other, element-wise (binary operator truediv).</td>
</tr>
</tbody>
</table>
**Table 64 – continued from previous page**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.truediv(other[, axis, level, ...])</code></td>
<td>Get Floating division of dataframe and other, element-wise (binary operator <code>truediv</code>).</td>
</tr>
<tr>
<td><code>DataFrame.floordiv(other[, axis, level, ...])</code></td>
<td>Get Integer division of dataframe and other, element-wise (binary operator <code>floordiv</code>).</td>
</tr>
<tr>
<td><code>DataFrame.mod(other[, axis, level, fill_value])</code></td>
<td>Get Modulo of dataframe and other, element-wise (binary operator <code>mod</code>).</td>
</tr>
<tr>
<td><code>DataFrame.pow(other[, axis, level, fill_value])</code></td>
<td>Get Exponential power of dataframe and other, element-wise (binary operator <code>pow</code>).</td>
</tr>
<tr>
<td><code>DataFrame.dot(other)</code></td>
<td>Compute the matrix multiplication between the DataFrame and other.</td>
</tr>
<tr>
<td><code>DataFrame.radd(other[, axis, level, fill_value])</code></td>
<td>Get Addition of dataframe and other, element-wise (binary operator <code>radd</code>).</td>
</tr>
<tr>
<td><code>DataFrame.rsub(other[, axis, level, fill_value])</code></td>
<td>Get Subtraction of dataframe and other, element-wise (binary operator <code>rsub</code>).</td>
</tr>
<tr>
<td><code>DataFrame.rmul(other[, axis, level, fill_value])</code></td>
<td>Get Multiplication of dataframe and other, element-wise (binary operator <code>rmul</code>).</td>
</tr>
<tr>
<td><code>DataFrame.rdiv(other[, axis, level, fill_value])</code></td>
<td>Get Floating division of dataframe and other, element-wise (binary operator <code>rtruediv</code>).</td>
</tr>
<tr>
<td><code>DataFrame.rtruediv(other[, axis, level, ...])</code></td>
<td>Get Floating division of dataframe and other, element-wise (binary operator <code>rtruediv</code>).</td>
</tr>
<tr>
<td><code>DataFrame.rfloordiv(other[, axis, level, ...])</code></td>
<td>Get Integer division of dataframe and other, element-wise (binary operator <code>rfloordiv</code>).</td>
</tr>
<tr>
<td><code>DataFrame.rmod(other[, axis, level, fill_value])</code></td>
<td>Get Modulo of dataframe and other, element-wise (binary operator <code>rmod</code>).</td>
</tr>
<tr>
<td><code>DataFrame.rpow(other[, axis, level, fill_value])</code></td>
<td>Get Exponential power of dataframe and other, element-wise (binary operator <code>rpow</code>).</td>
</tr>
<tr>
<td><code>DataFrame.lt(other[, axis, level])</code></td>
<td>Get Less than of dataframe and other, element-wise (binary operator <code>lt</code>).</td>
</tr>
<tr>
<td><code>DataFrame.gt(other[, axis, level])</code></td>
<td>Get Greater than of dataframe and other, element-wise (binary operator <code>gt</code>).</td>
</tr>
<tr>
<td><code>DataFrame.le(other[, axis, level])</code></td>
<td>Get Less than or equal to of dataframe and other, element-wise (binary operator <code>le</code>).</td>
</tr>
<tr>
<td><code>DataFrame.ge(other[, axis, level])</code></td>
<td>Get Greater than or equal to of dataframe and other, element-wise (binary operator <code>ge</code>).</td>
</tr>
<tr>
<td><code>DataFrame.ne(other[, axis, level])</code></td>
<td>Get Not equal to of dataframe and other, element-wise (binary operator <code>ne</code>).</td>
</tr>
<tr>
<td><code>DataFrame.eq(other[, axis, level])</code></td>
<td>Get Equal to of dataframe and other, element-wise (binary operator <code>eq</code>).</td>
</tr>
<tr>
<td><code>DataFrame.combine(other, func[, fill_value, ...])</code></td>
<td>Perform column-wise combine with another DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.combine_first(other)</code></td>
<td>Update null elements with value in the same location in <code>other</code>.</td>
</tr>
</tbody>
</table>
3.4.6 Function application, GroupBy & window

- **DataFrame.apply**(func[, axis, raw, ...]) Apply a function along an axis of the DataFrame.
- **DataFrame.applymap**(func) Apply a function to a Dataframe elementwise.
- **DataFrame.pipe**(func, *args, **kwargs) Apply func(self, *args, **kwargs).
- **DataFrame.agg**(func[, axis]) Aggregate using one or more operations over the specified axis.
- **DataFrame.aggregate**(func[, axis]) Aggregate using one or more operations over the specified axis.
- **DataFrame.transform**(func[, axis]) Call func on self producing a DataFrame with transformed values.
- **DataFrame.groupby**(by[, axis, level, ...]) Group DataFrame using a mapper or by a Series of columns.
- **DataFrame.rolling**(window[, min_periods, ...]) Provide rolling window calculations.
- **DataFrame.expanding**(min_periods[, center, axis]) Provide expanding transformations.
- **DataFrame.ewm**(com, span, halflife, alpha[, ...]) Provide exponential weighted (EW) functions.

3.4.7 Computations / descriptive stats

- **DataFrame.abs**() Return a Series/DataFrame with absolute numeric value of each element.
- **DataFrame.all**(axis, bool_only, skipna, level) Return whether all elements are True, potentially over an axis.
- **DataFrame.any**(axis, bool_only, skipna, level) Return whether any element is True, potentially over an axis.
- **DataFrame.clip**(lower, upper, axis, inplace) Trim values at input threshold(s).
- **DataFrame.corr**(method, min_periods) Compute pairwise correlation of columns, excluding NA/null values.
- **DataFrame.corrwith**(other[, axis, drop, method]) Compute pairwise correlation.
- **DataFrame.count**(axis, level, numeric_only) Count non-NA cells for each column or row.
- **DataFrame.cov**(min_periods, ddof) Compute pairwise covariance of columns, excluding NA/null values.
- **DataFrame.cummax**(axis, skipna) Return cumulative maximum over a DataFrame or Series axis.
- **DataFrame.cummin**(axis, skipna) Return cumulative minimum over a DataFrame or Series axis.
- **DataFrame.cumprod**(axis, skipna) Return cumulative product over a DataFrame or Series axis.
- **DataFrame.cumsum**(axis, skipna) Return cumulative sum over a DataFrame or Series axis.
- **DataFrame.describe**(percentiles, include, ...) Generate descriptive statistics.
- **DataFrame.diff**(periods, axis) First discrete difference of element.
- **DataFrame.eval**(expr[, inplace]) Evaluate a string describing operations on DataFrame columns.
- **DataFrame.kurt**(axis, skipna, level, ...) Return unbiased kurtosis over requested axis.
- **DataFrame.kurtosis**(axis, skipna, level, ...) Return unbiased kurtosis over requested axis.
- **DataFrame.mad**(axis, skipna, level) Return the mean absolute deviation of the values for the requested axis.

continues on next page
Table 66 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame.max</td>
<td>Return the maximum of the values for the requested axis.</td>
</tr>
<tr>
<td>DataFrame.mean</td>
<td>Return the mean of the values for the requested axis.</td>
</tr>
<tr>
<td>DataFrame.median</td>
<td>Return the median of the values for the requested axis.</td>
</tr>
<tr>
<td>DataFrame.min</td>
<td>Return the minimum of the values for the requested axis.</td>
</tr>
<tr>
<td>DataFrame.mode</td>
<td>Get the mode(s) of each element along the selected axis.</td>
</tr>
<tr>
<td>DataFrame.pct_change</td>
<td>Percentage change between the current and a prior element.</td>
</tr>
<tr>
<td>DataFrame.prod</td>
<td>Return the product of the values for the requested axis.</td>
</tr>
<tr>
<td>DataFrame.product</td>
<td>Return the product of the values for the requested axis.</td>
</tr>
<tr>
<td>DataFrame.quantile</td>
<td>Return values at the given quantile over requested axis.</td>
</tr>
<tr>
<td>DataFrame.rank</td>
<td>Compute numerical data ranks (1 through n) along axis.</td>
</tr>
<tr>
<td>DataFrame.round</td>
<td>Round a DataFrame to a variable number of decimal places.</td>
</tr>
<tr>
<td>DataFrame.sem</td>
<td>Return unbiased standard error of the mean over requested axis.</td>
</tr>
<tr>
<td>DataFrame.skew</td>
<td>Return unbiased skew over requested axis.</td>
</tr>
<tr>
<td>DataFrame.sum</td>
<td>Return the sum of the values for the requested axis.</td>
</tr>
<tr>
<td>DataFrame.std</td>
<td>Return sample standard deviation over requested axis.</td>
</tr>
<tr>
<td>DataFrame.var</td>
<td>Return unbiased variance over requested axis.</td>
</tr>
<tr>
<td>DataFrame.nunique</td>
<td>Count distinct observations over requested axis.</td>
</tr>
<tr>
<td>DataFrame.value_counts</td>
<td>Return a Series containing counts of unique rows in the DataFrame.</td>
</tr>
</tbody>
</table>

3.4.8 Reindexing / selection / label manipulation

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame.add_prefix</td>
<td>Prefix labels with string ( prefix ).</td>
</tr>
<tr>
<td>DataFrame.add_suffix</td>
<td>Suffix labels with string ( suffix ).</td>
</tr>
<tr>
<td>DataFrame.align</td>
<td>Align two objects on their axes with the specified join method.</td>
</tr>
<tr>
<td>DataFrame.at_time</td>
<td>Select values at particular time of day (e.g., 9:30AM).</td>
</tr>
<tr>
<td>DataFrame.between_time</td>
<td>Select values between particular times of the day (e.g., 9:00-9:30 AM).</td>
</tr>
<tr>
<td>DataFrame.drop</td>
<td>Drop specified labels from rows or columns.</td>
</tr>
<tr>
<td>DataFrame.drop_duplicates</td>
<td>Return DataFrame with duplicate rows removed.</td>
</tr>
<tr>
<td>DataFrame.duplicated</td>
<td>Return boolean Series denoting duplicate rows.</td>
</tr>
<tr>
<td>DataFrame.equals</td>
<td>Test whether two objects contain the same elements.</td>
</tr>
<tr>
<td>DataFrame.filter</td>
<td>Subset the dataframe rows or columns according to the specified index labels.</td>
</tr>
<tr>
<td>DataFrame.first</td>
<td>Select initial periods of time series data based on a date offset.</td>
</tr>
<tr>
<td>DataFrame.head</td>
<td>Return the first ( n ) rows.</td>
</tr>
<tr>
<td>DataFrame.idxmax</td>
<td>Return index of first occurrence of maximum over requested axis.</td>
</tr>
<tr>
<td>DataFrame.idxmin</td>
<td>Return index of first occurrence of minimum over requested axis.</td>
</tr>
</tbody>
</table>
**DataFrame.last**(offset) Select final periods of time series data based on a date offset.

**DataFrame.reindex**(**kwargs) Conform Series/DataFrame to new index with optional filling logic.

**DataFrame.reindex_like**(other[, method, ...]) Return an object with matching indices as other object.

**DataFrame.rename**(**kwargs) Alter axes labels.

**DataFrame.rename_axis**(**kwargs) Set the name of the axis for the index or columns.

**DataFrame.reset_index**(level, drop, ...) Reset the index, or a level of it.

**DataFrame.sample**(n, frac, replace, ...) Return a random sample of items from an axis of object.

**DataFrame.set_axis**(labels[, axis, inplace]) Assign desired index to given axis.

**DataFrame.set_index**(keys[, drop, append, ...]) Set the DataFrame index using existing columns.

**DataFrame.tail**(n) Return the last n rows.

**DataFrame.take**(indices[, axis, is_copy]) Return the elements in the given positional indices along an axis.

**DataFrame.truncate**(before, after, axis, copy) Truncate a Series or DataFrame before and after some index value.

### 3.4.9 Missing data handling

**DataFrame.backfill**(axis, inplace, limit, ...) Synonym for **DataFrame.fillna()** with method='bfill'.

**DataFrame.bfill**(axis, inplace, limit, downcast) Synonym for **DataFrame.fillna()** with method='bfill'.

**DataFrame.dropna**(axis, how, thresh, ...) Remove missing values.

**DataFrame.ffill**(axis, inplace, limit, downcast) Synonym for **DataFrame.fillna()** with method='ffill'.

**DataFrame.fillna**(value, method, axis, ...) Fill NA/NaN values using the specified method.

**DataFrame.isna()** Detect missing values.

**DataFrame.isnull()** Detect missing values.

**DataFrame.notna()** Detect existing (non-missing) values.

**DataFrame.notnull()** Detect existing (non-missing) values.

**DataFrame.pad**(axis, inplace, limit, downcast) Synonym for **DataFrame.fillna()** with method='ffill'.

**DataFrame.replace**(to_replace, value) Replace values given in to_replace with value.

### 3.4.10 Reshaping, sorting, transposing

**DataFrame.droplevel**(level[, axis]) Return DataFrame with requested index / column level(s) removed.

**DataFrame.pivot**(index, columns, values) Return reshaped DataFrame organized by given index / column values.

**DataFrame.pivot_table**(values, index, ...) Create a spreadsheet-style pivot table as a DataFrame.

**DataFrame.reorder_levels**(order[, ...]) Rearrange index levels using input order.

**DataFrame.sort_values**(by[, axis, ascending, ...]) Sort by the values along either axis.

continues on next page
Table 69 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.sort_index((axis, level, ...))</code></td>
<td>Sort object by labels (along an axis).</td>
</tr>
<tr>
<td><code>DataFrame.nlargest(n, columns[, keep])</code></td>
<td>Return the first <code>n</code> rows ordered by <code>columns</code> in descending order.</td>
</tr>
<tr>
<td><code>DataFrame.nsmallest(n, columns[, keep])</code></td>
<td>Return the first <code>n</code> rows ordered by <code>columns</code> in ascending order.</td>
</tr>
<tr>
<td><code>DataFrame.swaplevel([i, j, axis])</code></td>
<td>Swap levels i and j in a MultiIndex on a particular axis.</td>
</tr>
<tr>
<td><code>DataFrame.stack([level, dropna])</code></td>
<td>Stack the prescribed level(s) from columns to index.</td>
</tr>
<tr>
<td><code>DataFrame.unstack([level, fill_value])</code></td>
<td>Pivot a level of the (necessarily hierarchical) index labels.</td>
</tr>
<tr>
<td><code>DataFrame.swapaxes(axis1, axis2[, copy])</code></td>
<td>Interchange axes and swap values axes appropriately.</td>
</tr>
<tr>
<td><code>DataFrame.melt([id_vars, value_vars, ...])</code></td>
<td>Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.</td>
</tr>
<tr>
<td><code>DataFrame.explode(column[, ignore_index])</code></td>
<td>Transform each element of a list-like to a row, replicating index values.</td>
</tr>
<tr>
<td><code>DataFrame.squeeze([axis])</code></td>
<td>Squeeze 1 dimensional axis objects into scalars.</td>
</tr>
<tr>
<td><code>DataFrame.to_xarray()</code></td>
<td>Return an xarray object from the pandas object.</td>
</tr>
<tr>
<td><code>DataFrame.T</code></td>
<td>Transpose index and columns.</td>
</tr>
</tbody>
</table>

**property** `DataFrame.T`

### 3.4.11 Combining / comparing / joining / merging

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.append(other[, ignore_index, ...])</code></td>
<td>Append rows of <code>other</code> to the end of caller, returning a new object.</td>
</tr>
<tr>
<td><code>DataFrame.assign(**kwargs)</code></td>
<td>Assign new columns to a DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.compare(other[, align_axis, ...])</code></td>
<td>Compare to another DataFrame and show the differences.</td>
</tr>
<tr>
<td><code>DataFrame.join(other[, on, how, lsuffix, ...])</code></td>
<td>Join columns of another DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.merge(right[, how, on, left_on, ...])</code></td>
<td>Merge DataFrame or named Series objects with a database-style join.</td>
</tr>
<tr>
<td><code>DataFrame.update(other[, join, overwrite, ...])</code></td>
<td>Modify in place using non-NA values from another DataFrame.</td>
</tr>
</tbody>
</table>

### 3.4.12 Time Series-related

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.asfreq(freq[, method, how, ...])</code></td>
<td>Convert TimeSeries to specified frequency.</td>
</tr>
<tr>
<td><code>DataFrame.asof(where[, subset])</code></td>
<td>Return the last row(s) without any NaNs before <code>where</code>.</td>
</tr>
<tr>
<td><code>DataFrame.shift([periods, freq, axis, ...])</code></td>
<td>Shift index by desired number of periods with an optional time <code>freq</code>.</td>
</tr>
<tr>
<td><code>DataFrame.slice_shift([periods, axis])</code></td>
<td>Equivalent to <code>shift</code> without copying data.</td>
</tr>
<tr>
<td><code>DataFrame.tshift([periods, freq, axis])</code></td>
<td>(DEPRECATED) Shift the time index, using the index’s frequency if available.</td>
</tr>
<tr>
<td><code>DataFrame.first_valid_index()</code></td>
<td>Return index for first non-NA/null value.</td>
</tr>
<tr>
<td><code>DataFrame.last_valid_index()</code></td>
<td>Return index for last non-NA/null value.</td>
</tr>
</tbody>
</table>

continues on next page
DataFrame.resample(rule[, axis, closed, ...])  Resample time-series data.
DataFrame.to_period([freq, axis, copy])  Convert DataFrame from DatetimeIndex to PeriodIndex.
DataFrame.to_timestamp([freq, how, axis, copy])  Cast to DatetimeIndex of timestamps, at beginning of period.
DataFrame.tz_convert([tz[, axis, level, copy]])  Convert tz-aware axis to target time zone.
DataFrame.tz_localize([tz[, axis, level, ...]])  Localize tz-naive index of a Series or DataFrame to target time zone.

3.4.13 Metadata

DataFrame.attrs is a dictionary for storing global metadata for this DataFrame.

Warning: DataFrame.attrs is considered experimental and may change without warning.

DataFrame.attrs  Dictionary of global attributes on this object.

3.4.14 Plotting

DataFrame.plot is both a callable method and a namespace attribute for specific plotting methods of the form DataFrame.plot.<kind>.

DataFrame.plot([x, y, kind, ax, ...])  DataFrame plotting accessor and method

DataFrame.plot.area([x, y])  Draw a stacked area plot.
DataFrame.plot.bar([x, y])  Vertical bar plot.
DataFrame.plot.barh([x, y])  Make a horizontal bar plot.
DataFrame.plot.box([by])  Make a box plot of the DataFrame columns.
DataFrame.plot.density([bw_method, ind])  Generate Kernel Density Estimate plot using Gaussian kernels.
DataFrame.plot.hexbin(x, y[, C, ...])  Generate a hexagonal binning plot.
DataFrame.plot.hist([by, bins])  Draw one histogram of the DataFrame’s columns.
DataFrame.plot.kde([bw_method, ind])  Generate Kernel Density Estimate plot using Gaussian kernels.
DataFrame.plot.line([x, y])  Plot Series or DataFrame as lines.
DataFrame.plot.pie(**kwargs)  Generate a pie plot.
DataFrame.plot.scatter(x, y[, s, c])  Create a scatter plot with varying marker point size and color.
pandas.DataFrame.plot.area

DataFrame.plot.area(x=None, y=None, **kwargs)

Draw a stacked area plot.

An area plot displays quantitative data visually. This function wraps the matplotlib area function.

Parameters

- x [label or position, optional] Coordinates for the X axis. By default uses the index.
- y [label or position, optional] Column to plot. By default uses all columns.
- stacked [bool, default True] Area plots are stacked by default. Set to False to create a unstacked plot.
- **kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

- matplotlib.axes.Axes or numpy.ndarray Area plot, or array of area plots if subplots is True.

See also:

- DataFrame.plot Make plots of DataFrame using matplotlib / pylab.

Examples

Draw an area plot based on basic business metrics:

```python
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3, 9, 10, 6],
...     'signups': [5, 5, 6, 12, 14, 13],
...     'visits': [20, 42, 28, 62, 81, 50],
... }, index=pd.date_range(start='2018/01/01', end='2018/07/01',
...     freq='M'))
>>> ax = df.plot.area()
```

Area plots are stacked by default. To produce an unstacked plot, pass stacked=False:

```python
>>> ax = df.plot.area(stacked=False)
```

Draw an area plot for a single column:

```python
>>> ax = df.plot.area(y='sales')
```

Draw with a different x:

```python
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3],
...     'visits': [20, 42, 28],
...     'day': [1, 2, 3],
... })
>>> ax = df.plot.area(x='day')
```
3.4. DataFrame
3.4. DataFrame
**pandas.DataFrame.plot.bar**

`DataFrame.plot.bar(x=None, y=None, **kwargs)`

Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

**Parameters**

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- **color** [str, array_like, or dict, optional] The color for each of the DataFrame's columns. Possible values are:
  - A single color string referred to by name, RGB or RGBA code, for instance 'red' or '#a98d19'.
  - A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column's bar will be filled in green or yellow, alternatively.
  - A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called `a` and `b`, then passing `{a: 'green', b: 'red'}` will color bars for column `a` in green and bars for column `b` in red.

New in version 1.1.0.

- **kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

**Returns**

- `matplotlib.axes.Axes` or `np.ndarray` of them An ndarray is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

**See also:**

- `DataFrame.plot.barh` Horizontal bar plot.
- `DataFrame.plot` Make plots of a DataFrame.
- `matplotlib.pyplot.bar` Make a bar plot with matplotlib.

**Examples**

Basic plot.

```python
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
>>>           'rabbit', 'giraffe', 'coyote', 'horse']
```
>>> df = pd.DataFrame({'speed': speed,...
                        'lifespan': lifespan}, index=index)
>>> ax = df.plot.bar(rot=0)

Plot stacked bar charts for the DataFrame

```python
>>> ax = df.plot.bar(stacked=True)
```

Instead of nesting, the figure can be split by column with `subplots=True`. In this case, a `numpy.ndarray` of `matplotlib.axes.Axes` are returned.

```python
>>> axes = df.plot.bar(rot=0, subplots=True)
```  
If you don’t like the default colours, you can specify how you’d like each column to be colored.

```python
>>> axes = df.plot.bar(...
               rot=0, subplots=True, color={"speed": "red", "lifespan": "green"}
...
) >>> axes[1].legend(loc=2)
```

Plot a single column.

3.4. DataFrame
Chapter 3. API reference
Plot only selected categories for the DataFrame.

```python
>>> ax = df.plot.bar(x='lifespan', rot=0)
```

### pandas.DataFrame.plot.barh

DataFrame.plot.barh ($x$=None, $y$=None, **kwargs)

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

**Parameters**

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- **color** [str, array_like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:
• A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.

• A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column’s bar will be filled in green or yellow, alternatively.

• A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {'a': 'green', 'b': 'red'} will color bars for column a in green and bars for column b in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

DataFrame.plot.bar Vertical bar plot.
DataFrame.plot Make plots of DataFrame using matplotlib.
matplotlib.axes.Axes.bar Plot a vertical bar plot using matplotlib.

Examples

Basic example

>>> df = pd.DataFrame({"lab": ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')

Plot a whole DataFrame to a horizontal bar plot

>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant', ...
            'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({"speed": speed,
                      ...
                      'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
3.4. DataFrame
... 'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(y='speed')

Plot DataFrame versus the desired column

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant', 'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                    'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(x='lifespan')
```
3.4. DataFrame
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.DataFrame.plot.box

DataFrame.plot.box(by=None, **kwargs)
Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to 1.5*IQR (IQR = Q3 - Q1) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia’s entry for boxplot.

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

Parameters
   
   by [str or sequence] Column in the DataFrame to group by.

   **kwargs Additional keywords are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

DataFrame.boxplot Another method to draw a box plot.
Series.plot.box Draw a box plot from a Series object.
matplotlib.pyplot.boxplot Draw a box plot in matplotlib.

Examples

Draw a box plot from a DataFrame with four columns of randomly generated data.

```python
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```

pandas.DataFrame.plot.density

DataFrame.plot.density(bw_method=None, ind=None, **kwargs)
Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

   bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See scipy.stats.gaussian_kde for more information.

   ind [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.

   **kwargs Additional keyword arguments are documented in pandas.%(this-datatype)s.plot().

1778 Chapter 3. API reference
Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

scipy.stats.gaussian_kde  Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

![Graph showing a kernel density estimation with default bandwidth](image)

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)
```

```python
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:
3.4. DataFrame
For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)

>>> ax = df.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5])
```
pandas.DataFrame.plot.hexbin

DataFrame.plot.hexbin(x, y, C=None, reduce_C_function=None, gridsize=None, **kwargs)

Generate a hexagonal binning plot.

Generate a hexagonal binning plot of \( x \) versus \( y \). If \( C \) is None (the default), this is a histogram of the number of occurrences of the observations at \( (x[i], y[i]) \).

If \( C \) is specified, specifies values at given coordinates \( (x[i], y[i]) \). These values are accumulated for each hexagonal bin and then reduced according to reduce_C_function, having as default the NumPy’s mean function (numpy.mean()). (If \( C \) is specified, it must also be a 1-D sequence of the same length as \( x \) and \( y \), or a column label.)

**Parameters**

- \( x \) [int or str] The column label or position for \( x \) points.
- \( y \) [int or str] The column label or position for \( y \) points.
- \( C \) [int or str, optional] The column label or position for the value of \( (x, y) \) point.
- reduce_C_function [callable, default np.mean] Function of one argument that reduces all the values in a bin to a single number (e.g. np.mean, np.max, np.sum, np.std).
- gridsize [int or tuple of (int, int), default 100] The number of hexagons in the x-direction. The corresponding number of hexagons in the y-direction is chosen in a way that the hexagons are approximately regular. Alternatively, gridsize can be a tuple with two elements specifying the number of hexagons in the x-direction and the y-direction.
- **kwargs Additional keyword arguments are documented in DataFrame.plot().

**Returns**

matplotlib.AxesSubplot The matplotlib Axes on which the hexbin is plotted.

See also:

- DataFrame.plot Make plots of a DataFrame.
- matplotlib.pyplot.hexbin Hexagonal binning plot using matplotlib, the matplotlib function that is used under the hood.

**Examples**

The following examples are generated with random data from a normal distribution.

```python
>>> n = 10000
>>> df = pd.DataFrame({'x': np.random.randn(n),
...                    'y': np.random.randn(n)})
>>> ax = df.plot.hexbin(x='x', y='y', gridsize=20)
```

The next example uses \( C \) and np.sum as reduce_C_function. Note that ‘observations’ values ranges from 1 to 5 but the result plot shows values up to more than 25. This is because of the reduce_C_function.

```python
>>> n = 500
>>> df = pd.DataFrame(
...                   {'coord_x': np.random.uniform(-3, 3, size=n),
...                    'coord_y': np.random.uniform(30, 50, size=n),
...                    'observations': np.random.randint(1,5, size=n)}
...                   )
>>> ax = df.plot.hexbin(x='coord_x',
...                      y='coord_y',
...                      c='observations',
...                      gridsize=20,
...                      reduce_C_function=np.mean)
```
`pandas.DataFrame.plot.hist`

`DataFrame.plot.hist(by=None, bins=10, **kwargs)`

Draw one histogram of the DataFrame's columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one `matplotlib.axes.Axes`. This is useful when the DataFrame's Series are in a similar scale.

**Parameters**

- **by** [str or sequence, optional] Column in the DataFrame to group by.
- **bins** [int, default 10] Number of histogram bins to be used.
- ****kwargs Additional keyword arguments are documented in `DataFrame.plot()`.

**Returns**

- **class:matplotlib.AxesSubplot** Return a histogram plot.
See also:

**DataFrame.hist** Draw histograms per DataFrame’s Series.

**Series.hist** Draw a histogram with Series’ data.

Examples

When we draw a dice 6000 times, we expect to get each value around 1000 times. But when we draw two dices and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```python
def = pd.DataFrame(
    np.random.randint(1, 7, 6000),
    columns=['one'])
def['two'] = df['one'] + np.random.randint(1, 7, 6000)
ax = df.plot.hist(bins=12, alpha=0.5)
```
DataFrame.plot.kde

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

**Parameters**

- **bw_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See scipy.stats.gaussian_kde for more information.

- **ind** [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.

- **kwargs** Additional keyword arguments are documented in pandas.

**Returns**

matplotlib.axes.Axes or numpy.ndarray of them

See also:

- scipy.stats.gaussian_kde Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

**Examples**

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)

>>> ax = s.plot.kde(bw_method=3)
```

Finally, the **ind** parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame(
...   {'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...    'y': [4, 4, 4.5, 5, 5.5, 6, 6]},
... )
>>> ax = df.plot.kde()
```
Density

-1  0  1  2  3  4  5  6  7
3.4. DataFrame
A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

**pandas.DataFrame.plot.line**

`DataFrame.plot.line(x=None, y=None, **kwargs)`

Plot Series or DataFrame as lines.

This function is useful to plot lines using DataFrame’s values as coordinates.

**Parameters**

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
**color** [str, array_like, or dict, optional] The color for each of the DataFrame's columns. Possible values are:

- **A single color string referred to by name, RGB or RGBA code**, for instance 'red' or '#a98d19'.
- **A sequence of color strings referred to by name, RGB or RGBA code**, which will be used for each column recursively. For instance ['green', 'yellow'] each column's line will be filled in green or yellow, alternatively.
- **A dict of the form {column name: color}**, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {'a': 'green', 'b': 'red'} will color lines for column a in green and lines for column b in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in DataFrame.plot().**

Returns

- matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

- matplotlib.pyplot.plot Plot y versus x as lines and/or markers.

Examples

```python
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()

The following example shows the populations for some animals over the years.

```python
>>> df = pd.DataFrame({
...     'pig': [20, 18, 489, 675, 1776],
...     'horse': [4, 25, 281, 600, 1900],
```

```python
>>> lines = df.plot.line()
```

An example with subplots, so an array of axes is returned.

```python
>>> axes = df.plot.line(subplots=True)
>>> type(axes)
<class 'numpy.ndarray'>
```

Let's repeat the same example, but specifying colors for each column (in this case, for each animal).

```python
>>> axes = df.plot.line(subplots=True, color={'pig': 'pink', 'horse': '#742802'})
```

The following example shows the relationship between both populations.

```python
>>> lines = df.plot.line(x='pig', y='horse')
```
3.4. DataFrame
pandas.DataFrame.plot.pie

DataFrame.plot.pie(**kwargs)
Generate a pie plot.
A pie plot is a proportional representation of the numerical data in a column. This function wraps matplotlib.pyplot.pie() for the specified column. If no column reference is passed and subplots=True a pie plot is drawn for each numerical column independently.

Parameters

- y [int or label, optional] Label or position of the column to plot. If not provided, subplots=True argument must be passed.

- **kwargs Keyword arguments to pass on to DataFrame.plot().

Returns

matplotlib.axes.Axes or np.ndarray of them A NumPy array is returned when subplots is True.

See also:

- Series.plot.pie Generate a pie plot for a Series.
- DataFrame.plot Make plots of a DataFrame.

Examples

In the example below we have a DataFrame with the information about planet’s mass and radius. We pass the ‘mass’ column to the pie function to get a pie plot.

```python
>>> df = pd.DataFrame({'mass': [0.330, 4.87 , 5.97],
... 'radius': [2439.7, 6051.8, 6378.1]},
... index=['Mercury', 'Venus', 'Earth'])
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
>>> plot = df.plot.pie(subplots=True, figsize=(11, 6))
```

pandas.DataFrame.plot.scatter

DataFrame.plot.scatter(x, y, s=None, c=None, **kwargs)
Create a scatter plot with varying marker point size and color.
The coordinates of each point are defined by two dataframe columns and filled circles are used to represent each point. This kind of plot is useful to see complex correlations between two variables. Points could be for instance natural 2D coordinates like longitude and latitude in a map or, in general, any pair of metrics that can be plotted against each other.

Parameters

- x [int or str] The column name or column position to be used as horizontal coordinates for each point.
- y [int or str] The column name or column position to be used as vertical coordinates for each point.
- s [str, scalar or array_like, optional] The size of each point. Possible values are:
  - A string with the name of the column to be used for marker’s size.
  - A single scalar so all points have the same size.
pandas: powerful Python data analysis toolkit, Release 1.1.1

- A sequence of scalars, which will be used for each point’s size recursively. For instance, when passing [2,14] all points size will be either 2 or 14, alternatively.

Changed in version 1.1.0.

**c** [str, int or array_like, optional] The color of each point. Possible values are:

- A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
- A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each point’s color recursively. For instance ['green', 'yellow'] all points will be filled in green or yellow, alternatively.
- A column name or position whose values will be used to color the marker points according to a colormap.

**kwargs** Keyword arguments to pass on to DataFrame.plot().

Returns

- matplotlib.axes.Axes or numpy.ndarray of them

See also:

- matplotlib.pyplot.scatter Scatter plot using multiple input data formats.

Examples

Let’s see how to draw a scatter plot using coordinates from the values in a DataFrame’s columns.

```python
>>> df = pd.DataFrame([[5.1, 3.5, 0], [4.9, 3.0, 0], [7.0, 3.2, 1],
...                     [6.4, 3.2, 1], [5.9, 3.0, 2]],
...                     columns=['length', 'width', 'species'])
>>> ax1 = df.plot.scatter(x='length',
...                        y='width',
...                        c='DarkBlue')
```

And now with the color determined by a column as well.

```python
>>> ax2 = df.plot.scatter(x='length',
...                        y='width',
...                        c='species',
...                        colormap='viridis')
```

DataFrame.boxplot([column, by, ax, . . .]) Make a box plot from DataFrame columns.

DataFrame.hist([column, by, grid, . . .]) Make a histogram of the DataFrame’s.

### 3.4.15 Sparse accessor

Sparse-dtype specific methods and attributes are provided under the DataFrame.sparse accessor.

- DataFrame.sparse.density Ratio of non-sparse points to total (dense) data points.
pandas.DataFrame.sparse.density

DataFrame.sparse.density
Ratio of non-sparse points to total (dense) data points.

DataFrame.sparse.from_spmatrix(data[, ...])
Create a new DataFrame from a scipy sparse matrix.

DataFrame.sparse.to_coo()
Return the contents of the frame as a sparse SciPy COO matrix.

DataFrame.sparse.to_dense()
Convert a DataFrame with sparse values to dense.

pandas.DataFrame.sparse.from_spmatrix

classmethod DataFrame.sparse.from_spmatrix(data, index=None, columns=None)
Create a new DataFrame from a scipy sparse matrix.

New in version 0.25.0.

Parameters

- **data** [scipy.sparse.spmatrix] Must be convertible to csc format.
- **index, columns** [Index, optional] Row and column labels to use for the resulting DataFrame. Defaults to a RangeIndex.

Returns

DataFrame Each column of the DataFrame is stored as a arrays.SparseArray.

Examples

```python
>>> import scipy.sparse

>>> mat = scipy.sparse.eye(3)

>>> pd.DataFrame.sparse.from_spmatrix(mat)
   0  1  2
0  1.0 0.0 0.0
1  0.0 1.0 0.0
2  0.0 0.0 1.0
```

pandas.DataFrame.sparse.to_coo

DataFrame.sparse.to_coo()
Return the contents of the frame as a sparse SciPy COO matrix.

New in version 0.25.0.

Returns

coo_matrix [scipy.sparse.spmatrix] If the caller is heterogeneous and contains booleans or objects, the result will be of dtype=object. See Notes.
Notes

The dtype will be the lowest-common-denominator type (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. By numpy.find_common_type convention, mixing int64 and uint64 will result in a float64 dtype.

pandas.DataFrame.sparse.to_dense

Convert a DataFrame with sparse values to dense.

New in version 0.25.0.

Returns

DataFrame A DataFrame with the same values stored as dense arrays.

Examples

```python
>>> df = pd.DataFrame({"A": pd.arrays.SparseArray([0, 1, 0])})
>>> df.sparse.to_dense()
A
  0 0
  1 1
  2 0
```

Pandas and third-party libraries can extend NumPy’s type system (see `Extension types`). The top-level `array()` method can be used to create a new array, which may be stored in a `Series`, `Index`, or as a column in a `DataFrame`.

```python
array(data[, dtype, copy])
```

Create an array.

### 3.5.1 pandas.array

```python
pandas.array (data, dtype=None, copy=True)
```

Create an array.

New in version 0.24.0.

**Parameters**

- **data** [Sequence of objects] The scalars inside `data` should be instances of the scalar type for `dtype`. It’s expected that `data` represents a 1-dimensional array of data.

  When `data` is an Index or Series, the underlying array will be extracted from `data`.

- **dtype** [str, np.dtype, or ExtensionDtype, optional] The dtype to use for the array. This may be a NumPy dtype or an extension type registered with pandas using `pandas.api.extensions.register_extension_dtype()`.

  If not specified, there are two possibilities:

  1. When `data` is a `Series`, `Index`, or `ExtensionArray`, the `dtype` will be taken from the data.

  2. Otherwise, pandas will attempt to infer the `dtype` from the data.
Note that when `data` is a NumPy array, `data.dtype` is *not* used for inferring the array type. This is because NumPy cannot represent all the types of data that can be held in extension arrays.

Currently, pandas will infer an extension dtype for sequences of

<table>
<thead>
<tr>
<th>Scalar Type</th>
<th>Array Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>pandas.Interval</td>
<td>pandas.arrays.IntervalArray</td>
</tr>
<tr>
<td>pandas.Period</td>
<td>pandas.arrays.PeriodArray</td>
</tr>
<tr>
<td>datetime.datetime</td>
<td>pandas.arrays.DatetimeArray</td>
</tr>
<tr>
<td>datetime.timedelta</td>
<td>pandas.arrays.TimedeltaArray</td>
</tr>
<tr>
<td>int</td>
<td>pandas.arrays.IntegerArray</td>
</tr>
<tr>
<td>str</td>
<td>pandas.arrays.StringArray</td>
</tr>
<tr>
<td>bool</td>
<td>pandas.arrays.BooleanArray</td>
</tr>
</tbody>
</table>

For all other cases, NumPy’s usual inference rules will be used.

Changed in version 1.0.0: Pandas infers nullable-integer dtype for integer data, string dtype for string data, and nullable-boolean dtype for boolean data.

`copy` [bool, default True] Whether to copy the data, even if not necessary. Depending on the type of `data`, creating the new array may require copying data, even if `copy=False`.

Returns

**ExtensionArray** The newly created array.

Raises

**ValueError** When `data` is not 1-dimensional.

See also:

- `numpy.array` Construct a NumPy array.
- `Series` Construct a pandas Series.
- `Index` Construct a pandas Index.
- `arrays.PandasArray` ExtensionArray wrapping a NumPy array.
- `Series.array` Extract the array stored within a Series.

Notes

Omitting the `dtype` argument means pandas will attempt to infer the best array type from the values in the data. As new array types are added by pandas and 3rd party libraries, the “best” array type may change. We recommend specifying `dtype` to ensure that

1. the correct array type for the data is returned
2. the returned array type doesn’t change as new extension types are added by pandas and third-party libraries

Additionally, if the underlying memory representation of the returned array matters, we recommend specifying the `dtype` as a concrete object rather than a string alias or allowing it to be inferred. For example, a future version of pandas or a 3rd-party library may include a dedicated ExtensionArray for string data. In this event, the following would no longer return a `arrays.PandasArray` backed by a NumPy array.

```python
>>> pd.array(['a', 'b'], dtype=str)
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

This would instead return the new ExtensionArray dedicated for string data. If you really need the new array to be backed by a NumPy array, specify that in the `dtype`.
Finally, Pandas has arrays that mostly overlap with NumPy

- **arrays.DatetimeArray**
- **arrays.TimedeltaArray**

When data with a `datetime64[ns]` or `timedelta64[ns]` dtype is passed, pandas will always return a `DatetimeArray` or `TimedeltaArray` rather than a `PandasArray`. This is for symmetry with the case of timezone-aware data, which NumPy does not natively support.

```python
>>> pd.array(['2015', '2016'], dtype='datetime64[ns]')
<DatetimeArray>
['2015-01-01 00:00:00', '2016-01-01 00:00:00']
Length: 2, dtype: datetime64[ns]

>>> pd.array(['1H', '2H'], dtype='timedelta64[ns]')
<TimedeltaArray>
['0 days 01:00:00', '0 days 02:00:00']
Length: 2, dtype: timedelta64[ns]
```

### Examples

If a dtype is not specified, pandas will infer the best dtype from the values. See the description of `dtype` for the types pandas infers for.

```python
>>> pd.array([1, 2])
<IntegerArray>
[1, 2]
Length: 2, dtype: Int64

>>> pd.array([1, 2, np.nan])
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64

>>> pd.array(['a', None, 'c'])
<StringArray>
['a', <NA>, 'c']
Length: 3, dtype: string

<PeriodArray>
['2000-01-01', '2000-01-01']
Length: 2, dtype: period[D]
```

You can use the string alias for `dtype`

```python
>>> pd.array(['a', 'b', 'a'], dtype='category')
['a', 'b', 'a']
Categories (2, object): ['a', 'b']
```

Or specify the actual dtype
pandas: powerful Python data analysis toolkit, Release 1.1.1

>>> pd.array(['a', 'b', 'a'],
    dtype=pd.CategoricalDtype(['a', 'b', 'c'], ordered=True))
['a', 'b', 'a']
Categories (3, object): ['a' < 'b' < 'c']

If pandas does not infer a dedicated extension type a arrays.PandasArray is returned.

>>> pd.array([1.1, 2.2])
<PandasArray>
[1.1, 2.2]
Length: 2, dtype: float64

As mentioned in the “Notes” section, new extension types may be added in the future (by pandas or 3rd party libraries), causing the return value to no longer be a arrays.PandasArray. Specify the dtype as a NumPy dtype if you need to ensure there’s no future change in behavior.

>>> pd.array([1, 2], dtype=np.dtype("int32"))
<PandasArray>
[1, 2]
Length: 2, dtype: int32

data must be 1-dimensional. A ValueError is raised when the input has the wrong dimensionality.

>>> pd.array(1)
Traceback (most recent call last):
...
ValueError: Cannot pass scalar '1' to 'pandas.array'.

3.5.2 Datetime data

NumPy cannot natively represent timezone-aware datetimes. Pandas supports this with the arrays. DatetimeArray extension array, which can hold timezone-naive or timezone-aware values. 

Timestamp, a subclass of datetime.datetime, is pandas’ scalar type for timezone-naive or timezone-aware datetime data.

pandas.Timestamp

class pandas.Timestamp(ts_input=<object object>, freq=None, tz=None, unit=None, year=None, month=None, day=None, hour=None, minute=None, second=None, microsecond=None, nanosecond=None, tzinfo=None, *, fold=None)

Pandas replacement for python datetime.datetime object.

Timestamp is the pandas equivalent of python’s Datetime and is interchangeable with it in most cases. It’s the type used for the entries that make up a DatetimeIndex, and other timeseries oriented data structures in pandas.

Parameters

- ts_input [datetime-like, str, int, float] Value to be converted to Timestamp.
- freq [str, DateOffset] Offset which Timestamp will have.
- tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will
have.

**unit** [str] Unit used for conversion if `ts_input` is of type int or float. The valid values are `'D'`, `'h'`, `'m'`, `'s'`, `'ms'`, `'us'`, and `'ns'`. For example, `'s'` means seconds and `'ms'` means milliseconds.

**year, month, day** [int]

**hour, minute, second, microsecond** [int, optional, default 0]

**nanosecond** [int, optional, default 0] New in version 0.23.0.

**tzinfo** [datetime.tzinfo, optional, default None]

**fold** [{0, 1}, default None, keyword-only] Due to daylight saving time, one wall clock time can occur twice when shifting from summer to winter time; fold describes whether the datetime-like corresponds to the first (0) or the second time (1) the wall clock hits the ambiguous time

New in version 1.1.0.

**Notes**

There are essentially three calling conventions for the constructor. The primary form accepts four parameters. They can be passed by position or keyword.

The other two forms mimic the parameters from `datetime.datetime`. They can be passed by either position or keyword, but not both mixed together.

**Examples**

Using the primary calling convention:

This converts a datetime-like string

```python
>>> pd.Timestamp('2017-01-01T12')
Timestamp('2017-01-01 12:00:00')
```

This converts a float representing a Unix epoch in units of seconds

```python
>>> pd.Timestamp(1513393355.5, unit='s')
Timestamp('2017-12-16 03:02:35.500000')
```

This converts an int representing a Unix-epoch in units of seconds and for a particular timezone

```python
>>> pd.Timestamp(1513393355, unit='s', tz='US/Pacific')
Timestamp('2017-12-15 19:02:35-0800', tz='US/Pacific')
```

Using the other two forms that mimic the API for `datetime.datetime`:

```python
>>> pd.Timestamp(2017, 1, 1, 12)
Timestamp('2017-01-01 12:00:00')
```

```python
>>> pd.Timestamp(year=2017, month=1, day=1, hour=12)
Timestamp('2017-01-01 12:00:00')
```

### `pandas.Timestamp.asm8`  
`Timestamp.asm8`  
Return numpy datetime64 format in nanoseconds.

### `pandas.Timestamp.dayofweek`  
`Timestamp.dayofweek`  
Return day of the week.

### `pandas.Timestamp.dayofyear`  
`Timestamp.dayofyear`  
Return the day of the year.

### `pandas.Timestamp.days_in_month`  
`Timestamp.days_in_month`  
Return the number of days in the month.
pandas.Timestamp.daysinmonth

```
Timestamp.daysinmonth
```

Return the number of days in the month.

pandas.Timestamp.freqstr

```
property Timestamp.freqstr
```

Return the total number of days in the month.

pandas.Timestamp.is_leap_year

```
Timestamp.is_leap_year
```

Return True if year is a leap year.

pandas.Timestamp.is_month_end

```
Timestamp.is_month_end
```

Return True if date is last day of month.

pandas.Timestamp.is_month_start

```
Timestamp.is_month_start
```

Return True if date is first day of month.

pandas.Timestamp.is_quarter_end

```
Timestamp.is_quarter_end
```

Return True if date is last day of the quarter.

pandas.Timestamp.is_quarter_start

```
Timestamp.is_quarter_start
```

Return True if date is first day of the quarter.

pandas.Timestamp.is_year_end

```
Timestamp.is_year_end
```

Return True if date is last day of the year.
pandas.Timestamp.is_year_start

Timestamp.is_year_start
Return True if date is first day of the year.

pandas.Timestamp.quarter

Timestamp.quarter
Return the quarter of the year.

pandas.Timestamp.tz

property Timestamp.tz
Alias for tzinfo.

pandas.Timestamp.week

Timestamp.week
Return the week number of the year.

pandas.Timestamp.weekofyear

Timestamp.weekofyear
Return the week number of the year.

continues on next page
pandas.Timestamp.astimezone

Timestamp.astimezone(tz)
Convert tz-aware Timestamp to another time zone.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp
will be converted to. None will remove timezone holding UTC time.

Returns

converted [Timestamp]

Raises

TypeError If Timestamp is tz-naive.

pandas.Timestamp.ceil

Timestamp.ceil(freq, ambiguous='raise', nonexistent='raise')
return a new Timestamp ceiled to this resolution.

Parameters

freq [str] Frequency string indicating the ceiling resolution.

ambiguous [bool or {‘raise’, ‘NaT’}, default ‘raise’] The behavior is as follows:
• bool contains flags to determine if time is dst or not (note that this flag is only
  applicable for ambiguous fall dst dates).
• ‘NaT’ will return NaT for an ambiguous time.
• ‘raise’ will raise an AmbiguousTimeError for an ambiguous time.

New in version 0.24.0.

nonexistent [{‘raise’, ‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta}, default
‘raise’] A nonexistent time does not exist in a particular timezone where clocks
moved forward due to DST.
• ‘shift_forward’ will shift the nonexistent time forward to the closest existing
time.
• ‘shift_backward’ will shift the nonexistent time backward to the closest exist-
ing time.
• ‘NaT’ will return NaT where there are nonexistent times.
• timedelta objects will shift nonexistent times by the timedelta.
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Raises

ValueError if the freq cannot be converted.
pandas: powerful Python data analysis toolkit, Release 1.1.1

**pandas.Timestamp.combine**

```python
classmethod Timestamp.combine(date, time)
date, time -> datetime with same date and time fields.
```

**pandas.Timestamp.ctime**

```python
Timestamp.ctime()
Return ctime() style string.
```

**pandas.Timestamp.date**

```python
Timestamp.date()
Return date object with same year, month and day.
```

**pandas.Timestamp.day_name**

```python
Timestamp.day_name()
Return the day name of the Timestamp with specified locale.

Parameters
locale [str, default None (English locale)] Locale determining the language in which to return the day name.

Returns
day_name [string]
New in version 0.23.0: ..
```

**pandas.Timestamp.dst**

```python
Timestamp.dst()
Return self.tzinfo.dst(self).
```

**pandas.Timestamp.floor**

```python
Timestamp.floor(freq, ambiguous='raise', nonexistent='raise')
return a new Timestamp floored to this resolution.

Parameters
freq [str] Frequency string indicating the flooring resolution.
ambiguous [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:
  • bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
  • ‘NaT’ will return NaT for an ambiguous time.
  • ‘raise’ will raise an AmbiguousTimeError for an ambiguous time.
New in version 0.24.0.
```
nonexistent [{‘raise’, ‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta}, default ‘raise’} A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time.
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time.
- ‘NaT’ will return NaT where there are nonexistent times.
- timedelta objects will shift nonexistent times by the timedelta.
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

 Raises

 ValueError if the freq cannot be converted.

 pandas.Timestamp.fromisocalendar

 `Timestamp.fromisocalendar()`

 int, int, int -> Construct a date from the ISO year, week number and weekday.

 This is the inverse of the date.isocalendar() function

 pandas.Timestamp.fromisoformat

 `Timestamp.fromisoformat()`

 string -> datetime from datetime.isoformat() output

 pandas.Timestamp.fromordinal

classmethod `Timestamp.fromordinal` (ordinal, freq=None, tz=None)

 Passed an ordinal, translate and convert to a ts. Note: by definition there cannot be any tz info on the ordinal itself.

 Parameters

 ordinal [int] Date corresponding to a proleptic Gregorian ordinal.
 freq [str, DateOffset] Offset to apply to the Timestamp.
 tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for the Timestamp.
pandas.Timestamp.fromtimestamp

classmethod Timestamp.fromtimestamp(ts)
    timestamp[, tz] -> tz’s local time from POSIX timestamp.

pandas.Timestamp.isocalendar

Timestamp.isocalendar()
    Return a 3-tuple containing ISO year, week number, and weekday.

pandas.Timestamp.isoformat

Timestamp.isoformat()
    [sep] -> string in ISO 8601 format, YYYY-MM-DDT[HH[:MM[:SS[.mmm[uuu]]]]][+HH:MM]. sep is
    used to separate the year from the time, and defaults to ‘T’. timespec specifies what components of the time
    to include (allowed values are ‘auto’, ‘hours’, ‘minutes’, ‘seconds’, ‘milliseconds’, and ‘microseconds’).

pandas.Timestamp.isoweekday

Timestamp.isoweekday()
    Return the day of the week represented by the date. Monday == 1 . . . Sunday == 7

pandas.Timestamp.month_name

Timestamp.month_name()
    Return the month name of the Timestamp with specified locale.

    Parameters
        locale [str, default None (English locale)] Locale determining the language in which to
        return the month name.

    Returns
        month_name [string]
            New in version 0.23.0: ..

pandas.Timestamp.normalize

Timestamp.normalize()
    Normalize Timestamp to midnight, preserving tz information.
**pandas.Timestamp.now**

**classmethod** `Timestamp.now(tz=None)`

Return new Timestamp object representing current time local to tz.

**Parameters**

- **tz** [str or timezone object, default None] Timezone to localize to.

**pandas.Timestamp.replace**

`Timestamp.replace(year=None, month=None, day=None, hour=None, minute=None, second=None, microsecond=None, nanosecond=None, tzinfo=<class 'object'>, fold=0)`

Implements datetime.replace, handles nanoseconds.

**Parameters**

- **year** [int, optional]
- **month** [int, optional]
- **day** [int, optional]
- **hour** [int, optional]
- **minute** [int, optional]
- **second** [int, optional]
- **microsecond** [int, optional]
- **nanosecond** [int, optional]
- **tzinfo** [tz-convertible, optional]
- **fold** [int, optional, default is 0]

**Returns**

Timestamp with fields replaced

**pandas.Timestamp.round**

`Timestamp.round(freq, ambiguous='raise', nonexistent='raise')`

Round the Timestamp to the specified resolution.

**Parameters**

- **freq** [str] Frequency string indicating the rounding resolution.
- **ambiguous** [bool or {‘raise’, ‘NaT’}, default ‘raise’] The behavior is as follows:
  - bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
  - ‘NaT’ will return NaT for an ambiguous time.
  - ‘raise’ will raise an AmbiguousTimeError for an ambiguous time.

New in version 0.24.0.
nonexistent [{‘raise’, ‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta}, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time.
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time.
- ‘NaT’ will return NaT where there are nonexistent times.
- timedelta objects will shift nonexistent times by the timedelta.
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

a new Timestamp rounded to the given resolution of freq

Raises

ValueError if the freq cannot be converted

pandas.Timestamp.strptime

Timestamp.strptime(format -> strftime() style string.

pandas.Timestamp.strptime

classmethod Timestamp.strptime(string, format)

Function is not implemented. Use pd.to_datetime().

pandas.Timestamp.time

Timestamp.time()

Return time object with same time but with tzinfo=None.

pandas.Timestamp.timestamp

Timestamp.timestamp()

Return POSIX timestamp as float.
pandas.Timestamp.timetuple

Timestamp.timetuple()
Return time tuple, compatible with time.localtime().

pandas.Timestamp.timetz

Timestamp.timetz()
Return time object with same time and tzinfo.

pandas.Timestamp.to_datetime64

Timestamp.to_datetime64()
Return a numpy.datetime64 object with ‘ns’ precision.

pandas.Timestamp.to_julian_date

Timestamp.to_julian_date()
Convert TimeStamp to a Julian Date. 0 Julian date is noon January 1, 4713 BC.

pandas.Timestamp.to_numpy

Timestamp.to_numpy()
Convert the Timestamp to a NumPy datetime64.
New in version 0.25.0.
This is an alias method for Timestamp.to_datetime64(). The dtype and copy parameters are available here only for compatibility. Their values will not affect the return value.

Returns
numpy.datetime64

See also:

DatetimeIndex.to_numpy  Similar method for DatetimeIndex.

pandas.Timestamp.to_period

Timestamp.to_period()
Return an period of which this timestamp is an observation.
pandas.Timestamp.to_pydatetime

Timestamp.to_pydatetime()
Convert a Timestamp object to a native Python datetime object.
If warn=True, issue a warning if nanoseconds is nonzero.

pandas.Timestamp.today

classmethod Timestamp.today(cls, tz=None)
Return the current time in the local timezone. This differs from datetime.today() in that it can be localized to a passed timezone.

Parameters

tz [str or timezone object, default None] Timezone to localize to.

pandas.Timestamp.toordinal

Timestamp.toordinal()
Return proleptic Gregorian ordinal. January 1 of year 1 is day 1.

pandas.Timestamp.tz_convert

Timestamp.tz_convert(tz)
Convert tz-aware Timestamp to another time zone.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding UTC time.

Returns

converted [Timestamp]

Raises

TypeError If Timestamp is tz-naive.

pandas.Timestamp.tz_localize

Timestamp.tz_localize(tz, ambiguous='raise', nonexistent='raise')
Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding local time.

ambiguous [bool, ‘NaT’, default ‘raise’] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the ambiguous parameter dictates how ambiguous times should be handled.
The behavior is as follows:

- `bool` contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
- ‘NaT’ will return NaT for an ambiguous time.
- ‘raise’ will raise an AmbiguousTimeError for an ambiguous time.

**nonexistent** ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

The behavior is as follows:

- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time.
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time.
- ‘NaT’ will return NaT where there are nonexistent times.
- timedelta objects will shift nonexistent times by the timedelta.
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

**Returns**

- **localized** [Timestamp]

**Raises**

- **TypeError** If the Timestamp is tz-aware and tz is not None.

**pandas.Timestamp.tzname**

```
Timestamp.tzname()
Return self.tzinfo.tzname(self).
```

**pandas.Timestamp.utcfromtimestamp**

```
classmethod Timestamp.utcfromtimestamp(ts)
Construct a naive UTC datetime from a POSIX timestamp.
```

**pandas.Timestamp.utcnow**

```
classmethod Timestamp.utcnow()
Return a new Timestamp representing UTC day and time.
```
pandas.Timestamp.utcoffset

```
Timestamp.utcoffset()
    Return self.tzinfo.utcoffset(self).
```

pandas.Timestamp.utctimetuple

```
Timestamp.utctimetuple()
    Return UTC time tuple, compatible with time.localtime().
```

pandas.Timestamp.weekday

```
Timestamp.weekday()
    Return the day of the week represented by the date. Monday == 0 ... Sunday == 6
```

</table>

**pandas.Timestamp.freq**

A collection of timestamps may be stored in a `arrays.DatetimeArray`. For timezone-aware data, the `.dtype` of a DatetimeArray is a `DateTimeTzDtype`. For timezone-naive data, `np.dtype("datetime64[ns]")` is used.

If the data are tz-aware, then every value in the array must have the same timezone.

```python
arrays.DatetimeArray(values[, dtype, freq, copy])
```

Pandas ExtensionArray for tz-naive or tz-aware datetime data.

3.5. pandas arrays
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.arrays.DatetimeArray

class pandas.arrays.DatetimeArray(values, dtype=None, freq=None, copy=False)

Pandas ExtensionArray for tz-naive or tz-aware datetime data.

New in version 0.24.0.

Warning: DatetimeArray is currently experimental, and its API may change without warning. In particular, DatetimeArray.dtype is expected to change to always be an instance of an ExtensionDtype subclass.

Parameters

values [Series, Index, DatetimeArray, ndarray] The datetime data.

For DatetimeArray values (or a Series or Index boxing one), dtype and freq will be extracted from values.

dtype [numpy.dtype or DatetimeTZDtype] Note that the only NumPy dtype allowed is ‘datetime64[ns]’.

dtype [string or Offset, optional] The frequency.

copy [bool, default False] Whether to copy the underlying array of values.

Attributes

None

Methods

None

DatetimeTZDtype([unit, tz]) An ExtensionDtype for timezone-aware datetime data.

pandas.DatetimeTZDtype

class pandas.DatetimeTZDtype(unit='ns', tz=None)

An ExtensionDtype for timezone-aware datetime data.

This is not an actual numpy dtype, but a duck type.

Parameters

unit [str, default “ns”] The precision of the datetime data. Currently limited to "ns".

tz [str, int, or datetime.tzinfo] The timezone.

Raises

pytz.UnknownTimeZoneError When the requested timezone cannot be found.
Examples

```python
>>> pd.DatetimeTZDtype(tz='UTC')
datetime64[ns, UTC]

>>> pd.DatetimeTZDtype(tz='dateutil/US/Central')
datetime64[ns, tzfile('/usr/share/zoneinfo/US/Central')]```

Attributes

- **unit**
  The precision of the datetime data.
- **tz**
  The timezone.

```python
pandas.DatetimeTZDtype.unit

[property] DatetimeTZDtype.unit
The precision of the datetime data.

pandas.DatetimeTZDtype.tz

[property] DatetimeTZDtype.tz
The timezone.
```

Methods

- **None**

3.5.3 Timedelta data

NumPy can natively represent timedeltas. Pandas provides `Timedelta` for symmetry with `Timestamp`.

```python
Timedelta([value, unit])
Represents a duration, the difference between two dates or times.
```

```python
class pandas.Timedelta(value=<object object>, unit=None, **kwargs)
Represents a duration, the difference between two dates or times.

Timedelta is the pandas equivalent of python’s `datetime.timedelta` and is interchangeable with it in most cases.

Parameters

- **value** [Timedelta, timedelta, np.timedelta64, str, or int]
- **unit** [str, default ‘ns’] Denote the unit of the input, if input is an integer.
```
Possible values:

- ‘days’ or ‘day’
- ‘hours’, ‘hour’, ‘hr’, or ‘h’
- ‘minutes’, ‘minute’, ‘min’, or ‘m’
- ‘seconds’, ‘second’, or ‘sec’
- ‘milliseconds’, ‘millisecond’, ‘millis’, or ‘milli’
- ‘microseconds’, ‘microsecond’, ‘micros’, or ‘micro’

**kwargs Available kwargs: {days, seconds, microseconds, milliseconds, minutes, hours, weeks}. Values for construction in compat with datetime.timedelta. Numpy ints and floats will be coerced to python ints and floats.

Notes

The .value attribute is always in ns.

</tbody>
</table>

pandas.Timedelta.asm8

Timedelta.asm8

Return a numpy timedelta64 array scalar view.

Provides access to the array scalar view (i.e. a combination of the value and the units) associated with the numpy.timedelta64().view(), including a 64-bit integer representation of the timedelta in nanoseconds (Python int compatible).

Returns

numpy timedelta64 array scalar view Array scalar view of the timedelta in nanoseconds.
Examples

```python
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.asm8
numpy.timedelta64(8652000003042,'ns')

>>> td = pd.Timedelta('2 min 3 s')
>>> td.asm8
numpy.timedelta64(123000000000,'ns')

>>> td = pd.Timedelta('3 ms 5 us')
>>> td.asm8
numpy.timedelta64(3005000,'ns')

>>> td = pd.Timedelta(42, unit='ns')
>>> td.asm8
numpy.timedelta64(42,'ns')
```

pandas.Timedelta.components

```python
class Timedelta.components:
    Return a components namedtuple-like.
```

pandas.Timedelta.days

```python
class Timedelta.days:
    Number of days.
```

pandas.Timedelta.delta

```python
class Timedelta.delta:
    Return the timedelta in nanoseconds (ns), for internal compatibility.
    Returns
    int Timedelta in nanoseconds.
```

Examples

```python
>>> td = pd.Timedelta('1 days 42 ns')
>>> td.delta
8640000000042

>>> td = pd.Timedelta('3 s')
>>> td.delta
300000000

>>> td = pd.Timedelta('3 ms 5 us')
>>> td.delta
3005000
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

```python
>>> td = pd.Timedelta(42, unit='ns')
>>> td.delta
42
```

**pandas.Timedelta.microseconds**

Timedelta.microseconds

Number of microseconds (>= 0 and less than 1 second).

**pandas.Timedelta.nanoseconds**

Timedelta.nanoseconds

Return the number of nanoseconds (n), where 0 <= n < 1 microsecond.

Returns

int Number of nanoseconds.

See also:

*Timedelta.components* Return all attributes with assigned values (i.e. days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds).

**Examples**

**Using string input**

```python
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
```

```python
>>> td.nanoseconds
42
```

**Using integer input**

```python
>>> td = pd.Timedelta(42, unit='ns')
>>> td.nanoseconds
42
```

**pandas.Timedelta.resolution_string**

Timedelta.resolution_string

Return a string representing the lowest timedelta resolution.

Each timedelta has a defined resolution that represents the lowest OR most granular level of precision. Each level of resolution is represented by a short string as defined below:

Resolution: Return value

- Days: ‘D’
- Hours: ‘H’
- Minutes: ‘T’
• Seconds: ‘S’
• Milliseconds: ‘L’
• Microseconds: ‘U’
• Nanoseconds: ‘N’

Returns

str  Timedelta resolution.

Examples

>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.resolution_string
'N'

>>> td = pd.Timedelta('1 days 2 min 3 us')
>>> td.resolution_string
'U'

>>> td = pd.Timedelta('2 min 3 s')
>>> td.resolution_string
'S'

>>> td = pd.Timedelta(36, unit='us')
>>> td.resolution_string
'U'

pandas.Timedelta.seconds

Timedelta.seconds
Number of seconds (>= 0 and less than 1 day).

<table>
<thead>
<tr>
<th>freq</th>
<th>is_populated</th>
<th>value</th>
</tr>
</thead>
</table>

Methods

ceil(freq)  Return a new Timedelta ceiled to this resolution.
floor(freq)  Return a new Timedelta floored to this resolution.
round(freq)  Round the Timedelta to the specified resolution.
to_numpy  Convert the Timedelta to a NumPy timedelta64.
to_pytimedelta  Convert a pandas Timedelta object into a python timedelta object.

continues on next page
Table 90 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>to_timedelta64</code></td>
<td>Return a numpy.timedelta64 object with ‘ns’ precision.</td>
</tr>
<tr>
<td><code>total_seconds</code></td>
<td>Total seconds in the duration.</td>
</tr>
<tr>
<td><code>view</code></td>
<td>Array view compatibility.</td>
</tr>
</tbody>
</table>

**pandas.Timedelta.ceil**

Timedelta.ceil(freq)

Return a new Timedelta ceiled to this resolution.

**Parameters**

- freq [str] Frequency string indicating the ceiling resolution.

**pandas.Timedelta.floor**

Timedelta.floor(freq)

Return a new Timedelta floored to this resolution.

**Parameters**

- freq [str] Frequency string indicating the flooring resolution.

**pandas.Timedelta.isoformat**

Timedelta.isoformat()

**Returns**

- str

**See also:**

`Timestamp.isoformat`

**Notes**

The longest component is days, whose value may be larger than 365. Every component is always included, even if its value is 0. Pandas uses nanosecond precision, so up to 9 decimal places may be included in the seconds component. Trailing 0’s are removed from the seconds component after the decimal. We do not 0 pad components, so it’s …T5H…, not …T05H…
Examples

```python
td = pd.Timedelta(days=6, minutes=50, seconds=3, milliseconds=10, microseconds=10, nanoseconds=12)
```

```python
>>> td.isoformat()
'P6DT0H50M3.010010012S'
>>> pd.Timedelta(hours=1, seconds=10).isoformat()
'P0DT0H0M10S'
>>> pd.Timedelta(hours=1, seconds=10).isoformat()
'P0DT0H0M10S'
>>> pd.Timedelta(days=500.5).isoformat()
'P500DT12H0MS'
```

**pandas.Timedelta.round**

Timedelta.round(freq)

Round the Timedelta to the specified resolution.

**Parameters**

- `freq` [str]: Frequency string indicating the rounding resolution.

**Returns**

A new Timedelta rounded to the given resolution of `freq`.

**Raises**

ValueError if the freq cannot be converted.

**pandas.Timedelta.to_numpy**

Timedelta.to_numpy()

Convert the Timedelta to a NumPy timedelta64.

New in version 0.25.0.

This is an alias method for Timedelta.to_timedelta64(). The dtype and copy parameters are available here only for compatibility. Their values will not affect the return value.

**Returns**

numpy.timedelta64

See also:

Series.to_numpy Similar method for Series.
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.Timedelta.to_pytimedelta

Timedelta.to_pytimedelta()
Convert a pandas Timedelta object into a python timedelta object.
Timedelta objects are internally saved as numpy datetime64[ns] dtype. Use to_pytimedelta() to convert to
object dtype.

Returns
datetime.timedelta or numpy.array of datetime.timedelta

See also:

to_timedelta Convert argument to Timedelta type.

Notes
Any nanosecond resolution will be lost.

pandas.Timedelta.to_timedelta64

Timedelta.to_timedelta64()
Return a numpy.timedelta64 object with ‘ns’ precision.

pandas.Timedelta.total_seconds

Timedelta.total_seconds()
Total seconds in the duration.

pandas.Timedelta.view

Timedelta.view()
Array view compatibility.

</table>

A collection of timedeltas may be stored in a TimedeltaArray.
The `TimedeltaArray` class is a Pandas ExtensionArray for timedelta data. It was introduced in version 0.24.0.

### Parameters

- **values** [array-like] The timedelta data.
- **dtype** [numpy.dtype] Currently, only `numpy.dtype("timedelta64[ns]")` is accepted.
- **freq** [Offset, optional]
- **copy** [bool, default False] Whether to copy the underlying array of data.

### Attributes

None

### Methods

None

#### 3.5.4 Timespan data

Pandas represents spans of times as `Period` objects.

#### 3.5.5 Period

`Period([value, freq, ordinal, year, month, ...])` Represents a period of time.
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.Period

class pandas.Period(value=None, freq=None, ordinal=None, year=None, month=None, quarter=None, day=None, hour=None, minute=None, second=None)

Represents a period of time.

Parameters

- value [Period or str, default None] The time period represented (e.g., ‘4Q2005’).
- freq [str, default None] One of pandas period strings or corresponding objects.
- ordinal [int, default None] The period offset from the gregorian proleptic epoch.
- year [int, default None] Year value of the period.
- month [int, default 1] Month value of the period.
- quarter [int, default None] Quarter value of the period.
- day [int, default 1] Day value of the period.
- hour [int, default 0] Hour value of the period.
- minute [int, default 0] Minute value of the period.
- second [int, default 0] Second value of the period.

pandas.Period.day

Period.day
Get day of the month that a Period falls on.

Returns
int

See also:

Period.dayofweek Get the day of the week.
Period.dayofyear Get the day of the year.

Examples

```python
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.day
11
```

pandas.Period.dayofweek

Period.dayofweek
Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

Returns
int  Day of the week.

See also:

Period.dayofweek Day of the week the period lies in.
Period.weekday Alias of Period.dayofweek.
Period.day Day of the month.
Period.dayofyear Day of the year.

Examples

```python
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.dayofweek
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.
```python
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.dayofweek
6
>>> per.start_time.dayofweek
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```python
>>> per = pd.Period('2018-01', 'M')
>>> per.dayofweek
2
>>> per.end_time.dayofweek
2
```

### pandas.Period.dayofyear

`Period.dayofyear` Return the day of the year.

This attribute returns the day of the year on which the particular date occurs. The return value ranges between 1 to 365 for regular years and 1 to 366 for leap years.

**Returns**

- `int` The day of year.

**See also:**

- `Period.day` Return the day of the month.
- `Period.dayofweek` Return the day of week.
- `PeriodIndex.dayofyear` Return the day of year of all indexes.

### Examples

```python
>>> period = pd.Period("2015-10-23", freq='H')
>>> period.dayofyear
296
>>> period = pd.Period("2012-12-31", freq='D')
>>> period.dayofyear
366
>>> period = pd.Period("2013-01-01", freq='D')
>>> period.dayofyear
1
```
pandas.Period.days_in_month

Period.days_in_month
Get the total number of days in the month that this period falls on.

Returns
int

See also:

Period.daysinmonth Gets the number of days in the month.

DatetimeIndex.daysinmonth Gets the number of days in the month.

calendar.monthrange Returns a tuple containing weekday (0-6 ~ Mon-Sun) and number of days (28-31).

Examples

```python
>>> p = pd.Period('2018-2-17')
>>> p.days_in_month
28
```

```python
>>> pd.Period('2018-03-01').days_in_month
31
```
Handles the leap year case as well:

```python
>>> p = pd.Period('2016-2-17')
>>> p.days_in_month
29
```

pandas.Period.daysinmonth

Period.daysinmonth
Get the total number of days of the month that the Period falls in.

Returns
int

See also:

Period.days_in_month Return the days of the month.

Period.dayofyear Return the day of the year.
Examples

```python
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.daysinmonth
31
```

**pandas.Period.hour**

Period.hour
Get the hour of the day component of the Period.

Returns
- `int`: The hour as an integer, between 0 and 23.

See also:
- **Period.second**: Get the second component of the Period.
- **Period.minute**: Get the minute component of the Period.

Examples

```python
>>> p.hour
13
```

Period longer than a day

```python
>>> p = pd.Period("2018-03-11", freq="M")
>>> p.hour
0
```

**pandas.Period.minute**

Period.minute
Get minute of the hour component of the Period.

Returns
- `int`: The minute as an integer, between 0 and 59.

See also:
- **Period.hour**: Get the hour component of the Period.
- **Period.second**: Get the second component of the Period.
Examples

```python
>>> p.minute
3
```

`pandas.Period.qyear`

`Period.qyear`
Fiscal year the Period lies in according to its starting-quarter.

The `year` and the `qyear` of the period will be the same if the fiscal and calendar years are the same. When they are not, the fiscal year can be different from the calendar year of the period.

**Returns**

- `int` The fiscal year of the period.

**See also:**

`Period.year` Return the calendar year of the period.

**Examples**

If the natural and fiscal year are the same, `qyear` and `year` will be the same.

```python
>>> per = pd.Period('2018Q1', freq='Q')
>>> per.qyear
2018
>>> per.year
2018
```

If the fiscal year starts in April (`Q-MAR`), the first quarter of 2018 will start in April 2017. `year` will then be 2018, but `qyear` will be the fiscal year, 2018.

```python
>>> per = pd.Period('2018Q1', freq='Q-MAR')
>>> per.start_time
Timestamp('2017-04-01 00:00:00')
>>> per.qyear
2018
>>> per.year
2017
```

`pandas.Period.second`

`Period.second`
Get the second component of the Period.

**Returns**

- `int` The second of the Period (ranges from 0 to 59).

**See also:**

`Period.hour` Get the hour component of the Period.
**Period.minute** Get the minute component of the Period.

**Examples**

```python
>>> p.second
12
```

**pandas.Period.start_time**

Period.start_time

Get the Timestamp for the start of the period.

Returns

Timestamp

See also:

**Period.end_time** Return the end Timestamp.

**Period.dayofyear** Return the day of year.

**Period.daysinmonth** Return the days in that month.

**Period.dayofweek** Return the day of the week.

**Examples**

```python
>>> period = pd.Period('2012-1-1', freq='D')
>>> period
Period('2012-01-01', 'D')

>>> period.start_time
Timestamp('2012-01-01 00:00:00')

>>> period.end_time
Timestamp('2012-01-01 23:59:59.999999999')
```

**pandas.Period.week**

Period.week

Get the week of the year on the given Period.

Returns

int

See also:

**Period.dayofweek** Get the day component of the Period.

**Period.weekday** Get the day component of the Period.
Examples

```python
cp = pd.Period("2018-03-11", "H")
cp.week
10

cp = pd.Period("2018-02-01", "D")
cp.week
5

cp = pd.Period("2018-01-06", "D")
cp.week
1
```

`pandas.Period.weekday`

`Period.weekday`

Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

Returns

```
int  Day of the week.
```

See also:

- `Period.dayofweek`  Day of the week the period lies in.
- `Period.weekday`  Alias of `Period.dayofweek`.
- `Period.day`  Day of the month.
- `Period.dayofyear`  Day of the year.

Examples

```python
cper = pd.Period('2017-12-31 22:00', 'H')
cper.dayofweek
dayofweek
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```python
cper = pd.Period('2017-12-31 22:00', '4H')
cper.dayofweek
dayofweek
6
cper.start_time.dayofweek
dayofweek
6
```

For periods with a frequency higher than days, the last day of the period is returned.
>>> per = pd.Period('2018-01', 'M')
>>> per.dayofweek
2
>>> per.end_time.dayofweek
2

<table>

<th>end_time</th>
<th>freq</th>
<th>freqstr</th>
<th>is_leap_year</th>
<th>month</th>
<th>ordinal</th>
<th>quarter</th>
<th>weekofyear</th>
<th>year</th>
</tr>
</thead>
</table>

Methods

- `asfreq` Convert Period to desired frequency, at the start or end of the interval.
- `strftime` Returns the string representation of the `Period`, depending on the selected `fmt`.
- `to_timestamp` Return the Timestamp representation of the Period.

**pandas.Period.asfreq**

`Period.asfreq()` Convert Period to desired frequency, at the start or end of the interval.

**Parameters**

- `freq` [str] The desired frequency.
- `how` [{‘E’, ‘S’, ‘end’, ‘start’}, default ‘end’] Start or end of the timespan.

**Returns**

- `resampled` [Period]

**pandas.Period.strftime**

`Period.strftime()` Returns the string representation of the `Period`, depending on the selected `fmt`.

`fmt` must be a string containing one or several directives. The method recognizes the same directives as the `time.strftime()` function of the standard Python distribution, as well as the specific additional directives `%f`, `%E`, `%q`. (formatting & docs originally from scikits.timeries).
<table>
<thead>
<tr>
<th>Directive</th>
<th>Meaning</th>
<th>Notes</th>

<tr>
<td>%s</td>
<td>Second as a decimal number [00,61].</td>
<td>(4)</td>
</tr>
<tr>
<td>%U</td>
<td>Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0.</td>
<td>(5)</td>
</tr>
<tr>
<td>%W</td>
<td>Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday are considered to be in week 0.</td>
<td>(5)</td>
</tr>
<tr>
<td>%x</td>
<td>Locale’s appropriate date representation.</td>
<td></td>
</tr>
<tr>
<td>%X</td>
<td>Locale’s appropriate time representation.</td>
<td></td>
</tr>
<tr>
<td>%y</td>
<td>Year without century as a decimal number [00,99].</td>
<td></td>
</tr>
<tr>
<td>%Y</td>
<td>Year with century as a decimal number.</td>
<td></td>
</tr>
<tr>
<td>%z</td>
<td>Time zone name (no characters if no time zone exists).</td>
<td></td>
</tr>
<tr>
<td>%z</td>
<td>A literal ‘%’ character.</td>
<td></td>
</tr>
</tbody>
</table>

**Notes**

1. The `%f` directive is the same as `%y` if the frequency is not quarterly. Otherwise, it corresponds to the ‘fiscal’ year, as defined by the `qyear` attribute.
2. The `%F` directive is the same as `%Y` if the frequency is not quarterly. Otherwise, it corresponds to the ‘fiscal’ year, as defined by the `qyear` attribute.
3. The `%p` directive only affects the output hour field if the `%I` directive is used to parse the hour.
4. The range really is 0 to 61; this accounts for leap seconds and the (very rare) double leap seconds.
5. The `%U` and `%W` directives are only used in calculations when the day of the week and the year are specified.
Examples

```python
>>> a = Period(freq='Q-JUL', year=2006, quarter=1)
>>> a.strftime('%F-Q%q')
'2006-Q1'
>>> # Output the last month in the quarter of this date
>>> a.strftime('%b-%Y')
'Oct-2005'
>>> # Output the last month in the quarter of this date
>>> a.strftime('%b-%Y')
'Oct-2005'

>>> a = Period(freq='D', year=2001, month=1, day=1)
>>> a.strftime('%d-%b-%Y')
'01-Jan-2006'
>>> a.strftime('%b. %d, %Y was a %A')
'Jan. 01, 2001 was a Monday'
```

`pandas.Period.to_timestamp`

Period.to_timestamp() - Return the Timestamp representation of the Period.

Uses the target frequency specified at the part of the period specified by `how`, which is either Start or Finish.

**Parameters**

- `freq` [str or DateOffset] Target frequency. Default is ‘D’ if self.freq is week or longer and ‘S’ otherwise.

**Returns**

- `Timestamp`

**pandas.Period.now**

Period.now()

**arrays.PeriodArray**

class pandas.arrays.PeriodArray(values[, freq, dtype, copy])

Pandas ExtensionArray for storing Period data.

Users should use period_array() to create new instances.

**Parameters**

- **values** [Union[PeriodArray, Series[period], ndarray[int], PeriodIndex]] The data to store. These should be arrays that can be directly converted to ordinals without inference or copy (PeriodArray, ndarray[int64]), or a box around such an array (Series[period], PeriodIndex).

- **freq** [str or DateOffset] The freq to use for the array. Mostly applicable when values is an ndarray of integers, when freq is required. When values is a PeriodArray (or box around), it’s checked that values.freq matches freq.

- **dtype** [PeriodDtype, optional] A PeriodDtype instance from which to extract a freq. If both freq and dtype are specified, then the frequencies must match.
copy [bool, default False] Whether to copy the ordinals before storing.

See also:

period_array Create a new PeriodArray.
PeriodIndex Immutable Index for period data.

Notes

There are two components to a PeriodArray
• ordinals : integer ndarray
• freq : pd.tseries.offsets.Offset

The values are physically stored as a 1-D ndarray of integers. These are called “ordinals” and represent some kind of offset from a base.

The freq indicates the span covered by each element of the array. All elements in the PeriodArray have the same freq.

Attributes

None

Methods

None

PeriodDtype([freq]) An ExtensionDtype for Period data.

pandas.PeriodDtype
class pandas.PeriodDtype(freq=\text{None})
An ExtensionDtype for Period data.

This is not an actual numpy dtype, but a duck type.

Parameters

freq [str or DateOffset] The frequency of this PeriodDtype.

Examples

```python
>>> pd.PeriodDtype(freq='D')
period[D]

>>> pd.PeriodDtype(freq=pd.offsets.MonthEnd())
period[M]
```
Attributes

freq
The frequency object of this PeriodDtype.

pandas.PeriodDtype.freq

property PeriodDtype.freq
The frequency object of this PeriodDtype.

Methods
None

3.5.6 Interval data

Arbitrary intervals can be represented as Interval objects.

Interval
Immutable object implementing an Interval, a bounded slice-like interval.

pandas.Interval

class pandas.Interval
Immutable object implementing an Interval, a bounded slice-like interval.

Parameters
- left [orderable scalar] Left bound for the interval.
- right [orderable scalar] Right bound for the interval.
- closed [‘right’, ‘left’, ‘both’, ‘neither’], default ‘right’ Whether the interval is closed on the left-side, right-side, both or neither. See the Notes for more detailed explanation.

See also:
- IntervalIndex An Index of Interval objects that are all closed on the same side.
- cut Convert continuous data into discrete bins (Categorical of Interval objects).
- qcut Convert continuous data into bins (Categorical of Interval objects) based on quantiles.
- Period Represents a period of time.

Notes

The parameters left and right must be from the same type, you must be able to compare them and they must satisfy left <= right.

A closed interval (in mathematics denoted by square brackets) contains its endpoints, i.e. the closed interval [0, 5] is characterized by the conditions 0 <= x <= 5. This is what closed='both' stands for. An open interval (in mathematics denoted by parentheses) does not contain its endpoints, i.e. the open interval (0, 5) is characterized by the conditions 0 < x < 5. This is what closed='neither' stands for. Intervals can also be half-open or half-closed, i.e. [0, 5) is described by 0 <= x < 5(closed='left') and (0, 5] is described by 0 < x <= 5(closed='right').

3.5. pandas arrays 1861
Examples

It is possible to build Intervals of different types, like numeric ones:

```python
>>> iv = pd.Interval(left=0, right=5)
>>> iv
Interval(0, 5, closed='right')
```

You can check if an element belongs to it

```python
>>> 2.5 in iv
True
```

You can test the bounds (closed='right', so 0 < x <= 5):

```python
>>> 0 in iv
False
>>> 5 in iv
True
>>> 0.0001 in iv
True
```

Calculate its length

```python
>>> iv.length
5
```

You can operate with + and * over an Interval and the operation is applied to each of its bounds, so the result depends on the type of the bound elements

```python
>>> shifted_iv = iv + 3
>>> shifted_iv
Interval(3, 8, closed='right')
>>> extended_iv = iv * 10.0
>>> extended_iv
Interval(0.0, 50.0, closed='right')
```

To create a time interval you can use Timestamps as the bounds

```python
>>> year_2017 = pd.Interval(pd.Timestamp('2017-01-01 00:00:00'),
... pd.Timestamp('2018-01-01 00:00:00'),
... closed='left')
>>> pd.Timestamp('2017-01-01 00:00') in year_2017
True
>>> year_2017.length
Timedelta('365 days 00:00:00')
```

And also you can create string intervals

```python
>>> volume_1 = pd.Interval('Ant', 'Dog', closed='both')
>>> 'Bee' in volume_1
True
```
Attributes

</tbody>
</table>

pandas.Interval.closed

Interval.closed
Whether the interval is closed on the left-side, right-side, both or neither.

pandas.Interval.closed_left

Interval.closed_left
Check if the interval is closed on the left side.
For the meaning of closed and open see Interval.
Returns
bool True if the Interval is closed on the left-side.

pandas.Interval.closed_right

Interval.closed_right
Check if the interval is closed on the right side.
For the meaning of closed and open see Interval.
Returns
bool True if the Interval is closed on the left-side.

pandas.Interval.is_empty

Interval.is_empty
Indicates if an interval is empty, meaning it contains no points.
New in version 0.25.0.
Returns
bool or ndarray A boolean indicating if a scalar Interval is empty, or a boolean ndarray positionally indicating if an Interval in an IntervalArray or IntervalIndex is empty.

Examples

An Interval that contains points is not empty:

```python
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```python
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:

```python
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An IntervalArray or IntervalIndex returns a boolean ndarray positionally indicating if an Interval is empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'), ...
        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```

pandas.Interval.left

Interval.left
Left bound for the interval.

pandas.Interval.length

Interval.length
Return the length of the Interval.
pandas.Interval.mid

**Interval.mid**

Return the midpoint of the Interval.

pandas.Interval.open_left

**Interval.open_left**

Check if the interval is open on the left side.

For the meaning of *closed* and *open* see *Interval*.

Returns

**bool** True if the Interval is closed on the left-side.

pandas.Interval.open_right

**Interval.open_right**

Check if the interval is open on the right side.

For the meaning of *closed* and *open* see *Interval*.

Returns

**bool** True if the Interval is closed on the left-side.

pandas.Interval.right

**Interval.right**

Right bound for the interval.

Methods

**overlaps**

Check whether two Interval objects overlap.

pandas.Interval.overlaps

**Interval.overlaps()**

Check whether two Interval objects overlap.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

**Parameters**

**other** [Interval] Interval to check against for an overlap.

**Returns**

**bool** True if the two intervals overlap.
See also:

**IntervalArray.overlaps** The corresponding method for IntervalArray.

**IntervalIndex.overlaps** The corresponding method for IntervalIndex.

### Examples

```python
>>> i1 = pd.Interval(0, 2)
>>> i2 = pd.Interval(1, 3)
>>> i1.overlaps(i2)
True
>>> i3 = pd.Interval(4, 5)
>>> i1.overlaps(i3)
False
```

Intervals that share closed endpoints overlap:

```python
>>> i4 = pd.Interval(0, 1, closed='both')
>>> i5 = pd.Interval(1, 2, closed='both')
>>> i4.overlaps(i5)
True
```

Intervals that only have an open endpoint in common do not overlap:

```python
>>> i6 = pd.Interval(1, 2, closed='neither')
>>> i4.overlaps(i6)
False
```

### Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interval.closed</td>
<td>Whether the interval is closed on the left-side, right-side, both or neither.</td>
</tr>
<tr>
<td>Interval.closed_left</td>
<td>Check if the interval is closed on the left side.</td>
</tr>
<tr>
<td>Interval.closed_right</td>
<td>Check if the interval is closed on the right side.</td>
</tr>
<tr>
<td>Interval.is_empty</td>
<td>Indicates if an interval is empty, meaning it contains no points.</td>
</tr>
<tr>
<td>Interval.left</td>
<td>Left bound for the interval.</td>
</tr>
<tr>
<td>Interval.length</td>
<td>Return the length of the Interval.</td>
</tr>
<tr>
<td>Interval.mid</td>
<td>Return the midpoint of the Interval.</td>
</tr>
<tr>
<td>Interval.open_left</td>
<td>Check if the interval is open on the left side.</td>
</tr>
<tr>
<td>Interval.open_right</td>
<td>Check if the interval is open on the right side.</td>
</tr>
<tr>
<td>Interval.overlaps</td>
<td>Check whether two Interval objects overlap.</td>
</tr>
<tr>
<td>Interval.right</td>
<td>Right bound for the interval.</td>
</tr>
</tbody>
</table>

A collection of intervals may be stored in an `arrays.IntervalArray`.

```python
arrays.IntervalArray(data[, closed, dtype, ...])
```
**pandas.arrays.IntervalArray**

**class pandas.arrays.IntervalArray**(data, closed=None, dtype=None, copy=False, verify_integrity=True)

Pandas array for interval data that are closed on the same side.

New in version 0.24.0.

**Parameters**

- **data** [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalArray.
- **closed** [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.
- **dtype** [dtype or None, default None] If None, dtype will be inferred. New in version 0.23.0.
- **copy** [bool, default False] Copy the input data.
- **verify_integrity** [bool, default True] Verify that the IntervalArray is valid.

**See also:**

- **Index** The base pandas Index type.
- **Interval** A bounded slice-like interval; the elements of an IntervalArray.
- **interval_range** Function to create a fixed frequency IntervalIndex.
- **cut** Bin values into discrete Intervals.
- **qcut** Bin values into equal-sized Intervals based on rank or sample quantiles.

**Notes**

See the [user guide](#) for more.

**Examples**

A new IntervalArray can be constructed directly from an array-like of Interval objects:

```python
>>> pd.arrays.IntervalArray([pd.Interval(0, 1), pd.Interval(1, 5)])
<IntervalArray>
[[0, 1], (1, 5)]
Length: 2, closed: right, dtype: interval[int64]
```

It may also be constructed using one of the constructor methods: `IntervalArray.from_arrays()`, `IntervalArray.from_breaks()`, and `IntervalArray.from_tuples()`.

**Attributes**

- **left**
  - Return the left endpoints of each Interval in the IntervalArray as an Index.
- **right**
  - Return the right endpoints of each Interval in the IntervalArray as an Index.
- **closed**
  - Whether the intervals are closed on the left-side, right-side, both or neither.

Table 107 – continued from previous page

<table>
<thead>
<tr>
<th>Method Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mid</td>
<td>Return the midpoint of each Interval in the IntervalArray as an Index.</td>
</tr>
<tr>
<td>length</td>
<td>Return an Index with entries denoting the length of each Interval in the IntervalArray.</td>
</tr>
<tr>
<td>is_empty</td>
<td>Indicates if an interval is empty, meaning it contains no points.</td>
</tr>
<tr>
<td>is_non_overlapping_monotonic</td>
<td>Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.</td>
</tr>
</tbody>
</table>

`pandas.arrays.IntervalArray.left`

**property** IntervalArray.left

Return the left endpoints of each Interval in the IntervalArray as an Index.

`pandas.arrays.IntervalArray.right`

**property** IntervalArray.right

Return the right endpoints of each Interval in the IntervalArray as an Index.

`pandas.arrays.IntervalArray.closed`

**property** IntervalArray.closed

Whether the intervals are closed on the left-side, right-side, both or neither.

`pandas.arrays.IntervalArray.mid`

**property** IntervalArray.mid

Return the midpoint of each Interval in the IntervalArray as an Index.

`pandas.arrays.IntervalArray.length`

**property** IntervalArray.length

Return an Index with entries denoting the length of each Interval in the IntervalArray.

`pandas.arrays.IntervalArray.is_empty`

**IntervalArray.is_empty**

Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

**Returns**

- bool or ndarray  A boolean indicating if a scalar Interval is empty, or a boolean ndarray positionally indicating if an Interval in an IntervalArray or IntervalIndex is empty.
Examples

An Interval that contains points is not empty:

```python
gp.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```python
gp.Interval(0, 0, closed='right').is_empty
True
gp.Interval(0, 0, closed='left').is_empty
True
gp.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:

```python
gp.Interval(0, 0, closed='both').is_empty
False
```

An IntervalArray or IntervalIndex returns a boolean ndarray positionally indicating if an Interval is empty:

```python
ivs = [gp.Interval(0, 0, closed='neither'),
      ...  gp.Interval(1, 2, closed='neither')]
gp.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```python
ivs = [gp.Interval(0, 0, closed='neither'), np.nan]
gp.IntervalIndex(ivs).is_empty
array([ True, False])
```

**pandas.arrays.IntervalArray.is_non_overlapping_monotonic**

**property** IntervalArray.is_non_overlapping_monotonic

Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>from_arrays(left, right[, closed, copy, dtype])</td>
<td>Construct from two arrays defining the left and right bounds.</td>
</tr>
<tr>
<td>from_tuples(data[, closed, copy, dtype])</td>
<td>Construct an IntervalArray from an array-like of tuples.</td>
</tr>
<tr>
<td>from_breaks(breaks[, closed, copy, dtype])</td>
<td>Construct an IntervalArray from an array of splits.</td>
</tr>
<tr>
<td>contains(other)</td>
<td>Check elementwise if the Intervals contain the value.</td>
</tr>
<tr>
<td>overlaps(other)</td>
<td>Check elementwise if an Interval overlaps the values in the IntervalArray.</td>
</tr>
</tbody>
</table>

continues on next page
**set_closed**

Return an IntervalArray identical to the current one, but closed on the specified side.

**to_tuples**

Return an ndarray of tuples of the form (left, right).

---

**pandas.arrays.IntervalArray.from_arrays**

**classmethod** `IntervalArray.from_arrays(left, right, closed='right', copy=False, dtype=None)`

Construct from two arrays defining the left and right bounds.

**Parameters**

- `left` [array-like (1-dimensional)] Left bounds for each interval.
- `right` [array-like (1-dimensional)] Right bounds for each interval.
- `closed` [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.
- `copy` [bool, default False] Copy the data.
- `dtype` [dtype, optional] If None, dtype will be inferred.

**Returns**

IntervalArray

**Raises**

- **ValueError** When a value is missing in only one of `left` or `right`. When a value in `left` is greater than the corresponding value in `right`.

**See also:**

- `interval_range` Function to create a fixed frequency IntervalIndex.
- `IntervalArray.from_breaks` Construct an IntervalArray from an array of splits.
- `IntervalArray.from_tuples` Construct an IntervalArray from an array-like of tuples.

**Notes**

Each element of `left` must be less than or equal to the `right` element at the same position. If an element is missing, it must be missing in both `left` and `right`. A TypeError is raised when using an unsupported type for `left` or `right`. At the moment, ‘category’, ‘object’, and ‘string’ subtypes are not supported.

```python
>>> pd.arrays.IntervalArray.from_arrays([[0, 1, 2], [1, 2, 3]])
<IntervalArray>
[(0, 1], (1, 2], (2, 3]]
Length: 3, closed: right, dtype: interval[int64]
```
pandas.arrays.IntervalArray.from_tuples

classmethod IntervalArray.from_tuples(data, closed='right', copy=False, dtype=None)
Construct an IntervalArray from an array-like of tuples.

Parameters

- **data** [array-like (1-dimensional)] Array of tuples.
- **closed** [‘left’, ‘right’, ‘both’, ‘neither’], default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.
- **copy** [bool, default False] By-default copy the data, this is compat only and ignored.
- **dtype** [dtype or None, default None] If None, dtype will be inferred.

New in version 0.23.0.

Returns

IntervalArray

See also:

- interval_range Function to create a fixed frequency IntervallIndex.
- IntervalArray.from_arrays Construct an IntervalArray from a left and right array.
- IntervalArray.from_breaks Construct an IntervalArray from an array of splits.

Examples

```python
>>> pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 2)])
<IntervalArray>
[(0, 1], (1, 2]]
Length: 2, closed: right, dtype: interval[int64]
```

pandas.arrays.IntervalArray.from_breaks

classmethod IntervalArray.from_breaks(breaks, closed='right', copy=False, dtype=None)
Construct an IntervalArray from an array of splits.

Parameters

- **breaks** [array-like (1-dimensional)] Left and right bounds for each interval.
- **closed** [‘left’, ‘right’, ‘both’, ‘neither’], default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.
- **copy** [bool, default False] Copy the data.
- **dtype** [dtype or None, default None] If None, dtype will be inferred.

New in version 0.23.0.

Returns

IntervalArray

See also:
**interval_range**  Function to create a fixed frequency IntervalIndex.

*IntervalArray.from_arrays*  Construct from a left and right array.

*IntervalArray.from_tuples*  Construct from a sequence of tuples.

**Examples**

```python
>>> pd.arrays.IntervalArray.from_breaks([0, 1, 2, 3])
<IntervalArray>
[(0, 1], (1, 2], (2, 3])
Length: 3, closed: right, dtype: interval[int64]
```

**pandas.arrays.IntervalArray.contains**

*IntervalArray.contains*(*other*)

Check elementwise if the Intervals contain the value.

Return a boolean mask whether the value is contained in the Intervals of the IntervalArray.

New in version 0.25.0.

**Parameters**

*other*  [scalar]  The value to check whether it is contained in the Intervals.

**Returns**

*boolean array*

**See also:**

*Interval.contains*  Check whether Interval object contains value.

*IntervalArray.overlaps*  Check if an Interval overlaps the values in the IntervalArray.

**Examples**

```python
>>> intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4])
Length: 3, closed: right, dtype: interval[int64]

>>> intervals.contains(0.5)
array([ True, False, False])
```
pandas.arrays.IntervalArray.overlaps

\texttt{IntervalArray\_overlaps(\textit{other})}

Check elementwise if an Interval overlaps the values in the IntervalArray.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

\textbf{Parameters}

- \texttt{other} [IntervalArray] Interval to check against for an overlap.

\textbf{Returns}

\texttt{ndarray} Boolean array positionally indicating where an overlap occurs.

\textbf{See also:}

\texttt{Interval\_overlaps} Check whether two Interval objects overlap.

\textbf{Examples}

```
>>> data = [(0, 1), (1, 3), (2, 4)]
>>> intervals = pd.arrays.IntervalArray.from_tuples(data)
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]
Length: 3, closed: right, dtype: interval[int64]
```

```
>>> intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True, True, False])
```

Intervals that share closed endpoints overlap:

```
>>> intervals.overlaps(pd.Interval(1, 3, closed='left'))
array([ True, True, True])
```

Intervals that only have an open endpoint in common do not overlap:

```
>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False, True, False])
```

pandas.arrays.IntervalArray.set_closed

\texttt{IntervalArray\_set\_closed(\textit{closed})}

Return an IntervalArray identical to the current one, but closed on the specified side.

New in version 0.24.0.

\textbf{Parameters}

- \texttt{closed} [{‘left’, ‘right’, ‘both’, ‘neither’}] Whether the intervals are closed on the left-side, right-side, both or neither.

\textbf{Returns}
new_index  [IntervalArray]

Examples

```python
>>> index = pd.arrays.IntervalArray.from_breaks(range(4))
>>> index
<IntervalArray>
[(0, 1], (1, 2], (2, 3]]
Length: 3, closed: right, dtype: interval[int64]
>>> index.set_closed('both')
<IntervalArray>
[[0, 1], [1, 2], [2, 3]]
Length: 3, closed: both, dtype: interval[int64]
```

pandas.arrays.IntervalArray.to_tuples

IntervalArray.

to_tuples (na_tuple=True)

Return an ndarray of tuples of the form (left, right).

Parameters

na_tuple  [bool, default True] Returns NA as a tuple if True, (nan, nan), or just as the NA value itself if False, nan.

New in version 0.23.0.

Returns

tuples: ndarray

IntervalDtype([subtype])  An ExtensionDtype for Interval data.

pandas.IntervalDtype

class pandas.IntervalDtype (subtype=None)

An ExtensionDtype for Interval data.

This is not an actual numpy dtype, but a duck type.

Parameters

Examples

```python
>>> pd.IntervalDtype(subtype='int64')
interval[int64]
```
Attributes

subtype

The dtype of the Interval bounds.

pandas.IntervalDtypesubtype

property IntervalDtype subtype

The dtype of the Interval bounds.

Methods

None

3.5.7 Nullable integer

numpy.ndarray cannot natively represent integer-data with missing values. Pandas provides this through arrays.IntegerArray.

arrays.IntegerArray(values, mask[, copy]) Array of integer (optional missing) values.

pandas.arrays.IntegerArray

class pandas.arrays.IntegerArray(values, mask, copy=False) Array of integer (optional missing) values.

New in version 0.24.0.

Changed in version 1.0.0: Now uses pandas.NA as the missing value rather than numpy.nan.

Warning: IntegerArray is currently experimental, and its API or internal implementation may change without warning.

We represent an IntegerArray with 2 numpy arrays:

- data: contains a numpy integer array of the appropriate dtype
- mask: a boolean array holding a mask on the data, True is missing

To construct an IntegerArray from generic array-like input, use pandas.array() with one of the integer dtypes (see examples).

See Nullable integer data type for more.

Parameters

copy [bool, default False] Whether to copy the values and mask.

Returns

IntegerArray
Examples

Create an IntegerArray with `pandas.array()`.

```python
>>> int_array = pd.array([1, None, 3], dtype=pd.Int32Dtype())
>>> int_array
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: Int32
```

String aliases for the dtypes are also available. They are capitalized.

```python
>>> pd.array([1, None, 3], dtype='Int32')
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: Int32
```

```python
>>> pd.array([1, None, 3], dtype='UInt16')
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: UInt16
```

### 3.5.8 Categorical data

Pandas defines a custom data type for representing data that can take only a limited, fixed set of values. The dtype of a `Categorical` can be described by a `pandas.api.types.CategoricalDtype`.

<table>
<thead>
<tr>
<th>CategoricalDtype(categories, ordered)</th>
<th>Type for categorical data with the categories and orderedness.</th>
</tr>
</thead>
</table>

#### pandas.CategoricalDtype

**class** `pandas.CategoricalDtype(categories=None, ordered=False)`  
Type for categorical data with the categories and orderedness.  

**Parameters**

- **categories** [sequence, optional] Must be unique, and must not contain any nulls. The categories are stored in an Index, and if an index is provided the dtype of that index will be used.

- **ordered** [bool or None, default False] Whether or not this categorical is treated as a ordered categorical. None can be used to maintain the ordered value of existing categoricals when used in operations that combine categoricals, e.g. astype, and will resolve to False if there is no existing ordered to maintain.

**See also:**

- **Categorical** Represent a categorical variable in classic R / S-plus fashion.

**Notes**

This class is useful for specifying the type of a `Categorical` independent of the values. See `CategoricalDtype` for more.

**Examples**

```python
>>> t = pd.CategoricalDtype(categories=['b', 'a'], ordered=True)
>>> pd.Series(['a', 'b', 'a', 'c'], dtype=t)
0   a
1   b
2   a
3  NaN
dtype: category
Categories (2, object): ['b' < 'a']
```
An empty CategoricalDtype with a specific dtype can be created by providing an empty index. As follows,

```python
>>> pd.CategoricalDtype(pd.DatetimeIndex([])).categories.dtype
dtype('<M8[ns]')
```

### Attributes

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>categories</td>
<td>An Index containing the unique categories allowed.</td>
</tr>
<tr>
<td>ordered</td>
<td>Whether the categories have an ordered relationship.</td>
</tr>
</tbody>
</table>

#### pandas.CategoricalDtype.categories

**property** `CategoricalDtype.categories`  
An Index containing the unique categories allowed.

#### pandas.CategoricalDtype.ordered

**property** `CategoricalDtype.ordered`  
Whether the categories have an ordered relationship.

### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CategoricalDtype.categories</td>
<td>An Index containing the unique categories allowed.</td>
</tr>
<tr>
<td>CategoricalDtype.ordered</td>
<td>Whether the categories have an ordered relationship.</td>
</tr>
</tbody>
</table>

Categorical data can be stored in a `pandas.Categorical`:

```python
Categorical(values[, categories, ordered, ...])  
Represent a categorical variable in classic R / S-plus fashion.
```

#### pandas.Categorical

**class** `pandas.Categorical`  
Represent a categorical variable in classic R / S-plus fashion.

Categoricals can only take on only a limited, and usually fixed, number of possible values (categories). In contrast to statistical categorical variables, a Categorical might have an order, but numerical operations (additions, divisions, ...) are not possible.

All values of the Categorical are either in categories or np.nan. Assigning values outside of categories will raise a `ValueError`. Order is defined by the order of the categories, not lexical order of the values.

**Parameters**

- `values` [list-like] The values of the categorical. If categories are given, values not in categories will be replaced with NaN.
**categories** [Index-like (unique), optional] The unique categories for this categorical. If not given, the categories are assumed to be the unique values of values (sorted, if possible, otherwise in the order in which they appear).

**ordered** [bool, default False] Whether or not this categorical is treated as an ordered categorical. If True, the resulting categorical will be ordered. An ordered categorical respects, when sorted, the order of its categories attribute (which in turn is the categories argument, if provided).

**dtype** [CategoricalDtype] An instance of CategoricalDtype to use for this categorical.

Raises

- **ValueError** If the categories do not validate.
- **TypeError** If an explicit ordered=True is given but no categories and the values are not sortable.

See also:

- CategoricalDtype Type for categorical data.
- CategoricalIndex An Index with an underlying Categorical.

Notes

See the user guide for more.

Examples

```python
>>> pd.Categorical([1, 2, 3, 1, 2, 3])
[1, 2, 3, 1, 2, 3]
Categories (3, int64): [1, 2, 3]
```

```python
>>> pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'])
['a', 'b', 'c', 'a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Ordered Categoricals can be sorted according to the custom order of the categories and can have a min and max value.

```python
>>> c = pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'], ordered=True, ...
...                         categories=['c', 'b', 'a'])
>>> c
['a', 'b', 'c', 'a', 'b', 'c']
Categories (3, object): ['c' < 'b' < 'a']
>>> c.min()
'c'
```
Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>categories</td>
<td>The categories of this categorical.</td>
</tr>
<tr>
<td>codes</td>
<td>The category codes of this categorical.</td>
</tr>
<tr>
<td>ordered</td>
<td>Whether the categories have an ordered relationship.</td>
</tr>
<tr>
<td>dtype</td>
<td>The CategoricalDtype for this instance.</td>
</tr>
</tbody>
</table>

**pandas.Categorical.categories**

**property Categorical.categories**
The categories of this categorical.

- Setting assigns new values to each category (effectively a rename of each individual category).
- The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.
- Assigning to categories is a inplace operation!

**Raises**

**ValueError** If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories.

**See also:**

- rename_categories Rename categories.
- reorder_categories Reorder categories.
- add_categories Add new categories.
- remove_categories Remove the specified categories.
- remove_unused_categories Remove categories which are not used.
- set_categories Set the categories to the specified ones.

**pandas.Categorical.codes**

**property Categorical.codes**
The category codes of this categorical.

- Codes are an array of integers which are the positions of the actual values in the categories array.
- There is no setter, use the other categorical methods and the normal item setter to change values in the categorical.

**Returns**

**ndarray[int]** A non-writable view of the codes array.
pandas.Categorical.ordered

**property** Categorical.ordered

Whether the categories have an ordered relationship.

pandas.Categorical.dtype

**property** Categorical.dtype

The CategoricalDtype for this instance.

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>from_codes</td>
<td>Make a Categorical type from codes and categories or dtype.</td>
</tr>
<tr>
<td><strong>array</strong></td>
<td>The numpy array interface.</td>
</tr>
</tbody>
</table>

pandas.Categorical.from_codes

**classmethod** Categorical.from_codes(codes, categories=None, ordered=None, dtype=None)

Make a Categorical type from codes and categories or dtype.

This constructor is useful if you already have codes and categories/dtype and so do not need the (computation intensive) factorization step, which is usually done on the constructor.

If your data does not follow this convention, please use the normal constructor.

**Parameters**

- **codes** [array-like of int] An integer array, where each integer points to a category in categories or dtype.categories, or else is -1 for NaN.

- **categories** [index-like, optional] The categories for the categorical. Items need to be unique. If the categories are not given here, then they must be provided in dtype.

- **ordered** [bool, optional] Whether or not this categorical is treated as an ordered categorical. If not given here or in dtype, the resulting categorical will be unordered.

- **dtype** [CategoricalDtype or “category”, optional] If CategoricalDtype, cannot be used together with categories or ordered.

  New in version 0.24.0: When dtype is provided, neither categories nor ordered should be provided.

**Returns**

- Categorical
Examples

```python
>>> dtype = pd.CategoricalDtype(['a', 'b'], ordered=True)
>>> pd.Categorical.from_codes(codes=[0, 1, 0, 1], dtype=dtype)
['a', 'b', 'a', 'b']
Categories (2, object): ['a' < 'b']
```

```python
pandas.Categorical.__array__
```

Categorical.__array__(dtype=None)
The numpy array interface.

Returns

numpy.array A numpy array of either the specified dtype or, if dtype==None (default),
the same dtype as categorical.categories.dtype.

The alternative `Categorical.from_codes()` constructor can be used when you have the categories and integer
codes already:

```python
Categorical.from_codes(codes=[], categories, . . .)
```
Make a Categorical type from codes and categories or
dtype.

The dtype information is available on the Categorical

```python
Categorical.dtype
```
The CategoricalDtype for this instance.

```python
Categorical.categories
```
The categories of this categorical.

```python
Categorical.ordered
```
Whether the categories have an ordered relationship.

```python
Categorical.codes
```
The category codes of this categorical.

```python
np.asarray(categorical)
```
works by implementing the array interface. Be aware, that this converts the Cate-
gorical back to a NumPy array, so categories and order information is not preserved!

```python
Categorical.__array__((dtype))
```
The numpy array interface.

A Categorical can be stored in a Series or DataFrame. To create a Series of dtype category, use `cat =

```python
s.astype(dtype) or Series(..., dtype=dtype) where dtype is either
```

• the string 'category'

• an instance of CategoricalDtype.

If the Series is of dtype CategoricalDtype, Series.cat can be used to change the categorical data. See

Categorical accessor for more.

3.5. pandas arrays
3.5.9 Sparse data

Data where a single value is repeated many times (e.g. 0 or NaN) may be stored efficiently as a `arrays.SparseArray`.

```
arrays.SparseArray(data[, sparse_index, ...])  # An ExtensionArray for storing sparse data.
```

`pandas.arrays.SparseArray`

```
class pandas.arrays.SparseArray(data, sparse_index=None, index=None, fill_value=None, kind='integer', dtype=None, copy=False)
```

An ExtensionArray for storing sparse data.

Changed in version 0.24.0: Implements the ExtensionArray interface.

**Parameters**

- `data` [array-like] A dense array of values to store in the SparseArray. This may contain `fill_value`.
- `sparse_index` [SparseIndex, optional]
- `index` [Index]
- `fill_value` [scalar, optional] Elements in `data` that are `fill_value` are not stored in the SparseArray. For memory savings, this should be the most common value in `data`. By default, `fill_value` depends on the dtype of `data`:

<table>
<thead>
<tr>
<th>data.dtype</th>
<th>na_value</th>
</tr>
</thead>
<tbody>
<tr>
<td>float</td>
<td>np.nan</td>
</tr>
<tr>
<td>int</td>
<td>0</td>
</tr>
<tr>
<td>bool</td>
<td>False</td>
</tr>
<tr>
<td>datetime64</td>
<td>pd.NaT</td>
</tr>
<tr>
<td>timedelta64</td>
<td>pd.NaT</td>
</tr>
</tbody>
</table>

The fill value is potentially specified in three ways. In order of precedence, these are

1. The `fill_value` argument
2. `dtype.fill_value` if `fill_value` is None and `dtype` is a SparseDtype
3. `data.dtype.fill_value` if `fill_value` is None and `dtype` is not a SparseDtype and `data` is a SparseArray.

- `kind` [{'integer', 'block'}, default 'integer'] The type of storage for sparse locations.
  - ‘block’: Stores a block and `block_length` for each contiguous span of sparse values. This is best when sparse data tends to be clumped together, with large regions of fill-value values between sparse values.
  - ‘integer’: uses an integer to store the location of each sparse value.

- `dtype` [np.dtype or SparseDtype, optional] The dtype to use for the SparseArray. For numpy dtypes, this determines the dtype of `self.sp_values`. For SparseDtype, this determines `self.sp_values` and `self.fill_value`.

- `copy` [bool, default False] Whether to explicitly copy the incoming `data` array.
Examples

```python
>>> from pandas.arrays import SparseArray
>>> arr = SparseArray([0, 0, 1, 2])
>>> arr
[0, 0, 1, 2]
Fill: 0
IntIndex
Indices: array([2, 3], dtype=int32)
```

Attributes

```
None
```

Methods

```
None
```

```{python}
_SparseDtype([dtype, fill_value])_ Dtype for data stored in SparseArray.
```

**pandas.SparseDtype**

```{python}
class pandas.SparseDtype(dtype=<class 'numpy.float64'>, fill_value=None)
```

Dtype for data stored in SparseArray.

This dtype implements the pandas ExtensionDtype interface.

New in version 0.24.0.

**Parameters**

- **dtype** [str, ExtensionDtype, numpy.dtype, type, default numpy.float64] The dtype of the underlying array storing the non-fill value values.

- **fill_value** [scalar, optional] The scalar value not stored in the SparseArray. By default, this depends on `dtype`.

<table>
<thead>
<tr>
<th>dtype</th>
<th>na_value</th>
</tr>
</thead>
<tbody>
<tr>
<td>float</td>
<td>np.nan</td>
</tr>
<tr>
<td>int</td>
<td>0</td>
</tr>
<tr>
<td>bool</td>
<td>False</td>
</tr>
<tr>
<td>datetime64</td>
<td>pd.NaT</td>
</tr>
<tr>
<td>timedelta64</td>
<td>pd.NaT</td>
</tr>
</tbody>
</table>

The default value may be overridden by specifying a `fill_value`. 
The `Series.sparse` accessor may be used to access sparse-specific attributes and methods if the `Series` contains sparse values. See `Sparse accessor` for more.

### 3.5.10 Text data

When working with text data, where each valid element is a string or missing, we recommend using `StringDtype` (with the alias "string").

```
arrays.StringArray(values[, copy])
```

Extension array for string data.

**pandas.arrays.StringArray**

```
class pandas.arrays.StringArray(values, copy=False)
```

Extension array for string data.

New in version 1.0.0.

**Warning:** `StringArray` is considered experimental. The implementation and parts of the API may change without warning.

**Parameters**

- `values` [array-like] The array of data.

  **Warning:** Currently, this expects an object-dtype ndarray where the elements are Python strings or `pandas.NA`. This may change without warning in the future. Use `pandas.array()` with `dtype="string"` for a stable way of creating a `StringArray` from any sequence.

- `copy` [bool, default False] Whether to copy the array of data.

**See also:**

- `array` The recommended function for creating a `StringArray`.
- `Series.str` The string methods are available on Series backed by a `StringArray`. 

Notes

StringArray returns a BooleanArray for comparison methods.

Examples

```python
>>> pd.array(['This is', 'some text', None, 'data.'], dtype="string")
<StringArray>
['This is', 'some text', <NA>, 'data.]
Length: 4, dtype: string

Unlike arrays instantiated with dtype="object", StringArray will convert the values to strings.

```python
>>> pd.array([1, 1], dtype="object")
<PandasArray>
[1, 1]
Length: 2, dtype: object
>>> pd.array([1, 1], dtype="string")
<StringArray>
[1, 1]
Length: 2, dtype: string

However, instantiating StringArrays directly with non-strings will raise an error.

For comparison methods, StringArray returns a pandas.BooleanArray:

```python
>>> pd.array(['a', None, 'c'], dtype="string") == "a"
<BooleanArray>
[True, <NA>, False]
Length: 3, dtype: boolean
```

Attributes

None

Methods

None

StringDtype()  Extension dtype for string data.
### pandas.StringDtype

**Class** `pandas.StringDtype`  
Extension dtype for string data.

New in version 1.0.0.

**Warning:** StringDtype is considered experimental. The implementation and parts of the API may change without warning.  
In particular, StringDtype.na_value may change to no longer be `numpy.nan`.

**Examples**

```python
>>> pd.StringDtype()
StringDtype
```

**Attributes**

None

**Methods**

None

The `Series.str` accessor is available for `Series` backed by an `arrays.StringArray`. See String handling for more.

#### 3.5.11 Boolean data with missing values

The boolean dtype (with the alias "boolean") provides support for storing boolean data (True, False values) with missing values, which is not possible with a bool `numpy.ndarray`.

```python
arrays.BooleanArray(values, mask[, copy])  
Array of boolean (True/False) data with missing values.
```

**pandas.arrays.BooleanArray**

**Class** `pandas.arrays.BooleanArray(values, mask[, copy=False])`  
Array of boolean (True/False) data with missing values.

This is a pandas Extension array for boolean data, under the hood represented by 2 numpy arrays: a boolean array with the data and a boolean array with the mask (True indicating missing).

BooleanArray implements Kleene logic (sometimes called three-value logic) for logical operations. See Kleene logical operations for more.

To construct an BooleanArray from generic array-like input, use `pandas.array()` specifying `dtype=boolean` (see examples below).
New in version 1.0.0.

**Warning:** BooleanArray is considered experimental. The implementation and parts of the API may change without warning.

**Parameters**

values [numpy.ndarray] A 1-d boolean-dtype array with the data.

mask [numpy.ndarray] A 1-d boolean-dtype array indicating missing values (True indicates missing).

copy [bool, default False] Whether to copy the values and mask arrays.

**Returns**

BooleanArray

**Examples**

Create an BooleanArray with `pandas.array()`:

```python
>>> pd.array([True, False, None], dtype="boolean")
<BooleanArray>
[True, False, <NA>]
Length: 3, dtype: boolean
```

**Attributes**

None

**Methods**

None

---

**BooleanDtype**

Extension dtype for boolean data.

**pandas.BooleanDtype**

class pandas.BooleanDtype

Extension dtype for boolean data.

New in version 1.0.0.

**Warning:** BooleanDtype is considered experimental. The implementation and parts of the API may change without warning.
Examples

```python
>>> pd.BooleanDtype()
BooleanDtype
```

*Panel* was removed in 0.25.0. For prior documentation, see the 0.24 documentation

3.7 Index objects

3.7.1 Index

Many of these methods or variants thereof are available on the objects that contain an index (Series/DataFrame) and those should most likely be used before calling these methods directly.

| Index([data, dtype, copy, name, tupleize_cols]) | Immutable ndarray implementing an ordered, sliceable set. |

**pandas.Index**

**class pandas.Index** *(data=None, dtype=None, copy=False, name=None, tupleize_cols=True, **kwargs)*

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects.

**Parameters**

- **data** [array-like (1-dimensional)]
- **dtype** [NumPy dtype (default: object)] If dtype is None, we find the dtype that best fits the data. If an actual dtype is provided, we coerce to that dtype if it’s safe. Otherwise, an error will be raised.
- **copy** [bool] Make a copy of input ndarray.
- **name** [object] Name to be stored in the index.
- **tupleize_cols** [bool (default: True)] When True, attempt to create a MultiIndex if possible.

See also:
**RangeIndex**  Index implementing a monotonic integer range.

**CategoricalIndex**  Index of `Categoricals`.

**MultiIndex**  A multi-level, or hierarchical Index.

**IntervalIndex**  An Index of `Intervals`.

**DatetimeIndex**  Index of datetime64 data.

**TimedeltaIndex**  Index of timedelta64 data.

**PeriodIndex**  Index of Period data.

**Int64Index**  A special case of `Index` with purely integer labels.

**UInt64Index**  A special case of `Index` with purely unsigned integer labels.

**Float64Index**  A special case of `Index` with purely float labels.

### Notes

An Index instance can **only** contain hashable objects

### Examples

```python
>>> pd.Index([1, 2, 3])
Int64Index([1, 2, 3], dtype='int64')

>>> pd.Index(list('abc'))
Index(['a', 'b', 'c'], dtype='object')
```

### Attributes

- **T**  Return the transpose, which is by definition self.
- **array**  The ExtensionArray of the data backing this Series or Index.
- **asi8**  Integer representation of the values.
- **dtype**  Return the dtype object of the underlying data.
- **has_duplicates**  Check if the Index has duplicate values.
- **hasnans**  Return if I have any nans; enables various perf speedups.
- **inferred_type**  Return a string of the type inferred from the values.
- **is_all_dates**  Whether or not the index values only consist of dates.
- **is_monotonic**  Alias for `is_monotonic_increasing`.
- **is_monotonic_decreasing**  Return if the index is monotonic decreasing (only equal or decreasing) values.
- **is_monotonic_increasing**  Return if the index is monotonic increasing (only equal or increasing) values.
- **is_unique**  Return if the index has unique values.
- **name**  Return Index or MultiIndex name.
- **nbytes**  Return the number of bytes in the underlying data.
- **ndim**  Number of dimensions of the underlying data, by definition 1.
- **nlevels**  Number of levels.
- **shape**  Return a tuple of the shape of the underlying data.
- **size**  Return the number of elements in the underlying data.
values

Return an array representing the data in the Index.

*pandas.Index.T*

**property** Index.T

Return the transpose, which is by definition self.

*pandas.Index.array*

Index.array

The ExtensionArray of the data backing this Series or Index.

New in version 0.24.0.

**Returns**

ExtensionArray An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around numpy.ndarray.

.array differs .values which may require converting the data to a different form.

See also:

Index.to_numpy Similar method that always returns a NumPy array.

Series.to_numpy Similar method that always returns a NumPy array.

Notes

This table lays out the different array types for each extension dtype within pandas.

<table>
<thead>
<tr>
<th>dtype</th>
<th>array type</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>Categorical</td>
</tr>
<tr>
<td>period</td>
<td>PeriodArray</td>
</tr>
<tr>
<td>interval</td>
<td>IntervalArray</td>
</tr>
<tr>
<td>IntegerNA</td>
<td>IntegerArray</td>
</tr>
<tr>
<td>string</td>
<td>StringArray</td>
</tr>
<tr>
<td>boolean</td>
<td>BooleanArray</td>
</tr>
<tr>
<td>datetime64[ns, tz]</td>
<td>DatetimeArray</td>
</tr>
</tbody>
</table>

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes .array will be a arrays.NumpyExtensionArray wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use Series.to_numpy() instead.
Examples

For regular NumPy types like int, and float, a PandasArray is returned.

```python
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

For extension types, like Categorical, the actual ExtensionArray is returned

```python
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
['a', 'b', 'a']
Categories (2, object): ['a', 'b']
```

**pandas.Index.asi8**

**property** Index.asi8

Integer representation of the values.

**Returns**

- ndarray An ndarray with int64 dtype.

**pandas.Index.dtype**

Index.dtype

Return the dtype object of the underlying data.

**pandas.Index.has_duplicates**

**property** Index.has_duplicates

Check if the Index has duplicate values.

**Returns**

- bool Whether or not the Index has duplicate values.

Examples

```python
>>> idx = pd.Index([1, 5, 7, 7])
>>> idx.has_duplicates
True

>>> idx = pd.Index([1, 5, 7])
>>> idx.has_duplicates
False

>>> idx = pd.Index(["Watermelon", "Orange", "Apple",
... "Watermelon"]).astype("category")
>>> idx.has_duplicates
True
```
```python
>>> idx = pd.Index(["Orange", "Apple", "Watermelon"]).astype("category")
>>> idx.has_duplicates
False
```

**pandas.Index.hasnans**

```
Index.hasnans
Return if I have any nans; enables various perf speedups.
```

**pandas.Index.inferred_type**

```
Index.inferred_type
Return a string of the type inferred from the values.
```

**pandas.Index.is_all_dates**

```
Index.is_all_dates
Whether or not the index values only consist of dates.
```

**pandas.Index.is_monotonic**

```
property Index.is_monotonic
Alias for is_monotonic_increasing.
```

**pandas.Index.is_monotonic_decreasing**

```
property Index.is_monotonic_decreasing
Return if the index is monotonic decreasing (only equal or decreasing) values.
```

**Examples**

```python
>>> Index([3, 2, 1]).is_monotonic_decreasing
True
>>> Index([3, 2, 2]).is_monotonic_decreasing
True
>>> Index([3, 1, 2]).is_monotonic_decreasing
False
```
### pandas.Index.is_monotonic_increasing

**property** `Index.is_monotonic_increasing`

Return if the index is monotonic increasing (only equal or increasing) values.

**Examples**

```python
>>> Index([1, 2, 3]).is_monotonic_increasing
True
>>> Index([1, 2, 2]).is_monotonic_increasing
True
>>> Index([1, 3, 2]).is_monotonic_increasing
False
```

### pandas.Index.is_unique

`Index.is_unique`

Return if the index has unique values.

### pandas.Index.name

**property** `Index.name`

Return Index or MultiIndex name.

### pandas.Index.nbytes

**property** `Index.nbytes`

Return the number of bytes in the underlying data.

### pandas.Index.ndim

**property** `Index.ndim`

Number of dimensions of the underlying data, by definition 1.

### pandas.Index.nlevels

**property** `Index.nlevels`

Number of levels.
pandas: powerful Python data analysis toolkit, Release 1.1.1

**pandas.Index.shape**

*property Index.shape*

Return a tuple of the shape of the underlying data.

**pandas.Index.size**

*property Index.size*

Return the number of elements in the underlying data.

**pandas.Index.values**

*property Index.values*

Return an array representing the data in the Index.

**Warning:** We recommend using `Index.array` or `Index.to_numpy()`, depending on whether you need a reference to the underlying data or a NumPy array.

**Returns**

array: numpy.ndarray or ExtensionArray

**See also:**

*Index.array* Reference to the underlying data.

*Index.to_numpy* A NumPy array representing the underlying data.

<td><code>symmetric_difference</code> (other[, result_name, sort])</td>
<td>Compute the symmetric difference of two Index objects.</td>
</tr>
<tr>
<td><code>take</code> (indices[, axis, allow_fill, fill_value])</td>
<td>Return a new Index of the values selected by the indices.</td>
</tr>
<tr>
<td><code>to_flat_index</code> ()</td>
<td>Identity method.</td>
</tr>
<tr>
<td><code>to_frame</code> (index, name)</td>
<td>Create a DataFrame with a column containing the Index.</td>
</tr>
<tr>
<td><code>tolist()</code></td>
<td>Return a list of the values.</td>
</tr>
<tr>
<td><code>to_native_types</code> ([slicer])</td>
<td>Format specified values of self and return them.</td>
</tr>
<tr>
<td><code>to_numpy</code> (dtype, copy, na_value)</td>
<td>A NumPy ndarray representing the values in this Series or Index.</td>
</tr>
<tr>
<td><code>to_series</code> (index, name)</td>
<td>Create a Series with both index and values equal to the index keys.</td>
</tr>
<tr>
<td><code>tolist()</code></td>
<td>Return a list of the values.</td>
</tr>
<tr>
<td><code>transpose</code> (*args, **kwargs)</td>
<td>Return the transpose, which is by definition self.</td>
</tr>
<tr>
<td><code>union</code> (other[, sort])</td>
<td>Form the union of two Index objects.</td>
</tr>
<tr>
<td><code>unique</code> (level)</td>
<td>Return unique values in the index.</td>
</tr>
<tr>
<td><code>value_counts</code> ([normalize, sort, ascending, …])</td>
<td>Return a Series containing counts of unique values.</td>
</tr>
<tr>
<td><code>where</code> (cond[, other])</td>
<td>Replace values where the condition is False.</td>
</tr>
</tbody>
</table>
pandas.Index.all

Index.all (*args, **kwargs)
Return whether all elements are True.

Parameters

*args  These parameters will be passed to numpy.all.

**kwargs  These parameters will be passed to numpy.all.

Returns

all  [bool or array_like (if axis is specified)] A single element array_like may be converted to bool.

See also:

Index.any  Return whether any element in an Index is True.
Series.any  Return whether any element in a Series is True.
Series.all  Return whether all elements in a Series are True.

Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

Examples

all

True, because nonzero integers are considered True.

```python
>>> pd.Index([1, 2, 3]).all()
True
```

False, because 0 is considered False.

```python
>>> pd.Index([0, 1, 2]).all()
False
```

any

True, because 1 is considered True.

```python
>>> pd.Index([0, 0, 1]).any()
True
```

False, because 0 is considered False.

```python
>>> pd.Index([0, 0, 0]).any()
False
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

**pandas.Index.any**

Index.

*any* (*args, **kwargs)*

Return whether any element is True.

**Parameters**

* *args* These parameters will be passed to numpy.any.

**kwargs** These parameters will be passed to numpy.any.

**Returns**

*any* [bool or array_like (if axis is specified)] A single element array_like may be converted to bool.

**See also:**

* Index.all Return whether all elements are True.

* Series.all Return whether all elements are True.

**Notes**

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

**Examples**

```python
>>> index = pd.Index([0, 1, 2])
>>> index.any()
True
```

```python
>>> index = pd.Index([0, 0, 0])
>>> index.any()
False
```

**pandas.Index.append**

Index.

*append* (*other*)

Append a collection of Index options together.

**Parameters**

*other* [Index or list/tuple of indices]

**Returns**

*appended* [Index]
pandas.Index.argmax

Index.argmax (axis=None, skipna=True, *args, **kwargs)

Return int position of the largest value in the Series.

If the maximum is achieved in multiple locations, the first row position is returned.

Parameters

axis [{None}] Dummy argument for consistency with Series.

skipna [bool, default True] Exclude NA/null values when showing the result.

*args, **kwargs Additional arguments and keywords for compatibility with NumPy.

Returns

int Row position of the maximum value.

See also:

Series.argmax Return position of the maximum value.

Series.argmin Return position of the minimum value.

numpy.ndarray.argmax Equivalent method for numpy arrays.

Series.idxmax Return index label of the maximum values.

Series.idxmin Return index label of the minimum values.

Examples

Consider dataset containing cereal calories

```python
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,
... 'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
>>> s
Corn Flakes 100.0
Almond Delight 110.0
Cinnamon Toast Crunch 120.0
Cocoa Puff 110.0
dtype: float64
```

```python
>>> s.argmax()
2
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.
pandas.Index.argmin

Index.argmin(axis=None, skipna=True, *args, **kwargs)

Return int position of the smallest value in the Series.

If the minimum is achieved in multiple locations, the first row position is returned.

Parameters

axis [{None}] Dummy argument for consistency with Series.
skipna [bool, default True] Exclude NA/null values when showing the result.
*args, **kwargs Additional arguments and keywords for compatibility with NumPy.

Returns

int Row position of the minimum value.

See also:

Series.argmin Return position of the minimum value.
Series.argmax Return position of the maximum value.
numpy.ndarray.argmin Equivalent method for numpy arrays.
Series.idxmax Return index label of the maximum values.
Series.idxmin Return index label of the minimum values.

Examples

Consider dataset containing cereal calories

```
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,
...                   'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
```

```
>>> s
Corn Flakes    100.0
Almond Delight 110.0
Cinnamon Toast Crunch    120.0
Cocoa Puff            110.0
dtype: float64
```

```
>>> s.argmax() 2
>>> s.argmin() 0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.
pandas.Index.argsort

Index.argsort (*args, **kwargs)
Return the integer indices that would sort the index.

Parameters

*args Passed to numpy.ndarray.argsort.
**kwargs Passed to numpy.ndarray.argsort.

Returns

numpy.ndarray Integer indices that would sort the index if used as an indexer.

See also:

numpy.argsort Similar method for NumPy arrays.
Index.sort_values Return sorted copy of Index.

Examples

```python
>>> idx = pd.Index(['b', 'a', 'd', 'c'])
>>> idx
Index(['b', 'a', 'd', 'c'], dtype='object')

>>> order = idx.argsort()
>>> order
array([1, 0, 3, 2])

>>> idx[order]
Index(['a', 'b', 'c', 'd'], dtype='object')
```

pandas.Index.asof

Index.asof (label)
Return the label from the index, or, if not present, the previous one.

Assuming that the index is sorted, return the passed index label if it is in the index, or return the previous index label if the passed one is not in the index.

Parameters

label [object] The label up to which the method returns the latest index label.

Returns

object The passed label if it is in the index. The previous label if the passed label is not in the sorted index or NaN if there is no such label.

See also:

Series.asof Return the latest value in a Series up to the passed index.
merge_asof Perform an asof merge (similar to left join but it matches on nearest key rather than equal key).
Index.get_loc An asof is a thin wrapper around get_loc with method='pad'.
Examples

`Index.asof` returns the latest index label up to the passed label.

```python
>>> idx = pd.Index(['2013-12-31', '2014-01-02', '2014-01-03'])
>>> idx.asof('2014-01-01')
'2013-12-31'
```

If the label is in the index, the method returns the passed label.

```python
>>> idx.asof('2014-01-02')
'2014-01-02'
```

If all of the labels in the index are later than the passed label, NaN is returned.

```python
>>> idx.asof('1999-01-02')
nan
```

If the index is not sorted, an error is raised.

```python
>>> idx_not_sorted = pd.Index(['2013-12-31', '2015-01-02', ...
... '2014-01-03'])
>>> idx_not_sorted.asof('2013-12-31')
Traceback (most recent call last):
  ValueError: index must be monotonic increasing or decreasing
```

`pandas.Index.asof_locs`  

`Index.asof_locs`(where, mask)

Return the locations (indices) of labels in the index.

As in the `asof` function, if the label (a particular entry in where) is not in the index, the latest index label up to the passed label is chosen and its index returned.

If all of the labels in the index are later than a label in `where`, -1 is returned.  
`mask` is used to ignore NA values in the index during calculation.

**Parameters**

- **where** [Index] An Index consisting of an array of timestamps.
- **mask** [array-like] Array of booleans denoting where values in the original data are not NA.

**Returns**

- **numpy.ndarray** An array of locations (indices) of the labels from the Index which correspond to the return values of the `asof` function for every element in `where`. 
**pandas.Index.astype**

`Index.astype(dtype, copy=True)`

Create an Index with values cast to dtypes.

The class of a new Index is determined by dtype. When conversion is impossible, a ValueError exception is raised.

**Parameters**

- **dtype** [numpy dtype or pandas type] Note that any signed integer `dtype` is treated as `int64`, and any unsigned integer `dtype` is treated as `uint64`, regardless of the size.
- **copy** [bool, default True] By default, astype always returns a newly allocated object. If copy is set to False and internal requirements on dtype are satisfied, the original data is used to create a new Index or the original Index is returned.

**Returns**

- **Index** Index with values cast to specified dtype.

**pandas.Index.copy**

`Index.copy(name=None, deep=False, dtype=None, names=None)`

Make a copy of this object.

Name and dtype sets those attributes on the new object.

**Parameters**

- **name** [Label, optional] Set name for new object.
- **deep** [bool, default False]
- **dtype** [numpy dtype or pandas type, optional] Set dtype for new object.
- **names** [list-like, optional] Kept for compatibility with MultiIndex. Should not be used.

**Returns**

- **Index** Index refer to new object which is a copy of this object.

**Notes**

In most cases, there should be no functional difference from using `deep`, but if `deep` is passed it will attempt to deepcopy.

**pandas.Index.delete**

`Index.delete(loc)`

Make new Index with passed location(-s) deleted.

**Parameters**

- **loc** [int or list of int] Location of item(-s) which will be deleted. Use a list of locations to delete more than one value at the same time.

**Returns**

3.7. Index objects
Index New Index with passed location(-s) deleted.

See also:

numpy.delete Delete any rows and column from NumPy array (ndarray).

Examples

```python
define
>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx.delete(1)
Index(['a', 'c'], dtype='object')

>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx.delete([0, 2])
Index(['b'], dtype='object')
```

pandas.Index.difference

Index.difference(other, sort=None)  
Return a new Index with elements of index not in other.  
This is the set difference of two Index objects.

Parameters

- other [Index or array-like]  
- sort [False or None, default None] Whether to sort the resulting index. By default, the values are attempted to be sorted, but any TypeError from incomparable elements is caught by pandas.
  - None : Attempt to sort the result, but catch any TypeErrors from comparing incomparable elements.
  - False : Do not sort the result.

New in version 0.24.0.

Changed in version 0.24.1: Changed the default value from True to None (without change in behaviour).

Returns
difference [Index]

Examples

```python
define
>>> idx1 = pd.Index([2, 1, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.difference(idx2)
Int64Index([1, 2], dtype='int64')

>>> idx1.difference(idx2, sort=False)
Int64Index([2, 1], dtype='int64')
```
pandas.Index.drop

Index.drop(labels, errors='raise')
Make new Index with passed list of labels deleted.

Parameters

- labels [array-like]
- errors [{‘ignore’, ‘raise’}, default ‘raise’] If ‘ignore’, suppress error and existing labels are dropped.

Returns

- dropped [Index]

Raises

- KeyError If not all of the labels are found in the selected axis

pandas.Index.drop_duplicates

Index.drop_duplicates(keep='first')
Return Index with duplicate values removed.

Parameters

- keep [{‘first’, ‘last’, False}, default ‘first’]
  - ‘first’ : Drop duplicates except for the first occurrence.
  - ‘last’ : Drop duplicates except for the last occurrence.
  - False : Drop all duplicates.

Returns

- deduplicated [Index]

See also:

- Series.drop_duplicates Equivalent method on Series.
- DataFrame.drop_duplicates Equivalent method on DataFrame.
- Index.duplicated Related method on Index, indicating duplicate Index values.

Examples

Generate an pandas.Index with duplicate values.

```python
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'])
```

The keep parameter controls which duplicate values are removed. The value ‘first’ keeps the first occurrence for each set of duplicated entries. The default value of keep is ‘first’.

```python
>>> idx.drop_duplicates(keep='first')
Index(['lama', 'cow', 'beetle', 'hippo'], dtype='object')
```

The value ‘last’ keeps the last occurrence for each set of duplicated entries.
```python
>>> idx.drop_duplicates(keep='last')
Index(['cow', 'beetle', 'lama', 'hippo'], dtype='object')
```

The value `False` discards all sets of duplicated entries.

```python
>>> idx.drop_duplicates(keep=False)
Index(['cow', 'beetle', 'hippo'], dtype='object')
```

**pandas.Index.droplevel**

`Index.droplevel(level=0)`

Return index with requested level(s) removed.

If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

New in version 0.23.1: (support for non-MultiIndex)

**Parameters**

- `level` [int, str, or list-like, default 0] If a string is given, must be the name of a level. If list-like, elements must be names or indexes of levels.

**Returns**

- `Index` or `MultiIndex`

**pandas.Index.dropna**

`Index.dropna(how='any')`

Return Index without NA/NaN values.

**Parameters**

- `how` [{'any', 'all'}, default 'any'] If the Index is a MultiIndex, drop the value when any or all levels are NaN.

**Returns**

- `Index`

**pandas.Index.duplicated**

`Index.duplicated(keep='first')`

Indicate duplicate index values.

Duplicated values are indicated as `True` values in the resulting array. Either all duplicates, all except the first, or all except the last occurrence of duplicates can be indicated.

**Parameters**

- `keep` [{'first', 'last', False}, default 'first'] The value or values in a set of duplicates to mark as missing.
  - 'first': Mark duplicates as `True` except for the first occurrence.
  - 'last': Mark duplicates as `True` except for the last occurrence.
  - `False`: Mark all duplicates as `True`.

---

1910 Chapter 3. API reference
Returns

- numpy.ndarray

See also:

- `Series.duplicated` Equivalent method on pandas.Series.
- `DataFrame.duplicated` Equivalent method on pandas.DataFrame.
- `Index.drop_duplicates` Remove duplicate values from Index.

Examples

By default, for each set of duplicated values, the first occurrence is set to False and all others to True:

```python
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> idx.duplicated()
array([False, False, True, False, True])
```

which is equivalent to

```python
>>> idx.duplicated(keep='first')
array([False, False, True, False, True])
```

By using 'last', the last occurrence of each set of duplicated values is set on False and all others on True:

```python
>>> idx.duplicated(keep='last')
array([ True, False, True, False, False])
```

By setting keep on `False`, all duplicates are True:

```python
>>> idx.duplicated(keep=False)
array([ True, False, True, False, True])
```

**pandas.Index.equals**

`Index.equals(other)`

Determine if two Index object are equal.

The things that are being compared are:

- The elements inside the Index object.
- The order of the elements inside the Index object.

**Parameters**

- `other` [Any] The other object to compare against.

**Returns**

- `bool` True if “other” is an Index and it has the same elements and order as the calling index; False otherwise.
Examples

```python
>>> idx1 = pd.Index([1, 2, 3])
>>> idx1
Int64Index([1, 2, 3], dtype='int64')
>>> idx1.equals(pd.Index([1, 2, 3]))
True

The elements inside are compared

```python
>>> idx2 = pd.Index(['1', '2', '3'])
>>> idx2
Index(['1', '2', '3'], dtype='object')
>>> idx1.equals(idx2)
False

The order is compared

```python
>>> ascending_idx = pd.Index([1, 2, 3])
>>> ascending_idx
Int64Index([1, 2, 3], dtype='int64')
>>> descending_idx = pd.Index([3, 2, 1])
>>> descending_idx
Int64Index([3, 2, 1], dtype='int64')
>>> ascending_idx.equals(descending_idx)
False

The dtype is not compared

```python
>>> int64_idx = pd.Int64Index([1, 2, 3])
>>> int64_idx
Int64Index([1, 2, 3], dtype='int64')
>>> uint64_idx = pd.UInt64Index([1, 2, 3])
>>> uint64_idx
UInt64Index([1, 2, 3], dtype='uint64')
>>> int64_idx.equals(uint64_idx)
True
```

`pandas.Index.factorize`

`Index.factorize(sort=False, na_sentinel=-1)`

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. `factorize` is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

Parameters

- `sort` [bool, default False] Sort `uniques` and shuffle `codes` to maintain the relationship.
- `na_sentinel` [int, default -1] Value to mark “not found”.

Returns

- `codes` [ndarray] An integer ndarray that’s an indexer into `uniques`. `uniques.take(codes)` will have the same values as `values`. 

1912 Chapter 3. API reference
uniques [ndarray, Index, or Categorical] The unique valid values. When values is Categorical, uniques is a Categorical. When values is some other pandas object, an Index is returned. Otherwise, a 1-D ndarray is returned.

Note: Even if there’s a missing value in values, uniques will not contain an entry for it.

See also:

cut Discretize continuous-valued array.
unique Find the unique value in an array.

Examples

These examples all show factorize as a top-level method like pd.factorize(values). The results are identical for methods like Series.factorize().

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> codes
array([0, 0, 1, 2, 0]...)
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With sort=True, the uniques will be sorted, and codes will be shuffled so that the relationship is maintained.

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> codes
array([1, 1, 0, 2, 1]...)
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in codes with na_sentinel (-1 by default). Note that missing values are never included in uniques.

```python
>>> codes, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> codes
array([ 0, -1, 1, 2, 0]...)
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we’ve only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of uniques will differ. For Categoricals, a Categorical is returned.

```python
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1]...)
>>> uniques
['a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Notice that 'b' is in uniques.categories, despite not being present in cat.values.

For all other pandas objects, an Index of the appropriate type is returned.
```python
>>> cat = pd.Series(["a", "a", "c"])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1]...)
>>> uniques
Index(["a", "c"], dtype='object')
```

### pandas.Index.fillna

**Index.fillna**(value=None, downcast=None)

Fill NA/NaN values with the specified value.

**Parameters**

- **value** [scalar] Scalar value to use to fill holes (e.g. 0). This value cannot be a list-likes.
- **downcast** [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string 'infer' which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

**Returns**

Index

**See also:**

- **DataFrame.fillna** Fill NaN values of a DataFrame.
- **Series.fillna** Fill NaN Values of a Series.

### pandas.Index.format

**Index.format**(name=False, formatter=None, na_rep='NaN')

Render a string representation of the Index.

### pandas.Index.get_indexer

**Index.get_indexer**(target, method=None, limit=None, tolerance=None)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

**Parameters**

- **target** [Index]
- **method** [[None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'], optional]
  - default: exact matches only.
  - pad / ffill: find the PREVIOUS index value if no exact match.
  - backfill / bfill: use NEXT index value if no exact match
  - nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
- **limit** [int, optional] Maximum number of consecutive labels in target to match for inexact matches.
tolerance  [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation \( \text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance} \).

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

**Returns**

**indexer**  [ndarray of int] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

**Examples**

```python
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1, 2, -1])
```

Notice that the return value is an array of locations in `index` and `x` is marked by -1, as it is not in `index`.

**pandas.Index.get_indexer_for**

Index.get_indexer_for(target, **kwargs)

Guaranteed return of an indexer even when non-unique.

This dispatches to get_indexer or get_indexer_non_unique as appropriate.

**Returns**

**numpy.ndarray** List of indices.

**pandas.Index.get_indexer_non_unique**

Index.get_indexer_non_unique(target)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

**Parameters**

**target**  [Index]

**Returns**

**indexer**  [ndarray of int] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

**missing**  [ndarray of int] An indexer into the target of the values not found. These correspond to the -1 in the indexer array.
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.Index.get_level_values

`Index.get_level_values(level)`

Return an Index of values for requested level.

This is primarily useful to get an individual level of values from a MultiIndex, but is provided on Index as well for compatibility.

**Parameters**

- **level** [int or str] It is either the integer position or the name of the level.

**Returns**

- **Index** Calling object, as there is only one level in the Index.

**See also:**

- `MultiIndex.get_level_values` Get values for a level of a MultiIndex.

**Notes**

For Index, level should be 0, since there are no multiple levels.

**Examples**

```python
>>> idx = pd.Index(list('abc'))
>>> idx
Index(['a', 'b', 'c'], dtype='object')

Get level values by supplying `level` as integer:

```python
>>> idx.get_level_values(0)  
Index(['a', 'b', 'c'], dtype='object')
```

pandas.Index.get_loc

`Index.get_loc(key, method=None, tolerance=None)`

Get integer location, slice or boolean mask for requested label.

**Parameters**

- **key** [label]
- **method** [{None, ‘pad’/’ffill’, ‘backfill’/’bfill’, ‘nearest’}, optional]
  - default: exact matches only.
  - pad / ffill: find the PREVIOUS index value if no exact match.
  - backfill / bfill: use NEXT index value if no exact match
  - nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
- **tolerance** [int or float, optional] Maximum distance from index value for inexact matches. The value of the index at the matching location most satisfy the equation `abs(index[loc] - key) <= tolerance`. 
Retons

\texttt{loc}  [int if unique index, slice if monotonic index, else mask]

Examples

\begin{verbatim}
>>> unique_index = pd.Index(list('abc'))
>>> unique_index.get_loc('b')
1

>>> monotonic_index = pd.Index(list('abbc'))
>>> monotonic_index.get_loc('b')
slice(1, 3, None)

>>> non_monotonic_index = pd.Index(list('abcb'))
>>> non_monotonic_index.get_loc('b')
array([False, True, False, True])
\end{verbatim}

\texttt{pandas.Index.get_slice_bound}

\texttt{Index.get_slice_bound(label, side, kind)}

Calculate slice bound that corresponds to given label.

Returns leftmost (one-past-the-rightmost if \texttt{side}=='right') position of given label.

Parameters

\begin{itemize}
  \item \texttt{label}  [object]
  \item \texttt{side}  [[‘left’, ‘right’]]
  \item \texttt{kind}  [[‘loc’, ‘getitem’] or None]
\end{itemize}

Returns

\begin{itemize}
  \item \texttt{int}  Index of label.
\end{itemize}

\texttt{pandas.Index.get_value}

\texttt{Index.get_value(series, key)}

Fast lookup of value from 1-dimensional ndarray.

Only use this if you know what you’re doing.

Returns

\begin{itemize}
  \item \texttt{scalar} or \texttt{Series}
\end{itemize}
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.Index.groupby

Index.groupby(values)
Group the index labels by a given array of values.

Parameters

values [array] Values used to determine the groups.

Returns

dict {group name -> group labels}

pandas.Index.holds_integer

Index.holds_integer()
Whether the type is an integer type.

pandas.Index.identical

Index.identical(other)
Similar to equals, but checks that object attributes and types are also equal.

Returns

bool If two Index objects have equal elements and same type True, otherwise False.

pandas.Index.insert

Index.insert(loc, item)
Make new Index inserting new item at location.
Follows Python list.append semantics for negative values.

Parameters

loc [int]
item [object]

Returns

new_index [Index]

pandas.Index.intersection

Index.intersection(other, sort=False)
Form the intersection of two Index objects.
This returns a new Index with elements common to the index and other.

Parameters

other [Index or array-like]

sort [False or None, default False] Whether to sort the resulting index.
• False : do not sort the result.
• None : sort the result, except when self and other are equal or when the values cannot be compared.

New in version 0.24.0.

Changed in version 0.24.1: Changed the default from True to False, to match the behaviour of 0.23.4 and earlier.

Returns

intersection [Index]

Examples

```python
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.intersection(idx2)
Int64Index([3, 4], dtype='int64')
```

```python
pandas.Index.is_
```

Index.is_ (other)

More flexible, faster check like is but that works through views.

Note: this is not the same as Index.identical(), which checks that metadata is also the same.

Parameters

other [object] Other object to compare against.

Returns

bool True if both have same underlying data, False otherwise.

See also:

Index.identical Works like Index.is_ but also checks metadata.

```python
pandas.Index.is_boolean
```

Index.is_boolean()

Check if the Index only consists of booleans.

Returns

bool Whether or not the Index only consists of booleans.

See also:

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.
**is_mixed** Check if the Index holds data with mixed data types.

**Examples**

```python
>>> idx = pd.Index([True, False, True])
>>> idx.is_boolean()
True

>>> idx = pd.Index(["True", "False", "True"])
>>> idx.is_boolean()
False

>>> idx = pd.Index([True, False, "True"])
>>> idx.is_boolean()
False
```

**pandas.Index.is_categorical**

Index.is_categorical() Check if the Index holds categorical data.

**Returns**

- **bool** True if the Index is categorical.

**See also:**

- **CategoricalIndex** Index for categorical data.
- **is_boolean** Check if the Index only consists of booleans.
- **is_integer** Check if the Index only consists of integers.
- **is_floating** Check if the Index is a floating type.
- **is_numeric** Check if the Index only consists of numeric data.
- **is_object** Check if the Index is of the object dtype.
- **is_interval** Check if the Index holds Interval objects.
- **is_mixed** Check if the Index holds data with mixed data types.

**Examples**

```python
>>> idx = pd.Index(["Watermelon", "Orange", "Apple", ...
"Watermelon"]).astype("category")
>>> idx.is_categorical()
True

>>> idx = pd.Index([1, 3, 5, 7])
>>> idx.is_categorical()
False
```
```python
>>> s = pd.Series(["Peter", "Victor", "Elisabeth", "Mar"])
>>> s
0    Peter
1     Victor
2  Elisabeth
3      Mar
dtype: object
>>> s.index.is_categorical()
False
```

### pandas.Index.is_floating

`Index.is_floating()`

Check if the Index is a floating type.

The Index may consist of only floats, NaNs, or a mix of floats, integers, or NaNs.

**Returns**

`bool` Whether or not the Index only consists of only consists of floats, NaNs, or a mix of floats, integers, or NaNs.

**See also:**

- `is_boolean` Check if the Index only consists of booleans.
- `is_integer` Check if the Index only consists of integers.
- `is_numeric` Check if the Index only consists of numeric data.
- `is_object` Check if the Index is of the object dtype.
- `is_categorical` Check if the Index holds categorical data.
- `is_interval` Check if the Index holds Interval objects.
- `is_mixed` Check if the Index holds data with mixed data types.

**Examples**

```python
>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_floating()
True
```

```python
>>> idx = pd.Index([1.0, 2.0, np.nan, 4.0])
>>> idx.is_floating()
True
```

```python
>>> idx = pd.Index([1, 2, 3, 4, np.nan])
>>> idx.is_floating()
True
```

```python
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx.is_floating()
False
```
pandas.Index.is_integer

Index.is_integer()
Check if the Index only consists of integers.

Returns
bool Whether or not the Index only consists of integers.

See also:

is_boolean Check if the Index only consists of booleans.
is_floating Check if the Index is a floating type.
is_numeric Check if the Index only consists of numeric data.
is_object Check if the Index is of the object dtype.
is_categorical Check if the Index holds categorical data.
is_interval Check if the Index holds Interval objects.
is_mixed Check if the Index holds data with mixed data types.

Examples

```python
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx.is_integer()
True

>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_integer()
False

>>> idx = pd.Index(['Apple', 'Mango', 'Watermelon'])
>>> idx.is_integer()
False
```

pandas.Index.is_interval

Index.is_interval()
Check if the Index holds Interval objects.

Returns
bool Whether or not the Index holds Interval objects.

See also:

IntervalIndex Index for Interval objects.
is_boolean Check if the Index only consists of booleans.
is_integer Check if the Index only consists of integers.
is_floating Check if the Index is a floating type.
is_numeric Check if the Index only consists of numeric data.
is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_mixed Check if the Index holds data with mixed data types.

Examples

```python
>>> idx = pd.Index([pd.Interval(left=0, right=5),
...                   pd.Interval(left=5, right=10)])
>>> idx.is_interval()
True

>>> idx = pd.Index([1, 3, 5, 7])
>>> idx.is_interval()
False
```

pandas.Index.is_mixed

Index.is_mixed() Check if the Index holds data with mixed data types.

Returns

bool Whether or not the Index holds data with mixed data types.

See also:

is_boolean Check if the Index only consists of booleans.

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.

Examples

```python
>>> idx = pd.Index(['a', np.nan, 'b'])
>>> idx.is_mixed()
True

>>> idx = pd.Index([1.0, 2.0, 3.0, 5.0])
>>> idx.is_mixed()
False
```
**pandas.Index.is_numeric**

`Index.is_numeric()`  
Check if the Index only consists of numeric data.

**Returns**

`bool` Whether or not the Index only consists of numeric data.

**See also:**

- `is_boolean` Check if the Index only consists of booleans.
- `is_integer` Check if the Index only consists of integers.
- `is_floating` Check if the Index is a floating type.
- `is_object` Check if the Index is of the object dtype.
- `is_categorical` Check if the Index holds categorical data.
- `is_interval` Check if the Index holds Interval objects.
- `is_mixed` Check if the Index holds data with mixed data types.

**Examples**

```python
given_idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> given_idx.is_numeric()
True

idx = pd.Index([1, 2, 3.0])
>>> idx.is_numeric()
True

idx = pd.Index([1, 2, 3.4])
>>> idx.is_numeric()
True

idx = pd.Index([1, 2, 3.4, np.nan])
>>> idx.is_numeric()
True

idx = pd.Index([1, 2, 3.4, np.nan, "Apple"])
>>> idx.is_numeric()
False
```
**pandas.Index.is_object**

Index.is_object()  
Check if the Index is of the object dtype.

**Returns**

bool Whether or not the Index is of the object dtype.

**See also:**

- is_boolean Check if the Index only consists of booleans.
- is_integer Check if the Index only consists of integers.
- is_floating Check if the Index is a floating type.
- is_numeric Check if the Index only consists of numeric data.
- is_categorical Check if the Index holds categorical data.
- is_interval Check if the Index holds Interval objects.
- is_mixed Check if the Index holds data with mixed data types.

**Examples**

```python
>>> idx = pd.Index(['Apple', 'Mango', 'Watermelon'])
>>> idx.is_object()
True

>>> idx = pd.Index(['Apple', 'Mango', 2.0])
>>> idx.is_object()
True

>>> idx = pd.Index(['Watermelon', 'Orange', 'Apple', ...
                'Watermelon']).astype('category')
>>> idx.is_object()
False

>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_object()
False
```

**pandas.Index.is_type_compatible**

Index.is_type_compatible(kind)  
Whether the index type is compatible with the provided type.
pandas.Index.isin

Index.<code>isin</code>(values, level=None)

Return a boolean array where the index values are in values.

Compute boolean array of whether each index value is found in the passed set of values. The length of the returned boolean array matches the length of the index.

Parameters

- **values** [set or list-like] Sought values.
- **level** [str or int, optional] Name or position of the index level to use (if the index is a <em>MultiIndex</em>).

Returns

- **is_contained** [ndarray] NumPy array of boolean values.

See also:

<code>Series.isin</code> Same for Series.
<code>DataFrame.isin</code> Same method for DataFrames.

Notes

In the case of <em>MultiIndex</em> you must either specify <em>values</em> as a list-like object containing tuples that are the same length as the number of levels, or specify <em>level</em>. Otherwise it will raise a <code>ValueError</code>.

If <em>level</em> is specified:

- if it is the name of one and only one index level, use that level;
- otherwise it should be a number indicating level position.

Examples

```python
>>> idx = pd.Index([1,2,3])
>>> idx
Int64Index([1, 2, 3], dtype='int64')

Check whether each index value in a list of values.

```python
>>> idx.isin([1, 4])
array([ True, False, False])
```
To check across the levels of a MultiIndex, pass a list of tuples:

```python
>>> midx.isin([(1, 'red'), (3, 'red')])
array([ True, False, False])
```

For a DatetimeIndex, string values in `values` are converted to Timestamps.

```python
>>> dates = ['2000-03-11', '2000-03-12', '2000-03-13']
>>> dti = pd.to_datetime(dates)
>>> dti
DatetimeIndex(['2000-03-11', '2000-03-12', '2000-03-13'], dtype='datetime64[ns]', freq=None)
```

```python
>>> dti.isin(['2000-03-11'])
array([ True, False, False])
```

### pandas.Index.isna

**Index.isna()**

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None, numpy.NaN or pd.NaT, get mapped to `True` values. Everything else get mapped to `False` values. Characters such as empty strings `' '` or numpy.inf are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

**Returns**

`numpy.ndarray` A boolean array of whether my values are NA.

**See also:**

* `Index.notna` Boolean inverse of isna.
* `Index.dropna` Omit entries with missing values.
* `isna` Top-level isna.
* `Series.isna` Detect missing values in Series object.

### Examples

Show which entries in a pandas.Index are NA. The result is an array.

```python
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
```

```python
>>> idx.isna()
array([False, False, True])
```

Empty strings are not considered NA values. None is considered an NA value.
pandas: powerful Python data analysis toolkit, Release 1.1.1

```python
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.isna()
array([False, False, False, True])
```

For datetimes, Na\(T\) (Not a Time) is considered as an NA value.

```python
>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
... pd.Timestamp(''),
... None, pd.NaT])
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
              dtype='datetime64[ns]', freq=None)
>>> idx.isna()
array([False, True, True, True])
```

### pandas.Index.isnull

**Index.isnull()**

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None, numpy.\(\text{NaN}\) or pd.Na\(T\), get mapped to True values. Everything else get mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

**Returns**

- numpy.ndarray: A boolean array of whether my values are NA.

**See also:**

- Index.notna: Boolean inverse of isna.
- Index.dropna: Omit entries with missing values.
- isna: Top-level isna.
- Series.isna: Detect missing values in Series object.

**Examples**

Show which entries in a pandas.Index are NA. The result is an array.

```python
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.isna()
array([False, False, True])
```

Empty strings are not considered NA values. None is considered an NA value.

```python
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.isna()
array([False, False, False, True])
```
For datetimes, *NaT* (Not a Time) is considered as an NA value.

```python
>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
    ... pd.Timestamp(''), None, pd.NaT])
```

```python
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
               dtype='datetime64[ns]', freq=None)
```

```python
>>> idx.isna()
array([False, True, True, True])
```

**pandas.Index.item**

*Index.item()*

Return the first element of the underlying data as a python scalar.

**Returns**

- **scalar**  The first element of *%(klass)s*.

**Raises**

- **ValueError**  If the data is not length-1.

**pandas.Index.join**

*Index.join*(other, how='left', level=None, return_indexers=False, sort=False)

Compute join_index and indexers to conform data structures to the new index.

**Parameters**

- **other**  [Index]
- **how**  [{‘left’, ‘right’, ‘inner’, ‘outer’}]
- **level**  [int or level name, default None]
- **return_indexers**  [bool, default False]
- **sort**  [bool, default False]  Sort the join keys lexicographically in the result Index.  If 
  False, the order of the join keys depends on the join type (how keyword).

**Returns**

- **join_index**, *(left_indexer, right_indexer)*

**pandas.Index.map**

*Index.map*(mapper, na_action=None)

Map values using input correspondence (a dict, Series, or function).

**Parameters**

- **mapper**  [function, dict, or Series]  Mapping correspondence.
- **na_action**  [{None, ‘ignore’}]  If ‘ignore’, propagate NA values, without passing them to the mapping correspondence.

**Returns**

3.7. Index objects
applied [Union[Index, MultiIndex], inferred] The output of the mapping function applied to the index. If the function returns a tuple with more than one element a MultiIndex will be returned.

**pandas.Index.max**

```python
Index.max(\text{axis=None, skipna=True, } \ast \text{args, } \ast \ast \text{kwargs})
```

Return the maximum value of the Index.

**Parameters**

- `axis` [int, optional] For compatibility with NumPy. Only 0 or None are allowed.
- `skipna` [bool, default True] Exclude NA/null values when showing the result.
- `\ast \text{args, } \ast \ast \text{kwargs}` Additional arguments and keywords for compatibility with NumPy.

**Returns**

- `scalar` Maximum value.

**See also:**

- `Index.min` Return the minimum value in an Index.
- `Series.max` Return the maximum value in a Series.
- `DataFrame.max` Return the maximum values in a DataFrame.

**Examples**

```python
>>> idx = pd.Index([3, 2, 1])
>>> idx.max()
3

>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.max()
'c'
```

For a MultiIndex, the maximum is determined lexicographically.

```python
>>> idx = pd.MultiIndex.from_product([('a', 'b'), (2, 1)])
>>> idx.max()
('b', 2)
```

**pandas.Index.memory_usage**

```python
Index.memory_usage(\text{deep=False})
```

Memory usage of the values.

**Parameters**

- `deep` [bool] Introspect the data deeply, interrogate object dtypes for system-level memory consumption.

**Returns**

- `bytes used`
See also:

```
numpy.ndarray.nbytes  Total bytes consumed by the elements of the array.
```

**Notes**

Memory usage does not include memory consumed by elements that are not components of the array if `deep=False` or if used on PyPy.

### pandas.Index.min

```
Index.min(axis=None, skipna=True, *args, **kwargs)
```

Return the minimum value of the Index.

**Parameters**

- `axis` [{None}] Dummy argument for consistency with Series.
- `skipna` [bool, default True] Exclude NA/null values when showing the result.
- `*args, **kwargs` Additional arguments and keywords for compatibility with NumPy.

**Returns**

- `scalar` Minimum value.

See also:

```
Index.max  Return the maximum value of the object.
Series.min  Return the minimum value in a Series.
DataFrame.min  Return the minimum values in a DataFrame.
```

**Examples**

```
>>> idx = pd.Index([3, 2, 1])
>>> idx.min()
1

>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.min()
'a'
```

For a MultiIndex, the minimum is determined lexicographically.

```
>>> idx = pd.MultiIndex.from_product([['a', 'b'], (2, 1)])
>>> idx.min()
('a', 1)
```
pandas.Index.notna

Index.notna()

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

Returns

numpy.ndarray Boolean array to indicate which entries are not NA.

See also:

Index.notnull Alias of notna.

Index.isna Inverse of notna.

notna Top-level notna.

Examples

Show which entries in an Index are not NA. The result is an array.

```python
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([True, True, False])
```

Empty strings are not considered NA values. None is considered a NA value.

```python
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([True, True, True, False])
```

pandas.Index.notnull

Index.notnull()

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

Returns

numpy.ndarray Boolean array to indicate which entries are not NA.

See also:

Index.notnull Alias of notna.
**Index.isna** Inverse of notna.

**notna** Top-level notna.

### Examples

Show which entries in an Index are not NA. The result is an array.

```python
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([ True, True, False])
```

Empty strings are not considered NA values. None is considered a NA value.

```python
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([ True, True, True, False])
```

### pandas.Index.nunique

**Index.nunique** *(dropna=True)*

Return number of unique elements in the object.

Excludes NA values by default.

**Parameters**

- **dropna** [bool, default True] Don’t include NaN in the count.

**Returns**

- int

**See also:**

- DataFrame.nunique Method nunique for DataFrame.
- Series.count Count non-NA/null observations in the Series.

### Examples

```python
>>> s = pd.Series([1, 3, 5, 7, 7])
>>> s
0  1
1  3
2  5
3  7
4  7
dtype: int64

>>> s.nunique()
4
```
pandas.Index.putmask

Index.putmask (mask, value)
Return a new Index of the values set with the mask.

Returns
Index

See also:

numpy.ndarray.putmask

pandas.Index.ravel

Index.ravel (order='C')
Return an ndarray of the flattened values of the underlying data.

Returns
numpy.ndarray Flattened array.

See also:

numpy.ndarray.ravel

pandas.Index.reindex

Index.reindex (target, method=None, level=None, limit=None, tolerance=None)
Create index with target’s values.

Parameters

target [an iterable]

Returns

ew_index [pd.Index] Resulting index.
indexer [np.ndarray or None] Indices of output values in original index.

pandas.Index.rename

Index.rename (name, inplace=False)
Alter Index or MultiIndex name.

Able to set new names without level. Defaults to returning new index. Length of names must match number of levels in MultiIndex.

Parameters

name [label or list of labels] Name(s) to set.

inplace [bool, default False] Modifies the object directly, instead of creating a new Index or MultiIndex.

Returns

Index The same type as the caller or None if inplace is True.
See also:

**Index.set_names** Able to set new names partially and by level.

**Examples**

```python
>>> idx = pd.Index(['A', 'C', 'A', 'B'], name='score')
>>> idx.rename('grade')
Index(['A', 'C', 'A', 'B'], dtype='object', name='grade')

>>> idx = pd.MultiIndex.from_product([['python', 'cobra'], [2018, 2019]], names=['kind', 'year'])
>>> idx
MultiIndex([('python', 2018), ('python', 2019), ('cobra', 2018), ('cobra', 2019)], names=['kind', 'year'])

>>> idx.rename(['species', 'year'])
MultiIndex([('python', 2018), ('python', 2019), ('cobra', 2018), ('cobra', 2019)], names=['species', 'year'])

>>> idx.rename('species')
Traceback (most recent call last):
  TypeError: Must pass list-like as 'names'.
```

**pandas.Index.repeat**

**Index.repeat** *(repeats, axis=None)*

Repeat elements of a Index.

Returns a new Index where each element of the current Index is repeated consecutively a given number of times.

**Parameters**

- **repeats** [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Index.

- **axis** [None] Must be None. Has no effect but is accepted for compatibility with numpy.

**Returns**

- **repeated_index** [Index] Newly created Index with repeated elements.

**See also:**

**Series.repeat** Equivalent function for Series.

**numpy.repeat** Similar method for numpy.ndarray.
Examples

```python
>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx
Index(['a', 'b', 'c'], dtype='object')
>>> idx.repeat(2)
Index(['a', 'a', 'b', 'b', 'c', 'c'], dtype='object')
>>> idx.repeat([1, 2, 3])
Index(['a', 'b', 'b', 'c', 'c', 'c'], dtype='object')
```

**pandas.Index.searchsorted**

`Index.searchsorted(value, side='left', sorter=None)`

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted Index `self` such that, if the corresponding elements in `value` were inserted before the indices, the order of `self` would be preserved.

**Note:** The Index must be monotonically sorted, otherwise wrong locations will likely be returned. Pandas does not check this for you.

**Parameters**

- `value` [array_like] Values to insert into `self`.
- `side` [‘left’, ‘right’], optional] If ‘left’, the index of the first suitable location found is given. If ‘right’, return the last such index. If there is no suitable index, return either 0 or N (where N is the length of `self`).
- `sorter` [1-D array_like, optional] Optional array of integer indices that sort `self` into ascending order. They are typically the result of `np.argsort`.

**Returns**

- `int` or `array of int` A scalar or array of insertion points with the same shape as `value`.

Changed in version 0.24.0: If `value` is a scalar, an int is now always returned. Previously, scalar inputs returned an 1-item array for `Series` and `Categorical`.

**See also:**

- `sort_values` Sort by the values along either axis.
- `numpy.searchsorted` Similar method from NumPy.
Notes

Binary search is used to find the required insertion points.

Examples

```python
>>> ser = pd.Series([1, 2, 3])
>>> ser
0  1
1  2
2  3
dtype: int64

>>> ser.searchsorted(4)
3

>>> ser.searchsorted([0, 4])
array([0, 3])

>>> ser.searchsorted([1, 3], side='left')
array([0, 2])

>>> ser.searchsorted([1, 3], side='right')
array([1, 3])

>>> ser = pd.Categorical(
...    ['apple', 'bread', 'bread', 'cheese', 'milk'], ordered=True
...)

>>> ser
['apple', 'bread', 'bread', 'cheese', 'milk']
Categories (4, object): ['apple' < 'bread' < 'cheese' < 'milk']

>>> ser.searchsorted('bread')
1

>>> ser.searchsorted(['bread'], side='right')
array([3])
```

If the values are not monotonically sorted, wrong locations may be returned:

```python
>>> ser = pd.Series([2, 1, 3])
>>> ser
0  2
1  1
2  3
dtype: int64

>>> ser.searchsorted(1)
0  # wrong result, correct would be 1
```
pandas.Index.set_names

Index.set_names(names, level=None, inplace=False)

Set Index or MultiIndex name.

Able to set new names partially and by level.

Parameters

names [label or list of label] Name(s) to set.

level [int, label or list of int or label, optional] If the index is a MultiIndex, level(s) to set (None for all levels). Otherwise level must be None.

inplace [bool, default False] Modifies the object directly, instead of creating a new Index or MultiIndex.

Returns

Index The same type as the caller or None if inplace is True.

See also:

Index.rename Able to set new names without level.

Examples

```python
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx
Int64Index([1, 2, 3, 4], dtype='int64')
>>> idx.set_names('quarter')
Int64Index([1, 2, 3, 4], dtype='int64', name='quarter')

>>> idx = pd.MultiIndex.from_product([['python', 'cobra'],
... [2018, 2019]])
>>> idx
MultiIndex([('python', 2018),
('python', 2019),
('cobra', 2018),
('cobra', 2019),
],
)
>>> idx.set_names(['kind', 'year'], inplace=True)
>>> idx
MultiIndex([('python', 2018),
('python', 2019),
('cobra', 2018),
('cobra', 2019)],
names=['kind', 'year'])
>>> idx.set_names('species', level=0)
MultiIndex([('python', 2018),
('python', 2019),
('cobra', 2018),
('cobra', 2019),
],
names=['species', 'year'])
```
**pandas.Index.set_value**

Index.set_value(arr, key, value)

Fast lookup of value from 1-dimensional ndarray.

Deprecated since version 1.0.

**Notes**

Only use this if you know what you’re doing.

**pandas.Index.shift**

Index.shift(periods=1, freq=None)

Shift index by desired number of time frequency increments.

This method is for shifting the values of datetime-like indexes by a specified time increment a given number of times.

**Parameters**

- **periods** [int, default 1] Number of periods (or increments) to shift by, can be positive or negative.
- **freq** [pandas.DateOffset, pandas.Timedelta or str, optional] Frequency increment to shift by. If None, the index is shifted by its own freq attribute. Offset aliases are valid strings, e.g., ‘D’, ‘W’, ‘M’ etc.

**Returns**

pandas.Index  Shifted index.

**See also:**

Series.shift  Shift values of Series.

**Notes**

This method is only implemented for datetime-like index classes, i.e., DatetimeIndex, PeriodIndex and TimedeltaIndex.

**Examples**

Put the first 5 month starts of 2011 into an index.

```python
>>> month_starts = pd.date_range('1/1/2011', periods=5, freq='MS')
>>> month_starts
dtype='datetime64[ns]', freq='MS')
```

Shift the index by 10 days.
pandas: powerful Python data analysis toolkit, Release 1.1.1

```
>>> month_starts.shift(10, freq='D')
               '2011-05-11'],
             dtype='datetime64[ns]', freq=None)
```

The default value of `freq` is the `freq` attribute of the index, which is ‘MS’ (month start) in this example.

```
>>> month_starts.shift(10)
DatetimeIndex(['2011-11-01', '2011-12-01', '2012-01-01', '2012-02-01',
               '2012-03-01'],
             dtype='datetime64[ns]', freq='MS')
```

**pandas.Index.slice_indexer**

`Index.slice_indexer(start=None, end=None, step=None, kind=None)`  
Compute the slice indexer for input labels and step.

Index needs to be ordered and unique.

**Parameters**

- **start** [label, default None] If None, defaults to the beginning.
- **end** [label, default None] If None, defaults to the end.
- **step** [int, default None]
- **kind** [str, default None]

**Returns**

- **indexer** [slice]

**Raises**

- **KeyError** [If key does not exist, or key is not unique and index is] not ordered.

**Notes**

This function assumes that the data is sorted, so use at your own peril

**Examples**

This is a method on all index types. For example you can do:

```
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_indexer(start='b', end='c')
slice(1, 3, None)
```

```
>>> idx = pd.MultiIndex.from_arrays([list('abcd'), list('efgh')])
>>> idx.slice_indexer(start='b', end=('c', 'g'))
slice(1, 3, None)
```
pandas.Index.slice_locs

Index.slice_locs(start=None, end=None, step=None, kind=None)
Compute slice locations for input labels.

Parameters

- start [label, default None] If None, defaults to the beginning.
- end [label, default None] If None, defaults to the end.
- step [int, defaults None] If None, defaults to 1.
- kind [['loc', 'getitem'] or None]

Returns

- start, end [int]

See also:

Index.get_loc Get location for a single label.

Notes

This method only works if the index is monotonic or unique.

Examples

```python
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_locs(start='b', end='c')
(1, 3)
```

pandas.Index.sort

Index.sort(*args, **kwargs)
Use sort_values instead.

pandas.Index.sort_values

Index.sort_values(return_indexer=False, ascending=True, key=None)
Return a sorted copy of the index.

Return a sorted copy of the index, and optionally return the indices that sorted the index itself.

Parameters

- return_indexer [bool, default False] Should the indices that would sort the index be returned.
- ascending [bool, default True] Should the index values be sorted in an ascending order.
- key [callable, optional] If not None, apply the key function to the index values before sorting. This is similar to the key argument in the builtin sorted() function, with the notable difference that this key function should be vectorized. It should expect an Index and return an Index of the same shape.
New in version 1.1.0.

Returns

- **sorted_index** [pandas.Index] Sorted copy of the index.
- **indexer** [numpy.ndarray, optional] The indices that the index itself was sorted by.

See also:

- **Series.sort_values** Sort values of a Series.
- **DataFrame.sort_values** Sort values in a DataFrame.

 Examples

```python
>>> idx = pd.Index([10, 100, 1, 1000])
>>> idx
Int64Index([10, 100, 1, 1000], dtype='int64')
```

Sort values in ascending order (default behavior).

```python
>>> idx.sort_values()
Int64Index([1, 10, 100, 1000], dtype='int64')
```

Sort values in descending order, and also get the indices `idx` was sorted by.

```python
>>> idx.sort_values(ascending=False, return_indexer=True)
(Int64Index([1000, 100, 10, 1], dtype='int64'), array([3, 1, 0, 2]))
```

**pandas.Index.sortlevel**

Index.sortlevel(`level=None`, `ascending=True`, `sort_remaining=None`)

For internal compatibility with with the Index API.

Sort the Index. This is for compat with MultiIndex

**Parameters**

- **ascending** [bool, default True] False to sort in descending order

**Returns**

- **Index**

**pandas.Index.str**

Index.str()

Vectorized string functions for Series and Index.

NAs stay NA unless handled otherwise by a particular method. Patterned after Python’s string methods, with some inspiration from R’s stringr package.
Examples

```python
>>> s = pd.Series(["A_Str_Series"]) >>> s
0  A_Str_Series
dtype: object

0  [A, Str, Series]
dtype: object

0  AStrSeries
dtype: object
```

`pandas.Index.symmetric_difference`

`Index.symmetric_difference(other, result_name=None, sort=None)`

Compute the symmetric difference of two Index objects.

**Parameters**

- `other` [Index or array-like]
- `result_name` [str]
- `sort` [False or None, default None] Whether to sort the resulting index. By default, the values are attempted to be sorted, but any TypeError from incomparable elements is caught by pandas.
  - None : Attempt to sort the result, but catch any TypeErrors from comparing incomparable elements.
  - False : Do not sort the result.

New in version 0.24.0.

Changed in version 0.24.1: Changed the default value from True to None (without change in behaviour).

**Returns**

- `symmetric_difference` [Index]

**Notes**

`symmetric_difference` contains elements that appear in either `idx1` or `idx2` but not both. Equivalent to the Index created by `idx1.difference(idx2) | idx2.difference(idx1)` with duplicates dropped.
Examples

```python
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([2, 3, 4, 5])
>>> idx1.symmetric_difference(idx2)
Int64Index([1, 5], dtype='int64')
```

You can also use the `^` operator:

```python
>>> idx1 ^ idx2
Int64Index([1, 5], dtype='int64')
```

**pandas.Index.take**

`Index.take(indices, axis=0, allow_fill=True, fill_value=None, **kwargs)`

Return a new Index of the values selected by the indices.

For internal compatibility with numpy arrays.

**Parameters**

- `indices` [list] Indices to be taken.
- `axis` [int, optional] The axis over which to select values, always 0.
- `allow_fill` [bool, default True]
- `fill_value` [bool, default None] If allow_fill=True and fill_value is not None, indices specified by -1 is regarded as NA. If Index doesn’t hold NA, raise ValueError.

**Returns**

- `numpy.ndarray` Elements of given indices.

**See also:**

- `numpy.ndarray.take`

**pandas.Index.to_flat_index**

`Index.to_flat_index()`

Identity method.

New in version 0.24.0.

This is implemented for compatibility with subclass implementations when chaining.

**Returns**

- `pd.Index` Caller.

**See also:**

- `MultiIndex.to_flat_index` Subclass implementation.
pandas.Index.to_frame

Index.to_frame(index=True, name=None)
Create a DataFrame with a column containing the Index.
New in version 0.24.0.

Parameters

index [bool, default True] Set the index of the returned DataFrame as the original Index.

name [object, default None] The passed name should substitute for the index name (if it has one).

Returns

DataFrame DataFrame containing the original Index data.

See also:

Index.to_series Convert an Index to a Series.
Series.to_frame Convert Series to DataFrame.

Examples

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
   animal
animal  Ant
    Bear
   Cow
```

By default, the original Index is reused. To enforce a new Index:

```python
>>> idx.to_frame(index=False)
   animal
0    Ant
1    Bear
2     Cow
```

To override the name of the resulting column, specify name:

```python
>>> idx.to_frame(index=False, name='zoo')
   zoo
0    Ant
1    Bear
2     Cow
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.Index.to_list

Index.to_list()  
Return a list of the values.  
These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)  
Returns  
list  
See also:  

numpy.ndarray.tolist  Return the array as an a.ndim-levels deep nested list of Python scalars.

pandas.Index.to_native_types

Index.to_native_types(slicer=None, **kwargs)  
Format specified values of self and return them.  
Parameters  

slicer [int, array-like] An indexer into self that specifies which values are used in the formatting process.  

kwargs [dict] Options for specifying how the values should be formatted. These options include the following:  
1) na_rep [str] The value that serves as a placeholder for NULL values  
2) quoting [bool or None] Whether or not there are quoted values in self  
3) date_format [str] The format used to represent date-like values.  
Returns  

numpy.ndarray  Formatted values.

pandas.Index.to_numpy

Index.to_numpy(dtype=None, copy=False, na_value=<object object>, **kwargs)  
A NumPy ndarray representing the values in this Series or Index.  
New in version 0.24.0.  
Parameters  

dtype [str or numpy.dtype, optional] The dtype to pass to numpy.asarray().  

copy [bool, default False] Whether to ensure that the returned value is not a view on another array. Note that copy=False does not ensure that to_numpy() is no-copy. Rather, copy=True ensure that a copy is made, even if not strictly necessary.  

na_value [Any, optional] The value to use for missing values. The default value depends on dtype and the type of the array.  
New in version 1.0.0.
**kwargs Additional keywords passed through to the to_numpy method of the underlying array (for extension arrays).

New in version 1.0.0.

**Returns**
	numpy.ndarray

**See also:**

*Series.array* Get the actual data stored within.

*Index.array* Get the actual data stored within.

*DataFrame.to_numpy* Similar method for DataFrame.

**Notes**

The returned array will be the same up to equality (values equal in self will be equal in the returned array; likewise for values that are not equal). When self contains an ExtensionArray, the dtype may be different. For example, for a category-dtype Series, to_numpy() will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming copy=False). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, to_numpy() may require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, Series.array should be used instead.

This table lays out the different dtypes and default return types of to_numpy() for various dtypes within pandas.

<table>
<thead>
<tr>
<th>dtype</th>
<th>array type</th>
</tr>
</thead>
<tbody>
<tr>
<td>category[T]</td>
<td>ndarray[T] (same dtype as input)</td>
</tr>
<tr>
<td>period</td>
<td>ndarray[object] (Periods)</td>
</tr>
<tr>
<td>interval</td>
<td>ndarray[object] (Intervals)</td>
</tr>
<tr>
<td>IntegerNA</td>
<td>ndarray[object]</td>
</tr>
<tr>
<td>datetime64[ns]</td>
<td>datetime64[ns]</td>
</tr>
<tr>
<td>datetime64[ns, tz]</td>
<td>ndarray[object] (Timestamps)</td>
</tr>
</tbody>
</table>

**Examples**

```python
gpd.Series(pd.Categorical(['a', 'b', 'a']))
```

```python
gpd.Series(pd.Categorical(['a', 'b', 'a'], dtype=object))
```

Specify the *dtype* to control how datetime-aware data is represented. Use dtype=object to return an ndarray of pandas Timestamp objects, each with the correct tz.

```python
gpd.Series(pd.date_range('2000', periods=2, tz='CET'))
```

```
gpd.Series(pd.date_range('2000', periods=2, tz='CET'), dtype=object)
```

---

3.7. Index objects 1947
Or dtype='datetime64[ns]' to return an ndarray of native datetime64 values. The values are converted to UTC and the timezone info is dropped.

```python
>>> ser.to_numpy(dtype="datetime64[ns]"
... array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00...',
   dtype='datetime64[ns]')
```

### pandas.Index.to_series

Index.to_series(index=None, name=None)

Create a Series with both index and values equal to the index keys.

Useful with map for returning an indexer based on an index.

**Parameters**

- **index** [Index, optional] Index of resulting Series. If None, defaults to original index.
- **name** [str, optional] Name of resulting Series. If None, defaults to name of original index.

**Returns**

Series The dtype will be based on the type of the Index values.

**See also:**

- Index.to_frame Convert an Index to a DataFrame.
- Series.to_frame Convert Series to DataFrame.

**Examples**

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
```

By default, the original Index and original name is reused.

```python
>>> idx.to_series()
animal
Ant  Ant
Bear  Bear
Cow  Cow
Name: animal, dtype: object
```

To enforce a new Index, specify new labels to `index`:

```python
>>> idx.to_series(index=[0, 1, 2])
0   Ant
1   Bear
2   Cow
Name: animal, dtype: object
```

To override the name of the resulting column, specify `name`:
```python
>>> idx.to_series(name='zoo')
animal        
Ant    Ant
Bear   Bear
Cow    Cow
Name: zoo, dtype: object
```

### pandas.Index.tolist

**Index.tolist()**

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:

- `numpy.ndarray.tolist` Return the array as an a.ndim-levels deep nested list of Python scalars.

### pandas.Index.transpose

**Index.transpose(*args, **kwargs)**

Return the transpose, which is by definition self.

Returns

%(klass)s

### pandas.Index.union

**Index.union(other, sort=None)**

Form the union of two Index objects.

If the Index objects are incompatible, both Index objects will be cast to dtype('object') first.

Changed in version 0.25.0.

**Parameters**

- `other` [Index or array-like]
- `sort` [bool or None, default None] Whether to sort the resulting Index.

  - None : Sort the result, except when
    1. `self` and `other` are equal.
    2. `self` or `other` has length 0.
    3. Some values in `self` or `other` cannot be compared. A RuntimeWarning is issued in this case.
  - False : do not sort the result.
New in version 0.24.0.

Changed in version 0.24.1: Changed the default value from `True` to `None` (without change in behaviour).

**Returns**

```
union [Index]
```

**Examples**

**Union matching dtypes**

```python
g = pd.Index([1, 2, 3, 4])
g.union(h)
```

```
Int64Index([1, 2, 3, 4, 5, 6], dtype='int64')
```

**Union mismatched dtypes**

```python
g = pd.Index([1, 2, 3, 4])
g.union(h)
```

```
Index(['a', 'b', 'c', 'd', 1, 2, 3, 4], dtype='object')
```

**pandas.Index.unique**

```
Index.unique (level=None)
```

Return unique values in the index.

Unique values are returned in order of appearance, this does NOT sort.

**Parameters**

```
level [int or str, optional, default None] Only return values from specified level (for MultiIndex).
```

New in version 0.23.0.

**Returns**

```
Index without duplicates
```

**See also:**

```
unique
Series.unique
```
Index.objects 1951

pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.Index.value_counts

Index.value_counts(normalize=False, sort=True, ascending=False, bins=None, dropna=True)

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

Parameters

- **normalize** [bool, default False] If True then the object returned will contain the relative frequencies of the unique values.
- **sort** [bool, default True] Sort by frequencies.
- **ascending** [bool, default False] Sort in ascending order.
- **bins** [int, optional] Rather than count values, group them into half-open bins, a convenience for pd.cut, only works with numeric data.
- **dropna** [bool, default True] Don’t include counts of NaN.

Returns

Series

See also:

- **Series.count** Number of non-NA elements in a Series.
- **DataFrame.count** Number of non-NA elements in a DataFrame.
- **DataFrame.value_counts** Equivalent method on DataFrames.

Examples

```python
>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0  2
4.0  1
2.0  1
1.0  1
dtype: int64
```

With normalize set to True, returns the relative frequency by dividing all values by the sum of values.

```python
>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0  0.4
4.0  0.2
2.0  0.2
1.0  0.2
dtype: float64
```

**bins**

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.
pandas: powerful Python data analysis toolkit, Release 1.1.1

```python
>>> s.value_counts(bins=3)
(2.0, 3.0]  2
(0.996, 2.0]  2
(3.0, 4.0]  1
dtype: int64
```

```python
dropna

With `dropna` set to `False` we can also see NaN index values.
```
```python
>>> s.value_counts(dropna=False)
3.0  2
NaN  1
4.0  1
2.0  1
1.0  1
dtype: int64
```

### pandas.Index.where

`Index.where`(cond, other=None)

Replace values where the condition is False.

The replacement is taken from other.

**Parameters**

- **cond** [bool array-like with the same length as self] Condition to select the values on.
- **other** [scalar, or array-like, default None] Replacement if the condition is False.

**Returns**

- **pandas.Index** A copy of self with values replaced from other where the condition is False.

**See also:**

- **Series.where** Same method for Series.
- **DataFrame.where** Same method for DataFrame.

**Examples**

```python
>>> idx = pd.Index(['car', 'bike', 'train', 'tractor'])
>>> idx
Index(['car', 'bike', 'train', 'tractor'], dtype='object')
>>> idx.where(idx.isin(['car', 'train']), 'other')
Index(['car', 'other', 'train', 'other'], dtype='object')
```
Properties

- **Index.values**: Return an array representing the data in the Index.
- **Index.is_monotonic**: Alias for `is_monotonic_increasing`.
- **Index.is_monotonic_increasing**: Return if the index is monotonic increasing (only equal or increasing) values.
- **Index.is_monotonic_decreasing**: Return if the index is monotonic decreasing (only equal or decreasing) values.
- **Index.is_unique**: Return if the index has unique values.
- **Index.has_duplicates**: Check if the Index has duplicate values.
- **Index.hasnans**: Return if I have any nans; enables various perf speedups.
- **Index.dtype**: Return the dtype object of the underlying data.
- **Index.inferred_type**: Return a string of the type inferred from the values.
- **Index.is_all_dates**: Whether or not the index values only consist of dates.
- **Index.shape**: Return a tuple of the shape of the underlying data.
- **Index.name**: Return Index or MultiIndex name.
- **Index.names**: Property
- **Index.nbytes**: Return the number of bytes in the underlying data.
- **Index.ndim**: Number of dimensions of the underlying data, by definition 1.
- **Index.size**: Return the number of elements in the underlying data.
- **Index.empty**: Property
- **Index.T**: Return the transpose, which is by definition self.
- **Index.memory_usage**(*deep*)**: Memory usage of the values.

**pandas.Index.names**

**property Index.names**

**pandas.Index.empty**

**property Index.empty**

Modifying and computations

- **Index.all(**args, **kwargs)**: Return whether all elements are True.
- **Index.any(**args, **kwargs)**: Return whether any element is True.
- **Index.argmin(axis, skipna)**: Return int position of the smallest value in the Series.
- **Index.argmax(axis, skipna)**: Return int position of the largest value in the Series.
- **Index.copy(, deep, dtype, names)**: Make a copy of this object.
- **Index.delete(loc)**: Make new Index with passed location(-s) deleted.
- **Index.drop(labels[, errors])**: Make new Index with passed list of labels deleted.
- **Index.drop_duplicates(keep)**: Return Index with duplicate values removed.
- **Index.duplicated(keep)**: Indicate duplicate index values.
- **Index.equals(other)**: Determine if two Index object are equal.
- **Index.factorize(sort, na_sentinel)**: Encode the object as an enumerated type or categorical variable.

3.7.2 Numeric Index

`RangeIndex([start, stop, step, dtype, copy, ...])` Immutable Index implementing a monotonic integer range.

`Int64Index([data, dtype, copy, name])` Immutable ndarray implementing an ordered, sliceable set.

`UInt64Index([data, dtype, copy, name])` Immutable ndarray implementing an ordered, sliceable set.

`Float64Index([data, dtype, copy, name])` Immutable ndarray implementing an ordered, sliceable set.

**pandas.RangeIndex**

**class** `pandas.RangeIndex(start=None, stop=None, step=None, dtype=None, copy=False, name=None)`

Immutable Index implementing a monotonic integer range.

RangeIndex is a memory-saving special case of Int64Index limited to representing monotonic ranges. Using RangeIndex may in some instances improve computing speed.

This is the default index type used by DataFrame and Series when no explicit index is provided by the user.

**Parameters**

- `start` [int (default: 0), or other RangeIndex instance] If int and “stop” is not given, interpreted as “stop” instead.
- `stop` [int (default: 0)]
- `step` [int (default: 1)]
- `name` [object, optional] Name to be stored in the index.
- `copy` [bool, default False] Unused, accepted for homogeneity with other index types.

**See also:**

- `Index` The base pandas Index type.
- `Int64Index` Index of int64 data.
## Attributes

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>start</code></td>
<td>The value of the <code>start</code> parameter (0 if this was not supplied).</td>
</tr>
<tr>
<td><code>stop</code></td>
<td>The value of the <code>stop</code> parameter.</td>
</tr>
<tr>
<td><code>step</code></td>
<td>The value of the <code>step</code> parameter (1 if this was not supplied).</td>
</tr>
</tbody>
</table>

### pandas.RangeIndex.start

RangeIndex.`start`

The value of the `start` parameter (0 if this was not supplied).

### pandas.RangeIndex.stop

RangeIndex.`stop`

The value of the `stop` parameter.

### pandas.RangeIndex.step

RangeIndex.`step`

The value of the `step` parameter (1 if this was not supplied).

## Methods

### from_range(data[, name, dtype])

Create RangeIndex from a range object.

### pandas.RangeIndex.from_range

**classmethod** RangeIndex.`from_range`(data, name=None, dtype=None)

Create RangeIndex from a range object.

**Returns**

RangeIndex

## pandas.Int64Index

**class** pandas.`Int64Index`(data=None, dtype=None, copy=False, name=None)

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects. Int64Index is a special case of `Index` with purely integer labels.

**Parameters**

- **data** [array-like (1-dimensional)]
- **dtype** [NumPy dtype (default: int64)]
- **copy** [bool] Make a copy of input ndarray.

3.7. Index objects
**name** [object] Name to be stored in the index.

**See also:**

*Index* The base pandas Index type.

**Notes**

An Index instance can only contain hashable objects.

**Attributes**

None

**Methods**

None

---

**pandas.UInt64Index**

**class** pandas.*UInt64Index*(data=None, dtype=None, copy=False, name=None)

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects. UInt64Index is a special case of Index with purely unsigned integer labels.

**Parameters**

- **data** [array-like (1-dimensional)]
- **dtype** [NumPy dtype (default: uint64)]
- **copy** [bool] Make a copy of input ndarray.
- **name** [object] Name to be stored in the index.

**See also:**

*Index* The base pandas Index type.

**Notes**

An Index instance can only contain hashable objects.

**Attributes**

None
pandas: powerful Python data analysis toolkit, Release 1.1.1

Methods

None

pandas.Float64Index

class pandas.Float64Index(data=None, dtype=None, copy=False, name=None)

Immutable ndarray implementing an ordered, sliceable set. The basic object storing axis labels for all pandas objects. Float64Index is a special case of Index with purely float labels.

Parameters

- data [array-like (1-dimensional)]
- dtype [NumPy dtype (default: float64)]
- copy [bool] Make a copy of input ndarray.
- name [object] Name to be stored in the index.

See also:

Index The base pandas Index type.

Notes

An Index instance can only contain hashable objects.

</tbody>
</table>
3.7.3 CategoricalIndex

CategoricalIndex([data, categories, ...])  
Index based on an underlying Categorical.

pandas.CategoricalIndex

class pandas.CategoricalIndex(data=None, categories=None, ordered=None, dtype=None, copy=False, name=None)

Index based on an underlying Categorical.

CategoricalIndex, like Categorical, can only take on a limited, and usually fixed, number of possible values (categories). Also, like Categorical, it might have an order, but numerical operations (additions, divisions, ...) are not possible.

Parameters

- **data** [array-like (1-dimensional)] The values of the categorical. If categories are given, values not in categories will be replaced with NaN.

- **categories** [index-like, optional] The categories for the categorical. Items need to be unique.
  
  If the categories are not given here (and also not in dtype), they will be inferred from the data.

- **ordered** [bool, optional] Whether or not this categorical is treated as an ordered categorical.
  
  If not given here or in dtype, the resulting categorical will be unordered.

- **dtype** [CategoricalDtype or “category”, optional] If CategoricalDtype, cannot be used together with categories or ordered.

- **copy** [bool, default False] Make a copy of input ndarray.

- **name** [object, optional] Name to be stored in the index.

Raises

- **ValueError** If the categories do not validate.

- **TypeError** If an explicit ordered=True is given but no categories and the values are not sortable.

See also:

- **Index** The base pandas Index type.

- **Categorical** A categorical array.

- **CategoricalDtype** Type for categorical data.

Notes

See the user guide for more.
Examples

>>> pd.CategoricalIndex(["a", "b", "c", "a", "b", "c"])
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], categories=['a', 'b', 'c'], ordered=False, dtype='category')

CategoricalIndex can also be instantiated from a Categorical:

>>> c = pd.Categorical(["a", "b", "c", "a", "b", "c"])
>>> pd.CategoricalIndex(c)
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], categories=['a', 'b', 'c'], ordered=False, dtype='category')

Ordered CategoricalIndex can have a min and max value.

>>> ci = pd.CategoricalIndex(
...     ["a", "b", "c", "a", "b", "c"], ordered=True, categories=['c', 'b', 'a']
... )
>>> ci
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], categories=['c', 'b', 'a'], ordered=True, dtype='category')
>>> ci.min()
'c'

Attributes

<table>
<thead>
<tr>
<th>codes</th>
<th>The category codes of this categorical.</th>
</tr>
</thead>
<tbody>
<tr>
<td>categories</td>
<td>The categories of this categorical.</td>
</tr>
<tr>
<td>ordered</td>
<td>Whether the categories have an ordered relationship.</td>
</tr>
</tbody>
</table>

pandas.CategoricalIndex.codes

property CategoricalIndex.codes

The category codes of this categorical.

Codes are an array of integers which are the positions of the actual values in the categories array.

There is no setter, use the other categorical methods and the normal item setter to change values in the categorical.

Returns

    ndarray[int] A non-writable view of the codes array.
pandas.CategoricalIndex.categories

**property** CategoricalIndex.categories
The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).
The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.
Assigning to categories is an in-place operation!

**Raises**

* ValueError: If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

**See also:**
- rename_categories Rename categories.
- reorder_categories Reorder categories.
- add_categories Add new categories.
- remove_categories Remove the specified categories.
- remove_unused_categories Remove categories which are not used.
- set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.ordered

**property** CategoricalIndex.ordered
Whether the categories have an ordered relationship.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rename_categories(*args, **kwags)</td>
<td>Rename categories.</td>
</tr>
<tr>
<td>reorder_categories(*args, **kwags)</td>
<td>Reorder categories as specified in new_categories.</td>
</tr>
<tr>
<td>add_categories(*args, **kwags)</td>
<td>Add new categories.</td>
</tr>
<tr>
<td>remove_categories(*args, **kwags)</td>
<td>Remove the specified categories.</td>
</tr>
<tr>
<td>remove_unused_categories(*args, **kwags)</td>
<td>Remove categories which are not used.</td>
</tr>
<tr>
<td>set_categories(*args, **kwags)</td>
<td>Set the categories to the specified new_categories.</td>
</tr>
<tr>
<td>as_ordered(*args, **kwags)</td>
<td>Set the Categorical to be ordered.</td>
</tr>
<tr>
<td>as_unordered(*args, **kwags)</td>
<td>Set the Categorical to be unordered.</td>
</tr>
<tr>
<td>map(mapper)</td>
<td>Map values using input correspondence (a dict, Series, or function).</td>
</tr>
</tbody>
</table>
pandas.CategoricalIndex.rename_categories

CategoricalIndex.rename_categories(*args, **kwargs)

Rename categories.

Parameters

new_categories [list-like, dict-like or callable] New categories which will replace old categories.

- list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
- dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.
- callable: a callable that is called on all items in the old categories and whose return values comprise the new categories.

New in version 0.23.0.

inplace [bool, default False] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

Returns

cat [Categorical or None] With inplace=False, the new categorical is returned. With inplace=True, there is no return value.

Raises

ValueError If new categories are list-like and do not have the same number of items as the current categories or do not validate as categories

See also:

reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

Examples

>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]

For dict-like new_categories, extra keys are ignored and categories not in the dictionary are passed through

>>> c.rename_categories({'a': 'A', 'c': 'C'})
['A', 'A', 'b']
Categories (2, object): ['A', 'b']

3.7. Index objects
You may also provide a callable to create the new categories

```python
>>> c.rename_categories(lambda x: x.upper())
['A', 'A', 'B']
Categories (2, object): ['A', 'B']
```

**pandas.CategoricalIndex.reorder_categories**

CategoricalIndex.reorder_categories (*args, **kwargs)

Reorder categories as specified in new_categories.

new_categories need to include all old categories and no new category items.

**Parameters**

- **new_categories** [Index-like] The categories in new order.
- **ordered** [bool, optional] Whether or not the categorical is treated as an ordered categorical. If not given, do not change the ordered information.
- **inplace** [bool, default False] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

**Returns**

- **cat** [Categorical with reordered categories or None if inplace.]

**Raises**

ValueError If the new categories do not contain all old category items or any new ones

**See also:**

- rename_categories Rename categories.
- add_categories Add new categories.
- remove_categories Remove the specified categories.
- remove_unused_categories Remove categories which are not used.
- set_categories Set the categories to the specified ones.

**pandas.CategoricalIndex.add_categories**

CategoricalIndex.add_categories (*args, **kwargs)

Add new categories.

new_categories will be included at the last/highest place in the categories and will be unused directly after this call.

**Parameters**

- **new_categories** [category or list-like of category] The new categories to be included.
- **inplace** [bool, default False] Whether or not to add the categories inplace or return a copy of this categorical with added categories.

**Returns**

- **cat** [Categorical with new categories added or None if inplace.]
Raises

* ValueError If the new categories include old categories or do not validate as categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.remove_categories

CategoricalIndex.remove_categories(*args, **kwargs)
Remove the specified categories.

removals must be included in the old categories. Values which were in the removed categories will be set to NaN

Parameters

removals [category or list of categories] The categories which should be removed.
inplace [bool, default False] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

Returns

cat [Categorical with removed categories or None if inplace.]

Raises

* ValueError If the removals are not contained in the categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.remove_unused_categories

CategoricalIndex.remove_unused_categories(*args, **kwargs)
Remove categories which are not used.

Parameters

inplace [bool, default False] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

Returns

3.7. Index objects
cat  [Categorical with unused categories dropped or None if inplace.]

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.set_categories

CategoricalIndex.set_categories(*args, **kwargs)
Set the categories to the specified new_categories.

new_categories can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If rename=True, the categories will simply be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this method does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes, which does not considers a S1 string equal to a single char python string.

Parameters

new_categories  [Index-like] The categories in new order.
ordered  [bool, default False] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.
rename  [bool, default False] Whether or not the new_categories should be considered as a rename of the old categories or as reordered categories.
inplace  [bool, default False] Whether or not to reorder the categories in-place or return a copy of this categorical with reordered categories.

Returns

Categorical with reordered categories or None if inplace.

Raises

ValueError  If new_categories does not validate as categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.
pandas.CategoricalIndex.as_ordered

CategoricalIndex.as_ordered(*args, **kwargs)
Set the Categorical to be ordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to True.

Returns

Categorical Ordered Categorical.

pandas.CategoricalIndex.as_unordered

CategoricalIndex.as_unordered(*args, **kwargs)
Set the Categorical to be unordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to False.

Returns

Categorical Unordered Categorical.

pandas.CategoricalIndex.map

CategoricalIndex.map(mapper)
Map values using input correspondence (a dict, Series, or function).

Maps the values (their categories, not the codes) of the index to new categories. If the mapping correspondence is one-to-one the result is a CategoricalIndex which has the same order property as the original, otherwise an Index is returned.

If a dict or Series is used any unmapped category is mapped to NaN. Note that if this happens an Index will be returned.

Parameters

mapper [function, dict, or Series] Mapping correspondence.

Returns

pandas.CategoricalIndex or pandas.Index Mapped index.

See also:

Index.map Apply a mapping correspondence on an Index.
Series.map Apply a mapping correspondence on a Series.
Series.apply Apply more complex functions on a Series.
Examples

```python
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'])
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'], ordered=False, dtype='category')
>>> idx.map(lambda x: x.upper())
CategoricalIndex(['A', 'B', 'C'], categories=['A', 'B', 'C'], ordered=False, dtype='category')
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'third'})
CategoricalIndex(['first', 'second', 'third'], categories=['first', 'second', 'third'], ordered=False, dtype='category')
```

If the mapping is one-to-one the ordering of the categories is preserved:

```python
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'], ordered=True)
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'], ordered=True, dtype='category')
>>> idx.map({'a': 3, 'b': 2, 'c': 1})
CategoricalIndex([3, 2, 1], categories=[3, 2, 1], ordered=True, dtype='category')
```

If the mapping is not one-to-one an `Index` is returned:

```python
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'first'})
Index(['first', 'second', 'first'], dtype='object')
```

If a `dict` is used, all unmapped categories are mapped to `NaN` and the result is an `Index`:

```python
>>> idx.map({'a': 'first', 'b': 'second'})
Index(['first', 'second', nan], dtype='object')
```

Set the Categorical to be unordered.

Modifying and computations

*CategoricalIndex.map(mapper)*
Map values using input correspondence (a dict, Series, or function).

*CategoricalIndex.equals(other)*
Determine if two CategoricalIndex objects contain the same elements.

**pandas.CategoricalIndex.equals**

*CategoricalIndex.equals(other)*
Determine if two CategoricalIndex objects contain the same elements.

**Returns**

*bool* If two CategoricalIndex objects have equal elements True, otherwise False.

3.7.4 IntervalIndex

*IntervalIndex*(data[, closed, dtype, copy, ...])
Immutable index of intervals that are closed on the same side.

**pandas.IntervalIndex**

**class pandas.IntervalIndex**(data, closed=None, dtype=None, copy=False, name=None, verify_integrity=True)
Immutable index of intervals that are closed on the same side.

New in version 0.23.0.

**Parameters**

* data [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalIndex.

* closed [[‘left’, ‘right’, ‘both’, ‘neither’], default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.

* dtype [dtype or None, default None] If None, dtype will be inferred.

* copy [bool, default False] Copy the input data.

* name [object, optional] Name to be stored in the index.

* verify_integrity [bool, default True] Verify that the IntervalIndex is valid.

**See also:**

*Index* The base pandas Index type.

*Interval* A bounded slice-like interval; the elements of an IntervalIndex.

*interval_range* Function to create a fixed frequency IntervalIndex.
**cut** Bin values into discrete Intervals.
**qcut** Bin values into equal-sized Intervals based on rank or sample quantiles.

**Notes**

See the user guide for more.

**Examples**

A new `IntervalIndex` is typically constructed using `interval_range()`:

```python
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
closed='right',
dtype='interval[int64]')
```

It may also be constructed using one of the constructor methods: `IntervalIndex.from_arrays()`, `IntervalIndex.from_breaks()`, and `IntervalIndex.from_tuples()`.

See further examples in the doc strings of `interval_range` and the mentioned constructor methods.

**Attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>left</code></td>
<td>Return the left endpoints of each Interval in the IntervalArray as an Index.</td>
</tr>
<tr>
<td><code>right</code></td>
<td>Return the right endpoints of each Interval in the IntervalArray as an Index.</td>
</tr>
<tr>
<td><code>closed</code></td>
<td>Whether the intervals are closed on the left-side, right-side, both or neither.</td>
</tr>
<tr>
<td><code>mid</code></td>
<td>Return the midpoint of each Interval in the IntervalArray as an Index.</td>
</tr>
<tr>
<td><code>length</code></td>
<td>Return an Index with entries denoting the length of each Interval in the IntervalArray.</td>
</tr>
<tr>
<td><code>is_empty</code></td>
<td>Indicates if an interval is empty, meaning it contains no points.</td>
</tr>
<tr>
<td><code>is_non_overlapping_monotonic</code></td>
<td>Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.</td>
</tr>
<tr>
<td><code>is_overlapping</code></td>
<td>Return True if the IntervalIndex has overlapping intervals, else False.</td>
</tr>
<tr>
<td><code>values</code></td>
<td>Return the IntervalIndex’s data as an IntervalArray.</td>
</tr>
</tbody>
</table>
**pandas.IntervalIndex.left**

**property IntervalIndex.left**

Return the left endpoints of each Interval in the IntervalArray as an Index.

**pandas.IntervalIndex.right**

**property IntervalIndex.right**

Return the right endpoints of each Interval in the IntervalArray as an Index.

**pandas.IntervalIndex.closed**

IntervalIndex.closed

Whether the intervals are closed on the left-side, right-side, both or neither.

**pandas.IntervalIndex.mid**

IntervalIndex.mid

Return the midpoint of each Interval in the IntervalArray as an Index.

**pandas.IntervalIndex.length**

**property IntervalIndex.length**

Return an Index with entries denoting the length of each Interval in the IntervalArray.

**pandas.IntervalIndex.is_empty**

IntervalIndex.is_empty

Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

**Returns**

bool or ndarray A boolean indicating if a scalar Interval is empty, or a boolean ndarray positionally indicating if an Interval in an IntervalArray or IntervalIndex is empty.

**Examples**

An Interval that contains points is not empty:

```python
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:
An Interval that contains a single point is not empty:

```python
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An IntervalArray or IntervalIndex returns a boolean ndarray positionally indicating if an Interval is empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'),
         ...        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```

**pandas.IntervalIndex.is_non_overlapping_monotonic**

IntervalIndex.is_non_overlapping_monotonic
Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.

**pandas.IntervalIndex.is_overlapping**

property IntervalIndex.is_overlapping
Return True if the IntervalIndex has overlapping intervals, else False.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

Returns

- bool  Boolean indicating if the IntervalIndex has overlapping intervals.

See also:

- Interval.overlaps Check whether two Interval objects overlap.
- IntervalIndex.overlaps Check an IntervalIndex elementwise for overlaps.
Examples

```python
>>> index = pd.IntervalIndex.from_tuples([(0, 2), (1, 3), (4, 5)])
>>> index
IntervalIndex([(0, 2], (1, 3], (4, 5]],
            closed='right',
            dtype='interval[int64]')
>>> index.is_overlapping
True

Intervals that share closed endpoints overlap:

```python
>>> index = pd.interval_range(0, 3, closed='both')
>>> index
IntervalIndex([[0, 1], [1, 2], [2, 3]],
               closed='both',
               dtype='interval[int64]')
>>> index.is_overlapping
True

Intervals that only have an open endpoint in common do not overlap:

```python
>>> index = pd.interval_range(0, 3, closed='left')
>>> index
IntervalIndex([[0, 1), [1, 2), [2, 3)),
               closed='left',
               dtype='interval[int64]')
>>> index.is_overlapping
False
```

**pandas.IntervalIndex.values**

IntervalIndex.values

Return the IntervalIndex’s data as an IntervalArray.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>from_arrays</td>
<td>Construct from two arrays defining the left and right bounds.</td>
</tr>
<tr>
<td>from_tuples</td>
<td>Construct an IntervalIndex from an array-like of tuples.</td>
</tr>
<tr>
<td>from_breaks</td>
<td>Construct an IntervalIndex from an array of splits.</td>
</tr>
<tr>
<td>contains</td>
<td>Check elementwise if the Intervals contain the value.</td>
</tr>
<tr>
<td>overlaps</td>
<td>Check elementwise if an Interval overlaps the values in the IntervalArray.</td>
</tr>
<tr>
<td>set_closed</td>
<td>Return an IntervalArray identical to the current one, but closed on the specified side.</td>
</tr>
<tr>
<td>to_tuples</td>
<td>Return an ndarray of tuples of the form (left, right).</td>
</tr>
</tbody>
</table>
**pandas.IntervalIndex.from_arrays**

**classmethod** IntervalIndex.from_arrays(left, right, closed='right', name=None, copy=False, dtype=None)

Construct from two arrays defining the left and right bounds.

**Parameters**

- **left** [array-like (1-dimensional)] Left bounds for each interval.
- **right** [array-like (1-dimensional)] Right bounds for each interval.
- **closed** [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.
- **copy** [bool, default False] Copy the data.
- **dtype** [dtype, optional] If None, dtype will be inferred.

**Returns**

IntervalIndex

**Raises**

ValueError When a value is missing in only one of left or right. When a value in left is greater than the corresponding value in right.

**See also:**

- `interval_range` Function to create a fixed frequency IntervalIndex.
- IntervalIndex.from_breaks Construct an IntervalIndex from an array of splits.
- IntervalIndex.from_tuples Construct an IntervalIndex from an array-like of tuples.

**Notes**

Each element of left must be less than or equal to the right element at the same position. If an element is missing, it must be missing in both left and right. A TypeError is raised when using an unsupported type for left or right. At the moment, ‘category’, ‘object’, and ‘string’ subtypes are not supported.

**Examples**

```python
>>> pd.IntervalIndex.from_arrays([0, 1, 2], [1, 2, 3])
IntervalIndex([(0, 1], (1, 2], (2, 3]],
closed='right',
dtype='interval[int64]')
```
pandas.IntervalIndex.from_tuples

classmethod IntervalIndex.from_tuples(data, closed='right', name=None, copy=False, dtype=None)

Construct an IntervalIndex from an array-like of tuples.

Parameters

data [array-like (1-dimensional)] Array of tuples.
closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.
copy [bool, default False] By-default copy the data, this is compat only and ignored.
dtype [dtype or None, default None] If None, dtype will be inferred.

Returns

IntervalIndex

See also:

interval_range Function to create a fixed frequency IntervalIndex.
IntervalIndex.from_arrays Construct an IntervalIndex from a left and right array.
IntervalIndex.from_breaks Construct an IntervalIndex from an array of splits.

Examples

```python
>>> pd.IntervalIndex.from_tuples([(0, 1), (1, 2)])
IntervalIndex([(0, 1], (1, 2]),
closed='right',
dtype='interval[int64]')
```

pandas.IntervalIndex.from_breaks

classmethod IntervalIndex.from_breaks(breaks, closed='right', name=None, copy=False, dtype=None)

Construct an IntervalIndex from an array of splits.

Parameters

breaks [array-like (1-dimensional)] Left and right bounds for each interval.
closed [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.
copy [bool, default False] Copy the data.
dtype [dtype or None, default None] If None, dtype will be inferred.

Returns

IntervalIndex

See also:
**interval_range** Function to create a fixed frequency IntervalIndex.

**IntervalIndex.from_arrays** Construct from a left and right array.

**IntervalIndex.from_tuples** Construct from a sequence of tuples.

**Examples**

```python
>>> pd.IntervalIndex.from_breaks([0, 1, 2, 3])
IntervalIndex([(0, 1], (1, 2], (2, 3]],
closed='right',
dtype='interval[int64]')
```

**pandas.IntervalIndex.contains**

IntervalIndex.contains(*args, **kwargs)
Check elementwise if the Intervals contain the value.

Return a boolean mask whether the value is contained in the Intervals of the IntervalArray.

New in version 0.25.0.

**Parameters**

other [scalar] The value to check whether it is contained in the Intervals.

**Returns**

boolean array

**See also:**

Interval.contains Check whether Interval object contains value.

IntervalArray.overlaps Check if an Interval overlaps the values in the IntervalArray.

**Examples**

```python
>>> intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]]
Length: 3, closed: right, dtype: interval[int64]

>>> intervals.contains(0.5)
array([ True, False, False])
```
### pandas.IntervalIndex.overlaps

**IntervalIndex.overlaps(*args, **kwargs)**

Check elementwise if an Interval overlaps the values in the IntervalArray.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

New in version 0.24.0.

**Parameters**

- **other** [IntervalArray] Interval to check against for an overlap.

**Returns**

- **ndarray** Boolean array positionally indicating where an overlap occurs.

**See also:**

Interval.overlaps Check whether two Interval objects overlap.

**Examples**

```python
>>> data = [(0, 1), (1, 3), (2, 4)]
>>> intervals = pd.arrays.IntervalArray.from_tuples(data)
>>> intervals
 IntervalArray
[(0, 1], (1, 3], (2, 4]
Length: 3, closed: right, dtype: interval[int64]

>>> intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True,  True, False])

Intervals that share closed endpoints overlap:

```python
>>> intervals.overlaps(pd.Interval(1, 3, closed='left'))
array([ True,  True, True])
```  
Intervals that only have an open endpoint in common do not overlap:

```python
>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False,  True, False])
```  
### pandas.IntervalIndex.set_closed

**IntervalIndex.set_closed(*args, **kwargs)**

Return an IntervalArray identical to the current one, but closed on the specified side.

New in version 0.24.0.

**Parameters**

- **closed** [{’left’, ’right’, ’both’, ’neither’}] Whether the intervals are closed on the left-side, right-side, both or neither.

**Returns**
**Examples**

```python
>>> index = pd.arrays.IntervalArray.from_breaks(range(4))
>>> index
<IntervalArray>
[(0, 1], (1, 2], (2, 3]]
Length: 3, closed: right, dtype: interval[int64]

```

### pandas.IntervalIndex.to_tuples

`IntervalIndex.to_tuples(*args, **kwargs)`

Return an ndarray of tuples of the form (left, right).

**Parameters**

- `na_tuple` [bool, default True] Returns NA as a tuple if True, (nan, nan), or just as the NA value itself if False, nan.
  
  New in version 0.23.0.

**Returns**

- `tuples`: ndarray

</thead>
</table>

continues on next page
IntervalIndex.is_non_overlapping_monotonic
Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.

IntervalIndex.is_overlapping
Return True if the IntervalIndex has overlapping intervals, else False.

IntervalIndex.get_loc(key[, method, tolerance])
Get integer location, slice or boolean mask for requested label.

IntervalIndex.get_indexer(target[, method, ...])
Compute indexer and mask for new index given the current index.

IntervalIndex.set_closed(*args, **kwargs)
Return an IntervalArray identical to the current one, but closed on the specified side.

IntervalIndex.contains(*args, **kwargs)
Check elementwise if the Intervals contain the value.

IntervalIndex.overlaps(*args, **kwargs)
Check elementwise if an Interval overlaps the values in the IntervalArray.

IntervalIndex.to_tuples(*args, **kwargs)
Return an ndarray of tuples of the form (left, right).

### pandas.IntervalIndex.get_loc

**IntervalIndex.get_loc(key, method=None, tolerance=None)**
Get integer location, slice or boolean mask for requested label.

**Parameters**

- **key** [label]
- **method** [{None}, optional]
  - default: matches where the label is within an interval only.

**Returns**

- int if unique index, slice if monotonic index, else mask

**Examples**

```python
>>> i1, i2 = pd.Interval(0, 1), pd.Interval(1, 2)
>>> index = pd.IntervalIndex([i1, i2])
>>> index.get_loc(1)
0
```

You can also supply a point inside an interval.

```python
>>> index.get_loc(1.5)
1
```

If a label is in several intervals, you get the locations of all the relevant intervals.

```python
>>> i3 = pd.Interval(0, 2)
>>> overlapping_index = pd.IntervalIndex([i1, i2, i3])
>>> overlapping_index.get_loc(0.5)
array([ True, False,  True])
```

Only exact matches will be returned if an interval is provided.
>>> index.get_loc(pd.Interval(0, 1))
0

pandas.IntervalIndex.get_indexer

IntervalIndex.get_indexer(target, method=None, limit=None, tolerance=None)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

Parameters

- **target** [IntervalIndex or list of Intervals]
- **method** [[None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'], optional]
  - default: exact matches only.
  - pad / ffill: find the PREVIOUS index value if no exact match.
  - backfill / bfill: use NEXT index value if no exact match
  - nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
- **limit** [int, optional] Maximum number of consecutive labels in target to match for inexact matches.
- **tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation abs(index[indexer] - target) <= tolerance.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

Returns

- **indexer** [ndarray of int] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

Raises

- **NotImplementedError** If any method argument other than the default of None is specified as these are not yet implemented.

Examples

```python
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1, 2, -1])
```

Notice that the return value is an array of locations in index and x is marked by -1, as it is not in index.
### 3.7.5 MultiIndex

| MultiIndex(levels, codes, sortorder, ...) | A multi-level, or hierarchical, index object for pandas objects. |

**pandas.MultiIndex**

```python
class pandas.MultiIndex(levels=None, codes=None, sortorder=None, names=None, dtype=None, copy=False, name=None, verify_integrity=True, _set_identity=True)
```

A multi-level, or hierarchical, index object for pandas objects.

**Parameters**

- **levels** [sequence of arrays] The unique labels for each level.
- **codes** [sequence of arrays] Integers for each level designating which label at each location.
  - New in version 0.24.0.
- **sortorder** [optional int] Level of sortedness (must be lexicographically sorted by that level).
- **names** [optional sequence of objects] Names for each of the index levels. (name is accepted for compat).
- **copy** [bool, default False] Copy the meta-data.
- **verify_integrity** [bool, default True] Check that the levels/codes are consistent and valid.

**See also:**

- `MultiIndex.from_arrays` Convert list of arrays to MultiIndex.
- `MultiIndex.from_product` Create a MultiIndex from the cartesian product of iterables.
- `MultiIndex.from_tuples` Convert list of tuples to a MultiIndex.
- `MultiIndex.from_frame` Make a MultiIndex from a DataFrame.
- `Index` The base pandas Index type.

**Notes**

See the user guide for more.

**Examples**

A new `MultiIndex` is typically constructed using one of the helper methods `MultiIndex.from_arrays()`, `MultiIndex.from_product()` and `MultiIndex.from_tuples()`. For example (using `from_arrays`):

```python
>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex([(1, 'red'),
            (1, 'blue'),
            (2, 'red'),
            (2, 'blue')], names=['number', 'color'])
```

See further examples for how to construct a MultiIndex in the doc strings of the mentioned helper methods.
pandas: powerful Python data analysis toolkit, Release 1.1.1

Attributes

<table>
<thead>
<tr>
<th>names</th>
<th>Names of levels in MultiIndex.</th>
</tr>
</thead>
<tbody>
<tr>
<td>nlevels</td>
<td>Integer number of levels in this MultiIndex.</td>
</tr>
<tr>
<td>levshape</td>
<td>A tuple with the length of each level.</td>
</tr>
</tbody>
</table>

pandas.MultiIndex.names

property MultiIndex.names
Names of levels in MultiIndex.

pandas.MultiIndex.nlevels

property MultiIndex.nlevels
Integer number of levels in this MultiIndex.

pandas.MultiIndex.levshape

property MultiIndex.levshape
A tuple with the length of each level.

<table>
<thead>
<tr>
<th>levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>codes</td>
</tr>
</tbody>
</table>

Methods

from_arrays(arrays[, sortorder, names]) Convert arrays to MultiIndex.

from_tuples(tuples[, sortorder, names]) Convert list of tuples to MultiIndex.

from_product(iterables[, sortorder, names]) Make a MultiIndex from the cartesian product of multiple iterables.

from_frame(df[, sortorder, names]) Make a MultiIndex from a DataFrame.

set_levels(levels[, level, inplace, ...]) Set new levels on MultiIndex.

set_codes(codes[, level, inplace, ...]) Set new codes on MultiIndex.

to_frame([index, name]) Create a DataFrame with the levels of the MultiIndex as columns.

to_flat_index() Convert a MultiIndex to an Index of Tuples containing the level values.

is_lexsorted() Return True if the codes are lexicographically sorted.

sortlevel([level, ascending, sort_remaining]) Sort MultiIndex at the requested level.

droplevel([level]) Return index with requested level(s) removed.

swaplevel([i, j]) Swap level i with level j.

reorder_levels(order) Rearrange levels using input order.

remove_unused_levels() Create new MultiIndex from current that removes unused levels.

get_locs(seq) Get location for a sequence of labels.
pandas.MultiIndex.from_arrays

classmethod  MultiIndex.from_arrays(arrays, sortorder=None, names=<object object>)
Convert arrays to MultiIndex.

Parameters
arrays  [list / sequence of array-likes] Each array-like gives one level’s value for each
data point. len(arrays) is the number of levels.

sortorder  [int or None] Level of sortedness (must be lexicographically sorted by that
level).

names  [list / sequence of str, optional] Names for the levels in the index.

Returns
MultiIndex

See also:

MultiIndex.from_tuples  Convert list of tuples to MultiIndex.
MultiIndex.from_product  Make a MultiIndex from cartesian product of iterables.
MultiIndex.from_frame  Make a MultiIndex from a DataFrame.

Examples

```python
>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex([(1, 'red'),
           (1, 'blue'),
           (2, 'red'),
           (2, 'blue')],
          names=['number', 'color'])
```

pandas.MultiIndex.from_tuples

classmethod  MultiIndex.from_tuples(tuples, sortorder=None, names=None)
Convert list of tuples to MultiIndex.

Parameters
tuples  [list / sequence of tuple-likes] Each tuple is the index of one row/column.

sortorder  [int or None] Level of sortedness (must be lexicographically sorted by that
level).

names  [list / sequence of str, optional] Names for the levels in the index.

Returns
MultiIndex

See also:

MultiIndex.from_arrays  Convert list of arrays to MultiIndex.
MultiIndex.from_product  Make a MultiIndex from cartesian product of iterables.
**MultiIndex.from_frame** Make a MultiIndex from a DataFrame.

**Examples**

```python
>>> tuples = [(1, 'red'), (1, 'blue'),
...            (2, 'red'), (2, 'blue')]
>>> pd.MultiIndex.from_tuples(tuples, names=('number', 'color'))
MultiIndex([(1, 'red'),
            (1, 'blue'),
            (2, 'red'),
            (2, 'blue')],
           names=['number', 'color'])
```

**pandas.MultiIndex.from_product**

**classmethod** MultiIndex.from_product(*iterables*, sortorder=None, names=<object object>)

Make a MultiIndex from the cartesian product of multiple iterables.

**Parameters**

- **iterables** [list / sequence of iterables] Each iterable has unique labels for each level of the index.
- **sortorder** [int or None] Level of sortedness (must be lexicographically sorted by that level).
- **names** [list / sequence of str, optional] Names for the levels in the index.

Changed in version 1.0.0: If not explicitly provided, names will be inferred from the elements of iterables if an element has a name attribute

**Returns**

MultiIndex

**See also:**

**MultiIndex.from_arrays** Convert list of arrays to MultiIndex.

**MultiIndex.from_tuples** Convert list of tuples to MultiIndex.

**MultiIndex.from_frame** Make a MultiIndex from a DataFrame.

**Examples**

```python
>>> numbers = [0, 1, 2]
>>> colors = ['green', 'purple']
>>> pd.MultiIndex.from_product([numbers, colors],
                             names=['number', 'color'])
MultiIndex([(0, 'green'),
            (0, 'purple'),
            (1, 'green'),
            (1, 'purple'),
            (2, 'green'),
            (2, 'purple')],
           names=['number', 'color'])
```
pandas.MultiIndex.from_frame

**classmethod**  

`MultiIndex.from_frame(df, sortorder=None, names=None)`  
Make a MultiIndex from a DataFrame.  
New in version 0.24.0.

**Parameters**

- `df` [DataFrame] DataFrame to be converted to MultiIndex.
- `sortorder` [int, optional] Level of sortedness (must be lexicographically sorted by that level).
- `names` [list-like, optional] If no names are provided, use the column names, or tuple of column names if the columns is a MultiIndex. If a sequence, overwrite names with the given sequence.

**Returns**

`MultiIndex` The MultiIndex representation of the given DataFrame.

**See also:**

- `MultiIndex.from_arrays` Convert list of arrays to MultiIndex.
- `MultiIndex.from_tuples` Convert list of tuples to MultiIndex.
- `MultiIndex.from_product` Make a MultiIndex from cartesian product of iterables.

**Examples**

```python
>>> df = pd.DataFrame([[['HI', 'Temp'], ['HI', 'Precip']],
                    [['NJ', 'Temp'], ['NJ', 'Precip']],
                    columns=['a', 'b'])
>>> df
   a    b
0  HI  Temp
1  HI  Precip
2  NJ  Temp
3  NJ  Precip
```

```python
>>> pd.MultiIndex.from_frame(df)
MultiIndex([('HI', 'Temp'),
            ('HI', 'Precip'),
            ('NJ', 'Temp'),
            ('NJ', 'Precip')],
           names=['a', 'b'])
```

Using explicit names, instead of the column names

```python
>>> pd.MultiIndex.from_frame(df, names=['state', 'observation'])
MultiIndex([('HI', 'Temp'),
            ('HI', 'Precip'),
            ('NJ', 'Temp'),
            ('NJ', 'Precip')],
           names=['state', 'observation'])
```
pandas.MultiIndex.set_levels

```
MultiIndex.set_levels(levels, level=None, inplace=False, verify_integrity=True)
```

Set new levels on MultiIndex. Defaults to returning new index.

**Parameters**

- `levels` [sequence or list of sequence] New level(s) to apply.
- `level` [int, level name, or sequence of int/level names (default None)] Level(s) to set (None for all levels).
- `inplace` [bool] If True, mutates in place.
- `verify_integrity` [bool, default True] If True, checks that levels and codes are compatible.

**Returns**

- new index (of same type and class...etc)

**Examples**

```python
>>> idx = pd.MultiIndex.from_tuples(
...     [(1, "one"),
...      (1, "two"),
...      (2, "one"),
...      (2, "two"),
...      (3, "one"),
...      (3, "two")],
...     names=['foo', 'bar'])
```

```python
>>> idx.set_levels([['a', 'b', 'c'], [1, 2]])
```

```python
>>> idx.set_levels([['a', 'b', 'c'], [1, 2]], level=0)
```

(continues on next page)
names=['foo', 'bar'])
>>> idx.set_levels([['a', 'b'], [1, 2, 3, 4]], level=[0, 1])
MultiIndex([['a', 'b', 'c'], [1, 2, 3, 4]], level=[0, 1])
>>> idx.set_levels([['a', 'b', 'c'], [1, 2, 3, 4]], level=[0, 1]).levels
FrozenList([['a', 'b', 'c'], [1, 2, 3, 4]])

pandas.MultiIndex.set_codes

MultiIndex.set_codes(codes, level=None, inplace=False, verify_integrity=True)

Set new codes on MultiIndex. Defaults to returning new index.

New in version 0.24.0: New name for deprecated method set_labels.

Parameters

codes [sequence or list of sequence] New codes to apply.

level [int, level name, or sequence of int/level names (default None)] Level(s) to set (None for all levels).

inplace [bool] If True, mutates in place.

verify_integrity [bool (default True)] If True, checks that levels and codes are compatible.

Returns

new index (of same type and class... etc)
Examples

```python
>>> idx = pd.MultiIndex.from_tuples(
...     [(1, "one"), (1, "two"), (2, "one"), (2, "two")], names=["foo", "bar"]
... )
>>> idx
MultiIndex([(1, 'one'),
             (1, 'two'),
             (2, 'one'),
             (2, 'two')],
            names=['foo', 'bar'])
```

```python
>>> idx.set_codes([[1, 0, 1, 0], [0, 0, 1, 1]])
MultiIndex([(2, 'one'),
             (1, 'two'),
             (2, 'one'),
             (1, 'two')],
            names=['foo', 'bar'])
```

```python
>>> idx.set_codes([1, 0, 1, 0], level=0)
MultiIndex([(2, 'one'),
             (1, 'two'),
             (2, 'one'),
             (1, 'two')],
            names=['foo', 'bar'])
```

```python
>>> idx.set_codes([0, 0, 1, 1], level='bar')
MultiIndex([(1, 'one'),
             (1, 'one'),
             (2, 'two'),
             (2, 'two')],
            names=['foo', 'bar'])
```

```python
>>> idx.set_codes([[1, 0, 1, 0], [0, 0, 1, 1]], level=[0, 1])
MultiIndex([(2, 'one'),
             (1, 'one'),
             (2, 'two'),
             (1, 'two')],
            names=['foo', 'bar'])
```

**pandas.MultiIndex.to_frame**

`MultiIndex.to_frame(index=True, name=None)`

Create a DataFrame with the levels of the MultiIndex as columns.

Column ordering is determined by the DataFrame constructor with data as a dict.

New in version 0.24.0.

**Parameters**

- `index` [bool, default True] Set the index of the returned DataFrame as the original MultiIndex.
- `name` [list / sequence of str, optional] The passed names should substitute index level names.

**Returns**

- `DataFrame` [a DataFrame containing the original MultiIndex data.]
See also:

DataFrame Two-dimensional, size-mutable, potentially heterogeneous tabular data.

pandas.MultiIndex.to_flat_index

MultiIndex.to_flat_index()
Convert a MultiIndex to an Index of Tuples containing the level values.
New in version 0.24.0.

Returns

pd.Index Index with the MultiIndex data represented in Tuples.

Notes

This method will simply return the caller if called by anything other than a MultiIndex.

Examples

```python
>>> index = pd.MultiIndex.from_product(
...     [['foo', 'bar'], ['baz', 'qux']],
...     names=['a', 'b'])
>>> index.to_flat_index()
Index([('foo', 'baz'), ('foo', 'qux'),
     ('bar', 'baz'), ('bar', 'qux')],
     dtype='object')
```

pandas.MultiIndex.is_lexsorted

MultiIndex.is_lexsorted()
Return True if the codes are lexicographically sorted.

Returns

bool

Examples

In the below examples, the first level of the MultiIndex is sorted because a<b<c, so there is no need to look at the next level.

```python
>>> pd.MultiIndex.from_arrays([['a', 'b', 'c'], ['d', 'e', 'f']]).is_lexsorted()
True
>>> pd.MultiIndex.from_arrays([['a', 'b', 'c'], ['d', 'f', 'e']]).is_lexsorted()
True
```

In case there is a tie, the lexicographical sorting looks at the next level of the MultiIndex.
>>> pd.MultiIndex.from_arrays([[0, 1, 1], ['a', 'b', 'c']]).is_lexsorted()
True
>>> pd.MultiIndex.from_arrays([[0, 1, 1], ['a', 'c', 'b']]).is_lexsorted()
False
>>> pd.MultiIndex.from_arrays([['a', 'a', 'b', 'b'], ['aa', 'aa', 'bb', 'bb']]).is_lexsorted()
True
>>> pd.MultiIndex.from_arrays([['a', 'a', 'b', 'b'], ['bb', 'aa', 'aa', 'bb']]).is_lexsorted()
False

pandas.MultiIndex.sortlevel

MultiIndex.sortlevel(level=0, ascending=True, sort_remaining=True)
Sort MultiIndex at the requested level.

The result will respect the original ordering of the associated factor at that level.

Parameters

- **level** [list-like, int or str, default 0] If a string is given, must be a name of the level. If list-like must be names or ints of levels.
- **ascending** [bool, default True] False to sort in descending order. Can also be a list to specify a directed ordering.
- **sort_remaining** [sort by the remaining levels after level]

Returns

- **sorted_index** [pd.MultiIndex] Resulting index.
- **indexer** [np.ndarray] Indices of output values in original index.

pandas.MultiIndex.droplevel

MultiIndex.droplevel(level=0)
Return index with requested level(s) removed.

If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

New in version 0.23.1: (support for non-MultiIndex)

Parameters

- **level** [int, str, or list-like, default 0] If a string is given, must be the name of a level If list-like, elements must be names or indexes of levels.

Returns

- **Index or MultiIndex**
pandas.MultiIndex.swaplevel

MultiIndex.swaplevel(i=-2, j=-1)

Swap level i with level j.

Calling this method does not change the ordering of the values.

Parameters

- **i** [int, str, default -2] First level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.
- **j** [int, str, default -1] Second level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.

Returns

- **MultiIndex** A new MultiIndex.

See also:

Series.swaplevel Swap levels i and j in a MultiIndex.

DataFrame.swaplevel Swap levels i and j in a MultiIndex on a particular axis.

Examples

```python
>>> mi = pd.MultiIndex(levels=[['a', 'b'], ['bb', 'aa']],
                     codes=[[0, 0, 1, 1], [0, 1, 0, 1]])
>>> mi
MultiIndex([('a', 'bb'),
            ('a', 'aa'),
            ('b', 'bb'),
            ('b', 'aa')],
           )
>>> mi.swaplevel(0, 1)
MultiIndex([('bb', 'a'),
            ('aa', 'a'),
            ('bb', 'b'),
            ('aa', 'b')],
           )
```

pandas.MultiIndex.reorder_levels

MultiIndex.reorder_levels(order)

Rearrange levels using input order. May not drop or duplicate levels.

Parameters

- **order** [list of int or list of str] List representing new level order. Reference level by number (position) or by key (label).

Returns

- **MultiIndex**
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.MultiIndex.remove_unused_levels

MultiIndex.remove_unused_levels()
Create new MultiIndex from current that removes unused levels.
Unused level(s) means levels that are not expressed in the labels. The resulting MultiIndex will have the
same outward appearance, meaning the same .values and ordering. It will also be .equals() to the original.

Returns
MultiIndex

Examples

```python
>>> mi = pd.MultiIndex.from_product([range(2), list('ab')]
>>> mi
MultiIndex([(0, 'a'),
            (0, 'b'),
            (1, 'a'),
            (1, 'b')],
           )

>>> mi[2:]
MultiIndex([(l, 'a'),
            (l, 'b')],
           )

The 0 from the first level is not represented and can be removed

>>> mi2 = mi[2:].remove_unused_levels()
>>> mi2.levels
FrozenList([[[1], ['a', 'b']]])
```

pandas.MultiIndex.get_locs

MultiIndex.get_locs(seq)
Get location for a sequence of labels.

Parameters

seq [label, slice, list, mask or a sequence of such] You should use one of the above for
each level. If a level should not be used, set it to slice(None).

Returns
numpy.ndarray NumPy array of integers suitable for passing to iloc.

See also:

MultiIndex.get_loc Get location for a label or a tuple of labels.
MultiIndex.slice_locs Get slice location given start label(s) and end label(s).
Examples

```python
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')])

>>> mi.get_locs('b')
array([1, 2], dtype=int64)

>>> mi.get_locs([slice(None), ['e', 'f']])
array([1, 2], dtype=int64)

>>> mi.get_locs([[True, False, True], slice('e', 'f')])
array([2], dtype=int64)
```

IndexSlice
Create an object to more easily perform multi-index slicing.

```python
pandas.IndexSlice
pandas.IndexSlice = <pandas.core.indexing._IndexSlice object>
Create an object to more easily perform multi-index slicing.

See also:

```
MultiIndex.remove_unused_levels
```
New MultiIndex with no unused levels.

Notes

See Defined Levels for further info on slicing a MultiIndex.

Examples

```python
>>> midx = pd.MultiIndex.from_product([['A0','A1'], ['B0','B1','B2','B3']])
>>> columns = ['foo', 'bar']
>>> dfmi = pd.DataFrame(np.arange(16).reshape((len(midx), len(columns))),
                      index=midx, columns=columns)

Using the default slice command:

```python
>>> dfmi.loc[(slice(None), slice('B0', 'B1')), :]
   foo  bar
A0  B0   0  1
  B1  2  3
A1  B0   8  9
  B1 10 11
```

Using the IndexSlice class for a more intuitive command:

```python
>>> idx = pd.IndexSlice
>>> dfmi.loc[idx[:, 'B0':'B1'], :]
   foo  bar
A0  B0   0  1
  B1  2  3
```

</tbody>
</table>

pandas.MultiIndex.get_loc

MultiIndex.get_loc(key, method=None)

Get location for a label or a tuple of labels.

The location is returned as an integer/slice or boolean mask.

Parameters

- **key** [label or tuple of labels (one for each level)]
- **method** [None]

Returns

- **loc** [int, slice object or boolean mask] If the key is past the lexsort depth, the return may be a boolean mask array, otherwise it is always a slice or int.

See also:

- Index.get_loc The get_loc method for (single-level) index.
- MultiIndex.slice_locs Get slice location given start label(s) and end label(s).
- MultiIndex.get_locs Get location for a label/slice/list/mask or a sequence of such.

Notes

The key cannot be a slice, list of same-level labels, a boolean mask, or a sequence of such. If you want to use those, use MultiIndex.get_locs() instead.

Examples

```python
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')])

>>> mi.get_loc('b')
slice(1, 3, None)

>>> mi.get_loc(('b', 'e'))
1
```
pandas.MultiIndex.get_loc_level

**MultiIndex.get_loc_level** *(key, level=0, drop_level=True)*
Get location and sliced index for requested label(s)/level(s).

**Parameters**
- **key** [label or sequence of labels]
- **level** [int/level name or list thereof, optional]
- **drop_level** [bool, default True] If False, the resulting index will not drop any level.

**Returns**
- **loc** [A 2-tuple where the elements are:] Element 0: int, slice object or boolean array Element 1: The resulting sliced multiindex/index. If the key contains all levels, this will be None.

**See also:**
- **MultiIndex.get_loc** Get location for a label or a tuple of labels.
- **MultiIndex.get_locs** Get location for a label/slice/list/mask or a sequence of such.

**Examples**

```python
>>> mi = pd.MultiIndex.from_arrays([[list('abb'), list('def')],
                                  ...
                                  names=['A', 'B'])

>>> mi.get_loc_level('b')
(slice(1, 3, None), Index(['e', 'f'], dtype='object', name='B'))

>>> mi.get_loc_level('e', level='B')
(array([False, True, False]), Index(['b'], dtype='object', name='A'))

>>> mi.get_loc_level(['b', 'e'])
(1, None)
```

pandas.MultiIndex.get_indexer

**MultiIndex.get_indexer** *(target, method=None, limit=None, tolerance=None)*
Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

**Parameters**
- **target** [MultiIndex or list of tuples]
- **method** [{None, 'pad'/'ffill', 'backfill'/'bfill', 'nearest'}, optional]
  - default: exact matches only.
  - pad / ffill: find the PREVIOUS index value if no exact match.
  - backfill / bfill: use NEXT index value if no exact match
  - nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
limit [int, optional] Maximum number of consecutive labels in target to match for inexact matches.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation
abs(index[indexer] - target) <= tolerance.

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

Returns

indexer [ndarray of int] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

Examples

```python
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1, 2, -1])
```

Notice that the return value is an array of locations in index and x is marked by -1, as it is not in index.

pandas.MultiIndex.get_level_values

MultiIndex.get_level_values(level)

Return vector of label values for requested level.

Length of returned vector is equal to the length of the index.

Parameters

level [int or str] level is either the integer position of the level in the MultiIndex, or the name of the level.

Returns

values [Index] Values is a level of this MultiIndex converted to a single Index (or subclass thereof).

Examples

Create a MultiIndex:

```python
>>> mi = pd.MultiIndex.from_arrays((list('abc'), list('def')))
>>> mi.names = ['level_1', 'level_2']
```

Get level values by supplying level as either integer or name:

```python
>>> mi.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object', name='level_1')
>>> mi.get_level_values('level_2')
Index(['d', 'e', 'f'], dtype='object', name='level_2')
```
3.7.6 DatetimeIndex

DatetimeIndex([data, freq, tz, normalize, ...])  
Immutable ndarray-like of datetime64 data.

pandas.DatetimeIndex

class pandas.DatetimeIndex(data=None, freq=<object object>, tz=None, normalize=False, closed=None, ambiguous='raise', dayfirst=False, yearfirst=False, dtype=None, copy=False, name=None)

Immutable ndarray-like of datetime64 data.

Represented internally as int64, and which can be boxed to Timestamp objects that are subclasses of datetime and carry metadata.

Parameters

data [array-like (1-dimensional), optional] Optional datetime-like data to construct index with.

freq [str or pandas offset object, optional] One of pandas date offset strings or corresponding objects. The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation.

tz [pytz.timezone or dateutil.tz.tzfile or datetime.tzinfo or str] Set the Timezone of the data.

normalize [bool, default False] Normalize start/end dates to midnight before generating date range.

closed [[‘left’, ‘right’], optional] Set whether to include start and end that are on the boundary. The default includes boundary points on either end.

ambiguous [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the ambiguous parameter dictates how ambiguous times should be handled.

• ‘infer’ will attempt to infer fall dst-transition hours based on order
• bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
• ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

dayfirst [bool, default False] If True, parse dates in data with the day first order.

yearfirst [bool, default False] If True parse dates in data with the year first order.

dtype [numpy.dtype or DatetimeTZDtype or str, default None] Note that the only NumPy dtype allowed is ‘datetime64[ns]’.

copy [bool, default False] Make a copy of input ndarray.

name [label, default None] Name to be stored in the index.

See also:

Index The base pandas Index type.
TimedeltaIndex Index of timedelta64 data.
PeriodIndex Index of Period data.
to_datetime Convert argument to datetime.
**date_range** Create a fixed-frequency DatetimeIndex.

**Notes**

To learn more about the frequency strings, please see this link.

</tbody>
</table>
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.DatetimeIndex.year

**property** DatetimeIndex.year
The year of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(
    ...     pd.date_range("2000-01-01", periods=3, freq="Y")
    ... )
>>> datetime_series
0 2000-12-31
1 2001-12-31
2 2002-12-31
dtype: datetime64[ns]
>>> datetime_series.dt.year
0 2000
1 2001
2 2002
dtype: int64
```

pandas.DatetimeIndex.month

**property** DatetimeIndex.month
The month as January=1, December=12.

**Examples**

```python
>>> datetime_series = pd.Series(
    ...     pd.date_range("2000-01-01", periods=3, freq="M")
    ... )
>>> datetime_series
0 2000-01-31
1 2000-02-29
2 2000-03-31
dtype: datetime64[ns]
>>> datetime_series.dt.month
0 1
1 2
2 3
dtype: int64
```
pandas.DatetimeIndex.day

**property** DatetimeIndex.day
The day of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="D")
... )
>>> datetime_series
0 2000-01-01
1 2000-01-02
2 2000-01-03
dtype: datetime64[ns]
>>> datetime_series.dt.day
0 1
1 2
2 3
dtype: int64
```

pandas.DatetimeIndex.hour

**property** DatetimeIndex.hour
The hours of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="h")
... )
>>> datetime_series
0 2000-01-01 00:00:00
1 2000-01-01 01:00:00
2 2000-01-01 02:00:00
dtype: datetime64[ns]
>>> datetime_series.dt.hour
0 0
1 1
2 2
dtype: int64
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.DatetimeIndex.minute

**property** DatetimeIndex.minute
The minutes of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(
...   ...   pd.date_range("2000-01-01", periods=3, freq="T")
... )
>>> datetime_series
datetime_series
dtype: datetime64[ns]
>>> datetime_series.dt.minute
0 0
1 1
2 2
dtype: int64
```

pandas.DatetimeIndex.second

**property** DatetimeIndex.second
The seconds of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(
...   ...   pd.date_range("2000-01-01", periods=3, freq="s")
... )
>>> datetime_series
datetime_series
dtype: datetime64[ns]
>>> datetime_series.dt.second
0 0
1 1
2 2
dtype: int64
```
pandas.DatetimeIndex.microsecond

property DatetimeIndex.microsecond
The microseconds of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...    pd.date_range("2000-01-01", periods=3, freq="us")
... )
>>> datetime_series
0 2000-01-01 00:00:00.000000
1 2000-01-01 00:00:00.000001
2 2000-01-01 00:00:00.000002
dtype: datetime64[ns]
>>> datetime_series.dt.microsecond
0 0
1 1
2 2
dtype: int64
```

pandas.DatetimeIndex.nanosecond

property DatetimeIndex.nanosecond
The nanoseconds of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...    pd.date_range("2000-01-01", periods=3, freq="ns")
... )
>>> datetime_series
0 2000-01-01 00:00:00.000000000
1 2000-01-01 00:00:00.000000001
2 2000-01-01 00:00:00.000000002
dtype: datetime64[ns]
>>> datetime_series.dt.nanosecond
0 0
1 1
2 2
dtype: int64
```
`pandas.DatetimeIndex.date`

**property** `DatetimeIndex.date`  
Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).

`pandas.DatetimeIndex.time`

**property** `DatetimeIndex.time`  
Returns numpy array of datetime.time. The time part of the Timestamps.

`pandas.DatetimeIndex.timetz`

**property** `DatetimeIndex.timetz`  
Returns numpy array of datetime.time also containing timezone information. The time part of the Timestamps.

`pandas.DatetimeIndex.dayofyear`

**property** `DatetimeIndex.dayofyear`  
The ordinal day of the year.

`pandas.DatetimeIndex.weekofyear`

**property** `DatetimeIndex.weekofyear`  
The week ordinal of the year.  
Deprecated since version 1.1.0.  
weekofyear and week have been deprecated. Please use DatetimeIndex.isocalendar().week instead.

`pandas.DatetimeIndex.week`

**property** `DatetimeIndex.week`  
The week ordinal of the year.  
Deprecated since version 1.1.0.  
weekofyear and week have been deprecated. Please use DatetimeIndex.isocalendar().week instead.

`pandas.DatetimeIndex.dayofweek`

**property** `DatetimeIndex.dayofweek`  
The day of the week with Monday=0, Sunday=6.  
Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the `dt` accessor) or DatetimeIndex.
Series or Index  Containing integers indicating the day number.

See also:

Series.dt.dayofweek  Alias.
Series.dt.weekday  Alias.
Series.dt.day_name  Returns the name of the day of the week.

Examples

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31  5
2017-01-01  6
2017-01-02  0
2017-01-03  1
2017-01-04  2
2017-01-05  3
2017-01-06  4
2017-01-07  5
2017-01-08  6
Freq: D, dtype: int64
```

pandas.DatetimeIndex.weekday

property DatetimeIndex.weekday
The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the dt accessor) or DatetimeIndex.

Returns

Series or Index  Containing integers indicating the day number.

See also:

Series.dt.dayofweek  Alias.
Series.dt.weekday  Alias.
Series.dt.day_name  Returns the name of the day of the week.

Examples

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31  5
2017-01-01  6
2017-01-02  0
2017-01-03  1
2017-01-04  2
2017-01-05  3
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.DatetimeIndex.quarter

**property**  
DatetimeIndex.quarter

The quarter of the date.

pandas.DatetimeIndex.tz

**property**  
DatetimeIndex.tz

Return timezone, if any.

Returns

- `datetime.tzinfo`, `pytz.tzinfo.BaseTZInfo`, `dateutil.tz.tzfile`, or `None`  
  Returns `None` when the array is tz-naive.

pandas.DatetimeIndex.freq

**property**  
DatetimeIndex.freq

Return the frequency object if it is set, otherwise None.

pandas.DatetimeIndex.freqstr

**property**  
DatetimeIndex.freqstr

Return the frequency object as a string if its set, otherwise None.

pandas.DatetimeIndex.is_month_start

**property**  
DatetimeIndex.is_month_start

Indicates whether the date is the first day of the month.

Returns

- Series or array  
  For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

**See also:**

- `is_month_start`  
  Return a boolean indicating whether the date is the first day of the month.

- `is_month_end`  
  Return a boolean indicating whether the date is the last day of the month.
Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```python
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0 2018-02-27
1 2018-02-28
2 2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0 False
1 False
2 True
dtype: bool
>>> s.dt.is_month_end
0 False
1 True
2 False
dtype: bool
```

```python
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```

### pandas.DatetimeIndex.is_month_end

**property** DatetimeIndex.is_month_end

Indicates whether the date is the last day of the month.

**Returns**

- **Series or array** For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

**See also:**

- is_month_start Return a boolean indicating whether the date is the first day of the month.
- is_month_end Return a boolean indicating whether the date is the last day of the month.

**Examples**

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```python
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0 2018-02-27
1 2018-02-28
2 2018-03-01
dtype: datetime64[ns]
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

(continued from previous page)

```python
>>> s.dt.is_month_start
0   False
1   False
2    True
dtype: bool
>>> s.dt.is_month_end
0   False
1    True
2   False
dtype: bool
```

```python
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```

pandas.DatetimeIndex.is_quarter_start

**property** DatetimeIndex.is_quarter_start

Indicator for whether the date is the first day of a quarter.

**Returns**

is_quarter_start [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

quarter Return the quarter of the date.

is_quarter_end Similar property for indicating the quarter start.

**Examples**

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> df = pd.DataFrame({"dates": pd.date_range("2017-03-30", periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
...            is_quarter_start=df.dates.dt.is_quarter_start)
   dates    quarter  is_quarter_start
0 2017-03-30      1          False
1 2017-03-31      1          False
2 2017-04-01      2           True
3 2017-04-02      2          False
```

```python
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
              dtype='datetime64[ns]', freq='D')
```
pandas.DatetimeIndex.is_quarter_end

property DatetimeIndex.is_quarter_end
    Indicator for whether the date is the last day of a quarter.

Returns
    is_quarter_end [Series or DatetimeIndex] The same type as the original data with
    boolean values. Series will have the same name and index. DatetimeIndex will
    have the same name.

See also:
    quarter Return the quarter of the date.
    is_quarter_start Similar property indicating the quarter start.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30", ... periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter, ... is_quarter_end=df.dates.dt.is_quarter_end)
```

```
        dates  quarter  is_quarter_end
0  2017-03-30      1        False
1  2017-03-31      1        True
2  2017-04-01      2        False
3  2017-04-02      2        False
```

```python
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
               dtype='datetime64[ns]', freq='D')
```

```python
>>> idx.is_quarter_end
array([False, True, False, False])
```

pandas.DatetimeIndex.is_year_start

property DatetimeIndex.is_year_start
    Indicate whether the date is the first day of a year.

Returns
    Series or DatetimeIndex The same type as the original data with boolean values. Se-
    ries will have the same name and index. DatetimeIndex will have the same name.

See also:
**is_year_end** Similar property indicating the last day of the year.

**Examples**

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```python
dates = pd.Series(pd.date_range("2017-12-30", periods=3))
dates
0 2017-12-30
1 2017-12-31
2 2018-01-01
dtype: datetime64[ns]
```

```python
dates.dt.is_year_start
0 False
1 False
2 True
dtype: bool
```

```python
idx = pd.date_range("2017-12-30", periods=3)
datetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
dtype='datetime64[ns]', freq='D')
```

```python
idx.is_year_start
array([False, False, True])
```

**pandas.DatetimeIndex.is_year_end**

**property** `DatetimeIndex.is_year_end`  Indicate whether the date is the last day of the year.

**Returns**

Series or DatetimeIndex  The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

**is_year_start**  Similar property indicating the start of the year.

**Examples**

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```python
dates = pd.Series(pd.date_range("2017-12-30", periods=3))
dates
0 2017-12-30
1 2017-12-31
2 2018-01-01
dtype: datetime64[ns]
```
>>> dates.dt.is_year_end
0   False
1    True
2   False
dtype: bool

>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
dtype='datetime64[ns]', freq='D')

>>> idx.is_year_end
array([False,  True, False])

pandas.DatetimeIndex.is_leap_year

property DatetimeIndex.is_leap_year
Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary
day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not
by 400.

Returns

Series or ndarray  Booleans indicating if dates belong to a leap year.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on Date-
timeIndex.

>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
dtype='datetime64[ns]', freq='A-DEC')

>>> idx.is_leap_year
array([ True, False, False])

>>> dates_series = pd.Series(idx)
>>> dates_series
0 2012-12-31
1 2013-12-31
2 2014-12-31
dtype: datetime64[ns]

>>> dates_series.dt.is_leap_year
0   True
1   False
2   False
dtype: bool
**pandas.DatetimeIndex.inferred_freq**

`DatetimeIndex.inferred_freq`  
Tries to return a string representing a frequency guess, generated by infer_freq. Returns None if it can’t autodetect the frequency.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>normalize(*args, **kwargs)</code></td>
<td>Convert times to midnight.</td>
</tr>
<tr>
<td><code>strftime(*args, **kwargs)</code></td>
<td>Convert to Index using specified date_format.</td>
</tr>
<tr>
<td><code>snap(freq)</code></td>
<td>Snap time stamps to nearest occurring frequency.</td>
</tr>
<tr>
<td><code>tz_convert(*args, **kwargs)</code></td>
<td>Convert tz-aware Datetime Array/Index from one time zone to another.</td>
</tr>
<tr>
<td><code>tz_localize(tz [, ambiguous, nonexistent])</code></td>
<td>Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.</td>
</tr>
<tr>
<td><code>round(*args, **kwargs)</code></td>
<td>Perform round operation on the data to the specified freq.</td>

<tr>
<td><code>to_frame([index, name])</code></td>
<td>Create a DataFrame with a column containing the Index.</td>
</tr>
<tr>
<td><code>month_name(*args, **kwargs)</code></td>
<td>Return the month names of the DateTimeIndex with specified locale.</td>
</tr>
<tr>
<td><code>day_name(*args, **kwargs)</code></td>
<td>Return the day names of the DateTimeIndex with specified locale.</td>
</tr>
<tr>
<td><code>mean(*args, **kwargs)</code></td>
<td>Return the mean value of the Array.</td>
</tr>
</tbody>
</table>

**pandas.DatetimeIndex.normalize**

`DatetimeIndex.normalize(*args, **kwargs)`  
Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the `.dt` accessor, and directly on Datetime Array/Index.

**Returns**

`DatetimeArray, DatetimeIndex or Series`  The same type as the original data. Series
will have the same name and index. DatetimeIndex will have the same name.

See also:

floor  Floor the datetimes to the specified freq.
ceil  Ceil the datetimes to the specified freq.
round  Round the datetimes to the specified freq.

Examples

```python
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
...                      periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
               '2014-08-01 11:00:00+05:30',
               '2014-08-01 12:00:00+05:30'],
               dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30'],
               dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

pandas.DatetimeIndex.strftime

```
DatetimeIndex.strftime(*args, **kwargs)
```

Convert to Index using specified date_format.

Return an Index of formatted strings specified by date_format, which supports the same string format as the python standard library. Details of the string format can be found in python string format doc.

Parameters

- **date_format** [str] Date format string (e.g. “%Y-%m-%d”).

Returns

- **ndarray** NumPy ndarray of formatted strings.

See also:

to_datetime  Convert the given argument to datetime.

```
DatetimeIndex.normalize  Return DatetimeIndex with times to midnight.
```

```
DatetimeIndex.round  Round the DatetimeIndex to the specified freq.
```

```
DatetimeIndex.floor  Floor the DatetimeIndex to the specified freq.
```
Examples

```python
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                       periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
      'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```

pandas.DatetimeIndex.snap

DatetimeIndex.snap(freq='S')

Snap time stamps to nearest occurring frequency.

Returns

DatetimeIndex

pandas.DatetimeIndex.tz_convert

DatetimeIndex.tz_convert(*args, **kwargs)

Convert tz-aware Datetime Array/Index from one time zone to another.

Parameters

- **tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A tz of None will convert to UTC and remove the timezone information.

Returns

Array or Index

Raises

- TypeError If Datetime Array/Index is tz-naive.

See also:

- DatetimeIndex.tz A timezone that has a variable offset from UTC.
- DatetimeIndex.tz_localize Localize tz-naive DatetimeIndex to a given time zone, or remove timezone from a tz-aware DatetimeIndex.

Examples

With the tz parameter, we can change the DatetimeIndex to other time zones:

```python
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                      freq='H', periods=3, tz='Europe/Berlin')
```

```python
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00', '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
               dtype='datetime64[ns, Europe/Berlin]', freq='H')
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

```python
>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
               '2014-08-01 03:00:00-05:00',
               '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the `tz=None`, we can remove the timezone (after converting to UTC if necessary):

```python
>>> dti = pd.date_range(start='2014-08-01 09:00', freq='H',
                      periods=3, tz='Europe/Berlin')
```

```python
>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```python
>>> dti.tz_convert(None)
DatetimeIndex(['2014-08-01 07:00:00',
               '2014-08-01 08:00:00',
               '2014-08-01 09:00:00'],
              dtype='datetime64[ns]', freq='H')
```

### pandas.DatetimeIndex.tz_localize

**Datet imeIndex.tz_localize** *(tz, ambiguous='raise', nonexistent='raise')*

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone. Time zone localization helps to switch from time zone aware to time zone unaware objects.

**Parameters**

- **tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone to convert timestamps to. Passing `None` will remove the time zone information preserving local time.
- **ambiguous** ['infer', 'NaT', bool array, default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the ambiguous parameter dictates how ambiguous times should be handled.
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.
- **nonexistent** ['shift_forward', 'shift_backward, 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time

3.7. Index objects 2015
• ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
• ‘NaT’ will return NaT where there are nonexistent times
• timedelta objects will shift nonexistent times by the timedelta
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

Same type as self  Array/Index converted to the specified time zone.

Raises

TypeError  If the Datetime Array/Index is tz-aware and tz is not None.

See also:

DatetimeIndex.tz_convert  Convert tz-aware DatetimeIndex from one time zone to another.

Examples

```python
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'], dtype='datetime64[ns]', freq='D')

Localize DatetimeIndex in US/Eastern time zone:

```python
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
               '2018-03-02 09:00:00-05:00',
               '2018-03-03 09:00:00-05:00'], dtype='datetime64[ns, US/Eastern]', freq=None)
```

With the tz=None, we can remove the time zone information while keeping the local time (not converted to UTC):

```python
>>> tz_aware.tz_localize(None)
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'], dtype='datetime64[ns]', freq=None)
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```python
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:30:00',
                                ...    '2018-10-28 02:00:00',
                                ...    '2018-10-28 02:30:00',
                                ...    '2018-10-28 02:00:00',
                                ...    '2018-10-28 02:30:00',
                                ...    '2018-10-28 03:00:00',
                                ...    '2018-10-28 03:30:00']))
>>> s.dt.tz_localize('CET', ambiguous='infer')
0    2018-10-28 01:30:00+02:00
(continues on next page)
In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly

```python
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:20:00',
                               '2018-10-28 02:36:00',
                               '2018-10-28 03:46:00']))
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
0 2018-10-28 01:20:00+02:00
1 2018-10-28 02:36:00+02:00
2 2018-10-28 03:46:00+01:00
dtype: datetime64[ns, CET]
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a timedelta object or ‘shift_forward’ or ‘shift_backwards’.

```python
>>> s = pd.to_datetime(pd.Series(['2015-03-29 02:30:00',
                               '2015-03-29 03:30:00']))
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
0 2015-03-29 03:00:00+02:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]

>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
0 2015-03-29 01:59:59.999999999+01:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]

>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
0 2015-03-29 03:30:00+02:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```

**pandas.DatetimeIndex.round**

```
DatetimeIndex.round(*args, **kwargs)
```

Perform round operation on the data to the specified freq.

**Parameters**

- `freq` [str or Offset] The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

- `ambiguous` ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
• bool-ndarray where True signifies a DST time, False designates a non-DST
time (note that this flag is only applicable for ambiguous times)

• ‘NaT’ will return NaT where there are ambiguous times

• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

nonexistent ['shift_forward', 'shift_backward', ‘NaT’, timedelta, default ‘raise’] A
nonexistent time does not exist in a particular timezone where clocks moved for-
ward due to DST.

• ‘shift_forward’ will shift the nonexistent time forward to the closest existing
time

• ‘shift_backward’ will shift the nonexistent time backward to the closest exist-
ing time

• ‘NaT’ will return NaT where there are nonexistent times

• timedelta objects will shift nonexistent times by the timedelta

• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIn-
dex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(["2018-01-01 11:59:00", '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(["2018-01-01 12:00:00", '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.round("H")
0  2018-01-01 12:00:00
1  2018-01-01 12:00:00
2  2018-01-01 12:00:00
dtype: datetime64[ns]
```
pandas.DatetimeIndex.floor

DatetimeIndex.floor(*args, **kwargs)
Perform floor operation on the data to the specified freq.

Parameters

freq [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

ambiguous ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

nonexistent ['shift_forward', ‘shift_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
                '2018-01-01 12:01:00'], dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
```
Series

```python
>>> pd.Series(rng).dt.floor("H")
0 2018-01-01 11:00:00
1 2018-01-01 12:00:00
2 2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.DatetimeIndex.ceil

```python
datetimeIndex.ceil(*args, **kwargs)
```

Perform ceil operation on the data to the specified `freq`.

**Parameters**

- **freq** [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like `‘S’` (second) not `‘ME’` (month end). See frequency aliases for a list of possible `freq` values.
- **ambiguous** ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

- **nonexistent** ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

**Returns**

- DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.
ValueError if the *freq* cannot be converted.

Examples

**DatetimeIndex**

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
               dtype='datetime64[ns]', freq='T')
```

```python
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 13:00:00'],
               dtype='datetime64[ns]', freq=None)
```

**Series**

```python
>>> pd.Series(rng).dt.ceil("H")
0  2018-01-01 12:00:00
1  2018-01-01 12:00:00
2  2018-01-01 13:00:00
dtype: datetime64[ns]
```

**pandas.DatetimeIndex.to_period**

```
DatetimeIndex.to_period(*args, **kwargs)
```

Cast to PeriodArray/Index at a particular frequency.

Converts DatetimeArray/Index to PeriodArray/Index.

**Parameters**

- *freq* [str or Offset, optional] One of pandas’ offset strings or an Offset object. Will be inferred by default.

**Returns**

- PeriodArray/Index

**Raises**

- ValueError When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

**See also:**

- *PeriodIndex* Immutable ndarray holding ordinal values.
- *DatetimeIndex.to_pydatetime* Return DatetimeIndex as object.
Examples

```python
>>> df = pd.DataFrame({"y": [1, 2, 3]},
                    index=pd.to_datetime(["2000-03-31 00:00:00",
                                          "2000-05-31 00:00:00",
                                          "2000-08-31 00:00:00"]))
>>> df.index.to_period("M")
PeriodIndex(['2000-03', '2000-05', '2000-08'],
            dtype='period[M]', freq='M')
```

Infer the daily frequency

```python
>>> idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
            dtype='period[D]', freq='D')
```

**pandas.DatetimeIndex.to_perioddelta**

`DatetimeIndex.to_perioddelta(*args, **kwargs)`

Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified freq. Used for vectorized offsets.

**Parameters**

freq [Period frequency]

**Returns**

TimedeltaArray/Index

**pandas.DatetimeIndex.to_pydatetime**

`DatetimeIndex.to_pydatetime(*args, **kwargs)`

Return Datetime Array/Index as object ndarray of datetime.datetime objects.

**Returns**

datetimes [ndarray]

**pandas.DatetimeIndex.to_series**

`DatetimeIndex.to_series(keep_tz=<object object>, index=None, name=None)`

Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.

**Parameters**

keep_tz [optional, defaults True] Return the data keeping the timezone.

If keep_tz is True:

If the timezone is not set, the resulting Series will have a datetime64[ns] dtype.

Otherwise the Series will have an datetime64[ns, tz] dtype; the tz will be preserved.
If keep_tz is False:

Series will have a datetime64[ns] dtype. TZ aware objects will have the tz removed.

Changed in version 1.0.0: The default value is now True. In a future version, this keyword will be removed entirely. Stop passing the argument to obtain the future behavior and silence the warning.

**index** [Index, optional] Index of resulting Series. If None, defaults to original index.

**name** [str, optional] Name of resulting Series. If None, defaults to name of original index.

Returns

Series

```
pandas.DatetimeIndex.to_frame
```

**DatetimeIndex.to_frame** (*index=True, name=None*)

Create a DataFrame with a column containing the Index.

New in version 0.24.0.

Parameters

**index** [bool, default True] Set the index of the returned DataFrame as the original Index.

**name** [object, default None] The passed name should substitute for the index name (if it has one).

Returns

**DataFrame** DataFrame containing the original Index data.

See also:

- **Index.to_series** Convert an Index to a Series.
- **Series.to_frame** Convert Series to DataFrame.

Examples

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
    animal
   0    Ant
   1   Bear
   2   Cow
```

By default, the original Index is reused. To enforce a new Index:

```python
>>> idx.to_frame(index=False)
   animal
  0      Ant
  1     Bear
  2      Cow
```
To override the name of the resulting column, specify `name`:

```python
>>> idx.to_frame(index=False, name='zoo')
zoo
0  Ant
1  Bear
2  Cow
```

### pandas.DatetimeIndex.month_name

`DatetimeIndex.month_name(*args, **kwargs)`

Return the month names of the `DateTimeIndex` with specified locale.

New in version 0.23.0.

**Parameters**

- `locale` [str, optional] Locale determining the language in which to return the month name. Default is English locale.

**Returns**

- `Index` Index of month names.

**Examples**

```python
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
               dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```

### pandas.DatetimeIndex.day_name

`DatetimeIndex.day_name(*args, **kwargs)`

Return the day names of the `DateTimeIndex` with specified locale.

New in version 0.23.0.

**Parameters**

- `locale` [str, optional] Locale determining the language in which to return the day name. Default is English locale.

**Returns**

- `Index` Index of day names.
Examples

```python
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
dtype='datetime64[ns]', freq='D')
```

```
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

**pandas.DatetimeIndex.mean**

```
DatetimeIndex.mean(*args, **kwargs)
```

Return the mean value of the Array.

New in version 0.25.0.

**Parameters**

- `skipna` [bool, default True] Whether to ignore any NaT elements.

**Returns**

- `scalar` Timestamp or Timedelta.

**See also:**

- `numpy.ndarray.mean` Returns the average of array elements along a given axis.
- `Series.mean` Return the mean value in a Series.

**Notes**

mean is only defined for Datetime and Timedelta dtypes, not for Period.

**Time/date components**

pandas.DatetimeIndex.indexer_at_time

```
DatetimeIndex.indexer_at_time(time[, asof=False])
```

Return index locations of values at particular time of day (e.g. 9:30AM).

**Parameters**

- `time` [datetime.time or str] Time passed in either as object (datetime.time) or as string in appropriate format ("%H:%M", "%H%M", "%I:%M%p", "%I%M%p", "%H:%M:%S", "%H%M%S", "%I:%M:%S%p", "%I%M%S%p").

**Returns**

- `values_at_time` [array of integers]

**See also:**

- `indexer_between_time` Get index locations of values between particular times of day.
- `DataFrame.at_time` Select values at particular time of day.
pandas.datetime.indexer_between_time

pandas.DatetimeIndex.indexer_between_time(start_time, end_time, include_start=True, include_end=True)

Return index locations of values between particular times of day (e.g., 9:00-9:30AM).

Parameters

- **start_time**, **end_time** [datetime.time, str] Time passed either as object (datetime.time) or as string in appropriate format (“%H:%M”, “%H%M”, “%I:%M%p”, “%I%M%p”, “%H:%M:%S”, “%H%M%S”, “%I:%M:%S%p”, “%I%M%S%p”).
- **include_start** [bool, default True]
- **include_end** [bool, default True]

Returns

- **values_between_time** [array of integers]

See also:

- **indexer_at_time** Get index locations of values at particular time of day.
- **DataFrame.between_time** Select values between particular times of day.

Time-specific operations

- **DatetimeIndex.normalize(*args, **kwargs)** Convert times to midnight.
- **DatetimeIndex.strftime(*args, **kwargs)** Convert to Index using specified date_format.
- **DatetimeIndex.snap([freq])** Snap time stamps to nearest occurring frequency.
- **DatetimeIndex.tz_convert(*args, **kwargs)** Convert tz-aware Datetime Array/Index from one time zone to another.
- **DatetimeIndex.tz_localize(tz[, ambiguous, ...])** Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.
- **DatetimeIndex.round(*args, **kwargs)** Perform round operation on the data to the specified freq.
- **DatetimeIndex.floor(*args, **kwargs)** Perform floor operation on the data to the specified freq.
- **DatetimeIndex.ceil(*args, **kwargs)** Perform ceil operation on the data to the specified freq.
- **DatetimeIndex.month_name(*args, **kwargs)** Return the month names of the DateTimeIndex with specified locale.
- **DatetimeIndex.day_name(*args, **kwargs)** Return the day names of the DateTimeIndex with specified locale.

Conversion

- **DatetimeIndex.to_period(*args, **kwargs)** Cast to PeriodArray/Index at a particular frequency.
- **DatetimeIndex.to_perioddelta(*args, **kwargs)** Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified freq.
- **DatetimeIndex.to_pydatetime(*args, **kwargs)** Return Datetime Array/Index as object ndarray of datetime.datetime objects.
- **DatetimeIndex.to_series([keep_tz, index, name])** Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.

Table 167 – continued from previous page

| DatetimeIndex.to_frame | Create a DataFrame with a column containing the Index. |

Methods

| DatetimeIndex.mean | Return the mean value of the Array. |

3.7.7 TimedeltaIndex

| TimedeltaIndex | Immutable ndarray of timedelta64 data, represented internally as int64, and which can be boxed to timedelta objects. |

pandas.TimedeltaIndex

class pandas.TimedeltaIndex(data=None, unit=None, freq=<object object>, closed=None, dtype=\texttt{dtype('\textless m8[ns]\textgreater')}, copy=False, name=None)

Immutable ndarray of timedelta64 data, represented internally as int64, and which can be boxed to timedelta objects.

Parameters

- **data** [array-like (1-dimensional), optional] Optional timedelta-like data to construct index with.
- **unit** [unit of the arg (D,h,m,s,ms,us,ns) denote the unit, optional] Which is an integer/float number.
- **freq** [str or pandas offset object, optional] One of pandas date offset strings or corresponding objects. The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation.
- **copy** [bool] Make a copy of input ndarray.
- **name** [object] Name to be stored in the index.

See also:

- **Index** The base pandas Index type.
- **Timedelta** Represents a duration between two dates or times.
- **DatetimeIndex** Index of datetime64 data.
- **PeriodIndex** Index of Period data.
- **timedelta_range** Create a fixed-frequency TimedeltaIndex.
Notes

To learn more about the frequency strings, please see this link.

</tbody>
</table>

*pandas.TimedeltaIndex.days*

**property** TimedeltaIndex.days

Number of days for each element.

*pandas.TimedeltaIndex.seconds*

**property** TimedeltaIndex.seconds

Number of seconds (>= 0 and less than 1 day) for each element.

*pandas.TimedeltaIndex.microseconds*

**property** TimedeltaIndex.microseconds

Number of microseconds (>= 0 and less than 1 second) for each element.

*pandas.TimedeltaIndex.nanoseconds*

**property** TimedeltaIndex.nanoseconds

Number of nanoseconds (>= 0 and less than 1 microsecond) for each element.
**pandas.TimedeltaIndex.components**

**property TimedeltaIndex.components**

Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.

**Returns**

a DataFrame

**pandas.TimedeltaIndex.inferred_freq**

**TimedeltaIndex.inferred_freq**

Tries to return a string representing a frequency guess, generated by infer_freq. Returns None if it can’t autodetect the frequency.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>to_pytimedelta(*args, **kwargs)</td>
<td>Return Timedelta Array/Index as object ndarray of datetime.timedelta objects.</td>

<tr>
<td>mean(*args, **kwargs)</td>
<td>Return the mean value of the Array.</td>
</tr>
</tbody>
</table>

**pandas.TimedeltaIndex.to_pytimedelta**

**TimedeltaIndex.to_pytimedelta(*args, **kwargs)**

Return Timedelta Array/Index as object ndarray of datetime.timedelta objects.

**Returns**

datetimes [ndarray]

**pandas.TimedeltaIndex.to_series**

**TimedeltaIndex.to_series(index=None, name=None)**

Create a Series with both index and values equal to the index keys.

Useful with map for returning an indexer based on an index.

**Parameters**

index [Index, optional] Index of resulting Series. If None, defaults to original index.
name [str, optional] Name of resulting Series. If None, defaults to name of original index.

Returns

Series The dtype will be based on the type of the Index values.

See also:

Index.to_frame Convert an Index to a DataFrame.
Series.to_frame Convert Series to DataFrame.

Examples

>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')

By default, the original Index and original name is reused.

>>> idx.to_series()
animal
 Ant Ant
Bear Bear
Cow  Cow
Name: animal, dtype: object

To enforce a new Index, specify new labels to index:

>>> idx.to_series(index=[0, 1, 2])
0  Ant
1  Bear
2  Cow
Name: animal, dtype: object

To override the name of the resulting column, specify name:

>>> idx.to_series(name='zoo')
animal
Ant  Ant
Bear Bear
Cow  Cow
Name: zoo, dtype: object

pandas.TimedeltaIndex.round

TimedeltaIndex.round(*args, **kwargs)
Perform round operation on the data to the specified freq.

Parameters

freq [str or Offset] The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

ambiguous ['infer', boolndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
- ‘infer’ will attempt to infer fall dst-transition hours based on order
**bool-ndarray** where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)

- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

**nonexistent** ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

**Returns**

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**

ValueError if the freq cannot be converted.

**Examples**

**DatetimeIndex**

```python
g = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
gng = g
gng.round('H')
gng.round('H')
```

**Series**

```python
pd.Series(g).dt.round("H")
```

<table>

<th>2018-01-01 12:00:00</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2018-01-01 12:00:00</td>
</tr>
<tr>
<td>2</td>
<td>2018-01-01 12:00:00</td>
</tr>
</tbody>
</table>

dtype: datetime64[ns]
TimedeltaIndex.floor(*args, **kwargs)

Perform floor operation on the data to the specified freq.

Parameters

- **freq** [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

- **ambiguous** ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

- **nonexistent** ['shift_forward', 'shift_backward', ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

Returns

- **DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

- **ValueError if the freq cannot be converted.**

Examples

**DatetimelIndex**

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00', '2018-01-01 12:01:00'], dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
```
Series

```python
>>> pd.Series(rng).dt.floor("H")
0  2018-01-01 11:00:00
1  2018-01-01 12:00:00
2  2018-01-01 12:00:00
dtype: datetime64[ns]
```

**pandas.TimedeltaIndex.ceil**

*TimedeltaIndex.ceil(*args, **kwargs)*

Perform ceil operation on the data to the specified `freq`.

**Parameters**

- `freq` [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See *frequency aliases* for a list of possible `freq` values.

- `ambiguous` [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

New in version 0.24.0.

- `nonexistent` [‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

New in version 0.24.0.

**Returns**

- `DatetimeIndex`, `TimedeltaIndex`, or `Series` Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**
ValueError if the freq cannot be converted.

Examples

**DatetimeIndex**

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
              dtype='datetime64[ns]', freq='T')

>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-02 00:00:00'],
              dtype='datetime64[ns]', freq=None)
```

**Series**

```python
>>> pd.Series(rng).dt.ceil("H")
0  2018-01-01 12:00:00
1  2018-01-01 12:00:00
2  2018-01-02 00:00:00
dtype: datetime64[ns]
```

**pandas.TimedeltaIndex.to_frame**

TimedeltaIndex.to_frame(index=True, name=None)  
Create a DataFrame with a column containing the Index.  
New in version 0.24.0.

**Parameters**

index [bool, default True] Set the index of the returned DataFrame as the original Index.

name [object, default None] The passed name should substitute for the index name (if it has one).

**Returns**

DataFrame DataFrame containing the original Index data.

See also:

* Index.to_series Convert an Index to a Series.
* Series.to_frame Convert Series to DataFrame.
Examples

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
       animal
animal  Ant
       Bear
       Cow

By default, the original Index is reused. To enforce a new Index:

```python
>>> idx.to_frame(index=False)
        animal
         0  Ant
         1  Bear
         2  Cow
```

To override the name of the resulting column, specify `name`:

```python
>>> idx.to_frame(index=False, name='zoo')
         zoo
         0  Ant
         1  Bear
         2  Cow
```

**pandas.TimedeltaIndex.mean**

`TimedeltaIndex.mean(*args, **kwargs)`

Return the mean value of the Array.

New in version 0.25.0.

**Parameters**

- `skipna` [bool, default True] Whether to ignore any NaT elements.

**Returns**

- scalar Timestamp or Timedelta.

**See also:**

- `numpy.ndarray.mean` Returns the average of array elements along a given axis.
- `Series.mean` Return the mean value in a Series.

**Notes**

mean is only defined for Datetime and Timedelta dtypes, not for Period.
**Components**

### 3.7.8 PeriodIndex

**PeriodIndex**([data, ordinal, freq, tz, ...]) Immutable ndarray holding ordinal values indicating regular periods in time.

**pandas.PeriodIndex**

```python
class pandas.PeriodIndex(data=None, ordinal=None, freq=None, tz=None, dtype=None, copy=False, name=None, **fields)
```

Immutable ndarray holding ordinal values indicating regular periods in time.

Index keys are boxed to Period objects which carries the metadata (eg, frequency information).

**Parameters**

- **data** [array-like (1d int np.ndarray or PeriodArray), optional] Optional period-like data to construct index with.
copy [bool] Make a copy of input ndarray.

freq [str or period object, optional] One of pandas period strings or corresponding objects.

year [int, array, or Series, default None]
month [int, array, or Series, default None]
quarter [int, array, or Series, default None]
day [int, array, or Series, default None]
hour [int, array, or Series, default None]
minute [int, array, or Series, default None]
second [int, array, or Series, default None]
tz [object, default None] Timezone for converting datetime64 data to Periods.
dtype [str or PeriodDtype, default None]

See also:

Index The base pandas Index type.
Period Represents a period of time.
DatetimeIndex Index with datetime64 data.
TimedeltaIndex Index of timedelta64 data.
period_range Create a fixed-frequency PeriodIndex.

Examples

```python
>>> idx = pd.PeriodIndex(year=[2000, 2002], quarter=[1, 3])
>>> idx
PeriodIndex(['2000Q1', '2002Q3'], dtype='period[Q-DEC]', freq='Q-DEC')
```

Attributes

- `day` The days of the period.
- `dayofweek` The day of the week with Monday=0, Sunday=6.
- `dayofyear` The ordinal day of the year.
- `days_in_month` The number of days in the month.
- `daysinmonth` The number of days in the month.
- `freq` Return the frequency object if it is set, otherwise None.
- `freqstr` Return the frequency object as a string if its set, otherwise None.
- `hour` The hour of the period.
- `is_leap_year` Logical indicating if the date belongs to a leap year.
- `minute` The minute of the period.
- `month` The month as January=1, December=12.
- `quarter` The quarter of the date.
- `second` The second of the period.
- `week` The week ordinal of the year.
- `weekday` The day of the week with Monday=0, Sunday=6.
- `weekofyear` The week ordinal of the year.
Table 176 – continued from previous page

<table>
<thead>
<tr>
<th>year</th>
<th>The year of the period.</th>
</tr>
</thead>
</table>

**pandas.PeriodIndex.day**

**property** PeriodIndex.day
The days of the period.

**pandas.PeriodIndex.dayofweek**

**property** PeriodIndex.dayofweek
The day of the week with Monday=0, Sunday=6.

**pandas.PeriodIndex.dayofyear**

**property** PeriodIndex.dayofyear
The ordinal day of the year.

**pandas.PeriodIndex.days_in_month**

**property** PeriodIndex.days_in_month
The number of days in the month.

**pandas.PeriodIndex.daysinmonth**

**property** PeriodIndex.daysinmonth
The number of days in the month.

**pandas.PeriodIndex.freq**

**property** PeriodIndex.freq
Return the frequency object if it is set, otherwise None.

**pandas.PeriodIndex.freqstr**

**property** PeriodIndex.freqstr
Return the frequency object as a string if it is set, otherwise None.
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.PeriodIndex.hour

property PeriodIndex.hour
   The hour of the period.

pandas.PeriodIndex.is_leap_year

property PeriodIndex.is_leap_year
   Logical indicating if the date belongs to a leap year.

pandas.PeriodIndex.minute

property PeriodIndex.minute
   The minute of the period.

pandas.PeriodIndex.month

property PeriodIndex.month
   The month as January=1, December=12.

pandas.PeriodIndex.quarter

property PeriodIndex.quarter
   The quarter of the date.

pandas.PeriodIndex.second

property PeriodIndex.second
   The second of the period.

pandas.PeriodIndex.week

property PeriodIndex.week
   The week ordinal of the year.

pandas.PeriodIndex.weekday

property PeriodIndex.weekday
   The day of the week with Monday=0, Sunday=6.
pandas.PeriodIndex.weekofyear

**property** `PeriodIndex.weekofyear`  
The week ordinal of the year.

pandas.PeriodIndex.year

**property** `PeriodIndex.year`  
The year of the period.

<table>
<thead>
<tr>
<th>end_time</th>
<th>qyear</th>
<th>start_time</th>
</tr>
</thead>
</table>

**Methods**

<table>
<thead>
<tr>
<th><code>asfreq([freq, how])</code></th>
<th>Convert the Period Array/Index to the specified frequency <code>freq</code>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>strftime(*args, **kwargs)</code></td>
<td>Convert to Index using specified date_format.</td>
</tr>
<tr>
<td><code>to_timestamp(*args, **kwargs)</code></td>
<td>Cast to DatetimeArray/Index.</td>
</tr>
</tbody>
</table>

**pandas.PeriodIndex.asfreq**

`PeriodIndex.asfreq(freq=None, how='E')`  
Convert the Period Array/Index to the specified frequency `freq`.

**Parameters**

- `freq` [str] A frequency.
- `how` [str {‘E’, ‘S’}] Whether the elements should be aligned to the end or start within a period.
  - ‘E’, ‘END’, or ‘FINISH’ for end,
  - ‘S’, ‘START’, or ‘BEGIN’ for start.
  January 31st (‘END’) vs. January 1st (‘START’) for example.

**Returns**

- **Period Array/Index**  Constructed with the new frequency.
## Examples

```
>>> pidx = pd.period_range('2010-01-01', '2015-01-01', freq='A')
>>> pidx
dtype='period[A-DEC]', freq='A-DEC')
```

```
>>> pidx.asfreq('M')
PeriodIndex(['2010-12', '2011-12', '2012-12', '2013-12', '2014-12',
             '2015-12'], dtype='period[M]', freq='M')
```

```
>>> pidx.asfreq('M', how='S')
             '2015-01'], dtype='period[M]', freq='M')
```

### pandas.PeriodIndex.strftime

PeriodIndex.\texttt{strftime}(\*\textit{args}, \*\*\textit{kwargs})

Convert to Index using specified date\_format.

Return an Index of formatted strings specified by date\_format, which supports the same string format as the python standard library. Details of the string format can be found in python string format doc.

**Parameters**

- \texttt{date\_format} [str] Date format string (e.g. \texttt{"\%Y-\%m-\%d"}).

**Returns**

- \texttt{ndarray} NumPy ndarray of formatted strings.

**See also:**

- \texttt{to\_datetime} Convert the given argument to datetime.
- \texttt{DatetimeIndex.normalize} Return DatetimeIndex with times to midnight.
- \texttt{DatetimeIndex.round} Round the DatetimeIndex to the specified freq.
- \texttt{DatetimeIndex.floor} Floor the DatetimeIndex to the specified freq.

### Examples

```
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
                      periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
      'March 10, 2018, 09:00:02 AM'],
      dtype='object')
```
pandas.PeriodIndex.to_timestamp

PeriodIndex.to_timestamp(*args, **kwargs)
Cast to DatetimeArray/Index.

Parameters

freq [str or DateOffset, optional] Target frequency. The default is 'D' for week or longer, 'S' otherwise.

how [{‘s’, ‘e’, ‘start’, ‘end’}] Whether to use the start or end of the time period being converted.

Returns

DatetimeArray/Index

Properties

PeriodIndex.day
The days of the period.

PeriodIndex.dayofweek
The day of the week with Monday=0, Sunday=6.

PeriodIndex.dayofyear
The ordinal day of the year.

PeriodIndex.days_in_month
The number of days in the month.

PeriodIndex.daysinmonth
The number of days in the month.

PeriodIndex.end_time

PeriodIndex.freq
Return the frequency object if it is set, otherwise None.

PeriodIndex.freqstr
Return the frequency object as a string if its set, otherwise None.

PeriodIndex.hour
The hour of the period.

PeriodIndex.is_leap_year
Logical indicating if the date belongs to a leap year.

PeriodIndex.minute
The minute of the period.

PeriodIndex.month
The month as January=1, December=12.

PeriodIndex.quarter
The quarter of the date.

PeriodIndex.qyear

PeriodIndex.second
The second of the period.

PeriodIndex.start_time

PeriodIndex.week
The week ordinal of the year.

PeriodIndex.weekday
The day of the week with Monday=0, Sunday=6.

PeriodIndex.weekofyear
The week ordinal of the year.

PeriodIndex.year
The year of the period.

pandas.PeriodIndex.end_time

property PeriodIndex.end_time
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.PeriodIndex.qyear

property PeriodIndex.qyear

pandas.PeriodIndex.start_time

property PeriodIndex.start_time

3.8 Date offsets

3.8.1 DateOffset

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DateOffset</td>
<td>Standard kind of date increment used for a date range.</td>
</tr>
</tbody>
</table>

pandas.tseries.offsets.DateOffset

class pandas.tseries.offsets.DateOffset

Standard kind of date increment used for a date range.

Works exactly like relativedelta in terms of the keyword args you pass in, use of the keyword n is discouraged—you would be better off specifying n in the keywords you use, but regardless it is there for you. n is needed for DateOffset subclasses.

DateOffset work as follows. Each offset specify a set of dates that conform to the DateOffset. For example, Bday defines this set to be the set of dates that are weekdays (M-F). To test if a date is in the set of a DateOffset dateOffset we can use the is_on_offset method: dateOffset.is_on_offset(date).

If a date is not on a valid date, the rollback and rollforward methods can be used to roll the date to the nearest valid date before/after the date.

DateOffsets can be created to move dates forward a given number of valid dates. For example, Bday(2) can be added to a date to move it two business days forward. If the date does not start on a valid date, first it is moved to a valid date. Thus pseudo code is:

def __add__(date): date = rollback(date) # does nothing if date is valid return date + <n number of periods>

When a date offset is created for a negative number of periods, the date is first rolled forward. The pseudo code is:

def __add__(date): date = rollforward(date) # does nothing is date is valid return date + <n number of periods>

Zero presents a problem. Should it roll forward or back? We arbitrarily have it rollforward:

date + BDay(0) == BDay.rollforward(date)

Since 0 is a bit weird, we suggest avoiding its use.

Parameters
n [int, default 1] The number of time periods the offset represents.

normalize [bool, default False] Whether to round the result of a DateOffset addition down to the previous midnight.

**kwds** Temporal parameter that add to or replace the offset value.

Parameters that **add** to the offset (like Timedelta):

- years
- months
- weeks
- days
- hours
- minutes
- seconds
- microseconds
- nanoseconds

Parameters that **replace** the offset value:

- year
- month
- day
- weekday
- hour
- minute
- second
- microsecond
- nanosecond.

See also:

dateutil.relativedelta.relativedelta The relativedelta type is designed to be applied to an existing datetime and can replace specific components of that datetime, or represents an interval of time.

Examples

```python
>>> from pandas.tseries.offsets import DateOffset
>>> ts = pd.Timestamp('2017-01-01 09:10:11')
>>> ts + DateOffset(months=3)
Timestamp('2017-04-01 09:10:11')

>>> ts = pd.Timestamp('2017-01-01 09:10:11')
>>> ts + DateOffset(months=2)
Timestamp('2017-03-01 09:10:11')
```
Attributes

| base   | Returns a copy of the calling offset object with n=1 and all other attributes equal. |

`pandas.tseries.offsets.DateOffset.base`

DateOffset . `base`

Returns a copy of the calling offset object with n=1 and all other attributes equal.

</table>
pandas.tseries.offsets.BusinessDay.base

BusinessDay.base
   Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.BusinessDay.offset

BusinessDay.offset
   Alias for self._offset.

Methods

__call__(*args, **kwargs)  Call self as a function.
rollback
   Roll provided date backward to next offset only if not on offset.
rollforward
   Roll provided date forward to next offset only if not on offset.

pandas.tseries.offsets.BusinessDay.__call__

BusinessDay.__call__(*args, **kwargs)
   Call self as a function.

pandas.tseries.offsets.BusinessDay.rollback

BusinessDay.rollback()
   Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.
pandas.tseries.offsets.BusinessDay.rollforward

BusinessDay.rollforward()
    Roll provided date forward to next offset only if not on offset.

    Returns
    TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.CustomBusinessDay

class pandas.tseries.offsets.CustomBusinessDay

DateOffset subclass representing custom business days excluding holidays.

Parameters

n [int, default 1]

normalize [bool, default False] Normalize start/end dates to midnight before generating date range.

weekmask [str, Default ‘Mon Tue Wed Thu Fri’] Weekmask of valid business days, passed to numpy.busdaycalendar.
**holidays** [list] List/array of dates to exclude from the set of valid business days, passed to `numpy.busdaycalendar`.

**calendar** [pd.HolidayCalendar or np.busdaycalendar]

**offset** [timedelta, default timedelta(0)]

### Attributes

class pandas.tseries.offsets.MonthEnd
    DateOffset of one month end.
Attributes

```
base
Returns a copy of the calling offset object with n=1
and all other attributes equal.
```

```
pandas.tseries.offsets.MonthEnd.base
MonthEnd.base
Returns a copy of the calling offset object with n=1 and all other attributes equal.
```

```
freqstr
kwds
n
name
nanos
normalize
rule_code
```

Methods

```
__call__(*args, **kwargs)
Call self as a function.
```

```
rollback
Roll provided date backward to next offset only if
not on offset.
```

```
rollforward
Roll provided date forward to next offset only if not
on offset.
```

```
pandas.tseries.offsets.MonthEnd.__call__
MonthEnd.__call__(*args, **kwargs)
Call self as a function.
```

```
pandas.tseries.offsets.MonthEnd.rollback
MonthEnd.rollback()
Roll provided date backward to next offset only if not on offset.
```

Returns

```
TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.
```

pandas.tseries.offsets.MonthEnd.rollforward

MonthEnd.rollforward()
    Roll provided date forward to next offset only if not on offset.

Returns

    TimeStamp  Rolled timestamp if not on offset, otherwise unchanged timestamp.

**pandas.tseries.offsets.SemiMonthEnd.rollback**

SemiMonthEnd.rollback()
Roll provided date backward to next offset only if not on offset.

Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

**pandas.tseries.offsets.SemiMonthEnd.rollforward**

SemiMonthEnd.rollforward()
Roll provided date forward to next offset only if not on offset.

Returns

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

3.8. Date offsets
3.8.13 SemiMonthBegin

SemiMonthBegin

Two DateOffset’s per month repeating on the first day of the month and day_of_month.

Parameters

- **n** [int]
- **normalize** [bool, default False]
- **day_of_month** [int, \{2, 3,…,27\}, default 15]
Attributes

```
base
Returns a copy of the calling offset object with n=1 and all other attributes equal.
```

```
pandas.tseries.offsets.SemiMonthBegin.base
SemiMonthBegin.base
Returns a copy of the calling offset object with n=1 and all other attributes equal.

</thead>
</table>

**pandas.tseries.offsets.WeekOfMonth**

**class** pandas.tseries.offsets.WeekOfMonth

Describes monthly dates like “the Tuesday of the 2nd week of each month”.

**Parameters**

- n [int]
- week [int \{0, 1, 2, 3, \ldots\}, default 0] A specific integer for the week of the month. e.g. 0 is 1st week of month, 1 is the 2nd week, etc.
- weekday [int \{0, 1, \ldots, 6\}, default 0] A specific integer for the day of the week.
  - 0 is Monday
• 1 is Tuesday
• 2 is Wednesday
• 3 is Thursday
• 4 is Friday
• 5 is Saturday
• 6 is Sunday.

### 3.8.16 LastWeekOfMonth

<table>
<thead>
<tr>
<th>LastWeekOfMonth</th>
<th>Describes monthly dates in last week of month like “the last Tuesday of each month”.</th>
</tr>
</thead>
</table>
pandas.tseries.offsets.LastWeekOfMonth

class pandas.tseries.offsets.LastWeekOfMonth
Describes monthly dates in last week of month like “the last Tuesday of each month”.

Parameters

- **n** [int, default 1]
- **weekday** [int \{0, 1, …, 6\}, default 0] A specific integer for the day of the week.
  - 0 is Monday
  - 1 is Tuesday
  - 2 is Wednesday
  - 3 is Thursday
  - 4 is Friday
  - 5 is Saturday
  - 6 is Sunday.

Attributes

- **base**
  Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.LastWeekOfMonth.base

LastWeekOfMonth.base
Returns a copy of the calling offset object with n=1 and all other attributes equal.

<table>
<thead>
<tr>
<th>freqstr</th>
<th>kwds</th>
<th>n</th>
<th>name</th>
<th>nanos</th>
<th>normalize</th>
<th>rule_code</th>
<th>week</th>
<th>weekday</th>
</tr>
</thead>
</table>

Methods

- **__call__(**args, **kwargs)**
  Call self as a function.

- **rollback**
  Roll provided date backward to next offset only if not on offset.

- **rollforward**
  Roll provided date forward to next offset only if not on offset.

3.8. Date offsets
pandas.tseries.offsets.LastWeekOfMonth.__call__

```
LastWeekOfMonth.__call__(*args, **kwargs)
Call self as a function.
```

pandas.tseries.offsets.LastWeekOfMonth.rollback

```
LastWeekOfMonth.rollback()
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.
```

pandas.tseries.offsets.LastWeekOfMonth.rollforward

```
LastWeekOfMonth.rollforward()
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.BQuarterBegin.rollback

BQuarterBegin.rollback()
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.BQuarterBegin.rollforward

BQuarterBegin.rollforward()
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

3.8.25 FY5253

<table>
<thead>
<tr>
<th>FY5253</th>
<th>Describes 52-53 week fiscal year.</th>
</tr>
</thead>
</table>

pandas.tseries.offsets.FY5253

class pandas.tseries.offsets.FY5253

Describes 52-53 week fiscal year. This is also known as a 4-4-5 calendar.

It is used by companies that desire that their fiscal year always end on the same day of the week.

It is a method of managing accounting periods. It is a common calendar structure for some industries, such as retail, manufacturing and parking industry.

For more information see: https://en.wikipedia.org/wiki/4-4-5_calendar

The year may either:
  • end on the last X day of the Y month.
  • end on the last X day closest to the last day of the Y month.
X is a specific day of the week. Y is a certain month of the year

**Parameters**

- **n** [int] 
  - weekday [int \{0, 1, . . . , 6\}, default 0] A specific integer for the day of the week.
  - 0 is Monday
  - 1 is Tuesday
  - 2 is Wednesday
  - 3 is Thursday
  - 4 is Friday
  - 5 is Saturday
  - 6 is Sunday.
- **startingMonth** [int \{1, 2, . . . 12\}, default 1] The month in which the fiscal year ends.
- **variation** [str, default “nearest”] Method of employing 4-4-5 calendar.
  - There are two options:
  - “nearest” means year end is weekday closest to last day of month in year.
  - “last” means year end is final weekday of the final month in fiscal year.

3.8.26 FY5253Quarter

FY5253Quarter

DateOffset increments between business quarter dates for 52-53 week fiscal year (also known as a 4-4-5 calendar).
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.tseries.offsets.FY5253Quarter

class pandas.tseries.offsets.FY5253Quarter
DateOffset increments between business quarter dates for 52-53 week fiscal year (also known as a 4-4-5 calen-
dar).

It is used by companies that desire that their fiscal year always end on the same day of the week.

It is a method of managing accounting periods. It is a common calendar structure for some industries, such as
retail, manufacturing and parking industry.

For more information see: https://en.wikipedia.org/wiki/4-4-5_calendar

The year may either:
• end on the last X day of the Y month.
• end on the last X day closest to the last day of the Y month.
X is a specific day of the week. Y is a certain month of the year

startingMonth = 1 corresponds to dates like 1/31/2007, 4/30/2007, … startingMonth = 2 corresponds to dates

Parameters

n [int]

weekday [int {0, 1, …, 6}, default 0] A specific integer for the day of the week.
• 0 is Monday
• 1 is Tuesday
• 2 is Wednesday
• 3 is Thursday
• 4 is Friday
• 5 is Saturday
• 6 is Sunday.

startingMonth [int {1, 2, …, 12}, default 1] The month in which fiscal years end.

qtr_with_extra_week [int {1, 2, 3, 4}, default 1] The quarter number that has the leap or 14
week when needed.

variation [str, default “nearest”] Method of employing 4-4-5 calendar.

There are two options:
• “nearest” means year end is weekday closest to last day of month in year.
• “last” means year end is final weekday of the final month in fiscal year.

pandas.tseries.offsets.Minute.__call__

Minute.__call__(*args, **kwargs)
Call self as a function.

pandas.tseries.offsets.Minute.rollback

Minute.rollback()
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.
pandas.tseries.offsets.Minute.rollforward

```
Minute.rollforward()
```

Roll provided date forward to next offset only if not on offset.

**Returns**

**TimeStamp** Rolled timestamp if not on offset, otherwise unchanged timestamp.

### 3.8. Date offsets
3.9 Frequencies

| to_offset | Return DateOffset object from string or tuple representation or datetime.timedelta object.

3.9.1 pandas.tseries.frequencies.to_offset

pandas.tseries.frequencies.to_offset()

Return DateOffset object from string or tuple representation or datetime.timedelta object.

Parameters

- freq [str, tuple, datetime.timedelta, DateOffset or None]

Returns

- DateOffset or None

Raises
ValueError  If freq is an invalid frequency

See also:

DateOffset  Standard kind of date increment used for a date range.

Examples

```python
>>> to_offset("5min")
<5 * Minutes>
```

```python
>>> to_offset("1D1H")
<25 * Hours>
```

```python
>>> to_offset("2W")
<2 * Weeks: weekday=6>
```

```python
>>> to_offset("2B")
<2 * BusinessDays>
```

```python
>>> to_offset(pd.Timedelta(days=1))
<Day>
```

```python
>>> to_offset(Hour())
<Hour>
```

3.10 Window

Rolling objects are returned by .rolling calls: `pandas.DataFrame.rolling()`, `pandas.Series.rolling()`, etc. Expanding objects are returned by .expanding calls: `pandas.DataFrame.expanding()`, `pandas.Series.expanding()`, etc. ExponentialMovingWindow objects are returned by .ewm calls: `pandas.DataFrame.ewm()`, `pandas.Series.ewm()`, etc.

3.10.1 Standard moving window functions

</tr>
</tbody>
</table>

**pandas.core.window.rolling.Rolling.count**

`Rolling.count()`

The rolling count of any non-NaN observations inside the window.

**Returns**

- **Series or DataFrame**: Returned object type is determined by the caller of the rolling calculation.

**See also:**
- `pandas.Series.rolling` Calling object with Series data.
- `pandas.DataFrame.rolling` Calling object with DataFrames.
- `pandas.DataFrame.count` Count of the full DataFrame.

**Examples**

```python
>>> s = pd.Series([2, 3, np.nan, 10])
>>> s.rolling(2).count()
0    1.0
1    2.0
2    1.0
3    1.0
dtype: float64
>>> s.rolling(3).count()
0    1.0
1    2.0
2    2.0
3    2.0
dtype: float64
>>> s.rolling(4).count()
0    1.0
1    2.0
2    2.0
3    3.0
dtype: float64
```
pandas.core.window.rolling.Rolling.sum

Rolling.sum(*args, **kwargs)
Calculate rolling sum of given DataFrame or Series.

Parameters
*args, **kwargs For compatibility with other rolling methods. Has no effect on the computed value.

Returns
Series or DataFrame Same type as the input, with the same index, containing the rolling sum.

See also:
pandas.Series.sum Reducing sum for Series.
pandas.DataFrame.sum Reducing sum for DataFrame.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64

>>> s.rolling(3).sum()
0   NaN
1   NaN
2    6.0
3    9.0
4   12.0
dtype: float64

>>> s.expanding(3).sum()
0   NaN
1   NaN
2    6.0
3    9.0
4   15.0
dtype: float64

>>> s.rolling(3, center=True).sum()
0   NaN
1    6.0
2    9.0
3   12.0
4   NaN
dtype: float64
```

For DataFrame, each rolling sum is computed column-wise.
```python
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
>>> df
   A   B
0  1   1
1  2   4
2  3   9
3  4  16
4  5  25

>>> df.rolling(3).sum()
    A   B
0  NaN NaN
1  NaN NaN
2  6.0 14.0
3  9.0 29.0
4 12.0 50.0

**pandas.core.window.rolling.Rolling.mean**

Rolling.mean(*args, **kwargs)
Calculate the rolling mean of the values.

Parameters

*args Under Review.

**kwargs Under Review.

Returns

Series or DataFrame Returned object type is determined by the caller of the rolling calculation.

See also:

pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrames.
pandas.Series.mean Equivalent method for Series.
pandas.DataFrame.mean Equivalent method for DataFrame.

Examples

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0   NaN
1  1.5
2  2.5
3  3.5
dtype: float64

>>> s.rolling(3).mean()
0   NaN
1   NaN
2   2.0
3   3.0
dtype: float64
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.core.window.rolling.Rolling.median

Rolling.median(**kwargs)
Calculate the rolling median.

Parameters

**kwargs For compatibility with other rolling methods. Has no effect on the computed median.

Returns

Series or DataFrame Returned type is the same as the original object.

See also:
pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrames.
pandas.Series.median Equivalent method for Series.
pandas.DataFrame.median Equivalent method for DataFrame.

Examples

Compute the rolling median of a series with a window size of 3.

```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.rolling(3).median()
0    NaN
1    NaN
2    1.0
3    2.0
4    3.0
dtype: float64
```

pandas.core.window.rolling.Rolling.var

Rolling.var(ddof=1, *args, **kwargs)
Calculate unbiased rolling variance.

Normalized by N-1 by default. This can be changed using the ddof argument.

Parameters

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N – ddof, where N represents the number of elements.

*args, **kwargs For NumPy compatibility. No additional arguments are used.

Returns

Series or DataFrame Returns the same object type as the caller of the rolling calculation.

See also:
pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrames.
pandas.Series.var Equivalent method for Series.
pandas.DataFrame.var Equivalent method for DataFrame.
numpy.var Equivalent method for Numpy array.
Notes

The default $ddof$ of 1 used in `Series.var()` is different than the default $ddof$ of 0 in `numpy.var()`.
A minimum of 1 period is required for the rolling calculation.

Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
0    NaN
1    NaN
2    0.333333
3   1.000000
4   1.000000
5   1.333333
6   0.000000
dtype: float64

>>> s.expanding(3).var()
0    NaN
1    NaN
2    0.333333
3    0.916667
4    0.800000
5    0.700000
6    0.619048
dtype: float64
```

```
pandas.core.window.rolling.Rolling.std

Rolling.std($ddof=1$, *args, **kwargs)
Calculate rolling standard deviation.
Normalized by N-1 by default. This can be changed using the $ddof$ argument.

Parameters

$ddof$ [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - ddof$, where $N$ represents the number of elements.

*args, **kwargs For NumPy compatibility. No additional arguments are used.

Returns

Series or DataFrame Returns the same object type as the caller of the rolling calculation.

See also:
pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrames.
pandas.Series.std Equivalent method for Series.
pandas.DataFrame.std Equivalent method for DataFrame.
numpy.std Equivalent method for Numpy array.
```
Notes

The default $ddof$ of 1 used in Series.std is different than the default $ddof$ of 0 in numpy.std.

A minimum of one period is required for the rolling calculation.

Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0   NaN
1   NaN
2   0.577350
3   1.000000
4   1.000000
5   1.154701
6   0.000000
```

```python
dtype: float64
```
Examples

Performing a rolling minimum with a window size of 3.

```python
>>> s = pd.Series([4, 3, 5, 2, 6])
>>> s.rolling(3).min()
0   NaN
1   NaN
2   3.0
3   2.0
4   2.0
dtype: float64
```

pandas.core.window.rolling.Rolling.max

Rolling.max(*args, **kwargs)
Calculate the rolling maximum.

Parameters

*args, **kwargs
Arguments and keyword arguments to be passed into func.

Returns

Series or DataFrame
Return type is determined by the caller.

See also:

pandas.Series.rolling
Calling object with Series data.
pandas.DataFrame.rolling
Calling object with DataFrame data.
pandas.Series.max
Similar method for Series.
pandas.DataFrame.max
Similar method for DataFrame.

pandas.core.window.rolling.Rolling.corr

Rolling.corr(other=None, pairwise=None, **kwargs)
Calculate rolling correlation.

Parameters

other [Series, DataFrame, or ndarray, optional] If not supplied then will default to self.

pairwise [bool, default None] Calculate pairwise combinations of columns within a DataFrame. If other is not specified, defaults to True, otherwise defaults to False. Not relevant for Series.

**kwargs
Unused.

Returns

Series or DataFrame
Returned object type is determined by the caller of the rolling calculation.

See also:

pandas.Series.rolling
Calling object with Series data.
pandas.DataFrame.rolling
Calling object with DataFrames.
pandas.Series.corr
Equivalent method for Series.
pandas.DataFrame.corr
Equivalent method for DataFrame.
cov
Similar method to calculate covariance.
numpy.corrcoef
NumPy Pearson’s correlation calculation.
Notes

This function uses Pearson’s definition of correlation (https://en.wikipedia.org/wiki/Pearson_correlation_coefficient).

When other is not specified, the output will be self correlation (e.g. all 1’s), except for DataFrame inputs with pairwise set to True.

Function will return NaN for correlations of equal valued sequences; this is the result of a 0/0 division error.

When pairwise is set to False, only matching columns between self and other will be used.

When pairwise is set to True, the output will be a MultiIndex DataFrame with the original index on the first level, and the other DataFrame columns on the second level.

In the case of missing elements, only complete pairwise observations will be used.

Examples

The below example shows a rolling calculation with a window size of four matching the equivalent function call using numpy.corrcoef().

```python
>>> v1 = [3, 3, 3, 5, 8]
>>> v2 = [3, 4, 4, 4, 8]
>>> # numpy returns a 2X2 array, the correlation coefficient
>>> # is the number at entry [0][1]
>>> print(f"{np.corrcoef(v1[:-1], v2[:-1])[0][1]:.6f}"")
0.333333
>>> print(f"{np.corrcoef(v1[1:], v2[1:])[0][1]:.6f}"")
0.916949
>>> s1 = pd.Series(v1)
>>> s2 = pd.Series(v2)
>>> s1.rolling(4).corr(s2)
0    NaN
1    NaN
2    NaN
3  0.333333
4  0.916949
dtype: float64
```

The below example shows a similar rolling calculation on a DataFrame using the pairwise option.

```python
>>> print(np.corrcoef(matrix[:-1,0], matrix[:-1,1]).round(7))
[[ 1.00000000  0.62630014]
 [ 0.62630014  1.00000000]]
>>> print(np.corrcoef(matrix[1:,0], matrix[1:,1]).round(7))
[[ 1.00000000  0.55536810]
 [ 0.55536810  1.00000000]]
>>> df = pd.DataFrame(matrix, columns=['X','Y'])
>>> df
     X   Y
0  51.0  35.0
1  49.0  30.0
2  47.0  32.0
3  46.0  31.0
4  50.0  36.0
```
(continues on next page)
>>> df.rolling(4).corr(pairwise=True)
   X    Y
0 X  NaN  NaN
  Y  NaN  NaN
1 X  NaN  NaN
  Y  NaN  NaN
2 X  NaN  NaN
  Y  NaN  NaN
3 X  1.000000  0.626300
  Y  0.626300  1.000000
4 X  1.000000  0.555368
  Y  0.555368  1.000000

pandas.core.window.rolling.Rolling.cov

Rolling.cov(\texttt{other=None, pairwise=None, ddof=1, **kwargs})

Calculate the rolling sample covariance.

Parameters

\texttt{other} [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.

\texttt{pairwise} [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

\texttt{ddof} [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - \text{ddof} \), where \( N \) represents the number of elements.

\texttt{**kwargs} Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

\texttt{pandas.Series.rolling} Calling object with Series data.
\texttt{pandas.DataFrame.rolling} Calling object with DataFrame data.
\texttt{pandas.Series.cov} Similar method for Series.
\texttt{pandas.DataFrame.cov} Similar method for DataFrame.

pandas.core.window.rolling.Rolling.skew

Rolling.skew(\texttt{**kwargs})

Unbiased rolling skewness.

Parameters

\texttt{**kwargs} Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

\texttt{pandas.Series.rolling} Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrame data.
pandas.Series.skew Similar method for Series.
pandas.DataFrame.skew Similar method for DataFrame.

pandas.core.window.rolling.Rolling.kurt

Rolling.kurt(**kwargs)
Calculate unbiased rolling kurtosis.

This function uses Fisher’s definition of kurtosis without bias.

Parameters

**kwargs Under Review.

Returns

Series or DataFrame Returned object type is determined by the caller of the rolling calculation.

See also:
pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrames.
pandas.Series.kurt Equivalent method for Series.
pandas.DataFrame.kurt Equivalent method for DataFrame.
skpy.stats.skew Third moment of a probability density.

Notes

A minimum of 4 periods is required for the rolling calculation.

Examples

The example below will show a rolling calculation with a window size of four matching the equivalent function call using *scipy.stats*.

```python
>>> arr = [1, 2, 3, 4, 999]
>>> import scipy.stats
>>> print(f"{scipy.stats.kurtosis(arr[:-1], bias=False):.6f}")
-1.200000
>>> print(f"{scipy.stats.kurtosis(arr[1:], bias=False):.6f}")
3.999946
>>> s = pd.Series(arr)
>>> s.rolling(4).kurt()
0    NaN
1    NaN
2    NaN
3  -1.200000
4  3.999946
dtype: float64
```
Rolling.apply (func, raw=False, engine=None, engine_kwars=None, args=None, kwars=None)

Apply an arbitrary function to each rolling window.

Parameters

func [function] Must produce a single value from an ndarray input if raw=True or a single value from a Series if raw=False. Can also accept a Numba JIT function with engine='numba' specified.

Changed in version 1.0.0.

raw [bool, default None]

- False: passes each row or column as a Series to the function.
- True: the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

engine [str, default None]

- 'cython': Runs rolling apply through C-extensions from cython.
- 'numba': Runs rolling apply through JIT compiled code from numba. Only available when raw is set to True.
- None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.0.0.

engine_kwars [dict, default None]

- For 'cython' engine, there are no accepted engine_kwars
- For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwars for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False} and will be applied to both the func and the apply rolling aggregation.

New in version 1.0.0.

args [tuple, default None] Positional arguments to be passed into func.

kwars [dict, default None] Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.rolling Calling object with Series data.
pandas.DataFrame.rolling Calling object with DataFrame data.
pandas.Series.apply Similar method for Series.
pandas.DataFrame.apply Similar method for DataFrame.
Notes

See *Rolling apply* for extended documentation and performance considerations for the Numba engine.

**pandas.core.window.rolling.Rolling.aggregate**

Rolling.**aggregate**(func, *args, **kwargs)

Aggregate using one or more operations over the specified axis.

**Parameters**

- **func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series/Dataframe or when passed to Series/Dataframe.apply.
  
  Accepted combinations are:
  
  - function
  - string function name
  - list of functions and/or function names, e.g. [np.sum, 'mean']
  - dict of axis labels -> functions, function names or list of such.

- **args** Positional arguments to pass to func.

- **kwargs** Keyword arguments to pass to func.

**Returns**

- scalar, Series or DataFrame The return can be:
  
  - scalar : when Series.agg is called with single function
  - Series : when DataFrame.agg is called with a single function
  - DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

- **pandas.Series.rolling** Calling object with Series data.
- **pandas.DataFrame.rolling** Calling object with DataFrame data.

Notes

*agg* is an alias for *aggregate*. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]})
>>> df
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9
```
```python
>>> df.rolling(2).sum()
  A  B  C
0  NaN NaN NaN
1  3.0 9.0 15.0
2  5.0 11.0 17.0

>>> df.rolling(2).agg({'A': 'sum', 'B': 'min'})
   A  B
0  NaN NaN
1  3.0 4.0
2  5.0 5.0
```

**pandas.core.window.rolling.Rolling.quantile**

Rolling.quantile(quantile, interpolation='linear', **kwargs)

Calculate the rolling quantile.

**Parameters**

- **quantile** [float] Quantile to compute. 0 <= quantile <= 1.
- **interpolation** [{'linear', 'lower', 'higher', 'midpoint', 'nearest'}] New in version 0.23.0.

This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points \( i \) and \( j \):

- linear: \( i + (j - i) \times \text{fraction} \), where \( \text{fraction} \) is the fractional part of the index surrounded by \( i \) and \( j \).
- lower: \( i \).
- higher: \( j \).
- nearest: \( i \) or \( j \) whichever is nearest.
- midpoint: \( (i + j) / 2 \).

**kwargs** For compatibility with other rolling methods. Has no effect on the result.

**Returns**

- Series or DataFrame Returned object type is determined by the caller of the rolling calculation.

**See also:**

- **pandas.Series.quantile** Computes value at the given quantile over all data in Series.
- **pandas.DataFrame.quantile** Computes values at the given quantile over requested axis in DataFrame.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).quantile(.4, interpolation='lower')
0    NaN
1    1.0
2    2.0
3    3.0
dtype: float64
```
>>> s.rolling(2).quantile(.4, interpolation='midpoint')
0   NaN
1   1.5
2   2.5
3   3.5
dtype: float64

pandas.core.window.rolling.Window.mean

Window.mean(*args, **kwargs)
Calculate the window mean of the values.
Parameters
  *args  Under Review.
  **kwargs  Under Review.

Returns
  Series or DataFrame  Returned object type is determined by the caller of the window calculation.

See also:
  pandas.Series.window  Calling object with Series data.
  pandas.DataFrame.window  Calling object with DataFrames.
  pandas.Series.mean  Equivalent method for Series.
  pandas.DataFrame.mean  Equivalent method for DataFrame.

Examples

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0   NaN
1   1.5
2   2.5
3   3.5
dtype: float64

>>> s.rolling(3).mean()
0   NaN
1   NaN
2   2.0
3   3.0
dtype: float64
**pandas.core.window.rolling.Window.sum**

Window.sum(*args, **kwargs)

Calculate window sum of given DataFrame or Series.

**Parameters**

*args, **kwargs For compatibility with other window methods. Has no effect on the computed value.

**Returns**

Series or DataFrame Same type as the input, with the same index, containing the window sum.

**See also:**

pandas.Series.sum Reducing sum for Series.

pandas.DataFrame.sum Reducing sum for DataFrame.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64

>>> s.rolling(3).sum()
0    NaN
1    NaN
2     6.0
3     9.0
4    12.0
dtype: float64

>>> s.expanding(3).sum()
0    NaN
1    NaN
2     6.0
3    10.0
4    15.0
dtype: float64

>>> s.rolling(3, center=True).sum()
0    NaN
1     6.0
2     9.0
3    12.0
4    NaN
dtype: float64
```

For DataFrame, each window sum is computed column-wise.

---

2206 Chapter 3. API reference
```python
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
>>> df
        A  B
0       1  1
1       2  4
2       3  9
3       4 16
4       5 25

>>> df.rolling(3).sum()
        A  B
0       NaN  NaN
1       NaN  NaN
2       6.0 14.0
3       9.0 29.0
4      12.0 50.0
```

**pandas.core.window.rolling.Window.var**

Window.var(ddof=1, *args, **kwargs)

Calculate unbiased window variance.

New in version 1.0.0.

Normalized by N-1 by default. This can be changed using the ddof argument.

**Parameters**

- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- ***args, **kwargs** For NumPy compatibility. No additional arguments are used.

**Returns**

Series or DataFrame Returns the same object type as the caller of the window calculation.

**See also:**

- pandas.Series.window Calling object with Series data.
- pandas.DataFrame.window Calling object with DataFrames.
- pandas.Series.var Equivalent method for Series.
- pandas.DataFrame.var Equivalent method for DataFrame.
- numpy.var Equivalent method for Numpy array.

**Notes**

The default ddof of 1 used in Series.var() is different than the default ddof of 0 in numpy.var().

A minimum of 1 period is required for the rolling calculation.
Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
0    NaN
1    NaN
2    0.333333
3    1.000000
4    1.000000
5    1.333333
6    0.000000
dtype: float64

>>> s.expanding(3).var()
0    NaN
1    NaN
2    0.333333
3    0.916667
4    0.800000
5    0.700000
6    0.619048
dtype: float64
```

**pandas.core.window.rolling.Window.std**

`Window.std(ddof=1, *args, **kwargs)`

Calculate window standard deviation.

New in version 1.0.0.

Normalized by N-1 by default. This can be changed using the `ddof` argument.

- **Parameters**
  - `ddof` [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.

  - `*args, **kwargs` For NumPy compatibility. No additional arguments are used.

- **Returns**
  - `Series or DataFrame` Returns the same object type as the caller of the window calculation.

See also:

- `pandas.Series.window` Calling object with Series data.
- `pandas.DataFrame.window` Calling object with DataFrames.
- `pandas.Series.std` Equivalent method for Series.
- `pandas.DataFrame.std` Equivalent method for DataFrame.
- `numpy.std` Equivalent method for Numpy array.
Notes

The default `ddof` of 1 used in Series.std is different than the default `ddof` of 0 in numpy.std.

A minimum of one period is required for the rolling calculation.

Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0    NaN
1    NaN
2  0.577350
3  1.000000
4  1.000000
5  1.154701
6  0.000000
dtype: float64

>>> s.expanding(3).std()
0    NaN
1    NaN
2  0.577350
3  0.957427
4  0.894427
5  0.836660
6  0.786796
dtype: float64
```

pandas.core.window.expanding.Expanding.count

Expanding.count(**kwargs)

The expanding count of any non-NaN observations inside the window.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:

pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrames.
pandas.DataFrame.count Count of the full DataFrame.

Examples

```python
>>> s = pd.Series([2, 3, np.nan, 10])
>>> s.rolling(2).count()
0    1.0
1    2.0
2    1.0
3    1.0
dtype: float64
>>> s.rolling(3).count()
0    1.0
1    2.0
2    2.0
3    2.0
dtype: float64
>>> s.rolling(4).count()
0    1.0
1    2.0
2    2.0
3    3.0
dtype: float64
```

pandas.core.window.expanding.Expanding.sum

Expanding.sum(*args, **kwargs)

Calculate expanding sum of given DataFrame or Series.

Parameters

*args, **kwargs For compatibility with other expanding methods. Has no effect on the computed value.

Returns

Series or DataFrame Same type as the input, with the same index, containing the expanding sum.

See also:

pandas.Series.sum Reducing sum for Series.
pandas.DataFrame.sum Reducing sum for DataFrame.
Examples

```python
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

```python
>>> s.rolling(3).sum()
0    NaN
1    NaN
2    6.0
3    9.0
4    12.0
dtype: float64
```

```python
>>> s.expanding(3).sum()
0    NaN
1    NaN
2    6.0
3    10.0
4    15.0
dtype: float64
```

```python
>>> s.rolling(3, center=True).sum()
0    NaN
1    6.0
2    9.0
3    12.0
4    NaN
dtype: float64
```

For DataFrame, each expanding sum is computed column-wise.

```python
>>> df = pd.DataFrame({"A": s, "B": s ** 2})
>>> df
   A   B
0  1   1
1  2   4
2  3   9
3  4  16
4  5  25
```

```python
>>> df.rolling(3).sum()
   A   B
0  NaN NaN
1  NaN NaN
2  6.0 14.0
3  9.0 29.0
4 12.0 50.0
```
**pandas.core.window.expanding.Expanding.mean**

```python
Expanding.mean(*args, **kwargs)
```

Calculate the expanding mean of the values.

**Parameters**

- *args: Under Review.
- **kwargs: Under Review.

**Returns**

- **Series or DataFrame**: Returned object type is determined by the caller of the expanding calculation.

**See also:**

- `pandas.Series.expanding`: Calling object with Series data.
- `pandas.DataFrame.expanding`: Calling object with DataFrames.
- `pandas.DataFrame.mean`: Equivalent method for DataFrame.

**Examples**

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0   NaN
1   1.5
2   2.5
3   3.5
dtype: float64
```

```python
>>> s.rolling(3).mean()
0   NaN
1   NaN
2   2.0
3   3.0
dtype: float64
```

**pandas.core.window.expanding.Expanding.median**

```python
Expanding.median(**kwargs)
```

Calculate the expanding median.

**Parameters**

- **kwargs: For compatibility with other expanding methods. Has no effect on the computed median.

**Returns**

- **Series or DataFrame**: Returned type is the same as the original object.

**See also:**

- `pandas.Series.expanding`: Calling object with Series data.
- `pandas.DataFrame.expanding`: Calling object with DataFrames.
Examples

Compute the rolling median of a series with a window size of 3.

```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.rolling(3).median()
0   NaN
1   NaN
2   1.0
3   2.0
4   3.0
dtype: float64
```

`pandas.core.window.expanding.Expanding.var`

`Expanding.var(ddof=1, *args, **kwargs)`

Calculate unbiased expanding variance.

Normalized by N-1 by default. This can be changed using the `ddof` argument.

**Parameters**

- `ddof` [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.
- `*args, **kwargs` For NumPy compatibility. No additional arguments are used.

**Returns**

- `Series` or `DataFrame` Returns the same object type as the caller of the expanding calculation.

**See also:**

- `pandas.Series.expanding` Calling object with Series data.
- `pandas.DataFrame.expanding` Calling object with DataFrames.
- `pandas.Series.var` Equivalent method for Series.
- `pandas.DataFrame.var` Equivalent method for DataFrame.
- `numpy.var` Equivalent method for Numpy array.

**Notes**

The default `ddof` of 1 used in `Series.var()` is different than the default `ddof` of 0 in `numpy.var()`.

A minimum of 1 period is required for the rolling calculation.

**Examples**

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
0   NaN
1   NaN
2   0.333333
3   1.000000
4   1.000000
5   1.333333
6   0.000000
dtype: float64
```
>>> s.expanding(3).var()
0   NaN
1   NaN
2   0.333333
3   0.916667
4   0.800000
5   0.700000
6   0.619048
dtype: float64

pandas.core.window.expanding.Expanding.std

Expanding.std(ddof=1, *args, **kwargs)
Calculate expanding standard deviation.

Normalized by N-1 by default. This can be changed using the ddof argument.

Parameters

- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

- **args, **kwargs For NumPy compatibility. No additional arguments are used.

Returns

Series or DataFrame Returns the same object type as the caller of the expanding calculation.

See also:

- pandas.Series.expanding Calling object with Series data.
- pandas.DataFrame.expanding Calling object with DataFrames.
- pandas.Series.std Equivalent method for Series.
- pandas.DataFrame.std Equivalent method for DataFrame.
- numpy.std Equivalent method for Numpy array.

Notes

The default ddof of 1 used in Series.std is different than the default ddof of 0 in numpy.std.

A minimum of one period is required for the rolling calculation.

Examples

>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0   NaN
1   NaN
2   0.577350
3   1.000000
4   1.000000
5   1.154701
6   0.000000
dtype: float64
```python
>>> s.expanding(3).std()
0    NaN
1    NaN
2  0.577350
3  0.957427
4  0.894427
5  0.836660
6  0.786796
dtype: float64
```

**pandas.core.window.expanding.Expanding.min**

`Expanding.min(*args, **kwargs)`

Calculate the expanding minimum.

**Parameters**

**kwargs  Under Review.

**Returns**

*Series or DataFrame*  Returned object type is determined by the caller of the expanding calculation.

**Examples**

Performing a rolling minimum with a window size of 3.

```python
>>> s = pd.Series([4, 3, 5, 2, 6])
>>> s.rolling(3).min()
0    NaN
1    NaN
2    3.0
3    2.0
4    2.0
dtype: float64
```

**pandas.core.window.expanding.Expanding.max**

`Expanding.max(*args, **kwargs)`

Calculate the expanding maximum.

**Parameters**

*:args, **kwargs*  Arguments and keyword arguments to be passed into func.

**Returns**

*Series or DataFrame*  Return type is determined by the caller.

**See also:**

*pandas.Series.expanding*  Calling object with a Series.
*pandas.DataFrame.expanding*  Calling object with a DataFrame.
*pandas.Series.min*  Similar method for Series.
*pandas.DataFrame.min*  Similar method for DataFrame.
Expanding.corr (other=None, pairwise=None, **kwargs)
Calculate expanding correlation.

Parameters

other [Series, DataFrame, or ndarray, optional] If not supplied then will default to self.

pairwise [bool, default None] Calculate pairwise combinations of columns within a DataFrame. If other is not specified, defaults to True, otherwise defaults to False. Not relevant for Series.

**kwargs Unused.

Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:
pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrames.
pandas.Series.corr Equivalent method for Series.
pandas.DataFrame.corr Equivalent method for DataFrame.
cov Similar method to calculate covariance.
numpy.corrcoef NumPy Pearson’s correlation calculation.

Notes

This function uses Pearson’s definition of correlation (https://en.wikipedia.org/wiki/Pearson_correlation_coefficient).

When other is not specified, the output will be self correlation (e.g. all 1’s), except for DataFrame inputs with pairwise set to True.

Function will return NaN for correlations of equal valued sequences; this is the result of a 0/0 division error.

When pairwise is set to False, only matching columns between self and other will be used.

When pairwise is set to True, the output will be a MultiIndex DataFrame with the original index on the first level, and the other DataFrame columns on the second level.

In the case of missing elements, only complete pairwise observations will be used.
Examples

The below example shows a rolling calculation with a window size of four matching the equivalent function call using `numpy.corrcoef()`.

```python
>>> v1 = [3, 3, 3, 5, 8]
>>> v2 = [3, 4, 4, 4, 8]
>>> # numpy returns a 2x2 array, the correlation coefficient
>>> # is the number at entry [0][1]
>>> print(f"{np.corrcoef(v1[:-1], v2[:-1])[0][1]:.6f}")
0.333333
>>> print(f"{np.corrcoef(v1[1:], v2[1:])[0][1]:.6f}")
0.916949
>>> s1 = pd.Series(v1)
>>> s2 = pd.Series(v2)
>>> s1.rolling(4).corr(s2)
0 NaN
1 NaN
2 NaN
3 0.333333
4 0.916949
dtype: float64
```

The below example shows a similar rolling calculation on a DataFrame using the pairwise option.

```python
>>> print(np.corrcoef(matrix[:-1,0], matrix[:-1,1]).round(7))
[[1.0000000 0.6263001]
 [0.6263001 1.0000000]]
>>> print(np.corrcoef(matrix[1:,0], matrix[1:,1]).round(7))
[[1.0000000 0.5553681]
 [0.5553681 1.0000000]]
>>> df = pd.DataFrame(matrix, columns=['X','Y'])
>>> df.
0 51.0 35.0
1 49.0 30.0
2 47.0 32.0
3 46.0 31.0
4 50.0 36.0
>>> df.rolling(4).corr(pairwise=True)
```

```
x       y
0 NaN   NaN
1 NaN   NaN
2 NaN   NaN
3 x 1.000000 0.626300
y 0.626300 1.000000
2 x 1.000000 0.555368
y 0.555368 1.000000
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.core.window.expanding.Expanding.cov

Expanding.cov(other=None, pairwise=None, ddof=1, **kwargs)

Calculate the expanding sample covariance.

Parameters

other [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N – ddof, where N represents the number of elements.

**kwargs Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrame data.
pandas.Series.cov Similar method for Series.
pandas.DataFrame.cov Similar method for DataFrame.

pandas.core.window.expanding.Expanding.skew

Expanding.skew(**kwargs)

Unbiased expanding skewness.

Parameters

**kwargs Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrame data.
pandas.Series.skew Similar method for Series.
pandas.DataFrame.skew Similar method for DataFrame.

pandas.core.window.expanding.Expanding.kurt

Expanding.kurt(**kwargs)

Calculate unbiased expanding kurtosis.

This function uses Fisher’s definition of kurtosis without bias.

Parameters

**kwargs Under Review.

Returns
Series or DataFrame  Returned object type is determined by the caller of the expanding calculation.

See also:

pandas.Series.expanding  Calling object with Series data.
pandas.DataFrame.expanding  Calling object with DataFrames.
pandas.Series.kurt  Equivalent method for Series.
pandas.DataFrame.kurt  Equivalent method for DataFrame.
scipy.stats.skew  Third moment of a probability density.

Notes

A minimum of 4 periods is required for the expanding calculation.

Examples

The example below will show an expanding calculation with a window size of four matching the equivalent function call using scipy.stats.

```python
>>> arr = [1, 2, 3, 4, 999]
>>> import scipy.stats
>>> print(f"scipy.stats.kurtosis(arr[:-1], bias=\n:bias=False):.6f")
-1.200000
>>> print(f"scipy.stats.kurtosis(arr, bias=\n:bias=False):.6f")
4.999874
>>> s = pd.Series(arr)
>>> s.expanding(4).kurt()
0    NaN
1    NaN
2    NaN
3   -1.200000
4    4.999874
dtype: float64
```

pandas.core.window.expanding.Expanding.apply

Expanding .apply (func, raw=False, engine=None, engine_kwargs=None, args=None, kwargs=None)  
Apply an arbitrary function to each expanding window.

Parameters

- **func** [function] Must produce a single value from an ndarray input if raw=True or a single value from a Series if raw=False. Can also accept a Numba JIT function with engine='numba' specified.

  Changed in version 1.0.0.

- **raw** [bool, default None]

  - False: passes each row or column as a Series to the function.
  - True: the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

- **engine** [str, default None]

  - 'cython': Runs rolling apply through C-extensions from cython.
• 'numba': Runs rolling apply through JIT compiled code from numba. Only available when raw is set to True.
• None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.0.0.

engine_kwargs [dict, default None]

• For 'cython' engine, there are no accepted engine_kwargs
• For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False} and will be applied to both the func and the apply rolling aggregation.

New in version 1.0.0.

args [tuple, default None] Positional arguments to be passed into func.

kwargs [dict, default None] Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.expanding Calling object with Series data.
pandas.DataFrame.expanding Calling object with DataFrame data.
pandas.Series.aggregate Similar method for Series.
pandas.DataFrame.aggregate Similar method for DataFrame.

Notes

See Rolling apply for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.aggregate

Expanding.aggregate (func, *args, **kwargs)

Aggregates using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series/Dataframe or when passed to Series/Dataframe.apply.

Accepted combinations are:

• function
• string function name
• list of functions and/or function names, e.g. [np.sum, 'mean']
• dict of axis labels -> functions, function names or list of such.

*args Positional arguments to pass to func.

**kwargs Keyword arguments to pass to func.

Returns

scalar, Series or DataFrame The return can be:
• scalar: when Series.agg is called with single function
• Series: when DataFrame.agg is called with a single function
• DataFrame: when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:
pandas.DataFrame.aggregate Similar DataFrame method.
pandas.Series.aggregate Similar Series method.

Notes

agg is an alias for aggregate. Use the alias.
A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6], "C": [7, 8, 9]})
```

```plaintext
A  B  C
0 1 4 7
1 2 5 8
2 3 6 9
```

```python
>>> df.ewm(alpha=0.5).mean()
```

```plaintext
A  B  C
0 1.000000 4.000000 7.000000
1 1.666667 4.666667 7.666667
2 2.428571 5.428571 8.428571
```

pandas.core.window.expanding.Expanding.quantile

Expanding. **quantile**(quantile, interpolation='linear', **kwargs)
Calculate the expanding quantile.

**Parameters**

quantile [float] Quantile to compute. 0 <= quantile <= 1.

This optional parameter specifies the interpolation method to use, when the desired
quantile lies between two data points i and j:
• linear: \( i + (j - i) \times fraction \), where fraction is the fractional part of the index sur-
rounded by i and j.
• lower: i.
• higher: j.
• nearest: i or j whichever is nearest.
• midpoint: \( (i + j) / 2 \).

**kwargs For compatibility with other expanding methods. Has no effect on the result.
Returns

Series or DataFrame Returned object type is determined by the caller of the expanding calculation.

See also:

pandas.Series.quantile Computes value at the given quantile over all data in Series.
pandas.DataFrame.quantile Computes values at the given quantile over requested axis in DataFrame.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).quantile(.4, interpolation='lower')
0  NaN
1  1.0
2  2.0
3  3.0
dtype: float64

>>> s.rolling(2).quantile(.4, interpolation='midpoint')
0  NaN
1  1.5
2  2.5
3  3.5
dtype: float64
```

3.10.3 Exponentially-weighted moving window functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pandas.core.window.ewm.ExponentialMovingWindow.mean(*args, **kwargs)</td>
<td>Exponential weighted moving average.</td>
</tr>
<tr>
<td>pandas.core.window.ewm.ExponentialMovingWindow.std([bias])</td>

<td>Exponential weighted sample covariance.</td>
</tr>
</tbody>
</table>

pandas.core.window.ewm.ExponentialMovingWindow.mean

ExponentialMovingWindow.mean(*args, **kwargs)

Exponential weighted moving average.

Parameters

*args, **kwargs Arguments and keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is determined by the caller.

See also:

pandas.Series.ewm Calling object with Series data.
pandas.DataFrame.ewm Calling object with DataFrame data.
pandas.Series.mean Similar method for Series.
pandas.DataFrame.mean Similar method for DataFrame.
**pandas.core.window.ewm.ExponentialMovingWindow.std**

```python
ExponentialMovingWindow.std(bias=False, *args, **kwargs)
```

Exponential weighted moving stddev.

**Parameters**

- `bias` [bool, default False] Use a standard estimation bias correction.
- `*args, **kwargs` Arguments and keyword arguments to be passed into func.

**Returns**

- `Series or DataFrame` Return type is determined by the caller.

**See also:**

- `pandas.Series.ewm` Calling object with Series data.
- `pandas.DataFrame.ewm` Calling object with DataFrame data.
- `pandas.Series.std` Similar method for Series.
- `pandas.DataFrame.std` Similar method for DataFrame.

**pandas.core.window.ewm.ExponentialMovingWindow.var**

```python
ExponentialMovingWindow.var(bias=False, *args, **kwargs)
```

Exponential weighted moving variance.

**Parameters**

- `bias` [bool, default False] Use a standard estimation bias correction.
- `*args, **kwargs` Arguments and keyword arguments to be passed into func.

**Returns**

- `Series or DataFrame` Return type is determined by the caller.

**See also:**

- `pandas.Series.ewm` Calling object with Series data.
- `pandas.DataFrame.ewm` Calling object with DataFrame data.
- `pandas.Series.var` Similar method for Series.
- `pandas.DataFrame.var` Similar method for DataFrame.

**pandas.core.window.ewm.ExponentialMovingWindow.corr**

```python
ExponentialMovingWindow.corr(other=None, pairwise=None, **kwargs)
```

Exponential weighted sample correlation.

**Parameters**

- `other` [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.
- `pairwise` [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.
- `**kwargs` Keyword arguments to be passed into func.

**Returns**

- `Series or DataFrame` Return type is determined by the caller.
pandas: powerful Python data analysis toolkit, Release 1.1.1

See also:

- **pandas.Series.ewm** Calling object with Series data.
- **pandas.DataFrame.ewm** Calling object with DataFrame data.
- **pandas.Series.corr** Similar method for Series.
- **pandas.DataFrame.corr** Similar method for DataFrame.

**pandas.core.window.ewm.ExponentialMovingWindow.cov**

ExponentialMovingWindow.cov (other=None, pairwise=None, bias=False, **kwargs)

Exponential weighted sample covariance.

**Parameters**

- **other** [Series, DataFrame, or ndarray, optional] If not supplied then will default to self and produce pairwise output.
- **pairwise** [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.
- **bias** [bool, default False] Use a standard estimation bias correction.
- **kwargs** Keyword arguments to be passed into func.

**Returns**

- **Series or DataFrame** Return type is determined by the caller.

See also:

- **pandas.Series.ewm** Calling object with Series data.
- **pandas.DataFrame.ewm** Calling object with DataFrame data.
- **pandas.Series.cov** Similar method for Series.
- **pandas.DataFrame.cov** Similar method for DataFrame.

### 3.10.4 Window indexer

Base class for defining custom window boundaries.

- **api.indexers.BaseIndexer**([index_array, ...]) Base class for window bounds calculations.
- **api.indexers.FixedForwardWindowIndexer**([create window boundaries for fixed-length windows that include the current row.
- **api.indexers.VariableOffsetWindowIndexer**([create window boundaries based on a non-fixed offset such as a BusinessDay])
pandas.api.indexers.BaseIndexer

class pandas.api.indexers.BaseIndexer(index_array=None, window_size=0, **kwargs)
   Base class for window bounds calculations.

   Methods

   get_window_bounds([num_values, min_periods,...])
      Computes the bounds of a window.

pandas.api.indexers.BaseIndexer.get_window_bounds

BaseIndexer.get_window_bounds (num_values=0, min_periods=None, center=None, closed=None)
   Computes the bounds of a window.

   Parameters

   num_values [int, default 0] number of values that will be aggregated over
   window_size [int, default 0] the number of rows in a window
   min_periods [int, default None] min_periods passed from the top level rolling API
   center [bool, default None] center passed from the top level rolling API
   closed [str, default None] closed passed from the top level rolling API
   win_type [str, default None] win_type passed from the top level rolling API

   Returns

   A tuple of ndarray[int64], indicating the boundaries of each window

pandas.api.indexers.FixedForwardWindowIndexer

class pandas.api.indexers.FixedForwardWindowIndexer(index_array=None, window_size=0, **kwargs)
   Creates window boundaries for fixed-length windows that include the current row.

Examples

>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0

3.10. Window
```python
>>> indexer = pd.api.indexers.FixedForwardWindowIndexer(window_size=2)
>>> df.rolling(window=indexer, min_periods=1).sum()
B
0 1.0
1 3.0
2 2.0
3 4.0
4 4.0
```

**Methods**

```python
get_window_bounds([num_values, min_periods, ...])
```

Computes the bounds of a window.

**pandas.api.indexers.FixedForwardWindowIndexer.get_window_bounds**

FixedForwardWindowIndexer.get_window_bounds(num_values=0, min_periods=None, center=None, closed=None)

Computes the bounds of a window.

**Parameters**

- **num_values** [int, default 0] number of values that will be aggregated over
- **window_size** [int, default 0] the number of rows in a window
- **min_periods** [int, default None] min_periods passed from the top level rolling API
- **center** [bool, default None] center passed from the top level rolling API
- **closed** [str, default None] closed passed from the top level rolling API
- **win_type** [str, default None] win_type passed from the top level rolling API

**Returns**

A tuple of ndarray[int64], indicating the boundaries of each window

**pandas.api.indexers.VariableOffsetWindowIndexer**

class pandas.api.indexers.VariableOffsetWindowIndexer(index_array=None, window_size=0, index=None, offset=None, **kwargs)

Calculate window boundaries based on a non-fixed offset such as a BusinessDay
Methods

```python
get_window_bounds([num_values, min_periods, ...])
```

Computes the bounds of a window.

```python
pandas.api.indexers.VariableOffsetWindowIndexer.get_window_bounds
```

VariableOffsetWindowIndexer.get_window_bounds(num_values=0, min_periods=None, center=None, closed=None)

Computes the bounds of a window.

Parameters

- **num_values** [int, default 0] number of values that will be aggregated over
- **window_size** [int, default 0] the number of rows in a window
- **min_periods** [int, default None] min_periods passed from the top level rolling API
- **center** [bool, default None] center passed from the top level rolling API
- **closed** [str, default None] closed passed from the top level rolling API
- **win_type** [str, default None] win_type passed from the top level rolling API

Returns

A tuple of ndarray[int64], indicating the boundaries of each window

### 3.11 GroupBy

GroupBy objects are returned by groupby calls: `pandas.DataFrame.groupby()`, `pandas.Series.groupby()`, etc.

#### 3.11.1 Indexing, iteration

```python
GroupBy.__iter__()  Groupby iterator.
GroupBy.groups       Dict {group name -> group labels}.
GroupBy.indices      Dict {group name -> group indices}.
GroupBy.get_group(name[, obj]) Construct DataFrame from group with provided name.
```
pandas.core.groupby.GroupBy.__iter__

GroupBy.__iter__()

Groupby iterator.

Returns

Generator yielding sequence of (name, subsetted object)
for each group

pandas.core.groupby.GroupBy.groups

property GroupBy.groups

Dict {group name -> group labels}.

pandas.core.groupby.GroupBy.indices

property GroupBy.indices

Dict {group name -> group indices}.

pandas.core.groupby.GroupBy.get_group

GroupBy.get_group(name, obj=None)

Construct DataFrame from group with provided name.

Parameters

name [object] The name of the group to get as a DataFrame.

obj [DataFrame, default None] The DataFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used.

Returns

group [same type as obj]

Grouper(*args, **kwargs)

A Grouper allows the user to specify a groupby instruction for an object.

class pandas.Grouper(*args, **kwargs)

A Grouper allows the user to specify a groupby instruction for an object.

This specification will select a column via the key parameter, or if the level and/or axis parameters are given, a level of the index of the target object.

If axis and/or level are passed as keywords to both Grouper and groupby, the values passed to Grouper take precedence.

Parameters

key [str, defaults to None] Groupby key, which selects the grouping column of the target.

level [name/number, defaults to None] The level for the target index.

freq [str / frequency object, defaults to None] This will groupby the specified frequency if the target selection (via key or level) is a datetime-like object. For full specification of
available frequencies, please see here.

**axis** [str, int, defaults to 0] Number/name of the axis.

**sort** [bool, default to False] Whether to sort the resulting labels.

**closed** ['left' or 'right']) Closed end of interval. Only when *freq* parameter is passed.

**label** ['left' or 'right']) Interval boundary to use for labeling. Only when *freq* parameter is passed.

**convention** ['start', 'end', 'e', 's'] If grouper is PeriodIndex and *freq* parameter is passed.

**base** [int, default 0] Only when *freq* parameter is passed. For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0.

Deprecation: Since version 1.1.0: The new arguments that you should use are ‘offset’ or ‘origin’.

**loffset** [str, DateOffset, timedelta object] Only when *freq* parameter is passed.

Deprecation: Since version 1.1.0: loffset is only working for .resample(...) and not for Grouper (GH28302). However, loffset is also deprecated for .resample(...)

See: DataFrame.resample

**origin** [‘epoch’, ‘start’, ‘start_day’] The timestamp on which to adjust the grouping. The timezone of origin must match the timezone of the index. If a timestamp is not used, these values are also supported:

  * ‘epoch’: *origin* is 1970-01-01
  * ‘start’: *origin* is the first value of the timeseries
  * ‘start_day’: *origin* is the first day at midnight of the timeseries

New in version 1.1.0.

**offset** [Timedelta or str, default is None] An offset timedelta added to the origin.

New in version 1.1.0.

**Returns**

A specification for a groupby instruction

**Examples**

Syntactic sugar for df.groupby('A')

```python
>>> df = pd.DataFrame(
    ... {  
    ...     "Animal": ["Falcon", "Parrot", "Falcon", "Falcon", "Parrot"],  
    ...     "Speed": [100, 5, 200, 300, 15],  
    ... }  
    ...
>>> df
   Animal  Speed
0   Falcon    100
1    Parrot     5
2   Falcon    200
3   Falcon    300
4    Parrot     5
```

(continues on next page)
Specify a resample operation on the column ‘Publish date’

```python
>>> df = pd.DataFrame(
...     {
...         "Publish date": [pd.Timestamp("2000-01-02"),
...                         pd.Timestamp("2000-01-02"),
...                         pd.Timestamp("2000-01-09"),
...                         pd.Timestamp("2000-01-16")),
...         "ID": [0, 1, 2, 3],
...         "Price": [10, 20, 30, 40]
...     }
... )
```

```python
>>> df
df
```

<table>
<thead>
<tr>
<th>Publish date</th>
<th>ID</th>
<th>Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-02</td>
<td>0</td>
<td>10</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>1</td>
<td>20</td>
</tr>
<tr>
<td>2000-01-09</td>
<td>2</td>
<td>30</td>
</tr>
<tr>
<td>2000-01-16</td>
<td>3</td>
<td>40</td>
</tr>
</tbody>
</table>

```python
>>> df.groupby(pd.Grouper(key="Publish date", freq="1W")).mean()
```

<table>
<thead>
<tr>
<th>Publish date</th>
<th>ID</th>
<th>Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-02</td>
<td>0.5</td>
<td>15.0</td>
</tr>
<tr>
<td>2000-01-09</td>
<td>2</td>
<td>30.0</td>
</tr>
<tr>
<td>2000-01-16</td>
<td>3</td>
<td>40.0</td>
</tr>
</tbody>
</table>

If you want to adjust the start of the bins based on a fixed timestamp:

```python
>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
>>> ts
```

| 2000-10-01 23:30:00 | 0  |
| 2000-10-01 23:37:00 | 3  |
| 2000-10-01 23:44:00 | 6  |
| 2000-10-01 23:51:00 | 9  |
| 2000-10-01 23:58:00 | 12 |
| 2000-10-02 00:05:00 | 15 |
| 2000-10-02 00:12:00 | 18 |
| 2000-10-02 00:19:00 | 21 |
| 2000-10-02 00:26:00 | 24 |

Freq: 7T, dtype: int64

```python
>>> ts.groupby(pd.Grouper(freq='17min')).sum()
```

| 2000-10-01 23:14:00 | 0  |
| 2000-10-01 23:31:00 | 9  |
| 2000-10-01 23:48:00 | 21 |
| 2000-10-02 00:05:00 | 54 |
| 2000-10-02 00:22:00 | 24 |

Freq: 17T, dtype: int64
>>> ts.groupby(pd.Grouper(freq='17min', origin='epoch')).sum()
2000-10-01 23:18:00 0
2000-10-01 23:35:00 18
2000-10-01 23:52:00 27
2000-10-02 00:09:00 39
2000-10-02 00:26:00 24
Freq: 17T, dtype: int64

>>> ts.groupby(pd.Grouper(freq='17min', origin='2000-01-01')).sum()
2000-10-01 23:24:00 3
2000-10-01 23:41:00 15
2000-10-01 23:58:00 45
2000-10-02 00:15:00 45
Freq: 17T, dtype: int64

If you want to adjust the start of the bins with an offset Timedelta, the two following lines are equivalent:

>>> ts.groupby(pd.Grouper(freq='17min', origin='start')).sum()
2000-10-01 23:30:00 9
2000-10-01 23:47:00 21
2000-10-02 00:04:00 54
2000-10-02 00:21:00 24
Freq: 17T, dtype: int64

>>> ts.groupby(pd.Grouper(freq='17min', offset='23h30min')).sum()
2000-10-01 23:30:00 9
2000-10-01 23:47:00 21
2000-10-02 00:04:00 54
2000-10-02 00:21:00 24
Freq: 17T, dtype: int64

To replace the use of the deprecated base argument, you can now use offset, in this example it is equivalent to have base=2:

>>> ts.groupby(pd.Grouper(freq='17min', offset='2min')).sum()
2000-10-01 23:16:00 0
2000-10-01 23:33:00 9
2000-10-01 23:50:00 36
2000-10-02 00:07:00 39
2000-10-02 00:24:00 24
Freq: 17T, dtype: int64
3.11.2 Function application

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>GroupBy.apply(func, *args, **kwargs)</code></td>
<td>Apply function <code>func</code> group-wise and combine the results together.</td>

<td>Apply a function <code>func</code> with arguments to this GroupBy object and return the function’s result.</td>
</tr>
</tbody>
</table>

**pandas.core.groupby.GroupBy.apply**

`GroupBy.apply(func, *args, **kwargs)`

Apply function `func` group-wise and combine the results together.

The function passed to `apply` must take a dataframe as its first argument and return a DataFrame, Series or scalar. `apply` will then take care of combining the results back together into a single dataframe or series. `apply` is therefore a highly flexible grouping method.

While `apply` is a very flexible method, its downside is that using it can be quite a bit slower than using more specific methods like `agg` or `transform`. Pandas offers a wide range of method that will be much faster than using `apply` for their specific purposes, so try to use them before reaching for `apply`.

**Parameters**

- `func` [callable] A callable that takes a dataframe as its first argument, and returns a dataframe, a series or a scalar. In addition the callable may take positional and keyword arguments.
- `args, kwargs` [tuple and dict] Optional positional and keyword arguments to pass to `func`.

**Returns**

- `applied` [Series or DataFrame]

**See also:**

- `pipe` Apply function to the full GroupBy object instead of to each group.
- `aggregate` Apply aggregate function to the GroupBy object.
- `transform` Apply function column-by-column to the GroupBy object.
- `Series.apply` Apply a function to a Series.
- `DataFrame.apply` Apply a function to each row or column of a DataFrame.
pandas.core.groupby.GroupBy.agg

GroupBy.**agg**(func, *args, **kwargs)

pandas.core.groupby.SeriesGroupBy.aggregate

SeriesGroupBy.**aggregate**(func=None, *args, engine=None, engine_kwargs=None, **kwargs)

Aggregate using one or more operations over the specified axis.

**Parameters**

- `func` [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.
  
  Accepted combinations are:
  
  - function
  - string function name
  - list of functions and/or function names, e.g. [np.sum, 'mean']
  - dict of axis labels -> functions, function names or list of such.

  Can also accept a Numba JIT function with `engine='numba'` specified.

  If the `numba` engine is chosen, the function must be a user defined function with `values` and `index` as the first and second arguments respectively in the function signature. Each group’s index will be passed to the user defined function and optionally available for use.

  Changed in version 1.1.0.

- `*args` Positional arguments to pass to func

- `engine` [str, default None]
  
  - `cython`: Runs the function through C-extensions from cython.
  - `numba`: Runs the function through JIT compiled code from numba.
  - `None`: Defaults to `cython` or globally setting `compute.use_numba`

  New in version 1.1.0.

- `engine_kwargs` [dict, default None]
  
  - For `cython` engine, there are no accepted engine_kwargs
  - For `numba` engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwargs` for the `numba` engine is `{ 'nopython': True, 'nogil': False, 'parallel': False }` and will be applied to the function

  New in version 1.1.0.

- `**kwargs` Keyword arguments to be passed into func.

**Returns**

Series

See also:

- `Series.groupby.apply`
- `Series.groupby.transform`

3.11. GroupBy 2233
**Series.aggregate**

**Notes**

When using `engine='numba'`, there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4])
```

```text
0 1
1 2
2 3
3 4
dtype: int64
```

```python
>>> s.groupby([1, 1, 2, 2]).min()
```

```text
1 1
2 3
dtype: int64
```

```python
>>> s.groupby([1, 1, 2, 2]).agg('min')
```

```text
1 1
2 3
dtype: int64
```

```python
>>> s.groupby([1, 1, 2, 2]).agg(['min', 'max'])
```

```text
min max
1 1 2
2 3 4
```

The output column names can be controlled by passing the desired column names and aggregations as keyword arguments.

```python
>>> s.groupby([1, 1, 2, 2]).agg(
...     minimum='min',
...     maximum='max',
... )
```

```text
minimum maximum
1 1 2
2 3 4
```
DataFrameGroupBy.aggregate (func=None, *args, engine=None, engine_kwars=0, **kwargs)

Aggregate using one or more operations over the specified axis.

Parameters

- **func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

  Accepted combinations are:

  - function
  - string function name
  - list of functions and/or function names, e.g. [np.sum, 'mean']
  - dict of axis labels -> functions, function names or list of such.

  Can also accept a Numba JIT function with engine='numba' specified.

  If the 'numba' engine is chosen, the function must be a user defined function with values and index as the first and second arguments respectively in the function signature. Each group’s index will be passed to the user defined function and optionally available for use.

  Changed in version 1.1.0.

- **args** Positional arguments to pass to func

- **engine** [str, default None]

  - 'cython': Runs the function through C-extensions from cython.
  - 'numba': Runs the function through JIT compiled code from numba.
  - None: Defaults to 'cython' or globally setting compute.use_numba.

  New in version 1.1.0.

- **engine_kwars** [dict, default None]

  - For 'cython' engine, there are no accepted engine_kwars.
  - For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwars for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False} and will be applied to the function.

  New in version 1.1.0.

- **kwargs** Keyword arguments to be passed into func.

Returns

DataFrame

See also:

DataFrame.groupby.apply
DataFrame.groupby.transform
DataFrame.aggregate
Notes

When using engine='numba', there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Examples

```python
>>> df = pd.DataFrame(
...     {
...         "A": [1, 1, 2, 2],
...         "B": [1, 2, 3, 4],
...         "C": [0.362838, 0.227877, 1.267767, -0.562860],
...     }
... )

>>> df
  A  B     C
0  1  1  0.362838
1  1  2  0.227877
2  2  3  1.267767
3  2  4 -0.562860

The aggregation is for each column.

>>> df.groupby('A').agg('min')
     B     C
A
1  1  0.227877
2  3 -0.562860

Multiple aggregations

>>> df.groupby('A').agg(['min', 'max'])
        B     C
A  min max  min max
1  1  2  0.227877  0.362838
2  3  4 -0.562860  1.267767

Select a column for aggregation

>>> df.groupby('A').B.agg(['min', 'max'])
    min  max
A
1  1  2
2  3  4

Different aggregations per column

>>> df.groupby('A').agg({'B': ['min', 'max'], 'C': 'sum'})
     B     C
A  min max   sum
1  1  2  0.590715
2  3  4  0.704907
```
To control the output names with different aggregations per column, pandas supports “named aggregation”

```python
>>> df.groupby("A").agg(
...     b_min=pd.NamedAgg(column="B", aggfunc="min"),
...     c_sum=pd.NamedAgg(column="C", aggfunc="sum"))
```

```
b_min  c_sum
   A
1  1  0.590715
2  3  0.704907
```

- The keywords are the output column names
- The values are tuples whose first element is the column to select and the second element is the aggregation to apply to that column. Pandas provides the `pd.NamedAgg` namedtuple with the fields ['column', 'aggfunc'] to make it clearer what the arguments are. As usual, the aggregation can be a callable or a string alias.

See [Named aggregation](#) for more.

---

**pandas.core.groupby.SeriesGroupBy.transform**

`SeriesGroupBy.transform(func, *args, engine=None, engine_kwargs=None, **kwargs)`

Call function producing a like-indexed Series on each group and return a Series having the same indexes as the original object filled with the transformed values

**Parameters**

- `f` [function] Function to apply to each group.
  
  Can also accept a Numba JIT function with `engine='numba'` specified.

  If the 'numba' engine is chosen, the function must be a user defined function with `values` and `index` as the first and second arguments respectively in the function signature. Each group’s index will be passed to the user defined function and optionally available for use.

  Changed in version 1.1.0.

- `*args` Positional arguments to pass to func

- `engine` [str, default None]

  - 'cython': Runs the function through C-extensions from cython.
  
  - 'numba': Runs the function through JIT compiled code from numba.
  
  - None: Defaults to 'cython' or globally setting `compute.use_numba` New in version 1.1.0.

  `engine_kwargs` [dict, default None]

  - For 'cython' engine, there are no accepted `engine_kwargs`

  - For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwargs` for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}` and will be applied to the function

    New in version 1.1.0.

- `**kwargs` Keyword arguments to be passed into func.
Returns

Series

See also:

Series.groupby.apply
Series.groupby.aggregate
Series.transform

Notes

Each group is endowed the attribute ‘name’ in case you need to know which group you are working on.

The current implementation imposes three requirements on f:

• f must return a value that either has the same shape as the input subframe or can be broadcast to the shape of the input subframe. For example, if f returns a scalar it will be broadcast to have the same shape as the input subframe.

• if this is a DataFrame, f must support application column-by-column in the subframe. If f also supports application to the entire subframe, then a fast path is used starting from the second chunk.

• f must not mutate groups. Mutation is not supported and may produce unexpected results.

When using engine='numba', there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Examples

```python
>>> df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
... 'foo', 'bar'],
... 'B' : ['one', 'one', 'two', 'three',
... 'two', 'two'],
... 'C' : [1, 5, 5, 2, 5, 5],
... 'D' : [2.0, 5., 8., 1., 2., 9.]})
>>> grouped = df.groupby('A')
>>> grouped.transform(lambda x: (x - x.mean()) / x.std())
          C         D
0  0.115470  -0.577350
1  0.577350   0.000000
2  0.577350   1.154701
3 -0.115470  -1.000000
4  0.577350  -0.577350
5  0.577350   1.000000

Broadcast result of the transformation
```

```python
>>> grouped.transform(lambda x: x.max() - x.min())
          C         D
0   4.00000   6.00000
1   3.00000   8.00000
2   4.00000   6.00000
3   3.00000   8.00000
4   4.00000   6.00000
5   3.00000   8.00000
```
pandas.core.groupby.DataFrameGroupBy.transform

DataFrameGroupBy.transform(func, *args, engine=None, engine_kwars=None, **kwargs)

Call function producing a like-indexed DataFrame on each group and return a DataFrame having the same indexes as the original object filled with the transformed values.

Parameters

f [function] Function to apply to each group.

Can also accept a Numba JIT function with engine='numba' specified.

If the 'numba' engine is chosen, the function must be a user defined function with values and index as the first and second arguments respectively in the function signature. Each group’s index will be passed to the user defined function and optionally available for use.

Changed in version 1.1.0.

*args Positional arguments to pass to func

engine [str, default None]

- 'cython': Runs the function through C-extensions from cython.
- 'numba': Runs the function through JIT compiled code from numba.
- None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.1.0.

engine_kwars [dict, default None]

- For 'cython' engine, there are no accepted engine_kwars
- For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwars for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False} and will be applied to the function

New in version 1.1.0.

**kwargs Keyword arguments to be passed into func.

Returns

DataFrame

See also:

DataFrame.groupby.apply
DataFrame.groupby.aggregate
DataFrame.transform
Notes

Each group is endowed the attribute ‘name’ in case you need to know which group you are working on.

The current implementation imposes three requirements on f:

- f must return a value that either has the same shape as the input subframe or can be broadcast to the shape of the input subframe. For example, if f returns a scalar it will be broadcast to have the same shape as the input subframe.
- if this is a DataFrame, f must support application column-by-column in the subframe. If f also supports application to the entire subframe, then a fast path is used starting from the second chunk.
- f must not mutate groups. Mutation is not supported and may produce unexpected results.

When using engine='numba', there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Examples

```python
>>> df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar', 'foo', 'bar'],
            'B' : ['one', 'one', 'two', 'three', 'two', 'two'],
            'C' : [1, 5, 5, 2, 5, 5],
            'D' : [2.0, 5., 8., 1., 2., 9.]})
```
```bash
>>> grouped = df.groupby('A')
>>> grouped.transform(lambda x: (x - x.mean()) / x.std())
```
```
   C       D
0 -1.154701 -0.577350
1  0.577350  0.000000
2  0.577350  1.154701
3 -1.154701 -1.000000
4  0.577350 -0.577350
5  0.577350  1.000000
```
Broadcast result of the transformation

```python
>>> grouped.transform(lambda x: x.max() - x.min())
```
```
   C  D
0  4  6.0
1  3  8.0
2  4  6.0
3  3  8.0
4  4  6.0
5  3  8.0
```

pandas.core.groupby.GroupBy.pipe

GroupBy.pipe(func, *args, **kwargs)

Apply a function `func` with arguments to this GroupBy object and return the function’s result.

New in version 0.21.0.

Use .pipe when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing
You can write

```python
>>> (df.groupby('group')
... .pipe(f)
... .pipe(g, arg1=a)
... .pipe(h, arg2=b, arg3=c))
```

which is much more readable.

**Parameters**

- **func** [callable or tuple of (callable, str)] Function to apply to this GroupBy object or, alternatively, a (callable, data_keyword) tuple where data_keyword is a string indicating the keyword of callable that expects the GroupBy object.

- **args** [iterable, optional] Positional arguments passed into `func`.

- **kwargs** [dict, optional] A dictionary of keyword arguments passed into `func`.

**Returns**

- **object** [the return type of `func`]

**See also:**

- `Series.pipe` Apply a function with arguments to a series.
- `DataFrame.pipe` Apply a function with arguments to a dataframe.
- `apply` Apply function to each group instead of to the full GroupBy object.

**Notes**

See more here

**Examples**

```python
>>> df = pd.DataFrame({'A': 'a b a b'.split(), 'B': [1, 2, 3, 4]})
>>> df
   A  B
0  a  1
1  b  2
2  a  3
3  b  4
```

To get the difference between each groups maximum and minimum value in one pass, you can do

```python
>>> df.groupby('A').pipe(lambda x: x.max() - x.min())
```

```python
   B
A
a 2
b 2
```
### 3.11.3 Computations / descriptive stats

</tbody>
</table>
pandas.core.groupby.GroupBy.all

GroupBy.all (skipna=True)
Return True if all values in the group are truthful, else False.
Parameters
    skipna   [bool, default True] Flag to ignore nan values during truth testing.
Returns
    bool
See also:
    Series.groupby
    DataFrame.groupby

pandas.core.groupby.GroupBy.any

GroupBy.any (skipna=True)
Return True if any value in the group is truthful, else False.
Parameters
    skipna   [bool, default True] Flag to ignore nan values during truth testing.
Returns
    bool
See also:
    Series.groupby
    DataFrame.groupby

pandas.core.groupby.GroupBy.bfill

GroupBy.bfill (limit=None)
Backward fill the values.
Parameters
    limit   [int, optional] Limit of how many values to fill.
Returns
    Series or DataFrame Object with missing values filled.
See also:
    Series.backfill
    DataFrame.backfill
    Series.fillna
    DataFrame.fillna
pandas.core.groupby.GroupBy.backfill

GroupBy.backfill(limit=None)

Backward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.backfill
DataFrame.backfill
Series.fillna
DataFrame.fillna

pandas.core.groupby.GroupBy.count

GroupBy.count()

Compute count of group, excluding missing values.

Returns

Series or DataFrame Count of values within each group.

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.cumcount

GroupBy.cumcount(ascending=True)

Number each item in each group from 0 to the length of that group - 1.

Essentially this is equivalent to

```python
self.apply(lambda x: pd.Series(np.arange(len(x)), x.index))
```

Parameters

ascending [bool, default True] If False, number in reverse, from length of group - 1 to 0.

Returns

Series Sequence number of each element within each group.

See also:

ngroup Number the groups themselves.
Examples

```python
>>> df = pd.DataFrame([['a'], ['a'], ['a'], ['b'], ['b'], ['a']],
                   columns=['A'])
>>> df
   A
0  a
1  a
2  a
3  b
4  b
5  a
>>> df.groupby('A').cumcount()
   0  1  2  3  4  5
0  0  1  2  3  4  5
1  0  0  1  2  3  4
2  1  2  3  0  1  0
3  0  1  0  1  4  3
dtype: int64
>>> df.groupby('A').cumcount(ascending=False)
   0  1  2  3  4  5
0  3  2  1  1  0  0
1  0  1  2  3  0  4
2  0  1  3  1  2  1
3  0  0  3  4  5  5
dtype: int64
```

`pandas.core.groupby.GroupBy.cummax`

GroupBy.cummax(axis=0, **kwargs)
Cumulative max for each group.

Returns
Series or DataFrame

See also:
Series.groupby
DataFrame.groupby

`pandas.core.groupby.GroupBy.cummin`

GroupBy.cummin(axis=0, **kwargs)
Cumulative min for each group.

Returns
Series or DataFrame

See also:
Series.groupby
DataFrame.groupby
pandas.core.groupby.GroupBy.cumprod

GroupBy.cumprod(axis=0, *args, **kwargs)
Cumulative product for each group.

Returns
Series or DataFrame

See also:
Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.cumsum

GroupBy.cumsum(axis=0, *args, **kwargs)
Cumulative sum for each group.

Returns
Series or DataFrame

See also:
Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.ffill

GroupBy.ffill(limit=None)
Forward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns
Series or DataFrame Object with missing values filled.

See also:
Series.pad
DataFrame.pad
Series.fillna
DataFrame.fillna

pandas.core.groupby.GroupBy.first

GroupBy.first(numeric_only=False, min_count=-1)
Compute first of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns
Series or DataFrame Computed first of values within each group.
**pandas.core.groupby.GroupBy.head**

GroupBy.**head**(n=5)

Return first n rows of each group.

Similar to .apply(lambda x: x.head(n)), but it returns a subset of rows from the original DataFrame with original index and order preserved (as_index flag is ignored).

Does not work for negative values of n.

**Returns**

Series or DataFrame

See also:

*Series.groupby*
*DataFrame.groupby*

**Examples**

```python
def = pd.DataFrame([[1, 2], [1, 4], [5, 6]],
                   columns=['A', 'B'])
def.groupby('A').head(1)
A  B
0 1 2
2 5 6
def.groupby('A').head(-1)
Empty DataFrame
Columns: [A, B]
Index: []
```

**pandas.core.groupby.GroupBy.last**

GroupBy.**last**(numeric_only=False, min_count=-1)

Compute last of group values.

**Parameters**

- **numeric_only** [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

- **min_count** [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

**Returns**

Series or DataFrame  Computed last of values within each group.

**pandas.core.groupby.GroupBy.max**

GroupBy.**max**(numeric_only=False, min_count=-1)

Compute max of group values.

**Parameters**

- **numeric_only** [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

- **min_count** [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.
**pandas: powerful Python data analysis toolkit, Release 1.1.1**

**Returns**

**Series or DataFrame** Computed max of values within each group.

**pandas.core.groupby.GroupBy.mean**

```python
groupby.mean(numeric_only=True)
```

Compute mean of groups, excluding missing values.

**Parameters**

- **numeric_only** [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

**Returns**

**pandas.Series or pandas.DataFrame**

**See also:**

- **Series.groupby**
- **DataFrame.groupby**

**Examples**

```python
def pd.DataFrame({'A': [1, 1, 2, 1, 2],
                 'B': [np.nan, 2, 3, 4, 5],
                 'C': [1, 2, 1, 1, 2]}, columns=['A', 'B', 'C'])
```

Groupby one column and return the mean of the remaining columns in each group.

```python
def.groupby('A').mean()
```

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3.0</td>
<td>1.333333</td>
</tr>
<tr>
<td>2</td>
<td>4.0</td>
<td>1.500000</td>
</tr>
</tbody>
</table>

Groupby two columns and return the mean of the remaining column.

```python
def.groupby(['A', 'B']).mean()
```

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2.0</td>
<td>2</td>
</tr>
<tr>
<td></td>
<td>4.0</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>3.0</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>5.0</td>
<td>2</td>
</tr>
</tbody>
</table>

Groupby one column and return the mean of only particular column in the group.

```python
def.groupby('A')['B'].mean()
```

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3.0</td>
</tr>
<tr>
<td>2</td>
<td>4.0</td>
</tr>
</tbody>
</table>

Name: B, dtype: float64
pandas.core.groupby.GroupBy.median

GroupBy.median(numeric_only=True)
Compute median of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will
attempt to use everything, then use only numeric data.

Returns

Series or DataFrame Median of values within each group.

See also:
Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.min

GroupBy.min(numeric_only=False, min_count=-1)
Compute min of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will
attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If
fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed min of values within each group.

pandas.core.groupby.GroupBy.ngroup

GroupBy.ngroup(ascending=True)
Number each group from 0 to the number of groups - 1.

This is the enumerative complement of cumcount. Note that the numbers given to the groups match the order in
which the groups would be seen when iterating over the groupby object, not the order they are first observed.

Parameters

ascending [bool, default True] If False, number in reverse, from number of group - 1 to 0.

Returns

Series Unique numbers for each group.

See also:
cumcount Number the rows in each group.
Examples

```python
>>> df = pd.DataFrame({'A': list('aaabba'))
>>> df
   A
0  a  0
1  a  0
2  a  0
3  b  1
4  b  1
5  a  0
>>> df.groupby('A').ngroup()
0 0
1 0
2 0
3 1
4 1
5 0
dtype: int64
>>> df.groupby('A').ngroup(ascending=False)
0 1
1 1
2 1
3 0
4 0
5 1
dtype: int64
>>> df.groupby(["A", [1,1,2,3,2,1]]).ngroup()
0 0
1 0
2 1
3 3
4 2
5 0
dtype: int64
```

**pandas.core.groupby.GroupBy.nth**

`GroupBy.nth(n, dropna=None)`

Take the nth row from each group if n is an int, or a subset of rows if n is a list of ints.

If dropna, will take the nth non-null row, dropna is either `all` or `any`; this is equivalent to calling `dropna(how=dropna)` before the groupby.

**Parameters**

- **n** [int or list of ints] A single nth value for the row or a list of nth values.
- **dropna** [None or str, optional] Apply the specified dropna operation before counting which row is the nth row. Needs to be None, ‘any’ or ‘all’.

**Returns**

- `Series or DataFrame` N-th value within each group.

**See also**:

- `Series.groupby`
- `DataFrame.groupby`
Examples

```python
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
                     'B': [np.nan, 2, 3, 4, 5]}, columns=['A', 'B'])
>>> g = df.groupby('A')
>>> g.nth(0)
   B
A
1  NaN
2  3.0
>>> g.nth(1)
   B
A
1  2.0
2  5.0
>>> g.nth(-1)
   B
A
1  4.0
2  5.0
>>> g.nth([0, 1])
   B
A
1  NaN
1  2.0
2  3.0
2  5.0
```

Specifying `dropna` allows count ignoring NaN

```python
>>> g.nth(0, dropna='any')
   B
A
1  2.0
2  3.0
```

NaNs denote group exhausted when using dropna

```python
>>> g.nth(3, dropna='any')
   B
A
1  NaN
1  NaN
```

Specifying `as_index=False` in `groupby` keeps the original index.

```python
>>> df.groupby('A', as_index=False).nth(1)
   A  B
1  1  2.0
4  2  5.0
```
pandas.core.groupby.GroupBy.ohlc

GroupBy.ohlc()
Compute open, high, low and close values of a group, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

Returns

DataFrame Open, high, low and close values within each group.

See also:
Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.pad

GroupBy.pad(limit=None)
Forward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:
Series.pad
DataFrame.pad
Seriesfillna
DataFrame.fillna

pandas.core.groupby.GroupBy.prod

GroupBy.prod(numeric_only=True, min_count=0)
Compute prod of group values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed prod of values within each group.
pandas.core.groupby.GroupBy.rank

GroupBy.rank (method='average', ascending=True, na_option='keep', pct=False, axis=0)
Provide the rank of values within each group.

Parameters

- **method** [(‘average’, ‘min’, ‘max’, ‘first’, ‘dense’), default ‘average’]
  - average: average rank of group.
  - min: lowest rank in group.
  - max: highest rank in group.
  - first: ranks assigned in order they appear in the array.
  - dense: like ‘min’, but rank always increases by 1 between groups.

- **ascending** [bool, default True] False for ranks by high (1) to low (N).

- **na_option** [{‘keep’, ‘top’, ‘bottom’}, default ‘keep’]
  - keep: leave NA values where they are.
  - top: smallest rank if ascending.
  - bottom: smallest rank if descending.

- **pct** [bool, default False] Compute percentage rank of data within each group.

- **axis** [int, default 0] The axis of the object over which to compute the rank.

Returns

- DataFrame with ranking of values within each group

See also:

- Series.groupby
- DataFrame.groupby

pandas.core.groupby.GroupBy.pct_change

GroupBy.pct_change (periods=1, fill_method='pad', limit=None, freq=None, axis=0)
Calculate pct_change of each value to previous entry in group.

Returns

- Series or DataFrame Percentage changes within each group.

See also:

- Series.groupby
- DataFrame.groupby
pandas.core.groupby.GroupBy.size

GroupBy.size()
Compute group sizes.
Returns
DataFrame or Series Number of rows in each group as a Series if as_index is True or a
DataFrame if as_index is False.
See also:
Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.sem

GroupBy.sem(ddof=1)
Compute standard error of the mean of groups, excluding missing values.
For multiple groupings, the result index will be a MultiIndex.
Parameters
ddf [int, default 1] Degrees of freedom.
Returns
Series or DataFrame Standard error of the mean of values within each group.
See also:
Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.std

GroupBy.std(ddof=1)
Compute standard deviation of groups, excluding missing values.
For multiple groupings, the result index will be a MultiIndex.
Parameters
ddf [int, default 1] Degrees of freedom.
Returns
Series or DataFrame Standard deviation of values within each group.
See also:
Series.groupby
DataFrame.groupby
pandas.core.groupby.GroupBy.sum

GroupBy.sum(numeric_only=True, min_count=0)
Compute sum of group values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed sum of values within each group.

pandas.core.groupby.GroupBy.var

GroupBy.var(ddof=1)
Compute variance of groups, excluding missing values.
For multiple groupings, the result index will be a MultiIndex.

Parameters

ddof [int, default 1] Degrees of freedom.

Returns

Series or DataFrame Variance of values within each group.

See also:
Series.groupby
DataFrame.groupby

pandas.core.groupby.GroupBy.tail

GroupBy.tail(n=5)
Return last n rows of each group.
Similar to .apply(lambda x: x.tail(n)), but it returns a subset of rows from the original DataFrame with original index and order preserved (as_index flag is ignored).
Does not work for negative values of n.

Returns

Series or DataFrame

See also:
Series.groupby
DataFrame.groupby
Examples

```python
>>> df = pd.DataFrame([['a', 1], ['a', 2], ['b', 1], ['b', 2]], columns=['A', 'B'])
>>> df.groupby('A').tail(1)
   A  B
1 a  2
3 b  2
>>> df.groupby('A').tail(-1)
Empty DataFrame
Columns: [A, B]
Index: []
```

The following methods are available in both `SeriesGroupBy` and `DataFrameGroupBy` objects, but may differ slightly, usually in that the `DataFrameGroupBy` version usually permits the specification of an axis argument, and often an argument indicating whether to restrict application to columns of a specific data type.

</table>

### `pandas.core.groupby.DataFrameGroupBy.all`

**DataFrameGroupBy.all** *(skipna=True)*

Return True if all values in the group are truthful, else False.

**Parameters**

- `skipna` [bool, default True] Flag to ignore nan values during truth testing.

**Returns**

- `bool` |

See also:

- `Series.groupby`
- `DataFrame.groupby`

### `pandas.core.groupby.DataFrameGroupBy.any`

**DataFrameGroupBy.any** *(skipna=True)*

Return True if any value in the group is truthful, else False.

**Parameters**

- `skipna` [bool, default True] Flag to ignore nan values during truth testing.

**Returns**

- `bool` |

See also:

- `Series.groupby`
- `DataFrame.groupby`
pandas.core.groupby.DataFrameGroupBy.backfill

DataFrameGroupBy.backfill(limit=None)
Backward fill the values.

Parameters

- limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:
Series.backfill
DataFrame.backfill
Series.fillna
DataFrame.fillna

pandas.core.groupby.DataFrameGroupBy.bfill

DataFrameGroupBy.bfill(limit=None)
Backward fill the values.

Parameters

- limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:
Series.backfill
DataFrame.backfill
Series.fillna
DataFrame.fillna

pandas.core.groupby.DataFrameGroupBy.corr

property DataFrameGroupBy.corr
Compute pairwise correlation of columns, excluding NA/null values.

Parameters

- method [{‘pearson’, ‘kendall’, ‘spearman’} or callable] Method of correlation:
  - pearson : standard correlation coefficient
  - kendall : Kendall Tau correlation coefficient
  - spearman : Spearman rank correlation
  - callable: callable with input two 1d ndarrays and returning a float. Note that the returned matrix from corr will have 1 along the diagonals and will be symmetric regardless of the callable’s behavior.

New in version 0.24.0.

- min_periods [int, optional] Minimum number of observations required per pair of columns to have a valid result. Currently only available for Pearson and Spearman correlation.

Returns
DataFrame  Correlation matrix.

See also:
DataFrame.corrwith  Compute pairwise correlation with another DataFrame or Series.
Series.corr  Compute the correlation between two Series.

Examples

```python
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v
...>
>>> df = pd.DataFrame([(0.2, 0.3), (0.0, 0.6), (0.6, 0.0), (0.2, 0.1)],
...                     columns=['dogs', 'cats'])
...>
>>> df.corr(method=histogram_intersection)
     dogs   cats
dogs  1.0  0.3
cats  0.3  1.0
```

pandas.core.groupby.DataFrameGroupBy.count

DataFrameGroupBy.count()  
Compute count of group, excluding missing values.

Returns
DataFrame  Count of values within each group.

pandas.core.groupby.DataFrameGroupBy.cov

property DataFrameGroupBy.cov  
Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the covariance matrix of the columns of the DataFrame.

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as NaN.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

Parameters

min_periods  [int, optional] Minimum number of observations required per pair of columns to have a valid result.

ddf  [int, default 1] Delta degrees of freedom. The divisor used in calculations is \( N - \) ddf, where \( N \) represents the number of elements.

New in version 1.1.0.

Returns
DataFrame  The covariance matrix of the series of the DataFrame.

See also:
Series.cov  Compute covariance with another Series.
core.window.ExponentialMovingWindow.cov  Exponential weighted sample covariance.
**Notes**

Returns the covariance matrix of the DataFrame’s time series. The covariance is normalized by N-ddof.

For DataFrames that have Series that are missing data (assuming that data is missing at random) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.

**Examples**

```python
>>> df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
                   columns=['dogs', 'cats'])
```

```output
dogs  cats
dogs 0.666667 -1.000000
cats -1.000000 1.666667
```

```python
>>> np.random.seed(42)
```

```python
>>> df = pd.DataFrame(np.random.randn(1000, 5),
                   columns=['a', 'b', 'c', 'd', 'e'])
```

```output
a b c d e
0.998438 -0.020161 0.059277 -0.008943 0.014144
-0.020161 1.059352 -0.008543 -0.024738 0.009826
0.059277 -0.008543 1.010670 -0.001486 -0.000271
-0.008943 -0.024738 -0.001486 0.921297 -0.013692
0.014144 0.009826 -0.000271 -0.013692 0.977795
```

**Minimum number of periods**

This method also supports an optional `min_periods` keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```python
>>> np.random.seed(42)
```

```python
>>> df = pd.DataFrame(np.random.randn(20, 3),
                   columns=['a', 'b', 'c'])
```

```python
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
```

```python
>>> df.cov(min_periods=12)
```

```output
a b c
a 0.316741 NaN -0.150812
b NaN 1.248003 0.191417
c -0.150812 0.191417 0.895202
```
### DataFrameGroupBy.cumcount

DataFrameGroupBy.cumcount(ascending=True)

Number each item in each group from 0 to the length of that group - 1.

Essentially this is equivalent to

```python
self.apply(lambda x: pd.Series(np.arange(len(x)), x.index))
```

**Parameters**

- **ascending** [bool, default True] If False, number in reverse, from length of group - 1 to 0.

**Returns**

- **Series** Sequence number of each element within each group.

**See also:**

- `ngroup` Number the groups themselves.

**Examples**

```python
>>> df = pd.DataFrame([[a], [a], [a], [b], [b], [a]],
                    columns=['A'])
>>> df
   A
0  a
1  a
2  a
3  b
4  b
5  a
>>> df.groupby('A').cumcount()
0  0
1  1
2  2
3  0
4  1
5  3
```

```python
>>> df.groupby('A').cumcount(ascending=False)
0  3
1  2
2  1
3  1
4  0
5  0
```

...
pandas.core.groupby.DataFrameGroupBy.cummax

DataFrameGroupBy.cummax(axis=0, **kwargs)
Cumulative max for each group.
Returns
Series or DataFrame
See also:
Series.groupby
DataFrame.groupby

pandas.core.groupby.DataFrameGroupBy.cummin

DataFrameGroupBy.cummin(axis=0, **kwargs)
Cumulative min for each group.
Returns
Series or DataFrame
See also:
Series.groupby
DataFrame.groupby

pandas.core.groupby.DataFrameGroupBy.cumprod

DataFrameGroupBy.cumprod(axis=0, *args, **kwargs)
Cumulative product for each group.
Returns
Series or DataFrame
See also:
Series.groupby
DataFrame.groupby

pandas.core.groupby.DataFrameGroupBy.cumsum

DataFrameGroupBy.cumsum(axis=0, *args, **kwargs)
Cumulative sum for each group.
Returns
Series or DataFrame
See also:
Series.groupby
DataFrame.groupby
pandas.core.groupby.DataFrameGroupBy.describe

`DataFrameGroupBy.describe(**kwargs)`

Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

**Parameters**

- **percentiles** [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

- **include** ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for Series. Here are the options:
  - 'all': All columns of the input will be included in the output.
  - A list-like of dtypes: Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use 'category'
  - None (default): The result will include all numeric columns.

- **exclude** [list-like of dtypes or None (default), optional] A black list of data types to omit from the result. Ignored for Series. Here are the options:
  - A list-like of dtypes: Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To exclude pandas categorical columns, use 'category'
  - None (default): The result will exclude nothing.

- **datetime_is_numeric** [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

New in version 1.1.0.

**Returns**

Series or DataFrame Summary statistics of the Series or DataFrame provided.

**See also:**

- `DataFrame.count` Count number of non-NA/null observations.
- `DataFrame.max` Maximum of the values in the object.
- `DataFrame.min` Minimum of the values in the object.
- `DataFrame.mean` Mean of the values in the object.
- `DataFrame.std` Standard deviation of the observations.
- `DataFrame.select_dtypes` Subset of a DataFrame including/excluding columns based on their dtype.
Notes

For numeric data, the result’s index will include count, mean, std, min, max as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result’s index will include count, unique, top, and freq. The top is the most common value. The freq is the most common value’s frequency. Timestamps also include the first and last items.

If multiple object values have the highest count, then the count and top results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a DataFrame, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If include='all' is provided as an option, the result will include a union of attributes of each type.

The include and exclude parameters can be used to limit which columns in a DataFrame are analyzed for the output. The parameters are ignored when analyzing a Series.

Examples

Describing a numeric Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
dtype: float64
```

Describing a categorical Series.

```python
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count 4
unique 3
top a
freq 2
dtype: object
```

Describing a timestamp Series.

```python
>>> s = pd.Series([...
...   np.datetime64("2000-01-01"),
...   np.datetime64("2010-01-01"),
...   np.datetime64("2010-01-01")
... ])
>>> s.describe(datetime_is_numeric=True)
count 3
mean 2006-09-01 08:00:00
```

(continues on next page)
Describing a DataFrame. By default only numeric fields are returned.

```python
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d','e','f']),
                      'numeric': [1, 2, 3],
                      'object': ['a', 'b', 'c']})
```

```python
>>> df.describe()
```

```
          numeric
count     3.0
mean      2.0
std       1.0
min       1.0
25%       1.5
50%       2.0
75%       2.5
max       3.0
```

Describing all columns of a DataFrame regardless of data type.

```python
>>> df.describe(include='all')
```

```
          categorical  numeric      object
count        3.0       3.0       3.0
unique       3.0       NaN       3.0
top           f         NaN       a
freq         1.0       NaN       1.0
mean        NaN       2.0       NaN
std        NaN       1.0       NaN
min        NaN       1.0       NaN
25%        NaN       1.5       NaN
50%        NaN       2.0       NaN
75%        NaN       2.5       NaN
max        NaN       3.0       NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```python
>>> df.numeric.describe()
```

```
          numeric
count     3.0
mean      2.0
std       1.0
min       1.0
25%       1.5
50%       2.0
75%       2.5
max       3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a DataFrame description.

```python
>>> df.describe(include=[np.number])
```

(continues on next page)
Including only string columns in a DataFrame description.

```python
>>> df.describe(include=['object'])
  object
 count  3
 unique  3
  top a
  freq  1
```

Including only categorical columns from a DataFrame description.

```python
>>> df.describe(include=['category'])
  categorical
 count  3
 unique  3
  top f
  freq  1
```

Excluding numeric columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.number])
  categorical  object
 count      3   3
 unique      3   3
  top       f   a
  freq      1   1
```

Excluding object columns from a DataFrame description.

```python
>>> df.describe(exclude=['object'])
  categorical   numeric
 count        3   3.0
 unique       3   NaN
  top         f   NaN
  freq        1   NaN
 mean         NaN  2.0
 std          NaN  1.0
 min          NaN  1.0
 25%          NaN  1.5
 50%          NaN  2.0
 75%          NaN  2.5
 max          NaN  3.0
```
pandas.core.groupby.DataFrameGroupBy.diff

**property DataFrameGroupBy.diff**

First discrete difference of element.

Calculates the difference of a Dataframe element compared with another element in the Dataframe (default is element in previous row).

**Parameters**

- **periods** [int, default 1] Periods to shift for calculating difference, accepts negative values.
- **axis** [[0 or ‘index’, 1 or ‘columns’], default 0] Take difference over rows (0) or columns (1).

**Returns**

- **DataFrame** First differences of the Series.

**See also:**
- `DataFrame.pct_change` Percent change over given number of periods.
- `DataFrame.shift` Shift index by desired number of periods with an optional time freq.
- `Series.diff` First discrete difference of object.

**Notes**

For boolean dtypes, this uses `operator.xor()` rather than `operator.sub()`. The result is calculated according to current dtype in Dataframe, however dtype of the result is always float64.

**Examples**

**Difference with previous row**

```python
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
... 'b': [1, 1, 2, 3, 5, 8],
... 'c': [1, 4, 9, 16, 25, 36]})

>>> df
   a  b  c
0  1  1  1
1  2  1  4
2  3  2  9
3  4  3 16
4  5  5 25
5  6  8 36

>>> df.diff()
   a  b  c
0  NaN NaN NaN
1  1.0  0.0  3.0
2  1.0  1.0  5.0
3  1.0  1.0  7.0
4  1.0  2.0  9.0
5  1.0  3.0 11.0
```

**Difference with previous column**

```python
>>> df.diff(axis=1)
   a  b  c
0  NaN NaN NaN
1  0.0  0.0  3.0
2  1.0  1.0  5.0
3  1.0  1.0  7.0
4  1.0  2.0  9.0
5  1.0  3.0 11.0
```

(continues on next page)
1 NaN -1.0 3.0
2 NaN -1.0 7.0
3 NaN -1.0 13.0
4 NaN 0.0 20.0
5 NaN 2.0 28.0

Difference with 3rd previous row

```python
>>> df.diff(periods=3)
a  b  c
0 NaN NaN NaN
1 NaN NaN NaN
2 NaN NaN NaN
3 3.0 2.0 15.0
4 3.0 4.0 21.0
5 3.0 6.0 27.0
```

Difference with following row

```python
>>> df.diff(periods=-1)
a  b  c
0 -1.0 0.0 -3.0
1 -1.0 -1.0 -5.0
2 -1.0 -1.0 -7.0
3 -1.0 -2.0 -9.0
4 -1.0 -3.0 -11.0
5 NaN NaN NaN
```

Overflow in input dtype

```python
>>> df = pd.DataFrame({'a': [1, 0]}, dtype=np.uint8)
```

```python
>>> df.diff()
a
0 NaN
1 255.0
```

**pandas.core.groupby.DataFrameGroupBy.ffill**

DataFrameGroupBy.ffill(*limit=None*)

Forward fill the values.

**Parameters**

- **limit** [int, optional] Limit of how many values to fill.

**Returns**

- **Series** or **DataFrame** Object with missing values filled.

**See also:**

- **Series.pad**
- **DataFrame.pad**
- **Series.fillna**
- **DataFrame.fillna**
pandas.core.groupby.DataFrameGroupBy.fillna

**property DataFrameGroupBy.fillna**
Fill NA/NaN values using the specified method.

**Parameters**

- **value** [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

- **method** [{'backfill', 'bfill', 'pad', 'ffill', None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use next valid observation to fill gap.

- **axis** [[0 or `index`, 1 or `columns`]] Axis along which to fill missing values.

- **inplace** [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

- **limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

- **downcast** [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

**Returns**

DataFrame or None Object with missing values filled or None if inplace=True.

**See also:**

- **DataFrame** or None Object with missing values filled or None if inplace=True.

**Examples**

```python
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                     [3, 4, np.nan, 1],
...                     [np.nan, np.nan, np.nan, 5],
...                     [np.nan, 3, np.nan, 4]],
... columns=list('ABCD'))
>>> df
   A  B  C  D
0  NaN  2.0  NaN  0
1   3.0  4.0  NaN  1
2  NaN  NaN  NaN  5
3  NaN  3.0  NaN  4
>>> df.fillna(0)
   A  B  C  D
0  0.0  2.0  0.0  0
1  3.0  4.0  0.0  0
2  0.0  0.0  0.0  0
3  3.0  0.0  0.0  0
```

Replace all NaN elements with 0s.

```python
>>> df.fillna(0)
   A  B  C  D
0  0.0  2.0  0.0  0
1  3.0  4.0  0.0  0
2  0.0  0.0  0.0  0
3  3.0  0.0  0.0  0
```
We can also propagate non-null values forward or backward.

```python
>>> df.fillna(method='ffill')
  A   B   C   D
0  NaN  2.0  NaN  0
1  3.0  4.0  NaN  1
2  3.0  4.0  NaN  5
3  3.0  3.0  NaN  4
```

Replace all NaN elements in column ‘A’, ‘B’, ‘C’, and ‘D’, with 0, 1, 2, and 3 respectively.

```python
>>> values = {'A': 0, 'B': 1, 'C': 2, 'D': 3}
>>> df.fillna(value=values)
  A   B   C   D
0  0.0  2.0  2.0  0
1  3.0  4.0  2.0  1
2  0.0  1.0  2.0  5
3  0.0  3.0  2.0  4
```

Only replace the first NaN element.

```python
>>> df.fillna(value=values, limit=1)
  A   B   C   D
0  0.0  2.0  2.0  0
1  3.0  4.0  NaN  1
2  NaN  1.0  NaN  5
3  NaN  3.0  NaN  4
```

### pandas.core.groupby.DataFrameGroupBy.filter

DataFrameGroupBy.filter(func, dropna=True, *args, **kwargs)

Return a copy of a DataFrame excluding filtered elements.

Elements from groups are filtered if they do not satisfy the boolean criterion specified by func.

**Parameters**

- **func** [function] Function to apply to each subframe. Should return True or False.
- **dropna** [Drop groups that do not pass the filter. True by default;] If False, groups that evaluate False are filled with NaNs.

**Returns**

- **filtered** [DataFrame]
Notes

Each subframe is endowed the attribute `name` in case you need to know which group you are working on.

Examples

```python
>>> df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
... 'foo', 'bar'],
...                      'B' : [1, 2, 3, 4, 5, 6],
...                      'C' : [2.0, 5., 8., 1., 2., 9.]})
>>> grouped = df.groupby('A')
>>> grouped.filter(lambda x: x['B'].mean() > 3.)
A   B   C
1   bar 2  5.0
3   bar 4  1.0
5   bar 6  9.0
```

**pandas.core.groupby.DataFrameGroupBy.hist**

**property DataFrameGroupBy.hist**

Make a histogram of the DataFrame's.

A histogram is a representation of the distribution of data. This function calls matplotlib.pyplot.hist(), on each series in the DataFrame, resulting in one histogram per column.

**Parameters**

- `data` [DataFrame] The pandas object holding the data.
- `column` [str or sequence] If passed, will be used to limit data to a subset of columns.
- `by` [object, optional] If passed, then used to form histograms for separate groups.
- `grid` [bool, default True] Whether to show axis grid lines.
- `xlabelsize` [int, default None] If specified changes the x-axis label size.
- `xrot` [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.
- `ylabelsize` [int, default None] If specified changes the y-axis label size.
- `yrot` [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.
- `ax` [Matplotlib axes object, default None] The axes to plot the histogram on.
- `sharex` [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.
- `sharey` [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.
- `figsize` [tuple] The size in inches of the figure to create. Uses the value in matplotlib.rcParams by default.
- `layout` [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.
bins [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

backend [str, default None] Backend to use instead of the backend specified in the option plotting.backend. For instance, ‘matplotlib’. Alternatively, to specify the plotting.backend for the whole session, set pd.options.plotting.backend.

New in version 1.0.0.

legend [bool, default False] Whether to show the legend.

New in version 1.1.0.

**kwargs All other plotting keyword arguments to be passed to matplotlib.pyplot.hist().

Returns

matplotlib.AxesSubplot or numpy.ndarray of them

See also:

matplotlib.pyplot.hist Plot a histogram using matplotlib.

Examples

This example draws a histogram based on the length and width of some animals, displayed in three bins

```python
>>> df = pd.DataFrame({
...         'length': [1.5, 0.5, 1.2, 0.9, 3],
...         'width': [0.7, 0.2, 0.15, 0.2, 1.1],
...     }, index=['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```

pandas.core.groupby.DataFrameGroupBy.idxmax

property DataFrameGroupBy.idxmax

Return index of first occurrence of maximum over requested axis. NA/null values are excluded.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

Series Indexes of maxima along the specified axis.

Raises

ValueError

• If the row/column is empty

See also:
3.11. GroupBy
**Series.idxmax** Return index of the maximum element.

**Notes**

This method is the DataFrame version of `ndarray.argmax`.

**Examples**

Consider a dataset containing food consumption in Argentina.

```python
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
...                   'co2_emissions': [37.2, 19.66, 1712]},
...                   index=['Pork', 'Wheat Products', 'Beef'])
```

By default, it returns the index for the maximum value in each column.

```python
>>> df.idxmax()
consumption    Wheat Products
co2_emissions  Beef
```

To return the index for the maximum value in each row, use `axis="columns"`.

```python
>>> df.idxmax(axis="columns")
Pork       co2_emissions
Wheat Products consumption
Beef       co2_emissions
```

**pandas.core.groupby.DataFrameGroupBy.idxmin**

**property** DataFrameGroupBy.idxmin

Return index of first occurrence of minimum over requested axis.

NA/null values are excluded.

**Parameters**

- `axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.

- `skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**Returns**

- `Series` Indexes of minima along the specified axis.

**Raises**

- `ValueError`
• If the row/column is empty

See also:

Series.idxmin Return index of the minimum element.

Notes

This method is the DataFrame version of ndarray.argmin.

Examples

Consider a dataset containing food consumption in Argentina.

```python
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
                     'co2_emissions': [37.2, 19.66, 1712]},
                    index=['Pork', 'Wheat Products', 'Beef'])

>>> df
     consumption  co2_emissions
Pork        10.51          37.2
Wheat Products  103.11       19.66
Beef          55.48        1712.0
```

By default, it returns the index for the minimum value in each column.

```python
>>> df.idxmin()
consumption    Pork
co2_emissions  Wheat Products
dtype: object
```

To return the index for the minimum value in each row, use `axis="columns"`.

```python
>>> df.idxmin(axis="columns")
Pork    consumption
Wheat Products  co2_emissions
Beef    consumption
dtype: object
```

pandas.core.groupby.DataFrameGroupBy.mad

**property** DataFrameGroupBy.mad

Return the mean absolute deviation of the values for the requested axis.

**Parameters**

- `axis` [[index (0), columns (1)]] Axis for the function to be applied on.
- `skipna` [bool, default None] Exclude NA/null values when computing the result.
- `level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**Returns**

Series or DataFrame (if level specified)
DataFrameGroupBy.nunique (dropna=True)  
Return DataFrame with counts of unique elements in each position.

Parameters

- dropna [bool, default True] Don’t include NaN in the counts.

Returns

- nunique: DataFrame

Examples

```python
>>> df = pd.DataFrame(
    {'id': ['spam', 'egg', 'egg', 'spam', 'ham', 'ham'],
     'value1': [1, 5, 5, 2, 5, 5],
     'value2': list('abbaxy')})

>>> df
     id  value1 value2
0    spam     1     a
1     egg     5     b
2     egg     5     b
3    spam     2     a
4    ham     5     x
5    ham     5     y

>>> df.groupby('id').nunique()
     value1 value2
id
egg     1     1
ham     1     2
spam    2     1
```

Check for rows with the same id but conflicting values:

```python
>>> df.groupby('id').filter(lambda g: (g.nunique() > 1).any())
     id  value1 value2
0    spam     1     a
3    spam     2     a
4    ham     5     x
5    ham     5     y
```

DataFrameGroupBy.pad(limit=None)
Forward fill the values.

Parameters

- limit [int, optional] Limit of how many values to fill.

Returns

- Series or DataFrame Object with missing values filled.

See also:

- Series.pad
DataFrame.pad
Series.fillna
DataFrame.fillna

pandas.core.groupby.DataFrameGroupBy.pct_change

DataFrameGroupBy.pct_change(periods=1, fill_method='pad', limit=None, freq=None, axis=0)

Calculate pct_change of each value to previous entry in group.

Returns

Series or DataFrame Percentage changes within each group.

See also:

Series.groupby
DataFrame.groupby

pandas.core.groupby.DataFrameGroupBy.plot

property DataFrameGroupBy.plot
Class implementing the .plot attribute for groupby objects.

pandas.core.groupby.DataFrameGroupBy.quantile

DataFrameGroupBy.quantile(q=0.5, interpolation='linear')

Return group values at the given quantile, a la numpy.percentile.

Parameters

q [float or array-like, default 0.5 (50% quantile)] Value(s) between 0 and 1 providing the quantile(s) to compute.

interpolation [\{‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’\}] Method to use when the desired quantile falls between two points.

Returns

Series or DataFrame Return type determined by caller of GroupBy object.

See also:

Series.quantile Similar method for Series.
DataFrame.quantile Similar method for DataFrame.
numpy.percentile NumPy method to compute qth percentile.

Examples

```python
>>> df = pd.DataFrame({
...         'a': [1, 2, 3, 4],
...         'b': [5, 6, 7, 8]
... }, columns=['key', 'val'])
>>> df.groupby('key').quantile()
   val
key
a  2.0
b  3.0
```
DataFrameGroupBy.rank

DataFrameGroupBy.rank (method='average', ascending=True, na_option='keep', pct=False, axis=0)

Provide the rank of values within each group.

Parameters

- **method**
  - ['average', 'min', 'max', 'first', 'dense'], default 'average'
  - average: average rank of group.
  - min: lowest rank in group.
  - max: highest rank in group.
  - first: ranks assigned in order they appear in the array.
  - dense: like 'min', but rank always increases by 1 between groups.

- **ascending** [bool, default True] False for ranks by high (1) to low (N).

- **na_option**
  - ['keep', 'top', 'bottom'], default 'keep'
  - keep: leave NA values where they are.
  - top: smallest rank if ascending.
  - bottom: smallest rank if descending.

- **pct** [bool, default False] Compute percentage rank of data within each group.

- **axis** [int, default 0] The axis of the object over which to compute the rank.

Returns

DataFrame with ranking of values within each group

See also:

- Series.groupby
- DataFrame.groupby

DataFrameGroupBy.resample

DataFrameGroupBy.resample (rule, *args, **kwargs)

Provide resampling when using a TimeGrouper.

Given a grouper, the function resamples it according to a string "string" -> "frequency".

See the frequency aliases documentation for more details.

Parameters

- **rule** [str or DateOffset] The offset string or object representing target grouper conversion.

- **args, **kwargs** Possible arguments are how, fill_method, limit, kind and on, and other arguments of TimeGrouper.

Returns

Grouper Return a new grouper with our resampler appended.

See also:

- Grouper Specify a frequency to resample with when grouping by a key.
- DatetimeIndex.resample Frequency conversion and resampling of time series.
### Examples

```python
>>> idx = pd.date_range('1/1/2000', periods=4, freq='T')
>>> df = pd.DataFrame(data=4 * [range(2)],
...                   index=idx,
...                   columns=['a', 'b'])
>>> df.iloc[2, 0] = 5
>>> df
   a    b
0  0    1
1  0    1
2  5    1
3  0    1

Downsample the DataFrame into 3 minute bins and sum the values of the timestamps falling into a bin.

```python
>>> df.groupby('a').resample('3T').sum()
   a  b
0  0  2
   5  1
```

Upsample the series into 30 second bins.

```python
>>> df.groupby('a').resample('30S').sum()
   a  b
0  0  1
   2
   1
   0
   0
   0
   0
   1
   0
   3
   0
   5
```

Resample by month. Values are assigned to the month of the period.

```python
>>> df.groupby('a').resample('M').sum()
   a  b
0  0  3
   5
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```python
>>> df.groupby('a').resample('3T', closed='right').sum()
   a  b
0  1
   0
   2
   0
   0
   0
   0
   0
   5
   0
```

Downsample the series into 3 minute bins and close the right side of the bin interval, but label each bin using the right edge instead of the left.
pandas: powerful Python data analysis toolkit, Release 1.1.1

```python
>>> df.groupby('a').resample('3T', closed='right', label='right').sum()
a b
0 2000-01-01 00:00:00 0 1
2000-01-01 00:03:00 0 2
5 2000-01-01 00:03:00 5 1
```

pandas.core.groupby.DataFrameGroupBy.sample

DataFrameGroupBy.sample(n=None, frac=None, replace=False, weights=None, random_state=None)

Return a random sample of items from each group.

You can use random_state for reproducibility.

New in version 1.1.0.

Parameters

- **n** [int, optional] Number of items to return for each group. Cannot be used with frac and must be no larger than the smallest group unless replace is True. Default is one if frac is None.
- **frac** [float, optional] Fraction of items to return. Cannot be used with n.
- **replace** [bool, default False] Allow or disallow sampling of the same row more than once.
- **weights** [list-like, optional] Default None results in equal probability weighting. If passed a list-like then values must have the same length as the underlying DataFrame or Series object and will be used as sampling probabilities after normalization within each group. Values must be non-negative with at least one positive element within each group.
- **random_state** [int, array-like, BitGenerator, np.random.RandomState, optional] If int, array-like, or BitGenerator (NumPy>=1.17), seed for random number generator. If np.random.RandomState, use as numpy RandomState object.

Returns

Series or DataFrame A new object of same type as caller containing items randomly sampled within each group from the caller object.

See also:

- DataFrame.sample Generate random samples from a DataFrame object.
- numpy.random.choice Generate a random sample from a given 1-D numpy array.

Examples

```python
>>> df = pd.DataFrame(
...     {"a": ["red"] * 2 + ["blue"] * 2 + ["black"] * 2, "b": range(6)}
... )
>>> df
  a  b
0  red 0
1  red 1
2  blue 2
3  blue 3
4  black 4
5  black 5
```
Select one row at random for each distinct value in column a. The `random_state` argument can be used to guarantee reproducibility:

```python
df.groupby("a").sample(n=1, random_state=1)
```

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>black</td>
<td>4</td>
</tr>
<tr>
<td>2</td>
<td>blue</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>red</td>
<td>1</td>
</tr>
</tbody>
</table>

Set `frac` to sample fixed proportions rather than counts:

```python
df.groupby("a")["b"].sample(frac=0.5, random_state=2)
```

<table>
<thead>
<tr>
<th></th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>5</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Control sample probabilities within groups by setting weights:

```python
df.groupby("a").sample(
    n=1,
    weights=[1, 1, 1, 0, 0, 1],
    random_state=1,
)
```

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>black</td>
<td>5</td>
</tr>
<tr>
<td>2</td>
<td>blue</td>
<td>2</td>
</tr>
<tr>
<td>0</td>
<td>red</td>
<td>0</td>
</tr>
</tbody>
</table>

---

**pandas.core.groupby.DataFrameGroupBy.shift**

`DataFrameGroupBy.shift(periods=1, freq=None, axis=0, fill_value=None)`

Shift each group by periods observations.

If `freq` is passed, the index will be increased using the periods and the `freq`.

**Parameters**

- `periods` [int, default 1] Number of periods to shift.
- `freq` [str, optional] Frequency string.
- `axis` [axis to shift, default 0] Shift direction.
- `fill_value` [optional] The scalar value to use for newly introduced missing values.

    New in version 0.24.0.

**Returns**

- **Series or DataFrame** Object shifted within each group.

**See also:**

- `Index.shift` Shift values of `Index`.
- `tshift` Shift the time index, using the index’s frequency if available.
pandas.core.groupby.DataFrameGroupBy.size

DataFrameGroupBy.size()
Compute group sizes.

Returns

DataFrame or Series Number of rows in each group as a Series if as_index is True or a
Dataframe if as_index is False.

See also:
Series.groupby
DataFrame.groupby

pandas.core.groupby.DataFrameGroupBy.skew

property DataFrameGroupBy.skew
Return unbiased skew over requested axis.
Normalized by N-1.

Parameters

axis [[index (0), columns (1)]] Axis for the function to be applied on.
skipna [bool, default True] Exclude NA/null values when computing the result.
level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along
a particular level, collapsing into a Series.
numeric_only [bool, default None] Include only float, int, boolean columns. If None, will
attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

pandas.core.groupby.DataFrameGroupBy.take

property DataFrameGroupBy.take
Return the elements in the given positional indices along an axis.
This means that we are not indexing according to actual values in the index attribute of the object. We are
indexing according to the actual position of the element in the object.

Parameters

indices [array-like] An array of ints indicating which positions to take.
axis [[0 or `index`, 1 or `columns`, None], default 0] The axis on which to select elements.
0 means that we are selecting rows, 1 means that we are selecting columns.
is_copy [bool] Before pandas 1.0, is_copy=False can be specified to ensure that the
return value is an actual copy. Starting with pandas 1.0, take always returns a copy,
and the keyword is therefore deprecated.
Deprecation since version 1.0.0.

**kwargs For compatibility with numpy.take(). Has no effect on the output.

Returns
taken [same type as caller] An array-like containing the elements taken from the object.

See also:

- DataFrame.loc: Select a subset of a DataFrame by labels.
- DataFrame.iloc: Select a subset of a DataFrame by positions.
- numpy.take: Take elements from an array along an axis.

Examples

```python
def = pd.DataFrame([('falcon', 'bird', 389.0),
                   ('parrot', 'bird', 24.0),
                   ('lion', 'mammal', 80.5),
                   ('monkey', 'mammal', np.nan)],
                   columns=['name', 'class', 'max_speed'],
                   index=[0, 2, 3, 1])
def

name  class     max_speed
0      falcon   bird       389.0
2      parrot   bird       24.0
3      lion     mammal     80.5
1      monkey   mammal     NaN

Take elements at positions 0 and 3 along the axis 0 (default).
Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```python
def.take([0, 3])
```

<table>
<thead>
<tr>
<th>name</th>
<th>class</th>
<th>max_speed</th>
</tr>
</thead>
<tbody>
<tr>
<td>falcon</td>
<td>bird</td>
<td>389.0</td>
</tr>
<tr>
<td>monkey</td>
<td>mammal</td>
<td>NaN</td>
</tr>
</tbody>
</table>

Take elements at indices 1 and 2 along the axis 1 (column selection).

```python
def.take([1, 2], axis=1)
```

<table>
<thead>
<tr>
<th>class</th>
<th>max_speed</th>
</tr>
</thead>
<tbody>
<tr>
<td>bird</td>
<td>389.0</td>
</tr>
<tr>
<td>bird</td>
<td>24.0</td>
</tr>
<tr>
<td>mammal</td>
<td>80.5</td>
</tr>
<tr>
<td>mammal</td>
<td>NaN</td>
</tr>
</tbody>
</table>

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```python
def.take([-1, -2])
```

<table>
<thead>
<tr>
<th>name</th>
<th>class</th>
<th>max_speed</th>
</tr>
</thead>
<tbody>
<tr>
<td>monkey</td>
<td>mammal</td>
<td>NaN</td>
</tr>
<tr>
<td>lion</td>
<td>mammal</td>
<td>80.5</td>
</tr>
</tbody>
</table>
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.core.groupby.DataFrameGroupBy.tshift

**property DataFrameGroupBy.tshift**
Shift the time index, using the index’s frequency if available.

Deprecated since version 1.1.0: Use `shift` instead.

**Parameters**

- **periods** [int] Number of periods to move, can be positive or negative.
- **freq** [DateOffset, timedelta, or str, default None] Increment to use from the tseries module or time rule expressed as a string (e.g. ‘EOM’).
- **axis** [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Corresponds to the axis that contains the Index.

**Returns**

- **shifted** [Series/DataFrame]

**Notes**

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown.

The following methods are available only for `SeriesGroupBy` objects.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SeriesGroupBy.hist</code></td>
<td>Draw histogram of the input series using matplotlib.</td>
</tr>
<tr>
<td><code>SeriesGroupBy.nlargest</code></td>
<td>Return the largest $n$ elements.</td>
</tr>
<tr>
<td><code>SeriesGroupBy.nsmallest</code></td>
<td>Return the smallest $n$ elements.</td>
</tr>
<tr>
<td><code>SeriesGroupBy.nunique([dropna])</code></td>
<td>Return number of unique elements in the group.</td>
</tr>
<tr>
<td><code>SeriesGroupBy.unique</code></td>
<td>Return unique values of Series object.</td>
</tr>
<tr>
<td><code>SeriesGroupBy.value_counts([normalize, ...])</code></td>
<td></td>
</tr>
<tr>
<td><code>SeriesGroupBy.is_monotonic_increasing</code></td>
<td>Alias for <code>is_monotonic</code>.</td>
</tr>
<tr>
<td><code>SeriesGroupBy.is_monotonic_decreasing</code></td>
<td>Return boolean if values in the object are monotonic_decreasing.</td>
</tr>
</tbody>
</table>

pandas.core.groupby.SeriesGroupBy.hist

**property SeriesGroupBy.hist**
Draw histogram of the input series using matplotlib.

**Parameters**

- **by** [object, optional] If passed, then used to form histograms for separate groups.
- **ax** [matplotlib axis object] If not passed, uses `gca()`.
- **grid** [bool, default True] Whether to show axis grid lines.
- **xlabelsize** [int, default None] If specified changes the x-axis label size.
- **xrot** [float, default None] Rotation of x axis labels.
- **ylabelsize** [int, default None] If specified changes the y-axis label size.
- **yrot** [float, default None] Rotation of y axis labels.
- **figsize** [tuple, default None] Figure size in inches by default.
**bins** [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

**backend** [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, `matplotlib`. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

**legend** [bool, default False] Whether to show the legend.

New in version 1.1.0.

**kwargs** To be passed to the actual plotting function.

Returns

`matplotlib.AxesSubplot` A histogram plot.

See also:

`matplotlib.axes.Axes.hist` Plot a histogram using matplotlib.

---

**pandas.core.groupby.SeriesGroupBy.nlargest**

**property** `SeriesGroupBy.nlargest`

Return the largest \( n \) elements.

**Parameters**

- **n** [int, default 5] Return this many descending sorted values.
- **keep** [{‘first’, ‘last’, ‘all’}, default ‘first’] When there are duplicate values that cannot all fit in a Series of \( n \) elements:
  - **first** [return the first \( n \) occurrences in order] of appearance.
  - **last** [return the last \( n \) occurrences in reverse] order of appearance.
  - **all** [keep all occurrences. This can result in a Series of] size larger than \( n \).

**Returns**

`Series` The \( n \) largest values in the Series, sorted in decreasing order.

See also:

`Series.nsmallest` Get the \( n \) smallest elements.

`Series.sort_values` Sort Series by values.

`Series.head` Return the first \( n \) rows.
Notes

Faster than .sort_values(ascending=False).head(n) for small n relative to the size of the Series object.

Examples

```python
>>> countries_population = {"Italy": 59000000, "France": 65000000,
... "Malta": 434000, "Maldives": 434000,
... "Brunei": 434000, "Iceland": 337000,
... "Nauru": 11300, "Tuvalu": 11300,
... "Anguilla": 11300, "Montserrat": 5200}

>>> s = pd.Series(countries_population)

>>> s
Italy 59000000
France 65000000
Malta 434000
Maldives 434000
Brunei 434000
Iceland 337000
Nauru 11300
Tuvalu 11300
Anguilla 11300
Montserrat 5200
dtype: int64

The n largest elements where n=5 by default.

```python
>>> s.nlargest()
France 65000000
Italy 59000000
Malta 434000
Maldives 434000
Brunei 434000
dtype: int64
```

The n largest elements where n=3. Default keep value is ‘first’ so Malta will be kept.

```python
>>> s.nlargest(3)
France 65000000
Italy 59000000
Malta 434000
Maldives 434000
Brunei 434000
dtype: int64
```

The n largest elements where n=3 and keeping the last duplicates. Brunei will be kept since it is the last with value 434000 based on the index order.

```python
>>> s.nlargest(3, keep='last')
France 65000000
Italy 59000000
Brunei 434000
```

The n largest elements where n=3 with all duplicates kept. Note that the returned Series has five elements due to the three duplicates.
pandas: powerful Python data analysis toolkit, Release 1.1.1

```python
>>> s.nlargest(3, keep='all')
France   65000000
Italy    59000000
Malta    434000
Maldives 434000
Brunei   434000
dtype: int64
```

```python
pandas.core.groupby.SeriesGroupBy.nsmallest

**property** SeriesGroupBy.nsmallest
Return the smallest n elements.

**Parameters**

- **n** [int, default 5] Return this many ascending sorted values.
- **keep** [{'first', 'last', 'all'}, default 'first'] When there are duplicate values that cannot all fit in a Series of n elements:
  - **first** [return the first n occurrences in order] of appearance.
  - **last** [return the last n occurrences in reverse] order of appearance.
  - **all** [keep all occurrences. This can result in a Series of] size larger than n.

**Returns**

Series The n smallest values in the Series, sorted in increasing order.

**See also:**

- **Series.nlargest** Get the n largest elements.
- **Series.sort_values** Sort Series by values.
- **Series.head** Return the first n rows.

**Notes**

Faster than .sort_values().head(n) for small n relative to the size of the Series object.

**Examples**

```python
>>> countries_population = {'Italy': 59000000, 'France': 65000000,
...                        'Brunei': 434000, 'Malta': 434000,
...                        'Maldives': 434000, 'Iceland': 337000,
...                        'Nauru': 11300, 'Tuvalu': 11300,
...                        'Anguilla': 11300, 'Montserrat': 5200}
```

```python
>>> s = pd.Series(countries_population)
```
Montserrat 5200
dtype: int64

The $n$ smallest elements where $n=5$ by default.

```python
>>> s.nsmallest()
Montserrat    5200
     Nauru    11300
    Tuvalu     11300
   Anguilla    11300
   Iceland    337000
dtype: int64
```

The $n$ smallest elements where $n=3$. Default `keep` value is ‘first’ so Nauru and Tuvalu will be kept.

```python
>>> s.nsmallest(3)
Montserrat    5200
     Nauru    11300
    Tuvalu     11300
dtype: int64
```

The $n$ smallest elements where $n=3$ and keeping the last duplicates. Anguilla and Tuvalu will be kept since they are the last with value 11300 based on the index order.

```python
>>> s.nsmallest(3, keep='last')
Montserrat    5200
   Anguilla    11300
    Tuvalu     11300
dtype: int64
```

The $n$ smallest elements where $n=3$ with all duplicates kept. Note that the returned Series has four elements due to the three duplicates.

```python
>>> s.nsmallest(3, keep='all')
Montserrat    5200
     Nauru    11300
    Tuvalu     11300
  Anguilla     11300
dtype: int64
```

---

### pandas.core.groupby.SeriesGroupBy.nunique

SeriesGroupBy.nunique(dropna=True)

Return number of unique elements in the group.

**Returns**

- **Series**  Number of unique values within each group.
pandas.core.groupby.SeriesGroupBy.unique

property SeriesGroupBy.unique
Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

Returns

ndarray or ExtensionArray The unique values returned as a NumPy array. See Notes.

See also:
unique Top-level unique method for any 1-d array-like object.
Index.unique Return Index with unique values from an Index object.

Notes

Returns the unique values as a NumPy array. In case of an extension-array backed Series, a new ExtensionArray of that type with just the unique values is returned. This includes

- Categorical
- Period
- Datetime with Timezone
- Interval
- Sparse
- IntegerNA

See Examples section.

Examples

```python
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])
```

```python
>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```python
>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern') for _ in range(3)]).unique()
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]
```

An unordered Categorical will return categories in the order of appearance.

```python
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
['b', 'a', 'c']
Categories (3, object): ['b', 'a', 'c']
```

An ordered Categorical preserves the category ordering.

```python
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'), ordered=True)).unique()
['b', 'a', 'c']
Categories (3, object): ['a' < 'b' < 'c']
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

`pandas.core.groupby.SeriesGroupBy.value_counts`

```
SeriesGroupBy.value_counts(normalize=False, sort=True, ascending=False, bins=None, dropna=True)
```

`pandas.core.groupby.SeriesGroupBy.is_monotonic_increasing`

```
property SeriesGroupBy.is_monotonic_increasing

Alias for is_monotonic.
```

`pandas.core.groupby.SeriesGroupBy.is_monotonic_decreasing`

```
property SeriesGroupBy.is_monotonic_decreasing

Return boolean if values in the object are monotonic_decreasing.

Returns

bool
```

The following methods are available only for DataFrameGroupBy objects.

```
DataFrameGroupBy.corrwith

Compute pairwise correlation.

DataFrameGroupBy.boxplot([subplots, column,...])

Make box plots from DataFrameGroupBy data.
```

`pandas.core.groupby.DataFrameGroupBy.corrwith`

```
property DataFrameGroupBy.corrwith

Compute pairwise correlation.

Pairwise correlation is computed between rows or columns of DataFrame with rows or columns of Series or DataFrame. DataFrames are first aligned along both axes before computing the correlations.

Parameters

other [DataFrame, Series] Object with which to compute correlations.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' to compute column-wise, 1 or 'columns' for row-wise.

drop [bool, default False] Drop missing indices from result.

method [{'pearson', 'kendall', 'spearman'} or callable] Method of correlation:

- pearson : standard correlation coefficient
- kendall : Kendall Tau correlation coefficient
- spearman : Spearman rank correlation
- callable: callable with input two 1d ndarrays and returning a float.

New in version 0.24.0.

Returns

Series Pairwise correlations.

See also:

DataFrame.corr Compute pairwise correlation of columns.
pandas.core.groupby.DataFrameGroupBy.boxplot

DataFrameGroupBy.boxplot(subplots=True, column=None, fontsize=None, rot=0, grid=True, ax=None, figsize=None, layout=None, sharex=False, sharey=True, backend=None, **kwargs)

Make box plots from DataFrameGroupBy data.

Parameters

- **grouped** [Grouped DataFrame]
- **subplots** [bool]
  - False - no subplots will be used
  - True - create a subplot for each group.
- **column** [column name or list of names, or vector] Can be any valid input to groupby.
- **fontsize** [int or str]
- **rot** [label rotation angle]
- **grid** [Setting this to True will show the grid]
- **ax** [Matplotlib axis object, default None]
- **figsize** [A tuple (width, height) in inches]
- **layout** [tuple (optional)] The layout of the plot: (rows, columns).
- **sharex** [bool, default False] Whether x-axes will be shared among subplots.
  
  New in version 0.23.1.
- **sharey** [bool, default True] Whether y-axes will be shared among subplots.
  
  New in version 0.23.1.
- **backend** [str, default None] Backend to use instead of the backend specified in the option plotting.backend. For instance, `matplotlib`. Alternatively, to specify the plotting.backend for the whole session, set pd.options.plotting.backend.
  
  New in version 1.0.0.
- **kwargs** All other plotting keyword arguments to be passed to matplotlib's boxplot function.

Returns

- dict of key/value = group key/DataFrame.boxplot return value
- or DataFrame.boxplot return value in case subplots=figures=False
Examples

You can create boxplots for grouped data and show them as separate subplots:

```python
>>> import itertools

>>> tuples = [t for t in itertools.product(range(1000), range(4))]

>>> index = pd.MultiIndex.from_tuples(tuples, names=['lvl0', 'lvl1'])

>>> data = np.random.randn(len(index), 4)

>>> df = pd.DataFrame(data, columns=list('ABCD'), index=index)

>>> grouped = df.groupby(level='lvl1')

>>> grouped.boxplot(rot=45, fontsize=12, figsize=(8,10))
```

The `subplots=False` option shows the boxplots in a single figure.

```python
>>> grouped.boxplot(subplots=False, rot=45, fontsize=12)
```

3.12 Resampling

Resampler objects are returned by resample calls: `pandas.DataFrame.resample()`, `pandas.Series.resample()`.

3.12.1 Indexing, iteration

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Resampler.__iter__()</code></td>
<td>Resampler iterator.</td>
</tr>
<tr>
<td><code>Resampler.groups</code></td>
<td>Dict {group name -&gt; group labels}.</td>
</tr>
<tr>
<td><code>Resampler.indices</code></td>
<td>Dict {group name -&gt; group indices}.</td>
</tr>
<tr>
<td><code>Resampler.get_group(name[, obj])</code></td>
<td>Construct DataFrame from group with provided name.</td>
</tr>
</tbody>
</table>

**pandas.core.resample.Resampler.__iter__**

Resampler iterator.

```python
def __iter__(self):
    Resampler iterator.
    
    Returns
    -------
    Generator yielding sequence of (name, subsetted object)
    for each group.
```

See also:

`GroupBy.__iter__`
3.12. Resampling
pandas.core.resample.Resampler.groups

**property** `Resampler.groups`

Dict {group name -> group labels}.

pandas.core.resample.Resampler.indices

**property** `Resampler.indices`

Dict {group name -> group indices}.

pandas.core.resample.Resampler.get_group

`Resampler.get_group(name, obj=None)`

Construct DataFrame from group with provided name.  

**Parameters**

- `name` [object] The name of the group to get as a DataFrame.  
- `obj` [DataFrame, default None] The DataFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used.  

**Returns**

- `group` [same type as obj]

3.12.2 Function application

| `Resampler.apply(func, *args, **kwargs)` | Aggregate using one or more operations over the specified axis. |
| `Resampler.aggregate(func, *args, **kwargs)` | Aggregate using one or more operations over the specified axis. |
| `Resampler.transform(arg, *args, **kwargs)` | Call function producing a like-indexed Series on each group and return a Series with the transformed values. |
| `Resampler.pipe(func, *args, **kwargs)` | Apply a function `func` with arguments to this Resampler object and return the function’s result. |

pandas.core.resample.Resampler.apply

`Resampler.apply(func, *args, **kwargs)`  
Aggregate using one or more operations over the specified axis.  

**Parameters**

- `func` [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.  

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. [np.sum, 'mean']
- dict of axis labels -> functions, function names or list of such.

3.12. Resampling
*args  Positional arguments to pass to `func`.

**kwargs  Keyword arguments to pass to `func`.

Returns

**scalar, Series or DataFrame**  The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

- `DataFrame.groupby.aggregate`
- `DataFrame.resample.transform`
- `DataFrame.aggregate`

Notes

agg is an alias for aggregate. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> s = pd.Series([1,2,3,4,5],
                 index=pd.date_range('20130101', periods=5,freq='s'))
          2013-01-01 00:00:00   1
          2013-01-01 00:00:01   2
          2013-01-01 00:00:02   3
          2013-01-01 00:00:03   4
          2013-01-01 00:00:04   5
Freq: S, dtype: int64
```

```python
>>> r = s.resample('2s')
```

```python
>>> r.agg(np.sum)
          2013-01-01 00:00:00   3
          2013-01-01 00:00:02   7
          2013-01-01 00:00:04   5
Freq: 2S, dtype: int64
```

```python
>>> r.agg(['sum','mean','max'])

<table>
<thead>
<tr>
<th></th>
<th>sum</th>
<th>mean</th>
<th>max</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-01 00:00:00</td>
<td>3</td>
<td>1.5</td>
<td>2</td>
</tr>
<tr>
<td>2013-01-01 00:00:02</td>
<td>7</td>
<td>3.5</td>
<td>4</td>
</tr>
<tr>
<td>2013-01-01 00:00:04</td>
<td>5</td>
<td>5.0</td>
<td>5</td>
</tr>
</tbody>
</table>
```

```python
>>> r.agg({'result' : lambda x: x.mean() / x.std(),
         'total' : np.sum})

<table>
<thead>
<tr>
<th></th>
<th>total</th>
<th>result</th>
</tr>
</thead>
</table>
```

(continues on next page)
Resampler. **aggregate** *(func, *args, **kwargs)*

Aggregate using one or more operations over the specified axis.

**Parameters**

- **func**  [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

  Accepted combinations are:
  - function
  - string function name
  - list of functions and/or function names, e.g. `[np.sum, 'mean']`
  - dict of axis labels -> functions, function names or list of such.

- **args** Positional arguments to pass to `func`.

- **kwargs** Keyword arguments to pass to `func`.

**Returns**

- **scalar, Series or DataFrame**  The return can be:
  - scalar : when Series.agg is called with single function
  - Series : when DataFrame.agg is called with a single function
  - DataFrame : when DataFrame.agg is called with several functions

  Return scalar, Series or DataFrame.

**See also:**

- `DataFrame.groupby.aggregate`
- `DataFrame.resample.transform`
- `DataFrame.aggregate`

**Notes**

`agg` is an alias for `aggregate`. Use the alias.

A passed user-defined-function will be passed a Series for evaluation.
Examples

```python
>>> s = pd.Series([1,2,3,4,5],
                index=pd.date_range('20130101', periods=5,freq='s'))
2013-01-01 00:00:00    1
2013-01-01 00:00:01    2
2013-01-01 00:00:02    3
2013-01-01 00:00:03    4
2013-01-01 00:00:04    5
Freq: S, dtype: int64
```

```python
>>> r = s.resample('2s')
```

```python
>>> r.agg(np.sum)
2013-01-01 00:00:00  3
2013-01-01 00:00:02  7
2013-01-01 00:00:04  5
Freq: 2S, dtype: int64
```

```python
>>> r.agg(['sum','mean','max'])
       sum  mean  max
2013-01-01 00:00:00  3  1.5  2
2013-01-01 00:00:02  7  3.5  4
2013-01-01 00:00:04  5  5.0  5
```

```python
>>> r.agg({'result' : lambda x: x.mean() / x.std(),
         'total' : np.sum})
       total  result
2013-01-01 00:00:00  3  2.121320
2013-01-01 00:00:02  7  4.949747
2013-01-01 00:00:04  5  NaN
```

**pandas.core.resample.Resampler.transform**

Resampler.transform(arg, *args, **kwargs)

Call function producing a like-indexed Series on each group and return a Series with the transformed values.

Parameters

- **arg** [function] To apply to each group. Should return a Series with the same index.

Returns

- **transformed** [Series]
Examples

```python
>>> resampled.transform(lambda x: (x - x.mean()) / x.std())
```

**pandas.core.resample.Resampler.pipe**

Resampler.pipe(func, *args, **kwargs)

Apply a function `func` with arguments to this Resampler object and return the function’s result.

New in version 0.23.0.

Use `.pipe` when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing

```python
>>> h(g(f(df.groupby('group')), arg1=a), arg2=b, arg3=c)
```

You can write

```python
>>> (df.groupby('group')
... .pipe(f)
... .pipe(g, arg1=a)
... .pipe(h, arg2=b, arg3=c))
```

which is much more readable.

**Parameters**

- **func** [callable or tuple of (callable, str)] Function to apply to this Resampler object or, alternatively, a (callable, data_keyword) tuple where data_keyword is a string indicating the keyword of callable that expects the Resampler object.

- **args** [iterable, optional] Positional arguments passed into func.

- **kwargs** [dict, optional] A dictionary of keyword arguments passed into func.

**Returns**

- **object** [the return type of func.]

See also:

pandas.Series.pipe Apply a function with arguments to a series.

pandas.DataFrame.pipe Apply a function with arguments to a dataframe.

**apply** Apply function to each group instead of to the full Resampler object.

**Notes**

See more [here](#).
Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3, 4]},
                   index=pd.date_range('2012-08-02', periods=4))
>>> df
   A
2012-08-02    1
2012-08-03    2
2012-08-04    3
2012-08-05    4
```

To get the difference between each 2-day period’s maximum and minimum value in one pass, you can do

```python
>>> df.resample('2D').pipe(lambda x: x.max() - x.min())
   A
2012-08-02    1
2012-08-04    1
```

### 3.12.3 Upsampling

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ffill</code></td>
<td>Forward fill the values.</td>
</tr>
<tr>
<td><code>backfill</code></td>
<td>Backward fill the new missing values in the resampled data.</td>
</tr>
<tr>
<td><code>bfill</code></td>
<td>Backward fill the new missing values in the resampled data.</td>
</tr>
<tr>
<td><code>pad</code></td>
<td>Forward fill the values.</td>
</tr>
<tr>
<td><code>nearest</code></td>
<td>Resample by using the nearest value.</td>
</tr>
<tr>
<td><code>fillna</code></td>
<td>Fill missing values introduced by upsampling.</td>
</tr>
<tr>
<td><code>asfreq</code></td>
<td>Return the values at the new freq, essentially a reindex.</td>
</tr>
<tr>
<td><code>interpolate</code></td>
<td>Interpolate values according to different methods.</td>
</tr>
</tbody>
</table>

**pandas.core.resample.Resampler.ffill**

Resampler(ffill)(limit)

Forward fill the values.

**Parameters**

- `limit` [int, optional] Limit of how many values to fill.

**Returns**

An upsampled Series.

**See also:**

- `Series.fillna`
- `DataFrame.fillna`
pandas.core.resample.Resampler.backfill

Resampler.backfill(limit=None)
Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

Parameters

- limit [int, optional] Limit of how many values to fill.

Returns

Series, DataFrame An upsampled Series or DataFrame with backward filled NaN values.

See also:

- bfill Alias of backfill.
- fillna Fill NaN values using the specified method, which can be ‘backfill’.
- nearest Fill NaN values with nearest neighbor starting from center.
- pad Forward fill NaN values.
- Series.fillna Fill NaN values in the Series using the specified method, which can be ‘backfill’.
- DataFrame.fillna Fill NaN values in the DataFrame using the specified method, which can be ‘backfill’.

[1]

Examples

Resampling a Series:

```python
>>> s = pd.Series([1, 2, 3],
                 index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64

>>> s.resample('30min').backfill()
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64

>>> s.resample('15min').backfill(limit=2)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    NaN
2018-01-01 00:30:00    2.0
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
Freq: 15T, dtype: float64
```

(continues on next page)
Resampling a DataFrame that has missing values:

```python
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
                    index=pd.date_range('20180101', periods=3,
                    freq='h'))
>>> df
   a  b
2018-01-01 00:00:00  2.0  1
2018-01-01 01:00:00  NaN  3
2018-01-01 02:00:00  6.0  5

>>> df.resample('30min').backfill()
   a  b
2018-01-01 00:00:00  2.0  1
2018-01-01 00:30:00  NaN  3
2018-01-01 01:00:00  NaN  3
2018-01-01 01:30:00  6.0  5
2018-01-01 02:00:00  6.0  5

>>> df.resample('15min').backfill(limit=2)
   a   b
2018-01-01 00:00:00  2.0  1.0
2018-01-01 00:15:00  NaN  NaN
2018-01-01 00:30:00  NaN  3.0
2018-01-01 00:45:00  NaN  3.0

```

`pandas.core.resample.Resampler.bfill`

Resampler.bfill (limit=None)

Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

Parameters

- **limit** [int, optional]: Limit of how many values to fill.

Returns

- **Series, DataFrame**: An upsampled Series or DataFrame with backward filled NaN values.

See also:

- `bfill`: Alias of backfill.
**fillna** Fill NaN values using the specified method, which can be ‘backfill’.

**nearest** Fill NaN values with nearest neighbor starting from center.

**pad** Forward fill NaN values.

**Series.fillna** Fill NaN values in the Series using the specified method, which can be ‘backfill’.

**DataFrame.fillna** Fill NaN values in the DataFrame using the specified method, which can be ‘backfill’.

### References

### Examples

**Resampling a Series:**

```python
>>> s = pd.Series([1, 2, 3],
                 index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64

>>> s.resample('30min').backfill()
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64

>>> s.resample('15min').backfill(limit=2)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00   NaN
2018-01-01 00:30:00    2.0
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
2018-01-01 01:15:00   NaN
2018-01-01 01:30:00    3.0
2018-01-01 01:45:00    3.0
2018-01-01 02:00:00    3.0
Freq: 15T, dtype: float64
```

**Resampling a DataFrame that has missing values:**

```python
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
                    index=pd.date_range('20180101', periods=3, freq='h'))
>>> df
     a   b
2018-01-01 2.0 1
2018-01-01 NaN 3
2018-01-01 6.0 5
```
>>> df.resample('30min').backfill()
    a    b
2018-01-01 00:00:00  2.0 1.0
2018-01-01 00:30:00  NaN 3.0
2018-01-01 01:00:00  NaN 3.0
2018-01-01 01:30:00  6.0 5.0
2018-01-01 02:00:00  6.0 5.0

>>> df.resample('15min').backfill(limit=2)
    a    b
2018-01-01 00:00:00  2.0 1.0
2018-01-01 00:15:00  NaN NaN
2018-01-01 00:30:00  NaN 3.0
2018-01-01 00:45:00  NaN 3.0
2018-01-01 01:00:00  NaN 3.0
2018-01-01 01:15:00  NaN NaN
2018-01-01 01:30:00  6.0 5.0
2018-01-01 01:45:00  6.0 5.0
2018-01-01 02:00:00  6.0 5.0

pandas.core.resample.Resampler.pad

Resampler.pad(limit=None)
Forward fill the values.

Parameters

    limit [int, optional] Limit of how many values to fill.

Returns

    An upsampled Series.

See also:

    Series.fillna
    DataFrame.fillna

pandas.core.resample.Resampler.nearest

Resampler.nearest(limit=None)
Resample by using the nearest value.

When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The nearest method will replace NaN values that appeared in the resampled data with the value from the nearest member of the sequence, based on the index value. Missing values that existed in the original data will not be modified. If limit is given, fill only this many values in each direction for each of the original values.

Parameters

    limit [int, optional] Limit of how many values to fill.

Returns

    Series or DataFrame An upsampled Series or DataFrame with NaN values filled with their nearest value.

See also:

    backfill Backward fill the new missing values in the resampled data.
pad Forward fill NaN values.

Examples

```python
>>> s = pd.Series([1, 2],
...                 index=pd.date_range('20180101',
...                 periods=2,
...                 freq='1h'))
>>> s
2018-01-01 00:00:00  1
2018-01-01 01:00:00  2
Freq: H, dtype: int64

>>> s.resample('15min').nearest()
2018-01-01 00:00:00  1
2018-01-01 00:15:00  NaN
2018-01-01 00:30:00  2
2018-01-01 00:45:00  2
2018-01-01 01:00:00  2
Freq: 15T, dtype: int64
```

Limit the number of upsampled values imputed by the nearest:

```python
>>> s.resample('15min').nearest(limit=1)
2018-01-01 00:00:00  1.0
2018-01-01 00:15:00  1.0
2018-01-01 00:30:00  NaN
2018-01-01 00:45:00  2.0
2018-01-01 01:00:00  2.0
Freq: 15T, dtype: float64
```

pandas.core.resample.Resampler.fillna

Resampler.fillna(method, limit=None)
Fill missing values introduced by upsampling.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency).

Missing values that existed in the original data will not be modified.

Parameters

- **method** [{‘pad’, ‘backfill’, ‘ffill’, ‘bfill’, ‘nearest’}] Method to use for filling holes in resampled data
  - ‘pad’ or ‘ffill’: use previous valid observation to fill gap (forward fill).
  - ‘backfill’ or ‘bfill’: use next valid observation to fill gap.
  - ‘nearest’: use nearest valid observation to fill gap.

- **limit** [int, optional] Limit of how many consecutive missing values to fill.

Returns

Series or DataFrame An upsampled Series or DataFrame with missing values filled.

See also:

- backfill Backward fill NaN values in the resampled data.
**pad**  Forward fill NaN values in the resampled data.

**nearest**  Fill NaN values in the resampled data with nearest neighbor starting from center.

**interpolate**  Fill NaN values using interpolation.

**Series.fillna**  Fill NaN values in the Series using the specified method, which can be ‘bfill’ and ‘ffill’.

**DataFrame.fillna**  Fill NaN values in the DataFrame using the specified method, which can be ‘bfill’ and ‘ffill’.

**References**

[1]

**Examples**

Resampling a Series:

```python
>>> s = pd.Series([1, 2, 3],
...                 index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64
```

Without filling the missing values you get:

```python
>>> s.resample("30min").asfreq()
2018-01-01 00:00:00    1.0
2018-01-01 00:30:00    NaN
2018-01-01 01:00:00    2.0
2018-01-01 01:30:00    NaN
2018-01-01 02:00:00    3.0
Freq: 30T, dtype: float64
```

```python
>>> s.resample('30min').fillna("backfill")
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```python
>>> s.resample('15min').fillna("backfill", limit=2)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    NaN
2018-01-01 00:30:00    2.0
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
2018-01-01 01:15:00    NaN
2018-01-01 01:30:00    3.0
2018-01-01 01:45:00    3.0
2018-01-01 02:00:00    3.0
Freq: 15T, dtype: float64
```
```python
>>> s.resample('30min').fillna("pad")
2018-01-01 00:00:00 1
2018-01-01 00:30:00 1
2018-01-01 01:00:00 2
2018-01-01 01:30:00 2
2018-01-01 02:00:00 3
Freq: 30T, dtype: int64
```

```python
>>> s.resample('30min').fillna("nearest")
2018-01-01 00:00:00 1
2018-01-01 00:30:00 2
2018-01-01 01:00:00 2
2018-01-01 01:30:00 3
2018-01-01 02:00:00 3
Freq: 30T, dtype: int64
```

Missing values present before the upsampling are not affected.

```python
>>> sm = pd.Series([1, None, 3],
...                 index=pd.date_range('20180101', periods=3, freq='h'))
>>> sm
2018-01-01 00:00:00 1.0
2018-01-01 01:00:00 NaN
2018-01-01 02:00:00 3.0
Freq: H, dtype: float64
```

```python
>>> sm.resample('30min').fillna('backfill')
2018-01-01 00:00:00 1.0
2018-01-01 00:30:00 NaN
2018-01-01 01:00:00 NaN
2018-01-01 01:30:00 3.0
2018-01-01 02:00:00 3.0
Freq: 30T, dtype: float64
```

```python
>>> sm.resample('30min').fillna('pad')
2018-01-01 00:00:00 1.0
2018-01-01 00:30:00 1.0
2018-01-01 01:00:00 NaN
2018-01-01 01:30:00 NaN
2018-01-01 02:00:00 3.0
Freq: 30T, dtype: float64
```

```python
>>> sm.resample('30min').fillna('nearest')
2018-01-01 00:00:00 1.0
2018-01-01 00:30:00 NaN
2018-01-01 01:00:00 NaN
2018-01-01 01:30:00 3.0
2018-01-01 02:00:00 3.0
Freq: 30T, dtype: float64
```

Dataframe resampling is done column-wise. All the same options are available.

```python
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
...                    index=pd.date_range('20180101', periods=3, freq='h'))
>>> df
3.12. Resampling 2307
```

(continues on next page)
pandas.core.resample.Resampler.asfreq

Resampler.asfreq(fill_value=None)

Return the values at the new freq, essentially a reindex.

Parameters

fill_value [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

Returns

DataFrame or Series Values at the specified freq.

See also:

Series.asfreq
DataFrame.asfreq

pandas.core.resample.Resampler.interpolate

Resampler.interpolate(method='linear', axis=0, limit=None, inplace=False, limit_direction='forward', limit_area=None, downcast=None, **kwargs)

Interpolate values according to different methods.

Please note that only method='linear' is supported for DataFrame/Series with a MultiIndex.

Parameters

method [str, default ‘linear’] Interpolation technique to use. One of:

- ‘linear’: Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- ‘time’: Works on daily and higher resolution data to interpolate given length of interval.
- ‘index’, ‘values’: use the actual numerical values of the index.
- ‘pad’: Fill in NaNs using existing values.
- ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘spline’, ‘barycentric’, ‘polynomial’: Passed to scipy.interpolate.interp1d. These methods use the numerical values of the index. Both ‘polynomial’ and ‘spline’ require that you also specify an order (int), e.g. df.interpolate(method='polynomial', order=5).
from_derivatives': Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces 'piecewise_polynomial' interpolation method in scipy 0.18.

• 'axis': [[0 or 'index', 1 or 'columns', None], default None] Axis to interpolate along.

• 'limit': [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

• 'inplace': [bool, default False] Update the data in place if possible.

• 'limit_direction': [{'forward', 'backward', 'both'}], Optional] Consecutive NaNs will be filled in this direction.

  If limit is specified:
  • If 'method' is 'pad' or 'ffill', 'limit_direction' must be 'forward'.
  • If 'method' is 'backfill' or 'bfill', 'limit_direction' must be 'backwards'.

  If 'limit' is not specified:
  • If 'method' is 'backfill' or 'bfill', the default is 'backward'
  • else the default is 'forward'

Changed in version 1.1.0: raises ValueError if limit_direction is 'forward' or 'both' and method is 'backfill' or 'bfill'. raises ValueError if limit_direction is 'backward' or 'both' and method is 'pad' or 'ffill'.

• 'limit_area': [{None, 'inside', 'outside'}], default None] If limit is specified, consecutive NaNs will be filled with this restriction.

  • None: No fill restriction.
  • 'inside': Only fill NaNs surrounded by valid values (interpolate).
  • 'outside': Only fill NaNs outside valid values (extrapolate).

  New in version 0.23.0.

• 'downcast': [optional, 'infer' or None, defaults to None] Downcast dtypes if possible.

• '**kwargs': Keyword arguments to pass on to the interpolating function.

Returns

Series or DataFrame Returns the same object type as the caller, interpolated at some or all NaN values.

See also:

fillna Fill missing values using different methods.
scipy.interpolate.Akima1DInterpolator Piecewise cubic polynomials (Akima interpolator).
scipy.interpolate.BPoly.from_derivatives Piecewise polynomial in the Bernstein basis.
scipy.interpolate.interpl1d Interpolate a 1-D function.
scipy.interpolate.KroghInterpolator Interpolate polynomial (Krogh interpolator).
scipy.interpolate.PchipInterpolator PCHIP 1-d monotonic cubic interpolation.
scipy.interpolate.CubicSpline Cubic spline data interpolator.
Notes

The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the SciPy documentation and SciPy tutorial.

Examples

Filling in NaN in a Series via linear interpolation.

```python
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0 0.0
1 1.0
2 NaN
3 3.0
dtype: float64
>>> s.interpolate()
0 0.0
1 1.0
2 2.0
3 3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.

```python
>>> s = pd.Series([np.nan, "single_one", np.nan, ... "fill_two_more", np.nan, np.nan, np.nan, ... 4.71, np.nan])
>>> s
0 NaN
1 single_one
2 NaN
3 fill_two_more
4 NaN
5 NaN
6 NaN
7 4.71
8 NaN
dtype: object
>>> s.interpolate(method='pad', limit=2)
0 NaN
1 single_one
2 single_one
3 fill_two_more
4 fill_two_more
5 fill_two_more
6 NaN
7 4.71
8 4.71
dtype: object
```

Filling in NaN in a Series via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an order (int).
Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it to use for interpolation.

Using polynomial interpolation.

**pandas.core.resample.Resampler.count**

`Resampler.count()`
Compute count of group, excluding missing values.

**Returns**
- Series or DataFrame  Count of values within each group.

**See also:**
- Series.groupby
- DataFrame.groupby

**pandas.core.resample.Resampler.nunique**

`Resampler.nunique(_method='nunique')`
Return number of unique elements in the group.

**Returns**
- Series  Number of unique values within each group.

**pandas.core.resample.Resampler.first**

`Resampler.first(_method='first', *args, **kwargs)`
Compute first of group values.

**Parameters**
- **numeric_only** [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
- **min_count** [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

**Returns**
- Series or DataFrame  Computed first of values within each group.
pandas.core.resample.Resampler.last

\texttt{Resampler.last(_method='last', *args, **kwargs)}

Compute last of group values.

**Parameters**

- \texttt{numeric_only} [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

- \texttt{min_count} [int, default -1] The required number of valid values to perform the operation. If fewer than \texttt{min_count} non-NA values are present the result will be NA.

**Returns**

- **Series or DataFrame** Computed last of values within each group.

pandas.core.resample.Resampler.max

\texttt{Resampler.max(_method='max', *args, **kwargs)}

Compute max of group values.

**Parameters**

- \texttt{numeric_only} [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

- \texttt{min_count} [int, default -1] The required number of valid values to perform the operation. If fewer than \texttt{min_count} non-NA values are present the result will be NA.

**Returns**

- **Series or DataFrame** Computed max of values within each group.

pandas.core.resample.Resampler.mean

\texttt{Resampler.mean(_method='mean', *args, **kwargs)}

Compute mean of groups, excluding missing values.

**Parameters**

- \texttt{numeric_only} [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

**Returns**

- **pandas.Series or pandas.DataFrame**

See also:

- \texttt{Series.groupby}
- \texttt{DataFrame.groupby}
Examples

```python
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
... 'B': [np.nan, 2, 3, 4, 5],
... 'C': [1, 2, 1, 1, 2], columns=['A', 'B', 'C'])

Groupby one column and return the mean of the remaining columns in each group.

```python
>>> df.groupby('A').mean()
B   C
A  
1  3.0  1.333333
2  4.0  1.500000
```

Groupby two columns and return the mean of the remaining column.

```python
>>> df.groupby(['A', 'B']).mean()
C
A   B
1  2.0  2
   4.0  1
2  3.0  1
   5.0  2
```

Groupby one column and return the mean of only particular column in the group.

```python
>>> df.groupby('A')['B'].mean()
A
1  3.0
2  4.0
Name: B, dtype: float64
```

pandas.core.resample.Resampler.median

Resampler.median(_method='median', *args, **kwargs)
Compute median of groups, excluding missing values.
For multiple groupings, the result index will be a MultiIndex

Parameters

- numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

Returns

- Series or DataFrame Median of values within each group.

See also:

- Series.groupby
- DataFrame.groupby
pandas.core.resample.Resampler.min

Resampler.min(_method='min', *args, **kwargs)
Compute min of group values.

Parameters

   numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

   min_count [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame  Computed min of values within each group.

pandas.core.resample.Resampler.ohlc

Resampler.ohlc(_method='ohlc', *args, **kwargs)
Compute open, high, low and close values of a group, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

Returns

DataFrame  Open, high, low and close values within each group.

See also:

Series.groupby
DataFrame.groupby

pandas.core.resample.Resampler.prod

Resampler.prod(_method='prod', min_count=0, *args, **kwargs)
Compute prod of group values.

Parameters

   numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

   min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame  Computed prod of values within each group.

pandas.core.resample.Resampler.size

Resampler.size()
Compute group sizes.

Returns

DataFrame or Series  Number of rows in each group as a Series if as_index is True or a DataFrame if as_index is False.

See also:

Series.groupby
DataFrame.groupby
pandas.core.resample.Resampler.sem

`Resampler.sem(_method='sem', *args, **kwargs)`

Compute standard error of the mean of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

**Parameters**

- `ddof [int, default 1]` Degrees of freedom.

**Returns**

- `Series or DataFrame` Standard error of the mean of values within each group.

See also:
- `Series.groupby`
- `DataFrame.groupby`

pandas.core.resample.Resampler.std

`Resampler.std(ddof=1, *args, **kwargs)`

Compute standard deviation of groups, excluding missing values.

**Parameters**

- `ddof [int, default 1]` Degrees of freedom.

**Returns**

- `DataFrame or Series` Standard deviation of values within each group.

pandas.core.resample.Resampler.sum

`Resampler.sum(_method='sum', min_count=0, *args, **kwargs)`

Compute sum of group values.

**Parameters**

- `numeric_only [bool, default True]` Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

- `min_count [int, default 0]` The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

**Returns**

- `Series or DataFrame` Computed sum of values within each group.

pandas.core.resample.Resampler.var

`Resampler.var(ddof=1, *args, **kwargs)`

Compute variance of groups, excluding missing values.

**Parameters**

- `ddof [int, default 1]` Degrees of freedom.

**Returns**

- `DataFrame or Series` Variance of values within each group.
**pandas.core.resample.Resampler.quantile**

Resampler.quantile(q=0.5, **kwargs)

Return value at the given quantile.

New in version 0.24.0.

**Parameters**

- `q` [float or array-like, default 0.5 (50% quantile)]

**Returns**

DataFrame or Series Quantile of values within each group.

See also:

Series.quantile
DataFrame.quantile
DataFrameGroupBy.quantile

### 3.13 Style

Styler objects are returned by pandas.DataFrame.style.

#### 3.13.1 Styler constructor

| **Styler**(data[, precision, table_styles, ...]) | Helps style a DataFrame or Series according to the data with HTML and CSS. |
| **Styler.from_custom_template**(searchpath, name) | Factory function for creating a subclass of Styler. |

**pandas.io.formats.style.Styler**

class pandas.io.formats.style.Styler(data, precision=None, table_styles=None, uuid=None, caption=None, table_attributes=None, cell_ids=True, na_rep=None)

Helps style a DataFrame or Series according to the data with HTML and CSS.

**Parameters**

- `data` [Series or DataFrame] Data to be styled - either a Series or DataFrame.
- `precision` [int] Precision to round floats to, defaults to pd.options.display.precision.
- `table_styles` [list-like, default None] List of [selector: (attr, value)] dicts; see Notes.
- `uuid` [str, default None] A unique identifier to avoid CSS collisions; generated automatically.
- `caption` [str, default None] Caption to attach to the table.
- `table_attributes` [str, default None] Items that show up in the opening <table> tag in addition to automatic (by default) id.
- `cell_ids` [bool, default True] If True, each cell will have an id attribute in their HTML tag. The id takes the form T_<uuid>_row<num_row>_col<num_col> where <uuid> is the unique identifier, <num_row> is the row number and <num_col> is the column number.
**na_rep** [str, optional] Representation for missing values. If `na_rep` is None, no special formatting is applied.

    New in version 1.0.0.

**See also:**

**DataFrame.style** Return a Styler object containing methods for building a styled HTML representation for the DataFrame.

**Notes**

Most styling will be done by passing style functions into `Styler.apply` or `Styler.applymap`. Style functions should return values with strings containing CSS `'attr: value'` that will be applied to the indicated cells.

If using in the Jupyter notebook, Styler has defined a `_repr_html_` to automatically render itself. Otherwise call Styler.render to get the generated HTML.

CSS classes are attached to the generated HTML

- Index and Column names include `index_name` and `level<k>` where `k` is its level in a MultiIndex
- Index label cells include
  - `row_heading`
  - `row<n>` where `n` is the numeric position of the row
  - `level<k>` where `k` is the level in a MultiIndex
- Column label cells include `* col_heading` `* col<n>` where `n` is the numeric position of the column
  `* level<k>` where `k` is the level in a MultiIndex
- Blank cells include `blank`
- Data cells include `data`

**Methods**

**apply**(func[, axis, subset]) Apply a function column-wise, row-wise, or table-wise.

**applymap**(func[, subset]) Apply a function elementwise.

**background_gradient**(cmap, low, high, axis, ...) Color the background in a gradient style.

**bar**(subset, axis, color, width, align, ...) Draw bar chart in the cell backgrounds.

**clear**() Reset the styler, removing any previously applied styles.

**export**() Export the styles to applied to the current Styler.

**format**(formatter[, subset, na_rep]) Format the text display value of cells.

**from_custom_template**(searchpath, name) Factory function for creating a subclass of Styler.

**hide_columns**(subset) Hide columns from rendering.

**pandas.io.formats.style.Styler.apply**

Styler.apply(func, axis=0, subset=None, **kwargs)

Apply a function column-wise, row-wise, or table-wise.

Updates the HTML representation with the result.

**Parameters**

- **func** [function] func should take a Series or DataFrame (depending on axis), and return an object with the same shape. Must return a DataFrame with identical index and column labels when axis=None.

- **axis** [[0 or 'index', 1 or 'columns', None], default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.

- **subset** [IndexSlice] A valid indexer to limit data to before applying the function. Consider using a pandas.IndexSlice.

- ****kwargs [dict] Pass along to func.

**Returns**

- **self** [Styler]
Notes

The output shape of func should match the input, i.e. if x is the input row, column, or table (depending on axis), then func(x).shape == x.shape should be true.

This is similar to DataFrame.apply, except that axis=None applies the function to the entire DataFrame at once, rather than column-wise or row-wise.

Examples

```python
>>> def highlight_max(x):
...   return ['background-color: yellow' if v == x.max() else ''
...           for v in x]
... >>> df = pd.DataFrame(np.random.randn(5, 2))
>>> df.style.apply(highlight_max)
```

pandas.io.formats.style.Styler.applymap

Styler.applymap(func, subset=None, **kwargs)

Apply a function elementwise.

Parameters

- **func** [function] func should take a scalar and return a scalar.
- **subset** [IndexSlice] A valid indexer to limit data to before applying the function. Consider using a pandas.IndexSlice.
- **kwargs** [dict] Pass along to func.

Returns

self [Styler]

See also:

Styler.where

pandas.io.formats.style.Styler.background_gradient

Styler.background_gradient(cmap='PuBu', low=0, high=0, axis=0, subset=None, text_color_threshold=0.408, vmin=None, vmax=None)

Color the background in a gradient style.

The background color is determined according to the data in each column (optionally row). Requires matplotlib.

Parameters

- **cmap** [str or colormap] Matplotlib colormap.
- **low** [float] Compress the range by the low.
- **high** [float] Compress the range by the high.
axis  [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.

subset  [IndexSlice] A valid slice for data to limit the style application to.

text_color_threshold  [float or int] Luminance threshold for determining text color. Facilitates text visibility across varying background colors. From 0 to 1. 0 = all text is dark colored, 1 = all text is light colored.

New in version 0.24.0.

vmin  [float, optional] Minimum data value that corresponds to colormap minimum value. When None (default): the minimum value of the data will be used.

New in version 1.0.0.

vmax  [float, optional] Maximum data value that corresponds to colormap maximum value. When None (default): the maximum value of the data will be used.

New in version 1.0.0.

Returns

self  [Styler]

Raises

ValueError  If text_color_threshold is not a value from 0 to 1.

Notes

Set text_color_threshold or tune low and high to keep the text legible by not using the entire range of the color map. The range of the data is extended by low * (x.max() - x.min()) and high * (x.max() - x.min()) before normalizing.

pandas.io.formats.style.Styler.bar

Styler.bar  (subset=None, axis=0, color='#d65f5f', width=100, align='left', vmin=None, vmax=None)

Draw bar chart in the cell backgrounds.

Parameters

subset  [IndexSlice, optional] A valid slice for data to limit the style application to.

axis  [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.

color  [str or 2-tuple/list] If a str is passed, the color is the same for both negative and positive numbers. If 2-tuple/list is used, the first element is the color_negative and the second is the color_positive (eg: ['#d65f5f', '#5fba7d']).

width  [float, default 100] A number between 0 or 100. The largest value will cover width percent of the cell’s width.

align  [{‘left’, ‘zero’, ‘mid’}, default ‘left’] How to align the bars with the cells.

• ‘left’ : the min value starts at the left of the cell.
• ‘zero’ : a value of zero is located at the center of the cell.
• ‘mid’ : the center of the cell is at (max-min)/2, or if values are all negative (positive) the zero is aligned at the right (left) of the cell.

**vmin** [float, optional] Minimum bar value, defining the left hand limit of the bar drawing range, lower values are clipped to vmin. When None (default): the minimum value of the data will be used.

New in version 0.24.0.

**vmax** [float, optional] Maximum bar value, defining the right hand limit of the bar drawing range, higher values are clipped to vmax. When None (default): the maximum value of the data will be used.

New in version 0.24.0.

Returns
self [Styler]

`pandas.io.formats.style.Styler.clear`

Styler.clear()

Reset the styler, removing any previously applied styles.

Returns None.

`pandas.io.formats.style.Styler.export`

Styler.export()

Export the styles to applied to the current Styler.

Can be applied to a second style with Styler.use.

Returns
styles [list]

See also:

Styler.use

`pandas.io.formats.style.Styler.format`

Styler.format(formatter, subset=None, na_rep=None)

Format the text display value of cells.

Parameters

*formatter* [str, callable, dict or None] If formatter is None, the default formatter is used.

*subset* [IndexSlice] An argument to DataFrame.loc that restricts which elements formatter is applied to.

*na_rep* [str, optional] Representation for missing values. If na_rep is None, no special formatting is applied.

New in version 1.0.0.
Returns

self [Styler]

Notes

formatter is either a or a dict {column name: a} where a is one of

- str: this will be wrapped in: a.format(x)
- callable: called with the value of an individual cell

The default display value for numeric values is the “general” (g) format with pd.options.display.precision.precision.

Examples

```python
df = pd.DataFrame(np.random.randn(4, 2), columns=['a', 'b'])
df.style.format("{:.2%}")
df['c'] = ['a', 'b', 'c', 'd']
df.style.format({'c': str.upper})
```

pandas.io.formats.style.Styler.from_custom_template

classmethod Styler.from_custom_template(searchpath, name)

Factory function for creating a subclass of Styler.

Uses a custom template and Jinja environment.

Parameters

- searchpath [str or list] Path or paths of directories containing the templates.
- name [str] Name of your custom template to use for rendering.

Returns

MyStyler [subclass of Styler] Has the correct env and template class attributes set.

pandas.io.formats.style.Styler.hide_columns

Styler.hide_columns(subset)

Hide columns from rendering.

New in version 0.23.0.

Parameters

- subset [IndexSlice] An argument to DataFrame.loc that identifies which columns are hidden.

Returns

self [Styler]
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.io.formats.style.Styler.hide_index

Styler.hide_index()
Hide any indices from rendering.
New in version 0.23.0.

Returns

self [Styler]

pandas.io.formats.style.Styler.highlight_max

Styler.highlight_max(subset=None, color='yellow', axis=0)
Highlight the maximum by shading the background.

Parameters

subset [IndexSlice, default None] A valid slice for data to limit the style application to.
color [str, default ‘yellow’]
axis [[0 or ‘index’, 1 or ‘columns’, None], default 0] Apply to each column (axis=0 or ‘index’), to each row (axis=1 or ‘columns’), or to the entire DataFrame at once with axis=None.

Returns

self [Styler]

pandas.io.formats.style.Styler.highlight_min

Styler.highlight_min(subset=None, color='yellow', axis=0)
Highlight the minimum by shading the background.

Parameters

subset [IndexSlice, default None] A valid slice for data to limit the style application to.
color [str, default ‘yellow’]
axis [[0 or ‘index’, 1 or ‘columns’, None], default 0] Apply to each column (axis=0 or ‘index’), to each row (axis=1 or ‘columns’), or to the entire DataFrame at once with axis=None.

Returns

self [Styler]
pandas.io.formats.style.Styler.highlight_null

Styler.highlight_null(null_color='red', subset=None)
Shade the background null_color for missing values.

Parameters

null_color [str, default 'red']
subset [label or list of labels, default None] A valid slice for data to limit the style
application to.

Returns

self [Styler]

pandas.io.formats.style.Styler.pipe

Styler.pipe(func, *args, **kwargs)
Apply func(self, *args, **kwargs), and return the result.

New in version 0.24.0.

Parameters

func [function] Function to apply to the Styler. Alternatively, a (callable,
keyword) tuple where keyword is a string indicating the keyword of
callable that expects the Styler.

*args [optional] Arguments passed to func.

**kwargs [optional] A dictionary of keyword arguments passed into func.

Returns

object [] The value returned by func.

See also:

DataFrame.pipe Analogous method for DataFrame.

Styler.apply Apply a function row-wise, column-wise, or table-wise to modify the dataframe’s
styling.

Notes

Like DataFrame.pipe(), this method can simplify the application of several user-defined functions
to a styler. Instead of writing:

```
f(g(df.style.set_precision(3), arg1=a), arg2=b, arg3=c)
```

users can write:

```
(df.style.set_precision(3)
 .pipe(g, arg1=a)
 .pipe(f, arg2=b, arg3=c))
```
In particular, this allows users to define functions that take a styler object, along with other parameters, and return the styler after making styling changes (such as calling `Styler.apply()` or `Styler.set_properties()`). Using `.pipe`, these user-defined style “transformations” can be interleaved with calls to the built-in Styler interface.

### Examples

```python
>>> def format_conversion(styler):
...     return (styler.set_properties(**{'text-align': 'right'}))
...         .format({'conversion': '{:.1%}'}))
```

The user-defined `format_conversion` function above can be called within a sequence of other style modifications:

```python
>>> df = pd.DataFrame({'trial': list(range(5)),
...                   'conversion': [0.75, 0.85, np.nan, 0.7, 0.72]})
>>> (df.style
...     .highlight_min(subset=['conversion'], color='yellow')
...     .pipe(format_conversion)
...     .set_caption("Results with minimum conversion highlighted."))
```

### pandas.io.formats.style.Styler.render

`Styler.render(**kwargs)`

Render the built up styles to HTML.

**Parameters**

**kwargs Any additional keyword arguments are passed through to self. template.render. This is useful when you need to provide additional variables for a custom template.**

**Returns**

rendered [str] The rendered HTML.

### Notes

`Styler` objects have defined the `_repr_html_` method which automatically calls `self.render()` when it’s the last item in a Notebook cell. When calling `Styler.render()` directly, wrap the result in `IPython.display.HTML` to view the rendered HTML in the notebook.

Pandas uses the following keys in `render`. Arguments passed in `**kwargs` take precedence, so think carefully if you want to override them:

- head
- cellstyle
- body
- uuid
- precision
- table_styles
- caption
• table_attributes

**pandas.io.formats.style.Styler.set_caption**

Styler.set_caption(caption)
Set the caption on a Styler.

Parameters

- caption [str]

Returns

self [Styler]

**pandas.io.formats.style.Styler.set_na_rep**

Styler.set_na_rep(na_rep)
Set the missing data representation on a Styler.

New in version 1.0.0.

Parameters

- na_rep [str]

Returns

self [Styler]

**pandas.io.formats.style.Styler.set_precision**

Styler.set_precision(precision)
Set the precision used to render.

Parameters

- precision [int]

Returns

self [Styler]

**pandas.io.formats.style.Styler.set_properties**

Styler.set_properties(subset=None, **kwargs)
Method to set one or more non-data dependent properties or each cell.

Parameters

- subset [IndexSlice] A valid slice for data to limit the style application to.
- **kwargs [dict] A dictionary of property, value pairs to be set for each cell.

Returns

self [Styler]
Examples

```python
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_properties(color="white", align="right")
>>> df.style.set_properties(**{"background-color": "yellow"})
```

pandas.io.formats.style.Styler.set_table_attributes

Styler.set_table_attributes(attributes)

Set the table attributes.

These are the items that show up in the opening `<table>` tag in addition to to automatic (by default) id.

Parameters

- attributes [str]

Returns

- self [Styler]

Examples

```python
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_table_attributes('class="pure-table"')
# ... <table class="pure-table"> ...
```

pandas.io.formats.style.Styler.set_table_styles

Styler.set_table_styles(table_styles)

Set the table styles on a Styler.

These are placed in a `<style>` tag before the generated HTML table.

Parameters

- table_styles [list] Each individual table_style should be a dictionary with selector and props keys. selector should be a CSS selector that the style will be applied to (automatically prefixed by the table’s UUID) and props should be a list of tuples with (attribute, value).

Returns

- self [Styler]
Examples

```python
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_table_styles(
...    [{'selector': 'tr:hover',
...      'props': [('background-color', 'yellow')]}]
...)
```

**pandas.io.formats.style.Styler.set_uuid**

Set the uuid for a Styler.

**Parameters**

- **uuid** [str]

**Returns**

- **self** [Styler]

**pandas.io.formats.style.Styler.to_excel**

Write Styler to an Excel sheet.

To write a single Styler to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an ExcelWriter object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique `sheet_name`. With all data written to the file it is necessary to save the changes. Note that creating an ExcelWriter object with a file name that already exists will result in the contents of the existing file being erased.

**Parameters**

- **excel_writer** [str or ExcelWriter object] File path or existing ExcelWriter.
- **sheet_name** [str, default 'Sheet1'] Name of sheet which will contain DataFrame.
- **na_rep** [str, default ''] Missing data representation.
- **float_format** [str, optional] Format string for floating point numbers. For example `float_format="%.2f"` will format 0.1234 to 0.12.
- **columns** [sequence or list of str, optional] Columns to write.
- **header** [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.
- **index** [bool, default True] Write row names (index).
- **index_label** [str or sequence, optional] Column label for index column(s) if desired. If not specified, and `header` and `index` are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- **startrow** [int, default 0] Upper left cell row to dump data frame.
**startcol** [int, default 0] Upper left cell column to dump data frame.

**engine** [str, optional] Write engine to use, ‘openpyxl’ or ‘xlsxwriter’. You can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xlsm.writer`.

**merge_cells** [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.

**encoding** [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.

**inf_rep** [str, default ‘inf’] Representation for infinity (there is no native representation for infinity in Excel).

**verbose** [bool, default True] Display more information in the error logs.

**freeze_panes** [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

---

**See also:**

- **to_csv** Write DataFrame to a comma-separated values (csv) file.
- **ExcelWriter** Class for writing DataFrame objects into excel sheets.
- **read_excel** Read an Excel file into a pandas DataFrame.
- **read_csv** Read a comma-separated values (csv) file into DataFrame.

---

**Notes**

For compatibility with `to_csv()`, `to_excel` serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible write further data without rewriting the whole workbook.

---

**Examples**

Create, write to and save a workbook:

```python
>>> df1 = pd.DataFrame([[['a', 'b'], ['c', 'd']],
        ...     index=['row 1', 'row 2'],
        ...     columns=['col 1', 'col 2'])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```python
>>> df1.to_excel("output.xlsx",
        ...     sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:

```python
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```
ExcelWriter can also be used to append to an existing Excel file:

```python
>>> with pd.ExcelWriter('output.xlsx', mode='a') as writer:
    df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the `engine` keyword (the default engine is automatically chosen depending on the file extension):

```python
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```

### pandas.io.formats.style.Styler.use

**Styler.use**(styles)

Set the styles on the current Styler. Possibly uses uses styles from `Styler.export`.

**Parameters**

- **styles** [list] List of style functions.

**Returns**

- **self** [Styler]

**See also:**

- `Styler.export`

### pandas.io.formats.style.Styler.where

**Styler.where**(cond, value=None, other=None, subset=None, **kwargs)

Apply a function elementwise. Updates the HTML representation with a style which is selected in accordance with the return value of a function.

**Parameters**

- **cond** [callable] `cond` should take a scalar and return a boolean.
- **value** [str] Applied when `cond` returns true.
- **other** [str] Applied when `cond` returns false.
- **subset** [IndexSlice] A valid indexer to limit data to before applying the function. Consider using a pandas.IndexSlice.
- **kwargs** [dict] Pass along to `cond`.

**Returns**

- **self** [Styler]

**See also:**

- `Styler.applymap`
### 3.13.2 Styler properties

- `Styler.env`  
- `Styler.template`  
- `Styler.loader`

```python
pandas.io.formats.style.Styler.env
Styler.env = <jinja2.environment.Environment object>
```

```python
pandas.io.formats.style.Styler.template
Styler.template = <Template 'html.tpl'>
```

```python
pandas.io.formats.style.Styler.loader
Styler.loader = <jinja2.loaders.PackageLoader object>
```

### 3.13.3 Style application

- `Styler.apply(func[, axis, subset])`  
  - Apply a function column-wise, row-wise, or table-wise.
- `Styler.applymap(func[, subset])`  
  - Apply a function elementwise.
- `Styler.where(cond, value[, other, subset])`  
  - Apply a function elementwise.
- `Styler.format(formatter[, subset, na_rep])`  
  - Format the text display value of cells.
- `Styler.set_precision(precision)`  
  - Set the precision used to render.
- `Styler.set_table_styles(table_styles)`  
  - Set the table styles on a Styler.
- `Styler.set_table_attributes(attributes)`  
  - Set the table attributes.
- `Styler.set_caption(caption)`  
  - Set the caption on a Styler.
- `Styler.set_properties([subset])`  
  - Method to set one or more non-data dependent properties or each cell.
- `Styler.set_uuid(uuid)`  
  - Set the uuid for a Styler.
- `Styler.set_na_rep(na_rep)`  
  - Set the missing data representation on a Styler.
- `Styler.clear()`  
  - Reset the styler, removing any previously applied styles.
- `Styler.pipe(func, *args, **kwargs)`  
  - Apply `func(self, *args, **kwargs)`, and return the result.

### 3.13.4 Built-in styles

- `Styler.highlight_max([subset, color, axis])`  
  - Highlight the maximum by shading the background.
- `Styler.highlight_min([subset, color, axis])`  
  - Highlight the minimum by shading the background.
- `Styler.highlight_null([null_color, subset])`  
  - Shade the background `null_color` for missing values.
- `Styler.background_gradient([cmap, low, ...])`  
  - Color the background in a gradient style.
- `Styler.bar([subset, axis, color, width, ...])`  
  - Draw bar chart in the cell backgrounds.
3.13.5 Style export and import

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Styler.render(**kwargs)</code></td>
<td>Render the built up styles to HTML.</td>

<td>Helper function to convert DataFrame and Series to matplotlib.table.</td>
</tr>
</tbody>
</table>

3.14.1 pandas.plotting.andrews_curves

`pandas.plotting.andrews_curves(frame, class_column, ax=None, samples=200, color=None, colormap=None, **kwargs)`

Generate a matplotlib plot of Andrews curves, for visualising clusters of multivariate data.

Andrews curves have the functional form:

\[ f(t) = \frac{x_1}{\sqrt{2}} + x_2 \sin(t) + x_3 \cos(t) + x_4 \sin(2t) + x_5 \cos(2t) + \ldots \]

Where \( x \) coefficients correspond to the values of each dimension and \( t \) is linearly spaced between -\( \pi \) and +\( \pi \).

Each row of \( \text{frame} \) then corresponds to a single curve.

**Parameters**

- **frame** [DataFrame] Data to be plotted, preferably normalized to \((0.0, 1.0)\).
- **class_column** [Name of the column containing class names]
- **ax** [matplotlib axes object, default None]
- **samples** [Number of points to plot in each curve]
- **color** [list or tuple, optional] Colors to use for the different classes.
- **colormap** [str or matplotlib colormap object, default None] Colormap to select colors from.
  - If string, load colormap with that name from matplotlib.
**kwargs Options to pass to matplotlib plotting method.

**Returns**

class: `matplotlib.axis.Axes`

**Examples**

```python
>>> df = pd.read_csv(
...     'https://raw.github.com/pandas-dev/
...     'pandas/master/pandas/tests/io/data/csv/iris.csv'
... )
>>> pd.plotting.andrews_curves(df, 'Name')
```
3.14.2 pandas.plotting.autocorrelation_plot

pandas.plotting.autocorrelation_plot(series, ax=None, **kwargs)

Autocorrelation plot for time series.

Parameters

- **series**: [Time series]
- **ax**: [Matplotlib axis object, optional]
- **kwargs**: Options to pass to matplotlib plotting method.

Returns

- class: matplotlib.axis.Axes

Examples

The horizontal lines in the plot correspond to 95% and 99% confidence bands.

The dashed line is 99% confidence band.

```python
>>> spacing = np.linspace(-9 * np.pi, 9 * np.pi, num=1000)
>>> s = pd.Series(0.7 * np.random.rand(1000) + 0.3 * np.sin(spacing))
>>> pd.plotting.autocorrelation_plot(s)
```
3.14.3 pandas.plotting.bootstrap_plot

**pandas.plotting.bootstrap_plot** (series, fig=None, size=50, samples=500, **kwds)

Bootstrap plot on mean, median and mid-range statistics.

The bootstrap plot is used to estimate the uncertainty of a statistic by relying on random sampling with replacement [1]. This function will generate bootstrapping plots for mean, median and mid-range statistics for the given number of samples of the given size.

**Parameters**

- **series** [pandas.Series] Series from where to get the samplings for the bootstrapping.
- **fig** [matplotlib.figure.Figure, default None] If given, it will use the fig reference for plotting instead of creating a new one with default parameters.
- **size** [int, default 50] Number of data points to consider during each sampling. It must be less than or equal to the length of the series.
- **samples** [int, default 500] Number of times the bootstrap procedure is performed.
- **kwds** Options to pass to matplotlib plotting method.

**Returns**

- **matplotlib.figure.Figure** Matplotlib figure.

**See also:**

- DataFrame.plot Basic plotting for DataFrame objects.
- Series.plot Basic plotting for Series objects.

**Examples**

This example draws a basic bootstap plot for a Series.

```python
>>> s = pd.Series(np.random.uniform(size=100))
>>> pd.plotting.bootstrap_plot(s)
```

3.14.4 pandas.plotting.boxplot

**pandas.plotting.boxplot** (data, column=None, by=None, ax=None, fontsize=None, rot=0, grid=True, figsize=None, layout=None, return_type=None, **kwargs)

Make a box plot from DataFrame columns.

Make a box-and-whisker plot from DataFrame columns, optionally grouped by some other columns. A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of the box to show the range of the data. By default, they extend no more than $1.5 \times IQR (IQR = Q3 - Q1)$ from the edges of the box, ending at the farthest data point within that interval. Outliers are plotted as separate dots.

For further details see Wikipedia’s entry for boxplot.

**Parameters**

- **column** [str or list of str, optional] Column name or list of names, or vector. Can be any valid input to pandas.DataFrame.groupby().
- **by** [str or array-like, optional] Column in the DataFrame to pandas.DataFrame.groupby(). One box-plot will be done per value of columns in by.
- **ax** [object of class matplotlib.axes.Axes, optional] The matplotlib axes to be used by boxplot.
Boxplot parameters:

- **fontsize** [float or str] Tick label font size in points or as a string (e.g., `large`).
- **rot** [int or float, default 0] The rotation angle of labels (in degrees) with respect to the screen coordinate system.
- **grid** [bool, default True] Setting this to True will show the grid.
- **figsize** [A tuple (width, height) in inches] The size of the figure to create in matplotlib.
- **layout** [tuple (rows, columns), optional] For example, (3, 5) will display the subplots using 3 columns and 5 rows, starting from the top-left.
- **return_type** [[‘axes’, ‘dict’, ‘both’] or None, default ‘axes’] The kind of object to return. The default is **axes**.
  - ‘axes’ returns the matplotlib axes the boxplot is drawn on.
  - ‘dict’ returns a dictionary whose values are the matplotlib Lines of the boxplot.
  - ‘both’ returns a namedtuple with the axes and dict.
  - when grouping with by, a Series mapping columns to **return_type** is returned.
    - If **return_type** is None, a NumPy array of axes with the same shape as **layout** is returned.

**kwargs** All other plotting keyword arguments to be passed to **matplotlib.pyplot.boxplot**.

Returns

result See Notes.

See also:

- **Series.plot.hist** Make a histogram.
- **matplotlib.pyplot.boxplot** Matplotlib equivalent plot.

Notes

The return type depends on the **return_type** parameter:

- ‘axes’ : object of class matplotlib.axes.Axes
- ‘dict’ : dict of matplotlib.lines.Line2D objects
- ‘both’ : a namedtuple with structure (ax, lines)

For data grouped with by, return a Series of the above or a numpy array:

- **Series**
- **array** (for **return_type** = None)

Use **return_type=’dict’** when you want to tweak the appearance of the lines after plotting. In this case a dict containing the Lines making up the boxes, caps, fliers, medians, and whiskers is returned.

Examples

Boxplots can be created for every column in the dataframe by **df.boxplot()** or indicating the columns to be used:

```python
>>> np.random.seed(1234)
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                   columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
```
3.14. Plotting
Boxplots of variables distributions grouped by the values of a third variable can be created using the option `by`. For instance:

```python
>>> df = pd.DataFrame(np.random.randn(10, 2),
                   columns=['Col1', 'Col2'])
>>> boxplot = df.boxplot(by='X')
```

A list of strings (i.e. `['X', 'Y']`) can be passed to `boxplot` in order to group the data by combination of the variables in the x-axis:

```python
>>> df = pd.DataFrame(np.random.randn(10, 3),
                   columns=['Col1', 'Col2', 'Col3'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```

The layout of boxplot can be adjusted giving a tuple to `layout`:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                        layout=(2, 1))
```

Additional formatting can be done to the boxplot, like suppressing the grid (`grid=False`), rotating the labels...
Boxplot grouped by ['X', 'Y']

Col1

Col2
in the x-axis (i.e. rot=45) or changing the fontsize (i.e. fontsize=15):

```python
>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)
```

The parameter `return_type` can be used to select the type of element returned by `boxplot`. When `return_type='axes'` is selected, the matplotlib axes on which the boxplot is drawn are returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
>>> type(boxplot)
<class 'matplotlib.axes._subplots.AxesSubplot'>
```

When grouping with `by`, a Series mapping columns to `return_type` is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                       return_type='axes')
>>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                       return_type=None)
>>> type(boxplot)
<class 'numpy.ndarray'>
```
3.14.5 pandas.plotting.deregister_matplotlib_converters

```python
pandas.plotting.deregister_matplotlib_converters()

Remove pandas formatters and converters.
```

Removes the custom converters added by `register()`. This attempts to set the state of the registry back to the state before pandas registered its own units. Converters for pandas’ own types like Timestamp and Period are removed completely. Converters for types pandas overwrites, like `datetime.datetime`, are restored to their original value.

See also:

- `register_matplotlib_converters` Register pandas formatters and converters with matplotlib.

3.14.6 pandas.plotting.lag_plot

```python
pandas.plotting.lag_plot(series, lag=1, ax=None, **kwds)

Lag plot for time series.
```

Parameters

- `series` [Time series]
- `lag` [lag of the scatter plot, default 1]
- `ax` [Matplotlib axis object, optional]
- `**kwds` Matplotlib scatter method keyword arguments.

Returns

- `Axes` Matplotlib axes.

Examples

Lag plots are most commonly used to look for patterns in time series data.

Given the following time series

```python
>>> np.random.seed(5)
>>> x = np.cumsum(np.random.normal(loc=1, scale=5, size=50))
>>> s = pd.Series(x)
>>> s.plot()
```

A lag plot with `lag=1` returns

```python
>>> pd.plotting.lag_plot(s, lag=1)
```

3.14.7 pandas.plotting.parallel_coordinates

```python
pandas.plotting.parallel_coordinates(frame, class_column, cols=None, ax=None, color=None, use_columns=False, xticks=None, colormap=None, axvlines=True, axvlines_kwds=None, sort_labels=False, **kwargs)

Parallel coordinates plotting.
```

Parameters

- `frame` [DataFrame]
class_column [str] Column name containing class names.
cols [list, optional] A list of column names to use.
color [list or tuple, optional] Colors to use for the different classes.
use_columns [bool, optional] If true, columns will be used as xticks.
xticks [list or tuple, optional] A list of values to use for xticks.
colormap [str or matplotlib colormap, default None] Colormap to use for line colors.
axvlines [bool, optional] If true, vertical lines will be added at each xtick.
axvlines_kwds [keywords, optional] Options to be passed to axvline method for vertical lines.
sort_labels [bool, default False] Sort class_column labels, useful when assigning colors.
**kwds Options to pass to matplotlib plotting method.

Returns
class:matplotlib.axis.Axes

Examples

```python
>>> df = pd.read_csv(
...   'https://raw.github.com/pandas-dev/
...   'pandas/master/pandas/tests/io/data/csv/iris.csv'
... )
>>> pd.plotting.parallel_coordinates(
...   df, 'Name', color=('#556270', '#4ECDC4', '#C7F464')
... )
```

3.14.8 pandas.plotting.plot_params

pandas.plotting.plot_params = {'xaxis.compat': False}
Stores pandas plotting options.
Allows for parameter aliasing so you can just use parameter names that are the same as the plot function parameters, but is stored in a canonical format that makes it easy to breakdown into groups later.

3.14.9 pandas.plotting.radviz

pandas.plotting.radviz (frame, class_column, ax=None, color=None, colormap=None, **kwds)
Plot a multidimensional dataset in 2D.

Each Series in the DataFrame is represented as a evenly distributed slice on a circle. Each data point is rendered in the circle according to the value on each Series. Highly correlated Series in the DataFrame are placed closer on the unit circle.

RadViz allow to project a N-dimensional data set into a 2D space where the influence of each dimension can be interpreted as a balance between the influence of all dimensions.

More info available at the original article describing RadViz.

Parameters
frame [DataFrame] Object holding the data.
class_column [str] Column name containing the name of the data point category.
ax [matplotlib.axes.Axes, optional] A plot instance to which to add the information.
color [list[str] or tuple[str], optional] Assign a color to each category. Example: ['blue', 'green'].
colormap [str or matplotlib.colors.Colormap, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.
**kwds Options to pass to matplotlib scatter plotting method.

Returns
class:matplotlib.axes.Axes

See also:
plotting.andrews_curves Plot clustering visualization.

Examples

```python
>>> df = pd.DataFrame(
...     {
...         'SepalLength': [6.5, 7.7, 5.1, 5.8, 7.6, 5.0, 5.4, 4.6, 6.7, 4.6],
...         'SepalWidth': [3.0, 3.8, 3.8, 2.7, 3.0, 2.3, 3.0, 3.2, 3.3, 3.6],
...         'PetalLength': [5.5, 6.7, 1.9, 5.1, 6.6, 3.3, 4.5, 1.4, 5.7, 1.0],
...         'PetalWidth': [1.8, 2.2, 0.4, 1.9, 2.1, 1.0, 1.5, 0.2, 2.1, 0.2],
...         'Category': ['virginica', 'virginica', 'setosa', 'virginica', 'virginica', 'versicolor', 'versicolor', 'setosa', 'virginica', 'setosa']
...     }
... )
>>> pd.plotting.radviz(df, 'Category')
```

3.14.10 pandas.plotting.register_matplotlib_converters

pandas.plotting.register_matplotlib_converters()
Register pandas formatters and converters with matplotlib.

This function modifies the global matplotlib.units.registry dictionary. pandas adds custom converters for
- pd.Timestamp
- pd.Period
- np.datetime64
- datetime.datetime
- datetime.date
- datetime.time
See also: 

`deregister_matplotlib_converters` Remove pandas formatters and converters.

### 3.14.11 pandas.plotting.scatter_matrix

**pandas.plotting.scatter_matrix** *(frame, alpha=0.5, figsize=None, ax=None, grid=False, diagonal='hist', marker='.', density_kwds=None, hist_kwds=None, range_padding=0.05, **kwargs)*

Draw a matrix of scatter plots.

**Parameters**

- **frame** *DataFrame*
- **alpha** *[float, optional]* Amount of transparency applied.
- **figsize** *[((float, float), optional)]* A tuple (width, height) in inches.
- **ax** *[Matplotlib axis object, optional]*
- **grid** *[bool, optional]* Setting this to True will show the grid.
- **diagonal** *[{'hist', 'kde'}]* Pick between ‘kde’ and ‘hist’ for either Kernel Density Estimation or Histogram plot in the diagonal.
- **marker** *[str, optional]* Matplotlib marker type, default ‘.’.
- **density_kwds** *[keywords]* Keyword arguments to be passed to kernel density estimate plot.
- **hist_kwds** *[keywords]* Keyword arguments to be passed to hist function.
- **range_padding** *[float, default 0.05]* Relative extension of axis range in x and y with respect to (x_max - x_min) or (y_max - y_min).

**Returns**

*numpy.ndarray* A matrix of scatter plots.

**Examples**

```python
>>> df = pd.DataFrame(np.random.randn(1000, 4), columns=['A', 'B', 'C', 'D'])
>>> pd.plotting.scatter_matrix(df, alpha=0.2)
```

### 3.14.12 pandas.plotting.table

**pandas.plotting.table** *(ax, data, rowLabels=None, colLabels=None, **kwargs)*

Helper function to convert DataFrame and Series to matplotlib.table.

**Parameters**

- **ax** *[Matplotlib axes object]*
- **data** *[DataFrame or Series]* Data for table contents.

**Returns**

*matplotlib table object*
3.15 General utility functions

3.15.1 Working with options

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>describe_option(pat[, _print_desc])</code></td>
<td>Prints the description for one or more registered options.</td>
</tr>
<tr>
<td><code>reset_option(pat)</code></td>
<td>Reset one or more options to their default value.</td>
</tr>
<tr>
<td><code>get_option(pat)</code></td>
<td>Retrieves the value of the specified option.</td>
</tr>
<tr>
<td><code>set_option(pat, value)</code></td>
<td>Sets the value of the specified option.</td>
</tr>
<tr>
<td><code>option_context(*args)</code></td>
<td>Context manager to temporarily set options in the <code>with</code> statement context.</td>
</tr>
</tbody>
</table>

**pandas.describe_option**

```python
def pandas.describe_option(pat, _print_desc=False) = <pandas._config.config.CallableDynamicDoc object>
```

Prints the description for one or more registered options.

Call with not arguments to get a listing for all registered options.

Available options:

- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]
- io.excel.ods.[reader, writer]
- io.excel.xls.[reader, writer]
- io.excel.xlsb.[reader]
- io.excel.xlsxm.[reader, writer]
- io.excel.xlsx.[reader, writer]
- io.hdf.[default_format, dropna_table]
- io.parquet.[engine]
- mode.[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]
- plotting.[backend]
- plotting.matplotlib.[register_converters]

**Parameters**

- `pat` [str] Regexp pattern. All matching keys will have their description displayed.
- `_print_desc` [bool, default True] If True (default) the description(s) will be printed to stdout. Otherwise, the description(s) will be returned as a unicode string (for testing).

**Returns**

None by default, the description(s) as a unicode string if `_print_desc` is False
Notes

The available options with its descriptions:

- **compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True. Valid values: False, True [default: True] [currently: True]
- **compute.use_numba** [bool] Use the numba engine option for select operations if it is installed, the default is False. Valid values: False, True [default: False] [currently: False]
- **compute.use_numexpr** [bool] Use the numexpr library to accelerate computation if it is installed, the default is True. Valid values: False, True [default: True] [currently: True]
- **display.chop_threshold** [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
- **display.colheader_justify** ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]
- **display.column_space** No description available. [default: 12] [currently: 12]
- **display.date_dayfirst** [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]
- **display.date_yearfirst** [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]
- **display.encoding** [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]
- **display.expand_frame_repr** [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width. [default: True] [currently: True]
- **display.float_format** [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]
- **display.html.border** [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]
- **display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]
- **display.html.use_mathjax** [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]
- **display.large_repr** ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]
- **display.latex.escape** [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]
- **display.latex.longtable** :bool This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]
- **display.latex.multicolumn** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]
- **display.latex.multicolumn_format** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: 1] [currently: 1]
- **display.latex.multirow** [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]
- **display.latex.repr** [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]
- **display.max_categories** [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype “category”. [default: 8] [currently: 8]
- **display.max_columns** [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.
In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

display.max_colwidth [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]

display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]

display.max_info_rows [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

display.max_rows [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 15]

display.max_seq_items [int or None] when pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,’deep’ [default: True] [currently: True]

display.min_rows [int] The numbers of rows to show in a truncated view (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows. [default: 10] [currently: 10]

display.multi_sparse [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]

display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

display.precision [int] Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]

display.show_dimensions [boolean or ‘truncate’) Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.width [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

pandas: powerful Python data analysis toolkit, Release 1.1.1

io.hdf.default_format [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]

io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

mode.chained_assignment  [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]

mode.sim_interactive  [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

mode.use_inf_as_na  [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

mode.use_inf_as_null  [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)

plotting.backend  [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

plotting.matplotlib.register_converters  [bool or ‘auto’] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.reset_option  = <pandas._config.config.CallableDynamicDoc object>

Reset one or more options to their default value.

Pass “all” as argument to reset all options.

Available options:
- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]
• io.excel.ods.[reader, writer]
• io.excel.xls.[reader, writer]
• io.excel.xlsb.[reader]
• io.excel.xlsm.[reader, writer]
• io.excel.xlsx.[reader, writer]
• io.hdf.[default_format, dropna_table]
• io.parquet.[engine]
• mode.[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]
• plotting.[backend]
• plotting.matplotlib.[register_converters]

Parameters

**pat** [str/regex] If specified only options matching *prefix* will be reset. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. `x.y.z.option_name`), your code may break in future versions if new options with similar names are introduced.

Returns

None

Notes

The available options with its descriptions:

- **compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True
  
  Valid values: False, True [default: True] [currently: True]

- **compute.use_numba** [bool] Use the numba engine option for select operations if it is installed, the default is False
  
  Valid values: False, True [default: False] [currently: False]

- **compute.use_numexpr** [bool] Use the numexpr library to accelerate computation if it is installed, the default is True
  
  Valid values: False, True [default: True] [currently: True]

- **display.chop_threshold** [float or None] if set to a float value, all float values smaller than the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]

- **display.colheader_justify** ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]

- **display.column_space** No description available. [default: 12] [currently: 12]

- **display.date_dayfirst** [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]

- **display.date_yearfirst** [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]

- **display.encoding** [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]

- **display.expand_frame_repr** [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, **max_columns** is still respected, but the output will wrap-around across multiple “pages” if its width exceeds **display.width**. [default: True] [currently: True]

- **display.float_format** [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]

- **display.html.border** [int] A border=value attribute is inserted in the **<table>** tag for the DataFrame HTML repr. [default: 1] [currently: 1]

- **display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. [default: False] [currently: False]

- **display.html.use_mathjax** [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. [default: True] [currently: True]
display.large_repr ['truncate'/info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]
display.latex.escape [bool] This specifies if the to_latex method of a DataFrame uses escapes special characters. Valid values: False,True [default: True] [currently: True]
display.latex.longtable [bool] This specifies if the to_latex method of a DataFrame uses the longtable format. Valid values: False,True [default: False] [currently: False]
display.latex.multicolumn [bool] This specifies if the to_latex method of a DataFrame uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]
display.latex.multicolumn_format [bool] This specifies if the to_latex method of a DataFrame uses multi-columns to pretty-print MultiIndex columns. Valid values: False,True [default: l] [currently: l]
display.latex.multirow [bool] This specifies if the to_latex method of a DataFrame uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]
display.latex.repr [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]
display.max_categories [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype “category”. [default: 8] [currently: 8]
display.max_columns [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]
display.max_colwidth [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]
display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]
display.max_info_rows [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]
display.max_rows [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 15]
display.max_seq_items [int or None] when pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]
display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,‘deep’ [default: True] [currently: True]
display.min_rows [int] The numbers of rows to show in a truncated view (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows. [default: 10] [currently: 10]
display.multi_sparse [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]
display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]
display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]
**display.precision** [int] Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]

**display.show_dimensions** [boolean or ‘truncate’) Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

**display.unicode.ambiguous_as_wide** [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [currently: False]

**display.unicode.east_asian_width** [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [currently: False]

**display.width** [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

**io.hdf.default_format** [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]

**io.hdf.dropna_table** [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

**mode.chained_assignment** [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]

**mode.sim_interactive** [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

**mode.use_inf_as_na** [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

**mode.use_inf_as_null** [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use `use_inf_as_na` instead. [default: False] [currently: False] (Deprecated, use `mode.use_inf_as_na` instead.)

**plotting.backend** [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

**plotting.matplotlib.register_converters** [bool or ‘auto’.] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]
pandas.get_option

**pandas.get_option(pat)**  
Retrieves the value of the specified option.

**Available options:**

- **compute.**
  - use_bottleneck, use_numba, use_numexpr
- **display.**
  - chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format
  - html.border, table_schema, use_mathjax
  - display.large
  - display.latex.escape, longtable, multicolumn, multicolumn_format, multirow, repr
  - display.max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions
- **display.unicode.**
  - ambiguous_as_wide, east_asian_width
- **display.**
  - width
- **io.excel.**
  - ods.reader, writer
  - xls.reader, writer
  - xlsx.reader, writer
  - xlsb.reader
  - xlsm.reader, writer
  - xlsx.reader, writer
  - hdf.default_format, dropna_table
  - parquet.engine
- **mode.**
  - chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null
- **plotting.**
  - backend
  - matplotlib.register_converters

**Parameters**

- **pat** [str] Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.

**Returns**

- **result** [the value of the option]

**Raises**

- **OptionError** [if no such option exists]

**Notes**

The available options with its descriptions:

- **compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True  
  Valid values: False, True [default: True] [currently: True]

- **compute.use_numba** [bool] Use the numba engine option for select operations if it is installed, the default is False  
  Valid values: False, True [default: False] [currently: False]

- **compute.use_numexpr** [bool] Use the numexpr library to accelerate computation if it is installed, the default is True  
  Valid values: False, True [default: True] [currently: True]

- **display.chop_threshold** [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends.  
  [default: None] [currently: None]

- **display.colheader_justify** ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter.  
  [default: right] [currently: right]

- **display.column_space** No description available.  
  [default: 12] [currently: 12]
**display.date_dayfirst** [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]

**display.date_yearfirst** [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]

**display.encoding** [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]

**display.expand_frame_repr** [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width. [default: True] [currently: True]

**display.float_format** [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]

**display.html.border** [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]

**display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]

**display.html.use_mathjax** [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]

**display.large_repr** ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]

**display.latex.escape** [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: False] [currently: True]

**display.latex.longtable** [bool] This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]

**display.latex.multicolumn** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: False] [currently: False]

**display.latex.multicolumn_format** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]

**display.latex.repr** [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]

**display.max_categories** [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype “category”. [default: 8] [currently: 8]

**display.max_columns** [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

**display.max_colwidth** [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]

**display.max_info_columns** [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]

**display.max_info_rows** [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

**display.max_rows** [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

3.15. General utility functions 2361
In case python/IPython is running in a terminal and `large_repr` equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 15]

**display.max_seq_items** [int or None] when pretty-printing a long sequence, no more then `max_seq_items` will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

**display.memory_usage** [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when `df.info()` is called. Valid values True,False,’deep’ [default: True] [currently: True]

**display.min_rows** [int] The numbers of rows to show in a truncated view (when `max_rows` is exceeded). Ignored when `max_rows` is set to None or 0. When set to None, follows the value of `max_rows`. [default: 10] [currently: 10]

**display.multi_sparse** [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]

**display.notebook_repr_html** [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

**display.pprint_nest_depth** [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

**display.precision** [int] Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]

**display.show_dimensions** [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

**display.unicode.ambiguous_as_wide** [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

**display.unicode.east_asian_width** [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

**display.width** [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

**io.hdf.default_format** [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]
io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]
mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]
mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]
mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]
mode.use_inf_as_null [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)
plotting.backend [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]
plotting.matplotlib.register_converters [bool or ‘auto’] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

pandas.set_option

pandas.set_option(pat, value) = <pandas._config.config.CallableDynamicDoc object>
Sets the value of the specified option.

Available options:
- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]
- io.excel.[ods.[reader, writer]
- io.excel.xlsb.[reader]
- io.excel.xle.[reader, writer]
- io.excel.xls.[reader, writer]
- io.excel.xlsm.[reader, writer]
- io.excel.xlw.[reader, writer]
- io.hdf.[default_format, dropna_table]
- io.parquet.[engine]
- mode.[chained_assignment, sim_interactive, use_inf_as_na, use_inf_as_null]
- plotting.[backend]
- plotting.matplotlib.[register_converters]

Parameters
- pat [str] Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.
value  [object] New value of option.

Returns

None

Raises

OptionError if no such option exists

Notes

The available options with its descriptions:

- **compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True
  Valid values: False,True [default: True] [currently: True]

- **compute.use_numba** [bool] Use the numba engine option for select operations if it is installed, the default is False
  Valid values: False,True [default: False] [currently: False]

- **compute.use_numexpr** [bool] Use the numexpr library to accelerate computation if it is installed, the default is True
  Valid values: False,True [default: True] [currently: True]

- **display.chop_threshold** [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]

- **display.colheader_justify** ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]

- **display.column_space** No description available. [default: 12] [currently: 12]

- **display.date_dayfirst** [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]

- **display.date_yearfirst** [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]

- **display.encoding** [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]

- **display.expand_frame_repr** [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width. [default: True] [currently: True]

- **display.float_format** [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]

- **display.html.border** [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]

- **display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]

- **display.html.use_mathjax** [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]

- **display.large_repr** ['truncate’/’info’] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]

- **display.latex.escape** [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]

- **display.latex.longtable** [bool] This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]

- **display.latex.multicolumn** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]

- **display.latex.multicolumn_format** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: l] [currently: l]
display.latex.multirow [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]
display.latex.repr [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]
display.max_categories [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype “category”. [default: 8] [currently: 8]
display.max_columns [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.
In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]
display.max_colwidth [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]
display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]
display.max_info_rows [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]
display.max_rows [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.
In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 15]
display.max_seq_items [int or None] When pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string.
If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]
display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,’deep’ [default: True] [currently: True]
display.min_rows [int] The numbers of rows to show in a truncated view (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows. [default: 10] [currently: 10]
display.multi_sparse [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]
display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]
display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]
display.precision [int] Floating point output precision (number of significant digits). This is only a suggestion [default: 6] [currently: 6]
display.show_dimensions [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]
display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance [default: False] [currently: False]
display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance [default: False] [currently: False]
display.width [int] Width of the display in characters. In case python/IPython is running in a terminal this can
be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width.

[default: 80] [currently: 80]

io.hdf.default_format [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]

io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]

mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

mode.use_inf_as_null [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)

plotting.backend [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

plotting.matplotlib.register_converters [bool or ‘auto’.] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]
pandas: powerful Python data analysis toolkit, Release 1.1.1

pandas.option_context

class pandas.option_context(*args)

Context manager to temporarily set options in the with statement context.

You need to invoke as `option_context(pat, val, [(pat, val), ...]).`

Examples

```python
>>> with option_context('display.max_rows', 10, 'display.max_columns', 5):
...     ...
```

Methods

`__call__(func)`

Call self as a function.

pandas.option_context.__call__

option_context.__call__(func)

Call self as a function.

3.15.2 Testing functions

```
testing.assert_frame_equal(left, right[, ...,]

testing.assert_series_equal(left, right[, ...])

testing.assert_index_equal(left, right[, ...])

testing.assert_extension_array_equal(left, right)
```

pandas.testing.assert_frame_equal

```
pandas.testing.assert_frame_equal(left, right, check_dtypes=True, check_index_type='equiv',
check_column_type='equiv', check_frame_type=True,
check_less_precise=<object object>,
check_names=True, by_blocks=False,
check_exact=False, check_datetimelike_compat=False,
check_categorical=True, check_like=False,
check_freq=True, rtol=1e-05, atol=1e-08,
obj='DataFrame')
```

Check that left and right DataFrame are equal.

This function is intended to compare two DataFrames and output any differences. It is mostly intended for use in unit tests. Additional parameters allow varying the strictness of the equality checks performed.

Parameters

- `left` [DataFrame] First DataFrame to compare.
right [DataFrame] Second DataFrame to compare.

check_dtype [bool, default True] Whether to check the DataFrame dtype is identical.

check_index_type [bool or {'equiv'}, default 'equiv'] Whether to check the Index class, dtype and inferred_type are identical.

check_column_type [bool or {'equiv'}, default 'equiv'] Whether to check the columns class, dtype and inferred_type are identical. Is passed as the exact argument of assert_index_equal().

check_frame_type [bool, default True] Whether to check the DataFrame class is identical.

check_less_precise [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

When comparing two numbers, if the first number has magnitude less than 1e-5, we compare the two numbers directly and check whether they are equivalent within the specified precision. Otherwise, we compare the ratio of the second number to the first number and check whether it is equivalent to 1 within the specified precision.

Deprecated since version 1.1.0: Use rtol and atol instead to define relative/absolute tolerance, respectively. Similar to math.isclose().

check_names [bool, default True] Whether to check that the names attribute for both the index and column attributes of the DataFrame is identical.

by_blocks [bool, default False] Specify how to compare internal data. If False, compare by columns. If True, compare by blocks.

check_exact [bool, default False] Whether to compare number exactly.

check_datetimelike_compat [bool, default False] Compare datetime-like which is comparable ignoring dtype.

check_categorical [bool, default True] Whether to compare internal Categorical exactly.

check_like [bool, default False] If True, ignore the order of index & columns. Note: index labels must match their respective rows (same as in columns) - same labels must be with the same data.

check_freq [bool, default True] Whether to check the freq attribute on a DatetimeIndex or TimedeltaIndex.

rtol [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.

atol [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.

obj [str, default 'DataFrame'] Specify object name being compared, internally used to show appropriate assertion message.

See also:

assert_series_equal Equivalent method for asserting Series equality.

DataFrame.equals Check DataFrame equality.
Examples

This example shows comparing two DataFrames that are equal but with columns of differing dtypes.

```python
>>> from pandas._testing import assert_frame_equal
>>> df1 = pd.DataFrame({'a': [1, 2], 'b': [3, 4]})
>>> df2 = pd.DataFrame({'a': [1, 2], 'b': [3.0, 4.0]})
```

df1 equals itself.

```python
>>> assert_frame_equal(df1, df1)
```

df1 differs from df2 as column ‘b’ is of a different type.

```python
>>> assert_frame_equal(df1, df2)
Traceback (most recent call last):
...  
AssertionError: Attributes of DataFrame.iloc[:, 1] (column name="b") are different
```

Attribute “dtype” are different [left]: int64 [right]: float64

Ignore differing dtypes in columns with check_dtype.

```python
>>> assert_frame_equal(df1, df2, check_dtype=False)
```

pandas.testing.assert_series_equal

```python
pandas.testing.assert_series_equal (left, right, check_dtype=True, check_index_type='equiv', check_series_type=True, check_less_precise=<object object>, check_names=True, check_exact=False, check_datetimelike_compat=False, check_categorical=True, check_category_order=True, check_freq=True, rtol=1e-05, atol=1e-08, obj='Series')
```

Check that left and right Series are equal.

**Parameters**

- `left` [Series]
- `right` [Series]
- `check_dtype` [bool, default True] Whether to check the Series dtype is identical.
- `check_index_type` [bool or {'equiv'}, default 'equiv'] Whether to check the Index class, dtype and inferred_type are identical.
- `check_series_type` [bool, default True] Whether to check the Series class is identical.
- `check_less_precise` [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

When comparing two numbers, if the first number has magnitude less than 1e-5, we compare the two numbers directly and check whether they are equivalent within the specified precision. Otherwise, we compare the ratio of the second number to the first number and check whether it is equivalent to 1 within the specified precision.

Deprecated since version 1.1.0: Use rtol and atol instead to define relative/absolute tolerance, respectively. Similar to `math.isclose()`.
check_names [bool, default True] Whether to check the Series and Index names attribute.

check_exact [bool, default False] Whether to compare number exactly.

check_datetimelike_compat [bool, default False] Compare datetime-like which is comparable ignoring dtype.

check_categorical [bool, default True] Whether to compare internal Categorical exactly.

check_category_order [bool, default True] Whether to compare category order of internal Categoricals.

New in version 1.0.2.

check_freq [bool, default True] Whether to check the freq attribute on a DatetimeIndex or TimedeltaIndex.

rtol [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.

atol [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.

obj [str, default ‘Series’] Specify object name being compared, internally used to show appropriate assertion message.

pandas.testing.assert_index_equal

pandas.testing.assert_index_equal(left, right, exact='equiv', check_names=True, check_less_precise=<object object>, check_exact=True, check_categorical=True, rtol=1e-05, atol=1e-08, obj='Index')

Check that left and right Index are equal.

Parameters

left [Index]

right [Index]

exact [bool or {'equiv'}, default ‘equiv’] Whether to check the Index class, dtype and inferred_type are identical. If ‘equiv’, then RangeIndex can be substituted for Int64Index as well.

check_names [bool, default True] Whether to check the names attribute.

check_less_precise [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

Deprecated since version 1.1.0: Use rtol and atol instead to define relative/absolute tolerance, respectively. Similar to math.isclose().

check_exact [bool, default True] Whether to compare number exactly.

check_categorical [bool, default True] Whether to compare internal Categorical exactly.

rtol [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.

atol [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.
obj [str, default ‘Index’] Specify object name being compared, internally used to show appropriate assertion message.

**pandas.testing.assert_extension_array_equal**

pandas.testing.assert_extension_array_equal(left, right, check_dtype=True, index_values=None, check_less_precise=<object object>, check_exact=False, rtol=1e-05, atol=1e-08)

Check that left and right ExtensionArrays are equal.

**Parameters**

- **left, right** [ExtensionArray] The two arrays to compare.
- **check_dtype** [bool, default True] Whether to check if the ExtensionArray dtypes are identical.
- **index_values** [numpy.ndarray, default None] Optional index (shared by both left and right), used in output.
- **check_less_precise** [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.
  
  Deprecated since version 1.1.0: Use `rtol` and `atol` instead to define relative/absolute tolerance, respectively. Similar to `math.isclose()`.
- **check_exact** [bool, default False] Whether to compare number exactly.
- **rtol** [float, default 1e-5] Relative tolerance. Only used when check_exact is False.
  
  New in version 1.1.0.
- **atol** [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.
  
  New in version 1.1.0.

**Notes**

Missing values are checked separately from valid values. A mask of missing values is computed for each and checked to match. The remaining all-valid values are cast to object dtype and checked.

### 3.15.3 Exceptions and warnings

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>errors.AccessorRegistrationWarning</td>
<td>Warning for attribute conflicts in accessor registration.</td>
</tr>
<tr>
<td>errors.DtypeWarning</td>
<td>Warning raised when reading different dtypes in a column from a file.</td>
</tr>
<tr>
<td>errors.EmptyDataError</td>
<td>Exception that is thrown in <code>pd.read_csv</code> (by both the C and Python engines) when empty data or header is encountered.</td>
</tr>
<tr>
<td>errors.InvalidIndexError</td>
<td>Exception raised when attempting to use an invalid index key.</td>
</tr>
<tr>
<td>errors.MergeError</td>
<td>Error raised when problems arise during merging due to problems with input data.</td>
</tr>
</tbody>
</table>

continues on next page
### errors.NullFrequencyError
Error raised when a null freq attribute is used in an operation that needs a non-null frequency, particularly `DateTimeIndex.shift`, `TimedeltaIndex.shift`, `PeriodIndex.shift`.

### errors.NumbaUtilError
Error raised for unsupported Numba engine routines.

### errorsOutOfBoundsDatetime
Raised when encountering a timedelta value that cannot be represented as a timedelta64[ns].

### errorsOutOfBoundsTimedelta
Raised when encountering a timedelta value that cannot be represented as a timedelta64[ns].

### errors.ParserError
Exception that is raised by an error encountered in parsing file contents.

### errors.ParserWarning
Warning raised when reading a file that doesn’t use the default ‘c’ parser.

### errors.PerformanceWarning
Warning raised when there is a possible performance impact.

### errors.UnsortedIndexError
Error raised when attempting to get a slice of a MultiIndex, and the index has not been lexsorted.

### errors.UnsupportedFunctionCall
Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g.

</tr>
<tr>
<td></td>
<td>file.</td>
</tr>
</tbody>
</table>

This warning is issued when dealing with larger files because the dtype checking happens per chunk read.

Despite the warning, the CSV file is read with mixed types in a single column which will be an object type. See the examples below to better understand this issue.
Examples

This example creates and reads a large CSV file with a column that contains *int* and *str*.

```python
>>> df = pd.DataFrame({'a': ['1'] * 100000 + ['X'] * 100000 + ...
... ['1'] * 100000),
... 'b': ['b'] * 300000})
>>> df.to_csv('test.csv', index=False)
>>> df2 = pd.read_csv('test.csv')
... # DtypeWarning: Columns (0) have mixed types

Important to notice that *df2* will contain both *str* and *int* for the same input, ‘1’.

```python
>>> df2.iloc[262140, 0]
'1'
>>> type(df2.iloc[262140, 0])
<class 'str'>
>>> df2.iloc[262150, 0]
1
>>> type(df2.iloc[262150, 0])
<class 'int'>
```

One way to solve this issue is using the *dtype* parameter in the *read_csv* and *read_table* functions to explicit the conversion:

```python
>>> df2 = pd.read_csv('test.csv', sep=',', dtype={'a': str})

No warning was issued.

```python
>>> import os
>>> os.remove('test.csv')
```

**pandas.errors.EmptyDataError**

*exception pandas.errors.EmptyDataError*  
Exception that is thrown in *pd.read_csv* (by both the C and Python engines) when empty data or header is encountered.

**pandas.errors.InvalidIndexError**

*exception pandas.errors.InvalidIndexError*  
Exception raised when attempting to use an invalid index key.  
New in version 1.1.0.
pandas.errors.MergeError

exception pandas.errors.MergeError
Error raised when problems arise during merging due to problems with input data. Subclass of ValueError.

pandas.errors.NullFrequencyError

exception pandas.errors.NullFrequencyError
Error raised when a null freq attribute is used in an operation that needs a non-null frequency, particularly DatetimeIndex.shift, TimedeltaIndex.shift, PeriodIndex.shift.

pandas.errors.NumbaUtilError

exception pandas.errors.NumbaUtilError
Error raised for unsupported Numba engine routines.

pandas.errors.OutOfBoundsDatetime

exception pandas.errors.OutOfBoundsDatetime

pandas.errors.OutOfBoundsTimedelta

exception pandas.errors.OutOfBoundsTimedelta
Raised when encountering a timedelta value that cannot be represented as a timedelta64[ns].

pandas.errors.ParserError

exception pandas.errors.ParserError
Exception that is raised by an error encountered in parsing file contents.

This is a generic error raised for errors encountered when functions like read_csv or read_html are parsing contents of a file.

See also:
read_csv Read CSV (comma-separated) file into a DataFrame.
read_html Read HTML table into a DataFrame.

pandas.errors.ParserWarning

exception pandas.errors.ParserWarning
Warning raised when reading a file that doesn’t use the default ‘c’ parser.

Raised by pd.read_csv and pd.read_table when it is necessary to change parsers, generally from the default ‘c’ parser to ‘python’.

It happens due to a lack of support or functionality for parsing a particular attribute of a CSV file with the requested engine.

Currently, ‘c’ unsupported options include the following parameters:
1. sep other than a single character (e.g. regex separators)
2. skipfooter higher than 0
3. sep=None with delim_whitespace=False
The warning can be avoided by adding `engine='python'` as a parameter in `pd.read_csv` and `pd.read_table` methods.

See also:

**pd.read_csv**  Read CSV (comma-separated) file into DataFrame.

**pd.read_table**  Read general delimited file into DataFrame.

**Examples**

Using a `sep` in `pd.read_csv` other than a single character:

```python
>>> import io
>>> csv = '''a;b;c
... 1;1,8
... 1;2,1'''
>>> df = pd.read_csv(io.StringIO(csv), sep='[;,]')
... # ParserWarning: Falling back to the 'python' engine...
```

Adding `engine='python'` to `pd.read_csv` removes the Warning:

```python
>>> df = pd.read_csv(io.StringIO(csv), sep='[;,]', engine='python')
```

**pandas.errors.PerformanceWarning**

**exception** pandas.errors.PerformanceWarning  
Warning raised when there is a possible performance impact.

**pandas.errors.UnsortedIndexError**

**exception** pandas.errors.UnsortedIndexError  
Error raised when attempting to get a slice of a MultiIndex, and the index has not been lexsorted. Subclass of `KeyError`.

**pandas.errors.UnsupportedFunctionCall**

**exception** pandas.errors.UnsupportedFunctionCall  
Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g. `np.cumsum(groupby_object)`.

### 3.15.4 Data types related functionality

| api.types.union_categoricals(to_union[, ...]) | Combine list-like of Categorical-like, unioning categories. |
| api.types.infer_dtype | Efficiently infer the type of a passed val, or list-like array of values. |
| api.types.pandas_dtype(dtype) | Convert input into a pandas only dtype object or a numpy dtype object. |
pandas.api.types.union_categoricals

\`pandas.api.types.union_categoricals\` \(\text{to}_\text{union},\text{sort}_\text{categories}=\text{False},\text{ignore}_\text{order}=\text{False}\)  
Combine list-like of Categorical-like, unioning categories.  
All categories must have the same dtype.  

**Parameters**  

- `to_union` [list-like] Categorical, CategoricalIndex, or Series with dtype='category'.  
- `sort_categories` [bool, default False] If true, resulting categories will be lexsorted, otherwise they will be ordered as they appear in the data.  
- `ignore_order` [bool, default False] If true, the ordered attribute of the Categoricals will be ignored. Results in an unordered categorical.  

**Returns**  

Categorical  

**Raises**  

- TypeError  
  - all inputs do not have the same dtype  
  - all inputs do not have the same ordered property  
  - all inputs are ordered and their categories are not identical  
  - `sort_categories=True` and Categoricals are ordered  
- ValueError  
  Empty list of categoricals passed  

**Notes**  

To learn more about categories, see link  

**Examples**  

```python  
>>> from pandas.api.types import union_categoricals  
```

If you want to combine categoricals that do not necessarily have the same categories, `union_categoricals` will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```python  
>>> a = pd.Categorical(['b', 'c'])  
>>> b = pd.Categorical(['a', 'b'])  
>>> union_categoricals([a, b])  
['b', 'c', 'a', 'b']  
Categories (3, object): ['b', 'c', 'a']  
```

By default, the resulting categories will be ordered as they appear in the `categories` of the data. If you want the categories to be lexsorted, use `sort_categories=True` argument.

```python  
>>> union_categoricals([a, b], sort_categories=True)  
['b', 'c', 'a', 'b']  
Categories (3, object): ['a', 'b', 'c']  
```

`union_categoricals` also works with the case of combining two categoricals of the same categories and order information (e.g. what you could also `append` for).
>>> a = pd.Categorical(["a", "b"], ordered=True)
>>> b = pd.Categorical(["a", "b", "a"], ordered=True)

union_categoricals([a, b])
['a', 'b', 'a', 'b', 'a']
Categories (2, object): ['a' < 'b']

Raises TypeError because the categories are ordered and not identical.

>>> a = pd.Categorical(["a", "b"], ordered=True)
>>> b = pd.Categorical(["a", "b", "c"], ordered=True)
>>> union_categoricals([a, b])
Traceback (most recent call last):
  ...          
TypeError: to union ordered Categoricals, all categories must be the same

New in version 0.20.0

Ordered categoricals with different categories or orderings can be combined by using the ignore_ordered=True argument.

>>> a = pd.Categorical(["a", "b", "c"], ordered=True)
>>> b = pd.Categorical(["c", "b", "a"], ordered=True)
>>> union_categoricals([a, b], ignore_order=True)
['a', 'b', 'c', 'c', 'b', 'a']
Categories (3, object): ['a', 'b', 'c']

union_categoricals also works with a CategoricalIndex, or Series containing categorical data, but note that the resulting array will always be a plain Categorical

>>> a = pd.Series(["b", "c"], dtype='category')
>>> b = pd.Series(["a", "b"], dtype='category')
>>> union_categoricals([a, b])
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']

pandas.api.types.infer_dtype

pandas.api.types.infer_dtype()

Efficiently infer the type of a passed val, or list-like array of values. Return a string describing the type.

Parameters

value [scalar, list, ndarray, or pandas type]

skipna [bool, default True] Ignore NaN values when inferring the type.

Returns

str Describing the common type of the input data.

Results can include:

- string
- bytes
- floating
- integer
- mixed-integer
mixed-integer-float  
decimal  
complex  
categorical  
boolean  
datetime64  
datetime  
date  
timedelta64  
timedelta  
time  
period  
mixed  

Raises  

TypeError If ndarray-like but cannot infer the dtype

Notes

- ‘mixed’ is the catchall for anything that is not otherwise specialized
- ‘mixed-integer-float’ are floats and integers
- ‘mixed-integer’ are integers mixed with non-integers

Examples

```python
>>> infer_dtype(['foo', 'bar'])
'string'

>>> infer_dtype(['a', np.nan, 'b'], skipna=True)
'string'

>>> infer_dtype(['a', np.nan, 'b'], skipna=False)
'mixed'

>>> infer_dtype(['b'foo', 'b'bar'])
'bytes'

>>> infer_dtype([1, 2, 3])
'integer'

>>> infer_dtype([1, 2, 3.5])
'mixed-integer-float'

>>> infer_dtype([1.0, 2.0, 3.5])
'floating'
```
>>> infer_dtypes(['a', 1])
'mixed-integer'

>>> infer_dtypes([Decimal(1), Decimal(2.0)])
'decimal'

>>> infer_dtypes([True, False])
'boolean'

>>> infer_dtypes([True, False, np.nan])
'mixed'

>>> infer_dtypes([pd.Timestamp('20130101')])
'datetime'

>>> infer_dtypes([datetime.date(2013, 1, 1)])
'date'

>>> infer_dtypes([np.datetime64('2013-01-01')])
'datetime64'

>>> infer_dtypes([datetime.timedelta(0, 1, 1)])
'timedelta'

>>> infer_dtypes(pd.Series(list('aabc')).astype('category'))
'categorical'

**pandas.api.types.pandas_dtype**

`pandas.api.types.pandas_dtype(dtpe)`

Convert input into a pandas only dtype object or a numpy dtype object.

**Parameters**

- `dtype` [object to be converted]

**Returns**

- `np.dtype` or a pandas dtype

**Raises**

- TypeError if not a dtype

**Dtype introspection**

- `api.types.is_bool_dtype(arr_or_dtype)`  
  Check whether the provided array or dtype is of a boolean dtype.

- `api.types.is_categorical_dtype(arr_or_dtype)`  
  Check whether an array-like or dtype is of the Categorical dtype.

- `api.types.is_complex_dtype(arr_or_dtype)`  
  Check whether the provided array or dtype is of a complex dtype.

</table>

**pandas.api.types.is_bool_dtype**

pandas.api.types.is_bool_dtype(arr_or_dtype)  
Check whether the provided array or dtype is of a boolean dtype.

**Parameters**

- **arr_or_dtype** [array-like] The array or dtype to check.

**Returns**

- **boolean** Whether or not the array or dtype is of a boolean dtype.
Notes

An ExtensionArray is considered boolean when the `_is_boolean` attribute is set to True.

Examples

```python
>>> is_bool_dtype(str)
False
>>> is_bool_dtype(int)
False
>>> is_bool_dtype(bool)
True
>>> is_bool_dtype(np.bool_)
True
>>> is_bool_dtype(np.array(['a', 'b']))
False
>>> is_bool_dtype(pd.Series([1, 2]))
False
>>> is_bool_dtype(np.array([True, False]))
True
>>> is_bool_dtype(pd.Categorical([True, False]))
True
>>> is_bool_dtype(pd.arrays.SparseArray([True, False]))
True
```

**pandas.api.types.is_categorical_dtype**

`pandas.api.types.is_categorical_dtype(arr_or_dtype)`

Check whether an array-like or dtype is of the Categorical dtype.

**Parameters**

- `arr_or_dtype` [array-like] The array-like or dtype to check.

**Returns**

- `boolean` Whether or not the array-like or dtype is of the Categorical dtype.

**Examples**

```python
>>> is_categorical_dtype(object)
False
>>> is_categorical_dtype(CategoricalDtype())
True
>>> is_categorical_dtype([1, 2, 3])
False
>>> is_categorical_dtype(pd.Categorical([1, 2, 3]))
True
>>> is_categorical_dtype(pd.CategoricalIndex([1, 2, 3]))
True
```
pandas.api.types.is_complex_dtype

pandas.api.types.is_complex_dtype(arr_or_dtype)
Check whether the provided array or dtype is of a complex dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a complex dtype.

Examples

```python
>>> is_complex_dtype(str)
False
>>> is_complex_dtype(int)
False
>>> is_complex_dtype(np.complex_)
True
>>> is_complex_dtype(np.array(['a', 'b']))
False
>>> is_complex_dtype(pd.Series([1, 2]))
False
>>> is_complex_dtype(np.array([1 + 1j, 5]))
True
```

pandas.api.types.is_datetime64_any_dtype

pandas.api.types.is_datetime64_any_dtype(arr_or_dtype)
Check whether the provided array or dtype is of the datetime64 dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

bool Whether or not the array or dtype is of the datetime64 dtype.

Examples

```python
>>> is_datetime64_any_dtype(str)
False
>>> is_datetime64_any_dtype(int)
False
>>> is_datetime64_any_dtype(np.datetime64)  # can be tz-naive
True
>>> is_datetime64_any_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_any_dtype(np.array(['a', 'b']))
False
>>> is_datetime64_any_dtype(np.array([1, 2]))
False
>>> is_datetime64_any_dtype(np.array([], dtype="datetime64[ns]"))
```
pandas.api.types.is_datetime64_dtype

pandas.api.types.is_datetime64_dtype(arr_or_dtype)

Check whether an array-like or dtype is of the datetime64 dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the datetime64 dtype.

Examples

```python
>>> is_datetime64_dtype(object)
False
>>> is_datetime64_dtype(np.datetime64)
True
>>> is_datetime64_dtype(np.array([], dtype=int))
False
>>> is_datetime64_dtype(np.array([], dtype=np.datetime64))
True
>>> is_datetime64_dtype([1, 2, 3])
False
```

pandas.api.types.is_datetime64_ns_dtype

pandas.api.types.is_datetime64_ns_dtype(arr_or_dtype)

Check whether the provided array or dtype is of the datetime64[ns] dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

bool Whether or not the array or dtype is of the datetime64[ns] dtype.

Examples

```python
>>> is_datetime64_ns_dtype(str)
False
>>> is_datetime64_ns_dtype(int)
False
>>> is_datetime64_ns_dtype(np.datetime64)  # no unit
False
>>> is_datetime64_ns_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_ns_dtype(np.array(['a', 'b']))
```

3.15. General utility functions
False
>>> is_datetime64_ns_dtype(np.array([1, 2]))
False
>>> is_datetime64_ns_dtype(np.array([], dtype="datetime64"))  # no unit
False
>>> is_datetime64_ns_dtype(np.array([], dtype="datetime64[ps]"))  # wrong unit
False
>>> is_datetime64_ns_dtype(pd.DatetimeIndex([1, 2, 3], dtype="datetime64[ns]"))
True

pandas.api.types.is_datetime64tz_dtype

pandas.api.types.is_datetime64tz_dtype(arr_or_dtype)
Check whether an array-like or dtype is of a DatetimeTZDtype dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of a DatetimeTZDtype dtype.

Examples

>>> is_datetime64tz_dtype(object)
False
>>> is_datetime64tz_dtype([1, 2, 3])
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3]))  # tz-naive
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True

>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_datetime64tz_dtype(dtype)
True
>>> is_datetime64tz_dtype(s)
True

pandas.api.types.is_extension_type

pandas.api.types.is_extension_type(arr)
Check whether an array-like is of a pandas extension class instance.

Deprecated since version 1.0.0: Use is_extension_array_dtype instead.

Extension classes include categoricals, pandas sparse objects (i.e. classes represented within the pandas library and not ones external to it like scipy sparse matrices), and datetime-like arrays.

Parameters

arr [array-like] The array-like to check.

Returns
boolean  Whether or not the array-like is of a pandas extension class instance.

Examples

```python
>>> is_extension_type([1, 2, 3])
False
>>> is_extension_type(np.array([1, 2, 3]))
False
>>> cat = pd.Categorical([1, 2, 3])
>>> is_extension_type(cat)
True
>>> is_extension_type(pd.Series(cat))
True
>>> is_extension_type(pd.arrays.SparseArray([1, 2, 3]))
True
>>> from scipy.sparse import bsr_matrix
>>> is_extension_type(bsr_matrix([1, 2, 3]))
False
>>> is_extension_type(pd.DatetimeIndex([1, 2, 3]))
False
>>> is_extension_type(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True
>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_extension_type(s)
True
```

pandas.api.types.is_extension_array_dtype

pandas.api.types.is_extension_array_dtype(arr_or_dtype)
Check if an object is a pandas extension array type.

See the Use Guide for more.

Parameters:

arr_or_dtype [object] For array-like input, the .dtype attribute will be extracted.

Returns:

bool  Whether the arr_or_dtype is an extension array type.

Notes

This checks whether an object implements the pandas extension array interface. In pandas, this includes:

- Categorical
- Sparse
- Interval
- Period
- DatetimeArray
- TimedeltaArray

Third-party libraries may implement arrays or types satisfying this interface as well.
Examples

>>> from pandas.api.types import is_extension_array_dtype
>>> arr = pd.Categorical(['a', 'b'])
>>> is_extension_array_dtype(arr)
True
>>> is_extension_array_dtype(arr.dtype)
True

>>> arr = np.array(['a', 'b'])
>>> is_extension_array_dtype(arr.dtype)
False

pandas.api.types.is_float_dtype

pandas.api.types.is_float_dtype(arr_or_dtype)
Check whether the provided array or dtype is of a float dtype.
This function is internal and should not be exposed in the public API.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a float dtype.

Examples

>>> is_float_dtype(str)
False
>>> is_float_dtype(int)
False
>>> is_float_dtype(float)
True
>>> is_float_dtype(np.array(['a', 'b']))
False
>>> is_float_dtype(pd.Series([1, 2]))
False
>>> is_float_dtype(pd.Index([1, 2.]))
True

pandas.api.types.is_int64_dtype

pandas.api.types.is_int64_dtype(arr_or_dtype)
Check whether the provided array or dtype is of the int64 dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of the int64 dtype.
Notes

Depending on system architecture, the return value of `is_int64_dtype(int)` will be True if the OS uses 64-bit integers and False if the OS uses 32-bit integers.

Examples

```python
>>> is_int64_dtype(str)
False
>>> is_int64_dtype(np.int32)
False
>>> is_int64_dtype(np.int64)
True
>>> is_int64_dtype('int8')
False
>>> is_int64_dtype('Int8')
False
>>> is_int64_dtype(pd.Int64Dtype)
True
>>> is_int64_dtype(float)
False
>>> is_int64_dtype(np.uint64)  # unsigned
False
>>> is_int64_dtype(np.array(['a', 'b']))
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.int64))
True
>>> is_int64_dtype(pd.Index([1, 2.]))  # float
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.uint32))  # unsigned
False
```

**pandas.api.types.is_integer_dtype**

`pandas.api.types.is_integer_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of an integer dtype.

Unlike in `in_any_int_dtype`, timedelta64 instances will return False.

Changed in version 0.24.0: The nullable Integer dtypes (e.g. pandas.Int64Dtype) are also considered as integer by this function.

**Parameters**

- `arr_or_dtype` [array-like] The array or dtype to check.

**Returns**

- `boolean` Whether or not the array or dtype is of an integer dtype and not an instance of timedelta64.
Examples

```python
>>> is_integer_dtype(str)
False
>>> is_integer_dtype(int)
True
>>> is_integer_dtype(float)
False
>>> is_integer_dtype(np.uint64)
True
>>> is_integer_dtype('int8')
True
>>> is_integer_dtype('Int8')
True
>>> is_integer_dtype(pd.Int8Dtype)
True
>>> is_integer_dtype(np.datetime64)
False
>>> is_integer_dtype(np.timedelta64)
False
>>> is_integer_dtype(np.array(['a', 'b']))
False
>>> is_integer_dtype(pd.Series([1, 2]))
True
>>> is_integer_dtype(np.array([], dtype=np.timedelta64))
False
>>> is_integer_dtype(pd.Index([1, 2.]))  # float  # float
False

pandas.api.types.is_interval_dtype

pandas.api.types.is_interval_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the Interval dtype.
Parameters

arr_or_dtype  [array-like] The array-like or dtype to check.

Returns

boolean  Whether or not the array-like or dtype is of the Interval dtype.

Examples

```python
>>> is_interval_dtype(object)
False
>>> is_interval_dtype(IntervalDtype())
True
>>> is_interval_dtype([1, 2, 3])
False
>>> interval = pd.Interval(1, 2, closed="right")
>>> is_interval_dtype(interval)
False
>>> is_interval_dtype(pd.IntervalIndex([interval]))
True
```
pandas.api.types.is_numeric_dtype

**pandas.api.types.is_numeric_dtype(arr_or_dtype)**

Check whether the provided array or dtype is of a numeric dtype.

**Parameters**

- **arr_or_dtype** [array-like] The array or dtype to check.

**Returns**

- **boolean** Whether or not the array or dtype is of a numeric dtype.

**Examples**

```python
g>>> is_numeric_dtype(str)
False
g>>> is_numeric_dtype(int)
True
g>>> is_numeric_dtype(float)
True
g>>> is_numeric_dtype(np.uint64)
True
g>>> is_numeric_dtype(np.datetime64)
False
g>>> is_numeric_dtype(np.timedelta64)
False
g>>> is_numeric_dtype(np.array(['a', 'b']))
False
g>>> is_numeric_dtype(pd.Series([1, 2]))
True
g>>> is_numeric_dtype(pd.Index([1, 2.]))
True
g>>> is_numeric_dtype(np.array([], dtype=np.timedelta64))
False
```

pandas.api.types.is_object_dtype

**pandas.api.types.is_object_dtype(arr_or_dtype)**

Check whether an array-like or dtype is of the object dtype.

**Parameters**

- **arr_or_dtype** [array-like] The array-like or dtype to check.

**Returns**

- **boolean** Whether or not the array-like or dtype is of the object dtype.
Examples

```python
>>> is_object_dtype(object)
True
>>> is_object_dtype(int)
False
>>> is_object_dtype(np.array([], dtype=object))
True
>>> is_object_dtype(np.array([], dtype=int))
False
>>> is_object_dtype([1, 2, 3])
False
```

**pandas.api.types.is_period_dtype**

**pandas.api.types.is_period_dtype(arr_or_dtype)**

Check whether an array-like or dtype is of the Period dtype.

**Parameters**

- **arr_or_dtype** [array-like] The array-like or dtype to check.

**Returns**

- **boolean** Whether or not the array-like or dtype is of the Period dtype.

**Examples**

```python
>>> is_period_dtype(object)
False
>>> is_period_dtype(PeriodDtype(freq="D"))
True
>>> is_period_dtype([1, 2, 3])
False
>>> is_period_dtype(pd.Period("2017-01-01"))
False
>>> is_period_dtype(pd.PeriodIndex([], freq="A"))
True
```

**pandas.api.types.is_signed_integer_dtype**

**pandas.api.types.is_signed_integer_dtype(arr_or_dtype)**

Check whether the provided array or dtype is of a signed integer dtype.

Unlike in `in_any_int_dtype`, timedelta64 instances will return False.

Changed in version 0.24.0: The nullable Integer dtypes (e.g. pandas.Int64Dtype) are also considered as integer by this function.

**Parameters**

- **arr_or_dtype** [array-like] The array or dtype to check.

**Returns**

- **boolean** Whether or not the array or dtype is of a signed integer dtype and not an instance of timedelta64.
Examples

```python
>>> is_signed_integer_dtype(str)
False
>>> is_signed_integer_dtype(int)
True
>>> is_signed_integer_dtype(float)
False
>>> is_signed_integer_dtype(np.uint64)  # unsigned
False
>>> is_signed_integer_dtype('int8')
True
>>> is_signed_integer_dtype('Int8')
True
>>> is_signed_integer_dtype(pd.Int8Dtype)
True
>>> is_signed_integer_dtype(np.datetime64)
False
>>> is_signed_integer_dtype(np.timedelta64)
False
>>> is_signed_integer_dtype(np.array(['a', 'b']))
False
>>> is_signed_integer_dtype(pd.Series([1, 2]))
True
>>> is_signed_integer_dtype(np.array([], dtype=np.timedelta64))
False
>>> is_signed_integer_dtype(pd.Index([1, 2.]))  # float
False
>>> is_signed_integer_dtype(np.array([1, 2], dtype=np.uint32))  # unsigned
False
```

def pandas.api.types.is_string_dtype(arr_or_dtype):
    """Check whether the provided array or dtype is of the string dtype."
    """
    Parameters
    arr_or_dtype [array-like] The array or dtype to check.
    """
    """Returns"
    boolean Whether or not the array or dtype is of the string dtype.
    """

Examples

```python
>>> is_string_dtype(str)
True
>>> is_string_dtype(object)
True
>>> is_string_dtype(int)
False
>>> is_string_dtype(np.array(['a', 'b']))
True
```

(continues on next page)
is_string_dtype(pd.Series([1, 2]))
False

pandas.api.types.is_timedelta64_dtype

pandas.api.types.is_timedelta64_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the timedelta64 dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the timedelta64 dtype.

Examples

>>> is_timedelta64_dtype('object')
False
>>> is_timedelta64_dtype(np.timedelta64)
True
>>> is_timedelta64_dtype([1, 2, 3])
False
>>> is_timedelta64_dtype(pd.Series([], dtype="timedelta64[ns]")
True
>>> is_timedelta64_dtype('0 days')
False

pandas.api.types.is_timedelta64_ns_dtype

pandas.api.types.is_timedelta64_ns_dtype(arr_or_dtype)
Check whether the provided array or dtype is of the timedelta64[ns] dtype.

This is a very specific dtype, so generic ones like np.timedelta64 will return False if passed into this function.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of the timedelta64[ns] dtype.

Examples

>>> is_timedelta64_ns_dtype(np.dtype('m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.dtype('m8[ps]')) # Wrong frequency
False
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype='m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype=np.timedelta64))
False
pandas.api.types.is_unsigned_integer_dtype

pandas.api.types.

is_unsigned_integer_dtype(arr_or_dtype)

Check whether the provided array or dtype is of an unsigned integer dtype.

Changed in version 0.24.0: The nullable Integer dtypes (e.g. pandas.UInt64Dtype) are also considered as integer by this function.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of an unsigned integer dtype.

Examples

```python
>>> is_unsigned_integer_dtype(str)
False
>>> is_unsigned_integer_dtype(int)  # signed
False
>>> is_unsigned_integer_dtype(float)
False
>>> is_unsigned_integer_dtype(np.uint64)
True
>>> is_unsigned_integer_dtype('uint8')
True
>>> is_unsigned_integer_dtype('UInt8')
True
>>> is_unsigned_integer_dtype(pd.UInt8Dtype)
True
>>> is_unsigned_integer_dtype(np.array(['a', 'b']))
False
>>> is_unsigned_integer_dtype(pd.Series([1, 2]))  # signed
False
>>> is_unsigned_integer_dtype(pd.Index([1, 2.]))  # float
False
>>> is_unsigned_integer_dtype(np.array([1, 2], dtype=np.uint32))
True
```

pandas.api.types.is_sparse

pandas.api.types.

is_sparse(arr)

Check whether an array-like is a 1-D pandas sparse array.

Check that the one-dimensional array-like is a pandas sparse array. Returns True if it is a pandas sparse array, not another type of sparse array.

Parameters

arr [array-like] Array-like to check.

Returns

bool Whether or not the array-like is a pandas sparse array.
Examples

Returns *True* if the parameter is a 1-D pandas sparse array.

```python
>>> is_sparse(pd.arrays.SparseArray([0, 0, 1, 0]))
True
>>> is_sparse(pd.Series(pd.arrays.SparseArray([0, 0, 1, 0])))
True
```

Returns *False* if the parameter is not sparse.

```python
>>> is_sparse(np.array([0, 0, 1, 0]))
False
>>> is_sparse(pd.Series([0, 1, 0, 0]))
False
```

Returns *False* if the parameter is not a pandas sparse array.

```python
>>> from scipy.sparse import bsr_matrix
>>> is_sparse(bsr_matrix([0, 1, 0, 0]))
False
```

Returns *False* if the parameter has more than one dimension.

### Iterable introspection

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>api.types.is_dict_like(obj)</code></td>
<td>Check if the object is dict-like.</td>
</tr>
<tr>
<td><code>api.types.is_file_like(obj)</code></td>
<td>Check if the object is a file-like object.</td>
</tr>
<tr>
<td><code>api.types.is_list_like</code></td>
<td>Check if the object is list-like.</td>
</tr>
<tr>
<td><code>api.types.is_named_tuple(obj)</code></td>
<td>Check if the object is a named tuple.</td>
</tr>
<tr>
<td><code>api.types.is_iterator</code></td>
<td>Check if the object is an iterator.</td>
</tr>
</tbody>
</table>

### pandas.api.types.is_dict_like

`pandas.api.types.is_dict_like(obj)`

Check if the object is dict-like.

**Parameters**

- `obj` [The object to check]

**Returns**

- `is_dict_like` [bool] Whether `obj` has dict-like properties.
Examples

```python
>>> is_dict_like({1: 2})
True
>>> is_dict_like([1, 2, 3])
False
>>> is_dict_like(dict)
False
>>> is_dict_like(dict())
True
```

**pandas.api.types.is_file_like**

`pandas.api.types.is_file_like(obj)`

Check if the object is a file-like object.

For objects to be considered file-like, they must be an iterator AND have either a `read` and/or `write` method as an attribute.

Note: file-like objects must be iterable, but iterable objects need not be file-like.

**Parameters**

- `obj` [The object to check]

**Returns**

- `is_file_like` [bool] Whether `obj` has file-like properties.

Examples

```python
>>> import io
>>> buffer = io.StringIO("data")
>>> is_file_like(buffer)
True
>>> is_file_like([1, 2, 3])
False
```

**pandas.api.types.is_list_like**

`pandas.api.types.is_list_like()`

Check if the object is list-like.

Objects that are considered list-like are for example Python lists, tuples, sets, NumPy arrays, and Pandas Series.

Strings and datetime objects, however, are not considered list-like.

**Parameters**

- `obj` [object] Object to check.

- `allow_sets` [bool, default True] If this parameter is False, sets will not be considered list-like.

  New in version 0.24.0.

**Returns**

- `bool` Whether `obj` has list-like properties.
Examples

```python
>>> is_list_like([1, 2, 3])
True
>>> is_list_like([1, 2, 3])
True
>>> is_list_like(datetime(2017, 1, 1))
False
>>> is_list_like("foo")
False
>>> is_list_like(1)
False
>>> is_list_like(np.array([2]))
True
>>> is_list_like(np.array(2))
False
```

pandas.api.types.is_named_tuple

pandas.api.types.is_named_tuple(obj)
Check if the object is a named tuple.

Parameters

- **obj** [The object to check]

Returns

- **is_named_tuple** [bool] Whether *obj* is a named tuple.

Examples

```python
>>> from collections import namedtuple
>>> Point = namedtuple("Point", ["x", "y"])
>>> p = Point(1, 2)
>>> is_named_tuple(p)
True
>>> is_named_tuple((1, 2))
False
```

pandas.api.types.is_iterator

pandas.api.types.is_iterator()
Check if the object is an iterator.
This is intended for generators, not list-like objects.

Parameters

- **obj** [The object to check]

Returns

- **is_iter** [bool] Whether *obj* is an iterator.
Examples

```python
>>> is_iterator((x for x in []))
True
>>> is_iterator([1, 2, 3])
False
>>> is_iterator(datetime(2017, 1, 1))
False
>>> is_iterator("foo")
False
>>> is_iterator(1)
False
```

Scalar introspection

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>is_bool</code></td>
<td>Returns <code>bool</code></td>
</tr>
<tr>
<td><code>is_categorical</code></td>
<td>Check whether an array-like is a Categorical instance.</td>
</tr>
<tr>
<td><code>is_complex</code></td>
<td>Returns <code>bool</code></td>
</tr>
<tr>
<td><code>is_float</code></td>
<td>Returns <code>bool</code></td>
</tr>
<tr>
<td><code>is_hashable</code></td>
<td>Return <code>True</code> if <code>hash(obj)</code> will succeed, <code>False</code> otherwise.</td>
</tr>
<tr>
<td><code>is_integer</code></td>
<td>Returns <code>bool</code></td>
</tr>
<tr>
<td><code>is_interval</code></td>
<td>Check if the object is a number.</td>
</tr>
<tr>
<td><code>is_re</code></td>
<td>Check if the object is a regex pattern instance.</td>
</tr>
<tr>
<td><code>is_re_compilable</code></td>
<td>Check if the object can be compiled into a regex pattern instance.</td>
</tr>
</tbody>
</table>

`pandas.api.types.is_bool`

`pandas.api.types.is_bool()`

Returns `bool`
pandas.api.types.is_categorical

pandas.api.types.is_categorical(arr)
Check whether an array-like is a Categorical instance.

Parameters
arr [array-like] The array-like to check.

Returns
boolean Whether or not the array-like is of a Categorical instance.

Examples

```python
>>> is_categorical([1, 2, 3])
False
```

Categoricals, Series Categoricals, and CategoricalIndex will return True.

```python
>>> cat = pd.Categorical([1, 2, 3])
>>> is_categorical(cat)
True
>>> is_categorical(pd.Series(cat))
True
>>> is_categorical(pd.CategoricalIndex([1, 2, 3]))
True
```

pandas.api.types.is_complex

pandas.api.types.is_complex()
Returns
bool

pandas.api.types.is_float

pandas.api.types.is_float()
Returns
bool

pandas.api.types.is_hashable

pandas.api.types.is_hashable(obj)
Return True if hash(obj) will succeed, False otherwise.

Some types will pass a test against collections.abc.Hashable but fail when they are actually hashed with hash().

Distinguish between these and other types by trying the call to hash() and seeing if they raise TypeError.
Returns
bool
Examples

```python
>>> import collections
>>> a = ([],)
>>> isinstance(a, collections.abc.Hashable)
True
>>> is_hashable(a)
False
```

`pandas.api.types.is_integer`

`pandas.api.types.is_integer()`

Returns `bool`

`pandas.api.types.is_interval`

`pandas.api.types.is_interval()`

`pandas.api.types.is_number`

`pandas.api.types.is_number(obj)`

Check if the object is a number. Returns True when the object is a number, and False if is not.

Parameters:

- `obj` [any type] The object to check if is a number.

Returns

- `is_number` [bool] Whether `obj` is a number or not.

See also:

- `api.types.is_integer` Checks a subgroup of numbers.

Examples

```python
>>> pd.api.types.is_number(1)
True
>>> pd.api.types.is_number(7.15)
True
Booleans are valid because they are int subclass.

>>> pd.api.types.is_number(False)
True

>>> pd.api.types.is_number("foo")
False
>>> pd.api.types.is_number("5")
False
```
pandas.api.types.is_re

pandas.api.types.is_re(obj)
Check if the object is a regex pattern instance.
Parameters
    obj [The object to check]
Returns
    is_regex [bool] Whether \( \text{obj} \) is a regex pattern.

Examples

```python
>>> is_re(re.compile(".*"))
True
>>> is_re("foo")
False
```

pandas.api.types.is_re_compilable

pandas.api.types.is_re_compilable(obj)
Check if the object can be compiled into a regex pattern instance.
Parameters
    obj [The object to check]
Returns
    is_regex_compilable [bool] Whether \( \text{obj} \) can be compiled as a regex pattern.

Examples

```python
>>> is_re_compilable(".*")
True
>>> is_re_compilable(1)
False
```

pandas.api.types.is_scalar

pandas.api.types.is_scalar()
Parameters
    val [object] This includes:
    • numpy array scalar (e.g. np.int64)
    • Python builtin numerics
    • Python builtin byte arrays and strings
    • None
    • datetime.datetime
    • datetime.timedelta
• Period
• decimal.Decimal
• Interval
• DateOffset
• Fraction
• Number.

Returns

```
bool  Return True if given object is scalar.
```

Examples

```
>>> dt = datetime.datetime(2018, 10, 3)
>>> pd.api.types.is_scalar(dt)
True
```

```
>>> pd.api.types.is_scalar([2, 3])
False
```

```
>>> pd.api.types.is_scalar({0: 1, 2: 3})
False
```

```
>>> pd.api.types.is_scalar((0, 2))
False
```

pandas supports PEP 3141 numbers:

```
>>> from fractions import Fraction
>>> pd.api.types.is_scalar(Fraction(3, 5))
True
```

3.15.5 Bug report function

```
show_versions(as_json)
```

Provide useful information, important for bug reports.

```
pandas.show_versions(as_json=False)
```

Provide useful information, important for bug reports.

It comprises info about hosting operation system, pandas version, and versions of other installed relative packages.

Parameters

```
as_json [str or bool, default False]
```

- If False, outputs info in a human readable form to the console.
- If str, it will be considered as a path to a file. Info will be written to that file in JSON format.
3.16 Extensions

These are primarily intended for library authors looking to extend pandas objects.

<table>
<thead>
<tr>
<th>api.extensions.register_extension_dtype</th>
<th>Register an ExtensionType with pandas as class decorator.</th>
</tr>
</thead>
<tbody>
<tr>
<td>api.extensions.register_dataframe_accessor</td>
<td>Register a custom accessor on DataFrame objects.</td>
</tr>
<tr>
<td>api.extensions.register_series_accessor</td>
<td>Register a custom accessor on Series objects.</td>
</tr>
<tr>
<td>api.extensions.register_index_accessor</td>
<td>Register a custom accessor on Index objects.</td>
</tr>
<tr>
<td>api.extensions.ExtensionDtype()</td>
<td>A custom data type, to be paired with an ExtensionArray.</td>
</tr>
</tbody>
</table>

3.16.1 pandas.api.extensions.register_extension_dtype

pandas.api.extensions.register_extension_dtype(cls)

Register an ExtensionType with pandas as class decorator.

New in version 0.24.0.

This enables operations like \astype(name) for the name of the ExtensionDtype.

**Returns**

callable  A class decorator.

**Examples**

```python
>>> from pandas.api.extensions import register_extension_dtype
>>> from pandas.api.extensions import ExtensionDtype
>>> @register_extension_dtype
... class MyExtensionDtype(ExtensionDtype):
...     name = "myextension"
```

3.16.2 pandas.api.extensions.register_dataframe_accessor

pandas.api.extensions.register_dataframe_accessor(name)

Register a custom accessor on DataFrame objects.

**Parameters**

- **name** [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

**Returns**

callable  A class decorator.

**See also:**

- register_dataframe_accessor  Register a custom accessor on DataFrame objects.
- register_series_accessor  Register a custom accessor on Series objects.
- register_index_accessor  Register a custom accessor on Index objects.
Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```python
def __init__(self, pandas_object):  # noqa: E999
    ...
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```python
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```python
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:

```python
In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10),
...:                      "latitude": np.linspace(0, 20)})
In [2]: ds.geo.center
Out[2]: (5.0, 10.0)
In [3]: ds.geo.plot()  # plots data on a map
```
3.16.3 pandas.api.extensions.register_series_accessor

pandas.api.extensions.register_series_accessor(name)
Register a custom accessor on Series objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

Returns
callable A class decorator.

See also:
register_dataframe_accessor Register a custom accessor on DataFrame objects.
register_series_accessor Register a custom accessor on Series objects.
register_index_accessor Register a custom accessor on Index objects.

Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```python
def __init__(self, pandas_object): # noqa: E999 ...
```

For consistency with pandas methods, you should raise an AttributeError if the data passed to your accessor has an incorrect dtype.

```python
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```python
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:
In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10), ...:                     "latitude": np.linspace(0, 20)})
In [2]: ds.geo.center
Out[2]: (5.0, 10.0)
In [3]: ds.geo.plot()  # plots data on a map

3.16.4 pandas.api.extensions.register_index_accessor

pandas.api.extensions.register_index_accessor(name)

Register a custom accessor on Index objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

Returns
callable A class decorator.

See also:

register_dataframe_accessor Register a custom accessor on DataFrame objects.
register_series_accessor Register a custom accessor on Series objects.
register_index_accessor Register a custom accessor on Index objects.

Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```python
def __init__(self, pandas_object):  # noqa: E999
...```

For consistency with pandas methods, you should raise an AttributeError if the data passed to your accessor has an incorrect dtype.

```python
>>> pd.Series(['a', 'b']).dt
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```python
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
def center(self):
        # return the geographic center point of this DataFrame
```

(continues on next page)
lat = self._obj.latitude
lon = self._obj.longitude
return (float(lon.mean()), float(lat.mean()))

def plot(self):
    # plot this array's data on a map, e.g., using Cartopy
    pass

Back in an interactive IPython session:

```
In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10),
                      ...
                      "latitude": np.linspace(0, 20)})
In [2]: ds.geo.center
Out[2]: (5.0, 10.0)
In [3]: ds.geo.plot()  # plots data on a map
```

### 3.16.5 pandas.api.extensions.ExtensionDtype

class pandas.api.extensions.ExtensionDtype
A custom data type, to be paired with an ExtensionArray.

New in version 0.23.0.

See also:

- `extensions.register_extension_dtype`
- `extensions.ExtensionArray`

**Notes**

The interface includes the following abstract methods that must be implemented by subclasses:
- type
- name

The following attributes and methods influence the behavior of the dtype in pandas operations:
- _is_numeric
- _is_boolean
- _get_common_dtype

Optionally one can override `construct_array_type` for construction with the name of this dtype via the Registry.

See `extensions.register_extension_dtype()`.

- `construct_array_type`

The `na_value` class attribute can be used to set the default NA value for this type. `numpy.nan` is used by default.

ExtensionDtotypes are required to be hashable. The base class provides a default implementation, which relies on the `_metadata` class attribute. `_metadata` should be a tuple containing the strings that define your data type. For example, with `PeriodDtype` that’s the `freq` attribute.

**If you have a parametrized dtype you should set the `"_metadata"` class property.**

Ideally, the attributes in `_metadata` will match the parameters to your `ExtensionDtype.__init__` (if any). If any of the attributes in `_metadata` don’t implement the standard `__eq__` or `__hash__`, the default implementations here will not work.

Changed in version 0.24.0: Added `_metadata`, `__hash__`, and changed the default definition of `__eq__`. 
For interaction with Apache Arrow (pyarrow), a `__from_arrow__` method can be implemented: this method receives a pyarrow Array or ChunkedArray as only argument and is expected to return the appropriate pandas ExtensionArray for this dtype and the passed values:

```python
class ExtensionDtype:
    def __from_arrow__(
        self, array: Union[pyarrow.Array, pyarrow.ChunkedArray]
    ) -> ExtensionArray:
        ...
```

This class does not inherit from `abc.ABCMeta` for performance reasons. Methods and properties required by the interface raise `pandas.errors(AbstractMethodError` and no `register` method is provided for registering virtual subclasses.

**Attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>A character code (one of 'biufcmMOSUV'), default ‘O’</td>
</tr>
<tr>
<td>na_value</td>
<td>Default NA value to use for this type.</td>
</tr>
<tr>
<td>name</td>
<td>A string identifying the data type.</td>
</tr>
<tr>
<td>names</td>
<td>Ordered list of field names, or None if there are no fields.</td>
</tr>
<tr>
<td>type</td>
<td>The scalar type for the array, e.g.</td>
</tr>
</tbody>
</table>

**pandas.api.extensions.ExtensionDtype.kind**

**property** `ExtensionDtype.kind`

A character code (one of ‘biufcmMOSUV’), default ‘O’

This should match the NumPy dtype used when the array is converted to an ndarray, which is probably ‘O’ for object if the extension type cannot be represented as a built-in NumPy type.

**See also:**

- `numpy.dtype.kind`

**pandas.api.extensions.ExtensionDtype.na_value**

**property** `ExtensionDtype.na_value`

Default NA value to use for this type.

This is used in e.g. ExtensionArray.take. This should be the user-facing “boxed” version of the NA value, not the physical NA value for storage. e.g. for JSONArray, this is an empty dictionary.
pandas.api.extensions.ExtensionDtype.name

**property** `ExtensionDtype.name`

A string identifying the data type.

Will be used for display in, e.g. `Series.dtype`.

pandas.api.extensions.ExtensionDtype.names

**property** `ExtensionDtype.names`

Ordered list of field names, or None if there are no fields.

This is for compatibility with NumPy arrays, and may be removed in the future.

pandas.api.extensions.ExtensionDtype.type

**property** `ExtensionDtype.type`

The scalar type for the array, e.g. `int`.

It’s expected `ExtensionArray[item]` returns an instance of `ExtensionDtype.type` for scalar `item`, assuming that value is valid (not NA). NA values do not need to be instances of `type`.

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>construct_array_type()</code></td>
<td>Return the array type associated with this dtype.</td>
</tr>
<tr>
<td><code>construct_from_string(string)</code></td>
<td>Construct this type from a string.</td>
</tr>
<tr>

</table>

pandas.api.extensions.ExtensionDtype.construct_array_type

**classmethod** `ExtensionDtype.construct_array_type()`

Return the array type associated with this dtype.

Returns

`type`

pandas.api.extensions.ExtensionDtype.construct_from_string

**classmethod** `ExtensionDtype.construct_from_string(string)`

Construct this type from a string.

This is useful mainly for data types that accept parameters. For example, a period dtype accepts a frequency parameter that can be set as `period[H]` (where H means hourly frequency).

By default, in the abstract class, just the name of the type is expected. But subclasses can overwrite this method to accept parameters.

Parameters

- `string` [str] The name of the type, for example `category`.

Returns

`ExtensionDtype` Instance of the dtype.
Raises

**TypeError** If a class cannot be constructed from this ‘string’.

Examples

For extension dtypes with arguments the following may be an adequate implementation.

```python
>>> @classmethod
... def construct_from_string(cls, string):
...     pattern = re.compile(r"^my_type\[(?P<arg_name>.+)\]\$")
...     if match:
...         return cls(**match.groupdict())
...     else:
...         raise TypeError(
...             f"Cannot construct a '{cls.__name__}' from '{string}'"
...         )
```

---

**pandas.api.extensions.ExtensionDtype.is_dtype**

**classmethod** `ExtensionDtype.is_dtype(dtype)`

Check if we match ‘dtype’.

**Parameters**

- **dtype** [object] The object to check.

**Returns**

- **bool**

**Notes**

The default implementation is True if

1. `cls.construct_from_string(dtype)` is an instance of `cls`
2. `dtype` is an object and is an instance of `cls`
3. `dtype` has a `dtype` attribute, and any of the above conditions is true for `dtype.dtype`.

---

**3.16.6 pandas.api.extensions.ExtensionArray**

**class pandas.api.extensions.ExtensionArray**

Abstract base class for custom 1-D array types.

Pandas will recognize instances of this class as proper arrays with a custom type and will not attempt to coerce them to objects. They may be stored directly inside a `DataFrame` or `Series`.

New in version 0.23.0.
Notes

The interface includes the following abstract methods that must be implemented by subclasses:

- `_from_sequence`
- `_from_factorized`
- `__getitem__`
- `__len__`
- `__eq__`
- `dtype`
- `nbytes`
- `isna`
- `take`
- `copy`
- `_concat_same_type`

A default repr displaying the type, (truncated) data, length, and dtype is provided. It can be customized or replaced by by overriding:

- `__repr__`: A default repr for the ExtensionArray.
- `_formatter`: Print scalars inside a Series or DataFrame.

Some methods require casting the ExtensionArray to an ndarray of Python objects with `self.astype(object)`, which may be expensive. When performance is a concern, we highly recommend overriding the following methods:

- `fillna`
- `dropna`
- `unique`
- `factorize` / `_values_for_factorize`
- `argsort` / `_values_for_argsort`
- `searchsorted`

The remaining methods implemented on this class should be performant, as they only compose abstract methods. Still, a more efficient implementation may be available, and these methods can be overridden.

One can implement methods to handle array reductions.

- `reduce`

One can implement methods to handle parsing from strings that will be used in methods such as `pandas.io.parsers.read_csv`.

- `_from_sequence_of_strings`

This class does not inherit from `abc.ABCMeta` for performance reasons. Methods and properties required by the interface raise `pandas.errors(AbstractMethodError)` and no `register` method is provided for registering virtual subclasses.

ExtensionArrays are limited to 1 dimension.

They may be backed by none, one, or many NumPy arrays. For example, `pandas.Categorical` is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 address may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists. Pandas makes no assumptions on how the data are stored, just that it can be converted to a NumPy array. The ExtensionArray interface does not impose any rules on how this data is stored. However, currently, the backing data cannot be stored in attributes called `.values` or `._values` to ensure full compatibility with pandas internals. But other names as `.data`, `._data`, `._items`, ... can be freely used.

If implementing NumPy's `__array_ufunc__` interface, pandas expects that

1. You defer by returning `NotImplemented` when any Series are present in `inputs`. Pandas will extract the arrays and call the ufunc again.
2. You define a `_HANDLED_TYPES` tuple as an attribute on the class. Pandas inspect this to determine whether the ufunc is valid for the types present.

See NumPy universal functions for more.
By default, ExtensionArrays are not hashable. Immutable subclasses may override this behavior.

**pandas.api.extensions.ExtensionArray.argsort**

ExtensionArray.argsort (ascending=True, kind='quicksort', *args, **kwargs)

Return the indices that would sort this array.

**Parameters**

- `ascending` [bool, default True] Whether the indices should result in an ascending or descending sort.
- `*args, **kwargs`: Passed through to numpy.argsort().

**Returns**

- `ndarray`: Array of indices that sort self. If NaN values are contained, NaN values are placed at the end.

**See also:**

- numpy.argsort: Sorting implementation used internally.

**pandas.api.extensions.ExtensionArray.astype**

ExtensionArray.astype (dtype, copy=True)

Cast to a NumPy array with 'dtype'.

**Parameters**

- `dtype` [str or dtype] Typecode or data-type to which the array is cast.
- `copy` [bool, default True] Whether to copy the data, even if not necessary. If False, a copy is made only if the old dtype does not match the new dtype.

**Returns**

- `array`: NumPy ndarray with ‘dtype’ for its dtype.
pandas.api.extensions.ExtensionArray.copy

ExtensionArray.copy()
Return a copy of the array.

Returns
ExtensionArray

pandas.api.extensions.ExtensionArray.dropna

ExtensionArray.dropna()
Return ExtensionArray without NA values.

Returns
valid [ExtensionArray]

pandas.api.extensions.ExtensionArray.factorize

ExtensionArray.factorize(na_sentinel=-1)
Encode the extension array as an enumerated type.

Parameters
na_sentinel [int, default -1] Value to use in the codes array to indicate missing values.

Returns
codes [ndarray] An integer NumPy array that’s an indexer into the original ExtensionArray.
uniques [ExtensionArray] An ExtensionArray containing the unique values of self.

Note: uniques will not contain an entry for the NA value of the ExtensionArray if there are any missing values present in self.

See also:
factorize Top-level factorize method that dispatches here.

Notes

pandas.factorize() offers a sort keyword as well.
**pandas.api.extensions.ExtensionArrayfillna**

`ExtensionArray.fillna(value=None, method=None, limit=None)`  
Fill NA/NaN values using the specified method.

**Parameters**

- **value** [scalar, array-like] If a scalar value is passed it is used to fill all missing values. Alternatively, an array-like `value` can be given. It’s expected that the array-like have the same length as `self`.
- **method** [{'backfill', 'bfill', 'pad', 'ffill', None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use NEXT valid observation to fill gap.
- **limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled.

**Returns**

- `ExtensionArray` With NA/NaN filled.

**pandas.api.extensions.ExtensionArray.equals**

`ExtensionArray.equals(other)`  
Return if another array is equivalent to this array.

Equivalent means that both arrays have the same shape and dtype, and all values compare equal. Missing values in the same location are considered equal (in contrast with normal equality).

**Parameters**

- **other** [ExtensionArray] Array to compare to this Array.

**Returns**

- boolean Whether the arrays are equivalent.

**pandas.api.extensions.ExtensionArray.isna**

`ExtensionArray.isna()`  
A 1-D array indicating if each value is missing.

**Returns**

- `na_values` [Union[np.ndarray, ExtensionArray]] In most cases, this should return a NumPy ndarray. For exceptional cases like SparseArray, where returning an ndarray would be expensive, an ExtensionArray may be returned.
Notes

If returning an ExtensionArray, then

- `na_values._is_boolean` should be `True`
- `na_values` should implement `ExtensionArray._reduce()`
- `na_values.any` and `na_values.all` should be implemented

**pandas.api.extensions.ExtensionArray.ravel**

*ExtensionArray.ravel (order='C')*

Return a flattened view on this array.

**Parameters**

**Returns**

- `ExtensionArray`

**Notes**

- Because ExtensionArrays are 1D-only, this is a no-op.
- The “order” argument is ignored, is for compatibility with NumPy.

**pandas.api.extensions.ExtensionArray.repeat**

*ExtensionArray.repeat (repeats, axis=None)*

Repeat elements of a ExtensionArray.

Returns a new ExtensionArray where each element of the current ExtensionArray is repeated consecutively a given number of times.

**Parameters**

- `repeats` [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty ExtensionArray.
- `axis` [None] Must be None. Has no effect but is accepted for compatibility with numpy.

**Returns**

- `repeated_array` [ExtensionArray] Newly created ExtensionArray with repeated elements.

See also:

- `Series.repeat` Equivalent function for Series.
- `Index.repeat` Equivalent function for Index.
- `numpy.repeat` Similar method for `numpy.ndarray`.

- `ExtensionArray.take` Take arbitrary positions.
Examples

```python
>>> cat = pd.Categorical(['a', 'b', 'c'])
>>> cat
['a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']

>>> cat.repeat(2)
['a', 'a', 'b', 'b', 'c', 'c']
Categories (3, object): ['a', 'b', 'c']

>>> cat.repeat([1, 2, 3])
['a', 'b', 'b', 'c', 'c', 'c']
Categories (3, object): ['a', 'b', 'c']
```

```
pandas.api.extensions.ExtensionArray.searchsorted

ExtensionArray.searchsorted(value, side='left', sorter=None)

Find indices where elements should be inserted to maintain order.

New in version 0.24.0.

Find the indices into a sorted array `self` (a) such that, if the corresponding elements in `value` were inserted before the indices, the order of `self` would be preserved.

Assuming that `self` is sorted:

<table>
<thead>
<tr>
<th><code>side</code></th>
<th>returned index i satisfies</th>
</tr>
</thead>
<tbody>
<tr>
<td>left</td>
<td>self[i-1] &lt; value &lt;= self[i]</td>
</tr>
<tr>
<td>right</td>
<td>self[i-1] &lt;= value &lt; self[i]</td>
</tr>
</tbody>
</table>

Parameters

- **value** [array_like] Values to insert into `self`.
- **side** [{‘left’, ‘right’}, optional] If ‘left’, the index of the first suitable location found is given. If ‘right’, return the last such index. If there is no suitable index, return either 0 or N (where N is the length of `self`).
- **sorter** [1-D array_like, optional] Optional array of integer indices that sort array a into ascending order. They are typically the result of argsort.

Returns

- **array of ints** Array of insertion points with the same shape as `value`.

See also:

- `numpy.searchsorted` Similar method from NumPy.
```
pandas.api.extensions.ExtensionArray.shift

ExtensionArray.shift(periods=1, fill_value=None)
Shift values by desired number.
Newly introduced missing values are filled with self.dtype.na_value.
New in version 0.24.0.

Parameters

- **periods** [int, default 1] The number of periods to shift. Negative values are allowed for shifting backwards.
- **fill_value** [object, optional] The scalar value to use for newly introduced missing values. The default is self.dtype.na_value.

New in version 0.24.0.

Returns

ExtensionArray Shifted.

Notes

- If self is empty or periods is 0, a copy of self is returned.
- If periods > len(self), then an array of size len(self) is returned, with all values filled with self.dtype.na_value.

pandas.api.extensions.ExtensionArray.take

ExtensionArray.take(indices, allow_fill=False, fill_value=None)
Take elements from an array.

Parameters

- **indices** [sequence of int] Indices to be taken.
- **allow_fill** [bool, default False] How to handle negative values in indices.
  - False: negative values in indices indicate positional indices from the right (the default). This is similar to numpy.take().
  - True: negative values in indices indicate missing values. These values are set to fill_value. Any other other negative values raise a ValueError.
- **fill_value** [any, optional] Fill value to use for NA-indices when allow_fill is True. This may be None, in which case the default NA value for the type, self.dtype.na_value, is used.

For many ExtensionArrays, there will be two representations of fill_value: a user-facing “boxed” scalar, and a low-level physical NA value. fill_value should be the user-facing version, and the implementation should handle translating that to the physical version for processing the take if necessary.

Returns

ExtensionArray

Raises
**IndexError**  When the indices are out of bounds for the array.

**ValueError**  When *indices* contains negative values other than -1 and *allow_fill* is True.

See also:

numpy.take

api.extensions.take

Notes

ExtensionArray.take is called by Series.__getitem__, .loc, iloc, when *indices* is a sequence of values. Additionally, it’s called by Series.reindex(), or any other method that causes realignment, with a fill_value.

Examples

Here’s an example implementation, which relies on casting the extension array to object dtype. This uses the helper method pandas.api.extensions.take().

```python

def take(self, indices, allow_fill=False, fill_value=None):
    from pandas.core.algorithms import take

    # If the ExtensionArray is backed by an ndarray, then
    # just pass that here instead of coercing to object.
    data = self.astype(object)

    if allow_fill and fill_value is None:
        fill_value = self.dtype.na_value

    # fill value should always be translated from the scalar
    # type for the array, to the physical storage type for
    # the data, before passing to take.

    result = take(data, indices, fill_value=fill_value,
                  allow_fill=allow_fill)
    return self._from_sequence(result, dtype=self.dtype)
```

pandas.api.extensions.ExtensionArray.unique

ExtensionArray.unique()

Compute the ExtensionArray of unique values.

Returns

uniques  [ExtensionArray]
pandas.api.extensions.ExtensionArray.view

ExtensionArray.view(dtype=None)
Return a view on the array.

Parameters

dtype  [str, np.dtype, or ExtensionDtype, optional] Default None.

Returns

ExtensionArray or np.ndarray A view on the ExtensionArray’s data.

pandas.api.extensions.ExtensionArray._concat_same_type

classmethod ExtensionArray._concat_same_type(to_concat)
Concatenate multiple array of this dtype.

Parameters

to_concat  [sequence of this type]

Returns

ExtensionArray

pandas.api.extensions.ExtensionArray._formatter

ExtensionArray._formatter(boxed=False)
Formatting function for scalar values.
This is used in the default ‘__repr__’. The returned formatting function receives instances of your scalar type.

Parameters

boxed  [bool, default False] An indicated for whether or not your array is being printed within a Series, DataFrame, or Index (True), or just by itself (False). This may be useful if you want scalar values to appear differently within a Series versus on its own (e.g. quoted or not).

Returns

Callable[[Any], str] A callable that gets instances of the scalar type and returns a string. By default, repr() is used when boxed=False and str() is used when boxed=True.

pandas.api.extensions.ExtensionArray._from_factorized

classmethod ExtensionArray._from_factorized(values, original)
Reconstruct an ExtensionArray after factorization.

Parameters

values  [ndarray] An integer ndarray with the factorized values.

original  [ExtensionArray] The original ExtensionArray that factorize was called on.

See also:
factorize

ExtensionArray.factorize

pandas.api.extensions.ExtensionArray._from_sequence

classmethod ExtensionArray._from_sequence(scalars, dtype=None, copy=False)
Construct a new ExtensionArray from a sequence of scalars.

Parameters

- **scalars** [Sequence] Each element will be an instance of the scalar type for this array,
  cls.dtype.type or be converted into this type in this method.
- **dtype** [dtype, optional] Construct for this particular dtype. This should be a Dtype
  compatible with the ExtensionArray.
- **copy** [bool, default False] If True, copy the underlying data.

Returns

- ExtensionArray

pandas.api.extensions.ExtensionArray._from_sequence_of_strings

classmethod ExtensionArray._from_sequence_of_strings(strings, dtype=None, copy=False)
Construct a new ExtensionArray from a sequence of strings.

New in version 0.24.0.

Parameters

- **strings** [Sequence] Each element will be an instance of the scalar type for this array,
  cls.dtype.type.
- **dtype** [dtype, optional] Construct for this particular dtype. This should be a Dtype
  compatible with the ExtensionArray.
- **copy** [bool, default False] If True, copy the underlying data.

Returns

- ExtensionArray

pandas.api.extensions.ExtensionArray._reduce

ExtensionArray._reduce(name, skipna=True, **kwargs)
Return a scalar result of performing the reduction operation.

Parameters

- **name** [str] Name of the function, supported values are: { any, all, min, max, sum,
  mean, median, prod, std, var, sem, kurt, skew }.
- **skipna** [bool, default True] If True, skip NaN values.
- ****kwarg Additional keyword arguments passed to the reduction function. Currently,
  ddo is the only supported kwarg.

Returns
### pandas.api.extensions.ExtensionArray._values_for_argsort

**ExtensionArray._values_for_argsort()**

Return values for sorting.

**Returns**

- **ndarray**: The transformed values should maintain the ordering between values within the array.

**See also:**

*ExtensionArray.argsort*

### pandas.api.extensions.ExtensionArray._values_for_factorize

**ExtensionArray._values_for_factorize()**

Return an array and missing value suitable for factorization.

**Returns**

- **values** [ndarray]: An array suitable for factorization. This should maintain order and be a supported dtype (Float64, Int64, UInt64, String, Object). By default, the extension array is cast to object dtype.
- **na_value** [object]: The value in values to consider missing. This will be treated as NA in the factorization routines, so it will be coded as `na_sentinel` and not included in uniques. By default, `np.nan` is used.

**Notes**

The values returned by this method are also used in `pandas.util.hash_pandas_object()`.

### 3.16.7 pandas.arrays.PandasArray

**class pandas.arrays.PandasArray(values, copy=False)**

A pandas ExtensionArray for NumPy data.

New in version 0.24.0.

This is mostly for internal compatibility, and is not especially useful on its own.

**Parameters**

- **values** [ndarray]: The NumPy ndarray to wrap. Must be 1-dimensional.
- **copy** [bool, default False]: Whether to copy values.
Attributes

None

Methods

None

Additionally, we have some utility methods for ensuring your object behaves correctly.

\[\text{api.indexers.check_array_indexer(array, indexer)}\]

Check if \textit{indexer} is a valid array indexer for \textit{array}.

3.16.8 pandas.api.indexers.check_array_indexer

\texttt{pandas.api.indexers.check_array_indexer} \texttt{(array, indexer)}

Check if \textit{indexer} is a valid array indexer for \textit{array}.

For a boolean mask, \textit{array} and \textit{indexer} are checked to have the same length. The dtype is validated, and if it is an integer or boolean ExtensionArray, it is checked if there are missing values present, and it is converted to the appropriate numpy array. Other dtypes will raise an error.

Non-array indexers (integer, slice, Ellipsis, tuples, ..) are passed through as is.

New in version 1.0.0.

Parameters

- \texttt{array} \ [array-like] The array that is being indexed (only used for the length).
- \texttt{indexer} \ [array-like or list-like] The array-like that’s used to index. List-like input that is not yet a numpy array or an ExtensionArray is converted to one. Other input types are passed through as is.

Returns

- \texttt{numpy.ndarray} The validated indexer as a numpy array that can be used to index.

Raises

- \texttt{IndexError} When the lengths don’t match.
- \texttt{ValueError} When \textit{indexer} cannot be converted to a numpy ndarray to index (e.g. presence of missing values).

See also:

- \texttt{api.types.is_bool_dtype} Check if \textit{key} is of boolean dtype.
Examples

When checking a boolean mask, a boolean ndarray is returned when the arguments are all valid.

```python
>>> mask = pd.array([True, False])
>>> arr = pd.array([1, 2])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([True, False])
```

An IndexError is raised when the lengths don’t match.

```python
>>> mask = pd.array([True, False, True])
>>> pd.api.indexers.check_array_indexer(arr, mask)
Traceback (most recent call last):
  ...
IndexError: Boolean index has wrong length: 3 instead of 2.
```

NA values in a boolean array are treated as False.

```python
>>> mask = pd.array([True, pd.NA])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([True, False])
```

A numpy boolean mask will get passed through (if the length is correct):

```python
>>> mask = np.array([True, False])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([True, False])
```

Similarly for integer indexers, an integer ndarray is returned when it is a valid indexer, otherwise an error is (for integer indexers, a matching length is not required):

```python
>>> indexer = pd.array([0, 2], dtype="Int64")
>>> arr = pd.array([1, 2, 3])
>>> pd.api.indexers.check_array_indexer(arr, indexer)
array([0, 2])
```

```python
>>> indexer = pd.array([0, pd.NA], dtype="Int64")
>>> pd.api.indexers.check_array_indexer(arr, indexer)
Traceback (most recent call last):
  ...
ValueError: Cannot index with an integer indexer containing NA values
```

For non-integer/boolean dtypes, an appropriate error is raised:

```python
>>> indexer = np.array([0., 2.], dtype="float64")
>>> pd.api.indexers.check_array_indexer(arr, indexer)
Traceback (most recent call last):
  ...
IndexError: arrays used as indices must be of integer or boolean type
```

The sentinel `pandas.api.extensions.no_default` is used as the default value in some methods. Use an is comparison to check if the user provides a non-default value.

All contributions, bug reports, bug fixes, documentation improvements, enhancements, and ideas are welcome.

If you are brand new to pandas or open-source development, we recommend going through the GitHub “issues” tab to find issues that interest you. There are a number of issues listed under Docs and good first issue where you could start out. Once you’ve found an interesting issue, you can return here to get your development environment setup.

When you start working on an issue, it’s a good idea to assign the issue to yourself, so nobody else duplicates the work on it. GitHub restricts assigning issues to maintainers of the project only. In most projects, and until recently in pandas, contributors added a comment letting others know they are working on an issue. While this is ok, you need to check each issue individually, and it’s not possible to find the unassigned ones.

For this reason, we implemented a workaround consisting of adding a comment with the exact text `take`. When you do
it, a GitHub action will automatically assign you the issue (this will take seconds, and may require refreshing the page to see it). By doing this, it’s possible to filter the list of issues and find only the unassigned ones.

So, a good way to find an issue to start contributing to pandas is to check the list of unassigned good first issues and assign yourself one you like by writing a comment with the exact text `take`.

If for whatever reason you are not able to continue working with the issue, please try to unassign it, so other people know it’s available again. You can check the list of assigned issues, since people may not be working in them anymore. If you want to work on one that is assigned, feel free to kindly ask the current assignee if you can take it (please allow at least a week of inactivity before considering work in the issue discontinued).

Feel free to ask questions on the mailing list or on Gitter.

### 4.1.2 Bug reports and enhancement requests

Bug reports are an important part of making pandas more stable. Having a complete bug report will allow others to reproduce the bug and provide insight into fixing. See this stackoverflow article and this blogpost for tips on writing a good bug report.

Trying the bug-producing code out on the master branch is often a worthwhile exercise to confirm the bug still exists. It is also worth searching existing bug reports and pull requests to see if the issue has already been reported and/or fixed.

Bug reports must:

1. Include a short, self-contained Python snippet reproducing the problem. You can format the code nicely by using GitHub Flavored Markdown:

```python
>>> from pandas import DataFrame
>>> df = DataFrame(...)
...```

2. Include the full version string of pandas and its dependencies. You can use the built-in function:

```python
>>> import pandas as pd
>>> pd.show_versions()
```

3. Explain why the current behavior is wrong/not desired and what you expect instead.

The issue will then show up to the pandas community and be open to comments/ideas from others.

### 4.1.3 Working with the code

Now that you have an issue you want to fix, enhancement to add, or documentation to improve, you need to learn how to work with GitHub and the pandas code base.
Version control, Git, and GitHub

To the new user, working with Git is one of the more daunting aspects of contributing to pandas. It can very quickly become overwhelming, but sticking to the guidelines below will help keep the process straightforward and mostly trouble free. As always, if you are having difficulties please feel free to ask for help.

The code is hosted on GitHub. To contribute you will need to sign up for a free GitHub account. We use Git for version control to allow many people to work together on the project.

Some great resources for learning Git:

- the GitHub help pages.
- the NumPy’s documentation.
- Matthew Brett’s Pydagogue.

Getting started with Git

GitHub has instructions for installing git, setting up your SSH key, and configuring git. All these steps need to be completed before you can work seamlessly between your local repository and GitHub.

Forking

You will need your own fork to work on the code. Go to the pandas project page and hit the Fork button. You will want to clone your fork to your machine:

```bash
git clone https://github.com/your-user-name/pandas.git pandas-yourname
cd pandas-yourname
git remote add upstream https://github.com/pandas-dev/pandas.git
```

This creates the directory `pandas-yourname` and connects your repository to the upstream (main project) `pandas` repository.

Note that performing a shallow clone (with `--depth=N`, for some N greater or equal to 1) might break some tests and features as `pd.show_versions()` as the version number cannot be computed anymore.

Creating a development environment

To test out code changes, you’ll need to build pandas from source, which requires a C compiler and Python environment. If you’re making documentation changes, you can skip to Contributing to the documentation but you won’t be able to build the documentation locally before pushing your changes.

Using a Docker container

Instead of manually setting up a development environment, you can use Docker to automatically create the environment with just several commands. Pandas provides a DockerFile in the root directory to build a Docker image with a full pandas development environment.

Even easier, you can use the DockerFile to launch a remote session with Visual Studio Code, a popular free IDE, using the `.devcontainer.json` file. See https://code.visualstudio.com/docs/remote/containers for details.
Installing a C compiler

Pandas uses C extensions (mostly written using Cython) to speed up certain operations. To install pandas from source, you need to compile these C extensions, which means you need a C compiler. This process depends on which platform you’re using.

**Windows**

**Mac OS**

Information about compiler installation can be found here: https://devguide.python.org/setup/#macos

**Unix**

Some Linux distributions will come with a pre-installed C compiler. To find out which compilers (and versions) are installed on your system:

```bash
# for Debian/Ubuntu:
dpkg --list | grep compiler
# for Red Hat/RHEL/CentOS/Fedora:
yum list installed | grep -i --color compiler
```

GCC (GNU Compiler Collection), is a widely used compiler, which supports C and a number of other languages. If GCC is listed as an installed compiler nothing more is required. If no C compiler is installed (or you wish to install a newer version) you can install a compiler (GCC in the example code below) with:

```bash
# for recent Debian/Ubuntu:
sudo apt install build-essential
# for Red Hat/RHEL/CentOS/Fedora
yum groupinstall "Development Tools"
```

For other Linux distributions, consult your favourite search engine for compiler installation instructions.

Let us know if you have any difficulties by opening an issue or reaching out on Gitter.

Creating a Python environment

Now that you have a C compiler, create an isolated pandas development environment:

- Install either Anaconda or miniconda
- Make sure your conda is up to date (conda update conda)
- Make sure that you have cloned the repository
- cd to the pandas source directory

We’ll now kick off a three-step process:

1. Install the build dependencies
2. Build and install pandas
3. Install the optional dependencies
# Create and activate the build environment
conda env create -f environment.yml
conda activate pandas-dev

# or with older versions of Anaconda:
source activate pandas-dev

# Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517

At this point you should be able to import pandas from your locally built version:

```
$ python  # start an interpreter
>>> import pandas
0.22.0.dev0+29.g4ad6d4d74
```

This will create the new environment, and not touch any of your existing environments, nor any existing Python installation.

To view your environments:

```
conda info -e
```

To return to your root environment:

```
conda deactivate
```

See the full conda docs here.

### Creating a Python environment (pip)

If you aren’t using conda for your development environment, follow these instructions. You’ll need to have at least Python 3.6.1 installed on your system.

#### Unix/Mac OS with virtualenv

```
# Create a virtual environment
# Use an ENV_DIR of your choice. We’ll use ~/virtualenvs/pandas-dev
# Any parent directories should already exist
python3 -m venv ~/virtualenvs/pandas-dev

# Activate the virtualenv
. ~/virtualenvs/pandas-dev/bin/activate

# Install the build dependencies
python -m pip install -r requirements-dev.txt

# Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517
```

#### Unix/Mac OS with pyenv

Consult the docs for setting up pyenv here.
# Create a virtual environment
# Use an ENV_DIR of your choice. We'll use ~/Users/<yourname>/.pyenv/versions/pandas-dev

pyenv virtualenv <version> <name-to-give-it>

# For instance:
pyenv virtualenv 3.7.6 pandas-dev

# Activate the virtualenv
pyenv activate pandas-dev

# Now install the build dependencies in the cloned pandas repo
python -m pip install -r requirements-dev.txt

# Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517

Windows

Below is a brief overview on how to set-up a virtual environment with Powershell under Windows. For details please refer to the official virtualenv user guide

Use an ENV_DIR of your choice. We'll use ~\virtualenvs\pandas-dev where '~' is the folder pointed to by either $env:USERPROFILE (Powershell) or %USERPROFILE% (cmd.exe) environment variable. Any parent directories should already exist.

# Create a virtual environment
python -m venv $env:USERPROFILE\virtualenvs\pandas-dev

# Activate the virtualenv. Use activate.bat for cmd.exe
~\virtualenvs\pandas-dev\Scripts\Activate.ps1

# Install the build dependencies
python -m pip install -r requirements-dev.txt

# Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517

Creating a branch

You want your master branch to reflect only production-ready code, so create a feature branch for making your changes. For example:

git branch shiny-new-feature
git checkout shiny-new-feature

The above can be simplified to:

git checkout -b shiny-new-feature

This changes your working directory to the shiny-new-feature branch. Keep any changes in this branch specific to one bug or feature so it is clear what the branch brings to pandas. You can have many shiny-new-features and switch in between them using the git checkout command.
When creating this branch, make sure your master branch is up to date with the latest upstream master version. To update your local master branch, you can do:

```
git checkout master
git pull upstream master --ff-only
```

When you want to update the feature branch with changes in master after you created the branch, check the section on updating a PR.

### 4.1.4 Contributing to the documentation

Contributing to the documentation benefits everyone who uses pandas. We encourage you to help us improve the documentation, and you don’t have to be an expert on pandas to do so! In fact, there are sections of the docs that are worse off after being written by experts. If something in the docs doesn’t make sense to you, updating the relevant section after you figure it out is a great way to ensure it will help the next person.

**Documentation:**

- About the pandas documentation
- Updating a pandas docstring
- How to build the pandas documentation
  - Requirements
  - Building the documentation
  - Building master branch documentation

**About the pandas documentation**

The documentation is written in **reStructuredText**, which is almost like writing in plain English, and built using **Sphinx**. The Sphinx Documentation has an excellent introduction to reST. Review the Sphinx docs to perform more complex changes to the documentation as well.

Some other important things to know about the docs:

- The pandas documentation consists of two parts: the docstrings in the code itself and the docs in this folder `doc/`.
  
  The docstrings provide a clear explanation of the usage of the individual functions, while the documentation in this folder consists of tutorial-like overviews per topic together with some other information (what’s new, installation, etc).

- The docstrings follow a pandas convention, based on the **Numpy Docstring Standard**. Follow the **pandas docstring guide** for detailed instructions on how to write a correct docstring.
**pandas docstring guide**

**About docstrings and standards**

A Python docstring is a string used to document a Python module, class, function or method, so programmers can understand what it does without having to read the details of the implementation.

Also, it is a common practice to generate online (html) documentation automatically from docstrings. Sphinx serves this purpose.

The next example gives an idea of what a docstring looks like:

```python
def add(num1, num2):
    
    """
    Add up two integer numbers.
    
    This function simply wraps the `+` operator, and does not do anything interesting, except for illustrating what the docstring of a very simple function looks like.
    
    Parameters
    ----------
    num1 : int
        First number to add
    num2 : int
        Second number to add
    
    Returns
    -------
    int
        The sum of `num1` and `num2`
    
    See Also
    --------
    subtract : Subtract one integer from another
    
    Examples
    --------
    >>> add(2, 2)
    4
    >>> add(25, 0)
    25
    >>> add(10, -10)
    0
    """
    return num1 + num2
```

Some standards regarding docstrings exist, which make them easier to read, and allow them be easily exported to other formats such as html or pdf.

The first conventions every Python docstring should follow are defined in PEP-257.

As PEP-257 is quite broad, other more specific standards also exist. In the case of pandas, the numpy docstring convention is followed. These conventions are explained in this document:

- `numpydoc docstring guide` (which is based in the original Guide to NumPy/SciPy documentation)

`numpydoc` is a Sphinx extension to support the numpy docstring convention.

---

4.1. Contributing to pandas
The standard uses reStructuredText (reST). reStructuredText is a markup language that allows encoding styles in plain text files. Documentation about reStructuredText can be found in:

- Sphinx reStructuredText primer
- Quick reStructuredText reference
- Full reStructuredText specification

pandas has some helpers for sharing docstrings between related classes, see *Sharing docstrings*.

The rest of this document will summarize all the above guidelines, and will provide additional conventions specific to the pandas project.

**Writing a docstring**

**General rules**

Docstrings must be defined with three double-quotes. No blank lines should be left before or after the docstring. The text starts in the next line after the opening quotes. The closing quotes have their own line (meaning that they are not at the end of the last sentence).

On rare occasions reST styles like bold text or italics will be used in docstrings, but is it common to have inline code, which is presented between backticks. The following are considered inline code:

- The name of a parameter
- Python code, a module, function, built-in, type, literal... (e.g. `os, list, numpy.abs, datetime.date, True`)
- A pandas class (in the form `:class:`*pandas.Series* `)
- A pandas method (in the form `:meth:`*pandas.Series.sum* `)
- A pandas function (in the form `:func:`*pandas.to_datetime* `)

**Note:** To display only the last component of the linked class, method or function, prefix it with ~. For example, `:class:`~pandas.Series` will link to pandas.Series but only display the last part, Series as the link text. See Sphinx cross-referencing syntax for details.

**Good:**

```python
def add_values(arr):
    ""
    Add the values in `arr`.

    This is equivalent to Python `sum` of :meth:`pandas.Series.sum`.

    Some sections are omitted here for simplicity.
    ""
    return sum(arr)
```

**Bad:**

```python
def func():
    """Some function.
```
With several mistakes in the docstring.

It has a blank like after the signature `def func():`.

The text 'Some function' should go in the line after the opening quotes of the docstring, not in the same line.

There is a blank line between the docstring and the first line of code `foo = 1`.

The closing quotes should be in the next line, not in this one.""

```python
foo = 1
bar = 2
return foo + bar
```

Section 1: short summary

The short summary is a single sentence that expresses what the function does in a concise way.

The short summary must start with a capital letter, end with a dot, and fit in a single line. It needs to express what the object does without providing details. For functions and methods, the short summary must start with an infinitive verb.

Good:

```python
def astype(dtype):
    ""
    Cast Series type.

    This section will provide further details.
    ""
    pass
```

Bad:

```python
def astype(dtype):
    ""
    Casts Series type.

    Verb in third-person of the present simple, should be infinitive.
    ""
    pass
```

```python
def astype(dtype):
    ""
    Method to cast Series type.

    Does not start with verb.
    ""
    pass
```

(continues on next page)
Section 2: extended summary

The extended summary provides details on what the function does. It should not go into the details of the parameters, or discuss implementation notes, which go in other sections.

A blank line is left between the short summary and the extended summary. Every paragraph in the extended summary ends with a dot.

The extended summary should provide details on why the function is useful and their use cases, if it is not too generic.

Section 3: parameters

The details of the parameters will be added in this section. This section has the title “Parameters”, followed by a line with a hyphen under each letter of the word “Parameters”. A blank line is left before the section title, but not after, and not between the line with the word “Parameters” and the one with the hyphens.

After the title, each parameter in the signature must be documented, including *args and **kwargs, but not self.

The parameters are defined by their name, followed by a space, a colon, another space, and the type (or types). Note that the space between the name and the colon is important. Types are not defined for *args and **kwargs, but must be defined for all other parameters. After the parameter definition, it is required to have a line with the parameter description, which is indented, and can have multiple lines. The description must start with a capital letter, and finish with a dot.
For keyword arguments with a default value, the default will be listed after a comma at the end of the type. The exact form of the type in this case will be “int, default 0”. In some cases it may be useful to explain what the default argument means, which can be added after a comma “int, default -1, meaning all cpus”.

In cases where the default value is None, meaning that the value will not be used. Instead of “str, default None”, it is preferred to write “str, optional”. When None is a value being used, we will keep the form “str, default None”. For example, in `df.to_csv(compression=)`, None is not a value being used, but means that compression is optional, and no compression is being used if not provided. In this case we will use `str, optional`. Only in cases like `func(value=None)` and None is being used in the same way as 0 or foo would be used, then we will specify “str, int or None, default None”.

**Good:**

```python
class Series:
    def plot(self, kind, color='blue', **kwargs):
        ""
        Generate a plot.
        Render the data in the Series as a matplotlib plot of the specified kind.

        Parameters
        ----------
        kind : str
            Kind of matplotlib plot.
        color : str, default 'blue'
            Color name or rgb code.
        **kwargs
            These parameters will be passed to the matplotlib plotting function.
        ""
        pass
```

**Bad:**

```python
class Series:
    def plot(self, kind, **kwargs):
        ""
        Generate a plot.
        Render the data in the Series as a matplotlib plot of the specified kind.

        Note the blank line between the parameters title and the first parameter. Also, note that after the name of the parameter `kind` and before the colon, a space is missing.

        Also, note that the parameter descriptions do not start with a capital letter, and do not finish with a dot.

        Finally, the `**kwargs` parameter is missing.

        Parameters
        ----------
        kind: str
            kind of matplotlib plot
        ""
```

(continues on next page)
Parameter types

When specifying the parameter types, Python built-in data types can be used directly (the Python type is preferred to the more verbose string, integer, boolean, etc):

- int
- float
- str
- bool

For complex types, define the subtypes. For `dict` and `tuple`, as more than one type is present, we use the brackets to help read the type (curly brackets for `dict` and normal brackets for `tuple`):

- list of int
- dict of {str : int}
- tuple of (str, int, int)
- tuple of (str,)
- set of str

In case where there are just a set of values allowed, list them in curly brackets and separated by commas (followed by a space). If the values are ordinal and they have an order, list them in this order. Otherwise, list the default value first, if there is one:

- {0, 10, 25}
- {'simple', 'advanced'}
- {'low', 'medium', 'high'}
- {'cat', 'dog', 'bird'}

If the type is defined in a Python module, the module must be specified:

- datetime.date
- datetime.datetime
- decimal.Decimal

If the type is in a package, the module must be also specified:

- numpy.ndarray
- scipy.sparse.coo_matrix

If the type is a pandas type, also specify pandas except for `Series` and `DataFrame`:

- Series
- DataFrame
- pandas.Index
- pandas.Categorical
- pandas.arrays.SparseArray
If the exact type is not relevant, but must be compatible with a numpy array, array-like can be specified. If any type that can be iterated is accepted, iterable can be used:

- array-like
- iterable

If more than one type is accepted, separate them by commas, except the last two types, that need to be separated by the word ‘or’:

- int or float
- float, decimal.Decimal or None
- str or list of str

If None is one of the accepted values, it always needs to be the last in the list.

For axis, the convention is to use something like:

- axis: {0 or ‘index’, 1 or ‘columns’, None}, default None

Section 4: returns or yields

If the method returns a value, it will be documented in this section. Also if the method yields its output.

The title of the section will be defined in the same way as the “Parameters”. With the names “Returns” or “Yields” followed by a line with as many hyphens as the letters in the preceding word.

The documentation of the return is also similar to the parameters. But in this case, no name will be provided, unless the method returns or yields more than one value (a tuple of values).

The types for “Returns” and “Yields” are the same as the ones for the “Parameters”. Also, the description must finish with a dot.

For example, with a single value:

```python
def sample():
    """
    Generate and return a random number.
    The value is sampled from a continuous uniform distribution between 0 and 1.
    Returns
    -------
    float
    Random number generated.
    """
    return np.random.random()
```

With more than one value:

```python
import string

def random_letters():
    """
    Generate and return a sequence of random letters.
    The length of the returned string is also random, and is also returned.
    """
    return string.ascii_letters
```

(continues on next page)
Returns
-------
length : int
  Length of the returned string.
letters : str
  String of random letters.

""
length = np.random.randint(1, 10)
letters = ''.join(np.random.choice(string.ascii_lowercase)
               for i in range(length))
return length, letters

If the method yields its value:

def sample_values():
    ""
    Generate an infinite sequence of random numbers.
    
The values are sampled from a continuous uniform distribution between
0 and 1.
    ""
    Yields
    ------
    float
      Random number generated.
    ""
    while True:
        yield np.random.random()

Section 5: see also

This section is used to let users know about pandas functionality related to the one being documented. In rare
cases, if no related methods or functions can be found at all, this section can be skipped.

An obvious example would be the head() and tail() methods. As tail() does the equivalent as head() but at the
end of the Series or DataFrame instead of at the beginning, it is good to let the users know about it.

To give an intuition on what can be considered related, here there are some examples:

- loc and iloc, as they do the same, but in one case providing indices and in the other positions
- max and min, as they do the opposite
- iterrows, itertuples and items, as it is easy that a user looking for the method to iterate over
columns ends up in the method to iterate over rows, and vice-versa
- fillna and dropna, as both methods are used to handle missing values
- read_csv and to_csv, as they are complementary
- merge and join, as one is a generalization of the other
- astype and pandas.to_datetime, as users may be reading the documentation of astype to know
how to cast as a date, and the way to do it is with pandas.to_datetime
- where is related to numpy.where, as its functionality is based on it
When deciding what is related, you should mainly use your common sense and think about what can be useful for the users reading the documentation, especially the less experienced ones.

When relating to other libraries (mainly numpy), use the name of the module first (not an alias like np). If the function is in a module which is not the main one, like scipy.sparse, list the full module (e.g. scipy.sparse.coo_matrix).

This section has a header, “See Also” (note the capital S and A), followed by the line with hyphens and preceded by a blank line.

After the header, we will add a line for each related method or function, followed by a space, a colon, another space, and a short description that illustrates what this method or function does, why is it relevant in this context, and what the key differences are between the documented function and the one being referenced. The description must also end with a dot.

Note that in “Returns” and “Yields”, the description is located on the line after the type. In this section, however, it is located on the same line, with a colon in between. If the description does not fit on the same line, it can continue onto other lines which must be further indented.

For example:

```python
class Series:
    def head(self):
        """Return the first 5 elements of the Series.
        This function is mainly useful to preview the values of the Series without displaying the whole of it.
        """
        Returns
        ------
        Series
        Subset of the original series with the 5 first values.

        See Also
        -------
        Series.tail : Return the last 5 elements of the Series.
        Series.iloc : Return a slice of the elements in the Series, which can also be used to return the first or last n.
        """
        return self.iloc[:5]
```

**Section 6: notes**

This is an optional section used for notes about the implementation of the algorithm, or to document technical aspects of the function behavior.

Feel free to skip it, unless you are familiar with the implementation of the algorithm, or you discover some counter-intuitive behavior while writing the examples for the function.

This section follows the same format as the extended summary section.
Section 7: examples

This is one of the most important sections of a docstring, despite being placed in the last position, as often people understand concepts better by example than through accurate explanations.

Examples in docstrings, besides illustrating the usage of the function or method, must be valid Python code, that returns the given output in a deterministic way, and that can be copied and run by users.

Examples are presented as a session in the Python terminal. >>> is used to present code. … is used for code continuing from the previous line. Output is presented immediately after the last line of code generating the output (no blank lines in between). Comments describing the examples can be added with blank lines before and after them.

The way to present examples is as follows:

1. Import required libraries (except numpy and pandas)
2. Create the data required for the example
3. Show a very basic example that gives an idea of the most common use case
4. Add examples with explanations that give an idea of the most common use case

A simple example could be:

```python
class Series:

    def head(self, n=5):
        
        #
        # Return the first elements of the Series.
        #
        # This function is mainly useful to preview the values of the
        # Series without displaying all of it.
        #
        Parameters
        #
        # n : int
        #     Number of values to return.
        #
        Return
        #
        pandas.Series
        #     Subset of the original series with the n first values.
        #
        See Also
        #
        # tail : Return the last n elements of the Series.
        #
        Examples
        #
        >>> s = pd.Series(['Ant', 'Bear', 'Cow', 'Dog', 'Falcon',...
        #                    'Lion', 'Monkey', 'Rabbit', 'Zebra'])
        >>> s.head()
        0  Ant
        1  Bear
        2  Cow
        3  Dog
        4  Falcon
        dtype: object
```

(continues on next page)
With the `n` parameter, we can change the number of returned rows:

```python
>>> s.head(n=3)
0   Ant
1  Bear
2   Cow
dtype: object
```

```
""
return self.iloc[:n]
""
```

The examples should be as concise as possible. In cases where the complexity of the function requires long examples, it is recommended to use blocks with headers in bold. Use double star ** to make a text bold, like in **this example**.

**Conventions for the examples**

Code in examples is assumed to always start with these two lines which are not shown:

```python
import numpy as np
import pandas as pd
```

Any other module used in the examples must be explicitly imported, one per line (as recommended in PEP 8#imports) and avoiding aliases. Avoid excessive imports, but if needed, imports from the standard library go first, followed by third-party libraries (like matplotlib).

When illustrating examples with a single `Series` use the name `s`, and if illustrating with a single `DataFrame` use the name `df`. For indices, `idx` is the preferred name. If a set of homogeneous `Series` or `DataFrame` is used, name them `s1, s2, s3`.. or `df1, df2, df3`.. If the data is not homogeneous, and more than one structure is needed, name them with something meaningful, for example `df_main` and `df_to_join`.

Data used in the example should be as compact as possible. The number of rows is recommended to be around 4, but make it a number that makes sense for the specific example. For example in the `head` method, it requires to be higher than 5, to show the example with the default values. If doing the `mean`, we could use something like `[1, 2, 3]`, so it is easy to see that the value returned is the mean.

For more complex examples (grouping for example), avoid using data without interpretation, like a matrix of random numbers with columns A, B, C, D... And instead use a meaningful example, which makes it easier to understand the concept. Unless required by the example, use names of animals, to keep examples consistent. And numerical properties of them.

When calling the method, keywords arguments `head(n=3)` are preferred to positional arguments `head(3)`.

**Good:**

```python
class Series:
    
def mean(self):
        ""
        Compute the mean of the input.
        ""
        Examples
        -------
        >>> s = pd.Series([1, 2, 3])
        >>> s.mean()
        2
        ""
```
```python
deffillna(self, value):
    """
    Replace missing values by 'value'.
    
    Examples
    --------
    >>> s = pd.Series([1, np.nan, 3])
    >>> s.fillna(0)
    [1, 0, 3]
    """
    pass

def groupby_mean(self):
    """
    Group by index and return mean.
    
    Examples
    --------
    >>> s = pd.Series([380., 370., 24., 26],
    ...                 name='max_speed',
    ...                 index=['falcon', 'falcon', 'parrot', 'parrot'])
    >>> s.groupby_mean()
    index
    falcon     375.0
    parrot     25.0
    Name: max_speed, dtype: float64
    """
    pass

def contains(self, pattern, case_sensitive=True, na=numpy.nan):
    """
    Return whether each value contains 'pattern'.
    
    In this case, we are illustrating how to use sections, even
    if the example is simple enough and does not require them.
    
    Examples
    --------
    >>> s = pd.Series('Antelope', 'Lion', 'Zebra', np.nan)
    >>> s.contains(pattern='a')
    0 False
    1 False
    2  True
    3    NaN
    dtype: bool
    **Case sensitivity**
    
    With 'case_sensitive' set to 'False' we can match 'a' with both
    'a' and 'A':
    
    >>> s.contains(pattern='a', case_sensitive=False)
    0    True
    1   False
    ```
2  True
3  NaN
dtype: bool

**Missing values**

We can fill missing values in the output using the `na` parameter:

```python
>>> s.contains(pattern='a', na=False)
0   False
1   False
2    True
3   False
dtype: bool
```

Bad:

```python
def method(foo=None, bar=None):
    ""
    A sample DataFrame method.

    Do not import numpy and pandas.

    Try to use meaningful data, when it makes the example easier
to understand.

    Try to avoid positional arguments like in `df.method(1)`. They
can be all right if previously defined with a meaningful name,
like in `present_value(interest_rate)`, but avoid them otherwise.

    When presenting the behavior with different parameters, do not place
all the calls one next to the other. Instead, add a short sentence
explaining what the example shows.

    Examples
    --------
    >>> import numpy as np
    >>> import pandas as pd
    >>> df = pd.DataFrame(np.random.randn(3, 3),
                       columns=('a', 'b', 'c'))
    >>> df.method(1)
    21
    >>> df.method(bar=14)
    123
    ""
```

pass
Tips for getting your examples pass the doctests

Getting the examples pass the doctests in the validation script can sometimes be tricky. Here are some attention points:

- Import all needed libraries (except for pandas and numpy, those are already imported as import pandas as pd and import numpy as np) and define all variables you use in the example.

- Try to avoid using random data. However random data might be OK in some cases, like if the function you are documenting deals with probability distributions, or if the amount of data needed to make the function result meaningful is too much, such that creating it manually is very cumbersome. In those cases, always use a fixed random seed to make the generated examples predictable. Example:

```python
>>> np.random.seed(42)
>>> df = pd.DataFrame({'normal': np.random.normal(100, 5, 20)})
```

- If you have a code snippet that wraps multiple lines, you need to use ‘...’ on the continued lines:

```python
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], index=['a', 'b', 'c'],
                    columns=['A', 'B'])
```

- If you want to show a case where an exception is raised, you can do:

```python
>>> pd.to_datetime(['712-01-01'])
```

```
OutOfBoundsDatetime: Out of bounds nanosecond timestamp: 712-01-01 00:00:00
```

It is essential to include the “Traceback (most recent call last):”, but for the actual error only the error name is sufficient.

- If there is a small part of the result that can vary (e.g. a hash in an object representation), you can use ... to represent this part.

If you want to show that s.plot() returns a matplotlib AxesSubplot object, this will fail the doctest

```python
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at 0x7efd0c0b0690>
```

However, you can do (notice the comment that needs to be added)

```python
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at ...>
```

Plots in examples

There are some methods in pandas returning plots. To render the plots generated by the examples in the documentation, the .. plot:: directive exists.

To use it, place the next code after the “Examples” header as shown below. The plot will be generated automatically when building the documentation.
Examples
--------
.. plot::
   :context: close-figs
   >>> s = pd.Series([1, 2, 3])
   >>> s.plot()
   ""
   pass

Sharing docstrings

pandas has a system for sharing docstrings, with slight variations, between classes. This helps us keep docstrings consistent, while keeping things clear for the user reading. It comes at the cost of some complexity when writing.

Each shared docstring will have a base template with variables, like `{klass}`. The variables filled in later on using the `doc` decorator. Finally, docstrings can also be appended to with the `doc` decorator.

In this example, we’ll create a parent docstring normally (this is like `pandas.core.generic.NDFrame`). Then we’ll have two children (like `pandas.core.series.Series` and `pandas.core.frame.DataFrame`). We’ll substitute the class names in this docstring.

class Parent:
    @doc(klass="Parent")
    def my_function(self):
        """Apply my function to {klass}."""
        ...

class ChildA(Parent):
    @doc(Parent.my_function, klass="ChildA")
    def my_function(self):
        ...

class ChildB(Parent):
    @doc(Parent.my_function, klass="ChildB")
    def my_function(self):
        ...

The resulting docstrings are

```python
>>> print(Parent.my_function.__doc__)
Apply my function to Parent.
>>> print(ChildA.my_function.__doc__)
Apply my function to ChildA.
>>> print(ChildB.my_function.__doc__)
Apply my function to ChildB.
```

Notice:

1. We “append” the parent docstring to the children docstrings, which are initially empty.

Our files will often contain a module-level `_shared_doc_kwargs` with some common substitution values (things like `klass`, `axes`, etc).
You can substitute and append in one shot with something like

```python
@doc(template, **_shared_doc_kwargs)
def my_function(self):
    ...
```

where `template` may come from a module-level `_shared_docs` dictionary mapping function names to docstrings. Wherever possible, we prefer using `doc`, since the docstring-writing processes is slightly closer to normal.

See `pandas.core.generic.NDFrame.fillna` for an example template, and `pandas.core.series.Series.fillna` and `pandas.core.generic.frame.fillna` for the filled versions.

- The tutorials make heavy use of the `ipython` directive `sphinx` extension. This directive lets you put code in the documentation which will be run during the doc build. For example:

```python
.. ipython:: python
   :columns: 1

   x = 2
   x**3
```

will be rendered as:

```
In [1]: x = 2
In [2]: x**3
Out[2]: 8
```

Almost all code examples in the docs are run (and the output saved) during the doc build. This approach means that code examples will always be up to date, but it does make the doc building a bit more complex.

- Our API documentation files in `doc/source/reference` house the auto-generated documentation from the docstrings. For classes, there are a few subtleties around controlling which methods and attributes have pages auto-generated.

We have two autosummary templates for classes.

1. `_templates/autosummary/class.rst`. Use this when you want to automatically generate a page for every public method and attribute on the class. The `Attributes` and `Methods` sections will be automatically added to the class’ rendered documentation by numpydoc. See `DataFrame` for an example.

2. `_templates/autosummary/class_without_autosummary`. Use this when you want to pick a subset of methods / attributes to auto-generate pages for. When using this template, you should include an `Attributes` and `Methods` section in the class docstring. See `CategoricalIndex` for an example.

Every method should be included in a `toctree` in one of the documentation files in `doc/source/reference`, else `Sphinx` will emit a warning.

---

**Note:** The `.rst` files are used to automatically generate Markdown and HTML versions of the docs. For this reason, please *do not* edit `CONTRIBUTING.md` directly, but instead make any changes to `doc/source/development/contributing.rst`. Then, to generate `CONTRIBUTING.md`, use `pandoc` with the following command:

```bash
pandoc doc/source/development/contributing.rst -t markdown_github > CONTRIBUTING.md
```

The utility script `scripts/validate_docstrings.py` can be used to get a csv summary of the API documentation. And also validate common errors in the docstring of a specific class, function or method. The summary
also compares the list of methods documented in the files in doc/source/reference (which is used to generate the API Reference page) and the actual public methods. This will identify methods documented in doc/source/reference that are not actually class methods, and existing methods that are not documented in doc/source/reference.

**Updating a pandas docstring**

When improving a single function or method’s docstring, it is not necessarily needed to build the full documentation (see next section). However, there is a script that checks a docstring (for example for the DataFrame.mean method):

```
python scripts/validate_docstrings.py pandas.DataFrame.mean
```

This script will indicate some formatting errors if present, and will also run and test the examples included in the docstring. Check the pandas docstring guide for a detailed guide on how to format the docstring.

The examples in the docstring (‘doctests’) must be valid Python code, that in a deterministic way returns the presented output, and that can be copied and run by users. This can be checked with the script above, and is also tested on Travis. A failing doctest will be a blocker for merging a PR. Check the examples section in the docstring guide for some tips and tricks to get the doctests passing.

When doing a PR with a docstring update, it is good to post the output of the validation script in a comment on github.

**How to build the pandas documentation**

**Requirements**

First, you need to have a development environment to be able to build pandas (see the docs on creating a development environment above).

**Building the documentation**

So how do you build the docs? Navigate to your local doc/ directory in the console and run:

```
python make.py html
```

Then you can find the HTML output in the folder doc/build/html/.

The first time you build the docs, it will take quite a while because it has to run all the code examples and build all the generated docstring pages. In subsequent evocations, sphinx will try to only build the pages that have been modified.

If you want to do a full clean build, do:

```
python make.py clean
python make.py html
```

You can tell make.py to compile only a single section of the docs, greatly reducing the turn-around time for checking your changes.

```
# omit autosummary and API section
python make.py clean
python make.py --no-api
```

```
# compile the docs with only a single section, relative to the "source" folder.
# For example, compiling only this guide (doc/source/development/contributing.rst)
```

(continues on next page)
For comparison, a full documentation build may take 15 minutes, but a single section may take 15 seconds. Subsequent builds, which only process portions you have changed, will be faster.

You can also specify to use multiple cores to speed up the documentation build:

```
python make.py html --num-jobs 4
```

Open the following file in a web browser to see the full documentation you just built:

```
doc/build/html/index.html
```

And you’ll have the satisfaction of seeing your new and improved documentation!

### Building master branch documentation

When pull requests are merged into the pandas `master` branch, the main parts of the documentation are also built by Travis-CI. These docs are then hosted here, see also the *Continuous Integration* section.

#### 4.1.5 Contributing to the code base

**Code Base:**

- **Code standards**
- **Optional dependencies**
  - C (cpplint)
  - Python (PEP8 / black)
  - Import formatting
  - Pre-commit
  - Backwards compatibility
- **Type hints**
  - Style guidelines
  - pandas-specific types
  - Validating type hints
- **Testing with continuous integration**
- **Test-driven development/code writing**
  - Writing tests
  - Transitioning to pytest
- Using pytest
- Using hypothesis
- Testing warnings
  - Running the test suite
  - Running the performance test suite
  - Documenting your code

Code standards

Writing good code is not just about what you write. It is also about how you write it. During Continuous Integration testing, several tools will be run to check your code for stylistic errors. Generating any warnings will cause the test to fail. Thus, good style is a requirement for submitting code to pandas.

There is a tool in pandas to help contributors verify their changes before contributing them to the project:

```bash
./ci/code_checks.sh
```

The script verifies the linting of code files, it looks for common mistake patterns (like missing spaces around sphinx directives that make the documentation not being rendered properly) and it also validates the doctests. It is possible to run the checks independently by using the parameters lint, patterns and doctests (e.g. ./ci/code_checks.sh lint).

In addition, because a lot of people use our library, it is important that we do not make sudden changes to the code that could have the potential to break a lot of user code as a result, that is, we need it to be as backwards compatible as possible to avoid mass breakages.

Additional standards are outlined on the pandas code style guide

Optional dependencies

Optional dependencies (e.g. matplotlib) should be imported with the private helper pandas.compat._optional.import_optional_dependency. This ensures a consistent error message when the dependency is not met.

All methods using an optional dependency should include a test asserting that an ImportError is raised when the optional dependency is not found. This test should be skipped if the library is present.

All optional dependencies should be documented in Optional dependencies and the minimum required version should be set in the pandas.compat._optional.VERSIONS dict.

C (cpplint)

pandas uses the Google standard. Google provides an open source style checker called cpplint, but we use a fork of it that can be found here. Here are some of the more common cpplint issues:

- we restrict line-length to 80 characters to promote readability
- every header file must include a header guard to avoid name collisions if re-included

Continuous Integration will run the cpplint tool and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:
pandas: powerful Python data analysis toolkit, Release 1.1.1

You can also run this command on an entire directory if necessary:

```bash
cpplint --extensions=c,h --headers=h --filter=-readability/casting,-runtime/int,--build/include_subdir modified-c-directory
```

To make your commits compliant with this standard, you can install the ClangFormat tool, which can be downloaded here. To configure, in your home directory, run the following command:

```bash
clang-format style=google --dump-config > .clang-format
```

Then modify the file to ensure that any indentation width parameters are at least four. Once configured, you can run the tool as follows:

```bash
clang-format modified-c-file
```

This will output what your file will look like if the changes are made, and to apply them, run the following command:

```bash
clang-format -i modified-c-file
```

To run the tool on an entire directory, you can run the following analogous commands:

```bash
clang-format modified-c-directory/*.c modified-c-directory/*.h
```

```bash
clang-format -i modified-c-directory/*.c modified-c-directory/*.h
```

Do note that this tool is best-effort, meaning that it will try to correct as many errors as possible, but it may not correct all of them. Thus, it is recommended that you run `cpplint` to double check and make any other style fixes manually.

**Python (PEP8 / black)**

pandas follows the PEP8 standard and uses Black and Flake8 to ensure a consistent code format throughout the project.

Continuous Integration will run those tools and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```bash
black pandas
git diff upstream/master -u -- "*.py" | flake8 --diff
```

to auto-format your code. Additionally, many editors have plugins that will apply black as you edit files.

You should use a black version >= 19.10b0 as previous versions are not compatible with the pandas codebase.

If you wish to run these checks automatically, we encourage you to use pre-commits instead.

One caveat about `git diff upstream/master -u -- "*.py" | flake8 --diff`: this command will catch any stylistic errors in your changes specifically, but be beware it may not catch all of them. For example, if you delete the only usage of an imported function, it is stylistically incorrect to import an unused function. However, style-checking the diff will not catch this because the actual import is not part of the diff. Thus, for completeness, you should run this command, though it may take longer:

```bash
git diff upstream/master --name-only -- "*.py" | xargs -r flake8
```

Note that on OSX, the `-r` flag is not available, so you have to omit it and run this slightly modified command:
Windows does not support the `xargs` command (unless installed for example via the MinGW toolchain), but one can imitate the behaviour as follows:

```bash
for /f %i in ('git diff upstream/master --name-only -- "*.py"') do flake8 %i
```

This will get all the files being changed by the PR (and ending with .py), and run `flake8` on them, one after the other.

Note that these commands can be run analogously with `black`.

### Import formatting

pandas uses `isort` to standardise import formatting across the codebase.

A guide to import layout as per pep8 can be found [here](#).

A summary of our current import sections (in order):

- Future
- Python Standard Library
- Third Party
  - `pandas._libs`, `pandas.compat`, `pandas.util._*`, `pandas.errors` (largely not dependent on `pandas.core`)
  - `pandas.core.dtypes` (largely not dependent on the rest of `pandas.core`)
  - `Rest of pandas.core.*`
- Non-core `pandas.io`, `pandas.plotting`, `pandas.tseries`
- Local application/library specific imports

Imports are alphabetically sorted within these sections.

As part of Continuous Integration checks we run:

```bash
isort --check-only pandas
```

to check that imports are correctly formatted as per the `setup.cfg`.

If you see output like the below in Continuous Integration checks:

```
Check import format using isort
ERROR: /home/travis/build/pandas-dev/pandas/pandas/io/pytables.py Imports are incorrectly sorted
Check import format using isort DONE
The command "ci/code_checks.sh" exited with 1
```

You should run:

```bash
isort pandas/io/pytables.py
```

to automatically format imports correctly. This will modify your local copy of the files.

Alternatively, you can run a command similar to what was suggested for `black` and `flake8` right above:
git diff upstream/master --name-only -- "*.py" | xargs -r isort

Where similar caveats apply if you are on OSX or Windows.
You can then verify the changes look ok, then git commit and push.

Pre-commit

You can run many of these styling checks manually as we have described above. However, we encourage you to use pre-commit hooks instead to automatically run black, flake8, isort when you make a git commit. This can be done by installing pre-commit:

```
pip install pre-commit
```

and then running:

```
pre-commit install
```

from the root of the pandas repository. Now all of the styling checks will be run each time you commit changes without your needing to run each one manually. In addition, using this pre-commit hook will also allow you to more easily remain up-to-date with our code checks as they change.

Note that if needed, you can skip these checks with git commit --no-verify.

Backwards compatibility

Please try to maintain backward compatibility. pandas has lots of users with lots of existing code, so don’t break it if at all possible. If you think breakage is required, clearly state why as part of the pull request. Also, be careful when changing method signatures and add deprecation warnings where needed. Also, add the deprecated sphinx directive to the deprecated functions or methods.

If a function with the same arguments as the one being deprecated exist, you can use the pandas.util._decorators.deprecate:

```
from pandas.util._decorators import deprecate

deprecated('old_func', 'new_func', '1.1.0')
```

Otherwise, you need to do it manually:

```
import warnings

def old_func():
    """Summary of the function.
    .. deprecated:: 1.1.0
        Use new_func instead.
    ""
    warnings.warn('Use new_func instead.', FutureWarning, stacklevel=2)
    new_func()

def new_func():
    pass
```
You’ll also need to

1. Write a new test that asserts a warning is issued when calling with the deprecated argument
2. Update all of pandas existing tests and code to use the new argument

See Testing warnings for more.

Type hints

pandas strongly encourages the use of PEP 484 style type hints. New development should contain type hints and pull requests to annotate existing code are accepted as well!

Style guidelines

Types imports should follow the from typing import ... convention. So rather than

```python
import typing
primes: typing.List[int] = []
```

You should write

```python
from typing import List, Optional, Union
primes: List[int] = []
```

Optional should be used where applicable, so instead of

```python
maybe_primes: List[Union[int, None]] = []
```

You should write

```python
maybe_primes: List[Optional[int]] = []
```

In some cases in the code base classes may define class variables that shadow builtins. This causes an issue as described in Mypy 1775. The defensive solution here is to create an unambiguous alias of the builtin and use that without your annotation. For example, if you come across a definition like

```python
class SomeClass1:
    str = None
```

The appropriate way to annotate this would be as follows

```python
str_type = str
```

```python
class SomeClass2:
    str: str_type = None
```

In some cases you may be tempted to use cast from the typing module when you know better than the analyzer. This occurs particularly when using custom inference functions. For example

```python
from typing import cast
from pandas.core.dtypes.common import is_number
```
The limitation here is that while a human can reasonably understand that `is_number` would catch the `int` and `float` types mypy cannot make that same inference just yet (see mypy #5206. While the above works, the use of `cast` is strongly discouraged. Where applicable a refactor of the code to appease static analysis is preferable.

With custom types and inference this is not always possible so exceptions are made, but every effort should be exhausted to avoid `cast` before going down such paths.

### pandas-specific types

Commonly used types specific to pandas will appear in `pandas_typing` and you should use these where applicable. This module is private for now but ultimately this should be exposed to third party libraries who want to implement type checking against pandas.

For example, quite a few functions in pandas accept a `dtype` argument. This can be expressed as a string like "object", a numpy.dtype like `np.int64` or even a pandas ExtensionDtype like `pd.CategoricalDtype`. Rather than burden the user with having to constantly annotate all of those options, this can simply be imported and reused from the `pandas_typing` module.

```python
from pandas._typing import Dtype

def as_type(dtype: Dtype) -> ...:
    ...
```

This module will ultimately house types for repeatedly used concepts like “path-like”, “array-like”, “numeric”, etc... and can also hold aliases for commonly appearing parameters like `axis`. Development of this module is active so be sure to refer to the source for the most up to date list of available types.

### Validating type hints

pandas uses `mypy` to statically analyze the code base and type hints. After making any change you can ensure your type hints are correct by running

```
mypy pandas
```
Testing with continuous integration

The pandas test suite will run automatically on Travis-CI and Azure Pipelines continuous integration services, once your pull request is submitted. However, if you wish to run the test suite on a branch prior to submitting the pull request, then the continuous integration services need to be hooked to your GitHub repository. Instructions are here for Travis-CI and Azure Pipelines.

A pull-request will be considered for merging when you have an all ‘green’ build. If any tests are failing, then you will get a red ‘X’, where you can click through to see the individual failed tests. This is an example of a green build.

Note: Each time you push to your fork, a new run of the tests will be triggered on the CI. You can enable the auto-cancel feature, which removes any non-currently-running tests for that same pull-request, for Travis-CI here.

Test-driven development/code writing

pandas is serious about testing and strongly encourages contributors to embrace test-driven development (TDD). This development process “relies on the repetition of a very short development cycle: first the developer writes an (initially failing) automated test case that defines a desired improvement or new function, then produces the minimum amount of code to pass that test.” So, before actually writing any code, you should write your tests. Often the test can be taken from the original GitHub issue. However, it is always worth considering additional use cases and writing corresponding tests.

Adding tests is one of the most common requests after code is pushed to pandas. Therefore, it is worth getting in the habit of writing tests ahead of time so this is never an issue.

Like many packages, pandas uses pytest and the convenient extensions in numpy.testing.

Note: The earliest supported pytest version is 5.0.1.
Writing tests

All tests should go into the tests subdirectory of the specific package. This folder contains many current examples of tests, and we suggest looking to these for inspiration. If your test requires working with files or network connectivity, there is more information on the testing page of the wiki.

The pandas._testing module has many special assert functions that make it easier to make statements about whether Series or DataFrame objects are equivalent. The easiest way to verify that your code is correct is to explicitly construct the result you expect, then compare the actual result to the expected correct result:

```python
def test_pivot(self):
    data = {
        'index' : ['A', 'B', 'C', 'C', 'B', 'A'],
        'columns' : ['One', 'One', 'One', 'Two', 'Two', 'Two'],
        'values' : [1., 2., 3., 3., 2., 1.]
    }

    frame = DataFrame(data)
    pivoted = frame.pivot(index='index', columns='columns', values='values')

    expected = DataFrame({
        'One' : {'A' : 1., 'B' : 2., 'C' : 3.},
        'Two' : {'A' : 1., 'B' : 2., 'C' : 3.}
    })

    assert_frame_equal(pivoted, expected)
```

Please remember to add the Github Issue Number as a comment to a new test. E.g. “# brief comment, see GH#28907”

Transitioning to pytest

pandas existing test structure is mostly class-based, meaning that you will typically find tests wrapped in a class.

```python
class TestReallyCoolFeature:
    pass
```

Going forward, we are moving to a more functional style using the pytest framework, which offers a richer testing framework that will facilitate testing and developing. Thus, instead of writing test classes, we will write test functions like this:

```python
def test_really_cool_feature():
    pass
```

Using pytest

Here is an example of a self-contained set of tests that illustrate multiple features that we like to use.

- functional style: tests are like test_* and only take arguments that are either fixtures or parameters
- pytest.mark can be used to set metadata on test functions, e.g. skip or xfail.
- using parametrize: allow testing of multiple cases
- to set a mark on a parameter, pytest.param(..., marks=...) syntax should be used
- fixture, code for object construction, on a per-test basis
• using bare `assert` for scalars and truth-testing

• `tm.assert_series_equal` (and its counter part `tm.assert_frame_equal`), for pandas object comparisons.

• the typical pattern of constructing an expected and comparing versus the result

We would name this file `test_cool_feature.py` and put in an appropriate place in the `pandas/tests/` structure.

```python
import pytest
import numpy as np
import pandas as pd

@pytest.mark.parametrize('dtype', ['int8', 'int16', 'int32', 'int64'])
def test_dtypes(dtype):
    assert str(np.dtype(dtype)) == dtype

@pytest.mark.parametrize('dtype', ['float32', pytest.param('int16', marks=pytest.mark.skip),
                                     pytest.param('int32', marks=pytest.mark.xfail(reason='to show how it works'))])
def test_mark(dtype):
    assert str(np.dtype(dtype)) == 'float32'

@ pytest.fixture
def series():
    return pd.Series([1, 2, 3])

@ pytest.fixture(params=['int8', 'int16', 'int32', 'int64'])
def dtype(request):
    return request.param

def test_series(series, dtype):
    result = series.astype(dtype)
    assert result.dtype == dtype

    expected = pd.Series([1, 2, 3], dtype=dtype)
    tm.assert_series_equal(result, expected)
```

A test run of this yields

```bash
((pandas) bash-3.2$ pytest test_cool_feature.py -v
=========================== test session starts ===========================
platform darwin -- Python 3.6.2, pytest-3.6.0, py-1.4.31, pluggy-0.4.0
collected 11 items
tester.py::test_dtypes[int8] PASSED
tester.py::test_dtypes[int16] PASSED
tester.py::test_dtypes[int32] PASSED
tester.py::test_dtypes[int64] PASSED
tester.py::test_mark[float32] PASSED
tester.py::test_mark[int16] SKIPPED
tester.py::test_mark[int32] xfail
(continues on next page)
```

4.1. Contributing to pandas 2459
Tests that we have parametrized are now accessible via the test name, for example we could run these with `-k int8` to sub-select only those tests which match `int8`.

```
((pandas) bash-3.2$ pytest test_cool_feature.py -v -k int8
=========================== test session starts ===========================
platform darwin -- Python 3.6.2, pytest-3.6.0, py-1.4.31, pluggy-0.4.0
collected 11 items

test_cool_feature.py::test_dtypes[int8] PASSED

test_cool_feature.py::test_series[int8] PASSED
```

Using hypothesis

Hypothesis is a library for property-based testing. Instead of explicitly parametrizing a test, you can describe all valid inputs and let Hypothesis try to find a failing input. Even better, no matter how many random examples it tries, Hypothesis always reports a single minimal counterexample to your assertions - often an example that you would never have thought to test.

See Getting Started with Hypothesis for more of an introduction, then refer to the Hypothesis documentation for details.

```
import json
from hypothesis import given, strategies as st

any_json_value = st.deferred(lambda: st.one_of(
    st.none(), st.booleans(), st.floats(allow_nan=False), st.text(),
    st.lists(any_json_value), st.dictionaries(st.text(), any_json_value)
))

given(value=any_json_value)

def test_json_roundtrip(value):
    result = json.loads(json.dumps(value))
    assert value == result
```

This test shows off several useful features of Hypothesis, as well as demonstrating a good use-case: checking properties that should hold over a large or complicated domain of inputs.

To keep the Pandas test suite running quickly, parametrized tests are preferred if the inputs or logic are simple, with Hypothesis tests reserved for cases with complex logic or where there are too many combinations of options or subtle interactions to test (or think of!) all of them.
Testing warnings

By default, one of pandas CI workers will fail if any unhandled warnings are emitted.

If your change involves checking that a warning is actually emitted, use `tm.assert_produces_warning(ExpectedWarning)`.

```python
import pandas._testing as tm

df = pd.DataFrame()
with tm.assert_produces_warning(FutureWarning):
    df.some_operation()
```

We prefer this to the `pytest.warns` context manager because ours checks that the warning’s stacklevel is set correctly. The stacklevel is what ensures the user’s file name and line number is printed in the warning, rather than something internal to pandas. It represents the number of function calls from user code (e.g. `df.some_operation()`) to the function that actually emits the warning. Our linter will fail the build if you use `pytest.warns` in a test.

If you have a test that would emit a warning, but you aren’t actually testing the warning itself (say because it’s going to be removed in the future, or because we’re matching a 3rd-party library’s behavior), then use `pytest.mark.filterwarnings` to ignore the error.

```python
@pytest.mark.filterwarnings("ignore:msg:category")
def test_thing(self):
    ...
```

If the test generates a warning of class `category` whose message starts with `msg`, the warning will be ignored and the test will pass.

If you need finer-grained control, you can use Python’s usual `warnings` module to control whether a warning is ignored / raised at different places within a single test.

```python
with warnings.catch_warnings():
    warnings.simplefilter("ignore", FutureWarning)
    # Or use warnings.filterwarnings(...)  
```

Alternatively, consider breaking up the unit test.

Running the test suite

The tests can then be run directly inside your Git clone (without having to install pandas) by typing:

```bash
pytest pandas
```

The tests suite is exhaustive and takes around 20 minutes to run. Often it is worth running only a subset of tests first around your changes before running the entire suite.

The easiest way to do this is with:

```bash
pytest pandas/path/to/test.py -k regex_matching_test_name
```

Or with one of the following constructs:

```bash
pytest pandas/tests/[test-module].py
pytest pandas/tests/[test-module].py::[TestClass]
pytest pandas/tests/[test-module].py::[TestClass]:[test_method]
```
Using pytest-xdist, one can speed up local testing on multicore machines. To use this feature, you will need to install pytest-xdist via:

```
pip install pytest-xdist
```

Two scripts are provided to assist with this. These scripts distribute testing across 4 threads.

On Unix variants, one can type:

```
test_fast.sh
```

On Windows, one can type:

```
test_fast.bat
```

This can significantly reduce the time it takes to locally run tests before submitting a pull request.

For more, see the pytest documentation.

Furthermore one can run

```
pd.test()
```

with an imported pandas to run tests similarly.

### Running the performance test suite

Performance matters and it is worth considering whether your code has introduced performance regressions. pandas is in the process of migrating to asv benchmarks to enable easy monitoring of the performance of critical pandas operations. These benchmarks are all found in the pandas/asv_bench directory, and the test results can be found here.

To use all features of asv, you will need either conda or virtualenv. For more details please check the asv installation webpage.

To install asv:

```
pip install git+https://github.com/spacetelescope/asv
```

If you need to run a benchmark, change your directory to asv_bench/ and run:

```
asv continuous -f 1.1 upstream/master HEAD
```

You can replace HEAD with the name of the branch you are working on, and report benchmarks that changed by more than 10%. The command uses conda by default for creating the benchmark environments. If you want to use virtualenv instead, write:

```
asv continuous -f 1.1 -E virtualenv upstream/master HEAD
```

The -E virtualenv option should be added to all asv commands that run benchmarks. The default value is defined in asv.conf.json.

Running the full test suite can take up to one hour and use up to 3GB of RAM. Usually it is sufficient to paste only a subset of the results into the pull request to show that the committed changes do not cause unexpected performance regressions. You can run specific benchmarks using the -b flag, which takes a regular expression. For example, this will only run tests from a pandas/asv_bench/benchmarks/groupby.py file:
If you want to only run a specific group of tests from a file, you can do it using . as a separator. For example:

```
asv continuous -f 1.1 upstream/master HEAD -b ^groupby
```

will only run the GroupByMethods benchmark defined in groupby.py.

You can also run the benchmark suite using the version of pandas already installed in your current Python environment. This can be useful if you do not have virtualenv or conda, or are using the setup.py develop approach discussed above; for the in-place build you need to set PYTHONPATH, e.g. PYTHONPATH="$PWD/.." asv [remaining arguments]. You can run benchmarks using an existing Python environment by:

```
asv run -e -E existing
```

or, to use a specific Python interpreter:

```
asv run -e -E existing:python3.6
```

This will display stderr from the benchmarks, and use your local python that comes from your $PATH.

Information on how to write a benchmark and how to use asv can be found in the asv documentation.

### Documenting your code

Changes should be reflected in the release notes located in doc/source/whatsnew/vx.y.z.rst. This file contains an ongoing change log for each release. Add an entry to this file to document your fix, enhancement or (unavoidable) breaking change. Make sure to include the GitHub issue number when adding your entry (using :issue:`1234` where 1234 is the issue/pull request number).

If your code is an enhancement, it is most likely necessary to add usage examples to the existing documentation. This can be done following the section regarding documentation above. Further, to let users know when this feature was added, the versionadded directive is used. The sphinx syntax for that is:

```
.. versionadded:: 1.1.0
```

This will put the text New in version 1.1.0 wherever you put the sphinx directive. This should also be put in the docstring when adding a new function or method (example) or a new keyword argument (example).

#### 4.1.6 Contributing your changes to pandas

### Committing your code

Keep style fixes to a separate commit to make your pull request more readable.

Once you’ve made changes, you can see them by typing:

```
git status
```

If you have created a new file, it is not being tracked by git. Add it by typing:

```
git add path/to/file-to-be-added.py
```

Doing ‘git status’ again should give something like:
Finally, commit your changes to your local repository with an explanatory message. pandas uses a convention for commit message prefixes and layout. Here are some common prefixes along with general guidelines for when to use them:

- **ENH**: Enhancement, new functionality
- **BUG**: Bug fix
- **DOC**: Additions/updates to documentation
- **TST**: Additions/updates to tests
- **BLD**: Updates to the build process/scripts
- **PERF**: Performance improvement
- **TYP**: Type annotations
- **CLN**: Code cleanup

The following defines how a commit message should be structured. Please reference the relevant GitHub issues in your commit message using GH1234 or #1234. Either style is fine, but the former is generally preferred:

- a subject line with < 80 chars.
- One blank line.
- Optionally, a commit message body.

Now you can commit your changes in your local repository:

```
git commit -m
```

### Pushing your changes

When you want your changes to appear publicly on your GitHub page, push your forked feature branch’s commits:

```
git push origin shiny-new-feature
```

Here `origin` is the default name given to your remote repository on GitHub. You can see the remote repositories:

```
git remote -v
```

If you added the upstream repository as described above you will see something like:

```
origin git@github.com:yourname/pandas.git (fetch)
origin git@github.com:yourname/pandas.git (push)
upstream git://github.com/pandas-dev/pandas.git (fetch)
upstream git://github.com/pandas-dev/pandas.git (push)
```

Now your code is on GitHub, but it is not yet a part of the pandas project. For that to happen, a pull request needs to be submitted on GitHub.
Review your code

When you’re ready to ask for a code review, file a pull request. Before you do, once again make sure that you have followed all the guidelines outlined in this document regarding code style, tests, performance tests, and documentation. You should also double check your branch changes against the branch it was based on:

1. Navigate to your repository on GitHub – [https://github.com/your-user-name/pandas](https://github.com/your-user-name/pandas)
2. Click on Branches
3. Click on the Compare button for your feature branch
4. Select the base and compare branches, if necessary. This will be master and shiny-new-feature, respectively.

Finally, make the pull request

If everything looks good, you are ready to make a pull request. A pull request is how code from a local repository becomes available to the GitHub community and can be looked at and eventually merged into the master version. This pull request and its associated changes will eventually be committed to the master branch and available in the next release. To submit a pull request:

1. Navigate to your repository on GitHub
2. Click on the Pull Request button
3. You can then click on Commits and Files Changed to make sure everything looks okay one last time
4. Write a description of your changes in the Preview Discussion tab
5. Click Send Pull Request.

This request then goes to the repository maintainers, and they will review the code.

Updating your pull request

Based on the review you get on your pull request, you will probably need to make some changes to the code. In that case, you can make them in your branch, add a new commit to that branch, push it to GitHub, and the pull request will be automatically updated. Pushing them to GitHub again is done by:

```
git push origin shiny-new-feature
```

This will automatically update your pull request with the latest code and restart the Continuous Integration tests.

Another reason you might need to update your pull request is to solve conflicts with changes that have been merged into the master branch since you opened your pull request.

To do this, you need to “merge upstream master” in your branch:

```
git checkout shiny-new-feature
git fetch upstream
git merge upstream/master
```

If there are no conflicts (or they could be fixed automatically), a file with a default commit message will open, and you can simply save and quit this file.

If there are merge conflicts, you need to solve those conflicts. See for example at [https://help.github.com/articles/resolving-a-merge-conflict-using-the-command-line/](https://help.github.com/articles/resolving-a-merge-conflict-using-the-command-line/) for an explanation on how to do this. Once the conflicts are merged and the files where the conflicts were solved are added, you can run `git commit` to save those fixes.
If you have uncommitted changes at the moment you want to update the branch with master, you will need to `stash` them prior to updating (see the `stash docs`). This will effectively store your changes and they can be reapplied after updating.

After the feature branch has been update locally, you can now update your pull request by pushing to the branch on GitHub:

```
git push origin shiny-new-feature
```

**Delete your merged branch (optional)**

Once your feature branch is accepted into upstream, you’ll probably want to get rid of the branch. First, merge upstream master into your branch so git knows it is safe to delete your branch:

```
git fetch upstream
git checkout master
git merge upstream/master
```

Then you can do:

```
git branch -d shiny-new-feature
```

Make sure you use a lower-case `-d`, or else git won’t warn you if your feature branch has not actually been merged. The branch will still exist on GitHub, so to delete it there do:

```
git push origin --delete shiny-new-feature
```

### 4.1.7 Tips for a successful pull request

If you have made it to the *Review your code* phase, one of the core contributors may take a look. Please note however that a handful of people are responsible for reviewing all of the contributions, which can often lead to bottlenecks.

To improve the chances of your pull request being reviewed, you should:

- **Reference an open issue** for non-trivial changes to clarify the PR’s purpose
- **Ensure you have appropriate tests**. These should be the first part of any PR
- **Keep your pull requests as simple as possible**. Larger PRs take longer to review
- **Ensure that CI is in a green state**. Reviewers may not even look otherwise
- **Keep Updating your pull request**, either by request or every few days

### 4.2 pandas code style guide

**Table of contents:**

- Patterns
  - Using `foo.__class__`
- String formatting
4.2.1 Patterns

Using `foo.__class__`

pandas uses `type(foo)` instead of `foo.__class__` as it is making the code more readable. For example:

Good:

```python
foo = "bar"
type(foo)
```

Bad:

```python
foo = "bar"
foo.__class__
```

4.2.2 String formatting

Concatenated strings

Using f-strings

pandas uses f-strings formatting instead of `%' and `.format()` string formaters.

The convention of using f-strings on a string that is concatenated over several lines, is to prefix only the lines containing values which need to be interpreted.

For example:

Good:

```python
foo = "old_function"
bar = "new_function"

my_warning_message = {
    f"Warning, {foo} is deprecated, "
    "please use the new and way better "
    f"{bar}"}
```
Bad:

```python
foo = "old_function"
bar = "new_function"

my_warning_message = {
    f"Warning, {foo} is deprecated, "
    f"please use the new and way better "
    f"{bar}"}
```

White spaces

Only put white space at the end of the previous line, so there is no whitespace at the beginning of the concatenated string.

For example:

Good:

```python
example_string = {
    "Some long concatenated string, 
    "with good placement of the 
    "whitespaces"
}
```

Bad:

```python
example_string = {
    "Some long concatenated string,"
    " with bad placement of the"
    " whitespaces"
}
```

Representation function (aka ‘repr()’)

pandas uses ‘repr()’ instead of ‘%r’ and ‘!r’.

The use of ‘repr()’ will only happen when the value is not an obvious string.

For example:

Good:

```python
value = str
f"Unknown received value, got: {repr(value)}"
```

Good:

```python
value = str
f"Unknown received type, got: '{type(value).__name__}'"
```
4.2.3 Imports (aim for absolute)

In Python 3, absolute imports are recommended. Using absolute imports, doing something like `import string` will import the string module rather than `string.py` in the same directory. As much as possible, you should try to write out absolute imports that show the whole import chain from top-level pandas.

Explicit relative imports are also supported in Python 3 but it is not recommended to use them. Implicit relative imports should never be used and are removed in Python 3.

For example:

```python
# preferred
import pandas.core.common as com

# not preferred
from .common import test_base

# wrong
from common import test_base
```

4.2.4 Miscellaneous

Reading from a url

Good:

```python
from pandas.io.common import urlopen
with urlopen('http://www.google.com') as url:
    raw_text = url.read()
```

4.3 pandas maintenance

This guide is for pandas’ maintainers. It may also be interesting to contributors looking to understand the pandas development process and what steps are necessary to become a maintainer.

The main contributing guide is available at `Contributing to pandas`.

4.3.1 Roles

pandas uses two levels of permissions: `triage` and `core` team members.

Triage members can label and close issues and pull requests.

Core team members can label and close issues and pull request, and can merge pull requests.

GitHub publishes the full list of permissions.
4.3.2 Tasks

pandas is largely a volunteer project, so these tasks shouldn’t be read as “expectations” of triage and maintainers. Rather, they’re general descriptions of what it means to be a maintainer.

- Triage newly filed issues (see Issue triage)
- Review newly opened pull requests
- Respond to updates on existing issues and pull requests
- Drive discussion and decisions on stalled issues and pull requests
- Provide experience / wisdom on API design questions to ensure consistency and maintainability
- Project organization (run / attend developer meetings, represent pandas)

https://matthewrocklin.com/blog/2019/05/18/maintainer may be interesting background reading.

4.3.3 Issue triage

Here’s a typical workflow for triaging a newly opened issue.

1. Thank the reporter for opening an issue

   The issue tracker is many people’s first interaction with the pandas project itself, beyond just using the library. As such, we want it to be a welcoming, pleasant experience.

2. Is the necessary information provided?

   Ideally reporters would fill out the issue template, but many don’t. If crucial information (like the version of pandas they used), is missing feel free to ask for that and label the issue with “Needs info”. The report should follow the guidelines in Bug reports and enhancement requests. You may want to link to that if they didn’t follow the template.

   Make sure that the title accurately reflects the issue. Edit it yourself if it’s not clear.

3. Is this a duplicate issue?

   We have many open issues. If a new issue is clearly a duplicate, label the new issue as “Duplicate” assign the milestone “No Action”, and close the issue with a link to the original issue. Make sure to still thank the reporter, and encourage them to chime in on the original issue, and perhaps try to fix it.

   If the new issue provides relevant information, such as a better or slightly different example, add it to the original issue as a comment or an edit to the original post.

4. Is the issue minimal and reproducible?

   For bug reports, we ask that the reporter provide a minimal reproducible example. See https://matthewrocklin.com/blog/work/2018/02/28/minimal-bug-reports for a good explanation. If the example is not reproducible, or if it’s clearly not minimal, feel free to ask the reporter if they can provide and example or simplify the provided one. Do acknowledge that writing minimal reproducible examples is hard work. If the reporter is struggling, you can try to write one yourself and we’ll edit the original post to include it.

   If a reproducible example can’t be provided, add the “Needs info” label.

   If a reproducible example is provided, but you see a simplification, edit the original post with your simpler reproducible example.

5. Is this a clearly defined feature request?

   Generally, pandas prefers to discuss and design new features in issues, before a pull request is made. Encourage the submitter to include a proposed API for the new feature. Having them write a full docstring is a good way to pin down specifics.
We’ll need a discussion from several pandas maintainers before deciding whether the proposal is in scope for pandas.

6. **Is this a usage question?**

   We prefer that usage questions are asked on StackOverflow with the pandas tag. [https://stackoverflow.com/questions/tagged/pandas](https://stackoverflow.com/questions/tagged/pandas)

   If it’s easy to answer, feel free to link to the relevant documentation section, let them know that in the future this kind of question should be on StackOverflow, and close the issue.

7. **What labels and milestones should I add?**

   Apply the relevant labels. This is a bit of an art, and comes with experience. Look at similar issues to get a feel for how things are labeled.

   If the issue is clearly defined and the fix seems relatively straightforward, label the issue as “Good first issue”.

   Typically, new issues will be assigned the “Contributions welcome” milestone, unless it’s know that this issue should be addressed in a specific release (say because it’s a large regression).

**4.3.4 Closing issues**

Be delicate here: many people interpret closing an issue as us saying that the conversation is over. It’s typically best to give the reporter some time to respond or self-close their issue if it’s determined that the behavior is not a bug, or the feature is out of scope. Sometimes reporters just go away though, and we’ll close the issue after the conversation has died.

**4.3.5 Reviewing pull requests**

Anybody can review a pull request: regular contributors, triagers, or core-team members. Here are some guidelines to check.

- Tests should be in a sensible location.
- New public APIs should be included somewhere in `doc/source/reference/`.
- New / changed API should use the `versionadded` or `versionchanged` directives in the docstring.
- User-facing changes should have a `whatsnew` in the appropriate file.
- Regression tests should reference the original GitHub issue number like `# GH-1234`.

**4.3.6 Cleaning up old issues**

Every open issue in pandas has a cost. Open issues make finding duplicates harder, and can make it harder to know what needs to be done in pandas. That said, closing issues isn’t a goal on its own. Our goal is to make pandas the best it can be, and that’s best done by ensuring that the quality of our open issues is high.

Occasionally, bugs are fixed but the issue isn’t linked to in the Pull Request. In these cases, comment that “This has been fixed, but could use a test.” and label the issue as “Good First Issue” and “Needs Test”.

If an older issue doesn’t follow our issue template, edit the original post to include a minimal example, the actual output, and the expected output. Uniformity in issue reports is valuable.

If an older issue lacks a reproducible example, label it as “Needs Info” and ask them to provide one (or write one yourself if possible). If one isn’t provide reasonably soon, close it according to the policies in "Closing issues."
4.3.7 Cleaning up old pull requests

Occasionally, contributors are unable to finish off a pull request. If some time has passed (two weeks, say) since the last review requesting changes, gently ask if they’re still interested in working on this. If another two weeks or so passes with no response, thank them for their work and close the pull request. Comment on the original issue that “There’s a stalled PR at #1234 that may be helpful.”, and perhaps label the issue as “Good first issue” if the PR was relatively close to being accepted.

Additionally, core-team members can push to contributors branches. This can be helpful for pushing an important PR across the line, or for fixing a small merge conflict.

4.3.8 Becoming a pandas maintainer

The full process is outlined in our governance documents. In summary, we’re happy to give triage permissions to anyone who shows interest by being helpful on the issue tracker.

The current list of core-team members is at https://github.com/pandas-dev/pandas-governance/blob/master/people.md

4.4 Internals

This section will provide a look into some of pandas internals. It’s primarily intended for developers of pandas itself.

4.4.1 Indexing

In pandas there are a few objects implemented which can serve as valid containers for the axis labels:

- **Index**: the generic “ordered set” object, an ndarray of object dtype assuming nothing about its contents. The labels must be hashable (and likely immutable) and unique. Populates a dict of label to location in Cython to do \(O(1)\) lookups.
- **Int64Index**: a version of Index highly optimized for 64-bit integer data, such as time stamps
- **Float64Index**: a version of Index highly optimized for 64-bit float data
- **MultiIndex**: the standard hierarchical index object
- **DatetimeIndex**: An Index object with `Timestamp` boxed elements (impl are the int64 values)
- **TimedeltaIndex**: An Index object with `Timedelta` boxed elements (impl are the int64 values)
- **PeriodIndex**: An Index object with Period elements

There are functions that make the creation of a regular index easy:

- **date_range**: fixed frequency date range generated from a time rule or DateOffset. An ndarray of Python datetime objects
- **period_range**: fixed frequency date range generated from a time rule or DateOffset. An ndarray of Period objects, representing timespans

The motivation for having an Index class in the first place was to enable different implementations of indexing. This means that it’s possible for you, the user, to implement a custom Index subclass that may be better suited to a particular application than the ones provided in pandas.

From an internal implementation point of view, the relevant methods that an Index must define are one or more of the following (depending on how incompatible the new object internals are with the Index functions):

- **get_loc**: returns an “indexer” (an integer, or in some cases a slice object) for a label
• **slice_locs**: returns the “range” to slice between two labels
• **get_indexer**: Computes the indexing vector for reindexing / data alignment purposes. See the source / docstrings for more on this
• **get_indexer_non_unique**: Computes the indexing vector for reindexing / data alignment purposes when the index is non-unique. See the source / docstrings for more on this
• **reindex**: Does any pre-conversion of the input index then calls **get_indexer**
• **union, intersection**: computes the union or intersection of two Index objects
• **insert**: Inserts a new label into an Index, yielding a new object
• **delete**: Delete a label, yielding a new object
• **drop**: Deletes a set of labels
• **take**: Analogous to ndarray.take

**MultiIndex**

Internally, the MultiIndex consists of a few things: the levels, the integer codes (until version 0.24 named labels), and the level names:

```
In [1]: index = pd.MultiIndex.from_product([[range(3), ['one', 'two']],
                                           names=['first', 'second'])

In [2]: index
Out[2]:
MultiIndex([(0, 'one'),
            (0, 'two'),
            (1, 'one'),
            (1, 'two'),
            (2, 'one'),
            (2, 'two')],
           names=['first', 'second'])

In [3]: index.levels
Out[3]: FrozenList([[0, 1, 2], ['one', 'two']])

In [4]: index.codes
Out[4]: FrozenList([[0, 0, 1, 1, 2, 2], [0, 1, 0, 1, 0, 1]])

In [5]: index.names
Out[5]: FrozenList(['first', 'second'])
```

You can probably guess that the codes determine which unique element is identified with that location at each layer of the index. It’s important to note that sortedness is determined **solely** from the integer codes and does not check (or care) whether the levels themselves are sorted. Fortunately, the constructors from_tuples and from_arrays ensure that this is true, but if you compute the levels and codes yourself, please be careful.
pandas: powerful Python data analysis toolkit, Release 1.1.1

Values

pandas extends NumPy’s type system with custom types, like Categorical or datetimes with a timezone, so we have multiple notions of “values”. For 1-D containers (Index classes and Series) we have the following convention:

- cls._values refers is the “best possible” array. This could be an ndarray or ExtensionArray.

So, for example, Series[category]._values is a Categorical.

4.4.2 Subclassing pandas data structures

This section has been moved to Subclassing pandas data structures.

4.5 Extending pandas

While pandas provides a rich set of methods, containers, and data types, your needs may not be fully satisfied. pandas offers a few options for extending pandas.

4.5.1 Registering custom accessors

Libraries can use the decorators pandas.api.extensions.register_dataframe_accessor(), pandas.api.extensions.register_series_accessor(), and pandas.api.extensions.register_index_accessor(), to add additional “namespaces” to pandas objects. All of these follow a similar convention: you decorate a class, providing the name of attribute to add. The class’s __init__ method gets the object being decorated. For example:

```python
@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._validate(pandas_obj)
        self._obj = pandas_obj

    @staticmethod
    def _validate(obj):
        # verify there is a column latitude and a column longitude
        if 'latitude' not in obj.columns or 'longitude' not in obj.columns:
            raise AttributeError("Must have 'latitude' and 'longitude'.")

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Now users can access your methods using the geo namespace:
>>> ds = pd.DataFrame({'longitude': np.linspace(0, 10),
...     'latitude': np.linspace(0, 20)})

>>> ds.geo.center
(5.0, 10.0)

>>> ds.geo.plot()
# plots data on a map

This can be a convenient way to extend pandas objects without subclassing them. If you write a custom accessor, make a pull request adding it to our ecosystem page.

We highly recommend validating the data in your accessor's `__init__`. In our GeoAccessor, we validate that the data contains the expected columns, raising an `AttributeError` when the validation fails. For a Series accessor, you should validate the `dtype` if the accessor applies only to certain dtypes.

### 4.5.2 Extension types

New in version 0.23.0.

---

**Warning:** The `pandas.api.extensions.ExtensionDtype` and `pandas.api.extensions.ExtensionArray` APIs are new and experimental. They may change between versions without warning.

---

pandas defines an interface for implementing data types and arrays that extend NumPy's type system. pandas itself uses the extension system for some types that aren't built into NumPy (categorical, period, interval, datetime with timezone).

Libraries can define a custom array and data type. When pandas encounters these objects, they will be handled properly (i.e. not converted to an ndarray of objects). Many methods like `pandas.isna()` will dispatch to the extension type's implementation.

If you're building a library that implements the interface, please publicize it on ecosystem.extensions.

The interface consists of two classes.

**ExtensionDtype**

An `pandas.api.extensions.ExtensionDtype` is similar to a `numpy.dtype` object. It describes the data type. Implementors are responsible for a few unique items like the name.

One particularly important item is the `type` property. This should be the class that is the scalar type for your data. For example, if you were writing an extension array for IP Address data, this might be `ipaddress.IPv4Address`.

See the `extension dtype source` for interface definition.

New in version 0.24.0.

`pandas.api.extension.ExtensionDtype` can be registered to pandas to allow creation via a string dtype name. This allows one to instantiate `Series` and `.astype()` with a registered string name, for example `'category'` is a registered string accessor for the `CategoricalDtype`.

See the `extension dtype dtypes` for more on how to register dtypes.
ExtensionArray

This class provides all the array-like functionality. ExtensionArrays are limited to 1 dimension. An ExtensionArray is linked to an ExtensionDtype via the dtype attribute.

pandas makes no restrictions on how an extension array is created via its __new__ or __init__, and puts no restrictions on how you store your data. We do require that your array be convertible to a NumPy array, even if this is relatively expensive (as it is for Categorical).

They may be backed by none, one, or many NumPy arrays. For example, pandas.Categorical is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 addresses may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists.

See the extension array source for the interface definition. The docstrings and comments contain guidance for properly implementing the interface.

ExtensionArray operator support

New in version 0.24.0.

By default, there are no operators defined for the class ExtensionArray. There are two approaches for providing operator support for your ExtensionArray:

1. Define each of the operators on your ExtensionArray subclass.

2. Use an operator implementation from pandas that depends on operators that are already defined on the underlying elements (scalars) of the ExtensionArray.

Note: Regardless of the approach, you may want to set __array_priority__ if you want your implementation to be called when involved in binary operations with NumPy arrays.

For the first approach, you define selected operators, e.g., __add__, __le__, etc. that you want your ExtensionArray subclass to support.

The second approach assumes that the underlying elements (i.e., scalar type) of the ExtensionArray have the individual operators already defined. In other words, if your ExtensionArray named MyExtensionArray is implemented so that each element is an instance of the class MyExtensionElement, then if the operators are defined for MyExtensionElement, the second approach will automatically define the operators for MyExtensionArray.

A mixin class, ExtensionScalarOpsMixin supports this second approach. If developing an ExtensionArray subclass, for example MyExtensionArray, can simply include ExtensionScalarOpsMixin as a parent class of MyExtensionArray, and then call the methods _add_arithmetic_ops() and/or _add_comparison_ops() to hook the operators into your MyExtensionArray class, as follows:

```python
from pandas.api.extensions import ExtensionArray, ExtensionScalarOpsMixin

class MyExtensionArray(ExtensionArray, ExtensionScalarOpsMixin):
    pass

MyExtensionArray._add_arithmetic_ops()
MyExtensionArray._add_comparison_ops()
```
Note: Since pandas automatically calls the underlying operator on each element one-by-one, this might not be as performant as implementing your own version of the associated operators directly on the ExtensionArray.

For arithmetic operations, this implementation will try to reconstruct a new ExtensionArray with the result of the element-wise operation. Whether or not that succeeds depends on whether the operation returns a result that’s valid for the ExtensionArray. If an ExtensionArray cannot be reconstructed, an ndarray containing the scalars returned instead.

For ease of implementation and consistency with operations between pandas and NumPy ndarrays, we recommend not handling Series and Indexes in your binary ops. Instead, you should detect these cases and return `NotImplemented`. When pandas encounters an operation like `op(Series, ExtensionArray)`, pandas will

1. unbox the array from the Series(Series.array)
2. call `result = op(values, ExtensionArray)`
3. re-box the result in a Series

NumPy universal functions

`Series` implements `__array_ufunc__`. As part of the implementation, pandas unboxes the ExtensionArray from the Series, applies the ufunc, and re-boxes it if necessary.

If applicable, we highly recommend that you implement `__array_ufunc__` in your extension array to avoid coercion to an ndarray. See the numpy documentation for an example.

As part of your implementation, we require that you defer to pandas when a pandas container (Series, DataFrame, Index) is detected in inputs. If any of those is present, you should return `NotImplemented`. pandas will take care of unboxing the array from the container and re-calling the ufunc with the unwrapped input.

Testing extension arrays

We provide a test suite for ensuring that your extension arrays satisfy the expected behavior. To use the test suite, you must provide several pytest fixtures and inherit from the base test class. The required fixtures are found in https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/conftest.py.

To use a test, subclass it:

```python
from pandas.tests.extension import base

class TestConstructors(base.BaseConstructorsTests):
    pass
```

See https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/base/__init__.py for a list of all the tests available.
Compatibility with Apache Arrow

An ExtensionArray can support conversion to/from pyarrow arrays (and thus support for example serialization to the Parquet file format) by implementing two methods: ExtensionArray.__arrow_array__ and ExtensionDtype.__from_arrow__.

The ExtensionArray.__arrow_array__ ensures that pyarrow knows how to convert the specific extension array into a pyarrow.Array (also when included as a column in a pandas DataFrame):

```python
class MyExtensionArray(ExtensionArray):
    ...
    def __arrow_array__(self, type=None):
        # convert the underlying array values to a pyarrow Array
        import pyarrow
        return pyarrow.array(..., type=type)
```

The ExtensionDtype.__from_arrow__ method then controls the conversion back from pyarrow to a pandas ExtensionArray. This method receives a pyarrow Array or ChunkedArray as only argument and is expected to return the appropriate pandas ExtensionArray for this dtype and the passed values:

```python
class ExtensionDtype:
    ...
    def __from_arrow__(self, array: pyarrow.Array/ChunkedArray) -> ExtensionArray:
        ...
```

See more in the Arrow documentation.

Those methods have been implemented for the nullable integer and string extension dtypes included in pandas, and ensure roundtrip to pyarrow and the Parquet file format.

4.5.3 Subclassing pandas data structures

**Warning:** There are some easier alternatives before considering subclassing pandas data structures.

1. Extensible method chains with `pipe`
2. Use composition. See here.
3. Extending by registering an accessor
4. Extending by extension type

This section describes how to subclass pandas data structures to meet more specific needs. There are two points that need attention:

1. Override constructor properties.
2. Define original properties

**Note:** You can find a nice example in geopandas project.
Override constructor properties

Each data structure has several constructor properties for returning a new data structure as the result of an operation. By overriding these properties, you can retain subclasses through pandas data manipulations.

There are 3 constructor properties to be defined:

- `_constructor`: Used when a manipulation result has the same dimensions as the original.
- `_constructor_sliced`: Used when a manipulation result has one lower dimension(s) as the original, such as DataFrame single columns slicing.
- `_constructor_expanddim`: Used when a manipulation result has one higher dimension as the original, such as Series.to_frame()

Following table shows how pandas data structures define constructor properties by default.

<table>
<thead>
<tr>
<th>Property Attributes</th>
<th>Series</th>
<th>DataFrame</th>
</tr>
</thead>
<tbody>
<tr>
<td>_constructor</td>
<td>Series</td>
<td>DataFrame</td>
</tr>
<tr>
<td>_constructor_sliced</td>
<td>NotImplementedError</td>
<td>Series</td>
</tr>
<tr>
<td>_constructor_expanddim</td>
<td>DataFrame</td>
<td>NotImplementedError</td>
</tr>
</tbody>
</table>

Below example shows how to define SubclassedSeries and SubclassedDataFrame overriding constructor properties.

```python
class SubclassedSeries(pd.Series):
    @property
    def _constructor(self):
        return SubclassedSeries

    @property
    def _constructor_expanddim(self):
        return SubclassedDataFrame

class SubclassedDataFrame(pd.DataFrame):
    @property
    def _constructor(self):
        return SubclassedDataFrame

    @property
    def _constructor_sliced(self):
        return SubclassedSeries

>>> s = SubclassedSeries([1, 2, 3])
>>> type(s)
<class '__main__.SubclassedSeries'>

>>> to_framed = s.to_frame()
>>> type(to_framed)
<class '__main__.SubclassedDataFrame'>

>>> df = SubclassedDataFrame({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]})
>>> df
   A  B  C
0  1  4  7
```

(continues on next page)
Define original properties

To let original data structures have additional properties, you should let pandas know what properties are added. pandas maps unknown properties to data names overriding __getattr__. Defining original properties can be done in one of 2 ways:

1. Define _internal_names and _internal_names_set for temporary properties which WILL NOT be passed to manipulation results.
2. Define _metadata for normal properties which will be passed to manipulation results.

Below is an example to define two original properties, “internal_cache” as a temporary property and “added_property” as a normal property

```python
class SubclassedDataFrame2(pd.DataFrame):
    # temporary properties
    _internal_names = pd.DataFrame._internal_names + ['internal_cache']
    _internal_names_set = set(_internal_names)

    # normal properties
    _metadata = ['added_property']

    def __constructor__(self):
        return SubclassedDataFrame2

>>> df = SubclassedDataFrame2({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]})
>>> df
```
A  B  C
0 1 4 7
1 2 5 8
2 3 6 9

```python
>>> df.internal_cache = 'cached'
>>> df.added_property = 'property'

>>> df.internal_cache
cached
>>> df.added_property
property

# properties defined in _internal_names is reset after manipulation
>>> df[['A', 'B']].internal_cache
AttributeError: 'SubclassedDataFrame2' object has no attribute 'internal_cache'

# properties defined in _metadata are retained
>>> df[['A', 'B']].added_property
property
```

4.5.4 Plotting backends

Starting in 0.25 pandas can be extended with third-party plotting backends. The main idea is letting users select a plotting backend different than the provided one based on Matplotlib. For example:

```python
>>> pd.set_option('plotting.backend', 'backend.module')
>>> pd.Series([1, 2, 3]).plot()
```

This would be more or less equivalent to:

```python
>>> import backend.module
>>> backend.module.plot(pd.Series([1, 2, 3]))
```

The backend module can then use other visualization tools (Bokeh, Altair,...) to generate the plots.

Libraries implementing the plotting backend should use entry points to make their backend discoverable to pandas. The key is "pandas_plotting_backends". For example, pandas registers the default "matplotlib" backend as follows.

```
# in setup.py
setup(
    ...,
    entry_points={
        "pandas_plotting_backends": [
            "matplotlib = pandas:plotting._matplotlib",
        ],
    },
)
```

More information on how to implement a third-party plotting backend can be found at https://github.com/pandas-dev/pandas/blob/master/pandas/plotting/__init__.py#L1.

4.5. Extending pandas
4.6 Developer

This section will focus on downstream applications of pandas.

4.6.1 Storing pandas DataFrame objects in Apache Parquet format

The Apache Parquet format provides key-value metadata at the file and column level, stored in the footer of the Parquet file:

```python
5: optional list<KeyValue> key_value_metadata
```

where `KeyValue` is

```python
struct KeyValue {
  1: required string key
  2: optional string value
}
```

So that a `pandas.DataFrame` can be faithfully reconstructed, we store a pandas metadata key in the `FileMetaData` with the value stored as:

```python
{'index_columns': [descr0, descr1, ...],
 'column_indexes': [ci0, ci1, ..., ciN],
 'columns': [c0, c1, ...],
 'pandas_version': $VERSION,
 'creator': {
   'library': $LIBRARY,
   'version': $LIBRARY_VERSION
 }}
```

The “descriptor” values `descr0` in the 'index_columns' field are strings (referring to a column) or dictionaries with values as described below.

The `c0/ci0` and so forth are dictionaries containing the metadata for each column, including the index columns. This has JSON form:

```json
{ 'name': column_name,
  'field_name': parquet_column_name,
  'pandas_type': pandas_type,
  'numpy_type': numpy_type,
  'metadata': metadata }
```

See below for the detailed specification for these.

Index metadata descriptors

`RangeIndex` can be stored as metadata only, not requiring serialization. The descriptor format for these as is follows:

```python
index = pd.RangeIndex(0, 10, 2)
{'kind': 'range',
 'name': index.name,
 'start': index.start,
 'stop': index.stop,
 'step': index.step}
```

2482 Chapter 4. Development
Other index types must be serialized as data columns along with the other DataFrame columns. The metadata for these is a string indicating the name of the field in the data columns, for example '__index_level_0__'.

If an index has a non-None name attribute, and there is no other column with a name matching that value, then the index.name value can be used as the descriptor. Otherwise (for unnamed indexes and ones with names colliding with other column names) a disambiguating name with pattern matching __index_level__\d+__ should be used.

In cases of named indexes as data columns, name attribute is always stored in the column descriptors as above.

**Column metadata**

- **pandas_type** is the logical type of the column, and is one of:
  - Boolean: 'bool'
  - Integers: 'int8', 'int16', 'int32', 'int64', 'uint8', 'uint16', 'uint32', 'uint64'
  - Floats: 'float16', 'float32', 'float64'
  - Date and Time Types: 'datetime', 'datetimetz', 'timedelta'
  - String: 'unicode', 'bytes'
  - Categorical: 'categorical'
  - Other Python objects: 'object'

- The **numpy_type** is the physical storage type of the column, which is the result of \str\(\text{dtype}\) for the underlying NumPy array that holds the data. So for datetimetz this is \text{datetime64[ns]} and for categorical, it may be any of the supported integer categorical types.

- The metadata field is None except for:
  - datetimetz: {'timezone': zone, 'unit': 'ns'}, e.g. {'timezone': 'America/New_York', 'unit': 'ns'}. The 'unit' is optional, and if omitted it is assumed to be nanoseconds.
  - categorical: {'num_categories': K, 'ordered': is_ordered, 'type': $\text{STYPE}$}
    - Here 'type' is optional, and can be a nested pandas type specification here (but not categorical)
  - unicode: {'encoding': encoding}
    - The encoding is optional, and if not present is UTF-8
  - object: {'encoding': encoding}. Objects can be serialized and stored in BYTE_ARRAY Parquet columns. The encoding can be one of:
    - 'pickle'
    - 'bson'
    - 'json'
  - timedelta: {'unit': 'ns'}. The 'unit' is optional, and if omitted it is assumed to be nanoseconds.
    - This metadata is optional altogether

For types other than these, the 'metadata' key can be omitted. Implementations can assume None if the key is not present.

As an example of fully-formed metadata:
4.7 Policies

4.7.1 Version policy

Changed in version 1.0.0.

pandas uses a loose variant of semantic versioning (SemVer) to govern deprecations, API compatibility, and version numbering.

A pandas release number is made up of `MAJOR.MINOR.PATCH`.
API breaking changes should only occur in major releases. These changes will be documented, with clear guidance on what is changing, why it's changing, and how to migrate existing code to the new behavior.

Whenever possible, a deprecation path will be provided rather than an outright breaking change.

pandas will introduce deprecations in minor releases. These deprecations will preserve the existing behavior while emitting a warning that provide guidance on:

- How to achieve similar behavior if an alternative is available
- The pandas version in which the deprecation will be enforced.

We will not introduce new deprecations in patch releases.

Deprecations will only be enforced in major releases. For example, if a behavior is deprecated in pandas 1.2.0, it will continue to work, with a warning, for all releases in the 1.x series. The behavior will change and the deprecation removed in the next next major release (2.0.0).

Note: pandas will sometimes make behavior changing bug fixes, as part of minor or patch releases. Whether or not a change is a bug fix or an API-breaking change is a judgement call. We’ll do our best, and we invite you to participate in development discussion on the issue tracker or mailing list.

These policies do not apply to features marked as experimental in the documentation. pandas may change the behavior of experimental features at any time.

### 4.7.2 Python support

Pandas will only drop support for specific Python versions (e.g. 3.6.x, 3.7.x) in pandas major releases.

### 4.8 Roadmap

This page provides an overview of the major themes in pandas’ development. Each of these items requires a relatively large amount of effort to implement. These may be achieved more quickly with dedicated funding or interest from contributors.

An item being on the roadmap does not mean that it will necessarily happen, even with unlimited funding. During the implementation period we may discover issues preventing the adoption of the feature.

Additionally, an item not being on the roadmap does not exclude it from inclusion in pandas. The roadmap is intended for larger, fundamental changes to the project that are likely to take months or years of developer time. Smaller-scoped items will continue to be tracked on our issue tracker.

See Roadmap evolution for proposing changes to this document.

### 4.8.1 Extensibility

Pandas extension types allow for extending NumPy types with custom data types and array storage. Pandas uses extension types internally, and provides an interface for third-party libraries to define their own custom data types.

Many parts of pandas still unintentionally convert data to a NumPy array. These problems are especially pronounced for nested data.

We'd like to improve the handling of extension arrays throughout the library, making their behavior more consistent with the handling of NumPy arrays. We'll do this by cleaning up pandas’ internals and adding new methods to the extension array interface.
4.8.2 String data type

Currently, pandas stores text data in an `object`-dtype NumPy array. The current implementation has two primary drawbacks: First, `object`-dtype is not specific to strings: any Python object can be stored in an `object`-dtype array, not just strings. Second: this is not efficient. The NumPy memory model isn’t especially well-suited to variable width text data.

To solve the first issue, we propose a new extension type for string data. This will initially be opt-in, with users explicitly requesting `dtype="string"`. The array backing this string dtype may initially be the current implementation: an `object`-dtype NumPy array of Python strings.

To solve the second issue (performance), we’ll explore alternative in-memory array libraries (for example, Apache Arrow). As part of the work, we may need to implement certain operations expected by pandas users (for example the algorithm used in `Series.str.upper`). That work may be done outside of pandas.

4.8.3 Apache Arrow interoperability

Apache Arrow is a cross-language development platform for in-memory data. The Arrow logical types are closely aligned with typical pandas use cases.

We’d like to provide better-integrated support for Arrow memory and data types within pandas. This will let us take advantage of its I/O capabilities and provide for better interoperability with other languages and libraries using Arrow.

4.8.4 Block manager rewrite

We’d like to replace pandas current internal data structures (a collection of 1 or 2-D arrays) with a simpler collection of 1-D arrays.

Pandas internal data model is quite complex. A DataFrame is made up of one or more 2-dimensional “blocks”, with one or more blocks per dtype. This collection of 2-D arrays is managed by the BlockManager.

The primary benefit of the BlockManager is improved performance on certain operations (construction from a 2D array, binary operations, reductions across the columns), especially for wide DataFrames. However, the BlockManager substantially increases the complexity and maintenance burden of pandas.

By replacing the BlockManager we hope to achieve

- Substantially simpler code
- Easier extensibility with new logical types
- Better user control over memory use and layout
- Improved micro-performance
- Option to provide a C / Cython API to pandas’ internals

See these design documents for more.
4.8.5 Decoupling of indexing and internals

The code for getting and setting values in pandas’ data structures needs refactoring. In particular, we must clearly separate code that converts keys (e.g., the argument to `DataFrame.loc`) to positions from code that uses these positions to get or set values. This is related to the proposed BlockManager rewrite. Currently, the BlockManager sometimes uses label-based, rather than position-based, indexing. We propose that it should only work with positional indexing, and the translation of keys to positions should be entirely done at a higher level.

Indexing is a complicated API with many subtleties. This refactor will require care and attention. More details are discussed at https://github.com/pandas-dev/pandas/wiki/(Tentative)-rules-for-restructuring-indexing-code

4.8.6 Numba-accelerated operations

Numba is a JIT compiler for Python code. We’d like to provide ways for users to apply their own Numba-jitted functions where pandas accepts user-defined functions (for example, `Series.apply()`, `DataFrame.apply()`, `DataFrame.applymap()`, and in groupby and window contexts). This will improve the performance of user-defined-functions in these operations by staying within compiled code.

4.8.7 Documentation improvements

We’d like to improve the content, structure, and presentation of the pandas documentation. Some specific goals include

- Overhaul the HTML theme with a modern, responsive design (GH15556)
- Improve the “Getting Started” documentation, designing and writing learning paths for users different back-grounds (e.g. brand new to programming, familiar with other languages like R, already familiar with Python).
- Improve the overall organization of the documentation and specific subsections of the documentation to make navigation and finding content easier.

4.8.8 Performance monitoring

pandas uses airspeed velocity to monitor for performance regressions. ASV itself is a fabulous tool, but requires some additional work to be integrated into an open source project’s workflow.

The asv-runner organization, currently made up of pandas maintainers, provides tools built on top of ASV. We have a physical machine for running a number of project’s benchmarks, and tools managing the benchmark runs and reporting on results.

We’d like to fund improvements and maintenance of these tools to

- Be more stable. Currently, they’re maintained on the nights and weekends when a maintainer has free time.
- Tune the system for benchmarks to improve stability, following https://pyperf.readthedocs.io/en/latest/system.html
- Build a GitHub bot to request ASV runs before a PR is merged. Currently, the benchmarks are only run nightly.
4.8.9 Roadmap evolution

pandas continues to evolve. The direction is primarily determined by community interest. Everyone is welcome to review existing items on the roadmap and to propose a new item.

Each item on the roadmap should be a short summary of a larger design proposal. The proposal should include

1. Short summary of the changes, which would be appropriate for inclusion in the roadmap if accepted.
2. Motivation for the changes.
3. An explanation of why the change is in scope for pandas.
4. Detailed design: Preferably with example-usage (even if not implemented yet) and API documentation
5. API Change: Any API changes that may result from the proposal.

That proposal may then be submitted as a GitHub issue, where the pandas maintainers can review and comment on the design. The pandas mailing list should be notified of the proposal.

When there’s agreement that an implementation would be welcome, the roadmap should be updated to include the summary and a link to the discussion issue.

4.9 Developer meetings

We hold regular developer meetings on the second Wednesday of each month at 18:00 UTC. These meetings and their minutes are open to the public. All are welcome to join.

4.9.1 Minutes

The minutes of past meetings are available in this Google Document.

4.9.2 Calendar

This calendar shows all the developer meetings.

You can subscribe to this calendar with the following links:

- iCal
- Google calendar

Additionally, we’ll sometimes have one-off meetings on specific topics. These will be published on the same calendar.
This is the list of changes to pandas between each release. For full details, see the commit logs. For install and upgrade instructions, see Installation.

5.1 Version 1.1

5.1.1 What’s new in 1.1.1 (August 20, 2020)

These are the changes in pandas 1.1.1. See Release notes for a full changelog including other versions of pandas.

Fixed regressions

- Fixed regression in CategoricalIndex.format() where, when stringified scalars had different lengths, the shorter string would be right-filled with spaces, so it had the same length as the longest string (GH35439)
- Fixed regression in Series.truncate() when trying to truncate a single-element series (GH35544)
- Fixed regression where DataFrame.to_numpy() would raise a RuntimeError for mixed dtypes when converting to str (GH35455)
- Fixed regression where read_csv() would raise a ValueError when pandas.options.mode.use_inf_as_na was set to True (GH35493)
- Fixed regression where pandas.testing.assert_series_equal() would raise an error when non-numeric dtypes were passed with check_exact=True (GH35446)
- Fixed regression in .groupby(...).rolling(…) where column selection was ignored (GH35486)
- Fixed regression where DataFrame.interpolate() would raise a TypeError when the DataFrame was empty (GH35598)
- Fixed regression in DataFrame.shift() with axis=1 and heterogeneous dtypes (GH35488)
- Fixed regression in DataFrame.diff() with read-only data (GH35559)
- Fixed regression in .groupby(...).rolling(…) where a segfault would occur with center=True and an odd number of values (GH35552)
- Fixed regression in DataFrame.apply() where functions that altered the input in-place only operated on a single row (GH35462)
- Fixed regression in DataFrame.reset_index() would raise a ValueError on empty DataFrame with a MultiIndex with a datetime64 dtype level (GH35606, GH35657)
pandas: powerful Python data analysis toolkit, Release 1.1.1

- Fixed regression where `pandas.merge_asof()` would raise a `UnboundLocalError` when `left_index`, `right_index` and `tolerance` were set (GH3558)
- Fixed regression in `.groupby(..).rolling(..)` where a custom `BaseIndexer` would be ignored (GH35557)
- Fixed regression in `DataFrame.replace()` and `Series.replace()` where compiled regular expressions would be ignored during replacement (GH35680)
- Fixed regression in `aggregate()` where a list of functions would produce the wrong results if at least one of the functions did not aggregate (GH35490)
- Fixed memory usage issue when instantiating large `pandas.arrays.StringArray` (GH35499)

**Bug fixes**

- Bug in `Styler` whereby `cell_ids` argument had no effect due to other recent changes (GH35588) (GH35663)
- Bug in `pandas.testing.assert_series_equal()` and `pandas.testing.assert_frame_equal()` where extension dtypes were not ignored when `check_dtypes` was set to `False` (GH35715)
- Bug in `to_timedelta()` fails when `arg` is a `Series` with `Int64` dtype containing null values (GH35574)
- Bug in `.groupby(..).rolling(..)` where passing `closed` with column selection would raise a `ValueError` (GH35549)
- Bug in `DataFrame` constructor failing to raise `ValueError` in some cases when `data` and `index` have mismatched lengths (GH33437)

**Contributors**

A total of 20 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Ali McMaster
- Daniel Saxton

5.1.2 What’s new in 1.1.0 (July 28, 2020)

These are the changes in pandas 1.1.0. See Release notes for a full changelog including other versions of pandas.

Enhancements

KeyErrors raised by loc specify missing labels

Previously, if labels were missing for a .loc call, a KeyError was raised stating that this was no longer supported. Now the error message also includes a list of the missing labels (max 10 items, display width 80 characters). See GH34272.

All dtypes can now be converted to StringDtype

Previously, declaring or converting to StringDtype was in general only possible if the data was already only str or nan-like (GH31204). StringDtype now works in all situations where astype(str) or dtype=str work:

For example, the below now works:

```python
In [1]: ser = pd.Series([1, "abc", np.nan], dtype="string")
In [2]: ser
Out[2]:
0 1
1 abc
2 <NA>
Length: 3, dtype: string
In [3]: ser[0]
Out[3]: '1'
In [4]: pd.Series([1, 2, np.nan], dtype="Int64").astype("string")
Out[4]:
0 1
1 2
2 <NA>
Length: 3, dtype: string
```
Non-monotonic PeriodIndex Partial String Slicing

`PeriodIndex` now supports partial string slicing for non-monotonic indexes, mirroring `DatetimeIndex` behavior (GH31096)

For example:

```python
In [5]: dti = pd.date_range("2014-01-01", periods=30, freq="30D")
In [6]: pi = dti.to_period("D")
In [7]: ser_monotonic = pd.Series(np.arange(30), index=pi)
In [8]: shuffler = list(range(0, 30, 2)) + list(range(1, 31, 2))
In [9]: ser = ser_monotonic[shuffler]

In [10]: ser
Out[10]:
2014-01-01 0
2014-03-02 2
2014-05-01 4
2014-06-30 6
2014-08-29 8
...  
2015-09-23 21
2015-11-22 23
2016-01-21 25
2016-03-21 27
2016-05-20 29
Freq: D, Length: 30, dtype: int64

In [11]: ser["2014"]
Out[11]:
2014-01-01 0
2014-03-02 2
2014-05-01 4
2014-06-30 6
2014-08-29 8
2014-10-28 10
2014-12-27 12
2014-01-31 1
2014-04-01 3
2014-05-31 5
2014-07-30 7
2014-09-28 9
2014-11-27 11
Freq: D, Length: 13, dtype: int64

In [12]: ser.loc["May 2015"]
Out[12]:
2015-05-26 17
Freq: D, Length: 1, dtype: int64
```
Comparing two DataFrame or two Series and summarizing the differences

We’ve added DataFrame.compare() and Series.compare() for comparing two DataFrame or two Series (GH30429)

```python
In [13]: df = pd.DataFrame(
      ....:     {
      ....:         "col1": ["a", "a", "b", "b", "a"],
      ....:         "col2": [1.0, 2.0, 3.0, np.nan, 5.0],
      ....:         "col3": [1.0, 2.0, 3.0, 4.0, 5.0]
      ....:     },
      ....:     columns=["col1", "col2", "col3"],
      ....: )

In [14]: df
Out[14]:
   col1 col2 col3
0    a    1.0    1.0
1    a    2.0    2.0
2    b    3.0    3.0
3    b   NaN    4.0
4    a    5.0    5.0
5 rows x 3 columns

In [15]: df2 = df.copy()

In [16]: df2.loc[0, 'col1'] = 'c'

In [17]: df2.loc[2, 'col3'] = 4.0

In [18]: df2
Out[18]:
   col1 col2 col3
0    c    1.0    1.0
1    a    2.0    2.0
2    b    3.0    4.0
3    b   NaN    4.0
4    a    5.0    5.0
5 rows x 3 columns

In [19]: df.compare(df2)
Out[19]:
       col1       col3
self          other       self       other
0    a         c    NaN       NaN
2  NaN        NaN      3.0       4.0

[2 rows x 4 columns]
```

See User Guide for more details.
Allow NA in groupby key

With `groupby`, we’ve added a `dropna` keyword to `DataFrame.groupby()` and `Series.groupby()` in order to allow NA values in group keys. Users can define `dropna` to `False` if they want to include NA values in groupby keys. The default is set to `True` for `dropna` to keep backwards compatibility (GH3729).

```python
In [20]: df_list = [[1, 2, 3], [1, None, 4], [2, 1, 3], [1, 2, 2]]
In [21]: df_dropna = pd.DataFrame(df_list, columns=['a', 'b', 'c'])
In [22]: df_dropna
Out[22]:
        a  b  c
0      1  2.0 3
1      1  NaN 4
2      2  1.0 3
3      1  2.0 2
[4 rows x 3 columns]
```

# Default `dropna` is set to True, which will exclude NaNs in keys
```python
In [23]: df_dropna.groupby(by=['b'], dropna=True).sum()
Out[23]:
        a  c
   b   
1.0  2  3
2.0  2  5
```

# In order to allow NaN in keys, set `dropna` to False
```python
In [24]: df_dropna.groupby(by=['b'], dropna=False).sum()
Out[24]:
        a  c
   b   
1.0  2  3
2.0  2  5
NaN  1  4
```

The default setting of `dropna` argument is `True` which means NA are not included in group keys.

Sorting with keys

We’ve added a `key` argument to the `DataFrame` and `Series` sorting methods, including `DataFrame.sort_values()`, `DataFrame.sort_index()`, `Series.sort_values()`, and `Series.sort_index()`. The key can be any callable function which is applied column-by-column to each column used for sorting, before sorting is performed (GH27237). See `sort_values with keys` and `sort_index with keys` for more information.

```python
In [25]: s = pd.Series(['C', 'a', 'B'])
In [26]: s
Out[26]:
```

(continues on next page)
Note how this is sorted with capital letters first. If we apply the `Series.str.lower()` method, we get

```python
In [28]: s.sort_values(key=lambda x: x.str.lower())
Out[28]:
  0 C
  1 a
  2 B
Length: 3, dtype: object
```

When applied to a `DataFrame`, they key is applied per-column to all columns or a subset if `by` is specified, e.g.

```python
In [29]: df = pd.DataFrame({'a': ['C', 'C', 'a', 'a', 'B', 'B'],
                       'b': [1, 2, 3, 4, 5, 6]})
In [30]: df.sort_values(by=['a'], key=lambda col: col.str.lower())
Out[30]:
     a  b
  2  a  3
  3  a  4
  4  B  5
  5  B  6
  0  C  1
  1  C  2
[6 rows x 2 columns]
```

For more details, see examples and documentation in `DataFrame.sort_values()`, `Series.sort_values()`, and `sort_index()`. 
Fold argument support in Timestamp constructor

Timestamp: now supports the keyword-only fold argument according to PEP 495 similar to parent `datetime.datetime` class. It supports both accepting fold as an initialization argument and inferring fold from other constructor arguments (GH25057, GH31338). Support is limited to `dateutil` timezones as `pytz` doesn’t support fold.

For example:

```
In [32]: ts = pd.Timestamp("2019-10-27 01:30:00+00:00")
In [33]: ts.fold
Out[33]: 0
```

```
In [34]: ts = pd.Timestamp(year=2019, month=10, day=27, hour=1, minute=30, ...
   ....:   tz="dateutil/Europe/London", fold=1)
   ....:
In [35]: ts
Out[35]: Timestamp('2019-10-27 01:30:00+0000', tz='dateutil//usr/share/zoneinfo/
   →Europe/London')
```

For more on working with fold, see Fold subsection in the user guide.

Parsing timezone-aware format with different timezones in to_datetime

`to_datetime()` now supports parsing formats containing timezone names (%Z) and UTC offsets (%z) from different timezones then converting them to UTC by setting `utc=True`. This would return a `DatetimeIndex` with timezone at UTC as opposed to an `Index` with object dtype if `utc=True` is not set (GH32792).

For example:

```
In [36]: tz_strs = ["2010-01-01 12:00:00 +0100", "2010-01-01 12:00:00 -0100",
   ....:   "2010-01-01 12:00:00 +0300", "2010-01-01 12:00:00 +0400"]
   ....:
In [37]: pd.to_datetime(tz_strs, format='%Y-%m-%d %H:%M:%S %z', utc=True)
Out[37]:
DatetimeIndex(['2010-01-01 11:00:00+00:00', '2010-01-01 13:00:00+00:00',
   '2010-01-01 09:00:00+00:00', '2010-01-01 08:00:00+00:00'],
   dtype='datetime64[ns, UTC]', freq=None)
```

```
In [38]: pd.to_datetime(tz_strs, format='%Y-%m-%d %H:%M:%S %z')
Out[38]:
Index(['2010-01-01 12:00:00+01:00', '2010-01-01 12:00:00+01:00',
   '2010-01-01 12:00:00+03:00', '2010-01-01 12:00:00+04:00'],
   dtype='object')
```
Grouper and resample now supports the arguments origin and offset

Grouper and DataFrame.resample() now supports the arguments origin and offset. It let the user control the timestamp on which to adjust the grouping. (GH31809)

The bins of the grouping are adjusted based on the beginning of the day of the time series starting point. This works well with frequencies that are multiples of a day (like 30D) or that divides a day (like 90s or 1min). But it can create inconsistencies with some frequencies that do not meet this criteria. To change this behavior you can now specify a fixed timestamp with the argument origin.

Two arguments are now deprecated (more information in the documentation of DataFrame.resample()):

- base should be replaced by offset.
- loffset should be replaced by directly adding an offset to the index DataFrame after being resampled.

Small example of the use of origin:

In [39]: start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
In [40]: middle = '2000-10-02 00:00:00'
In [41]: rng = pd.date_range(start, end, freq='7min')
In [42]: ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
In [43]: ts
Out[43]:
2000-10-01 23:30:00    0
2000-10-01 23:37:00    3
2000-10-01 23:44:00    6
2000-10-01 23:51:00    9
2000-10-01 23:58:00   12
2000-10-02 00:05:00   15
2000-10-02 00:12:00   18
2000-10-02 00:19:00   21
2000-10-02 00:26:00   24
Freq: 7T, Length: 9, dtype: int64

Resample with the default behavior 'start_day' (origin is 2000-10-01 00:00:00):

In [44]: ts.resample('17min').sum()
Out[44]:
2000-10-01 23:14:00    0
2000-10-01 23:31:00    9
2000-10-01 23:48:00   21
2000-10-02 00:05:00   54
2000-10-02 00:22:00   24
Freq: 17T, Length: 5, dtype: int64

In [45]: ts.resample('17min', origin='start_day').sum()
Out[45]:
2000-10-01 23:14:00    0
2000-10-01 23:31:00    9
2000-10-01 23:48:00   21
2000-10-02 00:05:00   54
2000-10-02 00:22:00   24
Freq: 17T, Length: 5, dtype: int64

Resample using a fixed origin:
In [46]: ts.resample('17min', origin='epoch').sum()
Out[46]:
2000-10-01 23:18:00 0
2000-10-01 23:35:00 18
2000-10-01 23:52:00 27
2000-10-02 00:09:00 39
2000-10-02 00:26:00 24
Freq: 17T, Length: 5, dtype: int64

In [47]: ts.resample('17min', origin='2000-01-01').sum()
Out[47]:
2000-10-01 23:24:00 3
2000-10-01 23:41:00 15
2000-10-01 23:58:00 45
2000-10-02 00:15:00 45
Freq: 17T, Length: 4, dtype: int64

If needed you can adjust the bins with the argument offset (a `Timedelta`) that would be added to the default origin.

For a full example, see: Use origin or offset to adjust the start of the bins.

**fsspec now used for filesystem handling**

For reading and writing to filesystems other than local and reading from HTTP(S), the optional dependency `fsspec` will be used to dispatch operations (GH33452). This will give unchanged functionality for S3 and GCS storage, which were already supported, but also add support for several other storage implementations such as Azure Datalake and Blob, SSH, FTP, dropbox and github. For docs and capabilities, see the `fsspec` docs.

The existing capability to interface with S3 and GCS will be unaffected by this change, as `fsspec` will still bring in the same packages as before.

**Other enhancements**

- Compatibility with matplotlib 3.3.0 (GH34850)
- `IntegerArray.astype()` now supports `datetime64` dtype (GH32538)
- `IntegerArray` now implements the `sum` operation (GH33172)
- Added `pandas.errors.InvalidIndexError` (GH34570).
- Added `DataFrame.value_counts()` (GH5377)
- Added a `pandas.api.indexers.FixedForwardWindowIndexer()` class to support forward-looking windows during rolling operations.
- Added a `pandas.api.indexers.VariableOffsetWindowIndexer()` class to support rolling operations with non-fixed offsets (GH34994)
- `describe()` now includes a `datetime_is_numeric` keyword to control how datetime columns are summarized (GH30164, GH34798)
- `Styler` may now render CSS more efficiently where multiple cells have the same styling (GH30876)
- `highlight_null()` now accepts `subset` argument (GH31345)
- When writing directly to a sqlite connection `DataFrame.to_sql()` now supports the `multi` method (GH29921)
- pandas.errors.OptionError is now exposed in pandas.errors (GH27553)
- Added api.extensions.ExtensionArray.argmax() and api.extensions.ExtensionArray.argmin() (GH24382)
- timedelta_range() will now infer a frequency when passed start,stop, and periods (GH32377)
- Positional slicing on a IntervalIndex now supports slices with step > 1 (GH31658)
- Series.str now has a fullmatch method that matches a regular expression against the entire string in each row of the Series, similar to re.fullmatch (GH32806).
- DataFrame.sample() will now also allow array-like and BitGenerator objects to be passed to random_state as seeds (GH32503)
- Index.union() will now raise RunTimeWarning for MultiIndex objects if the object inside are un-sortable. Pass sort=False to suppress this warning (GH33015)
- Added Series.dt.isocalendar() and DatetimeIndex.isocalendar() that returns a DataFrame with year, week, and day calculated according to the ISO 8601 calendar (GH33206, GH34392).
- The DataFrame.to_feather() method now supports additional keyword arguments (e.g. to set the compression) that are added in pyarrow 0.17 (GH33422).
- The cut() will now accept parameter ordered with default ordered=True. If ordered=False and no labels are provided, an error will be raised (GH33141)
- DataFrame.to_csv(), DataFrame.to_pickle(), and DataFrame.to_json() now support passing a dict of compression arguments when using the gzip and bz2 protocols. This can be used to set a custom compression level, e.g., df.to_csv(path, compression={'method': 'gzip', 'compresslevel': 1}) (GH33196)
- melt() has gained an ignore_index (default True) argument that, if set to False, prevents the method from dropping the index (GH14440).
- Series.update() now accepts objects that can be coerced to a Series, such as dict and list, mirroring the behavior of DataFrame.update() (GH33215)
- transform() and aggregate() have gained engine and engine_kwags arguments that support executing functions with Numba (GH32854, GH33388)
- interpolate() now supports SciPy interpolation method scipy.interpolate.CubicSpline as method cubicspline (GH33670)
- DataFrameGroupBy and SeriesGroupBy now implement the sample method for doing random sampling within groups (GH31775)
- DataFrame.to_numpy() now supports the na_value keyword to control the NA sentinel in the output array (GH33820)
- Added api.extension.ExtensionArray.equals to the extension array interface, similar to Series.equals() (GH27081)
- The minimum supported dtypes version has increased to 105 in read_stata() and StataReader (GH26667).
- to_stata() supports compression using the compression keyword argument. Compression can either be inferred or explicitly set using a string or a dictionary containing both the method and any additional arguments that are passed to the compression library. Compression was also added to the low-level Stata-file writers StataWriter, StataWriter117, and StataWriterUTF8 (GH26599).
- HDFStore.put() now accepts a track_times parameter. This parameter is passed to the create_table method of PyTables (GH32682).
• Series.plot() and DataFrame.plot() now accepts xlabel and ylabel parameters to present labels on x and y axis (GH9093).
• Made pandas.core.window.rolling.Rolling and pandas.core.window.expanding. Expanding iterable(GH11704)
• Made option_context a contextlib.ContextDecorator, which allows it to be used as a decorator over an entire function (GH34253).
• DataFrame.to_csv() and Series.to_csv() now accept an errors argument (GH22610)
• transform() now allows func to be pad, backfill and cumcount (GH31260).
• read_json() now accepts an nrows parameter. (GH33916).
• DataFrame.hist(), Series.hist(), core.groupby.DataFrameGroupBy.hist(), and core.groupby.SeriesGroupBy.hist() have gained the legend argument. Set to True to show a legend in the histogram. (GH6279)
• concat() and append() now preserve extension dtypes, for example combining a nullable integer column with a numpy integer column will no longer result in object dtype but preserve the integer dtype (GH33607, GH34339, GH34095).
• read_gbq() now allows to disable progress bar (GH33360).
• read_gbq() now supports the max_results kwarg from pandas-gbq (GH34639).
• DataFrame.cov() and Series.cov() now support a new parameter ddof to support delta degrees of freedom as in the corresponding numpy methods (GH34611).
• DataFrame.to_html() and DataFrame.to_string()'s col_space parameter now accepts a list or dict to change only some specific columns’ width (GH28917).
• DataFrame.to_excel() can now also write OpenOffice spreadsheet (.ods) files (GH27222)
• explode() now accepts ignore_index to reset the index, similar to pd.concat() or DataFrame.sort_values() (GH34932).
• DataFrame.to_markdown() and Series.to_markdown() now accept index argument as an alias for tabulate’s showindex (GH32667)
• read_csv() now accepts string values like “0”, “0.0”, “1”, “1.0” as convertible to the nullable Boolean dtype (GH34859)
• pandas.core.window.ExponentialMovingWindow now supports a times argument that allows mean to be calculated with observations spaced by the timestamps in times (GH34839)
• DataFrame.agg() and Series.agg() now accept named aggregation for renaming the output columns/indexes. (GH26513)
• compute.use_numba now exists as a configuration option that utilizes the numba engine when available (GH33966, GH35374)
• Series.plot() now supports asymmetric error bars. Previously, if Series.plot() received a “2xN” array with error values for yerr and/or xerr, the left/lower values (first row) were mirrored, while the right/upper values (second row) were ignored. Now, the first row represents the left/lower error values and the second row the right/upper error values. (GH9536)
Notable bug fixes

These are bug fixes that might have notable behavior changes.

**MultiIndex.get_indexer interprets method argument correctly**

This restores the behavior of `MultiIndex.get_indexer()` with `method='backfill'` or `method='pad'` to the behavior before pandas 0.23.0. In particular, MultiIndexes are treated as a list of tuples and padding or backfilling is done with respect to the ordering of these lists of tuples (GH29896).

As an example of this, given:

```python
In [48]: df = pd.DataFrame({
    ....:     'a': [0, 0, 0, 0],
    ....:     'b': [0, 2, 3, 4],
    ....:     'c': ['A', 'B', 'C', 'D'],
    ....:}).set_index(['a', 'b'])
    ....:
In [49]: mi_2 = pd.MultiIndex.from_product([[0], [-1, 0, 1, 3, 4, 5]])
```

The differences in reindexing `df` with `mi_2` and using `method='backfill'` can be seen here:

- For pandas `>= 0.23, < 1.1.0`:
  ```python
  In [1]: df.reindex(mi_2, method='backfill')
  Out[1]:
  c
  0  -1  A
  0     A
  1     D
  3     A
  4     A
  5     C
  [6 rows x 1 columns]
  ```

- For pandas `<0.23, >= 1.1.0`:
  ```python
  In [50]: df.reindex(mi_2, method='backfill')
  Out[50]:
  c
  0  -1  A
  0     A
  1     B
  3     C
  4     D
  5     NaN
  [6 rows x 1 columns]
  ```

And the differences in reindexing `df` with `mi_2` and using `method='pad'` can be seen here:

- For pandas `>= 0.23, < 1.1.0`:
  ```python
  In [1]: df.reindex(mi_2, method='pad')
  Out[1]:
  c
  0  -1  NaN
  ```

</tbody>
</table>

pandas < 0.23, >= 1.1.0

```
In [51]: df.reindex(mi_2, method='pad')
Out[51]:
        c
0  -1  NaN
0   A
1   A
3   C
4   D
5   D
[6 rows x 1 columns]
```

Failed Label-Based Lookups Always Raise KeyError

Label lookups `series[key], series.loc[key]` and `frame.loc[key]` used to raise either `KeyError` or `TypeError` depending on the type of key and type of `Index`. These now consistently raise `KeyError (GH31867)`.

```
In [52]: ser1 = pd.Series(range(3), index=[0, 1, 2])
In [53]: ser2 = pd.Series(range(3), index=pd.date_range("2020-02-01", periods=3))

Previous behavior:
```
```
In [3]: ser1[1.5]
...  
TypeError: cannot do label indexing on Int64Index with these indexers [1.5] of type float

In [4] ser1["foo"]
...
KeyError: 'foo'

In [5]: ser1.loc[1.5]
...  
TypeError: cannot do label indexing on Int64Index with these indexers [1.5] of type float

In [6]: ser1.loc["foo"]
...  
KeyError: 'foo'

In [7]: ser2.loc[1]
...  
TypeError: cannot do label indexing on DatetimeIndex with these indexers [1] of type int

In [8]: ser2.loc[pd.Timestamp(0)]
```

(continues on next page)
...  
KeyError: Timestamp('1970-01-01 00:00:00')  

New behavior:

```
In [3]: ser1[1.5]  
...  
KeyError: 1.5  
In [4] ser1['foo']  
...  
KeyError: 'foo'  
In [5]: ser1.loc[1.5]  
...  
KeyError: 1.5  
In [6]: ser1.loc['foo']  
...  
KeyError: 'foo'  
In [7]: ser2.loc[1]  
...  
KeyError: 1  
In [8]: ser2.loc[pd.Timestamp(0)]  
...  
KeyError: Timestamp('1970-01-01 00:00:00')
```

Similarly, `DataFrame.at()` and `Series.at()` will raise a `TypeError` instead of a `ValueError` if an incompatible key is passed, and `KeyError` if a missing key is passed, matching the behavior of `.loc[]` (GH31722)

**Failed Integer Lookups on MultiIndex Raise KeyError**

Indexing with integers with a `MultiIndex` that has an integer-dtype first level incorrectly failed to raise `KeyError` when one or more of those integer keys is not present in the first level of the index (GH33539)

```
In [54]: idx = pd.Index(range(4))  
In [55]: dti = pd.date_range("2000-01-03", periods=3)  
In [56]: mi = pd.MultiIndex.from_product([idx, dti])  
In [57]: ser = pd.Series(range(len(mi)), index=mi)
```

Previous behavior:

```
In [5]: ser[[5]]  
Out[5]: Series([], dtype: int64)
```

New behavior:

```
In [5]: ser[[5]]  
...  
KeyError: '[5] not in index'
```
DataFrame.merge() preserves right frame’s row order

`DataFrame.merge()` now preserves the right frame’s row order when executing a right merge (GH27453)

In [58]: left_df = pd.DataFrame({'animal': ['dog', 'pig'],  
                         'max_speed': [40, 11]})

In [59]: right_df = pd.DataFrame({'animal': ['quetzal', 'pig'],  
                            'max_speed': [80, 11]})

In [60]: left_df
Out[60]:
         animal  max_speed
0       dog        40
1       pig        11

[2 rows x 2 columns]

In [61]: right_df
Out[61]:
         animal  max_speed
0     quetzal        80
1       pig        11

[2 rows x 2 columns]

Previous behavior:

`>> left_df.merge(right_df, on=['animal', 'max_speed'], how="right")`

<table>
<thead>
<tr>
<th>animal</th>
<th>max_speed</th>
</tr>
</thead>
<tbody>
<tr>
<td>pig</td>
<td>11</td>
</tr>
<tr>
<td>quetzal</td>
<td>80</td>
</tr>
</tbody>
</table>

New behavior:

In [62]: left_df.merge(right_df, on=['animal', 'max_speed'], how="right")
Out[62]:
         animal  max_speed
0     quetzal        80
1       pig        11

[2 rows x 2 columns]

Assignment to multiple columns of a DataFrame when some columns do not exist

Assignment to multiple columns of a `DataFrame` when some of the columns do not exist would previously assign the values to the last column. Now, new columns will be constructed with the right values. (GH13658)

In [63]: df = pd.DataFrame({'a': [0, 1, 2], 'b': [3, 4, 5]})

In [64]: df
Out[64]:
     a  b
0   0  3
1   1  4
2   2  5

(continues on next page)
Previous behavior:

```python
In [3]: df[['a', 'c']] = 1
In [4]: df
Out[4]:
   a  b
  0 1 1
  1 1 1
  2 1 1
[3 rows x 2 columns]
```

New behavior:

```python
In [65]: df[['a', 'c']] = 1
In [66]: df
Out[66]:
   a  b  c
  0 1 3 1
  1 1 4 1
  2 1 5 1
[3 rows x 3 columns]
```

Consistency across groupby reductions

Using `DataFrame.groupby()` with `as_index=True` and the aggregation `nunique` would include the grouping column(s) in the columns of the result. Now the grouping column(s) only appear in the index, consistent with other reductions. (GH32579)

```python
In [67]: df = pd.DataFrame({"a": ["x", "x", "y", "y"], "b": [1, 1, 2, 3]})
In [68]: df.groupby("a", as_index=True).nunique()
Out[68]:
   a  b
  0 1 1
  1 1 2
  2 1 3
[4 rows x 2 columns]
```

Previous behavior:

```python
In [3]: df.groupby("a", as_index=True).nunique()
Out[4]:
   a  b
  a
  x 1 1
  y 1 2
```
New behavior:

```python
In [69]: df.groupby("a", as_index=True).nunique()
Out[69]:
   b
  a
 x 1
 y 2
[2 rows x 1 columns]
```

Using `DataFrame.groupby()` with `as_index=False` and the function `idxmax, idxmin, mad, nunique, sem, skew, or std` would modify the grouping column. Now the grouping column remains unchanged, consistent with other reductions. (GH21090, GH10355)

Previous behavior:

```python
In [3]: df.groupby("a", as_index=False).nunique()
Out[4]:
   a  b
  0 1 1
 1 1 2
```

New behavior:

```python
In [70]: df.groupby("a", as_index=False).nunique()
Out[70]:
   a  b
  0 x 1
 1 y 2
[2 rows x 2 columns]
```

The method `size()` would previously ignore `as_index=False`. Now the grouping columns are returned as columns, making the result a `DataFrame` instead of a `Series`. (GH32599)

Previous behavior:

```python
In [3]: df.groupby("a", as_index=False).size()
Out[4]:
   a
  x  2
  y  2
dtype: int64
```

New behavior:

```python
In [71]: df.groupby("a", as_index=False).size()
Out[71]:
   a  size
  0 x  2
 1 y  2
[2 rows x 2 columns]
```
**agg() lost results with as_index=False when relabeling columns**

Previously `agg()` lost the result columns, when the `as_index` option was set to `False` and the result columns were relabeled. In this case the result values were replaced with the previous index (GH32240).

```python
In [72]: df = pd.DataFrame({
    "key": ["x", "y", "z", "x", "y", "z"],
    "val": [1.0, 0.8, 2.0, 3.0, 3.6, 0.75]})

In [73]: df
Out[73]:
   key  val
  0   x  1.00
  1   y  0.80
  2   z  2.00
  3   x  3.00
  4   y  3.60
  5   z  0.75

Previous behavior:

```python
In [2]: grouped = df.groupby("key", as_index=False)
In [3]: result = grouped.agg(min_val=pd.NamedAgg(column="val", aggfunc="min"))
In [4]: result
Out[4]:
   min_val
  0   x
  1   y
  2   z
```

New behavior:

```python
In [74]: grouped = df.groupby("key", as_index=False)
In [75]: result = grouped.agg(min_val=pd.NamedAgg(column="val", aggfunc="min"))
In [76]: result
Out[76]:
   key  min_val
  0   x    1.00
  1   y    0.80
  2   z    0.75
```

[3 rows x 2 columns]
apply and applymap on DataFrame evaluates first row/column only once

```
In [77]: df = pd.DataFrame({'a': [1, 2], 'b': [3, 6]})

In [78]: def func(row):
    ....:     print(row)
    ....:     return row
    ....:

Previous behavior:

```
In [4]: df.apply(func, axis=1)
   a    1
   b    3
Name: 0, dtype: int64
   a    1
   b    3
Name: 0, dtype: int64
   a    2
   b    6
Name: 1, dtype: int64
Out[4]:
   a  b
  0 1 3
  1 2 6

New behavior:

```
In [79]: df.apply(func, axis=1)
   a    1
   b    3
Name: 0, Length: 2, dtype: int64
   a    2
   b    6
Name: 1, Length: 2, dtype: int64
Out[79]:
   a  b
  0 1 3
  1 2 6
[2 rows x 2 columns]

Increased minimum versions for dependencies

Some minimum supported versions of dependencies were updated (GH33718, GH29766, GH29723, pytables >= 3.4.3). If installed, we now require:

<table>
<thead>
<tr>
<th>Package</th>
<th>Minimum Version</th>
<th>Required</th>
<th>Changed</th>
</tr>
</thead>
<tbody>
<tr>
<td>numpy</td>
<td>1.15.4</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>pytz</td>
<td>2015.4</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>python-dateutil</td>
<td>2.7.3</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>bottleneck</td>
<td>1.2.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>numexpr</td>
<td>2.6.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>pytest (dev)</td>
<td>4.0.2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
For **optional libraries** the general recommendation is to use the latest version. The following table lists the lowest version per library that is currently being tested throughout the development of pandas. Optional libraries below the lowest tested version may still work, but are not considered supported.

<table>
<thead>
<tr>
<th>Package</th>
<th>Minimum Version</th>
<th>Changed</th>
</tr>
</thead>
<tbody>
<tr>
<td>beautifulsoup4</td>
<td>4.6.0</td>
<td></td>
</tr>
<tr>
<td>fastparquet</td>

<td></td>
</tr>
<tr>
<td>xlwt</td>
<td>1.2.0</td>
<td></td>
</tr>
<tr>
<td>pandas-gbq</td>
<td>1.2.0</td>
<td>X</td>
</tr>
</tbody>
</table>

See *Dependencies* and *Optional dependencies* for more.

**Development Changes**

- The minimum version of Cython is now the most recent bug-fix version (0.29.16) (GH33334).

**Deprecations**

- Lookups on a *Series* with a single-item list containing a slice (e.g. `ser[[slice(0, 4)]]`) are deprecated and will raise in a future version. Either convert the list to a tuple, or pass the slice directly instead (GH31333).

- `DataFrame.mean()` and `DataFrame.median()` with `numeric_only=None` will include `datetime64` and `datetime64[ tz]` columns in a future version (GH29941).

- Setting values with `.loc` using a positional slice is deprecated and will raise in a future version. Use `.loc` with labels or `.iloc` with positions instead (GH31840).

- `DataFrame.to_dict()` has deprecated accepting short names for `orient` and will raise in a future version (GH32515).

- `Categorical.to_dense()` is deprecated and will be removed in a future version, use `np.asarray(cat)` instead (GH32639).

- The fastpath keyword in the `SingleBlockManager` constructor is deprecated and will be removed in a future version (GH33092).

- Providing suffixes as a set in `pandas.merge()` is deprecated. Provide a tuple instead (GH33740, GH34741).
• Indexing a `Series` with a multi-dimensional indexer like `[:, None]` to return an ndarray now raises a `FutureWarning`. Convert to a NumPy array before indexing instead (GH27837)

• `Index.is_mixed()` is deprecated and will be removed in a future version, check `index.inferred_type` directly instead (GH32922)

• Passing any arguments but the first one to `read_html()` as positional arguments is deprecated. All other arguments should be given as keyword arguments (GH27573).

• Passing any arguments but `path_or_buf` (the first one) to `read_json()` as positional arguments is deprecated. All other arguments should be given as keyword arguments (GH27573).

• Passing any arguments but the first two to `read_excel()` as positional arguments is deprecated. All other arguments should be given as keyword arguments (GH27573).

• `pandas.api.types.is_categorical()` is deprecated and will be removed in a future version; use `pandas.api.types.is_categorical_dtype()` instead (GH33385)

• `Index.get_value()` is deprecated and will be removed in a future version (GH19728)

• `Series.dt.week()` and `Series.dt.weekofyear()` are deprecated and will be removed in a future version, use `Series.dt.isocalendar().week()` instead (GH33595)

• `DatetimeIndex.week()` and `DatetimeIndex.weekofyear` are deprecated and will be removed in a future version, use `DatetimeIndex.isocalendar().week` instead (GH33595)

• `DateOffset.__call__()` is deprecated and will be removed in a future version, use `offset + other` instead (GH34171)

• `apply_index()` is deprecated and will be removed in a future version. Use `offset + other` instead (GH34580)

• `DataFrame.tshift()` and `Series.tshift()` are deprecated and will be removed in a future version, use `DataFrame.shift()` and `Series.shift()` instead (GH11631)

• Indexing an `Index` object with a float key is deprecated, and will raise an `IndexError` in the future. You can manually convert to an integer key instead (GH34191).

• The `squeeze` keyword in `groupby()` is deprecated and will be removed in a future version (GH32380)

• The `tz` keyword in `Period.to_timestamp()` is deprecated and will be removed in a future version; use `per.to_timestamp(...).tz_localize(tz)` instead (GH34522)

• `DatetimeIndex.to_perioddelta()` is deprecated and will be removed in a future version. Use `index - index.to_period(freq).to_timestamp()` instead (GH34853)

• `DataFrame.melt()` accepting a `value_name` that already exists is deprecated, and will be removed in a future version (GH34731)

• The `center` keyword in the `DataFrame.expanding()` function is deprecated and will be removed in a future version (GH20647)
Performance improvements

- Performance improvement in `Timedelta` constructor (GH30543)
- Performance improvement in `Timestamp` constructor (GH30543)
- Performance improvement in flex arithmetic ops between `DataFrame` and `Series` with `axis=0` (GH31296)
- Performance improvement in arithmetic ops between `DataFrame` and `Series` with `axis=1` (GH33600)
- The internal index method `_shallow_copy()` now copies cached attributes over to the new index, avoiding creating these again on the new index. This can speed up many operations that depend on creating copies of existing indexes (GH28584, GH32640, GH32669)
- Significant performance improvement when creating a `DataFrame` with sparse values from `scipy.sparse` matrices using the `DataFrame.sparse.from_spmatrix()` constructor (GH32821, GH32825, GH32826, GH32856, GH32858).
- Performance improvement for groupby methods `first()` and `last()` (GH34178)
- Performance improvement in `factorize()` for nullable (integer and Boolean) dtypes (GH33064).
- Performance improvement when constructing `Categorical` objects (GH33921)
- Fixed performance regression in `pandas.qcut()` and `pandas.cut()` (GH33921)
- Performance improvement in reductions (sum, prod, min, max) for nullable (integer and Boolean) dtypes (GH30982, GH33261, GH33442).
- Performance improvement in arithmetic operations between two `DataFrame` objects (GH32779)
- Performance improvement in `pandas.core.groupby.RollingGroupby` (GH34052)
- Performance improvement in arithmetic operations (sub, add, mul, div) for `MultiIndex` (GH34297)
- Performance improvement in `DataFrame[bool_indexer]` when `bool_indexer` is a list (GH33924)
- Significant performance improvement of `io.formats.style.Styler.render()` with styles added with various ways such as `io.formats.style.Styler.apply()`, `io.formats.style.Styler.applymap()` or `io.formats.style.Styler.bar()` (GH19917)

Bug fixes

Categorical

- Passing an invalid `fill_value` to `Categorical.take()` raises a `ValueError` instead of `TypeError` (GH33660)
- Combining a `Categorical` with integer categories and which contains missing values with a float dtype column in operations such as `concat()` or `append()` will now result in a float column instead of an object dtype column (GH33607)
- Bug where `merge()` was unable to join on non-unique categorical indices (GH28189)
- Bug when passing categorical data to `Index` constructor along with `dtype=object` incorrectly returning a `CategoricalIndex` instead of object-dtype `Index` (GH32167)
- Bug where `Categorical` comparison operator `__ne__` would incorrectly evaluate to `False` when either element was missing (GH32276)
- `Categorical.fillna()` now accepts `Categorical` other argument (GH32420)
- Repr of `Categorical` was not distinguishing between `int` and `str` (GH33676)
Datetimelike

- Passing an integer dtype other than `int64` to `np.array(period_index, dtype=...)` will now raise `TypeError` instead of incorrectly using `int64` (GH32255)
- `Series.to_timestamp()` now raises a `TypeError` if the axis is not a `PeriodIndex`. Previously an `AttributeError` was raised (GH33327)
- `Series.to_period()` now raises a `TypeError` if the axis is not a `DatetimeIndex`. Previously an `AttributeError` was raised (GH33327)
- `Period` no longer accepts tuples for the `freq` argument (GH34658)
- Bug in `Timestamp` where constructing a `Timestamp` from ambiguous epoch time and calling constructor again changed the `Timestamp.value()` property (GH24329)
- `DateTimeArray.searchsorted()`, `TimedeltaArray.searchsorted()`, `PeriodArray.searchsorted()` not recognizing non-pandas scalars and incorrectly raising `ValueError` instead of `TypeError` (GH30950)
- Bug in `Timestamp` where constructing `Timestamp` with dateutil timezone less than 128 nanoseconds before daylight saving time switch from winter to summer would result in nonexistent time (GH31043)
- Bug in `Period.to_timestamp()`, `Period.start_time()` with microsecond frequency returning a timestamp one nanosecond earlier than the correct time (GH31475)
- `Timestamp` raised a confusing error message when year, month or day is missing (GH31200)
- Bug in `DatetimeIndex` constructor incorrectly accepting `bool`-dtype inputs (GH32668)
- Bug in `DatetimeIndex.searchsorted()` not accepting a list or `Series` as its argument (GH32762)
- Bug where `PeriodIndex()` raised when passed a `Series` of strings (GH26109)
- Bug in `Timestamp` arithmetic when adding or subtracting an `np.ndarray` with `timedelta64` dtype (GH33296)
- Bug in `DatetimeIndex.to_period()` not inferring the frequency when called with no arguments (GH33358)
- Bug in `DatetimeIndex.tz_localize()` incorrectly retaining `freq` in some cases where the original `freq` is no longer valid (GH30511)
- Bug in `DatetimeIndex.intersection()` losing `freq` and timezone in some cases (GH33604)
- Bug in `DatetimeIndex.get_indexer()` where incorrect output would be returned for mixed datetime-like targets (GH33741)
- Bug in `DatetimeIndex` addition and subtraction with some types of `DateOffset` objects incorrectly retaining an invalid `freq` attribute (GH33779)
- Bug in `DatetimeIndex` where setting the `freq` attribute on an index could silently change the `freq` attribute on another index viewing the same data (GH33552)
- `DataFrame.min()` and `DataFrame.max()` were not returning consistent results with `Series.min()` and `Series.max()` when called on objects initialized with empty `pd.to_datetime()`
- Bug in `DatetimeIndex.intersection()` and `TimedeltaIndex.intersection()` with results not having the correct name attribute (GH33904)
- Bug in `DatetimeArray.__setitem__()`, `TimedeltaArray.__setitem__()`, `PeriodArray.__setitem__()` incorrectly allowing values with `int64` dtype to be silently cast (GH33717)
- Bug in subtracting `TimedeltaIndex` from `Period` incorrectly raising `TypeError` in some cases where it should succeed and `IncompatibleFrequency` in some cases where it should raise `TypeError` (GH33883)

- Bug in constructing a `Series` or `Index` from a read-only NumPy array with non-ns resolution which converted to object dtype instead of coercing to `datetime64[ns]` dtype when within the timestamp bounds (GH34843).

- The `freq` keyword in `Period, date_range(), period_range(), pd.tseries.frequencies.to_offset()` no longer allows tuples, pass as string instead (GH34703)

- Bug in `DataFrame.append()` when appending a `Series` containing a scalar tz-aware `Timestamp` to an empty `DataFrame` resulted in an object column instead of `datetime64[ns, tz]` dtype (GH35038)

- OutOfBoundsDatetime issues an improved error message when timestamp is out of implementation bounds. (GH32967)

- Bug in `AbstractHolidayCalendar.holidays()` when no rules were defined (GH31415)

- Bug in `Tick` comparisons raising `TypeError` when comparing against timedelta-like objects (GH34088)

- Bug in `Tick` multiplication raising `TypeError` when multiplying by a float (GH34486)

**Timedelta**

- Bug in constructing a `Timedelta` with a high precision integer that would round the `Timedelta` components (GH31354)

- Bug in dividing `np.nan` or `None` by `Timedelta` incorrectly returning `NaT` (GH31869)

- `Timedelta` now understands `µs` as an identifier for microsecond (GH32899)

- `Timedelta` string representation now includes nanoseconds, when nanoseconds are non-zero (GH32899)

- Bug in comparing a `Timedelta` object against an `np.ndarray` with `timedelta64` dtype incorrectly viewing all entries as unequal (GH33441)

- Bug in `timedelta_range()` that produced an extra point on a edge case (GH30353, GH33498)

- Bug in `DataFrame.resample()` that produced an extra point on a edge case (GH30353, GH13022, GH33498)

- Bug in `DataFrame.resample()` that ignored the `loffset` argument when dealing with `timedelta` (GH7687, GH33498)

- Bug in `Timedelta` and `pandas.to_timedelta()` that ignored the `unit` argument for string input (GH12136)

**Timezones**

- Bug in `to_datetime()` with `infer_datetime_format=True` where timezone names (e.g. UTC) would not be parsed correctly (GH33133)
Numeric

- Bug in `DataFrame.floordiv()` with axis=0 not treating division-by-zero like `Series.floordiv()` (GH31271)
- Bug in `to_numeric()` with string argument "uint64" and errors="coerce" silently fails (GH32394)
- Bug in `to_numeric()` with downcast="unsigned" fails for empty data (GH32493)
- Bug in `DataFrame.mean()` with numeric_only=False and either datetime64 dtype or PeriodDtype column incorrectly raising TypeError (GH32426)
- Bug in `DataFrame.count()` with level="foo" and index level "foo" containing NaNs causes segmentation fault (GH21824)
- Bug in `DataFrame.diff()` with axis=1 returning incorrect results with mixed dtypes (GH32995)
- Bug in `DataFrame.corr()` and `DataFrame.cov()` raising when handling nullable integer columns with pandas.NA (GH33803)
- Bug in arithmetic operations between `DataFrame` objects with non-overlapping columns with duplicate labels causing an infinite loop (GH35194)
- Bug in `DataFrame` and `Series` addition and subtraction between object-dtype objects and datetime64 dtype objects (GH33824)
- Bug in `Index.difference()` giving incorrect results when comparing a `Float64Index` and object `Index` (GH35217)
- Bug in `DataFrame` reductions (e.g. `df.min()`, `df.max()`) with ExtensionArray dtypes (GH34520, GH32651)
- `Series.interpolate()` and `DataFrame.interpolate()` now raise a ValueError if limit_direction is 'forward' or 'both' and method is 'backfill' or 'bfill' or limit_direction is 'backward' or 'both' and method is 'pad' or 'ffill' (GH34746)

Conversion

- Bug in `Series` construction from NumPy array with big-endian datetime64 dtype (GH29684)
- Bug in `Timedelta` construction with large nanoseconds keyword value (GH32402)
- Bug in `DataFrame` construction where sets would be duplicated rather than raising (GH32582)
- The `DataFrame` constructor no longer accepts a list of `DataFrame` objects. Because of changes to NumPy, `DataFrame` objects are now consistently treated as 2D objects, so a list of `DataFrame` objects is considered 3D, and no longer acceptable for the `DataFrame` constructor (GH32289).
- Bug in `DataFrame` when initiating a frame with lists and assign columns with nested list for MultiIndex (GH32173)
- Improved error message for invalid construction of list when creating a new index (GH35190)
Strings

- Bug in the `astype()` method when converting “string” dtype data to nullable integer dtype (GH32450).
- Fixed issue where taking `min` or `max` of a `StringArray` or `Series` with `StringDtype` type would raise. (GH31746)
- Bug in `Series.str.cat()` returning NaN output when other had `Index` type (GH33425)
- `pandas.api.dtypes.is_string_dtype()` no longer incorrectly identifies categorical series as string.

Interval

- Bug in `IntervalArray` incorrectly allowing the underlying data to be changed when setting values (GH32782)

Indexing

- `DataFrame.xs()` now raises a TypeError if a level keyword is supplied and the axis is not a `MultiIndex`. Previously an AttributeError was raised (GH33610)
- Bug in slicing on a `DatetimeIndex` with a partial-timestamp dropping high-resolution indices near the end of a year, quarter, or month (GH31064)
- Bug in `PeriodIndex.get_loc()` treating higher-resolution strings differently from `PeriodIndex.get_value()` (GH31172)
- Bug in `Series.at()` and `DataFrame.at()` not matching `.loc` behavior when looking up an integer in a `Float64Index` (GH31329)
- Bug in `PeriodIndex.is_monotonic()` incorrectly returning True when containing leading NaT entries (GH31437)
- Bug in `DatetimeIndex.get_loc()` raising KeyError with converted-integer key instead of the user-passed key (GH31425)
- Bug in `Series.xs()` incorrectly returning `Timestamp` instead of `datetime64` in some object-dtype cases (GH31630)
- Bug in `DataFrame.iat()` incorrectly returning `Timestamp` instead of `datetime` in some object-dtype cases (GH32809)
- Bug in `DataFrame.at()` when either columns or index is non-unique (GH33041)
- Bug in `Series.loc()` and `DataFrame.loc()` when indexing with an integer key on a object-dtype `Index` that is not all-integers (GH31905)
- Bug in `DataFrame.iat.__setitem__()` on a `DataFrame` with duplicate columns incorrectly setting values for all matching columns (GH15686, GH22036)
- Bug in `DataFrame.loc()` and `Series.loc()` with a `DatetimeIndex`, `TimedeltaIndex`, or `PeriodIndex` incorrectly allowing lookups of non-matching datetime-like dtypes (GH32650)
- Bug in `Series.__getitem__()` indexing with non-standard scalars, e.g. np.dtype (GH32684)
- Bug in `Index` constructor where an unhelpful error message was raised for NumPy scalars (GH33017)
- Bug in `DataFrame.lookup()` incorrectly raising an AttributeError when frame.index or frame.columns is not unique; this will now raise a `ValueError` with a helpful error message (GH33041)
• Bug in `Interval` where a `Timedelta` could not be added or subtracted from a `Timestamp` interval (GH32023)

• Bug in `DataFrame.copy()` not invalidating _item_cache after copy caused post-copy value updates to not be reflected (GH31784)

• Fixed regression in `DataFrame.loc()` and `Series.loc()` throwing an error when a `datetime64[ns, tz]` value is provided (GH32395)

• Bug in `Series.__getitem__()` with an integer key and a `MultiIndex` with leading integer level failing to raise `KeyError` if the key is not present in the first level (GH33355)

• Bug in `DataFrame.iloc()` when slicing a single column `DataFrame` with `ExtensionDtype` (e.g. `df.iloc[:, :1]`) returning an invalid result (GH32957)

• Bug in `DatetimeIndex.insert()` and `TimedeltaIndex.insert()` causing `index freq` to be lost when setting an element into an empty `Series` (GH33573)

• Bug in `Series.__setitem__()` with an `IntervalIndex` and a list-like key of integers (GH33473)

• Bug in `Series.__getitem__()` allowing missing labels with `np.ndarray`, `Index`, `Series` indexers but not list, these now all raise `KeyError` (GH33646)

• Bug in `DataFrame.truncate()` and `Series.truncate()` where index was assumed to be monotone increasing (GH33756)

• Indexing with a list of strings representing datetimes failed on `DatetimeIndex` or `PeriodIndex` (GH11278)

• Bug in `Series.at()` when used with a `MultiIndex` would raise an exception on valid inputs (GH26989)

• Bug in `DataFrame.loc()` with dictionary of values changes columns with `dtype` of `int` to `float` (GH34573)

• Bug in `Series.loc()` when used with a `MultiIndex` would raise an `IndexingError` when accessing a `None` value (GH34318)

• Bug in `DataFrame.reset_index()` and `Series.reset_index()` would not preserve data types on an empty `DataFrame` or `Series` with a `MultiIndex` (GH19602)

• Bug in `Series` and `DataFrame` indexing with a time key on a `DatetimeIndex` with `NaT` entries (GH35114)

**Missing**

• Calling `fillna()` on an empty `Series` now correctly returns a shallow copied object. The behaviour is now consistent with `index`, `DataFrame` and a non-empty `Series` (GH32543).

• Bug in `Series.replace()` when argument `to_replace` is of type dict/list and is used on a `Series` containing `<NA>` was raising a `TypeError`. The method now handles this by ignoring `<NA>` values when doing the comparison for the replacement (GH32621)

• Bug in `any()` and `all()` incorrectly returning `<NA>` for all `False` or all `True` values using the nullable Boolean `dtype` and with `skipna=False` (GH33253)

• Clarified documentation on `interpolate` with `method=akima`. The `der` parameter must be scalar or `None` (GH33426)

• `DataFrame.interpolate()` uses the correct axis convention now. Previously interpolating along columns lead to interpolation along indices and vice versa. Furthermore interpolating with methods `pad`, `ffill`, `bfill` and `backfill` are identical to using these methods with `DataFrame.fillna()` (GH12918, GH29146)
• Bug in `DataFrame.interpolate()` when called on a `DataFrame` with column names of string type was throwing a ValueError. The method is now independent of the type of the column names (GH33956)

• Passing NA into a format string using format specs will now work. For example `"{:1f}".format(pd.NA)` would previously raise a ValueError, but will now return the string "<NA>" (GH34740)

• Bug in `Series.map()` not raising on invalid na_action (GH32815)

**MultiIndex**

• `DataFrame.swaplevels()` now raises a TypeError if the axis is not a `MultiIndex`. Previously an AttributeError was raised (GH31126)

• Bug in `DataFrame.loc()` when used with a `MultiIndex`. The returned values were not in the same order as the given inputs (GH22797)

```python
In [80]: df = pd.DataFrame(np.arange(4),
    ....:     index=["a", "a", "b", "b"], [1, 2, 1, 2])

# Rows are now ordered as the requested keys
In [81]: df.loc[['b', 'a'], [2, 1], :]
Out[81]:
     b  c
0  2  3
1  1  2

[4 rows x 1 columns]
```

• Bug in `MultiIndex.intersection()` was not guaranteed to preserve order when sort=False. (GH31325)

• Bug in `DataFrame.truncate()` was dropping `MultiIndex` names. (GH34564)

```python
In [82]: left = pd.MultiIndex.from_arrays(["b", "a"], [2, 1])
In [83]: right = pd.MultiIndex.from_arrays(["a", "b", "c"], [1, 2, 3])

# Common elements are now guaranteed to be ordered by the left side
In [84]: left.intersection(right, sort=False)
Out[84]:
MultiIndex([('b', 2),
            ('a', 1),
            ])
```

• Bug when joining two `MultiIndex` without specifying level with different columns. Return-indexers parameter was ignored. (GH34074)
I/O

- Passing a set as names argument to `pandas.read_csv()`, `pandas.read_table()`, or `pandas.read_fwf()` will raise `ValueError`: Names should be an ordered collection. (GH34946)
- Bug in print-out when `display.precision` is zero. (GH20359)
- Bug in `read_json()` where integer overflow was occurring when json contains big number strings. (GH30320)
- `read_csv()` will now raise a `ValueError` when the arguments `header` and `prefix` both are not `None`. (GH27394)
- Bug in `DataFrame.to_json()` was raising `NotFoundError` when `path_or_buf` was an S3 URI (GH28375)
- Bug in `DataFrame.to_parquet()` overwriting pyarrow’s default for `coerce_timestamps`; following pyarrow’s default allows writing nanosecond timestamps with `version="2.0"` (GH31652).
- Bug in `read_csv()` was raising `TypeError` when `sep=None` was used in combination with `comment` keyword (GH31396)
- Bug in HDFStore that caused it to set to `int64` the dtype of a `datetime64` column when reading a `DataFrame` in Python 3 from fixed format written in Python 2 (GH31750)
- `read_sas()` now handles dates and datetimes larger than `Timestamp.max` returning them as `datetime` objects (GH20927)
- Bug in `DataFrame.to_json()` where `Timedelta` objects would not be serialized correctly with `date_format="iso"` (GH28256)
- `read_csv()` will raise a `ValueError` when the column names passed in `parse_dates` are missing in the DataFrame (GH31251)
- Bug in `read_excel()` where a UTF-8 string with a high surrogate would cause a segmentation violation (GH23809)
- Bug in `read_csv()` was causing a file descriptor leak on an empty file (GH31488)
- Bug in `read_csv()` was causing a segfault when there were blank lines between the header and data rows (GH28071)
- Bug in `read_csv()` was raising a misleading exception on a permissions issue (GH23784)
- Bug in `read_csv()` was raising an `IndexError` when `header=None` and two extra data columns
- Bug in `read_sas()` was raising an `AttributeError` when reading files from Google Cloud Storage (GH33069)
- Bug in `DataFrame.to_sql()` where an `AttributeError` was raised when saving an out of bounds date (GH26761)
- Bug in `read_excel()` did not correctly handle multiple embedded spaces in OpenDocument text cells. (GH32207)
- Bug in `read_json()` was raising `TypeError` when reading a list of Booleans into a `Series`. (GH31464)
- Bug in `pandas.io.json.json_normalize()` where location specified by `record_path` doesn’t point to an array. (GH26284)
- `pandas.read_hdf()` has a more explicit error message when loading an unsupported HDF file (GH9539)
- Bug in `read_feather()` was raising an `ArrowIOError` when reading an s3 or http file path (GH29055)
• Bug in `to_excel()` could not handle the column name `render` and was raising an `KeyError` (GH34331)
• Bug in `execute()` was raising a `ProgrammingError` for some DB-API drivers when the SQL statement contained the % character and no parameters were present (GH34211)
• Bug in `StataReader()` which resulted in categorical variables with different dtypes when reading data using an iterator. (GH31544)
• `HDFStore.keys()` has now an optional `include` parameter that allows the retrieval of all native HDF5 table names (GH29916)
• TypeError exceptions raised by `read_csv()` and `read_table()` were showing as `parser_f` when an unexpected keyword argument was passed (GH25648)
• Bug in `read_excel()` for ODS files removes 0.0 values (GH27222)
• Bug in `ujson.encode()` was raising an `OverflowError` with numbers larger than `sys.maxsize` (GH34395)
• Bug in `HDFStore.append_to_multiple()` was raising a `ValueError` when the `min_itemsize` parameter is set (GH11238)
• Bug in `create_table()` now raises an error when column argument was not specified in `data_columns` on input (GH28156)
• `read_json()` now could read line-delimited json file from a file url while `lines` and `chunksize` are set.
• Bug in `DataFrame.to_sql()` when reading DataFrames with `np.inf` entries with MySQL now has a more explicit `ValueError` (GH34431)
• Bug where capitalised files extensions were not decompressed by read_* functions (GH35164)
• Bug in `read_excel()` that was raising a `TypeError` when `header=None` and `index_col` is given as a list (GH31783)
• Bug in `read_excel()` where datetime values are used in the header in a `MultiIndex` (GH34748)
• `read_excel()` no longer takes `**kwds` arguments. This means that passing in the keyword argument `chunksize` now raises a `TypeError` (previously raised a `NotImplementedError`), while passing in the keyword argument `encoding` now raises a `TypeError` (GH34464)
• Bug in `DataFrame.to_records()` was incorrectly losing timezone information in timezone-aware datetime64 columns (GH32535)

**Plotting**

• `DataFrame.plot()` for line/bar now accepts color by dictionary (GH8193).
• Bug in `DataFrame.plot.hist()` where weights are not working for multiple columns (GH33173)
• Bug in `DataFrame.boxplot()` and `DataFrame.plot.boxplot()` lost color attributes of `medianprops`, `whiskerprops`, `capprops` and `boxprops` (GH30346)
• Bug in `DataFrame.hist()` where the order of column argument was ignored (GH29235)
• Bug in `DataFrame.plot.scatter()` that when adding multiple plots with different `cmap`, `colorbars` always use the first `cmap` (GH33389)
• Bug in `DataFrame.plot.scatter()` was adding a colorbar to the plot even if the argument `c` was assigned to a column containing color names (GH34316)
• Bug in `pandas.plotting.bootstrap_plot()` was causing cluttered axes and overlapping labels (GH34905)
• Bug in `DataFrame.plot.scatter()` caused an error when plotting variable marker sizes (GH32904)

**Groupby/resample/rolling**

• Using a `pandas.api.indexers.BaseIndexer` with count, min, max, median, skew, cov, corr will now return correct results for any monotonic `pandas.api.indexers.BaseIndexer` descendant (GH32865)

• `DataFrameGroupBy.mean()` and `SeriesGroupby.mean()` (and similarly for `median()`, `std()` and `var()`) now raise a `TypeError` if a non-accepted keyword argument is passed into it. Previously an `UnsupportedFunctionCall` was raised (AssertionError if `min_count` passed into `median()`) (GH31485)

• Bug in `GroupBy.apply()` raises `ValueError` when the `by` axis is not sorted, has duplicates, and the applied `func` does not mutate passed in objects (GH30667)

• Bug in `DataFrameGroupBy.transform()` produces an incorrect result with transformation functions (GH30918)

• `DataFrame.resample()` produces inconsistent type when aggregating `Boolean Series` (GH32894)

• `DataFrame.groupby()` and `Series.groupby()` produces inconsistent type when aggregating `Boolean Series` (GH32894)

• Bug in `DataFrameGroupBy.transform()` where a large negative number would be returned when the number of non-null values was below `min_count` for nullable integer dtypes (GH32861)

• Bug in `SeriesGroupBy.agg()` where any column name was accepted in the named aggregation of `SeriesGroupBy` previously. The behaviour now allows only `str` and callables else would raise `TypeError`. (GH34422)

• Bug in `DataFrame.groupby()` lost the name of the `Index` when one of the `agg` keys referenced an empty list (GH32580)

• Bug in `DataFrame.groupby()` raising an `AttributeError` when selecting a column and aggregating with `as_index=False` (GH35246).
• Bug in DataFrameGroupBy.first() and DataFrameGroupBy.last() that would raise an unnecessary ValueError when grouping on multiple Categoricals (GH34951)

Reshaping

• Bug effecting all numeric and Boolean reduction methods not returning subclassed data type. (GH25596)
• Bug in DataFrame.pivot_table() when only MultiIndexed columns is set (GH17038)
• Bug in DataFrame.unstack() and Series.unstack() can take tuple names in MultiIndexed data (GH19966)
• Bug in DataFrame.pivot_table() when margin is True and only column is defined (GH31016)
• Fixed incorrect error message in DataFrame.pivot() when columns is set to None. (GH30924)
• Bug in crosstab() when inputs are two Series and have tuple names, the output will keep a dummy MultiIndex as columns. (GH18321)
• DataFrame.pivot() can now take lists for index and columns arguments (GH21425)
• Bug in concat() where the resulting indices are not copied when copy=True (GH29879)
• Bug in SeriesGroupBy.aggregate() was resulting in aggregations being overwritten when they shared the same name (GH30880)
• Bug where Index.astype() would lose the name attribute when converting from Float64Index to Int64Index, or when casting to an ExtensionArray dtype (GH32013)
• Series.append() will now raise a TypeError when passed a DataFrame or a sequence containing DataFrame (GH31413)
• DataFrame.replace() and Series.replace() will raise a TypeError if to_replace is not an expected type. Previously the replace would fail silently (GH18634)
• Bug on inplace operation of a Series that was adding a column to the DataFrame from where it was originally dropped from (using inplace=True) (GH30484)
• Bug in DataFrame.apply() where callback was called with Series parameter even though raw=True requested. (GH32423)
• Bug in DataFrame.pivot_table() losing timezone information when creating a MultiIndex level from a column with timezone-aware dtype (GH32558)
• Bug in concat() where when passing a non-dict mapping as objs would raise a TypeError (GH32863)
• DataFrame.agg() now provides more descriptive SpecificationError message when attempting to aggregate a non-existent column (GH32755)
• Bug in DataFrame.unstack() when MultiIndex columns and MultiIndex rows were used (GH32624, GH24729 and GH28306)
• Appending a dictionary to a DataFrame without passing ignore_index=True will raise TypeError: Can only append a dict if ignore_index=True instead of TypeError: Can only append a :class:`Series` if ignore_index=True or if the :class:`Series` has a name (GH30871)
• Bug in DataFrame.corrwith(), DataFrame.memory_usage(), DataFrame.dot(), DataFrame.idxmin(), DataFrame.idxmax(), DataFrame.duplicated(), DataFrame.isin(), DataFrame.count(), Series.explode(), Series.asof() and DataFrame.asof() not returning subclassed types. (GH31331)
• Bug in `concat()` was not allowing for concatenation of `DataFrame` and `Series` with duplicate keys (GH33654)
• Bug in `cut()` raised an error when the argument `labels` contains duplicates (GH33141)
• Ensure only named functions can be used in `eval()` (GH32460)
• Bug in `DataFrame.aggregate()` and `Series.aggregate()` was causing a recursive loop in some cases (GH34224)
• Fixed bug in `melt()` where melting `MultiIndex` columns with `col_level > 0` would raise a `KeyError` on `id_vars` (GH34129)
• Bug in `Series.where()` with an empty `Series` and empty `cond` having non-bool dtype (GH34592)
• Fixed regression where `DataFrame.apply()` would raise `ValueError` for elements with S dtype (GH34529)

Sparse

• Creating a `SparseArray` from timezone-aware dtype will issue a warning before dropping timezone information, instead of doing so silently (GH32501)
• Bug in `arrays.SparseArray.from_spmatrix()` wrongly read scipy sparse matrix (GH31991)
• Bug in `Series.sum()` with `SparseArray` raised a `TypeError` (GH34526, GH34540)
• Bug where empty `DataFrame` could not be cast to `SparseDtype` (GH33113)
• Bug in `arrays.SparseArray()` was returning the incorrect type when indexing a sparse dataframe with an iterable (GH34526, GH34540)

ExtensionArray

• Fixed bug where `Series.value_counts()` would raise on empty input of Int64 dtype (GH33317)
• Fixed bug in `concat()` when concatenating `DataFrame` objects with non-overlapping columns resulting in object-dtype columns rather than preserving the extension dtype (GH27692, GH33027)
• Fixed bug where `StringArray.isna()` would return `False` for NA values when `pandas.options.mode.use_inf_as_na` was set to `True` (GH33655)
• Fixed bug in `Series` construction with EA dtype and index but no data or scalar data fails (GH26469)
• Fixed bug that caused `Series.__repr__()` to crash for extension types whose elements are multidimensional arrays (GH33770).
• Fixed bug where `Series.update()` would raise a `ValueError` for `ExtensionArray` dtypes with missing values (GH33980)
• Fixed bug where `StringArray.memory_usage()` was not implemented (GH33963)
• Fixed bug where `DataFrameGroupBy()` would ignore the `min_count` argument for aggregations on nullable Boolean dtypes (GH34051)
• Fixed bug where the constructor of `DataFrame` with `dtype='string'` would fail (GH27953, GH33623)
• Bug where DataFrame column set to scalar extension type was considered an object type rather than the extension type (GH34832)
• Fixed bug in IntegerArray.astype() to correctly copy the mask as well (GH34931).

Other

• Set operations on an object-dtype Index now always return object-dtype results (GH31401)
• Fixed pandas.testing.assert_series_equal() to correctly raise if the left argument is a different subclass with check_series_type=True (GH32670).
• Getting a missing attribute in a DataFrame.query() or DataFrame.eval() string raises the correct AttributeError (GH32408)
• Fixed bug in pandas.testing.assert_series_equal() where dtypes were checked for Interval and ExtensionArray operands when check_dtypes was False (GH32747)
• Bug in DataFrame.__dir__() caused a segfault when using unicode surrogates in a column name (GH25509)
• Bug in DataFrame.equals() and Series.equals() in allowing subclasses to be equal (GH34402).

5.2 Version 1.0

5.2.1 What’s new in 1.0.5 (June 17, 2020)

These are the changes in pandas 1.0.5. See Release notes for a full changelog including other versions of pandas.
**Fixed regressions**

- Fix regression in `read_parquet()` when reading from file-like objects (GH34467).
- Fix regression in reading from public S3 buckets (GH34626).

Note this disables the ability to read Parquet files from directories on S3 again (GH26388, GH34632), which was added in the 1.0.4 release, but is now targeted for pandas 1.1.0.

- Fixed regression in `replace()` raising an `AssertionError` when replacing values in an extension dtype with values of a different dtype (GH34530)

**Bug fixes**

- Fixed building from source with Python 3.8 fetching the wrong version of NumPy (GH34666)

**Contributors**

A total of 8 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Joris Van den Bossche
- MeeseeksMachine
- Natalie Jann +
- Pandas Development Team
- Simon Hawkins
- Tom Augspurger
- William Ayd
- alimcmaster1

**5.2.2 What’s new in 1.0.4 (May 28, 2020)**

These are the changes in pandas 1.0.4. See Release notes for a full changelog including other versions of pandas.

**Fixed regressions**

- Fix regression where `Series.isna()` and `DataFrame.isna()` would raise for categorical dtype when `pandas.options.mode.use_inf_as_na` was set to True (GH33594)
- Fix regression in `GroupBy.first()` and `GroupBy.last()` where None is not preserved in object dtype (GH32800)
- Fix regression in `DataFrame` reductions using `numeric_only=True` and `ExtensionArrays` (GH33256).
- Fix performance regression in `memory_usage(deep=True)` for object dtype (GH33012)
- Fix regression where `Categorical.replace()` would replace with NaN whenever the new value and replacement value were equal (GH33288)
- Fix regression where an ordered `Categorical` containing only NaN values would raise rather than returning NaN when taking the minimum or maximum (GH33450)
Fix regression in `DataFrameGroupBy.agg()` with dictionary input losing `ExtensionArray` dtypes (GH32194)

Fix to preserve the ability to index with the “nearest” method with xarray’s CFTimeIndex, an `Index` subclass (pydata/xarray#3751, GH32905).

Fix regression in `DataFrame.describe()` raising `TypeError: unhashable type: 'dict'` (GH32409)

Fix regression in `DataFrame.replace()` casts columns to `object` dtype if items in to_replace not in values (GH32988)

Fix regression in `Series.groupby()` would raise `ValueError` when grouping by `PeriodIndex` level (GH34010)

Fix regression in `GroupBy.rolling.apply()` ignores args and kwargs parameters (GH33433)

Fix regression in error message with `np.min` or `np.max` on unordered `Categorical` (GH33115)

Fix regression in `DataFrame.loc()` and `Series.loc()` throwing an error when a datetime64[ns, tz] value is provided (GH32395)

### Bug fixes

- Bug in `SeriesGroupBy.first()`, `SeriesGroupBy.last()`, `SeriesGroupBy.min()`, and `SeriesGroupBy.max()` returning floats when applied to nullable Booleans (GH33071)
- Bug in `Rolling.min()` and `Rolling.max()`: Growing memory usage after multiple calls when using a fixed window (GH30726)
- Bug in `to_parquet()` was not raising `PermissionError` when writing to a private s3 bucket with invalid creds. (GH27679)
- Bug in `to_csv()` was silently failing when writing to an invalid s3 bucket. (GH32486)
- Bug in `read_parquet()` was raising a `FileNotFoundError` when passed an s3 directory path. (GH26388)
- Bug in `to_parquet()` was throwing an `AttributeError` when writing a partitioned parquet file to s3 (GH27596)
- Bug in `GroupBy.quantile()` causes the quantiles to be shifted when the `by` axis contains NaN (GH33200, GH33569)

### Contributors

A total of 18 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Daniel Saxton
- JDbuka +
- Joris Van den Bossche
- Kaiqi Dong
- Mabel Villalba
- MeeseeksMachine
- MomIsBestFriend
5.2.3 What’s new in 1.0.3 (March 17, 2020)

These are the changes in pandas 1.0.3. See Release notes for a full changelog including other versions of pandas.

Fixed regressions

- Fixed regression in `resample.agg` when the underlying data is non-writeable (GH31710)
- Fixed regression in `DataFrame` exponentiation with reindexing (GH32685)

Bug fixes

Contributors

A total of 5 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- MeeseeksMachine
- Pandas Development Team
- Tom Augspurger
- William Ayd
- jbrockmendel

5.2.4 What’s new in 1.0.2 (March 12, 2020)

These are the changes in pandas 1.0.2. See Release notes for a full changelog including other versions of pandas.
Fixed regressions

Groupby

- Fixed regression in `groupby(..).agg()` which was failing on frames with `MultiIndex` columns and a custom function (GH31777)
- Fixed regression in `groupby(..).rolling(..).apply()` (RollingGroupby) where the `raw` parameter was ignored (GH31754)
- Fixed regression in `rolling(..).corr()` when using a time offset (GH31789)
- Fixed regression in `groupby(..).nunique()` which was modifying the original values if NaN values were present (GH31950)
- Fixed regression in `DataFrame.groupby` raising a `ValueError` from an internal operation (GH31802)
- Fixed regression in `groupby(..).agg()` calling a user-provided function an extra time on an empty input (GH31760)

I/O

- Fixed regression in `read_csv()` in which the `encoding` option was not recognized with certain file-like objects (GH31819)
- Fixed regression in `DataFrame.to_excel()` when the `columns` keyword argument is passed (GH31677)
- Fixed regression in `ExcelFile` where the stream passed into the function was closed by the destructor. (GH31467)
- Fixed regression where `read_pickle()` raised a `UnicodeDecodeError` when reading a py27 pickle with `MultiIndex` column (GH31988).

Reindexing/alignment

- Fixed regression in `Series.align()` when `other` is a `DataFrame` and `method` is not `None` (GH31785)
- Fixed regression in `DataFrame.reindex()` and `Series.reindex()` when reindexing with (tz-aware) index and `method=nearest` (GH26683)
- Fixed regression in `DataFrame.reindex_like()` on a `DataFrame` subclass raised an `AssertionError` (GH31925)
- Fixed regression in `DataFrame` arithmetic operations with mis-matched columns (GH31623)

Other

- Fixed regression in joining on `DatetimeIndex` or `TimedeltaIndex` to preserve `freq` in simple cases (GH32166)
- Fixed regression in `Series.shift()` with `datetime64` dtype when passing an integer `fill_value` (GH32591)
- Fixed regression in the repr of an object-dtype `Index` with bools and missing values (GH32146)
Indexing with Nullable Boolean Arrays

Previously indexing with a nullable Boolean array containing NA would raise a ValueError, however this is now permitted with NA being treated as False. (GH31503)

```
In [1]: s = pd.Series([1, 2, 3, 4])
In [2]: mask = pd.array([True, True, False, None], dtype="boolean")
In [3]: s
Out[3]:
0    1
1    2
2    3
3    4
Length: 4, dtype: int64
In [4]: mask
Out[4]:
<BooleanArray>
[True, True, False, <NA>]
Length: 4, dtype: boolean
```

```
pandas 1.0.0-1.0.1
```

```
>>> s[mask]
Traceback (most recent call last):
  ...
ValueError: cannot mask with array containing NA / NaN values
```

```
pandas 1.0.2
```

```
In [5]: s[mask]
Out[5]:
0    1
1    2
Length: 2, dtype: int64
```

Bug fixes

### Datetimelike

- Bug in `Series.astype()` not copying for tz-naive and tz-aware `datetime64` dtype (GH32490)
- Bug where `to_datetime()` would raise when passed `pd.NA` (GH32213)
- Improved error message when subtracting two `Timestamp` that result in an out-of-bounds `Timedelta` (GH31774)

### Categorical

- Fixed bug where `Categorical.from_codes()` improperly raised a `ValueError` when passed nullable integer codes. (GH31779)
- Fixed bug where `Categorical()` constructor would raise a `TypeError` when given a numpy array containing `pd.NA`. (GH31927)
- Bug in `Categorical` that would ignore or crash when calling `Series.replace()` with a list-like `to_replace` (GH31720)
I/O

- Using `pd.NA` with `DataFrame.to_json()` now correctly outputs a null value instead of an empty object (GH31615)
- Bug in `pandas.json_normalize()` when value in meta path is not iterable (GH31507)
- Fixed picking of `pandas.NA`. Previously a new object was returned, which broke computations relying on NA being a singleton (GH31847)
- Fixed bug in parquet roundtrip with nullable unsigned integer dtypes (GH31896).

Experimental dtypes

- Fixed bug in `DataFrame.convert_dtypes()` for columns that were already using the "string" dtype (GH31731).
- Fixed bug in `DataFrame.convert_dtypes()` for series with mix of integers and strings (GH32117)
- Fixed bug in `DataFrame.convert_dtypes()` where BooleanDtype columns were converted to `Int64` (GH32287)
- Fixed bug in setting values using a slice indexer with string dtype (GH31772)
- Fixed bug where `pandas.core.groupby.GroupBy.first()` and `pandas.core.groupby.GroupBy.last()` would raise a TypeError when groups contained pd.NA in a column of object dtype (GH32123)
- Fixed bug where `DataFrameGroupBy.mean()`, `DataFrameGroupBy.median()`, `DataFrameGroupBy.var()`, and `DataFrameGroupBy.std()` would raise a TypeError on `Int64` dtype columns (GH32219)

Strings

- Using `pd.NA` with `Series.str.repeat()` now correctly outputs a null value instead of raising error for vector inputs (GH31632)

Rolling

- Fixed rolling operations with variable window (defined by time duration) on decreasing time index (GH32385).

Contributors

A total of 25 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Anna Daglis +
- Daniel Saxton
- Irv Lustig
- Jan Škoda
- Joris Van den Bossche
- Justin Zheng
- Kaiqi Dong
- Kendall Masse
- Marco Gorelli
- Matthew Roeschke
5.2.5 What's new in 1.0.1 (February 5, 2020)

These are the changes in pandas 1.0.1. See Release notes for a full changelog including other versions of pandas.

Fixed regressions

- Fixed regression in DataFrame setting values with a slice (e.g. df[-4:] = 1) indexing by label instead of position (GH31469)
- Fixed regression when indexing a Series or DataFrame indexed by DatetimeIndex with a slice containing a datetime.date (GH31501)
- Fixed regression in DataFrame.__setitem__ raising an AttributeError with a MultiIndex and a non-monotonic indexer (GH31449)
- Fixed regression in Series multiplication when multiplying a numeric Series with >10000 elements with a timedelta-like scalar (GH31457)
- Fixed regression in .groupby().agg() raising an AssertionError for some reductions like min on object-dtype columns (GH31522)
- Fixed regression in .groupby() aggregations with categorical dtype using Cythonized reduction functions (e.g. first) (GH31450)
- Fixed regression in GroupBy.apply() if called with a function which returned a non-pandas non-scalar object (e.g. a list or numpy array) (GH31441)
- Fixed regression in DataFrame.groupby() whereby taking the minimum or maximum of a column with period dtype would raise a TypeError. (GH31471)
- Fixed regression in DataFrame.groupby() with an empty DataFrame grouping by a level of a MultiIndex (GH31670).
- Fixed regression in DataFrame.apply() with object dtype and non-reducing function (GH31505)
- Fixed regression in `to_datetime()` when parsing non-nanosecond resolution datetimes (GH31491)
- Fixed regression in `to_csv()` where specifying an `na_rep` might truncate the values written (GH31447)
- Fixed regression in `Categorical` construction with `numpy.str_.categories` (GH31499)
- Fixed regression in `DataFrame.loc()` and `DataFrame.iloc()` when selecting a row containing a single datetime64 or timedelta64 column (GH31649)
- Fixed regression where setting `pd.options.display.max_colwidth` was not accepting negative integer. In addition, this behavior has been deprecated in favor of using None (GH31532)
- Fixed regression in `objTOJSON.c` fix return-type warning (GH31463)
- Fixed regression in `qcut()` when passed a nullable integer. (GH31389)
- Fixed regression in assigning to a `Series` using a nullable integer dtype (GH31446)
- Fixed performance regression when indexing a `DataFrame` or `Series` with a `MultiIndex` for the index using a list of labels (GH31648)
- Fixed regression in `read_csv()` used in file like object `RawIOBase` is not recognize encoding option (GH31575)

**Deprecations**

- Support for negative integer for `pd.options.display.max_colwidth` is deprecated in favor of using None (GH31532)

**Bug fixes**

**Datetimelike**

- Fixed bug in `to_datetime()` raising when `cache=True` and out-of-bound values are present (GH31491)

**Numeric**

- Bug in dtypes being lost in `DataFrame.__invert__ (~ operator)` with mixed dtypes (GH31183) and for extension-array backed `Series` and `DataFrame` (GH23087)

**Plotting**

- Plotting tz-aware timeseries no longer gives UserWarning (GH31205)

**Interval**

- Bug in `Series.shift()` with `interval` dtype raising a `TypeError` when shifting an interval array of integers or datetimes (GH34195)

**Contributors**

A total of 15 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Daniel Saxton
- Guillaume Lemaitre
- Jeff Reback
- Joris Van den Bossche
5.2.6 What's new in 1.0.0 (January 29, 2020)

These are the changes in pandas 1.0.0. See Release notes for a full changelog including other versions of pandas.

Note: The pandas 1.0 release removed a lot of functionality that was deprecated in previous releases (see below for an overview). It is recommended to first upgrade to pandas 0.25 and to ensure your code is working without warnings, before upgrading to pandas 1.0.

New deprecation policy

Starting with Pandas 1.0.0, pandas will adopt a variant of SemVer to version releases. Briefly,

- Deprecations will be introduced in minor releases (e.g. 1.1.0, 1.2.0, 2.1.0, …)
- Deprecations will be enforced in major releases (e.g. 1.0.0, 2.0.0, 3.0.0, …)
- API-breaking changes will be made only in major releases (except for experimental features)

See Version policy for more.

Enhancements

Using Numba in rolling.apply and expanding.apply

We’ve added an engine keyword to apply() and apply() that allows the user to execute the routine using Numba instead of Cython. Using the Numba engine can yield significant performance gains if the apply function can operate on numpy arrays and the data set is larger (1 million rows or greater). For more details, see rolling apply documentation (GH28987, GH30936)
Defining custom windows for rolling operations

We’ve added a `pandas.api.indexers.BaseIndexer()` class that allows users to define how window bounds are created during rolling operations. Users can define their own `get_window_bounds` method on a `pandas.api.indexers.BaseIndexer()` subclass that will generate the start and end indices used for each window during the rolling aggregation. For more details and example usage, see the [custom window rolling documentation](#).

Converting to markdown

We’ve added `to_markdown()` for creating a markdown table (GH11052)

```python
In [1]: df = pd.DataFrame({"A": [1, 2, 3], "B": [1, 2, 3]}, index=['a', 'a', 'b'])

In [2]: print(df.to_markdown())
<table>
<thead>
<tr>
<th></th>
<th align="right">A</th>
<th align="right">B</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td align="right">1</td>
<td align="right">1</td>
</tr>
<tr>
<td>a</td>
<td align="right">2</td>
<td align="right">2</td>
</tr>
<tr>
<td>b</td>
<td align="right">3</td>
<td align="right">3</td>
</tr>
</tbody>
</table>
```

Experimental new features

Experimental NA scalar to denote missing values

A new `pd.NA` value (singleton) is introduced to represent scalar missing values. Up to now, pandas used several values to represent missing data: `np.nan` is used for this for float data, `np.nan` or `None` for object-dtype data and `pd.NaT` for datetime-like data. The goal of `pd.NA` is to provide a “missing” indicator that can be used consistently across data types. `pd.NA` is currently used by the nullable integer and boolean data types and the new string data type (GH28095).

**Warning**: Experimental: the behaviour of `pd.NA` can still change without warning.

For example, creating a Series using the nullable integer dtype:

```python
In [3]: s = pd.Series([1, 2, None], dtype="Int64")

In [4]: s
Out[4]:
0   1
1   2
2  <NA>
Length: 3, dtype: Int64

In [5]: s[2]
Out[5]: <NA>
```

Compared to `np.nan`, `pd.NA` behaves differently in certain operations. In addition to arithmetic operations, `pd.NA` also propagates as “missing” or “unknown” in comparison operations:

```python
In [6]: np.nan > 1
Out[6]: False
```

(continues on next page)
In [7]: pd.NA > 1  
Out[7]: <NA>

For logical operations, pd.NA follows the rules of the three-valued logic (or Kleene logic). For example:

In [8]: pd.NA | True  
Out[8]: True

For more, see NA section in the user guide on missing data.

**Dedicated string data type**

We’ve added StringDtype, an extension type dedicated to string data. Previously, strings were typically stored in object-dtype NumPy arrays. (GH29975)

**Warning:** StringDtype is currently considered experimental. The implementation and parts of the API may change without warning.

The 'string' extension type solves several issues with object-dtype NumPy arrays:

1. You can accidentally store a mixture of strings and non-strings in an object dtype array. A StringArray can only store strings.
2. object dtype breaks dtype-specific operations like DataFrame.select_dtypes(). There isn’t a clear way to select just text while excluding non-text, but still object-dtype columns.
3. When reading code, the contents of an object dtype array is less clear than string.

In [9]: pd.Series(['abc', None, 'def'], dtype=pd.StringDtype())  
Out[9]:  
0  abc
1  <NA>
2  def
Length: 3, dtype: string

You can use the alias "string" as well.

In [10]: s = pd.Series(['abc', None, 'def'], dtype="string")
In [11]: s  
Out[11]:  
0  abc
1  <NA>
2  def
Length: 3, dtype: string

The usual string accessor methods work. Where appropriate, the return type of the Series or columns of a DataFrame will also have string dtype.

In [12]: s.str.upper()  
Out[12]:  
0  ABC
1  <NA>
DEF Length: 3, dtype: string

In [13]: s.str.split('b', expand=True).dtypes
Out[13]:
0  string
1  string
Length: 2, dtype: object

String accessor methods returning integers will return a value with Int64Dtype

In [14]: s.str.count("a")
Out[14]:
0   1
1  <NA>
2   0
Length: 3, dtype: Int64

We recommend explicitly using the string data type when working with strings. See Text data types for more.

Boolean data type with missing values support

We’ve added BooleanDtype/BooleanArray, an extension type dedicated to boolean data that can hold missing values. The default bool data type based on a bool-dtype NumPy array, the column can only hold True or False, and not missing values. This new BooleanArray can store missing values as well by keeping track of this in a separate mask. (GH29555, GH30095, GH31131)

In [15]: pd.Series([True, False, None], dtype=pd.BooleanDtype())
Out[15]:
0   True
1  False
2  <NA>
Length: 3, dtype: boolean

You can use the alias "boolean" as well.

In [16]: s = pd.Series([True, False, None], dtype="boolean")

In [17]: s
Out[17]:
0   True
1  False
2  <NA>
Length: 3, dtype: boolean
convert_dtypes method to ease use of supported extension dtypes

In order to encourage use of the extension dtypes `StringDtype`, `BooleanDtype`, `Int64Dtype`, `Int32Dtype`, etc., that support `pd.NA`, the methods `DataFrame.convert_dtypes()` and `Series.convert_dtypes()` have been introduced. (GH29752) (GH30929)

Example:

```python
In [18]: df = pd.DataFrame({'x': ['abc', None, 'def'],
                       ....:             'y': [1, 2, np.nan],
                       ....:             'z': [True, False, True]})

In [19]: df
Out[19]:
   x    y    z
0  abc  1.0  True
1  NaN  2.0  False
2  def  NaN  True
[3 rows x 3 columns]

In [20]: df.dtypes
Out[20]:
   x    y    z
dtype: object  float64  bool

In [21]: converted = df.convert_dtypes()

In [22]: converted
Out[22]:
   x    y    z
0  abc  1.0  True
1  NaN  2.0  False
2  def  NaN  True
[3 rows x 3 columns]

In [23]: converted.dtypes
Out[23]:
   x    y    z
dtype: object  Int64  bool

This is especially useful after reading in data using readers such as `read_csv()` and `read_excel()`. See here for a description.
Other enhancements

- `DataFrame.to_string()` added the `max_colwidth` parameter to control when wide columns are truncated (GH9784)
- Added the `na_value` argument to `Series.to_numpy()`, `Index.to_numpy()` and `DataFrame.to_numpy()` to control the value used for missing data (GH30322)
- `MultiIndex.from_product()` infers level names from inputs if not explicitly provided (GH27292)
- `DataFrame.to_latex()` now accepts `caption` and `label` arguments (GH25436)
- DataFrames with `nullable integer`, the `new string dtype` and period data type can now be converted to pyarrow (>=0.15.0), which means that it is supported in writing to the Parquet file format when using the pyarrow engine (GH28368). Full roundtrip to parquet (writing and reading back in with `to_parquet()` / `read_parquet()`) is supported starting with pyarrow >= 0.16 (GH20612).
- `to_parquet()` now appropriately handles the `schema` argument for user defined schemas in the pyarrow engine. (GH30270)
- `DataFrame.to_json()` now accepts an `indent` integer argument to enable pretty printing of JSON output (GH12004)
- `read_stata()` can read Stata 119 dta files. (GH28250)
- Implemented pandas.core.window.Window.var() and pandas.core.window.Window.std() functions (GH26597)
- Added encoding argument to `DataFrame.to_string()` for non-ascii text (GH28766)
- Added encoding argument to `DataFrame.to_html()` for non-ascii text (GH28663)
- `Styler.background_gradient()` now accepts vmin and vmax arguments (GH12145)
- `Styler.format()` added the `na_rep` parameter to help format the missing values (GH21527, GH28358)
- `read_excel()` now can read binary Excel (.xlsb) files by passing engine='pyxlsb'. For more details and example usage, see the Binary Excel files documentation. Closes GH8540.
- The `partition_cols` argument in `DataFrame.to_parquet()` now accepts a string (GH27117)
- `pandas.read_json()` now parses NaN, Infinity and -Infinity (GH12213)
- DataFrame constructor preserve ExtensionArray dtype with ExtensionArray (GH11363)
- `DataFrame.sort_values()` and `Series.sort_values()` have gained `ignore_index` keyword to be able to reset index after sorting (GH30114)
- `DataFrame.sort_index()` and `Series.sort_index()` have gained `ignore_index` keyword to reset index (GH30114)
- `DataFrame.drop_duplicates()` has gained `ignore_index` keyword to reset index (GH30114)
- Added new writer for exporting Stata dta files in versions 118 and 119, `StataWriterUTF8`. These files formats support exporting strings containing Unicode characters. Format 119 supports data sets with more than 32,767 variables (GH23573, GH30959)
- `Series.map()` now accepts collections.abc.Mapping subclasses as a mapper (GH29733)
- Added an experimental `attrs` for storing global metadata about a dataset (GH29062)
- `Timestamp.fromisocalendar()` is now compatible with python 3.8 and above (GH28115)
- `DataFrame.to_pickle()` and `read_pickle()` now accept URL (GH30163)
Backwards incompatible API changes

Avoid using names from MultiIndex.levels

As part of a larger refactor to MultiIndex the level names are now stored separately from the levels (GH27242). We recommend using MultiIndex.names to access the names, and Index.set_names() to update the names.

For backwards compatibility, you can still access the names via the levels.

```
In [24]: mi = pd.MultiIndex.from_product([[1, 2], ['a', 'b']], names=['x', 'y'])
In [25]: mi.levels[0].name
Out[25]: 'x'
```

However, it is no longer possible to update the names of the MultiIndex via the level.

```
In [26]: mi.levels[0].name = "new name"
---------------------------------------------------------------------------
RuntimeError                               Traceback (most recent call last)
<ipython-input-26-65f4400a0c97> in <module>
----> 1 mi.levels[0].name = "new name"
/pandas-release/pandas/pandas/core/indexes/base.py in name(self, value)
    1178         # Used in MultiIndex.levels to avoid silently ignoring name_
    1179         if self._no_setting_name:
-> 1180             raise RuntimeError(
    1181             "Cannot set name on a level of a MultiIndex. Use 
    1182             'MultiIndex.set_names' instead."

RuntimeError: Cannot set name on a level of a MultiIndex. Use 'MultiIndex.set_names' instead.
```

To update, use MultiIndex.set_names, which returns a new MultiIndex.

```
In [28]: mi2 = mi.set_names("new name", level=0)
In [29]: mi2.names
Out[29]: FrozenList(['new name', 'y'])
```

New repr for IntervalArray

pandas.arrays.IntervalArray adopts a new __repr__ in accordance with other array classes (GH25022)

pandas 0.25.x

```
In [1]: pd.arrays.IntervalArray.from_tuples([(0, 1), (2, 3)])
Out[2]:
IntervalArray([(0, 1), (2, 3)],
               closed='right',
               dtype='interval[int64]')
```

pandas 1.0.0
Dataframe.rename now only accepts one positional argument

`DataFrame.rename()` would previously accept positional arguments that would lead to ambiguous or undefined behavior. From pandas 1.0, only the very first argument, which maps labels to their new names along the default axis, is allowed to be passed by position (GH29136).

---

For example, with pandas 0.25.x:

```python
>>> df = pd.DataFrame([[1]])
>>> df.rename((0: 1), {0: 2})
FutureWarning: ...
2
1 1
```

And with pandas 1.0:

```python
>>> df.rename((0: 1), {0: 2})
Traceback (most recent call last):
... TypeError: rename() takes from 1 to 2 positional arguments but 3 were given
```

Note that errors will now be raised when conflicting or potentially ambiguous arguments are provided.

---

For example, with pandas 0.25.x:

```python
>>> df.rename((0: 1), index={0: 2})
0
1 1
>>> df.rename(mapper={0: 1}, index={0: 2})
0
2 1
```

And with pandas 1.0:

```python
>>> df.rename((0: 1), index={0: 2})
Traceback (most recent call last):
... TypeError: Cannot specify both 'mapper' and any of 'index' or 'columns'
>>> df.rename(mapper={0: 1}, index={0: 2})
Traceback (most recent call last):
... TypeError: Cannot specify both 'mapper' and any of 'index' or 'columns'
```

You can still change the axis along which the first positional argument is applied by supplying the axis keyword argument.

---

```python
In [31]: df.rename({0: 1})
Out[31]:
```

(continues on next page)
If you would like to update both the index and column labels, be sure to use the respective keywords.

```python
In [33]: df.rename(index={0: 1}, columns={0: 2})
Out[33]:
   2
0  1
[1 rows x 1 columns]
```

**Extended verbose info output for DataFrame**

`DataFrame.info()` now shows line numbers for the columns summary (GH17304)

**pandas 0.25.x**

```python
>>> df = pd.DataFrame({"int_col": [1, 2, 3],
... "text_col": ["a", "b", "c"],
... "float_col": [0.0, 0.1, 0.2]})
>>> df.info(verbos=True)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 3 entries, 0 to 2
Data columns (total 3 columns):
  # Column Non-Null Count Dtype
  --- ------ -------------- -----  
  0 int_col 3 non-null int64
  1 text_col 3 non-null object
  2 float_col 3 non-null float64
memory usage: 152.0+ bytes
```

**pandas 1.0.0**

```python
In [34]: df = pd.DataFrame({"int_col": [1, 2, 3],
... "text_col": ["a", "b", "c"],
... "float_col": [0.0, 0.1, 0.2]})
...:
In [35]: df.info(verbos=True)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 3 entries, 0 to 2
Data columns (total 3 columns):
  # Column  Non-Null Count Dtype
  --- ------ -------------- ----- 
  0 int_col 3 non-null int64
  1 text_col 3 non-null object
```

(continues on next page)
2 float_col 3 non-null float64
dtypes: float64(1), int64(1), object(1)
memory usage: 200.0+ bytes

```
pandas.array() inference changes

pandas.array() now infers pandas’ new extension types in several cases (GH29791):

1. String data (including missing values) now returns a arrays.StringArray.
2. Integer data (including missing values) now returns a arrays.IntegerArray.
3. Boolean data (including missing values) now returns the new arrays.BooleanArray
```

```
pandas 0.25.x

```36``` pd.array(['a', None])
<PandasArray>
['a', None]
Length: 2, dtype: object
```37``` pd.array([1, None])
<PandasArray>
[1, None]
Length: 2, dtype: object

pandas 1.0.0

```36``` pd.array(['a', None])
<StringArray>
['a', <NA>]
Length: 2, dtype: string
```37``` pd.array([1, None])
<IntegerArray>
[1, <NA>]
Length: 2, dtype: Int64

As a reminder, you can specify the dtype to disable all inference.

arrays.IntegerArray now uses pandas.NA

arrays.IntegerArray now uses pandas.NA rather than numpy.nan as its missing value marker (GH29964).
```
pandas 0.25.x

```37``` a = pd.array([1, 2, None], dtype="Int64")
```38``` a
<IntegerArray>
[1, 2, NaN]
Length: 3, dtype: Int64
```39``` a[2]
nan

5.2. Version 1.0
This has a few API-breaking consequences.

**Converting to a NumPy ndarray**

When converting to a NumPy array missing values will be `pd.NA`, which cannot be converted to a float. So calling `np.asarray(integer_array, dtype="float")` will now raise.

### pandas 0.25.x

```python
>>> np.asarray(a, dtype="float")
array([ 1. , 2. , nan])
```

### pandas 1.0.0

```python
In [41]: np.asarray(a, dtype="float")
---------------------------------------------------------------------------
ValueError                                Traceback (most recent call last)
<ipython-input-41-4578f04da2b3> in
     1 np.asarray(a, dtype="float")
/opt/conda/envs/pandas/lib/python3.8/site-packages/numpy/core/_asarray.py in
     85     return array(a, dtype, copy=False, order=order)
86
87
/pandas-release/pandas/pandas/core/arrays/masked.py in __array__(self, dtype)
   217     We return an object array here to preserve our scalar values
   218     """
--> 219     return self.to_numpy(dtype=dtype)
   220
   221     def __arrow_array__(self, type=None):
/pandas-release/pandas/pandas/core/arrays/masked.py in to_numpy(self, dtype, copy, na_value)
   198     and na_value is libmissing.NA
   199     :
--> 200     raise ValueError(  
   201     f"cannot convert to '{dtype}'-dtype NumPy array "
   202     "with missing values. Specify an appropriate 'na_value' "

ValueError: cannot convert to 'float64'-dtype NumPy array with missing values. Specify an appropriate 'na_value' for this dtype.
```

Use `arrays.IntegerArray.to_numpy()` with an explicit `na_value` instead.
Reductions can return `pd.NA`

When performing a reduction such as a sum with `skipna=False`, the result will now be `pd.NA` instead of `np.nan` in presence of missing values (GH30958).

pandas 0.25.x

```python
>>> pd.Series(a).sum(skipna=False)
nan
```

pandas 1.0.0

```python
In [43]: pd.Series(a).sum(skipna=False)
Out[43]: <NA>
```

value_counts returns a nullable integer dtype

`Series.value_counts()` with a nullable integer dtype now returns a nullable integer dtype for the values.

pandas 0.25.x

```python
>>> pd.Series([2, 1, 1, None], dtype="Int64").value_counts().dtype
dtype('int64')
```

pandas 1.0.0

```python
In [44]: pd.Series([2, 1, 1, None], dtype="Int64").value_counts().dtype
Out[44]: Int64Dtype()
```

See [Experimental NA scalar to denote missing values](#) for more on the differences between `pandas.NA` and `numpy.nan`.

arrays.IntegerArray comparisons return arrays.BooleanArray

Comparison operations on an `arrays.IntegerArray` now returns an `arrays.BooleanArray` rather than a NumPy array (GH29964).

pandas 0.25.x

```python
>>> a = pd.array([1, 2, None], dtype="Int64")
>>> a
<IntegerArray>
[1, 2, NaN]
Length: 3, dtype: Int64

>>> a > 1
array([False, True, False])
```

pandas 1.0.0

```python
In [45]: a = pd.array([1, 2, None], dtype="Int64")

In [46]: a > 1
Out[46]:
```
Note that missing values now propagate, rather than always comparing unequal like `numpy.nan`. See *Experimental NA scalar to denote missing values* for more.

**By default Categorical.min() now returns the minimum instead of np.nan**

When `Categorical` contains `np.nan`, `Categorical.min()` no longer return `np.nan` by default (skipna=True) (GH25303)

```python
pandas 0.25.x
In [1]: pd.Categorical([1, 2, np.nan], ordered=True).min()
Out[1]: nan

pandas 1.0.0
In [47]: pd.Categorical([1, 2, np.nan], ordered=True).min()
Out[47]: 1
```

**Default dtype of empty pandas.Series**

Initialising an empty `pandas.Series` without specifying a dtype will raise a *DeprecationWarning* now (GH17261). The default dtype will change from `float64` to `object` in future releases so that it is consistent with the behaviour of `DataFrame` and `Index`.

```python
pandas 1.0.0
In [1]: pd.Series()
Out[2]:
DeprecationWarning: The default dtype for empty Series will be 'object' instead of 'float64' in a future version. Specify a dtype explicitly to silence this warning.
Series([], dtype: float64)
```

**Result dtype inference changes for resample operations**

The rules for the result dtype in `DataFrame.resample()` aggregations have changed for extension types (GH31359). Previously, pandas would attempt to convert the result back to the original dtype, falling back to the usual inference rules if that was not possible. Now, pandas will only return a result of the original dtype if the scalar values in the result are instances of the extension dtype’s scalar type.

```python
In [48]: df = pd.DataFrame({"A": ['a', 'b']}, dtype='category',
                   ....: index=pd.date_range('2000', periods=2))

In [49]: df
Out[49]:
        A
2000-01-01  a
```

(continues on next page)
pandas 0.25.x

```python
>>> df.resample("2D").agg(lambda x: 'a').A.dtype
CategoricalDtype(categories=['a', 'b'], ordered=False)
```

pandas 1.0.0

```python
In [50]: df.resample("2D").agg(lambda x: 'a').A.dtype
Out[50]: dtype('O')
```

This fixes an inconsistency between `resample` and `groupby`. This also fixes a potential bug, where the values of the result might change depending on how the results are cast back to the original dtype.

pandas 0.25.x

```python
>>> df.resample("2D").agg(lambda x: 'c')
   A
0  NaN
```

pandas 1.0.0

```python
In [51]: df.resample("2D").agg(lambda x: 'c')
Out[51]:
    A  
2000-01-01  c
[1 rows x 1 columns]
```

Increased minimum version for Python

Pandas 1.0.0 supports Python 3.6.1 and higher (GH29212).

Increased minimum versions for dependencies

Some minimum supported versions of dependencies were updated (GH29766, GH29723). If installed, we now require:

<table>
<thead>
<tr>
<th>Package</th>
<th>Minimum Version</th>
<th>Required</th>
<th>Changed</th>
</tr>
</thead>
<tbody>
<tr>
<td>numpy</td>
<td>1.13.3</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>pytz</td>
<td>2015.4</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>python-dateutil</td>
<td>2.6.1</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>bottleneck</td>
<td>1.2.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>numexpr</td>
<td>2.6.2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>pytest (dev)</td>
<td>4.0.2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For optional libraries the general recommendation is to use the latest version. The following table lists the lowest version per library that is currently being tested throughout the development of pandas. Optional libraries below the lowest tested version may still work, but are not considered supported.
Build changes

Pandas has added a pyproject.toml file and will no longer include cythonized files in the source distribution uploaded to PyPI (GH28341, GH20775). If you’re installing a built distribution (wheel) or via conda, this shouldn’t have any effect on you. If you’re building pandas from source, you should no longer need to install Cython into your build environment before calling pip install pandas.

Other API changes

- core.groupby.GroupBy.transform now raises on invalid operation names (GH27489)
- pandas.api.types.infer_dtype() will now return “integer-na” for integer and np.nan mix (GH27283)
- MultiIndex.from_arrays() will no longer infer names from arrays if names=None is explicitly provided (GH27292)
- In order to improve tab-completion, Pandas does not include most deprecated attributes when introspecting a pandas object using dir (e.g. dir(df)). To see which attributes are excluded, see an object’s _deprecations attribute, for example pd.DataFrame._deprecations (GH28805).
- The returned dtype of unique() now matches the input dtype. (GH27874)
- Changed the default configuration value for options.matplotlib.register_converters from True to "auto" (GH18720). Now, pandas custom formatters will only be applied to plots created by pandas, through plot(). Previously, pandas’ formatters would be applied to all plots created after a plot(). See units registration for more.
- Series.dropna() has dropped its **kwargs argument in favor of a single how parameter. Supplying anything else than how to **kwargs raised a TypeError previously (GH29388)
- When testing pandas, the new minimum required version of pytest is 5.0.1 (GH29664)
• `Series.str.__iter__()` was deprecated and will be removed in future releases (GH28277).

• Added `<NA>` to the list of default NA values for `read_csv()` (GH30821)

Documentation improvements

• Added new section on *Scaling to large datasets* (GH28315).

• Added sub-section on *Query MultiIndex* for HDF5 datasets (GH28791).

Deprecations

• `Series.item()` and `Index.item()` have been _undeprecated_ (GH29250)

• `Index.set_value` has been deprecated. For a given index `idx`, array `arr`, value in `idx` of `idx_val` and a new value of `val`, `idx.set_value(arr, idx_val, val)` is equivalent to `arr[idx.get_loc(idx_val)] = val`, which should be used instead (GH28621).

• `is_extension_type()` is deprecated, `is_extension_array_dtype()` should be used instead (GH29457)

• `eval()` keyword argument “truediv” is deprecated and will be removed in a future version (GH29812)

• `DateOffset.isAnchored()` and `DatetOffset.onOffset()` are deprecated and will be removed in a future version, use `DateOffset.is_anchored()` and `DateOffset.is_on_offset()` instead (GH30340)

• `pandas.tseries.frequencies.get_offset` is deprecated and will be removed in a future version, use `pandas.tseries.frequencies.to_offset` instead (GH4205)

• `Categorical.take_nd()` and `CategoricalIndex.take_nd()` are deprecated, use `Categorical.take()` and `CategoricalIndex.take()` instead (GH27745)

• The parameter `numeric_only` of `Categorical.min()` and `Categorical.max()` is deprecated and replaced with `skipna` (GH25303)

• The parameter `label` in `lreshape()` has been deprecated and will be removed in a future version (GH29742)

• `pandas.core.index` has been deprecated and will be removed in a future version, the public classes are available in the top-level namespace (GH19711)

• `pandas.json_normalize()` is now exposed in the top-level namespace. Usage of `json_normalize` as `pandas.io.json.json_normalize` is now deprecated and it is recommended to use `json_normalize` as `pandas.json_normalize()` instead (GH27586).

• The `numpy` argument of `pandas.read_json()` is deprecated (GH28512).

• `DataFrame.to_stata()`, `DataFrame.to_feather()`, and `DataFrame.to_parquet()` argument “frame” is deprecated, use “path” instead (GH23574)

• The deprecated internal attributes `_start`, `_stop` and `_step` of `RangeIndex` now raise a `FutureWarning` instead of a `DeprecationWarning` (GH26581)

• The `pandas.util.testing` module has been deprecated. Use the public API in `pandas.testing` documented at `Testing functions` (GH16232).

• `pandas.SparseArray` has been deprecated. Use `pandas.arrays.SparseArray` instead (arrays.SparseArray) (GH30642)
• The parameter `is_copy` of `Series.take()` and `DataFrame.take()` has been deprecated and will be removed in a future version. (GH27357)

• Support for multi-dimensional indexing (e.g. `index[:, None]`) on a `Index` is deprecated and will be removed in a future version, convert to a numpy array before indexing instead (GH30588)

• The `pandas.np` submodule is now deprecated. Import numpy directly instead (GH30296)

• The `pandas.datetime` class is now deprecated. Import from `datetime` instead (GH30610)

• `diff` will raise a `TypeError` rather than implicitly losing the dtype of extension types in the future. Convert to the correct dtype before calling `diff` instead (GH31025)

### Selecting Columns from a Grouped DataFrame

When selecting columns from a `DataFrameGroupBy` object, passing individual keys (or a tuple of keys) inside single brackets is deprecated, a list of items should be used instead. (GH23566) For example:

```python
df = pd.DataFrame({
    "A": ["foo", "bar", "foo", "bar", "foo", "bar", "foo", "foo"],
    "B": np.random.randn(8),
    "C": np.random.randn(8),
})
g = df.groupby('A')
# single key, returns SeriesGroupBy
g["B"]
# tuple of single key, returns SeriesGroupBy
g[['B',]]
# tuple of multiple keys, returns DataFrameGroupBy, raises FutureWarning
g[['B', 'C']]
# multiple keys passed directly, returns DataFrameGroupBy, raises FutureWarning
# (implicitly converts the passed strings into a single tuple)
g["B", 'C']
# proper way, returns DataFrameGroupBy
g[['B', 'C']]
```

### Removal of prior version deprecations/changes

**Removed SparseSeries and SparseDataFrame**

SparseSeries, SparseDataFrame and the `DataFrame.to_sparse` method have been removed (GH28425). We recommend using a Series or DataFrame with sparse values instead. See Migrating for help with migrating existing code.

**Matplotlib unit registration**

Previously, pandas would register converters with matplotlib as a side effect of importing pandas (GH18720). This changed the output of plots made via matplotlib plots after pandas was imported, even if you were using matplotlib directly rather than `plot()`.

To use pandas formatters with a matplotlib plot, specify

```python
>>> import pandas as pd
>>> pd.options.plotting.matplotlib.register_converters = True
```
Note that plots created by `DataFrame.plot()` and `Series.plot()` do register the converters automatically. The only behavior change is when plotting a date-like object via `matplotlib.pyplot.plot` or `matplotlib.Axes.plot`. See `Custom formatters for timeseries plots` for more.

Other removals

- Removed the previously deprecated keyword “index” from `read_stata()`, `StataReader`, and `StataReader.read()`, use “index_col” instead (GH17328)
- Removed `StataReader.data` method, use `StataReader.read()` instead (GH9493)
- Removed `pandas.plotting._matplotlib.tsplot` and `Series.plot()` instead (GH19980)
- `pandas.tseries.converter.register` has been moved to `pandas.plotting.register_matplotlib_converters()` (GH18307)
- `Series.plot()` no longer accepts positional arguments, pass keyword arguments instead (GH30003)
- `DataFrame.hist()` and `Series.hist()` no longer allows `figsize="default"`, specify figure size by passing a tuple instead (GH30003)
- Floordiv of integer-dtyped array by `Timedelta` now raises `TypeError` (GH21036)
- `TimedeltaIndex` and `DatetimeIndex` no longer accept non-nanosecond dtype strings like “timedelta64” or “datetime64”, use “timedelta64[ns]” and “datetime64[ns]” instead (GH24806)
- Changed the default “skipna” argument in `pandas.api.types.infer_dtype()` from False to True (GH24050)
- Removed `Series.ix` and `DataFrame.ix` (GH26438)
- Removed `Index.summary` (GH18217)
- Removed the previously deprecated keyword “fastpath” from the `Index` constructor (GH23110)
- Removed `Series.get_value`, `Series.set_value`, `DataFrame.get_value`, `DataFrame.set_value` (GH17739)
- Removed `Series.compound` and `DataFrame.compound` (GH26405)
- Changed the default “inplace” argument in `DataFrame.set_index()` and `Series.set_axis()` from None to False (GH27600)
- Removed `Series.cat.categorical`, `Series.cat.index`, `Series.cat.name` (GH24751)
- Removed the previously deprecated keyword “box” from `to_datetime()` and `to_timedelta()`; in addition these now always returns `DatetimeIndex`, `TimedeltaIndex`, `Index`, `Series`, or `DataFrame` (GH24486)
- `to_timedelta()`, `Timedelta`, and `TimedeltaIndex` no longer allow “M”, “y”, or “Y” for the “unit” argument (GH23264)
- Removed the previously deprecated keyword “time_rule” from (non-public) `offsets.generate_range`, which has been moved to `core.arrays._ranges.generate_range()` (GH24157)
- `DataFrame.loc()` or `Series.loc()` with listlike indexers and missing labels will no longer reindex (GH17295)
- `DataFrame.to_excel()` and `Series.to_excel()` with non-existent columns will no longer reindex (GH17295)
- Removed the previously deprecated keyword “join_axes” from `concat()`; use `reindex_like` on the result instead (GH22318)
- Removed the previously deprecated keyword “by” from `DataFrame.sort_index()`, use `DataFrame.sort_values()` instead (GH10726)
• Removed support for nested renaming in DataFrame.aggregate(), Series.aggregate(), core.groupby.DataFrameGroupBy.aggregate(), core.groupby.SeriesGroupBy.aggregate(), core.window.rolling.Rolling.aggregate() (GH18529)

• Passing datetime64 data to TimedeltaIndex or timedelta64 data to DatetimeIndex now raises TypeError (GH23539, GH23937)

• Passing int64 values to DatetimeIndex and a timezone now interprets the values as nanosecond timestamps in UTC, not wall times in the given timezone (GH24559)

• A tuple passed to DataFrame.groupby() is now exclusively treated as a single key (GH18314)

• Removed Index.contains, use key in index instead (GH30103)

• Addition and subtraction of int or integer-arrays is no longer allowed in Timestamp, DatetimeIndex, TimedeltaIndex, use obj + n * obj.freq instead of obj + n (GH22535)

• Removed Series.ptp (GH21614)

• Removed Series.from_array (GH18258)

• Removed DataFrame.from_items (GH18458)

• Removed DataFrame.as_matrix, Series.as_matrix (GH18458)

• Removed Series.asobject (GH18477)

• Removed DataFrame.as_blocks, Series.as_blocks, DataFrame.blocks, Series.blocks (GH17656)

• pandas.Series.str.cat() now defaults to aligning others, using join='left' (GH27611)

• pandas.Series.str.cat() does not accept list-likes within list-likes anymore (GH27611)

• Series.where() with Categorical dtype (or DataFrame.where() with Categorical column) no longer allows setting new categories (GH24114)

• Removed the previously deprecated keywords “start”, “end”, and “periods” from the DatetimeIndex, TimedeltaIndex, and PeriodIndex constructors; use date_range(), timedelta_range(), and period_range() instead (GH23919)

• Removed the previously deprecated keyword “verify_integrity” from the DatetimeIndex and TimedeltaIndex constructors (GH23919)

• Removed the previously deprecated keyword “fastpath” from pandas.core.internals.blocks.make_block (GH19265)

• Removed the previously deprecated keyword “dtype” from Block.make_block_same_class() (GH19434)

• Removed ExtensionArray._formatting_values. Use ExtensionArray._formatter instead. (GH23601)

• Removed MultiIndex.to_hierarchical (GH21613)

• Removed MultiIndex.labels, use MultiIndex.codes instead (GH23752)

• Removed the previously deprecated keyword “labels” from the MultiIndex constructor, use “codes” instead (GH23752)

• Removed MultiIndex.set_labels, use MultiIndex.set_codes() instead (GH23752)

• Removed the previously deprecated keyword “labels” from MultiIndex.set_codes(), MultiIndex.copy(), MultiIndex.drop(), use “codes” instead (GH23752)

• Removed support for legacy HDF5 formats (GH29787)
• Passing a dtype alias (e.g. ‘datetime64[ns, UTC]’) to DatetimeTZDtype is no longer allowed, use DatetimeTZDtype.construct_from_string() instead (GH23990)

• Removed the previously deprecated keyword “skip_footer” from read_excel(); use “skipfooter” instead (GH18836)

• read_excel() no longer allows an integer value for the parameter usecols, instead pass a list of integers from 0 to usecols inclusive (GH23635)

• Removed the previously deprecated keyword “convert_datetime64” from DataFrame.to_records() (GH18902)

• Removed IntervalIndex.from_intervals in favor of the IntervalIndex constructor (GH19263)

• Changed the default “keep_tz” argument in DatetimeIndex.to_series() from None to True (GH23739)

• Removed api.types.is_period and api.types.is_datetimetz (GH23917)

• Ability to read pickles containing Categorical instances created with pre-0.16 version of pandas has been removed (GH27538)

• Removed pandas.tseries.plotting.tsplot (GH18627)

• Removed the previously deprecated keywords “reduce” and “broadcast” from DataFrame.apply() (GH18577)

• Removed the previously deprecated assert_raises_regex function in pandas._testing (GH29174)

• Removed the previously deprecated FrozenNDArray class in pandas.core.indexes.frozen (GH29335)

• Removed the previously deprecated keyword “nthreads” from read_feather(), use “use_threads” instead (GH23053)

• Removed Index.is_lexsorted_for_tuple (GH29305)

• Removed support for nested renaming in DataFrame.aggregate(), Series.aggregate(), core.groupby.DataFrameGroupBy.aggregate(), core.groupby.SeriesGroupBy.aggregate(), core.window.rolling.Rolling.aggregate() (GH29608)

• Removed Series.valid; use Series.dropna() instead (GH18800)

• Removed DataFrame.is_copy, Series.is_copy (GH18812)

• Removed DataFrame.get_ftype_counts, Series.get_ftype_counts (GH18243)

• Removed DataFrame.ftypes, Series.ftypes (GH26744)

• Removed Index.get_duplicates, use idx[idx.duplicated()].unique() instead (GH20239)

• Removed Series.clip_upper, Series.clip_lower, DataFrame.clip_upper, DataFrame.clip_lower (GH24203)

• Removed the ability to alter DatetimeIndex.freq, TimedeltaIndex.freq, or PeriodIndex.freq (GH20772)

• Removed DatetimeIndex.offset (GH20730)

• Removed DatetimeIndex.asobject, TimedeltaIndex.asobject, PeriodIndex.asobject, use astype(object) instead (GH29801)

• Removed the previously deprecated keyword “order” from factorize() (GH19751)

• Removed the previously deprecated keyword “encoding” from read_stata() and DataFrame.to_stata() (GH21400)
• Changed the default “sort” argument in `concat()` from `None` to `False` (GH20613)

• Removed the previously deprecated keyword “raise_conflict” from `DataFrame.update()`, use “errors” instead (GH23585)

• Removed the previously deprecated keyword “n” from `DateTimeIndex.shift()`, `TimedeltaIndex.shift()`, `PeriodIndex.shift()` , use “periods” instead (GH22458)

• Removed the previously deprecated keywords “how”, “fill_method”, and “limit” from `DataFrame.resample()` (GH30139)

• Passing an integer to `Series.fillna()` or `DataFrame.fillna()` with `timedelta64[ns]` dtype now raises `TypeError` (GH24694)

• Passing multiple axes to `DataFrame.dropna()` is no longer supported (GH20995)

• Removed `Series.nonzero`, use `to_numpy().nonzero()` instead (GH24048)

• Passing floating dtype codes to `Categorical.from_codes()` is no longer supported, pass `codes.astype(np.int64)` instead (GH21775)

• Removed the previously deprecated keyword “pat” from `Series.str.partition()` and `Series.str.rpartition()`, use “sep” instead (GH23767)

• Removed `Series.put` (GH27106)

• Removed `Series.real, Series.imag` (GH27106)

• Removed `Series.to_dense, DataFrame.to_dense` (GH26684)

• Removed `Index.dtype_str, use str(index.dtype)` instead (GH27106)

• `Categorical.ravel()` returns a `Categorical` instead of a ndarray (GH27199)

• The ‘outer’ method on Numpy ufuncs, e.g. `np.subtract.outer` operating on `Series` objects is no longer supported, and will raise `NotImplementedError` (GH27198)

• Removed `Series.get_dtype_counts` and `DataFrame.get_dtype_counts` (GH27145)

• Changed the default “fill_value” argument in `Categorical.take()` from `True` to `False` (GH20841)

• Changed the default value for the `raw` argument in `Series.rolling().apply()`, `DataFrame.rolling().apply()`, `Series.expanding().apply()`, and `DataFrame.expanding().apply()` from `None` to `False` (GH20584)

• Removed deprecated behavior of `Series.argmin()` and `Series.argmax()`, use `Series.idxmin()` and `Series.idxmax()` for the old behavior (GH16955)

• Passing a tz-aware `datetime.datetime` or `Timestamp` into the `Timestamp` constructor with the `tz` argument now raises a `ValueError` (GH23621)

• Removed `Series.base, Index.base, Categorical.base, Series.flags, Index.flags, PeriodArray.flags, Series.strides, Index.strides, Series.itemsize, Index.itemsize, Series.data, Index.data` (GH20721)

• Changed `Timedelta.resolution()` to match the behavior of the standard library `datetime.timedelta.resolution`, for the old behavior, use `Timedelta.resolution_string()` (GH26839)

• Removed `Timestamp.weekday_name, DatetimeIndex.weekday_name, and Series.dt.weekday_name` (GH18164)

• Removed the previously deprecated keyword “errors” in `Timestamp.tz_localize()`, `DatetimeIndex.tz_localize()`, and `Series.tz_localize()` (GH22644)

• Changed the default “ordered” argument in `CategoricalDtype` from `None` to `False` (GH26336)
• *Series.set_axis()* and *DataFrame.set_axis()* now require “labels” as the first argument and “axis” as an optional named parameter (GH30089)

• Removed `to_msgpack`, `read_msgpack`, `DataFrame.to_msgpack`, `Series.to_msgpack` (GH27103)

• Removed `Series.compress` (GH21930)

• Removed the previously deprecated keyword “fill_value” from `Categorical.fillna()`, use “value” instead (GH19269)

• Removed the previously deprecated keyword “data” from `andrews_curves()`, use “frame” instead (GH6956)

• Removed the previously deprecated keyword “data” from `parallel_coordinates()`, use “frame” instead (GH6956)

• Removed the previously deprecated keyword “colors” from `parallel_coordinates()`, use “color” instead (GH6956)

• Removed the previously deprecated keywords “verbose” and “private_key” from `read_gbq()` (GH30200)

• Calling `np.array` and `np.asarray` on tz-aware `Series` and `DatetimeIndex` will now return an object array of tz-aware `Timestamp` (GH24596)

Performance improvements

• Performance improvement in *DataFrame* arithmetic and comparison operations with scalars (GH24990, GH29853)

• Performance improvement in indexing with a non-unique `IntervalIndex` (GH27489)

• Performance improvement in `MultiIndex.is_monotonic` (GH27495)

• Performance improvement in `cut()` when `bins` is an `IntervalIndex` (GH27668)

• Performance improvement when initializing a `DataFrame` using a range (GH30171)

• Performance improvement in `DataFrame.corr()` when method is "spearman" (GH28139)

• Performance improvement in `DataFrame.replace()` when provided a list of values to replace (GH28099)

• Performance improvement in `DataFrame.select_dtypes()` by using vectorization instead of iterating over a loop (GH28317)

• Performance improvement in `Categorical.searchsorted()` and `CategoricalIndex.searchsorted()` (GH28795)

• Performance improvement when comparing a `Categorical` with a scalar and the scalar is not found in the categories (GH29750)

• Performance improvement when checking if values in a `Categorical` are equal, equal or larger or larger than a given scalar. The improvement is not present if checking if the `Categorical` is less than or less than or equal than the scalar (GH29820)

• Performance improvement in `Index.equals()` and `MultiIndex.equals()` (GH29134)

• Performance improvement in `infer_dtype()` when `skipna` is True (GH28814)
Bug fixes

Categorical

- Added test to assert the `fillna()` raises the correct `ValueError` message when the value isn’t a value from categories (GH13628)
- Bug in `Categorical.astype()` where NaN values were handled incorrectly when casting to int (GH28406)
- `DataFrame.reindex()` with a `CategoricalIndex` would fail when the targets contained duplicates, and wouldn’t fail if the source contained duplicates (GH28107)
- Bug in `Categorical.astype()` not allowing for casting to extension dtypes (GH28668)
- Bug where `merge()` was unable to join on categorical and extension dtype columns (GH28668)
- `Categorical.searchsorted()` and `CategoricalIndex.searchsorted()` now work on unordered categories also (GH21667)
- Added test to assert roundtripping to parquet with `DataFrame.to_parquet()` or `read_parquet()` will preserve Categorical dtypes for string types (GH27955)
- Changed the error message in `Categorical.remove_categories()` to always show the invalid removals as a set (GH28669)
- Using date accessors on a categorical typed `Series` of datetimes was not returning an object of the same type as if one used the `str()` / `dt()` on a `Series` of that type. E.g. when accessing `Series.dt.tz_localize()` on a `Categorical` with duplicate entries, the accessor was skipping duplicates (GH27952)
- Bug in `DataFrame.replace()` and `Series.replace()` that would give incorrect results on categorical data (GH26988)
- Bug where calling `Categorical.min()` or `Categorical.max()` on an empty Categorical would raise a numpy exception (GH30227)
- The following methods now also correctly output values for unobserved categories when called through `groupby(..., observed=False)` (GH17605) *
  * `core.groupby.SeriesGroupBy.count()` *
  * `core.groupby.SeriesGroupBy.size()` *
  * `core.groupby.SeriesGroupBy.nunique()` *
  * `core.groupby.SeriesGroupBy.nth()` *

Datetimelike

- Bug in `Series.__setitem__()` incorrectly casting `np.timedelta64("NaT")` to `np.datetime64("NaT")` when inserting into a `Series` with datetime64 dtype (GH27311)
- Bug in `Series.dt()` property lookups when the underlying data is read-only (GH27529)
- Bug in `HDFStore.__getitem__` incorrectly reading tz attribute created in Python 2 (GH26443)
- Bug in `to_datetime()` where passing arrays of malformed `str` with errors=“coerce” could incorrectly lead to raise `ValueError` (GH28299)
- Bug in `core.groupby.SeriesGroupBy.nunique()` where `NaT` values were interfering with the count of unique values (GH27951)
- Bug in `Timestamp` subtraction when subtracting a `Timestamp` from a `np.datetime64` object incorrectly raising `TypeError` (GH28286)
• Addition and subtraction of integer or integer-dtype arrays with `Timestamp` will now raise `NullFrequencyError` instead of `ValueError` (GH28268)
• Bug in `Series` and `DataFrame` with integer dtype failing to raise `TypeError` when adding or subtracting a `np.datetime64` object (GH28080)
• Bug in `Series.astype()`, `Index.astype()`, and `DataFrame.astype()` failing to handle `NaT` when casting to an integer dtype (GH28492)
• Bug in `Week` with weekday incorrectly raising `AttributeError` instead of `TypeError` when adding or subtracting an invalid type (GH28530)
• Bug in `DataFrame` arithmetic operations when operating with a Series with dtype `timedelta64[ns]` (GH28049)
• Bug in `core.groupby.generic.SeriesGroupBy.apply()` raising `ValueError` when a column in the original DataFrame is a datetime and the column labels are not standard integers (GH28247)
• Bug in `pandas._config.localization.get_locales()` where the locales `-a` encodes the locales list as `windows-1252` (GH23638, GH24760, GH27368)
• Bug in `Series.var()` failing to raise `TypeError` when called with `timedelta64[ns]` dtype (GH28289)
• Bug in `DatetimeIndex.strftime()` and `Series.dt.strftime()` where `NaT` was converted to the string 'NaT' instead of `np.nan` (GH29578)
• Bug in masking datetime-like arrays with a boolean mask of an incorrect length not raising an `IndexError` (GH30308)
• Bug in `Timestamp.resolution` being a property instead of a class attribute (GH29910)
• Bug in `pandas.to_datetime()` when called with `None` raising `TypeError` instead of returning `NaT` (GH30011)
• Bug in `pandas.to_datetime()` failing for `deque`s when using `cache=True` (the default) (GH29403)
• Bug in `Series.item()` with datetime64 or timedelta64 dtype, `DatetimeIndex.item()`, and `TimedeltaIndex.item()` returning an integer instead of a `Timestamp` or `Timedelta` (GH30175)
• Bug in `DatetimeIndex` addition when adding a non-optimized `DateOffset` incorrectly dropping timezone information (GH30336)
• Bug in `DataFrame.drop()` where attempting to drop non-existent values from a DatetimeIndex would yield a confusing error message (GH30399)
• Bug in `DataFrame.append()` would remove the timezone-awareness of new data (GH30238)
• Bug in `Series.cummin()` and `Series.cummax()` with timezone-aware dtype incorrectly dropping its timezone (GH15553)
• Bug in `DatetimeArray`, `TimedeltaArray`, and `PeriodArray` where inplace addition and subtraction did not actually operate inplace (GH24115)
• Bug in `pandas.to_datetime()` when called with Series storing `IntegerArray` raising `TypeError` instead of returning Series (GH30050)
• Bug in `date_range()` with custom business hours as `freq` and given number of `periods` (GH30593)
• Bug in `PeriodIndex` comparisons with incorrectly casting integers to `Period` objects, inconsistent with the `Period` comparison behavior (GH30722)
• Bug in `DatetimeIndex.insert()` raising a `ValueError` instead of a `TypeError` when trying to insert a timezone-aware `Timestamp` into a timezone-naive `DatetimeIndex`, or vice-versa (GH30806)
pandas: powerful Python data analysis toolkit, Release 1.1.1

Timedelta

- Bug in subtracting a TimedeltaIndex or TimedeltaArray from a np.datetime64 object (GH29558)
- 

Timezones

- 
- 

Numeric

- Bug in DataFrame.quantile() with zero-column DataFrame incorrectly raising (GH23925)
- DataFrame flex inequality comparisons methods (DataFrame.lt(), DataFrame.le(), DataFrame.gt(), DataFrame.ge()) with object-dtype and complex entries failing to raise TypeError like their Series counterparts (GH28079)
- Bug in DataFrame logical operations (&, |, ^) not matching Series behavior by filling NA values (GH28741)
- Bug in DataFrame.interpolate() where specifying axis by name references variable before it is assigned (GH29142)
- Bug in Series.var() not computing the right value with a nullable integer dtype series not passing through ddof argument (GH29128)
- Improved error message when using frac > 1 and replace = False (GH27451)
- Bug in numeric indexes resulted in it being possible to instantiate an Int64Index, UInt64Index, or Float64Index with an invalid dtype (e.g. datetime-like) (GH29539)
- Bug in UInt64Index precision loss while constructing from a list with values in the np.uint64 range (GH29526)
- Bug in NumericIndex construction that caused indexing to fail when integers in the np.uint64 range were used (GH28023)
- Bug in NumericIndex construction that caused UInt64Index to be casted to Float64Index when integers in the np.uint64 range were used to index a DataFrame (GH28279)
- Bug in Series.interpolate() when using method='index' with an unsorted index, would previously return incorrect results. (GH21037)
- Bug in DataFrame.round() where a DataFrame with a CategoricalIndex of IntervalIndex columns would incorrectly raise a TypeError (GH30063)
- Bug in Series.pct_change() and DataFrame.pct_change() when there are duplicated indices (GH30463)
- Bug in DataFrame cumulative operations (e.g. cumsum, cummax) incorrect casting to object-dtype (GH19296)
- Bug in diff losing the dtype for extension types (GH30889)
- Bug in DataFrame.diff raising an IndexError when one of the columns was a nullable integer dtype (GH30967)
pandas: powerful Python data analysis toolkit, Release 1.1.1

Conversion

•

Strings

• Calling `Series.str.isalnum()` (and other “ismethods”) on an empty Series would return an object dtype instead of bool (GH29624)

Interval

• Bug in `IntervalIndex.get_indexer()` where a Categorical or CategoricalIndex target would incorrectly raise a TypeError (GH30063)

• Bug in `pandas.core.dtypes.cast.infer_dtype_from_scalar` where passing pandas_dtype=True did not infer IntervalDtype (GH30337)

• Bug in `Series` constructor where constructing a Series from a list of Interval objects resulted in object dtype instead of IntervalDtype (GH23563)

• Bug in IntervalDtype where the kind attribute was incorrectly set as None instead of "O" (GH30568)

• Bug in `IntervalIndex`, `IntervalArray`, and `Series` with interval data where equality comparisons were incorrect (GH24112)

Indexing

• Bug in assignment using a reverse slicer (GH26939)

• Bug in `DataFrame.explode()` would duplicate frame in the presence of duplicates in the index (GH28010)

• Bug in reindexing a PeriodIndex() with another type of index that contained a Period (GH28323)

• Fix assignment of column via .loc with numpy non-ns datetime type (GH27395)

• Bug in Float64Index.astype() where np.inf was not handled properly when casting to an integer dtype (GH28475)

• Index.union() could fail when the left contained duplicates (GH28257)

• Bug when indexing with .loc where the index was a CategoricalIndex with non-string categories didn’t work (GH17569, GH30225)

• Index.get_indexer_non_unique() could fail with TypeError in some cases, such as when searching for ints in a string index (GH28257)

• Bug in Float64Index.get_loc() incorrectly raising TypeError instead of KeyError (GH29189)

• Bug in DataFrame.loc() with incorrect dtype when setting Categorical value in 1-row DataFrame (GH25495)

• MultiIndex.get_loc() can’t find missing values when input includes missing values (GH19132)
• Bug in Series.__setitem__() incorrectly assigning values with boolean indexer when the length of new data matches the number of True values and new data is not a Series or an np.array (GH30567)

• Bug in indexing with a PeriodIndex incorrectly accepting integers representing years, use e.g. ser.loc["2007"] instead of ser.loc[2007] (GH30763)

Missing

•

MultiIndex

• Constructor for MultiIndex verifies that the given sortorder is compatible with the actual lexsort_depth if verify_integrity parameter is True (the default) (GH28735)

• Series and MultiIndex.drop with MultiIndex raise exception if labels not in given in level (GH8594)

I/O

• read_csv() now accepts binary mode file buffers when using the Python csv engine (GH23779)

• Bug in DataFrame.to_json() where using a Tuple as a column or index value and using orient="columns" or orient="index" would produce invalid JSON (GH20500)

• Improve infinity parsing. read_csv() now interprets Infinity, +Infinity, -Infinity as floating point values (GH10065)

• Bug in DataFrame.to_csv() where values were truncated when the length of na_rep was shorter than the text input data. (GH25099)

• Bug in DataFrame.to_string() where values were truncated using display options instead of outputting the full content (GH9784)

• Bug in DataFrame.to_json() where a datetime column label would not be written out in ISO format with orient="table" (GH28130)

• Bug in DataFrame.to_parquet() where writing to GCS would fail with engine='fastparquet' if the file did not already exist (GH28326)

• Bug in read_hdf() closing stores that it didn’t open when Exceptions are raised (GH28699)

• Bug in DataFrame.read_json() where using orient="index" would not maintain the order (GH28557)

• Bug in DataFrame.to_html() where the length of the formatters argument was not verified (GH28469)

• Bug in DataFrame.read_excel() with engine='ods' when sheet_name argument references a non-existent sheet (GH27676)

• Bug in pandas.io.formats.style.Styler() formatting for floating values not displaying decimals correctly (GH13257)

• Bug in DataFrame.to_html() when using formatters=<list> and max_cols together. (GH25955)
- Bug in `Styler.background_gradient()` not able to work with dtype `Int64` (GH28869)
- Bug in `DataFrame.to_clipboard()` which did not work reliably in ipython (GH22707)
- Bug in `read_json()` where default encoding was not set to `utf-8` (GH29565)
- Bug in `read_gbq()` now accepts `progress_bar_type` to display progress bar while the data downloads. (GH29857)
- Bug in `pandas.io.json.json_normalize()` where a missing value in the location specified by `record_path` would raise a `TypeError` (GH30148)
- Bug in `read_excel()` now accepts binary data (GH15914)
- Bug in `read_csv()` in which encoding handling was limited to just the string `utf-16` for the C engine (GH24130)

**Plotting**

- Bug in `Series.plot()` not able to plot boolean values (GH23719)
- Bug in `DataFrame.plot()` not able to plot when no rows (GH27758)
- Bug in `DataFrame.plot()` producing incorrect legend markers when plotting multiple series on the same axis (GH18222)
- Bug in `DataFrame.plot()` when `kind='box'` and data contains datetime or timedelta data. These types are now automatically dropped (GH22799)
- Bug in `DataFrame.plot.line()` and `DataFrame.plot.area()` produce wrong xlim in x-axis (GH27686, GH25160, GH24784)
- Bug where `DataFrame.boxplot()` would not accept a `color` parameter like `DataFrame.plot.box()` (GH26214)
- Bug in the `xticks` argument being ignored for `DataFrame.plot.bar()` (GH14119)
- `set_option()` now validates that the plot backend provided to 'plotting.backend' implements the backend when the option is set, rather than when a plot is created (GH28163)
- `DataFrame.plot()` now allow a `backend` keyword argument to allow changing between backends in one session (GH28619).
- Bug in color validation incorrectly raising for non-color styles (GH29122).
- Allow `DataFrame.plot.scatter()` to plot objects and datetime type data (GH18755, GH30391)
- Bug in `DataFrame.hist()`, `xrot=0` does not work with `by` and subplots (GH30288).

**Groupby/resample/rolling**

- Bug in `core.groupby.DataFrameGroupBy.apply()` only showing output from a single group when function returns an `Index` (GH28652)
- Bug in `DataFrame.groupby()` with multiple groups where an `IndexError` would be raised if any group contained all NA values (GH20519)
- Bug in `pandas.core.resample.Resampler.size()` and `pandas.core.resample.Resampler.count()` returning wrong dtype when used with an empty `Series` or `DataFrame` (GH28427)
• Bug in `DataFrame.rolling()` not allowing for rolling over datetimes when axis=1 (GH28192)
• Bug in `DataFrame.rolling()` not allowing rolling over multi-index levels (GH15584).
• Bug in `DataFrame.rolling()` not allowing rolling on monotonic decreasing time indexes (GH19248).
• Bug in `DataFrame.groupby()` not offering selection by column name when axis=1 (GH27614)
• Bug in `core.groupby.DataFrameGroupby.agg()` not able to use lambda function with named aggregation (GH27519)
• Bug in `DataFrame.groupby()` losing column name information when grouping by a categorical column (GH28787)
• Remove error raised due to duplicated input functions in named aggregation in `DataFrame.groupby()` and `Series.groupby()`. Previously error will be raised if the same function is applied on the same column and now it is allowed if new assigned names are different. (GH28426)
• `core.groupby.SeriesGroupBy.value_counts()` will be able to handle the case even when the Grouper makes empty groups (GH28479)
• Bug in `core.window.rolling.Rolling.quantile()` ignoring interpolation keyword argument when used within a groupby (GH28779)
• Bug in `DataFrame.groupby()` where any, all, nunique and transform functions would incorrectly handle duplicate column labels (GH21668)
• Bug in `core.groupby.DataFrameGroupBy.agg()` with timezone-aware datetime64 column incorrectly casting results to the original dtype (GH29641)
• Bug in `DataFrame.groupby()` when using axis=1 and having a single level columns index (GH30208)
• Bug in `DataFrame.groupby()` when using nunique on axis=1 (GH30253)
• Bug in `GroupBy.quantile()` with multiple list-like q value and integer column names (GH30289)
• `GroupBy.pct_change()` and `core.groupby.SeriesGroupBy.pct_change()` causes TypeError when fill_method is None (GH30463)
• Bug in `Rolling.count()` and `Expanding.count()` argument where min_periods was ignored (GH26996)

Reshaping

• Bug in `DataFrame.apply()` that caused incorrect output with empty `DataFrame` (GH28202, GH21959)
• Bug in `DataFrame.stack()` not handling non-unique indexes correctly when creating MultiIndex (GH28301)
• Bug in `pivot_table()` not returning correct type float when margins=True and aggfunc='mean' (GH24893)
• Bug `merge_asof()` could not use `datetime.timedelta` for tolerance kwarg (GH28098)
• Bug in `merge()`, did not append suffixes correctly with MultiIndex (GH28518)
• `qcut()` and `cut()` now handle boolean input (GH20303)
• Fix to ensure all int dtypes can be used in `merge_asof()` when using a tolerance value. Previously every non-int64 type would raise an erroneous `MergeError` (GH28870).
• Better error message in `get_dummies()` when `columns` isn’t a list-like value (GH28383)
pandas: powerful Python data analysis toolkit, Release 1.1.1

- Bug in `Index.join()` that caused infinite recursion error for mismatched MultiIndex name orders. (GH25760, GH28956)
- Bug in `Series.pct_change()` where supplying an anchored frequency would throw a ValueError (GH28664)
- Bug where `DataFrame.equals()` returned True incorrectly in some cases when two DataFrames had the same columns in different orders (GH28839)
- Bug in `DataFrame.replace()` that caused non-numeric replacer's dtype not respected (GH26632)
- Bug in `melt()` where supplying mixed strings and numeric values for `id_vars` or `value_vars` would incorrectly raise a ValueError (GH29718)
- Dtypes are now preserved when transposing a DataFrame where each column is the same extension dtype (GH30091)
- Bug in `merge_asof()` merging on a tz-aware left_index and right_on a tz-aware column (GH29864)
- Improved error message and docstring in `cut()` and `qcut()` when `labels=True` (GH13318)
- Bug in missing `fill_na` parameter to `DataFrame.unstack()` with list of levels (GH30740)

Sparse

- Bug in `SparseDataFrame` arithmetic operations incorrectly casting inputs to float (GH28107)
- Bug in `DataFrame.sparse` returning a Series when there was a column named `sparse` rather than the accessor (GH30758)
- Fixed `operator.xor()` with a boolean-dtype `SparseArray`. Now returns a sparse result, rather than object dtype (GH31025)

ExtensionArray

- Bug in `arrays.PandasArray` when setting a scalar string (GH28118, GH28150).
- Bug where nullable integers could not be compared to strings (GH28930)
- Bug where `DataFrame` constructor raised `ValueError` with list-like data and dtype specified (GH30280)

Other

- Trying to set the `display.precision`, `display.max_rows` or `display.max_columns` using `set_option()` to anything but a None or a positive int will raise a `ValueError` (GH23348)
- Using `DataFrame.replace()` with overlapping keys in a nested dictionary will no longer raise, now matching the behavior of a flat dictionary (GH27660)
- `DataFrame.to_csv()` and `Series.to_csv()` now support dicts as compression argument with key 'method' being the compression method and others as additional compression options when the compression method is 'zip'. (GH26023)
- Bug in `Series.diff()` where a boolean series would incorrectly raise a `TypeError` (GH17294)
- `Series.append()` will no longer raise a `TypeError` when passed a tuple of `Series` (GH28410)
- Fix corrupted error message when calling `pandas.libs._json.encode()` on a 0d array (GH18878)
pandas: powerful Python data analysis toolkit, Release 1.1.1

- Backtick quoting in `DataFrame.query()` and `DataFrame.eval()` can now also be used to use invalid identifiers like names that start with a digit, are python keywords, or are using single character operators. (GH27017)
- Bug in `pd.core.util.hashing.hash_pandas_object` where arrays containing tuples were incorrectly treated as non-hashable (GH28969)
- Bug in `DataFrame.append()` that raised `IndexError` when appending with empty list (GH28769)
- Fix `AbstractHolidayCalendar` to return correct results for years after 2030 (now goes up to 2200) (GH27790)
- Fixed `IntegerArray` returning `inf` rather than `NaN` for operations dividing by 0 (GH27398)
- Fixed `pow` operations for `IntegerArray` when the other value is 0 or 1 (GH29997)
- Bug in `Series.count()` raises if `use_inf_as_na` is enabled (GH29478)
- Bug in `Index` where a non-hashable name could be set without raising `TypeError` (GH29069)
- Bug in `DataFrame` constructor when passing a 2D `ndarray` and an extension dtype (GH12513)
- Bug in `DataFrame.to_csv()` when supplied a series with a `dtype="string"` and a `na_rep`, the `na_rep` was being truncated to 2 characters. (GH29975)
- Bug where `DataFrame.itertuples()` would incorrectly determine whether or not namedtuples could be used for dataframes of 255 columns (GH28282)
- Handle nested NumPy object arrays in `testing.assert_series_equal()` for `ExtensionArray` implementations (GH30841)
- Bug in `Index` constructor incorrectly allowing 2-dimensional input arrays (GH13601, GH27125)

5.3 Version 0.25

5.3.1 What’s new in 0.25.3 (October 31, 2019)

These are the changes in pandas 0.25.3. See Release notes for a full changelog including other versions of pandas.

Bug fixes

Groupby/resample/rolling

- Bug in DataFrameGroupBy.quantile() where NA values in the grouping could cause segfaults or incorrect results (GH28882)

Contributors

A total of 2 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Will Ayd
- William Ayd

5.3.2 What’s new in 0.25.2 (October 15, 2019)

These are the changes in pandas 0.25.2. See Release notes for a full changelog including other versions of pandas.

Note: Pandas 0.25.2 adds compatibility for Python 3.8 (GH28147).

Bug fixes

Indexing

- Fix regression in DataFrame.reindex() not following the limit argument (GH28631).
- Fix regression in RangeIndex.get_indexer() for decreasing RangeIndex where target values may be improperly identified as missing/present (GH28678)
pandas: powerful Python data analysis toolkit, Release 1.1.1

I/O

- Fix regression in notebook display where `<th>` tags were missing for `DataFrame.index` values (GH28204).
- Regression in `to_csv()` where writing a Series or DataFrame indexed by an `IntervalIndex` would incorrectly raise a `TypeError` (GH28210).
- Fix `to_csv()` with `ExtensionArray` with list-like values (GH28840).

Groupby/resample/rolling

- Bug incorrectly raising an `IndexError` when passing a list of quantiles to `pandas.core.groupby.DataFrameGroupBy.quantile()` (GH28113).
- Bug in `pandas.core.groupby.GroupBy.shift()`, `pandas.core.groupby.GroupBy.bfill()` and `pandas.core.groupby.GroupBy.ffill()` where timezone information would be dropped (GH19995, GH27992).

Other

- Compatibility with Python 3.8 in `DataFrame.query()` (GH27261).
- Fix to ensure that tab-completions in an IPython console does not raise warnings for deprecated attributes (GH27900).

Contributors

A total of 6 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

5.3.3 What’s new in 0.25.1 (August 21, 2019)

These are the changes in pandas 0.25.1. See Release notes for a full changelog including other versions of pandas.
I/O and LZMA

Some users may unknowingly have an incomplete Python installation lacking the `lzma` module from the standard library. In this case, `import pandas` failed due to an `ImportError` (GH27575). Pandas will now warn, rather than raising an `ImportError` if the `lzma` module is not present. Any subsequent attempt to use `lzma` methods will raise a `RuntimeError`. A possible fix for the lack of the `lzma` module is to ensure you have the necessary libraries and then re-install Python. For example, on MacOS installing Python with `pyenv` may lead to an incomplete Python installation due to unmet system dependencies at compilation time (like `xz`). Compilation will succeed, but Python might fail at run time. The issue can be solved by installing the necessary dependencies and then re-installing Python.

Bug fixes

Categorical

- Bug in `Categorical.fillna()` that would replace all values, not just those that are `NaN` (GH26215)

Datetimelike

- Bug in `to_datetime()` where passing a timezone-naive `DatetimeArray` or `DatetimeIndex` and `utc=True` would incorrectly return a timezone-naive result (GH27733)
- Bug in `Period.to_timestamp()` where a `Period` outside the `Timestamp` implementation bounds (roughly 1677-09-21 to 2262-04-11) would return an incorrect `Timestamp` instead of raising `OutOfBoundsDatetime` (GH19643)
- Bug in iterating over `DatetimeIndex` when the underlying data is read-only (GH28055)

Timezones

- Bug in `Index` where a numpy object array with a timezone aware `Timestamp` and `np.nan` would not return a `DatetimeIndex` (GH27011)

Numeric

- Bug in `Series.interpolate()` when using a timezone aware `DatetimeIndex` (GH27548)
- Bug when printing negative floating point complex numbers would raise an `IndexError` (GH27484)
- Bug where `DataFrame` arithmetic operators such as `DataFrame.mul()` with a `Series` with `axis=1` would raise an `AttributeError` on `DataFrame` larger than the minimum threshold to invoke `numexpr` (GH27636)
- Bug in `DataFrame` arithmetic where missing values in results were incorrectly masked with `NaN` instead of `Inf` (GH27464)
Conversion

- Improved the warnings for the deprecated methods `Series.real()` and `Series.imag()` (GH27610)

Interval

- Bug in `IntervalIndex` where `dir(obj)` would raise `ValueError` (GH27571)

Indexing

- Bug in partial-string indexing returning a NumPy array rather than a `Series` when indexing with a scalar like `.loc['2015']` (GH27516)
- Break reference cycle involving `Index` and other index classes to allow garbage collection of index objects without running the GC. (GH27585, GH27840)
- Fix regression in assigning values to a single column of a `DataFrame` with a `MultiIndex` columns (GH27841).
- Fix regression in `.ix` fallback with an `IntervalIndex` (GH27865).

Missing

- Bug in `pandas.isnull()` or `pandas.isna()` when the input is a type e.g. `type(pandas.Series())` (GH27482)

I/O

- Avoid calling `S3File.s3` when reading parquet, as this was removed in s3fs version 0.3.0 (GH27756)
- Better error message when a negative header is passed in `pandas.read_csv()` (GH27779)
- Follow the `min_rows` display option (introduced in v0.25.0) correctly in the HTML repr in the notebook (GH27991).

Plotting

- Added a `pandas_plotting_backends` entrypoint group for registering plot backends. See `Plotting backends` for more (GH26747).
- Fixed the re-instatement of Matplotlib datetime converters after calling `pandas.plotting.deregister_matplotlib_converters()` (GH27481).
- Fix compatibility issue with matplotlib when passing a pandas `Index` to a plot call (GH27775).
Groupby/resample/rolling

- Fixed regression in `pandas.core.groupby.DataFrameGroupBy.quantile()` raising when multiple quantiles are given (GH27526)
- Bug in `pandas.core.groupby.DataFrameGroupBy.transform()` where applying a timezone conversion lambda function would drop timezone information (GH27496)
- Bug in `pandas.core.groupby.GroupBy.nth()` where `observed=False` was being ignored for Categorical groupers (GH26385)
- Bug in windowing over read-only arrays (GH27766)
- Fixed segfault in `pandas.core.groupby.DataFrameGroupBy.quantile` when an invalid quantile was passed (GH27470)

Reshaping

- A `KeyError` is now raised if `.unstack()` is called on a `Series` or `DataFrame` with a flat `Index` passing a name which is not the correct one (GH18303)
- Bug `merge_asof()` could not merge `Timedelta` objects when passing `tolerance` kwarg (GH27642)
- Bug in `DataFrame.crosstab()` when `margins` set to `True` and `normalize` is not `False`, an error is raised. (GH27500)
- `DataFrame.join()` now suppresses the `FutureWarning` when the `sort` parameter is specified (GH21952)
- Bug in `DataFrame.join()` raising with readonly arrays (GH27943)

Sparse

- Bug in reductions for `Series` with Sparse dtypes (GH27080)

Other

- Bug in `Series.replace()` and `DataFrame.replace()` when replacing timezone-aware timestamps using a dict-like replacer (GH27720)
- Bug in `Series.rename()` when using a custom type indexer. Now any value that isn’t callable or dict-like is treated as a scalar. (GH27814)

Contributors

A total of 5 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Jeff Reback
- Joris Van den Bossche
- MeeseeksMachine +
- Tom Augspurger
- jbrockmendel
5.3.4 What’s new in 0.25.0 (July 18, 2019)

Warning: Starting with the 0.25.x series of releases, pandas only supports Python 3.5.3 and higher. See Dropping Python 2.7 for more details.

Warning: The minimum supported Python version will be bumped to 3.6 in a future release.

Warning: Panel has been fully removed. For N-D labeled data structures, please use xarray

Warning: read_pickle() and read_msgpack() are only guaranteed backwards compatible back to pandas version 0.20.3 (GH27082)

These are the changes in pandas 0.25.0. See Release notes for a full changelog including other versions of pandas.

Enhancements

Groupby aggregation with relabeling

Pandas has added special groupby behavior, known as “named aggregation”, for naming the output columns when applying multiple aggregation functions to specific columns (GH18366, GH26512).

In [1]: animals = pd.DataFrame({'kind': ['cat', 'dog', 'cat', 'dog'],
                             'height': [9.1, 6.0, 9.5, 34.0],
                             'weight': [7.9, 7.5, 9.9, 198.0]})

In [2]: animals.groupby("kind").agg(
   ...:     min_height=pd.NamedAgg(column='height', aggfunc='min'),
   ...:     max_height=pd.NamedAgg(column='height', aggfunc='max'),
   ...:     average_weight=pd.NamedAgg(column='weight', aggfunc=np.mean),
   ...: )

Out[3]:

    min_height  max_height  average_weight
kind      kind
  cat      9.1          9.5          8.90
  dog      6.0          34.0         102.75

(continues on next page)
Pass the desired column names as the \texttt{**kwargs} to \texttt{.agg}. The values of \texttt{**kwargs} should be tuples where the first element is the column selection, and the second element is the aggregation function to apply. Pandas provides the pandas.NamedAgg namedtuple to make it clearer what the arguments to the function are, but plain tuples are accepted as well.

\begin{Verbatim}
In [4]: animals.groupby("kind").agg(
    ...:     min_height=('height', 'min'),
    ...:     max_height=('height', 'max'),
    ...:     average_weight=('weight', np.mean),
    ...: )
Out[4]:
     min_height  max_height  average_weight
    kind
    cat     9.1       9.5            8.90
    dog     6.0      34.0           102.75
\end{Verbatim}

Named aggregation is the recommended replacement for the deprecated “dict-of-dicts” approach to naming the output of column-specific aggregations (\textit{Deprecate groupby.agg() with a dictionary when renaming}).

A similar approach is now available for Series groupby objects as well. Because there’s no need for column selection, the values can just be the functions to apply.

\begin{Verbatim}
In [5]: animals.groupby("kind").height.agg(
    ...:     min_height="min",
    ...:     max_height="max",
    ...: )
Out[5]:
     min_height  max_height
    kind
    cat        9.1        9.5
    dog        6.0       34.0
\end{Verbatim}

This type of aggregation is the recommended alternative to the deprecated behavior when passing a dict to a Series groupby aggregation (\textit{Deprecate groupby.agg() with a dictionary when renaming}).

See \texttt{Named aggregation} for more.
Groupby aggregation with multiple lambdas

You can now provide multiple lambda functions to a list-like aggregation in `pandas.core.groupby.GroupBy.agg` (GH26430).

```python
In [6]: animals.groupby('kind').height.agg([  
...: lambda x: x.iloc[0], lambda x: x.iloc[-1]  
...: ])
```

```bash
Out[6]:
<lambda_0> <lambda_1>
kind  
cat    9.1    9.5
dog    6.0  34.0
```

Previously, these raised a `SpecificationError`.

Better repr for MultiIndex

Printing of `MultiIndex` instances now shows tuples of each row and ensures that the tuple items are vertically aligned, so it’s now easier to understand the structure of the `MultiIndex`. (GH13480):

```python
In [8]: pd.MultiIndex.from_product([[a, 'abc'], range(500)])
```

```bash
Out[8]:
MultiIndex([('a', 0),  
('a', 1),  
('a', 2),  
('a', 3),  
('a', 4),  
('a', 5),  
('a', 6),  
('a', 7),  
('a', 8),  
('a', 9),  
...'abc', 490),  
('abc', 491),  
('abc', 492),  
('a', 490),  
...]  
...  
(continues on next page)
```
Previously, outputting a `MultiIndex` printed all the levels and codes of the `MultiIndex`, which was visually unappealing and made the output more difficult to navigate. For example (limiting the range to 5):

```python
In [1]: pd.MultiIndex.from_product([['a', 'abc'], range(5)])
Out[1]: MultiIndex(levels=[['a', 'abc'], [0, 1, 2, 3]],
...: codes=[[0, 0, 0, 0, 1, 1, 1, 1], [0, 1, 2, 3, 0, 1, 2, 3]])
```

In the new repr, all values will be shown, if the number of rows is smaller than `options.display.max_seq_items` (default: 100 items). Horizontally, the output will truncate, if it’s wider than `options.display.width` (default: 80 characters).

### Shorter truncated repr for Series and DataFrame

Currently, the default display options of pandas ensure that when a Series or DataFrame has more than 60 rows, its repr gets truncated to this maximum of 60 rows (the `display.max_rows` option). However, this still gives a repr that takes up a large part of the vertical screen estate. Therefore, a new option `display.min_rows` is introduced with a default of 10 which determines the number of rows showed in the truncated repr:

- For small Series or DataFrames, up to `max_rows` number of rows is shown (default: 60).
- For larger Series of DataFrame with a length above `max_rows`, only `min_rows` number of rows is shown (default: 10, i.e. the first and last 5 rows).

This dual option allows to still see the full content of relatively small objects (e.g. `df.head(20)` shows all 20 rows), while giving a brief repr for large objects.

To restore the previous behaviour of a single threshold, set `pd.options.display.min_rows = None`.

### Json normalize with max_level param support

`json_normalize()` normalizes the provided input dict to all nested levels. The new `max_level` parameter provides more control over which level to end normalization (GH23843):

The repr now looks like this:

```python
from pandas.io.json import json_normalize
data = [{
    'CreatedBy': {'Name': 'User001'},
    'Lookup': {'TextField': 'Some text',
               'UserField': {'Id': 'ID001', 'Name': 'Name001'}},
    'Image': {'a': 'b'}
}]
json_normalize(data, max_level=1)
```
Series.explode to split list-like values to rows

Series and DataFrame have gained the DataFrame.explode() methods to transform list-likes to individual rows. See section on Exploding list-like column in docs for more information (GH16538, GH10511)

Here is a typical use case. You have comma separated string in a column.

```python
In [9]: df = pd.DataFrame([{'var1': 'a,b,c', 'var2': 1},
                         {'var1': 'd,e,f', 'var2': 2}])

In [10]: df
Out[10]:
    var1 var2
   0  a,b,c    1
   1  d,e,f    2
[2 rows x 2 columns]
```

Creating a long form DataFrame is now straightforward using chained operations

```python
In [11]: df.assign(var1=df.var1.str.split(',')).explode('var1')
Out[11]:
    var1  var2
   0 a   1
   1 b   1
   0 c   1
   1 d   2
   1 e   2
   1 f   2
[6 rows x 2 columns]
```

Other enhancements

- DataFrame.plot() keywords logy, logx and loglog can now accept the value 'sym' for symlog scaling. (GH24867)
- Added support for ISO week year format (‘%G-%V-%u’) when parsing datetimes using to_datetime() (GH16607)
- Indexing of DataFrame and Series now accepts zerodim np.ndarray (GH24919)
- Timestamp.replace() now supports the fold argument to disambiguate DST transition times (GH25017)
- DataFrame.at_time() and Series.at_time() now support datetime.time objects with time-zones (GH24043)
- DataFrame.pivot_table() now accepts an observed parameter which is passed to underlying calls to DataFrame.groupby() to speed up grouping categorical data. (GH24923)
- Series.str has gained Series.str.casefold() method to removes all case distinctions present in a string (GH25405)
- DataFrame.set_index() now works for instances of abc.Iterator, provided their output is of the same length as the calling frame (GH22484, GH24984)
• `DatetimeIndex.union()` now supports the `sort` argument. The behavior of the sort parameter matches that of `Index.union()` (GH24994)

• `RangeIndex.union()` now supports the `sort` argument. If `sort=False` an unsorted `Int64Index` is always returned. `sort=None` is the default and returns a monotonically increasing `RangeIndex` if possible or a sorted `Int64Index` if not (GH24471)

• `TimedeltaIndex.intersection()` now also supports the `sort` keyword (GH24471)

• `DataFrame.rename()` now supports the `errors` argument to raise errors when attempting to rename nonexistent keys (GH13473)

• Added `Sparse accessor` for working with a DataFrame whose values are sparse (GH25681)

• `RangeIndex` has gained `start`, `stop`, and `step` attributes (GH25710)

• `datetime.timezone` objects are now supported as arguments to timezone methods and constructors (GH25065)

• `DataFrame.query()` and `DataFrame.eval()` now supports quoting column names with backticks to refer to names with spaces (GH6508)

• `merge_asof()` now gives a more clear error message when merge keys are categoricals that are not equal (GH26136)

• `pandas.core.window.Rolling()` supports exponential (or Poisson) window type (GH21303)

• Error message for missing required imports now includes the original import error’s text (GH23868)

• `DatetimeIndex` and `TimedeltaIndex` now have a `mean` method (GH24757)

• `DataFrame.describe()` now formats integer percentiles without decimal point (GH26660)

• Added support for reading SPSS .sav files using `read_spss()` (GH26537)

• Added new option `plotting.backend` to be able to select a plotting backend different than the existing `matplotlib` one. Use `pandas.set_option('plotting.backend', '<backend-module>')` where `<backend-module>` is a library implementing the pandas plotting API (GH14130)

• `pandas.offsets.BusinessHour` supports multiple opening hours intervals (GH15481)

• `read_excel()` can now use `openpyxl` to read Excel files via the `engine='openpyxl'` argument. This will become the default in a future release (GH11499)

• `pandas.io.excel.read_excel()` supports reading OpenDocument tables. Specify `engine='odf'` to enable. Consult the `IO User Guide` for more details (GH9070)

• `Interval`, `IntervalIndex`, and `IntervalArray` have gained an `is_empty` attribute denoting if the given interval(s) are empty (GH27219)

Backwards incompatible API changes

Indexing with date strings with UTC offsets

Indexing a `DataFrame` or `Series` with a `DatetimeIndex` with a date string with a UTC offset would previously ignore the UTC offset. Now, the UTC offset is respected in indexing. (GH24076, GH16785)

```python
In [12]: df = pd.DataFrame([0], index=pd.DatetimeIndex(['2019-01-01'], tz='US/Pacific'))
In [13]: df
Out[13]:
```

(continues on next page)
Previous behavior:

In [3]: df['2019-01-01 00:00:00+04:00':'2019-01-01 01:00:00+04:00']
Out[3]:
0
2019-01-01 00:00:00-08:00 0
[1 rows x 1 columns]

New behavior:

In [14]: df['2019-01-01 12:00:00+04:00':'2019-01-01 13:00:00+04:00']
Out[14]:
0
2019-01-01 00:00:00-08:00 0
[1 rows x 1 columns]

MultiIndex constructed from levels and codes

Constructing a MultiIndex with NaN levels or codes value < -1 was allowed previously. Now, construction with codes value < -1 is not allowed and NaN levels’ corresponding codes would be reassigned as -1. (GH19387)

Previous behavior:

In [1]: pd.MultiIndex(levels=[[np.nan, None, pd.NaT, 128, 2]],
                   codes=[[0, -1, 1, 2, 3, 4]])
   ...:
Out[1]: MultiIndex(levels=[nan, None, NaT, 128, 2],
                   codes=[[0, -1, 1, 2, 3, 4]])
In [2]: pd.MultiIndex(levels=[[1, 2]], codes=[[0, -2]])
Out[2]: MultiIndex(levels=[[1, 2]],
                   codes=[[0, -2]])

New behavior:

In [15]: pd.MultiIndex(levels=[[np.nan, None, pd.NaT, 128, 2]],
                   codes=[[0, -1, 1, 2, 3, 4]])
   ...:
Out[15]: MultiIndex([(nan,),
                    (nan,),
                    (nan,),
                    (nan,),
                    (128,),
                    ( 2,)])
In [16]: pd.MultiIndex(levels=[[1, 2]], codes=[[0, -2]])
---------------------------------------------------------------------------
ValueError Traceback (most recent call last)

Groupby.apply on DataFrame evaluates first group only once

The implementation of DataFrameGroupBy.apply() previously evaluated the supplied function consistently twice on the first group to infer if it is safe to use a fast code path. Particularly for functions with side effects, this was an undesired behavior and may have led to surprises. (GH2936, GH2656, GH7739, GH10519, GH12155, GH20084, GH21417)

Now every group is evaluated only a single time.

Previous behavior:

In [3]: df.groupby('a').apply(func)
   x
   x
   y
Out[3]:
   a  b

New behavior:

```
In [20]: df.groupby("a").apply(func)
  
Out[20]:
         a  b
0       0  1
1       1  2
[2 rows x 2 columns]
```

**Concatenating sparse values**

When passed DataFrames whose values are sparse, `concat()` will now return a `Series` or `DataFrame` with sparse values, rather than a `SparseDataFrame` (GH25702).

```
In [21]: df = pd.DataFrame({"A": pd.SparseArray([0, 1])})

Previous behavior:

```
In [2]: type(pd.concat([df, df]))
pandas.core.sparse.frame.SparseDataFrame
```

New behavior:

```
In [22]: type(pd.concat([df, df]))
Out[22]: pandas.core.frame.DataFrame
```

This now matches the existing behavior of `concat` on `Series` with sparse values. `concat()` will continue to return a `SparseDataFrame` when all the values are instances of `SparseDataFrame`.

This change also affects routines using `concat()` internally, like `get_dummies()`, which now returns a `DataFrame` in all cases (previously a `SparseDataFrame` was returned if all the columns were dummy encoded, and a `DataFrame` otherwise).

Providing any `SparseSeries` or `SparseDataFrame` to `concat()` will cause a `SparseSeries` or `SparseDataFrame` to be returned, as before.

**The `.str`-accessor performs stricter type checks**

Due to the lack of more fine-grained dtypes, `Series.str` so far only checked whether the data was of `object` dtype. `Series.str` will now infer the dtype data within the `Series`; in particular, 'bytes'-only data will raise an exception (except for `Series.str.decode()`, `Series.str.get()`, `Series.str.len()`, `Series.str.slice()`), see GH23163, GH23011, GH23551.

Previous behavior:

```
In [1]: s = pd.Series(np.array(['a', 'ba', 'cba'], 'S'), dtype=object)
```
In [2]: s
Out[2]:
0   b'a'
1   b'ba'
2   b'cba'
dtype: object

In [3]: s.str.startswith(b'a')
Out[3]:
0   True
1   False
2   False
dtype: bool

New behavior:

In [23]: s = pd.Series(np.array(\['a', 'ba', 'cba',\], 'S'), dtype=object)
In [24]: s
Out[24]:
0   b'a'
1   b'ba'
2   b'cba'
Length: 3, dtype: object
In [25]: s.str.startswith(b'a')
---------------------------------------------------------------------------
TypeError                                 Traceback (most recent call last)
<ipython-input-25-ac784692b361> in                                          
----> 1 s.str.startswith(b'a')
/pandas-release/pandas/pandas/core/strings.py in wrapper(self, *args, **kwargs)
    1998   f"inferred dtype '{self._inferred_dtype}'."

Categorical dtypes are preserved during groupby

Previously, columns that were categorical, but not the groupby key(s) would be converted to object dtype during groupby operations. Pandas now will preserve these dtypes. (GH18502)

In [26]: cat = pd.Categorical(["foo", "bar", "bar", "qux"], ordered=True)
In [27]: df = pd.DataFrame({'payload': [-1, -2, -1, -2], 'col': cat})
In [28]: df
Out[28]:
payload  col
0   -1  foo
1   -2  bar
2   -1  bar
pandas: powerful Python data analysis toolkit, Release 1.1.1

(continued from previous page)

3   -2   qux
[4 rows x 2 columns]

In [29]: df.dtypes
Out[29]:
payload   int64
col        category
Length: 2, dtype: object

Previous Behavior:

In [5]: df.groupby('payload').first().col.dtype
Out[5]: dtype('O')

New Behavior:

In [30]: df.groupby('payload').first().col.dtype
Out[30]: CategoricalDtype(categories=['bar', 'foo', 'qux'], ordered=True)

Incompatible Index type unions

When performing `Index.union()` operations between objects of incompatible dtypes, the result will be a base `Index` of dtype object. This behavior holds true for unions between `Index` objects that previously would have been prohibited. The dtype of empty `Index` objects will now be evaluated before performing union operations rather than simply returning the other `Index` object. `Index.union()` can now be considered commutative, such that `A.union(B) == B.union(A)` (GH23525).

Previous behavior:

In [1]: pd.period_range('19910905', periods=2).union(pd.Int64Index([1, 2, 3]))
...  
ValueError: can only call with other PeriodIndex-ed objects

In [2]: pd.Index([], dtype=object).union(pd.Index([1, 2, 3]))
Out[2]: Int64Index([1, 2, 3], dtype='int64')

New behavior:

In [31]: pd.period_range('19910905', periods=2).union(pd.Int64Index([1, 2, 3]))
Out[31]: Index(['1991-09-05', '1991-09-06', 1, 2, 3], dtype='object')

In [32]: pd.Index([], dtype=object).union(pd.Index([1, 2, 3]))
Out[32]: Index([1, 2, 3], dtype='object')

Note that integer- and floating-dtype indexes are considered “compatible”. The integer values are coerced to floating point, which may result in loss of precision. See Set operations on Index objects for more.
DataFrame groupby ffill/bfill no longer return group labels

The methods ffill, bfill, pad and backfill of DataFrameGroupBy previously included the group labels in the return value, which was inconsistent with other groupby transforms. Now only the filled values are returned. (GH21521)

```
In [33]: df = pd.DataFrame({"a": ["x", "y"], "b": [1, 2]})

In [34]: df
Out[34]:
   a  b
0  x  1
1  y  2
[2 rows x 2 columns]

Previous behavior:

In [3]: df.groupby("a").ffill()
Out[3]:
   a  b
0  x  1
1  y  2

New behavior:

In [35]: df.groupby("a").ffill()
Out[35]:
   b
0  1
1  2
[2 rows x 1 columns]
```

DataFrame describe on an empty categorical / object column will return top and freq

When calling DataFrame.describe() with an empty categorical / object column, the ‘top’ and ‘freq’ columns were previously omitted, which was inconsistent with the output for non-empty columns. Now the ‘top’ and ‘freq’ columns will always be included, with numpy.nan in the case of an empty DataFrame (GH26397)

```
In [36]: df = pd.DataFrame({"empty_col": pd.Categorical([])})

In [37]: df
Out[37]:
Empty DataFrame
Columns: [empty_col]
Index: []
[0 rows x 1 columns]

Previous behavior:

In [3]: df.describe()
Out[3]:
   empty_col
       None

(continues on next page)
New behavior:

```
In [38]: df.describe()
Out[38]:
   empty_col
      count   0
      unique  0
   top     NaN
   freq    NaN
[4 rows x 1 columns]
```

__str__ methods now call __repr__ rather than vice versa

Pandas has until now mostly defined string representations in a Pandas object's __str__/__unicode__/__bytes__ methods, and called __str__ from the __repr__ method, if a specific __repr__ method is not found. This is not needed for Python3. In Pandas 0.25, the string representations of Pandas objects are now generally defined in __repr__, and calls to __str__ in general now pass the call on to the __repr__, if a specific __str__ method doesn't exist, as is standard for Python. This change is backward compatible for direct usage of Pandas, but if you subclass Pandas objects and give your subclasses specific __str__/__repr__ methods, you may have to adjust your __str__/__repr__ methods (GH26495).

Indexing an IntervalIndex with Interval objects

Indexing methods for IntervalIndex have been modified to require exact matches only for Interval queries. IntervalIndex methods previously matched on any overlapping Interval. Behavior with scalar points, e.g. querying with an integer, is unchanged (GH16316).

```
In [39]: ii = pd.IntervalIndex.from_tuples([(0, 4), (1, 5), (5, 8)])
In [40]: ii
Out[40]:
IntervalIndex([(0, 4], (1, 5], (5, 8]
             closed='right',
             dtype='interval[int64]'
```

The in operator (__contains__) now only returns True for exact matches to Intervals in the IntervalIndex, whereas this would previously return True for any Interval overlapping an Interval in the IntervalIndex.

Previous behavior:

```
In [4]: pd.Interval(1, 2, closed='neither') in ii
Out[4]: True

In [5]: pd.Interval(-10, 10, closed='both') in ii
Out[5]: True
```

New behavior:
The `get_loc()` method now only returns locations for exact matches to `Interval` queries, as opposed to the previous behavior of returning locations for overlapping matches. A `KeyError` will be raised if an exact match is not found.

### Previous behavior:

```python
In [6]: ii.get_loc(pd.Interval(1, 5))
Out[6]: array([0, 1])

In [7]: ii.get_loc(pd.Interval(2, 6))
Out[7]: array([0, 1, 2])
```

### New behavior:

```python
In [6]: ii.get_loc(pd.Interval(1, 5))
Out[6]: 1

In [7]: ii.get_loc(pd.Interval(2, 6))
KeyError: Interval(2, 6, closed='right')
```

Likewise, `get_indexer()` and `get_indexer_non_unique()` will also only return locations for exact matches to `Interval` queries, with -1 denoting that an exact match was not found.

These indexing changes extend to querying a `Series` or `DataFrame` with an `IntervalIndex` index.

```python
In [43]: s = pd.Series(list('abc'), index=ii)
In [44]: s
Out[44]:
      0          4  a
      1          5  b
   5          8  c
Length: 3, dtype: object
```

Selecting from a `Series` or `DataFrame` using `[]` (`__getitem__`) or `loc` now only returns exact matches for `Interval` queries.

### Previous behavior:

```python
In [8]: s[pd.Interval(1, 5)]
Out[8]:
      0          4  a
      1          5  b
dtype: object

In [9]: s.loc[pd.Interval(1, 5)]
Out[9]:
      0          4  a
      1          5  b
dtype: object
```

### New behavior:

```python
In [8]: s[pd.Interval(1, 5)]
Out[8]:
      0          4  a
      1          5  b
dtype: object

In [9]: s.loc[pd.Interval(1, 5)]
KeyError: Interval(1, 6, closed='right')
```
Similarly, a `KeyError` will be raised for non-exact matches instead of returning overlapping matches.

**Previous behavior:**

```
In [9]: s[pd.Interval(2, 3)]
Out[9]:
(0, 4]  a
(1, 5]  b
dtype: object
```

```
In [10]: s.loc[pd.Interval(2, 3)]
Out[10]:
(0, 4]  a
(1, 5]  b
dtype: object
```

**New behavior:**

```
In [6]: s[pd.Interval(2, 3)]
---------------------------------------------------------------------------
KeyError: Interval(2, 3, closed='right')
```

```
In [7]: s.loc[pd.Interval(2, 3)]
---------------------------------------------------------------------------
KeyError: Interval(2, 3, closed='right')
```

The `overlaps()` method can be used to create a boolean indexer that replicates the previous behavior of returning overlapping matches.

**New behavior:**

```
In [47]: idxr = s.index.overlaps(pd.Interval(2, 3))
In [48]: idxr
Out[48]: array([ True,  True, False])
```

```
In [49]: s[idxr]
Out[49]:
(0, 4]  a
(1, 5]  b
Length: 2, dtype: object
```

```
In [50]: s.loc[idxr]
Out[50]:
(0, 4]  a
(1, 5]  b
Length: 2, dtype: object
```
Binary ufuncs on Series now align

Applying a binary ufunc like `numpy.power()` now aligns the inputs when both are `Series` (GH23293).

```python
In [51]: s1 = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
In [52]: s2 = pd.Series([3, 4, 5], index=['d', 'c', 'b'])

In [53]: s1
Out[53]:
          a  1
          b  2
          c  3
Length: 3, dtype: int64

In [54]: s2
Out[54]:
          d  3
          c  4
          b  5
Length: 3, dtype: int64

Previous behavior

```python
In [5]: np.power(s1, s2)
Out[5]:
          a   1
          b  16
          c 243
dtype: int64

New behavior

```python
In [55]: np.power(s1, s2)
Out[55]:
          a  1.0
          b 32.0
          c 81.0
d   NaN
Length: 4, dtype: float64

This matches the behavior of other binary operations in pandas, like `Series.add()`. To retain the previous behavior, convert the other `Series` to an array before applying the ufunc.

```python
In [56]: np.power(s1, s2.array)
Out[56]:
          a  1
          b 16
          c 243
Length: 3, dtype: int64
```
Categorical.argsort now places missing values at the end

Categorical.argsort() now places missing values at the end of the array, making it consistent with NumPy and the rest of pandas (GH21801).

Previous behavior

New behavior

Column order is preserved when passing a list of dicts to DataFrame

Starting with Python 3.7 the key-order of dict is guaranteed. In practice, this has been true since Python 3.6. The DataFrame constructor now treats a list of dicts in the same way as it does a list of OrderedDict, i.e. preserving the order of the dicts. This change applies only when pandas is running on Python>=3.6 (GH27309).

Previous Behavior:
The columns were lexicographically sorted previously.

New Behavior:
The column order now matches the insertion-order of the keys in the `dict`, considering all the records from top to bottom. As a consequence, the column order of the resulting DataFrame has changed compared to previous pandas versions.

```
In [61]: pd.DataFrame(data)
Out[61]:
   name state  age  hobby  finances
0   Joe   NY   18     NaN       NaN
1  Jane   KY   19  Minecraft       NaN
2  Jean   OK   20       NaN      good
[3 rows x 5 columns]
```

**Increased minimum versions for dependencies**

Due to dropping support for Python 2.7, a number of optional dependencies have updated minimum versions (GH25725, GH24942, GH25752). Independently, some minimum supported versions of dependencies were updated (GH23519, GH25554). If installed, we now require:

<table>
<thead>
<tr>
<th>Package</th>
<th>Minimum Version</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>numpy</td>
<td>1.13.3</td>
<td>X</td>
</tr>
<tr>
<td>pytz</td>
<td>2015.4</td>
<td>X</td>
</tr>
<tr>
<td>python-dateutil</td>
<td>2.6.1</td>
<td>X</td>
</tr>
<tr>
<td>bottleneck</td>
<td>1.2.1</td>
<td></td>
</tr>
<tr>
<td>numexpr</td>
<td>2.6.2</td>
<td></td>
</tr>
<tr>
<td>pytest (dev)</td>
<td>4.0.2</td>
<td></td>
</tr>
</tbody>
</table>

For optional libraries the general recommendation is to use the latest version. The following table lists the lowest version per library that is currently being tested throughout the development of pandas. Optional libraries below the lowest tested version may still work, but are not considered supported.

<table>
<thead>
<tr>
<th>Package</th>
<th>Minimum Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>beautifulsoup4</td>
<td>4.6.0</td>
</tr>
<tr>
<td>fastparquet</td>
<td>0.2.1</td>
</tr>
<tr>
<td>gcsfs</td>
<td>0.2.2</td>
</tr>

See Dependencies and Optional dependencies for more.
Other API changes

- **DatetimeTZDtype** will now standardize pytz time zones to a common timezone instance (GH24713)
- **Timestamp** and **Timedelta** scalars now implement the `to_numpy()` method as aliases to `Timestamp.to_datetime64()` and `Timedelta.to_timedelta64()`, respectively. (GH24653)
- **Timestamp.strptime()** will now raise a `NotImplementedError` (GH25016)
- Comparing **Timestamp** with unsupported objects now returns `NotImplemented` instead of raising `TypeError`. This implies that unsupported rich comparisons are delegated to the other object, and are now consistent with Python 3 behavior for `datetime` objects (GH24011)
- Bug in **DatetimeIndex.snap()** which didn’t preserving the name of the input `Index` (GH25575)
- The `arg` argument in `pandas.core.groupby.DataFrameGroupBy.agg()` has been renamed to `func` (GH26089)
- The `arg` argument in `pandas.core.window._Window.aggregate()` has been renamed to `func` (GH26372)
- Most Pandas classes had a `__bytes__` method, which was used for getting a python2-style bytestring representation of the object. This method has been removed as a part of dropping Python2 (GH26447)
- The `.str`-accessor has been disabled for 1-level **MultiIndex**, use `MultiIndex.to_flat_index()` if necessary (GH23679)
- Removed support of gtk package for clipboards (GH26563)
- Using an unsupported version of Beautiful Soup 4 will now raise an `ImportError` instead of a `ValueError` (GH27063)
- **Series.to_excel()** and **DataFrame.to_excel()** will now raise a `ValueError` when saving timezone aware data. (GH27008, GH7056)
- **ExtensionArray.argsort()** places NA values at the end of the sorted array. (GH21801)
- **DataFrame.to_hdf()** and **Series.to_hdf()** will now raise a `NotImplementedError` when saving a **MultiIndex** with extension data types for a fixed format. (GH7775)
- Passing duplicate names in `read_csv()` will now raise a `ValueError` (GH17346)

Deprecations

Sparse subclasses

The **SparseSeries** and **SparseDataFrame** subclasses are deprecated. Their functionality is better-provided by a **Series** or **DataFrame** with sparse values.

Previous way

```python
df = pd.SparseDataFrame({"A": [0, 0, 1, 2]})
df.dtypes
```

New way

```python
In [62]: df = pd.DataFrame({"A": pd.SparseArray([0, 0, 1, 2])})
In [63]: df.dtypes
Out[63]:
```

(continues on next page)
A Sparse[int64, 0]
Length: 1, dtype: object

The memory usage of the two approaches is identical. See Migrating for more (GH19239).

msgpack format

The msgpack format is deprecated as of 0.25 and will be removed in a future version. It is recommended to use pyarrow for on-the-wire transmission of pandas objects. (GH27084)

Other deprecations

- The deprecated .ix[] indexer now raises a more visible FutureWarning instead of DeprecationWarning (GH26438).
- Deprecated the units=M (months) and units=Y (year) parameters for units of pandas.to_timedelta(), pandas.Timedelta() and pandas.TimedeltaIndex() (GH16344)
- pandas.concat() has deprecated the join_axes-keyword. Instead, use DataFrame.reindex() or DataFrame.reindex_like() on the result or on the inputs (GH21951)
- The SparseArray.values attribute is deprecated. You can use np.asarray(...) or the SparseArray.to_dense() method instead (GH26421).
- The functions pandas.to_datetime() and pandas.to_timedelta() have deprecated the box keyword. Instead, use to_numpy() or Timestamp.to_datetime64() or Timedelta.to_timedelta64() (GH24416)
- The DataFrame.compound() and Series.compound() methods are deprecated and will be removed in a future version (GH26405).
- The internal attributes _start, _stop and _step attributes of RangeIndex have been deprecated. Use the public attributes start, stop and step instead (GH26581).
- The Series.ftype(), Series.ftypes() and DataFrame.ftypes() methods are deprecated and will be removed in a future version. Instead, use Series.dtype() and DataFrame.dtypes() (GH26705).
- The Series.get_values(), DataFrame.get_values(), Index.get_values(), SparseArray.get_values() and Categorical.get_values() methods are deprecated. One of np.asarray(...) or to_numpy() can be used instead (GH19617).
- The ‘outer’ method on NumPy ufuncs, e.g. np.subtract.outer has been deprecated on Series objects. Convert the input to an array with Series.array first (GH27186)
- Timedelta.resolution() is deprecated and replaced with Timedelta.resolution_string(). In a future version, Timedelta.resolution() will be changed to behave like the standard library datetime.timedelta.resolution (GH21344)
- read_table() has been undeprecated. (GH25220)
- Index.dtype_str is deprecated. (GH18262)
- Series.imag and Series.real are deprecated. (GH18262)
- Series.put() is deprecated. (GH18262)
- Index.item() and Series.item() is deprecated. (GH18262)
The default value `ordered=None` in `CategoricalDtype` has been deprecated in favor of `ordered=False`. When converting between categorical types `ordered=True` must be explicitly passed in order to be preserved. (GH26336)

- `Index.contains()` is deprecated. Use `key in index (__contains__)` instead (GH17753).
- `DataFrame.get_dtype_counts()` is deprecated. (GH18262)
- `Categorical.ravel()` will return a `Categorical` instead of a `np.ndarray` (GH27199)

### Removal of prior version deprecations/changes

- Removed Panel (GH25047, GH25191, GH25231)
- Removed the previously deprecated `sheetname` keyword in `read_excel()` (GH16442, GH20938)
- Removed the previously deprecated `TimeGrouper` (GH16942)
- Removed the previously deprecated `parse_cols` keyword in `read_excel()` (GH16488)
- Removed the previously deprecated `pd.options.html.border` (GH16970)
- Removed the previously deprecated `convert_objects` (GH11221)
- Removed the previously deprecated `select` method of `DataFrame` and `Series` (GH17633)
- Removed the previously deprecated behavior of `Series` treated as list-like in `rename_categories()` (GH17982)
- Removed the previously deprecated `DataFrame.reindex_axis` and `Series.reindex_axis` (GH17842)
- Removed the previously deprecated behavior of altering column or index labels with `Series.rename_axis()` or `DataFrame.rename_axis()` (GH17842)
- Removed the previously deprecated `tupleize_cols` keyword argument in `read_html()`, `read_csv()`, and `DataFrame.to_csv()` (GH17877, GH17820)
- Removed the previously deprecated `DataFrame.from.csv` and `Series.from_csv` (GH17812)
- Removed the previously deprecated `raise_on_error` keyword argument in `DataFrame.where()` and `DataFrame.mask()` (GH17744)
- Removed the previously deprecated `ordered` and `categories` keyword arguments in `astype` (GH17742)
- Removed the previously deprecated `cdate_range` (GH17691)
- Removed the previously deprecated `True` option for the `dropna` keyword argument in `SeriesGroupBy.nth()` (GH17493)
- Removed the previously deprecated `convert` keyword argument in `Series.take()` and `DataFrame.take()` (GH17352)
- Removed the previously deprecated behavior of arithmetic operations with `datetime.date` objects (GH21152)
Performance improvements

- Significant speedup in SparseArray initialization that benefits most operations, fixing performance regression introduced in v0.20.0 (GH24985)
- DataFrame.to_stata() is now faster when outputting data with any string or non-native endian columns (GH25045)
- Improved performance of Series.searchsorted(). The speedup is especially large when the dtype is int8/int16/int32 and the searched key is within the integer bounds for the dtype (GH22034)
- Improved performance of pandas.core.groupby.GroupBy.quantile() (GH20405)
- Improved performance of slicing and other selected operation on a RangeIndex (GH26565, GH26617, GH26722)
- RangeIndex now performs standard lookup without instantiating an actual hashtable, hence saving memory (GH16685)
- Improved performance of read_csv() by faster tokenizing and faster parsing of small float numbers (GH25784)
- Improved performance of read_csv() by faster parsing of N/A and boolean values (GH25804)
- Improved performance of IntervalIndex.is_monotonic, IntervalIndex.is_monotonic_increasing and IntervalIndex.is_monotonic_decreasing by removing conversion to MultiIndex (GH24813)
- Improved performance of DataFrame.to_csv() when writing datetime dtypes (GH25708)
- Improved performance of read_csv() by much faster parsing of MM/YYYY and DD/MM/YYYY datetime formats (GH25922)
- Improved performance of nanops for dtypes that cannot store NaNs. Speedup is particularly prominent for Series.all() and Series.any() (GH25070)
- Improved performance of Series.map() for dictionary mappers on categorical series by mapping the categories instead of mapping all values (GH23785)
- Improved performance of IntervalIndex.intersection() (GH24813)
- Improved performance of read_csv() by faster concatenating date columns without extra conversion to string for integer/float zero and float NaN; by faster checking the string for the possibility of being a date (GH25754)
- Improved performance of IntervalIndex.is_unique by removing conversion to MultiIndex (GH24813)
- Restored performance of DatetimeIndex.__iter__() by re-enabling specialized code path (GH26702)
- Improved performance when building MultiIndex with at least one CategoricalIndex level (GH22044)
- Improved performance by removing the need for a garbage collect when checking for SettingWithCopyWarning (GH27031)
- For to_datetime() changed default value of cache parameter to True (GH26043)
- Improved performance of DatetimeIndex and PeriodIndex slicing given non-unique, monotonic data (GH27136).
- Improved performance of pd.read_json() for index-oriented data. (GH26773)
- Improved performance of MultiIndex.shape() (GH27384).
Bug fixes

Categorical

- Bug in `DataFrame.at()` and `Series.at()` that would raise exception if the index was a `CategoricalIndex` (GH20629)
- Fixed bug in comparison of ordered `Categorical` that contained missing values with a scalar which sometimes incorrectly resulted in `True` (GH26504)
- Bug in `DataFrame.dropna()` when the DataFrame has a `CategoricalIndex` containing `Interval` objects incorrectly raised a `TypeError` (GH25087)

Datetimelike

- Bug in `to_datetime()` which would raise an (incorrect) `ValueError` when called with a date far into the future and the `format` argument specified instead of raising `OutOfBoundsDatetime` (GH23830)
- Bug in `to_datetime()` which would raise `InvalidIndexError`: Reindexing only valid uniquely valued Index objects when called with `cache=True`, with `arg` including at least two different elements from the set `{None, numpy.nan, pandas.NaT}` (GH22305)
- Bug in `DataFrame` and `Series` where timezone aware data with `dtype='datetime64[ns]` was not cast to naive (GH25843)
- Improved `Timestamp` type checking in various datetime functions to prevent exceptions when using a subclassed datetime (GH25851)
- Bug in `Series` and `DataFrame` repr where `np.datetime64('NaT')` and `np.timedelta64('NaT')` with `dtype=object` would be represented as `NaN` (GH25445)
- Bug in `to_datetime()` which does not replace the invalid argument with `NaT` when error is set to coerce (GH26122)
- Bug in adding `DateOffset` with nonzero month to `DatetimeIndex` would raise `ValueError` (GH26258)
- Bug in `to_datetime()` which raises unhandled `OverflowError` when called with mix of invalid dates and `NaN` values with `format='%Y%m%d' and error='coerce'` (GH25512)
- Bug in `isin()` for datetimelike indexes; `DatetimeIndex`, `TimedeltaIndex` and `PeriodIndex` where the `levels` parameter was ignored. (GH26675)
- Bug in `to_datetime()` which raises `TypeError` for `format='%Y%m%d'` when called for invalid integer dates with length >= 6 digits with `errors='ignore'` (GH26689)
- Bug when comparing a `PeriodIndex` against a zero-dimensional numpy array (GH26689)
- Bug in constructing a `Series` or `DataFrame` from a numpy `datetime64` array with a non-ns unit and out-of-bound timestamps generating rubbish data, which will now correctly raise an `OutOfBoundsDatetime` error (GH26206).
- Bug in `date_range()` with unnecessary `OverflowError` being raised for very large or very small dates (GH26651)
- Bug where adding `Timestamp` to a `np.timedelta64` object would raise instead of returning a `Timestamp` (GH24775)
- Bug where comparing a zero-dimensional numpy array containing a `np.datetime64` object to a `Timestamp` would incorrect raise `TypeError` (GH26916)
• Bug in `to_datetime()` which would raise `ValueError`: Tz-aware datetime.datetime cannot be converted to datetime64 unless utc=True when called with cache=True, with arg including datetime strings with different offset (GH26097)

Timedelta

• Bug in `TimedeltaIndex.intersection()` where for non-monotonic indices in some cases an empty Index was returned when in fact an intersection existed (GH25913)

• Bug with comparisons between `Timedelta` and `NaT` raising `TypeError` (GH26039)

• Bug when adding or subtracting a `BusinessHour` to a `Timestamp` with the resulting time landing in a following or prior day respectively (GH26381)

• Bug when comparing a `TimedeltaIndex` against a zero-dimensional numpy array (GH26689)

Timezones

• Bug in `DatetimeIndex.to_frame()` where timezone aware data would be converted to timezone naive data (GH25809)

• Bug in `to_datetime()` with utc=True and datetime strings that would apply previously parsed UTC offsets to subsequent arguments (GH24992)

• Bug in `Timestamp.tz_localize()` and `Timestamp.tz_convert()` does not propagate freq (GH25241)

• Bug in `Series.at()` where setting `Timestamp` with timezone raises `TypeError` (GH25506)

• Bug in `DataFrame.update()` when updating with timezone aware data would return timezone naive data (GH25807)

• Bug in `to_datetime()` where an uninformative `RuntimeError` was raised when passing a naive `Timestamp` with datetime strings with mixed UTC offsets (GH25978)

• Bug in `to_datetime()` with unit='ns' would drop timezone information from the parsed argument (GH26168)

• Bug in `DataFrame.join()` where joining a timezone aware index with a timezone aware column would result in a column of NaN (GH26335)

• Bug in `date_range()` where ambiguous or nonexistent start or end times were not handled by the ambiguous or nonexistent keywords respectively (GH27088)

• Bug in `DatetimeIndex.union()` when combining a timezone aware and timezone unaware `DatetimeIndex` (GH21671)

• Bug when applying a numpy reduction function (e.g. `numpy.minimum()`) to a timezone aware `Series` (GH15552)
Numeric

- Bug in `to_numeric()` in which large negative numbers were being improperly handled (GH24910)
- Bug in `to_numeric()` in which numbers were being coerced to float, even though `errors` was not `coerce` (GH24910)
- Bug in `to_numeric()` in which invalid values for `errors` were being allowed (GH26466)
- Bug in `format` in which floating point complex numbers were not being formatted to proper display precision and trimming (GH25514)
- Bug in error messages in `DataFrame.corr()` and `Series.corr()`. Added the possibility of using a callable. (GH25729)
- Bug in `Series.divmod()` and `Series.rdivmod()` which would raise an (incorrect) `ValueError` rather than return a pair of `Series` objects as result (GH25557)
- Raises a helpful exception when a non-numeric index is sent to `interpolate()` with methods which require numeric index. (GH21662)
- Bug in `eval()` when comparing floats with scalar operators, for example: `x < -0.1` (GH25928)
- Fixed bug where casting all-boolean array to integer extension array failed (GH25211)
- Bug in `divmod` with a `Series` object containing zeros incorrectly raising `AttributeError` (GH26987)
- Inconsistency in `Series` floor-division (`//`) and `divmod` filling positive//zero with `NaN` instead of `Inf` (GH27321)

Conversion

- Bug in `DataFrame.astype()` when passing a dict of columns and types the `errors` parameter was ignored. (GH25905)

Strings

- Bug in the `__name__` attribute of several methods of `Series.str`, which were set incorrectly (GH23551)
- Improved error message when passing `Series` of wrong dtype to `Series.str.cat()` (GH22722)
Interval

- Construction of *Interval* is restricted to numeric, *Timestamp* and *Timedelta* endpoints (GH23013)
- Fixed bug in *Series*/*DataFrame* not displaying NaN in *IntervalIndex* with missing values (GH25984)
- Bug in *IntervalIndex.get_loc()* where a *KeyError* would be incorrectly raised for a decreasing *IntervalIndex* (GH25860)
- Bug in *Index* constructor where passing mixed closed *Interval* objects would result in a *ValueError* instead of an object dtype *Index* (GH27172)

Indexing

- Improved exception message when calling *DataFrame.iloc()* with a list of non-numeric objects (GH25753).
- Improved exception message when calling .iloc or .loc with a boolean indexer with different length (GH26658).
- Bug in *KeyError* exception message when indexing a *MultiIndex* with a non-existent key not displaying the original key (GH27250).
- Bug in .iloc and .loc with a boolean indexer not raising an *IndexError* when too few items are passed (GH26658).
- Bug in *DataFrame.loc()* and *Series.loc()* where *KeyError* was not raised for a *MultiIndex* when the key was less than or equal to the number of levels in the *MultiIndex* (GH14885).
- Bug in which *DataFrame.append()* produced an erroneous warning indicating that a *KeyError* will be thrown in the future when the data to be appended contains new columns (GH22252).
- Bug in which *DataFrame.to_csv()* caused a segfault for a reindexed data frame, when the indices were single-level *MultiIndex* (GH26303).
- Fixed bug where assigning a *arrays.PandasArray* to a *pandas.core.frame.DataFrame* would raise error (GH26390)
- Allow keyword arguments for callable local reference used in the *DataFrame.query()* string (GH26426)
- Fixed a *KeyError* when indexing a *MultiIndex*’ level with a list containing exactly one label, which is missing (GH27148)
- Bug which produced *AttributeError* on partial matching *Timestamp* in a *MultiIndex* (GH26944)
- Bug in *Categorical* and *CategoricalIndex* with *Interval* values when using the in operator (__contains__) with objects that are not comparable to the values in the Interval (GH23705)
- Bug in *DataFrame.loc()* and *DataFrame.iloc()* on a *DataFrame* with a single timezone-aware datetime64[ns] column incorrectly returning a scalar instead of a *Series* (GH27110)
- Bug in *CategoricalIndex* and *Categorical* incorrectly raising *ValueError* instead of *TypeError* when a list is passed using the in operator (__contains__) (GH21729)
- Bug in setting a new value in a *Series* with a *Timedelta* object incorrectly casting the value to an integer (GH22717)
- Bug in *Series* setting a new key (__setitem__) with a timezone-aware datetime incorrectly raising *ValueError* (GH12862)
- Bug in *DataFrame.iloc()* when indexing with a read-only indexer (GH17192)
• Bug in `Series` setting an existing tuple key (`__setitem__`) with timezone-aware datetime values incorrectly raising `TypeError` (GH20441)

**Missing**

• Fixed misleading exception message in `Series.interpolate()` if argument `order` is required, but omitted (GH10633, GH24014).

• Fixed class type displayed in exception message in `DataFrame.dropna()` if invalid `axis` parameter passed (GH25555)

• A `ValueError` will now be thrown by `DataFrame.fillna()` when `limit` is not a positive integer (GH27042)

**MultiIndex**

• Bug in which incorrect exception raised by `Timedelta` when testing the membership of `MultiIndex` (GH24570)

**I/O**

• Bug in `DataFrame.to_html()` where values were truncated using display options instead of outputting the full content (GH17004)

• Fixed bug in missing text when using `to_clipboard()` if copying utf-16 characters in Python 3 on Windows (GH25040)

• Bug in `read_json()` for `orient='table'` when it tries to infer dtypes by default, which is not applicable as dtypes are already defined in the JSON schema (GH21345)

• Bug in `read_json()` for `orient='table'` and float index, as it infers index dtype by default, which is not applicable because index dtype is already defined in the JSON schema (GH25433)

• Bug in `read_json()` for `orient='table'` and string of float column names, as it makes a column name type conversion to `Timestamp`, which is not applicable because column names are already defined in the JSON schema (GH25435)

• Bug in `json_normalize()` for `errors='ignore'` where missing values in the input data, were filled in resulting `DataFrame` with the string "nan" instead of `numpy.nan` (GH25468)

• `DataFrame.to_html()` now raises `TypeError` when using an invalid type for the `classes` parameter instead of `AssertionError` (GH25608)

• Bug in `DataFrame.to_string()` and `DataFrame.to_latex()` that would lead to incorrect output when the `header` keyword is used (GH16718)

• Bug in `read_csv()` not properly interpreting the UTF8 encoded filenames on Windows on Python 3.6+ (GH15086)

• Improved performance in `pandas.read_stata()` and `pandas.io.stata.StataReader` when converting columns that have missing values (GH25772)

• Bug in `DataFrame.to_html()` where header numbers would ignore display options when rounding (GH17280)
• Bug in `read_hdf()` where reading a table from an HDF5 file written directly with PyTables fails with a ValueError when using a sub-selection via the `start` or `stop` arguments (GH11188)

• Bug in `read_hdf()` not properly closing store after a KeyError is raised (GH25766)

• Improved the explanation for the failure when value labels are repeated in Stata dta files and suggested workarounds (GH25772)

• Improved `pandas.read_stata()` and `pandas.io.stata.StataReader` to read incorrectly formatted 118 format files saved by Stata (GH25960)

• Improved the `col_space` parameter in `DataFrame.to_html()` to accept a string so CSS length values can be set correctly (GH25941)

• Fixed bug in loading objects from S3 that contain # characters in the URL (GH25945)

• Adds `use_bqstorage_api` parameter to `read_gbq()` to speed up downloads of large data frames. This feature requires version 0.10.0 of the pandas-gbq library as well as the google-cloud-bigquery-storage and fastavro libraries. (GH26104)

• Fixed memory leak in `DataFrame.to_json()` when dealing with numeric data (GH24889)

• Added `cache_dates=True` parameter to `read_csv()`, which allows to cache unique dates when they are parsed (GH25990)

• `DataFrame.to_excel()` now raises a ValueError when the caller’s dimensions exceed the limitations of Excel (GH26051)

• Fixed bug in `pandas.read_csv()` where a BOM would result in incorrect parsing using `engine='python'` (GH26545)

• `read_excel()` now raises a ValueError when input is of type `pandas.io.excel.ExcelFile` and `engine` param is passed since `pandas.io.excel.ExcelFile` has an engine defined (GH26566)

• Bug while selecting from HDFStore with `where=''` specified (GH26610).

• Fixed bug in `DataFrame.to_excel()` where custom objects (i.e. `PeriodIndex`) inside merged cells were not being converted into types safe for the Excel writer (GH27006)

• Bug in `read_hdf()` where reading a timezone aware `DatetimeIndex` would raise a TypeError (GH11926)

• Bug in `to_msgpack()` and `read_msgpack()` which would raise a ValueError rather than a FileNotFoundError for an invalid path (GH27160)

• Fixed bug in `DataFrame.to_parquet()` which would raise a ValueError when the dataframe had no columns (GH27339)

• Allow parsing of `PeriodDtype` columns when using `read_csv()` (GH26934)

**Plotting**

• Fixed bug where `api.extensions.ExtensionArray` could not be used in matplotlib plotting (GH25587)

• Bug in an error message in `DataFrame.plot()`. Improved the error message if non-numerics are passed to `DataFrame.plot()` (GH25481)

• Bug in incorrect ticklabel positions when plotting an index that are non-numeric / non-datetime (GH7612, GH15912, GH22334)
• Fixed bug causing plots of PeriodIndex timeseries to fail if the frequency is a multiple of the frequency rule code (GH14763)
• Fixed bug when plotting a DatetimeIndex with datetime.timezone.utc timezone (GH17173)

Groupby/resample/rolling

• Bug in pandas.core.resample.Resampler.agg() with a timezone aware index where OverflowError would raise when passing a list of functions (GH22660)
• Bug in pandas.core.groupby.DataFrameGroupBy.nunique() in which the names of column levels were lost (GH23222)
• Bug in pandas.core.groupby.GroupBy.agg() when applying an aggregation function to timezone aware data (GH23683)
• Bug in pandas.core.groupby.GroupBy.first() and pandas.core.groupby.GroupBy.last() where timezone information would be dropped (GH21603)
• Bug in pandas.core.groupby.GroupBy.size() when grouping only NA values (GH23050)
• Bug in Series.groupby() where observed kwarg was previously ignored (GH24880)
• Bug in Series.groupby() where using groupby with a MultiIndex Series with a list of labels equal to the length of the series caused incorrect grouping (GH25704)
• Ensured that ordering of outputs in groupby aggregation functions is consistent across all versions of Python (GH25692)
• Ensured that result group order is correct when grouping on an ordered Categorical and specifying observed=True (GH25871, GH25167)
• Bug in pandas.core.window.Rolling.min() and pandas.core.window.Rolling.max() that caused a memory leak (GH25893)
• Bug in pandas.core.window.Rolling.count() and pandas.core.window.Expanding.count was previously ignoring the axis keyword (GH13503)
• Bug in pandas.core.groupby.GroupBy.idmax() and pandas.core.groupby.GroupBy.idmin() with datetime column would return incorrect dtype (GH25444, GH15306)
• Bug in pandas.core.groupby.GroupBy.cumsum(), pandas.core.groupby.GroupBy.cumprod(), pandas.core.groupby.GroupBy.cummin() and pandas.core.groupby.GroupBy.cummax() with categorical column having absent categories, would return incorrect result or segfault (GH16771)
• Bug in pandas.core.groupby.GroupBy.nth() where NA values in the grouping would return incorrect results (GH26011)
• Bug in pandas.core.groupby.SeriesGroupBy.transform() where transforming an empty group would raise a ValueError (GH26208)
• Bug in pandas.core.frame.DataFrame.groupby() where passing a pandas.core.groupby.grouper.Grouper would return incorrect groups when using the .groups accessor (GH26326)
• Bug in pandas.core.groupby.GroupBy.agg() where incorrect results are returned for uint64 columns. (GH26310)
- Bug in `pandas.core.window.Rolling.median()` and `pandas.core.window.Rolling.quantile()` where MemoryError is raised with empty window (GH26005)
- Bug in `pandas.core.window.Rolling.median()` and `pandas.core.window.Rolling.quantile()` where incorrect results are returned with closed='left' and closed='neither' (GH26005)
- Improved `pandas.core.window.Rolling`, `pandas.core.window.Window` and `pandas.core.window.ExponentialMovingWindow` functions to exclude nuisance columns from results instead of raising errors and raise a `DataError` only if all columns are nuisance (GH12537)
- Bug in `pandas.core.window.Rolling.max()` and `pandas.core.window.Rolling.min()` where incorrect results are returned with an empty variable window (GH26005)
- Raise a helpful exception when an unsupported weighted window function is used as an argument of `pandas.core.window.Window.aggregate()` (GH26597)

**Reshaping**

- Bug in `pandas.merge()` adds a string of None, if None is assigned in suffixes instead of remain the column name as-is (GH24782).
- Bug in `merge()` when merging by index name would sometimes result in an incorrectly numbered index (missing index values are now assigned NA) (GH24212, GH25009)
- `to_records()` now accepts dtypes to its `column_dtypes` parameter (GH24895)
- Bug in `concat()` where order of `OrderedDict` (and `dict` in Python 3.6+) is not respected, when passed in as `objs` argument (GH21510)
- Bug in `pivot_table()` where columns with NaN values are dropped even if dropna argument is False, when the aggfunc argument contains a list (GH22159)
- Bug in `concat()` where the resulting freq of two `DatetimeIndex` with the same freq would be dropped (GH3232).
- Bug in `merge()` where merging with equivalent Categorical dtypes was raising an error (GH22501)
- Bug in `DataFrame` instantiating with a dict of iterators or generators (e.g. `pd.DataFrame({'A': reversed(range(3))})`) raised an error (GH26349).
- Bug in `DataFrame` instantiating with a range (e.g. `pd.DataFrame(range(3))`) raised an error (GH26342).
- Bug in `DataFrame` constructor when passing non-empty tuples would cause a segmentation fault (GH25691)
- Bug in `Series.apply()` failed when the series is a timezone aware `DatetimeIndex` (GH25959)
- Bug in `pandas.cut()` where large bins could incorrectly raise an error due to an integer overflow (GH26045)
- Bug in `DataFrame.sort_index()` where an error is thrown when a multi-indexed DataFrame is sorted on all levels with the initial level sorted last (GH26053)
- Bug in `Series.nlargest()` treats True as smaller than False (GH26154)
- Bug in `DataFrame.pivot_table()` with a `IntervalIndex` as pivot index would raise `TypeError` (GH25814)
- Bug in which `DataFrame.from_dict()` ignored order of `OrderedDict` when orient='index' (GH8425).
- Bug in `DataFrame.transpose()` where transposing a DataFrame with a timezone-aware datetime column would incorrectly raise `ValueError` (GH26825)
• Bug in `pivot_table()` when pivoting a timezone aware column as the values would remove timezone information (GH14948)
• Bug in `merge_asof()` when specifying multiple by columns where one is `datetime64[ns, tz]` dtype (GH26649)

Sparse

• Significant speedup in `SparseArray` initialization that benefits most operations, fixing performance regression introduced in v0.20.0 (GH24985)
• Bug in `SparseFrame` constructor where passing `None` as the data would cause `default_fill_value` to be ignored (GH16807)
• Bug in `SparseDataFrame` when adding a column in which the length of values does not match length of index, `AssertionError` is raised instead of raising `ValueError` (GH25484)
• Introduce a better error message in `Series.sparse.from_coo()` so it returns a `TypeError` for inputs that are not `coo` matrices (GH26554)
• Bug in `numpy.modf()` on a `SparseArray`. Now a tuple of `SparseArray` is returned (GH26946).

Build changes

• Fix install error with PyPy on macOS (GH26536)

ExtensionArray

• Bug in `factorize()` when passing an `ExtensionArray` with a custom `na_sentinel` (GH25696).
• `Series.count()` miscounts NA values in ExtensionArrays (GH26835)
• Added `Series.__array_ufunc__` to better handle NumPy ufuncs applied to Series backed by extension arrays (GH23293).
• Keyword argument `deep` has been removed from `ExtensionArray.copy()` (GH27083)

Other

• Removed unused C functions from vendored UltraJSON implementation (GH26198)
• Allow `Index` and `RangeIndex` to be passed to `numpy min` and `max` functions (GH26125)
• Use actual class name in repr of empty objects of a `Series` subclass (GH27001).
• Bug in `DataFrame` where passing an object array of timezone-aware `datetime` objects would incorrectly raise `ValueError` (GH13287)

5.4 Version 0.24

5.4.1 What’s new in 0.24.2 (March 12, 2019)

**Warning:** The 0.24.x series of releases will be the last to support Python 2. Future feature releases will support Python 3 only. See [Dropping Python 2.7](#) for more.

These are the changes in pandas 0.24.2. See [Release notes](#) for a full changelog including other versions of pandas.

**Fixed regressions**

- Fixed regression in `DataFrame.all()` and `DataFrame.any()` where `bool_only=True` was ignored (GH25101)
- Fixed issue in `DataFrame` construction with passing a mixed list of mixed types could segfault. (GH25075)
- Fixed regression in `DataFrame.apply()` causing `RecursionError` when dict-like classes were passed as argument. (GH25196)
- Fixed regression in `DataFrame.replace()` where `regex=True` was only replacing patterns matching the start of the string (GH25259)
- Fixed regression in `DataFrame.duplicated()`, where empty dataframe was not returning a boolean dtyped Series. (GH25184)
• Fixed regression in `Series.min()` and `Series.max()` where numeric_only=True was ignored when the Series contained Categorical data (GH25299)
• Fixed regression in subtraction between `Series` objects with datetime64[ns] dtype incorrectly raising OverflowError when the Series on the right contains null values (GH25317)
• Fixed regression in `TimedeltaIndex` where np.sum(index) incorrectly returned a zero-dimensional object instead of a scalar (GH25282)
• Fixed regression in `IntervalDtype` construction where passing an incorrect string with ‘Interval’ as a prefix could result in a RecursionError. (GH25338)
• Fixed regression in creating a period-dtype array from a read-only NumPy array of period objects. (GH25403)
• Fixed regression in `Categorical`, where constructing it from a categorical Series and an explicit categories= that differed from that in the Series created an invalid object which could trigger segfaults. (GH25318)
• Fixed regression in `to_timedelta()` losing precision when converting floating data to Timedelta data (GH25077).
• Fixed pip installing from source into an environment without NumPy (GH25193)
• Fixed regression in `DataFrame.replace()` where large strings of numbers would be coerced into int64, causing an OverflowError (GH25616)
• Fixed regression in `factorize()` when passing a custom na_sentinel value with sort=True (GH25409).
• Fixed regression in `DataFrame.to_csv()` writing duplicate line endings with gzip compress (GH25311)

### Bug fixes

#### I/O

• Better handling of terminal printing when the terminal dimensions are not known (GH25080)
• Bug in reading a HDF5 table-format `DataFrame` created in Python 2, in Python 3 (GH24925)
• Bug in reading a JSON with orient='table' generated by `DataFrame.to_json()` with index=False (GH25170)
• Bug where float indexes could have misaligned values when printing (GH25061)

#### Categorical

• Bug where calling `Series.replace()` on categorical data could return a Series with incorrect dimensions (GH24971)
  ...
  ...

#### Reshaping

• Bug in `transform()` where applying a function to a timezone aware column would return a timezone naive result (GH24198)
• Bug in `DataFrame.join()` when joining on a timezone aware `DatetimeIndex` (GH23931)

#### Visualization

• Bug in `Series.plot()` where a secondary y axis could not be set to log scale (GH25545)

#### Other

...
• Bug in `Series.is_unique()` where single occurrences of NaN were not considered unique (GH25180)
• Bug in `merge()` when merging an empty `DataFrame` with an `Int64` column or a non-empty `DataFrame` with an `Int64` column that is all NaN (GH25183)
• Bug in `IntervalTree` where a `RecursionError` occurs upon construction due to an overflow when adding endpoints, which also causes `IntervalIndex` to crash during indexing operations (GH25485)
• Bug in `Series.size` raising for some extension-array-backed `Series`, rather than returning the size (GH25580)
• Bug in resampling raising for nullable integer-dtype columns (GH25580)

These are the changes in pandas 0.24.1. See Release notes for a full changelog including other versions of pandas. See What's new in 0.24.0 (January 25, 2019) for the 0.24.0 changelog.

## API changes

### Changing the sort parameter for Index set operations

The default sort value for `Index.union()` has changed from True to None (GH24959). The default behavior, however, remains the same: the result is sorted, unless

1. self and other are identical
2. self or other is empty
3. self or other contain values that can not be compared (a RuntimeWarning is raised).

This change will allow sort=True to mean “always sort” in a future release.

The same change applies to `Index.difference()` and `Index.symmetric_difference()`, which would not sort the result when the values could not be compared.

The `sort` option for `Index.intersection()` has changed in three ways.

1. The default has changed from True to False, to restore the pandas 0.23.4 and earlier behavior of not sorting by default.
2. The behavior of sort=True can now be obtained with sort=None. This will sort the result only if the values in self and other are not identical.
3. The value sort=True is no longer allowed. A future version of pandas will properly support sort=True meaning “always sort”.

### Fixed regressions

- Fixed regression in `DataFrame.to_dict()` with records orient raising an AttributeError when the DataFrame contained more than 255 columns, or wrongly converting column names that were not valid python identifiers (GH24939, GH24940).
- Fixed regression in `read_sql()` when passing certain queries with MySQL/pymysql (GH24988).
- Fixed regression in `Index.intersection` incorrectly sorting the values by default (GH24959).
- Fixed regression in `merge()` when merging an empty DataFrame with multiple timezone-aware columns on one of the timezone-aware columns (GH25014).
- Fixed regression in `Series.rename_axis()` and `DataFrame.rename_axis()` where passing None failed to remove the axis name (GH25034).
- Fixed regression in `to_timedelta()` with box=False incorrectly returning a datetime64 object instead of a timedelta64 object (GH24961)
• Fixed regression where custom hashable types could not be used as column keys in `DataFrame.set_index()` (GH24969)

**Bug fixes**

**Reshaping**

• Bug in `DataFrame.groupby()` with `Grouper` when there is a time change (DST) and grouping frequency is '1d' (GH24972)

**Visualization**

• Fixed the warning for implicitly registered matplotlib converters not showing. See Restore Matplotlib datetime converter registration for more (GH24963).

**Other**

• Fixed AttributeError when printing a DataFrame’s HTML repr after accessing the IPython config object (GH25036)

5.4.3 What’s new in 0.24.0 (January 25, 2019)

**Warning:** The 0.24.x series of releases will be the last to support Python 2. Future feature releases will support Python 3 only. See Dropping Python 2.7 for more details.

This is a major release from 0.23.4 and includes a number of API changes, new features, enhancements, and performance improvements along with a large number of bug fixes.

Highlights include:

• *Optional Integer NA Support*
• *New APIs for accessing the array backing a Series or Index*
• *A new top-level method for creating arrays*
• *Store Interval and Period data in a Series or DataFrame*
• *Support for joining on two MultiIndexes*
Check the **API Changes** and **deprecations** before updating.

These are the changes in pandas 0.24.0. See **Release notes** for a full changelog including other versions of pandas.

### Enhancements

#### Optional integer NA support

Pandas has gained the ability to hold integer dtypes with missing values. This long requested feature is enabled through the use of **extension types**.

**Note:** IntegerArray is currently experimental. Its API or implementation may change without warning.

We can construct a **Series** with the specified dtype. The dtype string **Int64** is a pandas **ExtensionDtype**. Specifying a list or array using the traditional missing value marker of **np.nan** will infer to integer dtype. The display of the **Series** will also use the **NaN** to indicate missing values in string outputs.  (GH20700, GH20747, GH22441, GH21789, GH22346)

```python
In [1]: s = pd.Series([1, 2, np.nan], dtype='Int64')
In [2]: s
Out[2]:
0    1
1    2
2   <NA>
Length: 3, dtype: Int64
```

Operations on these dtypes will propagate **NaN** as other pandas operations.

```python
# arithmetic
In [3]: s + 1
Out[3]:
0    2
1    3
2   <NA>
Length: 3, dtype: Int64

# comparison
In [4]: s == 1
Out[4]:
0   True
1  False
2   <NA>
Length: 3, dtype: boolean

# indexing
In [5]: s.iloc[1:3]
Out[5]:
1    2
2   <NA>
Length: 2, dtype: Int64

# operate with other dtypes
In [6]: s + s.iloc[1:3].astype('Int8')
Out[6]:
```

(continues on next page)
0  <NA>  
1   4  
2  <NA>  
Length: 3, dtype: Int64
# coerce when needed
In [7]: s + 0.01  
Out[7]:  
0   1.01  
1   2.01  
2  NaN  
Length: 3, dtype: float64

These dtypes can operate as part of a DataFrame.

In [8]: df = pd.DataFrame({'A': s, 'B': [1, 1, 3], 'C': list('aab')})  
In [9]: df  
Out[9]:  
   A  B  C  
0  1  1  a  
1  2  1  a  
2 <NA> 3  b  
[3 rows x 3 columns]  
In [10]: df.dtypes  
Out[10]:  
       A   Int64  
       B   int64  
       C   object  
Length: 3, dtype: object

These dtypes can be merged, reshaped, and casted.

In [11]: pd.concat([df[['A']], df[['B', 'C']]], axis=1).dtypes  
Out[11]:  
       A   Int64  
       B   int64  
       C   object  
Length: 3, dtype: object  
In [12]: df['A'].astype(float)  
Out[12]:  
0  1.0  
1  2.0  
2  NaN  
Name: A, Length: 3, dtype: float64

Reduction and groupby operations such as sum work.

In [13]: df.sum()  
Out[13]:  
       A   3  
       B   5  
       C  aab  
Length: 3, dtype: object  
(continues on next page)
In [14]: df.groupby('B').A.sum()
Out[14]:
B
1 3
3 0
Name: A, Length: 2, dtype: Int64

**Warning:** The Integer NA support currently uses the capitalized dtype version, e.g. `Int8` as compared to the traditional `int8`. This may be changed at a future date.

See [Nullable integer data type](#) for more.

### Accessing the values in a Series or Index

`Series.array` and `Index.array` have been added for extracting the array backing a `Series` or `Index`. (GH19954, GH23623)

In [15]: idx = pd.period_range('2000', periods=4)
In [16]: idx.array
Out[16]:
<PeriodArray>
Length: 4, dtype: period[D]
In [17]: pd.Series(idx).array
Out[17]:
<PeriodArray>
Length: 4, dtype: period[D]

Historically, this would have been done with `series.values`, but with `.values` it was unclear whether the returned value would be the actual array, some transformation of it, or one of pandas custom arrays (like `Categorical`). For example, with `PeriodIndex`, `.values` generates a new ndarray of period objects each time.

In [18]: idx.values
Out[18]:
array([Period('2000-01-01', 'D'), Period('2000-01-02', 'D'),
       Period('2000-01-03', 'D'), Period('2000-01-04', 'D')], dtype=object)
In [19]: id(idx.values)
Out[19]: 140610594519520
In [20]: id(idx.values)
Out[20]: 140610658538880

If you need an actual NumPy array, use `Series.to_numpy()` or `Index.to_numpy()`.

In [21]: idx.to_numpy()
For Series and Indexes backed by normal NumPy arrays, `Series.array` will return a new array. `PandasArray`, which is a thin (no-copy) wrapper around a `numpy.ndarray`. `PandasArray` isn’t especially useful on its own, but it does provide the same interface as any extension array defined in pandas or by a third-party library.

```
In [23]: ser = pd.Series([1, 2, 3])
In [24]: ser.array
Out[24]:
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
In [25]: ser.to_numpy()
Out[25]:
array([1, 2, 3])
```

We haven’t removed or deprecated `Series.values` or `DataFrame.values`, but we highly recommend and using `.array` or `.to_numpy()` instead.

See `Dtypes` and `Attributes and Underlying Data` for more.

**pandas.array: a new top-level method for creating arrays**

A new top-level method `array()` has been added for creating 1-dimensional arrays (GH22860). This can be used to create any extension array, including extension arrays registered by 3rd party libraries. See the `dtypes docs` for more on extension arrays.

```
In [26]: pd.array([1, 2, np.nan], dtype='Int64')
Out[26]:
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64
In [27]: pd.array(['a', 'b', 'c'], dtype='category')
Out[27]:
['a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Passing data for which there isn’t dedicated extension type (e.g. float, integer, etc.) will return a new array. `PandasArray`, which is just a thin (no-copy) wrapper around a `numpy.ndarray` that satisfies the pandas extension array interface.

```
In [28]: pd.array([1, 2, 3])
Out[28]:
<IntegerArray>
[1, 2, 3]
Length: 3, dtype: Int64
```
On their own, a PandasArray isn’t a very useful object. But if you need write low-level code that works generically for any ExtensionArray, PandasArray satisfies that need.

Notice that by default, if no dtype is specified, the dtype of the returned array is inferred from the data. In particular, note that the first example of [1, 2, np.nan] would have returned a floating-point array, since NaN is a float.

```py
In [29]: pd.array([1, 2, np.nan])
Out[29]:
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64
```

### Storing Interval and Period data in Series and DataFrame

Interval and Period data may now be stored in a Series or DataFrame, in addition to an IntervalIndex and PeriodIndex like previously (GH19453, GH22862).

```py
In [30]: ser = pd.Series(pd.interval_range(0, 5))
In [31]: ser
Out[31]:
0 (0, 1]
1 (1, 2]
2 (2, 3]
3 (3, 4]
4 (4, 5]
Length: 5, dtype: interval

In [32]: ser.dtype
Out[32]: interval[int64]
```

For periods:

```py
In [33]: pser = pd.Series(pd.period_range("2000", freq="D", periods=5))
In [34]: pser
Out[34]:
0 2000-01-01
1 2000-01-02
2 2000-01-03
3 2000-01-04
4 2000-01-05
Length: 5, dtype: period[D]

In [35]: pser.dtype
Out[35]: period[D]
```

Previously, these would be cast to a NumPy array with object dtype. In general, this should result in better performance when storing an array of intervals or periods in a Series or column of a DataFrame.

Use Series.array to extract the underlying array of intervals or periods from the Series:

```py
In [36]: ser.array
Out[36]:
<IntervalArray>
[(0, 1], [1, 2], [2, 3], [3, 4], [4, 5]]
```

(continues on next page)
These return an instance of `arrays.IntervalArray` or `arrays.PeriodArray`, the new extension arrays that back interval and period data.

**Warning:** For backwards compatibility, `Series.values` continues to return a NumPy array of objects for Interval and Period data. We recommend using `Series.array` when you need the array of data stored in the `Series`, and `Series.to_numpy()` when you know you need a NumPy array.

See [Dtypes](#) and [Attributes and Underlying Data](#) for more.

### Joining with two multi-indexes

`DataFrame.merge()` and `DataFrame.join()` can now be used to join multi-indexed `DataFrame` instances on the overlapping index levels (GH6360)

See the [Merge, join, and concatenate](#) documentation section.

```python
In [38]: index_left = pd.MultiIndex.from_tuples([ ('K0', 'X0'), ('K0', 'X1'), ('K1', 'X2') ], names=['key', 'X'])

In [39]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'], 
                       'B': ['B0', 'B1', 'B2']}, index=index_left)

In [40]: index_right = pd.MultiIndex.from_tuples([ ('K0', 'Y0'), ('K1', 'Y1'), ('K2', 'Y2'), ('K2', 'Y3') ], names=['key', 'Y'])

In [41]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'], 
                        'D': ['D0', 'D1', 'D2', 'D3']}, index=index_right)

In [42]: left.join(right)
Out[42]:
   A  B  C  D
key X  Y
K0  X0 Y0 A0 B0 C0 D0
    X1 Y0 A1 B1 C0 D0
K1  X2 Y1 A2 B2 C1 D1
```

For earlier versions this can be done using the following.
In [43]: 

```python
pd.merge(left.reset_index(), right.reset_index(),
    ....:     on=['key'], how='inner').set_index(['key', 'X', 'Y'])
```

Out[43]:
```
    A   B   C   D
key X  Y
K0 A0 B0 C0 D0
  X1 A1 B1 C0 D0
K1 X2 Y1 A2 B2 C1 D1
```

[3 rows x 4 columns]

---

**read_html Enhancements**

`read_html()` previously ignored `colspan` and `rowspan` attributes. Now it understands them, treating them as sequences of cells with the same value. (GH17054)

In [44]: 

```python
result = pd.read_html('""
    ....:     <table>
    ....:     <thead>
    ....:     <tr>
    ....:         <th>A</th><th>B</th><th>C</th>
    ....:     </tr>
    ....:     </thead>
    ....:     <tbody>
    ....:         <tr>
    ....:             <td colspan="2">1</td><td>2</td>
    ....:         </tr>
    ....:     </tbody>
    ....:     <table>"
```

---

**Previous behavior:**

In [13]: result
Out [13]:
```
[ A B C
  0 1 2 NaN]
```

**New behavior:**

In [45]: result
Out[45]:
```
[ A B C
  0 1 1 2
  [1 rows x 3 columns]]
```
New Styler.pipe() method

The Styler class has gained a pipe() method. This provides a convenient way to apply users' predefined styling functions, and can help reduce "boilerplate" when using DataFrame styling functionality repeatedly within a notebook. (GH23229)

```python
In [46]: df = pd.DataFrame({'N': [1250, 1500, 1750], 'X': [0.25, 0.35, 0.50]})
In [47]: def format_and_align(styler):
   ....:     return (styler.format({'N': '{:,}', 'X': '{:.1%}'})
   ....:         .set_properties(**{'text-align': 'right'})
   ....:
In [48]: df.style.pipe(format_and_align).set_caption('Summary of results.')
Out[48]: <pandas.io.formats.style.Styler at 0x7fe1fd440280>
```

Similar methods already exist for other classes in pandas, including DataFrame.pipe(), GroupBy.pipe(), and Resampler.pipe().

Renaming names in a MultiIndex

DataFrame.rename_axis() now supports index and columns arguments and Series.rename_axis() supports index argument (GH19978). This change allows a dictionary to be passed so that some of the names of a MultiIndex can be changed.

Example:

```python
In [49]: mi = pd.MultiIndex.from_product([list('AB'), list('CD'), list('EF')], names=['AB', 'CD', 'EF'])
In [50]: df = pd.DataFrame(list(range(len(mi))), index=mi, columns=['N'])
In [51]: df
Out[51]:
      N
AB CD EF
A  C  E  0
     F  1
     D  2
     F  3
B  C  E  4
     F  5
     D  6
     F  7
[8 rows x 1 columns]
In [52]: df.rename_axis(index={'CD': 'New'})
Out[52]:
     N
AB New EF
A  C  E  0
     F  1
     D  2
```

(continues on next page)
F 3
B C E 4
F 5
D E 6
F 7
[8 rows x 1 columns]

See the Advanced documentation on renaming for more details.

Other enhancements

- `merge()` now directly allows merge between objects of type DataFrame and named Series, without the need to convert the Series object into a DataFrame beforehand (GH21220)
- ExcelWriter now accepts mode as a keyword argument, enabling append to existing workbooks when using the openpyxl engine (GH3441)
- FrozenList has gained the .union() and .difference() methods. This functionality greatly simplifies groupby's that rely on explicitly excluding certain columns. See Splitting an object into groups for more information (GH15475, GH15506).
- `DataFrame.to_parquet()` now accepts index as an argument, allowing the user to override the engine’s default behavior to include or omit the dataframe’s indexes from the resulting Parquet file. (GH20768)
- `read_feather()` now accepts columns as an argument, allowing the user to specify which columns should be read. (GH24025)
- `DataFrame.corr()` and `Series.corr()` now accept a callable for generic calculation methods of correlation, e.g. histogram intersection (GH22684)
- `DataFrame.to_string()` now accepts decimal as an argument, allowing the user to specify which decimal separator should be used in the output. (GH23614)
- `DataFrame.to_html()` now accepts render_links as an argument, allowing the user to generate HTML with links to any URLs that appear in the DataFrame. See the section on writing HTML in the IO docs for example usage. (GH2679)
- `pandas.read_csv()` now supports pandas extension types as an argument to dtype, allowing the user to use pandas extension types when reading CSVs. (GH23228)
- The `shift()` method now accepts fill_value as an argument, allowing the user to specify a value which will be used instead of NA/NaT in the empty periods. (GH15486)
- `to_datetime()` now supports the %Z and %z directive when passed into format (GH13486)
- `Series.mode()` and `DataFrame.mode()` now support the dropna parameter which can be used to specify whether NaN/NaT values should be considered (GH17534)
- `DataFrame.to_csv()` and `Series.to_csv()` now support the compression keyword when a file handle is passed. (GH21227)
- `Index.droplevel()` is now implemented also for flat indexes, for compatibility with MultiIndex (GH21115)
- `Series.droplevel()` and `DataFrame.droplevel()` are now implemented (GH20342)
- Added support for reading from/writing to Google Cloud Storage via the gcsfs library (GH19454, GH23094)
• **DataFrame.to_gbq()** and **read_gbq()** signature and documentation updated to reflect changes from the Pandas-GBQ library version 0.8.0. Adds a credentials argument, which enables the use of any kind of google-auth credentials. (GH21627, GH22557, GH23662)

• New method **HDFStore.walk()** will recursively walk the group hierarchy of an HDF5 file (GH10932)

• **read_html()** copies cell data across colspan and rowspan, and it treats all-th table rows as headers if header kwarg is not given and there is no thead (GH17054)

• **Series.nlargest()**, **Series.nsmallest()**, **DataFrame.nlargest()**, and **DataFrame.nsmallest()** now accept the value "all" for the keep argument. This keeps all ties for the nth largest/smallest value (GH16818)

• **IntervalIndex** has gained the **set_closed()** method to change the existing closed value (GH21670)

• **to_csv(), to_csv(), to_json(), and to_json()** now support compression='infer' to infer compression based on filename extension (GH15008). The default compression for to_csv, to_json, and to_pickle methods has been updated to 'infer' (GH22004).

• **DataFrame.to_sql()** now supports writing **TIMESTAMP WITH TIME ZONE** types for supported databases. For databases that don’t support timezones, datetime data will be stored as timezone unaware local timestamps. See the **Datetime data types** for implications (GH9086).

• **to_timedelta()** now supports iso-formatted timedelta strings (GH21877)

• **Series** and **DataFrame** now support **Iterable** objects in the constructor (GH2193)

• **DatetimeIndex** has gained the **DatetimeIndex.timetz** attribute. This returns the local time with timezone information. (GH21358)

• **round()**, **ceil()**, and **floor()** for **DatetimeIndex** and **Timestamp** now support an ambiguous argument for handling datetimes that are rounded to ambiguous times (GH18946) and a nonexistent argument for handling datetimes that are rounded to nonexistent times. See **Nonexistent times when localizing** (GH22647)

• The result of **resample()** is now iterable similar to **groupby()** (GH15314).

• **Series.resample()** and **DataFrame.resample()** have gained the **pandas.core.resample.Resampler.quantile()** (GH15023).

• **DataFrame.resample()** and **Series.resample()** with a **PeriodIndex** will now respect the base argument in the same fashion as with a **DatetimeIndex**. (GH23882)

• **pandas.api.types.is_list_like()** has gained a keyword **allow_sets** which is **True** by default; if **False**, all instances of **set** will not be considered “list-like” anymore (GH23061)

• **Index.to_frame()** now supports overriding column name(s) (GH22580).

• **Categorical.from_codes()** now can take a **dtype** parameter as an alternative to passing categories and ordered (GH24398).

• New attribute **__git_version__** will return git commit sha of current build (GH21295).

• Compatibility with Matplotlib 3.0 (GH22790).

• Added **Interval.overlaps(), arrays.IntervalArray.overlaps(), and IntervalIndex.overlaps()** for determining overlaps between interval-like objects (GH21998)

• **read_fwf()** now accepts keyword **infer_nrows** (GH15138).

• **to_parquet()** now supports writing a **DataFrame** as a directory of parquet files partitioned by a subset of the columns when engine = 'pyarrow' (GH23283)
pandas: powerful Python data analysis toolkit, Release 1.1.1

- `Timestamp.tz_localize()`, `DatetimeIndex.tz_localize()`, and `Series.tz_localize()` have gained the nonexistent argument for alternative handling of nonexistent times. See *Nonexistent times when localizing* (GH8917, GH24466)

- `Index.difference()`, `Index.intersection()`, `Index.union()`, and `Index.symmetric_difference()` now have an optional `sort` parameter to control whether the results should be sorted if possible (GH17839, GH24471)

- `read_excel()` now accepts `usecols` as a list of column names or callable (GH18273)

- `MultiIndex.to_flat_index()` has been added to flatten multiple levels into a single-level `Index` object.

- `DataFrame.to_stata()` and `pandas.io.stata.StataWriter117` can write mixed string columns to Stata strel format (GH23633)

- `DataFrame.between_time()` and `DataFrame.at_time()` have gained the `axis` parameter (GH8839)

- `DataFrame.to_records()` now accepts `index_dtypes` and `column_dtypes` parameters to allow different data types in stored column and index records (GH18146)

- `IntervalIndex` has gained the `is_overlapping` attribute to indicate if the `IntervalIndex` contains any overlapping intervals (GH23309)

- `pandas.DataFrame.to_sql()` has gained the `method` argument to control SQL insertion clause. See the *insertion method* section in the documentation. (GH8953)

- `DataFrame.corrwith()` now supports Spearman’s rank correlation, Kendall’s tau as well as callable correlation methods. (GH21925)

- `DataFrame.to_json()`, `DataFrame.to_csv()`, `DataFrame.to_pickle()`, and other export methods now support tilde(–) in path argument. (GH23473)

**Backwards incompatible API changes**

Pandas 0.24.0 includes a number of API breaking changes.

**Increased minimum versions for dependencies**

We have updated our minimum supported versions of dependencies (GH21242, GH18742, GH23774, GH24767). If installed, we now require:

<table>
<thead>
<tr>
<th>Package</th>
<th>Minimum Version</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>numpy</td>
<td>1.12.0</td>
<td>X</td>
</tr>
<tr>
<td>bottleneck</td>
<td>1.2.0</td>
<td></td>
</tr>
<tr>
<td>fastparquet</td>
<td>0.2.1</td>
<td></td>
</tr>
<tr>
<td>matplotlib</td>
<td>2.0.0</td>
<td></td>
</tr>
<tr>
<td>numexpr</td>
<td>2.6.1</td>
<td></td>
</tr>
<tr>
<td>pandas-gbq</td>
<td>0.8.0</td>
<td></td>
</tr>
<tr>
<td>pyarrow</td>
<td>0.9.0</td>
<td></td>
</tr>
<tr>
<td>pytables</td>
<td>3.4.2</td>
<td></td>
</tr>
<tr>
<td>scipy</td>
<td>0.18.1</td>
<td></td>
</tr>
<tr>
<td>xlrd</td>
<td>1.0.0</td>
<td></td>
</tr>
<tr>
<td>pytest (dev)</td>
<td>3.6</td>
<td></td>
</tr>
</tbody>
</table>
Additionally we no longer depend on feather-format for feather based storage and replaced it with references to pyarrow (GH21639 and GH23053).

**os.linesep is used for line_terminator of DataFrame.to_csv**

`DataFrame.to_csv()` now uses `os.linesep()` rather than '
' for the default line terminator (GH20353). This change only affects when running on Windows, where '
' was used for line terminator even when '
' was passed in `line_terminator`.

**Previous behavior** on Windows:

```
In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
                  ...:                  "string_with_crlf": ["a\r\nbc"]})
In [2]: # When passing file PATH to to_csv,
      ...: # line_terminator does not work, and csv is saved with '
'.
      ...: # Also, this converts all '
's in the data to '
'.
      ...: data.to_csv("test.csv", index=False, line_terminator='\n')
In [3]: with open("test.csv", mode='rb') as f:
      ...:     print(f.read())
Out[3]: b'string_with_lf,string_with_crlf\n"a\rbc","a\r\nbc"

In [4]: # When passing file OBJECT with newline option to
      ...: # to_csv, line_terminator works.
      ...: with open("test2.csv", mode='w', newline='\n') as f:
      ...:     data.to_csv(f, index=False, line_terminator='\n')
In [5]: with open("test2.csv", mode='rb') as f:
      ...:     print(f.read())
Out[5]: b'string_with_lf,string_with_crlf\n"a\nbc","a\r\nbc"
```

**New behavior** on Windows:

Passing `line_terminator` explicitly, set the line terminator to that character.

```
In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
                  ...:                  "string_with_crlf": ["a\r\nbc"]})
In [2]: data.to_csv("test.csv", index=False, line_terminator='\n')
In [3]: with open("test.csv", mode='rb') as f:
      ...:     print(f.read())
Out[3]: b'string_with_lf,string_with_crlf\n"a\nbc","a\r\nbc"

In [4]: data.to_csv("test.csv", index=False)
In [5]: with open("test2.csv", mode='rb') as f:
      ...:     print(f.read())
Out[5]: b'string_with_lf,string_with_crlf\n"a\nbc","a\r\nbc"
```

On Windows, the value of `os.linesep` is '
', so if `line_terminator` is not set, '
' is used for line terminator.
For file objects, specifying \texttt{newline} is not sufficient to set the line terminator. You must pass in the \texttt{line_terminator} explicitly, even in this case.

\begin{Verbatim}
In [1]: data = pd.DataFrame({"string_with_lf": ["a\nbc"],
...:   "string_with_crlf": ["a\r\nbc"]})

In [2]: with open("test2.csv", mode='w', newline='
') as f:
...:   data.to_csv(f, index=False)

In [3]: with open("test2.csv", mode='rb') as f:
...:   print(f.read())

Out[3]: b'string_with_lf,string_with_crlf\n"a\nbc","a\r\nbc"'
\end{Verbatim}

### Proper handling of \texttt{np.NaN} in a string data-typed column with the Python engine

There was bug in \texttt{read_excel()} and \texttt{read_csv()} with the Python engine, where missing values turned to 'nan' with \texttt{dtype=str} and \texttt{na_filter=True}. Now, these missing values are converted to the string missing indicator, \texttt{np.nan} (GH20377)

\textit{Previous behavior:}

\begin{Verbatim}
In [5]: data = 'a,b,c\n1,3
4,5,6'
In [6]: df = pd.read_csv(StringIO(data), engine='python', dtype=str, na_filter=True)
In [7]: df.loc[0, 'b']
Out[7]: 'nan'
\end{Verbatim}

\textit{New behavior:}

\begin{Verbatim}
In [53]: data = 'a,b,c\n1,3\n4,5,6'
In [54]: df = pd.read_csv(StringIO(data), engine='python', dtype=str, na_filter=True)
In [55]: df.loc[0, 'b']
Out[55]: nan
\end{Verbatim}

Notice how we now instead output \texttt{np.nan} itself instead of a stringified form of it.

### Parsing datetime strings with timezone offsets

Previously, parsing datetime strings with UTC offsets with \texttt{to_datetime()} or \texttt{DatetimeIndex} would automatically convert the datetime to UTC without timezone localization. This is inconsistent from parsing the same datetime string with \texttt{Timestamp} which would preserve the UTC offset in the \texttt{tz} attribute. Now, \texttt{to_datetime()} preserves the UTC offset in the \texttt{tz} attribute when all the datetime strings have the same UTC offset (GH17697, GH11736, GH22457)

\textit{Previous behavior:}

\begin{Verbatim}
In [2]: pd.to_datetime("2015-11-18 15:30:00+05:30")
Out[2]: Timestamp('2015-11-18 10:00:00')

In [3]: pd.Timestamp("2015-11-18 15:30:00+05:30")
Out[3]: Timestamp('2015-11-18 15:30:00+0530', tz='pytz.FixedOffset(330)')

# Different UTC offsets would automatically convert the datetimes to UTC (without a
UTC timezone)
\end{Verbatim}
In [4]: `pd.to_datetime(["2015-11-18 15:30:00+05:30", "2015-11-18 16:30:00+06:30"])`
Out[4]: DatetimeIndex(['2015-11-18 10:00:00', '2015-11-18 10:00:00'], dtype='datetime64[ns]', freq=None)

**New behavior:**

In [56]: `pd.to_datetime("2015-11-18 15:30:00+05:30")`
Out[56]: Timestamp('2015-11-18 15:30:00+0530', tz='pytz.FixedOffset(330)')

In [57]: `pd.Timestamp("2015-11-18 15:30:00+05:30")`
Out[57]: Timestamp('2015-11-18 15:30:00+0530', tz='pytz.FixedOffset(330)')

Parsing datetime strings with the same UTC offset will preserve the UTC offset in the tz

In [58]: `pd.to_datetime(["2015-11-18 15:30:00+05:30", ...
                          "2015-11-18 16:30:00+06:30"] * 2)`
Out[58]: DatetimeIndex(['2015-11-18 15:30:00+05:30', '2015-11-18 15:30:00+05:30'], dtype='datetime64[ns, pytz.FixedOffset(330)]', freq=None)

Parsing datetime strings with different UTC offsets will now create an Index of datetime.datetime objects with different UTC offsets

In [59]: `idx = pd.to_datetime(["2015-11-18 15:30:00+05:30", ...
                          "2015-11-18 16:30:00+06:30"])`
In [60]: `idx`
Out[60]: Index([2015-11-18 15:30:00+05:30, 2015-11-18 16:30:00+06:30], dtype='object')

In [61]: `idx[0]`
Out[61]: datetime.datetime(2015, 11, 18, 15, 30, tzinfo=tzoffset(None, 19800))

In [62]: `idx[1]`
Out[62]: datetime.datetime(2015, 11, 18, 16, 30, tzinfo=tzoffset(None, 23400))

Passing utc=True will mimic the previous behavior but will correctly indicate that the dates have been converted to UTC

In [63]: `pd.to_datetime(["2015-11-18 15:30:00+05:30", ...
                          "2015-11-18 16:30:00+06:30"], utc=True)`
Out[63]: DatetimeIndex(['2015-11-18 10:00:00+00:00', '2015-11-18 10:00:00+00:00'], dtype='datetime64[ns, UTC]', freq=None)

Parsing mixed-timezones with `read_csv()`

`read_csv()` no longer silently converts mixed-timezone columns to UTC (GH24987).

Previous behavior

```python
>>> import io
>>> content = """\n... a
... 2000-01-01T00:00:00+05:00
... 2000-01-01T00:00:00+06:00"
"""
>>> df = pd.read_csv(io.StringIO(content), parse_dates=['a'])
```

(continues on next page)
New behavior

```python
In [64]: import io
In [65]: content = ""
    ....: a
    ....: 2000-01-01T00:00:00+05:00
    ....: 2000-01-01T00:00:00+06:00"
    ....:
In [66]: df = pd.read_csv(io.StringIO(content), parse_dates=['a'])
In [67]: df.a
Out[67]:
0  2000-01-01 00:00:00+05:00
1  2000-01-01 00:00:00+06:00
Name: a, Length: 2, dtype: object
```

As can be seen, the `dtype` is object; each value in the column is a string. To convert the strings to an array of datetimes, the `date_parser` argument

```python
In [68]: df = pd.read_csv(io.StringIO(content), parse_dates=['a'],
    ....: date_parser=lambda col: pd.to_datetime(col, utc=True))
In [69]: df.a
Out[69]:
0  1999-12-31 19:00:00+00:00
1  1999-12-31 18:00:00+00:00
Name: a, Length: 2, dtype: datetime64[ns, UTC]
```

See Parsing datetime strings with timezone offsets for more.

### Time values in `pd.Series.dt.end_time` and `Period.to_timestamp()`

The time values in `Period` and `PeriodIndex` objects are now set to ‘23:59:59.999999999’ when calling `Series.dt.end_time`, `Period.end_time`, `PeriodIndex.end_time`, `Period.to_timestamp()` with `how='end'`, or `PeriodIndex.to_timestamp()` with `how='end'` (GH17157)

**Previous behavior:**

```python
In [2]: p = pd.Period('2017-01-01', 'D')
In [3]: pi = pd.PeriodIndex([p])
In [4]: pd.Series(pi).dt.end_time[0]
Out[4]: Timestamp(2017-01-01 00:00:00)
In [5]: p.end_time
```

**New behavior:**
Calling `Series.dt.end_time` will now result in a time of ‘23:59:59.999999999’ as is the case with `Period.end_time`, for example

```python
In [70]: p = pd.Period('2017-01-01', 'D)
In [71]: pi = pd.PeriodIndex([p])
Out[72]: Timestamp('2017-01-01 23:59:59.999999999')
In [73]: p.end_time
Out[73]: Timestamp('2017-01-01 23:59:59.999999999')
```

**Series.unique for timezone-aware data**

The return type of `Series.unique()` for datetime with timezone values has changed from an `numpy.ndarray` of `Timestamp` objects to a `arrays.DatetimeArray` (GH24024).

```python
In [74]: ser = pd.Series([pd.Timestamp('2000', tz='UTC'),
....:     pd.Timestamp('2000', tz='UTC'))
....:     pd.Timestamp('2000', tz='UTC'))
```

**Previous behavior:**

```python
In [3]: ser.unique()  
Out[3]: array([Timestamp('2000-01-01 00:00:00+0000', tz='UTC')], dtype=object)
```

**New behavior:**

```python
In [75]: ser.unique()  
Out[75]: <DatetimeArray>['2000-01-01 00:00:00+00:00']  
Length: 1, dtype: datetime64[ns, UTC]
```

**SparseArray data structure refactor**

SparseArray, the array backing `SparseSeries` and the columns in a `SparseDataFrame`, is now an extension array (GH21978, GH19056, GH22835). To conform to this interface and for consistency with the rest of pandas, some API breaking changes were made:

- SparseArray is no longer a subclass of `numpy.ndarray`. To convert a SparseArray to a NumPy array, use `numpy.asarray()`.
- SparseArray.dtype and SparseSeries.dtype are now instances of `SparseDtype`, rather than `np.dtype`. Access the underlying dtype with `SparseDtype.subtype`.
- `numpy.asarray(sparse_array)` now returns a dense array with all the values, not just the non-fill-value values (GH14167)
- SparseArray.take now matches the API of `pandas.api.extensions.ExtensionArray.take()` (GH19506):
  - The default value of `allow_fill` has changed from `False` to `True`.
  - The `out` and `mode` parameters are now longer accepted (previously, this raised if they were specified).
– Passing a scalar for indices is no longer allowed.

• The result of `concat()` with a mix of sparse and dense Series is a Series with sparse values, rather than a SparseSeries.

• `SparseDataFrame.combine` and `DataFrame.combine_first` no longer supports combining a sparse column with a dense column while preserving the sparse subtype. The result will be an object-dtype SparseArray.

• Setting `SparseArray.fill_value` to a fill value with a different dtype is now allowed.

• `DataFrame[column]` is now a Series with sparse values, rather than a SparseSeries, when slicing a single column with sparse values (GH23559).

• The result of `Series.where()` is now a Series with sparse values, like with other extension arrays (GH24077)

Some new warnings are issued for operations that require or are likely to materialize a large dense array:

• A `errors.PerformanceWarning` is issued when using fillna with a method, as a dense array is constructed to create the filled array. Filling with a value is the efficient way to fill a sparse array.

• A `errors.PerformanceWarning` is now issued when concatenating sparse Series with differing fill values. The fill value from the first sparse array continues to be used.

In addition to these API breaking changes, many Performance Improvements and Bug Fixes have been made.

Finally, a `Series.sparse` accessor was added to provide sparse-specific methods like `Series.sparse.from_coo()`.

```
In [76]: s = pd.Series([0, 0, 1, 1, 1], dtype='Sparse[int]')
In [77]: s.sparse.density
Out[77]: 0.6
```

get_dummies() always returns a DataFrame

Previously, when `sparse=True` was passed to `get_dummies()`, the return value could be either a `DataFrame` or a `SparseDataFrame`, depending on whether all or a just a subset of the columns were dummy-encoded. Now, a `DataFrame` is always returned (GH24284).

**Previous behavior**

The first `get_dummies()` returns a `DataFrame` because the column A is not dummy encoded. When just ["B", "C"] are passed to `get_dummies`, then all the columns are dummy-encoded, and a `SparseDataFrame` was returned.

```
In [2]: df = pd.DataFrame({'A': [1, 2], 'B': ['a', 'b'], 'C': ['a', 'a']})
In [3]: type(pd.get_dummies(df, sparse=True))
Out[3]: pandas.core.frame.DataFrame
In [4]: type(pd.get_dummies(df[ ['B', 'C']], sparse=True))
Out[4]: pandas.core.sparse.frame.SparseDataFrame
```

**New behavior**

Now, the return type is consistently a `DataFrame`. 

In [78]: type(pd.get_dummies(df, sparse=True))
Out[78]: pandas.core.frame.DataFrame

In [79]: type(pd.get_dummies(df[['B', 'C']], sparse=True))
Out[79]: pandas.core.frame.DataFrame

Note: There's no difference in memory usage between a SparseDataFrame and a DataFrame with sparse values. The memory usage will be the same as in the previous version of pandas.

**Raise ValueError in DataFrame.to_dict(orient='index')**

Bug in DataFrame.to_dict() raises ValueError when used with orient='index' and a non-unique index instead of losing data (GH22801)

In [80]: df = pd.DataFrame({'a': [1, 2], 'b': [0.5, 0.75]}, index=['A', 'A'])

In [81]: df
Out[81]:
<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>1</td>
<td>0.5</td>
</tr>
<tr>
<td>A</td>
<td>2</td>
<td>0.75</td>
</tr>
</tbody>
</table>

[2 rows x 2 columns]

In [82]: df.to_dict(orient='index')

---------------------------------------------------------------------------
ValueError Traceback (most recent call last)
<ipython-input-82-f5309a7c6adb> in <module>
----> 1 df.to_dict(orient='index')

/pandas-release/pandas/pandas/core/frame.py in to_dict(self, orient, into)
    1541    elif orient == "index":
    1542        if not self.index.is_unique:
-> 1543            raise ValueError("DataFrame index must be unique for orient=
    ""index".")
    1544            return into_c(
    1545                {t[0], dict(zip(self.columns, t[1:]))})

ValueError: DataFrame index must be unique for orient='index'.

**Tick DateOffset normalize restrictions**

Creating a Tick object (Day, Hour, Minute, Second, Milli, Micro, Nano) with normalize=True is no longer supported. This prevents unexpected behavior where addition could fail to be monotone or associative. (GH21427)

Previous behavior:

In [2]: ts = pd.Timestamp('2018-06-11 18:01:14')

In [3]: ts
Out[3]: Timestamp('2018-06-11 18:01:14')

(continues on next page)
In [4]: tic = pd.offsets.Hour(n=2, normalize=True)

...:

In [5]: tic
Out[5]: <2 * Hours>

In [6]: ts + tic
Out[6]: Timestamp('2018-06-11 00:00:00')

In [7]: ts + tic + tic + tic == ts + (tic + tic + tic)
Out[7]: False

**New behavior:**

In [83]: ts = pd.Timestamp('2018-06-11 18:01:14')

In [84]: tic = pd.offsets.Hour(n=2)

In [85]: ts + tic + tic + tic == ts + (tic + tic + tic)
Out[85]: True

**Period subtraction**

Subtraction of a Period from another Period will give a DateOffset, instead of an integer (GH21314)

**Previous behavior:**

In [2]: june = pd.Period('June 2018')

In [3]: april = pd.Period('April 2018')

In [4]: june - april
Out [4]: 2

**New behavior:**

In [86]: june = pd.Period('June 2018')

In [87]: april = pd.Period('April 2018')

In [88]: june - april
Out[88]: <2 * MonthEnds>

Similarly, subtraction of a Period from a PeriodIndex will now return an Index of DateOffset objects instead of an Int64Index

**Previous behavior:**

In [2]: pi = pd.period_range('June 2018', freq='M', periods=3)

In [3]: pi - pi[0]
Out[3]: Int64Index([0, 1, 2], dtype='int64')

**New behavior:**
In [89]: pi = pd.period_range('June 2018', freq='M', periods=3)
In [90]: pi - pi[0]
Out[90]: Index([<0 * MonthEnds>, <MonthEnd>, <2 * MonthEnds>], dtype='object')

Addition/subtraction of NaN from DataFrame

Adding or subtracting NaN from a DataFrame column with timedelta64[ns] dtype will now raise a TypeError instead of returning all-NaT. This is for compatibility with TimedeltaIndex and Series behavior (GH22163)

In [91]: df = pd.DataFrame([pd.Timedelta(days=1)])
In [92]: df
Out[92]:
0 1 days
[1 rows x 1 columns]

Previous behavior:

In [4]: df = pd.DataFrame([pd.Timedelta(days=1)])
In [5]: df - np.nan
Out[5]:
0    NaT

New behavior:

In [2]: df - np.nan
...  
TypeError: unsupported operand type(s) for -: 'TimedeltaIndex' and 'float'

DataFrame comparison operations broadcasting changes

Previously, the broadcasting behavior of DataFrame comparison operations (==, !=,...) was inconsistent with the behavior of arithmetic operations (+, −,...). The behavior of the comparison operations has been changed to match the arithmetic operations in these cases. (GH22880)

The affected cases are:

• operating against a 2-dimensional np.ndarray with either 1 row or 1 column will now broadcast the same way a np.ndarray would (GH23000).

• a list or tuple with length matching the number of rows in the DataFrame will now raise ValueError instead of operating column-by-column (GH22880).

• a list or tuple with length matching the number of columns in the DataFrame will now operate row-by-row instead of raising ValueError (GH22880).

In [93]: arr = np.arange(6).reshape(3, 2)
In [94]: df = pd.DataFrame(arr)

In [95]: df
Out[95]:
   0  1
0  0  1
1  2  3
2  4  5

[3 rows x 2 columns]

**Previous behavior:**

In [5]: df == arr[[0], :]
    ...: # comparison previously broadcast where arithmetic would raise
Out[5]:
   0  1
0  True  True
1  False False
2  False False
In [6]: df + arr[[0], :]

...  
ValueError: Unable to coerce to DataFrame, shape must be (3, 2): given (1, 2)

In [7]: df == (1, 2)
    ...: # length matches number of columns;
    ...: # comparison previously raised where arithmetic would broadcast
    ...
    
ValueError: Invalid broadcasting comparison [(1, 2)] with block values
In [8]: df + (1, 2)
Out[8]:
   0  1
0  1  3
1  3  5
2  5  7

In [9]: df == (1, 2, 3)
    ...: # length matches number of rows
    ...: # comparison previously broadcast where arithmetic would raise
Out[9]:
   0  1
0  False True
1  True False
2  False False
In [10]: df + (1, 2, 3)

...  
ValueError: Unable to coerce to Series, length must be 2: given 3

**New behavior:**

# Comparison operations and arithmetic operations both broadcast.
In [96]: df == arr[[0], :]
Out[96]:
   0  1
0  True  True
1  False False
2  False False

(continues on next page)
In [97]: df + arr[[0], :]
Out[97]:
   0 1  
0  0 2  
1  2 4  
2  4 6  

[3 rows x 2 columns]

# Comparison operations and arithmetic operations both broadcast.
In [98]: df == (1, 2)
Out[98]:
   0 1  
0 False False  
1 False False  
2 False False  

[3 rows x 2 columns]

In [99]: df + (1, 2)
Out[99]:
   0 1  
0 1 3  
1 3 5  
2 5 7  

[3 rows x 2 columns]

# Comparison operations and arithmetic operations both raise ValueError.
In [6]: df == (1, 2, 3)
...  
ValueError: Unable to coerce to Series, length must be 2: given 3

In [7]: df + (1, 2, 3)
...  
ValueError: Unable to coerce to Series, length must be 2: given 3

**DataFrame arithmetic operations broadcasting changes**

*DataFrame* arithmetic operations when operating with 2-dimensional *np.ndarray* objects now broadcast in the same way as *np.ndarray* broadcast. (GH23000)

In [100]: arr = np.arange(6).reshape(3, 2)
In [101]: df = pd.DataFrame(arr)

In [102]: df
Out[102]:
   0 1  
0 0 1  
1 2 3  
(continues on next page)
**Previous behavior:**

```python
In [5]: df + arr[[0], :]  # 1 row, 2 columns
   ...: ValueError: Unable to coerce to DataFrame, shape must be (3, 2): given (1, 2)
In [6]: df + arr[:, [1]]  # 1 column, 3 rows
   ...: ValueError: Unable to coerce to DataFrame, shape must be (3, 2): given (3, 1)
```

**New behavior:**

```python
In [103]: df + arr[[0], :]  # 1 row, 2 columns
Out[103]:
     0  1
0  0  2
1  2  4
2  4  6
[3 rows x 2 columns]

In [104]: df + arr[:, [1]]  # 1 column, 3 rows
Out[104]:
     0  1
0  1  2
1  5  6
2  9 10
[3 rows x 2 columns]
```

**Series and Index data-dtype incompatibilities**

Series and Index constructors now raise when the data is incompatible with a passed `dtype=` *(GH15832)*

**Previous behavior:**

```python
In [4]: pd.Series([-1], dtype="uint64")
Out [4]:
0  18446744073709551615
dtype: uint64
```

**New behavior:**

```python
In [4]: pd.Series([-1], dtype="uint64")
Out [4]:
...:
OverflowError: Trying to coerce negative values to unsigned integers
Concatenation changes

Calling `pandas.concat()` on a `Categorical` of ints with NA values now causes them to be processed as objects when concatenating with anything other than another `Categorical` of ints (GH19214)

```python
In [105]: s = pd.Series([0, 1, np.nan])
In [106]: c = pd.Series([0, 1, np.nan], dtype="category")
```

**Previous behavior**

```python
In [3]: pd.concat([s, c])
Out[3]:
0  0.0  
1  1.0  
2  NaN  
0  0.0  
1  1.0  
2  NaN  
dtype: float64
```

**New behavior**

```python
In [107]: pd.concat([s, c])
Out[107]:
0  0.0  
1  1.0  
2  NaN  
0  0.0  
1  1.0  
2  NaN  
Length: 6, dtype: float64
```

Datetimelike API changes

- For `DatetimeIndex` and `TimedeltaIndex` with non-`None` freq attribute, addition or subtraction of integer-dtyped array or `Index` will return an object of the same class (GH19959)
- `DateOffset` objects are now immutable. Attempting to alter one of these will now raise `AttributeError` (GH21341)
- `PeriodIndex` subtraction of another `PeriodIndex` will now return an object-dtype `Index` of `DateOffset` objects instead of raising a `TypeError` (GH20049)
- `cut()` and `qcut()` now returns a `DatetimeIndex` or `TimedeltaIndex` bins when the input is datetime or timedelta dtype respectively and `retbins=True` (GH19891)
- `DatetimeIndex.to_period()` and `Timestamp.to_period()` will issue a warning when timezone information will be lost (GH21333)
- `PeriodIndex.tz_convert()` and `PeriodIndex.tz_localize()` have been removed (GH21781)
Other API changes

- A newly constructed empty DataFrame with integer as the dtype will now only be cast to float64 if index is specified (GH22858)
- Series.str.cat() will now raise if others is a set (GH23009)
- Passing scalar values to DatetimeIndex or TimedeltaIndex will now raise TypeError instead of ValueError (GH23539)
- max_rows and max_cols parameters removed from HTMLFormatter since truncation is handled by DataFrameFormatter (GH23818)
- read_csv() will now raise a ValueError if a column with missing values is declared as having dtype bool (GH20591)
- The column order of the resultant DataFrame from MultiIndex.to_frame() is now guaranteed to match the MultiIndex.names order. (GH22420)
- Incorrectly passing a DatetimeIndex to MultiIndex.from_tuples(), rather than a sequence of tuples, now raises a TypeError rather than a ValueError (GH24024)
- pd.offsets.generate_range() argument time_rule has been removed; use offset instead (GH24157)
- In 0.23.x, pandas would raise a ValueError on a merge of a numeric column (e.g. int dtyped column) and an object dtyped column (GH9780). We have re-enabled the ability to merge object and other dtypes; pandas will still raise on a merge between a numeric and an object dtyped column that is composed only of strings (GH21681)
- Accessing a level of a MultiIndex with a duplicate name (e.g. in get_level_values()) now raises a ValueError instead of a KeyError (GH21678).
- Invalid construction of IntervalDtype will now always raise a TypeError rather than a ValueError if the subtype is invalid (GH21185)
- Trying to reindex a DataFrame with a non unique MultiIndex now raises a ValueError instead of an Exception (GH21770)
- Index subtraction will attempt to operate element-wise instead of raising TypeError (GH19369)
- pandas.io.formats.style.Styler supports a number-format property when using to_excel() (GH22015)
- DataFrame.corr() and Series.corr() now raise a ValueError along with a helpful error message instead of a KeyError when supplied with an invalid method (GH22298)
- shift() will now always return a copy, instead of the previous behaviour of returning self when shifting by 0 (GH22397)
- DataFrame.set_index() now gives a better (and less frequent) KeyError, raises a ValueError for incorrect types, and will not fail on duplicate column names with drop=True. (GH22484)
- Slicing a single row of a DataFrame with multiple ExtensionArrays of the same type now preserves the dtype, rather than coercing to object (GH22784)
- DateOffset attribute _cacheable and method _should_cache have been removed (GH23118)
- Series.searchsorted(), when supplied a scalar value to search for, now returns a scalar instead of an array (GH23801).
- Categorical.searchsorted(), when supplied a scalar value to search for, now returns a scalar instead of an array (GH23466).
• `Categorical.searchsorted()` now raises a `KeyError` rather than a `ValueError`, if a searched for key is not found in its categories (GH23466).

• `Index.hasnans()` and `Series.hasnans()` now always return a python boolean. Previously, a python or a numpy boolean could be returned, depending on circumstances (GH23294).

• The order of the arguments of `DataFrame.to_html()` and `DataFrame.to_string()` is rearranged to be consistent with each other. (GH23614)

• `CategoricalIndex.reindex()` now raises a `ValueError` if the target index is non-unique and not equal to the current index. It previously only raised if the target index was not of a categorical dtype (GH23963).

• `Series.to_list()` and `Index.to_list()` are now aliases of `Series.tolist` respectively `Index.tolist` (GH8826)

• The result of `SparseSeries.unstack()` is now a `DataFrame` with sparse values, rather than a `SparseDataFrame` (GH24372).

• `DatetimeIndex` and `TimedeltaIndex` no longer ignore the dtype precision. Passing a non-nanosecond resolution dtype will raise a `ValueError` (GH24753)

### Extension type changes

#### Equality and hashability

Pandas now requires that extension dtypes be hashable (i.e. the respective `ExtensionDtype` objects; hashability is not a requirement for the values of the corresponding `ExtensionArray`). The base class implements a default `__eq__` and `__hash__`. If you have a parametrized dtype, you should update the `ExtensionDtype._metadata` tuple to match the signature of your `__init__` method. See `pandas.api.extensions.ExtensionDtype` for more (GH22476).

#### New and changed methods

• `dropna()` has been added (GH21185)

• `repeat()` has been added (GH24349)

• The `ExtensionArray` constructor, `__from_sequence` now take the keyword arg `copy=False` (GH21185)

• `pandas.api.extensions.ExtensionArray.shift()` added as part of the basic `ExtensionArray` interface (GH22387).

• `searchsorted()` has been added (GH24350)

• Support for reduction operations such as `sum`, `mean` via opt-in base class method override (GH22762)

• `ExtensionArray.isna()` is allowed to return an `ExtensionArray` (GH22325).

#### Dtype changes

• `ExtensionDtype` has gained the ability to instantiate from string dtypes, e.g. `decimal` would instantiate a registered `DecimalDtype`; furthermore the `ExtensionDtype` has gained the method `construct_array_type` (GH21185)

• Added `ExtensionDtype._is_numeric` for controlling whether an extension dtype is considered numeric (GH22290).

• Added `pandas.api.types.register_extension_dtype()` to register an extension type with pandas (GH22664)

• Updated the `.type` attribute for `PeriodDtype`, `DatetimeTZDtype`, and `IntervalDtype` to be instances of the dtype (`Period`, `Timestamp`, and `Interval` respectively) (GH22938)
Operator support

A `Series` based on an `ExtensionArray` now supports arithmetic and comparison operators (GH19577). There are two approaches for providing operator support for an `ExtensionArray`:

1. Define each of the operators on your `ExtensionArray` subclass.
2. Use an operator implementation from pandas that depends on operators that are already defined on the underlying elements (scalars) of the `ExtensionArray`.

See the `ExtensionArray Operator Support` documentation section for details on both ways of adding operator support.

Other changes

- A default repr for `pandas.api.extensions.ExtensionArray` is now provided (GH23601).
- `ExtensionArray._formatting_values()` is deprecated. Use `ExtensionArray._formatter` instead. (GH23601)
- An `ExtensionArray` with a boolean dtype now works correctly as a boolean indexer. `pandas.api.types.is_bool_dtype()` now properly considers them boolean (GH22326)

Bug fixes

- Bug in `Series.get()` for `Series` using `ExtensionArray` and integer index (GH21257)
- `shift()` now dispatches to `ExtensionArray.shift()` (GH22386)
- `Series.combine()` works correctly with `ExtensionArray` inside of `Series` (GH20825)
- `Series.combine()` with scalar argument now works for any function type (GH21248)
- `Series.astype()` and `DataFrame.astype()` now dispatch to `ExtensionArray.astype()` (GH21185).
- Slicing a single row of a `DataFrame` with multiple `ExtensionArrays` of the same type now preserves the dtype, rather than coercing to object (GH22784)
- Bug when concatenating multiple `Series` with different extension dtypes not casting to object dtype (GH22994)
- `Series` backed by an `ExtensionArray` now work with `util.hash_pandas_object()` (GH23066)
- `DataFrame.stack()` no longer converts to object dtype for DataFrames where each column has the same extension dtype. The output `Series` will have the same dtype as the columns (GH23077).
- `Series.unstack()` and `DataFrame.unstack()` no longer convert extension arrays to object-dtype ndarrays. Each column in the output `DataFrame` will now have the same dtype as the input (GH23077).
- Bug when grouping `Dataframe.groupby()` and aggregating on `ExtensionArray` it was not returning the actual `ExtensionArray` dtype (GH23227).
- Bug in `pandas.merge()` when merging on an extension array-backed column (GH23020).
Deprecations

- **MultiIndex.labels** has been deprecated and replaced by **MultiIndex.codes**. The functionality is unchanged. The new name better reflects the natures of these codes and makes the MultiIndex API more similar to the API for **CategoricalIndex** (GH13443). As a consequence, other uses of the name labels in MultiIndex have also been deprecated and replaced with codes:
  - You should initialize a MultiIndex instance using a parameter named codes rather than labels.
  - MultiIndex.set_labels has been deprecated in favor of MultiIndex.set_codes().
  - For method MultiIndex.copy(), the labels parameter has been deprecated and replaced by a codes parameter.

- **DataFrame.to_stata(), read_stata(), StataReader and StataWriter** have deprecated the encoding argument. The encoding of a Stata dta file is determined by the file type and cannot be changed (GH21244)

- **MultiIndex.to_hierarchical()** is deprecated and will be removed in a future version (GH21613)

- **Series.ptp()** is deprecated. Use numpy.ptp instead (GH21614)

- **Series.compress()** is deprecated. Use Series[condition] instead (GH18262)

- The signature of **Series.to_csv()** has been uniformed to that of **DataFrame.to_csv()**: the name of the first argument is now path_or_buf, the order of subsequent arguments has changed, the header argument now defaults to True. (GH19715)

- **Categorical.from_codes()** has deprecated providing float values for the codes argument. (GH21767)

- **pandas.read_table()** is deprecated. Instead, use read_csv() passing sep="\t" if necessary. This deprecation has been removed in 0.25.0. (GH21948)

- **Series.str.cat()** has deprecated using arbitrary list-likes within list-likes. A list-like container may still contain many Series, Index or 1-dimensional np.ndarray, or alternatively, only scalar values. (GH21950)

- **FrozenNDArray.searchsorted()** has deprecated the v parameter in favor of value (GH14645)

- **DatetimeIndex.shift()** and **PeriodIndex.shift()** now accept periods argument instead of n for consistency with Index.shift() and Series.shift(). Using n throws a deprecation warning (GH22458, GH22912)

- The fastpath keyword of the different Index constructors is deprecated (GH23110).

- **Timestamp.tz_localize(), DatetimeIndex.tz_localize(), and Series.tz_localize()** have deprecated the errors argument in favor of the nonexistent argument (GH8917)

- The class **FrozenNDArray** has been deprecated. When unpickling, FrozenNDArray will be unpickled to np.ndarray once this class is removed (GH9031)

- The methods **DataFrame.update()** and **Panel.update()** have deprecated the raise_conflict=False|True keyword in favor of errors='ignore'|'raise' (GH23585)

- The methods **Series.str.partition()** and **Series.str.rpartition()** have deprecated the pat keyword in favor of sep (GH22676)

- Deprecated the nthreads keyword of **pandas.read_feather()** in favor of use_threads to reflect the changes in pyarrow>=0.11.0. (GH23053)

- **pandas.read_excel()** has deprecated accepting usecols as an integer. Please pass in a list of ints from 0 to usecols inclusive instead (GH23527)
pandas: powerful Python data analysis toolkit, Release 1.1.1

- Constructing a `TimedeltaIndex` from data with `datetime64`-dtyped data is deprecated, will raise `TypeError` in a future version (GH23539)
- Constructing a `DatetimeIndex` from data with `timedelta64`-dtyped data is deprecated, will raise `TypeError` in a future version (GH23675)
- The `keep_tz=False` option (the default) of the `keep_tz` keyword of `DatetimeIndex.to_series()` is deprecated (GH17832).
- Timezone converting a tz-aware `datetime.datetime` or `Timestamp` with `Timestamp` and the `tz` argument is now deprecated. Instead, use `Timestamp.tz_convert()` (GH23579)
- `pandas.api.types.is_period()` is deprecated in favor of `pandas.api.types.is_period_dtype` (GH23917)
- `pandas.api.types.is_datetimetz()` is deprecated in favor of `pandas.api.types.is_datetime64tz` (GH23917)
- Creating a `TimedeltaIndex`, `DatetimeIndex`, or `PeriodIndex` by passing range arguments `start`, `end`, and `periods` is deprecated in favor of `timedelta_range()`, `date_range()`, or `period_range()` (GH23919)
- Passing a string alias like 'datetime64[ns, UTC]' as the unit parameter to `DatetimeTZDtype` is deprecated. Use `DatetimeTZDtype.construct_from_string` instead (GH23990).
- The `skipna` parameter of `infer_dtype()` will switch to `True` by default in a future version of pandas (GH17066, GH24050)
- In `Series.where()` with Categorical data, providing an `other` that is not present in the categories is deprecated. Convert the categorical to a different dtype or add the `other` to the categories first (GH24077).
- `Series.clip_lower()`, `Series.clip_upper()`, `DataFrame.clip_lower()` and `DataFrame.clip_upper()` are deprecated and will be removed in a future version. Use `Series.clip(lower=threshold)`, `Series.clip(upper=threshold)` and the equivalent `DataFrame` methods (GH24203)
- `Series.nonzero()` is deprecated and will be removed in a future version (GH18262)
- Passing an integer to `Series.fillna()` and `DataFrame.fillna()` with `timedelta64[ns]` dtypes is deprecated, will raise `TypeError` in a future version. Use `obj.fillna(pd.Timedelta(...))` instead (GH24694)
- `Series.cat.categorical`, `Series.cat.name` and `Series.cat.index` have been deprecated. Use the attributes on `Series.cat` or `Series` directly. (GH24751).
- Passing a dtypes without a precision like `np.dtype('datetime64')` or `timedelta64` to `Index`, `DatetimeIndex` and `TimedeltaIndex` is now deprecated. Use the nanosecond-precision dtypes instead (GH24753).

**Integer addition/subtraction with datetimes and timedeltas is deprecated**

In the past, users could—in some cases—add or subtract integers or integer-dtype arrays from `Timestamp`, `DatetimeIndex` and `TimedeltaIndex`.

This usage is now deprecated. Instead add or subtract integer multiples of the object’s `freq` attribute (GH21939, GH23878).

*Previous behavior:*
In [6]: ts + 2

In [7]: tdi = pd.timedelta_range('1D', periods=2)
In [8]: tdi - np.array([2, 1])
Out[8]: TimedeltaIndex(["-1 days", '1 days'], dtype='timedelta64[ns]', freq=None)

In [9]: dti = pd.date_range('2001-01-01', periods=2, freq='7D')
In [10]: dti + pd.Index([1, 2])
Out[10]: DatetimeIndex(['2001-01-08', '2001-01-22'], dtype='datetime64[ns]', freq=None)

New behavior:

In [109]: ts + 2 * ts.freq
In [110]: tdi = pd.timedelta_range('1D', periods=2)
In [111]: tdi - np.array([2 * tdi.freq, 1 * tdi.freq])
Out[111]: TimedeltaIndex(["-1 days", '1 days'], dtype='timedelta64[ns]', freq=None)
In [112]: dti = pd.date_range('2001-01-01', periods=2, freq='7D')
In [113]: dti + pd.Index([1 * dti.freq, 2 * dti.freq])
Out[113]: DatetimeIndex(['2001-01-08', '2001-01-22'], dtype='datetime64[ns]', freq=None)

Passing integer data and a timezone to DatetimeIndex

The behavior of DatetimeIndex when passed integer data and a timezone is changing in a future version of pandas. Previously, these were interpreted as wall times in the desired timezone. In the future, these will be interpreted as wall times in UTC, which are then converted to the desired timezone (GH24559).

The default behavior remains the same, but issues a warning:

In [3]: pd.DatetimeIndex([946684800000000000], tz="US/Central")
/bin/ipython:1: FutureWarning:
    Integer values will be interpreted differently in a future version of pandas. Previously, these were viewed as datetime64[ns] values representing the wall time in the specified timezone. In the future, these will be viewed as datetime64[ns] values representing the wall time in UTC. This is similar to a nanosecond-precision UNIX epoch. To accept the future behavior, use
    pd.to_datetime(integer_data, utc=True).tz_convert(tz)
    To keep the previous behavior, use
    pd.to_datetime(integer_data).tz_localize(tz)

Out[3]: DatetimeIndex(['2000-01-01 00:00:00-06:00'], dtype='datetime64[ns, US/Central]', freq=None)
As the warning message explains, opt in to the future behavior by specifying that the integer values are UTC, and then converting to the final timezone:

```
In [114]: pd.to_datetime([946684800000000000], utc=True).tz_convert('US/Central')
Out[114]: DatetimeIndex(['1999-12-31 18:00:00-06:00'], dtype='datetime64[ns, US/Central]', freq=None)
```

The old behavior can be retained by directly localizing to the final timezone:

```
In [115]: pd.to_datetime([946684800000000000]).tz_localize('US/Central')
Out[115]: DatetimeIndex(['2000-01-01 00:00:00-06:00'], dtype='datetime64[ns, US/Central]', freq=None)
```

### Converting timezone-aware Series and Index to NumPy arrays

The conversion from a `Series` or `Index` with timezone-aware datetime data will change to preserve timezones by default (GH23569).

NumPy doesn’t have a dedicated dtype for timezone-aware datetimes. In the past, converting a `Series` or `DatetimeIndex` with timezone-aware datetimes would convert to a NumPy array by

1. converting the tz-aware data to UTC
2. dropping the timezone-info
3. returning a `numpy.ndarray` with `datetime64[ns]` dtype

Future versions of pandas will preserve the timezone information by returning an object-dtype NumPy array where each value is a `Timestamp` with the correct timezone attached

```
In [116]: ser = pd.Series(pd.date_range('2000', periods=2, tz='CET'))
In [117]: ser
Out[117]:
0  2000-01-01 00:00:00+01:00
1  2000-01-02 00:00:00+01:00
Length: 2, dtype: datetime64[ns, CET]
```

The default behavior remains the same, but issues a warning

```
In [8]: np.asarray(ser)
/bin/ipython:1: FutureWarning: Converting timezone-aware DatetimeArray to timezone-naive ndarray with 'datetime64[ns]' dtype. In the future, this will return an ndarray with 'object' dtype where each element is a 'pandas.Timestamp' with the correct 'tz'.

To accept the future behavior, pass 'dtype=object'.
To keep the old behavior, pass 'dtype="datetime64[ns]"'.

#!/bin/python3
Out[8]:
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'], dtype='datetime64[ns]')
```

The previous or future behavior can be obtained, without any warnings, by specifying the `dtype`
Previous behavior

```python
In [118]: np.asarray(ser, dtype='datetime64[ns]')
Out[118]:
array([  '1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
      dtype='datetime64[ns]')
```

Future behavior

```python
# New behavior
In [119]: np.asarray(ser, dtype=object)
Out[119]:
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
      Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
Or by using `Series.to_numpy()`
```

```python
In [120]: ser.to_numpy()
Out[120]:
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET', freq='D'),
      Timestamp('2000-01-02 00:00:00+0100', tz='CET', freq='D')],
      dtype=object)
In [121]: ser.to_numpy(dtype="datetime64[ns]")
Out[121]:
array([  '1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
      dtype='datetime64[ns]')
```

All the above applies to a `DatetimeIndex` with tz-aware values as well.

Removal of prior version deprecations/changes

- The `LongPanel` and `WidePanel` classes have been removed (GH10892)
- `Series.repeat()` has renamed the `reps` argument to `repeats` (GH14645)
- Several private functions were removed from the (non-public) module `pandas.core.common` (GH22001)
- Removal of the previously deprecated module `pandas.core.datetools` (GH14105, GH14094)
- Strings passed into `DataFrame.groupby()` that refer to both column and index levels will raise a `ValueError` (GH14432)
- `Index.repeat()` and `MultiIndex.repeat()` have renamed the `n` argument to `repeats` (GH14645)
- The `Series` constructor and `.astype` method will now raise a `ValueError` if timestamp dtypes are passed in without a unit (e.g. `np.datetime64`) for the `dtype` parameter (GH15987)
- Removal of the previously deprecated `as_indexer` keyword completely from `str.match()` (GH22356, GH6581)
- The modules `pandas.types`, `pandas.computation`, and `pandas.util.decorators` have been removed (GH16157, GH16250)
- Removed the `pandas.formats.style` shim for `pandas.io.formats.style.Styler` (GH16059)
- `pandas.pnow`, `pandas.match`, `pandas.groupby`, `pd.get_store`, `pd.Expr`, and `pd.Term` have been removed (GH15538, GH15940)
• Categorical.searchsorted() and Series.searchsorted() have renamed the v argument to value (GH14645)
• pandas.parser, pandas.lib, and pandas.tslib have been removed (GH15537)
• Index.searchsorted() have renamed the key argument to value (GH14645)
• DataFrame.consolidate and Series.consolidate have been removed (GH15501)
• Removal of the previously deprecated module pandas.json (GH19944)
• The module pandas.tools has been removed (GH15358, GH16005)
• SparseArray.get_values() and SparseArray.to_dense() have dropped the fill parameter (GH14686)
• DataFrame.sortlevel and Series.sortlevel have been removed (GH15099)
• SparseSeries.to_dense() has dropped the sparse_only parameter (GH14686)
• DataFrame.astype() and Series.astype() have renamed the raise_on_error argument to errors (GH14967)
• is_sequence, is_any_int_dtype, and is_floating_dtype have been removed from pandas.api.types (GH16163, GH16189)

Performance improvements

• Slicing Series and DataFrames with an monotonically increasing CategoricalIndex is now very fast and has speed comparable to slicing with an Int64Index. The speed increase is both when indexing by label (using .loc) and position(.iloc) (GH20395) Slicing a monotonically increasing CategoricalIndex itself (i.e. ci[1000:2000]) shows similar speed improvements as above (GH21659)
• Improved performance of CategoricalIndex.equals() when comparing to another CategoricalIndex (GH24023)
• Improved performance of Series.describe() in case of numeric dtypes (GH21274)
• Improved performance of pandas.core.groupby.GroupBy.rank() when dealing with tied rankings (GH21237)
• Improved performance of DataFrame.set_index() with columns consisting of Period objects (GH21582, GH21606)
• Improved performance of Series.at() and Index.get_value() for Extension Arrays values (e.g. Categorical) (GH24204)
• Improved performance of membership checks in Categorical and CategoricalIndex (i.e. x in cat-style checks are much faster). CategoricalIndex.contains() is likewise much faster (GH21369, GH21508)
• Improved performance of HDFStore.groups() (and dependent functions like HDFStore.keys()). (i.e. x in store checks are much faster) (GH21372)
• Improved the performance of pandas.get_dummies() with sparse=True (GH21997)
• Improved performance of IndexEngine.get_indexer_non_unique() for sorted, non-unique indexes (GH9466)
• Improved performance of PeriodIndex.unique() (GH23083)
• Improved performance of concat() for Series objects (GH23404)
• Improved performance of `DatetimeIndex.normalize()` and `Timestamp.normalize()` for time-zone naive or UTC datetimes (GH23634)

• Improved performance of `DatetimeIndex.tz_localize()` and various `DatetimeIndex` attributes with dateutil UTC timezone (GH23772)

• Fixed a performance regression on Windows with Python 3.7 of `read_csv()` (GH23516)

• Improved performance of `Categorical` constructor for `Series` objects (GH23814)

• Improved performance of `where()` for Categorical data (GH24077)

• Improved performance of iterating over a `Series`. Using `DataFrame.itertuples()` now creates iterators without internally allocating lists of all elements (GH20783)

• Improved performance of `Period` constructor, additionally benefitting `PeriodArray` and `PeriodIndex` creation (GH24084, GH24118)

• Improved performance of `tz-aware DatetimeArray` binary operations (GH24491)

Bug fixes

Categorical

• Bug in `Categorical.from_codes()` where NaN values in codes were silently converted to 0 (GH21767). In the future this will raise a `ValueError`. Also changes the behavior of `.from_codes([1.1, 2.0])`.

• Bug in `Categorical.sort_values()` where NaN values were always positioned in front regardless of `na_position` value. (GH22556).

• Bug when indexing with a boolean-valued `Categorical`. Now a boolean-valued `Categorical` is treated as a boolean mask (GH22665)

• Constructing a `CategoricalIndex` with empty values and boolean categories was raising a `ValueError` after a change to dtype coercion (GH22702).

• Bug in `Categorical.take()` with a user-provided fill_value not encoding the fill_value, which could result in a `ValueError`, incorrect results, or a segmentation fault (GH23296).

• In `Series.unstack()`, specifying a fill_value not present in the categories now raises a `TypeError` rather than ignoring the fill_value (GH23284)

• Bug when resampling `DataFrame.resample()` and aggregating on categorical data, the categorical dtype was getting lost. (GH23227)

• Bug in many methods of the `.str-accessor`, which always failed on calling the `CategoricalIndex.str` constructor (GH23555, GH23556)

• Bug in `Series.where()` losing the categorical dtype for categorical data (GH24077)

• Bug in `Categorical.apply()` where NaN values could be handled unpredictably. They now remain unchanged (GH24241)

• Bug in `Categorical` comparison methods incorrectly raising `ValueError` when operating against a `DataFrame` (GH24630)

• Bug in `Categorical.set_categories()` where setting fewer new categories with `rename=True` caused a segmentation fault (GH24675)
Datetimelike

- Fixed bug where two DateOffset objects with different normalize attributes could evaluate as equal (GH21404)
- Fixed bug where Timestamp.resolution() incorrectly returned 1-microsecond timedelta instead of 1-nanosecond timedelta (GH21336, GH21365)
- Bug in to_datetime() that did not consistently return an Index when box=True was specified (GH21864)
- Bug in DatetimeIndex comparisons where string comparisons incorrectly raises TypeError (GH22074)
- Bug in DatetimeIndex comparisons when comparing against timedelta64[ns] dtypes; in some cases TypeError was incorrectly raised, in others it incorrectly failed to raise (GH22074)
- Bug in DatetimeIndex comparisons when comparing against object-dtyped arrays (GH22074)
- Bug in DataFrame with datetime64[ns] dtype addition and subtraction with Timedelta-like objects (GH22005, GH22163)
- Bug in DataFrame with datetime64[ns] dtype addition and subtraction with DateOffset objects returning an object dtype instead of datetime64[ns] dtype (GH21610, GH22163)
- Bug in DataFrame with datetime64[ns] dtype comparing against NaT incorrectly (GH22242, GH22163)
- Bug in DataFrame with datetime64[ns] dtype subtracting Timestamp-like object incorrectly returned datetime64[ns] dtype instead of timedelta64[ns] dtype (GH8554, GH22163)
- Bug in DataFrame with datetime64[ns] dtype subtracting np.datetime64 object with non-nanosecond unit failing to convert to nanoseconds (GH18874, GH22163)
- Bug in DataFrame comparisons against Timestamp-like objects failing to raise TypeError for inequality checks with mismatched types (GH8932, GH22163)
- Bug in DataFrame with mixed dtypes including datetime64[ns] incorrectly raising TypeError on equality comparisons (GH13128, GH22163)
- Bug in DataFrame.values returning a DatetimeIndex for a single-column DataFrame with tz-aware datetime values. Now a 2-D numpy.ndarray of Timestamp objects is returned (GH24024)
- Bug in DataFrame.eq() comparison against NaT incorrectly returning True or NaN (GH15697, GH22163)
- Bug in DatetimeIndex subtraction that incorrectly failed to raise OverflowError (GH22492, GH22508)
- Bug in DatetimeIndex incorrectly allowing indexing with Timedelta object (GH20464)
- Bug in DatetimeIndex where frequency was being set if original frequency was None (GH22150)
- Bug in rounding methods of DatetimeIndex (round(), ceil(), floor()) and Timestamp (round(), ceil(), floor()) could give rise to loss of precision (GH22591)
- Bug in to_datetime() with an Index argument that would drop the name from the result (GH21697)
- Bug in PeriodIndex where adding or subtracting a timedelta or Tick object produced incorrect results (GH22988)
- Bug in the Series repr with period-dtype data missing a space before the data (GH23601)
- Bug in date_range() when decrementing a start date to a past end date by a negative frequency (GH23270)
- Bug in Series.min() which would return NaN instead of NaT when called on a series of NaT (GH23282)
- Bug in Series.combine_first() not properly aligning categoricals, so that missing values in self where not filled by valid values from other (GH24147)
- Bug in `DataFrame.combine()` with datetimelike values raising a TypeError (GH23079)
- Bug in `date_range()` with frequency of `Day` or higher where dates sufficiently far in the future could wrap around to the past instead of raising `OutOfBoundsDatetime` (GH14187)
- Bug in `period_range()` ignoring the frequency of `start` and `end` when those are provided as `Period` objects (GH20535).
- Bug in `PeriodIndex` with attribute `freq.n` greater than 1 where adding a `DateOffset` object would return incorrect results (GH23215)
- Bug in `Series` that interpreted string indices as lists of characters when setting datetimelike values (GH23451)
- Bug in `DataFrame` when creating a new column from an ndarray of `Timestamp` objects with timezones creating an object-dtype column, rather than datetime with timezone (GH23932)
- Bug in `Timestamp` constructor which would drop the frequency of an input `Timestamp` (GH22311)
- Bug in `DatetimeIndex` where constructing a `DatetimeIndex` from a `Categorical` or `CategoricalIndex` would incorrectly drop timezone information (GH18664)
- Bug in `DatetimeIndex` and `TimedeltaIndex` where indexing with `Ellipsis` would incorrectly lose the index’s `freq` attribute (GH21282)
- Clarified error message produced when passing an incorrect `freq` argument to `DatetimeIndex` with `NaT` as the first entry in the passed data (GH11587)
- Bug in `to_datetime()` where `box` and `utc` arguments were ignored when passing a `DataFrame` or `dict` of unit mappings (GH23760)
- Bug in `Series.dt` where the cache would not update properly after an in-place operation (GH24408)
- Bug in `PeriodIndex` where comparisons against an array-like object with length 1 failed to raise `ValueError` (GH23078)
- Bug in `DatetimeIndex.astype()`, `PeriodIndex.astype()` and `TimedeltaIndex.astype()` ignoring the sign of the `dtype` for unsigned integer dtypes (GH24405).
- Fixed bug in `Series.max()` with `datetime64[ns]`-dtype failing to return `NaT` when nulls are present and `skipna=False` is passed (GH24265)
- Bug in `to_datetime()` where arrays of datet ime objects containing both timezone-aware and timezone-naive datetimes would fail to raise `ValueError` (GH24569)
- Bug in `to_datetime()` with invalid datetime format doesn’t coerce input to `NaT` even if `errors='coerce'` (GH24763)
Timedelta

- Bug in `DataFrame` with `timedelta64[ns]` dtype division by `Timedelta`-like scalar incorrectly returning `timedelta64[ns]` dtype instead of `float64` dtype (GH20088, GH22163)
- Bug in adding a `Index` object dtype to a `Series` object dtype incorrectly raising `TypeError` (GH22390)
- Bug in multiplying a `Series` object dtype against a `timedelta` object (GH22390)
- Bug in `Series` object dtype when adding or subtracting an array or `Series` with `timedelta64[ns]` dtype (GH22390)
- Bug in `Index` object dtype when multiplying or dividing an array or `Series` with `timedelta64[ns]` dtype (GH22390)
- Bug in `TimedeltaIndex` incorrectly allowing indexing with `Timestamp` object (GH20464)
- Fixed bug where subtracting `Timedelta` from an object-dtyped array would raise `TypeError` (GH21980)
- Fixed bug in adding a `DataFrame` object with all-`timedelta64[ns]` dtypes to a `DataFrame` object with all-integer dtypes returning incorrect results instead of raising `TypeError` (GH22696)
- Bug in `TimedeltaIndex` where adding a timezone-aware datetime scalar incorrectly returned a timezone-naive `DatetimeIndex` (GH23215)
- Bug in `TimedeltaIndex` where adding `np.timedelta64('NaT')` incorrectly returned an all-`NaT` `DatetimeIndex` instead of an all-`NaT` `TimedeltaIndex` (GH23215)
- Bug in `Timedelta` and `to_timedelta()` have inconsistencies in supported unit string (GH21762)
- Bug in `TimedeltaIndex` division where dividing by another `TimedeltaIndex` raised `TypeError` instead of returning a `Float64Index` (GH23849, GH22631)
- Bug in `TimedeltaIndex` comparison operations where comparing against non-Timedelta-like objects would raise `TypeError` instead of returning all-False for `__eq__` and all-True for `__ne__` (GH24056)
- Bug in `Timedelta` comparisons when comparing with a `Tick` object incorrectly raising `TypeError` (GH24710)

Timezones

- Bug in `Index.shift()` where an `AssertionError` would raise when shifting across DST (GH8616)
- Bug in `Timestamp` constructor where passing an invalid timezone offset designator (Z) would not raise a `ValueError` (GH8910)
- Bug in `Timestamp.replace()` where replacing at a DST boundary would retain an incorrect offset (GH7825)
- Bug in `Series.replace()` with `datetime64[ns, tz]` data when replacing `NaT` (GH11792)
- Bug in `Timestamp` when passing different string date formats with a timezone offset would produce different timezone offsets (GH12064)
- Bug when comparing a tz-naive `Timestamp` to a tz-aware `DatetimeIndex` which would coerce the `DatetimeIndex` to tz-naive (GH12601)
- Bug in `Series.truncate()` with a tz-aware `DatetimeIndex` which would cause a core dump (GH9243)
- Bug in `Series` constructor which would coerce tz-aware and tz-naive `Timestamp` to tz-aware (GH13051)
- Bug in `Index` object dtype that did not localize integer data correctly (GH20964)
• Bug in `DatetimeIndex` where constructing with an integer and tz would not localize correctly (GH12619)

• Fixed bug where `DataFrame.describe()` and `Series.describe()` on tz-aware datetimes did not show first and last result (GH21328)

• Bug in `DatetimeIndex` comparisons failing to raise `TypeError` when comparing timezone-aware `DatetimeIndex` against `np.datetime64` (GH22074)

• Bug in `DataFrame` assignment with a timezone-aware scalar (GH19843)

• Bug in `DataFrame.asof()` that raised a `TypeError` when attempting to compare tz-naive and tz-aware timestamps (GH21846)

• Bug when constructing a `DatetimeIndex` with `Timestamp` constructed with the `replace` method across DST (GH18785)

• Bug when setting a new value with `DataFrame.loc()` with a `DatetimeIndex` with a DST transition (GH18308, GH20724)

• Bug in `Index.unique()` that did not re-localize tz-aware dates correctly (GH21737)

• Bug when indexing a `Series` with a DST transition (GH21846)

• Bug in `DataFrame.resample()` and `Series.resample()` where an `AmbiguousTimeError` or `NonExistentTimeError` would raise if a timezone aware timeseries ended on a DST transition (GH19375, GH10117)

• Bug in `DataFrame.drop()` and `Series.drop()` when specifying a tz-aware `Timestamp` key to drop from a `DatetimeIndex` with a DST transition (GH21761)

• Bug in `DatetimeIndex` constructor where `NaT` and `dateutil.tz.tzlocal` would raise an `OutOfBoundsDatetimeError` (GH23807)

• Bug in `DatetimeIndex.tz_localize()` and `Timestamp.tz_localize()` with `dateutil.tz.tzlocal` near a DST transition that would return an incorrectly localized datetime (GH23807)

• Bug in `Timestamp` constructor where a `dateutil.tz.tzutc` timezone passed with a `datetime` argument would be converted to a `pytz.UTC` timezone (GH23807)

• Bug in `to_datetime()` where utc=True was not respected when specifying a unit and errors='ignore' (GH23758)

• Bug in `to_datetime()` where utc=True was not respected when passing a `Timestamp` (GH24415)

• Bug in `DataFrame.any()` returns wrong value when axis=1 and the data is of datetimelike type (GH23070)

• Bug in `DatetimeIndex.to_period()` where a timezone aware index was converted to UTC first before creating `PeriodIndex` (GH22905)

• Bug in `DataFrame.tz_localize()`, `DataFrame.tz_convert()`, `Series.tz_localize()` , and `Series.tz_convert()` where copy=False would mutate the original argument in place (GH6326)

• Bug in `DataFrame.max()` and `DataFrame.min()` with axis=1 where a `Series` with NaN would be returned when all columns contained the same timezone (GH10390)
Offsets

- Bug in FY5253 where date offsets could incorrectly raise an AssertionError in arithmetic operations (GH14774)
- Bug in `DateOffset` where keyword arguments `week` and `milliseconds` were accepted and ignored. Passing these will now raise ValueError (GH19398)
- Bug in adding `DateOffset` with `DataFrame` or `PeriodIndex` incorrectly raising TypeError (GH23215)
- Bug in comparing `DateOffset` objects with non-DateOffset objects, particularly strings, raising ValueError instead of returning False for equality checks and True for not-equal checks (GH23524)

Numeric

- Bug in `Series __rmatmul__` doesn’t support matrix vector multiplication (GH21530)
- Bug in `factorize()` fails with read-only array (GH12813)
- Fixed bug in `unique()` handled signed zeros inconsistently: for some inputs 0.0 and -0.0 were treated as equal and for some inputs as different. Now they are treated as equal for all inputs (GH21866)
- Bug in `DataFrame.agg()`, `DataFrame.transform()` and `DataFrame.apply()` where, when supplied with a list of functions and `axis=1` (e.g. `df.apply(['sum', 'mean'], axis=1)`), a TypeError was wrongly raised. For all three methods such calculation are now done correctly. (GH16679).
- Bug in `Series` comparison against datetime-like scalars and arrays (GH22074)
- Bug in `DataFrame` multiplication between boolean dtype and integer returning object dtype instead of integer dtype (GH22047, GH22163)
- Bug in `DataFrame.apply()` where, when supplied with a string argument and additional positional or keyword arguments (e.g. `df.apply('sum', min_count=1)`) a TypeError was wrongly raised (GH22376)
- Bug in `DataFrame.astype()` to extension dtype may raise AttributeError (GH22578)
- Bug in `DataFrame` with timedelta64[ns] dtype arithmetic operations with ndarray with integer dtype incorrectly treating the ndarray as timedelta64[ns] dtype (GH23114)
- Bug in `Series.pow()` with object dtype NaN for 1 ** NA instead of 1 (GH22922).
- `Series.agg()` can now handle nans in methods like `numpy.nansum()` (GH19629)
- Bug in `Series.rank()` and `DataFrame.rank()` when `pct=True` and more than 2^34 rows are present. Full support for `keepdims` has not been implemented (GH24356).
Conversion

- Bug in `DataFrame.combine_first()` in which column types were unexpectedly converted to float (GH20699)
- Bug in `DataFrame.clip()` in which column types are not preserved and casted to float (GH24162)
- Bug in `DataFrame.clip()` when order of columns of dataframes doesn’t match, result observed is wrong in numeric values (GH20911)
- Bug in `DataFrame.astype()` where converting to an extension dtype when duplicate column names are present causes a RecursionError (GH24704)

Strings

- Bug in `Index.str.partition()` was not nan-safe (GH23558).
- Bug in `Index.str.split()` was not nan-safe (GH23677).
- Bug `Series.str.contains()` not respecting the na argument for a Categorical dtype Series (GH22158)
- Bug in `Index.str.cat()` when the result contained only NaN (GH24044)

Interval

- Bug in the `IntervalIndex` constructor where the closed parameter did not always override the inferred closed (GH19370)
- Bug in the `IntervalIndex` repr where a trailing comma was missing after the list of intervals (GH20611)
- Bug in `Interval` where scalar arithmetic operations did not retain the closed value (GH22313)
- Bug in `IntervalIndex` where indexing with datetime-like values raised a KeyError (GH20636)
- Bug in `IntervalTree` where data containing NaN triggered a warning and resulted in incorrect indexing queries with `IntervalIndex` (GH23352)

Indexing

- Bug in `DataFrame.ne()` fails if columns contain column name “dtype” (GH22383)
- The traceback from a KeyError when asking `.loc` for a single missing label is now shorter and more clear (GH21557)
- `PeriodIndex` now emits a KeyError when a malformed string is looked up, which is consistent with the behavior of `DatetimeIndex` (GH22803)
- When `.ix` is asked for a missing integer label in a `MultiIndex` with a first level of integer type, it now raises a KeyError, consistently with the case of a flat `Int64Index`, rather than falling back to positional indexing (GH21593)
- Bug in `Index.reindex()` when reindexing a tz-naive and tz-aware `DatetimeIndex` (GH8306)
- Bug in `Series.reindex()` when reindexing an empty series with a `datetime64[ns, tz]` dtype (GH20869)
- Bug in `DataFrame` when setting values with `.loc` and a timezone aware `DatetimeIndex` (GH11365)
pandas: powerful Python data analysis toolkit, Release 1.1.1

- **DataFrame.__getitem__** now accepts dictionaries and dictionary keys as list-likes of labels, consistently with **Series.__getitem__** (GH21294)
- Fixed **DataFrame[np.nan]** when columns are non-unique (GH21428)
- Bug when indexing **DatetimeIndex** with nanosecond resolution dates and timezones (GH11679)
- Bug where indexing with a Numpy array containing negative values would mutate the indexer (GH21867)
- Bug where mixed indexes wouldn’t allow integers for **.at** (GH19860)
- **Float64Index.get_loc** now raises **KeyError** when boolean key passed. (GH19087)
- Bug in **DataFrame.loc()** when indexing with an **IntervalIndex** (GH19977)
- **Index** no longer mangles None, NaN and NaT, i.e. they are treated as three different keys. However, for numeric Index all three are still coerced to a NaN (GH2332)
- Bug in **scalar in Index** if scalar is a float while the Index is of integer dtype (GH22085)
- Bug in **MultiIndex.set_levels()** when levels value is not subscriptable (GH23237)
- Bug where setting a timedelta column by Index causes it to be casted to double, and therefore lose precision (GH23511)
- Bug in **Index.union()** and **Index.intersection()** where name of the Index of the result was not computed correctly for certain cases (GH9943, GH9862)
- Bug in **Index slicing with boolean Index** may raise **TypeError** (GH22533)
- Bug in **PeriodArray.__setitem__** when accepting slice and list-like value (GH23978)
- Bug in **DatetimeIndex, TimedeltaIndex** where indexing with **Ellipsis** would lose their freq attribute (GH21282)
- Bug in **iat** where using it to assign an incompatible value would create a new column (GH23236)

**Missing**

- Bug in **DataFrame.fillna()** where a **ValueError** would raise when one column contained a **datetime64[ns, tz] dtype** (GH15522)
- Bug in **Series.hasnans()** that could be incorrectly cached and return incorrect answers if null elements are introduced after an initial call (GH19700)
- **Series.isin()** now treats all NaN-floats as equal also for np.object-dtype. This behavior is consistent with the behavior for float64 (GH22119)
- **unique()** no longer mangles NaN-floats and the NaT-object for np.object-dtype, i.e. NaT is no longer coerced to a NaN-value and is treated as a different entity. (GH22295)
- **DataFrame** and **Series** now properly handle numpy masked arrays with hardened masks. Previously, constructing a DataFrame or Series from a masked array with a hard mask would create a pandas object containing the underlying value, rather than the expected NaN. (GH24574)
- Bug in **DataFrame** constructor where **dtype** argument was not honored when handling numpy masked record arrays. (GH24874)
**MultiIndex**

- Bug in `io.formats.style.Styler.applymap()` where `subset=` with `MultiIndex` slice would reduce to `Series` (GH19861)
- Removed compatibility for `MultiIndex` pickles prior to version 0.8.0; compatibility with `MultiIndex` pickles from version 0.13 forward is maintained (GH21654)
- `MultiIndex.get_loc_level()` (and as a consequence, `.loc` on a `Series` or `DataFrame` with a `MultiIndex` index) will now raise a `KeyError`, rather than returning an empty slice, if asked a label which is present in the levels but is unused (GH22221)
- `MultiIndex` has gained the `MultiIndex.from_frame()`, it allows constructing a `MultiIndex` object from a `DataFrame` (GH22420)
- Fix `TypeError` in Python 3 when creating `MultiIndex` in which some levels have mixed types, e.g. when some labels are tuples (GH15457)

**I/O**

- Bug in `read_csv()` in which a column specified with `CategoricalDtype` of boolean categories was not being correctly coerced from string values to booleans (GH20498)
- Bug in `read_csv()` in which unicode column names were not being properly recognized with Python 2.x (GH13253)
- Bug in `DataFrame.to_sql()` when writing timezone aware data (`datetime64[ns, tz]` dtype) would raise a `TypeError` (GH9086)
- Bug in `DataFrame.to_sql()` where a naive `DatetimeIndex` would be written as `TIMESTAMP WITH TIMEZONE` type in supported databases, e.g. PostgreSQL (GH23510)
- Bug in `read_excel()` when `parse_cols` is specified with an empty dataset (GH9208)
- `read_html()` no longer ignores all-whitespace `<tr>` within `<thead>` when considering the `skiprows` and `header` arguments. Previously, users had to decrease their `header` and `skiprows` values on such tables to work around the issue. (GH21641)
- `read_excel()` will correctly show the deprecation warning for previously deprecated `sheetname` (GH17994)
- `read_csv()` and `read_table()` will throw `UnicodeError` and not coredump on badly encoded strings (GH22748)
- `read_csv()` will correctly parse timezone-aware datetimes (GH22256)
- Bug in `read_csv()` in which memory management was prematurely optimized for the C engine when the data was being read in chunks (GH23509)
- Bug in `read_csv()` in unnamed columns were being improperly identified when extracting a multi-index (GH23687)
- `read_sas()` will parse numbers in `sas7bdat`-files that have width less than 8 bytes correctly. (GH21616)
- `read_sas()` will correctly parse `sas7bdat` files with many columns (GH22628)
- `read_sas()` will correctly parse `sas7bdat` files with data page types having also bit 7 set (so page type is 128 + 256 = 384) (GH16615)
- Bug in `read_sas()` in which an incorrect error was raised on an invalid file format. (GH24548)
- Bug in `detect_client_encoding()` where potential IOError goes unhandled when importing in a mod_wsgi process due to restricted access to stdout. (GH21552)
- Bug in `DataFrame.to_html()` with `index=False` misses truncation indicators (...) on truncated DataFrame (GH15019, GH22783)
- Bug in `DataFrame.to_html()` with `index=False` when both columns and row index are MultiIndex (GH22579)
- Bug in `DataFrame.to_html()` with `index_names=False` displaying index name (GH22747)
- Bug in `DataFrame.to_html()` with `header=False` not displaying row index names (GH23788)
- Bug in `DataFrame.to_html()` with `sparsify=False` that caused it to raise TypeError (GH22887)
- Bug in `DataFrame.to_string()` that broke column alignment when `index=False` and width of first column’s values is greater than the width of first column’s header (GH16839, GH13032)
- Bug in `DataFrame.to_string()` that caused representations of `DataFrame` to not take up the whole window (GH22984)
- Bug in `DataFrame.to_csv()` where a single level MultiIndex incorrectly wrote a tuple. Now just the value of the index is written (GH19589).
- HDFStore will raise ValueError when the format kwarg is passed to the constructor (GH13291)
- Bug in `HDFStore.append()` when appending a DataFrame with an empty string column and `min_itemsize < 8` (GH12242)
- Bug in `read_csv()` in which memory leaks occurred in the C engine when parsing NaN values due to insufficient cleanup on completion or error (GH21353)
- Bug in `read_csv()` in which incorrect error messages were being raised when skipfooter was passed in along with nrows, iterator, or chunksize (GH23711)
- Bug in `read_csv()` in which MultiIndex index names were being improperly handled in the cases when they were not provided (GH23484)
- Bug in `read_csv()` in which unnecessary warnings were being raised when the dialect’s values conflicted with the default arguments (GH23761)
- Bug in `read_html()` in which the error message was not displaying the valid flavors when an invalid one was provided (GH23549)
- Bug in `read_excel()` in which extraneous header names were extracted, even though none were specified (GH11733)
- Bug in `read_excel()` in which column names were not being properly converted to string sometimes in Python 2.x (GH23874)
- Bug in `read_excel()` in which `index_col=None` was not being respected and parsing index columns anyway (GH18792, GH20480)
- Bug in `read_excel()` in which `usecols` was not being validated for proper column names when passed in as a string (GH20480)
- Bug in `DataFrame.to_dict()` when the resulting dict contains non-Python scalars in the case of numeric data (GH23753)
- `DataFrame.to_string()`, `DataFrame.to_html()`, `DataFrame.to_latex()` will correctly format output when a string is passed as the `float_format` argument (GH21625, GH22270)
- Bug in `read_csv()` that caused it to raise OverflowError when trying to use ‘inf’ as `na_value` with integer index column (GH17128)
- Bug in `read_csv()` that caused the C engine on Python 3.6+ on Windows to improperly read CSV filenames with accented or special characters (GH15086)
- Bug in `read_fwf()` in which the compression type of a file was not being properly inferred (GH22199)
- Bug in `pandas.io.json.json_normalize()` that caused it to raise `TypeError` when two consecutive elements of `record_path` are dicts (GH22706)
- Bug in `DataFrame.to_stata()`, `pandas.io.stata.StataWriter` and `pandas.io.stata.StataWriter117` where a exception would leave a partially written and invalid dta file (GH23573)
- Bug in `DataFrame.to_stata()` and `pandas.io.stata.StataWriter117` that produced invalid files when using `strLs` with non-ASCII characters (GH23573)
- Bug in `HDFStore` that caused it to raise `ValueError` when reading a Dataframe in Python 3 from fixed format written in Python 2 (GH24510)
- Bug in `DataFrame.to_string()` and more generally in the floating `repr` formatter. Zeros were not trimmed if `inf` was present in a columns while it was the case with NA values. Zeros are now trimmed as in the presence of NA (GH24861).
- Bug in the `repr` when truncating the number of columns and having a wide last column (GH24849).

**Plotting**

- Bug in `DataFrame.plot.scatter()` and `DataFrame.plot.hexbin()` caused x-axis label and tick-labels to disappear when colorbar was on in IPython inline backend (GH10611, GH10678, and GH20455)
- Bug in plotting a Series with datetimes using `matplotlib.axes.Axes.scatter()` (GH22039)
- Bug in `DataFrame.plot.bar()` caused bars to use multiple colors instead of a single one (GH20585)
- Bug in validating color parameter caused extra color to be appended to the given color array. This happened to multiple plotting functions using `matplotlib`. (GH20726)

**Groupby/resample/rolling**

- Bug in `pandas.core.window.Rolling.min()` and `pandas.core.window.Rolling.max()` with `closed='left'`, a datetime-like index and only one entry in the series leading to segfault (GH24718)
- Bug in `pandas.core.groupby.GroupBy.first()` and `pandas.core.groupby.GroupBy.last()` with `as_index=False` leading to the loss of timezone information (GH15884)
- Bug in `DataFrame.resample()` when downsampling across a DST boundary (GH8531)
- Bug in date anchoring for `DataFrame.resample()` with offset `Day` when n > 1 (GH24127)
- Bug where `ValueError` is wrongly raised when calling `count()` method of a `SeriesGroupBy` when the grouping variable only contains NaNs and numpy version < 1.13 (GH21956).
- Multiple bugs in `pandas.core.window.Rolling.min()` with `closed='left'` and a datetime-like index leading to incorrect results and also segfault. (GH21704)
- Bug in `pandas.core.resample.Resampler.apply()` when passing positional arguments to applied func (GH14615).
- Bug in `Series.resample()` when passing `numpy.timedelta64` to `offset` kwarg (GH7687).
- Bug in `pandas.core.resample.Resampler.asfreq()` when frequency of `TimedeltaIndex` is a subperiod of a new frequency (GH13022).
• Bug in pandas.core.groupby.SeriesGroupBy.mean() when values were integral but could not fit inside of int64, overflowing instead. (GH22487)

• pandas.core.groupby.RollingGroupby.agg() and pandas.core.groupby.ExpandingGroupby.agg() now support multiple aggregation functions as parameters (GH15072)

• Bug in DataFrame.resample() and Series.resample() when resampling by a weekly offset ('W') across a DST transition (GH9119, GH21459)

• Bug in DataFrame.expanding() in which the axis argument was not being respected during aggregations (GH23372)

• Bug in pandas.core.groupby.GroupBy.transform() which caused missing values when the input function can accept a DataFrame but renames it (GH23455).

• Bug in pandas.core.groupby.GroupBy.nth() where column order was not always preserved (GH20760)

• Bug in pandas.core.groupby.GroupBy.rank() with method='dense' and pct=True when a group has only one member would raise a ZeroDivisionError (GH23666).

• Calling pandas.core.groupby.GroupBy.rank() with empty groups and pct=True was raising a ZeroDivisionError (GH22519)

• Bug in DataFrame.resample() when resampling NaT in TimeDeltaIndex (GH13223).

• Bug in DataFrame.groupby() did not respect the observed argument when selecting a column and instead always used observed=False (GH23970)

• Bug in pandas.core.groupby.SeriesGroupBy.pct_change() or pandas.core.groupby.DataFrameGroupBy.pct_change() would previously work across groups when calculating the percent change, where it now correctly works per group (GH21200, GH21235).

• Bug preventing hash table creation with very large number (2^32) of rows (GH22805)

• Bug in groupby when grouping on categorical causes ValueError and incorrect grouping if observed=True and nan is present in categorical column (GH24740, GH21151).

**Reshaping**

• Bug in pandas.concat() when joining resampled DataFrames with timezone aware index (GH13783)

• Bug in pandas.concat() when joining only Series the names argument of concat is no longer ignored (GH23490)

• Bug in Series.combine_first() with datetime64[ns, tz] dtype which would return tz-naive result (GH21469)

• Bug in Series.where() and DataFrame.where() with datetime64[ns, tz] dtype (GH21546)

• Bug in DataFrame.where() with an empty DataFrame and empty cond having non-bool dtype (GH21947)

• Bug in Series.mask() and DataFrame.mask() with list conditionals (GH21891)

• Bug in DataFrame.replace() raises RecursionError when converting OutOfBounds datetime64[ns, tz] (GH20380)

• pandas.core.groupby.GroupBy.rank() now raises a ValueError when an invalid value is passed for argument na_option (GH22124)

• Bug in get_dummies() with Unicode attributes in Python 2 (GH22084)

• Bug in DataFrame.replace() raises RecursionError when replacing empty lists (GH22083)
• Bug in `Series.replace()` and `DataFrame.replace()` when dict is used as the `to_replace` value and one key in the dict is another key’s value, the results were inconsistent between using integer key and using string key (GH20656)

• Bug in `DataFrame.drop_duplicates()` for empty DataFrame which incorrectly raises an error (GH20516)

• Bug in `pandas.wide_to_long()` when a string is passed to the stubnames argument and a column name is a substring of that stubname (GH22468)

• Bug in `merge()` when merging `datetime64[ns, tz]` data that contained a DST transition (GH18885)

• Bug in `merge_asof()` when merging on float values within defined tolerance (GH22981)

• Bug in `pandas.concat()` when concatenating a multicolumn DataFrame with tz-aware data against a DataFrame with a different number of columns (GH22796)

• Bug in `merge_asof()` where confusing error message raised when attempting to merge with missing values (GH23189)

• Bug in `DataFrame.nsmallest()` and `DataFrame.nlargest()` for dataframes that have a `MultiIndex` for columns (GH23033).

• Bug in `pandas.melt()` when passing column names that are not present in `DataFrame` (GH23575)

• Bug in `DataFrame.append()` with a `Series` with a dateutil timezone would raise a `TypeError` (GH23682)

• Bug in `Series` construction when passing no data and `dtype=str` (GH22477)

• Bug in `cut()` with bins as an overlapping `IntervalIndex` where multiple bins were returned per item instead of raising a `ValueError` (GH23980)

• Bug in `pandas.concat()` when joining `Series` datetimetz with `Series` category would lose timezone (GH23816)

• Bug in `DataFrame.join()` when joining on partial `MultiIndex` would drop names (GH20452).

• `DataFrame.nlargest()` and `DataFrame.nsmallest()` now returns the correct n values when keep != ‘all’ also when tied on the first columns (GH22752)

• Constructing a DataFrame with an index argument that wasn’t already an instance of `Index` was broken (GH22227).

• Bug in `DataFrame` prevented list subclasses to be used to construction (GH21226)

• Bug in `DataFrame.unstack()` and `DataFrame.pivot_table()` returning a misleading error message when the resulting DataFrame has more elements than `int32` can handle. Now, the error message is improved, pointing towards the actual problem (GH20601)

• Bug in `DataFrame.unstack()` where a `ValueError` was raised when unstacking timezone aware values (GH18338)

• Bug in `DataFrame.stack()` where timezone aware values were converted to timezone naive values (GH19420)

• Bug in `merge_asof()` where a `TypeError` was raised when `by_col` were timezone aware values (GH21184)

• Bug showing an incorrect shape when throwing error during `DataFrame` construction. (GH20742)
Sparse

- Updating a boolean, datetime, or timedelta column to be Sparse now works (GH22367)
- Bug in `Series.to_sparse()` with Series already holding sparse data not constructing properly (GH22389)
- Providing a `sparse_index` to the `SparseArray` constructor no longer defaults the `na-value` to `np.nan` for all dtypes. The correct `na_value` for `data.dtype` is now used.
- Bug in `SparseArray.nbytes` under-reporting its memory usage by not including the size of its sparse index.
- Improved performance of `Series.shift()` for non-NA `fill_value`, as values are no longer converted to a dense array.
- Bug in `DataFrame.groupby` not including `fill_value` in the groups for non-NA `fill_value` when grouping by a sparse column (GH5078)
- Bug in unary inversion operator (~) on a `SparseSeries` with boolean values. The performance of this has also been improved (GH22835)
- Bug in `SparseArray.unique()` not returning the unique values (GH19595)
- Bug in `SparseArray.nonzero()` and `SparseDataFrame.dropna()` returning shifted/incorrect results (GH21172)
- Bug in `DataFrame.apply()` where dtypes would lose sparseness (GH23744)
- Bug in `concat()` when concatenating a list of `Series` with all-sparse values changing the `fill_value` and converting to a dense Series (GH24371)

Style

- `background_gradient()` now takes a `text_color_threshold` parameter to automatically lighten the text color based on the luminance of the background color. This improves readability with dark background colors without the need to limit the background colormap range. (GH21258)
- `background_gradient()` now also supports tablewise application (in addition to rowwise and columnwise) with `axis=None` (GH15204)
- `bar()` now also supports tablewise application (in addition to rowwise and columnwise) with `axis=None` and setting clipping range with `vmin` and `vmax` (GH21548 and GH21526). NaN values are also handled properly.

Build changes

- Building pandas for development now requires `cython` >= 0.28.2 (GH21688)
- Testing pandas now requires `hypothesis`>=3.58. You can find the `Hypothesis` docs here, and a pandas-specific introduction in the contributing guide. (GH22280)
- Building pandas on macOS now targets minimum macOS 10.9 if run on macOS 10.9 or above (GH23424)
Other

- Bug where C variables were declared with external linkage causing import errors if certain other C libraries were imported before Pandas. (GH24113)

5.5 Version 0.23

5.5.1 What’s new in 0.23.4 (August 3, 2018)

This is a minor bug-fix release in the 0.23.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

Warning: Starting January 1, 2019, pandas feature releases will support Python 3 only. See Dropping Python 2.7 for more.

What’s new in v0.23.4

- Fixed regressions
- Bug fixes
- Contributors
Fixed regressions

- Python 3.7 with Windows gave all missing values for rolling variance calculations (GH21813)

Bug fixes

Groupby/resample/rolling

- Bug where calling DataFrameGroupBy.agg() with a list of functions including ohlc as the non-initial element would raise a ValueError (GH21716)
- Bug in roll_quantile caused a memory leak when calling .rolling(...).quantile(q) with q in (0,1) (GH21965)

Missing

- Bug in Series.clip() and DataFrame.clip() cannot accept list-like threshold containing NaN (GH19992)

Contributors

A total of 6 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Jeff Reback
- MeeseeksMachine +
- Tom Augspurger
- chris-b1
- h-vetinari
- meeseeksdev[bot]

5.5.2 What’s new in 0.23.3 (July 7, 2018)

This release fixes a build issue with the sdist for Python 3.7 (GH21785) There are no other changes.

Contributors

A total of 2 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Tom Augspurger
- meeseeksdev[bot] +
5.5.3 What’s new in 0.23.2 (July 5, 2018)

This is a minor bug-fix release in the 0.23.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

Note: Pandas 0.23.2 is first pandas release that’s compatible with Python 3.7 (GH20552)

Warning: Starting January 1, 2019, pandas feature releases will support Python 3 only. See Dropping Python 2.7 for more.

What’s new in v0.23.2

- Logical reductions over entire DataFrame
- Fixed regressions
- Build changes
- Bug fixes
- Contributors

Logical reductions over entire DataFrame

DataFrame.all() and DataFrame.any() now accept axis=None to reduce over all axes to a scalar (GH19976)

```
In [1]: df = pd.DataFrame({"A": [1, 2], "B": [True, False]})
In [2]: df.all(axis=None)
Out[2]: False
```

This also provides compatibility with NumPy 1.15, which now dispatches to DataFrame.all. With NumPy 1.15 and pandas 0.23.1 or earlier, numpy.all() will no longer reduce over every axis:

```
>>> # NumPy 1.15, pandas 0.23.1
>>> np.any(pd.DataFrame({"A": [False], "B": [False]}))
A     False
B     False
dtype: bool
```

With pandas 0.23.2, that will correctly return False, as it did with NumPy < 1.15.

```
In [3]: np.any(pd.DataFrame({"A": [False], "B": [False]}))
Out[3]: False
```
Fixed regressions

- Fixed regression in `to_csv()` when handling file-like object incorrectly (GH21471)
- Re-allowed duplicate level names of a MultiIndex. Accessing a level that has a duplicate name by name still raises an error (GH19029).
- Bug in both `DataFrame.first_valid_index()` and `Series.first_valid_index()` raised for a row index having duplicate values (GH21441)
- Fixed printing of DataFrames with hierarchical columns with long names (GH21180)
- Fixed regression in `reindex()` and `groupby()` with a MultiIndex or multiple keys that contains categorical datetime-like values (GH21390).
- Fixed regression in unary negative operations with object dtype (GH21380)
- Bug in `Timestamp.ceil()` and `Timestamp.floor()` when timestamp is a multiple of the rounding frequency (GH21262)
- Fixed regression in `to_clipboard()` that defaulted to copying dataframes with space delimited instead of tab delimited (GH21104)

Build changes

- The source and binary distributions no longer include test data files, resulting in smaller download sizes. Tests relying on these data files will be skipped when using `pandas.test()`.(GH19320)

Bug fixes

Conversion

- Bug in constructing `Index` with an iterator or generator (GH21470)
- Bug in `Series.nlargest()` for signed and unsigned integer dtypes when the minimum value is present (GH21426)

Indexing

- Bug in `Index.get_indexer_non_unique()` with categorical key (GH21448)
- Bug in comparison operations for `MultiIndex` where error was raised on equality / inequality comparison involving a MultiIndex with `nlevels == 1` (GH21149)
- Bug in `DataFrame.drop()` behaviour is not consistent for unique and non-unique indexes (GH21494)
- Bug in `DataFrame.duplicated()` with a large number of columns causing a ‘maximum recursion depth exceeded’ (GH21524).

I/O

- Bug in `read_csv()` that caused it to incorrectly raise an error when `nrows=0, low_memory=True, and index_col` was not None (GH21141)
- Bug in `json_normalize()` when formatting the `record_prefix` with integer columns (GH21536)

Categorical

- Bug in rendering `Series` with `Categorical` dtype in rare conditions under Python 2.7 (GH21002)

Timezones

5.5. Version 0.23
• Bug in `Timestamp` and `DatetimeIndex` where passing a `Timestamp` localized after a DST transition would return a datetime before the DST transition (GH20854)

• Bug in comparing `DataFrame` with tz-aware `DatetimeIndex` columns with a DST transition that raised a `KeyError` (GH19970)

• Bug in `DatetimeIndex.shift()` where an `AssertionError` would raise when shifting across DST (GH8616)

• Bug in `Timestamp` constructor where passing an invalid timezone offset designator (Z) would not raise a `ValueError` (GH8910)

• Bug in `Timestamp.replace()` where replacing at a DST boundary would retain an incorrect offset (GH7825)

• Bug in `DatetimeIndex.reindex()` when reindexing a tz-naive and tz-aware `DatetimeIndex` (GH8306)

• Bug in `DatetimeIndex.resample()` when downspacing across a DST boundary (GH8531)

**Timedelta**

• Bug in `Timedelta` where non-zero timedeltas shorter than 1 microsecond were considered False (GH21484)

**Contributors**

A total of 17 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

Fixed regressions

Comparing Series with datetime.date

We’ve reverted a 0.23.0 change to comparing a Series holding datetimes and a datetime.date object (GH21152). In pandas 0.22 and earlier, comparing a Series holding datetimes and datetime.date objects would coerce the datetime.date to a datetime before comparing. This was inconsistent with Python, NumPy, and DatetimeIndex, which never consider a datetime and datetime.date equal.

In 0.23.0, we unified operations between DatetimeIndex and Series, and in the process changed comparisons between a Series of datetimes and datetime.date without warning.

We’ve temporarily restored the 0.22.0 behavior, so datetimes and dates may again compare equal, but restore the 0.23.0 behavior in a future release.

To summarize, here’s the behavior in 0.22.0, 0.23.0, 0.23.1:

```python
# 0.22.0... Silently coerce the datetime.date
>>> import datetime
>>> pd.Series(pd.date_range('2017', periods=2)) == datetime.date(2017, 1, 1)
0   True
1  False
dtype: bool

# 0.23.0... Do not coerce the datetime.date
>>> pd.Series(pd.date_range('2017', periods=2)) == datetime.date(2017, 1, 1)
0   False
1   False
dtype: bool

# 0.23.1... Coerce the datetime.date with a warning
>>> pd.Series(pd.date_range('2017', periods=2)) == datetime.date(2017, 1, 1)
/bin/python:1: FutureWarning: Comparing Series of datetimes with 'datetime.date'.
Currently, the 'datetime.date' is coerced to a datetime. In the future pandas will not coerce, and the values not compare equal to the 'datetime.date'.
To retain the current behavior, convert the 'datetime.date' to a
```

(continues on next page)
In addition, ordering comparisons will raise a `TypeError` in the future.

**Other fixes**

- Reverted the ability of `to_sql()` to perform multivalue inserts as this caused regression in certain cases (GH21103). In the future this will be made configurable.
- Fixed regression in the `DatetimeIndex.date` and `DatetimeIndex.time` attributes in case of timezone-aware data: `DatetimeIndex.time` returned a tz-aware time instead of tz-naive (GH21267) and `DatetimeIndex.date` returned incorrect date when the input date has a non-UTC timezone (GH21230).
- Fixed regression in `pandas.io.json.json_normalize()` when called with `None` values in nested levels in JSON, and to not drop keys with value as `None` (GH21158, GH21356).
- Bug in `to_csv()` causes encoding error when compression and encoding are specified (GH21241, GH21118)
- Bug preventing pandas from being importable with -OO optimization (GH21071)
- Bug in `Categorical.fillna()` incorrectly raising a `TypeError` when `value` the individual categories are iterable and `value` is an iterable (GH21097, GH19788)
- Fixed regression in constructors coercing NA values like `None` to strings when passing `dtype=str` (GH21083)
- Regression in `pivot_table()` where an ordered `Categorical` with missing values for the pivot's index would give a mis-aligned result (GH21133)
- Fixed regression in merging on boolean index/columns (GH21119).

**Performance improvements**

- Improved performance of `CategoricalIndex.is_monotonic_increasing()`, `CategoricalIndex.is_monotonic_decreasing()` and `CategoricalIndex.is_monotonic()` (GH21025)
- Improved performance of `CategoricalIndex.is_unique()` (GH21107)

**Bug fixes**

**Groupby/resample/rolling**

- Bug in `DataFrame.agg()` where applying multiple aggregation functions to a `DataFrame` with duplicated column names would cause a stack overflow (GH21063)
- Bug in `pandas.core.groupby.GroupBy.ffill()` and `pandas.core.groupby.GroupBy.bfill()` where the fill within a grouping would not always be applied as intended due to the implementations’ use of a non-stable sort (GH21207)
- Bug in `pandas.core.groupby.GroupBy.rank()` where results did not scale to 100% when specifying method='dense' and pct=True
- Bug in `pandas.DataFrame.rolling()` and `pandas.Series.rolling()` which incorrectly accepted a 0 window size rather than raising (GH21286)
Data-type specific

- Bug in Series.str.replace() where the method throws TypeError on Python 3.5.2 (GH21078)
- Bug in Timedelta where passing a float with a unit would prematurely round the float precision (GH14156)
- Bug in pandas.testing.assert_index_equal() which raised AssertionError incorrectly, when comparing two CategoricalIndex objects with param check_categorical=False (GH19776)

Sparse

- Bug in SparseArray.shape which previously only returned the shape SparseArray.sp_values (GH21126)

Indexing

- Bug in Series.reset_index() where appropriate error was not raised with an invalid level name (GH20925)
- Bug in interval_range() when start/periods or end/periods are specified with float start or end (GH21161)
- Bug in MultiIndex.set_names() where error raised for a MultiIndex with nlevels == 1 (GH21149)
- Bug in IntervalIndex constructors where creating an IntervalIndex from categorical data was not fully supported (GH21243, GH21253)
- Bug in MultiIndex.sort_index() which was not guaranteed to sort correctly with level=1; this was also causing data misalignment in particular DataFrame.stack() operations (GH20994, GH20945, GH21052)

Plotting

- New keywords (sharex, sharey) to turn on/off sharing of x/y-axis by subplots generated with pandas.DataFrame().groupby().boxplot() (GH20968)

I/O

- Bug in IO methods specifying compression='zip' which produced uncompressed zip archives (GH17778, GH21144)
- Bug in DataFrame.to_stata() which prevented exporting DataFrames to buffers and most file-like objects (GH21041)
- Bug in read_stata() and StataReader which did not correctly decode utf-8 strings on Python 3 from Stata 14 files (dta version 118) (GH21244)
- Bug in IO JSON read_json() reading empty JSON schema with orient='table' back to DataFrame caused an error (GH21287)

Reshaping

- Bug in concat() where error was raised in concatenating Series with numpy scalar and tuple names (GH21015)
- Bug in concat() warning message providing the wrong guidance for future behavior (GH21101)

Other

- Tab completion on Index in IPython no longer outputs deprecation warnings (GH21125)
- Bug preventing pandas being used on Windows without C++ redistributable installed (GH21106)
Contributors

5.5.5 What’s new in 0.23.0 (May 15, 2018)

This is a major release from 0.22.0 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- Round-trippable JSON format with ‘table’ orient.
- Instantiation from dicts respects order for Python 3.6+.
- Dependent column arguments for assign.
- Merging / sorting on a combination of columns and index levels.
- Extending pandas with custom types.
- Excluding unobserved categories from groupby.
- Changes to make output shape of DataFrame.apply consistent.

Check the API Changes and deprecations before updating.

Warning: Starting January 1, 2019, pandas feature releases will support Python 3 only. See Dropping Python 2.7 for more.

What’s new in v0.23.0

- New features
  - JSON read/write round-trippable with orient='table'
  - .assign() accepts dependent arguments
  - Merging on a combination of columns and index levels
  - Sorting by a combination of columns and index levels
  - Extending pandas with custom types (experimental)
  - New observed keyword for excluding unobserved categories in groupby
  - Rolling/Expanding.apply() accepts raw=False to pass a Series to the function
  - DataFrame.interpolate has gained the limit_area kwarg
  - get_dummies now supports dtype argument
  - Timedelta mod method
  - .rank() handles inf values when NaN are present
  - Series.str.cat has gained the join kwarg
  - DataFrame.astype performs column-wise conversion to Categorical
  - Other enhancements

- Backwards incompatible API changes
  - Dependencies have increased minimum versions
  - Instantiation from dicts preserves dict insertion order for python 3.6+
– Deprecate Panel
– pandas.core.common removals
– Changes to make output of DataFrame.apply consistent
– Concatenation will no longer sort
– Build changes
– Index division by zero fills correctly
– Extraction of matching patterns from strings
– Default value for the ordered parameter of CategoricalDtype
– Better pretty-printing of DataFrames in a terminal
– Datetimelike API changes
– Other API changes

• Deprecations
• Removal of prior version deprecations/changes
• Performance improvements
• Documentation changes
• Bug fixes
  – Categorical
  – Datetimelike
  – Timedelta
  – Timezones
  – Offsets
  – Numeric
  – Strings
  – Indexing
  – MultiIndex
  – I/O
  – Plotting
  – Groupby/resample/rolling
  – Sparse
  – Reshaping
  – Other

• Contributors
New features

**JSON read/write round-trippable with orient='table'**

A DataFrame can now be written to and subsequently read back via JSON while preserving metadata through usage of the `orient='table'` argument (see GH18912 and GH9146). Previously, none of the available `orient` values guaranteed the preservation of dtypes and index names, amongst other metadata.

```python
In [1]: df = pd.DataFrame({
    'foo': [1, 2, 3, 4],
    'bar': ['a', 'b', 'c', 'd'],
    'baz': pd.date_range('2018-01-01', freq='d', periods=4),
    'qux': pd.Categorical(['a', 'b', 'c', 'c'])},
    index=pd.Index(range(4), name='idx'))

In [2]: df
Out[2]:
     foo  bar     baz     qux
  idx
   0  1    a 2018-01-01    a
   1  2    b 2018-01-02    b
   2  3    c 2018-01-03    c
   3  4    d 2018-01-04    c

[4 rows x 4 columns]

In [3]: df.dtypes
Out[3]:
foo     int64
bar    object
baz  datetime64[ns]
qux   category
Length: 4, dtype: object

In [4]: df.to_json('test.json', orient='table')

In [5]: new_df = pd.read_json('test.json', orient='table')

In [6]: new_df
Out[6]:
     foo  bar     baz     qux
  idx
   0  1    a 2018-01-01    a
   1  2    b 2018-01-02    b
   2  3    c 2018-01-03    c
   3  4    d 2018-01-04    c

[4 rows x 4 columns]

In [7]: new_df.dtypes
Out[7]:
foo     int64
bar    object
baz  datetime64[ns]
qux   category
Length: 4, dtype: object
```

Please note that the string `index` is not supported with the round trip format, as it is used by default in `write_json`
to indicate a missing index name.

```python
In [8]: df.index.name = 'index'
In [9]: df.to_json('test.json', orient='table')
In [10]: new_df = pd.read_json('test.json', orient='table')
In [11]: new_df
Out[11]:
    foo  bar   baz   qux
 0   1     a 2018-01-01   a
 1   2     b 2018-01-02   b
 2   3     c 2018-01-03   c
 3   4     d 2018-01-04   c
[4 rows x 4 columns]
In [12]: new_df.dtypes
Out[12]:
foo    int64
bar   object
baz  datetime64[ns]
qux     category
Length: 4, dtype: object
```

**.assign() accepts dependent arguments**

The `DataFrame.assign()` now accepts dependent keyword arguments for python version later than 3.6 (see also PEP 468). Later keyword arguments may now refer to earlier ones if the argument is a callable. See the documentation [here](GH14207).

```python
In [13]: df = pd.DataFrame({'A': [1, 2, 3]})
In [14]: df
Out[14]:
  A
0  1
1  2
2  3
[3 rows x 1 columns]
In [15]: df.assign(B=df.A, C=lambda x: x['A'] + x['B'])
Out[15]:
  A  B  C
0  1  1  2
1  2  2  4
2  3  3  6
[3 rows x 3 columns]
```

**Warning:** This may subtly change the behavior of your code when you’re using `.assign()` to update an existing column. Previously, callables referring to other variables being updated would get the “old” values.
Previous behavior:
In [2]: df = pd.DataFrame({"A": [1, 2, 3]})

In [3]: df.assign(A=\lambda df: df.A + 1, C=\lambda df: df.A * -1)
Out[3]:
   A  C
0  2 -1
1  3 -2
2  4 -3

New behavior:
In [16]: df.assign(A=df.A + 1, C=\lambda df: df.A * -1)
Out[16]:
   A  C
0  2 -2
1  3 -3
2  4 -4

[3 rows x 2 columns]

Merging on a combination of columns and index levels

Strings passed to DataFrame.merge() as the on, left_on, and right_on parameters may now refer to either column names or index level names. This enables merging DataFrame instances on a combination of index levels and columns without resetting indexes. See the Merge on columns and levels documentation section. (GH14355)

In [17]: left_index = pd.Index(['K0', 'K0', 'K1', 'K2'], name='key1')

In [18]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
                      'B': ['B0', 'B1', 'B2', 'B3'],
                      'key2': ['K0', 'K1', 'K0', 'K1'],
                      index=left_index)

In [19]: right_index = pd.Index(['K0', 'K1', 'K2', 'K2'], name='key1')

In [20]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
                         'D': ['D0', 'D1', 'D2', 'D3'],
                         'key2': ['K0', 'K0', 'K0', 'K1'],
                         index=right_index)

In [21]: left.merge(right, on=['key1', 'key2'])
Out[21]:
   A  B  key2  C  D
key1
K0  A0  B0  K0  C0  D0
K1  A2  B2  K0  C1  D1
K2  A3  B3  K1  C3  D3
[3 rows x 5 columns]
Sorting by a combination of columns and index levels

Strings passed to `DataFrame.sort_values()` as the `by` parameter may now refer to either column names or index level names. This enables sorting `DataFrame` instances by a combination of index levels and columns without resetting indexes. See the *Sorting by Indexes and Values* documentation section. (GH14353)

```python
# Build MultiIndex
In [22]: idx = pd.MultiIndex.from_tuples([('a', 1), ('a', 2), ('a', 2),
                                     ....: ('b', 2), ('b', 1), ('b', 1)])

In [23]: idx.names = ['first', 'second']

# Build DataFrame
In [24]: df_multi = pd.DataFrame({'A': np.arange(6, 0, -1)},
                             index=idx)

In [25]: df_multi
Out[25]:
   A
first second
a   1   6
    2   5
    2   4
b   2   3
    1   2
    1   1

[6 rows x 1 columns]

# Sort by 'second' (index) and 'A' (column)
In [26]: df_multi.sort_values(by=['second', 'A'])
Out[26]:
   A
first second
b   1   1
    1   2
a   1   6
b   2   3
a   2   4
    2   5

[6 rows x 1 columns]
```

Extending pandas with custom types (experimental)

Pandas now supports storing array-like objects that aren’t necessarily 1-D NumPy arrays as columns in a DataFrame or values in a Series. This allows third-party libraries to implement extensions to NumPy’s types, similar to how pandas implemented categoricals, datetimes with timezones, periods, and intervals.

As a demonstration, we’ll use cyberpandas, which provides an `IPArray` type for storing ip addresses.

```python
In [1]: from cyberpandas import IPArray
In [2]: values = IPArray({
```
IPArray isn’t a normal 1-D NumPy array, but because it’s a pandas ExtensionArray, it can be stored properly inside pandas’ containers.

```
In [3]: ser = pd.Series(values)
In [4]: ser
Out[4]:
0 0.0.0.0
1 192.168.1.1
2 2001:db8:85a3::8a2e:370:7334
dtype: ip
```

Notice that the dtype is ip. The missing value semantics of the underlying array are respected:

```
In [5]: ser.isna()
Out[5]:
0   True
1  False
2  False
dtype: bool
```

For more, see the extension types documentation. If you build an extension array, publicize it on our ecosystem page.

**New observed keyword for excluding unobserved categories in groupby**

Grouping by a categorical includes the unobserved categories in the output. When grouping by multiple categorical columns, this means you get the cartesian product of all the categories, including combinations where there are no observations, which can result in a large number of groups. We have added a keyword `observed` to control this behavior, it defaults to `observed=False` for backward-compatibility. (GH14942, GH8138, GH15217, GH17594, GH8669, GH20583, GH20902)

```
In [27]: cat1 = pd.Categorical(["a", "a", "b", "b"],
    categories=["a", "b", "z"], ordered=True)
    ....:
In [28]: cat2 = pd.Categorical(["c", "d", "c", "d"],
    categories=["c", "d", "y"], ordered=True)
    ....:
In [29]: df = pd.DataFrame({"A": cat1, "B": cat2, "values": [1, 2, 3, 4]})
In [30]: df['C'] = ['foo', 'bar'] * 2
In [31]: df
Out[31]:
A  B  values  C
0 a  c    1  foo
1 a  d    2  bar
```

(continues on next page)
To show all values, the previous behavior:

```python
In [32]: df.groupby(['A', 'B', 'C'], observed=False).count()
Out[32]:
   values
   A  B  C
a  c  bar  NaN
   foo  1.0
   d  bar  1.0
   foo  NaN
b  c  foo  NaN
   d  bar  NaN
   foo  NaN
... ... ...
z  c  foo  NaN
   d  bar  NaN
   foo  NaN
   NaN
[18 rows x 1 columns]
```

To show only observed values:

```python
In [33]: df.groupby(['A', 'B', 'C'], observed=True).count()
Out[33]:
   values
   A  B  C
a  c  foo  1
   d  bar  1
b  c  foo  1
   d  bar  1
[4 rows x 1 columns]
```

For pivoting operations, this behavior is already controlled by the `dropna` keyword:

```python
In [34]: cat1 = pd.Categorical(['a', 'a', 'b', 'b'], categories=['a', 'b', 'z'], ordered=True)
In [35]: cat2 = pd.Categorical(['c', 'd', 'c', 'd'], categories=['c', 'd', 'y'], ordered=True)
In [36]: df = pd.DataFrame({'A': cat1, 'B': cat2, 'values': [1, 2, 3, 4]})
In [37]: df
Out[37]:
   A  B  values
0  a  c   1
1  a  d   2
2  b  c   3
3  b  d   4
```

(continues on next page)
[4 rows x 3 columns]

```
In [38]: pd.pivot_table(df, values='values', index=['A', 'B'],
                  ....: dropna=True)
Out[38]:
   values
  A  B
a  c  1
  d  2
b  c  3
  d  4
[4 rows x 1 columns]
```

```
In [39]: pd.pivot_table(df, values='values', index=['A', 'B'],
                  ....: dropna=False)
Out[39]:
   values
  A  B
a  c  1.0
  d  2.0
b  c  3.0
  d  4.0
y  NaN  
z  c  NaN
  d  NaN
  y  NaN
[9 rows x 1 columns]
```

**Rolling/Expanding.apply() accepts raw=False to pass a Series to the function**

Series.rolling().apply(), DataFrame.rolling().apply(), Series.expanding().apply(), and DataFrame.expanding().apply() have gained a raw=None parameter. This is similar to DataFrame.apply(). This parameter, if True allows one to send a np.ndarray to the applied function. If False a Series will be passed. The default is None, which preserves backward compatibility, so this will default to True, sending an np.ndarray. In a future version the default will be changed to False, sending a Series. (GH5071, GH20584)

```
In [40]: s = pd.Series(np.arange(5), np.arange(5) + 1)

In [41]: s
Out[41]:
  0  1
  1  2
  2  3
  3  4
  4  5
Length: 5, dtype: int64
```

Pass a Series:
In [42]: s.rolling(2, min_periods=1).apply(lambda x: x.iloc[-1], raw=False)
Out[42]:
   0   0.0
   1   1.0
   2   2.0
   3   3.0
   4   4.0
Length: 5, dtype: float64

Mimic the original behavior of passing a ndarray:

In [43]: s.rolling(2, min_periods=1).apply(lambda x: x[-1], raw=True)
Out[43]:
   0   0.0
   1   1.0
   2   2.0
   3   3.0
   4   4.0
Length: 5, dtype: float64

**DataFrame.interpolate has gained the limit_area kwarg**

*DataFrame.interpolate()* has gained a *limit_area* parameter to allow further control of which NaNs are replaced. Use *limit_area='inside'* to fill only NaNs surrounded by valid values or use *limit_area='outside'* to fill only NaNs outside the existing valid values while preserving those inside. (GH16284) See the full documentation here.

In [44]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan,
     ....: np.nan, 13, np.nan, np.nan])

In [45]: ser
Out[45]:
   0   NaN
   1   NaN
   2   5.0
   3   NaN
   4   NaN
   5   NaN
   6   13.0
   7   NaN
   8   NaN
Length: 9, dtype: float64

Fill one consecutive inside value in both directions

In [46]: ser.interpolate(limit_direction='both', limit_area='inside', limit=1)
Out[46]:
   0   NaN
   1   NaN
   2   5.0
   3   7.0
   4   NaN
   5   11.0
   6   13.0
(continues on next page)
Fill all consecutive outside values backward

In [47]: ser.interpolate(limit_direction='backward', limit_area='outside')
Out[47]:
0   5.0  
1   5.0  
2   5.0  
3   NaN  
4   NaN  
5   NaN  
6  13.0  
7   NaN  
8   NaN  
Length: 9, dtype: float64

Fill all consecutive outside values in both directions

In [48]: ser.interpolate(limit_direction='both', limit_area='outside')
Out[48]:
0   5.0  
1   5.0  
2   5.0  
3   NaN  
4   NaN  
5   NaN  
6  13.0  
7  13.0  
8  13.0  
Length: 9, dtype: float64

get_dummies now supports dtype argument

The `get_dummies()` now accepts a `dtype` argument, which specifies a dtype for the new columns. The default remains `uint8`. (GH18330)

In [49]: df = pd.DataFrame({'a': [1, 2], 'b': [3, 4], 'c': [5, 6]})
In [50]: pd.get_dummies(df, columns=['c']).dtypes
Out[50]:
a  int64
b  int64
c_5 uint8
c_6 uint8
Length: 4, dtype: object
In [51]: pd.get_dummies(df, columns=['c'], dtype=bool).dtypes
Out[51]:
a  int64
b  int64
c_5 bool
Length: 4, dtype: object

(continues on next page)
Timedelta mod method

mod(%) and divmod operations are now defined on Timedelta objects when operating with either timedelta-like or with numeric arguments. See the documentation here. (GH19365)

In [52]: td = pd.Timedelta(hours=37)
In [53]: td % pd.Timedelta(minutes=45)
Out[53]: Timedelta('0 days 00:15:00')

.rank() handles inf values when NaN are present

In previous versions, .rank() would assign inf elements NaN as their ranks. Now ranks are calculated properly. (GH6945)

In [54]: s = pd.Series([-np.inf, 0, 1, np.nan, np.inf])
In [55]: s
Out[55]:
0   -inf
1    0.0
2    1.0
3    NaN
4     inf
Length: 5, dtype: float64

Previous behavior:

In [11]: s.rank()
Out[11]:
0    1.0
1    2.0
2    3.0
3    NaN
4    NaN
dtype: float64

Current behavior:

In [56]: s.rank()
Out[56]:
0    1.0
1    2.0
2    3.0
3    NaN
4    4.0
Length: 5, dtype: float64

Furthermore, previously if you rank inf or -inf values together with NaN values, the calculation won’t distinguish NaN from infinity when using ‘top’ or ‘bottom’ argument.
In [57]: s = pd.Series([np.nan, np.nan, -np.inf, -np.inf])

In [58]: s
Out[58]:
0    NaN
1    NaN
2   -inf
3   -inf
Length: 4, dtype: float64

Previous behavior:

In [15]: s.rank(na_option='top')
Out[15]:
0   2.5
1   2.5
2   2.5
3   2.5
dtype: float64

Current behavior:

In [59]: s.rank(na_option='top')
Out[59]:
0   1.5
1   1.5
2   3.5
3   3.5
Length: 4, dtype: float64

These bugs were squashed:

- Bug in `DataFrame.rank()` and `Series.rank()` when method='dense' and pct=True in which percentile ranks were not being used with the number of distinct observations (GH15630)
- Bug in `Series.rank()` and `DataFrame.rank()` when ascending='False' failed to return correct ranks for infinity if NaN were present (GH19538)
- Bug in `DataFrameGroupBy.rank()` where ranks were incorrect when both infinity and NaN were present (GH20561)

`Series.str.cat` has gained the `join` kwarg

Previously, `Series.str.cat()` did not – in contrast to most of pandas – align `Series` on their index before concatenation (see GH18657). The method has now gained a keyword `join` to control the manner of alignment, see examples below and [here](#).

In v.0.23 `join` will default to None (meaning no alignment), but this default will change to 'left' in a future version of pandas.

In [60]: s = pd.Series(['a', 'b', 'c', 'd'])

In [61]: t = pd.Series(['b', 'd', 'e', 'c'], index=[1, 3, 4, 2])

In [62]: s.str.cat(t)
Out[62]:
0    NaN
(continues on next page)
Furthermore, `Series.str.cat()` now works for `CategoricalIndex` as well (previously raised a `ValueError`; see GH20842).

### DataFrame.astype performs column-wise conversion to Categorical

`DataFrame.astype()` can now perform column-wise conversion to `Categorical` by supplying the string 'category' or a `CategoricalDtype`. Previously, attempting this would raise a `NotImplementedError`. See the `Object creation` section of the documentation for more details and examples. (GH12860, GH18099)

Supplying the string 'category' performs column-wise conversion, with only labels appearing in a given column set as categories:

```python
In [64]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd'))
In [65]: df = df.astype('category')
In [66]: df['A'].dtype
Out[66]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=False)
In [67]: df['B'].dtype
Out[67]: CategoricalDtype(categories=['b', 'c', 'd'], ordered=False)
```

Supplying a `CategoricalDtype` will make the categories in each column consistent with the supplied dtype:

```python
In [68]: from pandas.api.types import CategoricalDtype
In [69]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd'))
In [70]: cdt = CategoricalDtype(categories=list('abcd'), ordered=True)
In [71]: df = df.astype(cdt)
In [72]: df['A'].dtype
Out[72]: CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)
In [73]: df['B'].dtype
Out[73]: CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)
```
Other enhancements

- Unary + now permitted for Series and DataFrame as numeric operator (GH16073)
- Better support for `to_excel()` output with the xlsxwriter engine. (GH16149)
- `pandas.tseries.frequencies.to_offset()` now accepts leading ‘+’ signs e.g. ‘+1h’. (GH18171)
- `MultiIndex.unique()` now supports the level= argument, to get unique values from a specific index level (GH18796)
- `pandas.io.formats.style.Styler` now has method `hide_index()` to determine whether the index will be rendered in output (GH14194)
- `pandas.io.formats.style.Styler` now has method `hide_columns()` to determine whether columns will be hidden in output (GH14194)
- Improved wording of `ValueError` raised in `to_datetime()` when unit= is passed with a non-convertible value (GH14350)
- `Series.fillna()` now accepts a Series or a dict as a value for a categorical dtype (GH17033)
- `pandas.read_clipboard()` updated to use qtpy, falling back to PyQt5 and then PyQt4, adding compatibility with Python3 and multiple python-qt bindings (GH17722)
- Improved wording of `ValueError` raised in `read_csv()` when the usecols argument cannot match all columns. (GH17301)
- `DataFrame.corrwith()` now silently drops non-numeric columns when passed a Series. Before, an exception was raised (GH18570).
- `IntervalIndex` now supports time zone aware `Interval` objects (GH18537, GH18538)
- `Series()` / `DataFrame()` tab completion also returns identifiers in the first level of a `MultiIndex()`. (GH16326)
- `read_excel()` has gained the `nrows` parameter (GH16645)
- `DataFrame.append()` can now in more cases preserve the type of the calling dataframe’s columns (e.g. if both are CategoricalIndex) (GH18359)
- `DataFrame.to_json()` and `Series.to_json()` now accept an index argument which allows the user to exclude the index from the JSON output (GH17394)
- `IntervalIndex.to_tuples()` has gained the `na_tuple` parameter to control whether NA is returned as a tuple of NA, or NA itself (GH18756)
- `Categorical.rename_categories`, `CategoricalIndex.rename_categories` and `Series.cat.rename_categories` can now take a callable as their argument (GH18862)
- `Interval` and `IntervalIndex` have gained a `length` attribute (GH18789)
- `Resampler` objects now have a functioning `pipe` method. Previously, calls to `pipe` were diverted to the mean method (GH17905).
- `is_scalar()` now returns True for DateOffset objects (GH18943).
- `DataFrame.pivot()` now accepts a list for the values= kwarg (GH17160).
- Added `pandas.api.extensions.register_dataframe_accessor()`, `pandas.api.extensions.register_series_accessor()`, and `pandas.api.extensions.register_index_accessor()`, accessor for libraries downstream of pandas to register custom accessors like `.cat` on pandas objects. See `Registering Custom Accessors` for more (GH14781).
• IntervalIndex.astype now supports conversions between subtypes when passed an IntervalDtype (GH19197)

• IntervalIndex and its associated constructor methods (from_arrays, from_breaks, from_tuples) have gained a dtype parameter (GH19262)

• Added pandas.core.groupby.SeriesGroupBy.is_monotonic_increasing() and pandas.core.groupby.SeriesGroupBy.is_monotonic_decreasing() (GH17015)

• For subclassed DataFrames, DataFrame.apply() will now preserve the Series subclass (if defined) when passing the data to the applied function (GH19822)

• DataFrame.from_dict() now accepts a columns argument that can be used to specify the column names when orient='index' is used (GH18529)

• Added option display.html.use_mathjax so MathJax can be disabled when rendering tables in Jupyter notebooks (GH19856, GH19824)

• DataFrame.replace() now supports the method parameter, which can be used to specify the replacement method when to_replace is a scalar, list or tuple and value is None (GH19632)

• Timestamp.month_name(), DatetimeIndex.month_name(), and Series.dt.month_name() are now available (GH12805)

• Timestamp.day_name() and DatetimeIndex.day_name() are now available to return day names with a specified locale (GH12806)

• DataFrame.to_sql() now performs a multi-value insert if the underlying connection supports itk rather than inserting row by row. SQLAlchemy dialects supporting multi-value inserts include: mysql, postgresql, sqlite and any dialect with supports_multivalues_insert. (GH14315, GH8953)

• read_html() now accepts a displayed_only keyword argument to controls whether or not hidden elements are parsed (True by default) (GH20027)

• read_html() now reads all <tbody> elements in a <table>, not just the first. (GH20690)

• quantile() and quantile() now accept the interpolation keyword, linear by default (GH20497)

• zip compression is supported via compression=zip in DataFrame.to_pickle(), Series.to_pickle(), DataFrame.to_csv(), Series.to_csv(), DataFrame.to_json(), Series.to_json(). (GH17778)

• WeekOfMonth constructor now supports n=0 (GH20517).

• DataFrame and Series now support matrix multiplication (@) operator (GH10259) for Python>=3.5

• Updated DataFrame.to_gbq() and pandas.read_gbq() signature and documentation to reflect changes from the Pandas-GBQ library version 0.4.0. Adds intersphinx mapping to Pandas-GBQ library. (GH20564)

• Added new writer for exporting Stata dta files in version 117, StataWriter117. This format supports exporting strings with lengths up to 2,000,000 characters (GH16450)

• to_hdf() and read_hdf() now accept an errors keyword argument to control encoding error handling (GH20835)

• cut() has gained the duplicates='raise' | 'drop' option to control whether to raise on duplicated edges (GH20947)

• date_range(), timedelta_range(), and interval_range() now return a linearly spaced index if start, stop, and periods are specified, but freq is not. (GH20808, GH20983, GH20976)
Backwards incompatible API changes

Dependencies have increased minimum versions

We have updated our minimum supported versions of dependencies (GH15184). If installed, we now require:

<table>
<thead>
<tr>
<th>Package</th>
<th>Minimum Version</th>
<th>Required</th>
<th>Issue</th>
</tr>
</thead>
<tbody>
<tr>
<td>python-dateutil</td>
<td>2.5.0</td>
<td>X</td>
<td>GH15184</td>
</tr>
<tr>

<td>GH20082</td>
</tr>
<tr>
<td>setuptools</td>
<td>24.2.0</td>
<td></td>
<td>GH20698</td>
</tr>
</tbody>
</table>

Instantiation from dicts preserves dict insertion order for python 3.6+

Until Python 3.6, dicts in Python had no formally defined ordering. For Python version 3.6 and later, dicts are ordered by insertion order, see PEP 468. Pandas will use the dict’s insertion order, when creating a `Series` or `DataFrame` from a dict and you’re using Python version 3.6 or higher. (GH19884)

Previous behavior (and current behavior if on Python < 3.6):

```
in [16]: pd.Series({'Income': 2000,
........:   'Expenses': -1500,
........:   'Taxes': -200,
........:   'Net result': 300})
```

```
Out[16]:
Expenses -1500
Income 2000
Net result 300
Taxes -200
dtype: int64
```

Note the Series above is ordered alphabetically by the index values.

New behavior (for Python >= 3.6):

```
in [74]: pd.Series({'Income': 2000,
........:   'Expenses': -1500,
........:   'Taxes': -200,
........:   'Net result': 300})
```

```
Out[74]:
Income 2000
Expenses -1500
Taxes -200
Net result 300
Length: 4, dtype: int64
```

Notice that the Series is now ordered by insertion order. This new behavior is used for all relevant pandas types (`Series`, `DataFrame`, `SparseSeries` and `SparseDataFrame`).

If you wish to retain the old behavior while using Python >= 3.6, you can use `.sort_index()`:

```
in [75]: pd.Series({'Income': 2000,
........:   'Expenses': -1500,
........:   'Taxes': -200,
```

(continues on next page)
.....:        'Net result': 300}).sort_index()
.....:
Out[75]:
Expenses  -1500
Income     2000
Net result  300
Taxes      -200
Length: 4, dtype: int64

Deprecate Panel

Panel was deprecated in the 0.20.x release, showing as a DeprecationWarning. Using Panel will now show a FutureWarning. The recommended way to represent 3-D data are with a MultiIndex on a DataFrame via the to_frame() or with the xarray package. Pandas provides a to_xarray() method to automate this conversion (GH13563, GH18324).

In [75]: import pandas._testing as tm

In [76]: p = tm.makePanel()

In [77]: p
Out[77]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 3 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D

Convert to a MultiIndex DataFrame

In [78]: p.to_frame()
Out[78]:
   major   minor
2000-01-03 A  0.469112  0.721555  0.404705
         B -1.135632  0.271860 -1.039268
         C  0.119209  0.276232 -1.344312
         D -2.104569  0.113648 -0.109050
2000-01-04 A -0.282863 -0.706771  0.577046
         B  1.212112 -0.424972 -0.370647
         C -1.044236 -1.087401  0.844885

pandas.core.common removals

The following error & warning messages are removed from pandas.core.common (GH13634, GH19769):

- PerformanceWarning
- UnsupportedFunctionCall
- UnsortedIndexError
- AbstractMethodError

These are available from import from pandas.errors (since 0.19.0).

Changes to make output of DataFrame.apply consistent

DataFrame.apply() was inconsistent when applying an arbitrary user-defined-function that returned a list-like with axis=1. Several bugs and inconsistencies are resolved. If the applied function returns a Series, then pandas will return a DataFrame; otherwise a Series will be returned, this includes the case where a list-like (e.g. tuple or list is returned) (GH16353, GH17437, GH17970, GH17348, GH17892, GH18573, GH17602, GH18775, GH18901, GH18919).

In [76]: df = pd.DataFrame(np.tile(np.arange(3), 6).reshape(6, -1) + 1,
                          columns=['A', 'B', 'C'])

In [77]: df
Out[77]:
          A  B  C
0   1   2   3
1   2   2   3
2   3   2   3
3   4   2   3
4   5   2   3

[6 rows x 3 columns]

Previous behavior: if the returned shape happened to match the length of original columns, this would return a DataFrame. If the return shape did not match, a Series with lists was returned.
In [3]: df.apply(lambda x: [1, 2, 3], axis=1)
Out[3]:
   A  B  C
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3

In [4]: df.apply(lambda x: [1, 2], axis=1)
Out[4]:
   0  1  2  3
0  [1, 2]
1  [1, 2]
2  [1, 2]
3  [1, 2]
4  [1, 2]
5  [1, 2]

dtype: object

New behavior: When the applied function returns a list-like, this will now always return a Series.

In [78]: df.apply(lambda x: [1, 2, 3], axis=1)
Out[78]:
   0  1  2  3
0  [1, 2]
1  [1, 2]
2  [1, 2]
3  [1, 2]
4  [1, 2]
5  [1, 2]

Length: 6, dtype: object

In [79]: df.apply(lambda x: [1, 2], axis=1)
Out[79]:
   0  1  2  3
0  [1, 2]
1  [1, 2]
2  [1, 2]
3  [1, 2]
4  [1, 2]
5  [1, 2]

Length: 6, dtype: object

To have expanded columns, you can use result_type='expand'

In [80]: df.apply(lambda x: [1, 2, 3], axis=1, result_type='expand')
Out[80]:
   0  1  2
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3

[6 rows x 3 columns]

To broadcast the result across the original columns (the old behaviour for list-likes of the correct length), you can use result_type='broadcast'. The shape must match the original columns.
In [81]: df.apply(lambda x: [1, 2, 3], axis=1, result_type='broadcast')
Out[81]:
    A  B  C
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3
[6 rows x 3 columns]

Returning a Series allows one to control the exact return structure and column names:

In [82]: df.apply(lambda x: pd.Series([1, 2, 3], index=['D', 'E', 'F']), axis=1)
Out[82]:
    D  E  F
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3
[6 rows x 3 columns]

Concatenation will no longer sort

In a future version of pandas pandas.concat() will no longer sort the non-concatenation axis when it is not already aligned. The current behavior is the same as the previous (sorting), but now a warning is issued when sort is not specified and the non-concatenation axis is not aligned (GH4588).

In [83]: df1 = pd.DataFrame({"a": [1, 2], "b": [1, 2]}, columns=['b', 'a'])
In [84]: df2 = pd.DataFrame({"a": [4, 5]})
In [85]: pd.concat([df1, df2])
Out[85]:
    b  a
  0  1.0 1
  1  2.0 2
  NaN 4
  NaN 5
[4 rows x 2 columns]

To keep the previous behavior (sorting) and silence the warning, pass sort=True

In [86]: pd.concat([df1, df2], sort=True)
Out[86]:
    a  b
  0  1  1.0
  1  2  2.0
  0  4  NaN
  1  5  NaN

(continues on next page)
To accept the future behavior (no sorting), pass `sort=False`

Note that this change also applies to `DataFrame.append()`, which has also received a `sort` keyword for controlling this behavior.

### Build changes

- Building pandas for development now requires `cython >= 0.24` (GH18613)
- Building from source now explicitly requires `setuptools` in `setup.py` (GH18113)
- Updated conda recipe to be in compliance with conda-build 3.0+ (GH18002)

### Index division by zero fills correctly

Division operations on `Index` and subclasses will now fill division of positive numbers by zero with `np.inf`, division of negative numbers by zero with `-np.inf` and `0 / 0` with `np.nan`. This matches existing `Series` behavior. (GH19322, GH19347)

**Previous behavior:**

| In [6]: index = pd.Int64Index([-1, 0, 1]) |
| In [7]: index / 0 |
| Out[7]: Int64Index([0, 0, 0], dtype='int64') |

# Previous behavior yielded different results depending on the type of zero in the divisor
| In [8]: index / 0.0 |
| Out[8]: Float64Index([-inf, nan, inf], dtype='float64') |

| In [9]: index = pd.UInt64Index([0, 1]) |
| In [10]: index / np.array([0, 0], dtype=np.uint64) |
| Out[10]: UInt64Index([0, 0], dtype='uint64') |

| In [11]: pd.RangeIndex(1, 5) / 0 |
| ZeroDivisionError: integer division or modulo by zero |

**Current behavior:**

| In [87]: index = pd.Int64Index([-1, 0, 1]) |
| In [88]: index / 0 |
| Out[88]: Float64Index([-inf, nan, inf], dtype='float64') |

# The result of division by zero should not depend on whether the zero is int or float
| In [89]: index / 0.0 |
| Out[89]: Float64Index([-inf, nan, inf], dtype='float64') |
In [90]: index = pd.UInt64Index([0, 1])

In [91]: index / np.array([0, 0], dtype=np.uint64)
Out[91]: Float64Index([nan, inf], dtype='float64')

In [92]: pd.RangeIndex(1, 5) / 0
Out[92]: Float64Index([inf, inf, inf, inf], dtype='float64')

Extraction of matching patterns from strings

By default, extracting matching patterns from strings with `str.extract()` used to return a `Series` if a single group was being extracted (a `DataFrame` if more than one group was extracted). As of Pandas 0.23.0 `str.extract()` always returns a `DataFrame`, unless `expand` is set to `False`. Finally, `None` was an accepted value for the `expand` parameter (which was equivalent to `False`), but now raises a `ValueError` (GH11386).

Previous behavior:

In [1]: s = pd.Series(['number 10', '12 eggs'])

In [2]: extracted = s.str.extract(r'.*(\d\d).*')

In [3]: extracted
Out [3]:
   0  10
   1  12
   dtype: object

In [4]: type(extracted)
Out [4]:
pandas.core.series.Series

New behavior:

In [93]: s = pd.Series(['number 10', '12 eggs'])

In [94]: extracted = s.str.extract(r'.*(\d\d).*')

In [95]: extracted
Out[95]:
   0
   0  10
   1  12
   [2 rows x 1 columns]

In [96]: type(extracted)
Out[96]: pandas.core.frame.DataFrame

To restore previous behavior, simply set `expand` to `False`:

In [97]: s = pd.Series(['number 10', '12 eggs'])

In [98]: extracted = s.str.extract(r'.*(\d\d).*', expand=False)
In [99]: extracted
Out[99]:
0   10
1   12
Length: 2, dtype: object

In [100]: type(extracted)
Out[100]: pandas.core.series.Series

Default value for the ordered parameter of CategoricalDtype

The default value of the ordered parameter for CategoricalDtype has changed from False to None to allow updating of categories without impacting ordered. Behavior should remain consistent for downstream objects, such as Categorical (GH18790)

In previous versions, the default value for the ordered parameter was False. This could potentially lead to the ordered parameter unintentionally being changed from True to False when users attempt to update categories if ordered is not explicitly specified, as it would silently default to False. The new behavior for ordered=None is to retain the existing value of ordered.

New behavior:

```python
In [2]: from pandas.api.types import CategoricalDtype
In [3]: cat = pd.Categorical(list('abcaba'), ordered=True, categories=list('cba'))
In [4]: cat
Out[4]:
[a, b, c, a, b, a]
Categories (3, object): [c < b < a]
In [5]: cdt = CategoricalDtype(categories=list('cbad'))
In [6]: cat.astype(cdt)
Out[6]:
[a, b, c, a, b, a]
Categories (4, object): [c < b < a < d]
```

Notice in the example above that the converted Categorical has retained ordered=True. Had the default value for ordered remained as False, the converted Categorical would have become unordered, despite ordered=False never being explicitly specified. To change the value of ordered, explicitly pass it to the new dtype, e.g. CategoricalDtype(categories=list('cbad'), ordered=False).

Note that the unintentional conversion of ordered discussed above did not arise in previous versions due to separate bugs that prevented astype from doing any type of category to category conversion (GH10696, GH18593). These bugs have been fixed in this release, and motivated changing the default value of ordered.
Better pretty-printing of DataFrames in a terminal

Previously, the default value for the maximum number of columns was `pd.options.display.max_columns=20`. This meant that relatively wide data frames would not fit within the terminal width, and pandas would introduce line breaks to display these 20 columns. This resulted in an output that was relatively difficult to read:

If Python runs in a terminal, the maximum number of columns is now determined automatically so that the printed data frame fits within the current terminal width (`pd.options.display.max_columns=0`) (GH17023). If Python runs as a Jupyter kernel (such as the Jupyter QtConsole or a Jupyter notebook, as well as in many IDEs), this value cannot be inferred automatically and is thus set to 20 as in previous versions. In a terminal, this results in a much nicer output:
Note that if you don’t like the new default, you can always set this option yourself. To revert to the old setting, you can run this line:

```
pd.options.display.max_columns = 20
```

**Datetimelike API changes**

- The default `Timedelta` constructor now accepts an ISO 8601 Duration string as an argument (GH19040)

- Subtracting `NaT` from a `Series` with `dtype='datetime64[ns]'` returns a `Series` with `dtype='timedelta64[ns]'` instead of `dtype='datetime64[ns]'` (GH18808)

- Addition or subtraction of `NaT` from `TimedeltaIndex` will return `TimedeltaIndex` instead of `DatetimeIndex` (GH19124)

- `TimedeltaIndex.shift()` and `TimedeltaIndex.shift()` will now raise `NullFrequencyError` (which subclasses `ValueError`, which was raised in older versions) when the index object frequency is `None` (GH19147)

- Addition and subtraction of `NaN` from a `Series` with `dtype='timedelta64[ns]'` will raise a `TypeError` instead of treating the `NaN` as `NaT` (GH19274)

- `NaT` division with `datetime.timedelta` will now return `NaN` instead of raising (GH17876)
- Operations between a `Series` with dtype `datetime64[ns]` and a `PeriodIndex` will correctly raise a `TypeError` (GH18850)
- Subtraction of `Series` with timezone-aware dtype `datetime64[ns]` with mis-matched timezones will raise a `TypeError` instead of `ValueError` (GH18817)
- `Timestamp` will no longer silently ignore unused or invalid `tz` or `tzinfo` keyword arguments (GH17690)
- `Timestamp` will no longer silently ignore invalid `freq` arguments (GH5168)
- `CacheableOffset` and `WeekDay` are no longer available in the `pandas.tseries.offsets` module (GH17830)
- `pandas.tseries.frequencies.get_freq_group()` and `pandas.tseries.frequencies.DAYS` are removed from the public API (GH18034)
- `Series.truncate()` and `DataFrame.truncate()` will raise a `ValueError` if the index is not sorted instead of an unhelpful `KeyError` (GH17935)
- `Series.first` and `DataFrame.first` will now raise a `TypeError` rather than `NotImplementedError` when the index is not a `DatetimeIndex` (GH20725).
- `Series.last` and `DataFrame.last` will now raise a `TypeError` rather than `NotImplementedError` when the index is not a `DatetimeIndex` (GH20725).
- Restricted `DateOffset` keyword arguments. Previously, `DateOffset` subclasses allowed arbitrary keyword arguments which could lead to unexpected behavior. Now, only valid arguments will be accepted. (GH17176, GH18226).
- `pandas.merge()` provides a more informative error message when trying to merge on timezone-aware and timezone-agnostic columns (GH15800)
- For `DatetimeIndex` and `TimedeltaIndex` with `freq=None`, addition or subtraction of integer-dtyped array or `Index` will raise a `NullFrequencyError` instead of `TypeError` (GH19895)
- `Timestamp` constructor now accepts a `nanosecond` keyword or positional argument (GH18898)
- `DatetimeIndex` will now raise an `AttributeError` when the `tz` attribute is set after instantiation (GH3746)
- `DatetimeIndex` with a `pytz` timezone will now return a consistent `pytz` timezone (GH18595)

**Other API changes**

- `Series.astype()` and `Index.astype()` with an incompatible dtype will now raise a `TypeError` rather than a `ValueError` (GH18231)
- Series construction with an object dtype-attribute datetime and `dtype=object` specified, will now return an `object`-dtyped `Series`, previously this would infer the datetime dtype (GH18231)
- A `Series` of dtype=category constructed from an empty dict will now have categories of dtype=object rather than dtype=float64, consistently with the case in which an empty list is passed (GH18515)
- All-NaN levels in a MultiIndex are now assigned `float` rather than `object` dtype, promoting consistency with `Index` (GH17929).
- Levels names of a MultiIndex (when not None) are now required to be unique: trying to create a MultiIndex with repeated names will raise a `ValueError` (GH18872)
- Both construction and renaming of `Index/MultiIndex` with non-hashable name/keys will now raise `TypeError` (GH20527)
• **Index.map()** can now accept Series and dictionary input objects (GH12756, GH18482, GH18509).

• **DataFrame.unstack()** will now default to filling with np.nan for object columns. (GH12815)

• **IntervalIndex** constructor will raise if the closed parameter conflicts with how the input data is inferred to be closed (GH18421)

• Inserting missing values into indexes will work for all types of indexes and automatically insert the correct type of missing value (NaN, NaT, etc.) regardless of the type passed in (GH18295)

• When created with duplicate labels, MultiIndex now raises a ValueError. (GH17464)

• **Series.fillna()** now raises a TypeError instead of a ValueError when passed a list, tuple or DataFrame as a value (GH18293)

• **pandas.DataFrame.merge()** no longer casts a float column to object when merging on int and float columns (GH16572)

• **pandas.merge()** now raises a ValueError when trying to merge on incompatible data types (GH9780)

• The default NA value for UInt64Index has changed from 0 to NaN, which impacts methods that mask with NA, such as UInt64Index.where() (GH18398)

• Refactored setup.py to use find_packages instead of explicitly listing out all subpackages (GH18535)

• Rearranged the order of keyword arguments in read_excel() to align with read_csv() (GH16672)

• *wide_to_long()* previously kept numeric-like suffixes as object dtype. Now they are cast to numeric if possible (GH17627)

• In read_excel(), the comment argument is now exposed as a named parameter (GH18735)

• Rearranged the order of keyword arguments in read_excel() to align with read_csv() (GH16672)

• The options html.border and mode.use_inf_as_null were deprecated in prior versions, these will now show FutureWarning rather than a DeprecationWarning (GH19003)

• **IntervalIndex** and IntervalDtype no longer support categorical, object, and string subtypes (GH19016)

• IntervalDtype now returns True when compared against 'interval' regardless of subtype, and IntervalDtype.name now returns 'interval' regardless of subtype (GH18980)

• KeyError now raises instead of ValueError in drop(), drop(), drop(), drop() when dropping a non-existent element in an axis with duplicates (GH19186)

• **Series.to_csv()** now accepts a compression argument that works in the same way as the compression argument in DataFrame.to_csv() (GH18958)

• Set operations (union, difference...) on IntervalIndex with incompatible index types will now raise a TypeError rather than a ValueError (GH19329)

• DateOffset objects render more simply, e.g. `<DateOffset: days=1>` instead of `<DateOffset: kwds={'days': 1}> (GH19403)

• Categorical.fillna now validates its value and method keyword arguments. It now raises when both or none are specified, matching the behavior of Series.fillna() (GH19682)

• pd.to_datetime('today') now returns a datetime, consistent with pd.Timestamp('today'); previously pd.to_datetime('today') returned a .normalized() datetime (GH19935)

• **Series.str.replace()** now takes an optional regex keyword which, when set to False, uses literal string replacement rather than regex replacement (GH16808)

• DatetimeIndex.strftime() and PeriodIndex.strftime() now return an Index instead of a numpy array to be consistent with similar accessors (GH20127)
• Constructing a Series from a list of length 1 no longer broadcasts this list when a longer index is specified (GH19714, GH20391).

• `DataFrame.to_dict()` with `orient='index'` no longer casts int columns to float for a DataFrame with only int and float columns (GH18580).

• A user-defined-function that is passed to `Series.rolling().aggregate()`, `DataFrame.rolling().aggregate()`, or its expanding cousins, will now always be passed a `Series`, rather than a `np.array`; `.apply()` only has the `raw` keyword, see here. This is consistent with the signatures of `.aggregate()` across pandas (GH20584).

• Rolling and Expanding types raise `NotImplementedError` upon iteration (GH11704).

Deprecations

• `Series.from_array` and `SparseSeries.from_array` are deprecated. Use the normal constructor `Series(.,)` and `SparseSeries(.,)` instead (GH18213).

• `DataFrame.as_matrix` is deprecated. Use `DataFrame.values` instead (GH18458).

• `Series.asobject`, `DatetimeIndex.asobject`, `PeriodIndex.asobject` and `TimeDeltaIndex.asobject` have been deprecated. Use `.astype(object)` instead (GH18572).

• Grouping by a tuple of keys now emits a `FutureWarning` and is deprecated. In the future, a tuple passed to 'by' will always refer to a single key that is the actual tuple, instead of treating the tuple as multiple keys. To retain the previous behavior, use a list instead of a tuple (GH18314).

• `Series.valid` is deprecated. Use `Series.dropna()` instead (GH18800).

• `read_excel()` has deprecated the `skip_footer` parameter. Use `skipfooter` instead (GH18836).

• `ExcelFile.parse()` has deprecated `sheetname` in favor of `sheet_name` for consistency with `read_excel()` (GH20920).

• The `is_copy` attribute is deprecated and will be removed in a future version (GH18801).

• `IntervalIndex.from_intervals` is deprecated in favor of the `IntervalIndex` constructor (GH19263).

• `DataFrame.from_items` is deprecated. Use `DataFrame.from_dict()` instead, or `DataFrame.from_dict(OrderedDict())` if you wish to preserve the key order (GH17320, GH17312).

• Indexing a `MultiIndex` or a `FloatIndex` with a list containing some missing keys will now show a `FutureWarning`, which is consistent with other types of indexes (GH17758).

• The `broadcast` parameter of `.apply()` is deprecated in favor of `result_type='broadcast'` (GH18577).

• The `reduce` parameter of `.apply()` is deprecated in favor of `result_type='reduce'` (GH18577).

• The `order` parameter of `factorize()` is deprecated and will be removed in a future release (GH19727).

• `Timestamp.weekday_name`, `DatetimeIndex.weekday_name`, and `Series.dt.weekday_name` are deprecated in favor of `Timestamp.day_name()`, `DatetimeIndex.day_name()`, and `Series.dt.day_name()` (GH12806).

• `pandas.tseries.plotting.tsplot` is deprecated. Use `Series.plot()` instead (GH18627).

• `Index.summary()` is deprecated and will be removed in a future version (GH18217).

• `NDFrame.get_fype_counts()` is deprecated and will be removed in a future version (GH18243).
The convert_datetime64 parameter in DataFrame.to_records() has been deprecated and will be removed in a future version. The NumPy bug motivating this parameter has been resolved. The default value for this parameter has also changed from True to None (GH18160).

Series.rolling().apply(), DataFrame.rolling().apply(), Series.expanding().apply(), and DataFrame.expanding().apply() have deprecated passing an np.array by default. One will need to pass the new raw parameter to be explicit about what is passed (GH20584).

The data, base, strides, flags and itemsize properties of the Series and Index classes have been deprecated and will be removed in a future version (GH20419).

DatetimeIndex.offset is deprecated. Use DatetimeIndex.freq instead (GH20716)

Floor division between an integer ndarray and a Timedelta is deprecated. Divide by Timedelta.value instead (GH19761)

Setting PeriodIndex.freq (which was not guaranteed to work correctly) is deprecated. Use PeriodIndex.asfreq() instead (GH20678)

Index.get_duplicates() is deprecated and will be removed in a future version (GH20239)

The previous default behavior of negative indices in Categorical.take is deprecated. In a future version it will change from meaning missing values to meaning positional indices from the right. The future behavior is consistent with Series.take() (GH20664).

Passing multiple axes to the axis parameter in DataFrame.dropna() has been deprecated and will be removed in a future version (GH20987)

Removal of prior version deprecations/changes

- Warnings against the obsolete usage Categorical(codes, categories), which were emitted for instance when the first two arguments to Categorical() had different dtypes, and recommended the use of Categorical.from_codes, have now been removed (GH8074)
- The levels and labels attributes of a MultiIndex can no longer be set directly (GH4039).
- pd.tseries.util.pivot_annual has been removed (deprecated since v0.19). Use pivot_table instead (GH18370)
- pd.tseries.util.isleapyear has been removed (deprecated since v0.19). Use .is_leap_year property in Datetime-likes instead (GH18370)
- pd.ordered_merge has been removed (deprecated since v0.19). Use pd.merge_ordered instead (GH18459)
- The SparseList class has been removed (GH14007)
- The pandas.io.wb and pandas.io.data stub modules have been removed (GH13735)
- Categorical.from_array has been removed (GH13854)
- The freq and how parameters have been removed from the rolling/expanding/ewm methods of DataFrame and Series (deprecated since v0.18). Instead, resample before calling the methods. (GH18601 & GH18668)
- DatetimeIndex.to_datetime, Timestamp.to_datetime, PeriodIndex.to_datetime, and Index.to_datetime have been removed (GH8254, GH14096, GH14113)
- read_csv() has dropped the skip_footer parameter (GH13386)
- read_csv() has dropped the as_recarray parameter (GH13373)
- read_csv() has dropped the buffer_lines parameter (GH13360)
pandas: powerful Python data analysis toolkit, Release 1.1.1

- `read_csv()` has dropped the `compact_ints` and `use_unsigned` parameters (GH13323)
- The `Timestamp` class has dropped the `offset` attribute in favor of `freq` (GH13593)
- The `Series`, `Categorical`, and `Index` classes have dropped the `reshape` method (GH13012)
- `pandas.tseries.frequencies.get_standard_freq` has been removed in favor of `pandas.tseries.frequencies.to_offset(freq).rule_code` (GH13874)
- The `freqstr` keyword has been removed from `pandas.tseries.frequencies.to_offset` in favor of `freq` (GH13874)
- The `Panel4D` and `PanelND` classes have been removed (GH13776)
- The `Panel` class has dropped the `to_long` and `toLong` methods (GH19077)
- The options `display.line_with` and `display.height` are removed in favor of `display.width` and `display.max_rows` respectively (GH4391, GH19107)
- The `labels` attribute of the `Categorical` class has been removed in favor of `Categorical.codes` (GH7768)
- The `flavor` parameter have been removed from `func:to_sql` method (GH13611)
- The modules `pandas.tools.hashing` and `pandas.util.hashing` have been removed (GH16223)
- The top-level functions `pd.rolling_*`, `pd.expanding_*` and `pd.ewm*` have been removed (Deprecated since v0.18). Instead, use the DataFrame/Series methods `rolling`, `expanding` and `ewm` (GH18723)
- Imports from `pandas.core.common` for functions such as `is_datetime64_dtype` are now removed. These are located in `pandas.api.types`. (GH13634, GH19769)
- The `infer_dst` keyword in `Series.tz_localize()`, `DatetimeIndex.tz_localize()` and `DatetimeIndex` have been removed. `infer_dst=True` is equivalent to `ambiguous='infer'`, and `infer_dst=False` to `ambiguous='raise'` (GH7963).
- When `.resample()` was changed from an eager to a lazy operation, like `.groupby()` in v0.18.0, we put in place compatibility (with a `FutureWarning`), so operations would continue to work. This is now fully removed, so a `Resampler` will no longer forward compat operations (GH20554)
- Remove long deprecated `axis=None` parameter from `.replace()` (GH20271)

**Performance improvements**

- Indexers on `Series` or `DataFrame` no longer create a reference cycle (GH17956)
- Added a keyword argument, `cache`, to `to_datetime()` that improved the performance of converting duplicate datetime arguments (GH11665)
- `DateOffset` arithmetic performance is improved (GH18218)
- Converting a `Series` of `Timedelta` objects to days, seconds, etc... sped up through vectorization of underlying methods (GH18092)
- Improved performance of `.map()` with a `Series/dict` input (GH15081)
- The overridden `Timedelta` properties of days, seconds and microseconds have been removed, leveraging their built-in Python versions instead (GH18242)
- `Series` construction will reduce the number of copies made of the input data in certain cases (GH17449)
- Improved performance of `Series.dt.date()` and `DatetimeIndex.date()` (GH18058)
- Improved performance of `Series.dt.time()` and `DatetimeIndex.time()` (GH18461)
• Improved performance of `IntervalIndex.symmetric_difference()` (GH18475)
• Improved performance of `DatetimeIndex` and `Series` arithmetic operations with Business-Month and Business-Quarter frequencies (GH18489)
• `Series() / DataFrame()` tab completion limits to 100 values, for better performance. (GH18587)
• Improved performance of `DataFrame.median()` with axis=1 when bottleneck is not installed (GH16468)
• Improved performance of `MultiIndex.get_loc()` for large indexes, at the cost of a reduction in performance for small ones (GH18519)
• Improved performance of `MultiIndex.remove_unused_levels()` when there are no unused levels, at the cost of a reduction in performance when there are (GH19289)
• Improved performance of `Index.get_loc()` for non-unique indexes (GH19478)
• Improved performance of pairwise `.rolling()` and `.expanding()` with `.cov()` and `.corr()` operations (GH17917)
• Improved performance of `pandas.core.groupby.GroupBy.rank()` (GH15779)
• Improved performance of variable `.rolling()` on `.min()` and `.max()` (GH19521)
• Improved performance of `pandas.core.groupby.GroupBy.ffill()` and `pandas.core.groupby.GroupBy.bfill()` (GH11296)
• Improved performance of `pandas.core.groupby.GroupBy.any()` and `pandas.core.groupby.GroupBy.all()` (GH15435)
• Improved performance of `pandas.core.groupby.GroupBy.pct_change()` (GH19165)
• Improved performance of `Series.isin()` in the case of categorical dtypes (GH20003)
• Improved performance of `getattr(Series, attr)` when the Series has certain index types. This manifested in slow printing of large Series with a `DatetimeIndex` (GH19764)
• Fixed a performance regression for `GroupBy.nth()` and `GroupBy.last()` with some object columns (GH19283)
• Improved performance of `pandas.core.arrays.Categorical.from_codes()` (GH18501)

Documentation changes

Thanks to all of the contributors who participated in the Pandas Documentation Sprint, which took place on March 10th. We had about 500 participants from over 30 locations across the world. You should notice that many of the API docstrings have greatly improved.

There were too many simultaneous contributions to include a release note for each improvement, but this GitHub search should give you an idea of how many docstrings were improved.

Special thanks to Marc Garcia for organizing the sprint. For more information, read the NumFOCUS blogpost recapping the sprint.

• Changed spelling of “numpy” to “NumPy”, and “python” to “Python”. (GH19017)
• Consistency when introducing code samples, using either colon or period. Rewrote some sentences for greater clarity, added more dynamic references to functions, methods and classes. (GH18941, GH18948, GH18973, GH19017)
• Added a reference to `DataFrame.assign()` in the concatenate section of the merging documentation (GH18665)
Bug fixes

Categorical

Warning: A class of bugs were introduced in pandas 0.21 with CategoricalDtype that affects the correctness of operations like merge, concat, and indexing when comparing multiple unordered Categorical arrays that have the same categories, but in a different order. We highly recommend upgrading or manually aligning your categories before doing these operations.

- Bug in Categorical.equals returning the wrong result when comparing two unordered Categorical arrays with the same categories, but in a different order (GH16603)
- Bug in pandas.api.types.union_categoricals() returning the wrong result when for unordered categoricals with the categories in a different order. This affected pandas.concat() with Categorical data (GH19096).
- Bug in pandas.merge() returning the wrong result when joining on an unordered Categorical that had the same categories but in a different order (GH19551)
- Bug in CategoricalIndex.get_indexer() returning the wrong result when target was an unordered Categorical that had the same categories as self but in a different order (GH19551)
- Bug in Index.astype() with a categorical dtype where the resultant index is not converted to a CategoricalIndex for all types of index (GH18630)
- Bug in Series.astype() and Categorical.astype() where an existing categorical data does not get updated (GH10696, GH18593)
- Bug in Series.str.split() with expand=True incorrectly raising an IndexError on empty strings (GH20002).
- Bug in Index constructor with dtype=CategoricalDtype(...) where categories and ordered are not maintained (GH19032)
- Bug in Series constructor with scalar and dtype=CategoricalDtype(...) where categories and ordered are not maintained (GH19565)
- Bug in Categorical.__iter__ not converting to Python types (GH19909)
- Bug in pandas.factorize() returning the unique codes for the uniques. This now returns a Categorical with the same dtype as the input (GH19721)
- Bug in pandas.factorize() including an item for missing values in the uniques return value (GH19721)
- Bug in Series.take() with categorical data interpreting -1 in indices as missing value markers, rather than the last element of the Series (GH20664)
Datetimelike

- Bug in `Series.__sub__()` subtracting a non-nanosecond `np.datetime64` object from a `Series` gave incorrect results (GH7996)
- Bug in `DatetimeIndex`, `TimedeltaIndex` addition and subtraction of zero-dimensional integer arrays gave incorrect results (GH19012)
- Bug in `DatetimeIndex` and `TimedeltaIndex` where adding or subtracting an array-like of `DateOffset` objects either raised (`np.array`, `pd.Index`) or broadcast incorrectly (`pd.Series`) (GH18849)
- Bug in `Series.__add__()` adding `Series` with dtype `timedelta64[ns]` to a timezone-aware `DatetimeIndex` incorrectly dropped timezone information (GH13905)
- Adding a `Period` object to a `datetime` or `Timestamp` object will now correctly raise a `TypeError` (GH17983)
- Bug in `Timestamp` where comparison with an array of `Timestamp` objects would result in a `RecursionError` (GH15183)
- Bug in `Series` floor-division where operating on a scalar `timedelta` raises an exception (GH18846)
- Bug in `DatetimeIndex` where the repr was not showing high-precision time values at the end of a day (e.g., 23:59:59.999999999) (GH19030)
- Bug in `.astype()` to non-ns `timedelta` units would hold the incorrect dtype (GH19176, GH19223, GH12425)
- Bug in subtracting `Series` from `NaT` incorrectly returning `NaT` (GH19158)
- Bug in `Series.truncate()` which raises `TypeError` with a monotonic `PeriodIndex` (GH17717)
- Bug in `pct_change()` using periods and `freq` returned different length outputs (GH7292)
- Bug in comparison of `DatetimeIndex` against `None` or `datetime.date` objects raising `TypeError` for `==` and `!=` comparisons instead of all-False and all-True, respectively (GH19301)
- Bug in `Timestamp` and `to_datetime()` where a string representing a barely out-of-bounds timestamp would be incorrectly rounded down instead of raising `OutOfBoundsDatetime` (GH19382)
- Bug in `Timestamp.floor()` `DatetimeIndex.floor()` where time stamps far in the future and past were not rounded correctly (GH19206)
- Bug in `to_datetime()` where passing an out-of-bounds datetime with `errors='coerce'` and `utc=True` would raise `OutOfBoundsDatetimetime` instead of parsing to `NaT` (GH19612)
- Bug in `DatetimeIndex` and `TimedeltaIndex` addition and subtraction where name of the returned object was not always set consistently. (GH19744)
- Bug in `DatetimeIndex` and `TimedeltaIndex` addition and subtraction where operations with numpy arrays raised `TypeError` (GH19847)
- Bug in `DatetimeIndex` and `TimedeltaIndex` where setting the `freq` attribute was not fully supported (GH20678)
Timedelta

- Bug in `Timedelta.__mul__()` where multiplying by NaT returned NaT instead of raising a `TypeError` (GH19819)
- Bug in `Series` with `dtype='timedelta64[ns]'` where addition or subtraction of `TimedeltaIndex` had results cast to `dtype='int64'` (GH17250)
- Bug in `Series` with `dtype='timedelta64[ns]'` where addition or subtraction of `TimedeltaIndex` could return a `Series` with an incorrect name (GH19043)
- Bug in `Timedelta.__floordiv__()` and `Timedelta.__rfloordiv__()` dividing by many incompatible numpy objects was incorrectly allowed (GH18846)
- Bug where dividing a scalar timedelta-like object with `TimedeltaIndex` performed the reciprocal operation (GH19125)
- Bug in `TimedeltaIndex` where division by a `Series` would return a `TimedeltaIndex` instead of a `Series` (GH19042)
- Bug in `Timedelta.__add__()`, `Timedelta.__sub__()` where adding or subtracting a np.timedelta64 object would return another np.timedelta64 instead of a `Timedelta` (GH19738)
- Bug in `Timedelta.__floordiv__()`, `Timedelta.__rfloordiv__()` where operating with a `Tick` object would raise a `TypeError` instead of returning a numeric value (GH19738)
- Bug in `Period.asfreq()` where periods near `datetime(1, 1, 1)` could be converted incorrectly (GH19643, GH19834)
- Bug in `Timedelta.total_seconds()` causing precision errors, for example `Timedelta('30S').total_seconds() == 30.000000000000004` (GH19458)
- Bug in `Timedelta.__rmod__()` where operating with a `numpy.timedelta64` returned a `timedelta64` object instead of a `Timedelta` (GH19820)
- Multiplication of `TimedeltaIndex` by `TimedeltaIndex` will now raise `TypeError` instead of raising `ValueError` in cases of length mis-match (GH19333)
- Bug in indexing a `TimedeltaIndex` with a np.timedelta64 object which was raising a `TypeError` (GH20393)

Timezones

- Bug in creating a `Series` from an array that contains both tz-naive and tz-aware values will result in a `Series` whose `dtype` is tz-aware instead of object (GH16406)
- Bug in comparison of timezone-aware `DatetimeIndex` against NaT incorrectly raising `TypeError` (GH19276)
- Bug in `DatetimeIndex.astype()` when converting between timezone aware datatypes, and converting from timezone aware to naive (GH18951)
- Bug in comparing `DatetimeIndex`, which failed to raise `TypeError` when attempting to compare timezone-aware and timezone-naive datetimelike objects (GH18162)
- Bug in localization of a naive, datetime string in a `Series` constructor with a `datetime64[ns, tz]` `dtype` (GH174151)
- `Timestamp.replace()` will now handle Daylight Savings transitions gracefully (GH18319)
- Bug in tz-aware `DatetimeIndex` where addition/subtraction with a `TimedeltaIndex` or array with `dtype='timedelta64[ns]'` was incorrect (GH17558)
• Bug in `DatetimeIndex.insert()` where inserting `NaT` into a timezone-aware index incorrectly raised (GH16357)

• Bug in `DataFrame` constructor, where tz-aware Datetimeindex and a given column name will result in an empty DataFrame (GH19157)

• Bug in `Timestamp.tz_localize()` where localizing a timestamp near the minimum or maximum valid values could overflow and return a timestamp with an incorrect nanosecond value (GH12677)

• Bug when iterating over `DatetimeIndex` that was localized with fixed timezone offset that rounded nanosecond precision to microseconds (GH19603)

• Bug in `DataFrame.diff()` that raised an `IndexError` with tz-aware values (GH18578)

• Bug in `melt()` that converted tz-aware dtypes to tz-naive (GH15785)

• Bug in `DataFrame.count()` that raised an `ValueError`, if `DataFrame.dropna()` was called for a single column with timezone-aware values. (GH13407)

Offsets

• Bug in WeekOfMonth and Week where addition and subtraction did not roll correctly (GH18510, GH18672, GH18864)

• Bug in WeekOfMonth and LastWeekOfMonth where default keyword arguments for constructor raised `ValueError` (GH19142)

• Bug in `FY5253Quarter`, LastWeekOfMonth where rollback and rollforward behavior was inconsistent with addition and subtraction behavior (GH18854)

• Bug in `FY5253` where datetime addition and subtraction incremented incorrectly for dates on the year-end but not normalized to midnight (GH18854)

• Bug in `FY5253` where date offsets could incorrectly raise an `AssertionError` in arithmetic operations (GH14774)

Numeric

• Bug in `Series` constructor with an int or float list where specifying `dtype=str`, `dtype='str'` or `dtype='U'` failed to convert the data elements to strings (GH16605)

• Bug in `Index` multiplication and division methods where operating with a `Series` would return an `Index` object instead of a `Series` object (GH19042)

• Bug in the `DataFrame` constructor in which data containing very large positive or very large negative numbers was causing `OverflowError` (GH18584)

• Bug in `Index` constructor with `dtype='uint64'` where int-like floats were not coerced to `UInt64Index` (GH18400)

• Bug in `DataFrame` flex arithmetic (e.g. `df.add(other, fill_value=foo)`) with a `fill_value` other than `None` failed to raise `NotImplementedError` in corner cases where either the frame or other has length zero (GH19522)

• Multiplication and division of numeric-dtyped `Index` objects with timedelta-like scalars returns `TimedeltaIndex` instead of raising `TypeError` (GH19333)

• Bug where `NaN` was returned instead of `0` by `Series.pct_change()` and `DataFrame.pct_change()` when `fill_method` is not `None` (GH19873)
Strings

- Bug in `Series.str.get()` with a dictionary in the values and the index not in the keys, raising `KeyError` (GH20671)

Indexing

- Bug in `Index` construction from list of mixed type tuples (GH18505)
- Bug in `Index.drop()` when passing a list of both tuples and non-tuples (GH18304)
- Bug in `DataFrame.drop()`, `Panel.drop()`, `Series.drop()`, `Index.drop()` where no `KeyError` is raised when dropping a non-existent element from an axis that contains duplicates (GH19186)
- Bug in indexing a datetimelike `Index` that raised `ValueError` instead of `IndexError` (GH18386)
- `Index.to_series()` now accepts `index` and `name` kwargs (GH18699)
- `DatetimeIndex.to_series()` now accepts `index` and `name` kwargs (GH18699)
- Bug in indexing non-scalar value from `Series` having non-unique `Index` will return value flattened (GH17610)
- Bug in indexing with iterator containing only missing keys, which raised no error (GH20748)
- Fixed inconsistency in `.ix` between list and scalar keys when the index has integer dtype and does not include the desired keys (GH20753)
- Bug in `__setitem__` when indexing a `DataFrame` with a 2-d boolean ndarray (GH18582)
- Bug in `str.extractall` when there were no matches empty `Index` was returned instead of appropriate `MultiIndex` (GH19034)
- Bug in `IntervalIndex` where empty and purely NA data was constructed inconsistently depending on the construction method (GH18421)
- Bug in `IntervalIndex.symmetric_difference()` where the symmetric difference with a non-`IntervalIndex` did not raise (GH18475)
- Bug in `IntervalIndex` where set operations that returned an empty `IntervalIndex` had the wrong dtype (GH19101)
- Bug in `DataFrame.drop_duplicates()` where no `KeyError` is raised when passing in columns that don’t exist on the `DataFrame` (GH19726)
- Bug in `Index` subclasses constructors that ignore unexpected keyword arguments (GH19348)
- Bug in `Index.difference()` when taking difference of an `Index` with itself (GH20040)
- Bug in `DataFrame.first_valid_index()` and `DataFrame.last_valid_index()` in presence of entire rows of NaNs in the middle of values (GH20499).
- Bug in `IntervalIndex` where some indexing operations were not supported for overlapping or non-monotonic `uint64` data (GH20636)
- Bug in `Series.is_unique` where extraneous output in stderr is shown if Series contains objects with `__ne__` defined (GH20661)
- Bug in `.loc` assignment with a single-element list-like incorrectly assigns as a list (GH19474)
- Bug in partial string indexing on a `Series/DataFrame` with a monotonic decreasing `DatetimeIndex` (GH19362)
- Bug in performing in-place operations on a `DataFrame` with a duplicate `Index` (GH17105)
pandas: powerful Python data analysis toolkit, Release 1.1.1

• Bug in `IntervalIndex.get_loc()` and `IntervalIndex.get_indexer()` when used with an `IntervalIndex` containing a single interval (GH17284, GH20921)
• Bug in `.loc` with a uint64 indexer (GH20722)

MultiIndex

• Bug in `MultiIndex.__contains__()` where non-tuple keys would return `True` even if they had been dropped (GH19027)
• Bug in `MultiIndex.set_labels()` which would cause casting (and potentially clipping) of the new labels if the level argument is not 0 or a list like `[0, 1, ...]` (GH19057)
• Bug in `MultiIndex.get_level_values()` which would return an invalid index on level of ints with missing values (GH17924)
• Bug in `MultiIndex.unique()` when called on empty `MultiIndex` (GH20568)
• Bug in `MultiIndex.unique()` which would not preserve level names (GH20570)
• Bug in `MultiIndex.remove_unused_levels()` which would fill nan values (GH18417)
• Bug in `MultiIndex.from_tuples()` which would fail to take zipped tuples in python3 (GH18434)
• Bug in `MultiIndex.get_loc()` which would fail to automatically cast values between float and int (GH18818, GH15994)
• Bug in `MultiIndex.get_loc()` which would cast boolean to integer labels (GH19086)
• Bug in `MultiIndex.get_loc()` which would fail to locate keys containing `NaN` (GH18485)
• Bug in `MultiIndex.get_loc()` in large `MultiIndex`, would fail when levels had different dtypes (GH18520)
• Bug in indexing where nested indexers having only numpy arrays are handled incorrectly (GH19686)

I/O

• `read_html()` now rewinds seekable IO objects after parse failure, before attempting to parse with a new parser. If a parser errors and the object is non-seekable, an informative error is raised suggesting the use of a different parser (GH17975)
• `DataFrame.to_html()` now has an option to add an id to the leading `<table>` tag (GH8496)
• Bug in `read_msgpack()` with a non existent file is passed in Python 2 (GH15296)
• Bug in `read_csv()` where a MultiIndex with duplicate columns was not being mangled appropriately (GH18062)
• Bug in `read_csv()` where missing values were not being handled properly when `keep_default_na=False` with dictionary `na_values` (GH19227)
• Bug in `read_csv()` causing heap corruption on 32-bit, big-endian architectures (GH20785)
• Bug in `read_csv()` where a file with 0 variables gave an `AttributeError` incorrectly. Now it gives an `EmptyDataError` (GH18184)
• Bug in `DataFrame.to_latex()` where pairs of braces meant to serve as invisible placeholders were escaped (GH18667)
• Bug in `DataFrame.to_latex()` where a NaN in a MultiIndex would cause an `IndexError` or incorrect output (GH14249)
• Bug in `DataFrame.to_latex()` where a non-string index-level name would result in an AttributeError (GH19981)

• Bug in `DataFrame.to_latex()` where the combination of an index name and the `index_names=False` option would result in incorrect output (GH18326)

• Bug in `DataFrame.to_latex()` where a MultiIndex with an empty string as its name would result in incorrect output (GH18669)

• Bug in `DataFrame.to_latex()` where missing space characters caused wrong escaping and produced non-valid latex in some cases (GH20859)

• Bug in `read_json()` where large numeric values were causing an OverflowError (GH18842)

• Bug in `DataFrame.to_parquet()` where an exception was raised if the write destination is S3 (GH19134)

  • `Interval` now supported in `DataFrame.to_excel()` for all Excel file types (GH19242)

  • `Timedelta` now supported in `DataFrame.to_excel()` for all Excel file types (GH19242, GH9155, GH19900)

• Bug in `pandas.io.stata.StataReader.value_labels()` raising an AttributeError when called on very old files. Now returns an empty dict (GH19417)

• Bug in `read_pickle()` when unpickling objects with `TimedeltaIndex` or `Float64Index` created with pandas prior to version 0.20 (GH19939)

• Bug in `pandas.io.json.json_normalize()` where sub-records are not properly normalized if any sub-records values are NoneType (GH20030)

• Bug in `usecols` parameter in `read_csv()` where error is not raised correctly when passing a string. (GH20529)

• Bug in `HDFStore.keys()` when reading a file with a soft link causes exception (GH20523)

• Bug in `HDFStore.select_column()` where a key which is not a valid store raised an AttributeError instead of a KeyError (GH17912)

**Plotting**

• Better error message when attempting to plot but matplotlib is not installed (GH19810).

• `DataFrame.plot()` now raises a `ValueError` when the x or y argument is improperly formed (GH18671)

• Bug in `DataFrame.plot()` when x and y arguments given as positions caused incorrect referenced columns for line, bar and area plots (GH20056)

• Bug in formatting tick labels with `datetime.time()` and fractional seconds (GH18478).

• `Series.plot.kde()` has exposed the args `ind` and `bw_method` in the docstring (GH18461). The argument `ind` may now also be an integer (number of sample points).

• `DataFrame.plot()` now supports multiple columns to the y argument (GH19699)
Groupby/resample/rolling

- Bug when grouping by a single column and aggregating with a class like list or tuple (GH18079)
- Fixed regression in DataFrame.groupby() which would not emit an error when called with a tuple key not in the index (GH18798)
- Bug in DataFrame.resample() which silently ignored unsupported (or mistyped) options for label, closed and convention (GH19303)
- Bug in DataFrame.groupby() where tuples were interpreted as lists of keys rather than as keys (GH17979, GH18249)
- Bug in DataFrame.groupby() where aggregation by first/last/min/max was causing timestamps to lose precision (GH19526)
- Bug in DataFrame.transform() where particular aggregation functions were being incorrectly cast to match the dtype(s) of the grouped data (GH1900)
- Bug in DataFrame.groupby() passing the on= kwarg, and subsequently using .apply() (GH17813)
- Bug in DataFrame.resample().aggregate not raising a KeyError when aggregating a non-existent column (GH16766, GH19566)
- Bug in DataFrameGroupBy.cumsum() and DataFrameGroupBy.cumprod() when skipna was passed (GH19806)
- Bug in DataFrame.resample() that dropped timezone information (GH13238)
- Bug in DataFrame.groupby() where transformations using np.all and np.any were raising a ValueError (GH20653)
- Bug in DataFrame.resample() where ffill, bfill, pad, backfill, fillna, interpolate, and asfreq were ignoring loffset. (GH20744)
- Bug in DataFrame.groupby() when applying a function that has mixed data types and the user supplied function can fail on the grouping column (GH20949)
- Bug in DataFrameGroupBy.rolling().apply() where operations performed against the associated DataFrameGroupBy object could impact the inclusion of the grouped item(s) in the result (GH14013)

Sparse

- Bug in which creating a SparseDataFrame from a dense Series or an unsupported type raised an uncontrolled exception (GH19374)
- Bug in SparseDataFrame.to_csv causing exception (GH19384)
- Bug in SparseSeries.memory_usage which caused segfault by accessing non sparse elements (GH19368)
- Bug in constructing a SparseArray: if data is a scalar and index is defined it will coerce to float64 regardless of scalar’s dtype. (GH19163)
Reshaping

- Bug in `DataFrame.merge()` where referencing a `CategoricalIndex` by name, where the `by` kwarg would `KeyError` (GH20777)
- Bug in `DataFrame.stack()` which fails trying to sort mixed type levels under Python 3 (GH18310)
- Bug in `DataFrame.unstack()` which casts int to float if `columns` is a `MultiIndex` with unused levels (GH17845)
- Bug in `DataFrame.unstack()` which raises an error if `index` is a `MultiIndex` with unused labels on the unstacked level (GH18562)
- Fixed construction of a `Series` from a `dict` containing NaN as key (GH18480)
- Fixed construction of a `DataFrame` from a `dict` containing NaN as key (GH18455)
- Disabled construction of a `Series` where len(index) > len(data) = 1, which previously would broadcast the data item, and now raises a `ValueError` (GH18819)
- Suppressed error in the construction of a `DataFrame` from a `dict` containing scalar values when the corresponding keys are not included in the passed index (GH18600)
- Fixed (changed from `object` to `float64`) dtype of `DataFrame` initialized with axes, no data, and `dtype=int` (GH19646)
- Bug in `Series.rank()` where Series containing NaT modifies the Series inplace (GH18521)
- Bug in `cut()` which fails when using readonly arrays (GH18773)
- Bug in `DataFrame.pivot_table()` which fails when the `aggfunc` arg is of type string. The behavior is now consistent with other methods like `agg` and `apply` (GH18713)
- Bug in `DataFrame.merge()` in which merging using `Index` objects as vectors raised an Exception (GH19427)
- Bug in `DataFrame.stack()`, `DataFrame.unstack()`, `Series.unstack()` which were not returning subclasses (GH15563)
- Bug in timezone comparisons, manifesting as a conversion of the index to UTC in `.concat()` (GH18523)
- Bug in `concat()` when concatenating sparse and dense series it returns only a `SparseDataFrame`. Should be a `DataFrame`. (GH18914, GH18686, and GH16874)
- Improved error message for `DataFrame.merge()` when there is no common merge key (GH19427)
- Bug in `DataFrame.merge()` which does an outer instead of a left join when being called with multiple `DataFrame` and some have non-unique indices (GH19624)
- `Series.rename()` now accepts `axis` as a kwarg (GH18589)
- Bug in `rename()` where an Index of same-length tuples was converted to a `MultiIndex` (GH19497)
- Comparisons between `Series` and `Index` would return a `Series` with an incorrect name, ignoring the Index’s name attribute (GH19582)
- Bug in `qcut()` where datetime and timedelta data with NaT present raised a `ValueError` (GH19768)
- Bug in `DataFrame.iterrows()`, which would infers strings not compliant to `ISO8601` to datetimes (GH19671)
- Bug in `Series` constructor with `Categorical` where a `ValueError` is not raised when an index of different length is given (GH19342)
- Bug in `DataFrame.astype()` where column metadata is lost when converting to categorical or a dictionary of dtypes (GH19920)
• Bug in `cut()` and `qcut()` where timezone information was dropped (GH19872)
• Bug in `Series` constructor with a `dtype=str`, previously raised in some cases (GH19853)
• Bug in `get_dummies()`, and `select_dtypes()`, where duplicate column names caused incorrect behavior (GH20848)
• Bug in `isna()`, which cannot handle ambiguous typed lists (GH20675)
• Bug in `concat()` which raises an error when concatenating TZ-aware dataframes and all-NaT dataframes (GH12396)
• Bug in `concat()` which raises an error when concatenating empty TZ-aware series (GH18447)

Other

• Improved error message when attempting to use a Python keyword as an identifier in a `numexpr` backed query (GH18221)
• Bug in accessing a `pandas.get_option()`, which raised `KeyError` rather than `OptionError` when looking up a non-existent option key in some cases (GH19789)
• Bug in `testing.assert_series_equal()` and `testing.assert_frame_equal()` for Series or DataFrames with differing unicode data (GH20503)

5.6 Version 0.22

5.6.1 v0.22.0 (December 29, 2017)

This is a major release from 0.21.1 and includes a single, API-breaking change. We recommend that all users upgrade to this version after carefully reading the release note (singular!).

Backwards incompatible API changes

Pandas 0.22.0 changes the handling of empty and all-NA sums and products. The summary is that

• The sum of an empty or all-NA Series is now 0
• The product of an empty or all-NA Series is now 1
• We’ve added a min_count parameter to .sum() and .prod() controlling the minimum number of valid values for the result to be valid. If fewer than min_count non-NA values are present, the result is NA. The default is 0. To return NaN, the 0.21 behavior, use min_count=1.
Some background: In pandas 0.21, we fixed a long-standing inconsistency in the return value of all-NA series depending on whether or not bottleneck was installed. See *Sum/prod of all-NaN or empty Series/DataFrames is now consistently NaN*. At the same time, we changed the sum and prod of an empty Series to also be NaN.

Based on feedback, we’ve partially reverted those changes.

**Arithmetic operations**

The default sum for empty or all-NA Series is now 0.

*pandas 0.21.x*

```
In [1]: pd.Series([]).sum()
Out[1]: nan

In [2]: pd.Series([np.nan]).sum()
Out[2]: nan
```

*pandas 0.22.0*

```
In [1]: pd.Series([]).sum()
Out[1]: 0.0

In [2]: pd.Series([np.nan]).sum()
Out[2]: 0.0
```

The default behavior is the same as pandas 0.20.3 with bottleneck installed. It also matches the behavior of NumPy’s `np.nansum` on empty and all-NA arrays.

To have the sum of an empty series return NaN (the default behavior of pandas 0.20.3 without bottleneck, or pandas 0.21.x), use the `min_count` keyword.

```
In [3]: pd.Series([]).sum(min_count=1)
Out[3]: nan
```

Thanks to the `skipna` parameter, the `.sum` on an all-NA series is conceptually the same as the `.sum` of an empty one with `skipna=True` (the default).

```
In [4]: pd.Series([np.nan]).sum(min_count=1)  # skipna=True by default
Out[4]: nan
```

The `min_count` parameter refers to the minimum number of *non-null* values required for a non-NA sum or product. `Series.prod()` has been updated to behave the same as `Series.sum()`, returning 1 instead.

```
In [5]: pd.Series([]).prod()
Out[5]: 1.0

In [6]: pd.Series([np.nan]).prod()
Out[6]: 1.0

In [7]: pd.Series([]).prod(min_count=1)
Out[7]: nan
```

These changes affect `DataFrame.sum()` and `DataFrame.prod()` as well. Finally, a few less obvious places in pandas are affected by this change.
Grouping by a categorical

Grouping by a Categorical and summing now returns 0 instead of NaN for categories with no observations. The product now returns 1 instead of NaN.

_pandas 0.21.x_

```python
In [8]: grouper = pd.Categorical(['a', 'a'], categories=['a', 'b'])

In [9]: pd.Series([1, 2]).groupby(grouper).sum()
Out[9]:
   a    3.0
   b   NaN
   dtype: float64
```

_pandas 0.22_

```python
In [8]: grouper = pd.Categorical(['a', 'a'], categories=['a', 'b'])

In [9]: pd.Series([1, 2]).groupby(grouper).sum()
Out[9]:
   a    3
   b    0
   Length: 2, dtype: int64
```

To restore the 0.21 behavior of returning NaN for unobserved groups, use `min_count>=1`.

```python
In [10]: pd.Series([1, 2]).groupby(grouper).sum(min_count=1)
Out[10]:
   a    3.0
   b   NaN
   Length: 2, dtype: float64
```

Resample

The sum and product of all-NA bins has changed from NaN to 0 for sum and 1 for product.

_pandas 0.21.x_

```python
In [11]: s = pd.Series([1, 1, np.nan, np.nan],
                   index=pd.date_range('2017', periods=4))
   ....:
   ....: s
Out[11]:
   2017-01-01    1.0
   2017-01-02    1.0
   2017-01-03   NaN
   2017-01-04   NaN
   Freq: D, dtype: float64

In [12]: s.resample('2d').sum()
Out[12]:
   2017-01-01    2.0
   2017-01-03   NaN
   Freq: 2D, dtype: float64
```

_pandas 0.22_
In [11]: s = pd.Series([1, 1, np.nan, np.nan],
                   index=pd.date_range('2017', periods=4))

In [12]: s.resample('2d').sum()
Out[12]:
2017-01-01    2.0
2017-01-03    0.0
Freq: 2D, Length: 2, dtype: float64

To restore the 0.21 behavior of returning NaN, use min_count>=1.

In [13]: s.resample('2d').sum(min_count=1)
Out[13]:
2017-01-01    2.0
2017-01-03   NaN
Freq: 2D, Length: 2, dtype: float64

In particular, upsampling and taking the sum or product is affected, as upsampling introduces missing values even if the original series was entirely valid.

pandas 0.21.x

In [14]: idx = pd.DatetimeIndex(['2017-01-01', '2017-01-02'])

In [15]: pd.Series([1, 2], index=idx).resample('12H').sum()
Out[15]:
2017-01-01 00:00:00    1.0
2017-01-01 12:00:00   NaN
2017-01-02 00:00:00    2.0
Freq: 12H, dtype: float64

pandas 0.22.0

In [14]: idx = pd.DatetimeIndex(['2017-01-01', '2017-01-02'])

In [15]: pd.Series([1, 2], index=idx).resample('12H').sum()
Out[15]:
2017-01-01 00:00:00    1
2017-01-01 12:00:00   0
2017-01-02 00:00:00    2
Freq: 12H, Length: 3, dtype: int64

Once again, the min_count keyword is available to restore the 0.21 behavior.

In [16]: pd.Series([1, 2], index=idx).resample('12H').sum(min_count=1)
Out[16]:
2017-01-01 00:00:00    1.0
2017-01-01 12:00:00   NaN
2017-01-02 00:00:00    2.0
Freq: 12H, Length: 3, dtype: float64
Rolling and expanding

Rolling and expanding already have a `min_periods` keyword that behaves similar to `min_count`. The only case that changes is when doing a rolling or expanding sum with `min_periods=0`. Previously this returned `NaN`, when fewer than `min_periods` non-NA values were in the window. Now it returns 0.

### pandas 0.21.1

```
In [17]: s = pd.Series([np.nan, np.nan])
In [18]: s.rolling(2, min_periods=0).sum()
Out[18]:
0    NaN
1    NaN
dtype: float64
```

### pandas 0.22.0

```
In [17]: s = pd.Series([np.nan, np.nan])
In [18]: s.rolling(2, min_periods=0).sum()
Out[18]:
0    0.0
1    0.0
Length: 2, dtype: float64
```

The default behavior of `min_periods=None`, implying that `min_periods` equals the window size, is unchanged.

### Compatibility

If you maintain a library that should work across pandas versions, it may be easiest to exclude pandas 0.21 from your requirements. Otherwise, all your `sum()` calls would need to check if the `Series` is empty before summing.

With `setuptools`, in your `setup.py` use:

```
install_requires=['pandas!=0.21.*', ...]
```

With `conda`, use

```
requirements:
  run:
    - pandas !=0.21.0, !=0.21.1
```

Note that the inconsistency in the return value for all-NA series is still there for pandas 0.20.3 and earlier. Avoiding pandas 0.21 will only help with the empty case.

5.7 Version 0.21

5.7.1 Version 0.21.1 (December 12, 2017)

This is a minor bug-fix release in the 0.21.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Temporarily restore matplotlib datetime plotting functionality. This should resolve issues for users who implicitly relied on pandas to plot datetimes with matplotlib. See here.
- Improvements to the Parquet IO functions introduced in 0.21.0. See here.

What’s new in v0.21.1

- Restore Matplotlib datetime converter registration
- New features
  - Improvements to the Parquet IO functionality
  - Other enhancements
- Deprecations
- Performance improvements
- Bug fixes
  - Conversion
  - Indexing
  - IO
  - Plotting
  - GroupBy/resample/rolling
  - Reshaping
  - Numeric
  - Categorical
  - String
- Contributors
**Restore Matplotlib datetime converter registration**

Pandas implements some matplotlib converters for nicely formatting the axis labels on plots with `datetime` or `Period` values. Prior to pandas 0.21.0, these were implicitly registered with matplotlib, as a side effect of `import pandas`.

In pandas 0.21.0, we required users to explicitly register the converter. This caused problems for some users who relied on those converters being present for regular `matplotlib.pyplot` plotting methods, so we’re temporarily reverting that change; pandas 0.21.1 again registers the converters on import, just like before 0.21.0.

We’ve added a new option to control the converters: `pd.options.plotting.matplotlib.register_converters`. By default, they are registered. Toggling this to False removes pandas’ formatters and restore any converters we overwrote when registering them (GH18301).

We’re working with the matplotlib developers to make this easier. We’re trying to balance user convenience (automatically registering the converters) with import performance and best practices (importing pandas shouldn’t have the side effect of overwriting any custom converters you’ve already set). In the future we hope to have most of the date-time formatting functionality in matplotlib, with just the pandas-specific converters in pandas. We’ll then gracefully deprecate the automatic registration of converters in favor of users explicitly registering them when they want them.

**New features**

**Improvements to the Parquet IO functionality**

- `DataFrame.to_parquet()` will now write non-default indexes when the underlying engine supports it. The indexes will be preserved when reading back in with `read_parquet()` (GH18581).
- `read_parquet()` now allows to specify the columns to read from a parquet file (GH18154)
- `read_parquet()` now allows to specify kwargs which are passed to the respective engine (GH18216)

**Other enhancements**

- `Timestamp.timestamp()` is now available in Python 2.7. (GH17329)
- `Grouper` and `TimeGrouper` now have a friendly repr output (GH18203).

**Deprecations**

- `pandas.tseries.register` has been renamed to `pandas.plotting.register_matplotlib_converters()` (GH18301)

**Performance improvements**

- Improved performance of plotting large series/dataframes (GH18236).
Bug fixes

Conversion

- Bug in `TimedeltaIndex` subtraction could incorrectly overflow when NaT is present (GH17791)
- Bug in `DatetimeIndex` subtracting datetimelike from DatetimeIndex could fail to overflow (GH18020)
- Bug in `IntervalIndex.copy()` when copying and `IntervalIndex` with non-default `closed` (GH18339)
- Bug in `DataFrame.to_dict()` where columns of datetime that are tz-aware were not converted to required arrays when used with `orient='records'`, raising TypeError (GH18372)
- Bug in `DateTimeIndex` and `date_range()` where mismatching tz-aware start and end timezones would not raise an err if `end.tzinfo` is None (GH18431)
- Bug in `Series.fillna()` which raised when passed a long integer on Python 2 (GH18159).

Indexing

- Bug in a boolean comparison of a `datetime.datetime` and a `datetime64[ns]` dtype Series (GH17965)
- Bug where a `MultiIndex` with more than a million records was not raising `AttributeError` when trying to access a missing attribute (GH18165)
- Bug in `IntervalIndex` constructor when a list of intervals is passed with non-default `closed` (GH18334)
- Bug in `Index.putmask` when an invalid mask passed (GH18368)
- Bug in masked assignment of a `timedelta64[ns]` dtype Series, incorrectly coerced to float (GH18493)

IO

- Bug in class:`pandas.io.stata.StataReader` not converting date/time columns with display formatting addressed (GH17990). Previously columns with display formatting were normally left as ordinal numbers and not converted to datetime objects.
- Bug in `read_csv()` when reading a compressed UTF-16 encoded file (GH18071)
- Bug in `read_csv()` for handling null values in index columns when specifying `na_filter=False` (GH5239)
- Bug in `read_csv()` when reading numeric category fields with high cardinality (GH18186)
- Bug in `DataFrame.to_csv()` when the table had `MultiIndex` columns, and a list of strings was passed in for `header` (GH5539)
- Bug in parsing integer datetime-like columns with specified format in `read_sql` (GH17855).
- Bug in `DataFrame.to_msgpack()` when serializing data of the `numpy.bool_` datatype (GH18390)
- Bug in `read_json()` not decoding when reading line delimited JSON from S3 (GH17200)
- Bug in `pandas.io.json.json_normalize()` to avoid modification of `meta` (GH18610)
- Bug in `to_latex()` where repeated `MultiIndex` values were not printed even though a higher level index differed from the previous row (GH14484)
- Bug when reading NaN-only categorical columns in `HDFStore` (GH18413)
• Bug in `DataFrame.to_latex()` with longtable=True where a latex multicolumn always spanned over three columns (GH17959)

Plotting

• Bug in `DataFrame.plot()` and `Series.plot()` with `DatetimeIndex` where a figure generated by them is not pickleable in Python 3 (GH18439)

GroupBy/resample/rolling

• Bug in `DataFrame.resample(...) .apply(...)` when there is a callable that returns different columns (GH15169)
• Bug in `DataFrame.resample(...)` when there is a time change (DST) and resampling frequency is 12h or higher (GH15549)
• Bug in `pd.DataFrameGroupBy.count()` when counting over a datetimelike column (GH13393)
• Bug in `rolling.var` where calculation is inaccurate with a zero-valued array (GH18430)

Reshaping

• Error message in `pd.merge_asof()` for key datatype mismatch now includes datatype of left and right key (GH18068)
• Bug in `pd.concat` when empty and non-empty DataFrames or Series are concatenated (GH18178 GH18187)
• Bug in `DataFrame.filter(...)` when unicode is passed as a condition in Python 2 (GH13101)
• Bug when merging empty DataFrames when `np.seterr(divide='raise')` is set (GH17776)

Numeric

• Bug in `pd.Series.rolling.skew()` and `rolling.kurt()` with all equal values has floating issue (GH18044)

Categorical

• Bug in `DataFrame.astype()` where casting to ‘category’ on an empty DataFrame causes a segmentation fault (GH18004)
• Error messages in the testing module have been improved when items have different CategoricalDtype (GH18069)
• CategoricalIndex can now correctly take a pd.api.types.CategoricalDtype as its dtype (GH18116)
• Bug in `Categorical.unique()` returning read-only codes array when all categories were NaN (GH18051)
• Bug in `DataFrame.groupby(axis=1)` with a CategoricalIndex (GH18432)
String

*Series.str.split()* will now propagate NaN values across all expanded columns instead of None (GH18450)

5.7.2 Version 0.21.0 (October 27, 2017)

This is a major release from 0.20.3 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

• Integration with Apache Parquet, including a new top-level `read_parquet()` function and `DataFrame.to_parquet()` method, see here.

• New user-facing `pandas.api.types.CategoricalDtype` for specifying categoricals independent of the data, see here.

• The behavior of `sum` and `prod` on all-NaN Series/DataFrames is now consistent and no longer depends on whether bottleneck is installed, and `sum` and `prod` on empty Series now return NaN instead of 0, see here.

• Compatibility fixes for pypy, see here.

• Additions to the `drop`, `reindex` and `rename` API to make them more consistent, see here.

• Addition of the new methods `DataFrame.infer_objects` (see here) and `GroupBy.pipe` (see here).

• Indexing with a list of labels, where one or more of the labels is missing, is deprecated and will raise a KeyError in a future version, see here.

Check the API Changes and deprecations before updating.
• New features
  – Integration with Apache Parquet file format
  – Method `infer_objects` type conversion
  – Improved warnings when attempting to create columns
  – Method `drop` now also accepts index/columns keywords
  – Methods `rename`, `reindex` now also accept axis keyword
  – `CategoricalDtype` for specifying categoricals
  – `GroupBy` objects now have a `pipe` method
  – `Categorical.rename_categories` accepts a dict-like
  – Other enhancements

• Backwards incompatible API changes
  – Dependencies have increased minimum versions
  – Sum/prod of all-NaN or empty Series/DataFrames is now consistently NaN
  – Indexing with a list with missing labels is deprecated
  – NA naming changes
  – Iteration of Series/Index will now return Python scalars
  – Indexing with a Boolean Index
  – `PeriodIndex` resampling
  – Improved error handling during item assignment in `pd.eval`
  – Dtype conversions
  – `MultiIndex` constructor with a single level
  – UTC localization with `Series`
  – Consistency of range functions
  – No automatic Matplotlib converters
  – Other API changes

• Deprecations
  – `Series.select` and `DataFrame.select`
  – `Series.argmax` and `Series.argmin`

• Removal of prior version deprecations/changes

• Performance improvements

• Documentation changes

• Bug fixes
  – Conversion
  – Indexing
  – IO
New features

Integration with Apache Parquet file format

Integration with Apache Parquet, including a new top-level `read_parquet()` and `DataFrame.to_parquet()` method, see here (GH15838, GH17438).

Apache Parquet provides a cross-language, binary file format for reading and writing data frames efficiently. Parquet is designed to faithfully serialize and de-serialize `DataFrame`s, supporting all of the pandas dtypes, including extension dtypes such as datetime with timezones.

This functionality depends on either the pyarrow or fastparquet library. For more details, see the IO docs on Parquet.

Method `infer_objects` type conversion

The `DataFrame.infer_objects()` and `Series.infer_objects()` methods have been added to perform dtype inference on object columns, replacing some of the functionality of the deprecated `convert_objects` method. See the documentation here for more details. (GH11221)

This method only performs soft conversions on object columns, converting Python objects to native types, but not any coercive conversions. For example:

```
In [1]: df = pd.DataFrame({'A': [1, 2, 3],
                      ...:                     'B': np.array([1, 2, 3], dtype='object'),
                      ...:                     'C': ['1', '2', '3'])

In [2]: df.dtypes
Out[2]:
A    int64
B    object
C    object
Length: 3, dtype: object

In [3]: df.infer_objects().dtypes
Out[3]:
A    int64
B    int64
```

(continues on next page)
Note that column 'C' was not converted - only scalar numeric types will be converted to a new type. Other types of conversion should be accomplished using the `to_numeric()` function (or `to_datetime()`, `to_timedelta()`).

```
In [4]: df = df.infer_objects()
In [5]: df['C'] = pd.to_numeric(df['C'], errors='coerce')
In [6]: df.dtypes
Out[6]:
    A    int64
    B    int64
    C    int64
    dtype: object
```

**Improved warnings when attempting to create columns**

New users are often puzzled by the relationship between column operations and attribute access on `DataFrame` instances (GH7175). One specific instance of this confusion is attempting to create a new column by setting an attribute on the `DataFrame`:

```
In [1]: df = pd.DataFrame({'one': [1., 2., 3.]})
In [2]: df.two = [4, 5, 6]
```

This does not raise any obvious exceptions, but also does not create a new column:

```
In [3]: df
Out[3]:
   one
   0 1.0
   1 2.0
   2 3.0
```

Setting a list-like data structure into a new attribute now raises a `UserWarning` about the potential for unexpected behavior. See `Attribute Access`.

**Method `drop` now also accepts index/columns keywords**

The `drop()` method has gained `index/columns` keywords as an alternative to specifying the `axis`. This is similar to the behavior of `reindex (GH12392)`.

For example:

```
In [7]: df = pd.DataFrame(np.arange(8).reshape(2, 4),
                     columns=['A', 'B', 'C', 'D'])
In [8]: df
Out[8]:
   A  B  C  D
```

(continues on next page)
In [9]: df.drop(['B', 'C'], axis=1)
Out[9]:
   A  D
0  0  3
1  4  7
[2 rows x 2 columns]

# the following is now equivalent
In [10]: df.drop(columns=['B', 'C'])
Out[10]:
   A  D
0  0  3
1  4  7
[2 rows x 2 columns]

### Methods rename, reindex now also accept axis keyword

The `DataFrame.rename()` and `DataFrame.reindex()` methods have gained the `axis` keyword to specify the axis to target with the operation (GH12392).

Here’s rename:

```python
In [11]: df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]})

In [12]: df.rename(str.lower, axis='columns')
Out[12]:
      a  b
0   1  4
1   2  5
2   3  6
[3 rows x 2 columns]

In [13]: df.rename(id, axis='index')
Out[13]:
       A    B
94659639659744  1  4
94659639659776  2  5
94659639659808  3  6
[3 rows x 2 columns]
```

And reindex:

```python
In [14]: df.reindex(['A', 'B', 'C'], axis='columns')
Out[14]:
   A  B  C
0  1  4 NaN
```

(continues on next page)
```python
In [15]: df.reindex([0, 1, 3], axis='index')
Out[15]:
   A  B
0  1.0 4.0
1  2.0 5.0
3  NaN NaN
[3 rows x 2 columns]
```

The “index, columns” style continues to work as before.

```python
In [16]: df.rename(index=id, columns=str.lower)
Out[16]:
      a  b
94659639659744  1 4
94659639659776  2 5
94659639659808  3 6
[3 rows x 2 columns]
```

```python
In [17]: df.reindex(index=[0, 1, 3], columns=['A', 'B', 'C'])
Out[17]:
   A  B  C
0  1.0 4.0  NaN
1  2.0 5.0  NaN
3  NaN NaN NaN
[3 rows x 3 columns]
```

We highly encourage using named arguments to avoid confusion when using either style.

**CategoricalDtype for specifying categoricals**

`pandas.api.types.CategoricalDtype` has been added to the public API and expanded to include the categories and ordered attributes. A CategoricalDtype can be used to specify the set of categories and orderedness of an array, independent of the data. This can be useful for example, when converting string data to a Categorical (GH14711, GH15078, GH16015, GH17643):

```python
In [18]: from pandas.api.types import CategoricalDtype

In [19]: s = pd.Series(['a', 'b', 'c', 'a'])  # strings

In [20]: dtype = CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)

In [21]: s.astype(dtype)
Out[21]:
0  a
1  b
2  c
3  a
```

(continues on next page)
One place that deserves special mention is in `read_csv()`. Previously, with `dtype={'col': 'category'}`, the returned values and categories would always be strings.

```python
In [22]: data = 'A,B
a,1
b,2
c,3'

In [23]: pd.read_csv(StringIO(data), dtype={'B': 'category'}).B.cat.categories
Out[23]: Index([1, 2, 3], dtype='object')
```

Notice the “object” dtype.

With a `CategoricalDtype` of all numerics, datetimes, or timedeltas, we can automatically convert to the correct type.

```python
In [24]: dtype = {'B': CategoricalDtype([1, 2, 3])}

In [25]: pd.read_csv(StringIO(data), dtype=dtype).B.cat.categories
Out[25]: Int64Index([1, 2, 3], dtype='int64')
```

The values have been correctly interpreted as integers.

The `.dtype` property of a `Categorical`, `CategoricalIndex` or a `Series` with categorical type will now return an instance of `CategoricalDtype`. While the repr has changed, `str(CategoricalDtype())` is still the string 'category'. We’ll take this moment to remind users that the preferred way to detect categorical data is to use `pandas.api.types.is_categorical_dtype()`, and not `str(dtype) == 'category'`. See the `CategoricalDtype docs` for more.

**GroupBy objects now have a pipe method**

GroupBy objects now have a `pipe` method, similar to the one on `DataFrame` and `Series`, that allow for functions that take a `GroupBy` to be composed in a clean, readable syntax. (GH17871)

For a concrete example on combining `.groupby` and `.pipe`, imagine having a DataFrame with columns for stores, products, revenue and sold quantity. We’d like to do a groupwise calculation of prices (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable.

First we set the data:

```python
In [26]: import numpy as np

In [27]: n = 1000

In [28]: df = pd.DataFrame({'Store': np.random.choice(['Store_1', 'Store_2'], n),
...:                     'Product': np.random.choice(['Product_1',
...:                                                 'Product_2',
...:                                                 'Product_3'
...:                                                 ], n),
...:                     'Revenue': (np.random.random(n) * 50 + 10).round(2),
...:                     'Quantity': np.random.randint(1, 10, size=n))
...

In [29]: df.head(2)
```
Now, to find prices per store/product, we can simply do:

```python
In [30]: (df.groupby(['Store', 'Product'])
    ....:   .pipe(lambda grp: grp.Revenue.sum() / grp.Quantity.sum())
    ....:   .unstack().round(2))
```

```
Out[30]:

<table>
<thead>
<tr>
<th>Product</th>
<th>Product_1</th>
<th>Product_2</th>
<th>Product_3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Store_1</td>
<td>6.73</td>
<td>6.72</td>
<td>7.14</td>
</tr>
<tr>
<td>Store_2</td>
<td>7.59</td>
<td>6.98</td>
<td>7.23</td>
</tr>
</tbody>
</table>
```

[2 rows x 3 columns]

See the documentation for more.

**Categorical.rename_categories accepts a dict-like**

rename_categories() now accepts a dict-like argument for new_categories. The previous categories are looked up in the dictionary's keys and replaced if found. The behavior of missing and extra keys is the same as in DataFrame.rename().

```python
In [31]: c = pd.Categorical(['a', 'a', 'b'])
In [32]: c.rename_categories({"a": "eh", "b": "bee"})
```

```
Out[32]: ['eh', 'eh', 'bee']
Categories (2, object): ['eh', 'bee']
```

**Warning:** To assist with upgrading pandas, rename_categories treats Series as list-like. Typically, Series are considered to be dict-like (e.g. in .rename, .map). In a future version of pandas rename_categories will change to treat them as dict-like. Follow the warning message’s recommendations for writing future-proof code.

```python
In [33]: c.rename_categories(pd.Series([0, 1], index=['a', 'c']))
```

```
FutureWarning:Treating Series 'new_categories' as a list-like and using the values. In a future version, 'rename_categories' will treat Series like a dictionary. For dict-like, use 'new_categories.to_dict()' For list-like, use 'new_categories.values'.
```

```
Out[33]: [0, 0, 1]
Categories (2, int64): [0, 1]
```
Other enhancements

New functions or methods

- `nearest()` is added to support nearest-neighbor upsampling (GH17496).
- `Index` has added support for a `to_frame` method (GH15230).

New keywords

- Added a `skipna` parameter to `infer_dtype()` to support type inference in the presence of missing values (GH17059).
- `Series.to_dict()` and `DataFrame.to_dict()` now support an `into` keyword which allows you to specify the `collections.Mapping` subclass that you would like returned. The default is `dict`, which is backwards compatible. (GH16122)
- `Series.set_axis()` and `DataFrame.set_axis()` now support the `inplace` parameter. (GH14636)
- `Series.to_pickle()` and `DataFrame.to_pickle()` have gained a `protocol` parameter (GH16252). By default, this parameter is set to `HIGHEST_PROTOCOL`.
- `read_feather()` has gained the `nthreads` parameter for multi-threaded operations (GH16359)
- `DataFrame.clip()` and `Series.clip()` have gained an `inplace` argument. (GH15388)
- `crosstab()` has gained a `margins_name` parameter to define the name of the row / column that will contain the totals when `margins=True`. (GH15972)
- `read_json()` now accepts a `chunksize` parameter that can be used when `lines=True`. If `chunksize` is passed, `read_json` now returns an iterator which reads in `chunksize` lines with each iteration. (GH17048)
- `read_json()` and `to_json()` now accept a `compression` argument which allows them to transparently handle compressed files. (GH17798)

Various enhancements

- Improved the import time of pandas by about 2.25x. (GH16764)
- Support for PEP 519 – Adding a file system path protocol on most readers (e.g. `read_csv()`) and writers (e.g. `DataFrame.to_csv()`) (GH13823).
- Added a `__fspath__` method to `pd.HDFStore`, `pd.ExcelFile`, and `pd.ExcelWriter` to work properly with the file system path protocol (GH13823).
- The `validate` argument for `merge()` now checks whether a merge is one-to-one, one-to-many, many-to-one, or many-to-many. If a merge is found to not be an example of specified merge type, an exception of type `MergeError` will be raised. For more, see here (GH16270)
- Added support for PEP 518 (`pyproject.toml`) to the build system (GH16745)
- `RangeIndex.append()` now returns a `RangeIndex` object when possible (GH16212)
- `Series.rename_axis()` and `DataFrame.rename_axis()` with `inplace=True` now return `None` while renaming the axis inplace. (GH15704)
- `api.types.infer_dtype()` now infers decimals. (GH15690)
- `DataFrame.select_dtypes()` now accepts scalar values for include/exclude as well as list-like. (GH16855)
• `date_range()` now accepts ‘YS’ in addition to ‘AS’ as an alias for start of year. (GH9313)
• `date_range()` now accepts ‘Y’ in addition to ‘A’ as an alias for end of year. (GH9313)
• `DataFrame.add_prefix()` and `DataFrame.add_suffix()` now accept strings containing the ‘%’ character. (GH17151)
• Read/write methods that infer compression (`read_csv()`, `read_table()`, `read_pickle()`, and `to_pickle()`) can now infer from path-like objects, such as `pathlib.Path`. (GH17206)
• `read_sas()` now recognizes much more of the most frequently used date (datetime) formats in SAS7BDAT files. (GH15871)
• `DataFrame.items()` and `Series.items()` are now present in both Python 2 and 3 and is lazy in all cases. (GH13918, GH17213)
• `pandas.io.formats.style.Styler.where()` has been implemented as a convenience for `pandas.io.formats.style.Styler.applymap()`. (GH17474)
• `MultiIndex.is_monotonic_decreasing()` has been implemented. Previously returned `False` in all cases. (GH16554)
• `read_excel()` raises `ImportError` with a better message if `xlrd` is not installed. (GH17613)
• `DataFrame.assign()` will preserve the original order of **kwargs for Python 3.6+ users instead of sorting the column names. (GH14207)
• `Series.reindex()`, `DataFrame.reindex()`, `Index.get_indexer()` now support list-like argument for tolerance. (GH17367)

**Backwards incompatible API changes**

**Dependencies have increased minimum versions**

We have updated our minimum supported versions of dependencies (GH15206, GH15543, GH15214). If installed, we now require:

<table>
<thead>
<tr>
<th>Package</th>
<th>Minimum Version</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numpy</td>
<td>1.9.0</td>
<td>X</td>
</tr>
<tr>
<td>Matplotlib</td>
<td>1.4.3</td>
<td></td>
</tr>
<tr>
<td>Scipy</td>
<td>0.14.0</td>
<td></td>
</tr>
<tr>
<td>Bottleneck</td>
<td>1.0.0</td>
<td></td>
</tr>
</tbody>
</table>

Additionally, support has been dropped for Python 3.4 (GH15251).

**Sum/prod of all-NaN or empty Series/DataFrames is now consistently NaN**

**Note:** The changes described here have been partially reverted. See the v0.22.0 Whatsnew for more.

The behavior of `sum` and `prod` on all-NaN Series/DataFrames no longer depends on whether `bottleneck` is installed, and return value of `sum` and `prod` on an empty Series has changed (GH9422, GH15507).

Calling `sum` or `prod` on an empty or all-NaN Series, or columns of a DataFrame, will result in NaN. See the docs.
Previously WITHOUT bottleneck installed:

```
In [2]: s.sum()
Out[2]: np.nan
```

Previously WITH bottleneck:

```
In [2]: s.sum()
Out[2]: 0.0
```

New behavior, without regard to the bottleneck installation:

```
In [34]: s.sum()
Out[34]: 0.0
```

Note that this also changes the sum of an empty Series. Previously this always returned 0 regardless of a bottleneck installation:

```
In [1]: pd.Series([]).sum()
Out[1]: 0
```

but for consistency with the all-NaN case, this was changed to return NaN as well:

```
In [35]: pd.Series([]).sum()
Out[35]: 0.0
```

**Indexing with a list with missing labels is deprecated**

Previously, selecting with a list of labels, where one or more labels were missing would always succeed, returning NaN for missing labels. This will now show a `FutureWarning`. In the future this will raise a `KeyError (GH15747)`. This warning will trigger on a `DataFrame` or a `Series` for using `.loc[]` or `[]` when passing a list-of-labels with at least 1 missing label. See the [deprecation docs](#).

```
In [36]: s = pd.Series([1, 2, 3])
In [37]: s
Out[37]:
0   1
1   2
2   3
Length: 3, dtype: int64

Previous behavior

```
In [4]: s.loc[[1, 2, 3]]
Out[4]:
1   2.0
2   3.0
3   NaN
dtype: float64
```

Current behavior
In [4]: s.loc[[1, 2, 3]]
Passing list-likes to .loc or [] with any missing label will raise
KeyError in the future, you can use .reindex() as an alternative.

See the documentation here:
https://pandas.pydata.org/pandas-docs/stable/indexing.html#deprecate-loc-reindex-
˓listlike

Out[4]:
1 2.0
2 3.0
3 NaN
dtype: float64

The idiomatic way to achieve selecting potentially not-found elements is via .reindex()

In [38]: s.reindex([1, 2, 3])
Out[38]:
1 2.0
2 3.0
3 NaN
Length: 3, dtype: float64

Selection with all keys found is unchanged.

In [39]: s.loc[[1, 2]]
Out[39]:
1 2
2 3
Length: 2, dtype: int64

NA naming changes

In order to promote more consistency among the pandas API, we have added additional top-level functions isna() and notna() that are aliases for isnull() and notnull(). The naming scheme is now more consistent with methods like .dropna() and .fillna(). Furthermore in all cases where .isnull() and .notnull() methods are defined, these have additional methods named .isna() and .notna(), these are included for classes Categorical, Index, Series, and DataFrame. (GH15001).

The configuration option pd.options.mode.use_inf_as_null is deprecated, and pd.options.mode.
use_inf_as_na is added as a replacement.

Iteration of Series/Index will now return Python scalars

Previously, when using certain iteration methods for a Series with dtype int or float, you would receive a numpy scalar, e.g. np.int64, rather than a Python int. Issue (GH10904) corrected this for Series.tolist() and list(Series). This change makes all iteration methods consistent, in particular, for __iter__() and .
map(); note that this only affects int/float dtypes. (GH13236, GH13258, GH14216).

In [40]: s = pd.Series([1, 2, 3])
In [41]: s
Out[41]:
0 1
Previously:

```
In [2]: type(list(s)[0])
Out[2]: numpy.int64
```

New behavior:

```
In [42]: type(list(s)[0])
Out[42]: int
```

Furthermore this will now correctly box the results of iteration for `DataFrame.to_dict()` as well.

```
In [43]: d = {'a': [1], 'b': ['b']}
In [44]: df = pd.DataFrame(d)
```

Previously:

```
In [8]: type(df.to_dict()['a'][0])
Out[8]: numpy.int64
```

New behavior:

```
In [45]: type(df.to_dict()['a'][0])
Out[45]: int
```

### Indexing with a Boolean Index

Previously when passing a boolean `Index` to `.loc`, if the index of the `Series/DataFrame` had boolean labels, you would get a label based selection, potentially duplicating result labels, rather than a boolean indexing selection (where `True` selects elements), this was inconsistent how a boolean numpy array indexed. The new behavior is to act like a boolean numpy array indexer. (GH17738)

Previous behavior:

```
In [46]: s = pd.Series([1, 2, 3], index=[False, True, False])
In [47]: s
Out[47]:
False  1
  True  2
  False 3
Length: 3, dtype: int64
```

```
In [59]: s.loc[pd.Index([True, False, True])]
Out[59]:
  True  2
  False 1
  False 3
  True  2
dtype: int64
```
Current behavior

```python
In [48]: s.loc[pd.Index([True, False, True])]
Out[48]:
False  1
False  3
Length: 2, dtype: int64
```

Furthermore, previously if you had an index that was non-numeric (e.g. strings), then a boolean Index would raise a
`KeyError`. This will now be treated as a boolean indexer.

Previously behavior:

```python
In [49]: s = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
In [50]: s
Out[50]:
a  1
b  2
c  3
Length: 3, dtype: int64
In [39]: s.loc[pd.Index([True, False, True])]
KeyError: "None of [Index([True, False, True], dtype='object')] are in the [index]"
```

Current behavior

```python
In [51]: s.loc[pd.Index([True, False, True])]
Out[51]:
a  1
c  3
Length: 2, dtype: int64
```

**PeriodIndex resampling**

In previous versions of pandas, resampling a `Series/DataFrame` indexed by a `PeriodIndex` returned a
`DatetimeIndex` in some cases (GH12884). Resampling to a multiplied frequency now returns a `PeriodIndex`
(GH15944). As a minor enhancement, resampling a `PeriodIndex` can now handle `NaT` values (GH13224)

Previous behavior:

```python
In [1]: pi = pd.period_range('2017-01', periods=12, freq='M')
In [2]: s = pd.Series(np.arange(12), index=pi)
In [3]: resampled = s.resample('2Q').mean()
In [4]: resampled
Out[4]:
2017-03-31  1.0
2017-09-30  5.5
2018-03-31 10.0
Freq: 2Q-DEC, dtype: float64
In [5]: resampled.index
Out[5]: DatetimeIndex(['2017-03-31', '2017-09-30', '2018-03-31'], dtype=˓→'datetime64[ns]', freq='2Q-DEC')
```
New behavior:

```python
In [52]: pi = pd.period_range('2017-01', periods=12, freq='M')
In [53]: s = pd.Series(np.arange(12), index=pi)
In [54]: resampled = s.resample('2Q').mean()
In [55]: resampled
Out[55]:
2017Q1   2.5
2017Q3   8.5
Freq: 2Q-DEC, Length: 2, dtype: float64
In [56]: resampled.index
Out[56]: PeriodIndex(['2017Q1', '2017Q3'], dtype='period[2Q-DEC]', freq='2Q-DEC')
```

Upsampling and calling `.ohlc()` previously returned a `Series`, basically identical to calling `.asfreq()`. OHLC upsampling now returns a `DataFrame` with columns open, high, low and close (GH13083). This is consistent with downsampling and `DatetimeIndex` behavior.

Previous behavior:

```python
In [1]: pi = pd.period_range(start='2000-01-01', freq='D', periods=10)
In [2]: s = pd.Series(np.arange(10), index=pi)
In [3]: s.resample('H').ohlc()
Out[3]:
2000-01-01 00:00 0.0
... ... ... ...
2000-01-10 23:00 NaN
Freq: H, Length: 240, dtype: float64
In [4]: s.resample('M').ohlc()
Out[4]:
          open  high  low  close
2000-01  0.0  9.0  0.0  9.0
```

New behavior:

```python
In [57]: pi = pd.period_range(start='2000-01-01', freq='D', periods=10)
In [58]: s = pd.Series(np.arange(10), index=pi)
In [59]: s.resample('H').ohlc()
Out[59]:
          open  high  low  close
2000-01-01 00:00 0.0  0.0  0.0  0.0
2000-01-01 01:00 NaN NaN NaN NaN
2000-01-01 02:00 NaN NaN NaN NaN
2000-01-01 03:00 NaN NaN NaN NaN
2000-01-01 04:00 NaN NaN NaN NaN
...     ...     ...     ...     ...
2000-01-10 19:00 NaN NaN NaN NaN
2000-01-10 20:00 NaN NaN NaN NaN
2000-01-10 21:00 NaN NaN NaN NaN
2000-01-10 22:00 NaN NaN NaN NaN
```
Improved error handling during item assignment in pd.eval

`pd.eval()` will now raise a `ValueError` when item assignment malfunctions, or inplace operations are specified, but there is no item assignment in the expression (GH16732)

Previously, if you attempted the following expression, you would get a not very helpful error message:

```python
In [3]: pd.eval("a = 1 + 2", target=arr, inplace=True)
...: IndexError: only integers, slices (':`), ellipsis ('`...`'), numpy.newaxis ('`None`') and integer or boolean arrays are valid indices
```

This is a very long way of saying numpy arrays don’t support string-item indexing. With this change, the error message is now this:

```python
In [3]: pd.eval("a = 1 + 2", target=arr, inplace=True)
...: ValueError: Cannot assign expression output to target
```

It also used to be possible to evaluate expressions inplace, even if there was no item assignment:

```python
In [4]: pd.eval("1 + 2", target=arr, inplace=True)
Out[4]: 3
```

However, this input does not make much sense because the output is not being assigned to the target. Now, a `ValueError` will be raised when such an input is passed in:

```python
In [4]: pd.eval("1 + 2", target=arr, inplace=True)
...: ValueError: Cannot operate inplace if there is no assignment
```
Dtype conversions

Previously assignments, `.where()` and `.fillna()` with a `bool` assignment, would coerce to same the type (e.g. int/float), or raise for datetimelikes. These will now preserve the bools with `object` dtypes. (GH16821).

```python
In [62]: s = pd.Series([1, 2, 3])

In [5]: s[1] = True

In [6]: s
Out[6]:
0   1
1   1
2   3
dtype: int64
```

New behavior

```python
In [63]: s[1] = True

In [64]: s
Out[64]:
0   1
1   True
2   3
Length: 3, dtype: object
```

Previously, as assignment to a datetimelike with a non-datetimelike would coerce the non-datetime-like item being assigned (GH14145).

```python
In [65]: s = pd.Series([pd.Timestamp('2011-01-01'), pd.Timestamp('2012-01-01')])

In [1]: s[1] = 1

In [2]: s
Out[2]:
0 2011-01-01 00:00:00.000000000
1 1970-01-01 00:00:00.000000001
Length: 2, dtype: datetime64[ns]
```

These now coerce to `object` dtype.

```python
In [66]: s[1] = 1

In [67]: s
Out[67]:
0 2011-01-01 00:00:00
1 1
Length: 2, dtype: object
```

- Inconsistent behavior in `.where()` with datetimelikes which would raise rather than coerce to `object` (GH16402)
- Bug in assignment against `int64` data with `np.ndarray` with `float64` dtype may keep `int64` dtype (GH14001)
**MultiIndex constructor with a single level**

The MultiIndex constructors no longer squeezes a MultiIndex with all length-one levels down to a regular Index. This affects all the MultiIndex constructors. (GH17178)

Previous behavior:

```
In [2]: pd.MultiIndex.from_tuples([('a',), ('b',)])
Out[2]: Index(['a', 'b'], dtype='object')
```

Length 1 levels are no longer special-cased. They behave exactly as if you had length 2+ levels, so a MultiIndex is always returned from all of the MultiIndex constructors:

```
In [68]: pd.MultiIndex.from_tuples([('a',), ('b',)])
Out[68]: MultiIndex([('a',),
                   ('b',)])
```

**UTC localization with Series**

Previously, `to_datetime()` did not localize datetime Series data when `utc=True` was passed. Now, `to_datetime()` will correctly localize Series with a `datetime64[ns, UTC]` dtype to be consistent with how list-like and Index data are handled. (GH6415).

Previous behavior

```
In [69]: s = pd.Series(['20130101 00:00:00'] * 3)
In [12]: pd.to_datetime(s, utc=True)
```

```
Out[12]:
0  2013-01-01
1  2013-01-01
2  2013-01-01
dtype: datetime64[ns]
```

New behavior

```
In [70]: pd.to_datetime(s, utc=True)
```

```
Out[70]:
0  2013-01-01 00:00:00+00:00
1  2013-01-01 00:00:00+00:00
2  2013-01-01 00:00:00+00:00
Length: 3, dtype: datetime64[ns, UTC]
```

Additionally, DataFrames with datetime columns that were parsed by `read_sql_table()` and `read_sql_query()` will also be localized to UTC only if the original SQL columns were timezone aware datetime columns.
Consistency of range functions

In previous versions, there were some inconsistencies between the various range functions: `date_range()`, `bdate_range()`, `period_range()`, `timedelta_range()`, and `interval_range()` (GH17471).

One of the inconsistent behaviors occurred when the `start`, `end` and `period` parameters were all specified, potentially leading to ambiguous ranges. When all three parameters were passed, `interval_range` ignored the `period` parameter, `period_range` ignored the `end` parameter, and the other range functions raised. To promote consistency among the range functions, and avoid potentially ambiguous ranges, `interval_range` and `period_range` will now raise when all three parameters are passed.

Previous behavior:

```python
In [2]: pd.interval_range(start=0, end=4, periods=6)
Out[2]:
IntervalIndex([0, 1, 2, 3],
closed='right',
dtype='interval[int64]')
```

```python
In [3]: pd.period_range(start='2017Q1', end='2017Q4', periods=6, freq='Q')
Out[3]:
PeriodIndex(['2017Q1', '2017Q2', '2017Q3', '2017Q4', '2018Q1', '2018Q2'],
closed='right',
dtype='period[Q-DEC]', freq='Q-DEC')
```

New behavior:

```python
In [2]: pd.interval_range(start=0, end=4, periods=6)
---------------------------------------------------------------------------
ValueError: Of the three parameters: start, end, and periods, exactly two must be
  specified
```

```python
In [3]: pd.period_range(start='2017Q1', end='2017Q4', periods=6, freq='Q')
---------------------------------------------------------------------------
ValueError: Of the three parameters: start, end, and periods, exactly two must be
  specified
```

Additionally, the endpoint parameter `end` was not included in the intervals produced by `interval_range`. However, all other range functions include `end` in their output. To promote consistency among the range functions, `interval_range` will now include `end` as the right endpoint of the final interval, except if `freq` is specified in a way which skips `end`.

Previous behavior:

```python
In [4]: pd.interval_range(start=0, end=4)
Out[4]:
IntervalIndex([0, 1, 2, 3],
closed='right',
dtype='interval[int64]')
```

New behavior:

```python
In [71]: pd.interval_range(start=0, end=4)
Out[71]:
IntervalIndex([0, 1, 2, 3, 4],
closed='right',
dtype='interval[int64]')
```
No automatic Matplotlib converters

Pandas no longer registers our `date`, `time`, `datetime`, `datetime64`, and `Period` converters with matplotlib when pandas is imported. Matplotlib plot methods (plt.plot, ax.plot,...), will not nicely format the x-axis for `DatetimeIndex` or `PeriodIndex` values. You must explicitly register these methods:

Pandas built-in `Series.plot` and `DataFrame.plot` will register these converters on first-use (GH17710).

**Note:** This change has been temporarily reverted in pandas 0.21.1, for more details see [here](#).

Other API changes

- The Categorical constructor no longer accepts a scalar for the `categories` keyword. (GH16022)
- Accessing a non-existent attribute on a closed `HDFStore` will now raise an `AttributeError` rather than a `ClosedFileError` (GH16301)
- `read_csv()` now issues a `UserWarning` if the `names` parameter contains duplicates (GH17095)
- `read_csv()` now treats 'null' and 'n/a' strings as missing values by default (GH16471, GH16078)
- `pandas.HDFStore`’s string representation is now faster and less detailed. For the previous behavior, use `pandas.HDFStore.info` (GH16503).
- Compression defaults in HDF stores now follow pytables standards. Default is no compression and if `complib` is missing and `complevel` > 0 `zlib` is used (GH15943)
- `Index.get_indexer_non_unique()` now returns a ndarray indexer rather than an `Index`; this is consistent with `Index.get_indexer()` (GH16819)
- Removed the `@slow` decorator from `pandas._testing`, which caused issues for some downstream packages’ test suites. Use `@pytest.mark.slow` instead, which achieves the same thing (GH16850)
- Moved definition of `MergeError` to the `pandas.errors` module.
- The signature of `Series.set_axis()` and `DataFrame.set_axis()` has been changed from `set_axis(axis, labels)` to `set_axis(labels, axis=0)`, for consistency with the rest of the API. The old signature is deprecated and will show a `FutureWarning` (GH14636)
- `Series.argmin()` and `Series.argmax()` will now raise a `TypeError` when used with `object` dtypes, instead of a `ValueError` (GH13595)
- `Period` is now immutable, and will now raise an `AttributeError` when a user tries to assign a new value to the `ordinal` or `freq` attributes (GH17116).
- `to_datetime()` when passed a tz-aware `origin=` kwarg will now raise a more informative `ValueError` rather than a `TypeError` (GH16842)
- `to_datetime()` now raises a `ValueError` when format includes `%W` or `%U` without also including day of the week and calendar year (GH16774)
- Renamed non-functional `index` to `index_col` in `read_stata()` to improve API consistency (GH16342)
- Bug in `DataFrame.drop()` caused boolean labels False and True to be treated as labels 0 and 1 respectively when dropping indices from a numeric index. This will now raise a `ValueError` (GH16877)
- Restricted `DateOffset` keyword arguments. Previously, `DateOffset` subclasses allowed arbitrary keyword arguments which could lead to unexpected behavior. Now, only valid arguments will be accepted. (GH17176)
Deprecations

- DataFrame.from_csv() and Series.from_csv() have been deprecated in favor of read_csv() (GH4191)
- read_excel() has deprecated sheetname in favor of sheet_name for consistency with .to_excel() (GH10559).
- read_excel() has deprecated parse_cols in favor of usecols for consistency with read_csv() (GH4988)
- read_csv() has deprecated the tupleize_cols argument. Column tuples will always be converted to a MultiIndex (GH17060)
- DataFrame.to_csv() has deprecated the tupleize_cols argument. MultiIndex columns will be always written as rows in the CSV file (GH17060)
- The convert parameter has been deprecated in the .take() method, as it was not being respected (GH16948)
- pd.options.html.border has been deprecated in favor of pd.options.display.html.border (GH15793).
- SeriesGroupBy.nth() has deprecated True in favor of 'all' for its kwarg dropna (GH11038).
- DataFrame.as_blocks() is deprecated, as this is exposing the internal implementation (GH17302)
- pd.TimeGrouper is deprecated in favor of pandas.Grouper (GH16747)
- cdate_range has been deprecated in favor of bdate_range(), which has gained weekmask and holidays parameters for building custom frequency date ranges. See the documentation for more details (GH17596)
- passing categories or ordered kwargs to Series.astype() is deprecated, in favor of passing a CategoricalDtype (GH17636)
- .get_value and .set_value on Series, DataFrame, Panel, SparseSeries, and SparseDataFrame are deprecated in favor of using .iat[] or .at[] accessors (GH15269)
- Passing a non-existent column in .to_excel(..., columns=) is deprecated and will raise a KeyError in the future (GH17295)
- raise_on_error parameter to Series.where(), Series.mask(), DataFrame.where(), DataFrame.mask() is deprecated, in favor of errors= (GH14968)
- Using DataFrame.rename_axis() and Series.rename_axis() to alter index or column labels is now deprecated in favor of using .rename. rename_axis may still be used to alter the name of the index or columns (GH17833).
- reindex_axis() has been deprecated in favor of reindex(). See here for more (GH17833).

Series.select and DataFrame.select

The Series.select() and DataFrame.select() methods are deprecated in favor of using df.loc[labels.map(crit)] (GH12401)

```python
In [72]: df = pd.DataFrame({'A': [1, 2, 3]}, index=['foo', 'bar', 'baz'])
```
Series.argmax and Series.argmin

The behavior of `Series.argmax()` and `Series.argmin()` have been deprecated in favor of `Series.idxmax()` and `Series.idxmin()`, respectively (GH16830).

For compatibility with NumPy arrays, `pd.Series` implements `argmax` and `argmin`. Since pandas 0.13.0, `argmax` has been an alias for `pandas.Series.idxmax()`, and `argmin` has been an alias for `pandas.Series.idxmin()`. They return the `label` of the maximum or minimum, rather than the `position`.

We’ve deprecated the current behavior of `Series.argmax` and `Series.argmin`. Using either of these will emit a `FutureWarning`. Use `Series.idxmax()` if you want the label of the maximum. Use `Series.values.argmax()` if you want the position of the maximum. Likewise for the minimum. In a future release `Series.argmax` and `Series.argmin` will return the position of the maximum or minimum.

Removal of prior version deprecations/changes

- `read_excel()` has dropped the `has_index_names` parameter (GH10967)
- The `pd.options.display.height` configuration has been dropped (GH3663)
- The `pd.options.display.line_width` configuration has been dropped (GH2881)
- The `pd.options.display.mpl_style` configuration has been dropped (GH12190)
- Index has dropped the `.sym_diff()` method in favor of `.symmetric_difference()` (GH12591)
- Categorical has dropped the `.order()` and `.sort()` methods in favor of `.sort_values()` (GH12882)
- `eval()` and `DataFrame.eval()` have changed the default of `inplace` from `None` to `False` (GH11149)
- The function `get_offset_name` has been dropped in favor of the `.freqstr` attribute for an offset (GH11834)
- pandas no longer tests for compatibility with hdf5-files created with pandas < 0.11 (GH17404).
Performance improvements

- Improved performance of instantiating SparseDataFrame (GH16773)
- Series.dt no longer performs frequency inference, yielding a large speedup when accessing the attribute (GH17210)
- Improved performance of set_categories() by not materializing the values (GH17508)
- Timestamp.microsecond no longer re-computes on attribute access (GH17331)
- Improved performance of the CategoricalIndex for data that is already categorical dtype (GH17513)
- Improved performance of RangeIndex.min() and RangeIndex.max() by using RangeIndex properties to perform the computations (GH17607)

Documentation changes

- Several NaT method docstrings (e.g. NaT.ctime()) were incorrect (GH17327)
- The documentation has had references to versions < v0.17 removed and cleaned up (GH17442, GH17442, GH17404 & GH17504)

Bug fixes

Conversion

- Bug in assignment against datetime-like data with int may incorrectly convert to datetime-like (GH14145)
- Bug in assignment against int64 data with np.ndarray with float64 dtype may keep int64 dtype (GH14001)
- Fixed the return type of IntervalIndex.is_non_overlapping_monotonic to be a Python bool for consistency with similar attributes/methods. Previously returned a numpy.bool_. (GH17237)
- Bug in IntervalIndex.is_non_overlapping_monotonic when intervals are closed on both sides and overlap at a point (GH16560)
- Bug in Series.fillna() returns frame when inplace=True and value is dict (GH16156)
- Bug in Timestamp.weekday_name returning a UTC-based weekday name when localized to a timezone (GH17354)
- Bug in Timestamp.replace when replacing tzinfo around DST changes (GH15683)
- Bug in Timedelta construction and arithmetic that would not propagate the Overflow exception (GH17367)
- Bug in astype() converting to object dtype when passed extension type classes (DateTimeTZDtype, CategoricalDtype) rather than instances. Now a TypeError is raised when a class is passed (GH17780).
- Bug in to_numeric() in which elements were not always being coerced to numeric when errors='coerce' (GH17007, GH17125)
- Bug in DataFrame and Series constructors where range objects are converted to int32 dtype on Windows instead of int64 (GH16804)
Indexing

- When called with a null slice (e.g. `df.iloc[:])`, the `iloc` and `loc` indexers return a shallow copy of the original object. Previously they returned the original object. (GH13873).
- When called on an unsorted `MultiIndex`, the `loc` indexer now will raise `UnsortedIndexError` only if proper slicing is used on non-sorted levels (GH16734).
- Fixes regression in 0.20.3 when indexing with a string on a `TimedeltaIndex` (GH16896).
- Fixed `TimedeltaIndex.get_loc()` handling of `np.timedelta64` inputs (GH16909).
- Fix `MultiIndex.sort_index()` ordering when ascending argument is a list, but not all levels are specified, or are in a different order (GH16934).
- Fixes bug where indexing with `np.inf` caused an `OverflowError` to be raised (GH16957)
- Bug in reindexing on an empty `CategoricalIndex` (GH16770)
- Fixes `DataFrame.loc` for setting with alignment and tz-aware `DatetimeIndex` (GH16889)
- Avoids `IndexError` when passing an `Index` or `Series` to `iloc` with older numpy (GH17193)
- Allow unicode empty strings as placeholders in multilevel columns in Python 2 (GH17099)
- Bug in `iloc` when used with inplace addition or assignment and an int indexer on a `MultiIndex` causing the wrong indexes to be read from and written to (GH17148)
- Bug in `isin()` in which checking membership in empty `Series` objects raised an error (GH16991)
- Bug in `CategoricalIndex` reindexing in which specified indices containing duplicates were not being respected (GH17323)
- Bug in intersection of `RangeIndex` with negative step (GH17296)
- Bug in `IntervalIndex` where performing a scalar lookup fails for included right endpoints of non-overlapping monotonic decreasing indexes (GH16417, GH17271)
- Bug in `DataFrame.first_valid_index()` and `DataFrame.last_valid_index()` when no valid entry (GH17400)
- Bug in `Series.rename()` when called with a callable, incorrectly alters the name of the `Series`, rather than the name of the `Index`. (GH17407)
- Bug in `String.str_get()` raises `IndexError` instead of inserting NaNs when using a negative index. (GH17704)

IO

- Bug in `read_hdf()` when reading a timezone aware index from fixed format HDFStore (GH17618)
- Bug in `read_csv()` in which columns were not being thoroughly de-duplicated (GH17060)
- Bug in `read_csv()` in which specified column names were not being thoroughly de-duplicated (GH17095)
- Bug in `read_csv()` in which non integer values for the header argument generated an unhelpful / unrelated error message (GH16338)
- Bug in `read_csv()` in which memory management issues in exception handling, under certain conditions, would cause the interpreter to segfault (GH14696, GH16798).
- Bug in `read_csv()` when called with `low_memory=False` in which a CSV with at least one column > 2GB in size would incorrectly raise a `MemoryError` (GH16798).
• Bug in `read_csv()` when called with a single-element list `header` would return a DataFrame of all NaN values (GH7757)

• Bug in `DataFrame.to_csv()` defaulting to ‘ascii’ encoding in Python 3, instead of ‘utf-8’ (GH17097)

• Bug in `read_stata()` where value labels could not be read when using an iterator (GH16923)

• Bug in `read_stata()` where the index was not set (GH16342)

• Bug in `read_html()` where import check fails when run in multiple threads (GH16928)

• Bug in `read_csv()` where automatic delimiter detection caused a `TypeError` to be thrown when a bad line was encountered rather than the correct error message (GH13374)

• Bug in `DataFrame.to_html()` with `notebook=True` where DataFrames with named indices or non-MultiIndex indices had undesired horizontal or vertical alignment for column or row labels, respectively (GH16792)

• Bug in `DataFrame.to_html()` in which there was no validation of the `justify` parameter (GH17527)

• Bug in `HDFStore.select()` when reading a contiguous mixed-data table featuring VLArray (GH17021)

• Bug in `to_json()` where several conditions (including objects with unprintable symbols, objects with deep recursion, overlong labels) caused segfaults instead of raising the appropriate exception (GH14256)

### Plotting

• Bug in plotting methods using `secondary_y` and `fontsize` not setting secondary axis font size (GH12565)

• Bug when plotting `timedelta` and `datetime` dtypes on y-axis (GH16953)

• Line plots no longer assume monotonic x data when calculating xlims, they show the entire lines now even for unsorted x data. (GH11310, GH11471)

• With matplotlib 2.0.0 and above, calculation of x limits for line plots is left to matplotlib, so that its new default settings are applied. (GH15495)

• Bug in `Series.plot.bar` or `DataFrame.plot.bar` with `y` not respecting user-passed `color` (GH16822)

• Bug causing `plotting.parallel_coordinates` to reset the random seed when using random colors (GH17525)

### GroupBy/resample/rolling

• Bug in `DataFrame.resample(...) .size()` where an empty DataFrame did not return a Series (GH14962)

• Bug in `infer_freq()` causing indices with 2-day gaps during the working week to be wrongly inferred as business daily (GH16624)

• Bug in `.rolling(...) .quantile()` which incorrectly used different defaults than `Series. quantile()` and `DataFrame.quantile()` (GH9413, GH16211)

• Bug in `groupby.transform()` that would coerce boolean dtypes back to float (GH16875)

• Bug in `Series.resample(...) .apply()` where an empty Series modified the source index and did not return the name of a Series (GH14313)

• Bug in `.rolling(...) .apply(...)` with a DataFrame with a DatetimeIndex, a window of a timedelta-convertible and `min_periods >= 1` (GH15305)
pandas: powerful Python data analysis toolkit, Release 1.1.1

- Bug in `DataFrame.groupby` where index and column keys were not recognized correctly when the number of keys equaled the number of elements on the groupby axis (GH16859)
- Bug in `groupby.nunique()` with `TimeGrouper` which cannot handle `NaT` correctly (GH17575)
- Bug in `DataFrame.groupby` where a single level selection from a `MultiIndex` unexpectedly sorts (GH17537)
- Bug in `DataFrame.groupby` where spurious warning is raised when `Grouper` object is used to override ambiguous column name (GH17383)
- Bug in `groupby` differs when passes as a list and as a scalar (GH17530)

Sparse

- Bug in `SparseSeries` raises `AttributeError` when a dictionary is passed in as data (GH16905)
- Bug in `SparseDataFrame.fillna()` not filling all NaNs when frame was instantiated from SciPy sparse matrix (GH16112)
- Bug in `SparseSeries.unstack()` and `SparseDataFrame.stack()` (GH16614, GH15045)
- Bug in `make_sparse()` treating two numeric/boolean data, which have same bits, as same when array dtype is object (GH17574)
- `SparseArray.all()` and `SparseArray.any()` are now implemented to handle `SparseArray`, these were used but not implemented (GH17570)

Reshaping

- Joining/Merging with a non unique `PeriodIndex` raised a `TypeError` (GH16871)
- Bug in `crosstab()` where non-aligned series of integers were casted to float (GH17005)
- Bug in merging with categorical dtypes with datetimelikes incorrectly raised a `TypeError` (GH16900)
- Bug when using `isin()` on a large object series and large comparison array (GH16012)
- Fixes regression from 0.20, `Series.aggregate()` and `DataFrame.aggregate()` allow dictionaries as return values again (GH16741)
- Fixes dtype of result with integer dtype input, from `pivot_table()` when called with `margins=True` (GH17013)
- Bug in `crosstab()` where passing two `Series` with the same name raised a `KeyError` (GH13279)
- `Series.argmin()`, `Series.argmax()`, and their counterparts on `DataFrame` and `groupby` objects work correctly with floating point data that contains infinite values (GH13595).
- Bug in `unique()` where checking a tuple of strings raised a `TypeError` (GH17108)
- Bug in `concat()` where order of result index was unpredictable if it contained non-comparable elements (GH17344)
- Fixes regression when sorting by multiple columns on a `datetime64` dtype `Series` with `NaT` values (GH16836)
- Bug in `pivot_table()` where the result’s columns did not preserve the categorical dtype of columns when `dropna` was `False` (GH17842)
- Bug in `DataFrame.drop_duplicates` where dropping with non-unique column names raised a `ValueError` (GH17836)
• Bug in `unstack()` which, when called on a list of levels, would discard the `fillna` argument (GH13971)
• Bug in the alignment of `range` objects and other list-likes with `DataFrame` leading to operations being performed row-wise instead of column-wise (GH17901)

**Numeric**

• Bug in `.clip()` with `axis=1` and a list-like for `threshold` is passed; previously this raised `ValueError` (GH15390)
• `Series.clip()` and `DataFrame.clip()` now treat NA values for upper and lower arguments as `None` instead of raising `ValueError` (GH17276).

**Categorical**

• Bug in `Series.isin()` when called with a categorical (GH16639)
• Bug in the categorical constructor with empty values and categories causing the `.categories` to be an empty `Float64Index` rather than an empty `Index` with object dtype (GH17248)
• Bug in categorical operations with `Series.cat` not preserving the original Series’ name (GH17509)
• Bug in `DataFrame.merge()` failing for categorical columns with boolean/int data types (GH17187)
• Bug in constructing a `Categorical/CategoricalDtype` when the specified `categories` are of categorical type (GH17884).

**PyPy**

• Compatibility with PyPy in `read_csv()` with `usecols=[<unsorted ints>]` and `read_json()` (GH17351)
• Split tests into cases for CPython and PyPy where needed, which highlights the fragility of index matching with `float('nan')`, `np.nan` and `NAT` (GH17351)
• Fix `DataFrame.memory_usage()` to support PyPy. Objects on PyPy do not have a fixed size, so an approximation is used instead (GH17228)

**Other**

• Bug where some inplace operators were not being wrapped and produced a copy when invoked (GH12962)
• Bug in `eval()` where the `inplace` parameter was being incorrectly handled (GH16732)

5.8 Version 0.20

5.8.1 Version 0.20.3 (July 7, 2017)

This is a minor bug-fix release in the 0.20.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

What’s new in v0.20.3

- Bug fixes
  - Conversion
  - Indexing
  - IO
  - Plotting
  - Reshaping
Bug fixes

- Fixed a bug in failing to compute rolling computations of a column-MultiIndexed DataFrame (GH16789, GH16825)
- Fixed a pytest marker failing downstream packages’ tests suites (GH16680)

Conversion

- Bug in pickle compat prior to the v0.20.x series, when UTC is a timezone in a Series/DataFrame/Index (GH16608)
- Bug in Series construction when passing a Series with dtype='category' (GH16524).
- Bug in DataFrame.astype() when passing a Series as the dtype kwarg. (GH16717).

Indexing

- Bug in Float64Index causing an empty array instead of None to be returned from .get(np.nan) on a Series whose index did not contain any NaNs (GH8569)
- Bug in MultiIndex.isin causing an error when passing an empty iterable (GH16777)
- Fixed a bug in a slicing DataFrame/Series that have a TimedeltaIndex (GH16637)

IO

- Bug in read_csv() in which files weren’t opened as binary files by the C engine on Windows, causing EOF characters mid-field, which would fail (GH16039, GH16559, GH16675)
- Bug in read_hdf() in which reading a Series saved to an HDF file in ‘fixed’ format fails when an explicit mode='r' argument is supplied (GH16583)
- Bug in DataFrame.to_latex() where bold_rows was wrongly specified to be True by default, whereas in reality row labels remained non-bold whatever parameter provided. (GH16707)
- Fixed an issue with DataFrame.style() where generated element ids were not unique (GH16780)
- Fixed loading a DataFrame with a PeriodIndex, from a format='fixed' HDFStore, in Python 3, that was written in Python 2 (GH16781)
Plotting

- Fixed regression that prevented RGB and RGBA tuples from being used as color arguments (GH16233)
- Fixed an issue with `DataFrame.plot.scatter()` that incorrectly raised a `KeyError` when categorical data is used for plotting (GH16199)

Reshaping

- `PeriodIndex/TimedeltaIndex.join` was missing the `sort=` kwarg (GH16541)
- Bug in joining on a `MultiIndex` with a `category` dtype for a level (GH16627).
- Bug in `merge()` when merging/joining with multiple categorical columns (GH16767)

Categorical

- Bug in `DataFrame.sort_values` not respecting the `kind` parameter with categorical data (GH16793)

5.8.2 Version 0.20.2 (June 4, 2017)

This is a minor bug-fix release in the 0.20.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

What’s new in v0.20.2

- **Enhancements**
- **Performance improvements**
- **Bug fixes**
  - Conversion
  - Indexing
  - IO
  - Plotting
  - GroupBy/resample/rolling
  - Sparse
  - Reshaping
  - Numeric
  - Categorical
  - Other
- **Contributors**

**Enhancements**

- Series provides a `to_latex` method (GH16180)
- A new groupby method `ngroup()`, parallel to the existing `cumcount()`, has been added to return the group order (GH11642); see here.

**Performance improvements**

- Performance regression fix when indexing with a list-like (GH16285)
- Performance regression fix for MultiIndexes (GH16319, GH16346)
- Improved performance of `.clip()` with scalar arguments (GH15400)
- Improved performance of groupby with categorical groupers (GH16413)
- Improved performance of `MultiIndex.remove_unused_levels()` (GH16556)
Bug fixes

- Silenced a warning on some Windows environments about “tput: terminal attributes: No such device or address” when detecting the terminal size. This fix only applies to python 3 (GH16496)
- Bug in using pathlib.Path or py.path.local objects with io functions (GH16291)
- Bug in `Index.symmetric_difference()` on two equal MultiIndex’s, results in a TypeError (GH13490)
- Bug in `DataFrame.update()` with overwrite=False and NaN values (GH15593)
- Passing an invalid engine to `read_csv()` now raises an informative ValueError rather than UnboundLocalError. (GH16511)
- Bug in `unique()` on an array of tuples (GH16519)
- Bug in `cut()` when labels are set, resulting in incorrect label ordering (GH16459)
- Fixed a compatibility issue with IPython 6.0’s tab completion showing deprecation warnings on Categoricals (GH16409)

Conversion

- Bug in `to_numeric()` in which empty data inputs were causing a segfault of the interpreter (GH16302)
- Silence numpy warnings when broadcasting DataFrame to Series with comparison ops (GH16378, GH16306)

Indexing

- Bug in `DataFrame.reset_index(level=)` with single level index (GH16263)
- Bug in partial string indexing with a monotonic, but not strictly-monotonic, index incorrectly reversing the slice bounds (GH16515)
- Bug in `MultiIndex.remove_unused_levels()` that would not return a MultiIndex equal to the original. (GH16556)

IO

- Bug in `read_csv()` when comment is passed in a space delimited text file (GH16472)
- Bug in `read_csv()` not raising an exception with nonexistent columns in usecols when it had the correct length (GH14671)
- Bug that would force importing of the clipboard routines unnecessarily, potentially causing an import error on startup (GH16288)
- Bug that raised IndexError when HTML-rendering an empty DataFrame (GH15953)
- Bug in `read_csv()` in which tarfile object inputs were raising an error in Python 2.x for the C engine (GH16530)
- Bug where `DataFrame.to_html()` ignored the index_names parameter (GH16493)
- Bug where `pd.read_hdf()` returns numpy strings for index names (GH13492)
- Bug in `HDFStore.select_as_multiple()` where start/stop arguments were not respected (GH16209)
Plotting

- Bug in `DataFrame.plot` with a single column and a list-like color (GH3486)
- Bug in `plot` where NaT in DatetimeIndex results in Timestamp.min (GH12405)
- Bug in `DataFrame.boxplot` where `figsize` keyword was not respected for non-grouped boxplots (GH11959)

GroupBy/resample/rolling

- Bug in creating a time-based rolling window on an empty DataFrame (GH15819)
- Bug in `rolling.cov()` with offset window (GH16058)
- Bug in `.resample()` and `.groupby()` when aggregating on integers (GH16361)

Sparse

- Bug in construction of `SparseDataFrame` from `scipy.sparse.dok_matrix` (GH16179)

Reshaping

- Bug in `DataFrame.stack` with unsorted levels in MultiIndex columns (GH16323)
- Bug in `pd.wide_to_long()` where no error was raised when i was not a unique identifier (GH16382)
- Bug in `Series.isin()` with a list of tuples (GH16394)
- Bug in construction of a DataFrame with mixed dtypes including an all-NaT column. (GH16395)
- Bug in `DataFrame.agg()` and `Series.agg()` with aggregating on non-callable attributes (GH16405)

Numeric

- Bug in `.interpolate()`, where `limit_direction` was not respected when `limit=None` (default) was passed (GH16282)

Categorical

- Fixed comparison operations considering the order of the categories when both categoricals are unordered (GH16014)
Other

- Bug in `DataFrame.drop()` with an empty-list with non-unique indices (GH16270)

5.8.3 Version 0.20.1 (May 5, 2017)

This is a major release from 0.19.2 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- New `.agg()` API for Series/DataFrame similar to the groupby-rolling-resample API’s, see here
- Integration with the feather-format, including a new top-level pd.read_feather() and DataFrame.to_feather() method, see here.
- The `.ix` indexer has been deprecated, see here
- Panel has been deprecated, see here
- Addition of an IntervalIndex and Interval scalar type, see here
- Improved user API when grouping by index levels in .groupby(), see here
- Improved support for UInt64 dtypes, see here
- A new orient for JSON serialization, orient='table', that uses the Table Schema spec and that gives the possibility for a more interactive repr in the Jupyter Notebook, see here
- Experimental support for exporting styled DataFrames (DataFrame.style) to Excel, see here
- Window binary corr/cov operations now return a MultiIndexed DataFrame rather than a Panel, as Panel is now deprecated, see here
- Support for S3 handling now uses s3fs, see here
- Google BigQuery support now uses the pandas-gbq library, see here

Warning: Pandas has changed the internal structure and layout of the code base. This can affect imports that are not from the top-level pandas.* namespace, please see the changes here.

Check the API Changes and deprecations before updating.

Note: This is a combined release for 0.20.0 and 0.20.1. Version 0.20.1 contains one additional change for backwards-compatibility with downstream projects using pandas’ utils routines. (GH16250)

What’s new in v0.20.0

- New features
  - Method `.agg()` API for DataFrame/Series
  - Keyword argument `dtype` for data IO
- Method .to_datetime() has gained an origin parameter
- GroupBy enhancements
- Better support for compressed URLs in read_csv
- Pickle file IO now supports compression
- UInt64 support improved
- GroupBy on categoricals
- Table schema output
- SciPy sparse matrix from/to SparseDataFrame
- Excel output for styled DataFrames
- IntervalIndex
- Other enhancements

- Backwards incompatible API changes
  - Possible incompatibility for HDF5 formats created with pandas < 0.13.0
  - Map on Index types now return other Index types
  - Accessing datetime fields of Index now return Index
  - pd.unique will now be consistent with extension types
  - S3 file handling
  - Partial string indexing changes
  - Concat of different float dtypes will not automatically upcast
  - pandas Google BigQuery support has moved
  - Memory usage for Index is more accurate
  - DataFrame.sort_index changes
  - GroupBy describe formatting
  - Window binary corr/cov operations return a MultiIndex DataFrame
  - HDFStore where string comparison
  - Index.intersection and inner join now preserve the order of the left Index
  - Pivot table always returns a DataFrame
  - Other API changes

- Reorganization of the library: privacy changes
  - Modules privacy has changed
  - pandas.errors
  - pandas.testing
  - pandas.plotting
  - Other development changes

- Deprecations
New features

Method agg API for DataFrame/Series

Series & DataFrame have been enhanced to support the aggregation API. This is a familiar API from groupby, window operations, and resampling. This allows aggregation operations in a concise way by using \texttt{agg()} and \texttt{transform()}. The full documentation is here (GH1623).

Here is a sample

\begin{verbatim}
In [1]: df = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
...:                   index=pd.date_range('1/1/2000', periods=10))
...:

In [2]: df.iloc[3:7] = np.nan

In [3]: df
\end{verbatim}

\begin{verbatim}
Out[3]:
      A         B         C
2000-01-01  0.469112  -0.282863  -1.509059
2000-01-02  -1.135632   1.212112  -0.173215
2000-01-03   0.119209  -1.044236  -0.861849
2000-01-04        NaN         NaN         NaN
2000-01-05        NaN         NaN         NaN
2000-01-06        NaN         NaN         NaN
2000-01-07        NaN         NaN         NaN
\end{verbatim}
One can operate using string function names, callables, lists, or dictionaries of these.

Using a single function is equivalent to .apply.

```python
In [4]: df.agg('sum')
Out[4]:
A  -1.068226
B  -1.387015
C  -4.892029
Length: 3, dtype: float64
```

Multiple aggregations with a list of functions.

```python
In [5]: df.agg(['sum', 'min'])
Out[5]:
       A       B       C
sum -1.068226 -1.387015 -4.892029
min -1.135632 -1.478427 -1.715002
```

Using a dict provides the ability to apply specific aggregations per column. You will get a matrix-like output of all of the aggregators. The output has one column per unique function. Those functions applied to a particular column will be NaN:

```python
In [6]: df.agg({'A': ['sum', 'min'], 'B': ['min', 'max']})
Out[6]:
        A        B
max  NaN  1.212112
min -1.135632 -1.715002
sum -1.068226     NaN
```

The API also supports a .transform() function for broadcasting results.

```python
In [7]: df.transform(['abs', lambda x: x - x.min()])
Out[7]:
          A        B        C
abs <lambda_0>  abs <lambda_0>  abs <lambda_0>
2000-01-01  0.469112  1.604745  0.282863  1.195563  1.509059  0.205944
2000-01-02  1.135632  0.000000  1.212112  2.690539  0.173215  1.541787
2000-01-03  0.119209  1.254841  1.044236  0.434191  0.861849  0.853153
2000-01-04  NaN      NaN      NaN      NaN      NaN      NaN
2000-01-05  NaN      NaN      NaN      NaN      NaN      NaN
2000-01-06  NaN      NaN      NaN      NaN      NaN      NaN
2000-01-07  NaN      NaN      NaN      NaN      NaN      NaN
2000-01-08  0.113648  1.249281  1.478427  0.000000  0.524988  2.239990
2000-01-09  0.404705  1.540338  0.577046  2.055473  1.715002  0.000000
2000-01-10  1.039268  0.096364  0.370647  1.107780  1.157892  0.557110
```
When presented with mixed dtypes that cannot be aggregated, .agg() will only take the valid aggregations. This is similar to how groupby .agg() works. (GH15015)

```
In [8]: df = pd.DataFrame({'A': [1, 2, 3],
...:                      'B': [1., 2., 3.],
...:                      'C': ['foo', 'bar', 'baz'],
...:                      'D': pd.date_range('20130101', periods=3))

In [9]: df.dtypes
Out[9]:
A     int64
B    float64
C     object
D  datetime64[ns]
Length: 3, dtype: object
```

```
In [10]: df.agg(['min', 'sum'])
Out[10]:
          A  B  C            D
min      1  1.0  bar 2013-01-01
sum      6  6.0 foobarbaz  NaT
```

**Keyword argument dtype for data IO**

The 'python' engine for read_csv(), as well as the read_fwf() function for parsing fixed-width text files and read_excel() for parsing Excel files, now accept the dtype keyword argument for specifying the types of specific columns (GH14295). See the io docs for more information.

```
In [11]: data = "a  b\n1  2\n3  4"

In [12]: pd.read_fwf(StringIO(data)).dtypes
Out[12]:
a     int64
b     int64
Length: 2, dtype: object

In [13]: pd.read_fwf(StringIO(data), dtype={'a': 'float64', 'b': 'object'}).dtypes
Out[13]:
a    float64
b    object
Length: 2, dtype: object
```
Method `.to_datetime()` has gained an `origin` parameter

`.to_datetime()` has gained a new parameter, `origin`, to define a reference date from where to compute the resulting timestamps when parsing numerical values with a specific `unit` specified. (GH11276, GH11745)

For example, with 1960-01-01 as the starting date:

```python
In [14]: pd.to_datetime([1, 2, 3], unit='D', origin=pd.Timestamp('1960-01-01'))
Out[14]: DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype='datetime64[ns]', freq=None)
```

The default is set at `origin='unix'`, which defaults to 1970-01-01 00:00:00, which is commonly called 'unix epoch' or POSIX time. This was the previous default, so this is a backward compatible change.

```python
In [15]: pd.to_datetime([1, 2, 3], unit='D')
Out[15]: DatetimeIndex(['1970-01-02', '1970-01-03', '1970-01-04'], dtype='datetime64[ns]', freq=None)
```

**GroupBy enhancements**

Strings passed to `DataFrame.groupby()` as the `by` parameter may now reference either column names or index level names. Previously, only column names could be referenced. This allows to easily group by a column and index level at the same time. (GH5677)

```python
In [16]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
   ...: ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']
   ...:
   ...
In [17]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])
In [18]: df = pd.DataFrame({'A': [1, 1, 1, 1, 2, 2, 3, 3],
   ...:                    'B': np.arange(8)},
   ...:                   index=index)
In [19]: df
Out[19]:
   first  second  
  bar    one    1  0
       two    1  1
  baz    one    1  2
       two    1  3
  foo    one    2  4
       two    2  5
  qux    one    3  6
       two    3  7
[8 rows x 2 columns]
In [20]: df.groupby(['second', 'A']).sum()
Out[20]:
   B
second A
  one  1  2
       2  4
```

(continues on next page)
Better support for compressed URLs in `read_csv`

The compression code was refactored (GH12688). As a result, reading dataframes from URLs in `read_csv()` or `read_table()` now supports additional compression methods: xz, bz2, and zip (GH14570). Previously, only gzip compression was supported. By default, compression of URLs and paths are now inferred using their file extensions. Additionally, support for bz2 compression in the python 2 C-engine improved (GH14874).

```python
In [21]: url = ('https://github.com/{repo}/raw/{branch}/{path}')
   ....:     .format(repo='pandas-dev/pandas',
   ....:             branch='master',
   ....:             path='pandas/tests/io/parser/data/salaries.csv.bz2'))
   ....:

# default, infer compression
In [22]: df = pd.read_csv(url, sep='\t', compression='infer')

# explicitly specify compression
In [23]: df = pd.read_csv(url, sep='\t', compression='bz2')

In [24]: df.head(2)
Out[24]:
     S  X  E  M
0  13876 1  1  1
1  11608 1  3  0

[2 rows x 4 columns]
```

Pickle file IO now supports compression

`read_pickle()`, `DataFrame.to_pickle()` and `Series.to_pickle()` can now read from and write to compressed pickle files. Compression methods can be an explicit parameter or be inferred from the file extension. See the docs here.

```python
In [25]: df = pd.DataFrame({'A': np.random.randn(1000),
   ....:                     'B': 'foo',
   ....:                     'C': pd.date_range('20130101', periods=1000, freq='s')})
   ....:

Using an explicit compression type

In [26]: df.to_pickle("data.pkl.compress", compression="gzip")

In [27]: rt = pd.read_pickle("data.pkl.compress", compression="gzip")

In [28]: rt.head()
```

(continues on next page)
The default is to infer the compression type from the extension (`compression='infer'`):

```python
In [29]: df.to_pickle("data.pkl.gz")
In [30]: rt = pd.read_pickle("data.pkl.gz")
In [31]: rt.head()
Out[31]:
   A   B   C
0 -1.344312 foo 2013-01-01 00:00:00
1  0.844885 foo 2013-01-01 00:00:01
2  1.075770 foo 2013-01-01 00:00:02
3 -0.109050 foo 2013-01-01 00:00:03
4  1.643563 foo 2013-01-01 00:00:04
```

```python
In [32]: df["A"].to_pickle("s1.pkl.bz2")
In [33]: rt = pd.read_pickle("s1.pkl.bz2")
In [34]: rt.head()
Out[34]:
0  -1.344312
1   0.844885
2   1.075770
3  -0.109050
4   1.643563
Name: A, Length: 5, dtype: float64
```

**UInt64 support improved**

Pandas has significantly improved support for operations involving unsigned, or purely non-negative, integers. Previously, handling these integers would result in improper rounding or data-type casting, leading to incorrect results. Notably, a new numerical index, `UInt64Index`, has been created (GH14937)

```python
In [35]: idx = pd.UInt64Index([1, 2, 3])
In [36]: df = pd.DataFrame({'A': ['a', 'b', 'c']}, index=idx)
In [37]: df.head()
Out[37]:
   A
0  a
1  b
2  c
```

- Bug in converting object elements of array-like objects to unsigned 64-bit integers (GH4471, GH14982)
- Bug in `Series.unique()` in which unsigned 64-bit integers were causing overflow (GH14721)
• Bug in DataFrame construction in which unsigned 64-bit integer elements were being converted to objects (GH14881)
• Bug in pd.read_csv() in which unsigned 64-bit integer elements were being improperly converted to the wrong data types (GH14983)
• Bug in pd.unique() in which unsigned 64-bit integers were causing overflow (GH14915)
• Bug in pd.value_counts() in which unsigned 64-bit integers were being erroneously truncated in the output (GH14934)

GroupBy on categoricals

In previous versions, .groupby(..., sort=False) would fail with a ValueError when grouping on a categorical series with some categories not appearing in the data. (GH13179)

In [38]: chromosomes = np.r_[np.arange(1, 23).astype(str), ['X', 'Y']]

In [39]: df = pd.DataFrame({
    ...:     'A': np.random.randint(100),
    ...:     'B': np.random.randint(100),
    ...:     'C': np.random.randint(100),
    ...:     'chromosomes': pd.Categorical(np.random.choice(chromosomes, 100),
    ...:         categories=chromosomes,
    ...:         ordered=True)
    ...: })

In [40]: df

Out[40]:
        A  B   C  chromosomes
0      87  22  81           4
1      87  22  81           3
2      87  22  81          22
3      87  22  81           2
4      87  22  81           6
   ...   ...  ...          ...
95     87  22  81           8
96     87  22  81          11
97     87  22  81           X
98     87  22  81           1
99     87  22  81          19

[100 rows x 4 columns]

Previous behavior:

In [3]: df[df.chromosomes != '1'].groupby('chromosomes', sort=False).sum()
---------------------------------------------------------------------------
ValueError: items in new_categories are not the same as in old categories

New behavior:

In [41]: df[df.chromosomes != '1'].groupby('chromosomes', sort=False).sum()
Out[41]:
   chromosomes  A   B   C
2           348  88  324

(continues on next page)
The new orient 'table' for `DataFrame.to_json()` will generate a Table Schema compatible string representation of the data.

```
In [42]: df = pd.DataFrame(
    ....:     {'A': [1, 2, 3],
    ....:      'B': ['a', 'b', 'c'],
    ....:      'C': pd.date_range('2016-01-01', freq='d', periods=3),
    ....:     index=pd.Index(range(3), name='idx'))
    ....:

In [43]: df
df
```

```
  0 1 a 2016-01-01
  1 2 b 2016-01-02
  2 3 c 2016-01-03
[3 rows x 3 columns]
```

```
In [44]: df.to_json(orient='table')
Out[44]:
       "schema": {"fields": [{"name": "idx", "type": "integer"},
                              {"name": "A", "type": "integer"},
                              {"name": "B", "type": "string"},
                              {"name": "C", "type": "datetime"}],
                  "primaryKey": ["idx"],
                  "pandas_version": "0.20.0"},
       "data": [{"idx": 0, "A": 1, "B": "a", "C": 2016-01-01T00:00:00.000Z"},
                 {"idx": 1, "A": 2, "B": "b", "C": 2016-01-02T00:00:00.000Z"},
                 {"idx": 2, "A": 3, "B": "c", "C": 2016-01-03T00:00:00.000Z"}]
```

See [IO: Table Schema for more information.](#)

Additionally, the repr for `DataFrame` and `Series` can now publish this JSON Table schema representation of the Series or DataFrame if you are using IPython (or another frontend like nteract using the Jupyter messaging protocol). This gives frontends like the Jupyter notebook and nteract more flexibility in how they display pandas objects, since they have more information about the data. You must enable this by setting the `display.html.table_schema` option to `True`.

---

**5.8. Version 0.20**

2801
SciPy sparse matrix from/to SparseDataFrame

Pandas now supports creating sparse dataframes directly from `scipy.sparse.spmatrix` instances. See the documentation for more information. (GH4343)

All sparse formats are supported, but matrices that are not in COOrdinate format will be converted, copying data as needed.

```python
from scipy.sparse import csr_matrix
arr = np.random.random(size=(1000, 5))
arr[arr < .9] = 0
sp_arr = csr_matrix(arr)
sdf = pd.SparseDataFrame(sp_arr)
sdf
```

To convert a SparseDataFrame back to sparse SciPy matrix in COO format, you can use:

```python
sdf.to_coo()
```

Excel output for styled DataFrames

Experimental support has been added to export DataFrame.style formats to Excel using the openpyxl engine. (GH15530)

For example, after running the following, styled.xlsx renders as below:

```python
In [45]: np.random.seed(24)
In [46]: df = pd.DataFrame({'A': np.linspace(1, 10, 10)})
In [47]: df = pd.concat([df, pd.DataFrame(np.random.RandomState(24).randn(10, 4),
                      columns=list('BCDE'))],
                      axis=1)
In [48]: df.iloc[0, 2] = np.nan
In [49]: df
Out[49]:
      A         B         C         D         E
0   1.0  1.329212 NaN -0.316280 -0.990810
1  2.0 -1.070816 -1.438713  0.564417  0.295722
2  3.0 -1.626404  0.219565  0.678805  1.889273
3  4.0  0.961538  0.104011 -0.481165  0.850222
4  5.0  1.453425  1.057737  0.165562  0.515018
5  6.0 -1.336936  0.562861  1.392855 -0.063328
6  7.0  0.121668  1.207603 -0.002040  1.627796
7  8.0  0.354493  1.037528 -0.385684  0.519818
8  9.0  1.686583 -1.325963  1.428984 -2.089354
9 10.0 -0.129820  0.631523 -0.586538  0.290720
[10 rows x 5 columns]
In [50]: styled = (df.style
......: .applymap(lambda val: 'color: %s %s' % ('red' if val < 0 else 'black'))
```

(continues on next page)
pandas has gained an `IntervalIndex` with its own dtype, `interval` as well as the `Interval` scalar type. These allow first-class support for interval notation, specifically as a return type for the categories in `cut()` and `qcut()`. The `IntervalIndex` allows some unique indexing, see the docs. (GH7640, GH8625)

**Warning:** These indexing behaviors of the `IntervalIndex` are provisional and may change in a future version of pandas. Feedback on usage is welcome.

Previous behavior:
The returned categories were strings, representing Intervals

```
In [1]: c = pd.cut(range(4), bins=2)
In [2]: c
Out[2]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3], (1.5, 3]]
Categories (2, object): [(-0.003, 1.5] < (1.5, 3]]
```

New behavior:

```
In [52]: c = pd.cut(range(4), bins=2)
In [53]: c
Out[53]:
```

See the *Style documentation* for more detail.
Furthermore, this allows one to bin other data with these same bins, with NaN representing a missing value similar to other dtypes.

```python
In [55]: pd.cut([0, 3, 5, 1], bins=c.categories)
Out[55]:
[(-0.003, 1.5], (1.5, 3.0], NaN, (-0.003, 1.5]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]
```

An IntervalIndex can also be used in Series and DataFrame as the index.

```python
In [56]: df = pd.DataFrame({'A': range(4),
                      'B': pd.cut([0, 3, 1, 1], bins=c.categories)}).set_index('B')
```

```python
In [57]: df
Out[57]:
   B
A
(-0.003, 1.5]  0
(1.5, 3.0]    1
(-0.003, 1.5]  2
(-0.003, 1.5]  3
[4 rows x 1 columns]
```

Selecting via a specific interval:

```python
In [58]: df.loc[pd.Interval(1.5, 3.0)]
Out[58]:
   A
Name: (1.5, 3.0], Length: 1, dtype: int64
```

Selecting via a scalar value that is contained in the intervals.

```python
In [59]: df.loc[0]
Out[59]:
   A
   B
(-0.003, 1.5]  0
(-0.003, 1.5]  2
(-0.003, 1.5]  3
[3 rows x 1 columns]
```
Other enhancements

- DataFrame.rolling() now accepts the parameter closed='right'|'left'|'both'|'neither' to choose the rolling window-endpoint closedness. See the documentation (GH13965)
- Integration with the feather-format, including a new top-level pd.read_feather() and DataFrame.to_feather() method, see here.
- Series.str.replace() now accepts a callable, as replacement, which is passed to re.sub (GH15055)
- Series.str.replace() now accepts a compiled regular expression as a pattern (GH15446)
- Series.sort_index accepts parameters kind and na_position (GH13589, GH14444)
- DataFrame and DataFrame.groupby() have gained a nunique() method to count the distinct values over an axis (GH14336, GH15197).
- DataFrame has gained a melt() method, equivalent to pd.melt(), for unpivoting from a wide to long format (GH12640).
- pd.read_excel() now preserves sheet order when using sheetname=None (GH9930)
- Multiple offset aliases with decimal points are now supported (e.g. 0.5min is parsed as 30s) (GH8419)
- .isnull() and .notnull() have been added to Index object to make them more consistent with the Series API (GH15300)
- New UnssortedIndexError (subclass of KeyError) raised when indexing/slicing into an unsorted MultiIndex (GH11897). This allows differentiation between errors due to lack of sorting or an incorrect key. See here
- MultiIndex has gained a .to_frame() method to convert to a DataFrame (GH12397)
- pd.cut and pd.qcut now support datetime64 and timedelta64 dtypes (GH14714, GH14798)
- pd.qcut has gained the duplicates='raise'|'drop' option to control whether to raise on duplicated edges (GH7751)
- Series provides a to_excel method to output Excel files (GH8825)
- The usecols argument in pd.read_csv() now accepts a callable function as a value (GH14154)
- The skiprows argument in pd.read_csv() now accepts a callable function as a value (GH10882)
- The nrows and chunksize arguments in pd.read_csv() are supported if both are passed (GH6774, GH15755)
- DataFrame.plot now prints a title above each subplot if suplots=True and title is a list of strings (GH14753)
- DataFrame.plot can pass the matplotlib 2.0 default color cycle as a single string as color parameter, see here. (GH15516)
- Series.interpolate() now supports timedelta as an index type with method='time' (GH6424)
- Addition of a level keyword to DataFrame/Series.rename to rename labels in the specified level of a MultiIndex (GH4160).
- DataFrame.reset_index() will now interpret a tuple index.name as a key spanning across levels of columns, if this is a MultiIndex (GH16164)
- Timedelta.isoformat method added for formatting Timedeltas as an ISO 8601 duration. See the Timedelta docs (GH15136)
- .select_dtypes() now allows the string datetimetz to generically select datetimes with tz (GH14910)
• The `.to_latex()` method will now accept `multicolumn` and `multirow` arguments to use the accompanying LaTeX enhancements

• `pd.merge_asof()` gained the option `direction='backward'|'forward'|'nearest'` (GH14887)

• Series/DataFrame.asfreq() have gained a `fill_value` parameter, to fill missing values (GH3715).

• Series/DataFrame.resample.asfreq have gained a `fill_value` parameter, to fill missing values during resampling (GH3715).

• `pandas.util.hash_pandas_object()` has gained the ability to hash a MultiIndex (GH15224)

• Series/DataFrame.squeeze() have gained the `axis` parameter. (GH15339)

• DataFrame.to_excel() has a new `freeze_panes` parameter to turn on Freeze Panes when exporting to Excel (GH15160)

• `pd.read_html()` will parse multiple header rows, creating a MultiIndex header. (GH13434).

• HTML table output skips `colspan` or `rowspan` attribute if equal to 1. (GH15403)

• `pandas.io.formats.style.Styler` template now has blocks for easier extension, see the example notebook (GH15649)

• `Styler.render()` now accepts **kwargs to allow user-defined variables in the template (GH15649)

• Compatibility with Jupyter notebook 5.0; MultiIndex column labels are left-aligned and MultiIndex row-labels are top-aligned (GH15379)

• TimedeltaIndex now has a custom date-tick formatter specifically designed for nanosecond level precision (GH8711)

• `pd.api.types.union_categoricals` gained the `ignore_ordered` argument to allow ignoring the ordered attribute of unioned categoricals (GH13410). See the categorical union docs for more information.

• DataFrame.to_latex() and DataFrame.to_string() now allow optional header aliases. (GH15536)

• Re-enable the `parse_dates` keyword of `pd.read_excel()` to parse string columns as dates (GH14326)

• Added `.empty` property to subclasses of `Index`. (GH15270)

• Enabled floor division for `Timedelta` and `TimedeltaIndex` (GH15828)

• `pandas.io.json.json_normalize()` gained the option `errors='ignore'|'raise'; the default is `errors='raise'` which is backward compatible. (GH14583)

• `pandas.io.json.json_normalize()` with an empty list will return an empty DataFrame (GH15534)

• `pandas.io.json.json_normalize()` has gained a `sep` option that accepts `str` to separate joined fields; the default is “.”, which is backward compatible. (GH14883)

• `MultiIndex.remove_unused_levels()` has been added to facilitate removing unused levels. (GH15694)

• `pd.read_csv()` will now raise a `ParserError` error whenever any parsing error occurs (GH15913, GH15925)

• `pd.read_csv()` now supports the `error_bad_lines` and `warn_bad_lines` arguments for the Python parser (GH15925)

• The `display.show_dimensions` option can now also be used to specify whether the length of a `Series` should be shown in its repr (GH7117).
- `parallel_coordinates()` has gained a `sort_labels` keyword argument that sorts class labels and the colors assigned to them (GH15908)
- Options added to allow one to turn on/off using `bottleneck` and `numexpr`, see here (GH16157)
- `DataFrame.style.bar()` now accepts two more options to further customize the bar chart. Bar alignment is set with `align='left' | 'mid' | 'zero'`, the default is “left”, which is backward compatible. You can now pass a list of `color=[color_negative, color_positive]` (GH14757)

**Backwards incompatible API changes**

**Possible incompatibility for HDF5 formats created with pandas < 0.13.0**

`pd.TimeSeries` was deprecated officially in 0.17.0, though has already been an alias since 0.13.0. It has been dropped in favor of `pd.Series` (GH15098).

This may cause HDF5 files that were created in prior versions to become unreadable if `pd.TimeSeries` was used. This is most likely to be for pandas < 0.13.0. If you find yourself in this situation, you can use a recent prior version of pandas to read in your HDF5 files, then write them out again after applying the procedure below.

There are a few ways you can work around this. If you have a 0.13.0 or earlier version of pandas installed:

```python
In [2]: s = pd.TimeSeries([1, 2, 3], index=pd.date_range('20130101', periods=3))

In [3]: s
Out[3]:
2013-01-01 1
2013-01-02 2
2013-01-03 3
Freq: D, dtype: int64

In [4]: type(s)
Out[4]: pandas.core.series.TimeSeries

In [5]: s = pd.Series(s)

In [6]: s
Out[6]:
2013-01-01 1
2013-01-02 2
2013-01-03 3
Freq: D, dtype: int64

In [7]: type(s)
Out[7]: pandas.core.series.Series
```

**Map on Index types now return other Index types**

`map` on an Index now returns an Index, not a numpy array (GH12766)

```python
In [60]: idx = pd.Index([1, 2])

In [61]: idx
Out[61]: Int64Index([1, 2], dtype='int64')

In [62]: mi = pd.MultiIndex.from_tuples([(1, 2), (2, 4)])
```

(continues on next page)
In [63]: mi
Out[63]:
MultiIndex([(1, 2),
            (2, 4)],
           )

Previous behavior:

In [5]: idx.map(lambda x: x * 2)
Out[5]: array([2, 4])

In [6]: idx.map(lambda x: (x, x * 2))
Out[6]: array([(1, 2), (2, 4)], dtype=object)

In [7]: mi.map(lambda x: x)
Out[7]: array([(1, 2), (2, 4)], dtype=object)

In [8]: mi.map(lambda x: x[0])
Out[8]: array([1, 2])

New behavior:

In [64]: idx.map(lambda x: x * 2)
Out[64]: Int64Index([2, 4], dtype='int64')

In [65]: idx.map(lambda x: (x, x * 2))
Out[65]: MultiIndex([(1, 2),
                   (2, 4)],
                   )

In [66]: mi.map(lambda x: x)
Out[66]: MultiIndex([(1, 2),
                   (2, 4)],
                   )

In [67]: mi.map(lambda x: x[0])
Out[67]: Int64Index([1, 2], dtype='int64')

map on a Series with datetime64 values may return int64 dtypes rather than int32

In [68]: s = pd.Series(pd.date_range('2011-01-02T00:00', '2011-01-02T02:00', freq='H')
                 .tz_localize('Asia/Tokyo'))

In [69]: s
Out[69]:
0 2011-01-02 00:00:00+09:00
1 2011-01-02 01:00:00+09:00
2 2011-01-02 02:00:00+09:00
Length: 3, dtype: datetime64[ns, Asia/Tokyo]

Previous behavior:

In [9]: s.map(lambda x: x.hour)
Out[9]:
(continues on next page)
0 0
1 1
2 2
dtype: int32

New behavior:

```
In [70]: s.map(lambda x: x.hour)
Out[70]:
0 0
1 1
2 2
Length: 3, dtype: int64
```

**Accessing datetime fields of Index now return Index**

The datetime-related attributes (see here for an overview) of `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex` previously returned numpy arrays. They will now return a new `Index` object, except in the case of a boolean field, where the result will still be a boolean ndarray. (GH15022)

Previous behaviour:

```
In [1]: idx = pd.date_range("2015-01-01", periods=5, freq='10H')
In [2]: idx.hour
Out[2]: array([ 0, 10, 20, 6, 16], dtype=int32)
```

New behavior:

```
In [71]: idx = pd.date_range("2015-01-01", periods=5, freq='10H')
In [72]: idx.hour
Out[72]: Int64Index([0, 10, 20, 6, 16], dtype='int64')
```

This has the advantage that specific `Index` methods are still available on the result. On the other hand, this might have backward incompatibilities: e.g. compared to numpy arrays, `Index` objects are not mutable. To get the original ndarray, you can always convert explicitly using `np.asarray(idx.hour)`.

**pd.unique will now be consistent with extension types**

In prior versions, using `Series.unique()` and `pandas.unique()` on `Categorical` and tz-aware data-types would yield different return types. These are now made consistent. (GH15903)

- Datetime tz-aware

  Previous behaviour:

  ```
  # Series
  In [5]: pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
  ...:               pd.Timestamp('20160101', tz='US/Eastern')]).unique()
  Out[5]: array([Timestamp('2016-01-01 00:00:00-0500', tz='US/Eastern')],
  →dtype=object)
  In [6]: pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
  ```
pandas: powerful Python data analysis toolkit, Release 1.1.1

(continued from previous page)

```python
...:     pd.Timestamp('20160101', tz='US/Eastern'))
Out[6]: array(['2016-01-01T05:00:00.000000000'], dtype='datetime64[ns]')

# Index
In [7]: pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
...:     pd.Timestamp('20160101', tz='US/Eastern')]).unique()
Out[7]: DatetimeIndex(['2016-01-01 00:00:00-05:00'], dtype='datetime64[ns, US/Eastern]', freq=None)

In [8]: pd.unique([pd.Timestamp('20160101', tz='US/Eastern'),
...:     pd.Timestamp('20160101', tz='US/Eastern')])
Out[8]: array(['2016-01-01T05:00:00.000000000'], dtype='datetime64[ns]')

New behavior:

```python
# Series, returns an array of Timestamp tz-aware
In [73]: pd.Series([pd.Timestamp(r'20160101', tz=r'US/Eastern'),
...:     pd.Timestamp(r'20160101', tz=r'US/Eastern')]).unique()
Out[73]: <DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]

In [74]: pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
...:     pd.Timestamp('20160101', tz='US/Eastern')]))
Out[74]: DatetimeIndex(['2016-01-01 00:00:00-05:00'], dtype='datetime64[ns, US/Eastern]', freq=None)

# Index, returns a DatetimeIndex
In [75]: pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
...:     pd.Timestamp('20160101', tz='US/Eastern')]).unique()
Out[75]: DatetimeIndex(['2016-01-01 00:00:00-05:00'], dtype='datetime64[ns, US/Eastern]', freq=None)

In [76]: pd.unique(pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
...:     pd.Timestamp('20160101', tz='US/Eastern')]))
Out[76]: DatetimeIndex(['2016-01-01 00:00:00-05:00'], dtype='datetime64[ns, US/Eastern]', freq=None)
```

- Categoricals

Previous behaviour:

```python
In [1]: pd.Series(list('baabc'), dtype='category').unique()
Out[1]:
[b, a, c]
Categories (3, object): [b, a, c]

In [2]: pd.unique(pd.Series(list('baabc'), dtype='category'))
Out[2]: array(['b', 'a', 'c'], dtype=object)
```

New behavior:
```python
# returns a Categorical
In [77]: pd.Series(list('baabc'), dtype='category').unique()
Out[77]:
['b', 'a', 'c']
Categories (3, object): ['b', 'a', 'c']

In [78]: pd.unique(pd.Series(list('baabc'), dtype='category'))
Out[78]:
['b', 'a', 'c']
Categories (3, object): ['b', 'a', 'c']
```

### S3 file handling

pandas now uses s3fs for handling S3 connections. This shouldn’t break any code. However, since s3fs is not a required dependency, you will need to install it separately, like boto in prior versions of pandas. (GH11915).

### Partial string indexing changes

**DatetimeIndex Partial String Indexing** now works as an exact match, provided that string resolution coincides with index resolution, including a case when both are seconds (GH14826). See Slice vs. Exact Match for details.

```python
In [79]: df = pd.DataFrame({'a': [1, 2, 3]}, pd.DatetimeIndex(['2011-12-31 23:59:59', '2012-01-01 00:00:00', '2012-01-01 00:00:01']))

In [4]: df['2011-12-31 23:59:59']
Out[4]:
   a
2011-12-31 23:59:59  1

In [5]: df['a']['2011-12-31 23:59:59']
Out[5]:
2011-12-31 23:59:59  1
Name: a, dtype: int64

In [4]: df['2011-12-31 23:59:59']
KeyError: '2011-12-31 23:59:59'

In [5]: df['a']['2011-12-31 23:59:59']
Out[5]: 1
```
Concat of different float dtypes will not automatically upcast

Previously, concat of multiple objects with different float dtypes would automatically upcast results to a dtype of float64. Now the smallest acceptable dtype will be used (GH13247)

```python
In [80]: df1 = pd.DataFrame(np.array([1.0], dtype=np.float32, ndmin=2))
In [81]: df1.dtypes
Out[81]:
   0 float32
Length: 1, dtype: object

In [82]: df2 = pd.DataFrame(np.array([np.nan], dtype=np.float32, ndmin=2))
In [83]: df2.dtypes
Out[83]:
   0 float32
Length: 1, dtype: object
```

Previous behavior:

```python
In [7]: pd.concat([df1, df2]).dtypes
Out[7]:
   0 float64
dtype: object
```

New behavior:

```python
In [84]: pd.concat([df1, df2]).dtypes
Out[84]:
   0 float32
Length: 1, dtype: object
```

pandas Google BigQuery support has moved

pandas has split off Google BigQuery support into a separate package pandas-gbq. You can conda install pandas-gbq -c conda-forge or pip install pandas-gbq to get it. The functionality of `read_gbq()` and `DataFrame.to_gbq()` remain the same with the currently released version of pandas-gbq=0.1.4. Documentation is now hosted here (GH15347)

Memory usage for Index is more accurate

In previous versions, showing `memory_usage()` on a pandas structure that has an index, would only include actual index values and not include structures that facilitated fast indexing. This will generally be different for `Index` and `MultiIndex` and less-so for other index types. (GH15237)

Previous behavior:

```python
In [8]: index = pd.Index(['foo', 'bar', 'baz'])
In [9]: index.memory_usage(deep=True)
Out[9]: 180
In [10]: index.get_loc('foo')
```
New behavior:

```python
In [8]: index = pd.Index(['foo', 'bar', 'baz'])
In [9]: index.memory_usage(deep=True)
Out[9]: 180
In [10]: index.get_loc('foo')
Out[10]: 0
In [11]: index.memory_usage(deep=True)
Out[11]: 260
```

### DataFrame.sort_index changes

In certain cases, calling `.sort_index()` on a MultiIndexed DataFrame would return the same DataFrame without seeming to sort. This would happen with a lexsorted, but non-monotonic levels. (GH15622, GH15687, GH14015, GH13431, GH15797)

This is *unchanged* from prior versions, but shown for illustration purposes:

```python
In [85]: df = pd.DataFrame(np.arange(6), columns=['value'],
                        index=pd.MultiIndex.from_product([list('BA'), range(3)]))
In [86]: df
Out[86]:
     value
B 0  0
   1  1
   2  2
A 0  3
   1  4
   2  5
[6 rows x 1 columns]
In [87]: df.index.is_lexsorted()
Out[87]: False
In [88]: df.index.is_monotonic
Out[88]: False
```

Sorting works as expected

```python
In [89]: df.sort_index()
Out[89]:
     value
A 0  3
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

(continued from previous page)

In [90]: df.sort_index().index.is_lexsorted()
Out[90]: True

In [91]: df.sort_index().index.is_monotonic
Out[91]: True

However, this example, which has a non-monotonic 2nd level, doesn’t behave as desired.

In [92]: df = pd.DataFrame({'value': [1, 2, 3, 4]},
                   index=pd.MultiIndex([['a', 'b'], ['bb', 'aa']],
                                    [[0, 0, 1, 1], [0, 1, 0, 1]]))

In [93]: df
Out[93]:
   value
  a bb 1
  aa 2
  b bb 3
  aa 4

Previous behavior:

In [11]: df.sort_index()
Out[11]:
   value
  a bb 1
  aa 2
  b bb 3
  aa 4

In [14]: df.sort_index().index.is_lexsorted()
Out[14]: True

In [15]: df.sort_index().index.is_monotonic
Out[15]: False

New behavior:

In [94]: df.sort_index()
Out[94]:
   value
  a aa 2
  bb 1
  b aa 4
  bb 3

(continues on next page)
In [95]: df.sort_index().index.is_lexsorted()
Out[95]: True

In [96]: df.sort_index().index.is_monotonic
Out[96]: True

GroupBy describe formatting

The output formatting of `groupby.describe()` now labels the `describe()` metrics in the columns instead of the index. This format is consistent with `groupby.agg()` when applying multiple functions at once. (GH4792)

Previous behavior:

```
In [1]: df = pd.DataFrame({'A': [1, 1, 2, 2], 'B': [1, 2, 3, 4]})
In [2]: df.groupby('A').describe()
Out[2]:
   B
A      
 1  count 2.000000
     mean 1.500000
     std  0.707107
     min  1.000000
     25%  1.250000
     50%  1.500000
     75%  1.750000
     max  2.000000
 2  count 2.000000
     mean 3.500000
     std  0.707107
     min  3.000000
     25%  3.250000
     50%  3.500000
     75%  3.750000
     max  4.000000
```

New behavior:

```
In [97]: df = pd.DataFrame({'A': [1, 1, 2, 2], 'B': [1, 2, 3, 4]})
In [98]: df.groupby('A').agg([np.mean, np.std, np.min, np.max])
Out[98]:
   B
A
 1  count 2.000000
     mean 1.500000
     std  0.707107
     min  1.000000
     25%  1.250000
     50%  1.500000
     75%  1.750000
     max  2.000000
 2  count 2.000000
     mean 3.500000
     std  0.707107
     min  3.000000
     25%  3.250000
     50%  3.500000
     75%  3.750000
     max  4.000000
```

(continues on next page)
In [99]: df.groupby('A').agg([np.mean, np.std, np.min, np.max])
Out[99]:
   B
   mean   std  amin  amax
A
1  1.5  0.707107  1   2
2  3.5  0.707107  3   4

Window binary corr/cov operations return a MultiIndex DataFrame

A binary window operation, like .corr() or .cov(), when operating on a .rolling()..expanding().
or .ewm() object, will now return a 2-level MultiIndexed DataFrame rather than a Panel, as Panel
is now deprecated, see here. These are equivalent in function, but a MultiIndexed DataFrame
enjoys more support in pandas. See the section on Windowed Binary Operations for more information. (GH15677)

In [100]: np.random.seed(1234)
In [101]: df = pd.DataFrame(np.random.rand(100, 2),
                     columns=['A', 'B'],
                     index=pd.date_range('20160101',
                                         periods=100, freq='D', name='foo'))
In [102]: df.tail()
Out[102]:
       bar        A        B
foo
2016-04-05  0.640880  0.126205
2016-04-06  0.171465  0.737086
2016-04-07  0.127029  0.369650
2016-04-08  0.604334  0.945553
2016-04-09  0.802374  0.945553

Previous behavior:

In [2]: df.rolling(12).corr()
Out[2]:
<class 'pandas.core.panel.Panel'>
Dimensions: 100 (items) x 2 (major_axis) x 2 (minor_axis)
Items axis: 2016-01-01 00:00:00 to 2016-04-09 00:00:00
Major_axis axis: A to B
Minor_axis axis: A to B

New behavior:
In [103]: res = df.rolling(12).corr()

In [104]: res.tail()
Out[104]:
   bar  A    B
foo  bar
2016-04-07  B -0.132090  1.000000
2016-04-08  A  1.000000 -0.145775
    B -0.145775  1.000000
2016-04-09  A  1.000000  0.119645
    B  0.119645  1.000000

[5 rows x 2 columns]

Retrieving a correlation matrix for a cross-section

In [105]: df.rolling(12).corr().loc['2016-04-07']
Out[105]:
   bar  A    B
foo  bar
2016-04-07  A  1.00000 -0.13209
    B -0.13209  1.00000

[2 rows x 2 columns]

HDFStore where string comparison

In previous versions most types could be compared to string column in a HDFStore usually resulting in an invalid comparison, returning an empty result frame. These comparisons will now raise a TypeError (GH15492)

In [106]: df = pd.DataFrame({'unparsed_date': ["2014-01-01", '2014-01-01']})

In [107]: df.to_hdf('store.h5', 'key', format='table', data_columns=True)

In [108]: df.dtypes
Out[108]:
unparsed_date    object
Length: 1, dtype: object

Previous behavior:

In [4]: pd.read_hdf('store.h5', 'key', where='unparsed_date > ts')
   File "<string>" line 1
   (unparsed_date > 1970-01-01 00:00:01.388552400)
          ^
SyntaxError: invalid token

New behavior:

In [18]: ts = pd.Timestamp('2014-01-01')

In [19]: pd.read_hdf('store.h5', 'key', where='unparsed_date > ts')
   TypeError: Cannot compare 2014-01-01 00:00:00 of type <class 'pandas.tslib.Timestamp'> to string column
Index.intersection and inner join now preserve the order of the left Index

*Index.intersection()* now preserves the order of the calling Index (left) instead of the other Index (right) (GH15582). This affects inner joins, *DataFrame.join()* and *merge()* , and the .align method.

- **Index.intersection**

```python
In [109]: left = pd.Index([2, 1, 0])
In [110]: left
Out[110]: Int64Index([2, 1, 0], dtype='int64')
In [111]: right = pd.Index([1, 2, 3])
In [112]: right
Out[112]: Int64Index([1, 2, 3], dtype='int64')
```

Previous behavior:

```python
In [4]: left.intersection(right)
Out[4]: Int64Index([1, 2], dtype='int64')
```

New behavior:

```python
In [113]: left.intersection(right)
Out[113]: Int64Index([2, 1], dtype='int64')
```

- **DataFrame.join and pd.merge**

```python
In [114]: left = pd.DataFrame({'a': [20, 10, 0]}, index=[2, 1, 0])
In [115]: left
Out[115]:
   a
2  20
1  10
0  0
[3 rows x 1 columns]
In [116]: right = pd.DataFrame({'b': [100, 200, 300]}, index=[1, 2, 3])
In [117]: right
Out[117]:
   b
1  100
2  200
3  300
[3 rows x 1 columns]
```

Previous behavior:

```python
In [4]: left.join(right, how='inner')
Out[4]:
   a  b
1  10  100
2  20  200
```

Chapter 5. Release notes
New behavior:

```
In [118]: left.join(right, how='inner')
Out[118]:
   a  b
2  20  200
1  10  100
[2 rows x 2 columns]
```

Pivot table always returns a DataFrame

The documentation for `pivot_table()` states that a DataFrame is always returned. Here a bug is fixed that allowed this to return a Series under certain circumstance. (GH4386)

```
In [119]: df = pd.DataFrame({'col1': [3, 4, 5],
                     'col2': ['C', 'D', 'E'],
                     'col3': [1, 3, 9]})
In [120]: df
Out[120]:
   col1  col2  col3
0     3     C     1
1     4     D     3
2     5     E     9
[3 rows x 3 columns]
```

Previous behavior:

```
In [2]: df.pivot_table('col1', index=['col3', 'col2'], aggfunc=np.sum)
Out[2]:
     col3  col2
col1
1     C     3
3     D     4
9     E     5
Name: col1, dtype: int64
```

New behavior:

```
In [121]: df.pivot_table('col1', index=['col3', 'col2'], aggfunc=np.sum)
Out[121]:
    col1
  col3  col2
1     C     3
3     D     4
9     E     5
[3 rows x 1 columns]
```
Other API changes

- `numexpr` version is now required to be >= 2.4.6 and it will not be used at all if this requisite is not fulfilled (GH15213).
- `CParserError` has been renamed to `ParserError` in `pd.read_csv()` and will be removed in the future (GH12665).
- `SparseArray.cumsum()` and `SparseSeries.cumsum()` will now always return `SparseArray` and `SparseSeries` respectively (GH12855).
- `DataFrame.applymap()` with an empty `DataFrame` will return a copy of the empty `DataFrame` instead of a `Series` (GH8222).
- `Series.map()` now respects default values of dictionary subclasses with a `__missing__` method, such as `collections.Counter` (GH15999).
- `.loc` has compat with `.ix` for accepting iterators, and NamedTuples (GH15120).
- `interpolate()` and `fillna()` will raise a `ValueError` if the `limit` keyword argument is not greater than 0. (GH9217)
- `pd.read_csv()` will now issue a `ParserWarning` whenever there are conflicting values provided by the dialect parameter and the user (GH14898).
- `pd.read_csv()` will now raise a `ValueError` for the C engine if the quote character is larger than one byte (GH11592).
- `inplace` arguments now require a boolean value, else a `ValueError` is thrown (GH14189).
- `pandas.api.types.is_datetime64_ns_dtype` will now report `True` on a tz-aware dtype, similar to `pandas.api.types.is_datetime64_any_dtype`.
- `DataFrame.asof()` will return a null filled `Series` instead the scalar `NaN` if a match is not found (GH15118).
- Specific support for `copy.copy()` and `copy.deepcopy()` functions on `NDFrame` objects (GH15444).
- `Series.sort_values()` accepts a one element list of bool for consistency with the behavior of `DataFrame.sort_values()` (GH15604).
- `.merge()` and `.join()` on category dtype columns will now preserve the category dtype when possible (GH10409).
- `SparseDataFrame.default_fill_value` will be 0, previously was `nan` in the return from `pd.get_dummies(..., sparse=True)` (GH15594).
- The default behaviour of `Series.str.match` has changed from extracting groups to matching the pattern. The extracting behaviour was deprecated since pandas version 0.13.0 and can be done with the `Series.str.extract` method (GH5224). As a consequence, the `as_indexer` keyword is ignored (no longer needed to specify the new behaviour) and is deprecated.
- `NaT` will now correctly report `False` for datetimelike boolean operations such as `is_month_start` (GH15781).
- `NaT` will now correctly return `np.nan` for `Timedelta` and `Period` accessors such as `days` and `quarter` (GH15782).
- `NaT` will now return `NaT` for `tz_localize` and `tz_convert` methods (GH15830).
- `DataFrame` and `Panel` constructors with invalid input will now raise `ValueError` rather than `PandasError`, if called with scalar inputs and not axes (GH15541).
DataFrame and Panel constructors with invalid input will now raise `ValueError` rather than `pandas.core.common.PandasError`, if called with scalar inputs and not axes; The exception `PandasError` is removed as well. (GH15541)

The exception `pandas.core.common.AmbiguousIndexError` is removed as it is not referenced (GH15541)

Reorganization of the library: privacy changes

Modules privacy has changed

Some formerly public python/c/c++/cython extension modules have been moved and/or renamed. These are all removed from the public API. Furthermore, the `pandas.core`, `pandas.compat`, and `pandas.util` top-level modules are now considered to be PRIVATE. If indicated, a deprecation warning will be issued if you reference these modules. (GH12588)

Some new subpackages are created with public functionality that is not directly exposed in the top-level namespace: `pandas.errors`, `pandas.plotting` and `pandas.testing` (more details below). Together with `pandas.api.types` and certain functions in the `pandas.io` and `pandas.tseries` submodules, these are now the public subpackages.

Further changes:

- The function `union_categoricals()` is now importable from `pandas.api.types`, formerly from `pandas.types.concat` (GH15998)

- The type import `pandas.tslib.NaTType` is deprecated and can be replaced by using `type(pandas.NaT)` (GH16146)

- The public functions in `pandas.tools.hashing` deprecated from that locations, but are now importable from `pandas.util` (GH16223)

5.8. Version 0.20
• The modules in pandas.util: decorators, print_versions, doctools, validators, depr_module are now private. Only the functions exposed in pandas.util itself are public (GH16223)

**pandas.errors**

We are adding a standard public module for all pandas exceptions & warnings pandas.errors. (GH14800). Previously these exceptions & warnings could be imported from pandas.core.common or pandas.io.common. These exceptions and warnings will be removed from the *.common locations in a future release. (GH15541)

The following are now part of this API:

```python
['DtypeWarning',
'EmptyDataError',
'OutOfBoundsDatetime',
'ParserError',
'ParserWarning',
'PerformanceWarning',
'UnsortedIndexWarning',
'UnsupportedFunctionCall']
```

**pandas.testing**

We are adding a standard module that exposes the public testing functions in pandas.testing (GH9895). Those functions can be used when writing tests for functionality using pandas objects.

The following testing functions are now part of this API:

• testing.assert_frame_equal()
• testing.assert_series_equal()
• testing.assert_index_equal()

**pandas.plotting**

A new public pandas.plotting module has been added that holds plotting functionality that was previously in either pandas.tools.plotting or in the top-level namespace. See the deprecations sections for more details.

**Other development changes**

• Building pandas for development now requires cython >= 0.23 (GH14831)
• Require at least 0.23 version of cython to avoid problems with character encodings (GH14699)
• Switched the test framework to use pytest (GH13097)
• Reorganization of tests directory layout (GH14854, GH15707).
Deprecations

Deprecate .ix

The .ix indexer is deprecated, in favor of the more strict .iloc and .loc indexers. .ix offers a lot of magic on the inference of what the user wants to do. To wit, .ix can decide to index positionally OR via labels, depending on the data type of the index. This has caused quite a bit of user confusion over the years. The full indexing documentation is here. (GH14218)

The recommended methods of indexing are:

- .loc if you want to label index
- .iloc if you want to positionally index.

Using .ix will now show a DeprecationWarning with a link to some examples of how to convert code here.

```
In [122]: df = pd.DataFrame({'A': [1, 2, 3],
                     ....:       'B': [4, 5, 6],
                     ....:       index=list('abc'))

In [123]: df
Out[123]:
   A  B
  a 1 4
  b 2 5
  c 3 6
[3 rows x 2 columns]
```

Previous behavior, where you wish to get the 0th and the 2nd elements from the index in the ‘A’ column.

```
In [3]: df.ix[[0, 2], 'A']
Out[3]:
   A
  a 1
  c 3
Name: A, dtype: int64
```

Using .loc. Here we will select the appropriate indexes from the index, then use label indexing.

```
In [124]: df.loc[df.index[[0, 2]], 'A']
Out[124]:
   A
  a 1
  c 3
Name: A, Length: 2, dtype: int64
```

Using .iloc. Here we will get the location of the ‘A’ column, then use positional indexing to select things.

```
In [125]: df.iloc[[0, 2], df.columns.get_loc('A')]
Out[125]:
   A
  a 1
  c 3
Name: A, Length: 2, dtype: int64
```
Panel is deprecated and will be removed in a future version. The recommended way to represent 3-D data are with a MultiIndex on a DataFrame via the `to_frame()` method or with the xarray package. Pandas provides a `to_xarray()` method to automate this conversion (GH13563).

```python
In [133]: import pandas._testing as tm

In [134]: p = tm.makePanel()

In [135]: p
Out[135]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 3 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

Convert to a MultiIndex DataFrame

```python
In [136]: p.to_frame()
Out[136]:
          ItemA    ItemB    ItemC
major minor
2000-01-03 A   0.628776 -1.409432  0.209395
  B       0.988138 -1.347533 -0.896581
  C   -0.938153  1.272395 -0.161137
  D  -0.223019 -0.591863 -1.051539
2000-01-04 A   0.186494  1.422986 -0.592886
  B  -0.072608  0.363565  1.104352
  C   1.239072 -1.449567  0.889157
  D  2.123692 -0.414505 -0.319561
2000-01-05 A   0.952478 -2.147855 -1.473116
  B  -0.550603 -0.014752 -0.431550
  C  0.139683 -1.195524  0.288377
  D  0.122273 -1.425795 -0.619993
[12 rows x 3 columns]
```

Convert to an xarray DataArray

```python
In [137]: p.to_xarray()
Out[137]:
xarray.DataArray (items: 3, major_axis: 3, minor_axis: 4)
array([[[ 0.628776,  0.988138, -0.938153, -0.223019],
        [ 0.186494, -0.072608, -1.239072,  2.123692],
        [ 0.952478, -0.550603,  0.139683,  0.122273]],
       [[-1.409432, -1.347533,  1.272395, -0.591863],
        [ 1.422986,  0.363565, -1.449567, -0.414505],
        [-2.147855, -0.014752, -1.195524, -1.425795]],
       [[ 0.209395, -0.896581, -0.161137, -1.051539],
        [-0.592886,  1.104352,  0.889157, -0.319561],
        [-1.473116, -0.431550,  0.288377, -0.619993]])
Coordinates:
  * items   (items) object 'ItemA' 'ItemB' 'ItemC'
(continues on next page)
Deprecate groupby.agg() with a dictionary when renaming

The `.groupby(..).agg(..)`, `.rolling(..).agg(..)`, and `.resample(..).agg(..)` syntax can accept a variable of inputs, including scalars, list, and a dict of column names to scalars or lists. This provides a useful syntax for constructing multiple (potentially different) aggregations.

However, `.agg(..)` can also accept a dict that allows ‘renaming’ of the result columns. This is a complicated and confusing syntax, as well as not consistent between `Series` and `DataFrame`. We are deprecating this ‘renaming’ functionality.

- We are deprecating passing a dict to a grouped/rolled/resampled `Series`. This allowed one to rename the resulting aggregation, but this had a completely different meaning than passing a dictionary to a grouped `DataFrame`, which accepts column-to-aggregations.
- We are deprecating passing a dict-of-dicts to a grouped/rolled/resampled `DataFrame` in a similar manner.

This is an illustrative example:

```python
In [126]: df = pd.DataFrame({'A': [1, 1, 1, 2, 2],
                        'B': range(5),
                        'C': range(5))

In [127]: df.groupby('A').agg({'B': 'sum', 'C': 'min'})
Out[127]:
   B  C
0  3  0
1  7  3
```

Here is a typical useful syntax for computing different aggregations for different columns. This is a natural, and useful syntax. We aggregate from the dict-to-list by taking the specified columns and applying the list of functions. This returns a `MultiIndex` for the columns (this is not deprecated).

```python
In [128]: df.groupby('A').agg({'B': 'sum', 'C': 'min'})
Out[128]:
   B  C
A   3  0
2   7  3
```

Here’s an example of the first deprecation, passing a dict to a grouped `Series`. This is a combination aggregation & renaming:

```python
In [6]: df.groupby('A').B.agg({'foo': 'count'})
FutureWarning: using a dict on a Series for aggregation
```
is deprecated and will be removed in a future version

```
Out[6]:
   foo
  A  
  1  3
  2  2
```

You can accomplish the same operation, more idiomatically by:

```
In [129]: df.groupby('A').B.agg(['count']).rename(columns={'count': 'foo'})
Out[129]:
   foo
  A  
  1  3
  2  2
[2 rows x 1 columns]
```

Here’s an example of the second deprecation, passing a dict-of-dict to a grouped DataFrame:

```
In [23]: (df.groupby('A')
    ...: .agg({'B': {'foo': 'sum'}, 'C': {'bar': 'min'}})
    ...: )
FutureWarning: using a dict with renaming is deprecated and will be removed in a future version
Out[23]:
   B   C
foo  bar
  A
  1  3  0
  2  7  3
```

You can accomplish nearly the same by:

```
In [130]: (df.groupby('A')
    ...: .agg({'B': 'sum', 'C': 'min'})
    ...: .rename(columns={'B': 'foo', 'C': 'bar'})
    ...: )
```

```
Out[130]:
   foo   bar
  A
  1  3  0
  2  7  3
[2 rows x 2 columns]
```
Deprecate .plotting

The `pandas.tools.plotting` module has been deprecated, in favor of the top level `pandas.plotting` module. All the public plotting functions are now available from `pandas.plotting` (GH12548).

Furthermore, the top-level `pandas.scatter_matrix` and `pandas.plot_params` are deprecated. Users can import these from `pandas.plotting` as well.

Previous script:

```python
pd.tools.plotting.scatter_matrix(df)
pd.scatter_matrix(df)
```

Should be changed to:

```python
pd.plotting.scatter_matrix(df)
```

Other deprecations

- `SparseArray.to_dense()` has deprecated the `fill` parameter, as that parameter was not being respected (GH14647)
- `SparseSeries.to_dense()` has deprecated the `sparse_only` parameter (GH14647)
- `Series.repeat()` has deprecated the `reps` parameter in favor of `repeats` (GH12662)
- The `Series` constructor and `.astype` method have deprecated accepting timestamp dtypes without a frequency (e.g. `np.datetime64`) for the `dtype` parameter (GH15524)
- `Index.repeat()` and `MultiIndex.repeat()` have deprecated the `n` parameter in favor of `repeats` (GH12662)
- `Categorical.searchsorted()` and `Series.searchsorted()` have deprecated the `v` parameter in favor of `value` (GH12662)
- `TimedeltaIndex.searchsorted()`, `DatetimeIndex.searchsorted()`, and `PeriodIndex.searchsorted()` have deprecated the key parameter in favor of `value` (GH12662)
- `DataFrame.astype()` has deprecated the `raise_on_error` parameter in favor of `errors` (GH14878)
- `Series.sortlevel` and `DataFrame.sortlevel` have been deprecated in favor of `Series.sort_index` and `DataFrame.sort_index` (GH15099)
- importing `concat` from `pandas.tools.merge` has been deprecated in favor of imports from the `pandas` namespace. This should only affect explicit imports (GH15358)
- `Series/DataFrame/Panel.consolidate()` been deprecated as a public method. (GH15483)
- The `as_indexer` keyword of `Series.str.match()` has been deprecated (ignored keyword) (GH15257).
- The following top-level `pandas.str` functions have been deprecated and will be removed in a future version (GH13790, GH15940)
  - `pd.pnow()`, replaced by `Period.now()`
  - `pd.Term`, is removed, as it is not applicable to user code. Instead use in-line string expressions in the where clause when searching in HDFStore
  - `pd.Expr`, is removed, as it is not applicable to user code.
  - `pd.match()`, is removed.
pandas: powerful Python data analysis toolkit, Release 1.1.1

- pd.groupby(), replaced by using the .groupby() method directly on a Series/DataFrame
- pd.get_store(), replaced by a direct call to pd.HDFStore(...)
- is_any_int_dtype, is_floating_dtype, and is_sequence are deprecated from pandas.api.types (GH16042)

Removal of prior version deprecations/changes

- The pandas.rpy module is removed. Similar functionality can be accessed through the rpy2 project. See the R interfacing docs for more details.
- The pandas.io.ga module with a google-analytics interface is removed (GH11308). Similar functionality can be found in the Google2Pandas package.
- pd.to_datetime and pd.to_timedelta have dropped the coerce parameter in favor of errors (GH13602)
- pandas.stats.fama_macbeth, pandas.stats.ols, pandas.stats.plm and pandas.stats.var, as well as the top-level pandas.fama_macbeth and pandas.ols routines are removed. Similar functionality can be found in the statsmodels package. (GH11898)
- The TimeSeries and SparseTimeSeries classes, aliases of Series and SparseSeries, are removed (GH10890, GH15098).
- Series.is_time_series is dropped in favor of Series.index.is_all_dates (GH15098)
- The deprecated irow, icol, iget and iget_value methods are removed in favor of iloc and iat as explained here (GH10711).
- The deprecated DataFrame.iterkv() has been removed in favor of DataFrame.iteritems() (GH10711)
- The Categorical constructor has dropped the name parameter (GH10632)
- Categorical has dropped support for NaN categories (GH10748)
- The take_last parameter has been dropped from duplicated(), drop_duplicates(), nlargest(), and nsmallest() methods (GH10236, GH10792, GH10920)
- Series, Index, and DataFrame have dropped the sort and order methods (GH10726)
- Where clauses in pytables are only accepted as strings and expressions types and not other data-types (GH12027)
- DataFrame has dropped the combineAdd and combineMult methods in favor of add and mul respectively (GH10735)

Performance improvements

- Improved performance of pd.wide_to_long() (GH14779)
- Improved performance of pd.factorize() by releasing the GIL with object dtype when inferred as strings (GH14859, GH16057)
- Improved performance of timeseries plotting with an irregular DatetimeIndex (or with compat_x=True) (GH15073).
- Improved performance of groupby().cummin() and groupby().cummax() (GH15048, GH15109, GH15561, GH15635)
- Improved performance and reduced memory when indexing with a MultiIndex (GH15245)
- When reading buffer object in `read_sas()` method without specified format, filepath string is inferred rather than buffer object. (GH14947)
- Improved performance of `.rank()` for categorical data (GH15498)
- Improved performance when using `.unstack()` (GH15503)
- Improved performance of merge/join on category columns (GH10409)
- Improved performance of `drop_duplicates()` on bool columns (GH12963)
- Improved performance of `pd.core.groupby.GroupBy.apply` when the applied function used the `.name` attribute of the group DataFrame (GH15062).
- Improved performance of `iloc` indexing with a list or array (GH15504).
- Improved performance of `Series.sort_index()` with a monotonic index (GH15694)
- Improved performance in `pd.read_csv()` on some platforms with buffered reads (GH16039)

### Bug fixes

#### Conversion

- Bug in `Timestamp.replace` now raises `TypeError` when incorrect argument names are given; previously this raised `ValueError` (GH15240)
- Bug in `Timestamp.replace` with compat for passing long integers (GH15030)
- Bug in `Timestamp` returning UTC based time/date attributes when a timezone was provided (GH13303, GH6538)
- Bug in `Timestamp` incorrectly localizing timezones during construction (GH11481, GH15777)
- Bug in `TimedeltaIndex` addition where overflow was being allowed without error (GH14816)
- Bug in `TimedeltaIndex` raising a `ValueError` when boolean indexing with `loc` (GH14946)
- Bug in catching an overflow in `Timestamp + Timedelta/Offset` operations (GH15126)
- Bug in `DatetimeIndex.round()` and `Timestamp.round()` floating point accuracy when rounding by milliseconds or less (GH14440, GH15578)
- Bug in `astype()` where `inf` values were incorrectly converted to integers. Now raises error now with `astype()` for Series and DataFrames (GH14265)
- Bug in `DataFrame(...).apply(to_numeric)` when values are of type `decimal.Decimal`. (GH14827)
- Bug in `describe()` when passing a numpy array which does not contain the median to the `percentiles` keyword argument (GH14908)
- Cleaned up `PeriodIndex` constructor, including raising on floats more consistently (GH13277)
- Bug in using `__deepcopy__` on empty NDFrame objects (GH15370)
- Bug in `.replace()` may result in incorrect dtypes. (GH12747, GH15765)
- Bug in `Series.replace` and `DataFrame.replace` which failed on empty replacement dicts (GH15289)
- Bug in `Series.replace` which replaced a numeric by string (GH15743)
- Bug in `Index` construction with `NaN` elements and integer dtype specified (GH15187)
- Bug in `Series` construction with a `datetimetz` (GH14928)
- Bug in `Series.dt.round()` inconsistent behaviour on `NaT`’s with different arguments (GH14940)
pandas: powerful Python data analysis toolkit, Release 1.1.1

- Bug in `Series` constructor when both `copy=True` and `dtype` arguments are provided (GH15125)
- Incorrect dtyped `Series` was returned by comparison methods (e.g., `lt`, `gt`, ...) against a constant for an empty `DataFrame` (GH15077)
- Bug in `Series.ffill()` with mixed dtypes containing tz-aware datetimes. (GH14956)
- Bug in `DataFrame.fillna()` where the argument `downcast` was ignored when `fillna` value was of type `dict` (GH15277)
- Bug in `.asfreq()`, where frequency was not set for empty `Series` (GH14320)
- Bug in `DataFrame` construction with nulls and datetimes in a list-like (GH15869)
- Bug in `DataFrame.fillna()` with tz-aware datetimes (GH15855)
- Bug in `is_string_dtype`, `is_timedelta64_ns_dtype`, and `is_string_like_dtype` in which an error was raised when `None` was passed in (GH15941)
- Bug in the return type of `pd.unique` on a `Categorical`, which was returning an `ndarray` and not a `Categorical` (GH15903)
- Bug in `Index.to_series()` where the index was not copied (and so mutating later would change the original), (GH15949)
- Bug in indexing with partial string indexing with a len-1 `DataFrame` (GH16071)
- Bug in `Series` construction where passing invalid `dtype` didn’t raise an error. (GH15520)

**Indexing**

- Bug in `Index` power operations with reversed operands (GH14973)
- Bug in `DataFrame.sort_values()` when sorting by multiple columns where one column is of type `int64` and contains `NaT` (GH14922)
- Bug in `DataFrame.reindex()` in which method was ignored when passing columns (GH14992)
- Bug in `DataFrame.loc` with indexing a `MultiIndex` with a `Series` indexer (GH14730, GH15424)
- Bug in `DataFrame.loc` with indexing a `MultiIndex` with a numpy array (GH15434)
- Bug in `Series.asof` which raised if the series contained all `np.nan` (GH15731)
- Bug in `.at` when selecting from a tz-aware column (GH15822)
- Bug in `Series.where()` and `DataFrame.where()` where array-like conditionals were being rejected (GH15414)
- Bug in `Series.where()` where TZ-aware data was converted to float representation (GH15701)
- Bug in `.loc` that would not return the correct `dtype` for scalar access for a `DataFrame` (GH11617)
- Bug in output formatting of a `MultiIndex` when names are integers (GH12223, GH15262)
- Bug in `Categorical.searchsorted()` where alphabetical instead of the provided categorical order was used (GH14522)
- Bug in `Series.iloc` where a `Categorical` object for list-like indexes input was returned, where a `Series` was expected. (GH14580)
- Bug in `DataFrame.isin` comparing datetimelike to empty frame (GH15473)
- Bug in `.reset_index()` when an all `NaN` level of a `MultiIndex` would fail (GH6322)
• Bug in `.reset_index()` when raising error for index name already present in MultiIndex columns (GH16120)

• Bug in creating a MultiIndex with tuples and not passing a list of names; this will now raise ValueError (GH15110)

• Bug in the HTML display with a MultiIndex and truncation (GH14882)

• Bug in the display of `.info()` where a qualifier (+) would always be displayed with a MultiIndex that contains only non-strings (GH15245)

• Bug in `pd.concat()` where the names of MultiIndex of resulting DataFrame are not handled correctly when None is presented in the names of MultiIndex of input DataFrame (GH15787)

• Bug in `DataFrame.sort_index()` and `Series.sort_index()` where na_position doesn’t work with a MultiIndex (GH14784, GH16604)

• Bug in `pd.concat()` when combining objects with a CategoricalIndex (GH16111)

• Bug in indexing with a scalar and a CategoricalIndex (GH16123)

IO

• Bug in `pd.to_numeric()` in which float and unsigned integer elements were being improperly casted (GH14941, GH15005)

• Bug in `pd.read_fwf()` where the skiprows parameter was not being respected during column width inference (GH11256)

• Bug in `pd.read_csv()` in which the dialect parameter was not being verified before processing (GH14898)

• Bug in `pd.read_csv()` in which missing data was being improperly handled with usecols (GH6710)

• Bug in `pd.read_csv()` in which a file containing a row with many columns followed by rows with fewer columns would cause a crash (GH14125)

• Bug in `pd.read_csv()` for the C engine where usecols were being indexed incorrectly with parse_dates (GH14792)

• Bug in `pd.read_csv()` with parse_dates when multi-line headers are specified (GH15376)

• Bug in `pd.read_csv()` with float_precision='round_trip' which caused a segfault when a text entry is parsed (GH15140)

• Bug in `pd.read_csv()` when an index was specified and no values were specified as null values (GH15835)

• Bug in `pd.read_csv()` in which certain invalid file objects caused the Python interpreter to crash (GH15337)

• Bug in `pd.read_csv()` in which invalid values for nrows and chunksize were allowed (GH15767)

• Bug in `pd.read_csv()` for the Python engine in which unhelpful error messages were being raised when parsing errors occurred (GH15910)

• Bug in `pd.read_csv()` in which the skipfooter parameter was not being properly validated (GH15925)

• Bug in `pd.to_csv()` in which there was numeric overflow when a timestamp index was being written (GH15982)

• Bug in `pd.util.hashing.hash_pandas_object()` in which hashing of categoricals depended on the ordering of categories, instead of just their values. (GH15143)

• Bug in `.to_json()` where lines=True and contents (keys or values) contain escaped characters (GH15096)
• Bug in `.to_json()` causing single byte ascii characters to be expanded to four byte unicode (GH15344)
• Bug in `.to_json()` for the C engine where rollover was not correctly handled for case where frac is odd and diff is exactly 0.5 (GH15716, GH15864)
• Bug in `pd.read_json()` for Python 2 where lines=True and contents contain non-ascii unicode characters (GH15132)
• Bug in `pd.read_msgpack()` in which Series categoricals were being improperly processed (GH14901)
• Bug in `pd.read_msgpack()` which did not allow loading of a dataframe with an index of type CategoricalIndex (GH15487)
• Bug in `pd.read_msgpack()` when deserializing a CategoricalIndex (GH15487)
• Bug in `DataFrame.to_records()` with converting a DatetimeIndex with a timezone (GH13937)
• Bug in `DataFrame.to_records()` which failed with unicode characters in column names (GH11879)
• Bug in `.to_sql()` when writing a DataFrame with numeric index names (GH15404).
• Bug in `DataFrame.to_html()` with index=False and max_rows raising in IndexError (GH14998)
• Bug in `pd.read_hdf()` passing a Timestamp to the where parameter with a non date column (GH15492)
• Bug in `DataFrame.to_stata()` and StataWriter which produces incorrectly formatted files to be produced for some locales (GH13856)
• Bug in StataReader and StataWriter which allows invalid encodings (GH15723)
• Bug in the Series repr not showing the length when the output was truncated (GH15962).

Plotting

• Bug in `DataFrame.hist` where plt.tight_layout caused an AttributeError (use matplotlib >= 2.0.1) (GH9351)
• Bug in `DataFrame.boxplot` where fontsize was not applied to the tick labels on both axes (GH15108)
• Bug in the date and time converters pandas registers with matplotlib not handling multiple dimensions (GH16026)
• Bug in `pd.scatter_matrix()` could accept either color or c, but not both (GH14855)

GroupBy/resample/rolling

• Bug in `.groupby(..).resample()` when passed the on= kwarg. (GH15021)
• Properly set __name__ and __qualname__ for Groupby.* functions (GH14620)
• Bug in GroupBy.get_group() failing with a categorical grouper (GH15155)
• Bug in `.groupby(...).rolling(...)` when on is specified and using a DatetimeIndex (GH15130, GH13966)
• Bug in groupby operations with timedelta64 when passing numeric_only=False (GH5724)
• Bug in groupby.apply() coercing object dtypes to numeric types, when not all values were numeric (GH14423, GH15421, GH15670)
• Bug in resample, where a non-string offset argument would not be applied when resampling a timeseries (GH13218)
• Bug in `DataFrame.groupby().describe()` when grouping on `Index` containing tuples (GH14848)
• Bug in `groupby().nunique()` with a datetimelike grouper where bins counts were incorrect (GH13453)
• Bug in `groupby.transform()` that would coerce the resultant dtypes back to the original (GH10972, GH11444)
• Bug in `groupby.agg()` incorrectly localizing timezone on `datetime` (GH15426, GH10668, GH13046)
• Bug in `.rolling/expanding()` functions where `count()` was not counting `np.Inf`, nor handling object dtypes (GH12541)
• Bug in `.rolling()` where `pd.Timedelta` or `datetime.timedelta` was not accepted as a window argument (GH15440)
• Bug in `Rolling.quantile` function that caused a segmentation fault when called with a quantile value outside of the range [0, 1] (GH15463)
• Bug in `DataFrame.resample().median()` if duplicate column names are present (GH14233)

Sparse

• Bug in `SparseSeries.reindex` on single level with list of length 1 (GH15447)
• Bug in repr-formatting a `SparseDataFrame` after a value was set on (a copy of) one of its series (GH15488)
• Bug in `SparseDataFrame` construction with lists not coercing to dtype (GH15682)
• Bug in sparse array indexing in which indices were not being validated (GH15863)

Reshaping

• Bug in `pd.merge_asof()` where `left_index` or `right_index` caused a failure when multiple `by` was specified (GH15676)
• Bug in `pd.merge_asof()` where `left_index/right_index` together caused a failure when tolerance was specified (GH15135)
• Bug in `DataFrame.pivot_table()` where `dropna=True` would not drop all-NaN columns when the columns was a category dtype (GH15193)
• Bug in `pd.melt()` where passing a tuple value for `value_vars` caused a `TypeError` (GH15348)
• Bug in `pd.pivot_table()` where no error was raised when values argument was not in the columns (GH14938)
• Bug in `pd.concat()` in which concatenating with an empty dataframe with `join='inner'` was being improperly handled (GH15328)
• Bug with `sort=True` in `DataFrame.join` and `pd.merge` when joining on indexes (GH15582)
• Bug in `DataFrame.nsmallest` and `DataFrame.nlargest` where identical values resulted in duplicated rows (GH15297)
• Bug in `pandas.pivot_table()` incorrectly raising `UnicodeError` when passing unicode input for `margins` keyword (GH13292)
Numeric

- Bug in `.rank()` which incorrectly ranks ordered categories (GH15420)
- Bug in `.corr()` and `.cov()` where the column and index were the same object (GH14617)
- Bug in `.mode()` where mode was not returned if was only a single value (GH15714)
- Bug in `pd.cut()` with a single bin on an all 0s array (GH15428)
- Bug in `pd.qcut()` with a single quantile and an array with identical values (GH15431)
- Bug in `pandas.tools.utils.cartesian_product()` with large input can cause overflow on windows (GH15265)
- Bug in `.eval()` which caused multi-line evals to fail with local variables not on the first line (GH15342)

Other

- Compat with SciPy 0.19.0 for testing on `.interpolate()` (GH15662)
- Compat for 32-bit platforms for `.qcut/cut`: bins will now be int64 dtype (GH14866)
- Bug in interactions with Qt when a QtApplication already exists (GH14372)
- Avoid use of `np.finfo()` during import pandas removed to mitigate deadlock on Python GIL misuse (GH14641)

5.9 Version 0.19

5.9.1 Version 0.19.2 (December 24, 2016)

This is a minor bug-fix release in the 0.19.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

Highlights include:
  • Compatibility with Python 3.6
  • Added a Pandas Cheat Sheet. (GH13202).

Enhancements

The pd.merge_asof(), added in 0.19.0, gained some improvements:
  • pd.merge_asof() gained left_index/right_index and left_by/right_by arguments (GH14253)
  • pd.merge_asof() can take multiple columns in by parameter and has specialized dtypes for better performance (GH13936)
Performance improvements

- Performance regression with PeriodIndex (GH14822)
- Performance regression in indexing with getitem (GH14930)
- Improved performance of .replace() (GH12745)
- Improved performance Series creation with a datetime index and dictionary data (GH14894)

Bug fixes

- Compat with python 3.6 for pickling of some offsets (GH14685)
- Compat with python 3.6 for some indexing exception types (GH14684, GH14689)
- Compat with python 3.6 for deprecation warnings in the test suite (GH14681)
- Compat with python 3.6 for Timestamp pickles (GH14689)
- Compat with dateutil==2.6.0; segfault reported in the testing suite (GH14621)
- Allow nanosecond in Timestamp.replace as a kwarg (GH14621)
- Bug in pd.read_csv in which aliasing was being done for na_values when passed in as a dictionary (GH14203)
- Bug in pd.read_csv in which column indices for a dict-like na_values were not being respected (GH14203)
- Bug in pd.read_csv where reading files fails, if the number of headers is equal to the number of lines in the file (GH14515)
- Bug in pd.read_csv for the Python engine in which an unhelpful error message was being raised when multi-char delimiters were not being respected with quotes (GH14582)
- Fix bugs (GH14734, GH13654) in pd.read_sas and pandas.io.sas.sas7bdat.SAS7BDATReader that caused problems when reading a SAS file incrementally.
- Bug in pd.read_csv for the Python engine in which an unhelpful error message was being raised when skipfooter was not being respected by Python’s CSV library (GH13879)
- Bug infillna() in which timezone aware datetime64 values were incorrectly rounded (GH14872)
- Bug in .groupby(..., sort=True) of a non-lexsorted MultiIndex when grouping with multiple levels (GH14776)
- Bug in pd.cut with negative values and a single bin (GH14652)
- Bug in pd.to_numeric where a 0 was not unsigned on a downcast='unsigned' argument (GH14401)
- Bug in plotting regular and irregular timeseries using shared axes (sharex=True or ax.twinx()) (GH13341, GH14322).
- Bug in not propagating exceptions in parsing invalid datetimes, noted in python 3.6 (GH14561)
- Bug in resampling a DatetimeIndex in local TZ, covering a DST change, which would raise AmbiguousTimeError (GH14682)
- Bug in indexing that transformed RecursionError into KeyError or IndexError (GH14554)
- Bug in HDFStore when writing a MultiIndex when using data_columns=True (GH14435)
- Bug in HDFStore.append() when writing a Series and passing a min_itemsize argument containing a value for the index (GH1412)
• Bug when writing to a HDFStore in table format with a min_itemsize value for the index and without asking to append (GH10381)
• Bug in Series.groupby.nunique() raising an IndexError for an empty Series (GH12553)
• Bug in DataFrame.nlargest and DataFrame.nsmallest when the index had duplicate values (GH13412)
• Bug in clipboard functions on linux with python2 with unicode and separators (GH13747)
• Bug in clipboard functions on Windows 10 and python 3 (GH14362, GH12807)
• Bug in .to_clipboard() and Excel compat (GH12529)
• Bug in DataFrame.combine_first() for integer columns (GH14687).
• Bug in pd.read_csv() in which the dtype parameter was not being respected for empty data (GH14712)
• Bug in pd.read_csv() in which the nrows parameter was not being respected for large input when using the C engine for parsing (GH7626)
• Bug in pd.merge_asof() could not handle timezone-aware DatetimeIndex when a tolerance was specified (GH14844)
• Explicit check in to_stata and StataWriter for out-of-range values when writing doubles (GH14618)
• Bug in .plot(kind='kde') which did not drop missing values to generate the KDE Plot, instead generating an empty plot. (GH14821)
• Bug in unstack() if called with a list of column(s) as an argument, regardless of the dtypes of all columns, they get coerced to object (GH11847)

5.9.2 Version 0.19.1 (November 3, 2016)

This is a minor bug-fix release from 0.19.0 and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

### What’s new in v0.19.1

- Performance improvements
- Bug fixes
- Contributors

#### Performance improvements

- Fixed performance regression in factorization of Period data (GH14338)
- Fixed performance regression in Series.asof(where) when where is a scalar (GH14461)
- Improved performance in DataFrame.asof(where) when where is a scalar (GH14461)
- Improved performance in .to_json() when lines=True (GH14408)
- Improved performance in certain types of loc indexing with a MultiIndex (GH14551).
Bug fixes

- Source installs from PyPI will now again work without cython installed, as in previous versions (GH14204)
- Compatability with Cython 0.25 for building (GH14496)
- Fixed regression where user-provided file handles were closed in read_csv (c engine) (GH14418).
- Fixed regression in DataFrame.quantile when missing values where present in some columns (GH14357).
- Fixed regression in Index.difference where the freq of a DatetimeIndex was incorrectly set (GH14323)
- Added back pandas.core.common.array_equivalent with a deprecation warning (GH14555).
- Bug in pd.read_csv for the C engine in which quotation marks were improperly parsed in skipped rows (GH14459)
- Bug in pd.read_csv for Python 2.x in which Unicode quote characters were no longer being respected (GH14477)
- Fixed regression in Index.append when categorical indices were appended (GH14545).
- Fixed regression in pd.DataFrame where constructor fails when given dict with None value (GH14381)
- Fixed regression in DatetimeIndex._maybe_cast_slice_bound when index is empty (GH14354).
- Bug in localizing an ambiguous timezone when a boolean is passed (GH14402)
- Bug in TimedeltaIndex addition with a Datetime-like object where addition overflow in the negative direction was not being caught (GH14068, GH14453)
- Bug in string indexing against data with objectIndex may raise AttributeError (GH14424)
- Correctly raise ValueError on empty input to pd.eval() and df.query() (GH13139)
- Bug in RangeIndex.intersection when result is a empty set (GH14364).
- Bug in groupby-transform broadcasting that could cause incorrect dtype coercion (GH14457)
- Bug in Series.__setitem__ which allowed mutating read-only arrays (GH14359).
- Bug in DataFrame.insert where multiple calls with duplicate columns can fail (GH14291)
- pd.merge() will raise ValueError with non-boolean parameters in passed boolean type arguments (GH14434)
- Bug in Timestamp where dates very near the minimum (1677-09) could underflow on creation (GH14415)
- Bug in pd.concat where names of the keys were not propagated to the resulting MultiIndex (GH14252)
- Bug in pd.concat where axis cannot take string parameters 'rows' or 'columns' (GH14369)
- Bug in pd.concat with dataframes heterogeneous in length and tuple keys (GH14438)
- Bug in MultiIndex.set_levels where illegal level values were still set after raising an error (GH13754)
- Bug in DataFrame.to_json where lines=True and a value contained a } character (GH14391)
- Bug in df.groupby causing an AttributeError when grouping a single index frame by a column and the index level (GH14327)
- Bug in df.groupby where TypeError raised when pd.Grouper(key=...) is passed in a list (GH14334)
- Bug in pd.pivot_table may raise TypeError or ValueError when index or columns is not scalar and values is not specified (GH14380)

5.9.3 Version 0.19.0 (October 2, 2016)

This is a major release from 0.18.1 and includes number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- `merge_asof()` for asof-style time-series joining, see here
- `.rolling()` is now time-series aware, see here
- `read_csv()` now supports parsing `Categorical` data, see here
- A function `union_categorical()` has been added for combining categoricals, see here
- `PeriodIndex` now has its own `period` dtype, and changed to be more consistent with other `Index` classes. See here
- Sparse data structures gained enhanced support of `int` and `bool` dtypes, see here
- Comparison operations with `Series` no longer ignores the index, see here for an overview of the API changes.
- Introduction of a pandas development API for utility functions, see here.
- Deprecation of `Panel4D` and `PanelND`. We recommend to represent these types of n-dimensional data with the xarray package.
- Removal of the previously deprecated modules `pandas.io.data`, `pandas.io.wb`, `pandas.tools.rplot`.

**Warning:** pandas >= 0.19.0 will no longer silence numpy ufunc warnings upon import, see here.

What’s new in v0.19.0

- **New features**
  - Function `merge_asof` for asof-style time-series joining
  - Method `.rolling()` is now time-series aware
  - Method `read_csv` has improved support for duplicate column names
  - Method `read_csv` supports parsing `Categorical` directly
  - `Categorical` concatenation
  - `Semi-month` offsets
  - `New Index` methods
  - `Google BigQuery` enhancements
  - `Fine-grained NumPy errstate`
  - Method `get_dummies` now returns integer dtypes
  - `Downcast values to smallest possible dtype` in `to_numeric`
  - pandas development API
  - Other enhancements
- **API changes**
- `Series.tolist()` will now return Python types
- `Series` operators for different indexes
  - Arithmetic operators
  - Comparison operators
  - Logical operators
  - Flexible comparison methods
- `Series` type promotion on assignment
- `Function .to_datetime()` changes
- Merging changes
- `Method .describe()` changes
- `Period` changes
  - The `PeriodIndex` now has period dtype
  - `Period('NaT')` now returns `pd.NaT`  
  - `PeriodIndex.values` now returns array of `Period` object
- `Index` + / – no longer used for set operations
- `Index.difference` and `.symmetric_difference` changes
- `Index.unique` consistently returns `Index`
- `MultiIndex constructors, groupby and set_index preserve categorical dtypes`
- `Function read_csv` will progressively enumerate chunks
- Sparse changes
  - Types `int64` and `bool` support enhancements
  - Operators now preserve dtypes
  - Other sparse fixes
- `Indexer` dtype changes
- Other API changes
- **Deprecations**
- **Removal of prior version deprecations(changes**
- **Performance improvements**
- **Bug fixes**
- **Contributors**
New features

Function `merge_asof` for asof-style time-series joining

A long-time requested feature has been added through the `merge_asof()` function, to support asof style joining of time-series (GH1870, GH13695, GH13709, GH13902). Full documentation is here.

The `merge_asof()` performs an asof merge, which is similar to a left-join except that we match on nearest key rather than equal keys.

```python
In [1]: left = pd.DataFrame({'a': [1, 5, 10],
                          'left_val': ['a', 'b', 'c']})
...:
In [2]: right = pd.DataFrame({'a': [1, 2, 3, 6, 7],
                          'right_val': [1, 2, 3, 6, 7]})
...:
In [3]: left
Out[3]:
   a  left_val
0  1      a
1  5      b
2 10      c
[3 rows x 2 columns]
In [4]: right
Out[4]:
   a  right_val
0  1       1
1  2       2
2  3       3
3  6       6
4  7       7
[5 rows x 2 columns]
```

We typically want to match exactly when possible, and use the most recent value otherwise.

```python
In [5]: pd.merge_asof(left, right, on='a')
Out[5]:
   a  left_val  right_val
0  1      a       1
1  5      b       3
2 10      c       7
[3 rows x 3 columns]
```

We can also match rows ONLY with prior data, and not an exact match.

```python
In [6]: pd.merge_asof(left, right, on='a', allow_exact_matches=False)
Out[6]:
   a  left_val  right_val
0  1      a     NaN
1  5      b       3
2 10      c       7
(continues on next page)```
In a typical time-series example, we have trades and quotes and we want to asof-join them. This also illustrates using the by parameter to group data before merging.

```
In [7]: trades = pd.DataFrame({
   ...:     'time': pd.to_datetime(['20160525 13:30:00.023',
   ...:                      '20160525 13:30:00.038',
   ...:                      '20160525 13:30:00.048',
   ...:                      '20160525 13:30:00.048',
   ...:                      '20160525 13:30:00.048']),
   ...:     'ticker': ['MSFT', 'MSFT',
   ...:               'GOOG', 'GOOG', 'AAPL'],
   ...:     'price': [51.95, 51.95,
   ...:                720.77, 720.92, 98.00],
   ...:     'quantity': [75, 155,
   ...:                   100, 100, 100]},
   ...: columns=['time', 'ticker', 'price', 'quantity'])
   ...

In [8]: quotes = pd.DataFrame({
   ...:     'time': pd.to_datetime(['20160525 13:30:00.023',
   ...:                      '20160525 13:30:00.023',
   ...:                      '20160525 13:30:00.030',
   ...:                      '20160525 13:30:00.041',

```

This returns a merged DataFrame with the entries in the same order as the original left passed DataFrame (trades in this case), with the fields of the quotes merged.

**Method `.rolling()` is now time-series aware**

`.rolling()` objects are now time-series aware and can accept a time-series offset (or convertible) for the window argument (GH13327, GH12995). See the full documentation [here](https://pandas.pydata.org/pandas-docs/stable/reference/api/pandas.DataFrame.rolling.html).

```
In [12]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
....:                   index=pd.date_range('20130101 09:00:00',
....:                   periods=5, freq='s'))
```

```
In [13]: dft.rolling(2).sum()
```

Out[13]:
```
<table>
<thead>
<tr>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-01 09:00:00</td>
</tr>
<tr>
<td>2013-01-01 09:00:01</td>
</tr>
<tr>
<td>2013-01-01 09:00:02</td>
</tr>
<tr>
<td>2013-01-01 09:00:03</td>
</tr>
<tr>
<td>2013-01-01 09:00:04</td>
</tr>
</tbody>
</table>
```

This is a regular frequency index. Using an integer window parameter works to roll along the window frequency.
2013-01-01 09:00:00 NaN
2013-01-01 09:00:01 1.0
2013-01-01 09:00:02 3.0
2013-01-01 09:00:03 NaN
2013-01-01 09:00:04 NaN

[5 rows x 1 columns]

In [15]: dft.rolling(2, min_periods=1).sum()
Out[15]:

[5 rows x 1 columns]

Specifying an offset allows a more intuitive specification of the rolling frequency.

In [16]: dft.rolling('2s').sum()
Out[16]:

[5 rows x 1 columns]

Using a non-regular, but still monotonic index, rolling with an integer window does not impart any special calculation.

In [17]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4],
....:                     index=pd.Index([pd.Timestamp('20130101 09:00:00'),
....:                               pd.Timestamp('20130101 09:00:02'),
....:                               pd.Timestamp('20130101 09:00:03'),
....:                               pd.Timestamp('20130101 09:00:04'),
....:                               pd.Timestamp('20130101 09:00:06')],
....:                     name='foo'))
In [18]: dft
Out[18]:

[5 rows x 1 columns]

In [19]: dft.rolling(2).sum()
Out[19]:

(continues on next page)
Using the time-specification generates variable windows for this sparse data.

```python
In [20]: dft.rolling('2s').sum()
Out[20]:
     B
foo
2013-01-01 09:00:00  NaN
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06   NaN
[5 rows x 1 columns]
```

Furthermore, we now allow an optional `on` parameter to specify a column (rather than the default of the index) in a DataFrame.

```python
In [21]: dft = dft.reset_index()
In [22]: dft
Out[22]:
     foo    B
0 2013-01-01 09:00:00  0.0
1 2013-01-01 09:00:02  1.0
2 2013-01-01 09:00:03  2.0
3 2013-01-01 09:00:05  NaN
4 2013-01-01 09:00:06  4.0
[5 rows x 2 columns]
```

```python
In [23]: dft.rolling('2s', on='foo').sum()
Out[23]:
     foo    B
0 2013-01-01 09:00:00  0.0
1 2013-01-01 09:00:02  1.0
2 2013-01-01 09:00:03  3.0
3 2013-01-01 09:00:05  NaN
4 2013-01-01 09:00:06  4.0
[5 rows x 2 columns]
```
Method `read_csv` has improved support for duplicate column names

Duplicate column names are now supported in `read_csv()` whether they are in the file or passed in as the `names` parameter (GH7160, GH9424)

In [24]: data = '0,1,2
3,4,5'
In [25]: names = ['a', 'b', 'a']

Previous behavior:

In [2]: pd.read_csv(StringIO(data), names=names)
Out[2]:
    a  b  a
   0  2  1  2
   1  5  4  5

The first a column contained the same data as the second a column, when it should have contained the values [0, 3].

New behavior:

In [26]: pd.read_csv(StringIO(data), names=names)

---------------------------------------------------------------------------
ValueError                                Traceback (most recent call last)
<ipython-input-26-a095135d9435> in <module>
----> 1 pd.read_csv(StringIO(data), names=names)
/pandas-release/pandas/pandas/io/parsers.py in read_csv(filepath_or_buffer, sep,
   684 )
   685     return _read(filepath_or_buffer, kwds)
/pandas-release/pandas/pandas/io/parsers.py in _read(filepath_or_buffer, kwds)
   449     _validate_names(kwds.get("names", None))
   450     # Create the parser.
/pandas-release/pandas/pandas/io/parsers.py in _validate_names(names)
   413     if names is not None:
   414         if len(names) != len(set(names)):
   ----> 415             raise ValueError("Duplicate names are not allowed.")
   416     if not is_list_like(names, allow_sets=False):
   417         raise ValueError("Names should be an ordered collection.")

ValueError: Duplicate names are not allowed.
Method **read_csv** supports parsing Categorical directly

The **read_csv()** function now supports parsing a Categorical column when specified as a dtype (GH10153). Depending on the structure of the data, this can result in a faster parse time and lower memory usage compared to converting to Categorical after parsing. See the io docs here.

```python
In [27]: data = 'col1,col2,col3
a,b,1
a,b,2
b,c,d,3'

In [28]: pd.read_csv(StringIO(data))
Out[28]:
       col1  col2  col3
0      a     b     1
1      a     b     2
2      b     c     3
[3 rows x 3 columns]

In [29]: pd.read_csv(StringIO(data)).dtypes
Out[29]:
       col1  col2  col3
object   object  int64

In [30]: pd.read_csv(StringIO(data), dtype='category').dtypes
Out[30]:
       col1  col2  col3
category category category

Individual columns can be parsed as a Categorical using a dict specification

```python
In [31]: pd.read_csv(StringIO(data), dtype={'col1': 'category'}).dtypes
Out[31]:
       col1  col2  col3
category  object  int64

In [32]: df = pd.read_csv(StringIO(data), dtype='category')

In [33]: df.dtypes
Out[33]:
       col1  col2  col3
category category category

Note: The resulting categories will always be parsed as strings (object dtype). If the categories are numeric they can be converted using the **to_numeric()** function, or as appropriate, another converter such as **to_datetime()**.

```python
In [34]: df['col3']
Out[34]:
0  1
1  2
```

(continues on next page)
2 3
Name: col3, Length: 3, dtype: category
Categories (3, object): ['1', '2', '3']

In [35]: df['col3'].cat.categories = pd.to_numeric(df['col3'].cat.categories)

In [36]: df['col3']
Out[36]:
0 1
1 2
2 3
Name: col3, Length: 3, dtype: category
Categories (3, int64): [1, 2, 3]

Categorical concatenation

- A function `union_categoricals()` has been added for combining categoricals, see [Unioning Categoricals](GH13361, GH13763, GH13846, GH14173)

```
In [37]: from pandas.api.types import union_categoricals
In [38]: a = pd.Categorical(['b', 'c'])
In [39]: b = pd.Categorical(['a', 'b'])
In [40]: union_categoricals([a, b])
Out[40]:
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

- `concat` and `append` now can concat category dtypes with different categories as object dtype (GH13524)

```
In [41]: s1 = pd.Series(['a', 'b'], dtype='category')
In [42]: s2 = pd.Series(['b', 'c'], dtype='category')

Previous behavior:
```
In [1]: pd.concat([s1, s2])
ValueError: incompatible categories in categorical concat
```

New behavior:
```
In [43]: pd.concat([s1, s2])
Out[43]:
      0   a
      1   b
      0   b
      1   c
Length: 4, dtype: object
```
Semi-month offsets

Pandas has gained new frequency offsets, SemiMonthEnd (‘SM’) and SemiMonthBegin (‘SMS’). These provide date offsets anchored (by default) to the 15th and end of month, and 15th and 1st of month respectively. (GH1543)

```python
In [44]: from pandas.tseries.offsets import SemiMonthEnd, SemiMonthBegin
```

**SemiMonthEnd:**

```python
In [45]: pd.Timestamp('2016-01-01') + SemiMonthEnd()
Out[45]: Timestamp('2016-01-15 00:00:00')
```

```python
In [46]: pd.date_range('2015-01-01', freq='SM', periods=4)
```

**SemiMonthBegin:**

```python
In [47]: pd.Timestamp('2016-01-01') + SemiMonthBegin()
Out[47]: Timestamp('2016-01-15 00:00:00')
```

```python
In [48]: pd.date_range('2015-01-01', freq='SMS', periods=4)
```

Using the anchoring suffix, you can also specify the day of month to use instead of the 15th.

```python
In [49]: pd.date_range('2015-01-01', freq='SMS-16', periods=4)
Out[49]: DatetimeIndex(['2015-01-01', '2015-01-16', '2015-02-01', '2015-02-16'], dtype='datetime64[ns]', freq='SMS-16')
```

```python
In [50]: pd.date_range('2015-01-01', freq='SM-14', periods=4)
Out[50]: DatetimeIndex(['2015-01-14', '2015-01-31', '2015-02-14', '2015-02-28'], dtype='datetime64[ns]', freq='SM-14')
```

New Index methods

The following methods and options are added to Index, to be more consistent with the Series and DataFrame API.

Index now supports the `.where()` function for same shape indexing (GH13170)

```python
In [51]: idx = pd.Index(['a', 'b', 'c'])
In [52]: idx.where([True, False, True])
Out[52]: Index(['a', nan, 'c'], dtype='object')
```

Index now supports `.dropna()` to exclude missing values (GH6194)

```python
In [53]: idx = pd.Index([1, 2, np.nan, 4])
In [54]: idx.dropna()
Out[54]: Float64Index([1.0, 2.0, 4.0], dtype='float64')
```

For MultiIndex, values are dropped if any level is missing by default. Specifying `how='all'` only drops values where all levels are missing.
Index now supports .str.extractall() which returns a DataFrame, see the docs here (GH10008, GH13156)

Index.astype() now accepts an optional boolean argument copy, which allows optional copying if the requirements on dtype are satisfied (GH13209)

Google BigQuery enhancements

- The read_gbq() method has gained the dialect argument to allow users to specify whether to use BigQuery’s legacy SQL or BigQuery’s standard SQL. See the docs for more details (GH13615).
- The to_gbq() method now allows the DataFrame column order to differ from the destination table schema (GH11359).
Fine-grained NumPy errstate

Previous versions of pandas would permanently silence numpy’s ufunc error handling when pandas was imported. Pandas did this in order to silence the warnings that would arise from using numpy ufuncs on missing data, which are usually represented as NaNs. Unfortunately, this silenced legitimate warnings arising in non-pandas code in the application. Starting with 0.19.0, pandas will use the numpy.errstate context manager to silence these warnings in a more fine-grained manner, only around where these operations are actually used in the pandas code base. (GH13109, GH13145)

After upgrading pandas, you may see new RuntimeWarnings being issued from your code. These are likely legitimate, and the underlying cause likely existed in the code when using previous versions of pandas that simply silenced the warning. Use numpy.errstate around the source of the RuntimeWarning to control how these conditions are handled.

Method get_dummies now returns integer dtypes

The pd.get_dummies function now returns dummy-encoded columns as small integers, rather than floats (GH8725). This should provide an improved memory footprint.

Previous behavior:

```python
In [1]: pd.get_dummies(['a', 'b', 'a', 'c']).dtypes
Out[1]:
a float64
b float64
c float64
dtype: object
```

New behavior:

```python
In [61]: pd.get_dummies(['a', 'b', 'a', 'c']).dtypes
Out[61]:
a uint8
b uint8
c uint8
Length: 3, dtype: object
```

Downcast values to smallest possible dtype in to_numeric

pd.to_numeric() now accepts a downcast parameter, which will downcast the data if possible to smallest specified numerical dtype (GH13352)

```python
In [62]: s = ['1', 2, 3]

In [63]: pd.to_numeric(s, downcast='unsigned')
Out[63]: array([1, 2, 3], dtype=uint8)

In [64]: pd.to_numeric(s, downcast='integer')
Out[64]: array([1, 2, 3], dtype=int8)
```
pandas development API

As part of making pandas API more uniform and accessible in the future, we have created a standard sub-package of pandas, pandas.api to hold public API’s. We are starting by exposing type introspection functions in pandas.api.types. More sub-packages and officially sanctioned API’s will be published in future versions of pandas (GH13147, GH13634)

The following are now part of this API:

```
In [65]: import pprint
In [66]: from pandas.api import types
In [67]: func = [f for f in dir(types) if not f.startswith('_')]
In [68]: pprint.pprint(func)
['CategoricalDtype', 'DatetimeTZDtype', 'IntervalDtype', 'PeriodDtype', 'infer_dtype', 'is_array_like', 'is_bool', 'is_bool_dtype', 'is_categorical', 'is_categorical_dtype', 'is_complex', 'is_complex_dtype', 'is_datetime64_any_dtype', 'is_datetime64_dtype', 'is_datetime64_ns_dtype', 'is_datetime64tz_dtype', 'is_dict_like', 'is_dtype_equal', 'is_extension_array_dtype', 'is_extension_type', 'is_file_like', 'is_float', 'is_float_dtype', 'is_hashable', 'is_int64_dtype', 'is_integer', 'is_integer_dtype', 'is_interval', 'is_interval_dtype', 'is_iterator', 'is_list_like', 'is_named_tuple', 'is_number', 'is_numeric_dtype', 'is_object_dtype', 'is_period_dtype', 'is_re', 'is_re_compilable', 'is_scalar', 'is_signed_integer_dtype', 'is_sparse', 'is_string_dtype',
```
Note: Calling these functions from the internal module pandas.core.common will now show a DeprecationWarning (GH13990)

Other enhancements

- **Timestamp** can now accept positional and keyword parameters similar to datetime.datetime() (GH10758, GH11630)

```python
In [69]: pd.Timestamp(2012, 1, 1)
Out[69]: Timestamp('2012-01-01 00:00:00')

In [70]: pd.Timestamp(year=2012, month=1, day=1, hour=8, minute=30)
Out[70]: Timestamp('2012-01-01 08:30:00')
```

- The `resample()` function now accepts a `on=` or `level=` parameter for resampling on a datetimelike column or MultiIndex level (GH13500)

```python
In [71]: df = pd.DataFrame({'date': pd.date_range('2015-01-01', freq='W', periods=5),
                      'a': np.arange(5),
                      index=pd.MultiIndex.from_arrays([pd.date_range('2015-01-01', freq='W', periods=5),
                                                      [1, 2, 3, 4, 5]],
                                                      names=['v', 'd']))

In [72]: df
Out[72]:
   date      a
 v d
1 2015-01-04 2015-01-04 0
2 2015-01-11 2015-01-11 1
3 2015-01-18 2015-01-18 2
4 2015-01-25 2015-01-25 3
5 2015-02-01 2015-02-01 4
[5 rows x 2 columns]

In [73]: df.resample('M', on='date').sum()
Out[73]:
     a
date
2015-01-31 6
```

(continues on next page)
• The `.get_credentials()` method of GbqConnector can now first try to fetch the application default credentials. See the docs for more details (GH13577).

• The `.tz_localize()` method of DatetimeIndex and Timestamp has gained the errors keyword, so you can potentially coerce nonexistent timestamps to NaT. The default behavior remains to raising a NonExistentTimeError (GH13057)

• `.to_hdf/read_hdf()` now accept path objects (e.g. pathlib.Path, py.path.local) for the file path (GH11773)

• The `pd.read_csv()` with engine='python' has gained support for the decimal (GH12933), na_filter (GH13321) and the memory_map option (GH13381).

• Consistent with the Python API, `pd.read_csv()` will now interpret +inf as positive infinity (GH13274)

• The `pd.read_html()` has gained support for the na_values, converters, keep_default_na options (GH13461)

• Categorical.astype() now accepts an optional boolean argument copy, effective when dtype is categorical (GH13209)

• DataFrame has gained the .asof() method to return the last non-NaN values according to the selected subset (GH13358)

• The DataFrame constructor will now respect key ordering if a list of OrderedDict objects are passed in (GH13304)

• `pd.read_html()` has gained support for the decimal option (GH12907)

• Series has gained the properties .is_monotonic, .is_monotonic_increasing, .is_monotonic_decreasing, similar to Index (GH13336)

• DataFrame.to_sql() now allows a single value as the SQL type for all columns (GH11886).

• Series.append now supports the ignore_index option (GH13677)

• `.to_stata()` and StataWriter can now write variable labels to Stata dta files using a dictionary to make column names to labels (GH13535, GH13536)

• `.to_stata()` and StataWriter will automatically convert datetime64[ns] columns to Stata format %tc, rather than raising a ValueError (GH12259)

• `read_stata()` and StataReader raise with a more explicit error message when reading Stata files with repeated value labels when convert_categoricals=True (GH13923)

• DataFrame.style will now render sparsified MultiIndexes (GH11655)

• DataFrame.style will now show column level names (e.g. DataFrame.columns.names)(GH13775)
• DataFrame has gained support to re-order the columns based on the values in a row using `df.sort_values(by='...', axis=1)` (GH10806)

```
In [75]: df = pd.DataFrame({'A': [2, 7], 'B': [3, 5], 'C': [4, 8]},
   ....:     index=['row1', 'row2'])
In [76]: df
Out[76]:
     A  B  C
row1 2  3  4
row2 7  5  8
[2 rows x 3 columns]
In [77]: df.sort_values(by='row2', axis=1)
Out[77]:
     B  A  C
row1 3  2  4
row2 5  7  8
[2 rows x 3 columns]
```

• Added documentation to I/O regarding the perils of reading in columns with mixed dtypes and how to handle it (GH13746)

• `to_html()` now has a `border` argument to control the value in the opening `<table>` tag. The default is the value of the `html.border` option, which defaults to 1. This also affects the notebook HTML repr, but since Jupyter’s CSS includes a border-width attribute, the visual effect is the same. (GH11563).

• Raise `ImportError` in the `sql` functions when `sqlalchemy` is not installed and a connection string is used (GH11920).

• Compatibility with matplotlib 2.0. Older versions of pandas should also work with matplotlib 2.0 (GH13333)

• `Timestamp`, `Period`, `DatetimeIndex`, `PeriodIndex` and `.dt` accessor have gained a `.is_leap_year` property to check whether the date belongs to a leap year. (GH13727)

• `astype()` will now accept a dict of column name to data types mapping as the `dtype` argument. (GH12086)

• The `pd.read_json` and `DataFrame.to_json` has gained support for reading and writing json lines with `lines` option see `Line delimited json` (GH9180)

• `read_excel()` now supports the `true_values` and `false_values` keyword arguments (GH13347)

• `groupby()` will now accept a scalar and a single-element list for specifying `level` on a non-`MultiIndex` grouper. (GH13907)

• Non-convertible dates in an excel date column will be returned without conversion and the column will be `object` dtype, rather than raising an exception (GH10001).

• `pd.Timedelta(None)` is now accepted and will return `NaT`, mirroring `pd.Timestamp` (GH13687)

• `pd.read_stata()` can now handle some format 111 files, which are produced by SAS when generating Stata dta files (GH11526)

• `Series` and `Index` now support `divmod` which will return a tuple of series or indices. This behaves like a standard binary operator with regards to broadcasting rules (GH14208).
API changes

Series.tolist() will now return Python types

Series.tolist() will now return Python types in the output, mimicking NumPy .tolist() behavior (GH10904)

```
In [78]: s = pd.Series([1, 2, 3])
```

Previous behavior:

```
In [7]: type(s.tolist()[0])
Out[7]: <class 'numpy.int64'>
```

New behavior:

```
In [79]: type(s.tolist()[0])
Out[79]: int
```

Series operators for different indexes

Following Series operators have been changed to make all operators consistent, including DataFrame (GH1134, GH4581, GH13538)

- Series comparison operators now raise ValueError when index are different.
- Series logical operators align both index of left and right hand side.

**Warning:** Until 0.18.1, comparing Series with the same length, would succeed even if the .index are different (the result ignores .index). As of 0.19.0, this will raise ValueError to be more strict. This section also describes how to keep previous behavior or align different indexes, using the flexible comparison methods like .eq.

As a result, Series and DataFrame operators behave as below:

**Arithmetic operators**

Arithmetic operators align both index (no changes).

```
In [80]: s1 = pd.Series([1, 2, 3], index=list('ABC'))
In [81]: s2 = pd.Series([2, 2, 2], index=list('ABD'))
In [82]: s1 + s2
Out[82]:
     A  3.0
     B  4.0
     C   NaN
     D   NaN
Length: 4, dtype: float64
```
In [83]: df1 = pd.DataFrame([1, 2, 3], index=list('ABC'))

In [84]: df2 = pd.DataFrame([2, 2, 2], index=list('ABD'))

In [85]: df1 + df2
Out[85]:
0    3.0
A    4.0
B     NaN
C     NaN
D     NaN
[4 rows x 1 columns]

Comparison operators

Comparison operators raise `ValueError` when `.index` are different.

**Previous behavior** (Series):
Series compared values ignoring the `.index` as long as both had the same length:

In [1]: s1 == s2
Out[1]:
A   False
B    True
C   False
dtype: bool

**New behavior** (Series):

In [2]: s1 == s2
Out[2]:
ValueError: Can only compare identically-labeled Series objects

**Note:** To achieve the same result as previous versions (compare values based on locations ignoring `.index`), compare both `.values`.

In [86]: s1.values == s2.values
Out[86]: array([False, True, False])

If you want to compare Series aligning its `.index`, see flexible comparison methods section below:

In [87]: s1.eq(s2)
Out[87]:
A   False
B    True
C   False
D   False
Length: 4, dtype: bool

**Current behavior** (DataFrame, no change):
Logical operators

Logical operators align both .index of left and right hand side.

Previous behavior (Series), only left hand side index was kept:

```python
In [4]: s1 = pd.Series([True, False, True], index=list('ABC'))
In [5]: s2 = pd.Series([True, True, True], index=list('ABD'))
In [6]: s1 & s2
Out[6]:
A   True
B   False
C   False
dtype: bool
```

New behavior (Series):

```python
In [88]: s1 = pd.Series([True, False, True], index=list('ABC'))
In [89]: s2 = pd.Series([True, True, True], index=list('ABD'))
In [90]: s1 & s2
Out[90]:
A   True
B   False
C   False
D   False
Length: 4, dtype: bool
```

Note: Series logical operators fill a NaN result with False.

Note: To achieve the same result as previous versions (compare values based on only left hand side index), you can use reindex_like:

```python
In [91]: s1 & s2.reindex_like(s1)
Out[91]:
A   True
B   False
C   False
D   False
Length: 3, dtype: bool
```

Current behavior (DataFrame, no change):

```python
In [92]: df1 = pd.DataFrame([True, False, True], index=list('ABC'))
In [93]: df2 = pd.DataFrame([True, True, True], index=list('ABD'))
In [94]: df1 & df2
```(continues on next page)
Flexible comparison methods

Series flexible comparison methods like `eq`, `ne`, `le`, `lt`, `ge` and `gt` now align both index. Use these operators if you want to compare two Series which has the different index.

```python
In [95]: s1 = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
In [96]: s2 = pd.Series([2, 2, 2], index=['b', 'c', 'd'])
In [97]: s1.eq(s2)
Out[97]:
   a   False
   b    True
   c   False
   d   False
Length: 4, dtype: bool
In [98]: s1.ge(s2)
Out[98]:
   a   False
   b    True
   c    True
   d   False
Length: 4, dtype: bool
```

Previously, this worked the same as comparison operators (see above).

Series type promotion on assignment

A Series will now correctly promote its dtype for assignment with incompat values to the current dtype (GH13234)

```python
In [99]: s = pd.Series()

Previous behavior:

In [2]: s['a'] = pd.Timestamp("2016-01-01")
In [3]: s['b'] = 3.0
TypeError: invalid type promotion

New behavior:

In [100]: s['a'] = pd.Timestamp("2016-01-01")
```

(continues on next page)
Function `.to_datetime()` changes

Previously if `.to_datetime()` encountered mixed integers/floats and strings, but no datetimes with errors='coerce' it would convert all to NaT.

**Previous behavior:**

```
In [2]: pd.to_datetime([1, 'foo'], errors='coerce')
Out[2]: DatetimeIndex(['NaT', 'NaT'], dtype='datetime64[ns]', freq=None)
```

**Current behavior:**

This will now convert integers/floats with the default unit of ns.

```
In [104]: pd.to_datetime([1, 'foo'], errors='coerce')
Out[104]: DatetimeIndex(['1970-01-01 00:00:00.000000001', 'NaT'], dtype='datetime64[ns]', freq=None)
```

**Bug fixes related to `.to_datetime()`:**

- Bug in `pd.to_datetime()` when passing integers or floats, and no unit and errors='coerce' (GH13180).
- Bug in `pd.to_datetime()` when passing invalid data types (e.g. bool); will now respect the errors keyword (GH13176)
- Bug in `pd.to_datetime()` which overflowed on `int8` and `int16` dtypes (GH13451)
- Bug in `pd.to_datetime()` raise AttributeError with NaN and the other string is not valid when errors='ignore' (GH12424)
- Bug in `pd.to_datetime()` did not cast floats correctly when unit was specified, resulting in truncated datetime (GH13834)

**Merging changes**

Merging will now preserve the dtype of the join keys (GH8596)

```
In [105]: df1 = pd.DataFrame({'key': [1], 'v1': [10]})
In [106]: df1
Out[106]:
   key  v1
0   1  10
```
In [107]: df2 = pd.DataFrame({'key': [1, 2], 'v1': [20, 30]})

In [108]: df2
Out[108]:
     key  v1
0     1  20
1     2  30
[2 rows x 2 columns]

Previous behavior:

In [5]: pd.merge(df1, df2, how='outer')
Out[5]:
     key  v1
0  1.0  10.0
1  1.0  20.0
2  2.0  30.0

In [6]: pd.merge(df1, df2, how='outer').dtypes
Out[6]:
key  float64
v1   float64
dtype: object

New behavior:

We are able to preserve the join keys

In [109]: pd.merge(df1, df2, how='outer')
Out[109]:
     key  v1_x  v1_y
0     1    10.0  20
1     2      NaN  30
[2 rows x 3 columns]

In [110]: pd.merge(df1, df2, how='outer').dtypes
Out[110]:
key     int64
v1_x    int64
v1_y    int64
Length: 2, dtype: object

Of course if you have missing values that are introduced, then the resulting dtype will be upcast, which is unchanged from previous.
In [112]: pd.merge(df1, df2, how='outer', on='key').dtypes
Out[112]:
key     int64
v1_x    float64
v1_y    int64
Length: 3, dtype: object

Method .describe() changes

Percentile identifiers in the index of a .describe() output will now be rounded to the least precision that keeps them distinct (GH13104)

In [113]: s = pd.Series([0, 1, 2, 3, 4])
In [114]: df = pd.DataFrame([0, 1, 2, 3, 4])

Previous behavior:
The percentiles were rounded to at most one decimal place, which could raise ValueError for a data frame if the percentiles were duplicated.

In [3]: s.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
Out[3]:
      count      mean      std      min      0.0%      0.1%      0.1%      0.1%      50%      99.9%      100.0%      100.0%      max
dtype: float64
In [4]: df.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
Out[4]:
... 
ValueError: cannot reindex from a duplicate axis

New behavior:

In [115]: s.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
Out[115]:
      count      mean      std      min      0.01%      0.05%      0.1%      0.1%      50%      99.9%      100.0%      100.0%      max
dtype: float64
Furthermore:

- Passing duplicated percentiles will now raise a `ValueError`.
- Bug in `.describe()` on a DataFrame with a mixed-dtype column index, which would previously raise a `TypeError` (GH13288)

### Period changes

The `PeriodIndex` now has period `dtype`. The period `dtype` is a pandas extension `dtype` like `category` or the `timezone aware dtype` ([datetime64[ns, tz]](GH13941)). As a consequence of this change, `PeriodIndex` no longer has an integer `dtype`:

#### Previous behavior:

```python
In [1]: pi = pd.PeriodIndex(['2016-08-01'], freq='D')

In [2]: pi
Out[2]: PeriodIndex(['2016-08-01'], dtype='int64', freq='D')

In [3]: pd.api.types.is_integer_dtype(pi)
Out[3]: True

In [4]: pi.dtype
Out[4]: dtype('int64')
```

#### New behavior:

```python
In [1]: pi = pd.PeriodIndex(['2016-08-01'], freq='D')

In [2]: pi
Out[2]: PeriodIndex(['2016-08-01'], dtype='period[D]', freq='D')

In [3]: pd.api.types.is_integer_dtype(pi)
Out[3]: False

In [4]: pi.dtype
Out[4]: PeriodIndex(['2016-08-01'], dtype='period[D]', freq='D')
```
In [117]: pi = pd.PeriodIndex(['2016-08-01'], freq='D')

In [118]: pi
Out[118]: PeriodIndex(['2016-08-01'], dtype='period[D]', freq='D')

In [119]: pd.api.types.is_integer_dtype(pi)
Out[119]: False

In [120]: pd.api.types.is_period_dtype(pi)
Out[120]: True

In [121]: pi.dtype
Out[121]: period[D]

In [122]: type(pi.dtype)
Out[122]: pandas.core.dtypes.dtypes.PeriodDtype

Period('NaT') now returns pd.NaT

Previously, Period has its own Period('NaT') representation different from pd.NaT. Now Period('NaT') has been changed to return pd.NaT. (GH12759, GH13582)

Previous behavior:

In [5]: pd.Period('NaT', freq='D')
Out[5]: Period('NaT', 'D')

New behavior:

These result in pd.NaT without providing freq option.

In [123]: pd.Period('NaT')
Out[123]: NaT

In [124]: pd.Period(None)
Out[124]: NaT

To be compatible with Period addition and subtraction, pd.NaT now supports addition and subtraction with int. Previously it raised ValueError.

Previous behavior:

In [5]: pd.NaT + 1
...:
ValueError: Cannot add integral value to Timestamp without freq.

New behavior:

In [125]: pd.NaT + 1
Out[125]: NaT

In [126]: pd.NaT - 1
Out[126]: NaT
**PeriodIndex.values now returns array of Period object**

`.values` is changed to return an array of `Period` objects, rather than an array of integers (GH13988).

**Previous behavior:**

```python
In [6]: pi = pd.PeriodIndex(['2011-01', '2011-02'], freq='M')
In [7]: pi.values
Out[7]: array([492, 493])
```

**New behavior:**

```python
In [127]: pi = pd.PeriodIndex(['2011-01', '2011-02'], freq='M')
In [128]: pi.values
Out[128]: array([<Period('2011-01', 'M')>, <Period('2011-02', 'M')>], dtype=object)
```

**Index + / – no longer used for set operations**

Addition and subtraction of the base Index type and of DatetimeIndex (not the numeric index types) previously performed set operations (set union and difference). This behavior was already deprecated since 0.15.0 (in favor using the specific `.union()` and `.difference()` methods), and is now disabled. When possible, + and − are now used for element-wise operations, for example for concatenating strings or subtracting datetimes (GH8227, GH14127).

**Previous behavior:**

```python
In [1]: pd.Index(['a', 'b']) + pd.Index(['a', 'c'])
FutureWarning: using '+' to provide set union with Indexes is deprecated, use '|' or .__union__()
Out[1]: Index(['a', 'b', 'c'], dtype='object')
```

**New behavior:** the same operation will now perform element-wise addition:

```python
In [129]: pd.Index(['a', 'b']) + pd.Index(['a', 'c'])
Out[129]: Index(['aa', 'bc'], dtype='object')
```

Note that numeric Index objects already performed element-wise operations. For example, the behavior of adding two integer Indexes is unchanged. The base `Index` is now made consistent with this behavior.

```python
In [130]: pd.Index([1, 2, 3]) + pd.Index([2, 3, 4])
Out[130]: Int64Index([3, 5, 7], dtype='int64')
```

Further, because of this change, it is now possible to subtract two DatetimeIndex objects resulting in a TimedeltaIndex:

**Previous behavior:**

```python
In [1]: (pd.DatetimeIndex(['2016-01-01', '2016-01-02']))
...: − pd.DatetimeIndex(['2016-01-02', '2016-01-03']))
FutureWarning: using '-' to provide set differences with datetimelike Indexes is deprecated, use .difference()
Out[1]: DatetimeIndex(['2016-01-01'], dtype='datetime64[ns]', freq=None)
```

**New behavior:**

```python
In [131]: (pd.DatetimeIndex(['2016-01-01', '2016-01-02']))
.....: − pd.DatetimeIndex(['2016-01-02', '2016-01-03']))
```
Index.difference and symmetric_difference changes

Index.difference and Index.symmetric_difference will now, more consistently, treat NaN values as any other values. (GH13514)

```python
In [132]: idx1 = pd.Index([1, 2, 3, np.nan])
In [133]: idx2 = pd.Index([0, 1, np.nan])

Previous behavior:

```python
In [3]: idx1.difference(idx2)
Out[3]: Float64Index([nan, 2.0, 3.0], dtype='float64')
In [4]: idx1.symmetric_difference(idx2)
Out[4]: Float64Index([0.0, nan, 2.0, 3.0], dtype='float64')
```

New behavior:

```python
In [134]: idx1.difference(idx2)
Out[134]: Float64Index([2.0, 3.0], dtype='float64')
In [135]: idx1.symmetric_difference(idx2)
Out[135]: Float64Index([0.0, 2.0, 3.0], dtype='float64')
```

Index.unique consistently returns Index

Index.unique() now returns unique values as an Index of the appropriate dtype. (GH13395). Previously, most Index classes returned np.ndarray, and DatetimeIndex, TimedeltaIndex and PeriodIndex returned Index to keep metadata like timezone.

Previous behavior:

```python
In [1]: pd.Index([1, 2, 3]).unique()
Out[1]: array([1, 2, 3])
In [2]: pd.DatetimeIndex(['2011-01-01', '2011-01-02', ...
   ...:     '2011-01-03'], tz='Asia/Tokyo').unique()
Out[2]: DatetimeIndex(['2011-01-01 00:00:00+09:00', '2011-01-02 00:00:00+09:00',
   ...:     '2011-01-03 00:00:00+09:00'],
   ...:     dtype='datetime64[ns, Asia/Tokyo]', freq=None)
```

New behavior:

```python
In [136]: pd.Index([1, 2, 3]).unique()
Out[136]: Int64Index([1, 2, 3], dtype='int64')
In [137]: pd.DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03'],
   ...:     tz='Asia/Tokyo').unique()
```

(continues on next page)
MultiIndex constructors, groupby and set_index preserve categorical dtypes

MultiIndex.from_arrays and MultiIndex.from_product will now preserve categorical dtype in MultiIndex levels (GH13743, GH13854).

```
In [138]: cat = pd.Categorical(['a', 'b'], categories=list("bac"))
In [139]: lvl1 = ['foo', 'bar']
In [140]: midx = pd.MultiIndex.from_arrays([cat, lvl1])
In [141]: midx
```

```
MultiIndex([('a', 'foo'),
             ('b', 'bar')])
```

Previous behavior:
```
In [4]: midx.levels[0]
Out[4]: Index(['b', 'a', 'c'], dtype='object')
In [5]: midx.get_level_values[0]
Out[5]: Index(['a', 'b'], dtype='object')
```

New behavior: the single level is now a CategoricalIndex:
```
In [142]: midx.levels[0]
Out[142]: CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False, dtype='category')
In [143]: midx.get_level_values(0)
Out[143]: CategoricalIndex(['a', 'b'], categories=['b', 'a', 'c'], ordered=False, dtype='category')
```

An analogous change has been made to MultiIndex.from_product. As a consequence, groupby and set_index also preserve categorical dtypes in indexes

```
In [144]: df = pd.DataFrame({"A": [0, 1], "B": [10, 11], "C": cat})
In [145]: df_grouped = df.groupby(by=['A', 'C']).first()
In [146]: df_set_idx = df.set_index(['A', 'C'])
```

Previous behavior:
```
In [11]: df_grouped.index.levels[1]
Out[11]: Index(['b', 'a', 'c'], dtype='object', name='C')
```
In [12]: df_grouped.reset_index().dtypes
Out[12]:
A    int64
C    object
B   float64
dtype: object

In [13]: df_set_idx.index.levels[1]
Out[13]: Index(['b', 'a', 'c'], dtype='object', name='C')
In [14]: df_set_idx.reset_index().dtypes
Out[14]:
A    int64
C    object
B    int64
dtype: object

New behavior:

In [147]: df_grouped.index.levels[1]
Out[147]: CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False,
-> name='C', dtype='category')
In [148]: df_grouped.reset_index().dtypes
Out[148]:
A    int64
C  category
B   float64
Length: 3, dtype: object
In [149]: df_set_idx.index.levels[1]
Out[149]: CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False,
-> name='C', dtype='category')
In [150]: df_set_idx.reset_index().dtypes
Out[150]:
A    int64
C  category
B    int64
Length: 3, dtype: object

Function read_csv will progressively enumerate chunks

When read_csv() is called with chunksize=n and without specifying an index, each chunk used to have an independently generated index from 0 to n−1. They are now given instead a progressive index, starting from 0 for the first chunk, from n for the second, and so on, so that, when concatenated, they are identical to the result of calling read_csv() without the chunksize= argument (GH12185).

In [151]: data = 'A,B
     0,1
     2,3
     4,5
     6,7'

Previous behavior:

In [2]: pd.concat(pd.read_csv(StringIO(data), chunksize=2))
Out[2]:
   A  B
 0  0  0
 1  1  1
 2  2  2
 3  3  3
 4  4  4
 5  5  5
 6  6  6
 7  7  7

(continues on next page)
New behavior:

In [152]: pd.concat(pd.read_csv(StringIO(data), chunksize=2))
Out[152]:
    A  B

[4 rows x 2 columns]

Sparse changes

These changes allow pandas to handle sparse data with more dtypes, and for work to make a smoother experience with data handling.

Types int64 and bool support enhancements

Sparse data structures now gained enhanced support of int64 and bool dtype (GH667, GH13849).

Previously, sparse data were float64 dtype by default, even if all inputs were of int or bool dtype. You had to specify dtype explicitly to create sparse data with int64 dtype. Also, fill_value had to be specified explicitly because the default was np.nan which doesn’t appear in int64 or bool data.

In [1]: pd.SparseArray([1, 2, 0, 0])
Out[1]:
[1.0, 2.0, 0.0, 0.0]
Fill: nan
IntIndex
Indices: array([0, 1, 2, 3], dtype=int32)

# specifying int64 dtype, but all values are stored in sp_values because
# fill_value default is np.nan
In [2]: pd.SparseArray([1, 2, 0, 0], dtype=np.int64)
Out[2]:
[1, 2, 0, 0]
Fill: nan
IntIndex
Indices: array([0, 1, 2, 3], dtype=int32)

In [3]: pd.SparseArray([1, 2, 0, 0], dtype=np.int64, fill_value=0)
Out[3]:
[1, 2, 0, 0]
Fill: 0
IntIndex
Indices: array([0, 1], dtype=int32)
As of v0.19.0, sparse data keeps the input dtype, and uses more appropriate fill_value defaults (0 for int64 dtype, False for bool dtype).

```python
In [153]: pd.SparseArray([1, 2, 0, 0], dtype=np.int64)
Out[153]:
[1, 2, 0, 0]
Fill: 0
IntIndex
Indices: array([0, 1], dtype=int32)

In [154]: pd.SparseArray([True, False, False, False])
Out[154]:
[True, False, False, False]
Fill: False
IntIndex
Indices: array([0], dtype=int32)
```

See the docs for more details.

**Operators now preserve dtypes**

- Sparse data structure now can preserve dtype after arithmetic ops (GH13848)

```python
s = pdSparseSeries([0, 2, 0, 1], fill_value=0, dtype=np.int64)
s.dtype
s + 1
```

- Sparse data structure now support astype to convert internal dtype (GH13900)

```python
s = pdSparseSeries([1., 0., 2., 0.], fill_value=0)
s
s.astype(np.int64)
```

astype fails if data contains values which cannot be converted to specified dtype. Note that the limitation is applied to fill_value which default is np.nan.

```python
In [7]: pdSparseSeries([1., np.nan, 2., np.nan]).astype(np.int64)
Out[7]:
ValueError: unable to coerce current fill_value nan to int64 dtype
```

**Other sparse fixes**

- Subclassed SparseDataFrame and SparseSeries now preserve class types when slicing or transposing. (GH13787)
- SparseArray with bool dtype now supports logical (bool) operators (GH14000)
- Bug in SparseSeries with MultiIndex [] indexing may raise IndexError (GH13144)
- Bug in SparseSeries with MultiIndex [] indexing result may have normal Index (GH13144)
- Bug in SparseDataFrame in which axis=None did not default to axis=0 (GH13048)
- Bug in SparseSeries and SparseDataFrame creation with object dtype may raise TypeError (GH11633)
- Bug in `SparseDataFrame` doesn’t respect passed `SparseArray` or `SparseSeries`’s dtype and `fill_value` (GH13866)
- Bug in `SparseArray` and `SparseSeries` don’t apply ufunc to `fill_value` (GH13853)
- Bug in `SparseSeries.abs` incorrectly keeps negative `fill_value` (GH13853)
- Bug in single row slicing on multi-type `SparseDataFrame` s, types were previously forced to float (GH13917)
- Bug in `SparseSeries` slicing changes integer dtype to float (GH8292)
- Bug in `SparseDataFrame` comparison ops may raise `TypeError` (GH13001)
- Bug in `SparseDataFrame.isnull` raises `ValueError` (GH8276)
- Bug in `SparseSeries` representation with bool dtype may raise `IndexError` (GH13110)
- Bug in `SparseSeries` and `SparseDataFrame` of bool or int64 dtype may display its values like float64 dtype (GH13110)
- Bug in sparse indexing using `SparseArray` with bool dtype may return incorrect result (GH13985)
- Bug in `SparseArray` created from `SparseSeries` may lose dtype (GH13999)
- Bug in `SparseSeries` comparison with dense returns normal `Series` rather than `SparseSeries` (GH13999)

### Indexer dtype changes

**Note:** This change only affects 64 bit python running on Windows, and only affects relatively advanced indexing operations

Methods such as `Index.get_indexer` that return an indexer array, coerce that array to a “platform int”, so that it can be directly used in 3rd party library operations like `numpy.take`. Previously, a platform int was defined as `np.int_` which corresponds to a C integer, but the correct type, and what is being used now, is `np.intp`, which corresponds to the C integer size that can hold a pointer (GH3033, GH13972).

These types are the same on many platform, but for 64 bit python on Windows, `np.int_` is 32 bits, and `np.intp` is 64 bits. Changing this behavior improves performance for many operations on that platform.

**Previous behavior:**

```
In [1]: i = pd.Index(['a', 'b', 'c'])
In [2]: i.get_indexer(['b', 'b', 'c']).dtype
Out[2]: dtype('int32')
```

**New behavior:**

```
In [1]: i = pd.Index(['a', 'b', 'c'])
In [2]: i.get_indexer(['b', 'b', 'c']).dtype
Out[2]: dtype('int64')
```
Other API changes

- `Timestamp.to_pydatetime` will issue a `UserWarning` when `warn=True`, and the instance has a non-zero number of nanoseconds, previously this would print a message to stdout (GH14101).
- `Series.unique()` with datetime and timezone now returns return array of `Timestamp` with timezone (GH13565).
- `Panel.to_sparse()` will raise a `NotImplementedError` exception when called (GH13778).
- `Index.reshape()` will raise a `NotImplementedError` exception when called (GH12882).
- `.filter()` enforces mutual exclusion of the keyword arguments (GH12399).
- `eval`’s upcasting rules for `float32` types have been updated to be more consistent with NumPy’s rules. New behavior will not upcast to `float64` if you multiply a pandas `float32` object by a scalar `float64` (GH12388).
- An `UnsupportedFunctionCall` error is now raised if NumPy ufuncs like `np.mean` are called on groupby or resample objects (GH12811).
- `__setitem__` will no longer apply a callable rhs as a function instead of storing it. Call `where` directly to get the previous behavior (GH13299).
- Calls to `.sample()` will respect the random seed set via `numpy.random.seed(n)` (GH13161).
- `Styler.apply` is now more strict about the outputs your function must return. For `axis=0` or `axis=1`, the output shape must be identical. For `axis=None`, the output must be a DataFrame with identical columns and index labels (GH13222).
- `Float64Index.astype(int)` will now raise `ValueError` if `Float64Index` contains NaN values (GH13149).
- `TimedeltaIndex.astype(int)` and `DatetimeIndex.astype(int)` will now return `Int64Index` instead of `np.array` (GH13209).
- Passing `Period` with multiple frequencies to normal `Index` now returns `Index` with `object` dtype (GH13664).
- `PeriodIndex.fillna` with `Period` has different freq now coerces to `object` dtype (GH13664).
- Faceted boxplots from `DataFrame.boxplot(by=col)` now return a `Series` when `return_type` is not `None`. Previously these returned an `OrderedDict`. Note that when `return_type=None`, the default, these still return a 2-D NumPy array (GH12216, GH7096).
- `pd.read_hdf` will now raise a `ValueError` instead of `KeyError`, if a mode other than `r`, `r+` and `a` is supplied. (GH13623)
- `pd.read_csv()`, `pd.read_table()`, and `pd.read_hdf()` raise the built-in `FileNotFoundError` exception for Python 3.x when called on a nonexistent file; this is back-ported as `IOError` in Python 2.x (GH14086).
- More informative exceptions are passed through the csv parser. The exception type would now be the original exception type instead of `CPARSERERROR` (GH13652).
- `pd.read_csv()` in the C engine will now issue a `ParserWarning` or raise a `ValueError` when `sep` encoded is more than one character long (GH14065)
- `DataFrame.values` will now return `float64` with a `DataFrame` of mixed `int64` and `uint64` dtypes, conforming to `np.find_common_type` (GH10364, GH13917).
- `.groupby().groups` will now return a dictionary of `Index` objects, rather than a dictionary of `np.ndarray` or lists (GH14293).
Deprecations

- Series.reshape and Categorical.reshape have been deprecated and will be removed in a subsequent release (GH12882, GH12882)
- PeriodIndex.to_datetime has been deprecated in favor of PeriodIndex.to_timestamp (GH8254)
- Timestamp.to_datetime has been deprecated in favor of Timestamp.to_pydatetime (GH8254)
- Index.to_datetime and DatetimeIndex.to_datetime have been deprecated in favor of pd.to_datetime (GH8254)
- pandas.core.datetools module has been deprecated and will be removed in a subsequent release (GH14094)
- SparseList has been deprecated and will be removed in a future version (GH13784)
- DataFrame.to_html() and DataFrame.to_latex() have dropped the colSpace parameter in favor of col_space (GH13857)
- DataFrame.to_sql() has deprecated the flavor parameter, as it is superfluous when SQLAlchemy is not installed (GH13611)
- Deprecated read_csv keywords:
  - compact_ints and use_unsigned have been deprecated and will be removed in a future version (GH13320)
  - buffer_lines has been deprecated and will be removed in a future version (GH13360)
  - as_recarray has been deprecated and will be removed in a future version (GH13373)
  - skip_footer has been deprecated in favor of skipfooter and will be removed in a future version (GH13349)
- top-level pd.ordered_merge() has been renamed to pd.merge_ordered() and the original name will be removed in a future version (GH13358)
- Timestamp.offset property (and named arg in the constructor), has been deprecated in favor of freq (GH12160)
- pd.tseries.util.pivot_annual is deprecated. Use pivot_table as alternative, an example is here (GH736)
- pd.tseries.util.isleapyear has been deprecated and will be removed in a subsequent release. Datetime-like now have a .is_leap_year property (GH13727)
- Panel4D and PanelND constructors are deprecated and will be removed in a future version. The recommended way to represent these types of n-dimensional data are with the xarray package. Pandas provides a to_xarray() method to automate this conversion (GH13564).
- pandas.tseries.frequencies.get_standard_freq is deprecated. Use pandas.tseries.frequencies.to_offset(freq).rule_code instead (GH13874)
- pandas.tseries.frequencies.to_offset's freqstr keyword is deprecated in favor of freq (GH13874)
- Categorical.from_array has been deprecated and will be removed in a future version (GH13854)
Removal of prior version deprecations/changes

- The SparsePanel class has been removed (GH13778)
- The pd.sandbox module has been removed in favor of the external library pandas-qt (GH13670)
- The pandas.io.data and pandas.io.wb modules are removed in favor of the pandas-datareader package (GH13724).
- The pandas.tools.rplot module has been removed in favor of the seaborn package (GH13855)
- DataFrame.to_csv() has dropped the engine parameter, as was deprecated in 0.17.1 (GH11274, GH13419)
- pd.DataFrame.to_dict() has dropped the outtype parameter in favor of orient (GH13627, GH8486)
- pd.Categorical has dropped setting of the ordered attribute directly in favor of the set_ordered method (GH13671)
- pd.Categorical has dropped the levels attribute in favor of categories (GH8376)
- DataFrame.to_sql() has dropped the mysql option for the flavor parameter (GH13611)
- Panel.shift() has dropped the lags parameter in favor of periods (GH14041)
- pd.Index has dropped the diff method in favor of difference (GH13669)
- pd.DataFrame has dropped the to_wide method in favor of to_panel (GH14039)
- Series.to_csv has dropped the nanRep parameter in favor of na_rep (GH13804)
- Series.xs, DataFrame.xs, Panel.xs, Panel.major_xs, and Panel.minor_xs have dropped the copy parameter (GH13781)
- str.split has dropped the return_type parameter in favor of expand (GH13701)
- Removal of the legacy time rules (offset aliases), deprecated since 0.17.0 (this has been alias since 0.8.0) (GH13590, GH13868). Now legacy time rules raises ValueError. For the list of currently supported offsets, see here.
- The default value for the return_type parameter for DataFrame.plot.box and DataFrame.boxplot changed from None to "axes". These methods will now return a matplotlib axes by default instead of a dictionary of artists. See here (GH6581).
- The tquery and uquery functions in the pandas.io.sql module are removed (GH5950).

Performance improvements

- Improved performance of sparse IntIndex.intersect (GH13082)
- Improved performance of sparse arithmetic with BlockIndex when the number of blocks are large, though recommended to use IntIndex in such cases (GH13082)
- Improved performance of DataFrame.quantile() as it now operates per-block (GH11623)
- Improved performance of float64 hash table operations, fixing some very slow indexing and groupby operations in python 3 (GH13166, GH13334)
- Improved performance of DataFrameGroupBy.transform (GH12737)
- Improved performance of Index and Series.duplicated (GH10235)
- Improved performance of Index.difference (GH12044)
• Improved performance of `RangeIndex.is_monotonic_increasing` and `is_monotonic_decreasing` (GH13749)
• Improved performance of datetime string parsing in `DatetimeIndex` (GH13692)
• Improved performance of hashing `Period` (GH12817)
• Improved performance of `factorize` of datetime with timezone (GH13750)
• Improved performance of by lazily creating indexing hashtables on larger Indexes (GH14266)
• Improved performance of `groupby.groups` (GH14293)
• Unnecessary materializing of a MultiIndex when introspecting for memory usage (GH14308)

Bug fixes

• Bug in `groupby().shift()`, which could cause a segfault or corruption in rare circumstances when grouping by columns with missing values (GH13813)
• Bug in `groupby().cumsum()` calculating `cumprod` when `axis=1` (GH13994)
• Bug in `pd.to_timedelta()` in which the `errors` parameter was not being respected (GH13613)
• Bug in `io.json.json_normalize()`, where non-ascii keys raised an exception (GH13213)
• Bug when passing a not-default-indexed `Series` as `xerr` or `yerr` in `.plot()` (GH11858)
• Bug in area plot draws legend incorrectly if subplot is enabled or legend is moved after plot (matplotlib 1.5.0 is required to draw area plot legend properly) (GH9161, GH13544)
• Bug in `DataFrame` assignment with an object-dtyped `Index` where the resultant column is mutable to the original object. (GH13522)
• Bug in matplotlib `AutoDataFormatter`; this restores the second scaled formatting and re-adds micro-second scaled formatting (GH13131)
• Bug in selection from a `HDFStore` with a fixed format and `start` and/or `stop` specified will now return the selected range (GH8287)
• Bug in `Categorical.from_codes()` where an unhelpful error was raised when an invalid ordered parameter was passed in (GH14058)
• Bug in `Series` construction from a tuple of integers on windows not returning default dtype (int64) (GH13646)
• Bug in `TimedeltaIndex` addition with a Datetime-like object where addition overflow was not being caught (GH14068)
• Bug in `.groupby(..).resample(..)` when the same object is called multiple times (GH13174)
• Bug in `.to_records()` when index name is a unicode string (GH13172)
• Bug in calling `.memory_usage()` on object which doesn’t implement (GH12924)
• Regression in `Series.quantile` with nans (also shows up in `.median()` and `.describe()`); furthermore now names the `Series` with the quantile (GH13098, GH13146)
• Bug in `SeriesGroupBy.transform` with datetime values and missing groups (GH13191)
• Bug where empty `Series` were incorrectly coerced in datetime-like numeric operations (GH13844)
• Bug in `Categorical` constructor when passed a `Categorical` containing datetimes with timezones (GH14190)
• Bug in `Series.str.extractall()` with str index raises `ValueError` (GH13156)
Bug in Series.str.extractall() with single group and quantifier (GH13382)

Bug in DatetimeIndex and Period subtraction raises ValueError or AttributeError rather than TypeError (GH13078)

Bug in Index and Series created with NaN and NaT mixed data may not have datetime64 dtype (GH13324)

Bug in Index and Series may ignore np.datetime64('nat') and np.timedelta64('nat') to infer dtype (GH13324)

Bug in PeriodIndex and Period subtraction raises AttributeError (GH13071)

Bug in PeriodIndex construction returning a float64 index in some circumstances (GH13067)

Bug in .resample(..) with a PeriodIndex not changing its freq appropriately when empty (GH13067)

Bug in .resample(..) with a PeriodIndex not retaining its type or name with an empty DataFrame appropriately when empty (GH13212)

Bug in groupby(..).apply(..) when the passed function returns scalar values per group (GH13468).

Bug in groupby(..).resample(..) where passing some keywords would raise an exception (GH13235)

Bug in .tz_convert on a tz-aware DateTimeIndex that relied on index being sorted for correct results (GH13306)

Bug in .tz_localize with dateutil.tz.tzlocal may return incorrect result (GH13583)

Bug in DatetimeTZDtype dtype with dateutil.tz.tzlocal cannot be regarded as valid dtype (GH13583)

Bug in pd.read_hdf() where attempting to load an HDF file with a single dataset, that had one or more categorical columns, failed unless the key argument was set to the name of the dataset. (GH13231)

Bug in .rolling() that allowed a negative integer window in construction of the Rolling() object, but would later fail on aggregation (GH13383)

Bug in Series indexing with tuple-valued data and a numeric index (GH13509)

Bug in printing pd.DataFrame where unusual elements with the object dtype were causing segfaults (GH13717)

Bug in ranking Series which could result in segfaults (GH13445)

Bug in various index types, which did not propagate the name of passed index (GH12309)

Bug in DatetimeIndex, which did not honour the copy=True (GH13205)

Bug in DatetimeIndex.is_normalized returns incorrectly for normalized date_range in case of local timezones (GH13459)

Bug in pd.concat and .append may coerces datetime64 and timedelta64 to object dtype containing python built-in datetime or timedelta rather than Timestamp or Timedelta (GH13626)

Bug in PeriodIndex.append may raises AttributeError when the result is object dtype (GH13221)

Bug in CategoricalIndex.append may accept normal list (GH13626)

Bug in pd.concat and .append with the same timezone get reset to UTC (GH7795)

Bug in Series and DataFrame .append raises AmbiguousTimeError if data contains datetime near DST boundary (GH13626)

Bug in DataFrame.to_csv() in which float values were being quoted even though quotations were specified for non-numeric values only (GH12922, GH13259)
• Bug in `DataFrame.describe()` raising `ValueError` with only boolean columns (GH13898)
• Bug in `MultiIndex` slicing where extra elements were returned when level is non-unique (GH12896)
• Bug in `.str.replace` does not raise `TypeError` for invalid replacement (GH13438)
• Bug in `MultiIndex.from_arrays` which didn’t check for input array lengths matching (GH13599)
• Bug in `cartesian_product` and `MultiIndex.from_product` which may raise with empty input arrays (GH12258)
• Bug in `pd.read_csv()` which may cause a segfault or corruption when iterating in large chunks over a stream/file under rare circumstances (GH13703)
• Bug in `pd.read_csv()` which caused errors to be raised when a dictionary containing scalars is passed in for `na_values` (GH12224)
• Bug in `pd.read_csv()` which caused BOM files to be incorrectly parsed by not ignoring the BOM (GH4793)
• Bug in `pd.read_csv()` with `engine='python'` which raised errors when a numpy array was passed in for `usecols` (GH12546)
• Bug in `pd.read_csv()` where the index columns were being incorrectly parsed when parsed as dates with a `thousands` parameter (GH14066)
• Bug in `pd.read_csv()` with `engine='python'` in which NaN values weren’t being detected after data was converted to numeric values (GH13314)
• Bug in `pd.read_csv()` in which the `nrows` argument was not properly validated for both engines (GH10476)
• Bug in `pd.read_csv()` with `engine='python'` in which infinities of mixed-case forms were not being interpreted properly (GH13274)
• Bug in `pd.read_csv()` with `engine='python'` in which trailing NaN values were not being parsed (GH13320)
• Bug in `pd.read_csv()` with `engine='python'` when reading from a `tempfile.TemporaryFile` on Windows with Python 3 (GH13398)
• Bug in `pd.read_csv()` that prevents `usecols` kwarg from accepting single-byte unicode strings (GH13219)
• Bug in `pd.read_csv()` that prevents `usecols` from being an empty set (GH13402)
• Bug in `pd.read_csv()` in the C engine where the NULL character was not being parsed as NULL (GH14012)
• Bug in `pd.read_csv()` with `engine='c'` in which NULL `quotechar` was not accepted even though `quoting` was specified as `None` (GH13411)
• Bug in `pd.read_csv()` with `engine='c'` in which fields were not properly cast to float when quoting was specified as non-numeric (GH13411)
• Bug in `pd.read_csv()` in Python 2.x with non-UTF8 encoded, multi-character separated data (GH13404)
• Bug in `pd.read_csv()`, where aliases for utf-xx (e.g. UTF-xx, UTF_xx, utf_xx) raised `UnicodeDecodeError` (GH13549)
• Bug in `pd.read_csv`, `pd.read_table`, `pd.read_fwf`, `pd.read_stata` and `pd.read_sas` where files were opened by parsers but not closed if both `chunksize` and `iterator` were `None`. (GH13940)
• Bug in `StataReader`, `StataWriter`, `XportReader` and `SAS7BDATReader` where a file was not properly closed when an error was raised. (GH13940)
• Bug in `pd.pivot_table()` where `margins_name` is ignored when `aggfunc` is a list (GH13354)
• Bug in `pd.Series.str.zfill`, `center`, `ljust`, `rjust`, and `pad` when passing non-integers, did not raise `TypeError` (GH13598)
• Bug in checking for any null objects in a `TimedeltaIndex`, which always returned `True` (GH13603)
• Bug in `Series` arithmetic raises `TypeError` if it contains datetime-like as `object` `dtype` (GH13043)
• Bug in `Series.isnull()` and `Series.notnull()` ignore `Period('NaT')` (GH13737)
• Bug in `.fillna(value=np.nan)` incorrectly raises `KeyError` on a category `dtype` `Series` (GH14021)
• Bug in extension `dtype` creation where the created types were not is/identical (GH13285)
• Bug in `.resample(..)` where incorrect warnings were triggered by IPython introspection (GH13618)
• Bug in `NaT - Period` raises `AttributeError` (GH13071)
• Bug in `Series` comparison may output incorrect result if rhs contains `NaT` with `object` `dtype` (GH13069)
• Bug in `.shift` raises `AmbiguousTimeError` if data contains datetime near DST boundary (GH13926)
• Bug in `pd.read_hdf()` returns incorrect result when a `DataFrame` with a `categorical` column and a query which doesn’t match any values (GH13792)
• Bug in `.iloc` when indexing with a non lexsorted `MultiIndex` (GH13797)
• Bug in `.loc` when indexing with date strings in a reverse sorted `DatetimeIndex` (GH14316)
• Bug in `Series` comparison operators when dealing with zero dim NumPy arrays (GH13006)
• Bug in `.combine_first` may return incorrect `dtype` (GH7630, GH10567)
• Bug in `groupby` where `apply` returns different result depending on whether first result is `None` or not (GH12824)
• Bug in `groupby(..).nth()` where the group key is included inconsistently if called after `.head()`/. `.tail()` (GH12839)
• Bug in `.to_html`, `.to_latex` and `.to_string` silently ignore custom datetime formatter passed through the formatters key word (GH10690)
• Bug in `DataFrame.iterrows()`, not yielding a `Series` subclass if defined (GH13977)
• Bug in `pd.to_numeric` when `errors='coerce'` and input contains non-hashable objects (GH13324)
• Bug in invalid `Timedelta` arithmetic and comparison may raise `ValueError` rather than `TypeError` (GH13624)
• Bug in invalid datetime parsing in `to_datetime` and `DatetimeIndex` may raise `TypeError` rather than `ValueError` (GH11169, GH11287)
• Bug in `Index` created with tz-aware `Timestamp` and mismatched tz option incorrectly coerces timezone (GH13692)
• Bug in `DatetimeIndex` with nanosecond frequency does not include timestamp specified with `end` (GH13672)
• Bug in `Series` when setting a slice with a `np.timedelta64` (GH14155)
• Bug in `Index` raises `OutOfBoundsDatetime` if `datetime` exceeds `datetime64[ns]` bounds, rather than coercing to object dtype (GH13663)
• Bug in `Index` may ignore specified `datetime64` or `timedelta64` passed as dtype (GH13981)
• Bug in `DatetimeIndex` may raise `OutOfBoundsDatetime` if input `np.datetime64` has other unit than `ns` (GH9114)
• Bug in `Series` creation with `np.datetime64` which has other unit than `ns` as object dtype results in incorrect values (GH13876)
• Bug in `resample` with timedelta data where data was casted to float (GH13119)
• Bug in `pd.isnull()` or `pd.notnull()` raise `TypeError` if input datetime-like has other unit than `ns` (GH13389)
• Bug in `pd.merge()` may raise `TypeError` if input datetime-like has other unit than `ns` (GH13389)
• Bug in `HDFStore/read_hdf()` discarded `DatetimeIndex.name` if `tz` was set (GH13884)
• Bug in `Categorical.remove_unused_categories()` changes `.codes` dtype to platform int (GH13261)
• Bug in `groupby` with `as_index=False` returns all NaN’s when grouping on multiple columns including a categorical one (GH13204)
• Bug in `df.groupby(...)[...].where` with `Int64Index` raised an error (GH13731)
• Bug in the CSS classes assigned to `DataFrame.style` for index names. Previously they were assigned "col_heading level<\n> col<\n>" where \n was the number of levels + 1. Now they are assigned "index_name level<\n>" where \n is the correct level for that MultiIndex.
• Bug where `pd.read_gbq()` could throw `ImportError: No module named discovery` as a result of a naming conflict with another python package called `apiclient` (GH13454)
• Bug in `Index.union` returns an incorrect result with a named empty index (GH13432)
• Bugs in `Index.difference` and `DataFrame.join` raise in Python3 when using mixed-integer indexes (GH13432, GH12814)
• Bug in `subtract` tz-aware `datetime.datetime` from tz-aware `datetime64` series (GH14088)
• Bug in `.to_excel()` when `DataFrame` contains a MultiIndex which contains a label with a NaN value (GH13511)
• Bug in invalid frequency offset string like “D1”, “-2-3H” may not raise `ValueError` (GH13930)
• Bug in `concat` and `groupby` for hierarchical frames with `RangeIndex` levels (GH13542)
• Bug in `Series.str.contains()` for Series containing only NaN values of object dtype (GH14171)
• Bug in `agg()` function on groupby dataframe changes dtype of `datetime64[ns]` column to `float64` (GH12821)

• Bug in using NumPy ufunc with `PeriodIndex` to add or subtract integer raise `IncompatibleFrequency`. Note that using standard operator like `+` or `-` is recommended, because standard operators use more efficient path (GH13980)

• Bug in operations on `NaT` returning `float` instead of `datetime64[ns]` (GH12941)

• Bug in `Series` flexible arithmetic methods (like `.add()`) raises `ValueError` when `axis=None` (GH13894)

• Bug in `DataFrame.to_csv()` with `MultiIndex` columns in which a stray empty line was added (GH6618)

• Bug in `DatetimeIndex`, `TimedeltaIndex` and `PeriodIndex.equals()` may return `True` when input isn’t `Index` but contains the same values (GH13107)

• Bug in assignment against datetime with timezone may not work if it contains datetime near DST boundary (GH14146)

• Bug in `pd.eval()` and HDFStore query truncating long float literals with python 2 (GH14241)

• Bug in `Index` raises `KeyError` displaying incorrect column when column is not in the df and columns contains duplicate values (GH13822)

• Bug in `Period` and `PeriodIndex` creating wrong dates when frequency has combined offset aliases (GH13874)

• Bug in `.to_string()` when called with an integer `line_width` and `index=False` raises an UnboundLocalError exception because `idx` referenced before assignment.

• Bug in `eval()` where the `resolvers` argument would not accept a list (GH14095)

• Bugs in `stack`, `get_dummies`, `make_axis_dummies` which don’t preserve categorical dtypes in (multi)indexes (GH13854)

• `PeriodIndex` can now accept `list` and `array` which contains `pd.NaT` (GH13430)

• Bug in `df.groupby` where `.median()` returns arbitrary values if grouped dataframe contains empty bins (GH13629)

• Bug in `Index.copy()` where name parameter was ignored (GH14302)

5.10 Version 0.18

5.10.1 Version 0.18.1 (May 3, 2016)

This is a minor bug-fix release from 0.18.0 and includes a large number of bug fixes along with several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- `.groupby(...)` has been enhanced to provide convenient syntax when working with `.rolling(...)`, `.expanding(...)` and `.resample(...)` per group, see [here](#).
- `pd.to_datetime()` has gained the ability to assemble dates from a DataFrame, see [here](#).
- Method chaining improvements, see [here](#).
- Custom business hour offset, see [here](#).
- Many bug fixes in the handling of sparse, see [here](#).
- Expanded the Tutorials section with a feature on modern pandas, courtesy of @TomAugsburger. (GH13045).

What’s new in v0.18.1

- **New features**
  - Custom business hour
  - Method `.groupby(...)` syntax with window and resample operations
  - Method chaining improvements
    - Methods `.where()` and `.mask()`
    - Methods `.loc[]`, `.iloc[]`, `.ix[]`
    - Indexing with `[]`
  - Partial string indexing on DatetimeIndex when part of a MultiIndex
  - Assembling datetimes
  - Other enhancements
- **Sparse changes**
- **API changes**
  - Method `.groupby(...).nth()` changes
  - NumPy function compatibility
  - Using `.apply` on GroupBy resampling
  - Changes in `read_csv` exceptions
  - Method `to_datetime` error changes
  - Other API changes
  - Deprecations
New features

Custom business hour

The CustomBusinessHour is a mixture of BusinessHour and CustomBusinessDay which allows you to specify arbitrary holidays. For details, see Custom Business Hour (GH11514)

```python
In [1]: from pandas.tseries.offsets import CustomBusinessHour
In [2]: from pandas.tseries.holiday import USFederalHolidayCalendar
In [3]: bhour_us = CustomBusinessHour(calendar=USFederalHolidayCalendar())
```

Friday before MLK Day

```python
In [4]: import datetime
In [5]: dt = datetime.datetime(2014, 1, 17, 15)
In [6]: dt + bhour_us
Out[6]: Timestamp('2014-01-17 16:00:00')
```

Tuesday after MLK Day (Monday is skipped because it’s a holiday)

```python
In [7]: dt + bhour_us * 2
Out[7]: Timestamp('2014-01-20 09:00:00')
```

Method .groupby(...) syntax with window and resample operations

 groupby(...) has been enhanced to provide convenient syntax when working with .rolling(...), .expanding(...) and .resample(...) per group, see (GH12486, GH12738).

You can now use .rolling(...) and .expanding(...) as methods on groupbys. These return another deferred object (similar to what .rolling() and .expanding() do on ungrouped pandas objects). You can then operate on these RollingGroupby objects in a similar manner.

Previously you would have to do this to get a rolling window mean per-group:

```python
                     ...:                   'B': np.arange(40))
In [9]: df
Out[9]:
     A  B
0   1  0
1   1  1
2   1  2
```
In [10]: df.groupby('A').apply(lambda x: x.rolling(4).B.mean())

Out[10]:
A
1   0   NaN
   1   NaN
   2   NaN
   3   1.5
   4   2.5
   ... 
35  35  33.5
36  34.5
37  35.5
38  36.5
39  37.5
Name: B, Length: 40, dtype: float64

Now you can do:

In [11]: df.groupby('A').rolling(4).B.mean()

Out[11]:
A
1   0   NaN
   1   NaN
   2   NaN
   3   1.5
   4   2.5
   ... 
35  35  33.5
36  34.5
37  35.5
38  36.5
39  37.5
Name: B, Length: 40, dtype: float64

For .resample(..) type of operations, previously you would have to:

In [12]: df = pd.DataFrame({'date': pd.date_range(start='2016-01-01',
        periods=4,
        freq='W'),
        'group': [1, 1, 2, 2],
        'val': [5, 6, 7, 8]}).set_index('date')

In [13]: df
Out[13]:

(continues on next page)
In [14]: df.groupby('group').apply(lambda x: x.resample('1D').ffill())

Out[14]:

<table>
<thead>
<tr>
<th>group</th>
<th>val</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>date</td>
<td></td>
</tr>
<tr>
<td>2016-01-03</td>
<td>1 5</td>
</tr>
<tr>
<td>2016-01-10</td>
<td>1 6</td>
</tr>
<tr>
<td>2016-01-17</td>
<td>2 7</td>
</tr>
<tr>
<td>2016-01-24</td>
<td>2 8</td>
</tr>
</tbody>
</table>

[4 rows x 2 columns]

Now you can do:

In [15]: df.groupby('group').resample('1D').ffill()

Out[15]:

<table>
<thead>
<tr>
<th>group</th>
<th>val</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>date</td>
<td></td>
</tr>
<tr>
<td>2016-01-03</td>
<td>1 5</td>
</tr>
<tr>
<td>2016-01-04</td>
<td>1 5</td>
</tr>
<tr>
<td>2016-01-05</td>
<td>1 5</td>
</tr>
<tr>
<td>2016-01-06</td>
<td>1 5</td>
</tr>
<tr>
<td>2016-01-07</td>
<td>1 5</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
<tr>
<td>2016-01-20</td>
<td>2 7</td>
</tr>
<tr>
<td>2016-01-21</td>
<td>2 7</td>
</tr>
<tr>
<td>2016-01-22</td>
<td>2 7</td>
</tr>
<tr>
<td>2016-01-23</td>
<td>2 7</td>
</tr>
<tr>
<td>2016-01-24</td>
<td>2 8</td>
</tr>
</tbody>
</table>

[16 rows x 2 columns]
Method chaining improvements

The following methods / indexers now accept a `callable`. It is intended to make these more useful in method chains, see the documentation. (GH11485, GH12533)

- `where()` and `mask()`
- `loc[]`, `iloc[]` and `ix[]`
- `[]` indexing

Methods `where()` and `mask()`

These can accept a callable for the condition and other arguments.

```python
In [16]: df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6], 'C': [7, 8, 9]})
In [17]: df.where(lambda x: x > 4, lambda x: x + 10)
Out[17]:
   A  B  C
0  5  14  7
1  12  5  8
2  13  6  9
[3 rows x 3 columns]
```

Methods `loc[]`, `iloc[]`, `ix[]`

These can accept a callable, and a tuple of callable as a slicer. The callable can return a valid boolean indexer or anything which is valid for these indexer’s input.

```python
# callable returns bool indexer
In [18]: df.loc[lambda x: x.A >= 2, lambda x: x.sum() > 10]
Out[18]:
   B  C
0  11  14  7
1  12  5  8
2  13  6  9
[2 rows x 2 columns]

# callable returns list of labels
In [19]: df.loc[lambda x: [1, 2], lambda x: ['A', 'B']]  
Out[19]:
   A  B
0  1  2
1  2  3
[2 rows x 2 columns]
```
Indexing with `[]`

Finally, you can use a callable in [ ] indexing of Series, DataFrame and Panel. The callable must return a valid input for [ ] indexing depending on its class and index type.

```
In [20]: df[lambda x: 'A']
Out[20]:
   0  1
0  2  3
Name: A, Length: 3, dtype: int64
```

Using these methods / indexers, you can chain data selection operations without using temporary variable.

```
In [21]: bb = pd.read_csv('data/baseball.csv', index_col='id')

In [22]: (bb.groupby(['year', 'team'])
            .sum()
            .loc[lambda df: df.r > 100])
Out[22]:
         stint  g  ab  r  X2b  X3b  hr  rbi  sb  cs  bb  so  hbp  sh  sf  gidp
    year team
2007   CIN    6  379  745  101  203  35   2  36  125.0  10.0  1.0  105  127.0  14.

[8 rows x 18 columns]
```

Partial string indexing on `DatetimeIndex` when part of a `MultiIndex`

Partial string indexing now matches on `DateTimeIndex` when part of a `MultiIndex` (GH10331)

```
In [23]: dft2 = pd.DataFrame(
            np.random.randn(20, 1),
    columns=['A'],
    index=pd.MultiIndex.from_product([pd.date_range('20130101', periods=10, freq='12H'), ['a', 'b']]))
```

(continues on next page)

(continues on next page)
Assembling datetimes

`pd.to_datetime()` has gained the ability to assemble datetimes from a passed in DataFrame or a dict. (GH8158).

```python
In [30]: df = pd.DataFrame({'year': [2015, 2016],
                       'month': [2, 3],
                       'day': [4, 5],
                       'hour': [2, 3]})

In [31]: df
Out[31]:
    year month  day  hour
0  2015     2     4     2
1  2016     3     5     3

[2 rows x 4 columns]
```

Assembling using the passed frame.

```python
In [32]: pd.to_datetime(df)
Out[32]:
0  2015-02-04 02:00:00
1  2016-03-05 03:00:00
Length: 2, dtype: datetime64[ns]
```

You can pass only the columns that you need to assemble.

```python
In [33]: pd.to_datetime(df[['year', 'month', 'day']])
Out[33]:
0  2015-02-04
1  2016-03-05
Length: 2, dtype: datetime64[ns]
```

Other enhancements

- `pd.read_csv()` now supports `delim_whitespace=True` for the Python engine (GH12958)
- `pd.read_csv()` now supports opening ZIP files that contains a single CSV, via extension inference or explicit `compression='zip'` (GH12175)
- `pd.read_csv()` now supports opening files using xz compression, via extension inference or explicit `compression='xz'` is specified; xz compressions is also supported by `DataFrame.to_csv` in the same way (GH11852)
- `pd.read_msgpack()` now always gives writeable ndarrays even when compression is used (GH12359).
- `pd.read_msgpack()` now supports serializing and de-serializing categoricals with msgpack (GH12573)
- `.to_json()` now supports `NDFrames` that contain categorical and sparse data (GH10778)
• `interpolate()` now supports method='akima' (GH7588).

• `pd.read_excel()` now accepts path objects (e.g. `pathlib.Path`, `py.path.local`) for the file path, in line with other `read_*` functions (GH12655)

• Added `.weekday_name` property as a component to `DatetimeIndex` and the `.dt` accessor. (GH11128)

• `Index.take` now handles `allow_fill` and `fill_value` consistently (GH12631)

```python
In [34]: idx = pd.Index([1., 2., 3., 4.], dtype='float')
# default, allow_fill=True, fill_value=None
In [35]: idx.take([2, -1])
Out[35]: Float64Index([3.0, 4.0], dtype='float64')
In [36]: idx.take([2, -1], fill_value=True)
Out[36]: Float64Index([3.0, nan], dtype='float64')
```

• `Index` now supports `.str.get_dummies()` which returns `MultiIndex`, see Creating Indicator Variables (GH10008, GH10103)

```python
In [37]: idx = pd.Index(["a|b", 'a|c', 'b|c'])
In [38]: idx.str.get_dummies('|')
Out [38]: MultiIndex([(1, 1, 0),
  (1, 0, 1),
  (0, 1, 1)], names=['a', 'b', 'c'])
```

• `pd.crosstab()` has gained a `normalize` argument for normalizing frequency tables (GH12569). Examples in the updated docs [here](https://pandas.pydata.org/pandas-docs/stable/user_guide/indexing.html#using-nested-arrays).

• `.resample(..).interpolate()` is now supported (GH12925)

• `.isin()` now accepts passed sets (GH12988)

### Sparse changes

These changes conform sparse handling to return the correct types and work to make a smoother experience with indexing.

`SparseArray.take` now returns a scalar for scalar input, `SparseArray` for others. Furthermore, it handles a negative indexer with the same rule as `Index` (GH10560, GH12796)

```python
s = pd.SparseArray([np.nan, np.nan, 1, 2, 3, np.nan, 4, 5, np.nan, 6])
s.take(0)
s.take([1, 2, 3])
```

• Bug in `SparseSeries[]` indexing with Ellipsis raises `KeyError` (GH9467)

• Bug in `SparseArray[]` indexing with tuples are not handled properly (GH12966)

• Bug in `SparseSeries.loc[]` with list-like input raises `TypeError` (GH10560)

• Bug in `SparseSeries.iloc[]` with scalar input may raise `IndexError` (GH10560)

• Bug in `SparseSeries.loc[]`, `.iloc[]` with slice returns `SparseArray`, rather than `SparseSeries` (GH10560)
• Bug in `SparseDataFrame.loc[]`, `.iloc[]` may result in dense `Series`, rather than `SparseSeries` (GH12787)

• Bug in `SparseArray` addition ignores `fill_value` of right hand side (GH12910)

• Bug in `SparseArray` mod raises `AttributeError` (GH12910)

• Bug in `SparseArray` pow calculates `1 ** np.nan` as `np.nan` which must be `1` (GH12910)

• Bug in `SparseArray` comparison output may incorrect result or raise `ValueError` (GH12971)

• Bug in `SparseSeries.__repr__` raises `TypeError` when it is longer than `max_rows` (GH10560)

• Bug in `SparseSeries.shape` ignores `fill_value` (GH10452)

• Bug in `SparseSeries` and `SparseArray` may have different `dtype` from its dense values (GH12908)

• Bug in `SparseSeries.to_frame()` results in `DataFrame`, rather than `SparseDataFrame` (GH9850)

• Bug in `SparseSeries.value_counts()` does not count `fill_value` (GH6749)

• Bug in `SparseArray.to_dense()` does not preserve `dtype` (GH10648)

• Bug in `SparseArray.to_dense()` incorrectly handle `fill_value` (GH12797)

• Bug in `SparseSeries.reindex` incorrectly handle `fill_value` (GH12797)

• Bug in `pd.concat()` of `SparseSeries` results in dense (GH10536)

• Bug in `pd.concat()` of `SparseDataFrame` incorrectly handle `fill_value` (GH9765)

• Bug in `pd.concat()` of `SparseDataFrame` may raise `AttributeError` (GH12174)

• Bug in `SparseArray.shift()` may raise `NameError` or `TypeError` (GH12908)

**API changes**

**Method .groupby(..).nth() changes**

The index in `.groupby(..).nth()` output is now more consistent when the `as_index` argument is passed (GH11039):

```python
In [39]: df = pd.DataFrame({'A': ['a', 'b', 'a'],
                      'B': [1, 2, 3]})

In [40]: df
Out[40]:
   A  B
0  a  1
1  b  2
2  a  3
[3 rows x 2 columns]
```

Previous behavior:

```python
In [3]: df.groupby('A', as_index=True)['B'].nth(0)
Out[3]:
   0  1
0  1
1  2
Name: B, dtype: int64
```

(continues on next page)
In [4]: df.groupby('A', as_index=False)['B'].nth(0)
Out[4]:
    0  1
    1  2
Name: B, dtype: int64

New behavior:

In [41]: df.groupby('A', as_index=True)['B'].nth(0)
Out[41]:
   A
  a 1
  b 2
Name: B, Length: 2, dtype: int64

In [42]: df.groupby('A', as_index=False)['B'].nth(0)
Out[42]:
    0  1
    1  2
Name: B, Length: 2, dtype: int64

Furthermore, previously, a .groupby would always sort, regardless if sort=False was passed with .nth().

In [43]: np.random.seed(1234)
In [44]: df = pd.DataFrame(np.random.randn(100, 2), columns=['a', 'b'])
In [45]: df['c'] = np.random.randint(0, 4, 100)

Previous behavior:

In [4]: df.groupby('c', sort=True).nth(1)
Out[4]:
   a  b
  c
  0 -0.334077  0.002118
  1  0.036142 -2.074978
  2 -0.720589  0.887163
  3  0.859588 -0.636524

In [5]: df.groupby('c', sort=False).nth(1)
Out[5]:
   a  b
  c
  0 -0.334077  0.002118
  1  0.036142 -2.074978
  2 -0.720589  0.887163
  3  0.859588 -0.636524

New behavior:

In [46]: df.groupby('c', sort=True).nth(1)
Out[46]:
   a  b
  c
  0 -0.334077  0.002118
  1  0.036142 -2.074978
  2 -0.720589  0.887163
  3  0.859588 -0.636524

(continues on next page)
0 -0.334077  0.002118
1  0.036142 -2.074978
2 -0.720589  0.887163
3  0.859588 -0.636524

[4 rows x 2 columns]

```
In [47]: df.groupby('c', sort=False).nth(1)
Out[47]:
   a    b
  c
2 -0.720589  0.887163
3  0.859588 -0.636524
0 -0.334077  0.002118
1  0.036142 -2.074978
[4 rows x 2 columns]
```

### NumPy function compatibility

Compatibility between pandas array-like methods (e.g. `sum` and `take`) and their `numpy` counterparts has been greatly increased by augmenting the signatures of the `pandas` methods so as to accept arguments that can be passed in from `numpy`, even if they are not necessarily used in the `pandas` implementation (GH12644, GH12638, GH12687)

- `.searchsorted()` for `Index` and `TimedeltaIndex` now accept a `sorter` argument to maintain compatibility with `numpy`'s `searchsorted` function (GH12238)
- Bug in `numpy` compatibility of `np.round()` on a `Series` (GH12600)

An example of this signature augmentation is illustrated below:

```python
sp = pd.SparseDataFrame([1, 2, 3])
sp

Previous behaviour:

```
In [2]: np.cumsum(sp, axis=0)
...
TypeError: cumsum() takes at most 2 arguments (4 given)
```

New behaviour:

```python
np.cumsum(sp, axis=0)
```

### Using `.apply` on `GroupBy` resampling

Using `apply` on resampling groupby operations (using a `pd.TimeGrouper`) now has the same output types as similar `apply` calls on other groupby operations. (GH11742).

```
in [48]: df = pd.DataFrame({'date': pd.to_datetime(['10/10/2000', '11/10/2000']),
          'value': [10, 13]})
       ....:
       ....:
```
In [49]: df
Out[49]:
    date  value
0  2000-10-10   10
1  2000-11-10   13
[2 rows x 2 columns]

Previous behavior:

In [1]: df.groupby(pd.TimeGrouper(key='date',
                             ...:     freq='M')).apply(lambda x: x.value.sum())
Out[1]:
    ...:     TypeError: cannot concatenate a non-NDFrame object
# Output is a Series
In [2]: df.groupby(pd.TimeGrouper(key='date',
                             ...:     freq='M')).apply(lambda x: x['value'].sum())
Out[2]:
    date    value
2000-10-31    10
2000-11-30    13
dtype: int64

New behavior:

# Output is a Series
In [55]: df.groupby(pd.TimeGrouper(key='date',
                             ...:     freq='M')).apply(lambda x: x['value'].sum())
Out[55]:
    date    value
2000-10-31    10
2000-11-30    13
Freq: M, dtype: int64
# Output is a DataFrame
In [56]: df.groupby(pd.TimeGrouper(key='date',
                             ...:     freq='M')).apply(lambda x: x[['value']].sum())
Out[56]:
    value
    date
    2000-10-31    10
    2000-11-30    13

Changes in read_csv exceptions

In order to standardize the read_csv API for both the c and python engines, both will now raise an EmptyDataError, a subclass of ValueError, in response to empty columns or header (GH12493, GH12506)

Previous behaviour:

In [1]: import io
In [2]: df = pd.read_csv(io.StringIO(''), engine='c')
ValueError: No columns to parse from file

In [3]: df = pd.read_csv(io.StringIO(''), engine='python')
...
StopIteration

New behaviour:

In [1]: df = pd.read_csv(io.StringIO(''), engine='c')
...
pandas.io.common.EmptyDataError: No columns to parse from file

In [2]: df = pd.read_csv(io.StringIO(''), engine='python')
...
pandas.io.common.EmptyDataError: No columns to parse from file

In addition to this error change, several others have been made as well:

• CPARSERERROR now sub-classes ValueError instead of just a Exception (GH12551)
• A CPARSERERROR is now raised instead of a generic Exception in read_csv when the c engine cannot parse a column (GH12506)
• A ValueError is now raised instead of a generic Exception in read_csv when the c engine encounters a NaN value in an integer column (GH12506)
• A ValueError is now raised instead of a generic Exception in read_csv when true_values is specified, and the c engine encounters an element in a column containing unencodable bytes (GH12506)
• pandas.parser.OverflowError exception has been removed and has been replaced with Python’s built-in OverflowError exception (GH12506)
• pd.read_csv() no longer allows a combination of strings and integers for the usecols parameter (GH12678)

**Method to_datetime error changes**

Bugs in pd.to_datetime() when passing a unit with convertible entries and errors='coerce' or non-convertible with errors='ignore'. Furthermore, an OutOfBoundsDateime exception will be raised when an out-of-range value is encountered for that unit when errors='raise'. (GH11758, GH13052, GH13059)

Previous behaviour:

In [27]: pd.to_datetime(1420043460, unit='s', errors='coerce')
Out[27]: NaT

In [28]: pd.to_datetime(11111111, unit='D', errors='ignore')
OverflowError: Python int too large to convert to C long

In [29]: pd.to_datetime(11111111, unit='D', errors='raise')
OverflowError: Python int too large to convert to C long

New behaviour:

In [2]: pd.to_datetime(1420043460, unit='s', errors='coerce')
Out[2]: Timestamp('2014-12-31 16:31:00')
In [3]: pd.to_datetime(11111111, unit='D', errors='ignore')
Out[3]: 11111111

In [4]: pd.to_datetime(11111111, unit='D', errors='raise')
OutOfBoundsDatetime: cannot convert input with unit 'D'

Other API changes

• `.swaplevel()` for Series, DataFrame, Panel, and MultiIndex now features defaults for its first two parameters `i` and `j` that swap the two innermost levels of the index. (GH12934)

• `.searchsorted()` for Index and TimedeltaIndex now accept a sorter argument to maintain compatibility with numpy's searchsorted function (GH12238)

• `Period` and `PeriodIndex` now raises `IncompatibleFrequency` error which inherits `ValueError` rather than raw `ValueError` (GH12615)

• `Series.apply` for category dtype now applies the passed function to each of the `.categories` (and not the `.codes`), and returns a category dtype if possible (GH12473)

• `read_csv` will now raise a `TypeError` if `parse_dates` is neither a boolean, list, or dictionary (matches the doc-string) (GH5636)

• The default for `.query()/.eval()` is now `engine=None`, which will use `numexpr` if it’s installed; otherwise it will fallback to the python engine. This mimics the pre-0.18.1 behavior if `numexpr` is installed (and which, previously, if `numexpr` was not installed, `.query()/.eval() would raise). (GH12749)

• `pd.show_versions()` now includes pandas_datareader version (GH12740)

• Provide a proper `__name__` and `__qualname__` attributes for generic functions (GH12021)

• `pd.concat(ignore_index=True)` now uses `RangeIndex` as default (GH12695)

• `pd.merge()` and `DataFrame.join()` will show a `UserWarning` when merging/joining a single- with a multi-leveled dataframe (GH9455, GH12219)

• Compat with `scipy > 0.17` for deprecated `piecewise_polynomial` interpolation method; support for the replacement `from_derivatives` method (GH12887)

Deprecations

• The method name `Index.sym_diff()` is deprecated and can be replaced by `Index.symmetric_difference()` (GH12591)

• The method name `Categorical.sort()` is deprecated in favor of `Categorical.sort_values()` (GH12882)
Performance improvements

- Improved speed of SAS reader (GH12656, GH12961)
- Performance improvements in .groupby(..).cumcount () (GH11039)
- Improved memory usage in pd.read_csv() when using skiprows=an_integer (GH13005)
- Improved performance of DataFrame.to_sql when checking case sensitivity for tables. Now only checks if table has been created correctly when table name is not lower case. (GH12876)
- Improved performance of Period construction and time series plotting (GH12903, GH11831).
- Improved performance of .str.encode() and .str.decode() methods (GH13008)
- Improved performance of to_numeric if input is numeric dtype (GH12777)
- Improved performance of sparse arithmetic with IntIndex (GH13036)

Bug fixes

- usecols parameter in pd.read_csv is now respected even when the lines of a CSV file are not even (GH12203)
- Bug in groupby.transform(..) when axis=1 is specified with a non-monotonic ordered index (GH12713)
- Bug in Period and PeriodIndex creation raises KeyError if freq="Minute" is specified. Note that “Minute” freq is deprecated in v0.17.0, and recommended to use freq="T" instead (GH11854)
- Bug in .resample(...).count () with a PeriodIndex always raising a TypeError (GH12774)
- Bug in .resample(...) with a PeriodIndex casting to a DatetimeIndex when empty (GH12868)
- Bug in .resample(...) with a PeriodIndex when resampling to an existing frequency (GH12770)
- Bug in printing data which contains Period with different freq raises ValueError (GH12615)
- Bug in Series construction with Categorical and dtype='category' is specified (GH12574)
- Bugs in concatenation with a coercible dtype was too aggressive, resulting in different dtypes in output formatting when an object was longer than display.max_rows (GH12411, GH12045, GH11594, GH10571, GH12211)
- Bug in float_format option with option not being validated as a callable. (GH12706)
- Bug in GroupBy.filter when dropna=False and no groups fulfilled the criteria (GH12768)
- Bug in __name__ of .cum* functions (GH12021)
- Bug in .astype() of a Float64Index/Int64Index to an Int64Index (GH12881)
- Bug in round tripping an integer based index in .to_json()/.read_json() when orient='index' (the default) (GH12866)
- Bug in plotting Categorical dtypes cause error when attempting stacked bar plot (GH13019)
- Compat with >= numpy 1.11 for NaT comparisons (GH12969)
- Bug in .drop() with a non-unique MultiIndex. (GH12701)
- Bug in .concat of datetime tz-aware and naive DataFrames (GH12467)
- Bug in correctly raising a ValueError in .resample(..).fillna(..) when passing a non-string (GH12952)
• Bug fixes in various encoding and header processing issues in `pd.read_sas()` (GH12659, GH12654, GH12647, GH12809)

• Bug in `pd.crosstab()` where would silently ignore `aggfunc` if `values=None` (GH12569).

• Potential segfault in `DataFrame.to_json` when serialising `datetime.time` (GH11473).

• Potential segfault in `DataFrame.to_json` when attempting to serialise 0d array (GH11299).

• Segfault in `to_json` when attempting to serialise a `DataFrame` or `Series` with non-ndarray values; now supports serialization of category, sparse, and `datetime64[ns, tz]` dtypes (GH10778).

• Bug in `DataFrame.to_json` with unsupported dtype not passed to default handler (GH12554).

• Bug in `.align` not returning the sub-class (GH12983)

• Bug in aligning a `Series` with a `DataFrame` (GH13037)

• Bug in ABCPanel in which `Panel4D` was not being considered as a valid instance of this generic type (GH12810)

• Bug in consistency of `.name` on `.groupby(..).apply(..)` cases (GH12363)

• Bug in `Timestamp.__repr__` that caused `pprint` to fail in nested structures (GH12622)

• Bug in `Timedelta.min` and `Timedelta.max`; the properties now report the true minimum/maximum `timedeltas` as recognized by pandas. See the documentation. (GH12727)

• Bug in `.quantile()` with interpolation may coerce to `float` unexpectedly (GH12772)

• Bug in `.quantile()` with empty `Series` may return scalar rather than empty `Series` (GH12772)

• Bug in `.loc` with out-of-bounds in a large indexer would raise `IndexError` rather than `KeyError` (GH12527)

• Bug in resampling when using a `TimedeltaIndex` and `.asfreq()`, would previously not include the final fencepost (GH12527)

• Bug in equality testing with a `Categorical` in a `DataFrame` (GH12564)

• Bug in `GroupBy.first()`, `.last()` returns incorrect row when `TimeGrouper` is used (GH7453)

• Bug in `pd.read_csv()` with the `c` engine when specifying `skiprows` with newlines in quoted items (GH10911, GH12775)

• Bug in `DataFrame` timezone lost when assigning tz-aware `datetime` `Series` with alignment (GH12981)

• Bug in `.value_counts()` when normalize=True and dropna=True where nulls still contributed to the normalized count (GH12558)

• Bug in `Series.value_counts()` loses name if its dtype is `category` (GH12835)

• Bug in `Series.value_counts()` loses timezone info (GH12835)

• Bug in `Series.value_counts(normalize=True)` with `Categorical` raises `UnboundLocalError` (GH12835)

• Bug in `Panel.fillna()` ignoring inplace=True (GH12633)

• Bug in `pd.read_csv()` when specifying `names`, `usecols`, and `parse_dates` simultaneously with the `c` engine (GH9755)

• Bug in `pd.read_csv()` when specifying `delim_whitespace=True` and `lineterminator` simultaneously with the `c` engine (GH12912)

• Bug in `Series.rename`, `DataFrame.rename` and `DataFrame.rename_axis` not treating `Series` as mappings to relabel (GH12623).
• Clean in .rolling.min and .rolling.max to enhance dtype handling (GH12373)
• Bug in groupby where complex types are coerced to float (GH12902)
• Bug in Series.map raises TypeError if its dtype is category or tz-aware datetime (GH12473)
• Bugs on 32bit platforms for some test comparisons (GH12972)
• Bug in index coercion when falling back from RangeIndex construction (GH12893)
• Better error message in window functions when invalid argument (e.g., a float window) is passed (GH12669)
• Bug in slicing subclassed DataFrame defined to return subclassed Series may return normal Series (GH1159)
• Bug in .str accessor methods may raise ValueError if input has name and the result is DataFrame or MultiIndex (GH12617)
• Bug in DataFrame.last_valid_index() and DataFrame.first_valid_index() on empty frames (GH12800)
• Bug in CategoricalIndex.get_loc returns different result from regular Index (GH12531)
• Bug in PeriodIndex.resample where name not propagated (GH12769)
• Bug in date_range closed keyword and timezones (GH12684).
• Bug in pd.concat raises AttributeError when input data contains tz-aware datetime and timedelta (GH12620)
• Bug in pd.concat did not handle empty Series properly (GH11082)
• Bug in .plot.bar alignment when width is specified with int (GH12979)
• Bug in fill_value is ignored if the argument to a binary operator is a constant (GH12723)
• Bug in pd.read_html() when using bs4 flavor and parsing table with a header and only one column (GH1917)
• Bug in .pivot_table when margins=True and dropna=True where nulls still contributed to margin count (GH12407)
• Bug in .pivot_table when dropna=False where table index/column names disappear (GH12133)
• Bug in pd.crosstab() when margins=True and dropna=False which raised (GH12642)
• Bug in Series.name when name attribute can be a hashable type (GH12610)
• Bug in .describe() resets categorical columns information (GH11558)
• Bug where loffset argument was not applied when calling resample().count() on a timeseries (GH12725)
• pd.read_excel() now accepts column names associated with keyword argument names (GH12870)
• Bug in pd.to_numeric() with Index returns np.ndarray, rather than Index (GH12777)
• Bug in pd.to_numeric() with datetime-like may raise TypeError (GH12777)
• Bug in pd.to_numeric() with scalar raises ValueError (GH12777)

5.10.2 Version 0.18.0 (March 13, 2016)

This is a major release from 0.17.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Warning: pandas 0.18.0 no longer supports compatibility with Python version 2.6 and 3.3 (GH7718, GH11273)
Warning: numexpr version 2.4.4 will now show a warning and not be used as a computation back-end for pandas because of some buggy behavior. This does not affect other versions (>= 2.1 and >= 2.4.6). (GH12489)

Highlights include:

- Moving and expanding window functions are now methods on Series and DataFrame, similar to .groupby, see here.
- Adding support for a RangeIndex as a specialized form of the Int64Index for memory savings, see here.
- API breaking change to the .resample method to make it more .groupby like, see here.
- Removal of support for positional indexing with floats, which was deprecated since 0.14.0. This will now raise a TypeError, see here.
- The .to_xarray() function has been added for compatibility with the xarray package, see here.
- The read_sas function has been enhanced to read sas7bdat files, see here.
- Addition of the .str.extractall() method, and API changes to the .str.extract() method and .str.cat() method.
- pd.test() top-level nose test runner is available (GH4327).

Check the API Changes and deprecations before updating.

What's new in v0.18.0

- New features
  - Window functions are now methods
  - Changes to rename
  - Range Index
  - Changes to str.extract
  - Addition of str.extractall
  - Changes to str.cat
  - Datetimelike rounding
  - Formatting of integers in FloatIndex
  - Changes to dtype assignment behaviors
  - Method to_xarray
  - Latex representation
  - pd.read_sas() changes
  - Other enhancements

- Backwards incompatible API changes
  - NaT and Timedelta operations
  - Changes to msgpack
  - Signature change for .rank
  - Bug in QuarterBegin with n=0
New features

Window functions are now methods

Window functions have been refactored to be methods on Series/DataFrame objects, rather than top-level functions, which are now deprecated. This allows these window-type functions, to have a similar API to that of .groupby. See the full documentation here (GH11603, GH12373)

```
In [1]: np.random.seed(1234)
In [2]: df = pd.DataFrame({'A': range(10), 'B': np.random.randn(10)})
In [3]: df
Out[3]:
     A      B
0   0  0.471435
1   1 -1.190976
2   2  1.432707
3   3 -0.312652
4   4 -0.720589
5   5  0.887163
6   6  0.859588
7   7 -0.636524
8   8  0.015696
9   9 -2.242685

[10 rows x 2 columns]
```

Previous behavior:

```
In [8]: pd.rolling_mean(df, window=3)
  FutureWarning: pd.rolling_mean is deprecated for DataFrame and will be removed in a future version, replace with
                  DataFrame.rolling(window=3, center=False).mean()
Out[8]:
```

(continues on next page)
A B
0 NaN NaN
1 NaN NaN
2 1 0.237722
3 2 -0.023640
4 3 0.133155
5 4 -0.048693
6 5 0.342054
7 6 0.370076
8 7 0.079587
9 8 -0.954504

New behavior:

In [4]: r = df.rolling(window=3)

These show a descriptive repr

In [5]: r
Out[5]: Rolling [window=3, center=False, axis=0]

with tab-completion of available methods and properties.

In [9]: r.<TAB>  # noQA E225, E999

9  8.0 1.0 -0.954504 1.162285

[10 rows x 4 columns]
```

Changes to rename

Series.rename and NDFrame.rename_axis can now take a scalar or list-like argument for altering the Series or axis name, in addition to their old behaviors of altering labels. (GH9494, GH11965)

```python
In [9]: s = pd.Series(np.random.randn(5))
In [10]: s.rename('newname')
```

```text
Out[10]:
0  1.150036
1  0.991946
2  0.953324
3 -2.021255
4 -0.334077
Name: newname, Length: 5, dtype: float64
```

```python
In [12]: df = pd.DataFrame(np.random.randn(5, 2))
In [12]: (df.rename_axis("indexname")
    ....: .rename_axis("columns_name", axis="columns")
    ....:)
```

```text
Out[12]:
columns_name   0   1
indexname      
0  0.002118  0.405453
1  0.289092  1.321158
```

(continues on next page)
The new functionality works well in method chains. Previously these methods only accepted functions or dicts mapping a *label* to a new label. This continues to work as before for function or dict-like values.

### Range Index

A `RangeIndex` has been added to the `Int64Index` sub-classes to support a memory saving alternative for common use cases. This has a similar implementation to the python `range` object (`xrange` in python 2), in that it only stores the start, stop, and step values for the index. It will transparently interact with the user API, converting to `Int64Index` if needed.

This will now be the default constructed index for `NDFrame` objects, rather than previous an `Int64Index`. (GH939, GH12070, GH12071, GH12109, GH12888)

Previous behavior:

```python
In [3]: s = pd.Series(range(1000))
In [4]: s.index
Out[4]: Int64Index([ 0, 1, 2, 3, 4, 5, 6, 7, 8, 9,
                   ... 990, 991, 992, 993, 994, 995, 996, 997, 998, 999],
                   dtype='int64',
                   length=1000)
In [6]: s.index.nbytes
Out[6]: 8000
```

New behavior:

```python
In [13]: s = pd.Series(range(1000))
In [14]: s.index
Out[14]: RangeIndex(start=0, stop=1000, step=1)
In [15]: s.index.nbytes
Out[15]: 128
```

### Changes to `str.extract`

The `.str.extract` method takes a regular expression with capture groups, finds the first match in each subject string, and returns the contents of the capture groups (GH11386).

In v0.18.0, the `expand` argument was added to `extract`.

- `expand=False`: it returns a `Series`, `Index`, or `DataFrame`, depending on the subject and regular expression pattern (same behavior as pre-0.18.0).
- `expand=True`: it always returns a `DataFrame`, which is more consistent and less confusing from the perspective of a user.
Currently the default is `expand=None` which gives a `FutureWarning` and uses `expand=False`. To avoid this warning, please explicitly specify `expand`.

```python
In [1]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'\[ab\](\d)', expand=None)
```
```
FutureWarning: currently extract(expand=None) means expand=False (return Index/Series/ →DataFrame)
but in a future version of pandas this will be changed to expand=True (return →DataFrame)
```

```python
Out[1]:
0 1
1 2
2 NaN
dtype: object
```

Extracting a regular expression with one group returns a Series if `expand=False`.

```python
In [16]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'\[ab\](\d)', expand=False)
```
```
Out[16]:
0 1
1 2
2 NaN
Length: 3, dtype: object
```

It returns a DataFrame with one column if `expand=True`.

```python
In [17]: pd.Series(['a1', 'b2', 'c3']).str.extract(r'\[ab\](\d)', expand=True)
```
```
Out[17]:
0 1
1 2
2 NaN
[3 rows x 1 columns]
```

Calling on an Index with a regex with exactly one capture group returns an Index if `expand=False`.

```python
In [18]: s = pd.Series(['a1', 'b2', 'c3'], ['A11', 'B22', 'C33'])
In [19]: s.index
```
```
Out[19]: Index(['A11', 'B22', 'C33'], dtype='object')
```

```python
In [20]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=False)
```
```
Out[20]: Index(['A', 'B', 'C'], dtype='object', name='letter')
```

It returns a DataFrame with one column if `expand=True`.

```python
In [21]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=True)
```
```
Out[21]:
letter
0 A
1 B
2 C
[3 rows x 1 columns]
```

Calling on an Index with a regex with more than one capture group raises `ValueError` if `expand=False`.
>>> s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=False)
ValueError: only one regex group is supported with Index

It returns a DataFrame if expand=True.

In [22]: s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=True)
Out[22]:
   letter 1
0    A 11
1    B 22
2    C 33
[3 rows x 2 columns]

In summary, extract (expand=True) always returns a DataFrame with a row for every subject string, and a column for every capture group.

Addition of str.extractall

The .str.extractall method was added (GH1386). Unlike extract, which returns only the first match.

In [23]: s = pd.Series(["a1a2", "b1", "c1"], ["A", "B", "C"])
In [24]: s
Out[24]:
A    a1a2
B     b1
C     c1
Length: 3, dtype: object
In [25]: s.str.extract(r"(?P<letter>[ab])(?P<digit>[0-9])", expand=False)
Out[25]:
   letter digit
A    a   1
B    b   1
C  NaN  NaN
[3 rows x 2 columns]

The extractall method returns all matches.

In [26]: s.str.extractall(r"(?P<letter>[ab])(?P<digit>[0-9])")
Out[26]:
   letter digit
     match
A  0    a   1
   1    a   2
B  0    b   1
[3 rows x 2 columns]
Changes to str.cat

The method `.str.cat()` concatenates the members of a Series. Before, if NaN values were present in the Series, calling `.str.cat()` on it would return NaN, unlike the rest of the Series.str.* API. This behavior has been amended to ignore NaN values by default. (GH11435).

A new, friendlier `ValueError` is added to protect against the mistake of supplying the `sep` as an arg, rather than as a kwarg. (GH11334).

```python
In [27]: pd.Series(['a', 'b', np.nan, 'c']).str.cat(sep=' ')
Out[27]: 'a b c'

In [28]: pd.Series(['a', 'b', np.nan, 'c']).str.cat(sep=' ', na_rep='?')
Out[28]: 'a b ? c'

In [2]: pd.Series(['a', 'b', np.nan, 'c']).str.cat(' ')
ValueError: Did you mean to supply a `sep` keyword?
```

Datetimelike rounding

`DatetimeIndex`, `Timestamp`, `TimedeltaIndex`, `Timedelta` have gained the `.round()`, `.floor()` and `.ceil()` method for datetimelike rounding, flooring and ceiling. (GH4314, GH11963)

Naive datetimes

```python
In [29]: dr = pd.date_range('20130101 09:12:56.1234', periods=3)
In [30]: dr
Out[30]: DatetimeIndex(['2013-01-01 09:12:56.123400', '2013-01-02 09:12:56.123400',
                    '2013-01-03 09:12:56.123400'],
                   dtype='datetime64[ns]', freq='D')

In [31]: dr.round('s')
Out[31]: DatetimeIndex(['2013-01-01 09:12:56', '2013-01-02 09:12:56',
                   '2013-01-03 09:12:56'],
                   dtype='datetime64[ns]', freq=None)

# Timestamp scalar
In [32]: dr[0]
Out[32]: Timestamp('2013-01-01 09:12:56.123400', freq='D')

In [33]: dr[0].round('10s')
Out[33]: Timestamp('2013-01-01 09:13:00')
```

Tz-aware are rounded, floored and ceiled in local times

```python
In [34]: dr = dr.tz_localize('US/Eastern')
In [35]: dr
Out[35]: DatetimeIndex(['2013-01-01 09:12:56.123400-05:00',
                    '2013-01-02 09:12:56.123400-05:00',
                    '2013-01-03 09:12:56.123400-05:00'],
                   dtype='datetime64[ns, US/Eastern]', freq=None)
```
In [36]: dr.round('s')
Out[36]:
DatetimeIndex(['2013-01-01 09:12:56-05:00', '2013-01-02 09:12:56-05:00',
                 '2013-01-03 09:12:56-05:00'],
dtype='datetime64[ns, US/Eastern]', freq=None)

Timedeltas

In [37]: t = pd.timedelta_range('1 days 2 hr 13 min 45 us', periods=3, freq='d')
In [38]: t
Out[38]:
TimedeltaIndex(['1 days 02:13:00.000045', '2 days 02:13:00.000045',
                 '3 days 02:13:00.000045'],
dtype='timedelta64[ns]', freq='D')
In [39]: t.round('10min')
Out[39]: TimedeltaIndex(['1 days 02:10:00', '2 days 02:10:00', '3 days 02:10:00'],
                         dtype='timedelta64[ns]', freq=None)

# Timedelta scalar
In [40]: t[0]
Out[40]: Timedelta('1 days 02:13:00.000045')
In [41]: t[0].round('2h')
Out[41]: Timedelta('1 days 02:00:00')

In addition, .round(), .floor() and .ceil() will be available through the .dt accessor of Series.

In [42]: s = pd.Series(dr)
In [43]: s
Out[43]:
0  2013-01-01 09:12:56.123400-05:00
1  2013-01-02 09:12:56.123400-05:00
2  2013-01-03 09:12:56.123400-05:00
Length: 3, dtype: datetime64[ns, US/Eastern]
In [44]: s.dt.round('D')
Out[44]:
0  2013-01-01 00:00:00-05:00
1  2013-01-02 00:00:00-05:00
2  2013-01-03 00:00:00-05:00
Length: 3, dtype: datetime64[ns, US/Eastern]
Formatting of integers in FloatIndex

Integers in FloatIndex, e.g. 1., are now formatted with a decimal point and a 0 digit, e.g. 1.0 (GH11713) This change not only affects the display to the console, but also the output of IO methods like .to_csv or .to_html.

Previous behavior:

```
In [2]: s = pd.Series([1, 2, 3], index=np.arange(3.))
In [3]: s
Out[3]:
0    1
1    2
2    3
dtype: int64
In [4]: s.index
Out[4]: Float64Index([0.0, 1.0, 2.0], dtype='float64')
In [5]: print(s.to_csv(path=None))
0,1
1,2
2,3
```

New behavior:

```
In [45]: s = pd.Series([1, 2, 3], index=np.arange(3.))
In [46]: s
Out[46]:
0.0    1
1.0    2
2.0    3
Length: 3, dtype: int64
In [47]: s.index
Out[47]: Float64Index([0.0, 1.0, 2.0], dtype='float64')
In [48]: print(s.to_csv(path_or_buf=None, header=False))
0.0,1
1.0,2
2.0,3
```

Changes to dtype assignment behaviors

When a DataFrame’s slice is updated with a new slice of the same dtype, the dtype of the DataFrame will now remain the same. (GH10503)

Previous behavior:

```
In [5]: df = pd.DataFrame({'a': [0, 1, 1],
                      'b': pd.Series([100, 200, 300], dtype='uint32')})
In [7]: df.dtypes
Out[7]:
a    int64
b    uint32
```

(continues on next page)
### New behavior:

```python
In [49]: df = pd.DataFrame({
    ...:     'a': [0, 1, 1],
    ...:     'b': pd.Series([100, 200, 300], dtype='uint32')})
    ...

In [50]: df.dtypes
Out[50]:
   a   int64
   b  uint32
Length: 2, dtype: object

In [51]: ix = df['a'] == 1

In [52]: df.loc[ix, 'b'] = df.loc[ix, 'b']

In [53]: df.dtypes
Out[53]:
   a   int64
   b  uint32
Length: 2, dtype: object
```

When a DataFrame’s integer slice is partially updated with a new slice of floats that could potentially be down-casted
to integer without losing precision, the dtype of the slice will be set to float instead of integer.

### Previous behavior:

```python
In [4]: df = pd.DataFrame(np.array(range(1,10)).reshape(3,3),
                     columns=list('abc'),
                     index=[[4,4,8], [8,10,12]])

In [5]: df
Out[5]:
   a  b  c
4  8  1  2  3
10  4  5  6
8  12  7  8  9

In [7]: df.ix[4, 'c'] = np.array([0., 1.])

In [8]: df
Out[8]:
   a  b  c
4  8  1  2  0
```

(continues on next page)
New behavior:

```python
In [54]: df = pd.DataFrame(np.array(range(1,10)).reshape(3,3),
..:          columns=list('abc'),
..:          index=[[4,4,8], [8,10,12]])

In [55]: df
Out[55]:
   a  b  c
4  8  1  2  3
10 4  5  6
8 12  7  8  9
[3 rows x 3 columns]
```

```python
In [56]: df.loc[4, 'c'] = np.array([0., 1.])

In [57]: df
Out[57]:
   a  b  c
4  8  1  2  0.0
10 4  5  1.0
8 12  7  8  9.0
[3 rows x 3 columns]
```

**Method to_xarray**

In a future version of pandas, we will be deprecating Panel and other > 2 ndim objects. In order to provide for continuity, all NDFrame objects have gained the `.to_xarray()` method in order to convert to xarray objects, which has a pandas-like interface for > 2 ndim. (GH11972)

See the xarray full-documentation here.

```python
In [1]: p = Panel(np.arange(2*3*4).reshape(2,3,4))

In [2]: p.to_xarray()
Out[2]:
<xarray.DataArray (items: 2, major_axis: 3, minor_axis: 4)>
array([[[ 0, 1, 2, 3],
        [ 4, 5, 6, 7],
        [ 8, 9,10,11]],
       [[12,13,14,15],
        [16,17,18,19],
        [20,21,22,23]]])
Coordinates:
* items     (items) int64 0 1
* major_axis (major_axis) int64 0 1 2
* minor_axis (minor_axis) int64 0 1 2 3
```
Latex representation

DataFrame has gained a \_repr\_latex\_() method in order to allow for conversion to latex in an ipython/jupyter notebook using nbconvert. (GH11778)

Note that this must be activated by setting the option pd.display.latex.repr=True (GH12182)

For example, if you have a jupyter notebook you plan to convert to latex using nbconvert, place the statement pd.display.latex.repr=True in the first cell to have the contained DataFrame output also stored as latex.

The options display.latex.escape and display.latex.longtable have also been added to the configuration and are used automatically by the to_latex method. See the available options docs for more info.

**pd.read_sas() changes**

read_sas has gained the ability to read SAS7BDAT files, including compressed files. The files can be read in entirety, or incrementally. For full details see here. (GH4052)

**Other enhancements**

- Handle truncated floats in SAS xport files (GH11713)
- Added option to hide index in Series.to_string (GH11729)
- read_excel now supports s3 urls of the format s3://bucketname/filename (GH11447)
- add support for AWS_S3_HOST env variable when reading from s3 (GH12198)
- A simple version of Panel.round() is now implemented (GH11763)
- For Python 3.x, round(DataFrame), round(Series), round(Panel) will work (GH11763)
- sys.getsizeof(obj) returns the memory usage of a pandas object, including the values it contains (GH11597)
- Series gained an is_unique attribute (GH11946)
- DataFrame.quantile and Series.quantile now accept interpolation keyword (GH10174).
- Added DataFrame.style.format for more flexible formatting of cell values (GH11692)
- DataFrame.select_dtypes now allows the np.float16 type code (GH11990)
- pivot_table() now accepts most iterables for the values parameter (GH12017)
- Added Google BigQuery service account authentication support, which enables authentication on remote servers. (GH11881, GH12572). For further details see here
- HDFStore is now iterable: for k in store is equivalent to for k in store.keys() (GH12221).
- Add missing methods/fields to .dt for Period (GH8848)
- The entire code base has been PEP-ified (GH12096)
Backwards incompatible API changes

- the leading white spaces have been removed from the output of `.to_string(index=False)` method (GH11833)
- the `out` parameter has been removed from the `Series.round()` method. (GH11763)
- `DataFrame.round()` leaves non-numeric columns unchanged in its return, rather than raises. (GH11885)
- `DataFrame.head(0)` and `DataFrame.tail(0)` return empty frames, rather than `self`. (GH11937)
- `Series.head(0)` and `Series.tail(0)` return empty series, rather than `self`. (GH11937)
- `to_msgpack` and `read_msgpack` encoding now defaults to 'utf-8'. (GH12170)
- the order of keyword arguments to text file parsing functions (.read_csv(), .read_table(), .read_fwf()) changed to group related arguments. (GH11555)
- `NaTType.isoformat` now returns the string 'NaT' to allow the result to be passed to the constructor of `Timestamp`. (GH12300)

NaT and Timedelta operations

NaT and Timedelta have expanded arithmetic operations, which are extended to `Series` arithmetic where applicable. Operations defined for `datetime64[ns]` or `timedelta64[ns]` are now also defined for `NaT` (GH11564).

NaT now supports arithmetic operations with integers and floats.

```python
In [58]: pd.NaT * 1
Out[58]: NaT

In [59]: pd.NaT * 1.5
Out[59]: NaT

In [60]: pd.NaT / 2
Out[60]: NaT

In [61]: pd.NaT * np.nan
Out[61]: NaT
```

NaT defines more arithmetic operations with `datetime64[ns]` and `timedelta64[ns]`.

```python
In [62]: pd.NaT / pd.NaT
Out[62]: nan

In [63]: pd.Timedelta('1s') / pd.NaT
Out[63]: nan
```

NaT may represent either a `datetime64[ns]` null or a `timedelta64[ns]` null. Given the ambiguity, it is treated as a `timedelta64[ns]`, which allows more operations to succeed.

```python
In [64]: pd.NaT + pd.NaT
Out[64]: NaT

# same as
In [65]: pd.Timedelta('1s') + pd.Timedelta('1s')
Out[65]: Timedelta('0 days 00:00:02')
```

as opposed to
In [3]: pd.Timestamp('19900315') + pd.Timestamp('19900315')
TypeError: unsupported operand type(s) for +: 'Timestamp' and 'Timestamp'

However, when wrapped in a `Series` whose `dtype` is `datetime64[ns]` or `timedelta64[ns]`, the `dtype` information is respected.

In [1]: pd.Series([pd.NaT], dtype='<M8[ns]') + pd.Series([pd.NaT], dtype='<M8[ns]')
TypeError: can only operate on a datetimes for subtraction, but the operator `__add__` was passed

Out[66]:
0    NaT
Length: 1, dtype: timedelta64[ns]

Timedelta division by floats now works.

In [67]: pd.Timedelta('1s') / 2.0
Out[67]: Timedelta('0 days 00:00:00.500000')

Subtraction by `Timedelta` in a `Series` by a `Timestamp` works (GH11925)

In [68]: ser = pd.Series(pd.timedelta_range('1 day', periods=3))

In [69]: ser
Out[69]:
0  1 days
1  2 days
2  3 days
Length: 3, dtype: timedelta64[ns]

In [70]: pd.Timestamp('2012-01-01') - ser
Out[70]:
0  2011-12-31
1  2011-12-30
2  2011-12-29
Length: 3, dtype: datetime64[ns]

NaT.isoformat() now returns 'NaT'. This change allows allows `pd.Timestamp` to rehydrate any timestamp like object from its isoformat (GH12300).

Changes to msgpack

Forward incompatible changes in `msgpack` writing format were made over 0.17.0 and 0.18.0; older versions of pandas cannot read files packed by newer versions (GH12129, GH10527).

Bugs in `to_msgpack` and `read_msgpack` introduced in 0.17.0 and fixed in 0.18.0, caused files packed in Python 2 unreadable by Python 3 (GH12142). The following table describes the backward and forward compat of msgpacks.

<table>
<thead>
<tr>
<th>Packed with</th>
<th>Can be unpacked with</th>
</tr>
</thead>
<tbody>
<tr>
<td>pre-0.17 / Python 2</td>
<td>any</td>
</tr>
<tr>
<td>pre-0.17 / Python 3</td>
<td>any</td>
</tr>
<tr>
<td>0.17 / Python 2</td>
<td>• ==0.17 / Python 2</td>
</tr>
<tr>
<td></td>
<td>• &gt;=0.18 / any Python</td>
</tr>
<tr>
<td>0.17 / Python 3</td>
<td>&gt;=0.18 / any Python</td>
</tr>
<tr>
<td>0.18</td>
<td>&gt;= 0.18</td>
</tr>
</tbody>
</table>

5.10. Version 0.18
0.18.0 is backward-compatible for reading files packed by older versions, except for files packed with 0.17 in Python 2, in which case only they can only be unpacked in Python 2.

### Signature change for .rank

Series.rank and DataFrame.rank now have the same signature (GH11759)

**Previous signature**

```python
In [3]: pd.Series([0,1]).rank(method='average', na_option='keep',
                   ascending=True, pct=False)
```

```
Out[3]:
   0 1
  1 2
dtype: float64
```

```python
In [4]: pd.DataFrame([0,1]).rank(axis=0, numeric_only=None,
                            method='average', na_option='keep',
                            ascending=True, pct=False)
```

```
Out[4]:
   0
  0 1
  1 2
```

**New signature**

```python
In [71]: pd.Series([0,1]).rank(axis=0, method='average', numeric_only=None,
                             na_option='keep', ascending=True, pct=False)
```

```
Out[71]:
   0 1.0
  1 2.0
Length: 2, dtype: float64
```

```python
In [72]: pd.DataFrame([0,1]).rank(axis=0, method='average', numeric_only=None,
                             na_option='keep', ascending=True, pct=False)
```

```
Out[72]:
   0
  0 1.0
  1 2.0
[2 rows x 1 columns]
```

### Bug in QuarterBegin with n=0

In previous versions, the behavior of the QuarterBegin offset was inconsistent depending on the date when the n parameter was 0. (GH11406)

The general semantics of anchored offsets for n=0 is to not move the date when it is an anchor point (e.g., a quarter start date), and otherwise roll forward to the next anchor point.
For the QuarterBegin offset in previous versions, the date would be rolled backwards if date was in the same month as the quarter start date.

This behavior has been corrected in version 0.18.0, which is consistent with other anchored offsets like MonthBegin and YearBegin.

**Resample API**

Like the change in the window functions API above, .resample(...) is changing to have a more groupby-like API. (GH11732, GH12702, GH12202, GH12332, GH12334, GH12348, GH12448).
pandas: powerful Python data analysis toolkit, Release 1.1.1

Previous API:

You would write a resampling operation that immediately evaluates. If a how parameter was not provided, it would default to how='mean'.

```
In [6]: df.resample('2s')
Out[6]:
    A     B     C     D
2010-01-01 09:00:00 0.485748 0.447351 0.357096 0.793615
2010-01-01 09:00:02 0.820801 0.794317 0.364034 0.531096
2010-01-01 09:00:04 0.433985 0.314582 0.424104 0.625733
2010-01-01 09:00:06 0.624988 0.609738 0.631665 0.612452
2010-01-01 09:00:08 0.510470 0.534317 0.573201 0.806949
```

You could also specify a how directly

```
In [7]: df.resample('2s', how='sum')
Out[7]:
    A     B     C     D
2010-01-01 09:00:00 0.971495 0.894701 0.714192 1.587231
2010-01-01 09:00:02 1.641602 1.588635 0.728068 1.062191
2010-01-01 09:00:04 0.867969 0.629165 0.848208 1.251465
2010-01-01 09:00:06 1.249976 1.219477 1.266330 1.224904
2010-01-01 09:00:08 1.020940 1.068634 1.146402 1.613897
```

New API:

Now, you can write `.resample(..)` as a 2-stage operation like `.groupby(..)`, which yields a Resampler.

```
In [82]: r = df.resample('2s')

In [83]: r
Out[83]: <pandas.core.resample.DatetimeIndexResampler object at 0x7fe2797b0b50>
```

**Downsampling**

You can then use this object to perform operations. These are downsampling operations (going from a higher frequency to a lower one).

```
In [84]: r.mean()
Out[84]:
    A     B     C     D
2010-01-01 09:00:00 0.485748 0.447351 0.357096 0.793615
2010-01-01 09:00:02 0.820801 0.794317 0.364034 0.531096
2010-01-01 09:00:04 0.433985 0.314582 0.424104 0.625733
2010-01-01 09:00:06 0.624988 0.609738 0.631665 0.612452
2010-01-01 09:00:08 0.510470 0.534317 0.573201 0.806949
[5 rows x 4 columns]
```

```
In [85]: r.sum()
Out[85]:
    A     B     C     D
2010-01-01 09:00:00 0.971495 0.894701 0.714192 1.587231
2010-01-01 09:00:02 1.641602 1.588635 0.728068 1.062191
2010-01-01 09:00:04 0.867969 0.629165 0.848208 1.251465
2010-01-01 09:00:06 1.249976 1.219477 1.266330 1.224904
2010-01-01 09:00:08 1.020940 1.068634 1.146402 1.613897
```

(continues on next page)
Furthermore, resample now supports `getitem` operations to perform the resample on specific columns.

```python
In [86]: r[['A','C']].mean()
Out[86]:
         A     C
2010-01-01 09:00:00 0.485748 0.357096
2010-01-01 09:00:02 0.820801 0.364034
2010-01-01 09:00:04 0.433985 0.424104
2010-01-01 09:00:06 0.624988 0.633165
2010-01-01 09:00:08 0.510470 0.573201
```

and `.aggregate` type operations.

```python
In [87]: r.agg({'A' : 'mean', 'B' : 'sum'})
Out[87]:
        A     B
2010-01-01 09:00:00 0.485748 0.894701
2010-01-01 09:00:02 0.820801 1.588635
2010-01-01 09:00:04 0.433985 0.629165
2010-01-01 09:00:06 0.624988 1.219477
2010-01-01 09:00:08 0.510470 1.068634
```

These accessors can of course, be combined

```python
In [88]: r[['A','B']].agg(['mean','sum'])
Out[88]:
          A    B
mean  sum  mean  sum
2010-01-01 09:00:00 0.485748 0.971495 0.447351 0.894701
2010-01-01 09:00:02 0.820801 1.641602 0.794317 1.588635
2010-01-01 09:00:04 0.433985 0.867969 0.314582 0.629165
2010-01-01 09:00:06 0.624988 1.249976 0.609738 1.219477
2010-01-01 09:00:08 0.510470 1.020940 0.534317 1.068634
```

**Upsampling**

Upsampling operations take you from a lower frequency to a higher frequency. These are now performed with the `Resampler` objects with `backfill()`, `ffill()`, `fillna()` and `asfreq()` methods.

```python
In [89]: s = pd.Series(np.arange(5, dtype='int64'),
                   index=pd.date_range('2010-01-01', periods=5, freq='Q'))
```

(continues on next page)
Out[90]:
2010-03-31  0
2010-06-30  1
2010-09-30  2
2010-12-31  3
2011-03-31  4
Freq: Q-DEC, Length: 5, dtype: int64

Previously

In [6]: s.resample('M', fill_method='ffill')
Out[6]:
2010-03-31  0
2010-04-30  0
2010-05-31  0
2010-06-30  1
2010-07-31  1
2010-08-31  1
2010-09-30  2
2010-10-31  2
2010-11-30  2
2010-12-31  3
2011-01-31  3
2011-02-28  3
2011-03-31  4
Freq: M, dtype: int64

New API

In [91]: s.resample('M').ffill()
Out[91]:
2010-03-31  0
2010-04-30  0
2010-05-31  0
2010-06-30  1
2010-07-31  1
2010-08-31  1
2010-09-30  2
2010-10-31  2
2010-11-30  2
2010-12-31  3
2011-01-31  3
2011-02-28  3
2011-03-31  4
Freq: M, Length: 13, dtype: int64

Note: In the new API, you can either downsample OR upsample. The prior implementation would allow you to pass an aggregator function (like mean) even though you were upsampling, providing a bit of confusion.
**Warning**: This new API for resample includes some internal changes for the prior-to-0.18.0 API, to work with a deprecation warning in most cases, as the resample operation returns a deferred object. We can intercept operations and just do what the (pre 0.18.0) API did (with a warning). Here is a typical use case:

```
In [4]: r = df.resample('2s')
```

```
In [6]: r*10
```

```
pandas/tseries/resample.py:80: FutureWarning: .resample() is now a deferred
˓→operation
use .resample(...).mean() instead of .resample(...)
```

```
Out[6]:
   A      B      C      D
2010-01-01 09:00:00  4.857476  4.473507  3.570960  7.936154
2010-01-01 09:00:02  8.208011  7.943173  3.640340  5.310957
2010-01-01 09:00:04  4.339846  3.145823  4.241039  6.257326
2010-01-01 09:00:06  6.249881  6.097384  6.331650  6.124518
2010-01-01 09:00:08  5.104699  5.343172  5.732009  8.069486
```

However, getting and assignment operations directly on a Resampler will raise a `ValueError`:

```
In [7]: r.iloc[0] = 5
```

```
ValueError: .resample() is now a deferred operation
use .resample(...).mean() instead of .resample(...)
```

There is a situation where the new API can not perform all the operations when using original code. This code is intending to resample every 2s, take the mean AND then take the min of those results.

```
In [4]: df.resample('2s').min()
```

```
Out[4]:
   A  0.433985  
   B  0.314582  
   C  0.357096  
   D  0.531096  
dtype: float64
```

The new API will:

```
In [92]: df.resample('2s').min()
```

```
Out[92]:
   0.191519  0.272593  0.276464  0.785359
   0.683463  0.712702  0.357817  0.500995
   0.364886  0.013768  0.075381  0.368824
   0.316836  0.568099  0.397203  0.436173
   0.218792  0.143767  0.442141  0.704581
```

The good news is the return dimensions will differ between the new API and the old API, so this should loudly raise an exception.

To replicate the original operation

```
In [93]: df.resample('2s').mean().min()
```

```
Out[93]:
   0.433985  
   0.314582  
   0.357096  
   0.531096  
dtype: float64
```
Changes to eval

In prior versions, new columns assignments in an eval expression resulted in an inplace change to the DataFrame. (GH9297, GH8664, GH10486)

In [94]: df = pd.DataFrame({'a': np.linspace(0, 10, 5), 'b': range(5)})

In [95]: df
Out[95]:
   a  b
0 0.0 0
1 2.5 1
2 5.0 2
3 7.5 3
4 10.0 4

[5 rows x 2 columns]

In [12]: df.eval('c = a + b')

FutureWarning: eval expressions containing an assignment currently default to operating inplace.
This will change in a future version of pandas, use inplace=True to avoid this warning.

In [13]: df
Out[13]:
   a  b  c
0 0.0 0 0.0
1 2.5 1 3.5
2 5.0 2 7.0
3 7.5 3 10.5
4 10.0 4 14.0

In version 0.18.0, a new inplace keyword was added to choose whether the assignment should be done inplace or return a copy.

In [96]: df
Out[96]:
   a  b  c
0 0.0 0 0.0
1 2.5 1 3.5
2 5.0 2 7.0
3 7.5 3 10.5
4 10.0 4 14.0

[5 rows x 3 columns]

In [97]: df.eval('d = c - b', inplace=False)
Out[97]:
   a  b  c  d
0 0.0 0 0.0 0.0
1 2.5 1 3.5 2.5
2 5.0 2 7.0 5.0

(continues on next page)
In [98]: df
Out[98]:
   a   b   c
0  0.0 0.0 0.0
1  2.5 1.0 3.5
2  5.0 2.0 7.0
3  7.5 3.0 10.5
4 10.0 4.0 14.0

[5 rows x 3 columns]

In [99]: df.eval('d = c - b', inplace=True)

In [100]: df
Out[100]:
   a   b   c   d
0  0.0 0.0 0.0  0.0
1  2.5 1.0 3.5  2.5
2  5.0 2.0 7.0  5.0
3  7.5 3.0 10.5 7.5
4 10.0 4.0 14.0 10.0

[5 rows x 4 columns]

Warning: For backwards compatibility, inplace defaults to True if not specified. This will change in a future version of pandas. If your code depends on an inplace assignment you should update to explicitly set inplace=True.

The inplace keyword parameter was also added the query method.

In [101]: df.query('a > 5')
Out[101]:
   a   b   c   d
0  0.0 0.0 0.0  0.0
1  2.5 1.0 3.5  2.5
2  5.0 2.0 7.0  5.0
3  7.5 3.0 10.5 7.5
4 10.0 4.0 14.0 10.0

[2 rows x 4 columns]

In [102]: df.query('a > 5', inplace=True)

In [103]: df
Out[103]:
   a   b   c   d
0  0.0 0.0 0.0  0.0
1  2.5 1.0 3.5  2.5
2  5.0 2.0 7.0  5.0
3  7.5 3.0 10.5 7.5
4 10.0 4.0 14.0 10.0

[2 rows x 4 columns]
**Warning:** Note that the default value for `inplace` in a query is `False`, which is consistent with prior versions.

eval has also been updated to allow multi-line expressions for multiple assignments. These expressions will be evaluated one at a time in order. Only assignments are valid for multi-line expressions.

```
In [104]: df
Out [104]:
   a  b  c  d  
3  7.5 3 10.5 7.5
4 10.0 4 14.0 10.0
[2 rows x 4 columns]
```

```
In [105]: df.eval(""
.......
.......
.......
"", inplace=True)
```

```
In [106]: df
Out [106]:
   a  b  c  d  e  f  g
3  7.5 3 10.5 15.0 -7.0 -3.5
4 10.0 4 14.0 20.0 -2.0 -1.0
[2 rows x 7 columns]
```

**Other API changes**

- `DataFrame.between_time` and `Series.between_time` now only parse a fixed set of time strings. Parsing of date strings is no longer supported and raises a `ValueError`. (GH11818)

```
In [107]: s = pd.Series(range(10), pd.date_range('2015-01-01', freq='H', periods=10))
```

```
In [108]: s.between_time("7:00am", "9:00am")
Out [108]:
2015-01-01 07:00:00 7
2015-01-01 08:00:00 8
2015-01-01 09:00:00 9
Freq: H, Length: 3, dtype: int64
```

This will now raise.

```
In [2]: s.between_time('20150101 07:00:00','20150101 09:00:00')
ValueError: Cannot convert arg ['20150101 07:00:00'] to a time.
```

- `.memory_usage()` now includes values in the index, as does memory_usage in `.info()` (GH11597)
- `DataFrame.to_latex()` now supports non-ascii encodings (e.g. `utf-8`) in Python 2 with the parameter `encoding` (GH7061)
- `pandas.merge()` and `DataFrame.merge()` will show a specific error message when trying to merge with an object that is not of type `DataFrame` or a subclass (GH12081)
• **DataFrame.unstack** and **Series.unstack** now take **fill_value** keyword to allow direct replacement of missing values when an unstack results in missing values in the resulting **DataFrame**. As an added benefit, specifying **fill_value** will preserve the data type of the original stacked data. (GH9746)

• As part of the new API for **window functions** and **resampling**, aggregation functions have been clarified, raising more informative error messages on invalid aggregations. (GH9052). A full set of examples are presented in **groupby**.

• Statistical functions for **NDFrame** objects (like **sum()**, **mean()**, **min()**) will now raise if non-numpy-compatible arguments are passed in for **kwargs** (GH12301)

• **.to_latex** and **.to_html** gain a decimal parameter like **.to_csv**; the default is '. ' (GH12031)

• More helpful error message when constructing a **DataFrame** with empty data but with indices (GH8020)

• **.describe()** will now properly handle bool dtype as a categorical (GH6625)

• More helpful error message with an invalid **.transform** with user defined input (GH10165)

• Exponentially weighted functions now allow specifying alpha directly (GH10789) and raise **ValueError** if parameters violate 0 < alpha <= 1 (GH12492)

## Deprecations

• The functions **pd.rolling_***, **pd.expanding_***, and **pd.ewm* are deprecated and replaced by the corresponding method call. Note that the new suggested syntax includes all of the arguments (even if default) (GH11603)

```python
In [1]: s = pd.Series(range(3))
In [2]: pd.rolling_mean(s,window=2,min_periods=1)
   FutureWarning: pd.rolling_mean is deprecated for Series and will be removed in a future version, replace with Series.rolling(min_periods=1,window=2,center=False).mean()
Out[2]:
   0   0.0
   1   0.5
   2   1.5
dtype: float64
In [3]: pd.rolling_cov(s, s, window=2)
   FutureWarning: pd.rolling_cov is deprecated for Series and will be removed in a future version, replace with Series.rolling(window=2).cov(other=<Series>)
Out[3]:
   0  NaN
   1   0.5
   2   0.5
dtype: float64
```

• The **freq** and **how** arguments to the **.rolling**, **.expanding**, and **.ewm** (new) functions are deprecated, and will be removed in a future version. You can simply resample the input prior to creating a window function. (GH11603).

For example, instead of **s.rolling(window=5,freq='D').max()** to get the max value on a rolling 5 Day window, one could use **s.resample('D').mean().rolling(window=5).max()**, which first resamples the data to daily data, then provides a rolling 5 day window.
• `pd.tseries.frequencies.get_offset_name` function is deprecated. Use offset’s `.freqstr` property as alternative (GH11192)

• `pandas.stats.fama_macbeth` routines are deprecated and will be removed in a future version (GH6077)

• `pandas.stats.ols`, `pandas.stats.plm` and `pandas.stats.var` routines are deprecated and will be removed in a future version (GH6077)

• show a `FutureWarning` rather than a `DeprecationWarning` on using long-time deprecated syntax in `HDFStore.select`, where the `where` clause is not a string-like (GH12027)

• The `pandas.options.display.mpl_style` configuration has been deprecated and will be removed in a future version of pandas. This functionality is better handled by matplotlib’s style sheets (GH11783).

**Removal of deprecated float indexers**

In GH4892 indexing with floating point numbers on a non-`Float64Index` was deprecated (in version 0.14.0). In 0.18.0, this deprecation warning is removed and these will now raise a `TypeError` (GH12165, GH12333)

```
In [109]: s = pd.Series([1, 2, 3], index=[4, 5, 6])

In [110]: s
Out[110]:
     4  1
     5  2
     6  3
Length: 3, dtype: int64

In [111]: s2 = pd.Series([1, 2, 3], index=list('abc'))

In [112]: s2
Out[112]:
a 1
b 2
c 3
Length: 3, dtype: int64
```

Previous behavior:

```
# this is label indexing
In [2]: s[5.0]
FutureWarning: scalar indexers for index type Int64Index should be integers and not floating point
Out[2]: 2

# this is positional indexing
In [3]: s.iloc[1.0]
FutureWarning: scalar indexers for index type Int64Index should be integers and not floating point
Out[3]: 2

# this is label indexing
In [4]: s.loc[5.0]
FutureWarning: scalar indexers for index type Int64Index should be integers and not floating point
Out[4]: 2

# .ix would coerce 1.0 to the positional 1, and index
```
In [5]: s2.ix[1.0] = 10
FutureWarning: scalar indexers for index type Index should be integers and not floating point

In [6]: s2
Out[6]:
   a  1
   b 10
   c  3
   dtype: int64

New behavior:
For iloc, getting & setting via a float scalar will always raise.

In [3]: s.iloc[2.0]
TypeError: cannot do label indexing on <class 'pandas.indexes.numeric.Int64Index'> with these indexers [2.0] of <type 'float'>

Other indexers will coerce to a like integer for both getting and setting. The FutureWarning has been dropped for .loc, .ix and [].

and setting

In [115]: s_copy = s.copy()
In [116]: s_copy[5.0] = 10
In [117]: s_copy
Out[117]:
      4   1
      5  10
      6   3
Length: 3, dtype: int64
In [118]: s_copy = s.copy()
In [119]: s_copy.loc[5.0] = 10
In [120]: s_copy
Out[120]:
      4   1
      5  10
      6   3
Length: 3, dtype: int64

Positional setting with .ix and a float indexer will ADD this value to the index, rather than previously setting the value by position.

In [3]: s2.ix[1.0] = 10
In [4]: s2
}(continues on next page)
Slicing will also coerce integer-like floats to integers for a non-Float64Index.

```
In [121]: s.loc[5.0:6]
Out[121]:
5  2
6  3
Length: 2, dtype: int64
```

Note that for floats that are NOT coercible to ints, the label based bounds will be excluded

```
In [122]: s.loc[5.1:6]
Out[122]:
6  3
Length: 1, dtype: int64
```

Float indexing on a Float64Index is unchanged.

```
In [123]: s = pd.Series([1, 2, 3], index=np.arange(3.))
In [124]: s[1.0]
Out[124]: 2
In [125]: s[1.0:2.5]
Out[125]:
1.0  2
2.0  3
Length: 2, dtype: int64
```

**Removal of prior version deprecations/changes**

- **Removal of** `rolling_corr_pairwise` **in favor of** `.rolling().corr(pairwise=True)` **(GH4950)**
- **Removal of** `expanding_corr_pairwise` **in favor of** `expanding().corr(pairwise=True)` **(GH4950)**
- **Removal of** `DataMatrix` **module. This was not imported into the pandas namespace in any event (GH12111)**
- **Removal of** `cols` **keyword in favor of** `subset` **in** `DataFrame.duplicated()` **and** `DataFrame.drop_duplicates()` **(GH6680)**
- **Removal of** the `read_frame` and `frame_query` (both aliases for `pd.read_sql`) **and** `write_frame` (alias of `to_sql`) **functions in the** `pd.io.sql` **namespace, deprecated since 0.14.0 (GH6292).**
- **Removal of the** `order` **keyword from** `factorize()` **(GH6930)**
Performance improvements

- Improved performance of `andrews_curves` (GH11534)
- Improved huge `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex`'s ops performance including `NaT` (GH10277)
- Improved performance of `pandas.concat` (GH11958)
- Improved performance of `StataReader` (GH11591)
- Improved performance in construction of `Categoricals` with `Series` of datetimes containing `NaT` (GH12077)
- Improved performance of ISO 8601 date parsing for dates without separators (GH11899), leading zeros (GH11871) and with white space preceding the time zone (GH9714)

Bug fixes

- Bug in `GroupBy.size` when data-frame is empty. (GH11699)
- Bug in `Period.end_time` when a multiple of time period is requested (GH11738)
- Regression in `.clip` with tz-aware datetimes (GH11838)
- Bug in `date_range` when the boundaries fell on the frequency (GH11804, GH12409)
- Bug in consistency of passing nested dicts to `.groupby(...).agg(...)` (GH9052)
- Accept unicode in `Timedelta` constructor (GH11995)
- Bug in value label reading for `StataReader` when reading incrementally (GH12014)
- Bug in vectorized `DateOffset` when `n` parameter is 0 (GH11370)
- Compat for numpy 1.11 w.r.t. `NaT` comparison changes (GH12049)
- Bug in `read_csv` when reading from a `StringIO` in threads (GH11790)
- Bug in not treating `NaT` as a missing value in datetimelikes when factorizing & with `Categoricals` (GH12077)
- Bug in `getitem` when the values of a `Series` were tz-aware (GH12089)
- Bug in `Series.str.get_dummies` when one of the variables was ‘name’ (GH12180)
- Bug in `pd.concat` while concatenating tz-aware `NaT` series. (GH11693, GH11755, GH12217)
- Bug in `pd.read_stata` with version <= 108 files (GH12232)
- Bug in `Series.resample` using a frequency of Nano when the index is a `DatetimeIndex` and contains non-zero nanosecond parts (GH12037)
- Bug in resampling with `.nunique` and a sparse index (GH12352)
- Removed some compiler warnings (GH12471)
- Work around compat issues with `boto` in python 3.5 (GH11915)
- Bug in `NaT` subtraction from `Timestamp` or `DatetimeIndex` with timezones (GH11718)
- Bug in subtraction of `Series` of a single tz-aware `Timestamp` (GH12290)
- Use compat iterators in PY2 to support `.next()` (GH12299)
- Bug in `Timedelta.round` with negative values (GH11690)
- Bug in `.loc` against `CategoricalIndex` may result in normal `Index` (GH11586)
- Bug in `DataFrame.info` when duplicated column names exist (GH11761)
- Bug in `.copy` of datetime tz-aware objects (GH11794)
- Bug in `Series.apply` and `Series.map` where `timedelta64` was not boxed (GH11349)
- Bug in `DataFrame.set_index()` with tz-aware `Series` (GH12358)
- Bug in subclasses of `DataFrame` where `AttributeError` did not propagate (GH11808)
- Bug in `DataFrame.set_index()` with tz-aware `Series` (GH12358)
- Bug in `Series.apply` and `Series.map` where `timedelta64` was not boxed (GH11349)
- Bug in `DataFrame.query` containing an assignment (GH8664)
- Bug in `from_msgpack` where `__contains__()` fails for columns of the unpacked `DataFrame`, if the `DataFrame` has object columns. (GH11880)
- Bug in `.resample` on categorical data with `TimedeltaIndex` (GH12169)
- Bug in timezone info lost when broadcasting scalar datetime to `DataFrame` (GH11682)
- Bug in `Index` creation from `Timestamp` with mixed tz coerces to UTC (GH11488)
- Bug in `DataFrame.groupby` using keyword arguments (GH11614)
- Bug in `DataFrame.duplicated` and `drop_duplicates` causing spurious matches when setting `keep=False` (GH11864)
- Bug in `.loc` result with duplicated key may have `Index` with incorrect dtype (GH11497)
- Bug in `pd.rolling_median` where memory allocation failed even with sufficient memory (GH11696)
- Bug in `DataFrame.style` with spurious zeros (GH12134)
- Bug in `DataFrame.style` with integer columns not starting at 0 (GH12125)
- Bug in `.style.bar` may not render properly using specific browser (GH11678)
- Bug in rich comparison of `Timedelta` with a `numpy.array` of `Timedelta` that caused an infinite recursion (GH11835)
- Bug in `DataFrame.round` dropping column index name (GH11986)
- Bug in `df.replace` while replacing value in mixed dtype `DataFrame` (GH11698)
- Bug in `Index` prevents copying name of passed `Index`, when a new name is not provided (GH11933)
- Bug in `read_excel` failing to read any non-empty sheets when empty sheets exist and `sheetname=None` (GH11711)
- Bug in `read_excel` failing to raise `NotImplemented` error when keywords `parse_dates` and `date_parser` are provided (GH11544)
- Bug in `read_sql` with `pymysql` connections failing to return chunked data (GH11522)
- Bug in `.to_csv` ignoring formatting parameters `decimal`, `na_rep`, `float_format` for float indexes (GH11553)
• Bug in Int64Index and Float64Index preventing the use of the modulo operator (GH9244)
• Bug in MultiIndex.drop for not lexsorted MultiIndexes (GH12078)
• Bug in DataFrame when masking an empty DataFrame (GH11859)
• Bug in .plot potentially modifying the colors input when the number of columns didn’t match the number of series provided (GH12039).
• Bug in Series.plot failing when index has a CustomBusinessDay frequency (GH7222).
• Bug in .to_sql for datetime.time values with sqlite fallback (GH8341)
• Bug in read_excel failing to read data with one column when squeeze=True (GH12157)
• Bug in read_excel failing to read one empty column (GH12292, GH9002)
• Bug in .groupby where a KeyError was not raised for a wrong column if there was only one row in the dataframe (GH11741)
• Bug in .read_csv with dtype specified on empty data producing an error (GH12048)
• Bug in .read_csv where strings like ‘2E’ are treated as valid floats (GH12237)
• Bug in building pandas with debugging symbols (GH12123)
• Removed millisecond property of DatetimeIndex. This would always raise a ValueError (GH12019).
• Bug in Series constructor with read-only data (GH11502)
• Removed pandas._testing.choice(). Should use np.random.choice(), instead. (GH12386)
• Bug in .loc setitem indexer preventing the use of a TZ-aware DatetimeIndex (GH12050)
• Bug in .style indexes and MultiIndexes not appearing (GH11655)
• Bug in to_msgpack and from_msgpack which did not correctly serialize or deserialize NaT (GH12307).
• Bug in .skew and .kurt due to roundoff error for highly similar values (GH11974)
• Bug in Timestamp constructor where microsecond resolution was lost if HHMMSS were not separated with ‘:’ (GH10041)
• Bug in buffer_rd_bytes src->buffer could be freed more than once if reading failed, causing a segfault (GH12098)
• Bug in crosstab where arguments with non-overlapping indexes would return a KeyError (GH10291)
• Bug in DataFrame.apply in which reduction was not being prevented for cases in which dtype was not a numpy dttype (GH12244)
• Bug when initializing categorical series with a scalar value. (GH12336)
• Bug when specifying a UTC DatetimeIndex by setting utc=True in .to_datetime (GH11934)
• Bug when increasing the buffer size of CSV reader in read_csv (GH12494)
• Bug when setting columns of a DataFrame with duplicate column names (GH12344)

5.10. Version 0.18

5.11 Version 0.17

5.11.1 Version 0.17.1 (November 21, 2015)

Note: We are proud to announce that pandas has become a sponsored project of the (NumFOCUS organization). This will help ensure the success of development of pandas as a world-class open-source project.

This is a minor bug-fix release from 0.17.0 and includes a large number of bug fixes along several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Support for Conditional HTML Formatting, see here
- Releasing the GIL on the csv reader & other ops, see here
- Fixed regression in DataFrame.drop_duplicates from 0.16.2, causing incorrect results on integer values (GH11376)

What’s new in v0.17.1

- New features
  - Conditional HTML formatting
- Enhancements
- API changes
  - Deprecations
- Performance improvements
- Bug fixes
- Contributors

New features

Conditional HTML formatting

Warning: This is a new feature and is under active development. We’ll be adding features an possibly making breaking changes in future releases. Feedback is welcome.

We’ve added experimental support for conditional HTML formatting: the visual styling of a DataFrame based on the data. The styling is accomplished with HTML and CSS. Accesses the styler class with the pandas.DataFrame.style, attribute, an instance of Styler with your data attached.

Here’s a quick example:

```python
In [1]: np.random.seed(123)
In [2]: df = pd.DataFrame(np.random.randn(10, 5), columns=list('abcde'))
```
In [3]: html = df.style.background_gradient(cmap='viridis', low=.5)

We can render the HTML to get the following table.
Styler interacts nicely with the Jupyter Notebook. See the documentation for more.

Enhancements

- DatetimeIndex now supports conversion to strings with astype(str) (GH10442)
- Support for compression (gzip/bz2) in pandas.DataFrame.to_csv() (GH7615)
- pd.read_* functions can now also accept pathlib.Path, or py._path.local.LocalPath objects for the filepath_or_buffer argument. (GH11033) - The DataFrame and Series functions .to_csv(), .to_html() and .to_latex() can now handle paths beginning with tildes (e.g. ~/Documents/) (GH11438)
- DataFrame now uses the fields of a namedtuple as columns, if columns are not supplied (GH11181)
- DataFrame.itertuples() now returns namedtuple objects, when possible. (GH11269, GH11625)
- Added axvlines_kwds to parallel coordinates plot (GH10709)
- Option to .info() and .memory_usage() to provide for deep introspection of memory consumption. Note that this can be expensive to compute and therefore is an optional parameter. (GH11595)

In [4]: df = pd.DataFrame({'A': ['foo'] * 1000}) # noqa: F821

In [5]: df['B'] = df['A'].astype('category')

# shows the '+' as we have object dtypes
In [6]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000 entries, 0 to 999
Data columns (total 2 columns):
   # Column Non-Null Count  Dtype
---  ------ -------------- -----  
   0   A     1000 non-null object
   1   B     1000 non-null  category
dtypes: category(1), object(1)
memory usage: 9.0+ KB

# we have an accurate memory assessment (but can be expensive to compute this)
In [7]: df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000 entries, 0 to 999
Data columns (total 2 columns):
   # Column Non-Null Count  Dtype
---  ------ -------------- -----  
   0   A     1000 non-null object
   1   B     1000 non-null  category
dtypes: category(1), object(1)
memory usage: 75.5 KB

- Index now has a fillna method (GH10089)
pandas: powerful Python data analysis toolkit, Release 1.1.1

In [8]: pd.Index([1, np.nan, 3]).fillna(2)
Out[8]: Float64Index([1.0, 2.0, 3.0], dtype='float64')

• Series of type category now make .str.<...> and .dt.<...> accessor methods / properties available, if the categories are of that type. (GH10661)

In [9]: s = pd.Series(list('aabb')).astype('category')

In [10]: s
Out[10]:    0   a
      1   a
      2   b
      3   b
Length: 4, dtype: category
Categories (2, object): ['a', 'b']

In [11]: s.str.contains("a")
Out[11]:
0   True
1   True
2  False
3  False
Length: 4, dtype: bool

In [12]: date = pd.Series(pd.date_range('1/1/2015', periods=5)).astype('category')

In [13]: date
Out[13]:
0  2015-01-01
1  2015-01-02
2  2015-01-03
3  2015-01-04
4  2015-01-05
Length: 5, dtype: category

In [14]: date.dt.day
Out[14]:
0   1
1   2
2   3
3   4
4   5
Length: 5, dtype: int64

• pivot_table now has a margins_name argument so you can use something other than the default of ‘All’ (GH3335)

• Implement export of datetime64[ns, tz] dtypes with a fixed HDF5 store (GH11411)

• Pretty printing sets (e.g. in DataFrame cells) now uses set literal syntax (\{x, y\}) instead of Legacy Python syntax (set([x, y])) (GH11215)

• Improve the error message in pandas.io.gbq.to_gbq() when a streaming insert fails (GH11285) and when the DataFrame does not match the schema of the destination table (GH11359)
pandas: powerful Python data analysis toolkit, Release 1.1.1

API changes

- raise NotImplementedError in Index.shift for non-supported index types (GH8038)
- min and max reductions on datetime64 and timedelta64 dtyped series now result in NaT and not nan (GH11245).
- Indexing with a null key will raise a TypeError, instead of a ValueError (GH11356)
- Series.ptp will now ignore missing values by default (GH11163)

Deprecations

- The pandas.io.ga module which implements google-analytics support is deprecated and will be removed in a future version (GH11308)
- Deprecate the engine keyword in .to_csv(), which will be removed in a future version (GH11274)

Performance improvements

- Checking monotonic-ness before sorting on an index (GH11080)
- Series.dropna performance improvement when its dtype can’t contain NaN (GH11159)
- Release the GIL on most datetime field operations (e.g. DatetimeIndex.year, Series.dt.year), normalization, and conversion to and from Period, DatetimeIndex.to_period and PeriodIndex.to_timestamp (GH11263)
- Release the GIL on some rolling algs: rolling_median, rolling_mean, rolling_max, rolling_min, rolling_var, rolling_kurt, rolling_skew (GH11450)
- Release the GIL when reading and parsing text files in read_csv, read_table (GH11272)
- Improved performance of rolling_median (GH11450)
- Improved performance of to_excel (GH11352)
- Performance bug in repr of Categorical categories, which was rendering the strings before chopping them for display (GH11305)
- Performance improvement in Categorical.remove_unused_categories, (GH11643).
- Improved performance of Series constructor with no data and DatetimeIndex (GH11433)
- Improved performance of shift, cumprod, and cumsum with groupby (GH4095)

Bug fixes

- SparseArray.__iter__() now does not cause PendingDeprecationWarning in Python 3.5 (GH11622)
- Regression from 0.16.2 for output formatting of long floats/nan, restored in (GH11302)
- Series.sort_index() now correctly handles the inplace option (GH11402)
- Incorrectly distributed .c file in the build on PyPi when reading a csv of floats and passing na_values=<a scalar> would show an exception (GH11374)
- Bug in .to_latex() output broken when the index has a name (GH10660)
- Bug in `HDFStore.append` with strings whose encoded length exceeded the max unencoded length (GH11234)
- Bug in merging `datetime64[ns, tz]` dtypes (GH11405)
- Bug in `HDFStore.select` when comparing with a numpy scalar in a where clause (GH11283)
- Bug in using `DataFrame.ix` with a MultiIndex indexer (GH11372)
- Bug in `date_range` with ambiguous endpoints (GH11626)
- Prevent adding new attributes to the accessors `.str`, `.dt` and `.cat`. Retrieving such a value was not possible, so error out on setting it. (GH10673)
- Bug in `tz-conversions` with an ambiguous time and `.dt` accessors (GH11295)
- Bug in output formatting when using an index of ambiguous times (GH11619)
- Bug in comparisons of Series vs list-likes (GH11339)
- Bug in `DataFrame.replace` with a `datetime64[ns, tz]` and a non-compat to_replace (GH11326, GH11153)
- Bug in `isnull` where `numpy.datetime64('NaT')` in a `numpy.array` was not determined to be null(GH11206)
- Bug in list-like indexing with a mixed-integer Index (GH11320)
- Bug in `pivot_table` with `margins=True` when indexes are of `Categorical` dtype (GH10993)
- Bug in `DataFrame.plot` cannot use hex strings colors (GH10299)
- Regression in `DataFrame.drop_duplicates` from 0.16.2, causing incorrect results on integer values (GH11376)
- Bug in `pd.eval` where unary ops in a list error (GH11235)
- Bug in `squeeze()` with zero length arrays (GH11230, GH8999)
- Bug in `describe()` dropping column names for hierarchical indexes (GH11517)
- Bug in `DataFrame.pct_change()` not propagating `axis` keyword on `.fillna` method (GH11550)
- Bug in `.to_csv()` when a mix of integer and string column names are passed as the `columns` parameter (GH11637)
- Bug in indexing with a range, (GH11652)
- Bug in inference of numpy scalars and preserving `dtype` when setting columns (GH11638)
- Bug in `to_sql` using unicode column names giving `UnicodeEncodeError` with (GH11431).
- Fix regression in setting of `xticks` in `plot` (GH11529).
- Bug in `holiday.dates` where observance rules could not be applied to holiday and doc enhancement (GH11477, GH11533)
- Fix plotting issues when having plain `Axes` instances instead of `SubplotAxes` (GH11520, GH11556).
- Bug in `DataFrame.to_latex()` produces an extra rule when `header=False` (GH7124)
- Bug in `df.groupby(...).apply(func)` when a `func` returns a `Series` containing a new datetimelike column (GH11324)
- Bug in `pandas.json` when file to load is big (GH11344)
- Bugs in `to_excel` with duplicate columns (GH11007, GH10982, GH10970)
- Fixed a bug that prevented the construction of an empty series of `dtype` `datetime64[ns, tz]` (GH11245).
• Bug in `read_excel` with MultiIndex containing integers (GH11317)
• Bug in `to_excel` with openpyxl 2.2+ and merging (GH11408)
• Bug in `DataFrame.to_dict()` produces a `np.datetime64` object instead of `Timestamp` when only datetime is present in data (GH11327)
• Bug in `DataFrame.corr()` raises exception when computes Kendall correlation for DataFrames with boolean and not boolean columns (GH11560)
• Bug in the link-time error caused by C inline functions on FreeBSD 10+ (with clang) (GH10510)
• Bug in `DataFrame.to_csv` in passing through arguments for formatting MultiIndexes, including `date_format` (GH7791)
• Bug in `DataFrame.join()` with `how='right'` producing a TypeError (GH11519)
• Bug in `Series.quantile` with empty list results has `Index` with object dtype (GH11588)
• Bug in `pd.merge` results in empty `Int64Index` rather than `Index(dtype=object)` when the merge result is empty (GH11588)
• Bug in `Categorical.remove_unused_categories` when having NaN values (GH11599)
• Bug in `DataFrame.to_sparse()` loses column names for MultiIndexes (GH11600)
• Bug in `DataFrame.round()` with non-unique column index producing a Fatal Python error (GH11611)
• Bug in `DataFrame.round()` with `decimals` being a non-unique indexed Series producing extra columns (GH11618)

5.11.2 Version 0.17.0 (October 9, 2015)

This is a major release from 0.16.2 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

**Warning:** pandas >= 0.17.0 will no longer support compatibility with Python version 3.2 (GH9118)

**Warning:** The pandas.io.data package is deprecated and will be replaced by the pandas-datareader package. This will allow the data modules to be independently updated to your pandas installation. The API for pandas-datareader v0.1.1 is exactly the same as in pandas v0.17.0 (GH8961, GH10861).

After installing pandas-datareader, you can easily change your imports:

```python
from pandas.io import data, wb
```

becomes

```python
from pandas_datareader import data, wb
```

Highlights include:

- Release the Global Interpreter Lock (GIL) on some cython operations, see [here](#)
- Plotting methods are now available as attributes of the `.plot` accessor, see [here](#)
- The sorting API has been revamped to remove some long-time inconsistencies, see [here](#)
- Support for a `datetime64[ns]` with timezones as a first-class dtype, see [here](#)
- The default for `to_datetime` will now be to `raise` when presented with unparseable formats, previously this would return the original input. Also, date parse functions now return consistent results. See [here](#)
- The default for dropna in HDFStore has changed to False, to store by default all rows even if they are all NaN, see [here](#)
- Datetime accessor (dt) now supports `Series.dt.strftime` to generate formatted strings for datetime-likes, and `Series.dt.total_seconds` to generate each duration of the timedelta in seconds. See [here](#)
Period and PeriodIndex can handle multiplied freq like 3D, which corresponding to 3 days span. See here

Development installed versions of pandas will now have PEP440 compliant version strings (GH9518)

Development support for benchmarking with the Air Speed Velocity library (GH8361)

Support for reading SAS xport files, see here

Documentation comparing SAS to pandas, see here

Removal of the automatic TimeSeries broadcasting, deprecated since 0.8.0, see here

Display format with plain text can optionally align with Unicode East Asian Width, see here

Compatibility with Python 3.5 (GH11097)

Compatibility with matplotlib 1.5.0 (GH11111)

Check the API Changes and deprecations before updating.

What’s new in v0.17.0

- New features
  - Datetime with TZ
  - Releasing the GIL
  - Plot submethods
  - Additional methods for dt accessor
    - Series.dt.strftime
    - Series.dt.total_seconds
  - Period frequency enhancement
  - Support for SAS XPORT files
  - Support for math functions in .eval()
  - Changes to Excel with MultiIndex
  - Google BigQuery enhancements
  - Display alignment with Unicode East Asian width
  - Other enhancements

- Backwards incompatible API changes
  - Changes to sorting API
  - Changes to to_datetime and to_timedelta
    - Error handling
    - Consistent parsing
  - Changes to Index comparisons
  - Changes to boolean comparisons vs. None
  - HDFStore dropna behavior
  - Changes to display.precision option
  - Changes to Categorical.unique
New features

Datetime with TZ

We are adding an implementation that natively supports datetime with timezones. A Series or a DataFrame column previously could be assigned a datetime with timezones, and would work as an object dtype. This had performance issues with a large number rows. See the docs for more details. (GH8260, GH10763, GH11034).

The new implementation allows for having a single-timezone across all rows, with operations in a performant manner.

```python
In [1]: df = pd.DataFrame({'A': pd.date_range('20130101', periods=3),
                      'B': pd.date_range('20130101', periods=3, tz='US/Eastern'),
                      'C': pd.date_range('20130101', periods=3, tz='CET')})

In [2]: df
Out[2]:
     A          B          C
0 2013-01-01 2013-01-01 00:00:00-05:00 2013-01-01 00:00:00+01:00
1 2013-01-02 2013-01-02 00:00:00-05:00 2013-01-02 00:00:00+01:00
2 2013-01-03 2013-01-03 00:00:00-05:00 2013-01-03 00:00:00+01:00

[3 rows x 3 columns]

In [3]: df.dtypes
Out[3]:
A    datetime64[ns]
B  datetime64[ns, US/Eastern]
C  datetime64[ns, CET]
Length: 3, dtype: object

In [4]: df.B
Out[4]:
0 2013-01-01 00:00:00-05:00
1 2013-01-02 00:00:00-05:00
2 2013-01-03 00:00:00-05:00
Name: B, Length: 3, dtype: datetime64[ns, US/Eastern]

In [5]: df.B.dt.tz_localize(None)
Out[5]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
Name: B, Length: 3, dtype: datetime64[ns]
This uses a new-dtype representation as well, that is very similar in look-and-feel to its numpy cousin `datetime64[ns]`

```
In [6]: df['B'].dtype
Out[6]: datetime64[ns, US/Eastern]
In [7]: type(df['B'].dtype)
Out[7]: pandas.core.dtypes.dtypes.DatetimeTZDtype
```

**Note:** There is a slightly different string repr for the underlying `DatetimeIndex` as a result of the dtype changes, but functionally these are the same.

Previous behavior:

```
In [1]: pd.date_range('20130101', periods=3, tz='US/Eastern')
Out[1]: DatetimeIndex(['2013-01-01 00:00:00-05:00', '2013-01-02 00:00:00-05:00',
  '2013-01-03 00:00:00-05:00'],
  dtype='datetime64[ns]', freq='D', tz='US/Eastern')
In [2]: pd.date_range('20130101', periods=3, tz='US/Eastern').dtype
Out[2]: dtype('<M8[ns]')
```

New behavior:

```
In [8]: pd.date_range('20130101', periods=3, tz='US/Eastern')
Out[8]: DatetimeIndex(['2013-01-01 00:00:00-05:00', '2013-01-02 00:00:00-05:00',
  '2013-01-03 00:00:00-05:00'],
  dtype='datetime64[ns, US/Eastern]', freq='D')
In [9]: pd.date_range('20130101', periods=3, tz='US/Eastern').dtype
Out[9]: datetime64[ns, US/Eastern]
```

### Releasing the GIL

We are releasing the global-interpreter-lock (GIL) on some cython operations. This will allow other threads to run simultaneously during computation, potentially allowing performance improvements from multi-threading. Notably `groupby`, `nsmallest`, `value_counts` and some indexing operations benefit from this. (GH8882)

For example the groupby expression in the following code will have the GIL released during the factorization step, e.g. `df.groupby('key').sum()` as well as the `.sum()` operation.

```
N = 1000000
ngroups = 10
df = DataFrame({'key': np.random.randint(0, ngroups, size=N),
              'data': np.random.randn(N)})
df.groupby('key')['data'].sum()
```

Releasing of the GIL could benefit an application that uses threads for user interactions (e.g. QT), or performing multi-threaded computations. A nice example of a library that can handle these types of computation-in-parallel is the `dask` library.
Plot submethods

The Series and DataFrame .plot() method allows for customizing plot types by supplying the kind keyword arguments. Unfortunately, many of these kinds of plots use different required and optional keyword arguments, which makes it difficult to discover what any given plot kind uses out of the dozens of possible arguments.

To alleviate this issue, we have added a new, optional plotting interface, which exposes each kind of plot as a method of the .plot attribute. Instead of writing series.plot(kind=<kind>, ...), you can now also use series.plot.<kind>(...):

```python
In [10]: df = pd.DataFrame(np.random.rand(10, 2), columns=['a', 'b'])
In [11]: df.plot.bar()
```

As a result of this change, these methods are now all discoverable via tab-completion:

```python
In [12]: df.plot.<TAB>  # noqa: E225, E999
    df.plot.area  df.plot.barh  df.plot.density  df.plot.hist  df.plot.line
    df.plot.scatter
    df.plot.bar  df.plot.box  df.plot.hexbin  df.plot.kde  df.plot.pie
```

Each method signature only includes relevant arguments. Currently, these are limited to required arguments, but in the future these will include optional arguments, as well. For an overview, see the new Plotting API documentation.

Additional methods for dt accessor

Series.dt.strftime

We are now supporting a Series.dt.strftime method for datetime-likes to generate a formatted string (GH10110). Examples:

```python
# DatetimeIndex
In [13]: s = pd.Series(pd.date_range('20130101', periods=4))

In [14]: s
Out[14]:
0    2013-01-01
```

(continues on next page)
In [15]: s.dt.strftime('%Y/%m/%d')

Out[15]:
0  2013/01/01
1  2013/01/02
2  2013/01/03
3  2013/01/04
Length: 4, dtype: object

# PeriodIndex
In [16]: s = pd.Series(pd.period_range('20130101', periods=4))

In [17]: s
Out[17]:
0  2013-01-01
1  2013-01-02
2  2013-01-03
3  2013-01-04
Length: 4, dtype: period[D]

In [18]: s.dt.strftime('%Y/%m/%d')
Out[18]:
0  2013/01/01
1  2013/01/02
2  2013/01/03
3  2013/01/04
Length: 4, dtype: object

The string format is as the python standard library and details can be found here

**Series.dt.total_seconds**

pd.Series of type timedelta64 has new method .dt.total_seconds() returning the duration of the timedelta in seconds (GH10817)

# TimedeltaIndex
In [19]: s = pd.Series(pd.timedelta_range('1 minutes', periods=4))

In [20]: s
Out[20]:
0  0 days 00:01:00
1  1 days 00:01:00
2  2 days 00:01:00
3  3 days 00:01:00
Length: 4, dtype: timedelta64[ns]

In [21]: s.dt.total_seconds()
Out[21]:
0   60.0
1  86460.0
2 172860.0

Period frequency enhancement

Period, PeriodIndex and period_range can now accept multiplied freq. Also, Period.freq and PeriodIndex.freq are now stored as a DateOffset instance like DatetimeIndex, and not as str (GH7811)

A multiplied freq represents a span of corresponding length. The example below creates a period of 3 days. Addition and subtraction will shift the period by its span.

```
In [22]: p = pd.Period('2015-08-01', freq='3D')
In [23]: p
Out[23]: Period('2015-08-01', '3D')
In [24]: p + 1
Out[24]: Period('2015-08-04', '3D')
In [25]: p - 2
Out[25]: Period('2015-07-26', '3D')
In [26]: p.to_timestamp()
Out[26]: Timestamp('2015-08-01 00:00:00')
In [27]: p.to_timestamp(how='E')
Out[27]: Timestamp('2015-08-03 23:59:59.999999999')
```

You can use the multiplied freq in PeriodIndex and period_range.

```
In [28]: idx = pd.period_range('2015-08-01', periods=4, freq='2D')
In [29]: idx
Out[29]: PeriodIndex(['2015-08-01', '2015-08-03', '2015-08-05', '2015-08-07'], dtype='period[2D]', freq='2D')
In [30]: idx + 1
Out[30]: PeriodIndex(['2015-08-03', '2015-08-05', '2015-08-07', '2015-08-09'], dtype='period[2D]', freq='2D')
```

Support for SAS XPORT files

`read_sas()` provides support for reading SAS XPORT format files. (GH4052).

```
df = pd.read_sas('sas_xport.xpt')
```

It is also possible to obtain an iterator and read an XPORT file incrementally.

```
for df in pd.read_sas('sas_xport.xpt', chunksize=10000):
    do_something(df)
```

See the docs for more details.
Support for math functions in .eval()

.eval() now supports calling math functions (GH4893)

```python
df = pd.DataFrame({'a': np.random.randn(10)})
df.eval("b = sin(a)")
```

The support math functions are \( \sin, \cos, \exp, \log, \expm1, \log1p, \sqrt, \sinh, \cosh, \tanh, \arcsin, \arccos, \arctan, \arccosh, \arcsinh, \arctanh, \text{abs} \) and \( \arctan2 \).

These functions map to the intrinsics for the NumExpr engine. For the Python engine, they are mapped to NumPy calls.

Changes to Excel with MultiIndex

In version 0.16.2 a DataFrame with MultiIndex columns could not be written to Excel via `to_excel`. That functionality has been added (GH10564), along with updating `read_excel` so that the data can be read back with, no loss of information, by specifying which columns/rows make up the MultiIndex in the `header` and `index_col` parameters (GH4679)

See the documentation for more details.

```python
In [31]: df = pd.DataFrame([[1, 2, 3, 4], [5, 6, 7, 8]],
                        columns=pd.MultiIndex.from_product(
                        [[['foo', 'bar'], ['a', 'b']], names=['col1', 'col2']]),
                        index=pd.MultiIndex.from_product([[1], ['j', 'k']],
                        names=['i1', 'i2']))

In [32]: df
Out[32]:
     col1  foo  bar
   col2  a  b  a  b
     i1  j  k
j  1  1  2  3  4
k  5  6  7  8
[2 rows x 4 columns]

In [33]: df.to_excel('test.xlsx')

In [34]: df = pd.read_excel('test.xlsx', header=[0, 1], index_col=[0, 1])

In [35]: df
Out[35]:
     col1  foo  bar
   col2  a  b  a  b
     i1  j  k
j  1  1  2  3  4
k  5  6  7  8
[2 rows x 4 columns]
```

Previously, it was necessary to specify the `has_index_names` argument in `read_excel`, if the serialized data had index names. For version 0.17.0 the output format of `to_excel` has been changed to make this keyword unnecessary - the change is shown below.

</tbody>
</table>

**Warning:** Excel files saved in version 0.16.2 or prior that had index names will still able to be read in, but the `has_index_names` argument must specified to `True`.

**Google BigQuery enhancements**

- Added ability to automatically create a table/dataset using the `pandas.io.gbq.to_gbq()` function if the destination table/dataset does not exist. *(GH8325, GH11121).*
- Added ability to replace an existing table and schema when calling the `pandas.io.gbq.to_gbq()` function via the `if_exists` argument. See the docs for more details *(GH8325).*
- `InvalidColumnOrder` and `InvalidPageToken` in the `gbq` module will raise `ValueError` instead of `IOError`.
- The `generate_bq_schema()` function is now deprecated and will be removed in a future version *(GH11121)*
- The `gbq` module will now support Python 3 *(GH11094).*
Display alignment with Unicode East Asian width

**Warning:** Enabling this option will affect the performance for printing of DataFrame and Series (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters its width is corresponding to 2 alphabets. If a DataFrame or Series contains these characters, the default output cannot be aligned properly. The following options are added to enable precise handling for these characters.

- `display.unicode.east_asian_width`: Whether to use the Unicode East Asian Width to calculate the display text width. (GH2612)
- `display.unicode.ambiguous_as_wide`: Whether to handle Unicode characters belong to Ambiguous as Wide. (GH11102)

```python
In [36]: df = pd.DataFrame({'UK': ['UK', ''], 'Alice': ['Alice', '']})
In [37]: df
```

<table>
<thead>
<tr>
<th>0</th>
<th>Alice</th>
<th>UK</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```python
In [38]: pd.set_option('display.unicode.east_asian_width', True)
In [39]: df
```

<table>
<thead>
<tr>
<th>0</th>
<th>Alice</th>
<th>UK</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For further details, see [here](#)

**Other enhancements**

- Support for openpyxl >= 2.2. The API for style support is now stable (GH10125)
- `merge` now accepts the argument `indicator` which adds a Categorical-type column (by default called `_merge`) to the output object that takes on the values (GH8790)

<table>
<thead>
<tr>
<th>Observation Origin</th>
<th>_merge value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Merge key only in 'left' frame</td>
<td>left_only</td>
</tr>
<tr>
<td>Merge key only in 'right' frame</td>
<td>right_only</td>
</tr>
<tr>
<td>Merge key in both frames</td>
<td>both</td>
</tr>
</tbody>
</table>

```python
In [40]: df1 = pd.DataFrame({'col1':[0,1], 'col_left': ['a','b']})
In [41]: df2 = pd.DataFrame({'col1':[1,2,2],'col_right': [2,2,2]})
```

(continues on next page)
In [42]: pd.merge(df1, df2, on='col1', how='outer', indicator=True)
Out[42]:
   col1 col_left col_right  _merge
0    0      a       NaN   left_only
1    1      b       2.0    both
2    2     NaN       2.0  right_only
3    2     NaN       2.0  right_only
[4 rows x 4 columns]

For more, see the updated docs
• `pd.to_numeric` is a new function to coerce strings to numbers (possibly with coercion) (GH11133)
• `pd.merge` will now allow duplicate column names if they are not merged upon (GH10639).
• `pd.pivot` will now allow passing index as None (GH3962).
• `pd.concat` will now use existing Series names if provided (GH10698).

In [43]: foo = pd.Series([1, 2], name='foo')
In [44]: bar = pd.Series([1, 2])
In [45]: baz = pd.Series([4, 5])

Previous behavior:
In [1]: pd.concat([foo, bar, baz], 1)
Out[1]:
   0 1 2
0  1 1 4
1  2 2 5

New behavior:
In [46]: pd.concat([foo, bar, baz], 1)
Out[46]:
   foo  0 1
   0   1 1 4
   1   2 2 5
[2 rows x 3 columns]

• DataFrame has gained the `nlargest` and `nsmallest` methods (GH10393)
• Add a `limit_direction` keyword argument that works with `limit` to enable `interpolate` to fill NaN values forward, backward, or both (GH9218, GH10420, GH11115)

In [47]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan, np.nan, 13])
In [48]: ser.interpolate(limit=1, limit_direction='both')
Out[48]:
0   NaN
1   5.0
2   5.0
3   7.0
4   NaN
(continues on next page)
- Added a `DataFrame.round` method to round the values to a variable number of decimal places (GH10568).

```python
In [49]: df = pd.DataFrame(np.random.random([3, 3]),
                   ....:     columns=['A', 'B', 'C'],
                   ....:     index=['first', 'second', 'third'])

In [50]: df
Out[50]:
   A    B    C
first  0.126970  0.966718  0.260476
second  0.897237  0.376750  0.336222
third  0.451376  0.840255  0.123102
[3 rows x 3 columns]
In [51]: df.round(2)
Out[51]:
   A    B    C
first  0.13  0.97  0.26
second  0.90  0.38  0.34
third  0.45  0.84  0.12
[3 rows x 3 columns]
In [52]: df.round({'A': 0, 'C': 2})
Out[52]:
   A    B    C
first  0.0  0.966718  0.26
second  1.0  0.376750  0.34
third  0.0  0.840255  0.12
[3 rows x 3 columns]
```

- `drop_duplicates` and `duplicated` now accept a `keep` keyword to target first, last, and all duplicates. The `take_last` keyword is deprecated, see here (GH6511, GH8505)

```python
In [53]: s = pd.Series(['A', 'B', 'C', 'A', 'B', 'D'])
In [54]: s.drop_duplicates()
Out[54]:
   0  A
   1  B
   2  C
   5  D
Length: 4, dtype: object
In [55]: s.drop_duplicates(keep='last')
Out[55]:
   2  C
   3  A
   4  B
(continues on next page)
Reindex now has a `tolerance` argument that allows for finer control of *Limits on filling while reindexing* (GH10411):

```python
In [57]: df = pd.DataFrame({'x': range(5),
                      ....:           't': pd.date_range('2000-01-01', periods=5)})

In [58]: df.reindex([0.1, 1.9, 3.5],
                ....:       method='nearest',
                ....:       tolerance=0.2)

Out[58]:
          x  t
0.1  0.0 2000-01-01
1.9  2.0 2000-01-03
3.5  NaN NaT

[3 rows x 2 columns]
```

When used on a DatetimeIndex, TimedeltaIndex or PeriodIndex, `tolerance` will coerced into a Timedelta if possible. This allows you to specify tolerance with a string:

```python
In [59]: df = df.set_index('t')

In [60]: df.reindex(pd.to_datetime(['1999-12-31']),
                 ....:       method='nearest',
                 ....:       tolerance='1 day')

Out[60]:
          x
1999-12-31  0

[1 rows x 1 columns]
```

tolerance is also exposed by the lower level `Index.get_indexer` and `Index.get_loc` methods.

- Added functionality to use the `base` argument when resampling a TimeDeltaIndex (GH10530)
- DatetimeIndex can be instantiated using strings contains NaT (GH7599)
- `to_datetime` can now accept the `yearfirst` keyword (GH7599)
- `pandas.tseries.offsets` larger than the Day offset can now be used with a Series for addition/subtraction (GH10699). See the docs for more details.
- `pd.Timedelta.total_seconds()` now returns Timedelta duration to ns precision (previously microsecond precision) (GH10939)
- `PeriodIndex` now supports arithmetic with np.ndarray (GH10638)
• Support pickling of Period objects (GH10439)
• .as_blocks will now take a copy optional argument to return a copy of the data, default is to copy (no change in behavior from prior versions), (GH9607)
• regex argument to DataFrame.filter now handles numeric column names instead of raising ValueError (GH10384).
• Enable reading gzip compressed files via URL, either by explicitly setting the compression parameter or by inferring from the presence of the HTTP Content-Encoding header in the response (GH8685)
• Enable writing Excel files in memory using StringIO/BytesIO (GH7074)
• Enable serialization of lists and dicts to strings in ExcelWriter (GH8188)
• SQL io functions now accept a SQLAlchemy connectable. (GH7877)
• pd.read_sql and to_sql can accept database URI as con parameter (GH10214)
• read_sql_table will now allow reading from views (GH10750).
• Enable writing complex values to HDFStores when using the table format (GH10447)
• Enable pd.read_hdf to be used without specifying a key when the HDF file contains a single dataset (GH10443)
• pd.read stata will now read Stata 118 type files. (GH9882)
• msgpack submodule has been updated to 0.4.6 with backward compatibility (GH10581)
• DataFrame.to_dict now accepts orient='index' keyword argument (GH10844).
• DataFrame.apply will return a Series of dicts if the passed function returns a dict and reduce=True (GH8735).
• Allow passing kwargs to the interpolation methods (GH10378).
• Improved error message when concatenating an empty iterable of Dataframe objects (GH9157)
• pd.read_csv can now read bz2-compressed files incrementally, and the C parser can read bz2-compressed files from AWS S3 (GH11070, GH11072).
  • In pd.read_csv, recognize s3n:// and s3a:// URLs as designating S3 file storage (GH11070, GH11071).
  • Read CSV files from AWS S3 incrementally, instead of first downloading the entire file. (Full file download still required for compressed files in Python 2.) (GH11070, GH11073)
  • pd.read_csv is now able to infer compression type for files read from AWS S3 storage (GH11070, GH11074).

Backwards incompatible API changes

Changes to sorting API

The sorting API has had some longtime inconsistencies. (GH9816, GH8239).
Here is a summary of the API PRIOR to 0.17.0:
• Series.sort is INPLACE while DataFrame.sort returns a new object.
• Series.order returns a new object
• It was possible to use Series/DataFrame.sort_index to sort by values by passing the by keyword.
Series/DataFrame.sortlevel worked only on a MultiIndex for sorting by index.

To address these issues, we have revamped the API:

- We have introduced a new method, `DataFrame.sort_values()`, which is the merger of `DataFrame.sort()`, `Series.sort()`, and `Series.order()`, to handle sorting of values.
- The existing methods `Series.sort()`, `Series.order()`, and `DataFrame.sort()` have been deprecated and will be removed in a future version.
- The `by` argument of `DataFrame.sort_index()` has been deprecated and will be removed in a future version.
- The existing method `.sort_index()` will gain the `level` keyword to enable level sorting.

We now have two distinct and non-overlapping methods of sorting. A * marks items that will show a `FutureWarning`.

To sort by the values:

<table>
<thead>
<tr>
<th>Previous</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>*Series.order()</td>
<td>Series.sort_values()</td>
</tr>
<tr>
<td>*Series.sort()</td>
<td>Series.sort_values(inplace=True)</td>
</tr>
<tr>
<td>*DataFrame.sort(columns=...)</td>
<td>DataFrame.sort_values(by=...)</td>
</tr>
</tbody>
</table>

To sort by the index:

<table>
<thead>
<tr>
<th>Previous</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.sort_index()</td>
<td>Series.sort_index()</td>
</tr>
<tr>
<td>Series.sortlevel(level=...)</td>
<td>Series.sort_index(level=...)</td>
</tr>
<tr>
<td>DataFrame.sort_index()</td>
<td>DataFrame.sort_index()</td>
</tr>
<tr>
<td>DataFrame.sortlevel(level=...)</td>
<td>DataFrame.sort_index(level=...)</td>
</tr>
<tr>
<td>*DataFrame.sort()</td>
<td>DataFrame.sort_index()</td>
</tr>
</tbody>
</table>

We have also deprecated and changed similar methods in two Series-like classes, Index and Categorical.

<table>
<thead>
<tr>
<th>Previous</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>*Index.order()</td>
<td>Index.sort_values()</td>
</tr>
<tr>
<td>*Categorical.order()</td>
<td>Categorical.sort_values()</td>
</tr>
</tbody>
</table>

### Changes to `to_datetime` and `to_timedelta`

#### Error handling

The default for `pd.to_datetime` error handling has changed to `errors='raise'`. In prior versions it was `errors='ignore'`. Furthermore, the `coerce` argument has been deprecated in favor of `errors='coerce'`. This means that invalid parsing will raise rather that return the original input as in previous versions. (GH10636)

Previous behavior:

```
In [2]: pd.to_datetime(['2009-07-31', 'asd'])
Out[2]: array(['2009-07-31', 'asd'], dtype=object)
```

New behavior:

```
In [2]: pd.to_datetime(['2009-07-31', 'asd'], errors='raise')
```
In [3]: pd.to_datetime(['2009-07-31', 'asd'])
ValueError: Unknown string format

Of course you can coerce this as well.

In [61]: pd.to_datetime(['2009-07-31', 'asd'], errors='coerce')
Out[61]: DatetimeIndex(['2009-07-31', 'NaT'], dtype='datetime64[ns]', freq=None)

To keep the previous behavior, you can use errors='ignore':

In [62]: pd.to_datetime(['2009-07-31', 'asd'], errors='ignore')
Out[62]: Index(['2009-07-31', 'asd'], dtype='object')

Furthermore, pd.to_timedelta has gained a similar API, of errors='raise'|'ignore'|'coerce', and the coerce keyword has been deprecated in favor of errors='coerce'.

Consistent parsing

The string parsing of to_datetime, Timestamp and DatetimeIndex has been made consistent. (GH7599)

Prior to v0.17.0, Timestamp and to_datetime may parse year-only datetime-string incorrectly using today's date, otherwise DatetimeIndex uses the beginning of the year. Timestamp and to_datetime may raise ValueError in some types of datetime-string which DatetimeIndex can parse, such as a quarterly string.

Previous behavior:

In [1]: pd.Timestamp('2012Q2')
ValueError: Unable to parse 2012Q2
...
# Results in today's date.
In [2]: pd.Timestamp('2014')
Out [2]: 2014-08-12 00:00:00

v0.17.0 can parse them as below. It works on DatetimeIndex also.

New behavior:

In [63]: pd.Timestamp('2012Q2')
Out[63]: Timestamp('2012-04-01 00:00:00')

In [64]: pd.Timestamp('2014')
Out[64]: Timestamp('2014-01-01 00:00:00')

In [65]: pd.DatetimeIndex(['2012Q2', '2014'])
Out[65]: DatetimeIndex(['2012-04-01', '2014-01-01'], dtype='datetime64[ns]',
˓ freq=None)

Note: If you want to perform calculations based on today’s date, use Timestamp.now() and pandas.tseries.offsets.

In [66]: import pandas.tseries.offsets as offsets

In [67]: pd.Timestamp.now()
Changes to Index comparisons

Operator equal on Index should behavior similarly to Series (GH9947, GH10637)

Starting in v0.17.0, comparing Index objects of different lengths will raise a ValueError. This is to be consistent with the behavior of Series.

Previous behavior:

```python
In [2]: pd.Index([1, 2, 3]) == pd.Index([1, 4, 5])
Out[2]: array([ True, False, False], dtype=bool)

In [3]: pd.Index([1, 2, 3]) == pd.Index([2])
Out[3]: array([False, True, False], dtype=bool)

In [4]: pd.Index([1, 2, 3]) == pd.Index([1, 2])
Out[4]: False
```

New behavior:

```python
In [8]: pd.Index([1, 2, 3]) == pd.Index([1, 4, 5])
Out[8]: array([ True, False, False], dtype=bool)

In [9]: pd.Index([1, 2, 3]) == pd.Index([2])
ValueError: Lengths must match to compare

In [10]: pd.Index([1, 2, 3]) == pd.Index([1, 2])
ValueError: Lengths must match to compare
```

Note that this is different from the numpy behavior where a comparison can be broadcast:

```python
In [69]: np.array([1, 2, 3]) == np.array([1])
Out[69]: array([ True, False, False])
```

or it can return False if broadcasting can not be done:

```python
In [70]: np.array([1, 2, 3]) == np.array([1, 2])
Out[70]: False
```
Changes to boolean comparisons vs. None

Boolean comparisons of a Series vs None will now be equivalent to comparing with np.nan, rather than raise TypeError. (GH1079).

```python
In [71]: s = pd.Series(range(3))
In [72]: s.iloc[1] = None
In [73]: s
Out[73]:
0  0.0
1  NaN
2  2.0
Length: 3, dtype: float64
```

Previous behavior:

```python
In [5]: s == None
TypeError: Could not compare <type 'NoneType'> type with Series
```

New behavior:

```python
In [74]: s == None
Out[74]:
0  False
1  False
2  False
Length: 3, dtype: bool
```

Usually you simply want to know which values are null.

```python
In [75]: s.isnull()
Out[75]:
0  False
1  True
2  False
Length: 3, dtype: bool
```

**Warning:** You generally will want to use isnull/notnull for these types of comparisons, as isnull/notnull tells you which elements are null. One has to be mindful that nan's don’t compare equal, but None's do. Note that Pandas/numpy uses the fact that np.nan != np.nan, and treats None like np.nan.

```python
In [76]: None == None
Out[76]: True
In [77]: np.nan == np.nan
Out[77]: False
```
HDFStore dropna behavior

The default behavior for HDFStore write functions with `format='table'` is now to keep rows that are all missing. Previously, the behavior was to drop rows that were all missing save the index. The previous behavior can be replicated using the `dropna=True` option. (GH9382)

Previous behavior:

```
In [78]: df_with_missing = pd.DataFrame({'col1': [0, np.nan, 2],
       ....:       'col2': [1, np.nan, np.nan]})

In [79]: df_with_missing
Out[79]:
   col1  col2
0   0.0  1.0
1   NaN  NaN
2   2.0  NaN

[3 rows x 2 columns]
```

```
In [27]:
    df_with_missing.to_hdf('file.h5',
                        'df_with_missing',
                        format='table',
                        mode='w')

In [28]:
    pd.read_hdf('file.h5', 'df_with_missing')
Out[28]:
   col1  col2
0    0   1.0
2    2   NaN
```

New behavior:

```
In [80]:
    df_with_missing.to_hdf('file.h5',
                        'df_with_missing',
                        format='table',
                        mode='w')

In [81]:
    pd.read_hdf('file.h5', 'df_with_missing')
Out[81]:
   col1  col2
0    0   1.0
1   NaN  NaN
2    2   NaN

[3 rows x 2 columns]
```

See the docs for more details.
Changes to display.precision option

The display.precision option has been clarified to refer to decimal places (GH10451).

Earlier versions of pandas would format floating point numbers to have one less decimal place than the value in display.precision.

In [1]: pd.set_option('display.precision', 2)
In [2]: pd.DataFrame({'x': [123.456789]})
Out[2]:
    x
0  123.5

If interpreting precision as “significant figures” this did work for scientific notation but that same interpretation did not work for values with standard formatting. It was also out of step with how numpy handles formatting.

Going forward the value of display.precision will directly control the number of places after the decimal, for regular formatting as well as scientific notation, similar to how numpy’s precision print option works.

In [82]: pd.set_option('display.precision', 2)
In [83]: pd.DataFrame({'x': [123.456789]})
Out[83]:
    x
0  123.46

To preserve output behavior with prior versions the default value of display.precision has been reduced to 6 from 7.

Changes to Categorical.unique

Categorical.unique now returns new Categoricals with categories and codes that are unique, rather than returning np.array (GH10508)

- unordered category: values and categories are sorted by appearance order.
- ordered category: values are sorted by appearance order, categories keep existing order.

In [84]: cat = pd.Categorical(['C', 'A', 'B', 'C'],
                    categories=['A', 'B', 'C'],
                    ordered=True)
In [85]: cat
Out[85]:
['C', 'A', 'B', 'C']
Categories (3, object): ['A' < 'B' < 'C']

In [86]: cat.unique()
Out[86]:
['C', 'A', 'B']
Categories (3, object): ['A' < 'B' < 'C']

In [87]: cat = pd.Categorical(['C', 'A', 'B', 'C'],
                    categories=['A', 'B', 'C'],
                    ordered=True)
Changes to bool passed as header in parsers

In earlier versions of pandas, if a bool was passed the header argument of read_csv, read_excel, or read_html it was implicitly converted to an integer, resulting in header=0 for False and header=1 for True (GH6113)

A bool input to header will now raise a TypeError

Other API changes

- Line and kde plot with subplots=True now uses default colors, not all black. Specify color='k' to draw all lines in black (GH9894)
- Calling the .value_counts() method on a Series with a categorical dtype now returns a Series with a CategoricalIndex (GH10704)
- The metadata properties of subclasses of pandas objects will now be serialized (GH10553).
- groupby using Categorical follows the same rule as Categorical.unique described above (GH10508)
- When constructing DataFrame with an array of complex64 dtype previously meant the corresponding column was automatically promoted to the complex128 dtype. Pandas will now preserve the itemsize of the input for complex data (GH10952)
- some numeric reduction operators would return ValueError, rather than TypeError on object types that includes strings and numbers (GH11131)
- Passing currently unsupported chunksize argument to read_excel or ExcelFile.parse will now raise NotImplementedError (GH8011)
- Allow an ExcelFile object to be passed into read_excel (GH11198)
- DatetimeIndex.union does not infer freq if self and the input have None as freq (GH11086)
- NaT’s methods now either raise ValueError, or return np.nan or NaT (GH9513)
## Deprecations

- For **Series** the following indexing functions are deprecated (GH10177).

<table>
<thead>
<tr>
<th>Deprecated Function</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>.irow(i)</td>
<td>.iloc[i] or .iat[i]</td>
</tr>
<tr>
<td>.iget(i)</td>
<td>.iloc[i] or .iat[i]</td>
</tr>
<tr>
<td>.iget_value(i)</td>
<td>.iloc[i] or .iat[i]</td>
</tr>
</tbody>
</table>

- For **DataFrame** the following indexing functions are deprecated (GH10177).

<table>
<thead>
<tr>
<th>Deprecated Function</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>.irow(i)</td>
<td>.iloc[i]</td>
</tr>
<tr>
<td>.iget_value(i, j)</td>
<td>.iloc[i, j] or .iat[i, j]</td>
</tr>
<tr>
<td>.icol(j)</td>
<td>.iloc[:, j]</td>
</tr>
</tbody>
</table>

**Note:** These indexing function have been deprecated in the documentation since 0.11.0.

- **Categorical.name** was deprecated to make **Categorical** more **numpy.ndarray** like. Use `Series(cat, name="whatever")` instead (GH10482).

- Setting missing values (NaN) in a **Categorical**'s categories will issue a warning (GH10748). You can still have missing values in the values.

- **drop_duplicates** and **duplicated**'s *take_last* keyword was deprecated in favor of **keep**. (GH6511, GH8505)

- **Series.nsmallest** and **nlargest**'s *take_last* keyword was deprecated in favor of **keep**. (GH10792)

- **DataFrame.combineAdd** and **DataFrame.combineMult** are deprecated. They can easily be replaced by using the add and mul methods: `DataFrame.add(other, fill_value=0)` and `DataFrame.mul(other, fill_value=1.)` (GH10735).

- **TimeSeries** deprecated in favor of **Series** (note that this has been an alias since 0.13.0), (GH10890)

- **SparsePanel** deprecated and will be removed in a future version (GH11157).

- **Series.is_time_series** deprecated in favor of **Series.index.is_all_dates** (GH11135)

- **Legacy offsets** (like 'A@JAN') are deprecated (note that this has been alias since 0.8.0) (GH10878)

- **WidePanel** deprecated in favor of **Panel**, **LongPanel** in favor of **DataFrame** (note these have been aliases since < 0.11.0), (GH10892)

- **DataFrame.convert_objects** has been deprecated in favor of type-specific functions `pd.to_datetime`, `pd.to_timestamp` and `pd.to_numeric` (new in 0.17.0) (GH11133).
Removal of prior version deprecations/changes

- Removal of `na_last` parameters from `Series.order()` and `Series.sort()`, in favor of `na_position`. (GH5231)
- Remove of `percentile_width` from `.describe()`, in favor of `percentiles`. (GH7088)
- Removal of `colSpace` parameter from `DataFrame.to_string()`, in favor of `col_space`, circa 0.8.0 version.
- Removal of automatic time-series broadcasting (GH2304)

```python
In [90]: np.random.seed(1234)
In [91]: df = pd.DataFrame(np.random.randn(5, 2),
                columns=list('AB'),
                index=pd.date_range('2013-01-01', periods=5))

In [92]: df
Out[92]:
     A          B
2013-01-01  0.471435 -1.190976
2013-01-02  1.432707 -0.312652

[5 rows x 2 columns]
• Remove table keyword in HDFStore.put/append, in favor of using format= (GH4645)
• Remove kind in read_excel/ExcelFile as its unused (GH4712)
• Remove infer_type keyword from pd.read_html as its unused (GH4770, GH7032)
• Remove offset and timeRule keywords from Series.tshift/shift, in favor of freq (GH4853, GH4864)
• Remove pd.load/pd.save aliases in favor of pd.to_pickle/pd.read_pickle (GH3787)

**Performance improvements**

• Development support for benchmarking with the Air Speed Velocity library (GH8361)
• Added vbench benchmarks for alternative ExcelWriter engines and reading Excel files (GH7171)
• Performance improvements in Categorical.value_counts (GH10804)
• Performance improvements in SeriesGroupBy.nunique and SeriesGroupBy.value_counts and SeriesGroupby.transform (GH10820, GH11077)
• Performance improvements in DataFrame.drop_duplicates with integer dtypes (GH10917)
• Performance improvements in DataFrame.duplicated with wide frames. (GH10161, GH11180)
• 4x improvement in timedelta string parsing (GH6755, GH10426)
• 8x improvement in timedelta64 and datetime64 ops (GH6755)
• Significantly improved performance of indexing MultiIndex with slicers (GH10287)
• 8x improvement in iloc using list-like input (GH10791)
• Improved performance of Series.isin for datetimelike/integer Series (GH10287)
• 20x improvement in concat of Categoricals when categories are identical (GH10587)
• Improved performance of to_datetime when specified format string is ISO8601 (GH10178)
• 2x improvement of Series.value_counts for float dtype (GH10821)
• Enable infer_datetime_format in to_datetime when date components do not have 0 padding (GH11142)
• Regression from 0.16.1 in constructing DataFrame from nested dictionary (GH11084)
• Performance improvements in addition/subtraction operations for DateOffset with Series or DatetimeIndex (GH10744, GH11205)

**Bug fixes**

• Bug in incorrect computation of .mean() on timedelta64[ns] because of overflow (GH9442)
• Bug in .isin on older numpies (GH11232)
• Bug in DataFrame.to_html(index=False) renders unnecessary name row (GH10344)
• Bug in DataFrame.to_latex() the column_format argument could not be passed (GH9402)
• Bug in DatetimeIndex when localizing with NaT (GH10477)
• Bug in Series.dt ops in preserving meta-data (GH10477)
• Bug in preserving NaT when passed in an otherwise invalid to_datetime construction (GH10477)
• Bug in `DataFrame.apply` when function returns categorical series. (GH9573)
• Bug in `to_datetime` with invalid dates and formats supplied (GH10154)
• Bug in `Index.drop_duplicates` dropping name(s) (GH10115)
• Bug in `Series.quantile` dropping name (GH10881)
• Bug in `pd.Series` when setting a value on an empty `Series` whose index has a frequency. (GH10193)
• Bug in `pd.Series.interpolate` with invalid order keyword values. (GH10633)
• Bug in `DataFrame.plot` raises `ValueError` when color name is specified by multiple characters (GH10387)
• Bug in `Index` construction with a mixed list of tuples (GH10697)
• Bug in `DataFrame.reset_index` when index contains `NaT`. (GH10388)
• Bug in `ExcelReader` when worksheet is empty (GH6403)
• Bug in `BinGrouper.group_info` where returned values are not compatible with base class (GH10914)
• Bug in clearing the cache on `DataFrame.pop` and a subsequent inplace op (GH10912)
• Bug in indexing with a mixed-integer `Index` causing an `ImportError` (GH10610)
• Bug in `Series.count` when index has nulls (GH10946)
• Bug in picking of a non-regular freq `DatetimeIndex` (GH11002)
• Bug causing `DataFrame.where` to not respect the `axis` parameter when the frame has a symmetric shape. (GH9736)
• Bug in `Table.select_column` where name is not preserved (GH10392)
• Bug in `offsets.generate_range` where start and end have finer precision than offset (GH9907)
• Bug in `pd.rolling_*` where `Series.name` would be lost in the output (GH10565)
• Bug in `stack` when index or columns are not unique. (GH10417)
• Bug in setting a `Panel` when an axis has a MultiIndex (GH10360)
• Bug in `USFederalHolidayCalendar` where `USMemorialDay` and `USMartinLutherKingJr` were incorrect (GH10278 and GH9760)
• Bug in `.sample()` where returned object, if set, gives unnecessary `SettingWithCopyWarning` (GH10738)
• Bug in `.sample()` where weights passed as `Series` were not aligned along axis before being treated positionally, potentially causing problems if weight indices were not aligned with sampled object. (GH10738)
• Regression fixed in (GH9311, GH6620, GH9345), where groupby with a datetime-like converting to float with certain aggregators (GH10979)
• Bug in `DataFrame.interpolate` with `axis=1` and `inplace=True` (GH10395)
• Bug in `io.sql.get_schema` when specifying multiple columns as primary key (GH10385).
• Bug in `groupby(sort=False)` with datetime-like `Categorical` raises `ValueError` (GH10505)
• Bug in `groupby(axis=1)` with `filter()` throws `IndexError` (GH11041)
• Bug in `test_categorical` on big-endian builds (GH10425)
• Bug in `Series.shift` and `DataFrame.shift` not supporting categorical data (GH9416)
• Bug in `Series.map` using categorical `Series` raises `AttributeError` (GH10324)
• Bug in MultiIndex.get_level_values including Categorical raises AttributeError (GH10460)
• Bug in pd.get_dummies with sparse=True not returning SparseDataFrame (GH10531)
• Bug in Index subtypes (such as PeriodIndex) not returning their own type for .drop and .insert methods (GH10620)
• Bug in algos.outer_join_indexer when right array is empty (GH10618)
• Bug in filter (regression from 0.16.0) and transform when grouping on multiple keys, one of which is datetime-like (GH10114)
• Bug in to_datetime and to_timedelta causing Index name to be lost (GH10875)
• Bug in len(DataFrame.groupby) causing IndexError when there’s a column containing only NaNs (GH11016)
• Bug that caused segfault when resampling an empty Series (GH10228)
• Bug in DatetimeIndex and PeriodIndex.value_counts resets name from its result, but retains in result's Index. (GH10150)
• Bug in pd.eval using numexpr engine coerces 1 element numpy array to scalar (GH10546)
• Bug in pd.concat with axis=0 when column is of dtype category (GH10177)
• Bug in read_msgpack where input type is not always checked (GH10369, GH10630)
• Bug in pd.read_csv with kwarg index_col=False, index_col=['a', 'b'] or dtype (GH10413, GH10467, GH10577)
• Bug in Series.from_csv with header kwarg not setting the Series.name or the Series.index. name (GH10483)
• Bug in groupby.var which caused variance to be inaccurate for small float values (GH10448)
• Bug in Series.plot(kind='hist') Y Label not informative (GH10485)
• Bug in read_csv when using a converter which generates a uint8 type (GH9266)
• Bug causes memory leak in time-series line and area plot (GH9003)
• Bug when setting a Panel sliced along the major or minor axes when the right-hand side is a DataFrame (GH11014)
• Bug that returns None and does not raise NotImplementedError when operator functions (e.g. .add) of Panel are not implemented (GH7692)
• Bug in line and kde plot cannot accept multiple colors when subplots=True (GH9894)
• Bug in DataFrame.plot raises ValueError when color name is specified by multiple characters (GH10387)
• Bug in left and right align of Series with MultiIndex may be inverted (GH10665)
• Bug in left and right join of with MultiIndex may be inverted (GH10741)
• Bug in read_stata when reading a file with a different order set in columns (GH10757)
• Bug in Categorical may not representing properly when category contains tz or Period (GH10713)
• Bug in Categorical.__iter__ may not returning correct datetime and Period (GH10713)
• Bug in indexing with a PeriodIndex on an object with a PeriodIndex (GH4125)
• Bug in read_csv with engine='c': EOF preceded by a comment, blank line, etc. was not handled correctly (GH10728, GH10548)
• Reading “famafrench” data via `DataReader` results in HTTP 404 error because of the website url is changed (GH10591).

• Bug in `read_msgpack` where DataFrame to decode has duplicate column names (GH9618)

• Bug in `io.common.get_filepath_or_buffer` which caused reading of valid S3 files to fail if the bucket also contained keys for which the user does not have read permission (GH10604)

• Bug in vectorised setting of timestamp columns with python `datetime.date` and numpy `datetime64` (GH10408, GH10412)

• Bug in `Index.take` may add unnecessary `freq` attribute (GH10791)

• Bug in `merge` with empty DataFrame may raise `IndexError` (GH10824)

• Bug in `to_latex` where unexpected keyword argument for some documented arguments (GH10888)

• Bug in indexing of large DataFrame where `IndexError` is uncaught (GH10645 and GH10692)

• Bug in `read_csv` when using the `nrows` or `chunksize` parameters if file contains only a header line (GH9535)

• Bug in serialization of category types in HDF5 in presence of alternate encodings. (GH10366)

• Bug in `pd.DataFrame` when constructing an empty DataFrame with a string dtype (GH9428)

• Bug in `pd.DataFrame.diff` when DataFrame is not consolidated (GH10907)

• Bug in `pd.unique` for arrays with the `datetime64` or `timedelta64` dtype that meant an array with object dtype was returned instead the original dtype (GH9431)

• Bug in `TimedeltaIndex` raising error when slicing from 0s (GH10583)

• Bug in `DatetimeIndex.take` and `TimedeltaIndex.take` may not raise `IndexError` against invalid index (GH10295)

• Bug in `Series([np.nan]).astype('M8[ms]')`, which now returns `Series([pd.NaT])` (GH10747)

• Bug in `PeriodIndex.order` reset freq (GH10295)

• Bug in `date_range` when freq divides end as nanos (GH10885)

• Bug in `iloc` allowing memory outside bounds of a Series to be accessed with negative integers (GH10779)

• Bug in `read_msgpack` where encoding is not respected (GH10581)

• Bug preventing access to the first index when using `iloc` with a list containing the appropriate negative integer (GH10547, GH10779)

• Bug in `TimedeltaIndex` formatter causing error while trying to save DataFrame with `TimedeltaIndex` using `to_csv` (GH10833)

• Bug in `DataFrame.where` when handling Series slicing (GH10218, GH9558)

• Bug where `pd.read_gbq` throws `ValueError` when Bigquery returns zero rows (GH10273)

• Bug in `to_json` which was causing segmentation fault when serializing 0-rank ndarray (GH9576)

• Bug in plotting functions may raise `IndexError` when plotted on `GridSpec` (GH10819)

• Bug in plot result may show unnecessary minor ticklabels (GH10657)

• Bug in `groupby` incorrect computation for aggregation on DataFrame with `NaT` (E.g first, last, min). (GH10590, GH11010)

• Bug when constructing `DataFrame` where passing a dictionary with only scalar values and specifying columns did not raise an error (GH10856)
pandas: powerful Python data analysis toolkit, Release 1.1.1

- Bug in `.var()` causing roundoff errors for highly similar values (GH10242)
- Bug in `DataFrame.plot(subplots=True)` with duplicated columns outputs incorrect result (GH10962)
- Bug in `Index` arithmetic may result in incorrect class (GH10638)
- Bug in `date_range` results in empty if freq is negative annually, quarterly and monthly (GH11018)
- Bug in `DatetimeIndex` cannot infer negative freq (GH11018)
- Remove use of some deprecated numpy comparison operations, mainly in tests. (GH10569)
- Bug in `Index` dtype may not applied properly (GH11017)
- Bug in `io.gbq` when testing for minimum google api client version (GH10652)
- Bug in `DataFrame` construction from nested `dict` with `timedelta` keys (GH11129)
- Bug in `.fillna` against may raise `TypeError` when data contains datetime dtype (GH7095, GH11153)
- Bug in `.groupby` when number of keys to group by is same as length of index (GH11185)
- Bug in `convert_objects` where converted values might not be returned if all null and `coerce` (GH9589)
- Bug in `convert_objects` where `copy` keyword was not respected (GH9589)

5.12 Version 0.16

5.12.1 Version 0.16.2 (June 12, 2015)

This is a minor bug-fix release from 0.16.1 and includes a large number of bug fixes along some new features (\texttt{pipe()} method), enhancements, and performance improvements.

We recommend that all users upgrade to this version.

Highlights include:

- A new \texttt{pipe} method, see \texttt{here}
- Documentation on how to use \texttt{numba} with \texttt{pandas}, see \texttt{here}

What’s new in v0.16.2

- \textit{New features}
  - \textit{Pipe}
  - \textit{Other enhancements}
New features

Pipe

We’ve introduced a new method `DataFrame.pipe()`. As suggested by the name, pipe should be used to pipe data through a chain of function calls. The goal is to avoid confusing nested function calls like

```python
# df is a DataFrame
# f, g, and h are functions that take and return DataFrames
f(g(h(df), arg1=1), arg2=2, arg3=3)  # noqa F821
```

The logic flows from inside out, and function names are separated from their keyword arguments. This can be rewritten as

```python
(df.pipe(h)  # noqa F821
 .pipe(g, arg1=1)  # noqa F821
 .pipe(f, arg2=2, arg3=3)  # noqa F821
)
```

Now both the code and the logic flow from top to bottom. Keyword arguments are next to their functions. Overall the code is much more readable.

In the example above, the functions `f`, `g`, and `h` each expected the DataFrame as the first positional argument. When the function you wish to apply takes its data anywhere other than the first argument, pass a tuple of `(function, keyword)` indicating where the DataFrame should flow. For example:

```
In [1]: import statsmodels.formula.api as sm
In [2]: bb = pd.read_csv('data/baseball.csv', index_col='id')
# sm.ols takes (formula, data)
In [3]: (bb.query('h > 0')
    ...: .assign(ln_h=lambda df: np.log(df.h))
    ...: .pipe((sm.ols, 'data'), 'hr ~ ln_h + year + g + C(lg)')
    ...: .fit()
    ...: .summary()
    ...: )
```

```
Out[3]:<class 'statsmodels.iolib.summary.Summary'>
```

```
""
```

OLS Regression Results

==============================================================================
Dep. Variable: hr R-squared: 0.685
Model: OLS Adj. R-squared: 0.665
Method: Least Squares F-statistic: 34.28
Date: Thu, 20 Aug 2020 Prob (F-statistic): 3.48e-15
```

(continues on next page)
warnings:

[1] Standard Errors assume that the covariance matrix of the errors is correctly specified.
[2] The condition number is large, 1.49e+07. This might indicate that there are strong multicollinearity or other numerical problems.

The pipe method is inspired by unix pipes, which stream text through processes. More recently dplyr and magrittr have introduced the popular (%>%) pipe operator for R.

See the documentation for more. (GH10129)

Other enhancements

- Added rsplit to Index/Series StringMethods (GH10303)
- Removed the hard-coded size limits on the DataFrame HTML representation in the IPython notebook, and leave this to IPython itself (only for IPython v3.0 or greater). This eliminates the duplicate scroll bars that appeared in the notebook with large frames (GH10231).

  Note that the notebook has a toggle output scrolling feature to limit the display of very large frames (by clicking left of the output). You can also configure the way DataFrames are displayed using the pandas options, see here.

  axis parameter of DataFrame.quantile now accepts also index and column. (GH9543)

API changes

- Holiday now raises NotImplementedError if both offset and observance are used in the constructor instead of returning an incorrect result (GH10217).
Performance improvements

• Improved Series.resample performance with dtype=datetime64[ns] (GH7754)
• Increase performance of str.split when expand=True (GH10081)

Bug fixes

• Bug in Series.hist raises an error when a one row Series was given (GH10214)
• Bug where HDFStore.select modifies the passed columns list (GH7212)
• Bug in Categorical repr with display.width of None in Python 3 (GH10087)
• Bug in to_json with certain orients and a CategoricalIndex would segfault (GH10317)
• Bug where some of the nan functions do not have consistent return dtypes (GH10251)
• Bug in DataFrame.quantile on checking that a valid axis was passed (GH9543)
• Bug in groupby.apply aggregation for Categorical not preserving categories (GH10138)
• Bug in to_csv where date_format is ignored if the datetime is fractional (GH10209)
• Bug in DataFrame.to_json with mixed data types (GH10289)
• Bug in cache updating when consolidating (GH10264)
• Bug in mean() where integer dtypes can overflow (GH10172)
• Bug where Panel.from_dict does not set dtype when specified (GH10058)
• Bug in Index.union raises AttributeError when passing array-likes. (GH10149)
• Bug in Timestamp’s’ microsecond, quarter, dayofyear, week and daysinmonth properties return np.int type, not built-in int. (GH10050)
• Bug in NaT raises AttributeError when accessing to daysinmonth, dayofweek properties. (GH10096)
• Bug in Index repr when using the max_seq_items=None setting (GH10182).
• Bug in getting timezone data with dateutil on various platforms (GH9059, GH8639, GH9663, GH10121)
• Bug in displaying datetimes with mixed frequencies; display ‘ms’ datetimes to the proper precision. (GH10170)
• Bug in setitem where type promotion is applied to the entire block (GH10280)
• Bug in Series arithmetic methods may incorrectly hold names (GH10068)
• Bug in GroupBy.get_group when grouping on multiple keys, one of which is categorical. (GH10132)
• Bug in DatetimeIndex and TimedeltaIndex names are lost after timedelta arithmetics (GH9926)
• Bug in DataFrame construction from nested dict with datetime64 (GH10160)
• Bug in Series construction from dict with datetime64 keys (GH9456)
• Bug in Series.plot(label="LABEL") not correctly setting the label (GH10119)
• Bug in plot not defaulting to matplotlib axes.grid setting (GH9792)
• Bug causing strings containing an exponent, but no decimal to be parsed as int instead of float in engine='python' for the read_csv parser (GH9565)
• Bug in Series.align resets name when fill_value is specified (GH10067)
• Bug in read_csv causing index name not to be set on an empty DataFrame (GH10184)
• Bug in SparseSeries.abs resets name (GH10241)
• Bug in TimedeltaIndex slicing may reset freq (GH10292)
• Bug in GroupBy.get_group raises ValueError when group key contains NaT (GH6992)
• Bug in SparseSeries constructor ignores input data name (GH10258)
• Bug in Categorical.remove_categories causing a ValueError when removing the NaN category if underlying dtype is floating-point (GH10156)
• Bug where infer_freq infers time rule (WOM-5XXX) unsupported by to_offset (GH9425)
• Bug in DataFrame.to_hdf() where table format would raise a seemingly unrelated error for invalid (non-string) column names. This is now explicitly forbidden. (GH9057)
• Bug to handle masking empty DataFrame (GH10126).
• Bug where MySQL interface could not handle numeric table/column names (GH10255)
• Bug in read_csv with a date_parser that returned a datetime64 array of other time resolution than [ns] (GH10245)
• Bug in Panel.apply when the result has ndim=0 (GH10332)
• Bug in read_hdf where auto_close could not be passed (GH9327).
• Bug in read_hdf where open stores could not be used (GH10330).
• Bug in adding empty DataFrames, now results in a DataFrame that .equals an empty DataFrame (GH10181).
• Bug in to_hdf and HDFStore which did not check that complib choices were valid (GH4582, GH8874).

5.12.2 Version 0.16.1 (May 11, 2015)

This is a minor bug-fix release from 0.16.0 and includes a large number of bug fixes along several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Support for a CategoricalIndex, a category based index, see here
- New section on how-to-contribute to pandas, see here
- Revised “Merge, join, and concatenate” documentation, including graphical examples to make it easier to understand each operations, see here
- New method sample for drawing random samples from Series, DataFrames and Panels. See here
- The default Index printing has changed to a more uniform format, see here
- BusinessHour datetime-offset is now supported, see here
- Further enhancement to the .str accessor to make string operations easier, see here

What’s new in v0.16.1

- Enhancements
  - CategoricalIndex
- Sample
- String methods enhancements
- Other enhancements

- API changes
- Deprecations
- Index representation
- Performance improvements
- Bug fixes
- Contributors

**Warning:** In pandas 0.17.0, the sub-package `pandas.io.data` will be removed in favor of a separately installable package (GH8961).

**Enhancements**

**CategoricalIndex**

We introduce a `CategoricalIndex`, a new type of index object that is useful for supporting indexing with duplicates. This is a container around a `Categorical` (introduced in v0.15.0) and allows efficient indexing and storage of an index with a large number of duplicated elements. Prior to 0.16.1, setting the index of a DataFrame/Series with a category dtype would convert this to regular object-based Index.

```python
In [1]: df = pd.DataFrame({'A': np.arange(6),
                      'B': pd.Series(list('aabbca'))
                      .astype('category', categories=list('cab'))
                      })

In [2]: df
Out[2]:
   A  B
0  0  a
1  1  a
2  2  b
3  3  b
4  4  c
5  5  a

In [3]: df.dtypes
Out[3]:
A    int64
B  category
dtype: object

In [4]: df.B.cat.categories
Out[4]: Index(['c', 'a', 'b'], dtype='object')
```

Setting the index, will create a `CategoricalIndex`
indexing with \_getitem\_/.iloc/.loc/.ix works similarly to an Index with duplicates. The indexers MUST be in the category or the operation will raise.

```python
In [7]: df2.loc['a']
Out[7]:
 A
B
a 0
a 1
a 5
```

and preserves the CategoricalIndex

```python
In [8]: df2.loc['a'].index
Out[8]: CategoricalIndex(['a', 'a', 'a'], categories=['c', 'a', 'b'], ordered=False, name='B', dtype='category')
```

sorting will order by the order of the categories

```python
In [9]: df2.sort_index()
Out[9]:
 A
B
c 4
a 0
a 1
a 5
b 2
b 3
```

groupby operations on the index will preserve the index nature as well

```python
In [10]: df2.groupby(level=0).sum()
Out[10]:
 A
B
 c 4
 a 6
```

```python
In [11]: df2.groupby(level=0).sum().index
Out[11]: CategoricalIndex(['c', 'a', 'b'], categories=['c', 'a', 'b'], ordered=False, name='B', dtype='category')
```

reindexing operations, will return a resulting index based on the type of the passed indexer, meaning that passing a list will return a plain-old-Index; indexing with a Categorical will return a CategoricalIndex, indexed according to the categories of the PASSED Categorical dtype. This allows one to arbitrarily index these even with values NOT in the categories, similarly to how you can reindex ANY pandas index.

```python
In [12]: df2.reindex(['a', 'e'])
Out[12]:
(continues on next page)
A
B
a 0.0
a 1.0
a 5.0
e NaN

In [13]: df2.reindex(['a', 'e']).index
Out[13]: pd.Index(['a', 'a', 'a', 'e'], dtype='object', name='B')

In [14]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde')))
Out[14]:
   A
  B
  a 0.0
  a 1.0
  a 5.0
e NaN

In [15]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde'))).index
Out[15]: pd.CategoricalIndex(['a', 'a', 'a', 'e'],
categories=['a', 'b', 'c', 'd', 'e'],
ordered=False, name='B',
dtype='category')

See the documentation for more. (GH7629, GH10038, GH10039)

Sample

Series, DataFrames, and Panels now have a new method: *sample()*. The method accepts a specific number of rows or columns to return, or a fraction of the total number of rows or columns. It also has options for sampling with or without replacement, for passing in a column for weights for non-uniform sampling, and for setting seed values to facilitate replication. (GH2419)

In [1]: example_series = pd.Series([0, 1, 2, 3, 4, 5])

# When no arguments are passed, returns 1
In [2]: example_series.sample()
Out[2]:
   3  3
Length: 1, dtype: int64

# One may specify either a number of rows:
In [3]: example_series.sample(n=3)
Out[3]:
   2  2
   1  1
   0  0
Length: 3, dtype: int64

# Or a fraction of the rows:
In [4]: example_series.sample(frac=0.5)
Out[4]:
   1  1
   5  5

(continues on next page)
3 3
Length: 3, dtype: int64

# weights are accepted.
In [5]: example_weights = [0, 0, 0.2, 0.2, 0.2, 0.4]

In [6]: example_series.sample(n=3, weights=example_weights)
Out[6]:
2 2
4 4
3 3
Length: 3, dtype: int64

# weights will also be normalized if they do not sum to one, # and missing values will be treated as zeros.
In [7]: example_weights2 = [0.5, 0, 0, 0, None, np.nan]

In [8]: example_series.sample(n=1, weights=example_weights2)
Out[8]:
0 0
Length: 1, dtype: int64

When applied to a DataFrame, one may pass the name of a column to specify sampling weights when sampling from rows.

In [9]: df = pd.DataFrame({'col1': [9, 8, 7, 6], 'weight_column': [0.5, 0.4, 0.1, 0]})

In [10]: df.sample(n=3, weights='weight_column')
Out[10]:
   col1  weight_column
0     9           0.5
1     8           0.4
2     7           0.1

[3 rows x 2 columns]

String methods enhancements

Continuing from v0.16.0, the following enhancements make string operations easier and more consistent with standard python string operations.

- Added StringMethods (.str accessor) to Index (GH9068)

  The .str accessor is now available for both Series and Index.

In [11]: idx = pd.Index(['jack', 'jill', 'jesse', 'frank'])

In [12]: idx.str.strip()
Out[12]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')

One special case for the .str accessor on Index is that if a string method returns bool, the .str accessor will return a np.array instead of a boolean Index (GH8875). This enables the following expression to work naturally:
In [13]: idx = pd.Index(['a1', 'a2', 'b1', 'b2'])

In [14]: s = pd.Series(range(4), index=idx)

In [15]: s
Out[15]:
  a1  0
  a2  1
  b1  2
  b2  3
Length: 4, dtype: int64

In [16]: idx.str.startswith('a')
Out[16]:
array([ True, True, False, False])

In [17]: s[s.index.str.startswith('a')]
Out[17]:
  a1  0
  a2  1
Length: 2, dtype: int64

- The following new methods are accessible via .str accessor to apply the function to each values. (GH9766, GH9773, GH10031, GH10045, GH10052)

<table>
<thead>
<tr>
<th>Methods</th>
<th>capitalize()</th>
<th>swapcase()</th>
<th>normalize()</th>
<th>partition()</th>
<th>rpartition()</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>index()</td>
<td>rindex()</td>
<td>translate()</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- split now takes expand keyword to specify whether to expand dimensionality. return_type is deprecated. (GH9847)

In [18]: s = pd.Series(['a,b', 'a,c', 'b,c'])

# return Series
In [19]: s.str.split(',')
Out[19]:
  0 [a, b]
  1 [a, c]
  2 [b, c]
Length: 3, dtype: object

# return DataFrame
In [20]: s.str.split(',', expand=True)
Out[20]:
     0  1
  0  a  b
  1  a  c
  2  b  c
[3 rows x 2 columns]

In [21]: idx = pd.Index(['a,b', 'a,c', 'b,c'])

# return Index
In [22]: idx.str.split(',')
Out[22]: Index([['a', 'b'], ['a', 'c'], ['b', 'c']], dtype='object')
# return MultiIndex
In [23]: idx.str.split(',', expand=True)
Out[23]:
MultiIndex([('a', 'b'), ('a', 'c'), ('b', 'c')],

• Improved `extract` and `get_dummies` methods for `Index.str` (GH9980)

### Other enhancements

• `BusinessHour` offset is now supported, which represents business hours starting from 09:00 - 17:00 on `BusinessDay` by default. See `Here` for details. (GH7905)

```python
In [24]: pd.Timestamp('2014-08-01 09:00') + pd.tseries.offsets.BusinessHour()
Out[24]: Timestamp('2014-08-01 10:00:00')

In [25]: pd.Timestamp('2014-08-01 07:00') + pd.tseries.offsets.BusinessHour()
Out[25]: Timestamp('2014-08-01 10:00:00')

In [26]: pd.Timestamp('2014-08-01 16:30') + pd.tseries.offsets.BusinessHour()
Out[26]: Timestamp('2014-08-04 09:30:00')
```

• `DataFrame.diff` now takes an `axis` parameter that determines the direction of differencing (GH9727)
• Allow `clip`, `clip_lower`, and `clip_upper` to accept array-like arguments as thresholds (This is a regression from 0.11.0). These methods now have an `axis` parameter which determines how the Series or DataFrame will be aligned with the threshold(s). (GH6966)
• `DataFrame.mask()` and `Series.mask()` now support same keywords as `where` (GH8801)
• `drop` function can now accept `errors` keyword to suppress `ValueError` raised when any of label does not exist in the target data. (GH6736)

```python
In [27]: df = pd.DataFrame(np.random.randn(3, 3), columns=['A', 'B', 'C'])
In [28]: df.drop(['A', 'X'], axis=1, errors='ignore')
Out[28]:
   B    C
0 -0.706771 -1.039575
1 -0.424972  0.567020
2 -1.087401 -0.673690
[3 rows x 2 columns]
```

• Add support for separating years and quarters using dashes, for example 2014-Q1. (GH9688)
• Allow conversion of values with dtype `datetime64` or `timedelta64` to strings using `astype(str)` (GH9757)
• `get_dummies` function now accepts `sparse` keyword. If set to `True`, the return `DataFrame` is sparse, e.g. `SparseDataFrame`. (GH8823)
• `Period` now accepts `datetime64` as value input. (GH9054)
• Allow timedelta string conversion when leading zero is missing from time definition, ie 0:00:00 vs 00:00:00. (GH9570)

• Allow Panel.shift with axis='items' (GH9890)

• Trying to write an excel file now raises NotImplementedError if the DataFrame has a MultiIndex instead of writing a broken Excel file. (GH9794)

• Allow Categorical.add_categories to accept Series or np.array. (GH9927)

• Add/delete str/dt/cat accessors dynamically from __dir__. (GH9910)

• Add normalize as a dt accessor method. (GH10047)

• DataFrame and Series now have _constructor_expanddim property as overridable constructor for one higher dimensionality data. This should be used only when it is really needed, see here

• pd.lib.infer_dtypes now returns 'bytes' in Python 3 where appropriate. (GH10032)

API changes

• When passing in an ax to df.plot(..., ax=ax), the share kwarg will now default to False. The result is that the visibility of xlabels and xticklabels will not anymore be changed. You have to do that by yourself for the right axes in your figure or set share=True explicitly (but this changes the visible for all axes in the figure, not only the one which is passed in!). If pandas creates the subplots itself (e.g. no passed in ax kwarg), then the default is still share=True and the visibility changes are applied.

• assign() now inserts new columns in alphabetical order. Previously the order was arbitrary. (GH9777)

• By default, read_csv and read_table will now try to infer the compression type based on the file extension. Set compression=None to restore the previous behavior (no decompression). (GH9770)

Deprecations

• Series.str.split's return_type keyword was removed in favor of expand (GH9847)

Index representation

The string representation of Index and its sub-classes have now been unified. These will show a single-line display if there are few values; a wrapped multi-line display for a lot of values (but less than display.max_seq_items; if lots of items (>display.max_seq_items) will show a truncated display (the head and tail of the data). The formatting for MultiIndex is unchanged (a multi-line wrapped display). The display width responds to the option display.max_seq_items, which is defaulted to 100. (GH6482)

Previous behavior

```
In [2]: pd.Index(range(4), name='foo')
Out[2]: Int64Index([0, 1, 2, 3], dtype='int64')

In [3]: pd.Index(range(104), name='foo')
Out[3]: Int64Index([0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, ...], dtype='int64')
```
**In [4]:**  `pd.date_range('20130101', periods=4, name='foo', tz='US/Eastern')`

```
Out[4]:
<class 'pandas.tseries.index.DatetimeIndex'>
[2013-01-01 00:00:00-05:00, ..., 2013-01-04 00:00:00-05:00]
Length: 4, Freq: D, Timezone: US/Eastern
```

**In [5]:**  `pd.date_range('20130101', periods=104, name='foo', tz='US/Eastern')`

```
Out[5]:

    'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb',
    'ccc', 'dddd'], categories=['a', 'bb', 'ccc', 'dddd'], ordered=True, name='foobarlo',
    dtype='category', length=400)
```

**In [36]:**  `pd.date_range('20130101', periods=4, name='foo', tz='US/Eastern')`

```
(continues on next page)
```
Performance improvements

- Improved csv write performance with mixed dtypes, including datetimes by up to 5x (GH9940)
- Improved csv write performance generally by 2x (GH9940)
- Improved the performance of pd.lib.max_len_string_array by 5-7x (GH10024)

Bug fixes

- Bug where labels did not appear properly in the legend of DataFrame.plot(), passing label= arguments works, and Series indices are no longer mutated. (GH9542)
- Bug in json serialization causing a segfault when a frame had zero length. (GH9805)
- Bug in read_csv where missing trailing delimiters would cause segfault. (GH5664)
- Bug in retaining index name on appending (GH9862)
- Bug in scatter_matrix draws unexpected axis ticklabels (GH5662)
- Fixed bug in StataWriter resulting in changes to input DataFrame upon save (GH9795).
- Bug in transform causing length mismatch when null entries were present and a fast aggregator was being used (GH9697)
- Bug in equals causing false negatives when block order differed (GH9330)
- Bug in grouping with multiple `pd.Grouper` where one is non-time based (GH10063)
- Bug in `read_sql_table` error when reading postgres table with timezone (GH7139)
- Bug in `DataFrame` slicing may not retain metadata (GH9776)
- Bug where `TimedeltaIndex` were not properly serialized in fixed HDFStore (GH9635)
- Bug with `TimedeltaIndex` constructor ignoring name when given another `TimedeltaIndex` as data (GH10025).
- Bug in `DataFrameFormatter._get_formatted_index` with not applying `max_colwidth` to the `DataFrame` index (GH7856)
- Bug in `.loc` with a read-only ndarray data source (GH10043)
- Bug in `groupby.apply()` that would raise if a passed user defined function either returned only None (for all input). (GH9685)
- Always use temporary files in pytables tests (GH9992)
- Bug in plotting continuously using `secondary_y` may not show legend properly. (GH9610, GH9779)
- Bug in `DataFrame.plot(kind="hist")` results in TypeError when `DataFrame` contains non-numeric columns (GH9853)
- Bug where repeated plotting of `DataFrame` with a `DatetimeIndex` may raise TypeError (GH9852)
- Bug in `setup.py` that would allow an incompat cython version to build (GH9827)
- Bug in plotting `secondary_y` incorrectly attaches `right_ax` property to secondary axes specifying itself recursively. (GH9861)
- Bug in `Series.quantile` on empty `Series` of type `Datetime` or `Timedelta` (GH9675)
- Bug in `where` causing incorrect results when upcasting was required (GH9731)
- Bug in `FloatArrayFormatter` where decision boundary for displaying “small” floats in decimal format is off by one order of magnitude for a given display.precision (GH9764)
- Fixed bug where `DataFrame.plot()` raised an error when both `color` and `style` keywords were passed and there was no color symbol in the style strings (GH9671)
- Not showing a `DeprecationWarning` on combining list-likes with an `Index` (GH10083)
- Bug in `read_csv` and `read_table` when using `skip_rows` parameter if blank lines are present. (GH9832)
- Bug in `read_csv()` interprets `index_col=True` as 1 (GH9798)
- Bug in index equality comparisons using `==` failing on `Index/MultiIndex` type incompatibility (GH9785)
- Bug in which `SparseDataFrame` could not take `nan` as a column name (GH8822)
- Bug in `to_msgpack` and `read_msgpack` zlib and blosc compression support (GH9783)
- Bug `GroupBy.size` doesn’t attach index name properly if grouped by `TimeGrouper` (GH9925)
- Bug causing an exception in slice assignments because `length_of_indexer` returns wrong results (GH9995)
- Bug in csv parser causing lines with initial white space plus one non-space character to be skipped. (GH9710)
- Bug in C csv parser causing spurious NaNs when data started with newline followed by white space. (GH10022)
- Bug causing elements with a null group to spill into the final group when grouping by a `Categorical` (GH9603)
- Bug where `.iloc` and `.loc` behavior is not consistent on empty dataframes (GH9964)
• Bug in invalid attribute access on a TimedeltaIndex incorrectly raised ValueError instead of AttributeError (GH9680)

• Bug in unequal comparisons between categorical data and a scalar, which was not in the categories (e.g. Series(Categorical(list("abc"), ordered=True)) > "d". This returned False for all elements, but now raises a TypeError. Equality comparisons also now return False for == and True for !=. (GH9848)

• Bug in DataFrame __setitem__ when right hand side is a dictionary (GH9874)

• Bug in where when dtype is datetime64/timedelta64, but dtype of other is not (GH9804)

• Bug in MultiIndex.sortlevel() results in unicode level name breaks (GH9856)

• Bug in which groupby.transform incorrectly enforced output dtypes to match input dtypes. (GH9807)

• Bug in DataFrame constructor when columns parameter is set, and data is an empty list (GH9939)

• Bug in bar plot with log=True raises TypeError if all values are less than 1 (GH9905)

• Bug in horizontal bar plot ignores log=True (GH9905)

• Bug in PyTables queries that did not return proper results using the index (GH8265, GH9676)

• Bug where dividing a dataframe containing values of type Decimal by another Decimal would raise. (GH9787)

• Bug where using DataFrames asfreq would remove the name of the index. (GH9885)

• Bug causing extra index point when resample BM/BQ (GH9756)

• Changed caching in AbstractHolidayCalendar to be at the instance level rather than at the class level as the latter can result in unexpected behaviour. (GH9552)

• Fixed latex output for MultiIndexed dataframes (GH9778)

• Bug causing an exception when setting an empty range using DataFrame.loc (GH9596)

• Bug in hiding ticklabels with subplots and shared axes when adding a new plot to an existing grid of axes (GH9158)

• Bug in transform and filter when grouping on a categorical variable (GH9921)

• Bug in transform when groups are equal in number and dtype to the input index (GH9700)

• Google BigQuery connector now imports dependencies on a per-method basis. (GH9713)

• Updated BigQuery connector to no longer use deprecated oauth2client.tools.run() (GH8327)

• Bug in subclassed DataFrame. It may not return the correct class, when slicing or subsetting it. (GH9632)

• Bug in .median() where non-float null values are not handled correctly (GH10040)

• Bug in Series.fillna() where it raises if a numerically convertible string is given (GH10092)

5.12.3 Version 0.16.0 (March 22, 2015)

This is a major release from 0.15.2 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- DataFrame.assign method, see here
- Series.to_coo/from_coo methods to interact with scipy.sparse, see here
- Backwards incompatible change to Timedelta to conform the .seconds attribute with datetime.timedelta, see here
- Changes to the .loc slicing API to conform with the behavior of .ix see here
- Changes to the default for ordering in the Categorical constructor, see here
What's new in v0.16.0

- **New features**
  - DataFrame assign
  - Interaction with scipy.sparse
  - String methods enhancements
  - Other enhancements
- **Backwards incompatible API changes**
  - Changes in timedelta
  - Indexing changes
  - Categorical changes
  - Other API changes
  - Deprecations
  - Removal of prior version deprecations/changes
- **Performance improvements**
- **Bug fixes**
- **Contributors**

New features

**DataFrame assign**

Inspired by dplyr's mutate verb, DataFrame has a new `assign()` method. The function signature for `assign` is simply `**kwargs`. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a `Series` or `NumPy` array), or a function of one argument to be called on the `DataFrame`. The new values are inserted, and the entire DataFrame (with all original and new columns) is returned.

```python
In [1]: iris = pd.read_csv('data/iris.data')
In [2]: iris.head()
```

```
Out[2]:
          SepalLength  SepalWidth  PetalLength  PetalWidth    Name
0          5.1         3.5         1.4         0.2  Iris-setosa
1          4.9         3.0         1.4         0.2  Iris-setosa
2          4.7         3.2         1.3         0.2  Iris-setosa
3          4.6         3.1         1.5         0.2  Iris-setosa
4          5.0         3.6         1.4         0.2  Iris-setosa
```
Above was an example of inserting a precomputed value. We can also pass in a function to be evaluated.

```python
In [4]: iris.assign(sepal_ratio=lambda x: (x['SepalWidth'] / x['SepalLength'])).head()
```

```
Out[4]:
```

```
```

The power of `assign` comes when used in chains of operations. For example, we can limit the DataFrame to just those with a Sepal Length greater than 5, calculate the ratio, and plot

```python
In [5]: iris = pd.read_csv('data/iris.data')
```

```python
In [6]: (iris.query('SepalLength > 5')
```

```python
```

```python
```

See the documentation for more. (GH9229)
Interaction with scipy.sparse

Added SparseSeries.to_coo() and SparseSeries.from_coo() methods (GH8048) for converting to and from scipy.sparse.coo_matrix instances (see here). For example, given a SparseSeries with MultiIndex we can convert to a scipy.sparse.coo_matrix by specifying the row and column labels as index levels:

```
s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
s.index = pd.MultiIndex.from_tuples([(1, 2, 'a', 0),
                                  (1, 2, 'a', 1),
                                  (1, 1, 'b', 0),
                                  (1, 1, 'b', 1),
                                  (2, 1, 'b', 0),
                                  (2, 1, 'b', 1)],
                        names=['A', 'B', 'C', 'D'])
s
# SparseSeries
ss = s.to_sparse()
s
A, rows, columns = ss.to_coo(row_levels=['A', 'B'],
                            column_levels=['C', 'D'],
                            sort_labels=False)
A
A.todense()
rows
columns
```

The from_coo method is a convenience method for creating a SparseSeries from a scipy.sparse.coo_matrix:

```
from scipy import sparse
A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])),
                      shape=(3, 4))
A
A.todense()
ss = pd.SparseSeries.from_coo(A)
ss
```

String methods enhancements

- Following new methods are accessible via .str accessor to apply the function to each values. This is intended to make it more consistent with standard methods on strings. (GH9282, GH9352, GH9386, GH9387, GH9439)

<table>
<thead>
<tr>
<th>Methods</th>
<th>isalnum()</th>
<th>isalpha()</th>
<th>isdigit()</th>
<th>isdigit()</th>
<th>isspace()</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```
In [7]: s = pd.Series(['abcd', '3456', 'EFGH'])
```

(continues on next page)
• Series.str.pad() and Series.str.center() now accept fillchar option to specify filling character (GH9352)

```python
In [10]: s = pd.Series(['12', '300', '25'])
In [11]: s.str.pad(5, fillchar='_')
```

```
Out[11]:
0 ___12
1 __300
2 ___25
Length: 3, dtype: object
```

• Added Series.str.slice_replace(), which previously raised NotImplementedError (GH8888)

```python
In [12]: s = pd.Series(['ABCD', 'EFGH', 'IJK'])
In [13]: s.str.slice_replace(1, 3, 'X')
```

```
Out[13]:
0 AXD
1 EXH
2 IX
Length: 3, dtype: object
```

Other enhancements

• Reindex now supports method='nearest' for frames or series with a monotonic increasing or decreasing index (GH9258):

```python
In [15]: df = pd.DataFrame({'x': range(5)})
In [16]: df.reindex([0.2, 1.8, 3.5], method='nearest')
```

(continues on next page)
This method is also exposed by the lower level `Index.get_indexer` and `Index.get_loc` methods.

- The `read_excel()` function’s `sheetname` argument now accepts a list and `None`, to get multiple or all sheets respectively. If more than one sheet is specified, a dictionary is returned. (GH9450)

```python
# Returns the 1st and 4th sheet, as a dictionary of DataFrames.
pd.read_excel('path_to_file.xls', sheetname=['Sheet1', 3])
```

- Allow Stata files to be read incrementally with an iterator; support for long strings in Stata files. See the docs [here](GH9493:).

- Paths beginning with `~` will now be expanded to begin with the user’s home directory (GH9066)

- Added time interval selection in `get_data_yahoo` (GH9071)

- Added `Timestamp.to_datetime64()` to complement `Timedelta.to_timedelta64()` (GH9255)

- `tseries.frequencies.to_offset()` now accepts `Timedelta` as input (GH9064)

- Lag parameter was added to the autocorrelation method of `Series`, defaults to lag-1 autocorrelation (GH9192)

- `Timedelta` will now accept `nanoseconds` keyword in constructor (GH9273)

- SQL code now safely escapes table and column names (GH8986)

- Added auto-complete for `Series.str.<tab>`, `Series.dt.<tab>` and `Series.cat.<tab>` (GH9322)

- `Index.get_indexer` now supports `method='pad'` and `method='backfill'` even for any target array, not just monotonic targets. These methods also work for monotonic decreasing as well as monotonic increasing indexes (GH9258).

- `Index.asof` now works on all index types (GH9258).

- A verbose argument has been augmented in `io.read_excel()`, defaults to False. Set to True to print sheet names as they are parsed. (GH9450)

- Added `days_in_month` (compatibility alias `daysinmonth`) property to `Timestamp`, `DatetimeIndex`, `Period`, `PeriodIndex`, and `Series.dt` (GH9572)

- Added decimal option in `to_csv` to provide formatting for non-`'.'` decimal separators (GH781)

- Added `normalize` option for `Timestamp` to normalized to midnight (GH8794)

- Added example for `DataFrame` import to R using HDF5 file and `rhdf5` library. See the [documentation](GH9636) for more.
Backwards incompatible API changes

Changes in timedelta

In v0.15.0 a new scalar type `Timedelta` was introduced, that is a sub-class of `datetime.timedelta`. Mentioned here was a notice of an API change w.r.t. the `.seconds` accessor. The intent was to provide a user-friendly set of accessors that give the ‘natural’ value for that unit, e.g. if you had a `Timedelta('1 day, 10:11:12')`, then `.seconds` would return 12. However, this is at odds with the definition of `datetime.timedelta`, which defines `.seconds` as $10 \times 3600 + 11 \times 60 + 12 = 36672$.

So in v0.16.0, we are restoring the API to match that of `datetime.timedelta`. Further, the component values are still available through the `.components` accessor. This affects the `.seconds` and `.microseconds` accessors, and removes the `.hours`, `.minutes`, `.milliseconds` accessors. These changes affect `TimedeltaIndex` and the Series `.dt` accessor as well. (GH9185, GH9139)

```
In [2]: t = pd.Timedelta('1 day, 10:11:12.100123')
In [3]: t.days
Out[3]: 1
In [4]: t.seconds
Out[4]: 12
In [5]: t.microseconds
Out[5]: 123
```

Previous behavior

```
In [17]: t = pd.Timedelta('1 day, 10:11:12.100123')
In [18]: t.days
Out[18]: 1
In [19]: t.seconds
Out[19]: 36672
In [20]: t.microseconds
Out[20]: 100123
```

New behavior

Using `.components` allows the full component access

```
In [21]: t.components
Out[21]: Components(days=1, hours=10, minutes=11, seconds=12, milliseconds=100, microseconds=123, nanoseconds=0)
In [22]: t.components.seconds
Out[22]: 12
```
Indexing changes

The behavior of a small sub-set of edge cases for using `.loc` have changed (GH8613). Furthermore we have improved the content of the error messages that are raised:

- Slicing with `.loc` where the start and/or stop bound is not found in the index is now allowed; this previously would raise a `KeyError`. This makes the behavior the same as `.ix` in this case. This change is only for slicing, not when indexing with a single label.

```python
In [23]: df = pd.DataFrame(np.random.randn(5, 4),
   ....:     columns=list('ABCD'),
   ....:     index=pd.date_range('20130101', periods=5))

In [24]: df
Out[24]:
   A    B    C    D
2013-01-01 0.469112 -0.282863 -1.509059 -1.135632
2013-01-02 1.212112 -0.173215  0.119209 -1.044236
2013-01-03 -0.861849 -2.104569 -0.494929  1.071804
2013-01-04  0.721555 -0.706771 -1.039575  0.271860
2013-01-05 -0.424972  0.567020  0.276232 -1.087401
[5 rows x 4 columns]

In [25]: s = pd.Series(range(5), [-2, -1, 1, 2, 3])

In [26]: s
Out[26]:
   -2  0
   -1  1
    1  2
    2  3
    3  4
Length: 5, dtype: int64
```

Previous behavior

```python
In [4]: df.loc['2013-01-02':'2013-01-10']
KeyError: 'stop bound [2013-01-10] is not in the [index]'

In [6]: s.loc[-10:3]
KeyError: 'start bound [-10] is not the [index]'
```

New behavior

```python
In [27]: df.loc['2013-01-02':'2013-01-10']
Out[27]:
   A    B    C    D
2013-01-02 1.212112 -0.173215  0.119209 -1.044236
2013-01-03 -0.861849 -2.104569 -0.494929  1.071804
2013-01-04  0.721555 -0.706771 -1.039575  0.271860
2013-01-05 -0.424972  0.567020  0.276232 -1.087401
[4 rows x 4 columns]

In [28]: s.loc[-10:3]
Out[28]:
   -2  0
   -1  1
    1  2
    2  3
    3  4
(continues on next page)
```
- Allow slicing with float-like values on an integer index for `.ix`. Previously this was only enabled for `.loc`:

  Previous behavior

  ```python
  In [8]: s.ix[-1.0:2]
  TypeError: the slice start value [-1.0] is not a proper indexer for this index
  →type (Int64Index)
  ```

  New behavior

  ```python
  In [2]: s.ix[-1.0:2]
  Out[2]:
  -1  1
   1  2
   2  3
  dtype: int64
  ```

- Provide a useful exception for indexing with an invalid type for that index when using `.loc`. For example trying to use `.loc` on an index of type `DatetimeIndex` or `PeriodIndex` or `TimedeltaIndex`, with an integer (or a float).

  Previous behavior

  ```python
  In [4]: df.loc[2:3]
  KeyError: 'start bound [2] is not the [index]'
  ```

  New behavior

  ```python
  In [4]: df.loc[2:3]
  TypeError: Cannot do slice indexing on <class 'pandas.tseries.index.DatetimeIndex'> with <type 'int'> keys
  ```

**Categorical changes**

In prior versions, Categoricals that had an unspecified ordering (meaning no ordered keyword was passed) were defaulted as ordered Categoricals. Going forward, the ordered keyword in the Categorical constructor will default to False. Ordering must now be explicit.

Furthermore, previously you could change the ordered attribute of a Categorical by just setting the attribute, e.g. `cat.ordered=True`; This is now deprecated and you should use `cat.as_ordered()` or `cat.as_unordered()`. These will by default return a new object and not modify the existing object. (GH9347, GH9190)

Previous behavior

```python
In [3]: s = pd.Series([0, 1, 2], dtype='category')
In [4]: s
(continues on next page)```
Out[4]:
0 0
1 1
2 2
dtype: category
Categories (3, int64): [0 < 1 < 2]

In [5]: s.cat.ordered
Out[5]: True

In [6]: s.cat.ordered = False

In [7]: s
Out[7]:
0 0
1 1
2 2
dtype: category
Categories (3, int64): [0, 1, 2]

New behavior

In [29]: s = pd.Series([0, 1, 2], dtype='category')

In [30]: s
Out[30]:
0 0
1 1
2 2
Length: 3, dtype: category
Categories (3, int64): [0, 1, 2]

In [31]: s.cat.ordered
Out[31]: False

In [32]: s = s.cat.as_ordered()

In [33]: s
Out[33]:
0 0
1 1
2 2
Length: 3, dtype: category
Categories (3, int64): [0 < 1 < 2]

In [34]: s.cat.ordered
Out[34]: True

# you can set in the constructor of the Categorical
In [35]: s = pd.Series(pd.Categorical([0, 1, 2], ordered=True))

In [36]: s
Out[36]:
0 0
1 1
2 2
Length: 3, dtype: category
For ease of creation of series of categorical data, we have added the ability to pass keywords when calling .
astype(). These are passed directly to the constructor.

```python
In [54]: s = pd.Series(["a", "b", "c", "a"]).astype('category', ordered=True)

In [55]: s
Out[55]:
0   a
1   b
2   c
3   a
dtype: category
Categories (3, object): [a < b < c]
```

```python
In [56]: s = (pd.Series(["a", "b", "c", "a"])
       ....: .astype('category', categories=list('abcdef'), ordered=False))

In [57]: s
Out[57]:
0   a
1   b
2   c
3   a
dtype: category
Categories (6, object): [a, b, c, d, e, f]
```

**Other API changes**

- `Index.duplicated now returns np.array(dtype=bool)` rather than `Index(dtype=object)` containing bool values. (GH8875)

- `DataFrame.to_json now returns accurate type serialisation for each column for frames of mixed dtype` (GH9037)

Previously data was coerced to a common dtype before serialisation, which for example resulted in integers being serialised to floats:

```python
In [2]: pd.DataFrame({'i': [1,2], 'f': [3.0, 4.2]}).to_json()
Out[2]: '{"f":{"0":3.0,"1":4.2},"i":{"0":1.0,"1":2.0}}'
```

Now each column is serialised using its correct dtype:

```python
In [2]: pd.DataFrame({'i': [1,2], 'f': [3.0, 4.2]}).to_json()
Out[2]: '{"f":{"0":3.0,"1":4.2},"i":{"0":1,"1":2}}'
```

- `DatetimeIndex, PeriodIndex and TimedeltaIndex.summary now output the same format.` (GH9116)

- `TimedeltaIndex.freqstr now output the same string format as DatetimeIndex.` (GH9116)
• Bar and horizontal bar plots no longer add a dashed line along the info axis. The prior style can be achieved with matplotlib’s `axhline` or `axvline` methods (GH9088).

• Series accessors `.dt`, `.cat` and `.str` now raise AttributeError instead of TypeError if the series does not contain the appropriate type of data (GH9617). This follows Python’s built-in exception hierarchy more closely and ensures that tests like `hasattr(s, 'cat')` are consistent on both Python 2 and 3.

• Series now supports bitwise operation for integral types (GH9016). Previously even if the input dtypes were integral, the output dtype was coerced to bool.

Previous behavior

```
In [2]: pd.Series([0, 1, 2, 3], list('abcd')) | pd.Series([4, 4, 4, 4], list('abcd'))
Out[2]:
a True
b True
c True
d True
dtype: bool
```

New behavior. If the input dtypes are integral, the output dtype is also integral and the output values are the result of the bitwise operation.

```
In [2]: pd.Series([0, 1, 2, 3], list('abcd')) | pd.Series([4, 4, 4, 4], list('abcd'))
Out[2]:
a  4
b  5
c  6
d  7
dtype: int64
```

• During division involving a Series or DataFrame, `0/0` and `0//0` now give `np.nan` instead of `np.inf` (GH9144, GH8445)

Previous behavior

```
In [2]: p = pd.Series([0, 1])
In [3]: p / 0
Out[3]:
0   inf
1   inf
dtype: float64
```

```
In [4]: p // 0
Out[4]:
0   inf
1   inf
dtype: float64
```

New behavior

```
In [38]: p = pd.Series([0, 1])
In [39]: p / 0
Out[39]:
0   NaN
```
1   inf
Length: 2, dtype: float64

In [40]: p // 0
Out[40]:
0   NaN
1   inf
Length: 2, dtype: float64

- `Series.values_counts` and `Series.describe` for categorical data will now put `NaN` entries at the end. (GH9443)
- `Series.describe` for categorical data will now give counts and frequencies of 0, not `NaN`, for unused categories (GH9443)
- Due to a bug fix, looking up a partial string label with `DatetimeIndex.asof` now includes values that match the string, even if they are after the start of the partial string label (GH9258).

Old behavior:

```python
In [4]: pd.to_datetime(['2000-01-31', '2000-02-28']).asof('2000-02')
Out[4]: Timestamp('2000-01-31 00:00:00')
```

Fixed behavior:

```python
In [41]: pd.to_datetime(['2000-01-31', '2000-02-28']).asof('2000-02')
Out[41]: Timestamp('2000-02-28 00:00:00')
```

To reproduce the old behavior, simply add more precision to the label (e.g., use `2000-02-01` instead of `2000-02`).

**Deprecations**

- The `rplot` trellis plotting interface is deprecated and will be removed in a future version. We refer to external packages like `seaborn` for similar but more refined functionality (GH3445). The documentation includes some examples how to convert your existing code from `rplot` to `seaborn` here.

- The `pandas.sandbox.qtpandas` interface is deprecated and will be removed in a future version. We refer users to the external package `pandas-qt`. (GH9615)

- The `pandas.rpy` interface is deprecated and will be removed in a future version. Similar functionality can be accessed through the `rpy2` project (GH9602)

- Adding `DatetimeIndex/PeriodIndex` to another `DatetimeIndex/PeriodIndex` is being deprecated as a set-operation. This will be changed to a `TypeError` in a future version. `.union()` should be used for the union set operation. (GH9094)

- Subtracting `DatetimeIndex/PeriodIndex` from another `DatetimeIndex/PeriodIndex` is being deprecated as a set-operation. This will be changed to an actual numeric subtraction yielding a `TimeDeltaIndex` in a future version. `.difference()` should be used for the differencing set operation. (GH9094)
Removal of prior version deprecations/changes

- DataFrame.pivot_table and crosstab's rows and cols keyword arguments were removed in favor of index and columns (GH6581)
- DataFrame.to_excel and DataFrame.to_csv cols keyword argument was removed in favor of columns (GH6581)
- Removed convert_dummies in favor of get_dummies (GH6581)
- Removed value_range in favor of describe (GH6581)

Performance improvements

- Fixed a performance regression for .loc indexing with an array or list-like (GH9126).
- DataFrame.to_json 30x performance improvement for mixed dtype frames. (GH9037)
- Performance improvements in MultiIndex.duplicated by working with labels instead of values (GH9125)
- Improved the speed of nunique by calling unique instead of value_counts (GH9129, GH7771)
- Performance improvement of up to 10x in DataFrame.count and DataFrame.dropna by taking advantage of homogeneous/heterogeneous dtypes appropriately (GH9136)
- Performance improvement of up to 20x in DataFrame.count when using a MultiIndex and the level keyword argument (GH9163)
- Performance and memory usage improvements in merge when key space exceeds int64 bounds (GH9151)
- Performance improvements in multi-key groupby (GH9429)
- Performance improvements in MultiIndex.sortlevel (GH9445)
- Performance and memory usage improvements in DataFrame.duplicated (GH9398)
- Cythonized Period (GH9440)
- Decreased memory usage on to_hdf (GH9648)

Bug fixes

- Changed .to_html to remove leading/trailing spaces in table body (GH4987)
- Fixed issue using read_csv on s3 with Python 3 (GH9452)
- Fixed compatibility issue in DatetimeIndex affecting architectures where numpy.int_ defaults to numpy.int32 (GH8943)
- Bug in Panel indexing with an object-like (GH9140)
- Bug in the returned Series.dt.components index was reset to the default index (GH9247)
- Bug in Categorical.__getitem__/__setitem__ with listlike input getting incorrect results from indexer coercion (GH9469)
- Bug in partial setting with a DatetimeIndex (GH9478)
- Bug in groupby for integer and datetime64 columns when applying an aggregator that caused the value to be changed when the number was sufficiently large (GH9311, GH6620)
- Fixed bug in `to_sql` when mapping a `Timestamp` object column (datetime column with timezone info) to the appropriate sqlalchemy type (GH9085).
- Fixed bug in `to_sql` when mapping a `Timestamp` object column to the appropriate sqlalchemy type (GH9083).
- Bug in `.loc` partial setting with `np.datetime64` (GH9516)
- Incorrect dtypes inferred on datetimelike looking `Series` & on `.xs` slices (GH9477)
- Items in `Categorical.unique()` (and `s.unique() if s is of dtype category`) now appear in the order in which they are originally found, not in sorted order (GH9331). This is now consistent with the behavior for other dtypes in pandas.
- Fixed bug on big endian platforms which produced incorrect results in StataReader (GH8688).
- Bug in `MultiIndex.has_duplicates` when having many levels causes an indexer overflow (GH9075, GH5873)
- Bug in `pivot` and `unstack` where `nan` values would break index alignment (GH4862, GH7401, GH7403, GH7405, GH7466, GH9497)
- Bug in `left join` on `MultiIndex` with `sort=True` or null values (GH9210).
- Bug in `MultiIndex` where inserting new keys would fail (GH9250).
- Bug in `groupby` when key space exceeds int64 bounds (GH9096).
- Bug in `unstack` with `TimedeltaIndex` or `DatetimeIndex` and nulls (GH9491).
- Bug in `rank` where comparing floats with tolerance will cause inconsistent behaviour (GH8365).
- Fixed character encoding bug in `read_stata` and StataReader when loading data from a URL (GH9231).
- Bug in `adding offsets.Nano` to other offsets raises `TypeError` (GH9284)
- Bug in `datetime_index.iteration`, related to (GH8890), fixed in (GH9100)
- Bugs in `resample` around DST transitions. This required fixing offset classes so they behave correctly on DST transitions. (GH5172, GH8744, GH8653, GH9173, GH9468).
- Bug in `binary operator method (eg .mul())` alignment with integer levels (GH9463).
- Bug in `boxplot`, scatter and hexbin plot may show an unnecessary warning (GH8877)
- Bug in `subplot` with `layout kw` may show unnecessary warning (GH9464)
- Bug in using grouper functions that need passed through arguments (e.g. axis), when using wrapped function (e.g. `fillna`), (GH9221)
- `DataFrame` now properly supports simultaneous `copy` and `dtype` arguments in constructor (GH9099)
- Bug in `read_csv` when using skiprows on a file with CR line endings with the c engine. (GH9079)
- `isnull` now detects NaT in `PeriodIndex` (GH9129)
- Bug in `groupby .nth()` with a multiple column groupby (GH8979)
- Bug in `DataFrame.where` and `Series.where` coerce numerics to string incorrectly (GH9280)
- Bug in `DataFrame.where` and `Series.where` raise `ValueError` when string list-like is passed. (GH9280)
- Accessing `Series.str` methods on with non-string values now raises `TypeError` instead of producing incorrect results (GH9184)
- Bug in `DatetimeIndex.__contains__` when index has duplicates and is not monotonic increasing (GH9512)
• Fixed division by zero error for `Series.kurt()` when all values are equal (GH9197)
• Fixed issue in the `xlsxwriter` engine where it added a default ‘General’ format to cells if no other format was applied. This prevented other row or column formatting being applied. (GH9167)
• Fixes issue with `index_col=False` when `usecols` is also specified in `read_csv`. (GH9082)
• Bug where `wide_to_long` would modify the input stub names list (GH9204)
• Bug in `to_sql` not storing float64 values using double precision. (GH9009)
• SparseSeries and SparsePanel now accept zero argument constructors (same as their non-sparse counterparts) (GH9272).
• Regression in merging Categorical and object dtypes (GH9426)
• Bug in `read_csv` with buffer overflows with certain malformed input files (GH9205)
• Bug in groupby `MultiIndex` with missing pair (GH9049, GH9344)
• Fixed bug in `Series.groupby` where grouping on MultiIndex levels would ignore the sort argument (GH9444)
• Fix bug in `DataFrame.Groupby` where `sort=False` is ignored in the case of Categorical columns. (GH8868)
• Fixed bug with reading CSV files from Amazon S3 on python 3 raising a TypeError (GH9452)
• Bug in the Google BigQuery reader where the ‘jobComplete’ key may be present but False in the query results (GH8728)
• Bug in `Series.values_counts` with excluding NaN for categorical type `Series` with `dropna=True` (GH9443)
• Fixed missing numeric_only option for `DataFrame.std/var/sem` (GH9201)
• Support constructing `Panel` or `Panel4D` with scalar data (GH8285)
• Series text representation disconnected from `max_rows/max_columns` (GH7508).
• Series number formatting inconsistent when truncated (GH8532).

Previous behavior

```
In [2]: pd.options.display.max_rows = 10
In [3]: s = pd.Series([1,1,1,1,1,1,1,1,1,1,0.9999,1,1]*10)
In [4]: s
Out[4]:
   0    1.0000
   1    1.0000
   2    1.0000
   ...    ...
  127  0.9999
  128   1.0000
  129   1.0000

Length: 130, dtype: float64
```

New behavior

```
0    1.0000
1    1.0000
2    1.0000
3    1.0000
4    1.0000
```
... 125 1.0000 126 1.0000 127 0.9999 128 1.0000 129 1.0000 dtype: float64

- A Spurious `SettingWithCopy` Warning was generated when setting a new item in a frame in some cases (GH8730)

The following would previously report a `SettingWithCopy` Warning.

```python
In [42]: df1 = pd.DataFrame({'x': pd.Series(['a', 'b', 'c']),
                      'y': pd.Series(['d', 'e', 'f'])})

In [43]: df2 = df1["x"]

In [44]: df2['y'] = ['g', 'h', 'i']
```

5.13  Version 0.15

5.13.1  Version 0.15.2 (December 12, 2014)

This is a minor release from 0.15.1 and includes a large number of bug fixes along with several new features, enhancements, and performance improvements. A small number of API changes were necessary to fix existing bugs. We recommend that all users upgrade to this version.

- Enhancements
- API Changes
- Performance Improvements
- Bug Fixes

API changes

- Indexing in MultiIndex beyond lex-sort depth is now supported, though a lexically sorted index will have a better performance. (GH2646)

```python
In [1]: df = pd.DataFrame({
       'jim': [0, 0, 1, 1],
       'joe': ['x', 'x', 'z', 'y'],
       'jolie': np.random.rand(4)
}).set_index(['jim', 'joe'])

In [2]: df
Out[2]:
      jolie
     jim  joe
0    x  0.126970
  x  0.966718
1    z  0.260476
  y  0.897237
[4 rows x 1 columns]

In [3]: df.index.lexsort_depth
Out[3]: 1

# in prior versions this would raise a KeyError
# will now show a PerformanceWarning

In [4]: df.loc[(1, 'z')]
Out[4]:
      jolie
     jim  joe
1    z  0.260476
```

(continues on next page)
### lexically sorting

```python
In [5]: df2 = df.sort_index()

In [6]: df2
Out[6]:
    jolie
   jim   joe
0    x  0.126970
     x  0.966718
1    y  0.897237
     z  0.260476
[4 rows x 1 columns]
```

```python
In [7]: df2.index.lexsort_depth
Out[7]:
[97x678]2

In [8]: df2.loc[(1,'z')]
Out[8]:
    jolie
   jim   joe
1    z  0.260476
[1 rows x 1 columns]
```

• Bug in unique of Series with category dtype, which returned all categories regardless whether they were “used” or not (see GH8559 for the discussion). Previous behaviour was to return all categories:

```python
In [3]: cat = pd.Categorical(['a', 'b', 'a'], categories=['a', 'b', 'c'])

In [4]: cat
Out[4]:
[a, b, a]
Categories (3, object): [a < b < c]

In [5]: cat.unique()
Out[5]: array(['a', 'b', 'c'], dtype=object)
```

Now, only the categories that do effectively occur in the array are returned:

```python
In [9]: cat = pd.Categorical(['a', 'b', 'a'], categories=['a', 'b', 'c'])

In [10]: cat.unique()
Out[10]:
['a', 'b']
Categories (2, object): ['a', 'b']
```

• Series.all and Series.any now support the level and skipna parameters. Series.all, Series.any, Index.all, and Index.any no longer support the out and keepdims parameters, which existed for compatibility with ndarray. Various index types no longer support the all and any aggregation functions and will now raise TypeError. (GH8302).

• Allow equality comparisons of Series with a categorical dtype and object dtype; previously these would raise TypeError (GH8938)
• Bug in NDFrame: conflicting attribute/column names now behave consistently between getting and setting. Previously, when both a column and attribute named y existed, data.y would return the attribute, while data.y = z would update the column (GH8994)

```python
In [11]: data = pd.DataFrame({'x': [1, 2, 3]})
In [12]: data.y = 2
In [13]: data['y'] = [2, 4, 6]

In [14]: data
Out[14]:
   x  y
0 1  2
1 2  4
2 3  6

[3 rows x 2 columns]

# this assignment was inconsistent
In [15]: data.y = 5
```

Old behavior:

```python
In [6]: data.y
Out[6]: 2

In [7]: data['y'].values
Out[7]: array([5, 5, 5])
```

New behavior:

```python
In [16]: data.y
Out[16]: 5

In [17]: data['y'].values
Out[17]: array([2, 4, 6])
```

• Timestamp('now') is now equivalent to Timestamp.now() in that it returns the local time rather than UTC. Also, Timestamp('today') is now equivalent to Timestamp.today() and both have tz as a possible argument. (GH9000)

• Fix negative step support for label-based slices (GH8753)

Old behavior:

```python
In [1]: s = pd.Series(np.arange(3), ['a', 'b', 'c'])
Out[1]:
   a  0
   b  1
   c  2
dtype: int64

In [2]: s.loc['c':'a':-1]
Out[2]:
   c  2
dtype: int64
```

New behavior:
Enhancements

Categorical enhancements:

- Added ability to export Categorical data to Stata (GH8633). See here for limitations of categorical variables exported to Stata data files.

- Added flag `order_categoricals` to StataReader and read_stata to select whether to order imported categorical data (GH8836). See here for more information on importing categorical variables from Stata data files.

- Added ability to export Categorical data to/to from HDF5 (GH7621). Queries work the same as if it was an object array. However, the `category` dtyped data is stored in a more efficient manner. See here for an example and caveats w.r.t. prior versions of pandas.

- Added support for `searchsorted()` on `Categorical` class (GH8420).

Other enhancements:

- Added the ability to specify the SQL type of columns when writing a DataFrame to a database (GH8778). For example, specifying to use the sqlalchemy `String` type instead of the default `Text` type for string columns:

```python
from sqlalchemy.types import String
data.to_sql('data_dtype', engine, dtype={'Col_1': String})  # noqa F821
```

- `Series.all` and `Series.any` now support the `level` and `skipna` parameters (GH8302):

```python
In [20]: s = pd.Series([[False, True, False], index=[0, 0, 1])

In [21]: s.any(level=0)
Out [21]:
0  True
1  False
Length: 2, dtype: bool
```

- Panel now supports the `all` and `any` aggregation functions. (GH8302):

```python
>>> p = pd.Panel(np.random.rand(2, 5, 4) > 0.1)
>>> p.all()
    0 1 2 3
0 True True True True
1 True False True True
2 True True True True
3 False True False True
4 True True True True
```

- Added support for `utcfromtimestamp()`, `fromtimestamp()`, and `combine()` on `Timestamp` class (GH5351).
• Added Google Analytics (pandas.io.ga) basic documentation (GH8835). See here.
• Timedelta arithmetic returns NotImplemented in unknown cases, allowing extensions by custom classes (GH8813).
• Timedelta now supports arithmetic with numpy.ndarray objects of the appropriate dtype (numpy 1.8 or newer only) (GH8884).
• Added Timedelta.to_timedelta64() method to the public API (GH8884).
• Added gbq.generate_bq_schema() function to the gbq module (GH8325).
• Series now works with map objects the same way as generators (GH8909).
• Added context manager to HDFStore for automatic closing (GH8791).
• to_datetime gains an exact keyword to allow for a format to not require an exact match for a provided format string (if its False). exact defaults to True (meaning that exact matching is still the default) (GH8904)
• Added axvlines boolean option to parallel_coordinates plot function, determines whether vertical lines will be printed, default is True
• Added ability to read table footers to read_html (GH8552)
• to_sql now infers data types of non-NA values for columns that contain NA values and have dtype object (GH8778).

Performance

• Reduce memory usage when skiprows is an integer in read_csv (GH8681)
• Performance boost for to_datetime conversions with a passed format=, and the exact=False (GH8904)

Bug fixes

• Bug in concat of Series with category dtype which were coercing to object. (GH8641)
• Bug in Timestamp-Timestamp not returning a Timedelta type and datelike-datelike ops with timezones (GH8865)
• Made consistent a timezone mismatch exception (either tz operated with None or incompatible timezone), will now return TypeError rather than ValueError (a couple of edge cases only), (GH8865)
• Bug in using a pd.Grouper(key=...) with no level/axis or level only (GH8795, GH8866)
• Report a TypeError when invalid/no parameters are passed in a groupby (GH8015)
• Bug in packaging pandas with py2app/cx_Freeze (GH8602, GH8831)
• Bug in groupby signatures that didn’t include *args or **kwargs (GH8733).
• io.data.Options now raises RemoteDataError when no expiry dates are available from Yahoo and when it receives no data from Yahoo (GH8761), (GH8783).
• Unclear error message in csv parsing when passing dtype and names and the parsed data is a different data type (GH8833)
• Bug in slicing a MultiIndex with an empty list and at least one boolean indexer (GH8781)
• io.data.Options now raises RemoteDataError when no expiry dates are available from Yahoo (GH8761).
• Timedelta kwargs may now be numpys ints and floats (GH8757).
- Fixed several outstanding bugs for Timedelta arithmetic and comparisons (GH8813, GH5963, GH5436).
- `sql_schema` now generates dialect appropriate CREATE TABLE statements (GH8697)
- `slice` string method now takes step into account (GH8754)
- **Bug** in `BlockManager` where setting values with different type would break block integrity (GH8850)
- **Bug** in `DatetimeIndex` when using time object as key (GH8667)
- **Bug** in `merge` where how='left' and sort=False would not preserve left frame order (GH7331)
- **Bug** in `MultiIndex.reindex` where reindexing at level would not reorder labels (GH4088)
- **Bug** in certain operations with dateutil timezones, manifesting with dateutil 2.3 (GH8639)
- Regression in DatetimeIndex iteration with a Fixed/Local offset timezone (GH8890)
- **Bug** in `to_datetime` when parsing a nanoseconds using the %f format (GH8989)
- `io.data.Options` now raises RemoteDataError when no expiry dates are available from Yahoo and when it receives no data from Yahoo (GH8761), (GH8783).
- Fix: The font size was only set on x axis if vertical or the y axis if horizontal. (GH8765)
- Fixed division by 0 when reading big csv files in python 3 (GH8621)
- **Bug** in outputting a MultiIndex with to_html, index=False which would add an extra column (GH8452)
- Imported categorical variables from Stata files retain the ordinal information in the underlying data (GH8836).
- Defined `.size` attribute across NDFrame objects to provide compat with numpy >= 1.9.1; buggy with np. array_split (GH8846)
- Skip testing of histogram plots for matplotlib <= 1.2 (GH8648).
- **Bug** where `get_data_google` returned object dtypes (GH3995)
- **Bug** in `DataFrame.stack(..., dropna=False)` when the `DataFrame`'s columns is a MultiIndex whose labels do not reference all its levels. (GH8844)
- **Bug** in that Option context applied on __enter__ (GH8514)
- **Bug** in resample that causes a ValueError when resampling across multiple days and the last offset is not calculated from the start of the range (GH8683)
- **Bug** where `DataFrame.plot(kind='scatter')` fails when checking if an np.array is in the DataFrame (GH8852)
- `in` pd.infer_freq/DataFrame.inferred_freq that prevented proper sub-daily frequency inference when the index contained DST days (GH8772).
- **Bug** where index name was still used when plotting a series with use_index=False (GH8558).
- **Bugs** when trying to stack multiple columns, when some (or all) of the level names are numbers (GH8584).
- **Bug** in `MultiIndex` where __contains__ returns wrong result if index is not lexically sorted or unique (GH7724)
- **BUG CSV:** fix problem with trailing white space in skipped rows, (GH8679), (GH8661), (GH8983)
- **Regression** in `Timestamp` does not parse ‘Z’ zone designator for UTC (GH8777)
- **Bug** in `StataWriter` the produces writes strings with 244 characters irrespective of actual size (GH8969)
- Fixed ValueError raised by cummin/cummax when datetime64 Series contains NaT. (GH8965)
- **Bug** in `DataReader` returns object dtype if there are missing values (GH8980)
Bug in plotting if sharex was enabled and index was a timeseries, would show labels on multiple axes (GH3964).

Bug where passing a unit to the TimedeltaIndex constructor applied the to nano-second conversion twice. (GH9011).

Bug in plotting of a period-like array (GH9012)

5.13.2 Version 0.15.1 (November 9, 2014)

This is a minor bug-fix release from 0.15.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

- Enhancements
- API Changes
- Bug Fixes

API changes

- `s.dt.hour` and other `.dt` accessors will now return `np.nan` for missing values (rather than previously -1), (GH8689)

\begin{verbatim}
In [1]: s = pd.Series(pd.date_range('20130101', periods=5, freq='D'))
In [2]: s.iloc[2] = np.nan
In [3]: s
Out [3]:
\end{verbatim}
previous behavior:

```
In [6]: s.dt.hour
Out[6]:
0   0
1   0
2  -1
3   0
4   0
dtype: int64
```

current behavior:

```
In [4]: s.dt.hour
Out[4]:
0   0.0
1   0.0
2  NaN
3   0.0
4   0.0
Length: 5, dtype: float64
```

- `groupby` with `as_index=False` will not add erroneous extra columns to result (GH8582):

  previous behavior:

  ```
  In [4]: df.groupby(ts, as_index=False).max()
  Out[4]:
   NaN  jim  joe
  0  72  81
  ```

```
• groupby will not erroneously exclude columns if the column name conflicts with the grouper name (GH8112):

```
In [10]: df = pd.DataFrame({'jim': range(5), 'joe': range(5, 10)})
In [11]: df
Out[11]:
   jim  joe
0    0   5
1    1   6
2    2   7
3    3   8
4    4   9
[5 rows x 2 columns]
In [12]: gr = df.groupby(df['jim'] < 2)
```

previous behavior (excludes 1st column from output):

```
In [4]: gr.apply(sum)
Out[4]:
   joe
jim False 24
     True 11
```

current behavior:

```
In [13]: gr.apply(sum)
Out[13]:
   jim  joe
     jim
jim False  9  24
     True  1  11
[2 rows x 2 columns]
```

• Support for slicing with monotonic decreasing indexes, even if start or stop is not found in the index (GH7860):

```
In [14]: s = pd.Series(['a', 'b', 'c', 'd'], [4, 3, 2, 1])
```
previous behavior:

```
In [8]: s.loc[3.5:1.5]
KeyError: 3.5
```

current behavior:

```
In [16]: s.loc[3.5:1.5]
Out[16]:
3   b
2   c
Length: 2, dtype: object
```

- `io.data.Options` has been fixed for a change in the format of the Yahoo Options page (GH8612), (GH8741)

**Note:** As a result of a change in Yahoo’s option page layout, when an expiry date is given, `Options` methods now return data for a single expiry date. Previously, methods returned all data for the selected month.

The `month` and `year` parameters have been undeprecated and can be used to get all options data for a given month.

If an expiry date that is not valid is given, data for the next expiry after the given date is returned.

Option data frames are now saved on the instance as `callsYYMMDD` or `putsYYMMDD`. Previously they were saved as `callsMMYY` and `putsMMYY`. The next expiry is saved as `calls` and `puts`.

New features:
- The expiry parameter can now be a single date or a list-like object containing dates.
- A new property `expiry_dates` was added, which returns all available expiry dates.

Current behavior:

```
In [17]: from pandas.io.data import Options

In [18]: aapl = Options('aapl', 'yahoo')

In [19]: aapl.get_call_data().iloc[0:5, 0:1]
Out[19]:
Last
Strike Expiry Type Symbol      
80 2014-11-14 call AAPL141114C00080000 29.05
84 2014-11-14 call AAPL141114C00084000 24.80
85 2014-11-14 call AAPL141114C00085000 24.05
86 2014-11-14 call AAPL141114C00086000 22.76
87 2014-11-14 call AAPL141114C00087000 21.74
```

(continues on next page)
In [20]: aapl.expiry_dates
Out[20]:
[datetime.date(2014, 11, 14),
datetime.date(2014, 11, 22),
datetime.date(2014, 11, 28),
datetime.date(2014, 12, 5),
datetime.date(2014, 12, 12),
datetime.date(2014, 12, 20),
datetime.date(2015, 1, 17),

</tr>
</tbody>
</table>

- pandas now also registers the `datetime64` dtype in matplotlib’s units registry to plot such values as datetimes. This is activated once pandas is imported. In previous versions, plotting an array of `datetime64` values will have resulted in plotted integer values. To keep the previous behaviour, you can do `del matplotlib.units.registry[np.datetime64]` (GH8614).

**Enhancements**

- `concat` permits a wider variety of iterables of pandas objects to be passed as the first parameter (GH8645):

  In [17]: from collections import deque
  In [18]: df1 = pd.DataFrame([1, 2, 3])
  In [19]: df2 = pd.DataFrame([4, 5, 6])
  
  previous behavior:
  In [7]: pd.concat(deque((df1, df2)))
  TypeError: first argument must be a list-like of pandas objects, you passed an object of type "deque"
  
  current behavior:
  In [20]: pd.concat(deque((df1, df2)))
  Out[20]:
<table>
<thead>
<tr>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 1</td>
</tr>
<tr>
<td>1 2</td>
</tr>
<tr>
<td>2 3</td>
</tr>
<tr>
<td>0 4</td>
</tr>
</tbody>
</table>
• Represent `MultiIndex` labels with a dtype that utilizes memory based on the level size. In prior versions, the memory usage was a constant 8 bytes per element in each level. In addition, in prior versions, the reported memory usage was incorrect as it didn’t show the usage for the memory occupied by the underlying data array. (GH8456)

```
In [21]: dfi = pd.DataFrame(1, index=pd.MultiIndex.from_product([['a'], range(1000)]), columns=['A'])

previous behavior:
```

```
# this was underreported in prior versions
In [1]: dfi.memory_usage(index=True)
Out[1]:
Index 8000 # took about 24008 bytes in < 0.15.1
A 8000
dtype: int64
```

current behavior:

```
In [22]: dfi.memory_usage(index=True)
Out[22]:
Index 52080
A 8000
Length: 2, dtype: int64
```

• Added Index properties `is_monotonic_increasing` and `is_monotonic_decreasing` (GH8680).

• Added option to select columns when importing Stata files (GH7935)

• Qualify memory usage in `DataFrame.info()` by adding + if it is a lower bound (GH8578)

• Raise errors in certain aggregation cases where an argument such as `numeric_only` is not handled (GH8592).

• Added support for 3-character ISO and non-standard country codes in `io.wb.download()` (GH8482)

• World Bank data requests now will warn/raise based on an `errors` argument, as well as a list of hard-coded country codes and the World Bank’s JSON response. In prior versions, the error messages didn’t look at the World Bank’s JSON response. Problem-inducing input were simply dropped prior to the request. The issue was that many good countries were cropped in the hard-coded approach. All countries will work now, but some bad countries will raise exceptions because some edge cases break the entire response. (GH8482)

• Added option to `Series.str.split()` to return a `DataFrame` rather than a `Series` (GH8428)

• Added option to `df.info(null_counts=None|True|False)` to override the default display options and force showing of the null-counts (GH8701)
Bug fixes

- Bug in unpickling of a CustomBusinessDay object (GH8591)
- Bug in coercing Categorical to a records array, e.g. df.to_records() (GH8626)
- Bug in Categorical not created properly with Series.to_frame() (GH8626)
- Bug in coercing in astype of a Categorical of a passed pd.Categorical (this now raises TypeError correctly), (GH8626)
- Bug in cut/qcut when using Series and retbins=True (GH8589)
- Bug in writing Categorical columns to an SQL database with to_sql (GH8624).
- Bug in comparing Categorical of datetime raising when being compared to a scalar datetime (GH8687)
- Bug in selecting from a Categorical with .iloc (GH8623)
- Bug in groupby-transform with a Categorical (GH8623)
- Bug in duplicated/drop_duplicates with a Categorical (GH8623)
- Bug in Categorical reflected comparison operator raising if the first argument was a numpy array scalar (e.g. np.int64) (GH8658)
- Bug in Panel indexing with a list-like (GH8710)
- Compat issue is DataFrame.dtypes when options.mode.use_inf_as_null is True (GH8722)
- Bug in read_csv, dialect parameter would not take a string (GH8703)
- Bug in slicing a MultiIndex level with an empty-list (GH8737)
- Bug in numeric index operations of add/sub with Float/Index Index with numpy arrays (GH8608)
- Bug in setitem with empty indexer and unwanted coercion of dtypes (GH8669)
- Bug in ix/loc block splitting on setitem (manifests with integer-like dtypes, e.g. datetime64) (GH8607)
- Bug when doing label based indexing with integers not found in the index for non-unique but monotonic indexes (GH8680).
- Bug when indexing a Float64Index with np.nan on numpy 1.7 (GH8980).
- Fix shape attribute for MultiIndex (GH8609)
- Bug in GroupBy where a name conflict between the grouper and columns would break groupby operations (GH7115, GH8112)
- Fixed a bug where plotting a column y and specifying a label would mutate the index name of the original DataFrame (GH8494)
- Fix regression in plotting of a DatetimeIndex directly with matplotlib (GH8614).
- Bug in date_range where partially-specified dates would incorporate current date (GH6961)
- Bug in Setting by indexer to a scalar value with a mixed-dtype Panel4d was failing (GH8702)
- Bug whereDataReader's would fail if one of the symbols passed was invalid. Now returns data for valid symbols and np.nan for invalid (GH8494)
- Bug in get_quote_yahoo that wouldn’t allow non-float return values (GH5229).

5.13.3 Version 0.15.0 (October 18, 2014)

This is a major release from 0.14.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Warning: pandas >= 0.15.0 will no longer support compatibility with NumPy versions < 1.7.0. If you want to use the latest versions of pandas, please upgrade to NumPy >= 1.7.0 (GH7711)

• Highlights include:
  – The Categorical type was integrated as a first-class pandas type, see here
  – New scalar type Timedelta, and a new index type TimedeltaIndex, see here
- New datetimelike properties accessor `.dt` for Series, see *Datetimelike Properties*
- New DataFrame default display for `df.info()` to include memory usage, see *Memory Usage*
- `read_csv` will now by default ignore blank lines when parsing, see *here*
- API change in using Indexes in set operations, see *here*
- Enhancements in the handling of timezones, see *here*
- A lot of improvements to the rolling and expanding moment functions, see *here*
- Internal refactoring of the `Index` class to no longer sub-class `ndarray`, see *Internal Refactoring*
- dropping support for `PyTables` less than version 3.0.0, and `numexpr` less than version 2.1 (GH7990)
- Split indexing documentation into *Indexing and Selecting Data* and *MultiIndex / Advanced Indexing*
- Split out string methods documentation into *Working with Text Data*

• Check the *API Changes* and *deprecations* before updating

• *Other Enhancements*

• *Performance Improvements*

• *Bug Fixes*

---

**Warning:** In 0.15.0 `Index` has internally been refactored to no longer sub-class `ndarray` but instead subclass `PandasObject`, similarly to the rest of the pandas objects. This change allows very easy sub-classing and creation of new index types. This should be a transparent change with only very limited API implications (See the *Internal Refactoring*)

---

**Warning:** The refactoring in `Categorical` changed the two argument constructor from “codes/labels and levels” to “values and levels (now called ‘categories’)”. This can lead to subtle bugs. If you use `Categorical` directly, please audit your code before updating to this pandas version and change it to use the `from_codes()` constructor. See more on `Categorical here`

---

**New features**

**Categoricals in Series/DataFrame**

*Categorical* can now be included in *Series* and *DataFrames* and gained new methods to manipulate. Thanks to Jan Schulz for much of this API/implementation. (GH3943, GH5313, GH5314, GH7444, GH7839, GH7848, GH7864, GH7914, GH7768, GH8006, GH3678, GH8075, GH8076, GH8143, GH8453, GH8518).

For full docs, see the *categorical introduction* and the *API documentation*.

```
In [1]: df = pd.DataFrame({"id": [1, 2, 3, 4, 5, 6],
                    ...
                    "raw_grade": ['a', 'b', 'b', 'a', 'a', 'e']})
    ...

In [2]: df["grade"] = df["raw_grade"].astype("category")

In [3]: df["grade"]
Out[3]:
0    a
```
1 b
2 b
3 a
4 a
5 e
Name: grade, Length: 6, dtype: category
Categories (3, object): ['a', 'b', 'e']

# Rename the categories
In [4]: df['grade'].cat.categories = ['very good', 'good', 'very bad']

# Reorder the categories and simultaneously add the missing categories
In [5]: df['grade'] = df['grade'].cat.set_categories(
    ...: ['very bad', 'bad',
    ...:     'medium', 'good', 'very good'])

In [6]: df['grade']
Out[6]:
0 very good
1 good
2 good
3 very good
4 very good
5 very bad
Name: grade, Length: 6, dtype: category
Categories (5, object): ['very bad', 'bad', 'medium', 'good', 'very good']

In [7]: df.sort_values('grade')
Out[7]:
   id raw_grade  grade
5   6         e  very bad
1   2         b    good
2   3         b    good
0   1         a  very good
3   4         a  very good
4   5         a  very good
[6 rows x 3 columns]

In [8]: df.groupby('grade').size()
Out[8]:
grade
very bad     1
bad          0
medium       0
good         2
very good    3
Length: 5, dtype: int64

- pandas.core.group_agg and pandas.core.factor_agg were removed. As an alternative, construct a dataframe and use df.groupby(<group>).agg(<func>).
- Supplying “codes/labels and levels” to the Categorical constructor is not supported anymore. Supplying two arguments to the constructor is now interpreted as “values and levels (now called ‘categories’)”. Please change your code to use the from_codes() constructor.
- The Categorical.labels attribute was renamed to Categorical.codes and is read only. If you want to manipulate codes, please use one of the API methods on Categoricals.
• The `Categorical.levels` attribute is renamed to `Categorical.categories`.

### TimedeltaIndex/Scalar

We introduce a new scalar type `Timedelta`, which is a subclass of `datetime.timedelta`, and behaves in a similar manner, but allows compatibility with `np.timedelta64` types as well as a host of custom representation, parsing, and attributes. This type is very similar to how `Timestamp` works for `datetimes`. It is a nice-API box for the type. See the [docs](https://pandas.pydata.org/pandas-docs/stable/reference/typing.html) (GH3009, GH4533, GH8209, GH8187, GH8190, GH7869, GH7661, GH8345, GH8471)

**Warning:** `Timedelta` scalars (and `TimedeltaIndex`) component fields are *not the same* as the component fields on a `datetime.timedelta` object. For example, `.seconds` on a `datetime.timedelta` object returns the total number of seconds combined between `hours`, `minutes` and `seconds`. In contrast, the pandas `Timedelta` breaks out hours, minutes, microseconds and nanoseconds separately.

```python
# Timedelta accessor
In [9]: tds = pd.Timedelta('31 days 5 min 3 sec')
In [10]: tds.minutes
Out[10]: 5L
In [11]: tds.seconds
Out[11]: 3L

# datetime.timedelta accessor
# this is 5 minutes * 60 + 3 seconds
In [12]: tds.to_pytimedelta().seconds
Out[12]: 303
```

**Note:** this is no longer true starting from v0.16.0, where full compatibility with `datetime.timedelta` is introduced. See the 0.16.0 [whatsnew entry](https://pandas.pydata.org/pandas-docs/stable/whatsnew/v0.16.0.html)

**Warning:** Prior to 0.15.0 `pd.to_timedelta` would return a `Series` for list-like/`Series` input, and a `np.timedelta64` for scalar input. It will now return a `TimedeltaIndex` for list-like input, `Series` for `Series` input, and `Timedelta` for scalar input.

The arguments to `pd.to_timedelta` are now `(arg,unit='ns',box=True,coerce=False)`, previously were `(arg,box=True,unit='ns')` as these are more logical.

```python
Construct a scalar
In [9]: pd.Timedelta('1 days 06:05:01.00003')
Out[9]: Timedelta('1 days 06:05:01.000030')
In [10]: pd.Timedelta('15.5us')
Out[10]: Timedelta('0 days 00:00:00.000015500')
In [11]: pd.Timedelta('1 hour 15.5us')
Out[11]: Timedelta('0 days 01:00:00.000015500')

# negative Timedeltas have this string repr
# to be more consistent with datetime.timedelta conventions
In [12]: pd.Timedelta('-1us')
Out[12]: Timedelta('-1 days +23:59:59.999999')
```

(continues on next page)
Access fields for a Timedelta

```
In [14]: td = pd.Timedelta('1 hour 3m 15.5us')
In [15]: td.seconds
Out[15]: 3780
In [16]: td.microseconds
Out[16]: 15
In [17]: td.nanoseconds
Out[17]: 500
```

Construct a TimedeltaIndex

```
In [18]: pd.TimedeltaIndex(['1 days', '1 days, 00:00:05', 
                   '2 days 00:00:02'], 
                   np.timedelta64(2, 'D'), 
                   datetime.timedelta(days=2, seconds=2))
```

Constructing a TimedeltaIndex with a regular range

```
In [19]: pd.timedelta_range('1 days', periods=5, freq='D')
Out[19]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'], 
                       dtype='timedelta64[ns]', freq='D')
```

```
In [20]: pd.timedelta_range(start='1 days', end='2 days', freq='30T')
Out[20]: TimedeltaIndex(['1 days 00:00:00', '1 days 00:30:00', '1 days 01:00:00', 
                       '1 days 01:30:00', '1 days 02:00:00', '1 days 02:30:00', 
                       '1 days 03:00:00', '1 days 03:30:00', '1 days 04:00:00', 
                       '1 days 04:30:00', '1 days 05:00:00', '1 days 05:30:00', 
                       '1 days 06:00:00', '1 days 06:30:00', '1 days 07:00:00', 
                       '1 days 07:30:00', '1 days 08:00:00', '1 days 08:30:00', 
                       '1 days 09:00:00', '1 days 09:30:00', '1 days 10:00:00', 
                       '1 days 10:30:00', '1 days 11:00:00', '1 days 11:30:00', 
                       '1 days 12:00:00', '1 days 12:30:00', '1 days 13:00:00', 
                       '1 days 13:30:00', '1 days 14:00:00', '1 days 14:30:00', 
                       '1 days 15:00:00', '1 days 15:30:00', '1 days 16:00:00', 
                       '1 days 16:30:00', '1 days 17:00:00', '1 days 17:30:00', 
                       '1 days 18:00:00', '1 days 18:30:00', '1 days 19:00:00', 
                       '1 days 19:30:00', '1 days 20:00:00', '1 days 20:30:00', 
                       '1 days 21:00:00', '1 days 21:30:00', '1 days 22:00:00', 
                       '1 days 22:30:00', '1 days 23:00:00', '1 days 23:30:00', 
                       '2 days 00:00:00'], 
                       dtype='timedelta64[ns]', freq='30T')
```

You can now use a TimedeltaIndex as the index of a pandas object
In [21]: s = pd.Series(np.arange(5),
               index=pd.timedelta_range('1 days', periods=5, freq='s'))

In [22]: s
Out[22]:
1 days 00:00:00 0
1 days 00:00:01 1
1 days 00:00:02 2
1 days 00:00:03 3
1 days 00:00:04 4
Freq: S, Length: 5, dtype: int64

You can select with partial string selections

In [23]: s['1 day 00:00:02']
Out[23]: 2

In [24]: s['1 day': '1 day 00:00:02']
Out[24]:
1 days 00:00:00 0
1 days 00:00:01 1
1 days 00:00:02 2
Freq: S, Length: 3, dtype: int64

Finally, the combination of TimedeltaIndex with DatetimeIndex allow certain combination operations that are NaT preserving:

In [25]: tdi = pd.TimedeltaIndex(['1 days', pd.NaT, '2 days'])

In [26]: tdi.tolist()
Out[26]: [Timedelta('1 days 00:00:00'), NaT, Timedelta('2 days 00:00:00')]

In [27]: dti = pd.date_range('20130101', periods=3)

In [28]: dti.tolist()
Out[28]: [Timestamp('2013-01-01 00:00:00', freq='D'),
          Timestamp('2013-01-02 00:00:00', freq='D'),
          Timestamp('2013-01-03 00:00:00', freq='D')]

In [29]: (dti + tdi).tolist()
Out[29]: [Timestamp('2013-01-02 00:00:00'), NaT, Timestamp('2013-01-05 00:00:00')]

In [30]: (dti - tdi).tolist()
Out[30]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2013-01-01 00:00:00')]

• iteration of a Series e.g. list(Series(...)) of timedelta64[ns] would prior to v0.15.0 return np.timedelta64 for each element. These will now be wrapped in Timedelta.
Memory usage

Implemented methods to find memory usage of a DataFrame. See the FAQ for more. (GH6852).

A new display option display.memory_usage (see Options and settings) sets the default behavior of the memory_usage argument in the df.info() method. By default display.memory_usage is True.

```python
In [31]: dtypes = ['int64', 'float64', 'datetime64[ns]', 'timedelta64[ns]',
    ....: 'complex128', 'object', 'bool']
    ....:

In [32]: n = 5000

In [33]: data = {t: np.random.randint(100, size=n).astype(t) for t in dtypes}

In [34]: df = pd.DataFrame(data)

In [35]: df['categorical'] = df['object'].astype('category')

In [36]: df.info()
```

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
   # Column     Non-Null Count   Dtype
     ---        --------------   -----  
      0 int64     5000 non-null  int64
      1 float64   5000 non-null  float64
      2 datetime64[ns]  5000 non-null datetime64[ns]
      3 timedelta64[ns]  5000 non-null timedelta64[ns]
      4 complex128  5000 non-null complex128
      5 object     5000 non-null  object
      6 bool       5000 non-null  bool
      7 categorical 5000 non-null  category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1),
   object(1), timedelta64[ns](1)
memory usage: 289.1+ KB
```

Additionally memory_usage() is an available method for a dataframe object which returns the memory usage of each column.

```python
In [37]: df.memory_usage(index=True)
```

```
Out[37]:
Index                       128
int64                       40000
float64                     40000
datetime64[ns]              40000
timedelta64[ns]             40000
complex128                  80000
object                       40000
bool                         5000
categorical                 10920
Length: 9, dtype: int64
```
Series.dt accessor

Series has gained an accessor to succinctly return datetime like properties for the values of the Series, if its a datetime/period like Series. (GH7207) This will return a Series, indexed like the existing Series. See the docs

```python
# datetime
In [38]: s = pd.Series(pd.date_range('20130101 09:10:12', periods=4))

In [39]: s
Out[39]:
0  2013-01-01 09:10:12
1  2013-01-02 09:10:12
2  2013-01-03 09:10:12
3  2013-01-04 09:10:12
Length: 4, dtype: datetime64[ns]

In [40]: s.dt.hour
Out[40]:
0    9
1    9
2    9
3    9
Length: 4, dtype: int64

In [41]: s.dt.second
Out[41]:
0   12
1   12
2   12
3   12
Length: 4, dtype: int64

In [42]: s.dt.day
Out[42]:
0    1
1    2
2    3
3    4
Length: 4, dtype: int64

In [43]: s.dt.freq
Out[43]: 'D'
```

This enables nice expressions like this:

```python
In [44]: s[s.dt.day == 2]
Out[44]:
1  2013-01-02 09:10:12
Length: 1, dtype: datetime64[ns]
```

You can easily produce tz aware transformations:

```python
In [45]: stz = s.dt.tz_localize('US/Eastern')

In [46]: stz
Out[46]:
0  2013-01-01 09:10:12-05:00
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.1.1

1 2013-01-02 09:10:12-05:00
2 2013-01-03 09:10:12-05:00
3 2013-01-04 09:10:12-05:00
Length: 4, dtype: datetime64[ns, US/Eastern]

In [47]: stz.dt.tz
Out[47]: <DstTzInfo 'US/Eastern' LMT-1 day, 19:04:00 STD>

You can also chain these types of operations:

In [48]: s.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out[48]:
0 2013-01-01 04:10:12-05:00
1 2013-01-02 04:10:12-05:00
2 2013-01-03 04:10:12-05:00
3 2013-01-04 04:10:12-05:00
Length: 4, dtype: datetime64[ns, US/Eastern]

The .dt accessor works for period and timedelta dtypes.

# period
In [49]: s = pd.Series(pd.period_range('20130101', periods=4, freq='D'))

In [50]: s
Out[50]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
3 2013-01-04
Length: 4, dtype: period[D]

In [51]: s.dt.year
Out[51]:
0 2013
1 2013
2 2013
3 2013
Length: 4, dtype: int64

In [52]: s.dt.day
Out[52]:
0 1
1 2
2 3
3 4
Length: 4, dtype: int64

# timedelta
In [53]: s = pd.Series(pd.timedelta_range('1 day 00:00:05', periods=4, freq='s'))

In [54]: s
Out[54]:
0 1 days 00:00:05
1 1 days 00:00:06
2 1 days 00:00:07
3 1 days 00:00:08

(continues on next page)
In [55]: s.dt.days
Out[55]:
0 1
1 1
2 1
3 1
Length: 4, dtype: int64

In [56]: s.dt.seconds
Out[56]:
0 5
1 6
2 7
3 8
Length: 4, dtype: int64

In [57]: s.dt.components
Out[57]:
      days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0       1       0        0        5              0             0             0
1       1       0        0        6              0             0             0
2       1       0        0        7              0             0             0
3       1       0        0        8              0             0             0

[4 rows x 7 columns]

Timezone handling improvements

• tz_localize(None) for tz-aware Timestamp and DatetimeIndex now removes timezone holding
local time, previously this resulted in Exception or TypeError (GH7812)

In [58]: ts = pd.Timestamp('2014-08-01 09:00', tz='US/Eastern')

In [59]: ts
Out[59]: Timestamp('2014-08-01 09:00:00-04:00', tz='US/Eastern')

In [60]: ts.tz_localize(None)
Out[60]: Timestamp('2014-08-01 09:00:00')

In [61]: didx = pd.date_range(start='2014-08-01 09:00', freq='H',
...:                      periods=10, tz='US/Eastern')

In [62]: didx
Out[62]:
DatetimeIndex(['2014-08-01 09:00:00-04:00', '2014-08-01 10:00:00-04:00',
              '2014-08-01 11:00:00-04:00', '2014-08-01 12:00:00-04:00',
              '2014-08-01 13:00:00-04:00', '2014-08-01 14:00:00-04:00',
              '2014-08-01 15:00:00-04:00', '2014-08-01 16:00:00-04:00',
              '2014-08-01 17:00:00-04:00', '2014-08-01 18:00:00-04:00'],
               dtype='datetime64[ns, US/Eastern]', freq='H')

In [63]: didx.tz_localize(None)
Out[63]:
DatetimeIndex(['2014-08-01 09:00:00', '2014-08-01 10:00:00',
              '2014-08-01 11:00:00', '2014-08-01 12:00:00',
              '2014-08-01 13:00:00', '2014-08-01 14:00:00',
              '2014-08-01 15:00:00', '2014-08-01 16:00:00',
              '2014-08-01 17:00:00', '2014-08-01 18:00:00'],
       dtype='datetime64[ns]', freq=None)

• tz_localize now accepts the ambiguous keyword which allows for passing an array of bools indicating whether the date belongs in DST or not, ‘NaT’ for setting transition times to NaT, ‘infer’ for inferring DST/non-DST, and ‘raise’ (default) for an AmbiguousTimeError to be raised. See the docs for more details (GH7943)

• DataFrame.tz_localize and DataFrame.tz_convert now accepts an optional level argument for localizing a specific level of a MultiIndex (GH7846)

• Timestamp.tz_localize and Timestamp.tz_convert now raise TypeError in error cases, rather than Exception (GH8025)

• a timeseries/index localized to UTC when inserted into a Series/DataFrame will preserve the UTC timezone (rather than being a naive datetime64[ns]) as object dtype (GH8411)

• Timestamp.__repr__ displays dateutil.tz.tzoffset info (GH7907)

Rolling/expanding moments improvements

• rolling_min(), rolling_max(), rolling_cov(), and rolling_corr() now return objects with all NaN when len(arg) < min_periods <= window rather than raising. (This makes all rolling functions consistent in this behavior). (GH7766)

Prior to 0.15.0

In [64]: s = pd.Series([10, 11, 12, 13])

In [15]: pd.rolling_min(s, window=10, min_periods=5)
ValueError: min_periods (5) must be <= window (4)

New behavior

In [4]: pd.rolling_min(s, window=10, min_periods=5)
Out[4]:
0   NaN
1   NaN
2   NaN
3   NaN
dtype: float64

• rolling_max(), rolling_min(), rolling_sum(), rolling_mean(), rolling_median(), rolling_std(), rolling_var(), rolling_skew(), rolling_kurt(), rolling_quantile(), rolling_cov(), rolling_corr(), rolling_corr_pairwise(), rolling_window(), and rolling_apply() with center=True previously would return a result of the same structure as the input arg with NaN in the final (window-1)/2 entries.

Now the final (window-1)/2 entries of the result are calculated as if the input arg were followed by (window-1)/2 NaN values (or with shrinking windows, in the case of rolling_apply()). (GH7925, GH8269)

Prior behavior (note final value is NaN):
In [7]: pd.rolling_sum(Series(range(4)), window=3, min_periods=0, center=True)
Out[7]:
0   1
1   3
2   6
3  NaN
dtype: float64

New behavior (note final value is 5 = sum([2, 3, NaN])):

In [7]: pd.rolling_sum(pd.Series(range(4)), window=3,
....: min_periods=0, center=True)
Out[7]:
0   1
1   3
2   6
3   5
dtype: float64

- rolling_window() now normalizes the weights properly in rolling mean mode (mean=True) so that the
calculated weighted means (e.g. ‘triang’, ‘gaussian’) are distributed about the same means as those calculated
without weighting (i.e. ‘boxcar’). See the note on normalization for further details. (GH7618)

In [65]: s = pd.Series([10.5, 8.8, 11.4, 9.7, 9.3])

Behavior prior to 0.15.0:

In [39]: pd.rolling_window(s, window=3, win_type='triang', center=True)
Out[39]:
0   NaN
1  6.583333
2  6.883333
3  6.683333
4   NaN
dtype: float64

New behavior

In [10]: pd.rolling_window(s, window=3, win_type='triang', center=True)
Out[10]:
0   NaN
1   9.875
2  10.325
3  10.025
4   NaN
dtype: float64

- Removed center argument from all expanding_ functions (see list), as the results produced when
center=True did not make much sense. (GH7925)
- Added optional ddof argument to expanding_cov() and rolling_cov(). The default value of 1 is
backwards-compatible. (GH8279)
- Documented the ddof argument to expanding_var(), expanding_std(), rolling_var(), and
rolling_std(). These functions’ support of a ddof argument (with a default value of 1) was previously
undocumented. (GH8064)
- ewma(), ewmstd(), ewmvol(), ewmvar(), ewmcov(), and ewmcorr() now interpret min_periods
in the same manner that the rolling_*() and expanding_*() functions do: a given result entry will be
NaN if the (expanding, in this case) window does not contain at least min_periods values. The previous behavior was to set to NaN the min_periods entries starting with the first non-NaN value. (GH7977)

Prior behavior (note values start at index 2, which is min_periods after index 0 (the index of the first non-empty value)):

```python
In [66]: s = pd.Series([1, None, None, None, 2, 3])
```

```python
In [51]: ewma(s, com=3., min_periods=2)
Out[51]:
0    NaN
1    NaN
2  1.000000
3  1.000000
4  1.571429
5  2.189189
dtype: float64
```

New behavior (note values start at index 4, the location of the 2nd (since min_periods=2) non-empty value):

```python
In [2]: pd.ewma(s, com=3., min_periods=2)
```

```python
Out[2]:
0    NaN
1    NaN
2    NaN
3    NaN
4  1.759644
5  2.383784
dtype: float64
```

- `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now have an optional adjust argument, just like `ewma()` does, affecting how the weights are calculated. The default value of adjust is True, which is backwards-compatible. See Exponentially weighted moment functions for details. (GH7911)

- `ewma()`, `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now have an optional ignore_na argument. When ignore_na=False (the default), missing values are taken into account in the weights calculation. When ignore_na=True (which reproduces the pre-0.15.0 behavior), missing values are ignored in the weights calculation. (GH7543)

```python
In [7]: pd.ewma(pd.Series([None, 1., 8.]), com=2.)
```

```python
Out[7]:
0   NaN
1  1.0
2  5.2
dtype: float64
```

```python
In [8]: pd.ewma(pd.Series([1., None, 8.]), com=2.,
   ....: ignore_na=True) # pre-0.15.0 behavior
```

```python
Out[8]:
0  1.0
1  1.0
2  5.2
dtype: float64
```

```python
In [9]: pd.ewma(pd.Series([1., None, 8.]), com=2.,
   ....: ignore_na=False) # new default
```

```python
Out[9]:
0  1.000000
```
Warning: By default (ignore_na=False) the ewm*() functions' weights calculation in the presence of missing values is different than in pre-0.15.0 versions. To reproduce the pre-0.15.0 calculation of weights in the presence of missing values one must specify explicitly ignore_na=True.

• Bug in expanding_cov(), expanding_corr(), rolling_cov(), rolling_cor(), ewmcov(), and ewmcorr() returning results with columns sorted by name and producing an error for non-unique columns: now handles non-unique columns and returns columns in original order (except for the case of two DataFrames with pairwise=False, where behavior is unchanged) (GH7542)
• Bug in rolling_count() and expanding_*() functions unnecessarily producing error message for zero-length data (GH8056)
• Bug in rolling_apply() and expanding_apply() interpreting min_periods=0 as min_periods=1 (GH8080)
• Bug in expanding_std() and expanding_var() for a single value producing a confusing error message (GH7900)
• Bug in rolling_std() and rolling_var() for a single value producing 0 rather than NaN (GH7900)
• Bug in ewmstd(), ewmvol(), ewmvar(), and ewmcov() calculation of de-biasing factors when bias=False (the default). Previously an incorrect constant factor was used, based on adjust=True, ignore_na=True, and an infinite number of observations. Now a different factor is used for each entry, based on the actual weights (analogous to the usual N/(N-1) factor). In particular, for a single point a value of NaN is returned when bias=False, whereas previously a value of (approximately) 0 was returned.

For example, consider the following pre-0.15.0 results for ewmvar(..., bias=False), and the corresponding debiasing factors:

\begin{verbatim}
In [67]: s = pd.Series([1., 2., 0., 4.])
In [89]: ewmvar(s, com=2., bias=False)
Out[89]:
   0   -2.775558e-16
   1      3.000000e-01
   2      9.556787e-01
   3      3.585799e+00
dtype: float64
In [90]: ewmvar(s, com=2., bias=False) / ewmvar(s, com=2., bias=True)
Out[90]:
   0     1.25
   1     1.25
   2     1.25
   3     1.25
dtype: float64
\end{verbatim}

Note that entry 0 is approximately 0, and the debiasing factors are a constant 1.25. By comparison, the following 0.15.0 results have a NaN for entry 0, and the debiasing factors are decreasing (towards 1.25):
In [14]: pd.ewmvar(s, com=2., bias=False)
Out[14]:
0   NaN
1  0.500000
2  1.210526
3  4.089069
dtype: float64

In [15]: pd.ewmvar(s, com=2., bias=False) / pd.ewmvar(s, com=2., bias=True)
Out[15]:
0   NaN
1  2.083333
2  1.583333
3  1.425439
dtype: float64

See Exponentially weighted moment functions for details. (GH7912)

Improvements in the SQL IO module

- Added support for a chunksize parameter to to_sql function. This allows DataFrame to be written in chunks and avoid packet-size overflow errors (GH8062).
- Added support for a chunksize parameter to read_sql function. Specifying this argument will return an iterator through chunks of the query result (GH2908).
- Added support for writing datetime.date and datetime.time object columns with to_sql (GH6932).
- Added support for specifying a schema to read from/write to with read_sql_table and to_sql (GH7441, GH7952). For example:

```python
df.to_sql('table', engine, schema='other_schema')  # noqa F821
pd.read_sql_table('table', engine, schema='other_schema')  # noqa F821
```

- Added support for writing NaN values with to_sql (GH2754).
- Added support for writing datetime64 columns with to_sql for all database flavors (GH7103).

Backwards incompatible API changes

Breaking changes

API changes related to Categorical (see here for more details):

- The Categorical constructor with two arguments changed from “codes/labels and levels” to “values and levels (now called ‘categories’)”. This can lead to subtle bugs. If you use Categorical directly, please audit your code by changing it to use the from_codes() constructor.

An old function call like (prior to 0.15.0):

```python
pd.Categorical([0,1,0,2,1], levels=['a', 'b', 'c'])
```

will have to adapted to the following to keep the same behaviour:
In [2]: pd.Categorical.from_codes([0, 1, 0, 2, 1], categories=['a', 'b', 'c'])
Out[2]:
[a, b, a, c, b]
Categories (3, object): [a, b, c]

API changes related to the introduction of the Timedelta scalar (see above for more details):

- Prior to 0.15.0 to_timedelta() would return a Series for list-like/Series input, and a np.
timedelta64 for scalar input. It will now return a TimedeltaIndex for list-like input, Series for Series input, and Timedelta for scalar input.

For API changes related to the rolling and expanding functions, see detailed overview above.

Other notable API changes:

- Consistency when indexing with .loc and a list-like indexer when no values are found.

In [68]: df = pd.DataFrame([['a'], ['b']], index=[1, 2])
In [69]: df
Out[69]:
0  a
2  b
[2 rows x 1 columns]

In prior versions there was a difference in these two constructs:
- df.loc[[3]] would return a frame reindexed by 3 (with all np.nan values)
- df.loc[[3],:] would raise KeyError.

Both will now raise a KeyError. The rule is that at least 1 indexer must be found when using a list-like and .loc (GH7999)

Furthermore in prior versions these were also different:
- df.loc[[1,3]] would return a frame reindexed by [1,3]
- df.loc[[1,3],:] would raise KeyError.

Both will now return a frame reindex by [1,3]. E.g.

In [3]: df.loc[[1, 3]]
Out[3]:
0  1  a
3  NaN

In [4]: df.loc[[1, 3], :]
Out[4]:
0  1  a
3  NaN

This can also be seen in multi-axis indexing with a Panel.

```python
>>> p = pd.Panel(np.arange(2 * 3 * 4).reshape(2, 3, 4),
...               items=['ItemA', 'ItemB'],
...               major_axis=[1, 2, 3],
```

(continues on next page)
The following would raise `KeyError` prior to 0.15.0:

```python
In [5]:
Out[5]:
   ItemA  ItemD
0     3    NaN
1     7    NaN
2    11    NaN
```

Furthermore, `.loc` will raise if no values are found in a MultiIndex with a list-like indexer:

```python
In [70]: s = pd.Series(np.arange(3, dtype='int64'),
                index=pd.MultiIndex.from_product([['A'],
                                                   ['foo', 'bar', 'baz']],
                                              names=['one', 'two'])).sort_index()
In [71]: s.loc['D']
```

```python
KeyError: "['D'] not in index"
```

- Assigning values to `None` now considers the dtype when choosing an ‘empty’ value (GH7941).

Previously, assigning to `None` in numeric containers changed the dtype to object (or errored, depending on the call). It now uses `NaN`:

```python
In [73]: s = pd.Series([1, 2, 3])
In [74]: s.loc[0] = None
In [75]: s
```

```python
0   NaN
1   2.0
2   3.0
Length: 3, dtype: float64
```

`NaN` is now used similarly for datetime containers.
For object containers, we now preserve None values (previously these were converted to NaN values).

```python
In [76]: s = pd.Series(["a", "b", "c"])
In [77]: s.loc[0] = None
In [78]: s
Out[78]:
0   None
1     b
2     c
Length: 3, dtype: object
```

To insert a NaN, you must explicitly use np.nan. See the docs.

- In prior versions, updating a pandas object inplace would not reflect in other python references to this object. (GH8511, GH5104)

```python
In [79]: s = pd.Series([1, 2, 3])
In [80]: s2 = s
In [81]: s += 1.5

Behavior prior to v0.15.0

# the original object
In [5]: s
Out[5]:
0     2.5
1     3.5
2     4.5
dtype: float64

# a reference to the original object
In [7]: s2
Out[7]:
0     1
1     2
2     3
dtype: int64

This is now the correct behavior

# the original object
In [82]: s
Out[82]:
0     2.5
1     3.5
2     4.5
Length: 3, dtype: float64

# a reference to the original object
In [83]: s2
Out[83]:
0     2.5
1     3.5
```
• Made both the C-based and Python engines for read_csv and read_table ignore empty lines in input as well as white space-filled lines, as long as sep is not white space. This is an API change that can be controlled by the keyword parameter skip_blank_lines. See the docs (GH4466).

• A timeseries/index localized to UTC when inserted into a Series/DataFrame will preserve the UTC timezone and inserted as object dtype rather than being converted to a naive datetime64[ns] (GH8411).

• Bug in passing a DatetimeIndex with a timezone that was not being retained in DataFrame construction from a dict (GH7822).

In prior versions this would drop the timezone, now it retains the timezone, but gives a column of object dtype:

```python
In [84]: i = pd.date_range('1/1/2011', periods=3, freq='10s', tz='US/Eastern')
In [85]: i
Out[85]: DatetimeIndex(['2011-01-01 00:00:00-05:00', '2011-01-01 00:00:10-05:00',
                   '2011-01-01 00:00:20-05:00'],
                  dtype='datetime64[ns, US/Eastern]', freq='10S')
In [86]: df = pd.DataFrame({'a': i})
In [87]: df
Out[87]:
   a
0 2011-01-01 00:00:00-05:00
1 2011-01-01 00:00:10-05:00
2 2011-01-01 00:00:20-05:00

[3 rows x 1 columns]
```

Previously this would have yielded a column of datetime64 dtype, but without timezone info.

The behaviour of assigning a column to an existing dataframe as df['a'] = i remains unchanged (this already returned an object column with a timezone).

• When passing multiple levels to stack(), it will now raise a ValueError when the levels aren’t all level names or all level numbers (GH7660). See Reshaping by stacking and unstacking.

• Raise a ValueError in df.to_hdf with ‘fixed’ format, if df has non-unique columns as the resulting file will be broken (GH7761).

• SettingWithCopy raise/warnings (according to the option mode.chained_assignment) will now be issued when setting a value on a sliced mixed-dtype DataFrame using chained-assignment. (GH7845, GH7950)
• merge, DataFrame.merge, and ordered_merge now return the same type as the left argument (GH7737).

• Previously an enlargement with a mixed-dtype frame would act unlike .append which will preserve dtypes (related GH2578, GH8176):

```python
In [89]: df = pd.DataFrame([[True, 1], [False, 2]],
                      columns=["female", "fitness"])

In [90]: df
Out[90]:
     female  fitness
0      True     1
1     False     2

[2 rows x 2 columns]
```

```python
In [91]: df.dtypes
Out[91]:
female  bool
fitness   int64
Length: 2, dtype: object

# dtypes are now preserved
```

```python
In [93]: df
Out[93]:
     female  fitness
0      True     1
1     False     2
2     False     2

[3 rows x 2 columns]
```

```python
In [94]: df.dtypes
Out[94]:
female  bool
fitness   int64
Length: 2, dtype: object
```

• Series.to_csv() now returns a string when path=None, matching the behaviour of DataFrame.to_csv() (GH8215).

• read_hdf now raises IOError when a file that doesn’t exist is passed in. Previously, a new, empty file was created, and a KeyError raised (GH7715).

• DataFrame.info() now ends its output with a newline character (GH8114).
- Concatenating no objects will now raise a `ValueError` rather than a bare `Exception`.
- Merge errors will now be sub-classes of `ValueError` rather than raw `Exception` (GH8501)
- `DataFrame.plot` and `Series.plot` keywords are now have consistent orders (GH8037)

**Internal refactoring**

In 0.15.0 `Index` has internally been refactored to no longer sub-class `ndarray` but instead subclass `PandasObject`, similarly to the rest of the pandas objects. This change allows very easy sub-classing and creation of new index types. This should be a transparent change with only very limited API implications (GH5080, GH7439, GH7796, GH8024, GH8367, GH7997, GH8522):

- you may need to unpickle pandas version < 0.15.0 pickles using `pd.read_pickle` rather than `pickle.load`. See `pickle docs`
- when plotting with a `PeriodIndex`, the matplotlib internal axes will now be arrays of `Period` rather than a `PeriodIndex` (this is similar to how a `DatetimeIndex` passes arrays of datetimes now)
- MultiIndexes will now raise similarly to other pandas objects w.r.t. truth testing, see here (GH7897).
- When plotting a `DatetimeIndex` directly with matplotlib’s `plot` function, the axis labels will no longer be formatted as dates but as integers (the internal representation of a `datetime64`). UPDATE This is fixed in 0.15.1, see here.

**Deprecations**

- The attributes `Categorical labels` and `levels` attributes are deprecated and renamed to `codes` and `categories`.
- The `outtype` argument to `pd.DataFrame.to_dict` has been deprecated in favor of `orient`. (GH7840)
- The `convert_dummies` method has been deprecated in favor of `get_dummies` (GH8140)
- The `infer_dst` argument in `tz_localize` will be deprecated in favor of `ambiguous` to allow for more flexibility in dealing with DST transitions. Replace `infer_dst=True` with `ambiguous='infer'` for the same behavior (GH7943). See the docs for more details.
- The top-level `pd.value_range` has been deprecated and can be replaced by `.describe()` (GH8481)
- The `Index` set operations `+` and `−` were deprecated in order to provide these for numeric type operations on certain index types. `+` can be replaced by `.union()` or `|`, and `−` by `.difference()`. Further the method name `Index.diff()` is deprecated and can be replaced by `Index.difference()` (GH8226)

```python
# +
pd.Index(['a', 'b', 'c']) + pd.Index(['b', 'c', 'd'])

# should be replaced by
pd.Index(['a', 'b', 'c']).union(pd.Index(['b', 'c', 'd']))

# −
pd.Index(['a', 'b', 'c']) − pd.Index(['b', 'c', 'd'])

# should be replaced by
pd.Index(['a', 'b', 'c']).difference(pd.Index(['b', 'c', 'd']))
```

- The `infer_types` argument to `read_html()` now has no effect and is deprecated (GH7762, GH7032).
Removal of prior version deprecations/changes

- Remove DataFrame.delevel method in favor of DataFrame.reset_index

Enhancements

Enhancements in the importing/exporting of Stata files:

- Added support for bool, uint8, uint16 and uint32 data types in to_stata (GH7097, GH7365)
- Added conversion option when importing Stata files (GH8527)
- DataFrame.to_stata and StataWriter check string length for compatibility with limitations imposed in dta files where fixed-width strings must contain 244 or fewer characters. Attempting to write Stata dta files with strings longer than 244 characters raises a ValueError. (GH7858)
- read_stata and StataReader can import missing data information into a DataFrame by setting the argument convert_missing to True. When using this options, missing values are returned as StataMissingValue objects and columns containing missing values have object data type. (GH8045)

Enhancements in the plotting functions:

- Added layout keyword to DataFrame.plot. You can pass a tuple of (rows, columns), one of which can be -1 to automatically infer (GH6667, GH8071).
- Allow to pass multiple axes to DataFrame.plot, hist and boxplot (GH5353, GH6970, GH7069)
- Added support for c, colormap and colorbar arguments for DataFrame.plot with kind='scatter' (GH7780)
- Histogram from DataFrame.plot with kind='hist' (GH7809), See the docs.
- Boxplot from DataFrame.plot with kind='box' (GH7998), See the docs.

Other:

- read_csv now has a keyword parameter float_precision which specifies which floating-point converter the C engine should use during parsing, see here (GH8002, GH8044)
- Added searchsorted method to Series objects (GH7447)
- describe() on mixed-types DataFrames is more flexible. Type-based column filtering is now possible via the include/exclude arguments. See the docs (GH8164).

```
In [95]: df = pd.DataFrame({'catA': ['foo', 'foo', 'bar'] * 8,
        ....:      'catB': ['a', 'b', 'c', 'd'] * 6,
        ....:      'numC': np.arange(24),
        ....:      'numD': np.arange(24.) + .5})

In [96]: df.describe(include=['object'])
Out[96]:
   catA  catB
count 24  24
unique 2  4
top   foo  b
freq  16  6

[4 rows x 2 columns]
In [97]: df.describe(include=['number', 'object'], exclude=['float'])
```
Out[97]:

catA  catB  numC
count 24 24 24.000000
unique 2 4 NaN
top  foo  b  NaN
freq 16 6 NaN
mean NaN NaN 11.500000
std NaN NaN 7.071068
min NaN NaN 0.000000
25% NaN NaN 5.750000
50% NaN NaN 11.500000
75% NaN NaN 17.250000
max NaN NaN 23.000000
[11 rows x 3 columns]

Requesting all columns is possible with the shorthand ‘all’

In [98]: df.describe(include='all')
Out[98]:
catA  catB  numC  numD
count 24 24 24.000000 24.000000
unique 2 4 NaN  NaN
top  foo  b  NaN  NaN
freq 16 6 NaN  NaN
mean NaN NaN 11.500000 12.000000
std NaN NaN 7.071068 7.071068
min NaN NaN 0.000000  0.500000
25% NaN NaN 5.750000 6.250000
50% NaN NaN 11.500000 12.000000
75% NaN NaN 17.250000 17.750000
max NaN NaN 23.000000 23.500000
[11 rows x 4 columns]

Without those arguments, describe will behave as before, including only numerical columns or, if none are, only categorical columns. See also the docs

• Added split as an option to the orient argument in pd.DataFrame.to_dict. (GH7840)

• The get_dummies method can now be used on DataFrames. By default only categorical columns are encoded as 0’s and 1’s, while other columns are left untouched.

In [99]: df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['c', 'c', 'b'], 'C': [1, 2, 3]})

In [100]: pd.get_dummies(df)
Out[100]:

          A_a  A_b  B_b  B_c
0  1  1  0  0  1
1  2  0  1  0  1
2  3  1  0  1  0
[3 rows x 5 columns]

• PeriodIndex supports resolution as the same as DatetimeIndex (GH7708)
- `pandas.tseries.holiday` has added support for additional holidays and ways to observe holidays (GH7070)
- `pandas.tseries.holiday.Holiday` now supports a list of offsets in Python3 (GH7070)
- `pandas.tseries.holiday.Holiday` now supports a `days_of_week` parameter (GH7070)
- `GroupBy.nth()` now supports selecting multiple `nth` values (GH7910)

```python
In [101]: business_dates = pd.date_range(start='4/1/2014', end='6/30/2014', freq='B')
In [102]: df = pd.DataFrame(1, index=business_dates, columns=['a', 'b'])
# get the first, 4th, and last date index for each month
In [103]: df.groupby([df.index.year, df.index.month]).nth([0, 3, -1])
Out[103]:
         a  b
2014  4  1  1
        4  1  1
        5  1  1
        6  1  1
        6  1  1
[9 rows x 2 columns]
```

- `Period` and `PeriodIndex` supports addition/subtraction with timedelta-likes (GH7966)

  If `Period freq` is D,H,T,S,L,U,N, Timedelta-like can be added if the result can have same freq. Otherwise, only the same offsets can be added.

```python
In [104]: idx = pd.period_range('2014-07-01 09:00', periods=5, freq='H')
In [105]: idx
Out[105]: PeriodIndex(
['2014-07-01 09:00', '2014-07-01 10:00', '2014-07-01 11:00',
 '2014-07-01 12:00', '2014-07-01 13:00'],
dtype='period[H]', freq='H')
In [106]: idx + pd.offsets.Hour(2)
Out[106]: PeriodIndex(
['2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00',
 '2014-07-01 14:00', '2014-07-01 15:00'],
dtype='period[H]', freq='H')
In [107]: idx + pd.Timedelta('120m')
Out[107]: PeriodIndex(
['2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00',
 '2014-07-01 14:00', '2014-07-01 15:00'],
dtype='period[H]', freq='H')
In [108]: idx = pd.period_range('2014-07', periods=5, freq='M')
In [109]: idx
Out[109]: PeriodIndex(
dtype='period[M]', freq='M')
```
In [110]: idx = pd.offsets.MonthEnd(3)
                      dtype='period[M]', freq='M')

- Added experimental compatibility with openpyxl for versions >= 2.0. The DataFrame.to_excel method engine keyword now recognizes openpyxl1 and openpyxl2 which will explicitly require openpyxl v1 and v2 respectively, failing if the requested version is not available. The openpyxl engine is a now a meta-engine that automatically uses whichever version of openpyxl is installed. (GH7177)

- DataFrame.fillna can now accept a DataFrame as a fill value (GH8377)

- Passing multiple levels to stack() will now work when multiple level numbers are passed (GH7660). See Reshaping by stacking and unstacking.

- set_names(), set_labels(), and set_levels() methods now take an optional level keyword argument to all modification of specific level(s) of a MultiIndex. Additionally set_names() now accepts a scalar string value when operating on an Index or on a specific level of a MultiIndex (GH7792)

In [111]: idx = pd.MultiIndex.from_product([['a'], range(3), list("pqr")],
                                      names=['foo', 'bar', 'baz'])

In [112]: idx.set_names('qux', level=0)
Out[112]: 
MultiIndex([('a', 0, 'p'),
             ('a', 0, 'q'),
             ('a', 0, 'r'),
             ('a', 1, 'p'),
             ('a', 1, 'q'),
             ('a', 1, 'r'),
             ('a', 2, 'p'),
             ('a', 2, 'q'),
             ('a', 2, 'r')],
           names=['qux', 'bar', 'baz'])

In [113]: idx.set_names(['qux', 'corge'], level=[0, 1])
Out[113]: 
MultiIndex([('a', 'a', 'p'),
             ('a', 'a', 'q'),
             ('a', 'a', 'r'),
             ('a', 'b', 'p'),
             ('a', 'b', 'q'),
             ('a', 'b', 'r'),
             ('a', 'c', 'p'),
             ('a', 'c', 'q'),
             ('a', 'c', 'r')],
           names=['qux', 'corge', 'baz'])

In [114]: idx.set_levels(['a', 'b', 'c'], level='bar')
Out[114]: 
MultiIndex([('a', 'a', 'p'),
             ('a', 'a', 'q'),
             ('a', 'a', 'r'),
             ('a', 'b', 'p'),
             ('a', 'b', 'q'),
             ('a', 'b', 'r'),
             ('a', 'c', 'p'),
             ('a', 'c', 'q'),
             ('a', 'c', 'r')],
           names=['qux', 'corge', 'baz'])

(continues on next page)
('a', 'c', 'p'),
('a', 'c', 'q'),
('a', 'c', 'r'),
names=['foo', 'bar', 'baz'])

In [115]: idx.set_levels([['a', 'b', 'c'], [1, 2, 3]], level=[1, 2])
Out[115]:
MultiIndex([(a, 'a', 1),
 (a, 'a', 2),
 (a, 'a', 3),
 (a, 'b', 1),
 (a, 'b', 2),
 (a, 'b', 3),
 (a, 'c', 1),
 (a, 'c', 2),
 (a, 'c', 3)],
 names=['foo', 'bar', 'baz'])

• Index.isin now supports a level argument to specify which index level to use for membership tests (GH7892, GH7890)

In [1]: idx = pd.MultiIndex.from_product([[0, 1], ['a', 'b', 'c']])

In [2]: idx.values
Out[2]: array([[0, 'a'), (0, 'b'), (0, 'c'), (1, 'a'), (1, 'b'), (1, 'c')],
       dtype=object)

In [3]: idx.isin(['a', 'c', 'e'], level=1)
Out[3]: array([True, False, True, True, False, True], dtype=bool)

• Index now supports duplicated and drop_duplicates. (GH4060)

In [116]: idx = pd.Index([1, 2, 3, 4, 1, 2])

In [117]: idx
Out[117]: Int64Index([1, 2, 3, 4, 1, 2], dtype='int64')

In [118]: idx.duplicated()
Out[118]: array([False, False, False, False, True, True])

In [119]: idx.drop_duplicates()
Out[119]: Int64Index([1, 2, 3, 4], dtype='int64')

• add copy=True argument to pd.concat to enable pass through of complete blocks (GH8252)

• Added support for numpy 1.8+ data types (bool_, int_, float_, string_) for conversion to R dataframe (GH8400)
Performance

- Performance improvements in `DatetimeIndex.__iter__` to allow faster iteration (GH7683)
- Performance improvements in `Period` creation (and `PeriodIndex` setitem) (GH5155)
- Improvements in `Series.transform` for significant performance gains (revised) (GH6496)
- Performance improvements in `StataReader` when reading large files (GH8040, GH8073)
- Performance improvements in `StataWriter` when writing large files (GH8079)
- Performance and memory usage improvements in multi-key `groupby` (GH8128)
- Performance improvements in `groupby .agg` and `.apply` where builtins max/min were not mapped to numpy/cythonized versions (GH7722)
- Performance improvement in writing to sql (`to_sql`) of up to 50% (GH8208).
- Performance benchmarking of `groupby` for large value of `ngroups` (GH6787)
- Performance improvement in `CustomBusinessDay`, `CustomBusinessMonth` (GH8236)
- Performance improvement for `MultiIndex.values` for multi-level indexes containing datetimes (GH8543)

Bug fixes

- Bug in `pivot_table`, when using margins and a dict `aggfunc` (GH8349)
- Bug in `read_csv` where `squeeze=True` would return a view (GH8217)
- Bug in checking of table name in `read_sql` in certain cases (GH7826).
- Bug in `DataFrame.groupby` where `Grouper` does not recognize level when frequency is specified (GH7885)
- Bug in `DataFrame.groupby` where `Grouper` does not recognize level when frequency is specified (GH7885)
- Bug in `MultiIndex` slicing with missing indexers (GH7866)
- Bug in `MultiIndex` slicing with various edge cases (GH8132)
- Regression in `MultiIndex` indexing with a non-scalar type object (GH7914)
- Bug in `Timestamp` comparisons with `==` and `int64` dtype (GH8058)
• Bug in pickles contains `DateOffset` may raise `AttributeError` when `normalize` attribute is referred internally (GH7748)

• Bug in `Panel` when using `major_xs` and `copy=False` is passed (deprecation warning fails because of missing warnings) (GH8152).

• Bug in pickle deserialization that failed for pre-0.14.1 containers with dup items trying to avoid ambiguity when matching block and manager items, when there’s only one block there’s no ambiguity (GH7794).

• Bug in putting a `PeriodIndex` into a `Series` would convert to `int64` dtype, rather than `object` of `Periods` (GH7932).

• Bug in `HDFStore` iteration when passing a where (GH8014)

• Bug in `DataFrameGroupby.transform` when transforming with a passed non-sorted key (GH8046, GH8430).

• Bug in repeated timeseries line and area plot may result in `ValueError` or incorrect kind (GH7733).

• Bug in inference in a `MultiIndex` with `datetime.date` inputs (GH7888).

• Bug in `get` where an `IndexError` would not cause the default value to be returned (GH7725).

• Bug in `offsets.apply`, `rollforward` and `rollback` may reset nanosecond (GH7697).

• Bug in `offsets.apply`, `rollforward` and `rollback` may raise `AttributeError` if `Timestamp` has `dateutil tzinfo` (GH7697).

• Bug in sorting a `MultiIndex` frame with a `Float64Index` (GH8017).

• Bug in inconsistent panel setitem with a rhs of a `DataFrame` for alignment (GH7763).

• Bug in `is_superperiod` and `is_subperiod` cannot handle higher frequencies than `S` (GH7760, GH7772, GH7803).

• Bug in 32-bit platforms with `Series.shift` (GH8129).

• Bug in `PeriodIndex.unique` returns `int64 np.ndarray` (GH7540).

• Bug in `groupby.apply` with a non-affecting mutation in the function (GH8467).

• Bug in `DataFrame.reset_index` which has `MultiIndex contains PeriodIndex or DatetimeIndex with tz` raises `ValueError` (GH7746, GH7793).

• Bug in `DataFrame.plot` with subplots=True may draw unnecessary minor xticks and yticks (GH7801).

• Bug in `StataReader` which did not read variable labels in 117 files due to difference between Stata documentation and implementation (GH7816).

• Bug in `StataReader` where strings were always converted to 244 characters-fixed width irrespective of underlying string size (GH7858).

• Bug in `DataFrame.plot` and `Series.plot` may ignore `rot` and `fontsize` keywords (GH7844).

• Bug in `DatetimeIndex.value_counts` doesn’t preserve `tz` (GH7735).

• Bug in `PeriodIndex.value_counts` results in `Int64Index` (GH7735).

• Bug in `DataFrame.join` when doing left join on index and there are multiple matches (GH5391).

• Bug in `GroupBy.transform()` where int groups with a transform that didn’t preserve the index were incorrectly truncated (GH7972).

• Bug in `groupby` where callable objects without name attributes would take the wrong path, and produce a `DataFrame` instead of a `Series` (GH7929).

• Bug in `groupby` error message when a `DataFrame` grouping column is duplicated (GH7511)
• Bug in `read_html` where the `infer_types` argument forced coercion of date-likes incorrectly (GH7762, GH7032).

• Bug in `Series.str.cat` with an index which was filtered as to not include the first item (GH7857).

• Bug in `Timestamp` cannot parse nanosecond from string (GH7878).

• Bug in `Timestamp` with string offset and tz results incorrect (GH7833).

• Bug in `tslib.tz_convert` and `tslib.tz_convert_single` may return different results (GH7798).

• Bug in `DatetimeIndex.intersection` of non-overlapping timestamps with tz raises `IndexError` (GH7880).

• Bug in alignment with TimeOps and non-unique indexes (GH8363).

• Bug in `GroupBy.filter()` where fast path vs. slow path made the filter return a non scalar value that appeared valid but wasn’t (GH7870).

• Bug in `date_range()`/`DatetimeIndex()` when the timezone was inferred from input dates yet incorrect times were returned when crossing DST boundaries (GH7835, GH7901).

• Bug in `to_excel()` where a negative sign was being prepended to positive infinity and was absent for negative infinity (GH7949).

• Bug in area plot draws legend with incorrect `alpha` when `stacked=True` (GH8027).

• Period and `PeriodIndex` addition/subtraction with `np.timedelta64` results in incorrect internal representations (GH7740).

• Bug in `Holiday` with no offset or observance (GH7987).

• Bug in `DataFrame.to_latex` formatting when columns or index is a `MultiIndex` (GH7982).

• Bug in `DateOffset` around Daylight Savings Time produces unexpected results (GH5175).

• Bug in `DataFrame.shift` where empty columns would throw `ZeroDivisionError` on numpy 1.7 (GH8019).

• Bug in installation where `html_encoding/*.html` wasn’t installed and therefore some tests were not running correctly (GH7927).

• Bug in `read_html` where bytes objects were not tested for in `_read` (GH7927).

• Bug in `DataFrame.stack()` when one of the column levels was a datelike (GH8039).

• Bug in broadcasting numpy scalars with `DataFrame` (GH8116).

• Bug in `pivot_table` performed with nameless index and columns raises `KeyError` (GH8103).

• Bug in `DataFrame.plot(kind='scatter')` draws points and errorbars with different colors when the color is specified by `c` keyword (GH8081).

• Bug in `Float64Index` where `iat` and `at` were not testing and were failing (GH8092).

• Bug in `DataFrame.boxplot()` where y-limits were not set correctly when producing multiple axes (GH7528, GH5517).

• Bug in `read_csv` where line comments were not handled correctly given a custom line terminator or `delim_whitespace=True` (GH8122).

• Bug in `read_html` where empty tables caused a `StopIteration` (GH7575).

• Bug in `read_html` where empty tables caused a `StopIteration` (GH7575).

• Bug in casting when setting a column in a same-dtype block (GH7704).

• Bug in accessing groups from a `GroupBy` when the original grouper was a tuple (GH8121).

• Bug in `.at` that would accept integer indexers on a non-integer index and do fallback (GH7814).
• Bug with kde plot and NaNs (GH8182)
• Bug in GroupBy.count with float32 data type were nan values were not excluded (GH8169).
• Bug with stacked barplots and NaNs (GH8175).
• Bug in resample with non evenly divisible offsets (e.g. ’7s’) (GH8371)
• Bug in interpolation methods with the limit keyword when no values needed interpolating (GH7173).
• Bug where col_space was ignored in DataFrame.to_string() when header=False (GH8230).
• Bug with DateTimeIndex.asof incorrectly matching partial strings and returning the wrong date (GH8245).
• Bug in plotting methods modifying the global matplotlib rcParams (GH8242).
• Bug in DataFrame.__setitem__ that caused errors when setting a dataframe column to a sparse array (GH8131)
• Bug where DataFrame.boxplot() failed when entire column was empty (GH8181).
• Bug with messed variables in radviz visualization (GH8199).
• Bug in interpolation methods with the limit keyword when no values needed interpolating (GH7173).
• Bug where col_space was ignored in DataFrame.to_string() when header=False (GH8230).
• Bug into_clipboard that would clip long column data (GH8305)
• Bug in DataFrame terminal display: Setting max_column/max_rows to zero did not trigger auto-resizing of dfs to fit terminal width/height (GH7180).
• Bug in OLS where running with “cluster” and “nw_lags” parameters did not work correctly, but also did not throw an error (GH5884).
• Bug in DataFrame.dropna that interpreted non-existent columns in the subset argument as the ‘last column’ (GH8303)
• Bug in Index.intersection on non-monotonic non-unique indexes (GH8362).
• Bug in masked series assignment where mismatching types would break alignment (GH8387)
• Bug in NDFrame.equals gives false negatives with dtype=object (GH8437)
• Bug in assignment with indexer where type diversity would break alignment (GH8258)
• Bug in NDFrame.loc indexing when row/column names were lost when target was a list/ndarray (GH6552)
• Regression in NDFrame.loc indexing when rows/columns were converted to Float64Index if target was an empty list/ndarray (GH7774)
• Bug in Series that allows it to be indexed by a DataFrame which has unexpected results. Such indexing is no longer permitted (GH8444)
• Bug in item assignment of a DataFrame with MultiIndex columns where right-hand-side columns were not aligned (GH7655)
• Suppress FutureWarning generated by NumPy when comparing object arrays containing Nan for equality (GH7065)
• Bug in DataFrame.eval() where the dtype of the not operator (~) was not correctly inferred as bool.

This is a minor release from 0.14.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

- Highlights include:
  - New methods `select_dtypes()` to select columns based on the dtype and `sem()` to calculate the standard error of the mean.
  - Support for dateutil timezones (see `docs`).
  - Support for ignoring full line comments in the `read_csv()` text parser.
  - New documentation section on `Options and Settings`.
  - Lots of bug fixes.

5.14.1 Version 0.14.1 (July 11, 2014)
API changes

- Openpyxl now raises a ValueError on construction of the openpyxl writer instead of warning on pandas import (GH7284).

- For StringMethods.extract, when no match is found, the result - only containing NaN values - now also has dtype=object instead of float (GH7242)

- Period objects no longer raise a TypeError when compared using == with another object that isn’t a Period. Instead when comparing a Period with another object using == if the other object isn’t a Period False is returned. (GH7376)

- Previously, the behaviour on resetting the time or not in offsets.apply, rollforward and rollback operations differed between offsets. With the support of the normalize keyword for all offsets(see below) with a default value of False (preserve time), the behaviour changed for certain offsets (BusinessMonthBegin, MonthEnd, BusinessMonthEnd, CustomBusinessMonthEnd, BusinessYearBegin, LastWeekOfMonth, FY5253Quarter, LastWeekOfMonth, Easter):

```
In [6]: from pandas.tseries import offsets
In [7]: d = pd.Timestamp('2014-01-01 09:00')
# old behaviour < 0.14.1
In [8]: d + offsets.MonthEnd()
Out[8]: pd.Timestamp('2014-01-31 00:00:00')
```

Starting from 0.14.1 all offsets preserve time by default. The old behaviour can be obtained with normalize=True

```
# new behaviour
In [1]: d + offsets.MonthEnd()
Out[1]: Timestamp('2014-01-31 09:00:00')
In [2]: d + offsets.MonthEnd(normalize=True)
Out[2]: Timestamp('2014-01-31 00:00:00')
```

Note that for the other offsets the default behaviour did not change.

- Add back #N/A N/A as a default NA value in text parsing. (regression from 0.12) (GH5521)

- Raise a TypeError on inplace-setting with a .where and a non np.nan value as this is inconsistent with a set-item expression like df[mask] = None (GH7656)

Enhancements

- Add dropna argument to value_counts and nunique (GH5569).

- Add select_dtypes() method to allow selection of columns based on dtype (GH7316). See the docs.

- All offsets supports the normalize keyword to specify whether offsets.apply, rollforward and rollback resets the time (hour, minute, etc) or not (default False, preserves time) (GH7156):

```python
import pandas.tseries.offsets as offsets
day = offsets.Day()
day.apply(pd.Timestamp('2014-01-01 09:00'))

day = offsets.Day(normalize=True)
day.apply(pd.Timestamp('2014-01-01 09:00'))
```
PeriodIndex is represented as the same format as DatetimeIndex (GH7601)

StringMethods now work on empty Series (GH7242)

The file parsers read_csv and read_table now ignore line comments provided by the parameter comment, which accepts only a single character for the C reader. In particular, they allow for comments before file data begins (GH2685)

Add NotImplementedError for simultaneous use of chunksize and nrows for read_csv() (GH6774).

Tests for basic reading of public S3 buckets now exist (GH7281).

read_html now sports an encoding argument that is passed to the underlying parser library. You can use this to read non-ascii encoded web pages (GH7323).

read_excel now supports reading from URLs in the same way that read_csv does. (GH6809)

Support for dateutil timezones, which can now be used in the same way as pytz timezones across pandas. (GH4688)

```
In [3]: rng = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
                      ...:                 tz='dateutil/Europe/London')
                      ...

In [4]: rng.tz
Out[4]: tzfile('/usr/share/zoneinfo/Europe/London')
```

See the docs.

Implemented sem (standard error of the mean) operation for Series, DataFrame, Panel, and Groupby (GH6897)

Add nlargest and nsmallest to the Series groupby allowlist, which means you can now use these methods on a SeriesGroupBy object (GH7053).

All offsets apply, rollforward and rollback can now handle np.datetime64, previously results in ApplyTypeError (GH7452)

Period and PeriodIndex can contain NaT in its values (GH7485)

Support pickling Series, DataFrame and Panel objects with non-unique labels along item axis (index, columns and items respectively) (GH7370).

Improved inference of datetime/timedelta with mixed null objects. Regression from 0.13.1 in interpretation of an object Index with all null elements (GH7431)

### Performance

- Improvements in dtype inference for numeric operations involving yielding performance gains for dtypes: int64, timedelta64, datetime64 (GH7223)
- Improvements in Series.transform for significant performance gains (GH6496)
- Improvements in DataFrame.transform with ufuncs and built-in grouper functions for significant performance gains (GH7383)
- Regression in groupby aggregation of datetime64 dtypes (GH7555)
- Improvements in MultiIndex.from_product for large iterables (GH7627)
Experimental

- `pandas.io.data.Options` has a new method, `get_all_data` method, and now consistently returns a MultiIndexed DataFrame (GH5602)
- `io.gbq.read_gbq` and `io.gbq.to_gbq` were refactored to remove the dependency on the Google bq.py command line client. This submodule now uses http/2 and the Google apiclient and oauth2client API client libraries which should be more stable and, therefore, reliable than bq.py. See the docs. (GH6937).

Bug fixes

- Bug in `DataFrame.where` with a symmetric shaped frame and a passed other of a DataFrame (GH7506)
- Bug in Panel indexing with a MultiIndex axis (GH7516)
- Regression in datetimelike slice indexing with a duplicated index and non-exact end-points (GH7523)
- Bug in setitem with list-of-lists and single vs mixed types (GH7551)
- Bug in time ops with non-aligned Series (GH7500)
- Bug in timedelta inference when assigning an incomplete Series (GH7592)
- Bug in groupby `.nth` with a Series and integer-like column name (GH7559)
- Bug in `Series.set` with a boolean accessor (GH7407)
- Bug in `value_counts` where NaT did not qualify as missing (NaN) (GH7423)
- Bug in `to_timedelta` that accepted invalid units and misinterpreted ‘m/h’ (GH7611, GH6423)
- Bug in line plot doesn’t set correct `xlim` if `secondary_y=True` (GH7459)
- Bug in grouped `hist` and `scatter` plots use old `figsize` default (GH7394)
- Bug in plotting subplots with `DataFrame.plot.hist` clears passed `ax` even if the number of subplots is one (GH7391).
- Bug in plotting subplots with `DataFrame.boxplot` with `by` kw raises `ValueError` if the number of subplots exceeds 1 (GH7391).
- Bug in `DataFrame.bar` and `barh` plot raises `TypeError` when `bottom` and `left` keyword is specified (GH7226)
- Bug in `Index.delete` does not preserve `name` and `freq` attributes (GH7302)
• Bug in `DataFrame.query()`/`eval` where local string variables with the @ sign were being treated as temporaries attempting to be deleted (GH7300).
• Bug in `Float64Index` which didn’t allow duplicates (GH7149).
• Bug in `DataFrame.replace()` where truthy values were being replaced (GH7140).
• Bug in `StringMethods.extract()` where a single match group Series would use the matcher’s name instead of the group name (GH7313).
• Bug in `isnull()` when mode.use_inf_as_null == True where isnull wouldn’t test True when it encountered an inf/-inf (GH7315).
• Bug in inferred_freq results in None for eastern hemisphere timezones (GH7310)
• Bug in `Easter` returns incorrect date when offset is negative (GH7195)
• Bug in broadcasting with `.div`, integer dtypes and divide-by-zero (GH7325)
• Bug in `CustomBusinessDay.apply` raises NameError when np.datetime64 object is passed (GH7196)
• Bug in `MultiIndex.append`, `concat` and `pivot_table` don’t preserve timezone (GH6606)
• Bug in `.loc` with a list of indexers on a single-multi index level (that is not nested) (GH7349)
• Bug in `Series.map` when mapping a dict with tuple keys of different lengths (GH7333)
• Bug all `StringMethods` now work on empty Series (GH7242)
• Fix delegation of `read_sql` to `read_sql_query` when query does not contain 'select' (GH7324).
• Bug where a string column name assignment to a `DataFrame` with a `Float64Index` raised a TypeError during a call to np.isnan (GH7366).
• Bug where `NDFrame.replace()` didn’t correctly replace objects with Period values (GH7379).
• Bug in `.ix` getitem should always return a Series (GH7150)
• Bug in `MultiIndex` slicing with incomplete indexers (GH7399)
• Bug in `MultiIndex` slicing with a step in a sliced level (GH7400)
• Bug where negative indexers in `DatetimeIndex` were not correctly sliced (GH7408)
• Bug where NaT wasn’t repr’d correctly in a `MultiIndex` (GH7406, GH7409).
• Bug where bool objects were converted to nan in `convert_objects` (GH7416).
• Bug in `quantile` ignoring the axis keyword argument (GH7306)
• Bug where nanops._maybe_null_out doesn’t work with complex numbers (GH7353)
• Bug in several nanops functions when axis==0 for 1-dimensional nan arrays (GH7354)
• Bug where nanops.nanmedian doesn’t work when axis==None (GH7352)
• Bug where nanops._has_infs doesn’t work with many dtypes (GH7357)
• Bug in StataReader.data where reading a 0-observation dta failed (GH7369)
• Bug in StataReader when reading Stata 13 (117) files containing fixed width strings (GH7360)
• Bug in StataWriter where encoding was ignored (GH7286)
• Bug in `DatetimeIndex` comparison doesn’t handle NaT properly (GH7529)
• Bug in passing input with tzinfo to some offsets apply, rollforward or rollback resets tzinfo or raises ValueError (GH7465)
• Bug in `DatetimeIndex.to_period`, `PeriodIndex.asobject`, `PeriodIndex.to_timestamp` doesn’t preserve name (GH7485)

• Bug in `DatetimeIndex.to_period` and `PeriodIndex.to_timestamp` handle NaT incorrectly (GH7228)

• Bug in `offsets.apply`, `rollforward` and `rollback` may return normal datetime (GH7502)

• Bug in `resample` raises `ValueError` when target contains NaT (GH7227)

• Bug in `Timestamp.tz_localize` resets nanosecond info (GH7534)

• Bug in `DatetimeIndex.asobject` raises `ValueError` when it contains NaT (GH7539)

• Bug in `timestamp.__new__` doesn’t preserve nanosecond properly (GH7610)

• Bug in `Index.astype(float)` where it would return an object dtype `Index` (GH7464).

• Bug in `DataFrame.reset_index` loses tz (GH3950)

• Bug in `DatetimeIndex.freqstr` raises `AttributeError` when freq is None (GH7606)

• Bug in `GroupBy.size` created by `TimeGrouper` raises `AttributeError` (GH7453)

• Bug in single column bar plot is misaligned (GH7498).

• Bug in `area plot` with tz-aware time series raises `ValueError` (GH7471)

• Bug in `non-monotonic Index.union` may preserve name incorrectly (GH7458)

• Bug in `DatetimeIndex.intersection` doesn’t preserve timezone (GH4690)

• Bug in `rolling_var` where a window larger than the array would raise an error(GH7297)

• Bug with last plotted timeseries dictating `xlim` (GH2960)

• Bug with `secondary_y` axis not being considered for timeseries `xlim` (GH3490)

• Bug in `Float64Index` assignment with a non scalar indexer (GH7586)

• Bug in `pandas.core.strings.str_contains` does not properly match in a case insensitive fashion when `regex=False` and `case=False` (GH7505)

• Bug in `expanding_cov`, `expanding_corr`, `rolling_cov`, and `rolling_corr` for two arguments with mismatched index (GH7512)

• Bug in `to_sql` taking the boolean column as text column (GH7678)

• Bug in `grouped hist` doesn’t handle `rot` kw and `sharex` kw properly (GH7234)

• Bug in `.loc` performing fallback integer indexing with object dtype indices (GH7496)

• Bug (regression) in `PeriodIndex` constructor when passed `Series` objects (GH7701).

5.14.2 Version 0.14.0 (May 31, 2014)

This is a major release from 0.13.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

• Highlights include:
  – Officially support Python 3.4
  – SQL interfaces updated to use sqlalchemy, See Here.
  – Display interface changes, See Here
  – MultiIndexing Using Slicers, See Here.
  – Ability to join a singly-indexed DataFrame with a MultiIndexed DataFrame, see Here
  – More consistency in groupby results and more flexible groupby specifications, See Here
  – Holiday calendars are now supported in CustomBusinessDay, see Here
  – Several improvements in plotting functions, including: hexbin, area and pie plots, see Here.
  – Performance doc section on I/O operations, See Here

• Other Enhancements
• API Changes
• Text Parsing API Changes
• Groupby API Changes
• Performance Improvements
• Prior Deprecations
• Deprecations
• Known Issues
• Bug Fixes

Warning: In 0.14.0 all DataFrame based containers have undergone significant internal refactoring. Before that each block of homogeneous data had its own labels and extra care was necessary to keep those in sync with the parent container’s labels. This should not have any visible user/API behavior changes (GH6745)
API changes

- `read_excel` uses 0 as the default sheet (GH6573)
- `iloc` will now accept out-of-bounds indexers for slices, e.g. a value that exceeds the length of the object being indexed. These will be excluded. This will make pandas conform more with python/numpy indexing of out-of-bounds values. A single indexer that is out-of-bounds and drops the dimensions of the object will still raise `IndexError` (GH6296, GH6299). This could result in an empty axis (e.g. an empty DataFrame being returned)

```python
In [1]: df1 = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))

In [2]: df1
Out[2]:
       A       B
0  0.469112 -0.282863
1 -1.509059 -1.135632
2  1.212112 -0.173215
3  0.119209 -1.044236
4 -0.861849 -2.104569
[5 rows x 2 columns]

In [3]: df1.iloc[:, 2:3]
Out[3]:
Empty DataFrame
Columns: []
Index: [0, 1, 2, 3, 4]
[5 rows x 0 columns]

In [4]: df1.iloc[:, 1:3]
Out[4]:
       B
0 -0.282863
1 -1.135632
2 -0.173215
3 -1.044236
4 -2.104569
[5 rows x 1 columns]

In [5]: df1.iloc[4:6]
Out[5]:
       A       B
4  0.861849 -2.104569
[1 rows x 2 columns]
```

These are out-of-bounds selections

```python
>>> df1.iloc[[4, 5, 6]]
IndexError: positional indexers are out-of-bounds

>>> df1.iloc[:, 4]
IndexError: single positional indexer is out-of-bounds
```

- Slicing with negative start, stop & step values handles corner cases better (GH6531):
- `df.iloc[:-len(df)]` is now empty
- `df.iloc[len(df)::]` now enumerates all elements in reverse

- The `DataFrame.interpolate()` keyword `downcast default` has been changed from `infer` to `None`. This is to preserve the original dtype unless explicitly requested otherwise (GH6290).

- When converting a dataframe to HTML it used to return `Empty DataFrame`. This special case has been removed, instead a header with the column names is returned (GH6062).

- Series and Index now internally share more common operations, e.g. `factorize()`, `nunique()`, `value_counts()` are now supported on Index types as well. The `Series.weekday` property from is removed from Series for API consistency. Using a DatetimeIndex/PeriodIndex method on a Series will now raise a `TypeError` (GH4551, GH4056, GH5519, GH6380, GH7206).

- Add `is_month_start`, `is_month_end`, `is_quarter_start`, `is_quarter_end`, `is_year_start`, `is_year_end` accessors for `DateTimeIndex / Timestamp` which return a boolean array of whether the timestamp(s) are at the start/end of the month/quarter/year defined by the frequency of the `DateTimeIndex / Timestamp` (GH4565, GH6998).

- Local variable usage has changed in `pandas.eval() / DataFrame.eval() / DataFrame.query()` (GH5987). For the `DataFrame` methods, two things have changed
  - Column names are now given precedence over locals
  - Local variables must be referred to explicitly. This means that even if you have a local variable that is not a column you must still refer to it with the '@' prefix.
  - You can have an expression like `df.query('@a < a')` with no complaints from pandas about ambiguity of the name a.
  - The top-level `pandas.eval()` function does not allow you use the '@' prefix and provides you with an error message telling you so.
  - `NameResolutionError` was removed because it isn’t necessary anymore.

- Define and document the order of column vs index names in `query/eval` (GH6676)

- `concat` will now concatenate mixed Series and DataFrames using the Series name or numbering columns as needed (GH2385). See the docs

- Slicing and advanced/boolean indexing operations on Index classes as well as `Index.delete()` and `Index.drop()` methods will no longer change the type of the resulting index (GH6440, GH7040)

```
In [6]: i = pd.Index([1, 2, 3, 'a', 'b', 'c'])

In [7]: i[[0, 1, 2]]
Out[7]: Index([1, 2, 3], dtype='object')

In [8]: i.drop(['a', 'b', 'c'])
Out[8]: Index([1, 2, 3], dtype='object')
```

Previously, the above operation would return `Int64Index`. If you’d like to do this manually, use `Index.astype()`

```
In [9]: i[[0, 1, 2]].astype(np.int_)
Out[9]: Int64Index([1, 2, 3], dtype='int64')
```

- `set_index` no longer converts MultiIndexes to an Index of tuples. For example, the old behavior returned an Index in this case (GH6459):
# Old behavior, casted MultiIndex to an Index

```python
In [10]: tuple_ind
Out[10]: Index([('a', 'c'), ('a', 'd'), ('b', 'c'), ('b', 'd')], dtype='object')
```

```python
In [11]: df_multi.set_index(tuple_ind)
Out[11]:
   0    1
(a, c) 0.471435 -1.190976
(a, d) 1.432707 -0.312652
(b, c) -0.720589  0.887163
(b, d)  0.859588 -0.636524
[4 rows x 2 columns]
```

# New behavior

```python
In [12]: mi
Out[12]: MultiIndex([('a', 'c'),
                  ('a', 'd'),
                  ('b', 'c'),
                  ('b', 'd')],
                  )
```

```python
In [13]: df_multi.set_index(mi)
Out[13]:
   0    1
 a c  0.471435 -1.190976
d  1.432707 -0.312652
 b c -0.720589  0.887163
d  0.859588 -0.636524
[4 rows x 2 columns]
```

This also applies when passing multiple indices to `set_index`:

```python
# Old output, 2-level MultiIndex of tuples
In [14]: df_multi.set_index([df_multi.index, df_multi.index])
Out[14]:
   0    1
(a, c) (a, c) 0.471435 -1.190976
(a, d) (a, d) 1.432707 -0.312652
(b, c) (b, c) -0.720589  0.887163
(b, d) (b, d)  0.859588 -0.636524
[4 rows x 2 columns]
```

# New output, 4-level MultiIndex

```python
In [15]: df_multi.set_index([df_multi.index, df_multi.index])
Out[15]:
   0    1
 a c a c  0.471435 -1.190976
da d  1.432707 -0.312652
 b c b c -0.720589  0.887163
bd bd  0.859588 -0.636524
[4 rows x 2 columns]
```

• **pairwise** keyword was added to the statistical moment functions `rolling_cov`, `rolling_corr`,
ewmcov, ewmcorr, expanding_cov, expanding_corr to allow the calculation of moving window covariance and correlation matrices (GH4950). See Computing rolling pairwise covariances and correlations in the docs.

```
In [1]: df = pd.DataFrame(np.random.randn(10, 4), columns=list('ABCD'))
In [4]: covs = pd.rolling_cov(df[['A', 'B', 'C']],
                        ...:                      df[['B', 'C', 'D']],
                        ...:                      5,
                        ...:                      pairwise=True)
In [5]: covs[df.index[-1]]
Out[5]:
         B      C      D
A  0.035310  0.326593 -0.505430
B  0.137748 -0.006888 -0.005383
C -0.006888  0.861040  0.020762
```

- Series.iteritems() is now lazy (returns an iterator rather than a list). This was the documented behavior prior to 0.14. (GH6760)
- Added nunique and value_counts functions to Index for counting unique elements. (GH6734)
- stack and unstack now raise a ValueError when the level keyword refers to a non-unique item in the Index (previously raised a KeyError). (GH6738)
- drop unused order argument from Series.sort; args now are in the same order as Series.order; add na_position arg to conform to Series.order (GH6847)
- default sorting algorithm for Series.order is now quicksort, to conform with Series.sort (and numpy defaults)
- add inplace keyword to Series.order/sort to make them inverses (GH6859)
- DataFrame.sort now places NaNs at the beginning or end of the sort according to the na_position parameter. (GH3917)
- accept TextFileReader in concat, which was affecting a common user idiom (GH6583), this was a regression from 0.13.1
- Added factorize functions to Index and Series to get indexer and unique values (GH7090)
- describe on a DataFrame with a mix of Timestamp and string like objects returns a different Index (GH7088). Previously the index was unintentionally sorted.
- Arithmetic operations with only bool dtypes now give a warning indicating that they are evaluated in Python space for +, -, and * operations and raise for all others (GH7011, GH6762, GH7015, GH7210)

```
>>> x = pd.Series(np.random.rand(10) > 0.5)
>>> y = True
>>> x + y  # warning generated: should do x | y instead
UserWarning: evaluating in Python space because the '+' operator is not supported by numexpr for the bool dtype, use '|' instead
>>> x / y  # this raises because it doesn't make sense
NotImplementedError: operator '/' not implemented for bool dtypes
```

- In HDFStore, select_as_multiple will always raise a KeyError, when a key or the selector is not found (GH6177)
- df['col'] = value and df.loc[:, 'col'] = value are now completely equivalent; previously the .loc would not necessarily coerce the dtype of the resultant series (GH6149)
• `dtypes` and `ftypes` now return a series with `dtype=object` on empty containers (GH5740)
• `df.to_csv` will now return a string of the CSV data if neither a target path nor a buffer is provided (GH6061)
• `pd.infer_freq()` will now raise a `TypeError` if given an invalid `Series/Index` type (GH6407, GH6463)
• A tuple passed to `DataFrame.sort_index` will be interpreted as the levels of the index, rather than requiring a list of tuple (GH4370)
• all offset operations now return `Timestamp` types (rather than `datetime`), Business/Week frequencies were incorrect (GH4069)
• `to_excel` now converts `np.inf` into a string representation, customizable by the `inf_rep` keyword argument (Excel has no native inf representation) (GH6782)
• Replace `pandas.compat.scipy.scoreatpercentile` with `numpy.percentile` (GH6810)
• `.quantile` on a `datetime[ns]` series now returns `Timestamp` instead of `np.datetime64` objects (GH6810)
• change `AssertionError` to `TypeError` for invalid types passed to `concat` (GH6583)
• Raise a `TypeError` when `DataFrame` is passed an iterator as the `data` argument (GH5357)

Display changes

• The default way of printing large DataFrames has changed. DataFrames exceeding `max_rows` and/or `max_columns` are now displayed in a centrally truncated view, consistent with the printing of a `pandas.Series` (GH5603).

In previous versions, a DataFrame was truncated once the dimension constraints were reached and an ellipse (...) signaled that part of the data was cut off.

```python
In [1]: import pandas as pd
In [2]: import numpy as np
In [3]: pd.options.display.max_rows = 6
In [4]: pd.options.display.max_columns = 6
In [5]: index = pd.DatetimeIndex(start='2001-01-01', freq='D', periods=10)
In [6]: pd.DataFrame(np.arange(10*10).reshape((10,10)), index=index)
Out[6]:
   0  1  2  3  4  5
2001-01-01  0  1  2  3  4  5 ...
2001-01-02 10 11 12 13 14 15 ...
2001-01-03 20 21 22 23 24 25 ...
2001-01-04 30 31 32 33 34 35 ...
2001-01-05 40 41 42 43 44 45 ...
2001-01-06 50 51 52 53 54 55 ...
   ...   ...   ...   ...   ...   ...
[10 rows x 10 columns]
```
In the current version, large DataFrames are centrally truncated, showing a preview of head and tail in both dimensions.

```python
In [24]: pd.DataFrame(np.arange(10*10).reshape((10,10)),index=index)
Out[24]:
          0  1  2  ...  7  8  9
2001-01-01 0  1  2  ...  7  8  9
2001-01-02 10 11 12  ... 17 18 19
2001-01-03 20 21 22  ... 27 28 29
...       ...       ...     ...   ...   ...
2001-01-08 70 71 72  ... 77 78 79
2001-01-09 80 81 82  ... 87 88 89
2001-01-10 90 91 92  ... 97 98 99

[10 rows x 10 columns]
```

- allow option 'truncate' for `display.show_dimensions` to only show the dimensions if the frame is truncated (GH6547).

The default for `display.show_dimensions` will now be `truncate`. This is consistent with how Series display length.

```python
In [16]: dfd = pd.DataFrame(np.arange(25).reshape(-1, 5),
                         index=[0, 1, 2, 3, 4],
                         columns=[0, 1, 2, 3, 4])

# show dimensions since this is truncated
In [17]: with pd.option_context('display.max_rows', 2, 'display.max_columns', 2,
                             'display.show_dimensions', 'truncate'):
    print(dfd)
   0 ... 4
  0  1  2  3  4
  1  5  6  7  8  9
  2 10 11 12 13 14
  3 15 16 17 18 19
  4 20 21 22 23 24

[5 rows x 5 columns]

# will not show dimensions since it is not truncated
In [18]: with pd.option_context('display.max_rows', 10, 'display.max_columns', 40,
                             'display.show_dimensions', 'truncate'):
    print(dfd)
   0  1  2  3  4
  0  1  2  3  4
  1  5  6  7  8  9
  2 10 11 12 13 14
  3 15 16 17 18 19
  4 20 21 22 23 24
```

- Regression in the display of a MultiIndexed Series with `display.max_rows` is less than the length of the series (GH7101)

- Fixed a bug in the HTML repr of a truncated Series or DataFrame not showing the class name with the `large_repr` set to ‘info’ (GH7105)
• The `verbose` keyword in `DataFrame.info()`, which controls whether to shorten the `info` representation, is now `None` by default. This will follow the global setting in `display.max_info_columns`. The global setting can be overridden with `verbose=True` or `verbose=False`.

• Fixed a bug with the `info` repr not honoring the `display.max_info_columns` setting (GH6939)

• Offset/freq info now in Timestamp `__repr__` (GH4553)

## Text parsing API changes

`read_csv()`/`read_table()` will now be noisier w.r.t invalid options rather than falling back to the PythonParser.

• Raise `ValueError` when `sep` specified with `delim_whitespace=True` in `read_csv()`/`read_table()` (GH6607)

• Raise `ValueError` when `engine='c'` specified with unsupported options in `read_csv()`/`read_table()` (GH6607)

• Raise `ValueError` when fallback to python parser causes options to be ignored (GH6607)

• Produce `ParserWarning` on fallback to python parser when no options are ignored (GH6607)

• Translate `sep='\s+'` to `delim_whitespace=True` in `read_csv()`/`read_table()` if no other C-unsupported options specified (GH6607)

## GroupBy API changes

More consistent behavior for some groupby methods:

• `groupby head` and `tail` now act more like `filter` rather than an aggregation:

```
In [19]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=['A', 'B'])
In [20]: g = df.groupby('A')
In [21]: g.head(1)  # filters DataFrame
Out[21]:
   A  B
0  1  2
2  5  6
[2 rows x 2 columns]
In [22]: g.apply(lambda x: x.head(1))  # used to simply fall-through
Out[22]:
   A  B
A  1  2
5  2  6
[2 rows x 2 columns]
```

• `groupby head` and `tail` respect column selection:

```
In [23]: g[['B']].head(1)
Out[23]:
   B
0  2
2  6
```

(continues on next page)
• groupby nth now reduces by default; filtering can be achieved by passing `as_index=False`. With an optional `dropna` argument to ignore NaN. See the docs.

Reducing

```python
In [24]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])
In [25]: g = df.groupby('A')
In [26]: g.nth(0)
Out[26]:
   B
A  
  1 NaN
  5  6.0
[2 rows x 1 columns]
# this is equivalent to g.first()
In [27]: g.nth(0, dropna='any')
Out[27]:
   B
A  
  1  4.0
  5  6.0
[2 rows x 1 columns]
# this is equivalent to g.last()
In [28]: g.nth(-1, dropna='any')
Out[28]:
   B
A  
  1  4.0
  5  6.0
[2 rows x 1 columns]
```

Filtering

```python
In [29]: gf = df.groupby('A', as_index=False)
In [30]: gf.nth(0)
Out[30]:
   A   B
 0  1  NaN
 2  5  6.0
[2 rows x 2 columns]
In [31]: gf.nth(0, dropna='any')
Out[31]:
   A   B
 0  1  NaN
 2  5  6.0
```

(continues on next page)
A B
A
1 1 4.0
5 5 6.0
[2 rows x 2 columns]

• groupby will now not return the grouped column for non-cython functions (GH5610, GH5614, GH6732), as its already the index

In [32]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6], [5, 8]], columns=[A, B])
In [33]: g = df.groupby(A)
In [34]: g.count()
Out[34]:
A B
0 1 1
1 5 2
[2 rows x 1 columns]
In [35]: g.describe()
Out[35]:
A B
count mean std min 25% 50% 75% max
count mean std min 25% 50% 75% max
0 2.0 1.0 0.0 1.0 1.0 1.0 1.0 4.0 NaN 4.0 4.0 4.0 4.0
1 2.0 7.0 1.414214 6.0 6.5 7.0 7.5 8.0
[2 rows x 8 columns]

• passing as_index will leave the grouped column in-place (this is not change in 0.14.)

In [36]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6], [5, 8]], columns=[A, B])
In [37]: g = df.groupby(A, as_index=False)
In [38]: g.count()
Out[38]:
A B
0 1 1
1 5 2
[2 rows x 2 columns]
In [39]: g.describe()
Out[39]:
A B
count mean  std  min 25% 50% 75% max count mean  std  min 25% 50% 75% max
0 2.0 1.0 0.0 1.0 1.0 1.0 1.0 1.0 4.0 NaN 4.0 4.0 4.0 4.0
1 2.0 7.0 1.414214 6.0 6.5 7.0 7.5 8.0
[Continues on next page]
• Allow specification of a more complex groupby via `pd.Grouper`, such as grouping by a Time and a string field simultaneously. See the docs. (GH3794)

• Better propagation/preservation of Series names when performing groupby operations:
  – `SeriesGroupBy.agg` will ensure that the name attribute of the original series is propagated to the result (GH6265).
  – If the function provided to `GroupBy.apply` returns a named series, the name of the series will be kept as the name of the column index of the DataFrame returned by `GroupBy.apply` (GH6124). This facilitates `DataFrame.stack` operations where the name of the column index is used as the name of the inserted column containing the pivoted data.

**SQL**

The SQL reading and writing functions now support more database flavors through SQLAlchemy (GH2717, GH4163, GH5950, GH6292). All databases supported by SQLAlchemy can be used, such as PostgreSQL, MySQL, Oracle, Microsoft SQL server (see documentation of SQLAlchemy on included dialects).

The functionality of providing DBAPI connection objects will only be supported for sqlite3 in the future. The 'mysql' flavor is deprecated.

The new functions `read_sql_query()` and `read_sql_table()` are introduced. The function `read_sql()` is kept as a convenience wrapper around the other two and will delegate to specific function depending on the provided input (database table name or sql query).

In practice, you have to provide a SQLAlchemy engine to the sql functions. To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to. For an in-memory sqlite database:

```python
In [40]: from sqlalchemy import create_engine

# Create your connection.
In [41]: engine = create_engine('sqlite:///::memory::)
```

This engine can then be used to write or read data to/from this database:

```python
In [42]: df = pd.DataFrame({'A': [1, 2, 3], 'B': ['a', 'b', 'c']})
In [43]: df.to_sql('db_table', engine, index=False)
```

You can read data from a database by specifying the table name:

```python
In [44]: pd.read_sql_table('db_table', engine)
Out[44]:
   A  B
0  1  a
1  2  b
2  3  c
```

[3 rows x 2 columns]
or by specifying a sql query:

```python
In [45]: pd.read_sql_query('SELECT * FROM db_table', engine)
Out[45]:
          A  B
0        1  a
1        2  b
2        3  c
[3 rows x 2 columns]
```

Some other enhancements to the sql functions include:

- support for writing the index. This can be controlled with the `index` keyword (default is True).
- specify the column label to use when writing the index with `index_label`.
- specify string columns to parse as datetimes with the `parse_dates` keyword in `read_sql_query()` and `read_sql_table()`.

**Warning:** Some of the existing functions or function aliases have been deprecated and will be removed in future versions. This includes: `tquery`, `uquery`, `read_frame`, `frame_query`, `write_frame`.

**Warning:** The support for the ‘mysql’ flavor when using DBAPI connection objects has been deprecated. MySQL will be further supported with SQLAlchemy engines (GH6900).

### Multi-indexing using slicers

In 0.14.0 we added a new way to slice MultiIndexed objects. You can slice a MultiIndex by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see *Selection by Label*, including slices, lists of labels, labels, and boolean indexers.

You can use `slice(None)` to select all the contents of that level. You do not need to specify all the deeper levels, they will be implied as `slice(None)`.

As usual, **both sides** of the slicers are included as this is label indexing.

See *the docs* See also issues (GH6134, GH4036, GH3057, GH2598, GH5641, GH7106)

**Warning:**

You should specify all axes in the `.loc` specifier, meaning the indexer for the `index` and for the `columns`. Their are some ambiguous cases where the passed indexer could be mis-interpreted as indexing both axes, rather than into say the MultiIndex for the rows.

You should do this:

```python
>>> df.loc[(slice('A1', 'A3'), ...), :] # noqa: E901
```

rather than this:

```python
>>> df.loc[(slice('A1', 'A3'), ...)] # noqa: E901
```
In [46]: def mklbl(prefix, n):
   ....:    return ["%s%d" % (prefix, i) for i in range(n)]
   ....:

In [47]: index = pd.MultiIndex.from_product([mklbl('A', 4),
   ....:    mklbl('B', 2),
   ....:    mklbl('C', 4),
   ....:    mklbl('D', 2)])
   ....:

In [48]: columns = pd.MultiIndex.from_tuples([('a', 'foo'), ('a', 'bar'),
   ....:    ('b', 'foo'), ('b', 'bah')],
   ....:    names=['lvl0', 'lvl1'])
   ....:

In [49]: df = pd.DataFrame(np.arange(len(index) * len(columns)).reshape((len(index),
   ....:    len(columns))),
   ....:    index=index,
   ....:    columns=columns).sort_index().sort_index(axis=1)
   ....:

In [50]: df
Out[50]:
lvl0    a    b
lvl1     bar  foo  bah  foo
A0  B0  C0  D0  1  0  3  2
   D1  5  4  7  6
   C1  9  8 11 10
   D1 13 12 15 14
   C2 17 16 19 18
   ...    ...    ...    ...
A3  B1  C1  D1 237 236 239 238
   C2 241 240 243 242
   D1 245 244 247 246
   C3 249 248 251 250
   D1 253 252 255 254
[64 rows x 4 columns]

Basic MultiIndex slicing using slices, lists, and labels.

In [51]: df.loc[(slice('A1', 'A3'), slice(None), ['C1', 'C3']), :]
Out[51]:
lvl0    a    b
lvl1     bar  foo  bah  foo
A1  B0  C1  D0  73  72  75  74
   D1  77  76  79  78
   C3  89  88  91  90
   D1  93  92  95  94
   B1  C1  D0 105 104 107 106
   ...    ...    ...    ...
A3  B0  C3  D1 221 220 223 222
   B1  C1  D0 233 232 235 234
   D1 237 236 239 238
(continues on next page)
You can use a `pd.IndexSlice` to shortcut the creation of these slices

```
In [52]: idx = pd.IndexSlice

In [53]: df.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]
```

```
Out[53]:
lvl0   a   b
lvl1  foo  foo
A0 B0 C1 D0   8   10
   D1  12  14
   C3 D0  24  26
   D1  28  30
   B1 C1 D0  40  42
... ... ...
A3 B0 C3 D1 220 222
   B1 C1 D0 232 234
   D1 236 238
   C3 D0 248 250
   D1 252 254

[32 rows x 2 columns]
```

It is possible to perform quite complicated selections using this method on multiple axes at the same time.

```
In [54]: df.loc['A1', (slice(None), 'foo')]
```

```
Out[54]:
lvl0   a   b
lvl1  foo  foo
B0 C0 D0  64  66
   D1  68  70
   C1 D0  72  74
   D1  76  78
   C2 D0  80  82
... ... ...
B1 C1 D1 108 110
   C2 D0 112 114
   D1 116 118
   C3 D0 120 122
   D1 124 126

[16 rows x 2 columns]
```

```
In [55]: df.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]
```

```
Out[55]:
lvl0   a   b
lvl1  foo  foo
A0 B0 C1 D0   8   10
   D1  12  14
   C3 D0  24  26
   D1  28  30
   B1 C1 D0  40  42
... ... ...
```

(continues on next page)
Using a boolean indexer you can provide selection related to the values.

```
In [56]: mask = df[('a', 'foo')] > 200

In [57]: df.loc[idx[mask, :, ['C1', 'C3']], idx[:, 'foo']]
Out[57]:
  lvl0   a   b
  lvl1 foo foo
   A3 B0 C1 D1 204 206
   C3 D0 216 218
   D1 220 222
   B1 C1 D0 232 234
   D1 236 238
   C3 D0 248 250
   D1 252 254

[7 rows x 2 columns]
```

You can also specify the axis argument to .loc to interpret the passed slicers on a single axis.

```
In [58]: df.loc(axis=0)[:, :, ['C1', 'C3']]
Out[58]:
  lvl0   a   b
  lvl1 bar foo bah foo
   A0 B0 C0 D0  1   0   3   2
   D1 13 12 15 14
   C3 D0 25 24 27 26
   D1 29 28 31 30
   B1 C1 D0 41 40 43 42
   ... ... ... ... ...
   A3 B0 C3 D1 221 220 223 222
   B1 C1 D0 233 232 235 234
   D1 237 236 239 238
   C3 D0 249 248 251 250
   D1 253 252 255 254

[32 rows x 4 columns]
```

Furthermore you can set the values using these methods

```
In [59]: df2 = df.copy()

In [60]: df2.loc(axis=0)[:, :, ['C1', 'C3']] = -10

In [61]: df2
Out[61]:
  lvl0   a   b
  lvl1 bar foo bah foo
   A0 B0 C0 D0  1   0   3   2
   D1 13 12 15 14
   C3 D0 25 24 27 26
   D1 29 28 31 30
   B1 C1 D0 41 40 43 42
   ... ... ... ... ...
   A3 B0 C3 D1 221 220 223 222
   B1 C1 D0 233 232 235 234
   D1 237 236 239 238
   C3 D0 249 248 251 250
   D1 253 252 255 254

[32 rows x 4 columns]
```
```python
D1  5  4  7  6
C1  D0 -10 -10 -10 -10
     D1 -10 -10 -10 -10
     C2  D0  17  16  19  18
     D1 -10 -10 -10 -10
...  ...  ...  ...  ...
A3  B1  C1  D1 -10 -10 -10 -10
     C2  D0  241 240 243 242
     D1  245 244 247 246
     C3  D0 -10 -10 -10 -10
     D1 -10 -10 -10 -10
```

You can use a right-hand-side of an alignable object as well.

```python
In [62]: df2 = df.copy()
In [63]: df2.loc[idx[:, :, ['C1', 'C3']], :] = df2 * 1000
In [64]: df2
Out[64]:
```

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>b</td>

<td>253000</td>
<td>252000</td>
<td>255000</td>
</tr>
</tbody>
</table>
```

[64 rows x 4 columns]

### Plotting

- Hexagonal bin plots from `DataFrame.plot` with `kind='hexbin'` (GH5478), See the docs.
- `DataFrame.plot` and `Series.plot` now supports area plot with specifying `kind='area'` (GH6656), See the docs.
- Pie plots from `Series.plot` and `DataFrame.plot` with `kind='pie'` (GH6976), See the docs.
- Plotting with Error Bars is now supported in the `.plot` method of `DataFrame` and `Series` objects (GH3796, GH6834), See the docs.
- `DataFrame.plot` and `Series.plot` now support a `table` keyword for plotting `matplotlib.Table`, See the docs. The `table` keyword can receive the following values.
  - `False`: Do nothing (default).
  - `True`: Draw a table using the `DataFrame` or `Series` called `plot` method. Data will be transposed to meet `matplotliblib`'s default layout.
DataFrame or Series: Draw matplotlib.table using the passed data. The data will be drawn as displayed in print method (not transposed automatically). Also, helper function pandas.tools.plotting.table is added to create a table from DataFrame and Series, and add it to an matplotlib.Axes.

- `plot(legend='reverse')` will now reverse the order of legend labels for most plot kinds. (GH6014)
- Line plot and area plot can be stacked by `stacked=True` (GH6656)
- Following keywords are now acceptable for `DataFrame.plot()` with `kind='bar'` and `kind='barh'`:
  - `width`: Specify the bar width. In previous versions, static value 0.5 was passed to matplotlib and it cannot be overwritten. (GH6604)
  - `align`: Specify the bar alignment. Default is `center` (different from matplotlib). In previous versions, pandas passes `align='edge'` to matplotlib and adjust the location to `center` by itself, and it results `align` keyword is not applied as expected. (GH4525)
  - `position`: Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1(right/top-end). Default is 0.5 (center). (GH6604)

Because of the default `align` value changes, coordinates of bar plots are now located on integer values (0.0, 1.0, 2.0 ...). This is intended to make bar plot be located on the same coordinates as line plot. However, bar plot may differs unexpectedly when you manually adjust the bar location or drawing area, such as using `set_xlim`, `set_ylim`, etc. In this cases, please modify your script to meet with new coordinates.

- The `parallel_coordinates()` function now takes argument `color` instead of `colors`. A FutureWarning is raised to alert that the old `colors` argument will not be supported in a future release. (GH6956)
- The `parallel_coordinates()` and `andrews_curves()` functions now take positional argument `frame` instead of `data`. A FutureWarning is raised if the old `data` argument is used by name. (GH6956)
- `DataFrame.boxplot()` now supports layout keyword (GH6769)
- `DataFrame.boxplot()` has a new keyword argument, `return_type`. It accepts 'dict', 'axes', or 'both', in which case a namedtuple with the matplotlib axes and a dict of matplotlib Lines is returned.

Prior version deprecations/changes

There are prior version deprecations that are taking effect as of 0.14.0.

- Remove `DateRange` in favor of `DatetimeIndex` (GH6816)
- Remove `column` keyword from `DataFrame.sort` (GH4370)
- Remove `precision` keyword from `set_eng_float_format()` (GH395)
- Remove `force_unicode` keyword from `DataFrame.to_string()`, `DataFrame.to_latex()`, and `DataFrame.to_html()`; these function encode in unicode by default (GH2224, GH2225)
- Remove `nanRep` keyword from `DataFrame.to_csv()` and `DataFrame.to_string()` (GH275)
- Remove `unique` keyword from `HDFStore.select_column()` (GH3256)
- Remove `inferTimeRule` keyword from `Timestamp.offset()` (GH1042)
- Remove `name` keyword from `get_data_yahoo()` and `get_data_google()` (commit b921d1a)
- Remove `offset` keyword from `DatetimeIndex` constructor (commit 3136390)
- Remove `time_rule` from several rolling-moment statistical functions, such as `rolling_sum()` (GH1042)
• Removed neg -- boolean operations on numpy arrays in favor of inv ~, as this is going to be deprecated in numpy 1.9 (GH6960)

Deprecations

• The \texttt{pivot\_table()}/\texttt{DataFrame.pivot\_table()} and \texttt{crosstab()} functions now take arguments \texttt{index} and \texttt{columns} instead of \texttt{rows} and \texttt{cols}. A FutureWarning is raised to alert that the old \texttt{rows} and \texttt{cols} arguments will not be supported in a future release (GH5505)

• The \texttt{DataFrame.drop\_duplicates()} and \texttt{DataFrame.duplicated()} methods now take argument \texttt{subset} instead of \texttt{cols} to better align with \texttt{DataFrame.dropna()}. A FutureWarning is raised to alert that the old \texttt{cols} arguments will not be supported in a future release (GH6680)

• The \texttt{DataFrame.to\_csv()} and \texttt{DataFrame.to\_excel()} functions now takes argument \texttt{columns} instead of \texttt{cols}. A FutureWarning is raised to alert that the old \texttt{cols} arguments will not be supported in a future release (GH6645)

• Indexers will warn FutureWarning when used with a scalar indexer and a non-floating point Index (GH4892, GH6960)

```
# non-floating point indexes can only be indexed by integers / labels
In [1]: pd.Series(1, np.arange(5))[3.0]
   pandas/core/index.py:469: FutureWarning: scalar indexers for index type Int64Index should be integers and not floating point
Out[1]: 1

In [2]: pd.Series(1, np.arange(5)).iloc[3.0]
   pandas/core/index.py:469: FutureWarning: scalar indexers for index type Int64Index should be integers and not floating point
Out[2]: 1

In [3]: pd.Series(1, np.arange(5)).iloc[3.0:4]
   pandas/core/index.py:527: FutureWarning: slice indexers when using iloc should be integers and not floating point
Out[3]:
   3 1
   dtype: int64

# these are Float64Indexes, so integer or floating point is acceptable
In [4]: pd.Series(1, np.arange(5.))[3]
Out[4]: 1

In [5]: pd.Series(1, np.arange(5.))[3.0]
Out[6]: 1
```

• Numpy 1.9 compat w.r.t. deprecation warnings (GH6960)

• \texttt{Panel.shift()} now has a function signature that matches \texttt{DataFrame.shift()}. The old positional argument \texttt{lags} has been changed to a keyword argument \texttt{periods} with a default value of 1. A FutureWarning is raised if the old argument \texttt{lags} is used by name. (GH6910)

• The \texttt{order} keyword argument of \texttt{factorize()} will be removed. (GH6926)

• Remove the \texttt{copy} keyword from \texttt{DataFrame.xs()}, \texttt{Panel.major\_xs()}, \texttt{Panel.minor\_xs()}. A view will be returned if possible, otherwise a copy will be made. Previously the user could think that \texttt{copy=False} would ALWAYS return a view. (GH6894)

• The \texttt{parallel\_coordinates()} function now takes argument \texttt{color} instead of \texttt{colors}. A FutureWarning is raised to alert that the old \texttt{colors} argument will not be supported in a future release.
The `parallel_coordinates()` and `andrews_curves()` functions now take positional argument `frame` instead of `data`. A `FutureWarning` is raised if the old `data` argument is used by name. (GH6956)

The support for the `mysql` flavor when using DBAPI connection objects has been deprecated. MySQL will be further supported with SQLAlchemy engines (GH6900).

The following `io.sql` functions have been deprecated: `tquery, uquery, read_frame, frame_query, write_frame`.

The `percentile_width` keyword argument in `describe()` has been deprecated. Use the `percentiles` keyword instead, which takes a list of percentiles to display. The default output is unchanged.

The default return type of `boxplot()` will change from a dict to a matplotlib Axes in a future release. You can use the future behavior now by passing `return_type='axes'` to `boxplot`.

**Known issues**

- OpenPyXL 2.0.0 breaks backwards compatibility (GH7169)

**Enhancements**

- DataFrame and Series will create a MultiIndex object if passed a tuples dict, See the docs (GH3323)

```python
In [65]: pd.Series({('a', 'b'): 1, ('a', 'a'): 0,
                   ....:          ('a', 'c'): 2, ('b', 'a'): 3, ('b', 'b'): 4})
Out[65]:
   a b
   a 1
   b 4
Length: 5, dtype: int64
```

```python
In [66]: pd.DataFrame({('a', 'b'): {('A', 'B'): 1, ('A', 'C'): 2},
                   ....:           ('a', 'a'): {('A', 'C'): 3, ('A', 'B'): 4},
                   ....:           ('a', 'c'): {('A', 'B'): 5, ('A', 'C'): 6},
                   ....:           ('b', 'a'): {('A', 'C'): 7, ('A', 'B'): 8},
                   ....:           ('b', 'b'): {('A', 'D'): 9, ('A', 'B'): 10}})
Out[66]:
     a b
   A B 1.0 4.0 5.0 8.0 10.0
   C 2.0 3.0 6.0 7.0 NaN
   D NaN NaN NaN NaN 9.0
[3 rows x 5 columns]
```

- Added the `sym_diff` method to Index (GH5543)
- `DataFrame.to_latex` now takes a longtable keyword, which if True will return a table in a longtable environment. (GH6617)
- Add option to turn off escaping in `DataFrame.to_latex` (GH6472)
pd.read_clipboard will, if the keyword sep is unspecified, try to detect data copied from a spreadsheet and parse accordingly. (GH6223)

Joining a singly-indexed DataFrame with a MultiIndexed DataFrame (GH3662)

See the docs. Joining MultiIndex DataFrames on both the left and right is not yet supported ATM.

```
In [67]: household = pd.DataFrame({'household_id': [1, 2, 3],
                               'male': [0, 1, 0],
                               'wealth': [196087.3, 316478.7, 294750],
                               columns=['household_id', 'male', 'wealth'])
In [68]: household
Out[68]:
            male  wealth
household_id
1          0   196087.3
2          1   316478.7
3          0     294750
[3 rows x 2 columns]
```

```
In [69]: portfolio = pd.DataFrame({'household_id': [1, 2, 2, 3, 3, 3, 4],
                              'asset_id': ["nl0000301109", "nl0000289783", "gb00b03mlx29", "gb00b03mlx29", "lu0197800237", "nl0000289965", np.nan],
                              'name': ["ABN Amro", "Robeco", "Royal Dutch Shell", "Royal Dutch Shell", "AAB Eastern Europe Equity Fund", "Postbank BioTech Fonds", np.nan],

• **read_excel** can now read milliseconds in Excel dates and times with xlrd >= 0.9.3. (GH5945)
• **pd.stats.moments.rolling_var** now uses Welford’s method for increased numerical stability (GH6817)
• **pd.expanding_apply** and **pd.rolling_apply** now take args and kwargs that are passed on to the func (GH6289)
• **DataFrame.rank()** now has a percentage rank option (GH5971)
• **Series.rank()** now has a percentage rank option (GH5971)
• **Series.rank()** and **DataFrame.rank()** now accept method='dense' for ranks without gaps (GH6514)
• Support passing **encoding** with xlwt (GH3710)
• Refactor **Block** classes removing **Block.items** attributes to avoid duplication in item handling (GH6745, GH6988).
• Testing statements updated to use specialized asserts (GH6175)

**Performance**

• Performance improvement when converting **DatetimeIndex** to floating ordinals using **DatetimeConverter** (GH6636)
• Performance improvement for **DataFrame.shift** (GH5609)
• Performance improvement in indexing into a MultiIndexed Series (GH5567)
• Performance improvements in single-dtyped indexing (GH6484)
• Improve performance of DataFrame construction with certain offsets, by removing faulty caching (e.g. MonthEnd,BusinessMonthEnd), (GH6479)
• Improve performance of **CustomBusinessDay** (GH6584)
• Improve performance of slice indexing on Series with string keys (GH6341, GH6372)
• Performance improvement for **DataFrame.from_records** when reading a specified number of rows from an iterable (GH6700)
• Performance improvements in timedelta conversions for integer dtypes (GH6754)
• Improved performance of compatible pickles (GH6899)
• Improve performance in certain reindexing operations by optimizing take_2d (GH6749)
• GroupBy.count() is now implemented in Cython and is much faster for large numbers of groups (GH7016).

Experimental
There are no experimental changes in 0.14.0

Bug fixes
• Bug in Series ValueError when index doesn’t match data (GH6532)
• Prevent segfault due to MultiIndex not being supported in HDFStore table format (GH1848)
• Bug in pd.DataFrame.sort_index where mergesort wasn’t stable when ascending=False (GH6399)
• Bug in pd.tseries.frequencies.to_offset when argument has leading zeros (GH6391)
• Bug in version string gen. for dev versions with shallow clones / install from tarball (GH6127)
• Inconsistent tz parsing Timestamp / to_datetime for current year (GH5958)
• Indexing bugs with reordered indexes (GH6252, GH6254)
• Bug in .xs with a Series multiindex (GH6258, GH5684)
• Bug in conversion of a string types to a DatetimeIndex with a specified frequency (GH6273, GH6274)
• Bug in eval where type-promotion failed for large expressions (GH6205)
• Bug in interpolate with inplace=True (GH6281)
• HDFStore.remove now handles start and stop (GH6177)
• HDFStore.select_as_multiple handles start and stop the same way as select (GH6177)
• HDFStore.select_as_coordinates and select_column works with a where clause that results in filters (GH6177)
• Regression in join of non_unique_indexes (GH6329)
• Issue with groupby agg with a single function and a a mixed-type frame (GH6337)
• Bug in DataFrame.replace() when passing a non-bool to_replace argument (GH6332)
• Raise when trying to align on different levels of a MultiIndex assignment (GH3738)
• Bug in setting complex dtypes via boolean indexing (GH6345)
• Bug in TimeGrouper/resample when presented with a non-monotonic DatetimeIndex that would return invalid results. (GH4161)
• Bug in index name propagation in TimeGrouper/resample (GH4161)
• TimeGrouper has a more compatible API to the rest of the groupers (e.g. groups was missing) (GH3881)
• Bug in multiple grouping with a TimeGrouper depending on target column order (GH6764)
• Bug in pd.eval when parsing strings with possible tokens like ‘&’ (GH6351)
• Bug correctly handle placements of -inf in Panels when dividing by integer 0 (GH6178)
• DataFrame.shift with axis=1 was raising (GH6371)
- Disabled clipboard tests until release time (run locally with nosetests -A disabled) (GH6048).
- Bug in DataFrame.replace() when passing a nested dict that contained keys not in the values to be replaced (GH6342).
- str.match ignored the na flag (GH6609).
- Bug in take with duplicate columns that were not consolidated (GH6240).
- Bug in interpolate changing dtypes (GH6290).
- Bug in Series.get, was using a buggy access method (GH6383).
- Bug in hdfstore queries of the form where=[('date', '>=', datetime(2013,1,1)), ('date', '<=', datetime(2014,1,1))] (GH6313).
- Bug in DataFrame.dropna with duplicate indices (GH6355).
- Regression in chained getitem indexing with embedded list-like from 0.12 (GH6394).
- Float64Index with nans not comparing correctly (GH6401).
- eval/query expressions with strings containing the @ character will now work (GH6366).
- Bug in Series.reindex when specifying a method with some nan values was inconsistent (noted on a resample) (GH6418).
- Bug in DataFrame.replace() where nested dicts were erroneously depending on the order of dictionary keys and values (GH5338).
- Performance issue in concatenating with empty objects (GH3259).
- Clarify sorting of sym_diff on Index objects with NaN values (GH6444).
- Regression in MultiIndex.from_product with a DatetimeIndex as input (GH6439).
- Bug in str.extract when passed a non-default index (GH6348).
- Bug in str.split when passed pat=None and n=1 (GH6466).
- Bug in io.data.DataReader when passed "F-F_Momentum_Factor" and data_source="famafrench" (GH6460).
- Bug in sum of a timedelta64[ns] series (GH6462).
- Bug in resample with a timezone and certain offsets (GH6397).
- Bug in iat/iloc with duplicate indices on a Series (GH6493).
- Bug in read_html where nan’s were incorrectly being used to indicate missing values in text. Should use the empty string for consistency with the rest of pandas (GH5129).
- Bug in read_html tests where redirected invalid URLs would make one test fail (GH6445).
- Bug in multi-axis indexing using .loc on non-unique indices (GH6504).
- Bug that caused _ref_locs corruption when slice indexing across columns axis of a DataFrame (GH6525).
- Regression from 0.13 in the treatment of numpy datetime64 non-ns dtypes in Series creation (GH6529).
- .names attribute of MultiIndexes passed to set_index are now preserved (GH6459).
- Bug in setitem with a duplicate index and an alignable rhs (GH6541).
- Bug in setitem with .loc on mixed integer Indexes (GH6546).
- Bug in pd.read_stata which would use the wrong data types and missing values (GH6327).
• Bug in `DataFrame.to_stata` that lead to data loss in certain cases, and could be exported using the wrong data types and missing values (GH6335)
• StataWriter replaces missing values in string columns by empty string (GH6802)
• Inconsistent types in `Timestamp` addition/subtraction (GH6543)
• Bug in preserving frequency across `Timestamp` addition/subtraction (GH4547)
• Bug in empty list lookup caused `IndexError` exceptions (GH6536, GH6551)
• `Series.quantile` raising on an object `dtype` (GH6555)
• Bug in `.xs` with a `nan` in level when dropped (GH6574)
• Bug in `fillna` with `method='bfill/ffill'` and `datetime64[ns]` `dtype` (GH6587)
• Bug in sql writing with mixed dtypes possibly leading to data loss (GH6509)
• Bug in `Series.pop` (GH6600)
• Bug in `iloc` indexing when positional indexer matched `Int64Index` of the corresponding axis and no re-ordering happened (GH6612)
• Bug in `fillna` with `limit` and `value` specified
• Bug in `DataFrame.to_stata` when columns have non-string names (GH4558)
• Bug in compat with `np.compress`, surfaced in (GH6658)
• Bug in binary operations with a rhs of a `Series` not aligning (GH6681)
• Bug in `DataFrame.to_stata` which incorrectly handles `nan` values and ignores `with_index` keyword argument (GH6685)
• Bug in resample with extra bins when using an evenly divisible frequency (GH4076)
• Bug in consistency of groupby aggregation when passing a custom function (GH6715)
• Bug in resample when `how=None` resample freq is the same as the axis frequency (GH5955)
• Bug in downcasting inference with empty arrays (GH6733)
• Bug in `obj.blocks` on sparse containers dropping all but the last items of same for `dtype` (GH6748)
• Bug in unpickling `NaT` (NaTTyep) (GH4606)
• Bug in `DataFrame.replace()` where regex meta characters were being treated as regex even when `regex=False` (GH6777).
• Bug in `timedelta` ops on 32-bit platforms (GH6808)
• Bug in setting a tz-aware index directly via `.index` (GH6785)
• Bug in `expressions.py` where numexpr would try to evaluate arithmetic ops (GH6762).
• Bug in `Makefile` where it didn’t remove Cython generated C files with `make clean` (GH6768)
• Bug with `numpy < 1.7.2` when reading long strings from `HDFStore` (GH6166)
• Bug in `DataFrame._reduce` where non bool-like (0/1) integers were being converted into bools. (GH6806)
• Regression from 0.13 with `fillna` and a `Series` on `datetime-like` (GH6344)
• Bug in `DataFrame.replace()` where changing a `dtype` through replacement would only replace the first occurrence of a value (GH6689)
• Better error message when passing a frequency of ‘MS’ in `Period` construction (GH5332)
• Bug in Series.__unicode__ when max_rows=None and the Series has more than 1000 rows. (GH6863)
• Bug in groupby.get_group where a datelike wasn’t always accepted (GH5267)
• Bug in groupBy.get_group created by TimeGrouper raises AttributeError (GH6914)
• Bug in DatetimeIndex.tz_localize and DatetimeIndex.tz_convert converting NaT incorrectly (GH5546)
• Bug in arithmetic operations affecting NaT (GH6873)
• Bug in Series.str.extract where the resulting Series from a single group match wasn’t renamed to the group name
• Bug in DataFrame.to_csv where setting index=False ignored the header kwarg (GH6186)
• Bug in DataFrame.plot and Series.plot, where the legend behave inconsistently when plotting to the same axes repeatedly (GH6678)
• Internal tests for patching __finalize__ / bug in merge not finalizing (GH6923, GH6927)
• accept TextFileReader in concat, which was affecting a common user idiom (GH6583)
• Bug in C parser with leading white space (GH3374)
• Bug in C parser with delim_whitespace=True and \r-delimited lines
• Bug in python parser with explicit MultiIndex in row following column header (GH6893)
• Bug in Series.rank and DataFrame.rank that caused small floats (<1e-13) to all receive the same rank (GH6886)
• Bug in DataFrame.apply with functions that used *args or **kwargs and returned an empty result (GH6952)
• Bug in sum/mean on 32-bit platforms on overflows (GH6915)
• Moved Panel.shift to NDFrame.slice_shift and fixed to respect multiple dtypes. (GH6959)
• Bug in enabling subplots=True in DataFrame.plot only has single column raises TypeError, and Series.plot raises AttributeError (GH6951)
• Bug in DataFrame.plot draws unnecessary axes when enabling subplots and kind=scatter (GH6951)
• Bug in read_csv from a filesystem with non-utf-8 encoding (GH6807)
• Bug in iloc when setting / aligning (GH6766)
• Bug causing UnicodeEncodeError when get_dummies called with unicode values and a prefix (GH6885)
• Bug in timeseries-with-frequency plot cursor display (GH5453)
• Bug surfaced in groupby.plot when using a Float64Index (GH7025)
• Stopped tests from failing if options data isn’t able to be downloaded from Yahoo (GH7034)
• Bug in parallel_coordinates and radviz where reordering of class column caused possible color/class mismatch (GH6956)
• Bug in radviz and andrews_curves where multiple values of ‘color’ were being passed to plotting method (GH6956)
• Bug in Float64Index.isin() where containing NaNs would make indices claim that they contained all the things (GH7066).
• Bug in DataFrame.boxplot where it failed to use the axis passed as the ax argument (GH3578)
• Bug in the XlsxWriter and XlwtWriter implementations that resulted in datetime columns being formatted without the time (GH7075) were being passed to plotting method

• read_fwf() treats None in colspec like regular python slices. It now reads from the beginning or until the end of the line when colspec contains a None (previously raised a TypeError)

• Bug in cache coherence with chained indexing and slicing; add _is_view property to NDFrame to correctly predict views; mark is_copy on xs only if its an actual copy (and not a view) (GH7084)

• Bug in DatetimeIndex creation from string ndarray with dayfirst=True (GH5917)

• Bug in MultiIndex.from_arrays created from DatetimeIndex doesn’t preserve freq and tz (GH7090)

• Bug in unstack raises ValueError when MultiIndex contains PeriodIndex (GH4342)

• Bug in boxplot and hist draws unnecessary axes (GH6769)

• Regression in groupby.nth() for out-of-bounds indexers (GH6621)

• Bug in quantile with datetime values (GH6965)

• Bug in Dataframe.set_index, reindex and pivot don’t preserve DatetimeIndex and PeriodIndex attributes (GH3950, GH5878, GH6631)

• Bug in MultiIndex.get_level_values doesn’t preserve DatetimeIndex and PeriodIndex attributes (GH7092)

• Bug in Groupby doesn’t preserve tz (GH3950)

• Bug in PeriodIndex partial string slicing (GH6716)

• Bug in the HTML repr of a truncated Series or DataFrame not showing the class name with the large_repr set to ‘info’ (GH7105)

• Bug in DatetimeIndex specifying freq raises ValueError when passed value is too short (GH7098)

• Fixed a bug with the info repr not honoring the display.max_info_columns setting (GH6939)

• Bug PeriodIndex string slicing with out of bounds values (GH5407)

• Fixed a memory error in the hashtable implementation/factorizer on resizing of large tables (GH7157)

• Bug in isnull when applied to 0-dimensional object arrays (GH7176)

• Bug in query/eval where global constants were not looked up correctly (GH7178)

• Bug in recognizing out-of-bounds positional list indexers with iloc and a multi-axis tuple indexer (GH7189)

• Bug in setitem with a single value, MultiIndex and integer indices (GH7190, GH7218)

• Bug in expressions evaluation with reversed ops, showing in series-dataframe ops (GH7198, GH7192)

• Bug in multi-axis indexing with > 2 ndim and a MultiIndex (GH7199)

• Fix a bug where invalid eval/query operations would blow the stack (GH5198)

5.15 Version 0.13

5.15.1 Version 0.13.1 (February 3, 2014)

This is a minor release from 0.13.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- Added `infer_datetime_format` keyword to `read_csv/to_datetime` to allow speedups for homogeneously formatted datetimes.
- Will intelligently limit display precision for datetime/timedelta formats.
- Enhanced Panel `apply()` method.
• Suggested tutorials in new Tutorials section.
• Our pandas ecosystem is growing. We now feature related projects in a new Pandas Ecosystem section.
• Much work has been taking place on improving the docs, and a new Contributing section has been added.
• Even though it may only be of interest to devs, we <3 our new CI status page: ScatterCI.

**Warning:** 0.13.1 fixes a bug that was caused by a combination of having numpy < 1.8, and doing chained assignment on a string-like array. Please review the docs, chained indexing can have unexpected results and should generally be avoided.

This would previously segfault:

```python
In [1]: df = pd.DataFrame({'A': np.array(['foo', 'bar', 'bah', 'foo', 'bar'])})
In [2]: df['A'].iloc[0] = np.nan
In [3]: df
Out[3]:
    A
0  NaN
1  bar
2  bah
3  foo
4  bar
```

The recommended way to do this type of assignment is:

```python
In [4]: df = pd.DataFrame({'A': np.array(['foo', 'bar', 'bah', 'foo', 'bar'])})
In [5]: df.loc[0, 'A'] = np.nan
In [6]: df
Out[6]:
    A
0  NaN
1  bar
2  bah
3  foo
4  bar
```

**Output formatting enhancements**

• df.info() view now display dtype info per column (GH5682)
• df.info() now honors the option max_info_rows, to disable null counts for large frames (GH5974)

```python
In [7]: max_info_rows = pd.get_option('max_info_rows')
In [8]: df = pd.DataFrame({'A': np.random.randn(10),
                          'B': np.random.randn(10),
                          'C': pd.date_range('20130101', periods=10))
In [9]: df.iloc[3:6, [0, 2]] = np.nan
```
# set to not display the null counts
In [10]: pd.set_option('max_info_rows', 0)

In [11]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10 entries, 0 to 9
Data columns (total 3 columns):
# Column Dtype
--- ------ -----  
0 A       float64  
1 B       float64  
2 C       datetime64[ns]  
dtypes: datetime64[ns](1), float64(2)
memory usage: 368.0 bytes

# this is the default (same as in 0.13.0)
In [12]: pd.set_option('max_info_rows', max_info_rows)

In [13]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10 entries, 0 to 9
Data columns (total 3 columns):
# Column Non-Null Count Dtype
--- ------ -------------- -----  
0 A 7 non-null     float64  
1 B 10 non-null    float64  
2 C 7 non-null     datetime64[ns]  
dtypes: datetime64[ns](1), float64(2)
memory usage: 368.0 bytes

• Add **show_dimensions** display option for the new DataFrame repr to control whether the dimensions print.

In [14]: df = pd.DataFrame([[1, 2], [3, 4]])

In [15]: pd.set_option('show_dimensions', False)

In [16]: df
Out[16]:
0 1 2 3 4
0 1 2
1 3 4

In [17]: pd.set_option('show_dimensions', True)

In [18]: df
Out[18]:
0 1 2 3 4
0 1 2
1 3 4
[2 rows x 2 columns]

• The **ArrayFormatter** for datetime and timedelta64 now intelligently limit precision based on the values in the array (**GH3401**)

Previously output might look like:
Now the output looks like:

```
In [19]: df = pd.DataFrame([pd.Timestamp('20010101'),
                   pd.Timestamp('20040601')], columns=['age'])
In [20]: df['today'] = pd.Timestamp('20130419')
In [21]: df['diff'] = df['today'] - df['age']
In [22]: df
```

```
Out[22]:
   age       today       diff
0 2001-01-01 2013-04-19  4491 days
1 2004-06-01 2013-04-19  3244 days
```

**API changes**

- Add -NaN and -nan to the default set of NA values (GH5952). See *NA Values*.
- Added `Series.str.get_dummies` vectorized string method (GH6021), to extract dummy/indicator variables for separated string columns:

```
In [23]: s = pd.Series(['a', 'a|b', np.nan, 'a|c'])
In [24]: s.str.get_dummies(sep='|')
```

```
a b c
0 1 0 0
1 1 1 0
2 0 0 0
3 1 0 1
```

- Added the `NDFrame.equals()` method to compare if two NDFrames are equal have equal axes, dtypes, and values. Added the `array_equivalent` function to compare if two ndarrays are equal. NaNs in identical locations are treated as equal. (GH5283) See also the docs for a motivating example.

```
df = pd.DataFrame({'col': ['foo', 0, np.nan]})
df2 = pd.DataFrame({'col': [np.nan, 0, 'foo']}, index=[2, 1, 0])
df.equals(df2)
df.equals(df2.sort_index())
```

- `DataFrame.apply` will use the `reduce` argument to determine whether a Series or a DataFrame should be returned when the DataFrame is empty (GH6007).

Previously, calling `DataFrame.apply` an empty DataFrame would return either a DataFrame if there were no columns, or the function being applied would be called with an empty Series to guess whether a Series or DataFrame should be returned:
In [32]: def applied_func(col):
   ....:     print("Apply function being called with: ", col)
   ....:     return col.sum()
   ....:
In [33]: empty = DataFrame(columns=['a', 'b'])
In [34]: empty.apply(applied_func)
Apply function being called with: Series([], Length: 0, dtype: float64)
Out[34]:
a  NaN
b  NaN
Length: 2, dtype: float64

Now, when apply is called on an empty DataFrame: if the reduce argument is True a Series will returned, if it is False a DataFrame will be returned, and if it is None (the default) the function being applied will be called with an empty series to try and guess the return type.

In [35]: empty.apply(applied_func, reduce=True)
Out[35]:
a  NaN
b  NaN
Length: 2, dtype: float64
In [36]: empty.apply(applied_func, reduce=False)
Out[36]:
Empty DataFrame
Columns: [a, b]
Index: []
[0 rows x 2 columns]

Prior version deprecations/changes

There are no announced changes in 0.13 or prior that are taking effect as of 0.13.1

Deprecations

There are no deprecations of prior behavior in 0.13.1

Enhancements

- pd.read_csv and pd.to_datetime learned a new infer_datetime_format keyword which greatly improves parsing perf in many cases. Thanks to @exual for suggesting and @danbirken for rapidly implementing. (GH5490, GH6021)

If parse_dates is enabled and this flag is set, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by ~5-10x.
• **date_format** and **datetime_format** keywords can now be specified when writing to excel files (GH4133)

• **MultiIndex.from_product** convenience function for creating a MultiIndex from the cartesian product of a set of iterables (GH6055):

```python
In [25]: shades = ['light', 'dark']
In [26]: colors = ['red', 'green', 'blue']
In [27]: pd.MultiIndex.from_product([shades, colors], names=['shade', 'color'])
Out[27]:
MultiIndex([('light', 'red'),
            ('light', 'green'),
            ('light', 'blue'),
            ('dark', 'red'),
            ('dark', 'green'),
            ('dark', 'blue')],
           names=['shade', 'color'])
```

• **Panel apply()** will work on non-ufuncs. See the docs.

```python
In [28]: import pandas._testing as tm
In [29]: panel = tm.makePanel(5)
In [30]: panel
Out[30]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D
In [31]: panel['ItemA']
Out[31]:
       A     B     C     D
2000-01-03 -0.673690 0.577046 -1.344312 -1.469388
2000-01-04 0.113648 -1.715002 0.844885 0.357021
2000-01-05 -1.478427 -1.039268 1.075770 -0.674600
2000-01-06 0.524988 -0.370647 -0.109050 -1.776904
2000-01-07 0.404705 -1.157892 1.643563 -0.968914
[5 rows x 4 columns]
```

Specifying an apply that operates on a Series (to return a single element)

```python
In [32]: panel.apply(lambda x: x.dtype, axis='items')
Out[32]:
       A     B     C     D
2000-01-03 float64 float64 float64 float64
2000-01-04 float64 float64 float64 float64
2000-01-05 float64 float64 float64 float64
2000-01-06 float64 float64 float64 float64
2000-01-07 float64 float64 float64 float64
[5 rows x 4 columns]
```

A similar reduction type operation
In [33]: panel.apply(lambda x: x.sum(), axis='major_axis')
Out[33]:
<table>
<thead>
<tr>
<th>ItemA</th>
<th>ItemB</th>
<th>ItemC</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>-1.108775</td>
<td>-1.090118</td>
</tr>
<tr>
<td>B</td>
<td>-3.705764</td>
<td>0.409204</td>
</tr>
<tr>
<td>C</td>
<td>2.110856</td>
<td>2.960500</td>
</tr>
<tr>
<td>D</td>
<td>-4.532785</td>
<td>0.303202</td>
</tr>
</tbody>
</table>

[4 rows x 3 columns]

This is equivalent to

In [34]: panel.sum('major_axis')
Out[34]:
<table>
<thead>
<tr>
<th>ItemA</th>
<th>ItemB</th>
<th>ItemC</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>-1.108775</td>
<td>-1.090118</td>
</tr>
<tr>
<td>B</td>
<td>-3.705764</td>
<td>0.409204</td>
</tr>
<tr>
<td>C</td>
<td>2.110856</td>
<td>2.960500</td>
</tr>
<tr>
<td>D</td>
<td>-4.532785</td>
<td>0.303202</td>
</tr>
</tbody>
</table>

[4 rows x 3 columns]

A transformation operation that returns a Panel, but is computing the z-score across the major_axis

In [35]: result = panel.apply(lambda x: (x - x.mean()) / x.std(), axis='major_axis')

In [36]: result
Out[36]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D

In [37]: result['ItemA']

Out[37]:
<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-03</td>
<td>-0.535778</td>
<td>1.500802</td>
<td>-1.506416</td>
<td>-0.681456</td>
</tr>
<tr>
<td>2000-01-04</td>

2000-01-07  0.783051 -0.198053  0.919339 -1.052721
[5 rows x 4 columns]

Performance

Performance improvements for 0.13.1

- Series datetime/timedelta binary operations (GH5801)
- DataFrame `count/dropna` for axis=1
- Series.str.contains now has a `regex=False` keyword which can be faster for plain (non-regex) string patterns. (GH5879)
- Series.str.extract (GH5944)
- dtypes/ftypes methods (GH5968)
- indexing with object dtypes (GH5968)
• DataFrame.apply (GH6013)
• Regression in JSON IO (GH5765)
• Index construction from Series (GH6150)

Experimental

There are no experimental changes in 0.13.1

Bug fixes

• Bug in io.wb.get_countries not including all countries (GH6008)
• Bug in Series replace with timestamp dict (GH5797)
• read_csv/read_table now respects the prefix kwarg (GH5732).
• Bug in selection with missing values via .ix from a duplicate indexed DataFrame failing (GH5835)
• Fix issue of boolean comparison on empty DataFrames (GH5808)
• Bug in isnull handling NaT in an object array (GH5443)
• Bug in to_datetime when passed a np.nan or integer datelike and a format string (GH5863)
• Bug in groupby dtype conversion with datetimelike (GH5869)
• Regression in handling of empty Series as indexers to Series (GH5877)
• Bug in internal caching, related to (GH5727)
• Testing bug in reading JSON/msgpack from a non-filepath on windows under py3 (GH5874)
• Bug when assigning to .ix[tuple(…)] (GH5896)
• Bug in fully reindexing a Panel (GH5905)
• Bug in idxmin/max with object dtypes (GH5914)
• Bug in BusinessDay when adding n days to a date not on offset when n>5 and n%5==0 (GH5890)
• Bug in assigning to chained series with a series via ix (GH5928)
• Bug in creating an empty DataFrame, copying, then assigning (GH5932)
• Bug in DataFrame.tail with empty frame (GH5846)
• Bug in propagating metadata on resample (GH5862)
• Fixed string-representation of NaT to be "NaN" (GH5708)
• Fixed string-representation for Timestamp to show nanoseconds if present (GH5912)
• pd.match not returning passed sentinel
• Panel.to_frame() no longer fails when major_axis is a MultiIndex (GH5402).
• Bug in pd.read_msgpack with inferring a DateTimeIndex frequency incorrectly (GH5947)
• Fixed to_datetime for array with both Tz-aware datetimes and NaT’s (GH5961)
• Bug in rolling skew/kurtosis when passed a Series with bad data (GH5749)
• Bug in scipy interpolate methods with a datetime index (GH5975)
• Bug in NaT comparison if a mixed datetime/np.datetime64 with NaT were passed (GH5968)
- Fixed bug with `pd.concat` losing dtype information if all inputs are empty (GH5742)
- Recent changes in IPython cause warnings to be emitted when using previous versions of pandas in QTConsole, now fixed. If you're using an older version and need to suppress the warnings, see (GH5922).
- Bug in merging `timedelta` dtypes (GH5695)
- Bug in plotting `scatter_matrix` function. Wrong alignment among diagonal and off-diagonal plots, see (GH5497).
- Regression in Series with a MultiIndex via `ix` (GH6018)
- Bug in Series `xs` with a MultiIndex (GH6018)
- Bug in Series construction of mixed type with datelike and an integer (which should result in object type and not automatic conversion) (GH6028)
- Possible segfault when chained indexing with an object array under NumPy 1.7.1 (GH6026, GH6056)
- Bug in setting using fancy indexing a single element with a non-scalar (e.g. a list), (GH6043)
- `to_sql` did not respect `if_exists` (GH4110 GH4304)
- Regression in `.get` (None) indexing from 0.12 (GH5652)
- Subtle `iloc` indexing bug, surfaced in (GH6059)
- Bug with insert of strings into `DatetimeIndex` (GH5818)
- Fixed unicode bug in `to_html/HTML` repr (GH6098)
- Fixed missing arg validation in `get_options_data` (GH6105)
- Bug in assignment with duplicate columns in a frame where the locations are a slice (e.g. next to each other) (GH6120)
- Bug in propagating `_ref_locs` during construction of a DataFrame with dups index/columns (GH6121)
- Bug in `DataFrame.apply` when using mixed datelike reductions (GH6125)
- Bug in `DataFrame.append` when appending a row with different columns (GH6129)
- Bug in `DataFrame` construction with recarray and non-ns datetime dtype (GH6140)
- Bug in `.loc` setitem indexing with a dataframe on rhs, multiple item setting, and a datetimelike (GH6152)
- Fixed a bug in `query/eval` during lexicographic string comparisons (GH6155).
- Fixed a bug in `query` where the index of a single-element Series was being thrown away (GH6148).
- Bug in `HDFStore` on appending a dataframe with MultiIndexed columns to an existing table (GH6167)
- Consistency with dtypes in setting an empty DataFrame (GH6171)
- Bug in selecting on a MultiIndex `HDFStore` even in the presence of under specified column spec (GH6169)
- Bug in `nanops.var` with `ddof=1` and 1 elements would sometimes return `inf` rather than `nan` on some platforms (GH6136)
- Bug in Series and DataFrame bar plots ignoring the `use_index` keyword (GH6209)
- Bug in groupby with mixed str/int under python3 fixed; `argsort` was failing (GH6212)

5.15.2 Version 0.13.0 (January 3, 2014)

This is a major release from 0.12.0 and includes a number of API changes, several new features and enhancements along with a large number of bug fixes.

Highlights include:

- support for a new index type `Float64Index` and other Indexing enhancements
- `HDFStore` has a new string based syntax for query specification
- support for new methods of interpolation
- updated `timedelta` operations
- a new string manipulation method `extract`
- Nanosecond support for Offsets
- `isin` for DataFrames

Several experimental features are added, including:

- new `eval/query` methods for expression evaluation
- support for `msgpack` serialization
- an i/o interface to Google’s `BigQuery`

Their are several new or updated docs sections including:
• **Comparison with SQL**, which should be useful for those familiar with SQL but still learning pandas.

• **Comparison with R**, idiom translations from R to pandas.

• **Enhancing Performance**, ways to enhance pandas performance with `eval/query`.

---

**Warning:** In 0.13.0 Series has internally been refactored to no longer sub-class `ndarray` but instead subclass `NDFrame`, similar to the rest of the pandas containers. This should be a transparent change with only very limited API implications. See **Internal Refactoring**

---

**API changes**

• **read_excel** now supports an integer in its `sheetname` argument giving the index of the sheet to read in (GH4301).

• Text parser now treats anything that reads like inf ("inf", "Inf", "-Inf", "iNf", etc.) as infinity. (GH4220, GH4219), affecting `read_table`, `read_csv`, etc.

• pandas now is Python 2/3 compatible without the need for 2to3 thanks to @jtratner. As a result, pandas now uses iterators more extensively. This also led to the introduction of substantive parts of the Benjamin Peterson’s six library into compat. (GH4384, GH4375, GH4372)

• pandas.util.compat and pandas.util.py3compat have been merged into pandas.compat.

• `pandas.compat` now includes many functions allowing 2/3 compatibility. It contains both list and iterator versions of range, filter, map and zip, plus other necessary elements for Python 3 compatibility. `lmap`, `lzip`, `lrange` and `lfilter` all produce lists instead of iterators, for compatibility with `numpy`, `subscripting` and `pandas constructors.`(GH4384, GH4375, GH4372)

• Series.get with negative indexers now returns the same as `[ ]` (GH4390)

• Changes to how Index and MultiIndex handle metadata (levels, labels, and names) (GH4039):

```python
# previously, you would have set levels or labels directly
>>> pd.index.levels = [[1, 2, 3, 4], [1, 2, 4, 4]]

# now, you use the set_levels or set_labels methods
>>> index = pd.index.set_levels([[1, 2, 3, 4], [1, 2, 4, 4]])

# similarly, for names, you can rename the object
# but setting names is not deprecated
>>> index = pd.index.set_names(["bob", "cranberry"])

# and all methods take an inplace kwarg - but return None
>>> pd.index.set_names(["bob", "cranberry"], inplace=True)
```

• All division with NDFrame objects is now `truedivision`, regardless of the future import. This means that operating on pandas objects will by default use floating point division, and return a floating point dtype. You can use `//` and `floordiv` to do integer division.

**Integer division**

```python
In [3]: arr = np.array([1, 2, 3, 4])

In [4]: arr2 = np.array([5, 3, 2, 1])

In [5]: arr / arr2
Out[5]: array([0, 0, 1, 4])
```

(continues on next page)
In [6]: pd.Series(arr) // pd.Series(arr2)
Out[6]:
0   0
1   0
2   1
3   4
dtype: int64

True Division

In [7]: pd.Series(arr) / pd.Series(arr2)  # no future import required
Out[7]:
0  0.200000
1  0.666667
2  1.500000
3  4.000000
dtype: float64

- Infer and downcast dtype if downcast='infer' is passed to fillna/ffill/bfill (GH4604)
- __nonzero__ for all NDFrame objects, will now raise a ValueError, this reverts back to (GH1073, GH4633) behavior. See gotchas for a more detailed discussion.

This prevents doing boolean comparison on entire pandas objects, which is inherently ambiguous. These all will raise a ValueError.

```python
>>> df = pd.DataFrame({'A': np.random.randn(10),
... 'B': np.random.randn(10),
... 'C': pd.date_range('20130101', periods=10))
...}
...if df:
...    pass
...Traceback (most recent call last):
...    ValueError: The truth value of a DataFrame is ambiguous. Use a.empty, a.bool(), a.item(), a.any() or a.all().
```

```python
>>> df1 = df
>>> df2 = df
>>> df1 and df2
Traceback (most recent call last):
...    ValueError: The truth value of a DataFrame is ambiguous. Use a.empty, a.bool(), a.item(), a.any() or a.all().
```

```python
>>> d = [1, 2, 3]
>>> s1 = pd.Series(d)
>>> s2 = pd.Series(d)
>>> s1 and s2
Traceback (most recent call last):
...    ValueError: The truth value of a DataFrame is ambiguous. Use a.empty, a.bool(), a.item(), a.any() or a.all().
```

Added the .bool() method to NDFrame objects to facilitate evaluating of single-element boolean Series:
In [1]: pd.Series([True]).bool()
Out[1]: True

In [2]: pd.Series([False]).bool()
Out[2]: False

In [3]: pd.DataFrame([[True]]).bool()
Out[3]: True

In [4]: pd.DataFrame([[False]]).bool()
Out[4]: False

• All non-Index NDFrames (Series, DataFrame, Panel, Panel4D, SparsePanel, etc.), now support the entire set of arithmetic operators and arithmetic flex methods (add, sub, mul, etc.). SparsePanel does not support pow or mod with non-scalars. (GH3765)

• Series and DataFrame now have a mode() method to calculate the statistical mode(s) by axis/Series. (GH5367)

• Chained assignment will now by default warn if the user is assigning to a copy. This can be changed with the option mode.chained_assignment, allowed options are raise/warn/None. See the docs.

```python
In [5]: dfc = pd.DataFrame({'A': ['aaa', 'bbb', 'ccc'], 'B': [1, 2, 3]})
In [6]: pd.set_option('chained_assignment', 'warn')
```

The following warning / exception will show if this is attempted.

```python
In [7]: dfc.loc[0]['A'] = 1111
```

```
Traceback (most recent call last)
...  # setting with copy warning
SettingWithCopyWarning:
   A value is trying to be set on a copy of a slice from a DataFrame. Try using .loc[row_index,col_indexer] = value instead
```

Here is the correct method of assignment.

```python
In [8]: dfc.loc[0, 'A'] = 11
```

```python
In [9]: dfc
```

```
Out[9]:
   A  B
0  11 1
1  bbb 2
2  ccc 3
```

• Panel.reindex has the following call signature Panel.reindex(items=None, major_axis=None, minor_axis=None, **kwargs) to conform with other NDFrame objects. See Internal Refactoring for more information.

• Series.argmin and Series.argmax are now aliased to Series.idxmin and Series.idxmax. These return the index of the min or max element respectively. Prior to 0.13.0 these would return the position of the min / max element. (GH6214)
Prior version deprecations/changes

These were announced changes in 0.12 or prior that are taking effect as of 0.13.0

- Remove deprecated `Factor` (GH3650)
- Remove deprecated `set_printoptions/reset_printoptions` (GH3046)
- Remove deprecated `_verbose_info` (GH3215)
- Remove deprecated `read_clipboard/to_clipboard/ExcelFile/ExcelWriter` from pandas. `io.parsers` (GH3717) These are available as functions in the main pandas namespace (e.g. `pd.read_clipboard`)
- default for `tupleize_cols` is now `False` for both `to_csv` and `read_csv`. Fair warning in 0.12 (GH3604)
- default for `display.max_seq_len` is now 100 rather than `None`. This activates truncated display (“...”) of long sequences in various places. (GH3391)

Deprecations

Deprecated in 0.13.0

- deprecated `iterkv`, which will be removed in a future release (this was an alias of `iteritems` used to bypass `2to3`’s changes). (GH4384, GH4375, GH4372)
- deprecated the string method `match`, whose role is now performed more idiomatically by `extract`. In a future release, the default behavior of `match` will change to become analogous to `contains`, which returns a boolean indexer. (Their distinction is strictness: `match` relies on `re.match` while `contains` relies on `re.search`.) In this release, the deprecated behavior is the default, but the new behavior is available through the keyword argument `as_indexer=True`.

Indexing API changes

Prior to 0.13, it was impossible to use a label indexer (`.loc/.ix`) to set a value that was not contained in the index of a particular axis. (GH2578). See the docs

In the `Series` case this is effectively an appending operation

```
In [10]: s = pd.Series([1, 2, 3])

In [11]: s
Out[11]:
0 1
1 2
2 3
dtype: int64

In [13]: s
Out[13]:
0 1.0
1 2.0
2 3.0
5 5.0
dtype: float64
```
In [14]: dfi = pd.DataFrame(np.arange(6).reshape(3, 2),
                    columns=['A', 'B'])

In [15]: dfi
Out[15]:
     A  B
0   0  1
1   2  3
2   4  5

This would previously KeyError

In [16]: dfi.loc[:, 'C'] = dfi.loc[:, 'A']

In [17]: dfi
Out[17]:
     A  B  C
0   0  1  0
1   2  3  2
2   4  5  4

This is like an append operation.

In [18]: dfi.loc[3] = 5

In [19]: dfi
Out[19]:
     A  B  C
0   0  1  0
1   2  3  2
2   4  5  4
3   5  5  5

A Panel setting operation on an arbitrary axis aligns the input to the Panel

In [20]: p = pd.Panel(np.arange(16).reshape(2, 4, 2),
                    items=['Item1', 'Item2'],
                    major_axis=pd.date_range('2001/1/12', periods=4),
                    minor_axis=['A', 'B'], dtype='float64')

In [21]: p
Out[21]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 2 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2001-01-12 00:00:00 to 2001-01-15 00:00:00
Minor_axis axis: A to B

In [22]: p.loc[:, :, 'C'] = pd.Series([30, 32], index=p.items)

In [23]: p
Out[23]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 3 (minor_axis)
Items axis: Item1 to Item2
Float64Index API change

- Added a new index type, Float64Index. This will be automatically created when passing floating values in index creation. This enables a pure label-based slicing paradigm that makes [], ix, loc for scalar indexing and slicing work exactly the same. See the docs (GH263)

Construction is by default for floating type values.

Scalar selection for [], ix, loc will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to 3.0)

The only positional indexing is via iloc

A scalar index that is not found will raise KeyError

Slicing is ALWAYS on the values of the index, for [], ix, loc and ALWAYS positional with iloc
2.0 1
3.0 2
dtype: int64

In [28]: s.loc[2:4]
Out[28]:
2.0 1
3.0 2
dtype: int64

In [29]: s.iloc[2:4]
Out[29]:
3.0 2
4.5 3
dtype: int64

In float indexes, slicing using floats are allowed

In [30]: s[2.1:4.6]
Out[30]:
3.0 2
4.5 3
dtype: int64

In [31]: s.loc[2.1:4.6]
Out[31]:
3.0 2
4.5 3
dtype: int64

• Indexing on other index types are preserved (and positional fallback for [], ix), with the exception, that floating point slicing on indexes on non Float64Index will now raise a TypeError.

In [1]: pd.Series(range(5))[3.5]
TypeError: the label [3.5] is not a proper indexer for this index type
  →(Int64Index)

In [1]: pd.Series(range(5))[3.5:4.5]
TypeError: the slice start [3.5] is not a proper indexer for this index type
  →(Int64Index)

Using a scalar float indexer will be deprecated in a future version, but is allowed for now.

In [3]: pd.Series(range(5))[3.0]
Out[3]: 3
HDFStore API changes

- Query Format Changes. A much more string-like query format is now supported. See the docs.

```python
In [32]: path = 'test.h5'

In [33]: dfq = pd.DataFrame(np.random.randn(10, 4),
...:                     columns=list('ABCD'),
...:                     index=pd.date_range('20130101', periods=10))

In [34]: dfq.to_hdf(path, 'dfq', format='table', data_columns=True)
```

Use boolean expressions, with in-line function evaluation.

```python
In [35]: pd.read_hdf(path, 'dfq',
...:                where="index>Timestamp('20130104') & columns=[A', 'B']")

Out[35]:
    A   B
2013-01-05 -0.424972 0.567020
2013-01-06 -0.673690 0.113648
2013-01-07  0.404705 0.577046
2013-01-08 -0.370647 -1.157892
2013-01-09  1.075770 -0.109050
2013-01-10  0.357021 -0.674600
```

Use an inline column reference

```python
In [36]: pd.read_hdf(path, 'dfq',
...:                where="A>0 or C>0")

Out[36]:
    A   B   C   D
2013-01-01  0.469112 -0.282863 -1.509059 -1.135632
2013-01-02  1.212112 -0.173215  0.119209 -1.044236
2013-01-04  0.721555 -0.706771 -1.039575  0.271860
2013-01-05 -0.424972  0.567020  0.276232 -1.087401
2013-01-07  0.404705  0.577046 -1.715002 -1.039268
2013-01-09  1.075770 -0.109050  1.643563 -1.469388
2013-01-10  0.357021 -0.674600 -1.776904 -0.968914
```

- the format keyword now replaces the table keyword; allowed values are fixed(f) or table(t) the same defaults as prior < 0.13.0 remain, e.g. put implies fixed format and append implies table format. This default format can be set as an option by setting io.hdf.default_format.

```python
In [37]: path = 'test.h5'

In [38]: df = pd.DataFrame(np.random.randn(10, 2))

In [39]: df.to_hdf(path, 'df_table', format='table')

In [40]: df.to_hdf(path, 'df_table2', append=True)

In [41]: df.to_hdf(path, 'df_fixed')

In [42]: with pd.HDFStore(path) as store:
...:     print(store)
```
• Significant table writing performance improvements

• handle a passed Series in table format (GH4330)

• can now serialize a timedelta64[ns] dtype in a table (GH3577), See the docs.

• added an is_open property to indicate if the underlying file handle is_open; a closed store will now report ‘CLOSED’ when viewing the store (rather than raising an error) (GH4409)

• a close of a HDFStore now will close that instance of the HDFStore but will only close the actual file if the ref count (by PyTables) w.r.t. all of the open handles are 0. Essentially you have a local instance of HDFStore referenced by a variable. Once you close it, it will report closed. Other references (to the same file) will continue to operate until they themselves are closed. Performing an action on a closed file will raise ClosedFileError

```python
In [43]: path = 'test.h5'
In [44]: df = pd.DataFrame(np.random.randn(10, 2))
In [45]: store1 = pd.HDFStore(path)
In [46]: store2 = pd.HDFStore(path)
In [47]: store1.append('df', df)
In [48]: store2.append('df2', df)
In [49]: store1
Out[49]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5
In [50]: store2
Out[50]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5
In [51]: store1.close()
In [52]: store2
Out[52]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5
In [53]: store2.close()
In [54]: store2
Out[54]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5
```

• removed the _quiet attribute, replace by a DuplicateWarning if retrieving duplicate rows from a table (GH4367)
• removed the warn argument from open. Instead a PossibleDataLossError exception will be raised if you try to use mode='w' with an OPEN file handle (GH4367)
• allow a passed locations array or mask as a where condition (GH4467). See the docs for an example.
• add the keyword dropna=True to append to change whether ALL nan rows are not written to the store (default is True, ALL nan rows are NOT written), also settable via the option io.hdf.dropna_table (GH4625)
• pass through store creation arguments; can be used to support in-memory stores

DataFrame repr changes

The HTML and plain text representations of DataFrame now show a truncated view of the table once it exceeds a certain size, rather than switching to the short info view (GH4886, GH5550). This makes the representation more consistent as small DataFrames get larger.

<table>
<thead>
<tr>
<th>Date</th>
<th>2010-03-29</th>
<th>2010-03-30</th>
</tr>
</thead>
<tbody>
<tr>
<td>...</td>
<td>... ... ... ... ... ...</td>
<td></td>
</tr>
</tbody>
</table>

771 rows × 6 columns

To get the info view, call DataFrame.info(). If you prefer the info view as the repr for large DataFrames, you can set this by running set_option('display.large_repr', 'info').

Enhancements

• df.to_clipboard() learned a new excel keyword that let’s you paste df data directly into excel (enabled by default). (GH5070).
• read_html now raises a URLError instead of catching and raising a ValueError (GH4303, GH4305)
• Added a test for read_clipboard() and to_clipboard() (GH4282)
• Clipboard functionality now works with PySide (GH4282)
• Added a more informative error message when plot arguments contain overlapping color and style arguments (GH4402)
• to_dict now takes records as a possible out type. Returns an array of column-keyed dictionaries. (GH4936)
• NaN handing in get_dummies (GH4446) with dummy_na

```python
# previously, nan was erroneously counted as 2 here
# now it is not counted at all
In [55]: pd.get_dummies([1, 2, np.nan])
Out[55]:
   1.0  2.0
0   1   0
1   0   1
2   0   0
# unless requested
```

(continues on next page)
• timedelta64[ns] operations. See the docs.

Warning: Most of these operations require numpy >= 1.7

Using the new top-level to_timedelta, you can convert a scalar or array from the standard timedelta format (produced by to_csv) into a timedelta type (np.timedelta64 in nanoseconds).

A Series of dtype timedelta64[ns] can now be divided by another timedelta64[ns] object, or astyped to yield a float64 dtyped Series. This is frequency conversion. See the docs for the docs.
# to days
In [67]: td / np.timedelta64(1, 'D')
Out[67]:
0   31.000000
1   31.000000
2   31.003507
3     NaN
dtype: float64

In [68]: td.astype('timedelta64[D]')
Out[68]:
0   31.0
1   31.0
2   31.0
3     NaN
dtype: float64

# to seconds
In [69]: td / np.timedelta64(1, 's')
Out[69]:
0   2678400.0
1   2678400.0
2   2678703.0
3     NaN
dtype: float64

In [70]: td.astype('timedelta64[s]')
Out[70]:
0   2678400.0
1   2678400.0
2   2678703.0
3     NaN
dtype: float64

Dividing or multiplying a timedelta64[ns] Series by an integer or integer Series

In [71]: td * -1
Out[71]:
0  -31 days +00:00:00
1  -31 days +00:00:00
2  -32 days +23:54:57
3     NaT
dtype: timedelta64[ns]

In [72]: td * pd.Series([1, 2, 3, 4])
Out[72]:
0   31 days 00:00:00
1   62 days 00:00:00
2   93 days 00:15:09
3     NaT
dtype: timedelta64[ns]

Absolute DateOffset objects can act equivalently to timedeltas

In [73]: from pandas import offsets

In [74]: td + offsets.Minute(5) + offsets.Milli(5)
(continues on next page)
Fillna is now supported for timedeltas

```python
In [75]: td.fillna(pd.Timedelta(0))
Out[75]:
0  31 days 00:00:00
1  31 days 00:00:00
2  31 days 00:05:03
3   0 days 00:00:00
dtype: timedelta64[ns]
```

```python
In [76]: td.fillna(datetime.timedelta(days=1, seconds=5))
Out[76]:
0  31 days 00:00:00
1  31 days 00:00:00
2  31 days 00:05:03
3   1 days 00:00:05
dtype: timedelta64[ns]
```

You can do numeric reduction operations on timedeltas.

```python
In [77]: td.mean()
Out[77]: Timedelta('31 days 00:01:41')
```

```python
In [78]: td.quantile(.1)
Out[78]: Timedelta('31 days 00:00:00')
```

- `plot(kind='kde')` now accepts the optional parameters `bw_method` and `ind`, passed to `scipy.stats.gaussian_kde()` (for scipy >= 0.11.0) to set the bandwidth, and to `gkde.evaluate()` to specify the indices at which it is evaluated, respectively. See scipy docs. (GH4298)

- DataFrame constructor now accepts a numpy masked record array (GH3478)

- The new vectorized string method `extract` return regular expression matches more conveniently.

Elements that do not match return NaN. Extracting a regular expression with more than one group returns a DataFrame with one column per group.
Elements that do not match return a row of NaN. Thus, a Series of messy strings can be converted into a like-indexed Series or DataFrame of cleaned-up or more useful strings, without necessitating get() to access tuples or re.match objects.

Named groups like

```
In [81]: pd.Series(['a1', 'b2', 'c3']).str.extract(
    ....:   '(?P<letter>[ab])(?P<digit>\d)')
```

```
Out[81]:
          letter digit
    0       a       1
    1       b       2
    2  NaN  NaN
```

and optional groups can also be used.

```
In [82]: pd.Series(['a1', 'b2', '3']).str.extract(
    ....:   '(?P<letter>[ab])?(?P<digit>\d)')
```

```
Out[82]:
          letter digit
    0       a       1
    1       b       2
    2  NaN       3
```

• read_stata now accepts Stata 13 format (GH4291)

• read_fwf now infers the column specifications from the first 100 rows of the file if the data has correctly separated and properly aligned columns using the delimiter provided to the function (GH4488).

• support for nanosecond times as an offset

**Warning:** These operations require numpy >= 1.7

Period conversions in the range of seconds and below were reworked and extended up to nanoseconds. Periods in the nanosecond range are now available.

```
In [83]: pd.date_range('2013-01-01', periods=5, freq='5N')
```

```
Out[83]:
 DatetimeIndex(['2013-01-01 00:00:00',
               '2013-01-01 00:00:00.000000005',
               '2013-01-01 00:00:00.000000010',
               '2013-01-01 00:00:00.000000015',
               '2013-01-01 00:00:00.000000020'],
dtype='datetime64[ns]', freq='5N')
```

or with frequency as offset

```
In [84]: pd.date_range('2013-01-01', periods=5, freq=pd.offsets.Nano(5))
```

```
Out[84]:
 DatetimeIndex(['2013-01-01 00:00:00',
               '2013-01-01 00:00:00.000000005',
               '2013-01-01 00:00:00.000000010',
               '2013-01-01 00:00:00.000000015',
               '2013-01-01 00:00:00.000000020'],
dtype='datetime64[ns]', freq='5N')
```
Timestamps can be modified in the nanosecond range

```python
In [85]: t = pd.Timestamp('20130101 09:01:02')
In [86]: t + pd.tseries.offsets.Nano(123)
Out[86]: Timestamp('2013-01-01 09:01:02.000000123')
```

- A new method, `isin` for DataFrames, which plays nicely with boolean indexing. The argument to `isin`, what we’re comparing the DataFrame to, can be a DataFrame, Series, dict, or array of values. See the docs for more.

To get the rows where any of the conditions are met:

```python
In [87]: dfi = pd.DataFrame({'A': [1, 2, 3, 4], 'B': ['a', 'b', 'f', 'n']})
In [88]: dfi
Out[88]:
   A  B
0  1  a
1  2  b
2  3  f
3  4  n
In [89]: other = pd.DataFrame({'A': [1, 3, 3, 7], 'B': ['e', 'f', 'f', 'e']})
In [90]: mask = dfi.isin(other)
In [91]: mask
Out[91]:
   A  B
0  True False
1  False False
2  True  True
3  False  False
In [92]: dfi[mask.any(1)]
Out[92]:
   A  B
0  1  a
2  3  f
```

- Series now supports a `to_frame` method to convert it to a single-column DataFrame (GH5164)
- All R datasets listed here http://stat.ethz.ch/R-manual/R-devel/library/datasets/html/00Index.html can now be loaded into Pandas objects

```python
# note that pandas.rpy was deprecated in v0.16.0
import pandas.rpy.common as com
com.load_data('Titanic')
```

- `tz_localize` can infer a fall daylight savings transition based on the structure of the unlocalized data (GH4230), see the docs
- `DatetimeIndex` is now in the API documentation, see the docs
- `json_normalize()` is a new method to allow you to create a flat table from semi-structured JSON data. See the docs (GH1067)
- Added PySide support for the qtpandas DataFrameModel and DataFrameWidget.
- Python csv parser now supports usecols (GH4335)
• Frequencies gained several new offsets:
  – LastWeekOfMonth (GH4637)
  – FY5253, and FY5253Quarter (GH4511)
• DataFrame has a new interpolate method, similar to Series (GH4434, GH1892)

```python
In [93]: df = pd.DataFrame({"A": [1, 2.1, np.nan, 4.7, 5.6, 6.8],  
      ....:       'B': [.25, np.nan, np.nan, 4, 12.2, 14.4]})
In [94]: df.interpolate()
Out[94]:
    A    B
0   1.0  0.25
1  2.1  1.50
2  3.4  2.75
3  4.7  4.00
4  5.6 12.20
5  6.8 14.40
```

Additionally, the method argument to interpolate has been expanded to include 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'barycentric', 'krogh', 'piecewise_polynomial', 'pchip', 'polynomial', 'spline'. The new methods require scipy. Consult the Scipy reference guide and documentation for more information about when the various methods are appropriate. See the docs.

Interpolate now also accepts a limit keyword argument. This works similar tofillna's limit:

```python
In [95]: ser = pd.Series([1, 3, np.nan, np.nan, np.nan, 11])
In [96]: ser.interpolate(limit=2)
Out[96]:
    0   1.0
    1   3.0
    2   5.0
    3   7.0
    4  NaN
    5  11.0
dtype: float64
```

• Added wide_to_long panel data convenience function. See the docs.

```python
In [97]: np.random.seed(123)
In [98]: df = pd.DataFrame({"A1970": {0 : "a", 1 : "b", 2 : "c"},  
      ....:       "A1980": {0 : "d", 1 : "e", 2 : "f"},  
      ....:       "B1970": {0 : 2.5, 1 : 1.2, 2 : 0.7},  
      ....:       "B1980": {0 : 3.2, 1 : 1.3, 2 : 1.1},  
      ....:       "X" : dict(zip(range(3), np.random.randn(3)))})
In [99]: df["id"] = df.index
In [100]: df
Out[100]:
0      a       d      2.5     3.2  1.961553 0
1      b       e      1.2     1.3 -0.819620 1
2      c       f      0.7     1.1 -0.693257 2
```
(continues on next page)
In [101]: pd.wide_to_long(df, ["A", "B"], i="id", j="year")
Out[101]:
    id  year
 0  1970  -1.085631   a  2.5
 1  1970   0.997345   b  1.2
 2  1970   0.282978   c  0.7
 0  1980  -1.085631   d  3.2
 1  1980   0.997345   e  1.3
 2  1980   0.282978   f  0.1

• `to_csv` now takes a `date_format` keyword argument that specifies how output datetime objects should be formatted. Datetimes encountered in the index, columns, and values will all have this formatting applied. (GH4313)

• `DataFrame.plot` will scatter plot x versus y by passing `kind='scatter'` (GH2215)

• Added support for Google Analytics v3 API segment IDs that also supports v2 IDs. (GH5271)

**Experimental**

• The new `eval()` function implements expression evaluation using `numexpr` behind the scenes. This results in large speedups for complicated expressions involving large DataFrames/Series. For example,

```python
In [102]: nrows, ncols = 20000, 100
In [103]: df1, df2, df3, df4 = [pd.DataFrame(np.random.randn(nrows, ncols))
    ......:         for _ in range(4)]

# eval with NumExpr backend
In [104]: %timeit pd.eval('df1 + df2 + df3 + df4')
21.6 ms ± 2.22 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

# pure Python evaluation
In [105]: %timeit df1 + df2 + df3 + df4
24.1 ms ± 3.43 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)
```

For more details, see the the docs

• Similar to `pandas.eval`, `DataFrame` has a new `DataFrame.eval` method that evaluates an expression in the context of the DataFrame. For example,

```python
In [106]: df = pd.DataFrame(np.random.randn(10, 2), columns=['a', 'b'])
In [107]: df.eval('a + b')
Out[107]:
   0  -0.685204
   1   1.589745
   2   0.325441
   3  -1.784153
```

(continues on next page)
query() method has been added that allows you to select elements of a DataFrame using a natural query syntax nearly identical to Python syntax. For example:

```python
In [108]: n = 20
In [109]: df = pd.DataFrame(np.random.randint(n, size=(n, 3)), columns=['a', 'b', 'c'])
In [110]: df.query('a < b < c')
Out[110]:
   a  b  c
11  1  5  8
15  8 16 19
```

selects all the rows of df where \( a < b < c \) evaluates to True. For more details see the docs.

- `pd.read_msgpack()` and `pd.to_msgpack()` are now a supported method of serialization of arbitrary pandas (and python objects) in a lightweight portable binary format. See the docs

**Warning:** Since this is an EXPERIMENTAL LIBRARY, the storage format may not be stable until a future release.

```python
def = pd.DataFrame(np.random.rand(5, 2), columns=list('AB'))
df.to_msgpack('foo.msg')
pd.read_msgpack('foo.msg')

s = pd.Series(np.random.rand(5), index=pd.date_range('20130101', periods=5))
pd.to_msgpack('foo.msg', df, s)
pd.read_msgpack('foo.msg')
```

You can pass `iterator=True` to iterator over the unpacked results

```python
for o in pd.read_msgpack('foo.msg', iterator=True):
    print(o)
```

- `pandas.io.gbq` provides a simple way to extract from, and load data into, Google’s BigQuery Data Sets by way of pandas DataFrames. BigQuery is a high performance SQL-like database service, useful for performing ad-hoc queries against extremely large datasets. See the docs

```python
from pandas.io import gbq

# A query to select the average monthly temperatures in the
# in the year 2000 across the USA. The dataset,
# publicata:samples.gsod, is available on all BigQuery accounts,
# and is based on NOAA gsod data.
```
query = """SELECT station_number as STATION, month as MONTH, AVG(mean_temp) as MEAN_TEMP
FROM publicdata:samples.gsod
WHERE YEAR = 2000
GROUP BY STATION, MONTH
ORDER BY STATION, MONTH ASC"""

# Fetch the result set for this query

# Your Google BigQuery Project ID
# To find this, see your dashboard:
# https://console.developers.google.com/iam-admin/projects?authuser=0
projectid = 'xxxxxxxxx'
df = gbq.read_gbq(query, project_id=projectid)

# Use pandas to process and reshape the dataset

df2 = df.pivot(index='STATION', columns='MONTH', values='MEAN_TEMP')
df3 = pd.concat([df2.min(), df2.mean(), df2.max()],
                axis=1, keys=['Min Temp', 'Mean Temp', 'Max Temp'])

The resulting DataFrame is:

<table>
<thead>
<tr>
<th>MONTH</th>
<th>Min Temp</th>
<th>Mean Temp</th>
<th>Max Temp</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>-53.33667</td>
<td>39.827892</td>
<td>89.770968</td>
</tr>
<tr>
<td>2</td>

<td>48.861228</td>
<td>94.996428</td>
</tr>
<tr>
<td>12</td>
<td>-50.332258</td>
<td>42.286879</td>
<td>94.396774</td>
</tr>
</tbody>
</table>

**Warning:** To use this module, you will need a BigQuery account. See <https://cloud.google.com/products/big-query> for details.

As of 10/10/13, there is a bug in Google’s API preventing result sets from being larger than 100,000 rows. A patch is scheduled for the week of 10/14/13.
## Internal refactoring

In 0.13.0 there is a major refactor primarily to subclass `Series` from `NDFrame`, which is the base class currently for `DataFrame` and `Panel`, to unify methods and behaviors. `Series` formerly subclassed directly from `ndarray`. (GH4080, GH3862, GH816)

**Warning:** There are two potential incompatibilities from < 0.13.0

- Using certain numpy functions would previously return a `Series` if passed a `Series` as an argument. This seems only to affect `np.ones_like`, `np.empty_like`, `np.diff` and `np.where`. These now return `ndarrays`.

```python
In [111]: s = pd.Series([1, 2, 3, 4])
```

Numpy Usage

```python
In [112]: np.ones_like(s)
Out[112]: array([1, 1, 1, 1])

In [113]: np.diff(s)
Out[113]: array([1, 1, 1])

In [114]: np.where(s > 1, s, np.nan)
Out[114]: array([nan, 2., 3., 4.])
```

Pandonic Usage

```python
In [115]: pd.Series(1, index=s.index)
Out[115]:
   0  1
   1  1
   2  1
   3  1
   dtype: int64

In [116]: s.diff()
Out[116]:
       0    NaN
       1    1.0
       2    1.0
       3    1.0
   dtype: float64

In [117]: s.where(s > 1)
Out[117]:
       0    NaN
       1    2.0
       2    3.0
       3    4.0
   dtype: float64
```

- Passing a `Series` directly to a cython function expecting an `ndarray` type will no long work directly, you must pass `Series.values`, See *Enhancing Performance*

- `Series(0.5)` would previously return the scalar 0.5, instead this will return a 1-element `Series`

- This change breaks `rpy2<=2.3.8` an Issue has been opened against `rpy2` and a workaround is detailed in `GH5698`. Thanks @JanSchulz.

- Pickle compatibility is preserved for pickles created prior to 0.13. These must be unpickled with `pd`.
read_pickle, see *Pickling.*

- Refactor of series.py/frame.py/panel.py to move common code to generic.py
  - added _setup_axes to created generic NDFrame structures
  - moved methods
    * from_axes, _wrap_array, axes, ix, loc, iloc, shape, empty, swapaxes, transpose, pop
    * __iter__, keys, __contains__, __len__, __neg__, __invert__
    * convert_objects, as_blocks, as_matrix, values
    * __getstate__, __setstate__ (compat remains in frame/panel)
    * __getattr__, __setattr__
    * _indexed_same, reindex_like, align, where, mask
    * fillna, replace (Series replace is now consistent with DataFrame)
    * filter (also added axis argument to selectively filter on a different axis)
    * reindex, reindex_axis, take
    * truncate (moved to become part of NDFrame)

- These are API changes which make Panel more consistent with DataFrame
  - swapaxes on a Panel with the same axes specified now return a copy
  - support attribute access for setting
  - filter supports the same API as the original DataFrame filter

- Reindex called with no arguments will now return a copy of the input object

- TimeSeries is now an alias for Series. the property is_time_series can be used to distinguish (if desired)

- Refactor of Sparse objects to use BlockManager
  - Created a new block type in internals, SparseBlock, which can hold multi-dtypes and is non-consolidatable. SparseSeries and SparseDataFrame now inherit more methods from there hierarchy (Series/DataFrame), and no longer inherit from SparseArray (which instead is the object of the SparseBlock)
  - Sparse suite now supports integration with non-sparse data. Non-float sparse data is supportable (partially implemented)
  - Operations on sparse structures within DataFrames should preserve sparseness, merging type operations will convert to dense (and back to sparse), so might be somewhat inefficient
  - enable setitem on SparseSeries for boolean/integer/slices
  - SparsePanels implementation is unchanged (e.g. not using BlockManager, needs work)

- added ftypes method to Series/DataFrame, similar to dtypes, but indicates if the underlying is sparse/dense (as well as the dtype)

- All NDFrame objects can now use __finalize__() to specify various values to propagate to new objects from an existing one (e.g. name in Series will follow more automatically now)

- Internal type checking is now done via a suite of generated classes, allowing isinstance(value, klass) without having to directly import the klass, courtesy of @jtratner
Bug fixes

- **HDFStore**
  - raising an invalid `TypeError` rather than `ValueError` when appending with a different block ordering (GH4096)
  - `read_hdf` was not respecting as passed `mode` (GH4504)
  - appending a 0-len table will work correctly (GH4273)
  - `to_hdf` was raising when passing both arguments `append` and `table` (GH4584)
  - reading from a store with duplicate columns across dtypes would raise (GH4767)
  - Fixed a bug where `ValueError` wasn’t correctly raised when column names weren’t strings (GH4956)
  - A zero length series written in Fixed format not deserializing properly. (GH4708)
  - Fixed decoding perf issue on py3 (GH5441)
  - Validate levels in a MultiIndex before storing (GH5527)
  - Correctly handle `data_columns` with a Panel (GH5717)

- Fixed bug in `tslib.tz_convert(vals, tz1, tz2)`: it could raise `IndexError` exception while trying to access `trans[pos + 1]` (GH4496)

- The `by` argument now works correctly with the `layout` argument (GH4102, GH4014) in `.hist` plotting methods
- Fixed bug in `PeriodIndex.map` where using `str` would return the str representation of the index (GH4136)
- Fixed test failure `test_time_series_plot_color_with_empty_kwargs` when using custom matplotlib default colors (GH4345)
- Fix running of stata IO tests. Now uses temporary files to write (GH4353)
- Fixed an issue where `DataFrame.sum` was slower than `DataFrame.mean` for integer valued frames (GH4365)
- `read_html` tests now work with Python 2.6 (GH4351)
- Fixed bug where network testing was throwing `NameError` because a local variable was undefined (GH4381)
- In `to_json`, raise if a passed `orient` would cause loss of data because of a duplicate index (GH4359)
- In `to_json`, fix date handling so milliseconds are the default timestamp as the docstring says (GH4362)
- `as_index` is no longer ignored when doing groupby apply (GH4648, GH3417)
- JSON NaT handling fixed, NaTs are now serialized to `null` (GH4498)
- Fixed JSON handling of escapable characters in JSON object keys (GH4593)
- Fixed passing `keep_default_na=False` when `na_values=None` (GH4318)
- Fixed bug with `values` raising an error on a DataFrame with duplicate columns and mixed dtypes, surfaced in (GH4377)
- Fixed bug with duplicate columns and type conversion in `read_json` when `orient='split'` (GH4377)
- Fixed JSON bug where locales with decimal separators other than ‘.’ threw exceptions when encoding / decoding certain values. (GH4918)
- Fix `.iat` indexing with a `PeriodIndex` (GH4390)
- Fixed an issue where `PeriodIndex` joining with self was returning a new instance rather than the same instance (GH4379); also adds a test for this for the other index types
- Fixed a bug with all the dtypes being converted to object when using the CSV cparsor with the usecols parameter (GH3192)
- Fix an issue in merging blocks where the resulting DataFrame had partially set `_ref_locs` (GH4403)
- Fixed an issue where hist subplots were being overwritten when they were called using the top level matplotlib API (GH4408)
- Fixed a bug where calling `Series.astype(str)` would truncate the string (GH4405, GH4437)
- Fixed a py3 compat issue where bytes were being repr’d as tuples (GH4455)
- Fixed Panel attribute naming conflict if item is named ‘a’ (GH3440)
- Fixed an issue where duplicate indexes were raising when plotting (GH4486)
- Fixed an issue where cumsum and cumprod didn’t work with bool dtypes (GH4170, GH4440)
- Fixed Panel slicing issued in `xs` that was returning an incorrect dimmed object (GH4016)
- Fix resampling bug where custom reduce function not used if only one group (GH3849, GH4494)
- Fixed Panel assignment with a transposed frame (GH3830)
- Raise on set indexing with a Panel and a Panel as a value which needs alignment (GH3777)
- frozenset objects now raise in the `Series` constructor (GH4482, GH4480)
- Fixed issue with sorting a duplicate MultiIndex that has multiple dtypes (GH4516)
• Fixed bug in `DataFrame.set_values` which was causing name attributes to be lost when expanding the index. (GH3742, GH4039)
• Fixed issue where individual `names`, `levels` and `labels` could be set on `MultiIndex` without validation (GH3714, GH4039)
• Fixed (GH3334) in `pivot_table`. Margins did not compute if values is the index.
• Fix bug in having a rhs of `np.timedelta64` or `np.offsets.DateOffset` when operating with dates (GH4532)
• Fix arithmetic with series/datetimeindex and `np.timedelta64` not working the same (GH4134) and buggy timedelta in NumPy 1.6 (GH4135)
• Fix bug in `pd.read_clipboard` on windows with PY3 (GH4561); not decoding properly
• `tslib.get_period_field()` and `tslib.get_period_field_arr()` now raise if code argument out of range (GH4519, GH4520)
• Fix boolean indexing on an empty series loses index names (GH4235), `infer_dtype` works with empty arrays.
• Fix reindexing with multiple axes; if an axes match was not replacing the current axes, leading to a possible lazy frequency inference issue (GH3317)
• Fixed issue where `DataFrame.apply` was reraising exceptions incorrectly (causing the original stack trace to be truncated).
• Fix selection with `ix/loc` and non_unique selectors (GH4619)
• Fix assignment with `iloc/loc` involving a dtype change in an existing column (GH4312, GH5702) have internal `setitem_with_indexer` in core/indexing to use `Block.setitem`
• Fixed bug where thousands operator was not handled correctly for floating point numbers in csv_import (GH4322)
• Fix an issue with `CacheableOffset` not properly being used by many DateOffset; this prevented the DateOffset from being cached (GH4609)
• Fix boolean comparison with a DataFrame on the lhs, and a list/tuple on the rhs (GH4576)
• Fix error/dtype conversion with `setitem` of `None` on Series/DataFrame (GH4667)
• Fix decoding based on a passed in non-default encoding in `pd.read_stata` (GH4626)
• Fix `DataFrame.from_records` with a plain-vanilla ndarray. (GH4727)
• Fix some inconsistencies with `Index.rename` and `MultiIndex.rename`, etc. (GH4718, GH4628)
• Bug in using `iloc/loc` with a cross-sectional and duplicate indices (GH4726)
• Bug with using `QUOTE_NONE` with `to_csv` causing Exception. (GH4328)
• Bug with Series indexing not raising an error when the right-hand-side has an incorrect length (GH2702)
• Bug in MultiIndexing with a partial string selection as one part of a MultiIndex (GH4758)
• Bug with reindexing on the index with a non-unique index will now raise `ValueError` (GH4746)
• Bug in setting with `loc/ix` a single indexer with a MultiIndex axis and a NumPy array, related to (GH3777)
• Bug in concatenation with duplicate columns across dtypes not merging with axis=0 (GH4771, GH4975)
• Bug in `iloc` with a slice index failing (GH4771)
• Incorrect error message with no colspecs or width in `read_fwf`. (GH4774)
• Fix bugs in indexing in a Series with a duplicate index (GH4548, GH4550)
• Fixed bug with reading compressed files with read_fwf in Python 3. (GH3963)
• Fixed an issue with a duplicate index and assignment with a dtype change (GH4686)
• Fixed an issue related to ticklocs/ticklabels with log scale bar plots across different versions of matplotlib (GH4789)
• Suppressed DeprecationWarning associated with internal calls issued by repr() (GH4391)
• Fixed an issue with a duplicate index and duplicate selector with .loc (GH4825)
• Fixed an issue with DataFrame.sort_index where, when sorting by a single column and passing a list for ascending, the argument for ascending was being interpreted as True (GH4839, GH4846)
• Fixed Panel.tshift not working. Added freq support to Panel.shift (GH4853)
• Fix an issue in TextFileReader w/ Python engine (i.e. PythonParser) with thousands != ," (GH4596)
• Bug in getitem with a duplicate index when using where (GH4879)
• Fix Type inference code coerces float column into datetime (GH4601)
• Fixed _ensure_numeric does not check for complex numbers (GH4902)
• Fixed a bug in Series.hist where two figures were being created when the by argument was passed (GH4112, GH4113).
• Fixed a bug in convert_objects for > 2 ndims (GH4937)
• Fixed a bug in DataFrame/Panel cache insertion and subsequent indexing (GH4939, GH5424)
• Fixed string methods for FrozenNDArray and FrozenList (GH4929)
• Fixed a bug with setting invalid or out-of-range values in indexing enlargement scenarios (GH4940)
• Tests for fillna on empty Series (GH4346), thanks @immerrr
• Fixed copy() to shallow copy axes/indices as well and thereby keep separate metadata. (GH4202, GH4830)
• Fixed skiprows option in Python parser for read_csv (GH4382)
• Fixed bug preventing cut from working with np.inf levels without explicitly passing labels (GH3415)
• Fixed wrong check for overlapping in DatetimeIndex.union (GH4564)
• Fixed conflict between thousands separator and date parser in csv_parser (GH4678)
• Fix appending when dtypes are not the same (error showing mixing float/np.datetime64) (GH4993)
• Fix repr for DateOffset. No longer show duplicate entries in kwds. Removed unused offset fields. (GH4638)
• Fixed wrong index name during read_csv if using usecols. Applies to csv parser only. (GH4201)
• Timestamp objects can now appear in the left hand side of a comparison operation with a Series or DataFrame object (GH4982).
• Fix a bug when indexing with np.nan via iloc/loc (GH5016)
• Fixed a bug where low memory c parser could create different types in different chunks of the same file. Now coerces to numerical type or raises warning. (GH3866)
• Fix a bug where reshaping a Series to its own shape raised TypeError (GH4554) and other reshaping issues.
• Bug in setting with ix/loc and a mixed int/string index (GH4544)
• Make sure series-series boolean comparisons are label based (GH4947)
• Bug in multi-level indexing with a Timestamp partial indexer (GH4294)
• Tests/fix for MultiIndex construction of an all-nan frame (GH4078)
• Fixed a bug where `read_html()` wasn’t correctly inferring values of tables with commas (GH5029)
• Fixed a bug where `read_html()` wasn’t providing a stable ordering of returned tables (GH4770, GH5029).
• Fixed a bug where `read_html()` was incorrectly parsing when passed `index_col=0` (GH5066).
• Fixed a bug where `read_html()` was incorrectly inferring the type of headers (GH5048).
• Fixed a bug where `DatetimeIndex` joins with `PeriodIndex` caused a stack overflow (GH3899).
• Fixed a bug where `groupby` objects didn’t allow plots (GH5102).
• Fixed a bug where `groupby` objects weren’t tab-completing column names (GH5102).
• Fixed a bug where `groupby.plot()` and friends were duplicating figures multiple times (GH5102).
• Provide automatic conversion of `object` dtypes on `fillna`, related (GH5103)
• Fixed a bug where default options were being overwritten in the option parser cleaning (GH5121).
• Treat a list/ndarray identically for `iloc` indexing with list-like (GH5006)
• Fix `MultiIndex.get_level_values()` with missing values (GH5074)
• Fix bound checking for `Timestamp()` with `datetime64` input (GH4065)
• Fix a bug where `TestReadHtml` wasn’t calling the correct `read_html()` function (GH5150).
• Fix a bug with `NDFrame.replace()` which made replacement appear as though it was (incorrectly) using regular expressions (GH5143).
• Fix better error message for `to_datetime` (GH4928)
• Made sure different locales are tested on travis-ci (GH4918). Also adds a couple of utilities for getting locales and setting locales with a context manager.
• Fixed segfault on `isnull(MultiIndex)` (now raises an error instead) (GH5123, GH5125)
• Allow duplicate indices when performing operations that align (GH5185, GH5639)
• Compound dtypes in a constructor raise `NotImplementedError` (GH5191)
• Bug in comparing duplicate frames (GH4421) related
• Bug in `describe` on duplicate frames
• Bug in `to_datetime` with a format and `coerce=True` not raising (GH5195)
• Bug in `loc` setting with multiple indexers and a rhs of a Series that needs broadcasting (GH5206)
• Fixed bug where inplace setting of levels or labels on `MultiIndex` would not clear cached values property and therefore return wrong values. (GH5215)
• Fixed bug where filtering a grouped DataFrame or Series did not maintain the original ordering (GH4621).
• Fixed `Period` with a business date freq to always roll-forward if on a non-business date. (GH5203)
• Fixed bug in Excel writers where frames with duplicate column names weren’t written correctly. (GH5235)
• Fixed issue with `drop` and a non-unique index on Series (GH5248)
• Fixed segfault in C parser caused by passing more names than columns in the file. (GH5156)
• Fix `Series.isin` with date/time-like dtypes (GH5021)
• C and Python Parser can now handle the more common MultiIndex column format which doesn’t have a row for index names (GH4702)
• Bug when trying to use an out-of-bounds date as an object dtype (GH5312)
• Bug when trying to display an embedded PandasObject (GH5324)
• Allows operating of Timestamps to return a datetime if the result is out-of-bounds related (GH5312)
• Fix return value/type signature of initObjToJSON() to be compatible with numpy’s import_array() (GH5334, GH5326)
• Bug when renaming then set_index on a DataFrame (GH5344)
• Test suite no longer leaves around temporary files when testing graphics. (GH5347) (thanks for catching this @yarikoptic!)
• Fixed html tests on win32. (GH4580)
• Make sure that head/tail are iloc based, (GH5370)
• Fixed bug for PeriodIndex string representation if there are 1 or 2 elements. (GH5372)
• The GroupBy methods transform and filter can be used on Series and DataFrames that have repeated (non-unique) indices. (GH4620)
• Fix empty series not printing name in repr (GH4651)
• Make tests create temp files in temp directory by default. (GH5419)
• pd.to_timedelta of a scalar returns a scalar (GH5410)
• pd.to_timedelta accepts NaN and NaT, returning NaT instead of raising (GH5437)
• performance improvements in isnull on larger size pandas objects
• Fixed various setitem with 1d ndarray that does not have a matching length to the indexer (GH5508)
• Bug in getitem with a MultiIndex and iloc (GH5528)
• Bug in delitem on a Series (GH5542)
• Bug fix in apply when using custom function and objects are not mutated (GH5545)
• Bug in selecting from a non-unique index with loc (GH5553)
• Bug in groupby returning non-consistent types when user function returns a None, (GH5592)
• Work around regression in numpy 1.7.0 which erroneously raises IndexError from ndarray.item(GH5666)
• Bug in repeated indexing of object with resultant non-unique index (GH5678)
• Bug in fillna with Series and a passed series/dict (GH5703)
• Bug in groupby transform with a datetime-like grouper (GH5712)
• Bug in MultiIndex selection in PY3 when using certain keys (GH5725)
• Row-wise concat of differing dtypes failing in certain cases (GH5754)

5.16 Version 0.12

5.16.1 Version 0.12.0 (July 24, 2013)

This is a major release from 0.11.0 and includes several new features and enhancements along with a large number of bug fixes.

Highlights include a consistent I/O API naming scheme, routines to read html, write MultiIndexes to csv files, read & write STATA data files, read & write JSON format files, Python 3 support for HDFStore, filtering of groupby expressions via filter, and a revamped replace routine that accepts regular expressions.

API changes

• The I/O API is now much more consistent with a set of top level reader functions accessed like pd. read_csv() that generally return a pandas object.
  - read_csv
  - read_excel
  - read_hdf
  - read_sql
  - read_json
  - read_html
  - read_stata
  - read_clipboard

The corresponding writer functions are object methods that are accessed like df.to_csv()
pandas: powerful Python data analysis toolkit, Release 1.1.1

– to_clipboard
• Fix modulo and integer division on Series,DataFrames to act similarly to float dtypes to return np.nan
or np.inf as appropriate (GH3590). This correct a numpy bug that treats integer and float dtypes
differently.

• Add squeeze keyword to groupby to allow reduction from DataFrame -> Series if groups are unique. This
is a Regression from 0.10.1. We are reverting back to the prior behavior. This means groupby will return the
same shaped objects whether the groups are unique or not. Revert this issue (GH2893) with (GH3596).
In [2]: df2 = pd.DataFrame([{"val1": 1, "val2": 20},
...:
{"val1": 1, "val2": 19},
...:
{"val1": 1, "val2": 27},
...:
{"val1": 1, "val2": 12}])
In [3]: def func(dataf):
...:
return dataf["val2"] - dataf["val2"].mean()
...:
In [4]: # squeezing the result frame to a series (because we have unique groups)
...: df2.groupby("val1", squeeze=True).apply(func)

• Raise on iloc when boolean indexing with a label based indexer mask e.g. a boolean Series, even with integer labels, will raise. Since iloc is purely positional based, the labels on the Series are not alignable (GH3631) This case is rarely used, and there are plenty of alternatives. This preserves the iloc API to be purely positional based.

In [6]: df = pd.DataFrame(range(5), index=list('ABCDE'), columns=['a'])
In [7]: mask = (df.a % 2 == 0)
In [8]: mask
Out[8]:
     A   B   C   D   E
Name: a, dtype: bool
# this is what you should use
In [9]: df.loc[mask]
Out[9]:
     a
  A   0
  C   2
  E   4

# this will work as well
In [10]: df.iloc[mask.values]
Out[10]:
     a
  A   0
  C   2
  E   4
df.iloc[mask] will raise a ValueError

• The raise_on_error argument to plotting functions is removed. Instead, plotting functions raise a TypeError when the dtype of the object is object to remind you to avoid object arrays whenever possible and thus you should cast to an appropriate numeric dtype if you need to plot something.

• Add colormap keyword to DataFrame plotting methods. Accepts either a matplotlib colormap object (ie, matplotlib.cm.jet) or a string name of such an object (ie, 'jet'). The colormap is sampled to select the color for each column. Please see Colormaps for more information. (GH3860)

• DataFrame.interpolate() is now deprecated. Please use DataFrame.fillna() and DataFrame.replace() instead. (GH3582, GH3675, GH3676)

• the method and axis arguments of DataFrame.replace() are deprecated

• DataFrame.replace 's infer_types parameter is removed and now performs conversion by default. (GH3907)
• Add the keyword allow_duplicates to DataFrame.insert to allow a duplicate column to be inserted if True, default is False (same as prior to 0.12) (GH3679)
• Implement __nonzero__ for NDFrame objects (GH3691, GH3696)
• IO api
  – added top-level function read_excel to replace the following. The original API is deprecated and will be removed in a future version

```python
from pandas.io.parsers import ExcelFile
xls = ExcelFile('path_to_file.xls')
xls.parse('Sheet1', index_col=None, na_values=['NA'])
```

With

```python
import pandas as pd
pd.read_excel('path_to_file.xls', 'Sheet1', index_col=None, na_values=['NA'])
```

  – added top-level function read_sql that is equivalent to the following

```python
from pandas.io.sql import read_frame
read_frame(...)
```

• DataFrame.to_html and DataFrame.to_latex now accept a path for their first argument (GH3702)
• Do not allow astypes on datetime64[ns] except to object, and timedelta64[ns] to object/int (GH3425)
• The behavior of datetime64 dtypes has changed with respect to certain so-called reduction operations (GH3726). The following operations now raise a TypeError when performed on a Series and return an empty Series when performed on a DataFrame similar to performing these operations on, for example, a DataFrame of slice objects:
  – sum, prod, mean, std, var, skew, kurt, corr, and cov
• read_html now defaults to None when reading, and falls back on bs4 + html5lib when lxml fails to parse. a list of parsers to try until success is also valid
• The internal pandas class hierarchy has changed (slightly). The previous PandasObject now is called PandasContainer and a new PandasObject has become the base class for PandasContainer as well as Index, Categorical, GroupBy, SparseList, and SparseArray (+ their base classes). Currently, PandasObject provides string methods (from StringMixin). (GH4090, GH4092)
• New StringMixin that, given a __unicode__ method, gets python 2 and python 3 compatible string methods (__str__, __bytes__, and __repr__). Plus string safety throughout. Now employed in many places throughout the pandas library. (GH4090, GH4092)

**IO enhancements**

• pd.read_html() can now parse HTML strings, files or urls and return DataFrames, courtesy of @cpcloud. (GH3477, GH3605, GH3606, GH3616). It works with a single parser backend: BeautifulSoup4 + html5lib. See the docs

You can use pd.read_html() to read the output from DataFrame.to_html() like so

```python
In [11]: df = pd.DataFrame({'a': range(3), 'b': list('abc')})
In [12]: print(df)
```
a  b  
0 0  a  
1 1  b  
2 2  c  

In [13]: html = df.to_html()
In [14]: alist = pd.read_html(html, index_col=0)
In [15]: print(df == alist[0])

Note that alist here is a Python list so pd.read_html() and DataFrame.to_html() are not inverses.
- pd.read_html() no longer performs hard conversion of date strings (GH3656).

**Warning:** You may have to install an older version of BeautifulSoup4, See the installation docs

- Added module for reading and writing Stata files: pandas.io.stata (GH1512) accessible via read_stata top-level function for reading, and to_stata DataFrame method for writing, See the docs
- Added module for reading and writing json format files: pandas.io.json accessible via read_json top-level function for reading, and to_json DataFrame method for writing, See the docs various issues (GH1226, GH3804, GH3876, GH3867, GH1305)
- MultiIndex column support for reading and writing csv format files
  - The header option in read_csv now accepts a list of the rows from which to read the index.
  - The option, tupleize_cols can now be specified in both to_csv and read_csv, to provide compatibility for the pre 0.12 behavior of writing and reading MultiIndex columns via a list of tuples. The default in 0.12 is to write lists of tuples and not interpret list of tuples as a MultiIndex column.

Note: The default behavior in 0.12 remains unchanged from prior versions, but starting with 0.13, the default to write and read MultiIndex columns will be in the new format. (GH3571, GH1651, GH3141)
- If an index_col is not specified (e.g. you don’t have an index, or wrote it with df.to_csv(..., index=False), then any names on the columns index will be lost.

In [16]: from pandas._testing import makeCustomDataframe as mkdf
In [17]: df = mkdf(5, 3, r_idx_nlevels=2, c_idx_nlevels=4)
In [18]: df.to_csv('mi.csv')
In [19]: print(open('mi.csv').read())

- Support for HDFStore (via PyTables 3.0.0) on Python3
- Iterator support via `read_hdf` that automatically opens and closes the store when iteration is finished. This is only for tables

**In [25]:** path = 'store_iterator.h5'
**In [26]:** pd.DataFrame(np.random.randn(10, 2)).to_hdf(path, 'df', table=True)
**In [27]:** for df in pd.read_hdf(path, 'df', chunksize=3):
    ....:     print(df)
    ....:     0 1
    ....:     0 0.713216 -0.778461
    ....:     1 -0.661062 0.862877
    ....:     2 0.344342 0.149565
    ....:     3 -0.626968 -0.875772
    ....:     4 -0.930687 -0.218983
    ....:     5 0.949965 -0.442354
    ....:     6 -0.402985 1.111358
    ....:     7 -0.241527 -0.670477
    ....:     8 0.049355 0.632633
    ....:     9 -1.502767 -1.225492

- `read_csv` will now throw a more informative error message when a file contains no columns, e.g., all newline characters
Other enhancements

- **DataFrame.replace()** now allows regular expressions on contained Series with object dtype. See the examples section in the regular docs *Replacing via String Expression*

For example you can do

```python
In [21]: df = pd.DataFrame({'a': list('ab..'), 'b': [1, 2, 3, 4]})
In [22]: df.replace(regex=r'^\s*.\s*', value=np.nan)
Out[22]:
   a  b
0  a  1
1  b  2
2  NaN  3
3  NaN  4
```

...to replace all occurrences of the string `. ` with zero or more instances of surrounding white space with NaN.

Regular string replacement still works as expected. For example, you can do

```python
In [23]: df.replace('.', np.nan)
Out[23]:
   a  b
0  a  1
1  b  2
2  NaN  3
3  NaN  4
```

...to replace all occurrences of the string `. ` with NaN.

- **pd.melt()** now accepts the optional parameters *var_name* and *value_name* to specify custom column names of the returned DataFrame.

- **pd.set_option()** now allows N option, value pairs (GH3667).

  Let’s say that we had an option `'a.b'` and another option `'b.c'`. We can set them at the same time:

```python
In [31]: pd.get_option('a.b')
Out[31]: 2
In [32]: pd.get_option('b.c')
Out[32]: 3
In [33]: pd.set_option('a.b', 1, 'b.c', 4)
In [34]: pd.get_option('a.b')
Out[34]: 1
In [35]: pd.get_option('b.c')
Out[35]: 4
```

- The **filter** method for group objects returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

```python
In [24]: sf = pd.Series([1, 1, 2, 3, 3, 3])
In [25]: sf.groupby(sf).filter(lambda x: x.sum() > 2)
```

(continues on next page)
The argument of `filter` must a function that, applied to the group as a whole, returns `True` or `False`. Another useful operation is filtering out elements that belong to groups with only a couple members.

```python
In [26]: dff = pd.DataFrame({'A': np.arange(8), 'B': list('aabbbbcc'))
In [27]: dff.groupby('B').filter(lambda x: len(x) > 2)
Out[27]:
   A  B
0  0  b
1  1  b
2  2  b
3  3  b
4  4  b
5  5  b
6  6  b
7  7  b
```

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with NaNs.

```python
In [28]: dff.groupby('B').filter(lambda x: len(x) > 2, dropna=False)
Out[28]:
   A  B
0 NaN NaN
1 NaN NaN
2 2.0 b
3 3.0 b
4 4.0 b
5 5.0 b
6 NaN NaN
7 NaN NaN
```

- Series and DataFrame `hist` methods now take a `figsize` argument (GH3834)
- DatetimeIndexes no longer try to convert mixed-integer indexes during join operations (GH3877)
- `Timestamp.min` and `Timestamp.max` now represent valid ` Timestamp` instances instead of the default date-time.min and datetime.max (respectively), thanks @SleepingPills
- `read_html` now raises when no tables are found and BeautifulSoup==4.2.0 is detected (GH4214)

**Experimental features**

- Added experimental `CustomBusinessDay` class to support `DateOffsets` with custom holiday calendars and custom weekmasks. (GH2301)

  **Note:** This uses the `numpy.busdaycalendar` API introduced in Numpy 1.7 and therefore requires Numpy 1.7.0 or newer.

```python
In [29]: from pandas.tseries.offsets import CustomBusinessDay
In [30]: from datetime import datetime
```
# As an interesting example, let's look at Egypt where
# a Friday-Saturday weekend is observed.
In [31]: weekmask_egypt = 'Sun Mon Tue Wed Thu'

# They also observe International Workers' Day so let's
# add that for a couple of years
In [32]: holidays = ['2012-05-01', \n                   datetime(2013, 5, 1), \n                   np.datetime64('2014-05-01')]

In [33]: bday_egypt = CustomBusinessDay(holidays=holidays, weekmask=weekmask_egypt)

In [34]: dt = datetime(2013, 4, 30)

In [35]: print(dt + 2 * bday_egypt)
2013-05-05 00:00:00

In [36]: dts = pd.date_range(dt, periods=5, freq=bday_egypt)

In [37]: print(pd.Series(dts.weekday, dts).map(pd.Series('Mon Tue Wed Thu Fri Sat Sun'.split())))

2013-04-30 Tue
2013-05-02 Thu
2013-05-05 Sun
2013-05-06 Mon
2013-05-07 Tue
Freq: C, dtype: object

Bug fixes

- Plotting functions now raise a TypeError before trying to plot anything if the associated objects have have a
dtype of object (GH1818, GH3572, GH3911, GH3912), but they will try to convert object arrays to numeric
arrays if possible so that you can still plot, for example, an object array with floats. This happens before any
drawing takes place which eliminates any spurious plots from showing up.
-fillna methods now raise a TypeError if the value parameter is a list or tuple.
- Series.str now supports iteration (GH3638). You can iterate over the individual elements of each string in
the Series. Each iteration yields a Series with either a single character at each index of the original
Series or NaN. For example,

In [38]: strs = 'go', 'bow', 'joe', 'slow'

In [39]: ds = pd.Series(strs)

In [40]: for s in ds.str:
   ....:     print(s)
   ....:
0  g
1  b
2  j
3  s
dtype: object
0  o
1  o

(continues on next page)
The last element yielded by the iterator will be a `Series` containing the last element of the longest string in the `Series` with all other elements being `NaN`. Here since 'slow' is the longest string and there are no other strings with the same length 'w' is the only non-null string in the yielded `Series`.

- **HDFStore**
  - will retain index attributes (freq, tz, name) on recreation (GH3499)
  - will warn with a `AttributeConflictWarning` if you are attempting to append an index with a different frequency than the existing, or attempting to append an index with a different name than the existing
  - support datelike columns with a timezone as `.data.columns` (GH2852)
- **Non-unique index support clarified** (GH3468).
  - Fix assigning a new index to a duplicate index in a DataFrame would fail (GH3468)
  - Fix construction of a DataFrame with a duplicate index
  - `.ref_locs` support to allow duplicative indices across dtypes, allows `iget` support to always find the index (even across dtypes) (GH2194)
  - `applymap` on a DataFrame with a non-unique index now works (removed warning) (GH2786), and fix (GH3230)
  - `to_csv` to handle non-unique columns (GH3495)
  - Duplicate indexes with `get_item` will return items in the correct order (GH3455, GH3457) and handle missing elements like unique indices (GH3561)
  - Duplicate indexes with and empty DataFrame.from_records will return a correct frame (GH3562)
  - `Concat` to produce a non-unique columns when duplicates are across dtypes is fixed (GH3602)
  - Allow `insert/delete` to non-unique columns (GH3679)
pandas: powerful Python data analysis toolkit, Release 1.1.1

- Non-unique indexing with a slice via `loc` and friends fixed (GH3659)
- Allow insert/delete to non-unique columns (GH3679)
- Extend `reindex` to correctly deal with non-unique indices (GH3679)
- `DataFrame.itertuples()` now works with frames with duplicate column names (GH3873)
- Bug in non-unique indexing via `iloc` (GH4017); added `takeable` argument to `reindex` for location-based taking
- Allow non-unique indexing in series via `.ix/.loc` and `__getitem__` (GH4246)
- Fixed non-unique indexing memory allocation issue with `.ix/.loc` (GH4280)

* DataFrame.from_records did not accept empty recarrays (GH3682)
* `read_html` now correctly skips tests (GH3741)
* Fixed a bug where DataFrame.replace with a compiled regular expression in the `to_replace` argument wasn’t working (GH3907)
* Improved `network` test decorator to catch IOError (and therefore URLError as well). Added `with_connectivity_check` decorator to allow explicitly checking a website as a proxy for seeing if there is network connectivity. Plus, new `optional_args` decorator factory for decorators. (GH3910, GH3914)
* Fixed testing issue where too many sockets where open thus leading to a connection reset issue (GH3982, GH3985, GH4028, GH4054)
* Fixed failing tests in test_yahoo, test_google where symbols were not retrieved but were being accessed (GH3982, GH3985, GH4028, GH4054)
* Series.hist will now take the figure from the current environment if one is not passed
* Fixed bug where a 1xN DataFrame would barf on a 1xN mask (GH4071)
* Fixed running of `tox` under python3 where the pickle import was getting rewritten in an incompatible way (GH4062, GH4063)
* Fixed bug where sharex and sharey were not being passed to grouped_hist (GH4089)
* Fixed bug in DataFrame.replace where a nested dict wasn’t being iterated over when `regex=False` (GH4115)
* Fixed bug in the parsing of microseconds when using the `format` argument in `to_datetime` (GH4152)
* Fixed bug in PandasAutoDateLocator where `invert_xaxis` triggered incorrectly `MilliSecondLocator` (GH3990)
* Fixed bug in plotting that wasn’t raising on invalid colormap for matplotlib 1.1.1 (GH4215)
* Fixed the legend displaying in `DataFrame.plot(kind='kde')` (GH4216)
* Fixed bug where Index slices weren’t carrying the name attribute (GH4226)
* Fixed bug in initializing `DatetimeIndex` with an array of strings in a certain time zone (GH4229)
* Fixed bug where html5lib wasn’t being properly skipped (GH4265)
* Fixed bug where `get_data_famafrench` wasn’t using the correct file edges (GH4281)

5.17 Version 0.11

5.17.1 Version 0.11.0 (April 22, 2013)

This is a major release from 0.10.1 and includes many new features and enhancements along with a large number of bug fixes. The methods of Selecting Data have had quite a number of additions, and Dtype support is now full-fledged. There are also a number of important API changes that long-time pandas users should pay close attention to.

There is a new section in the documentation, *10 Minutes to Pandas*, primarily geared to new users.

There is a new section in the documentation, *Cookbook*, a collection of useful recipes in pandas (and that we want contributions!).

There are several libraries that are now *Recommended Dependencies*

**Selection choices**

Starting in 0.11.0, object selection has had a number of user-requested additions in order to support more explicit location based indexing. Pandas now supports three types of multi-axis indexing.

- `.loc` is strictly label based, will raise `KeyError` when the items are not found, allowed inputs are:
  - A single label, e.g. 5 or 'a', (note that 5 is interpreted as a label of the index. This use is not an integer position along the index)
  - A list or array of labels ['a', 'b', 'c']
  - A slice object with labels 'a': 'f', (note that contrary to usual python slices, both the start and the stop are included!)
– A boolean array

See more at Selection by Label

• .iloc is strictly integer position based (from 0 to length-1 of the axis), will raise IndexError when the requested indices are out of bounds. Allowed inputs are:
  – An integer e.g. 5
  – A list or array of integers [4, 3, 0]
  – A slice object with ints 1:7
  – A boolean array

See more at Selection by Position

• .ix supports mixed integer and label based access. It is primarily label based, but will fallback to integer positional access. .ix is the most general and will support any of the inputs to .loc and .iloc, as well as support for floating point label schemes. .ix is especially useful when dealing with mixed positional and label based hierarchical indexes.

As using integer slices with .ix have different behavior depending on whether the slice is interpreted as position based or label based, it’s usually better to be explicit and use .iloc or .loc.

See more at Advanced Indexing and Advanced Hierarchical.

Selection deprecations

Starting in version 0.11.0, these methods may be deprecated in future versions.

• irow
• icol
• iget_value

See the section Selection by Position for substitutes.

Dtypes

Numeric dtypes will propagate and coexist in DataFrames. If a dtype is passed (either directly via the dtype keyword, a passed ndarray, or a passed Series, then it will be preserved in DataFrame operations. Furthermore, different numeric dtypes will NOT be combined. The following example will give you a taste.

```python
In [1]: df1 = pd.DataFrame(np.random.randn(8, 1), columns=['A'], dtype='float32')
In [2]: df1
Out[2]:
     A
0  0.469112
1 -0.282863
2 -1.509058
3 -1.135632
4  1.212112
5 -0.173215
6  0.119209
7 -1.044236
```

(continues on next page)
Out[3]:
A float32
dtype: object

In [4]: df2 = pd.DataFrame({'A': pd.Series(np.random.randn(8), dtype='float16'),
...:                      'B': pd.Series(np.random.randn(8)),
...:                      'C': pd.Series(range(8), dtype='uint8')})

...:

In [5]: df2
Out[5]:
   A     B     C
0 -0.861816 -0.424972  0
1 -2.105469  0.567020  1
2 -0.494873  0.276232  2
3  1.072266 -1.087401  3
4  0.721680 -0.673690  4
5 -0.706543  0.113648  5
6 -1.040039 -1.478427  6
7  0.271973  0.524988  7

In [6]: df2.dtypes
Out[6]:
A float16
B float64
C uint8
dtype: object

# here you get some upcasting
In [7]: df3 = df1.reindex_like(df2).fillna(value=0.0) + df2

In [8]: df3
Out[8]:
   A     B     C
0 -0.392704 -0.424972  0.0
1 -2.388332  0.567020  1.0
2 -2.003932  0.276232  2.0
3 -2.063367 -1.087401  3.0
4  1.933792 -0.673690  4.0
5 -0.879758  0.113648  5.0
6 -0.920830 -1.478427  6.0
7 -0.772263  0.524988  7.0

In [9]: df3.dtypes
Out[9]:
A float32
B float64
dtype: object
Dtype conversion

This is lower-common-denominator upcasting, meaning you get the dtype which can accommodate all of the types

```python
In [10]: df3.values.dtype
Out[10]: dtype('float64')
```

Conversion

```python
In [11]: df3.astype('float32').dtypes
Out[11]:
A   float32
B   float32
C   float32
dtype: object
```

Mixed conversion

```python
In [12]: df3['D'] = '1.'
In [13]: df3['E'] = '1'

In [14]: df3.convert_objects(convert_numeric=True).dtypes
Out[14]:
A   float32
B   float64
C   float64
D   float64
E    int64
dtype: object
```

# same, but specific dtype conversion
```python
In [15]: df3['D'] = df3['D'].astype('float16')
In [16]: df3['E'] = df3['E'].astype('int32')
```

```python
In [17]: df3.dtypes
Out[17]:
A   float32
B   float64
C   float64
D    float16
E    int32
dtype: object
```

Forcing date coercion (and setting NaT when not datelike)
```python
In [18]: import datetime
In [19]: s = pd.Series([datetime.datetime(2001, 1, 1, 0, 0), 'foo', 1.0, 1, pd.Timestamp('20010104'), '20010105'], dtype='O')
   ....:
```
```python
In [20]: s.convert_objects(convert_dates='coerce')
Out[20]:
0  2001-01-01
1    NaT
2    NaT
(continues on next page)```
Dtype gotchas

Platform gotchas

Starting in 0.11.0, construction of DataFrame/Series will use default dtypes of `int64` and `float64`, regardless of platform. This is not an apparent change from earlier versions of pandas. If you specify dtypes, they WILL be respected, however (GH2837).

The following will all result in `int64` dtypes

```python
In [21]: pd.DataFrame([1, 2], columns=['a']).dtypes
```

```
Out[21]:

<table>
<thead>
<tr>
<th>a</th>
<th>int64</th>
</tr>
</thead>
<tbody>
<tr>
<td>dtype: object</td>
<td></td>
</tr>
</tbody>
</table>
```

```python
In [22]: pd.DataFrame({'a': [1, 2]}).dtypes
```

```
Out[22]:

<table>
<thead>
<tr>
<th>a</th>
<th>int64</th>
</tr>
</thead>
<tbody>
<tr>
<td>dtype: object</td>
<td></td>
</tr>
</tbody>
</table>
```

```python
In [23]: pd.DataFrame({'a': 1}, index=range(2)).dtypes
```

```
Out[23]:

<table>
<thead>
<tr>
<th>a</th>
<th>int64</th>
</tr>
</thead>
<tbody>
<tr>
<td>dtype: object</td>
<td></td>
</tr>
</tbody>
</table>
```

Keep in mind that `DataFrame(np.array([1, 2]))` WILL result in `int32` on 32-bit platforms!

Upcasting gotchas

Performing indexing operations on integer type data can easily upcast the data. The dtype of the input data will be preserved in cases where nans are not introduced.

```python
In [24]: dfi = df3.astype('int32')
```

```python
In [25]: dfi['D'] = dfi['D'].astype('int64')
```

```python
In [26]: dfi
```

```
<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>-2</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>-2</td>
<td>0</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>0</td>
<td>-1</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
<td>0</td>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
<td>0</td>
<td>5</td>
<td>1</td>
</tr>
<tr>
<td>6</td>
<td>0</td>
<td>-1</td>
<td>6</td>
<td>1</td>
</tr>
<tr>
<td>7</td>
<td>0</td>
<td>0</td>
<td>7</td>
<td>1</td>
</tr>
</tbody>
</table>
```

```python
In [27]: dfi.dtypes
```

```
<table>
<thead>
<tr>
<th>A</th>
<th>int32</th>
</tr>
</thead>
</table>
```

(continues on next page)
casted = df[df > 0]

Datetimes conversion

Datetime64[ns] columns in a DataFrame (or a Series) allow the use of np.nan to indicate a nan value, in addition to the traditional NaT, or not-a-time. This allows convenient nan setting in a generic way. Furthermore datetime64[ns] columns are created by default, when passed datetimelike objects (this change was introduced in 0.10.1) (GH2809, GH2810).

```
In [12]: df = pd.DataFrame(np.random.randn(6, 2), pd.date_range('20010102', periods=6), columns=['A', 'B'])
In [13]: df['timestamp'] = pd.Timestamp('20010103')
In [14]: df
Out[14]:
   A         B         timestamp
0  0.404705  0.577046  2001-01-03
1 -1.715002 -1.039268  2001-01-03
2 -0.370647 -1.157892  2001-01-03
3 -1.344312  0.844885  2001-01-03
4  1.075770 -0.109050  2001-01-03
5  1.643563 -1.469388  2001-01-03

# datetime64[ns] out of the box
In [15]: df.dtypes.value_counts()
Out[15]:
float64    2
datetime64[ns]    1
dtype: int64

# use the traditional nan, which is mapped to NaT internally
In [16]: df.loc[df.index[2:4], ['A', 'timestamp']] = np.nan
In [17]: df
Out[17]:
   A         B         timestamp
0  0.404705  0.577046  2001-01-03
1 -1.715002 -1.039268  2001-01-03
2   NaN     NaN         NaT
3 -1.344312  0.844885  2001-01-03
4  1.075770 -0.109050  2001-01-03
5  1.643563 -1.469388  2001-01-03

Astype conversion on datetime64[ns] to object, implicitly converts NaT to np.nan
In [18]: s = pd.Series([datetime.datetime(2001, 1, 2, 0, 0) for i in range(3)])

In [19]: s.dtype
Out[19]: dtype('<M8[ns]')

In [20]: s[1] = np.nan

In [21]: s
Out[21]:
0 2001-01-02
1 NaT
2 2001-01-02
dtype: datetime64[ns]

In [22]: s.dtype
Out[22]: dtype('<M8[ns]')

In [23]: s = s.astype('O')

In [24]: s
Out[24]:
0 2001-01-02 00:00:00
1 NaT
2 2001-01-02 00:00:00
dtype: object

In [25]: s.dtype
Out[25]: dtype('O')

API changes

- Added to_series() method to indices, to facilitate the creation of indexers (GH3275)
- HDFStore
  - added the method select_column to select a single column from a table as a Series.
  - deprecated the unique method, can be replicated by select_column(key, column).unique()
  - min_itemsize parameter to append will now automatically create data_columns for passed keys

Enhancements

- Improved performance of df.to_csv() by up to 10x in some cases. (GH3059)
- Numexpr is now a Recommended Dependencies, to accelerate certain types of numerical and boolean operations
- Bottleneck is now a Recommended Dependencies, to accelerate certain types of nan operations
- HDFStore
  - support read_hdf/to_hdf API similar to read_csv/to_csv

In [26]: df = pd.DataFrame({'A': range(5), 'B': range(5)})

In [27]: df.to_hdf('store.h5', 'table', append=True)

In [28]: pd.read_hdf('store.h5', 'table', where=['index > 2'])
Out[28]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>4</td>
</tr>
</tbody>
</table>

- Provide dotted attribute access to get from stores, e.g. `store.df == store['df']`
- New keywords `iterator=boolean`, and `chunksize=number_in_a_chunk` are provided to support iteration on `select` and `select_as_multiple` (GH3076)

- You can now select timestamps from an unordered timeseries similarly to an ordered timeseries (GH2437)
- You can now select with a string from a DataFrame with a datelike index, in a similar way to a Series (GH3070)

```python
In [29]: idx = pd.date_range("2001-10-1", periods=5, freq='M')
In [30]: ts = pd.Series(np.random.rand(len(idx)), index=idx)
In [31]: ts['2001']
Out[31]:
          2001-10-31 0.117967
          2001-11-30 0.702184
          2001-12-31 0.414034
Freq: M, dtype: float64
In [32]: df = pd.DataFrame({'A': ts})
In [33]: df['2001']
Out[33]:
          A
2001-10-31 0.117967
2001-11-30 0.702184
2001-12-31 0.414034
```

- Squeeze to possibly remove length 1 dimensions from an object.

```python
>>> p = pd.Panel(np.random.randn(3, 4, 4), items=['ItemA', 'ItemB', 'ItemC'],
...               major_axis=pd.date_range('20010102', periods=4),
...               minor_axis=['A', 'B', 'C', 'D'])
>>> p
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 4 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2001-01-02 00:00:00 to 2001-01-05 00:00:00
Minor_axis axis: A to D
>>> p.reindex(items=['ItemA']).squeeze()
                   A   B   C   D
2001-01-02 0.926089 -2.026458 0.501277 0.204683
2001-01-03 -0.076524 1.081161 1.141361 0.479243
2001-01-04 0.641817 -0.185352 1.824568 0.809152
2001-01-05 0.575237 0.669934 1.398014 -0.399338
```

```
>>> p.reindex(items=['ItemA'], minor=['B']).squeeze()
2001-01-02 -2.026458
2001-01-03  1.081161
2001-01-04 -0.185352
```
In `pd.io.data.Options`,

- Fix bug when trying to fetch data for the current month when already past expiry.
- Now using lxml to scrape html instead of BeautifulSoup (lxml was faster).
- New instance variables for calls and puts are automatically created when a method that creates them is called. This works for current month where the instance variables are simply `calls` and `puts`. Also works for future expiry months and save the instance variable as `callsMMYY` or `putsMMYY`, where `MMYY` are, respectively, the month and year of the option’s expiry.
- `Options.get_near_stock_price` now allows the user to specify the month for which to get relevant options data.
- `Options.get_forward_data` now has optional kwargs `near` and `above_below`. This allows the user to specify if they would like to only return forward looking data for options near the current stock price. This just obtains the data from `Options.get_near_stock_price` instead of `Options.get_xxx_data()` (GH2758).

- Cursor coordinate information is now displayed in time-series plots.
- added option `display.max_seq_items` to control the number of elements printed per sequence pprinting it. (GH2979)
- added option `display.chop_threshold` to control display of small numerical values. (GH2739)
- added option `display.max_info_rows` to prevent `verbose_info` from being calculated for frames above 1M rows (configurable). (GH2807, GH2918)
- `value_counts()` now accepts a “normalize” argument, for normalized histograms. (GH2710).
- `DataFrame.from_records` now accepts not only dicts but any instance of the collections.Mapping ABC.
- added option `display.mpl_style` providing a sleeker visual style for plots. Based on https://gist.github.com/huyng/816622 (GH3075).
- Treat boolean values as integers (values 1 and 0) for numeric operations. (GH2641)
- `to_html()` now accepts an optional “escape” argument to control reserved HTML character escaping (enabled by default) and escapes `&`, in addition to `<` and `>`. (GH2919)

See the full release notes or issue tracker on GitHub for a complete list.

5.18 Version 0.10

5.18.1 Version 0.10.1 (January 22, 2013)

This is a minor release from 0.10.0 and includes new features, enhancements, and bug fixes. In particular, there is substantial new HDFStore functionality contributed by Jeff Reback.

An undesired API breakage with functions taking the `inplace` option has been reverted and deprecation warnings added.

### API changes

- Functions taking an `inplace` option return the calling object as before. A deprecation message has been added
- Groupby aggregations Max/Min no longer exclude non-numeric data (GH2700)
- Resampling an empty DataFrame now returns an empty DataFrame instead of raising an exception (GH2640)
- The file reader will now raise an exception when NA values are found in an explicitly specified integer column instead of converting the column to float (GH2631)
- `DatetimeIndex.unique` now returns a `DatetimeIndex` with the same name and timezone instead of an array (GH2563)

### New features

- MySQL support for database (contribution from Dan Allan)

### HDFStore

You may need to upgrade your existing data files. Please visit the compatibility section in the main docs.

You can designate (and index) certain columns that you want to be able to perform queries on a table, by passing a list to `data_columns`

```python
In [1]: store = pd.HDFStore('store.h5')
In [2]: df = pd.DataFrame(np.random.randn(8, 3),
                      index=pd.date_range('1/1/2000', periods=8),
                      columns=['A', 'B', 'C'])
```

(continues on next page)
In [3]: df['string'] = 'foo'
In [4]: df.loc[df.index[4:6], 'string'] = np.nan
In [5]: df.loc[df.index[7:9], 'string'] = 'bar'
In [6]: df['string2'] = 'cool'

In [7]: df
Out[7]:
   A    B    C   string  string2
0  2000-01-01  0.469112 -0.282863   foo        cool
1  2000-01-02 -1.135632  1.212112  -0.173215   foo        cool
2  2000-01-03   0.119209 -1.044236  -0.861849   foo        cool
3  2000-01-04  -2.104569 -0.494929  1.071804   foo        cool
4  2000-01-05   0.721555 -0.706771 -1.039575  NaN        cool
5  2000-01-06   0.271860 -0.424972  0.567020  NaN        cool
6  2000-01-07   0.276232 -1.087401 -0.673690   foo        cool
7  2000-01-08   0.113648 -1.478427  0.524988  bar        cool

# on-disk operations
In [8]: store.append('df', df, data_columns=['B', 'C', 'string', 'string2'])

In [9]: store.select('df', 'B>0 and string==\'foo\''
Out[9]:
   A    B    C   string  string2
0  2000-01-02 -1.135632  1.212112  -0.173215   foo        cool

# this is in-memory version of this type of selection
In [10]: df[(df.B > 0) & (df.string == 'foo')]
Out[10]:
   A    B    C   string  string2
0  2000-01-02 -1.135632  1.212112  -0.173215   foo        cool

Retrieving unique values in an indexable or data column.

# note that this is deprecated as of 0.14.0
# can be replicated by: store.select_column('df','index').unique()
store.unique('df', 'index')
store.unique('df', 'string')

You can now store datetime64 in data columns

In [11]: df_mixed = df.copy()

In [12]: df_mixed['datetime64'] = pd.Timestamp('20010102')

In [13]: df_mixed.loc[df_mixed.index[3:4], ['A', 'B']] = np.nan

In [14]: store.append('df_mixed', df_mixed)

In [15]: df_mixed1 = store.select('df_mixed')

In [16]: df_mixed1
Out[16]:
You can pass `columns` keyword to select to filter a list of the return columns, this is equivalent to passing a Term('columns',list_of_columns_to_filter)

HDFStore now serializes MultiIndex dataframes when appending tables.

In [19]: index = pd.MultiIndex(levels=[['foo', 'bar', 'baz', 'qux'],
                           ....: ['one', 'two', 'three'],
                           ....: labels=[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3],
                           ....: [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],
                           ....: names=['foo', 'bar'])
In [20]: df = pd.DataFrame(np.random.randn(10, 3), index=index,
                          columns=['A', 'B', 'C'])
In [21]: df

foo bar
foo one -0.116619 0.295575 -1.047704

two -0.600874 -1.039266  0.824758  

Multi-table creation via *append_to_multiple* and selection via *select_as_multiple* can create/select from multiple tables and return a combined result, by using *where* on a selector table.

In [19]: df_mt = pd.DataFrame(np.random.randn(8, 6),  
                        index=pd.date_range('1/1/2000', periods=8),  
                        columns=['A', 'B', 'C', 'D', 'E', 'F'])  

In [20]: df_mt['foo'] = 'bar'  

# you can also create the tables individually  
In [21]: store.append_to_multiple({ 'df1_mt': ['A', 'B'], 'df2_mt': None),  
                               df_mt, selector='df1_mt')  

In [22]: store  
Out[22]:  
<class 'pandas.io.pytables.HDFStore'>  
File path: store.h5  

# individual tables were created  
In [23]: store.select('df1_mt')  
Out[23]:  
          A    B  
2000-01-01  0.404705  0.577046  
2000-01-02 -1.344312  0.844885  
2000-01-03  0.357021 -0.674600  

Enhancements

- **HDFStore** now can read native PyTables table format tables
  
  You can pass `nan_rep = 'my_nan_rep'` to append, to change the default nan representation on disk (which converts to/from `np.nan`), this defaults to `nan`.

- You can pass `index` to `append`. This defaults to `True`. This will automagically create indices on the *indexables* and *data columns* of the table

- You can pass `chunksize=an integer` to `append`, to change the writing chunksize (default is 50000). This will significantly lower your memory usage on writing.

- You can pass `expectedrows=an integer` to the first `append`, to set the TOTAL number of expected rows that PyTables will expected. This will optimize read/write performance.

- `Select` now supports passing `start` and `stop` to provide selection space limiting in selection.

- Greatly improved ISO8601 (e.g., yyyy-mm-dd) date parsing for file parsers (GH2698)

- Allow `DataFrame.merge` to handle combinatorial sizes too large for 64-bit integer (GH2690)

- Series now has unary negation (-series) and inversion (~series) operators (GH2686)

- `DataFrame.plot` now includes a `logx` parameter to change the x-axis to log scale (GH2327)

- Series arithmetic operators can now handle constant and ndarray input (GH2574)

- ExcelFile now takes a `kind` argument to specify the file type (GH2613)

- A faster implementation for Series.str methods (GH2602)

**Bug Fixes**
• **HDFStore** tables can now store `float32` types correctly (cannot be mixed with `float64` however)

• Fixed Google Analytics prefix when specifying request segment (GH2713).

• Function to reset Google Analytics token store so users can recover from improperly setup client secrets (GH2687).

• Fixed groupby bug resulting in segfault when passing in MultiIndex (GH2706)

• Fixed bug where passing a Series with datetime64 values into `to_datetime` results in bogus output values (GH2699)

• Fixed bug in pattern in HDFStore expressions when pattern is not a valid regex (GH2694)

• Fixed performance issues while aggregating boolean data (GH2692)

• When given a boolean mask key and a Series of new values, Series `__setitem__` will now align the incoming values with the original Series (GH2686)

• Fixed MemoryError caused by performing counting sort on sorting MultiIndex levels with a very large number of combinatorial values (GH2684)

• Fixed bug that causes plotting to fail when the index is a DatetimeIndex with a fixed-offset timezone (GH2683)

• Corrected business day subtraction logic when the offset is more than 5 bdays and the starting date is on a weekend (GH2680)

• Fixed C file parser behavior when the file has more columns than data (GH2668)

• Fixed file reader bug that misaligned columns with data in the presence of an implicit column and a specified `usecols` value

• DataFrames with numerical or datetime indices are now sorted prior to plotting (GH2609)

• Fixed DataFrame.from_records error when passed columns, index, but empty records (GH2633)

• Several bug fixed for Series operations when dtype is datetime64 (GH2689, GH2629, GH2626)

See the [full release notes](https://github.com/pandas-dev/pandas/releases) or issue tracker on GitHub for a complete list.

5.18.2 Version 0.10.0 (December 17, 2012)

This is a major release from 0.9.1 and includes many new features and enhancements along with a large number of bug fixes. There are also a number of important API changes that long-time pandas users should pay close attention to.

**File parsing new features**

The delimited file parsing engine (the guts of `read_csv` and `read_table`) has been rewritten from the ground up and now uses a fraction the amount of memory while parsing, while being 40% or more faster in most use cases (in some cases much faster).

There are also many new features:

- Much-improved Unicode handling via the `encoding` option.
- Column filtering (`usecols`)
- Dtype specification (`dtype` argument)
- Ability to specify strings to be recognized as True/False
- Ability to yield NumPy record arrays (`as_recarray`)
- High performance `delim_whitespace` option
- Decimal format (e.g. European format) specification
- Easier CSV dialect options: `escapechar`, `lineterminator`, `quotechar`, etc.
- More robust handling of many exceptional kinds of files observed in the wild

**API changes**

**Deprecated DataFrame BINOP TimeSeries special case behavior**

The default behavior of binary operations between a DataFrame and a Series has always been to align on the DataFrame’s columns and broadcast down the rows, **except** in the special case that the DataFrame contains time series. Since there are now method for each binary operator enabling you to specify how you want to broadcast, we are phasing out this special case (Zen of Python: Special cases aren’t special enough to break the rules). Here’s what I’m talking about:

```
In [1]: import pandas as pd

In [2]: df = pd.DataFrame(np.random.randn(6, 4),

You will get a deprecation warning in the 0.10.x series, and the deprecated functionality will be removed in 0.11 or later.

**Altered resample default behavior**

The default time series resample binning behavior of daily D and higher frequencies has been changed to closed='left', label='left'. Lower frequencies are unaffected. The prior defaults were causing a great deal of confusion for users, especially resampling data to daily frequency (which labeled the aggregated group with the end of the interval: the next day).

In [1]: dates = pd.date_range('1/1/2000', '1/5/2000', freq='4h')
In [2]: series = pd.Series(np.arange(len(dates)), index=dates)

Freq: D, dtype: int64

- Infinity and negative infinity are no longer treated as NA by isnull and notnull. That they ever were was a relic of early pandas. This behavior can be re-enabled globally by the mode.use_inf_as_null option:

In [6]: s = pd.Series([1.5, np.inf, 3.4, -np.inf])

In [7]: pd.isnull(s)
Out[7]:
0   False
1   False
2   False

(continues on next page)
3  False
Length: 4, dtype: bool

In [8]: s.fillna(0)
Out[8]:
   0 1.500000
   1      inf
   2  3.400000
   3     -inf
Length: 4, dtype: float64

In [9]: pd.set_option('use_inf_as_null', True)

In [10]: pd.isnull(s)
Out[10]:
   0  False
   1   True
   2  False
   3   True
Length: 4, dtype: bool

In [11]: s.fillna(0)
Out[11]:
   0  1.5
   1   0.0
   2  3.4
   3   0.0
Length: 4, dtype: float64

In [12]: pd.reset_option('use_inf_as_null')

• Methods with the inplace option now all return None instead of the calling object. E.g. code written like
df = df.fillna(0, inplace=True) may stop working. To fix, simply delete the unnecessary variable assignment.

• pandas.merge no longer sorts the group keys (sort=False) by default. This was done for performance reasons: the group-key sorting is often one of the more expensive parts of the computation and is often unnecessary.

• The default column names for a file with no header have been changed to the integers 0 through N − 1. This is to create consistency with the DataFrame constructor with no columns specified. The v0.9.0 behavior (names X0, X1,...) can be reproduced by specifying prefix='X':

In [6]: import io
   
In [7]: data = ('a,b,c
                   ...
                   ...
                   ...
                   '1,Yes,2
                   ...
                   '3,No,4')
                   ...

In [8]: print(data)
a,b,c
1,Yes,2
3,No,4

In [9]: pd.read_csv(io.StringIO(data), header=None)
Out[9]:

(continues on next page)
In [10]: pd.read_csv(io.StringIO(data), header=None, prefix='X')
Out[10]:
<table>
<thead>
<tr>
<th>X0</th>
<th>X1</th>
<th>X2</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>b</td>
<td>c</td>
</tr>
<tr>
<td>1 1</td>
<td>Yes</td>
<td>2</td>
</tr>
<tr>
<td>2 3</td>
<td>No</td>
<td>4</td>
</tr>
</tbody>
</table>

- Values like 'Yes' and 'No' are not interpreted as boolean by default, though this can be controlled by new `true_values` and `false_values` arguments:

```python
In [11]: print(data)
a,b,c
1,Yes,2
3,No,4
In [12]: pd.read_csv(io.StringIO(data))
Out[12]:
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>Yes 2</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>No 4</td>
</tr>
</tbody>
</table>
In [13]: pd.read_csv(io.StringIO(data), true_values=['Yes'], false_values=['No'])
Out[13]:
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>True 2</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>False 4</td>
</tr>
</tbody>
</table>
```

- The file parsers will not recognize non-string values arising from a converter function as NA if passed in the `na_values` argument. It’s better to do post-processing using the `replace` function instead.

- Calling `fillna` on Series or DataFrame with no arguments is no longer valid code. You must either specify a fill value or an interpolation method:

```python
In [14]: s = pd.Series([np.nan, 1., 2., np.nan, 4])
In [15]: s
Out[15]:
0    NaN
1    1.0
2    2.0
3    NaN
4    4.0
dtype: float64
In [16]: s.fillna(0)
Out[16]:
0    0.0
1    1.0
2    2.0
3    0.0
4    4.0
dtype: float64
```

(continues on next page)
In [17]: s.fillna(method='pad')
Out[17]:
0  NaN
1  1.0
2  2.0
3  2.0
4  4.0
dtype: float64

Convenience methods `ffill` and `bfill` have been added:

In [18]: s.ffill()
Out[18]:
0  NaN
1  1.0
2  2.0
3  2.0
4  4.0
dtype: float64

- `Series.apply` will now operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a DataFrame

In [19]: def f(x):
    ....:     return pd.Series([x, x**2], index=['x', 'x^2'])
    ....:

In [20]: s = pd.Series(np.random.rand(5))
In [21]: s
Out[21]:
0  0.340445
1  0.984729
2  0.919540
3  0.037772
4  0.861549
dtype: float64
In [22]: s.apply(f)
Out[22]:
        x    x^2
0  0.340445  0.115903
1  0.984729  0.969691
2  0.919540  0.845555
3  0.037772  0.001427
4  0.861549  0.742267

- New API functions for working with pandas options (GH2097):
  - `get_option` / `set_option` - get/set the value of an option. Partial names are accepted. - `reset_option` - reset one or more options to their default value. Partial names are accepted. - `describe_option` - print a description of one or more options. When called with no arguments, print all registered options.

Note: `set_printoptions`/`reset_printoptions` are now deprecated (but functioning), the print options now live under “display.XYZ”. For example:
**New features**

**Wide DataFrame printing**

Instead of printing the summary information, pandas now splits the string representation across multiple rows by default:

```python
In [24]: wide_frame = pd.DataFrame(np.random.randn(5, 16))

In [25]: wide_frame
```

The old behavior of printing out summary information can be achieved via the `expand_frame_repr` print option:

```python
In [26]: pd.set_option('expand_frame_repr', False)
```

The width of each line can be changed via `line_width` (80 by default):

```python
pd.set_option('line_width', 40)
```

```
pandas: powerful Python data analysis toolkit, Release 1.1.1

In [23]: pd.get_option("display.max_rows")
Out[23]: 15

• to_string() methods now always return unicode strings (GH2224).

New features

2000-01-08  0.655457 1.117949 -2.782376 string 1

[8 rows x 5 columns]

In [69]: df1.get_dtype_counts()

Out[69]:

float64 3
int64   1
object  1
dtype: int64

• performance improvements on table writing

• support for arbitrarily indexed dimensions

• SparseSeries now has a density property (GH2384)
• enable `Series.str.strip/lstrip/rstrip` methods to take an input argument to strip arbitrary characters (GH2411)
• implement `value_vars` in `melt` to limit values to certain columns and add `melt` to pandas namespace (GH2412)

**Bug Fixes**

• added `Term` method of specifying where conditions (GH1996).
• `del store['df']` now call `store.remove('df')` for store deletion
• deleting of consecutive rows is much faster than before
• `min_itemsize` parameter can be specified in table creation to force a minimum size for indexing columns (the previous implementation would set the column size based on the first append)
• indexing support via `create_table_index` (requires PyTables >= 2.3) (GH698).
• appending on a store would fail if the table was not first created via `put`
• fixed issue with missing attributes after loading a pickled dataframe (GH2431)
• minor change to select and remove: require a table ONLY if where is also provided (and not None)

**Compatibility**

0.10 of `HDFStore` is backwards compatible for reading tables created in a prior version of pandas, however, query terms using the prior (undocumented) methodology are unsupported. You must read in the entire file and write it out using the new format to take advantage of the updates.

**N dimensional panels (experimental)**

Adding experimental support for Panel4D and factory functions to create n-dimensional named panels. Here is a taste of what to expect.

```python
In [58]: p4d = Panel4D(np.random.randn(2, 2, 5, 4),
                  labels=['Label1','Label2'],
                  items=['Item1', 'Item2'],
                  major_axis=date_range('1/1/2000', periods=5),
                  minor_axis=['A', 'B', 'C', 'D'])
In [59]: p4d
Out[59]:
<class 'pandas.core.panelnd.Panel4D'>
Dimensions: 2 (labels) x 2 (items) x 5 (major_axis) x 4 (minor_axis)
Labels axis: Label1 to Label2
Items axis: Item1 to Item2
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

5.19 Version 0.9

5.19.1 Version 0.9.1 (November 14, 2012)

This is a bug fix release from 0.9.0 and includes several new features and enhancements along with a large number of bug fixes. The new features include by-column sort order for DataFrame and Series, improved NA handling for the rank method, masking functions for DataFrame, and intraday time-series filtering for DataFrame.

New features

• *Series.sort*, *DataFrame.sort*, and *DataFrame.sort_index* can now be specified in a per-column manner to support multiple sort orders (GH928)

```python
In [2]: df = pd.DataFrame(np.random.randint(0, 2, (6, 3)),
                   columns=['A', 'B', 'C'])
In [3]: df.sort(['A', 'B'], ascending=[1, 0])
```

```
Out[3]:
    A  B  C
0  0  1  1
1  0  1  1
2  0  0  1
3  1  0  0
4  1  0  0
5  1  0  0
```

• *DataFrame.rank* now supports additional argument values for the *na_option* parameter so missing values can be assigned either the largest or the smallest rank (GH1508, GH2159)

```python
In [1]: df = pd.DataFrame(np.random.randn(6, 3), columns=['A', 'B', 'C'])
In [3]: df.rank()
```

```
Out[3]:
    A  B  C
0  3.0 2.0 1.0
1  1.0 3.0 2.0
2  Nan Nan Nan
3  Nan Nan Nan
4  Nan Nan Nan
5  2.0 1.0 3.0
[6 rows x 3 columns]
In [4]: df.rank(na_option='top')
```

```
Out[4]:
    A  B  C
0  6.0 5.0 4.0
1  4.0 6.0 5.0
2  2.0 2.0 2.0
3  2.0 2.0 2.0
4  2.0 2.0 2.0
5  5.0 4.0 6.0
```

(continues on next page)
In [5]: df.rank(na_option='bottom')
Out[5]:
       A    B    C
0   3.0  2.0  1.0
1   1.0  3.0  2.0
2   5.0  5.0  5.0
3   5.0  5.0  5.0
4   5.0  5.0  5.0
5   2.0  1.0  3.0

• DataFrame has new `where` and `mask` methods to select values according to a given boolean mask (GH2109, GH2151)

Dataframe currently supports slicing via a boolean vector the same length as the Dataframe (inside the `[]`). The returned DataFrame has the same number of columns as the original, but is sliced on its index.

In [6]: df = DataFrame(np.random.randn(5, 3), columns=['A','B','C'])
In [7]: df
Out[7]:
       A    B    C
0  0.276232 -1.087401 -0.673690
1  0.113648 -1.478427  0.524988
2  0.404705  0.577046 -1.715002
3 -1.039268 -0.370647 -1.157892
4 -1.344312  0.844885  1.075770

In [8]: df[df['A'] > 0]
Out[8]:
       A    B    C
0  0.276232 -1.087401 -0.673690
1  0.113648 -1.478427  0.524988
2  0.404705  0.577046 -1.715002
3   NaN   NaN   NaN

If a DataFrame is sliced with a DataFrame based boolean condition (with the same size as the original DataFrame), then a DataFrame the same size (index and columns) as the original is returned, with elements that do not meet the boolean condition as `NaN`. This is accomplished via the new method `DataFrame.where`. In addition, `where` takes an optional `other` argument for replacement.

In [9]: df[df>0]
Out[9]:
       A    B    C
0  0.276232   NaN   NaN
1  0.113648   NaN  0.524988
2  0.404705  0.577046   NaN
3   NaN   NaN   NaN

(continues on next page)
Furthermore, `where` now aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via `.ix` (but on the contents rather than the axis labels).

```
In [12]: df2 = df.copy()

In [13]: df2[ df2[1:4] > 0 ] = 3

In [14]: df2
Out[14]:
   A       B       C
0  0.276232 NaN   NaN
1  0.113648 NaN  0.524988
2  0.404705  0.577046 NaN
3   NaN   NaN   NaN
4   NaN  0.844885  1.075770
```

`DataFrame.mask` is the inverse boolean operation of `where`.

```
In [15]: df.mask(df<=0)
Out[15]:
   A       B       C
0  0.276232 NaN   NaN
1  0.113648 NaN  0.524988
2  0.404705  0.577046 NaN
3   NaN   NaN   NaN
4   NaN  0.844885  1.075770
```
- Enable referencing of Excel columns by their column names (GH1936)

```python
In [16]: xl = pd.ExcelFile('data/test.xls')
In [17]: xl.parse('Sheet1', index_col=0, parse_dates=True,
   ....:     parse_cols='A:D')
   ....:
Out[17]:
      A      B      C      D
   2000-01-03  0.980269  3.685731 -0.364217 -1.159738
   2000-01-04  1.047916 -0.041232 -0.161812  0.212549
   2000-01-05  0.498581  0.731168 -0.537677  1.346270
   2000-01-06  1.120202  1.567621  0.003641  0.675253
   2000-01-07 -0.487094  0.571455 -1.611639  0.103469
   2000-01-08  0.836649  0.246462  0.588543  1.062782
   2000-01-09 -0.157161  1.340307  1.195778 -1.097007
[7 rows x 4 columns]
```

- Added option to disable pandas-style tick locators and formatters using `series.plot(x_compat=True)` or `pandas.plot_params['x_compat'] = True` (GH2205)
- Existing TimeSeries methods `at_time` and `between_time` were added to DataFrame (GH2149)
- DataFrame.dot can now accept ndarrays (GH2042)
- DataFrame.drop now supports non-unique indexes (GH2101)
- Panel.shift now supports negative periods (GH2164)
- DataFrame now support unary ~ operator (GH2110)

### API changes

- Upsampling data with a PeriodIndex will result in a higher frequency TimeSeries that spans the original time window

```python
In [1]: prng = pd.period_range('2012Q1', periods=2, freq='Q')
In [2]: s = pd.Series(np.random.randn(len(prng)), prng)
In [4]: s.resample('M')
Out[4]:
   2012-01  -1.471992
   2012-02   NaN
   2012-03   NaN
   2012-04 -0.493593
   2012-05   NaN
   2012-06   NaN
Freq: M, dtype: float64
```

- Period.end_time now returns the last nanosecond in the time interval (GH2124, GH2125, GH1764)

```python
In [18]: p = pd.Period('2012')
In [19]: p.end_time
Out[19]: Timestamp('2012-12-31 23:59:59.999999999')
```

- File parsers no longer coerce to float or bool for columns that have custom converters specified (GH2184)
In [20]: import io

In [21]: data = ('A,B,C
....:
....:  '00001,001,5
....:  '00002,002,6')

In [22]: pd.read_csv(io.StringIO(data), converters={'A': lambda x: x.strip()})
Out[22]:
    A   B  C
   0  00001  1  5
   1  00002  2  6

[2 rows x 3 columns]

See the full release notes or issue tracker on GitHub for a complete list.

5.19.2 Version 0.9.0 (October 7, 2012)

This is a major release from 0.8.1 and includes several new features and enhancements along with a large number of bug fixes. New features include vectorized unicode encoding/decoding for Series.str, to_latex method to DataFrame, more flexible parsing of boolean values, and enabling the download of options data from Yahoo! Finance.
New features

- Add `encode` and `decode` for unicode handling to vectorized string processing methods in `Series.str` (GH1706)
- Add `DataFrame.to_latex` method (GH1735)
- Add convenient expanding window equivalents of all rolling_* ops (GH1785)
- Add Options class to pandas.io.data for fetching options data from Yahoo! Finance (GH1748, GH1739)
- More flexible parsing of boolean values (Yes, No, TRUE, FALSE, etc) (GH1691, GH1295)
- Add `level` parameter to `Series.reset_index`
- `TimeSeries.between_time` can now select times across midnight (GH1871)
- Series constructor can now handle generator as input (GH1679)
- `DataFrame.dropna` can now take multiple axes (tuple/list) as input (GH924)
- Enable `skip_footer` parameter in ExcelFile.parse (GH1843)

API changes

- The default column names when `header=None` and no columns names passed to functions like `read_csv` has changed to be more Pythonic and amenable to attribute access:

```
In [1]: import io
In [2]: data = ('0,0,1
   ...:  1,1,0
   ...:  0,1,0')
In [3]: df = pd.read_csv(io.StringIO(data), header=None)
In [4]: df
Out[4]:
   0  1  2
0  0  0  1
1  1  1  0
2  0  1  0
[3 rows x 3 columns]
```

- Creating a Series from another Series, passing an index, will cause reindexing to happen inside rather than treating the Series like an ndarray. Technically improper usages like `Series(df[col1], index=df[col2])` that worked before “by accident” (this was never intended) will lead to all NA Series in some cases. To be perfectly clear:

```
In [5]: sl = pd.Series([1, 2, 3])
In [6]: sl
Out[6]:
0  1
1  2
2  3
Length: 3, dtype: int64
```
pandas: powerful Python data analysis toolkit, Release 1.1.1

(continued from previous page)

In [7]: s2 = pd.Series(s1, index=['foo', 'bar', 'baz'])

In [8]: s2
Out[8]:
foo    NaN
bar    NaN
baz    NaN
Length: 3, dtype: float64

- Deprecated `day_of_year` API removed from PeriodIndex, use `dayofyear` (GH1723)
- Don’t modify NumPy suppress printoption to True at import time
- The internal HDF5 data arrangement for DataFrames has been transposed. Legacy files will still be readable by HDFStore (GH1834, GH1824)
- Legacy cruft removed: pandas.stats.misc.quantileTS
- Use ISO8601 format for Period repr: monthly, daily, and on down (GH1776)
- Empty DataFrame columns are now created as object dtype. This will prevent a class of TypeErrors that was occurring in code where the dtype of a column would depend on the presence of data or not (e.g. a SQL query having results) (GH1783)
- Setting parts of DataFrame/Panel using ix now aligns input Series/DataFrame (GH1630)
- `first` and `last` methods in GroupBy no longer drop non-numeric columns (GH1809)
- Resolved inconsistencies in specifying custom NA values in text parser. `na_values` of type dict no longer override default NAs unless `keep_default_na` is set to false explicitly (GH1657)
- `DataFrame.dot` will not do data alignment, and also work with Series (GH1915)

See the full release notes or issue tracker on GitHub for a complete list.

## 5.20 Version 0.8

### 5.20.1 Version 0.8.1 (July 22, 2012)

This release includes a few new features, performance enhancements, and over 30 bug fixes from 0.8.0. New features include notably NA friendly string processing functionality and a series of new plot types and options.

**New features**

- Add *vectorized string processing methods* accessible via Series.str (GH620)
- Add option to disable adjustment in EWMA (GH1584)
- *Radviz plot* (GH1566)
- *Parallel coordinates plot*
- *Bootstrap plot*
- Per column styles and secondary y-axis plotting (GH1559)
- New datetime converters millisecond plotting (GH1599)
- Add option to disable “sparse” display of hierarchical indexes (GH1538)
- Series/DataFrame’s `set_index` method can *append levels* to an existing Index/MultiIndex (GH1569, GH1577)
**Performance improvements**

- Improved implementation of rolling min and max (thanks to Bottleneck !)
- Add accelerated 'median' GroupBy option (GH1358)
- Significantly improve the performance of parsing ISO8601-format date strings with DatetimeIndex or to_datetime (GH1571)
- Improve the performance of GroupBy on single-key aggregations and use with Categorical types
- Significant datetime parsing performance improvements

**Contributors**

A total of 5 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

- Chang She
- Skipper Seabold
- Todd DeLuca +
- Vytautas Janciauskas
- Wes McKinney

**5.20.2 Version 0.8.0 (June 29, 2012)**

This is a major release from 0.7.3 and includes extensive work on the time series handling and processing infrastructure as well as a great deal of new functionality throughout the library. It includes over 700 commits from more than 20 distinct authors. Most pandas 0.7.3 and earlier users should not experience any issues upgrading, but due to the migration to the NumPy datetime64 dtype, there may be a number of bugs and incompatibilities lurking. Lingering incompatibilities will be fixed ASAP in a 0.8.1 release if necessary. See the full release notes or issue tracker on GitHub for a complete list.

**Support for non-unique indexes**

All objects can now work with non-unique indexes. Data alignment / join operations work according to SQL join semantics (including, if application, index duplication in many-to-many joins)

**NumPy datetime64 dtype and 1.6 dependency**

Time series data are now represented using NumPy’s datetime64 dtype; thus, pandas 0.8.0 now requires at least NumPy 1.6. It has been tested and verified to work with the development version (1.7+) of NumPy as well which includes some significant user-facing API changes. NumPy 1.6 also has a number of bugs having to do with nanosecond resolution data, so I recommend that you steer clear of NumPy 1.6’s datetime64 API functions (though limited as they are) and only interact with this data using the interface that pandas provides.

See the end of the 0.8.0 section for a “porting” guide listing potential issues for users migrating legacy code bases from pandas 0.7 or earlier to 0.8.0.

Bug fixes to the 0.7.x series for legacy NumPy < 1.6 users will be provided as they arise. There will be no more further development in 0.7.x beyond bug fixes.
Time Series changes and improvements

Note: With this release, legacy scikits.timeseries users should be able to port their code to use pandas.

Note: See documentation for overview of pandas timeseries API.

- New datetime64 representation speeds up join operations and data alignment, reduces memory usage, and improve serialization / deserialization performance significantly over datetime.datetime

- High performance and flexible resample method for converting from high-to-low and low-to-high frequency. Supports interpolation, user-defined aggregation functions, and control over how the intervals and result labeling are defined. A suite of high performance Cython/C-based resampling functions (including Open-High-Low-Close) have also been implemented.

- Revamp of frequency aliases and support for frequency shortcuts like ‘15min’, or ‘1h30min’

- New DatetimeIndex class supports both fixed frequency and irregular time series. Replaces now deprecated DateRange class

- New PeriodIndex and Period classes for representing time spans and performing calendar logic, including the 12 fiscal quarterly frequencies <timeseries.quarterly>. This is a partial port of, and a substantial enhancement to, elements of the scikits.timeseries code base. Support for conversion between PeriodIndex and DatetimeIndex

- New Timestamp data type subclasses datetime.datetime, providing the same interface while enabling working with nanosecond-resolution data. Also provides easy time zone conversions.

- Enhanced support for time zones. Add tz_convert and tz_localize methods to TimeSeries and DataFrame. All timestamps are stored as UTC; Timestamps from DatetimeIndex objects with time zone set will be localized to local time. Time zone conversions are therefore essentially free. User needs to know very little about pytz library now; only time zone names as as strings are required. Time zone-aware timestamps are equal if and only if their UTC timestamps match. Operations between time zone-aware time series with different time zones will result in a UTC-indexed time series.

- Time series string indexing conveniences / shortcuts: slice years, year and month, and index values with strings

- Enhanced time series plotting: adaptation of scikits.timeseries matplotlib-based plotting code

- New date_range, bdate_range, and period_range factory functions

- Robust frequency inference function infer_freq and inferred_freq property of DatetimeIndex, with option to infer frequency on construction of DatetimeIndex

- to_datetime function efficiently parses array of strings to DatetimeIndex. DatetimeIndex will parse array or list of strings to datetime64

- Optimized support for datetime64-dtype data in Series and DataFrame columns

- New NaT (Not-a-Time) type to represent NA in timestamp arrays

- Optimize Series.asof for looking up “as of” values for arrays of timestamps

- Milli, Micro, Nano date offset objects

- Can index time series with datetime.time objects to select all data at particular time of day (TimeSeries.at_time) or between two times (TimeSeries.between_time)

- Add tshift method for leading/lagging using the frequency (if any) of the index, as opposed to a naive lead/lag using shift
Other new features

- New `cut` and `qcut` functions (like R’s cut function) for computing a categorical variable from a continuous variable by binning values either into value-based (`cut`) or quantile-based (`qcut`) bins
- Rename `Factor` to `Categorical` and add a number of usability features
- Add `limit` argument to `fillna/reindex`
- More flexible multiple function application in `GroupBy`, and can pass list (name, function) tuples to get result in particular order with given names
- Add flexible `replace` method for efficiently substituting values
- Enhanced `read_csv/read_table` for reading time series data and converting multiple columns to dates
- Add `comments` option to parser functions: `read_csv`, etc.
- Add `dayfirst` option to parser functions for parsing international DD/MM/YYYY dates
- Allow the user to specify the CSV reader `dialect` to control quoting etc.
- Handling `thousands` separators in `read_csv` to improve integer parsing.
- Enable unstacking of multiple levels in one shot. Alleviate `pivot_table` bugs (empty columns being introduced)
- Move to klib-based hash tables for indexing; better performance and less memory usage than Python’s dict
- Add first, last, min, max, and prod optimized GroupBy functions
- New `ordered_merge` function
- Add flexible `comparison` instance methods `eq`, `ne`, `lt`, `gt`, etc. to `DataFrame`, `Series`
- Improve `scatter_matrix` plotting function and add histogram or kernel density estimates to diagonal
- Add ‘kde’ plot option for density plots
- Support for converting `DataFrame` to R `data.frame` through `rpy2`
- Improved support for complex numbers in `Series` and `DataFrame`
- Add `pct_change` method to all data structures
- Add `max_colwidth` configuration option for `DataFrame` console output
- Interpolate `Series` values using index values
- Can select multiple columns from `GroupBy`
- Add `update` methods to `Series/DataFrame` for updating values in place
- Add `any` and `all` method to `DataFrame`

New plotting methods

```python
import pandas as pd
fx = pd.read_pickle('data/fx_prices')
import matplotlib.pyplot as plt

Series.plot now supports a `secondary_y` option:
```
plt.figure()
fx['FR'].plot(style='g')
fx['IT'].plot(style='k--', secondary_y=True)

Vytautas Jancauskas, the 2012 GSOC participant, has added many new plot types. For example, 'kde' is a new option:

```
In [1]: s = pd.Series(np.concatenate((np.random.randn(1000),
    ...
    np.random.randn(1000) * 0.5 + 3)))
    ...
In [2]: plt.figure()
Out[2]: <Figure size 640x480 with 0 Axes>
In [3]: s.hist(density=True, alpha=0.2)
Out[3]: <matplotlib.axes._subplots.AxesSubplot at 0x7fe2782bc670>
In [4]: s.plot(kind='kde')
Out[4]: <matplotlib.axes._subplots.AxesSubplot at 0x7fe2782bc670>
```

See the plotting page for much more.

**Other API changes**

- Deprecation of offset, time_rule, and timeRule arguments names in time series functions. Warnings will be printed until pandas 0.9 or 1.0.

**Potential porting issues for pandas <= 0.7.3 users**

The major change that may affect you in pandas 0.8.0 is that time series indexes use NumPy's datetime64 data type instead of dtype=object arrays of Python's built-in datetime.datetime objects. DateRange has been replaced by DatetimeIndex but otherwise behaved identically. But, if you have code that converts DateRange or Index objects that used to contain datetime.datetime values to plain NumPy arrays, you may have bugs lurking with code using scalar values because you are handing control over to NumPy:

```
In [5]: import datetime
In [6]: rng = pd.date_range('1/1/2000', periods=10)
In [7]: rng[5]
Out[7]: Timestamp('2000-01-06 00:00:00', freq='D')
In [8]: isinstance(rng[5], datetime.datetime)
Out[8]: True
In [9]: rng_asarray = np.asarray(rng)
In [10]: scalar_val = rng_asarray[5]
In [11]: type(scalar_val)
Out[11]: numpy.datetime64
```
pandas’s Timestamp object is a subclass of datetime.datetime that has nanosecond support (the nanosecond field store the nanosecond value between 0 and 999). It should substitute directly into any code that used datetime.datetime values before. Thus, I recommend not casting DatetimeIndex to regular NumPy arrays.

If you have code that requires an array of datetime.datetime objects, you have a couple of options. First, the astype(object) method of DatetimeIndex produces an array of Timestamp objects:

```python
In [12]: stamp_array = rng.astype(object)
In [13]: stamp_array
Out[13]:
Index(['2000-01-01 00:00:00', '2000-01-02 00:00:00', '2000-01-03 00:00:00',
       '2000-01-04 00:00:00', '2000-01-05 00:00:00', '2000-01-06 00:00:00',
       '2000-01-07 00:00:00', '2000-01-08 00:00:00', '2000-01-09 00:00:00',
       '2000-01-10 00:00:00'],
      dtype='object')
In [14]: stamp_array[5]
Out[14]: Timestamp('2000-01-06 00:00:00', freq='D')
```

To get an array of proper datetime.datetime objects, use the to_pydatetime method:

```python
In [15]: dt_array = rng.to_pydatetime()
In [16]: dt_array
Out[16]:
array([datetime.datetime(2000, 1, 1, 0, 0),
       datetime.datetime(2000, 1, 2, 0, 0),
       datetime.datetime(2000, 1, 3, 0, 0),
       datetime.datetime(2000, 1, 4, 0, 0),
       datetime.datetime(2000, 1, 5, 0, 0),
       datetime.datetime(2000, 1, 6, 0, 0),
       datetime.datetime(2000, 1, 7, 0, 0),
       datetime.datetime(2000, 1, 8, 0, 0),
       datetime.datetime(2000, 1, 9, 0, 0),
       datetime.datetime(2000, 1, 10, 0, 0)),
      dtype=object)
In [17]: dt_array[5]
Out[17]: datetime.datetime(2000, 1, 6, 0, 0)
```

matplotlib knows how to handle datetime.datetime but not Timestamp objects. While I recommend that you plot time series using TimeSeries.plot, you can either use to_pydatetime or register a converter for the Timestamp type. See matplotlib documentation for more on this.

```
Warning: There are bugs in the user-facing API with the nanosecond datetime64 unit in NumPy 1.6. In particular, the string version of the array shows garbage values, and conversion to dtype=object is similarly broken.
```

```python
In [18]: rng = pd.date_range('1/1/2000', periods=10)
In [19]: rng
   '2000-01-09', '2000-01-10'],
   dtype='datetime64[ns]', freq='D')
In [20]: np.asarray(rng)
```
Out[20]:
array(['2000-01-01T00:00:00.000000000', '2000-01-02T00:00:00.000000000',
      '2000-01-03T00:00:00.000000000', '2000-01-04T00:00:00.000000000',
      '2000-01-05T00:00:00.000000000', '2000-01-06T00:00:00.000000000',
      '2000-01-07T00:00:00.000000000', '2000-01-08T00:00:00.000000000',
      '2000-01-09T00:00:00.000000000', '2000-01-10T00:00:00.000000000'],
dtype='datetime64[ns]')

In [21]: converted = np.asarray(rng, dtype=object)

In [22]: converted[5]
Out[22]: Timestamp('2000-01-06 00:00:00', freq='D')

Trust me: don’t panic. If you are using NumPy 1.6 and restrict your interaction with `datetime64` values to pandas’s API you will be just fine. There is nothing wrong with the data-type (a 64-bit integer internally); all of the important data processing happens in pandas and is heavily tested. I strongly recommend that you do not work directly with `datetime64` arrays in NumPy 1.6 and only use the pandas API.

Support for non-unique indexes: In the latter case, you may have code inside a `try:`... `catch:` block that failed due to the index not being unique. In many cases it will no longer fail (some method like `append` still check for uniqueness unless disabled). However, all is not lost: you can inspect `index.is_unique` and raise an exception explicitly if it is `False` or go to a different code branch.

5.21 Version 0.7

5.21.1 Version 0.7.3 (April 12, 2012)

This is a minor release from 0.7.2 and fixes many minor bugs and adds a number of nice new features. There are also a couple of API changes to note; these should not affect very many users, and we are inclined to call them “bug fixes” even though they do constitute a change in behavior. See the full release notes or issue tracker on GitHub for a complete list.

New features

• New fixed width file reader, read_fwf
• New scatter_matrix function for making a scatter plot matrix

```python
from pandas.tools.plotting import scatter_matrix
scatter_matrix(df, alpha=0.2)  # noqa F821
```

• Add stacked argument to Series and DataFrame’s plot method for stacked bar plots.

```python
df.plot(kind='bar', stacked=True)  # noqa F821
```

```python
df.plot(kind='barh', stacked=True)  # noqa F821
```

• Add log x and y scaling options to DataFrame.plot and Series.plot
• Add kurt methods to Series and DataFrame for computing kurtosis
NA boolean comparison API change

Reverted some changes to how NA values (represented typically as NaN or None) are handled in non-numeric Series:

```python
In [1]: series = pd.Series(['Steve', np.nan, 'Joe'])
In [2]: series == 'Steve'
Out[2]:
0    True
1   False
2   False
Length: 3, dtype: bool
In [3]: series != 'Steve'
Out[3]:
0   False
1    True
2    True
Length: 3, dtype: bool
```

In comparisons, NA / NaN will always come through as False except with != which is True. Be very careful with boolean arithmetic, especially negation, in the presence of NA data. You may wish to add an explicit NA filter into boolean array operations if you are worried about this:

```python
In [4]: mask = series == 'Steve'
In [5]: series[mask & series.notnull()]
Out[5]:
0    Steve
Length: 1, dtype: object
```

While propagating NA in comparisons may seem like the right behavior to some users (and you could argue on purely technical grounds that this is the right thing to do), the evaluation was made that propagating NA everywhere, including in numerical arrays, would cause a large amount of problems for users. Thus, a “practicality beats purity” approach was taken. This issue may be revisited at some point in the future.

Other API changes

When calling apply on a grouped Series, the return value will also be a Series, to be more consistent with the groupby behavior with DataFrame:

```python
In [6]: df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar',
                          'foo', 'bar', 'foo', 'foo'],
                     'B': ['one', 'one', 'two', 'three',
                          'two', 'two', 'one', 'three'],
                     'C': np.random.randn(8),
                     'D': np.random.randn(8))
In [7]: df
Out[7]:
     A    B        C        D
0  foo  one  0.469112 -0.861849
1  bar  one -0.282863  2.104569
2  foo  two -1.509059  0.494929
3  bar  three -1.135632  1.071804
4  foo  two  1.212112  0.721555
```

(continues on next page)
5 bar two -0.173215 -0.706771
6 foo one 0.119209 -1.039575
7 foo three -1.044236 0.271860

[8 rows x 4 columns]

5.21.2 Version 0.7.2 (March 16, 2012)

This release targets bugs in 0.7.1, and adds a few minor features.

New features

- Add additional tie-breaking methods in DataFrame.rank (GH874)
- Add ascending parameter to rank in Series, DataFrame (GH875)
- Add coerce_float option to DataFrame.from_records (GH893)
- Add sort_columns parameter to allow unsorted plots (GH918)
- Enable column access via attributes on GroupBy (GH882)
- Can pass dict of values to DataFrame.fillna (GH661)
- Can select multiple hierarchical groups by passing list of values in .ix (GH134)
- Add axis option to DataFrame.fillna (GH174)
- Add level keyword to drop for dropping values from a level (GH159)

Performance improvements

- Use khash for Series.value_counts, add raw function to algorithms.py (GH861)
- Intercept __builtin__.__sum in groupby (GH885)

Contributors

5.21.3 Version 0.7.1 (February 29, 2012)

This release includes a few new features and addresses over a dozen bugs in 0.7.0.

**New features**

- Add `to_clipboard` function to pandas namespace for writing objects to the system clipboard (GH774)
- Add `itertuples` method to DataFrame for iterating through the rows of a dataframe as tuples (GH818)
- Add ability to pass `fill_value` and method to DataFrame and Series align method (GH806, GH807)
- Add `fill_value` option to `reindex`, `align` methods (GH784)
- Enable `concat` to produce DataFrame from Series (GH787)
- Add `between` method to Series (GH802)
- Add HTML representation hook to DataFrame for the IPython HTML notebook (GH773)
- Support for reading Excel 2007 XML documents using openpyxl

**Performance improvements**

- Improve performance and memory usage of `fillna` on DataFrame
- Can concatenate a list of Series along axis=1 to obtain a DataFrame (GH787)

**Contributors**

A total of 9 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

5.21.4 Version 0.7.0 (February 9, 2012)

New features

• New unified *merge function* for efficiently performing full gamut of database / relational-algebra operations. Refactored existing join methods to use the new infrastructure, resulting in substantial performance gains (GH220, GH249, GH267)

• New *unified concatenation function* for concatenating Series, DataFrame or Panel objects along an axis. Can form union or intersection of the other axes. Improves performance of `Series.append` and `DataFrame.append` (GH468, GH479, GH273)

• *Can* pass multiple DataFrames to `DataFrame.append` to concatenate (stack) and multiple Series to `Series.append` too

• *Can* pass list of dicts (e.g., a list of JSON objects) to `DataFrame构造` (GH526)

• You can now *set multiple columns* in a DataFrame via `__getitem__`, useful for transformation (GH342)

• Handle differently-indexed output values in `DataFrame.apply` (GH498)

```python
In [1]: df = pd.DataFrame(np.random.randn(10, 4))
In [2]: df.apply(lambda x: x.describe())
Out[2]:
         0      1      2      3
count 10.0000 10.0000 10.0000 10.0000
mean  0.1909 -0.3951 -0.7319 -0.4031
std   0.7309  0.8133  1.1120  0.9619
min  -0.8618 -2.1046 -1.7769 -1.4694
25%  -0.4114 -0.6987 -1.5014 -1.0766
50%   0.3808 -0.2280 -1.1919 -1.0041
75%   0.6584  0.0579 -0.0343  0.4617
max   1.2121  0.5770  1.6436  1.0718
```

• *Added* `reorder_levels` method to Series and DataFrame (GH534)

• *Added* dict-like get function to `DataFrame` and Panel (GH521)

• *Added* `DataFrame.iterrows` method for efficiently iterating through the rows of a DataFrame

• *Added* `DataFrame.to_panel` with code adapted from `LongPanel.to_long`

• *Added* `reindex_axis` method added to DataFrame

• *Added* level option to binary arithmetic functions on DataFrame and Series

• *Added* level option to the `reindex` and `align` methods on Series and DataFrame for broadcasting values across a level (GH542, GH552, others)

• *Added* attribute-based item access to Panel and add IPython completion (GH563)

• *Added* logy option to `Series.plot` for log-scaling on the Y axis

• *Added* index and header options to `DataFrame.to_string`

• *Can* pass multiple DataFrames to `DataFrame.join` to join on index (GH115)

• *Can* pass multiple Panels to `Panel.join` (GH115)

• *Added* `justify` argument to `DataFrame.to_string` to allow different alignment of column headers
• Add `sort` option to `GroupBy` to allow disabling sorting of the group keys for potential speedups (GH595)

• Can pass `MaskedArray` to `Series` constructor (GH563)

• Add Panel item access via attributes and IPython completion (GH554)

• Implement `DataFrame.lookup`, fancy-indexing analogue for retrieving values given a sequence of row and column labels (GH338)

• Can pass a `list of functions` to aggregate with `groupby` on a `DataFrame`, yielding an aggregated result with hierarchical columns (GH166)

• Can call `cummin` and `cummax` on `Series` and `DataFrame` to get cumulative minimum and maximum, respectively (GH647)

• `value_range` added as utility function to get min and max of a dataframe (GH288)

• Added `encoding` argument to `read_csv`, `read_table`, `to_csv` and `from_csv` for non-ascii text (GH717)

• Added `abs` method to pandas objects

• Added `crosstab` function for easily computing frequency tables

• Added `isin` method to index objects

• Added `level` argument to `xs` method of `DataFrame`.

### API changes to integer indexing

One of the potentially riskiest API changes in 0.7.0, but also one of the most important, was a complete review of how integer indexes are handled with regard to label-based indexing. Here is an example:

```
In [3]: s = pd.Series(np.random.randn(10), index=range(0, 20, 2))

In [4]: s
Out[4]:
0  -1.294524
2   0.413738
4   0.276662
6  -0.472035
8  -0.013960
10 -0.362543
12 -0.006154
14  0.923061
16  0.895717
18  0.805244
Length: 10, dtype: float64

In [5]: s[0]
Out[5]: -1.2945235902555294

In [6]: s[2]
Out[6]: 0.41373810535784006

In [7]: s[4]
Out[7]: 0.2766617129497566
```

This is all exactly identical to the behavior before. However, if you ask for a key not contained in the Series, in versions 0.6.1 and prior, Series would `fall back` on a location-based lookup. This now raises a `KeyError`:
pandas: powerful Python data analysis toolkit, Release 1.1.1

In [2]: s[1]
KeyError: 1

This change also has the same impact on DataFrame:

```
In [3]: df = pd.DataFrame(np.random.randn(8, 4), index=range(0, 16, 2))
In [4]: df
```

```
0 1 2 3
0 0.88427 0.3363 -0.1787 0.03162
2 0.14451 -0.1415 0.2504 0.58374
4 -1.44779 -0.9186 -1.4996 0.27163
6 -0.26598 -2.4184 -0.2658 0.11503
8 -0.58776 0.3144 -0.8566 0.61941
10 0.10940 -0.7175 -1.0108 0.47990
12 -1.16919 -0.3087 -0.6049 -0.43544
14 -0.07337 0.3410 0.0424 -0.16037
```

In [5]: df.ix[3]
KeyError: 3

In order to support purely integer-based indexing, the following methods have been added:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.iget_value(i)</td>
<td>Retrieve value stored at location i</td>
</tr>
<tr>
<td>Series.iget(i)</td>
<td>Alias for iget_value</td>
</tr>
<tr>
<td>DataFrame.irow(i)</td>
<td>Retrieve the i-th row</td>
</tr>
<tr>
<td>DataFrame.icol(j)</td>
<td>Retrieve the j-th column</td>
</tr>
<tr>
<td>DataFrame.iget_value(i, j)</td>
<td>Retrieve the value at row i and column j</td>
</tr>
</tbody>
</table>

**API tweaks regarding label-based slicing**

Label-based slicing using `ix` now requires that the index be sorted (monotonic) **unless** both the start and endpoint are contained in the index:

```
In [1]: s = pd.Series(np.random.randn(6), index=list('gmkaec'))
In [2]: s
Out[2]:
g -1.182230
m -0.276183
k -0.243550
a  1.628992
e  0.073308
c -0.539890
dtype: float64
```

Then this is OK:

```
In [3]: s.ix['k':'e']
Out[3]:
k -0.243550
a  1.628992
e  0.073308
dtype: float64
```
But this is not:

```
In [12]: s ix['b':'h']
KeyError 'b'
```

If the index had been sorted, the “range selection” would have been possible:

```
In [4]: s2 = s.sort_index()
In [5]: s2
Out[5]:
a 1.628992
c -0.539890
e 0.073308
g -1.182230
k -0.243550
m -0.276183
dtype: float64
In [6]: s2 ix['b':'h']
Out[6]:
c -0.539890
e 0.073308
g -1.182230
dtype: float64
```

### Changes to Series [] operator

As as notational convenience, you can pass a sequence of labels or a label slice to a Series when getting and setting values via [] (i.e. the __getitem__ and __setitem__ methods). The behavior will be the same as passing similar input to ix except in the case of integer indexing:

```
In [8]: s = pd.Series(np.random.randn(6), index=list('acegkm'))
In [9]: s
Out[9]:
a -1.206412
c 2.565646
e 1.431256
g 1.340309
k -1.170299
m -0.226169
Length: 6, dtype: float64
In [10]: s[['m', 'a', 'c', 'e']]
Out[10]:
m -0.226169
a -1.206412
c 2.565646
e 1.431256
Length: 4, dtype: float64
In [11]: s['b':'l']
Out[11]:
c 2.565646
e 1.431256
```

(continues on next page)
In the case of integer indexes, the behavior will be exactly as before (shadowing ndarray):

```python
In [13]: s = pd.Series(np.random.randn(6), index=range(0, 12, 2))
```

```python
In [14]: s[[4, 0, 2]]
```

```python
Out[14]:
4  0.132003
0  0.410835
2  0.813850
Length: 3, dtype: float64
```

```python
In [15]: s[1:5]
```

```python
Out[15]:
2  0.813850
4  0.132003
6 -0.827317
8 -0.076467
Length: 4, dtype: float64
```

If you wish to do indexing with sequences and slicing on an integer index with label semantics, use `ix`.

**Other API changes**

- The deprecated `LongPanel` class has been completely removed
- If `Series.sort` is called on a column of a DataFrame, an exception will now be raised. Before it was possible to accidentally mutate a DataFrame’s column by doing `df[col].sort()` instead of the side-effect free method `df[col].order()` (GH316)
- Miscellaneous renames and deprecations which will (harmlessly) raise `FutureWarning`
- `drop` added as an optional parameter to `DataFrame.reset_index` (GH699)

**Performance improvements**

- `Cythonized GroupBy aggregations` no longer presort the data, thus achieving a significant speedup (GH93). GroupBy aggregations with Python functions significantly sped up by clever manipulation of the ndarray data type in Cython (GH496).
- Better error message in DataFrame constructor when passed column labels don’t match data (GH497)
- Substantially improve performance of multi-GroupBy aggregation when a Python function is passed, reuse ndarray object in Cython (GH496)
- Can store objects indexed by tuples and floats in HDFStore (GH492)
pandas: powerful Python data analysis toolkit, Release 1.1.1

- Don’t print length by default in Series.to_string, add length option (GH489)
- Improve Cython code for multi-groupby to aggregate without having to sort the data (GH93)
- Improve MultiIndex reindexing speed by storing tuples in the MultiIndex, test for backwards unpickling compatibility
- Improve column reindexing performance by using specialized Cython take function
- Further performance tweaking of Series.__getitem__ for standard use cases
- Avoid Index dict creation in some cases (i.e. when getting slices, etc.), regression from prior versions
- Friendlier error message in setup.py if NumPy not installed
- Use common set of NA-handling operations (sum, mean, etc.) in Panel class also (GH536)
- Default name assignment when calling reset_index on DataFrame with a regular (non-hierarchical) index (GH476)
- Use Cythonized groupers when possible in Series/DataFrame stat ops with level parameter passed (GH545)
- Ported skiplist data structure to C to speed up rolling_median by about 5-10x in most typical use cases (GH374)

5.22 Version 0.6

5.22.1 Version 0.6.1 (December 13, 2011)

New features

- Can append single rows (as Series) to a DataFrame
- Add Spearman and Kendall rank correlation options to Series.corr and DataFrame.corr (GH428)
- Added get_value and set_value methods to Series, DataFrame, and Panel for very low-overhead access (>2x faster in many cases) to scalar elements (GH437, GH438). set_value is capable of producing an enlarged object.
- Add PyQt table widget to sandbox (GH435)
- DataFrame.align can accept Series arguments and an axis option (GH461)
- Implement new SparseArray and SparseList data structures. SparseSeries now derives from SparseArray (GH463)
- Better console printing options (GH453)
- Implement fast data ranking for Series and DataFrame, fast versions of scipy.stats.rankdata (GH428)
- Implement DataFrame.from_items alternate constructor (GH444)
- DataFrame.convert_objects method for inferring better dtypes for object columns (GH302)
- Add rolling_corr_pairwise function for computing Panel of correlation matrices (GH189)
- Add margins option to pivot_table for computing subgroup aggregates (GH114)
- Add Series.from_csv function (GH482)
- Can pass DataFrame/DataFrame and DataFrame/Series to rolling_corr/rolling_cov (GH #462)
- MultiIndex.get_level_values can accept the level name

Performance improvements

- Improve memory usage of DataFrame.describe (do not copy data unnecessarily) (PR #425)
- Optimize scalar value lookups in the general case by 25% or more in Series and DataFrame
- Fix performance regression in cross-sectional count in DataFrame, affecting DataFrame.dropna speed
- Column deletion in DataFrame copies no data (computes views on blocks) (GH #158)

Contributors

5.22.2 Version 0.6.0 (November 25, 2011)

New features

• Added melt function to pandas.core.reshape
• Added level parameter to group by level in Series and DataFrame descriptive statistics (GH313)
• Added head and tail methods to Series, analogous to to DataFrame (GH296)
• Added Series.isin function which checks if each value is contained in a passed sequence (GH289)
• Added float_format option to Series.to_string
• Added skip_footer (GH291) and converters (GH343) options to read_csv and read_table
• Added drop_duplicates and duplicated functions for removing duplicate DataFrame rows and checking for duplicate rows, respectively (GH319)
• Implemented operators `&`, `|`, `^`, `-` on DataFrame (GH347)
• Added Series.mad, mean absolute deviation
• Added QuarterEnd DateOffset (GH321)
• Added dot to DataFrame (GH65)
• Added orient option to Panel.from_dict (GH359, GH301)
• Added orient option to DataFrame.from_dict
• Added passing list of tuples or list of lists to DataFrame.from_records (GH357)
• Added multiple levels to groupby (GH103)
• Allow multiple columns in by argument of DataFrame.sort_index (GH92, GH362)
• Added fast get_value and put_value methods to DataFrame (GH360)
• Added cov instance methods to Series and DataFrame (GH194, GH362)
• Added kind=`bar` option to DataFrame.plot (GH348)
• Added idxmin and idxmax to Series and DataFrame (GH286)
• Added read_clipboard function to parse DataFrame from clipboard (GH300)
• Added nunique function to Series for counting unique elements (GH297)
• Made DataFrame constructor use Series name if no columns passed (GH373)
• Support regular expressions in read_table/read_csv (GH364)
• Added DataFrame.to_html for writing DataFrame to HTML (GH387)
• Added support for MaskedArray data in DataFrame, masked values converted to NaN (GH396)
• Added DataFrame.boxplot function (GH368)
• Can pass extra args, kwds to DataFrame.apply (GH376)
• Implement DataFrame.join with vector on argument (GH312)
• **Added** legend boolean flag to `DataFrame.plot` (GH324)
• **Can** pass multiple levels to `stack` and `unstack` (GH370)
• **Can** pass multiple values columns to `pivot_table` (GH381)
• **Use** Series name in `GroupBy` for result index (GH363)
• **Added** `raw` option to `DataFrame.apply` for performance if only need `ndarray` (GH309)
• Added proper, tested weighted least squares to standard and panel OLS (GH303)

**Performance enhancements**

• VBENCH Cythonized `cache_readonly`, resulting in substantial micro-performance enhancements throughout the code base (GH361)
• VBENCH Special Cython matrix iterator for applying arbitrary reduction operations with 3-5x better performance than `np.apply_along_axis` (GH309)
• VBENCH Improved performance of `MultiIndex.from_tuples`
• VBENCH Special Cython matrix iterator for applying arbitrary reduction operations
• VBENCH + DOCUMENT **Add** `raw` option to `DataFrame.apply` for getting better performance when
• VBENCH Faster cythonized count by level in `Series` and `DataFrame` (GH341)
• VBENCH? Significant `GroupBy` performance enhancement with multiple keys with many “empty” combinations
• VBENCH New Cython vectorized function `map_infer` speeds up `Series.apply` and `Series.map` significantly when passed elementwise Python function, motivated by (GH355)
• VBENCH Significantly improved performance of `Series.order`, which also makes `np.unique` called on a `Series` faster (GH327)
• VBENCH Vastly improved performance of `GroupBy` on axes with a `MultiIndex` (GH299)

**Contributors**

A total of 8 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

5.23 Version 0.5

5.23.1 Version 0.5.0 (October 24, 2011)

New features

- Added `DataFrame.align` method with standard join options
- Added `parse_dates` option to `read_csv` and `read_table` methods to optionally try to parse dates in the index columns
- Added `nrows`, `chunksize`, and `iterator` arguments to `read_csv` and `read_table`. The last two return a new `TextParser` class capable of lazily iterating through chunks of a flat file (GH242)
- Added ability to join on multiple columns in `DataFrame.join` (GH214)
- Added private `_get_duplicates` function to `Index` for identifying duplicate values more easily (ENH5c)
- Added column attribute access to `DataFrame`.
- Added Python tab completion hook for `DataFrame` columns. (GH233, GH230)
- Implemented `Series.describe` for `Series` containing objects (GH241)
- Added `inner join` option to `DataFrame.join` when joining on key(s) (GH248)
- Implemented selecting `DataFrame` columns by passing a list to `__getitem__` (GH253)
- Implemented `&` and `|` to intersect / union `Index` objects, respectively (GH261)
- Added `pivot_table` convenience function to pandas namespace (GH234)
- Implemented `Panel.rename_axis` function (GH243)
- `DataFrame` will show index level names in console output (GH334)
- Implemented `Panel.take`
- Added `set_eng_float_format` for alternate `DataFrame` floating point string formatting (ENH61)
- Added convenience `set_index` function for creating a `DataFrame` index from its existing columns
- Implemented `groupby` hierarchical index level name (GH223)
- Added support for different delimiters in `DataFrame.to_csv` (GH244)
- TODO: DOCS ABOUT TAKE METHODS

Performance enhancements

- VBENCH Major performance improvements in file parsing functions `read_csv` and `read_table`
- VBENCH Added Cython function for converting tuples to ndarray very fast. Speeds up many MultiIndex-related operations
- VBENCH Refactored merging / joining code into a tidy class and disabled unnecessary computations in the float/object case, thus getting about 10% better performance (GH211)
- VBENCH Improved speed of `DataFrame.xs` on mixed-type `DataFrame` objects by about 5x, regression from 0.3.0 (GH215)
- VBENCH With new `DataFrame.align` method, speeding up binary operations between differently-indexed `DataFrame` objects by 10-25%.
- VBENCH Significantly sped up conversion of nested dict into DataFrame (GH212)
- VBENCH Significantly speed up DataFrame __repr__ and count on large mixed-type DataFrame objects

**Contributors**

A total of 9 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

**5.24 Version 0.4**

**5.24.1 Versions 0.4.1 through 0.4.3 (September 25 - October 9, 2011)**

**New features**

- Added Python 3 support using 2to3 (GH200)
- Added name attribute to Series, now prints as part of Series.__repr__
- Added instance methods isnull and notnull to Series (GH209, GH203)
- Added Series.align method for aligning two series with choice of join method (ENH56)
- Added method get_level_values to MultiIndex (GH188)
- Set values in mixed-type DataFrame objects via .ix indexing attribute (GH135)
- Added new DataFrame methods get_dtype_counts and property dtypes (ENHdc)
- Added ignore_index option to DataFrame.append to stack DataFrames (ENH1b)
- read_csv tries to sniff delimiters using csv.Sniffer (GH146)
- read_csv can read multiple columns into a MultiIndex; DataFrame’s to_csv method writes out a corresponding MultiIndex (GH151)
- DataFrame.rename has a new copy parameter to rename a DataFrame in place (ENHed)
- Enable unstacking by name (GH142)
- Enable sortlevel to work by level (GH141)
Performance enhancements

- Altered binary operations on differently-indexed SparseSeries objects to use the integer-based (dense) alignment logic which is faster with a larger number of blocks (GH205)
- Wrote faster Cython data alignment / merging routines resulting in substantial speed increases
- Improved performance of isnull and notnull, a regression from v0.3.0 (GH187)
- Refactored code related to DataFrame.join so that intermediate aligned copies of the data in each DataFrame argument do not need to be created. Substantial performance increases result (GH176)
- Substantially improved performance of generic Index.intersection and Index.union
- Implemented BlockManager.take resulting in significantly faster take performance on mixed-type DataFrame objects (GH104)
- Improved performance of Series.sort_index
- Significant groupby performance enhancement: removed unnecessary integrity checks in DataFrame internals that were slowing down slicing operations to retrieve groups
- Optimized _ensure_index function resulting in performance savings in type-checking Index objects
- Wrote fast time series merging / joining methods in Cython. Will be integrated later into DataFrame.join and related functions
