       1.4.4 Comparison with other tools ............................. 60
       1.4.5 Community tutorials ..................................... 142

2 User Guide .................................................................. 145
   2.1 10 minutes to pandas ........................................... 145
       2.1.1 Object creation ............................................. 145
       2.1.2 Viewing data ................................................. 147
       2.1.3 Selection ...................................................... 149
       2.1.4 Missing data ................................................ 154
       2.1.5 Operations ................................................... 154
       2.1.6 Merge ........................................................ 157
       2.1.7 Grouping ...................................................... 159
       2.1.8 Reshaping ..................................................... 160
       2.1.9 Time series ................................................. 162
       2.1.10 Categoricals ............................................... 164
       2.1.11 Plotting ..................................................... 165
       2.1.12 Getting data in/out ....................................... 167
       2.1.13 Gotchas ..................................................... 169
   2.2 Intro to data structures ......................................... 169
       2.2.1 Series ........................................................ 169
       2.2.2 DataFrame ................................................... 175
   2.3 Essential basic functionality .................................... 192
       2.3.1 Head and tail ................................................. 192
       2.3.2 Attributes and underlying data .......................... 192
       2.3.3 Accelerated operations ...................................... 195
       2.3.4 Flexible binary operations ............................... 195
       2.3.5 Descriptive statistics ....................................... 204
       2.3.6 Function application ....................................... 212
       2.3.7 Reindexing and altering labels ......................... 224
       2.3.8 Iteration ..................................................... 234
       2.3.9 .dt accessor ................................................ 237
       2.3.10 Vectorized string methods .............................. 241
2.3.11 Sorting .......................................................... 241
2.3.12 Copying .......................................................... 248
2.3.13 dtypes .......................................................... 248
2.3.14 Selecting columns based on dtype ......................... 259

2.4 IO tools (text, CSV, HDF5, …) .................................. 262
2.4.1 CSV & text files ................................................. 263
2.4.2 JSON .......................................................... 298
2.4.3 HTML .......................................................... 312
2.4.4 LaTeX ......................................................... 321
2.4.5 XML .......................................................... 322
2.4.6 Excel files ..................................................... 333
2.4.7 OpenDocument Spreadsheets ................................. 340
2.4.8 Binary Excel (.xlsb) files .................................... 340
2.4.9 Clipboard ....................................................... 341
2.4.10 Pickling ......................................................... 341
2.4.11 msgpack ....................................................... 345
2.4.12 HDF5 (PyTables) ............................................. 345
2.4.13 Feather ....................................................... 372
2.4.14 Parquet ....................................................... 373
2.4.15 ORC ........................................................ 376
2.4.16 SQL queries ................................................... 377
2.4.17 Google BigQuery ............................................. 384
2.4.18 Stata format ................................................... 384
2.4.19 SAS formats .................................................. 387
2.4.20 SPSS formats .................................................. 387
2.4.21 Other file formats ........................................... 388
2.4.22 Performance considerations ................................. 388

2.5 Indexing and selecting data .................................... 391
2.5.1 Different choices for indexing .............................. 392
2.5.2 Basics .......................................................... 393
2.5.3 Attribute access .............................................. 395
2.5.4 Slicing ranges .................................................. 397
2.5.5 Selection by label ............................................. 398
2.5.6 Selection by position ......................................... 403
2.5.7 Selection by callable ......................................... 406
2.5.8 Combining positional and label-based indexing ............ 408
2.5.9 Indexing with list with missing labels is deprecated .... 409
2.5.10 Selecting random samples .................................. 411
2.5.11 Setting with enlargement ................................... 413
2.5.12 Fast scalar value getting and setting ..................... 414
2.5.13 Boolean indexing ............................................ 415
2.5.14 Indexing with isin ........................................... 417
2.5.15 The where() Method and Masking ....................... 419
2.5.16 Setting with enlargement conditionally using numpy() 423
2.5.17 The query() Method .......................................... 424
2.5.18 Duplicate data .............................................. 434
2.5.19 Dictionary-like get() method .............................. 437
2.5.20 Looking up values by index/column labels ................. 437
2.5.21 Index objects .................................................. 438
2.5.22 Set / reset index ............................................. 441
2.5.23 Returning a view versus a copy ............................ 443

2.6 MultiIndex / advanced indexing ................................ 447
2.6.1 Hierarchical indexing (MultiIndex) ......................... 447
2.6.2 Advanced indexing with hierarchical index ................ 453

</table>
pandas is an open source, BSD-licensed library providing high-performance, easy-to-use data structures and data analysis tools for the Python programming language.

Getting started

New to pandas? Check out the getting started guides. They contain an introduction to pandas’ main concepts and links to additional tutorials.

To the getting started guides

User guide

The user guide provides in-depth information on the key concepts of pandas with useful background information and explanation.

To the user guide

API reference

The reference guide contains a detailed description of the pandas API. The reference describes how the methods work and which parameters can be used. It assumes that you have an understanding of the key concepts.

To the reference guide

Developer guide

Saw a typo in the documentation? Want to improve existing functionalities? The contributing guidelines will guide you through the process of improving pandas.

To the development guide
1.1 Installation

Working with conda?
pandas is part of the Anaconda distribution and can be installed with Anaconda or Miniconda:

```
conda install pandas
```

Prefer pip?
pandas can be installed via pip from PyPI.

```
pip install pandas
```

In-depth instructions?
Installing a specific version? Installing from source? Check the advanced installation page.

Learn more

1.2 Intro to pandas

When working with tabular data, such as data stored in spreadsheets or databases, pandas is the right tool for you. pandas will help you to explore, clean, and process your data. In pandas, a data table is called a `DataFrame`.

To introduction tutorial
To user guide

pandas supports the integration with many file formats or data sources out of the box (csv, excel, sql, json, parquet, ...). Importing data from each of these data sources is provided by function with the prefix `read_*`. Similarly, the `to_*` methods are used to store data.

To introduction tutorial
To user guide

Straight to tutorial...
Selecting or filtering specific rows and/or columns? Filtering the data on a condition? Methods for slicing, selecting, and extracting the data you need are available in pandas.

pandas provides plotting your data out of the box, using the power of Matplotlib. You can pick the plot type (scatter, bar, boxplot,…) corresponding to your data.

There is no need to loop over all rows of your data table to do calculations. Data manipulations on a column work elementwise. Adding a column to a DataFrame based on existing data in other columns is straightforward.

Basic statistics (mean, median, min, max, counts…) are easily calculable. These or custom aggregations can be applied on the entire data set, a sliding window of the data, or grouped by categories. The latter is also known as the split-apply-combine approach.

Change the structure of your data table in multiple ways. You can melt() your data table from wide to long/tidy form or pivot() from long to wide format. With aggregations built-in, a pivot table is created with a single command.

Multiple tables can be concatenated both column wise and row wise as database-like join/merge operations are provided to combine multiple tables of data.

pandas has great support for time series and has an extensive set of tools for working with dates, times, and time-indexed data.
Data sets do not only contain numerical data. pandas provides a wide range of functions to clean textual data and extract useful information from it.

1.3 Coming from...

Are you familiar with other software for manipulating tabular data? Learn the pandas-equivalent operations compared to software you already know:

The R programming language provides the `data.frame` data structure and multiple packages, such as `tidyverse` use and extend `data.frame` for convenient data handling functionalities similar to pandas.

Already familiar to `SELECT`, `GROUP BY`, `JOIN`, etc.? Most of these SQL manipulations do have equivalents in pandas.

The `data set` included in the STATA statistical software suite corresponds to the pandas `DataFrame`. Many of the operations known from STATA have an equivalent in pandas.

Users of Excel or other spreadsheet programs will find that many of the concepts are transferrable to pandas.

The SAS statistical software suite also provides the `data set` corresponding to the pandas `DataFrame`. Also SAS vectorized operations, filtering, string processing operations, and more have similar functions in pandas.
1.4 Tutorials

For a quick overview of pandas functionality, see 10 Minutes to pandas.

You can also reference the pandas cheat sheet for a succinct guide for manipulating data with pandas.

The community produces a wide variety of tutorials available online. Some of the material is enlisted in the community contributed Community tutorials.

1.4.1 Installation

The easiest way to install pandas is to install it as part of the Anaconda distribution, a cross platform distribution for data analysis and scientific computing. This is the recommended installation method for most users.

Instructions for installing from source, PyPI, ActivePython, various Linux distributions, or a development version are also provided.

Python version support

Officially Python 3.7.1 and above, 3.8, and 3.9.

Installing pandas

Installing with Anaconda

Installing pandas and the rest of the NumPy and SciPy stack can be a little difficult for inexperienced users.

The simplest way to install not only pandas, but Python and the most popular packages that make up the SciPy stack (IPython, NumPy, Matplotlib, . . .) is with Anaconda, a cross-platform (Linux, macOS, Windows) Python distribution for data analytics and scientific computing.

After running the installer, the user will have access to pandas and the rest of the SciPy stack without needing to install anything else, and without needing to wait for any software to be compiled.

Installation instructions for Anaconda can be found here.

A full list of the packages available as part of the Anaconda distribution can be found here.

Another advantage to installing Anaconda is that you don’t need admin rights to install it. Anaconda can install in the user’s home directory, which makes it trivial to delete Anaconda if you decide (just delete that folder).

Installing with Miniconda

The previous section outlined how to get pandas installed as part of the Anaconda distribution. However this approach means you will install well over one hundred packages and involves downloading the installer which is a few hundred megabytes in size.

If you want to have more control on which packages, or have a limited internet bandwidth, then installing pandas with Miniconda may be a better solution.

Conda is the package manager that the Anaconda distribution is built upon. It is a package manager that is both cross-platform and language agnostic (it can play a similar role to a pip and virtualenv combination).

Miniconda allows you to create a minimal self contained Python installation, and then use the Conda command to install additional packages.
First you will need Conda to be installed and downloading and running the Miniconda will do this for you. The installer can be found here

The next step is to create a new conda environment. A conda environment is like a virtualenv that allows you to specify a specific version of Python and set of libraries. Run the following commands from a terminal window:

```
conda create -n name_of_my_env python
```

This will create a minimal environment with only Python installed in it. To put your self inside this environment run:

```
source activate name_of_my_env
```

On Windows the command is:

```
activate name_of_my_env
```

The final step required is to install pandas. This can be done with the following command:

```
conda install pandas
```

To install a specific pandas version:

```
conda install pandas=0.20.3
```

To install other packages, IPython for example:

```
conda install ipython
```

To install the full Anaconda distribution:

```
conda install anaconda
```

If you need packages that are available to pip but not conda, then install pip, and then use pip to install those packages:

```
conda install pip
pip install django
```

**Installing from PyPI**

pandas can be installed via pip from PyPI.

```
pip install pandas
```

**Installing with ActivePython**

Installation instructions for ActivePython can be found here. Versions 2.7, 3.5 and 3.6 include pandas.
**Installing using your Linux distribution's package manager.**

The commands in this table will install pandas for Python 3 from your distribution.

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Status</th>
<th>Download / Repository Link</th>
<th>Install method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debian</td>
<td>stable</td>
<td>official Debian repository</td>
<td>sudo apt-get install python3-pandas</td>
</tr>
<tr>
<td>Debian &amp; Ubuntu</td>
<td>unstable (latest packages)</td>
<td>NeuroDebian</td>
<td>sudo apt-get install python3-pandas</td>
</tr>
<tr>
<td>Ubuntu</td>
<td>stable</td>

<td>yum install python3-pandas</td>
</tr>
</tbody>
</table>

**However,** the packages in the Linux package managers are often a few versions behind, so to get the newest version of pandas, it’s recommended to install using the `pip` or `conda` methods described above.

**Handling ImportErrors**

If you encounter an `ImportError`, it usually means that Python couldn’t find pandas in the list of available libraries. Python internally has a list of directories it searches through, to find packages. You can obtain these directories with:

```python
import sys
sys.path
```

One way you could be encountering this error is if you have multiple Python installations on your system and you don’t have pandas installed in the Python installation you’re currently using. In Linux/Mac you can run `which python` on your terminal and it will tell you which Python installation you’re using. If it’s something like “/usr/bin/python”, you’re using the Python from the system, which is not recommended.

It is highly recommended to use `conda`, for quick installation and for package and dependency updates. You can find simple installation instructions for pandas in this document: installation instructions [getting_started.html].

**Installing from source**

See the `contributing guide` for complete instructions on building from the git source tree. Further, see `creating a development environment` if you wish to create a pandas development environment.
Running the test suite

pandas is equipped with an exhaustive set of unit tests, covering about 97% of the code base as of this writing. To run it on your machine to verify that everything is working (and that you have all of the dependencies, soft and hard, installed), make sure you have pytest >= 6.0 and Hypothesis >= 3.58, then run:

```bash
>>> pd.test()
running: pytest --skip-slow --skip-network C:\Users\TP\Anaconda3\envs\py36\lib\site-packages\pandas
================================= test session starts ==============================
platform win32 -- Python 3.6.2, pytest-3.6.0, py-1.4.34, pluggy-0.4.0
rootdir: C:\Users\TP\Documents\Python\pandasdev\pandas, inifile: setup.cfg
collected 12145 items / 3 skipped

..................................................................S......

.........................................................................

================================= 12130 passed, 12 skipped in 368.339 seconds ===============
```

Dependencies

<table>
<thead>
<tr>
<th>Package</th>
<th>Minimum supported version</th>
</tr>
</thead>
<tbody>
<tr>
<td>NumPy</td>
<td>1.17.3</td>
</tr>
<tr>
<td>python-dateutil</td>
<td>2.7.3</td>
</tr>
<tr>
<td>pytz</td>
<td>2017.3</td>
</tr>
</tbody>
</table>

Recommended dependencies

- **numexpr**: for accelerating certain numerical operations. numexpr uses multiple cores as well as smart chunking and caching to achieve large speedups. If installed, must be Version 2.7.0 or higher.
- **bottleneck**: for accelerating certain types of nan evaluations. bottleneck uses specialized cython routines to achieve large speedups. If installed, must be Version 1.2.1 or higher.

**Note:** You are highly encouraged to install these libraries, as they provide speed improvements, especially when working with large data sets.

Optional dependencies

pandas has many optional dependencies that are only used for specific methods. For example, pandas.read_hdf() requires the pytables package, while DataFrame.to_markdown() requires the tabulate package. If the optional dependency is not installed, pandas will raise an ImportError when the method requiring that dependency is called.
Visualization

<table>

</tbody>
</table>

HTML

<table>
<thead>
<tr>
<th>Dependency</th>
<th>Minimum Version</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>BeautifulSoup4</td>
<td>4.6.0</td>
<td>HTML parser for read_html</td>
</tr>
<tr>
<td>html5lib</td>
<td>1.0.1</td>
<td>HTML parser for read_html</td>
</tr>
<tr>
<td>lxml</td>
<td>4.3.0</td>
<td>HTML parser for read_html</td>
</tr>
</tbody>
</table>

One of the following combinations of libraries is needed to use the top-level read_html() function:

- BeautifulSoup4 and html5lib
- BeautifulSoup4 and lxml
- BeautifulSoup4 and html5lib and lxml
- Only lxml, although see HTML Table Parsing for reasons as to why you should probably not take this approach.

Warning:

- if you install BeautifulSoup4 you must install either lxml or html5lib or both. read_html() will not work with only BeautifulSoup4 installed.
You are highly encouraged to read *HTML Table Parsing gotchas*. It explains issues surrounding the installation and usage of the above three libraries.

1.4.2 Package overview

pandas is a Python package providing fast, flexible, and expressive data structures designed to make working with “relational” or “labeled” data both easy and intuitive. It aims to be the fundamental high-level building block for doing practical, **real-world** data analysis in Python. Additionally, it has the broader goal of becoming the most powerful and flexible open source data analysis/manipulation tool available in any language. It is already well on its way toward this goal.

pandas is well suited for many different kinds of data:

- Tabular data with heterogeneously-typed columns, as in an SQL table or Excel spreadsheet
- Ordered and unordered (not necessarily fixed-frequency) time series data.
- Arbitrary matrix data (homogeneously typed or heterogeneous) with row and column labels
- Any other form of observational / statistical data sets. The data need not be labeled at all to be placed into a pandas data structure

The two primary data structures of pandas, **Series** (1-dimensional) and **DataFrame** (2-dimensional), handle the vast majority of typical use cases in finance, statistics, social science, and many areas of engineering. For R users, **DataFrame** provides everything that R’s **data.frame** provides and much more. pandas is built on top of NumPy and is intended to integrate well within a scientific computing environment with many other 3rd party libraries.

Here are just a few of the things that pandas does well:

- Easy handling of **missing data** (represented as NaN) in floating point as well as non-floating point data
- Size mutability: columns can be **inserted and deleted** from DataFrame and higher dimensional objects
- Automatic and explicit **data alignment**: objects can be explicitly aligned to a set of labels, or the user can simply ignore the labels and let Series, DataFrame, etc. automatically align the data for you in computations
- Powerful, flexible **group by** functionality to perform split-apply-combine operations on data sets, for both aggregating and transforming data
- Make it **easy to convert** ragged, differently-indexed data in other Python and NumPy data structures into DataFrame objects
- Intelligent label-based **slicing, fancy indexing, and subsetting** of large data sets
• Intuitive **merging** and **joining** data sets
• Flexible **reshaping** and pivoting of data sets
• **Hierarchical** labeling of axes (possible to have multiple labels per tick)
• Robust IO tools for loading data from **flat files** (CSV and delimited), Excel files, databases, and saving / loading data from the ultrafast **HDF5 format**
• **Time series**-specific functionality: date range generation and frequency conversion, moving window statistics, date shifting, and lagging.

Many of these principles are here to address the shortcomings frequently experienced using other languages / scientific research environments. For data scientists, working with data is typically divided into multiple stages: munging and cleaning data, analyzing / modeling it, then organizing the results of the analysis into a form suitable for plotting or tabular display. pandas is the ideal tool for all of these tasks.

Some other notes
• pandas is **fast**. Many of the low-level algorithmic bits have been extensively tweaked in **Cython** code. However, as with anything else generalization usually sacrifices performance. So if you focus on one feature for your application you may be able to create a faster specialized tool.
• pandas is a dependency of **statsmodels**, making it an important part of the statistical computing ecosystem in Python.
• pandas has been used extensively in production in financial applications.

### Data structures

</tr>
</tbody>
</table>

**Why more than one data structure?**

The best way to think about the pandas data structures is as flexible containers for lower dimensional data. For example, DataFrame is a container for Series, and Series is a container for scalars. We would like to be able to insert and remove objects from these containers in a dictionary-like fashion.

Also, we would like sensible default behaviors for the common API functions which take into account the typical orientation of time series and cross-sectional data sets. When using the N-dimensional array (ndarrays) to store 2- and 3-dimensional data, a burden is placed on the user to consider the orientation of the data set when writing functions; axes are considered more or less equivalent (except when C- or Fortran-contiguosness matters for performance). In pandas, the axes are intended to lend more semantic meaning to the data; i.e., for a particular data set, there is likely to be a “right” way to orient the data. The goal, then, is to reduce the amount of mental effort required to code up data transformations in downstream functions.

For example, with tabular data (Dataframe) it is more semantically helpful to think of the **index** (the rows) and the **columns** rather than axis 0 and axis 1. Iterating through the columns of the DataFrame thus results in more readable code:

```python
for col in df.columns:
    series = df[col]
    # do something with series
```
Mutability and copying of data

All pandas data structures are value-mutable (the values they contain can be altered) but not always size-mutable. The length of a Series cannot be changed, but, for example, columns can be inserted into a DataFrame. However, the vast majority of methods produce new objects and leave the input data untouched. In general we like to favor immutability where sensible.

Getting support

The first stop for pandas issues and ideas is the Github Issue Tracker. If you have a general question, pandas community experts can answer through Stack Overflow.

Community

pandas is actively supported today by a community of like-minded individuals around the world who contribute their valuable time and energy to help make open source pandas possible. Thanks to all of our contributors.

If you’re interested in contributing, please visit the contributing guide.

pandas is a NumFOCUS sponsored project. This will help ensure the success of the development of pandas as a world-class open-source project and makes it possible to donate to the project.

Project governance

The governance process that pandas project has used informally since its inception in 2008 is formalized in Project Governance documents. The documents clarify how decisions are made and how the various elements of our community interact, including the relationship between open source collaborative development and work that may be funded by for-profit or non-profit entities.

Wes McKinney is the Benevolent Dictator for Life (BDFL).

Development team

The list of the Core Team members and more detailed information can be found on the people’s page of the governance repo.

Institutional partners

The information about current institutional partners can be found on pandas website page.

1.4.3 Getting started tutorials

What kind of data does pandas handle?

I want to start using pandas

```
In [1]: import pandas as pd
```

To load the pandas package and start working with it, import the package. The community agreed alias for pandas is pd, so loading pandas as pd is assumed standard practice for all of the pandas documentation.

**pandas data table representation**

I want to store passenger data of the Titanic. For a number of passengers, I know the name (characters), age (integers) and sex (male/female) data.

```
In [2]: df = pd.DataFrame({
    ...:     "Name": [
    ...:         "Braund, Mr. Owen Harris",
    ...:         "Allen, Mr. William Henry",
    ...:         "Bonnell, Miss. Elizabeth",
    ...:     ],
    ...:     "Age": [22, 35, 58],
    ...:     "Sex": ["male", "male", "female"],
    ...: })
```

1.4. Tutorials
To manually store data in a table, create a DataFrame. When using a Python dictionary of lists, the dictionary keys will be used as column headers and the values in each list as columns of the DataFrame.

A DataFrame is a 2-dimensional data structure that can store data of different types (including characters, integers, floating point values, categorical data and more) in columns. It is similar to a spreadsheet, a SQL table or the data.frame in R.

- The table has 3 columns, each of them with a column label. The column labels are respectively Name, Age and Sex.
- The column Name consists of textual data with each value a string, the column Age are numbers and the column Sex is textual data.

In spreadsheet software, the table representation of our data would look very similar:
Each column in a DataFrame is a Series

I’m just interested in working with the data in the column Age

```
In [4]: df['Age']
Out [4]:
0  22
1  35
2  58
Name: Age, dtype: int64
```

When selecting a single column of a pandas DataFrame, the result is a pandas Series. To select the column, use the column label in between square brackets [].

**Note:** If you are familiar to Python dictionaries, the selection of a single column is very similar to selection of dictionary values based on the key.

You can create a Series from scratch as well:

```
In [5]: ages = pd.Series([22, 35, 58], name="Age")
In [6]: ages
Out [6]:
0  22
1  35
2  58
Name: Age, dtype: int64
```

A pandas Series has no column labels, as it is just a single column of a DataFrame. A Series does have row labels.

**Do something with a DataFrame or Series**

I want to know the maximum Age of the passengers

We can do this on the DataFrame by selecting the Age column and applying max():

```
In [7]: df['Age'].max()
Out [7]: 58
```

Or to the Series:

```
In [8]: ages.max()
Out [8]: 58
```

As illustrated by the max() method, you can do things with a DataFrame or Series. pandas provides a lot of functionalities, each of them a method you can apply to a DataFrame or Series. As methods are functions, do not forget to use parentheses ()

I’m interested in some basic statistics of the numerical data of my data table

```
In [9]: df.describe()
Out [9]:
```

(continues on next page)
The `describe()` method provides a quick overview of the numerical data in a DataFrame. As the Name and Sex columns are textual data, these are by default not taken into account by the `describe()` method.

Many pandas operations return a DataFrame or a Series. The `describe()` method is an example of a pandas operation returning a pandas Series or a pandas DataFrame.

Check more options on `describe` in the user guide section about aggregations with `describe`

**Note:** This is just a starting point. Similar to spreadsheet software, pandas represents data as a table with columns and rows. Apart from the representation, also the data manipulations and calculations you would do in spreadsheet software are supported by pandas. Continue reading the next tutorials to get started!

- Import the package, aka `import pandas as pd`
- A table of data is stored as a pandas DataFrame
- Each column in a DataFrame is a Series
- You can do things by applying a method to a DataFrame or Series

A more extended explanation to DataFrame and Series is provided in the introduction to data structures.

```
in [1]: import pandas as pd
```

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- PassengerId: Id of every passenger.
- Survived: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- Pclass: There are 3 classes: Class 1, Class 2 and Class 3.
- Name: Name of passenger.
- Sex: Gender of passenger.
- Age: Age of passenger.
- SibSp: Indication that passenger have siblings and spouse.
- Parch: Whether a passenger is alone or have family.
- Ticket: Ticket number of passenger.
- Fare: Indicating the fare.
- Cabin: The cabin of passenger.
- Embarked: The embarked category.
How do I read and write tabular data?

I want to analyze the Titanic passenger data, available as a CSV file.

```python
In [2]: titanic = pd.read_csv("data/titanic.csv")
```

pandas provides the `read_csv()` function to read data stored as a csv file into a pandas DataFrame. pandas supports many different file formats or data sources out of the box (csv, excel, sql, json, parquet, ...), each of them with the prefix `read_*`.

Make sure to always have a check on the data after reading in the data. When displaying a DataFrame, the first and last 5 rows will be shown by default:

```python
In [3]: titanic
Out[3]:
   PassengerId  Survived  Pclass  Name               Sex  Age  SibSp  Parch  Ticket  Fare  Cabin  Embarked
0            1         0       3  Braund, Mr. Owen Harris  male  22.0      1      0  A/5 21171  7.2500  NaN     S
1            2         1       1  Cumings, Mrs. John Bradley (Florence Briggs Th... female  38.0      1      1  PC 17599  71.2833    C85     C
2            3         3       1  Heikkinen, Miss. Laina        male  26.0      0      0  STON/O2. 3101282  7.9250  NaN     S
3            4         1       1  Futrelle, Mrs. Jacques Heath (Lily May Peel) female  35.0      0      0    113803  53.1000  C123     S
4            5         0       3    Allen, Mr. William Henry       male  35.0      0      3          NaN        NaN     NaN     S
5          886         0       2          NaN        NaN     NaN     NaN
6          887         0       2          NaN        NaN     NaN     NaN
7          888         1       1          NaN        NaN     NaN     NaN
8          889         0       3          NaN        NaN     NaN     NaN
9          890         1       1          NaN        NaN     NaN     NaN
10         891         0       3          NaN        NaN     NaN     NaN
```

I want to see the first 8 rows of a pandas DataFrame.

```python
In [4]: titanic.head(8)
Out[4]:
   PassengerId  Survived  Pclass  Name             Sex  Age  SibSp  Parch  Ticket  Fare  Cabin  Embarked
0            1         0       3  Braund, Mr. Owen Harris  male  22.0      1      0  A/5 21171  7.2500  NaN     S
1            2         1       1  Cumings, Mrs. John Bradley (Florence Briggs Th... female  38.0      1      1  PC 17599  71.2833    C85     C
2            3         3       1  Heikkinen, Miss. Laina        male  26.0      0      0  STON/O2. 3101282  7.9250  NaN     S
3            4         1       1  Futrelle, Mrs. Jacques Heath (Lily May Peel) female  35.0      0      0    113803  53.1000  C123     S
```

(continues on next page)
To see the first N rows of a DataFrame, use the head() method with the required number of rows (in this case 8) as argument.

**Note:** Interested in the last N rows instead? pandas also provides a tail() method. For example, titanic.tail(10) will return the last 10 rows of the DataFrame.

A check on how pandas interpreted each of the column data types can be done by requesting the pandas dtypes attribute:

```
In [5]: titanic.dtypes
Out[5]:
PassengerId    int64
Survived       int64
Pclass         int64
Name           object
Sex            object
Age            float64
SibSp          int64
Parch          int64
Ticket         object
Fare           float64
Cabin          object
Embarked       object
dtype: object
```

For each of the columns, the used data type is enlisted. The data types in this DataFrame are integers (int64), floats (float64) and strings (object).

**Note:** When asking for the dtypes, no brackets are used! dtypes is an attribute of a DataFrame and Series. Attributes of DataFrame or Series do not need brackets. Attributes represent a characteristic of a DataFrame/Series, whereas a method (which requires brackets) do something with the DataFrame/Series as introduced in the first tutorial.

My colleague requested the Titanic data as a spreadsheet.

```
In [6]: titanic.to_excel("titanic.xlsx", sheet_name="passengers", index=False)
```

Whereas read_* functions are used to read data to pandas, the to_* methods are used to store data. The to_excel() method stores the data as an excel file. In the example here, the sheet_name is named passengers instead of the default Sheet1. By setting index=False the row index labels are not saved in the spreadsheet.

The equivalent read function read_excel() will reload the data to a DataFrame:

```
In [7]: titanic = pd.read_excel("titanic.xlsx", sheet_name="passengers")
```
I'm interested in a technical summary of a DataFrame

The method `info()` provides technical information about a DataFrame, so let's explain the output in more detail:

- It is indeed a DataFrame.
- There are 891 entries, i.e. 891 rows.
- Each row has a row label (aka the index) with values ranging from 0 to 890.
- The table has 12 columns. Most columns have a value for each of the rows (all 891 values are non-null). Some columns do have missing values and less than 891 non-null values.
- The columns Name, Sex, Cabin and Embarked consists of textual data (strings, aka object). The other columns are numerical data with some of them whole numbers (aka integer) and others are real numbers (aka float).
- The kind of data (characters, integers,...) in the different columns are summarized by listing the dtypes.
- The approximate amount of RAM used to hold the DataFrame is provided as well.
- Getting data in to pandas from many different file formats or data sources is supported by read_* functions.
- Exporting data out of pandas is provided by different to_* methods.
This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- **PassengerId**: Id of every passenger.
- **Survived**: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- **Pclass**: There are 3 classes: Class 1, Class 2 and Class 3.
- **Name**: Name of passenger.
- **Sex**: Gender of passenger.
- **Age**: Age of passenger.
- **SibSp**: Indication that passenger have siblings and spouse.
- **Parch**: Whether a passenger is alone or have family.
- **Ticket**: Ticket number of passenger.
- **Fare**: Indicating the fare.
- **Cabin**: The cabin of passenger.
- **Embarked**: The embarked category.

```python
In [2]: titanic = pd.read_csv("data/titanic.csv")
In [3]: titanic.head()
```

```
      PassengerId  Survived  Pclass     Name       Sex   Age  SibSp  Parch  Ticket  Fare  Cabin  Embarked
0          1          0      3  Braund, Mr. Owen Harris   male  22.0      1      0   A/5 21171  7.2500   NaN      S
1          2          1      1 Cumings, Mrs. John Bradley (Florence Briggs Th... female  38.0      1      0    PC 17599 11.1500  29.7500    C
2          3          0      3  Heikkinen, Miss. Laina    female  26.0      1      0  STON/O2. 3101282  7.9250   NaN      S
3          4          0      3  Futrelle, Mrs. Jacques Heath (Lily May Peel)  female  35.0      1      0  113803  53.1000 117.5000    S
4          5          0      3           Allen, Mr. William Henry   male  35.0      0      0  373450  8.0500   NaN      S
```

**How do I select a subset of a DataFrame?**

**How do I select specific columns from a DataFrame?**

I’m interested in the age of the Titanic passengers.

```python
In [4]: ages = titanic["Age"]
In [5]: ages.head()
(continues on next page)```
To select a single column, use square brackets [] with the column name of the column of interest.

Each column in a DataFrame is a Series. As a single column is selected, the returned object is a pandas Series. We can verify this by checking the type of the output:

```python
In [6]: type(titanic["Age"])
Out[6]: pandas.core.series.Series
```

And have a look at the shape of the output:

```python
In [7]: titanic["Age"].shape
Out[7]: (891,)
```

`DataFrame.shape` is an attribute (remember tutorial on reading and writing, do not use parentheses for attributes) of a pandas Series and DataFrame containing the number of rows and columns: (nrows, ncols). A pandas Series is 1-dimensional and only the number of rows is returned.

I’m interested in the age and sex of the Titanic passengers.

```python
In [8]: age_sex = titanic["Age", "Sex"]
In [9]: age_sex.head()
Out[9]:
          Age  Sex
0      22.0  male
1      38.0  female
2      26.0  female
3      35.0  female
4      35.0   male
```

To select multiple columns, use a list of column names within the selection brackets [].

**Note:** The inner square brackets define a Python list with column names, whereas the outer brackets are used to select the data from a pandas DataFrame as seen in the previous example.

The returned data type is a pandas DataFrame:

```python
In [10]: type(titanic["Age", "Sex"])
Out[10]: pandas.core.frame.DataFrame

In [11]: titanic["Age", "Sex"].shape
Out[11]: (891, 2)
```

The selection returned a DataFrame with 891 rows and 2 columns. Remember, a DataFrame is 2-dimensional with both a row and column dimension.

For basic information on indexing, see the user guide section on indexing and selecting data.
How do I filter specific rows from a DataFrame?

I’m interested in the passengers older than 35 years.

```
In [12]: above_35 = titanic[titanic["Age"] > 35]
In [13]: above_35.head()
Out[13]:
   PassengerId  Survived  Pclass     Name                                    Sex  Age  SibSp  Parch         Ticket    Fare  Cabin    Embarked
0           2       1       1  Cumings, Mrs. John Bradley (Florence Briggs Th...  female  38.0    0    0 PC17599  71.2833   C85        C
1           7       0       1  McCarthy, Mr. Timothy J                                                                 male  54.0    0    0          17463  51.8625   E46        S
2          12       1       1  Bonnell, Miss. Elizabeth                                                                 female  58.0    0    0  113783  26.5500  C103        S
3          13       0       3  Andersson, Mr. Anders Johan                                                                 female  39.0    1    5  347082  31.2750   NaN        S
4          15       1       2  Hewlett, Mrs. (Mary D Kingcome)                                                                 female  55.0    0    0  248706  16.0000   NaN        S
```

To select rows based on a conditional expression, use a condition inside the selection brackets `[]`.

The condition inside the selection brackets `titanic["Age"] > 35` checks for which rows the `Age` column has a value larger than 35:

```
In [14]: titanic["Age"] > 35
Out[14]:
0    False
1     True
2    False
3    False
4    False
   ...
886  False
887  False
888  False
889  False
890  False
Name: Age, Length: 891, dtype: bool
```

The output of the conditional expression (>, but also ==, !=, <=, ... would work) is actually a pandas Series of boolean values (either True or False) with the same number of rows as the original DataFrame. Such a Series of boolean values can be used to filter the DataFrame by putting it in between the selection brackets `[]`. Only rows for which the value is True will be selected.

We know from before that the original Titanic DataFrame consists of 891 rows. Let’s have a look at the number of rows which satisfy the condition by checking the `shape` attribute of the resulting DataFrame `above_35`:

```
In [15]: above_35.shape
Out[15]: (217, 12)
```

I’m interested in the Titanic passengers from cabin class 2 and 3.

```
In [16]: class_23 = titanic[titanic["Pclass"].isin([2, 3])]
(continues on next page)
```
Similar to the conditional expression, the `isin()` conditional function returns a `True` for each row the values are in the provided list. To filter the rows based on such a function, use the conditional function inside the selection brackets `[]`. In this case, the condition inside the selection brackets `titanic["Pclass"].isin([2, 3])` checks for which rows the `Pclass` column is either 2 or 3.

The above is equivalent to filtering by rows for which the class is either 2 or 3 and combining the two statements with an | (or) operator:

```
In [18]: class_23 = titanic[(titanic["Pclass"] == 2) | (titanic["Pclass"] == 3)]
```

I want to work with passenger data for which the age is known.

```
In [20]: age_no_na = titanic[titanic["Age"].notna()]
```

See the dedicated section in the user guide about boolean indexing or about the `isin` function.
The `notna()` conditional function returns a True for each row the values are not an Null value. As such, this can be combined with the selection brackets [] to filter the data table.

You might wonder what actually changed, as the first 5 lines are still the same values. One way to verify is to check if the shape has changed:

```
In [22]: age_no_na.shape
Out[22]: (714, 12)
```

For more dedicated functions on missing values, see the user guide section about handling missing data.

### How do I select specific rows and columns from a DataFrame?

I’m interested in the names of the passengers older than 35 years.

```
In [23]: adult_names = titanic.loc[titanic["Age"] > 35, "Name"]

In [24]: adult_names.head()
Out[24]:
   1     Cumings, Mrs. John Bradley (Florence Briggs Th...
  6   McCarthy, Mr. Timothy J
 11   Bonnell, Miss. Elizabeth
 13  Andersson, Mr. Anders Johan
 15  Hewlett, Mrs. (Mary D Kingcome)
Name: Name, dtype: object
```

In this case, a subset of both rows and columns is made in one go and just using selection brackets [] is not sufficient anymore. The `loc/iloc` operators are required in front of the selection brackets[]. When using `loc/iloc`, the part before the comma is the rows you want, and the part after the comma is the columns you want to select.

When using the column names, row labels or a condition expression, use the `loc` operator in front of the selection brackets[]. For both the part before and after the comma, you can use a single label, a list of labels, a slice of labels, a conditional expression or a colon. Using a colon specifies you want to select all rows or columns.

I’m interested in rows 10 till 25 and columns 3 to 5.

```
In [25]: titanic.iloc[9:25, 2:5]
Out[25]:
   Pclass  Name        Sex
   9    2      Nasser, Mrs. Nicholas (Adele Achem)  female
  10    3  Sandstrom, Miss. Marguerite Rut  female
  11    1  Bonnell, Miss. Elizabeth  female
  12    3  Saundercoc, Mr. William Henry    male
  13    3  Andersson, Mr. Anders Johan    male
      ...        ...         ...
```

(continues on next page)
Again, a subset of both rows and columns is made in one go and just using selection brackets [ ] is not sufficient anymore. When specifically interested in certain rows and/or columns based on their position in the table, use the `iloc` operator in front of the selection brackets [ ].

When selecting specific rows and/or columns with `loc` or `iloc`, new values can be assigned to the selected data. For example, to assign the name `anonymous` to the first 3 elements of the third column:

```
In [26]: titanic.iloc[0:3, 3] = "anonymous"
In [27]: titanic.head()
Out[27]:
   PassengerId  Survived  Pclass  Name                  Sex  Age     SibSp  Parch    Ticket  Fare  Cabin Embarked
0            1         0        3  anonymous            male  22.0     1        0   A/5 21171  7.2500  NaN      S
1            2         1        1            NaN            38.0     1        0  PC 17599  71.2833  C85      C
2            3         1        3            NaN            26.0     0        0  STON/O2. 3101282  7.9250  NaN      S
3            4         1        1 Futrelle, Mrs. Jacques Heath (Lily May Peel)  female   35.0     1        0  113803  53.1000  C123      S
4            5         0        3  Allen, Mr. William Henry            male  35.0     0        0  373450  8.0500  NaN      S
```

See the user guide section on `different choices for indexing` to get more insight in the usage of `loc` and `iloc`.

- When selecting subsets of data, square brackets [ ] are used.
- Inside these brackets, you can use a single column/row label, a list of column/row labels, a slice of labels, a conditional expression or a colon.
- Select specific rows and/or columns using `loc` when using the row and column names
- Select specific rows and/or columns using `iloc` when using the positions in the table
- You can assign new values to a selection based on `loc/iloc`.

A full overview of indexing is provided in the user guide pages on `indexing and selecting data`.

```
In [1]: import pandas as pd
In [2]: import matplotlib.pyplot as plt

For this tutorial, air quality data about $NO_2$ is used, made available by openaq and using the `py-openaq` package. The `air_quality_no2.csv` data set provides $NO_2$ values for the measurement stations `FR04014`, `BETR801` and `London Westminster` in respectively Paris, Antwerp and London.

In [3]: air_quality = pd.read_csv("data/air_quality_no2.csv", index_col=0, parse_
˓→dates=True)
```
In [4]: air_quality.head()
Out[4]:
<table>
<thead>
<tr>
<th>datetime</th>
<th>station_antwerp</th>
<th>station_paris</th>
<th>station_london</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019-05-07 02:00:00</td>
<td>NaN</td>
<td>NaN</td>
<td>23.0</td>
</tr>
<tr>
<td>2019-05-07 03:00:00</td>
<td>50.5</td>
<td>25.0</td>
<td>19.0</td>
</tr>
<tr>
<td>2019-05-07 04:00:00</td>
<td>45.0</td>
<td>27.7</td>
<td>19.0</td>
</tr>
<tr>
<td>2019-05-07 05:00:00</td>
<td>NaN</td>
<td>50.4</td>
<td>16.0</td>
</tr>
<tr>
<td>2019-05-07 06:00:00</td>
<td>NaN</td>
<td>61.9</td>
<td>NaN</td>
</tr>
</tbody>
</table>

**Note:** The usage of the `index_col` and `parse_dates` parameters of the `read_csv` function to define the first (0th) column as index of the resulting DataFrame and convert the dates in the column to `Timestamp` objects, respectively.

**How to create plots in pandas?**

I want a quick visual check of the data.

In [5]: air_quality.plot()
Out[5]: <AxesSubplot:xlabel='datetime'>
With a DataFrame, pandas creates by default one line plot for each of the columns with numeric data.

I want to plot only the columns of the data table with the data from Paris.

```
In [6]: air_quality["station_paris"].plot()
Out[6]: <AxesSubplot:xlabel='datetime'>
```
To plot a specific column, use the selection method of the subset data tutorial in combination with the `plot()` method. Hence, the `plot()` method works on both Series and DataFrame.

I want to visually compare the $NO_2$ values measured in London versus Paris.

```
In [7]: air_quality.plot.scatter(x="station_london", y="station_paris", alpha=0.5)
Out[7]: <AxesSubplot:xlabel='station_london', ylabel='station_paris'>
```
Apart from the default line plot when using the `plot` function, a number of alternatives are available to plot data. Let’s use some standard Python to get an overview of the available plot methods:

```python
In [8]: [
   ...:     method_name
   ...:     for method_name in dir(air_quality.plot)
   ...:     if not method_name.startswith("_")
   ...: ]
   ...
Out[8]: ['area', 'bar', 'barh', 'box', 'density', 'hexbin', 'hist', 'kde', 'line', 'pie', 'scatter']
```

**Note:** In many development environments as well as IPython and Jupyter Notebook, use the TAB button to get an overview of the available methods, for example `air_quality.plot + TAB`. 
One of the options is `DataFrame.plot.box()`, which refers to a boxplot. The box method is applicable on the air quality example data:

```python
In [9]: air_quality.plot.box()
Out[9]: <AxesSubplot:>
```

For an introduction to plots other than the default line plot, see the user guide section about supported plot styles.

I want each of the columns in a separate subplot.

```python
In [10]: axs = air_quality.plot.area(figsize=(12, 4), subplots=True)
```
Separate subplots for each of the data columns are supported by the `subplots` argument of the `plot` functions. The built-in options available in each of the pandas plot functions are worth reviewing.

Some more formatting options are explained in the user guide section on `plot formatting`.

I want to further customize, extend or save the resulting plot.

```python
In [11]: fig, axs = plt.subplots(figsize=(12, 4))
In [12]: air_quality.plot.area(ax=axs)
Out[12]: <AxesSubplot:xlabel='datetime'>
In [13]: axs.set_ylabel("NO$_2$ concentration")
Out[13]: Text(0, 0.5, 'NO$_2$ concentration')
In [14]: fig.savefig("no2_concentrations.png")
```

Each of the plot objects created by pandas is a `matplotlib` object. As `Matplotlib` provides plenty of options to customize plots, making the link between pandas and Matplotlib explicit enables all the power of `matplotlib` to the plot. This strategy is applied in the previous example:

```python
fig, axs = plt.subplots(figsize=(12, 4))  # Create an empty matplotlib Figure and Axes
air_quality.plot.area(ax=axs)  # Use pandas to put the area plot on the prepared Figure/Axes
axs.set_ylabel("NO$_2$ concentration")  # Do any matplotlib customization you like
fig.savefig("no2_concentrations.png")  # Save the Figure/Axes using the existing matplotlib method.
```

- The `.plot.*` methods are applicable on both Series and DataFrames
- By default, each of the columns is plotted as a different element (line, boxplot,...)
- Any plot created by pandas is a Matplotlib object.

A full overview of plotting in pandas is provided in the `visualization pages`.

For this tutorial, air quality data about $NO_2$ is used, made available by openaq and using the `py-openaq` package. The `air_quality_no2.csv` data set provides $NO_2$ values for the measurement stations `FR04014`, `BETR801` and `London Westminster` in respectively Paris, Antwerp and London.
In [2]: air_quality = pd.read_csv("data/air_quality_no2.csv", index_col=0, parse_→dates=True)

In [3]: air_quality.head()
Out[3]:

<table>
<thead>
<tr>
<th>station_antwerp</th>
<th>station_paris</th>
<th>station_london</th>
</tr>
</thead>
<tbody>
<tr>
<td>datetime</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2019-05-07 02:00:00</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2019-05-07 03:00:00</td>
<td>50.5</td>
<td>25.0</td>
</tr>
<tr>
<td>2019-05-07 04:00:00</td>
<td>45.0</td>
<td>27.7</td>
</tr>
<tr>
<td>2019-05-07 05:00:00</td>
<td>NaN</td>
<td>50.4</td>
</tr>
<tr>
<td>2019-05-07 06:00:00</td>
<td>NaN</td>
<td>61.9</td>
</tr>
</tbody>
</table>

**How to create new columns derived from existing columns?**

I want to express the NO\textsubscript{2} concentration of the station in London in mg/m\textsuperscript{3}

*(If we assume temperature of 25 degrees Celsius and pressure of 1013 hPa, the conversion factor is 1.882)*

In [4]: air_quality[“london_mg_per_cubic”] = air_quality[“station_london”] * 1.882

In [5]: air_quality.head()
Out[5]:

<table>
<thead>
<tr>
<th>station_antwerp</th>
<th>station_paris</th>
<th>station_london</th>
<th>london_mg_per_cubic</th>
</tr>
</thead>
<tbody>
<tr>
<td>datetime</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2019-05-07 02:00:00</td>
<td>NaN</td>
<td>NaN</td>
<td>23.0</td>
</tr>
<tr>
<td>2019-05-07 03:00:00</td>
<td>50.5</td>
<td>25.0</td>
<td>35.2</td>
</tr>
<tr>
<td>2019-05-07 04:00:00</td>
<td>45.0</td>
<td>27.7</td>
<td>35.2</td>
</tr>
<tr>
<td>2019-05-07 05:00:00</td>
<td>NaN</td>
<td>50.4</td>
<td>30.8</td>
</tr>
<tr>
<td>2019-05-07 06:00:00</td>
<td>NaN</td>
<td>61.9</td>
<td>NaN</td>
</tr>
</tbody>
</table>

To create a new column, use the [] brackets with the new column name at the left side of the assignment.

**Note:** The calculation of the values is done element-wise. This means all values in the given column are multiplied by the value 1.882 at once. You do not need to use a loop to iterate each of the rows!

I want to check the ratio of the values in Paris versus Antwerp and save the result in a new column

In [6]: air_quality[“ratio_paris_antwerp”] = {  
...:     air_quality[“station_paris”] / air_quality[“station_antwerp”]  
...: }

In [7]: air_quality.head()
The calculation is again element-wise, so the `/` is applied for the values in each row.

Also other mathematical operators (+, -, \*, /) or logical operators (<, >, =,...) work element wise. The latter was already used in the subset data tutorial to filter rows of a table using a conditional expression.

If you need more advanced logic, you can use arbitrary Python code via `apply()`.

I want to rename the data columns to the corresponding station identifiers used by openAQ.

In [8]:
```
air_quality_renamed = air_quality.rename(
    ...:     columns={
    ...:         "station_antwerp": "BETR801",
    ...:         "station_paris": "FR04014",
    ...:         "station_london": "London Westminster",
    ...:     })
```

In [9]:
```
air_quality_renamed.head()
```

The `rename()` function can be used for both row labels and column labels. Provide a dictionary with the keys the current names and the values the new names to update the corresponding names.

The mapping should not be restricted to fixed names only, but can be a mapping function as well. For example, converting the column names to lowercase letters can be done using a function as well:
In [10]: air_quality_renamed = air_quality_renamed.rename(columns=str.lower)

In [11]: air_quality_renamed.head()

Out[11]:
<table>
<thead>
<tr>
<th>date</th>
<th>Paris Antwerp</th>
<th>London Westminster</th>
<th>London Mg Per Cubic</th>
<th>Ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019-05-07 02:00:00</td>
<td>NaN</td>
<td>NaN</td>
<td>23.0</td>
<td>43.286</td>
</tr>
<tr>
<td>2019-05-07 03:00:00</td>
<td>50.5</td>
<td>25.0</td>
<td>19.0</td>
<td>35.758</td>
</tr>
<tr>
<td>2019-05-07 04:00:00</td>
<td>45.0</td>
<td>27.7</td>
<td>19.0</td>
<td>35.758</td>
</tr>
<tr>
<td>2019-05-07 05:00:00</td>
<td>NaN</td>
<td>50.4</td>
<td>16.0</td>
<td>30.112</td>
</tr>
<tr>
<td>2019-05-07 06:00:00</td>
<td>NaN</td>
<td>61.9</td>
<td>NaN</td>
<td>NaN</td>
</tr>
</tbody>
</table>

Details about column or row label renaming is provided in the user guide section on renaming labels.

- Create a new column by assigning the output to the DataFrame with a new column name in between the [].
- Operations are element-wise, no need to loop over rows.
- Use rename with a dictionary or function to rename row labels or column names.

The user guide contains a separate section on column addition and deletion.

In [1]: import pandas as pd

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- **PassengerId**: Id of every passenger.
- **Survived**: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- **Pclass**: There are 3 classes: Class 1, Class 2 and Class 3.
- **Name**: Name of passenger.
- **Sex**: Gender of passenger.
- **Age**: Age of passenger.
- **SibSp**: Indication that passenger have siblings and spouse.
- **Parch**: Whether a passenger is alone or have family.
- **Ticket**: Ticket number of passenger.
- **Fare**: Indicating the fare.
- **Cabin**: The cabin of passenger.
- **Embarked**: The embarked category.

In [2]: titanic = pd.read_csv("data/titanic.csv")

In [3]: titanic.head()

Out[3]:
<table>
<thead>
<tr>
<th>PassengerId</th>
<th>Survived</th>
<th>Pclass</th>
<th>Name</th>
<th>Sex</th>
<th>Age</th>
<th>SibSp</th>
<th>Parch</th>
<th>Ticket</th>

<th>Cabin</th>
<th>Embarked</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
How to calculate summary statistics?

Aggregating statistics

What is the average age of the Titanic passengers?

```python
In [4]: titanic["Age"].mean()
Out[4]: 29.69911764705882
```

Different statistics are available and can be applied to columns with numerical data. Operations in general exclude missing data and operate across rows by default.

What is the median age and ticket fare price of the Titanic passengers?

```python
In [5]: titanic[["Age", "Fare"]].median()
Out[5]:
Age    28.0000
Fare   14.4542
dtype: float64
```

The statistic applied to multiple columns of a DataFrame (the selection of two columns return a DataFrame, see the subset data tutorial) is calculated for each numeric column.

The aggregating statistic can be calculated for multiple columns at the same time. Remember the describe function from first tutorial tutorial?

```python
In [6]: titanic[["Age", "Fare"]].describe()
Out [6]:
             Age   Fare
count  714.000000  891.000000
mean  29.699118  32.204208
std   14.526497  49.693429
min   0.420000   0.000000
25%   20.125000  7.910400
50%   28.000000  14.454200
75%   38.000000  31.000000
max   80.000000  512.329200
```

Instead of the predefined statistics, specific combinations of aggregating statistics for given columns can be defined using the DataFrame.agg() method:
In [7]: titanic.agg(
        ...:     { 
        ...:         "Age": ["min", "max", "median", "skew"], 
        ...:         "Fare": ["min", "max", "median", "mean"], 
        ...:     } 
        ...: )

Out[7]:

<table>
<thead>
<tr>
<th></th>
<th>Age</th>
<th>Fare</th>
</tr>
</thead>
<tbody>
<tr>
<td>min</td>
<td>0.420000</td>
<td>0.000000</td>
</tr>
<tr>
<td>max</td>
<td>80.000000</td>
<td>512.329200</td>
</tr>
<tr>
<td>median</td>
<td>28.000000</td>
<td>14.454200</td>
</tr>
<tr>
<td>skew</td>
<td>0.389108</td>
<td>NaN</td>
</tr>
<tr>
<td>mean</td>
<td>NaN</td>
<td>32.204208</td>
</tr>
</tbody>
</table>

Details about descriptive statistics are provided in the user guide section on [descriptive statistics](#).

### Aggregating statistics grouped by category

What is the average age for male versus female Titanic passengers?

In [8]: titanic["Sex", "Age"].groupby("Sex").mean()

Out[8]:

<table>
<thead>
<tr>
<th>Sex</th>
<th>Age</th>
</tr>
</thead>
<tbody>
<tr>
<td>female</td>
<td>27.915709</td>
</tr>
<tr>
<td>male</td>
<td>30.726645</td>
</tr>
</tbody>
</table>

As our interest is the average age for each gender, a subselection on these two columns is made first: `titanic["Sex", "Age"]`. Next, the `groupby()` method is applied on the `Sex` column to make a group per category. The average age for each gender is calculated and returned.

Calculating a given statistic (e.g. `mean` age) for each category in a column (e.g. male/female in the `Sex` column) is a common pattern. The `groupby` method is used to support this type of operations. More general, this fits in the more general split-apply-combine pattern:

- **Split** the data into groups
- **Apply** a function to each group independently
- **Combine** the results into a data structure

The apply and combine steps are typically done together in pandas.

In the previous example, we explicitly selected the 2 columns first. If not, the `mean` method is applied to each column containing numerical columns:

In [9]: titanic.groupby("Sex").mean()

Out[9]:

<table>
<thead>
<tr>
<th>Sex</th>
<th>PassengerId</th>
<th>Survived</th>
<th>Pclass</th>
<th>Age</th>
<th>SibSp</th>
<th>Parch</th>
<th>Fare</th>
</tr>
</thead>
<tbody>
<tr>
<td>female</td>
<td>431.028662</td>
<td>0.742038</td>
<td>2.159236</td>
<td>27.915709</td>
<td>0.694268</td>
<td>0.649682</td>
<td>44.479818</td>
</tr>
<tr>
<td>male</td>
<td>454.147314</td>
<td>0.188908</td>
<td>2.389948</td>
<td>30.726645</td>
<td>0.429809</td>
<td>0.235702</td>
<td>25.523893</td>
</tr>
</tbody>
</table>

It does not make much sense to get the average value of the `Pclass` if we are only interested in the average age for each gender, the selection of columns (rectangular brackets [ ] as usual) is supported on the grouped data as well:
In [10]: titanic.groupby("Sex")["Age"].mean()
Out[10]:
   Sex
female  27.915709
   male   30.726645
Name: Age, dtype: float64

Note: The Pclass column contains numerical data but actually represents 3 categories (or factors) with respectively the labels ‘1’, ‘2’ and ‘3’. Calculating statistics on these does not make much sense. Therefore, pandas provides a Categorical data type to handle this type of data. More information is provided in the user guide Categorical data section.

What is the mean ticket fare price for each of the sex and cabin class combinations?

In [11]: titanic.groupby(["Sex", "Pclass"])["Fare"].mean()
Out[11]:
   Sex Pclass
female 1   106.125798
      2    21.970121
      3    16.118810
male   1   67.226127
      2    19.741782
      3    12.661633
Name: Fare, dtype: float64

Grouping can be done by multiple columns at the same time. Provide the column names as a list to the groupby() method.

A full description on the split-apply-combine approach is provided in the user guide section on groupby operations.

Count number of records by category

What is the number of passengers in each of the cabin classes?

In [12]: titanic["Pclass"].value_counts()
Out[12]:
491
216
184
Name: Pclass, dtype: int64

The value_counts() method counts the number of records for each category in a column.

The function is a shortcut, as it is actually a groupby operation in combination with counting of the number of records within each group:

In [13]: titanic.groupby("Pclass")["Pclass"].count()
Out[13]:
   Pclass
1    216
2    184
pandas: powerful Python data analysis toolkit, Release 1.3.1

3 491
Name: Pclass, dtype: int64

Note: Both size and count can be used in combination with groupby. Whereas size includes NaN values and just provides the number of rows (size of the table), count excludes the missing values. In the value_counts method, use the dropna argument to include or exclude the NaN values.

The user guide has a dedicated section on value_counts, see page on discretization.

- Aggregation statistics can be calculated on entire columns or rows
- groupby provides the power of the split-apply-combine pattern
- value_counts is a convenient shortcut to count the number of entries in each category of a variable

A full description on the split-apply-combine approach is provided in the user guide pages about groupby operations.

In [1]: import pandas as pd

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- PassengerId: Id of every passenger.
- Survived: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- Pclass: There are 3 classes: Class 1, Class 2 and Class 3.
- Name: Name of passenger.
- Sex: Gender of passenger.
- Age: Age of passenger.
- SibSp: Indication that passenger have siblings and spouse.
- Parch: Whether a passenger is alone or have family.
- Ticket: Ticket number of passenger.
- Fare: Indicating the fare.
- Cabin: The cabin of passenger.
- Embarked: The embarked category.

In [2]: titanic = pd.read_csv("data/titanic.csv")

In [3]: titanic.head()

Out[3]:
    PassengerId  Survived  Pclass   Name                                      Sex  Age  SibSp  Parch Ticket  Fare Cabin Embarked
0            1         0       3  Braund, Mr. Owen Harris  male  22.0     1       0    A/5 21171  7.25 NaN     S
1            2         1       1  Cumings, Mrs. John Bradley (Florence Briggs Th... female 38.0     1       0     PC 17599  71.28 C85  C
2            3         0       3    Heikkinen, Miss. Laina  female 26.0     0       0 STON/O2. 3101282  7.92 NaN     S

4            5         0       3      Allen, Mr. William Henry  male 35.0     0       0   373450  8.05 NaN     S

40 Chapter 1. Getting started
This tutorial uses air quality data about $NO_2$ and Particulate matter less than 2.5 micrometers, made available by openaq and using the py-openaq package. The `air_quality_long.csv` data set provides $NO_2$ and $PM_{2.5}$ values for the measurement stations FR04014, BETR801 and London Westminster in respectively Paris, Antwerp and London.

The air-quality data set has the following columns:

- **city**: city where the sensor is used, either Paris, Antwerp or London
- **country**: country where the sensor is used, either FR, BE or GB
- **location**: the id of the sensor, either FR04014, BETR801 or London Westminster
- **parameter**: the parameter measured by the sensor, either $NO_2$ or Particulate matter
- **value**: the measured value
- **unit**: the unit of the measured parameter, in this case ‘$\mu g/m^3$’

and the index of the `DataFrame` is `datetime`, the datetime of the measurement.

**Note**: The air-quality data is provided in a so-called *long format* data representation with each observation on a separate row and each variable a separate column of the data table. The long/narrow format is also known as the tidy data format.

```python
In [4]: air_quality = pd.read_csv(
   ...: "data/air_quality_long.csv", index_col="date.utc", parse_dates=True
   ...:)
   ...

In [5]: air_quality.head()
Out[5]:
city country location parameter value unit
date.utc
2019-06-18 06:00:00+00:00 Antwerpen BE BETR801 pm25 18.0 µg/m$^3$
2019-06-17 08:00:00+00:00 Antwerpen BE BETR801 pm25 6.5 µg/m$^3$
2019-06-17 07:00:00+00:00 Antwerpen BE BETR801 pm25 18.5 µg/m$^3$
2019-06-17 06:00:00+00:00 Antwerpen BE BETR801 pm25 16.0 µg/m$^3$
2019-06-17 05:00:00+00:00 Antwerpen BE BETR801 pm25 7.5 µg/m$^3$
```

**How to reshape the layout of tables?**

**Sort table rows**

I want to sort the Titanic data according to the age of the passengers.

```python
In [6]: titanic.sort_values(by="Age").head()
Out[6]:
PassengerId Survived Pclass  Name     Sex  Age     SibSp  Parch Ticket  Fare  Cabin Embarked
803 804 1 3 Thomas, Master. Assad Alexander male 0.42  0 1 2625 8.5167 NaN    C
755 756 1 2 Hamalainen, Master. Viljo male 0.67  1 1 250649 14.5000 NaN   S
644 645 1 3 Baclini, Miss. Eugenie female 0.75  1 2 2666 19.2583 NaN    C
```

(continues on next page)
I want to sort the Titanic data according to the cabin class and age in descending order.

```python
In [7]: titanic.sort_values(by=['Pclass', 'Age'], ascending=False).head()
Out[7]:
    PassengerId  Survived  Pclass    Name       Sex   Age SibSp  
   851          0        3  Svensson, Mr. Johan   male  74.0    0  
   116          0        3    Connors, Mr. Patrick   male  70.5    0  
   280          0        3    Duane, Mr. Frank    male  65.0    0  
   483          0        3  Turkula, Mrs. (Hedwig) female  63.0    0  
   326          0        3  Nysveen, Mr. Johan Hansen   male  61.0    0  
```

With `Series.sort_values()`, the rows in the table are sorted according to the defined column(s). The index will follow the row order.

More details about sorting of tables is provided in the using guide section on sorting data.

### Long to wide table format

Let’s use a small subset of the air quality data set. We focus on \(NO_2\) data and only use the first two measurements of each location (i.e. the head of each group). The subset of data will be called `no2_subset`

```python
# filter for no2 data only
In [8]: no2 = air_quality[air_quality["parameter"] == "no2"]

# use 2 measurements (head) for each location (groupby)
In [9]: no2_subset = no2.sort_index().groupby(["location"]).head(2)

In [10]: no2_subset
Out[10]:
    city   country    location parameter    unit date.utc  
 0  Antwerpen     BE  BETR801        no2 m3  2019-04-09 01:00:00+00:00
 1  Paris         FR  FRG04014        no2 m3  2019-04-09 01:00:00+00:00
 2  London        GB  London Westminster no2 m3  2019-04-09 02:00:00+00:00
 3  Antwerpen     BE  BETR801        no2 m3  2019-04-09 02:00:00+00:00
 4  Paris         FR  FRG04014        no2 m3  2019-04-09 02:00:00+00:00
 5  London        GB  London Westminster no2 m3  2019-04-09 03:00:00+00:00
```

(continues on next page)
I want the values for the three stations as separate columns next to each other

```
In [11]: no2_subset.pivot(columns="location", values="value")
Out[11]:
   location     BETR801     FR04014  London  Westminster
date.utc    
2019-04-09 01:00:00+00:00    22.5    24.4        NaN    
2019-04-09 02:00:00+00:00    53.5    27.4    67.0    
2019-04-09 03:00:00+00:00   NaN    NaN    67.0    
```

The `pivot()` function is purely reshaping of the data: a single value for each index/column combination is required.

As pandas support plotting of multiple columns (see plotting tutorial) out of the box, the conversion from long to wide table format enables the plotting of the different time series at the same time:

```
In [12]: no2.head()
Out[12]:
   city country location parameter value unit
date.utc    
2019-06-21 00:00:00+00:00  Paris   FR   FR04014    no2     20.0  µg/m³
2019-06-20 23:00:00+00:00  Paris   FR   FR04014    no2     21.8  µg/m³
2019-06-20 22:00:00+00:00  Paris   FR   FR04014    no2     26.5  µg/m³
2019-06-20 21:00:00+00:00  Paris   FR   FR04014    no2     24.9  µg/m³
2019-06-20 20:00:00+00:00  Paris   FR   FR04014    no2     21.4  µg/m³
```

```
In [13]: no2.pivot(columns="location", values="value").plot()
Out[13]: <AxesSubplot:xlabel='date.utc'>
```

1.4. Tutorials
**Note:** When the `index` parameter is not defined, the existing index (row labels) is used.

For more information about `pivot()`, see the user guide section on **pivoting DataFrame objects**.

### Pivot table

I want the mean concentrations for $NO_2$ and $PM_{2.5}$ in each of the stations in table form.

```python
In [14]: air_quality.pivot_table(
    ....:     values="value", index="location", columns="parameter", aggfunc="mean"
    ....: )
    ....:
Out[14]:
          parameter    no2     pm25
    location             
    BETR801       26.950920  23.169492
    FR04014       29.374284    NaN
    London Westminster 29.740050  13.443568
```

In the case of `pivot()`, the data is only rearranged. When multiple values need to be aggregated (in this specific case, the values on different time steps) `pivot_table()` can be used, providing an aggregation function (e.g. mean).
on how to combine these values.

Pivot table is a well known concept in spreadsheet software. When interested in summary columns for each variable separately as well, put the margin parameter to True:

```
In [15]: air_quality.pivot_table(
       ...:     values="value",
       ...:     index="location",
       ...:     columns="parameter",
       ...:     aggfunc="mean",
       ...:     margins=True,
       ...: )
```

```
Out[15]:
<table>
<thead>
<tr>
<th>parameter</th>
<th>no2</th>
<th>pm25</th>
<th>All</th>
</tr>
</thead>
<tbody>
<tr>
<td>location</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>BETR801</td>
<td>26.950920</td>
<td>23.169492</td>
<td>24.982353</td>
</tr>
<tr>
<td>FR04014</td>
<td>29.374284</td>
<td>NaN</td>
<td>29.374284</td>
</tr>
<tr>
<td>All</td>
<td>29.430316</td>
<td>14.386849</td>
<td>24.222743</td>
</tr>
</tbody>
</table>
```

For more information about `pivot_table()`, see the user guide section on [pivot tables](https://pandas.pydata.org/docs/reference/api/pandas.DataFrame.pivot.html).

**Note:** In case you are wondering, `pivot_table()` is indeed directly linked to `groupby()`. The same result can be derived by grouping on both `parameter` and `location`:

```
air_quality.groupby(["parameter", "location"]).mean()
```

Have a look at `groupby()` in combination with `unstack()` at the user guide section on [combining stats and groupby](https://pandas.pydata.org/docs/reference/api/pandas.DataFrame.groupby.html).

### Wide to long format

Starting again from the wide format table created in the previous section:

```
In [16]: no2_pivoted = no2.pivot(columns="location", values="value").reset_index()
```

```
In [17]: no2_pivoted.head()
```

```
Out[17]:
<table>
<thead>
<tr>
<th>location</th>
<th>date.utc</th>
<th>BETR801</th>
<th>FR04014</th>
<th>London Westminster</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019-04-09</td>
<td>01:00:00+00:00</td>
<td>22.5</td>
<td>24.4</td>
<td>NaN</td>
</tr>
<tr>
<td>2019-04-09</td>
<td>02:00:00+00:00</td>
<td>53.5</td>
<td>27.4</td>
<td>67.0</td>
</tr>
<tr>
<td>2019-04-09</td>
<td>03:00:00+00:00</td>
<td>54.5</td>
<td>34.2</td>
<td>67.0</td>
</tr>
<tr>
<td>2019-04-09</td>
<td>04:00:00+00:00</td>
<td>34.5</td>
<td>48.5</td>
<td>41.0</td>
</tr>
<tr>
<td>2019-04-09</td>
<td>05:00:00+00:00</td>
<td>46.5</td>
<td>59.5</td>
<td>41.0</td>
</tr>
</tbody>
</table>
```

I want to collect all air quality $NO_2$ measurements in a single column (long format)

```
In [18]: no_2 = no2_pivoted.melt(id_vars="date.utc")
```

```
In [19]: no_2.head()
```

```
Out[19]:
<table>
<thead>
<tr>
<th>date.utc</th>
<th>location</th>
<th>value</th>
</tr>
</thead>
</table>
(continues on next page)
The pandas.melt() method on a DataFrame converts the data table from wide format to long format. The column headers become the variable names in a newly created column.

The solution is the short version on how to apply pandas.melt(). The method will melt all columns NOT mentioned in id_vars together into two columns: A column with the column header names and a column with the values itself. The latter column gets by default the name value.

The pandas.melt() method can be defined in more detail:

```python
In [20]: no_2 = no2_pivoted.melt(
       ...:     id_vars="date.utc",
       ...:     value_vars=["BETR801", "FR04014", "London Westminster"],
       ...:     value_name="NO_2",
       ...:     var_name="id_location",
       ...:     )

In [21]: no_2.head()
Out[21]:
       date.utc  id_location  NO_2
0 2019-04-09 01:00:00+00:00  BETR801   22.5
1 2019-04-09 02:00:00+00:00  BETR801   53.5
2 2019-04-09 03:00:00+00:00  BETR801   54.5
3 2019-04-09 04:00:00+00:00  BETR801   34.5
4 2019-04-09 05:00:00+00:00  BETR801   46.5
```

The result in the same, but in more detail defined:

- value_vars defines explicitly which columns to melt together
- value_name provides a custom column name for the values column instead of the default column name value
- var_name provides a custom column name for the column collecting the column header names. Otherwise it takes the index name or a default variable

Hence, the arguments value_name and var_name are just user-defined names for the two generated columns. The columns to melt are defined by id_vars and value_vars.

Conversion from wide to long format with pandas.melt() is explained in the user guide section on reshaping by melt.

- Sorting by one or more columns is supported by sort_values
- The pivot function is purely restructuring of the data, pivot_table supports aggregations
- The reverse of pivot (long to wide format) is melt (wide to long format)

A full overview is available in the user guide on the pages about reshaping and pivoting.

In [1]: import pandas as pd

For this tutorial, air quality data about NO₂ is used, made available by openaq and downloaded using the py-openaq package.
The `air_quality_no2_long.csv` data set provides \( NO_2 \) values for the measurement stations `FR04014`, `BETR801` and `London Westminster` in respectively Paris, Antwerp and London.

```python
In [2]: air_quality_no2 = pd.read_csv("data/air_quality_no2_long.csv",
...:             parse_dates=True)
...:
In [3]: air_quality_no2 = air_quality_no2[\{"date.utc", "location",
...:             "parameter", "value"\}]
...:
In [4]: air_quality_no2.head()
Out[4]:
   date.utc location parameter  value
0 2019-06-21 00:00:00+00:00  FR04014 no2  20.0
1 2019-06-20 23:00:00+00:00  FR04014 no2  21.8
2 2019-06-20 22:00:00+00:00  FR04014 no2  26.5
3 2019-06-20 21:00:00+00:00  FR04014 no2  24.9
4 2019-06-20 20:00:00+00:00  FR04014 no2  21.4
```

For this tutorial, air quality data about Particulate matter less than 2.5 micrometers is used, made available by `openaq` and downloaded using the `py-openaq` package.

The `air_quality_pm25_long.csv` data set provides \( PM_{25} \) values for the measurement stations `FR04014`, `BETR801` and `London Westminster` in respectively Paris, Antwerp and London.

```python
In [5]: air_quality_pm25 = pd.read_csv("data/air_quality_pm25_long.csv",
...:             parse_dates=True)
...:
In [6]: air_quality_pm25 = air_quality_pm25[\{"date.utc", "location",
...:             "parameter", "value"\}]
...:
In [7]: air_quality_pm25.head()
Out[7]:
   date.utc location parameter  value
0 2019-06-18 06:00:00+00:00  BETR801  pm25  18.0
1 2019-06-17 08:00:00+00:00  BETR801  pm25   6.5
2 2019-06-17 07:00:00+00:00  BETR801  pm25  18.5
3 2019-06-17 06:00:00+00:00  BETR801  pm25  16.0
4 2019-06-17 05:00:00+00:00  BETR801  pm25   7.5
```

**How to combine data from multiple tables?**

**Concatenating objects**

I want to combine the measurements of \( NO_2 \) and \( PM_{25} \), two tables with a similar structure, in a single table.

```python
In [8]: air_quality = pd.concat([air_quality_pm25, air_quality_no2], axis=0)
In [9]: air_quality.head()
Out[9]:
   date.utc location parameter  value
(continues on next page)```
The `concat()` function performs concatenation operations of multiple tables along one of the axis (row-wise or column-wise).

By default concatenation is along axis 0, so the resulting table combines the rows of the input tables. Let’s check the shape of the original and the concatenated tables to verify the operation:

```
In [10]: print('Shape of the ``air_quality_pm25`` table: ', air_quality_pm25.shape)
Shape of the ``air_quality_pm25`` table: (1110, 4)
In [11]: print('Shape of the ``air_quality_no2`` table: ', air_quality_no2.shape)
Shape of the ``air_quality_no2`` table: (2068, 4)
In [12]: print('Shape of the resulting ``air_quality`` table: ', air_quality.shape)
Shape of the resulting ``air_quality`` table: (3178, 4)
```

Hence, the resulting table has 3178 = 1110 + 2068 rows.

**Note:** The `axis` argument will return in a number of pandas methods that can be applied along an axis. A DataFrame has two corresponding axes: the first running vertically downwards across rows (axis 0), and the second running horizontally across columns (axis 1). Most operations like concatenation or summary statistics are by default across rows (axis 0), but can be applied across columns as well.

Sorting the table on the datetime information illustrates also the combination of both tables, with the parameter column defining the origin of the table (either no2 from table `air_quality_no2` or pm25 from table `air_quality_pm25`):

```
In [13]: air_quality = air_quality.sort_values("date.utc")
In [14]: air_quality.head()
Out[14]:
   date.utc location  parameter  value
  0 2067 2019-05-07 01:00:00+00:00 London Westminster no2  23.0
  1 1003 2019-05-07 01:00:00+00:00  FR04014 no2  25.0
  2 100 2019-05-07 01:00:00+00:00 BETR801 pm25  12.5
  3 1098 2019-05-07 01:00:00+00:00 BETR801 pm25  50.5
  4 1109 2019-05-07 01:00:00+00:00 London Westminster pm25  8.0
```

In this specific example, the parameter column provided by the data ensures that each of the original tables can be identified. This is not always the case. the `concat` function provides a convenient solution with the `keys` argument, adding an additional (hierarchical) row index. For example:

```
In [15]: air_quality_ = pd.concat([air_quality_pm25, air_quality_no2], keys=["PM25", ...
    ...: "NO2"])
In [16]: air_quality_.head()
Out[16]:
   date.utc location parameter  value
  PM25 0 2019-06-18 06:00:00+00:00 BETR801 pm25  18.0
```
Hierarchical indexing or MultiIndex is an advanced and powerful pandas feature to analyze higher dimensional data.

Multi-indexing is out of scope for this pandas introduction. For the moment, remember that the function `reset_index` can be used to convert any level of an index to a column, e.g. `air_quality.reset_index(level=0)`

Feel free to dive into the world of multi-indexing at the user guide section on advanced indexing.

More options on table concatenation (row and column wise) and how `concat` can be used to define the logic (union or intersection) of the indexes on the other axes is provided at the section on object concatenation.

### Join tables using a common identifier

Add the station coordinates, provided by the stations metadata table, to the corresponding rows in the measurements table.

**Warning:** The air quality measurement station coordinates are stored in a data file `air_quality_stations.csv`, downloaded using the `py-openaq` package.

Add the station coordinates, provided by the stations metadata table, to the corresponding rows in the measurements table.

```python
In [17]: stations_coord = pd.read_csv("data/air_quality_stations.csv")
In [18]: stations_coord.head()
Out[18]:
   location coordinates.latitude  coordinates.longitude
0  BELAL01         51.23619             4.38522
1  BELHB23         51.17030             4.34100
2  BELLD01         51.10998             5.00486
3  BELLD02         51.12038             5.02155
4  BELR833         51.32766             4.36226
```

**Note:** The stations used in this example (FR04014, BETR801 and London Westminster) are just three entries enlisted in the metadata table. We only want to add the coordinates of these three to the measurements table, each on the corresponding rows of the `air_quality` table.

```python
In [19]: air_quality.head()
Out[19]:
   date.utc location         parameter  value
2067 2019-05-07 01:00:00+00:00 London Westminster no2  23.0
1003 2019-05-07 01:00:00+00:00             FR04014  no2  25.0
100 2019-05-07 01:00:00+00:00 BETR801 pm25  12.5
1098 2019-05-07 01:00:00+00:00 BETR801 pm25  50.5
1109 2019-05-07 01:00:00+00:00 London Westminster pm25  8.0
```
In [20]: air_quality = pd.merge(air_quality, stations_coord, how="left", on="location")

In [21]: air_quality.head()
Out[21]:

<table>
<thead>
<tr>
<th>date.utc</th>
<th>location</th>
<th>parameter</th>
<th>value</th>
<th>coordinates.</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019-05-07 01:00:00+00:00</td>
<td>London Westminster</td>
<td>no2</td>
<td>23.0</td>
<td>51.0</td>
</tr>
<tr>

<td>51.0</td>
</tr>
</tbody>
</table>

Using the `merge()` function, for each of the rows in the `air_quality` table, the corresponding coordinates are added from the `air_quality_stations_coord` table. Both tables have the column `location` in common which is used as a key to combine the information. By choosing the `left` join, only the locations available in the `air_quality` (left) table, i.e. FR04014, BETR801 and London Westminster, end up in the resulting table. The `merge` function supports multiple join options similar to database-style operations.

Add the parameter full description and name, provided by the parameters metadata table, to the measurements table.

**Warning:** The air quality parameters metadata are stored in a data file `air_quality_parameters.csv`, downloaded using the `py-openaq` package.

In [22]: air_quality_parameters = pd.read_csv("data/air_quality_parameters.csv")

In [23]: air_quality_parameters.head()
Out[23]:

<table>

</tbody>
</table>
Compared to the previous example, there is no common column name. However, the parameter column in the air_quality table and the id column in the air_quality_parameters_name both provide the measured variable in a common format. The left_on and right_on arguments are used here (instead of just on) to make the link between the two tables.

pandas supports also inner, outer, and right joins. More information on join/merge of tables is provided in the user guide section on database style merging of tables. Or have a look at the comparison with SQL page.

- Multiple tables can be concatenated both column-wise and row-wise using the concat function.
- For database-like merging/joining of tables, use the merge function.

See the user guide for a full description of the various facilities to combine data tables.

```
In [1]: import pandas as pd
In [2]: import matplotlib.pyplot as plt
```

For this tutorial, air quality data about NO₂ and Particulate matter less than 2.5 micrometers is used, made available by openaq and downloaded using the py-openaq package. The air_quality_no2_long.csv data set provides NO₂ values for the measurement stations FR04014, BETR801 and London Westminster in respectively Paris, Antwerp and London.

```
In [3]: air_quality = pd.read_csv("data/air_quality_no2_long.csv")
In [4]: air_quality = air_quality.rename(columns={"date.utc": "datetime"})
In [5]: air_quality.head()
Out[5]:
   city country  datetime location  parameter  value unit
0  Paris    FR  2019-06-21 00:00:00+00:00   FR04014   no2    20.0 µg/m³
1  Paris    FR  2019-06-20 23:00:00+00:00   FR04014   no2    21.8 µg/m³
2  Paris    FR  2019-06-20 22:00:00+00:00   FR04014   no2    26.5 µg/m³
3  Paris    FR  2019-06-20 21:00:00+00:00   FR04014   no2    24.9 µg/m³
4  Paris    FR  2019-06-20 20:00:00+00:00   FR04014   no2    21.4 µg/m³
```

```
In [6]: air_quality.city.unique()
Out[6]: array(['Paris', 'Antwerpen', 'London'], dtype=object)
```

How to handle time series data with ease?

Using pandas datetime properties

I want to work with the dates in the column datetime as datetime objects instead of plain text

```
In [7]: air_quality["datetime"] = pd.to_datetime(air_quality["datetime"])
In [8]: air_quality["datetime"]
Out[8]:
0    2019-06-21 00:00:00+00:00
```

(continues on next page)
Initially, the values in `datetime` are character strings and do not provide any datetime operations (e.g. extract the year, day of the week...). By applying the `to_datetime` function, pandas interprets the strings and convert these to `datetime` (i.e. `datetime64[ns, UTC]`) objects. In pandas we call these datetime objects similar to `datetime`. datetime from the standard library as `pandas.Timestamp`.

Note: As many data sets do contain datetime information in one of the columns, pandas input function like `pandas.read_csv()` and `pandas.read_json()` can do the transformation to dates when reading the data using the `parse_dates` parameter with a list of the columns to read as Timestamp:

```python
pd.read_csv("../data/air_quality_no2_long.csv", parse_dates=["datetime")
```

Why are these `pandas.Timestamp` objects useful? Let’s illustrate the added value with some example cases.

What is the start and end date of the time series data set we are working with?

```python
In [9]: air_quality["datetime"].min(), air_quality["datetime"].max()
Out[9]:
(Timestamp('2019-05-07 01:00:00+0000', tz='UTC'),
 Timestamp('2019-06-21 00:00:00+0000', tz='UTC'))
```

Using `pandas.Timestamp` for datetimes enables us to calculate with date information and make them comparable. Hence, we can use this to get the length of our time series:

```python
In [10]: air_quality["datetime"].max() - air_quality["datetime"].min()
Out[10]: Timedelta('44 days 23:00:00')
```

The result is a `pandas.Timedelta` object, similar to `datetime.timedelta` from the standard Python library and defining a time duration.

The various time concepts supported by pandas are explained in the user guide section on time related concepts.

I want to add a new column to the DataFrame containing only the month of the measurement

```python
In [11]: air_quality["month"] = air_quality["datetime"].dt.month

In [12]: air_quality.head()
Out[12]:
   city country      datetime location  parameter  value  unit  month
0  Paris   FR 2019-06-21 00:00:00+00:00 FR04014  no2  20.0  µg/m³    6
1  Paris   FR 2019-06-20 23:00:00+00:00 FR04014  no2  21.8  µg/m³    6
2  Paris   FR 2019-06-20 22:00:00+00:00 FR04014  no2  26.5  µg/m³    6
3  Paris   FR 2019-06-20 21:00:00+00:00 FR04014  no2  24.9  µg/m³    6
4  Paris   FR 2019-06-20 20:00:00+00:00 FR04014  no2  21.4  µg/m³    6
```
By using Timestamp objects for dates, a lot of time-related properties are provided by pandas. For example the month, but also year, weekofyear, quarter,... All of these properties are accessible by the dt accessor.

An overview of the existing date properties is given in the time and date components overview table. More details about the dt accessor to return datetime like properties are explained in a dedicated section on the dt accessor.

What is the average $NO_2$ concentration for each day of the week for each of the measurement locations?

```
In [13]: air_quality.groupby(
        ....: [air_quality["datetime"].dt.weekday, "location"])["value"].mean()
Out[13]:
   datetime location             value
0  0  BETR801  27.875000
     FR04014  24.856250
     London Westminster  23.969697
1  1  BETR801  22.214286
     FR04014  30.999359
     London Westminster  24.977612
2  2  BETR801  21.896552
     FR04014  23.274306
     London Westminster  24.859155
     ...  
5  5  FR04014  25.266154
     London Westminster  24.977612
6  6  BETR801  21.896552
     FR04014  23.274306
     London Westminster  24.859155
Name: value, Length: 21, dtype: float64
```

Remember the split-apply-combine pattern provided by groupby from the tutorial on statistics calculation? Here, we want to calculate a given statistic (e.g. mean $NO_2$) for each weekday and for each measurement location. To group on weekdays, we use the datetime property weekday (with Monday=0 and Sunday=6) of pandas Timestamp, which is also accessible by the dt accessor. The grouping on both locations and weekdays can be done to split the calculation of the mean on each of these combinations.

**Danger:** As we are working with a very short time series in these examples, the analysis does not provide a long-term representative result!

Plot the typical $NO_2$ pattern during the day of our time series of all stations together. In other words, what is the average value for each hour of the day?

```
In [14]: fig, axs = plt.subplots(figsize=(12, 4))

In [15]: air_quality.groupby(air_quality["datetime"].dt.hour)["value"].mean().plot(
            ....: kind='bar', rot=0, ax=axs
            ....: )
Out[15]: <AxesSubplot:xlabel='datetime'>

In [16]: plt.xlabel("Hour of the day");  # custom x label using matplotlib
In [17]: plt.ylabel("$NO_2 (µg/m^3)$");
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

Similar to the previous case, we want to calculate a given statistic (e.g. mean 𝑁 𝑂2 ) for each hour of the day and
we can use the split-apply-combine approach again. For this case, we use the datetime property hour of pandas
Timestamp, which is also accessible by the dt accessor.
Datetime as index
In the tutorial on reshaping, pivot() was introduced to reshape the data table with each of the measurements
locations as a separate column:
In [18]: no_2 = air_quality.pivot(index="datetime", columns="location", values="value
˓→")
In [19]: no_2.head()
Out[19]:
location
datetime
2019-05-07 01:00:00+00:00
2019-05-07 02:00:00+00:00
2019-05-07 03:00:00+00:00
2019-05-07 04:00:00+00:00
2019-05-07 05:00:00+00:00

Note: By pivoting the data, the datetime information became the index of the table. In general, setting a column as
an index can be achieved by the set_index function.
Working with a datetime index (i.e. DatetimeIndex) provides powerful functionalities. For example, we do not
need the dt accessor to get the time series properties, but have these properties available on the index directly:
In [20]: no_2.index.year, no_2.index.weekday
Out[20]:
(Int64Index([2019, 2019, 2019, 2019, 2019, 2019, 2019, 2019, 2019, 2019,
...
dtype='int64', name='datetime', length=1033),
Int64Index([1, 1, 1, 1, 1, 1, 1, 1, 1, 1,
...
3, 3, 3, 3, 3, 3, 3, 3, 3, 4],
dtype='int64', name='datetime', length=1033))

54

Chapter 1. Getting started


Some other advantages are the convenient subsetting of time period or the adapted time scale on plots. Let’s apply this on our data.

Create a plot of the \(NO_2\) values in the different stations from the 20th of May till the end of 21st of May

```{=latex}
\textbf{In [21]}: no_2["2019-05-20":"2019-05-21"].plot();
```

By providing a string that parses to a datetime, a specific subset of the data can be selected on a DatetimeIndex. More information on the DatetimeIndex and the slicing by using strings is provided in the section on time series indexing.

**Resample a time series to another frequency**

Aggregate the current hourly time series values to the monthly maximum value in each of the stations.

```{=latex}
\textbf{In [22]}: \text{monthly\_max} = no_2\.resample("M").\text{max()}

\textbf{In [23]}: \text{monthly\_max}

\textbf{Out [23]}:

\begin{verbatim}
location     BETR801   FR04014  London Westminster
datetime     2019-05-31 00:00:00+00:00  74.5   97.0   97.0
             2019-06-30 00:00:00+00:00  52.5   84.7   52.0
\end{verbatim}
```
A very powerful method on time series data with a datetime index, is the ability to \texttt{resample()} time series to another frequency (e.g., converting secondly data into 5-minutely data).

The \texttt{resample()} method is similar to a groupby operation:

- it provides a time-based grouping, by using a string (e.g. M, 5H,...) that defines the target frequency
- it requires an aggregation function such as \texttt{mean}, \texttt{max}...

An overview of the aliases used to define time series frequencies is given in the \textit{offset aliases overview table}.

When defined, the frequency of the time series is provided by the \texttt{freq} attribute:

```python
In [24]: monthly_max.index.freq
Out[24]: <MonthEnd>
```

Make a plot of the daily mean $NO_2$ value in each of the stations.

```python
In [25]: no_2.resample("D").mean().plot(style="-o", figsize=(10, 5));
```

More details on the power of time series resampling is provided in the user guide section on \textit{resampling}.

- Valid date strings can be converted to datetime objects using \texttt{to_datetime} function or as part of read functions.
- Datetime objects in pandas support calculations, logical operations and convenient date-related properties using the \texttt{dt} accessor.
- A \texttt{DatetimeIndex} contains these date-related properties and supports convenient slicing.
- \texttt{Resample} is a powerful method to change the frequency of a time series.

A full overview on time series is given on the pages on \textit{time series and date functionality}.

```python
In [1]: import pandas as pd
```

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- PassengerId: Id of every passenger.
- Survived: This feature have value 0 and 1. 0 for not survived and 1 for survived.
• Pclass: There are 3 classes: Class 1, Class 2 and Class 3.
• Name: Name of passenger.
• Sex: Gender of passenger.
• Age: Age of passenger.
• SibSp: Indication that passenger have siblings and spouse.
• Parch: Whether a passenger is alone or have family.
• Ticket: Ticket number of passenger.
• Fare: Indicating the fare.
• Cabin: The cabin of passenger.
• Embarked: The embarked category.

```
In [2]: titanic = pd.read_csv("data/titanic.csv")
In [3]: titanic.head()
Out[3]:
PassengerId Survived  Pclass  Name                    
0 1 0 3  Braund, Mr. Owen Harris  
1 2 1 1  Cumings, Mrs. John Bradley (Florence Briggs Th...  
2 3 1 3  Heikkinen, Miss. Laina  
3 4 1 1  Futrelle, Mrs. Jacques Heath (Lily May Peel)  
4 5 0 3  Allen, Mr. William Henry  
... 886 887 888 889 890  
Name: Name, Length: 891, dtype: object
```

How to manipulate textual data?

Make all name characters lowercase.

```
In [4]: titanic["Name"].str.lower()
Out[4]:
0 braund, mr. owen harris  
1 cumings, mrs. john bradley (florence briggs th...  
2 heikkinen, miss. laina  
3 futrelle, mrs. jacques heath (lily may peel)  
4 allen, mr. william henry  
... 886 montvila, rev. juozas  
887 graham, miss. margaret edith  
888 johnston, miss. catherine helen "carrie"  
889 behr, mr. karl howell  
890 dooley, mr. patrick
Name: Name, Length: 891, dtype: object
```

To make each of the strings in the Name column lowercase, select the Name column (see the tutorial on selection of data), add the str accessor and apply the lower method. As such, each of the strings is converted element-wise.

Similar to datetime objects in the time series tutorial having a dt accessor, a number of specialized string methods are available when using the str accessor. These methods have in general matching names with the equivalent built-in

1.4. Tutorials 57
string methods for single elements, but are applied element-wise (remember *element-wise calculations*) on each of the values of the columns.

Create a new column `Surname` that contains the surname of the passengers by extracting the part before the comma.

```python
In [5]: titanic["Name"].str.split(",")
Out [5]:
0      [Braund, Mr. Owen Harris]
1    [Cumings, Mrs. John Bradley (Florence Briggs ...]
2      [Heikkinen, Miss. Laina]
3  [Futrelle, Mrs. Jacques Heath (Lily May Peel)]
4     [Allen, Mr. William Henry]
      ...
886  [Montvila, Rev. Juozas]
887   [Graham, Miss. Margaret Edith]
888 [Johnston, Miss. Catherine Helen "Carrie"]
889   [Behr, Mr. Karl Howell]
890   [Dooley, Mr. Patrick]
Name: Name, Length: 891, dtype: object
```

Using the `Series.str.split()` method, each of the values is returned as a list of 2 elements. The first element is the part before the comma and the second element is the part after the comma.

```python
In [6]: titanic["Surname"] = titanic["Name"].str.split(",").str.get(0)
In [7]: titanic["Surname"]
Out [7]:
0  Braund
1  Cumings
2  Heikkinen
3  Futrelle
4    Allen
      ...
886 Montvila
887  Graham
888   Johnston
889   Behr
890  Dooley
Name: Surname, Length: 891, dtype: object
```

As we are only interested in the first part representing the surname (element 0), we can again use the `str` accessor and apply `Series.str.get()` to extract the relevant part. Indeed, these string functions can be concatenated to combine multiple functions at once!

More information on extracting parts of strings is available in the user guide section on *splitting and replacing strings*.

Extract the passenger data about the countesses on board of the Titanic.

```python
In [8]: titanic["Name"].str.contains("Countess")
Out [8]:
0   False
1   False
2   False
3   False
4   False
      ...
886  False
887  False
888  False
```

(continues on next page)
889 False
890 False
Name: Name, Length: 891, dtype: bool

In [9]: titanic[titanic["Name"].str.contains("Countess")]
Out[9]:
   PassengerId  Survived  Pclass   Name                                                      
0            759       1       1  Rothes, the Countess. of (Lucy Noel Martha Dye... 
1            760   female   33.0  3 Rothes

(Interested in her story? See Wikipedia!)  
The string method Series.str.contains() checks for each of the values in the column Name if the string contains the word Countess and returns for each of the values True (Countess is part of the name) or False (Countess is not part of the name). This output can be used to subselect the data using conditional (boolean) indexing introduced in the subsetting of data tutorial. As there was only one countess on the Titanic, we get one row as a result.

Note: More powerful extractions on strings are supported, as the Series.str.contains() and Series.str.extract() methods accept regular expressions, but out of scope of this tutorial.

More information on extracting parts of strings is available in the user guide section on string matching and extracting. Which passenger of the Titanic has the longest name?

In [10]: titanic["Name"].str.len()
Out[10]:
0     23
1     51
2     22
3     44
4     24
     ...
886   21
887   28
888   40
889   21
890   19
Name: Name, Length: 891, dtype: int64

To get the longest name we first have to get the lengths of each of the names in the Name column. By using pandas string methods, the Series.str.len() function is applied to each of the names individually (element-wise).

In [11]: titanic["Name"].str.len().idxmax()
Out[11]: 307

Next, we need to get the corresponding location, preferably the index label, in the table for which the name length is the largest. The idxmax() method does exactly that. It is not a string method and is applied to integers, so no str is used.

In [12]: titanic.loc[titanic["Name"].str.len().idxmax(), "Name"]
Out[12]: 'Penasco y Castellana, Mrs. Victor de Satode (Maria Josefa Perez de Soto y... Vallejo)'

1.4. Tutorials
Based on the index name of the row (307) and the column (Name), we can do a selection using the `loc` operator, introduced in the tutorial on subsetting.

In the “Sex” column, replace values of “male” by “M” and values of “female” by “F”.

```
In [13]: titanic["Sex_short"] = titanic["Sex"].replace({"male": "M", "female": "F"})
```

```
In [14]: titanic["Sex_short"]
Out[14]:
   0   M
   1   F
   2   F
   3   F
   4   M
     ..
  886  M
  887  F
  888  F
  889  M
  890  M
Name: Sex_short, Length: 891, dtype: object
```

Whereas `replace()` is not a string method, it provides a convenient way to use mappings or vocabularies to translate certain values. It requires a dictionary to define the mapping `{from : to}`.

**Warning:** There is also a `replace()` method available to replace a specific set of characters. However, when having a mapping of multiple values, this would become:

```
titanic["Sex_short"] = titanic["Sex"].str.replace("female", "F")
titanic["Sex_short"] = titanic["Sex_short"].str.replace("male", "M")
```

This would become cumbersome and easily lead to mistakes. Just think (or try out yourself) what would happen if those two statements are applied in the opposite order…

- String methods are available using the `str` accessor.
- String methods work element-wise and can be used for conditional indexing.
- The `replace` method is a convenient method to convert values according to a given dictionary.

A full overview is provided in the user guide pages on working with text data.

### 1.4.4 Comparison with other tools

**Comparison with R / R libraries**

Since pandas aims to provide a lot of the data manipulation and analysis functionality that people use R for, this page was started to provide a more detailed look at the R language and its many third party libraries as they relate to pandas. In comparisons with R and CRAN libraries, we care about the following things:

- **Functionality / flexibility**: what can/cannot be done with each tool
- **Performance**: how fast are operations. Hard numbers/benchmarks are preferable
- **Ease-of-use**: Is one tool easier/harder to use (you may have to be the judge of this, given side-by-side code comparisons)

This page is also here to offer a bit of a translation guide for users of these R packages.
For transfer of DataFrame objects from pandas to R, one option is to use HDF5 files, see External compatibility for an example.

**Quick reference**

We’ll start off with a quick reference guide pairing some common R operations using dplyr with pandas equivalents.

**Querying, filtering, sampling**

<table>
<thead>
<tr>
<th>R</th>
<th>pandas</th>
</tr>
</thead>
<tbody>
<tr>
<td>dim(df)</td>
<td>df.shape</td>
</tr>
<tr>
<td>head(df)</td>
<td>df.head()</td>
</tr>
<tr>
<td>slice(df, 1:10)</td>
<td>df.ioc[:9]</td>
</tr>
<tr>
<td>filter(df, col1 == 1, col2 == 1)</td>
<td>df.query(&quot;col1 == 1 &amp; col2 == 1&quot;)</td>
</tr>
<tr>
<td>df[df$col1 == 1 &amp; df$col2 == 1]</td>
<td>df[(df.col1 == 1) &amp; (df.col2 == 1)]</td>
</tr>
<tr>
<td>select(df, col1, col2)</td>
<td>df[['col1', 'col2']]</td>
</tr>
<tr>
<td>select(df, col1:col3)</td>
<td>df.loc[:, 'col1':'col3']</td>
</tr>
<tr>
<td>select(df, -(col1:col3))</td>
<td>df.drop(cols_to_drop, axis=1) but see'</td>
</tr>
<tr>
<td>distinct(select(df, col1))</td>
<td>df[['col1']].drop_duplicates()</td>
</tr>
<tr>
<td>distinct(select(df, col1, col2))</td>
<td>df[['col1', 'col2']].drop_duplicates()</td>
</tr>
<tr>
<td>sample_n(df, 10)</td>
<td>df.sample(n=10)</td>
</tr>
<tr>
<td>sample_frac(df, 0.01)</td>
<td>df.sample(frac=0.01)</td>
</tr>
</tbody>
</table>

**Sorting**

<table>
<thead>
<tr>
<th>R</th>
<th>pandas</th>
</tr>
</thead>
<tbody>
<tr>
<td>arrange(df, col1, col2)</td>
<td>df.sort_values(['col1', 'col2'])</td>
</tr>
<tr>
<td>arrange(df, desc(col1))</td>
<td>df.sort_values('col1', ascending=False)</td>
</tr>
</tbody>
</table>

**Transforming**

<table>
<thead>
<tr>
<th>R</th>
<th>pandas</th>
</tr>
</thead>
<tbody>
<tr>
<td>select(df, col_one = col1)</td>
<td>df.rename(columns={'col1': 'col_one'})['col_one']</td>
</tr>
<tr>
<td>rename(df, col_one = col1)</td>
<td>df.rename(columns={'col1': 'col_one'})</td>
</tr>
<tr>
<td>mutate(df, c=a-b)</td>
<td>df.assign(c=df['a']-df['b'])</td>
</tr>
</tbody>
</table>

1 R’s shorthand for a subrange of columns (select(df, col1:col3)) can be approached cleanly in pandas, if you have the list of columns, for example df[cols[1:3]] or df.drop(cols[1:3]), but doing this by column name is a bit messy.
Grouping and summarizing

<table>
<thead>
<tr>
<th>R</th>
<th>pandas</th>
</tr>
</thead>
<tbody>
<tr>
<td>summary(df)</td>
<td>df.describe()</td>
</tr>
<tr>
<td>gdf &lt;- group_by(df, col1)</td>
<td>gdf = df.groupby('col1')</td>
</tr>
<tr>
<td>summarise(gdf, avg=mean(col1, na.rm=TRUE))</td>
<td>df.groupby('col1').agg({'col1': 'mean'})</td>
</tr>
<tr>
<td>summarise(gdf, total=sum(col1))</td>
<td>df.groupby('col1').sum()</td>
</tr>
</tbody>
</table>

Base R

Slicing with R's `c`

R makes it easy to access `data.frame` columns by name

```r
df <- data.frame(a=rnorm(5), b=rnorm(5), c=rnorm(5), d=rnorm(5), e=rnorm(5))
df[, c("a", "c", "e")]
```

or by integer location

```r
df <- data.frame(matrix(rnorm(1000), ncol=100))
df[, c(1:10, 25:30, 40, 50:100)]
```

Selecting multiple columns by name in pandas is straightforward

```python
In [1]: df = pd.DataFrame(np.random.randn(10, 3), columns=list("abc"))

In [2]: df["a", "c"]
Out[2]:
   a         c
0  0.469112 -1.509059
1 -1.135632 -0.173215
2  0.119209  0.861849
3 -2.104569  1.071804
4  0.721555 -1.039575
5  0.271860  0.567020
6  0.276232 -0.673690
7  0.113648  0.524988
8  0.404705 -1.715002
9 -1.039268 -1.157892

In [3]: df.loc[:, ["a", "c"]]
Out[3]:
   a         c
0  0.469112 -1.509059
1 -1.135632 -0.173215
2  0.119209  0.861849
3 -2.104569  1.071804
4  0.721555 -1.039575
5  0.271860  0.567020
6  0.276232 -0.673690
7  0.113648  0.524988
8  0.404705 -1.715002
9 -1.039268 -1.157892
```
Selecting multiple noncontiguous columns by integer location can be achieved with a combination of the `iloc` indexer attribute and `numpy.r_`.

```
In [4]: named = list("abcdefg")
In [5]: n = 30
In [6]: columns = named + np.arange(len(named), n).tolist()
In [7]: df = pd.DataFrame(np.random.randn(n, n), columns=columns)
In [8]: df.iloc[:, np.r_[:10, 24:30]]
Out[8]:
    a  b  c  d  e  f  g ...
0 -1.344312 0.844885 1.075770 -0.109050 1.643563 -1.469388 0.357021 ... -0.
1 -968914 -1.170299 -0.226169 0.410835 0.813850 0.132003 -0.827317 ...
2 -0.076467 -1.187678 1.130127 -1.436737 -1.413681 1.607920 1.024180 ...
... ...
24 0.725238 0.624607 -0.141185 -0.143948 -0.328162 2.095086 -0.608888 ...
25 1.492125 -0.068190 0.681456 1.221829 -0.434352 1.204815 -0.195612 ...
26 1.262419 1.950057 0.301038 -0.933858 0.814946 0.181439 -0.110015 ...
27 1.944517 0.423443 -0.141185 -0.143948 -0.328162 2.095086 -0.608888 ...
28 1.534623 0.190624 0.775807 1.008500 1.424017 0.717110 ...
29 1.534623 0.190624 0.775807 1.008500 1.424017 0.717110 ...
30 1.944517 0.423443 -0.141185 -0.143948 -0.328162 2.095086 -0.608888 ...
```

The `groupby()` method is similar to base R `aggregate` function.

```
In [9]: df = pd.DataFrame({
    ...:     ...:
```

(continues on next page)
In [10]: g = df.groupby(["by1", "by2"])

In [11]: g["v1", "v2"].mean()

Out[11]:

<table>
<thead>
<tr>
<th>by1</th>
<th>by2</th>
<th>v1</th>
<th>v2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>95</td>
<td>5.0</td>
<td>55.0</td>
</tr>
<tr>
<td>99</td>
<td>5.0</td>
<td>55.0</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>95</td>
<td>7.0</td>
<td>77.0</td>
</tr>
<tr>
<td>99</td>
<td>NaN</td>
<td>NaN</td>
<td></td>
</tr>
<tr>
<td>big</td>
<td>damp</td>
<td>3.0</td>
<td>33.0</td>
</tr>
<tr>
<td>blue</td>
<td>dry</td>
<td>3.0</td>
<td>33.0</td>
</tr>
<tr>
<td>red</td>
<td>red</td>
<td>4.0</td>
<td>44.0</td>
</tr>
<tr>
<td>wet</td>
<td>1.0</td>
<td>11.0</td>
<td></td>
</tr>
</tbody>
</table>

For more details and examples see the groupby documentation.

match / %in%

A common way to select data in R is using %in% which is defined using the function match. The operator %in% is used to return a logical vector indicating if there is a match or not:

```R
s <- 0:4
s %in% c(2, 4)
```

The isin() method is similar to R %in% operator:

```python
In [12]: s = pd.Series(np.arange(5), dtype=np.float32)

In [13]: s.isin([2, 4])
```

Out[13]:

<table>
<thead>
<tr>
<th>0</th>
<th>False</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>False</td>
</tr>
</tbody>
</table>
The `match` function returns a vector of the positions of matches of its first argument in its second:

```r
s <- 0:4
match(s, c(2,4))
```

For more details and examples see the reshaping documentation.

**tapply**

tapply is similar to `aggregate`, but data can be in a ragged array, since the subclass sizes are possibly irregular. Using a data.frame called `baseball`, and retrieving information based on the array `team`:

```r
baseball <-
data.frame(team = gl(5, 5,
  labels = paste("Team", LETTERS[1:5])),
  player = sample(letters, 25),
  batting.average = runif(25, .200, .400))
tapply(baseball$batting.average, baseball.example$team, max)
```

In pandas we may use `pivot_table()` method to handle this:

```python
In [14]: import random
In [15]: import string
In [16]: baseball = pd.DataFrame({
       "team": ["team %d" % (x + 1) for x in range(5)] * 5,
       "player": random.sample(list(string.ascii_lowercase), 25),
       "batting avg": np.random.uniform(0.200, 0.400, 25),
       })
In [17]: baseball.pivot_table(values="batting avg", columns="team", aggfunc=np.max)
Out[17]:
         team  team 1  team 2  team 3  team 4  team 5
batting avg 0.352134 0.295327 0.397191 0.394457 0.396194
```

For more details and examples see the reshaping documentation.
The `query()` method is similar to the base R `subset` function. In R you might want to get the rows of a `data.frame` where one column’s values are less than another column’s values:

```r
df <- data.frame(a=rnorm(10), b=rnorm(10))
subset(df, a < b)
df[df$a <= df$b,]  # note the comma
```

In pandas, there are a few ways to perform subsetting. You can use `query()` or pass an expression as if it were an index/slice as well as standard boolean indexing:

```python
In [18]: df = pd.DataFrame({"a": np.random.randn(10), "b": np.random.randn(10)})

In [19]: df.query("a <= b")
Out[19]:
   a   b
0  1.74950  0.552887
2 -0.023167  0.148084
3 -0.495291 -0.300218
4 -0.860736  0.197378
5 -1.334146  1.720780
6 -0.290098  0.083515
8  0.238636  0.946550

In [20]: df[df["a"] <= df["b"]]
Out[20]:
   a   b
0  1.74950  0.552887
2 -0.023167  0.148084
3 -0.495291 -0.300218
4 -0.860736  0.197378
5 -1.334146  1.720780
6 -0.290098  0.083515
8  0.238636  0.946550

In [21]: df.loc[df["a"] <= df["b"]]
Out[21]:
   a   b
0  1.74950  0.552887
2 -0.023167  0.148084
3 -0.495291 -0.300218
4 -0.860736  0.197378
5 -1.334146  1.720780
6 -0.290098  0.083515
8  0.238636  0.946550
```

For more details and examples see the `query documentation`. 

with

An expression using a data.frame called `df` in R with the columns `a` and `b` would be evaluated using `with` like so:

```r
df <- data.frame(a=rnorm(10), b=rnorm(10))
with(df, a + b)
df$a + df$b  # same as the previous expression
```

In pandas the equivalent expression, using the `eval()` method, would be:

```python
In [22]: df = pd.DataFrame({"a": np.random.randn(10), "b": np.random.randn(10)})
In [23]: df.eval("a + b")
Out[23]:
   0   -0.091430
   1   -2.483890
   2    0.252728
   3    0.626444
   4   -0.261740
   5    2.149503
   6   -0.332214
   7    0.799331
   8   -2.377245
   9    2.104677
dtype: float64

In [24]: df["a"] + df["b"]  # same as the previous expression
Out[24]:
   0   -0.091430
   1   -2.483890
   2    0.252728
   3    0.626444
   4   -0.261740
   5    2.149503
   6   -0.332214
   7    0.799331
   8   -2.377245
   9    2.104677
dtype: float64
```

In certain cases `eval()` will be much faster than evaluation in pure Python. For more details and examples see the `eval` documentation.

**plyr**

`plyr` is an R library for the split-apply-combine strategy for data analysis. The functions revolve around three data structures in R, `a` for arrays, `l` for lists, and `d` for `data.frame`. The table below shows how these data structures could be mapped in Python.

<table>
<thead>
<tr>
<th>R</th>
<th>Python</th>
</tr>
</thead>
<tbody>
<tr>
<td>array</td>
<td>list</td>
</tr>
<tr>
<td>lists</td>
<td>dictionary or list of objects</td>
</tr>
<tr>
<td>data.frame</td>
<td>dataframe</td>
</tr>
</tbody>
</table>
**ddply**

An expression using a data.frame called `df` in R where you want to summarize `x` by `month`:

```r
require(plyr)

df <- data.frame(
  x = runif(120, 1, 168),
  y = runif(120, 7, 334),
  z = runif(120, 1.7, 20.7),
  month = rep(c(5,6,7,8),30),
  week = sample(1:4, 120, TRUE)
)

ddply(df, .(month, week), summarize,
  mean = round(mean(x), 2),
  sd = round(sd(x), 2))
```

In pandas the equivalent expression, using the `groupby()` method, would be:

```python
In [25]: df = pd.DataFrame(
    .....:       
    .....:       "x": np.random.uniform(1.0, 168.0, 120),
    .....:       "y": np.random.uniform(7.0, 334.0, 120),
    .....:       "z": np.random.uniform(1.7, 20.7, 120),
    .....:       "month": [5, 6, 7, 8] * 30,
    .....:       "week": np.random.randint(1, 4, 120),
    .....:     }
    .....: )
    .....: 
    .....: 
In [26]: grouped = df.groupby(["month", "week"])

In [27]: grouped["x"].agg([np.mean, np.std])
```

```
Out[27]:
   mean      std
month week
5  1  63.653367  40.601965
  2  78.126605  53.342400
  3  92.091886  57.630110
6  1  81.747070  54.339218
  2  70.971205  54.687287
  3 100.968344  54.010081
7  1  61.576332  38.842474
  2  61.733510  48.209013
  3  71.688795  37.595638
8  1  62.741922  34.618153
  2  91.774627  49.790202
  3  73.936856  60.773900
```

For more details and examples see the `groupby` documentation.
reshape / reshape2

melt.array

An expression using a 3 dimensional array called `a` in R where you want to melt it into a data.frame:

```r
a <- array(c(1:23, NA), c(2,3,4))
data.frame(melt(a))
```

In Python, since `a` is a list, you can simply use list comprehension.

```python
In [28]: a = np.array(list(range(1, 24)) + [np.NAN]).reshape(2, 3, 4)

In [29]: pd.DataFrame([[tuple(list(x) + [val]) for x, val in np.ndenumerate(a)]]
```

```
Out[29]:
          0  1  2  3
0    0  0  0  1.0
1    0  0  1  2.0
2    0  2  0  3.0
3    0  0  3  4.0
4    0  1  0  5.0
         ... ...
19   1  1  3  20.0
20   1  2  0  21.0
21   1  2  1  22.0
22   1  2  2  23.0
23   1  2  3  NaN

[24 rows x 4 columns]
```

melt.list

An expression using a list called `a` in R where you want to melt it into a data.frame:

```r
a <- as.list(c(1:4, NA))
data.frame(melt(a))
```

In Python, this list would be a list of tuples, so `DataFrame()` method would convert it to a dataframe as required.

```python
In [30]: a = list(enumerate(list(range(1, 5)) + [np.NAN]))

In [31]: pd.DataFrame(a)
```

```
Out[31]:
   0 1
0 0 1.0
1 1 2.0
2 2 3.0
3 3 4.0
4 4 NaN
```

For more details and examples see the Into to Data Structures documentation.
melt.data.frame

An expression using a data.frame called cheese in R where you want to reshape the data.frame:

```r
cheese <- data.frame(
    first = c('John', 'Mary'),
    last = c('Doe', 'Bo'),
    height = c(5.5, 6.0),
    weight = c(130, 150)
)
melt(cheese, id=c("first", "last"))
```

In Python, the `melt()` method is the R equivalent:

```python
In [32]: cheese = pd.DataFrame(
    ....:     {
    ....:         "first": ["John", "Mary"],
    ....:         "last": ["Doe", "Bo"],
    ....:         "height": [5.5, 6.0],
    ....:         "weight": [130, 150],
    ....:     }
    ....: )
    ....:
In [33]: pd.melt(cheese, id_vars=["first", "last"])
Out[33]:
    first last variable  value
   0  John  Doe   height    5.5
   1  Mary   Bo   height    6.0
   2  John  Doe   weight  130.0
   3  Mary   Bo   weight  150.0

In [34]: cheese.set_index(["first", "last"]).stack()  # alternative way
Out[34]:
    first last
  John  Doe   height    5.5
       weight  130.0
  Mary  Bo    height    6.0
       weight  150.0
dtype: float64
```

For more details and examples see the reshaping documentation.

cast

In R `acast` is an expression using a data.frame called df in R to cast into a higher dimensional array:

```r
df <- data.frame(
    x = runif(12, 1, 168),
    y = runif(12, 7, 334),
    z = runif(12, 1.7, 20.7),
    month = rep(c(5,6,7),4),
    week = rep(c(1,2, 6)
    )
```

(continues on next page)
In Python the best way is to make use of \texttt{pivot_table()}: 

\begin{verbatim}
In [35]: df = pd.DataFrame(
    ....:     { 
    ....:         "x": np.random.uniform(1.0, 168.0, 12),
    ....:         "y": np.random.uniform(7.0, 334.0, 12),
    ....:         "z": np.random.uniform(1.7, 20.7, 12),
    ....:         "month": [5, 6, 7] * 4,
    ....:         "week": [1, 2] * 6,
    ....:     } 
    ....: )

In [36]: mdf = pd.melt(df, id_vars=["month", "week"])

In [37]: pd.pivot_table(
    ....:     mdf,
    ....:     values="value",
    ....:     index=["variable", "week"],
    ....:     columns=["month"],
    ....:     aggfunc=np.mean,
    ....:     )
\end{verbatim}

\begin{verbatim}
Out[37]:
   month 5 6 7
variable week
   x      93.888747 98.762034 55.219673
   2     94.391427 38.112932 83.942781
   y      94.306912 279.454811 227.840449
   2     87.392662 193.028166 173.899260
   z      11.016009 10.079307 16.170549
   2     8.476111 17.638509 19.003494
\end{verbatim}

Similarly for \texttt{dcast} which uses a data.frame called \texttt{df} in R to aggregate information based on \texttt{Animal} and \texttt{FeedType}:

\begin{verbatim}
df <- data.frame(
  Animal = c('Animal1', 'Animal2', 'Animal3', 'Animal2', 'Animal1',
             'Animal2', 'Animal3'),
  FeedType = c('A', 'B', 'A', 'A', 'B', 'B', 'A'),
  Amount = c(10, 7, 4, 2, 5, 6, 2)
)

dcast(df, Animal ~ FeedType, sum, fill=NaN)
# Alternative method using base R
with(df, tapply(Amount, list(Animal, FeedType), sum))
\end{verbatim}

Python can approach this in two different ways. Firstly, similar to above using \texttt{pivot_table()}: 

\begin{verbatim}
In [38]: df = pd.DataFrame(
    ....:     {
    ....:         "Animal": [
    ....:             "Animal1",
    ....:         ]
    ....: )
\end{verbatim}
In [39]: df.pivot_table(values="Amount", index="Animal", columns="FeedType", aggfunc="sum")
Out[39]:

<table>
<thead>
<tr>
<th>Animal</th>
<th>FeedType</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A</td>
</tr>
<tr>
<td>Animal1</td>
<td>10.0</td>
</tr>
<tr>
<td>Animal2</td>
<td>2.0</td>
</tr>
<tr>
<td>Animal3</td>
<td>6.0</td>
</tr>
</tbody>
</table>

The second approach is to use the `groupby()` method:

In [40]: df.groupby(["Animal", "FeedType"])["Amount"].sum()
Out[40]:

<table>
<thead>
<tr>
<th>Animal</th>
<th>FeedType</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A</td>
</tr>
<tr>
<td>Animal1</td>
<td>10</td>
</tr>
<tr>
<td>Animal2</td>
<td>2</td>
</tr>
<tr>
<td>Animal3</td>
<td>6</td>
</tr>
</tbody>
</table>

Name: Amount, dtype: int64

For more details and examples see the reshaping documentation or the groupby documentation.

factor

pandas has a data type for categorical data.

cut(c(1,2,3,4,5,6), 3)
factor(c(1,2,3,2,2,3))

In pandas this is accomplished with `pd.cut` and `astype("category")`:

In [41]: pd.cut(pd.Series([1, 2, 3, 4, 5, 6]), 3)
Out[41]:

<table>
<thead>
<tr>
<th></th>
<th>0 (0.995, 2.667]</th>
<th>1 (0.995, 2.667]</th>
<th>2 (2.667, 4.333]</th>
<th>3 (2.667, 4.333]</th>
<th>4 (4.333, 6.0]</th>
<th>5 (4.333, 6.0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.995, 2.667</td>
<td>0.995, 2.667</td>
<td>2.667, 4.333</td>
<td>2.667, 4.333</td>
<td>4.333, 6.0</td>
<td>4.333, 6.0</td>
</tr>
<tr>
<td>1</td>
<td>2.667, 4.333</td>
<td>2.667, 4.333</td>
<td>4.333, 6.0</td>
<td>4.333, 6.0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>4.333, 6.0</td>
<td>4.333, 6.0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

dtype: category
Categories (3, interval[float64, right]): [(0.995, 2.667] < (2.667, 4.333] < (4.333, 6.0]
In [42]: pd.Series([1, 2, 3, 2, 2, 3]).astype("category")
Out[42]:
0 1
1 2
2 3
3 2
4 2
5 3
dtype: category
Categories (3, int64): [1, 2, 3]

For more details and examples see categorical introduction and the API documentation. There is also a documentation regarding the differences to R’s factor.

Comparison with SQL

Since many potential pandas users have some familiarity with SQL, this page is meant to provide some examples of how various SQL operations would be performed using pandas.

If you’re new to pandas, you might want to first read through 10 Minutes to pandas to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```python
In [1]: import pandas as pd
In [2]: import numpy as np
```

Most of the examples will utilize the tips dataset found within pandas tests. We’ll read the data into a DataFrame called tips and assume we have a database table of the same name and structure.

```python
In [3]: url = (
...:   "https://raw.github.com/pandas-dev/
...:   "pandas/master/pandas/tests/io/data/csv/tips.csv"
...: )
...:
In [4]: tips = pd.read_csv(url)
In [5]: tips
Out[5]:
   total_bill  tip  sex  smoker  day  time  size
0     16.99  1.01  Female    No  Sun  Dinner   2
1     10.34  1.66    Male     No  Sun  Dinner   3
2     21.01  3.50    Male     No  Sun  Dinner   3
3     23.68  3.31    Male     No  Sun  Dinner   2
4     24.59  3.61  Female    No  Sun  Dinner   4
          ...    ...    ...    ...    ...    ...
239   29.03  5.92    Male     No  Sat  Dinner   3
240   27.18  2.00  Female     Yes  Sat  Dinner   2
241   22.67  2.00    Male     Yes  Sat  Dinner   2
242   17.82  1.75    Male     No  Sat  Dinner   2
243   18.78  3.00  Female    No  Thur  Dinner   2
[244 rows x 7 columns]
```
Covers vs. in place operations

Most pandas operations return copies of the Series/DataFrame. To make the changes “stick”, you’ll need to either assign to a new variable:

```
sorted_df = df.sort_values("col1")
```

or overwrite the original one:

```
df = df.sort_values("col1")
```

**Note:** You will see an `inplace=True` keyword argument available for some methods:

```
df.sort_values("col1", inplace=True)
```

Its use is discouraged. *More information.*

**SELECT**

In SQL, selection is done using a comma-separated list of columns you’d like to select (or a * to select all columns):

```
SELECT total_bill, tip, smoker, time
FROM tips;
```

With pandas, column selection is done by passing a list of column names to your DataFrame:

```python
In [6]: tips["total_bill", "tip", "smoker", "time"]
```

```
Out[6]:
     total_bill   tip  smoker  time
0  16.990000  1.010000   No  Dinner
1  10.338000  1.660000   No  Dinner
2  21.008000  3.500000   No  Dinner
3  23.688000  3.310000   No  Dinner
4  24.592000  3.610000   No  Dinner
..       ...     ...    ...     ...
239  29.032000  5.920000   No  Dinner
240  27.178000  2.000000   Yes Dinner
241  22.668000  2.000000   Yes Dinner
242  17.822000  1.750000   No  Dinner
243  18.778000  3.000000   No  Dinner

[244 rows x 4 columns]
```

Calling the DataFrame without the list of column names would display all columns (akin to SQL’s *).

In SQL, you can add a calculated column:

```
SELECT *, tip/total_bill as tip_rate
FROM tips;
```

With pandas, you can use the `DataFrame.assign()` method of a DataFrame to append a new column:
In [7]: tips.assign(tip_rate=tips["tip"] / tips["total_bill"])

Out[7]:

<table>
<thead>
<tr>
<th>total_bill</th>
<th>tip</th>
<th>sex</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
<th>tip_rate</th>
</tr>
</thead>
<tbody>
<tr>

<td>0.159744</td>
</tr>
</tbody>
</table>

[244 rows x 8 columns]

WHERE

Filtering in SQL is done via a WHERE clause.

SELECT *
FROM tips
WHERE time = 'Dinner';

DataFrames can be filtered in multiple ways; the most intuitive of which is using boolean indexing.

In [8]: tips[tips["total_bill"] > 10]

Out[8]:

<table>
<thead>
<tr>
<th>total_bill</th>
<th>tip</th>
<th>sex</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>16.99</td>
<td>1.01</td>
<td>Female</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>2</td>
</tr>
<tr>
<td>10.34</td>
<td>1.66</td>
<td>Male</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>3</td>
</tr>
<tr>
<td>21.01</td>
<td>3.50</td>
<td>Male</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>3</td>
</tr>
<tr>
<td>23.68</td>
<td>3.31</td>
<td>Male</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>2</td>
</tr>
<tr>
<td>24.59</td>
<td>3.61</td>
<td>Female</td>
<td>No</td>
<td>Sun</td>
<td>Dinner</td>
<td>4</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>29.03</td>
<td>5.92</td>
<td>Male</td>
<td>No</td>
<td>Sat</td>
<td>Dinner</td>
<td>3</td>
</tr>
<tr>
<td>27.18</td>
<td>2.00</td>
<td>Female</td>
<td>Yes</td>
<td>Sat</td>
<td>Dinner</td>
<td>2</td>
</tr>
<tr>
<td>22.67</td>
<td>2.00</td>
<td>Male</td>
<td>Yes</td>
<td>Sat</td>
<td>Dinner</td>
<td>2</td>
</tr>
<tr>
<td>18.78</td>
<td>1.75</td>
<td>Male</td>
<td>No</td>
<td>Sat</td>
<td>Dinner</td>
<td>2</td>
</tr>
<tr>
<td>243 18.78</td>
<td>3.00</td>
<td>Female</td>
<td>No</td>
<td>Thur</td>
<td>Dinner</td>
<td>2</td>
</tr>
</tbody>
</table>

[227 rows x 7 columns]

The above statement is simply passing a Series of True/False objects to the DataFrame, returning all rows with True.

In [9]: is_dinner = tips["time"] == "Dinner"

In [10]: is_dinner

Out[10]:

<p>| | |</p>
<table>
<thead>
<tr>

243   True
Name: time, Length: 244, dtype: bool

In [11]: is_dinner.value_counts()
Out[11]:
True   176
False   68
Name: time, dtype: int64

In [12]: tips[is_dinner]
Out[12]:
  total_bill  tip  sex  smoker  day  time  size
0     16.99  1.01  Female     No  Sun   Dinner   2
1     10.34  1.66    Male     No  Sun   Dinner   3
2     21.01  3.50    Male     No  Sun   Dinner   3
3     23.68  3.31    Male     No  Sun   Dinner   2
4     24.59  3.61  Female     No  Sun   Dinner   4
...     ...   ...     ...     ...     ...     ...
239   29.03  5.92    Male     No  Sat   Dinner   3
240   27.18  2.00  Female     Yes  Sat   Dinner   2
241   22.67  2.00    Male     Yes  Sat   Dinner   2
242   17.82  1.75    Male     Yes  Sat   Dinner   2
243   18.78  3.00  Female     Yes  Thur  Dinner   2
[176 rows x 7 columns]

Just like SQL's `OR` and `AND`, multiple conditions can be passed to a DataFrame using `|` (OR) and `&` (AND).

Tips of more than $5 at Dinner meals:

```
SELECT *
FROM tips
WHERE time = 'Dinner' AND tip > 5.00;
```

In [13]: tips[(tips['time'] == 'Dinner') & (tips['tip'] > 5.00)]
Out[13]:
  total_bill  tip  sex  smoker  day  time  size
 23     39.42  7.58    Male     No  Sat   Dinner   4
 44     30.40  5.60    Male     No  Sun   Dinner   4
 47     32.40  6.00    Male     No  Sun   Dinner   4
 52     34.81  5.20  Female     No  Sun   Dinner   4
 59     48.27  6.73    Male     No  Sat   Dinner   4
116    29.93  5.07    Male     No  Sun   Dinner   4
155    29.85  5.14  Female     No  Sun   Dinner   4
170    50.81 10.00  Female     Yes  Sat   Dinner   3
172     7.25  5.15    Male     Yes  Sun   Dinner   2
181    23.33  5.65  Female     Yes  Sun   Dinner   2
183    23.17  6.50    Male     Yes  Sun   Dinner   4
211    25.89  5.16    Male     Yes  Sat   Dinner   4
212    48.33  9.00    Male     No  Sat   Dinner   4
214    28.17  6.50  Female     Yes  Sat   Dinner   3
```
Tips by parties of at least 5 diners OR bill total was more than $45:

```sql
SELECT *
FROM tips
WHERE size >= 5 OR total_bill > 45;
```

```python
In [14]: tips[(tips['size'] >= 5) | (tips['total_bill'] > 45)]
Out[14]:
     total_bill  tip  sex  smoker  day   time  size
   0      59.00  6.73  Male    No   Sat  Dinner   4
  125   125.00  4.20  Female    No   Thur  Lunch   6
   141   141.00  6.70  Male    No   Thur  Lunch   6
   142   142.00  5.00  Male    No   Thur  Lunch   5
   143   143.00  5.00  Female    No   Thur  Lunch   6
   155   155.00  5.14  Female    No   Sun   Dinner   5
   156   156.00  5.00  Male    No   Sun   Dinner   6
   170   170.00 10.00  Male   Yes   Sat  Dinner   3
   182   182.00  3.50  Male   Yes   Sun  Dinner   3
   185   185.00  5.00  Male    No   Sun   Dinner   5
   187   187.00  2.00  Male   Yes   Sun  Dinner   5
   212   212.00  9.00  Male    No  Sat   Dinner   4
   216   216.00  3.00  Male    No  Sat   Dinner   5
```

NULL checking is done using the `notna()` and `isna()` methods.

```python
In [15]: frame = pd.DataFrame(
    ...: )
    ...:
In [16]: frame
Out[16]:
     col1 col2
    0     A   F
    1     B  NaN
    2   NaN   G
    3     C   H
    4     D   I

Assume we have a table of the same structure as our DataFrame above. We can see only the records where `col2` IS NULL with the following query:

```sql
SELECT *
FROM frame
WHERE col2 IS NULL;
```

```python
In [17]: frame[frame["col2"].isna()]
Out[17]:
     col1 col2
    0     A   F
    1     B  NaN
```

Getting items where `col1` IS NOT NULL can be done with `notna()`.
**GROUP BY**

In pandas, SQL’s `GROUP BY` operations are performed using the similarly named `groupby()` method. `groupby()` typically refers to a process where we’d like to split a dataset into groups, apply some function (typically aggregation), and then combine the groups together.

A common SQL operation would be getting the count of records in each group throughout a dataset. For instance, a query getting us the number of tips left by sex:

```sql
SELECT sex, count(*)
FROM tips
GROUP BY sex;
/*
Female 87
Male 157
*/
```

The pandas equivalent would be:

```python
In [19]: tips.groupby("sex").size()
Out[19]:
   sex
Female    87
   Male    157
```

Notice that in the pandas code we used `size()` and not `count()`. This is because `count()` applies the function to each column, returning the number of `NOT NULL` records within each.

```python
In [20]: tips.groupby("sex").count()
Out[20]:
   sex
          total_bill  tip  smoker  day  time  size
Female     87      87      87      87      87      87
Male       157     157     157     157     157     157
```

Alternatively, we could have applied the `count()` method to an individual column:

```python
In [21]: tips.groupby("sex")["total_bill"]["count()"
Out[21]:
   sex
Female    87
   Male    157
```

Name: total_bill, dtype: int64
Multiple functions can also be applied at once. For instance, say we’d like to see how tip amount differs by day of the week - `agg()` allows you to pass a dictionary to your grouped DataFrame, indicating which functions to apply to specific columns.

```sql
SELECT day, AVG(tip), COUNT(*)
FROM tips
GROUP BY day;
/*
Fri  2.734737    19
Sat  2.993103    87
Sun  3.255132    76
Thu  2.771452    62
*/
```

```python
In [22]: tips.groupby("day").agg({"tip": np.mean, "day": np.size})
Out[22]:
         tip  day
    day
Fri  2.734737  19
Sat  2.993103  87
Sun  3.255132  76
Thu  2.771452  62
```

Grouping by more than one column is done by passing a list of columns to the `groupby()` method.

```sql
SELECT smoker, day, COUNT(*), AVG(tip)
FROM tips
GROUP BY smoker, day;
/*
smoker  day
No  Fri   4  2.812500
  Sat  45  3.102889
  Sun  57  3.167895
  Thu  45  2.673778
Yes Fri   15 2.714000
  Sat  42  2.875476
  Sun  19  3.516842
  Thu  17  3.030000
*/
```

```python
In [23]: tips.groupby(["smoker", "day"]).agg({"tip": [np.size, np.mean]})
Out[23]:
         tip   size  mean
    size
smoker day
No  Fri   4  2.812500
    Sat  45  3.102889
    Sun  57  3.167895
    Thu  45  2.673778
Yes Fri  15  2.714000
    Sat  42  2.875476
    Sun  19  3.516842
    Thu  17  3.030000
```
JOIN

JOINs can be performed with `join()` or `merge()`. By default, `join()` will join the DataFrames on their indices. Each method has parameters allowing you to specify the type of join to perform (LEFT, RIGHT, INNER, FULL) or the columns to join on (column names or indices).

```python
In [24]: df1 = pd.DataFrame({"key": ["A", "B", "C", "D"], "value": np.random.randn(4)})
   ...: 
In [25]: df2 = pd.DataFrame({"key": ["B", "D", "D", "E"], "value": np.random.randn(4)})
```

Assume we have two database tables of the same name and structure as our DataFrames.
Now let’s go over the various types of JOINs.

INNER JOIN

```sql
SELECT *
FROM df1
INNER JOIN df2
  ON df1.key = df2.key;
```

```python
# merge performs an INNER JOIN by default
In [26]: pd.merge(df1, df2, on="key")
Out[26]:
   key  value_x  value_y
0   B  -0.282863  1.212112
1   D  -1.135632  0.119209
2   D  -1.135632 -0.173215
```

`merge()` also offers parameters for cases when you’d like to join one DataFrame’s column with another DataFrame’s index.

```python
In [27]: indexed_df2 = df2.set_index("key")
In [28]: pd.merge(df1, indexed_df2, left_on="key", right_index=True)
Out[28]:
   key  value_x  value_y
0   B -0.282863  1.212112
1   D -1.135632 -0.173215
2   D -1.135632  0.119209
```

LEFT OUTER JOIN

Show all records from df1.

```sql
SELECT *
FROM df1
LEFT OUTER JOIN df2
  ON df1.key = df2.key;
```
In [29]: pd.merge(df1, df2, on="key", how="left")
Out[29]:
   key  value_x  value_y
0   A    0.469112   NaN
1   B   -0.282863  1.212112
2   C   -1.509059   NaN
3   D  -1.135632 -0.173215
4   D  -1.135632  0.119209

RIGHT JOIN

Show all records from df2.

```
SELECT *
FROM df1
RIGHT OUTER JOIN df2
  ON df1.key = df2.key;
```

In [30]: pd.merge(df1, df2, on="key", how="right")
Out[30]:
   key  value_x  value_y
0   B   -0.282863  1.212112
1   D  -1.135632 -0.173215
2   D  -1.135632  0.119209
3   E   NaN   -1.044236

FULL JOIN

pandas also allows for FULL JOINs, which display both sides of the dataset, whether or not the joined columns find a match. As of writing, FULL JOINs are not supported in all RDBMS (MySQL).

Show all records from both tables.

```
SELECT *
FROM df1
FULL OUTER JOIN df2
  ON df1.key = df2.key;
```

In [31]: pd.merge(df1, df2, on="key", how="outer")
Out[31]:
   key  value_x  value_y
0   A    0.469112   NaN
1   B   -0.282863  1.212112
2   C   -1.509059   NaN
3   D  -1.135632 -0.173215
4   D  -1.135632  0.119209
5   E   NaN   -1.044236
UNION

UNION ALL can be performed using `concat()`.

```python
In [32]: df1 = pd.DataFrame(
    ....:     {"city": ["Chicago", "San Francisco", "New York City"], "rank": range(1, 4)}
    ....: )
    ....:

In [33]: df2 = pd.DataFrame(
    ....:     {"city": ["Chicago", "Boston", "Los Angeles"], "rank": [1, 4, 5]}
    ....: )
    ....:

SELECT city, rank
FROM df1
UNION ALL
SELECT city, rank
FROM df2;
/*
city rank
Chicago 1
San Francisco 2
New York City 3
Chicago 1
Boston 4
Los Angeles 5
*/

In [34]: pd.concat([df1, df2])
Out[34]:
       city  rank
0    Chicago     1
1  San Francisco     2
2  New York City     3
0    Chicago     1
1   Boston      4
2  Los Angeles     5

SQL's UNION is similar to UNION ALL, however UNION will remove duplicate rows.

```python
SELECT city, rank
FROM df1
UNION
SELECT city, rank
FROM df2;
-- notice that there is only one Chicago record this time
/*
city rank
Chicago 1
San Francisco 2
New York City 3
Boston 4
Los Angeles 5
*/
```

In pandas, you can use `concat()` in conjunction with `drop_duplicates()`.
In [35]: pd.concat([df1, df2]).drop_duplicates()
Out[35]:
          city  rank
0  Chicago     1
1  San Francisco     2
2 New York City     3
1   Boston     4
2 Los Angeles     5

LIMIT

SELECT * FROM tips
LIMIT 10;

In [36]: tips.head(10)
Out[36]:
         total_bill  tip     sex  smoker  day    time  size
0      16.99     1.01 Female  No    Sun  Dinner    2
1      10.34     1.66   Male  No    Sun  Dinner    3
2      21.01     3.50   Male  No    Sun  Dinner    3
3      23.68     3.11   Male  No    Sun  Dinner    2
4      24.59     3.61 Female  No    Sun  Dinner    4
5      25.29     4.71   Male  No    Sun  Dinner    4
6       8.77     2.00   Male  No    Sun  Dinner    2
7      26.88     3.12   Male  No    Sun  Dinner    4
8      15.04     1.96   Male  No    Sun  Dinner    2
9      14.78     3.23   Male  No    Sun  Dinner    2

```
-- Oracle’s RANK() analytic function

```sql
SELECT * FROM (  
    SELECT  
        t.*,  
        RANK() OVER(PARTITION BY sex ORDER BY tip) AS rnk  
    FROM tips t  
    WHERE tip < 2  
)  
WHERE rnk < 3  
ORDER BY sex, rnk;
```

Let’s find tips with (rank < 3) per gender group for (tips < 2). Notice that when using `rank(method='min')` function `rnk_min` remains the same for the same `tip` (as Oracle’s RANK() function)

```plain
In [40]: (  
    ....:     tips[tips["tip"] < 2]  
    ....:     .assign(rnk_min=tips.groupby(["sex"])["tip"].rank(method="min"))  
    ....:     .query("rnk_min < 3")  
    ....:     .sort_values(["sex", "rnk_min")  
    ....: )  
    ....:
Out[40]:

**UPDATE**

```sql
UPDATE tips
SET tip = tip*2
WHERE tip < 2;
```

```python
In [41]: tips.loc[tips["tip"] < 2, "tip"] *= 2
```

**DELETE**

```sql
DELETE FROM tips
WHERE tip > 9;
```

In pandas we select the rows that should remain instead of deleting them:

```python
In [42]: tips = tips.loc[tips["tip"] <= 9]
```
Comparison with spreadsheets

Since many potential pandas users have some familiarity with spreadsheet programs like Excel, this page is meant to provide some examples of how various spreadsheet operations would be performed using pandas. This page will use terminology and link to documentation for Excel, but much will be the same/similar in Google Sheets, LibreOffice Calc, Apple Numbers, and other Excel-compatible spreadsheet software.

If you’re new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```
In [1]: import pandas as pd
In [2]: import numpy as np
```

Data structures

General terminology translation

<table>
<thead>
<tr>
<th>pandas</th>
<th>Excel</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrame</td>
<td>worksheet</td>
</tr>
<tr>
<td>Series</td>
<td>column</td>
</tr>
<tr>
<td>Index</td>
<td>row headings</td>
</tr>
<tr>
<td>row</td>
<td>row</td>
</tr>
<tr>
<td>NaN</td>
<td>empty cell</td>
</tr>
</tbody>
</table>

**DataFrame**

A DataFrame in pandas is analogous to an Excel worksheet. While an Excel workbook can contain multiple worksheets, pandas DataFrames exist independently.

**Series**

A Series is the data structure that represents one column of a DataFrame. Working with a Series is analogous to referencing a column of a spreadsheet.

**Index**

Every DataFrame and Series has an Index, which are labels on the rows of the data. In pandas, if no index is specified, a RangeIndex is used by default (first row = 0, second row = 1, and so on), analogous to row headings/numbers in spreadsheets.

In pandas, indexes can be set to one (or multiple) unique values, which is like having a column that is used as the row identifier in a worksheet. Unlike most spreadsheets, these Index values can actually be used to reference the rows. (Note that this can be done in Excel with structured references.) For example, in spreadsheets, you would reference the first row as A1:Z1, while in pandas you could use populations.loc['Chicago'].

Index values are also persistent, so if you re-order the rows in a DataFrame, the label for a particular row don’t change.
See the indexing documentation for much more on how to use an Index effectively.

**Copies vs. in place operations**

Most pandas operations return copies of the Series/DataFrame. To make the changes “stick”, you’ll need to either assign to a new variable:

```python
sorted_df = df.sort_values("col1")
```

or overwrite the original one:

```python
df = df.sort_values("col1")
```

**Note:** You will see an inplace=True keyword argument available for some methods:

```python
df.sort_values("col1", inplace=True)
```

Its use is discouraged. More information.

**Data input / output**

**Constructing a DataFrame from values**

In a spreadsheet, values can be typed directly into cells.

A pandas DataFrame can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```python
In [3]: df = pd.DataFrame({"x": [1, 3, 5], "y": [2, 4, 6]})
```

**Reading external data**

Both Excel and pandas can import data from various sources in various formats.
CSV

Let’s load and display the tips dataset from the pandas tests, which is a CSV file. In Excel, you would download and then open the CSV. In pandas, you pass the URL or local path of the CSV file to `read_csv()`:

```
In [5]: url = ('https://raw.github.com/pandas-dev/pandas/master/pandas/tests/io/data/csv/tips.csv')

In [6]: tips = pd.read_csv(url)

In [7]: tips
Out[7]:
   total_bill  tip  sex  smoker  day  time  size
0     16.99  1.01  Female   No  Sun  Dinner   2
1     10.34  1.66    Male   No  Sun  Dinner   3
2     21.01  3.50    Male   No  Sun  Dinner   3
3     23.68  3.31    Male   No  Sun  Dinner   2
...     ...    ...     ...     ...     ...     ...
239   29.03  5.92    Male   No  Sat  Dinner   3
240   27.18  2.00  Female    Yes  Sat  Dinner   2
241   22.67  2.00    Male    Yes  Sat  Dinner   2
242   17.82  1.75    Male   No  Sat  Dinner   2
243   18.78  3.00  Female   No  Thur  Dinner   2
[244 rows x 7 columns]
```

Like Excel’s Text Import Wizard, `read_csv` can take a number of parameters to specify how the data should be parsed. For example, if the data was instead tab delimited, and did not have column names, the pandas command would be:

```
tips = pd.read_csv("tips.csv", sep="\t", header=None)
```

# alternatively, `read_table` is an alias to `read_csv` with tab delimiter
tips = pd.read_table("tips.csv", header=None)

Excel files

Excel opens various Excel file formats by double-clicking them, or using the Open menu. In pandas, you use special methods for reading and writing from/to Excel files.

Let’s first create a new Excel file based on the tips dataframe in the above example:

```
tips.to_excel("./tips.xlsx")
```

Should you wish to subsequently access the data in the tips.xlsx file, you can read it into your module using

```
tips_df = pd.read_excel("./tips.xlsx", index_col=0)
```

You have just read in an Excel file using pandas!
Limiting output

Spreadsheet programs will only show one screenful of data at a time and then allow you to scroll, so there isn’t really a need to limit output. In pandas, you’ll need to put a little more thought into controlling how your DataFrames are displayed.

By default, pandas will truncate output of large DataFrames to show the first and last rows. This can be overridden by changing the pandas options, or using `DataFrame.head()` or `DataFrame.tail()`.

```
In [8]: tips.head(5)
Out[8]:
         total_bill  tip  sex  smoker day     time  size
0       16.99   1.01 Female  No  Sun  Dinner     2
1       10.34   1.66  Male  No  Sun  Dinner     3
2       21.01   3.50  Male  No  Sun  Dinner     3
3       23.68   3.31  Male  No  Sun  Dinner     2
4       24.59   3.61 Female  No  Sun  Dinner     4
```

Exporting data

By default, desktop spreadsheet software will save to its respective file format (.xlsx, .ods, etc). You can, however, save to other file formats.

*pandas can create Excel files, CSV, or a number of other formats.*

Data operations

Operations on columns

In spreadsheets, formulas are often created in individual cells and then dragged into other cells to compute them for other columns. In pandas, you’re able to do operations on whole columns directly.

pandas provides vectorized operations by specifying the individual Series in the DataFrame. New columns can be assigned in the same way. The `DataFrame.drop()` method drops a column from the DataFrame.

```
In [9]: tips["total_bill"] = tips["total_bill"] - 2
In [10]: tips["new_bill"] = tips["total_bill"] / 2
In [11]: tips
Out[11]:
         total_bill  tip  sex  smoker day     time  size  new_bill
0       14.99   1.01 Female  No  Sun  Dinner     2    7.495
1        8.34   1.66  Male  No  Sun  Dinner     3    4.170
2       19.01   3.50  Male  No  Sun  Dinner     3    9.505
3       21.68   3.31  Male  No  Sun  Dinner     2   10.840
4       22.59   3.61 Female  No  Sun  Dinner     4   11.295
...     ...     ...     ...     ...     ...     ...     ...
239    27.03   5.92  Male  No  Sat  Dinner     3   13.515
240    25.18   2.00 Female  Yes  Sat  Dinner     2   12.590
241    20.67   2.00  Male  Yes  Sat  Dinner     2   10.335
242    15.82   1.75  Male  No  Sat  Dinner     2     7.910
243    16.78   3.00 Female  No  Thur  Dinner     2     8.390
```

(continues on next page)
Note that we aren’t having to tell it to do that subtraction cell-by-cell — pandas handles that for us. See how to create new columns derived from existing columns.

Filtering

In Excel, filtering is done through a graphical menu.
DataFrames can be filtered in multiple ways; the most intuitive of which is using boolean indexing.

```
In [13]: tips[tips["total_bill"] > 10]
Out[13]:
    total_bill  tip  sex  smoker  day  time  size
0   14.99  1.01  Female   No  Sun  Dinner   2
2   19.01  3.50    Male    No  Sun  Dinner   3
3   21.68  3.31    Male    No  Sun  Dinner   2
4   22.59  3.61  Female   No  Sun  Dinner   4
```
The above statement is simply passing a Series of True/False objects to the DataFrame, returning all rows with True.

```python
In [14]: is_dinner = tips["time"] == "Dinner"
In [15]: is_dinner
Out[15]:
   0    True
   1    True
   2    True
   3    True
   4    True
      ... 
 239   True
 240   True
 241   True
 242   True
 243   True
Name: time, Length: 244, dtype: bool

In [16]: is_dinner.value_counts()
Out[16]:
   True    176
  False     68
Name: time, dtype: int64

In [17]: tips[is_dinner]
Out[17]:
   total_bill  tip  sex  smoker  day  time  size
   0       14.99  1.01 Female   No   Sun  Dinner  2
   1        8.34  1.66    Male   No   Sun  Dinner  3
   2       19.01  3.50    Male   No   Sun  Dinner  3
   3       21.68  3.31    Male   No   Sun  Dinner  2
   4       22.59  3.61 Female   No   Sun  Dinner  4
      ...  ...    ...   ...    ...   ...    ...
 239      27.03  5.92    Male   No   Sat  Dinner  3
 240      25.18  2.00 Female   Yes   Sat  Dinner  2
 241      20.67  2.00    Male   Yes   Sat  Dinner  2
 242      15.82  1.75    Male   No   Sat  Dinner  2
 243      16.78  3.00 Female   No   Thur  Dinner  2
[176 rows x 7 columns]
If/then logic

Let’s say we want to make a bucket column with values of low and high, based on whether the total_bill is less or more than $10.

In spreadsheets, logical comparison can be done with conditional formulas. We’d use a formula of =IF(A2 < 10, "low", "high"), dragged to all cells in a new bucket column.

In [18]: tips["bucket"] = np.where(tips["total_bill"] < 10, "low", "high")

In [19]: tips

Out[19]:

<table>
<thead>
<tr>
<th>total_bill</th>
<th>tip</th>
<th>sex</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
<th>bucket</th>
</tr>
</thead>
<tbody>
<tr>

<td>high</td>
</tr>
</tbody>
</table>

The same operation in pandas can be accomplished using the where method from numpy.
Date functionality

This section will refer to “dates”, but timestamps are handled similarly.

We can think of date functionality in two parts: parsing, and output. In spreadsheets, date values are generally parsed automatically, though there is a DATEVALUE function if you need it. In pandas, you need to explicitly convert plain text to datetime objects, either while reading from a CSV or once in a DataFrame.

Once parsed, spreadsheets display the dates in a default format, though the format can be changed. In pandas, you’ll generally want to keep dates as datetime objects while you’re doing calculations with them. Outputting parts of dates (such as the year) is done through date functions in spreadsheets, and datetime properties in pandas.

Given date1 and date2 in columns A and B of a spreadsheet, you might have these formulas:

<table>
<thead>
<tr>
<th>column</th>
<th>formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>date1_year</td>
<td>=YEAR(A2)</td>
</tr>
<tr>
<td>date2_month</td>
<td>=MONTH(B2)</td>
</tr>
<tr>
<td>date1_next</td>
<td>=DATE(YEAR(A2),MONTH(A2)+1,1)</td>
</tr>
<tr>
<td>months_between</td>
<td>=DATEDIF(A2,B2,&quot;M&quot;)</td>
</tr>
</tbody>
</table>

The equivalent pandas operations are shown below.

```
In [20]: tips["date1"] = pd.Timestamp("2013-01-15")
In [21]: tips["date2"] = pd.Timestamp("2015-02-15")
In [22]: tips["date1_year"] = tips["date1"].dt.year
In [23]: tips["date2_month"] = tips["date2"].dt.month
In [24]: tips["date1_next"] = tips["date1"] + pd.offsets.MonthBegin()
In [25]: tips["months_between"] = tips["date2"].dt.to_period("M") - tips["date1"].dt.to_period("M")
In [26]: tips["date1", "date2", "date1_year", "date2_month", "date1_next", "months_between"]
```

```
Out[26]:
          date1       date2      date1_year  date2_month  date1_next  months_between
          ...        ...        ...        ...        ...        ...        ...
[244 rows x 6 columns]
```
See *Time series / date functionality* for more details.

**Selection of columns**

In spreadsheets, you can select columns you want by:

- Hiding columns
- Deleting columns
- Referencing a range from one worksheet into another

Since spreadsheet columns are typically named in a header row, renaming a column is simply a matter of changing the text in that first cell.

The same operations are expressed in pandas below.

**Keep certain columns**

```python
In [27]: tips["sex", "total_bill", "tip"]
Out[27]:
   sex  total_bill  tip
0  Female     14.99  1.01
1   Male       8.34  1.66
2   Male      19.01  3.50
3   Male      21.68  3.31
4  Female     22.59  3.61
   ...      ...  ...  ...
239  Male      27.03  5.92
240  Female    25.18  2.00
241  Male      20.67  2.00
242  Male      15.82  1.75
243  Female    16.78  3.00
```

[244 rows x 3 columns]

**Drop a column**

```python
In [28]: tips.drop("sex", axis=1)
Out[28]:
   total_bill  tip  smoker  day  time  size
0      14.99  1.01    No  Sun  Dinner    2
1       8.34  1.66    No  Sun  Dinner    3
2      19.01  3.50    No  Sun  Dinner    3
3      21.68  3.31    No  Sun  Dinner    2
4      22.59  3.61    No  Sun  Dinner    4
   ...     ...    ...     ...     ...   ...
239    27.03  5.92    No  Sat  Dinner    3
240    25.18  2.00    No  Sat  Dinner    2
241    20.67  2.00    Yes  Sat  Dinner    2
242    15.82  1.75    No  Sat  Dinner    2
243    16.78  3.00    No  Thur  Dinner    2
```

[244 rows x 6 columns]
Rename a column

```python
In [29]: tips.rename(columns={"total_bill": "total_bill_2")
Out[29]:
   total_bill_2  tip  sex  smoker  day  time  size
0     14.99  1.01  Female   No  Sun  Dinner  2
1     8.34  1.66   Male   No  Sun  Dinner  3
2    19.01  3.50   Male   No  Sun  Dinner  3
3    21.68  3.31   Male   No  Sun  Dinner  2
4    22.59  3.61  Female   No  Sun  Dinner  4
   ...   ...   ...   ...   ...   ...   ...
239  27.03  5.92   Male   No  Sat  Dinner  3
240  25.18  2.00  Female   Yes  Sat  Dinner  2
241  20.67  2.00   Male   Yes  Sat  Dinner  2
242  15.82  1.75   Male   No  Sat  Dinner  2
243  16.78  3.00  Female   No  Thur  Dinner  2
[244 rows x 7 columns]
```

Sorting by values

Sorting in spreadsheets is accomplished via the sort dialog.

Pandas has a `DataFrame.sort_values()` method, which takes a list of columns to sort by.

```python
In [30]: tips = tips.sort_values(["sex", "total_bill")
In [31]: tips
Out[31]:
   total_bill  tip  sex  smoker  day  time  size
67     1.07  1.00  Female   Yes  Sat  Dinner  1
92     3.75  1.00  Female   Yes  Fri  Dinner  2
111    5.25  1.00  Female   No  Sat  Dinner  1
```

(continues on next page)
String processing

Finding length of string

In spreadsheets, the number of characters in text can be found with the `LEN` function. This can be used with the `TRIM` function to remove extra whitespace.

```python
LEN(TRIM(A2))
```

You can find the length of a character string with `Series.str.len()`. In Python 3, all strings are Unicode strings. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```python
In [32]: tips["time"].str.len()
Out[32]:
   67    6
   92    6
  111    6
  145    5
  135    5
   ... ...
  182    6
  156    6
   59    6
  212    6
  170    6
Name: time, Length: 244, dtype: int64

In [33]: tips["time"].str.rstrip().str.len()
Out[33]:
   67    6
   92    6
  111    6
  145    5
  135    5
   ... ...
  182    6
  156    6
   59    6
  212    6
  170    6
Name: time, Length: 244, dtype: int64
```

Note this will still include multiple spaces within the string, so isn’t 100% equivalent.
Finding position of substring

The **FIND** spreadsheet function returns the position of a substring, with the first character being 1.

You can find the position of a character in a column of strings with the `Series.str.find()` method. `find` searches for the first position of the substring. If the substring is found, the method returns its position. If not found, it returns −1. Keep in mind that Python indexes are zero-based.

```
In [34]: tips["sex"].str.find("ale")
Out[34]:
67 3
92 3
111 3
145 3
135 3
...
182 1
156 1
59 1
212 1
170 1
Name: sex, Length: 244, dtype: int64
```

Extracting substring by position

Spreadsheets have a **MID** formula for extracting a substring from a given position. To get the first character:

```
=MID(A2,1,1)
```

With pandas you can use `[ ]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.
In [35]: tips["sex"].str[0:1]
Out[35]:
67   F
92   F
111  F
145  F
135  F
   ..
182  M
156  M
 59  M
212  M
170  M
Name: sex, Length: 244, dtype: object

Extracting nth word

In Excel, you might use the Text to Columns Wizard for splitting text and retrieving a specific column. (Note it's possible to do so through a formula as well.)

The simplest way to extract words in pandas is to split the strings by spaces, then reference the word by index. Note there are more powerful approaches should you need them.

In [36]: firstlast = pd.DataFrame({"String": ["John Smith", "Jane Cook"]})
In [37]: firstlast["First_Name"] = firstlast["String"].str.split(" ", expand=True)[0]
In [38]: firstlast["Last_Name"] = firstlast["String"].str.rsplit(" ", expand=True)[0]
In [39]: firstlast
Out[39]:
          String  First_Name  Last_Name
0     John Smith       John       John
1     Jane Cook        Jane        Jane

Changing case

Spreadsheets provide UPPER, LOWER, and PROPER functions for converting text to upper, lower, and title case, respectively.

The equivalent pandas methods are Series.str.upper(), Series.str.lower(), and Series.str.title().

In [40]: firstlast = pd.DataFrame({"string": ["John Smith", "Jane Cook"]})
In [41]: firstlast["upper"] = firstlast["string"].str.upper()
In [42]: firstlast["lower"] = firstlast["string"].str.lower()
In [43]: firstlast["title"] = firstlast["string"].str.title()
In [44]: firstlast
Out[44]:
          string  upper  lower  title
Merging

The following tables will be used in the merge examples:

<p>| | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>A</td>
<td>0.469112</td>
<td>#N/A</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>B</td>
<td>-0.282863</td>
<td>1.212112</td>
<td>#N/A</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>C</td>
<td>-1.509059</td>
<td>#N/A</td>
<td>0.119209</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>D</td>
<td>-1.135632</td>
<td>-0.173215</td>
<td>0.119209</td>
<td></td>
</tr>
</tbody>
</table>

In Excel, there are merging of tables can be done through a VLOOKUP.

Pandas DataFrames have a merge() method, which provides similar functionality. The data does not have to be sorted ahead of time, and different join types are accomplished via the how keyword.
In [51]: left_join = df1.merge(df2, on="key", how="left")

In [52]: left_join
Out[52]:
key  value_x  value_y
0   A      0.469112   NaN
1   B     -0.282863  1.212112
2   C    -1.509059   NaN
3   D    -1.135632 -0.173215
4   D    -1.135632  0.119209

In [53]: right_join = df1.merge(df2, on="key", how="right")

In [54]: right_join
Out[54]:
key  value_x  value_y
0   B     -0.282863  1.212112
1   D    -1.135632 -0.173215
2   D    -1.135632  0.119209
3   E     NaN     -1.044236

In [55]: outer_join = df1.merge(df2, on="key", how="outer")

In [56]: outer_join
Out[56]:
key  value_x  value_y
0   A      0.469112   NaN
1   B     -0.282863  1.212112
2   C    -1.509059   NaN
3   D    -1.135632 -0.173215
4   D    -1.135632  0.119209
5   E     NaN     -1.044236

merge has a number of advantages over VLOOKUP:

- The lookup value doesn’t need to be the first column of the lookup table
- If multiple rows are matched, there will be one row for each match, instead of just the first
- It will include all columns from the lookup table, instead of just a single specified column
- It supports more complex join operations
Other considerations

Fill Handle

Create a series of numbers following a set pattern in a certain set of cells. In a spreadsheet, this would be done by shift+drag after entering the first number or by entering the first two or three values and then dragging.

This can be achieved by creating a series and assigning it to the desired cells.

```python
In [57]: df = pd.DataFrame({"AAA": [1] * 8, "BBB": list(range(0, 8))})

In [58]: df
Out[58]:
   AAA  BBB
0    1    0
1    1    1
2    1    2
3    1    3
4    1    4
5    1    5
6    1    6
7    1    7
```

```python
In [59]: series = list(range(1, 5))

In [60]: series
Out[60]: [1, 2, 3, 4]

In [61]: df.loc[2:5, "AAA"] = series

In [62]: df
Out[62]:
   AAA  BBB
0    1    0
1    1    1
2    1    2
3    2    3
4    3    4
5    4    5
6    1    6
7    1    7
```

Drop Duplicates

Excel has built-in functionality for removing duplicate values. This is supported in pandas via `drop_duplicates()`.

```python
In [63]: df = pd.DataFrame(
   ....:     {"class": ["A", "A", "A", "B", "C", "D"],
   ....:      "student_count": [42, 35, 42, 50, 47, 45],
   ....:      "all_pass": ["Yes", "Yes", "Yes", "No", "No", "Yes"],
   ....: },
   ....: )

(continues on next page)
```
In [64]: df.drop_duplicates()
Out[64]:
          class  student_count  all_pass
0         A             42     Yes
1         A              35     Yes
3         B              50      No
4         C              47      No
5         D              45     Yes

In [65]: df.drop_duplicates(["class", "student_count"])
Out[65]:
          class  student_count  all_pass
0         A             42     Yes
1         A              35     Yes
3         B              50      No
4         C              47      No
5         D              45     Yes

Pivot Tables

PivotTables from spreadsheets can be replicated in pandas through Reshaping and pivot tables. Using the tips dataset again, let’s find the average gratuity by size of the party and sex of the server.

In Excel, we use the following configuration for the PivotTable:

The equivalent in pandas:

In [66]: pd.pivot_table(tips, values="tip", index=["size"], columns=["sex"], aggfunc=np.average
       ....:
       .....:
Out[66]:
                    size
        sex      Female  Male
       (blank)            5.225

Adding a row
Assuming we are using a RangeIndex (numbered 0, 1, etc.), we can use DataFrame.append() to add a row
to the bottom of a DataFrame.
In [67]: df
Out[67]:
class student_count all_pass
0
A
42
Yes
1
A
35
Yes
2
A
42
Yes
3
B
50
No
4
C
47
No
5
D

Find and Replace
Excel’s Find dialog takes you to cells that match, one by one. In pandas, this operation is generally done for an entire
column or DataFrame at once through conditional expressions.

[244 rows x 7 columns]
Comparison with SAS

For potential users coming from SAS this page is meant to demonstrate how different SAS operations would be performed in pandas.

If you’re new to pandas, you might want to first read through 10 Minutes to pandas to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```python
In [1]: import pandas as pd
In [2]: import numpy as np
```

Data structures

General terminology translation

</table>

**DataFrame**

A DataFrame in pandas is analogous to a SAS data set - a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set using SAS’s DATA step, can also be accomplished in pandas.

**Series**

A Series is the data structure that represents one column of a DataFrame. SAS doesn’t have a separate data structure for a single column, but in general, working with a Series is analogous to referencing a column in the DATA step.

**Index**

Every DataFrame and Series has an Index - which are labels on the rows of the data. SAS does not have an exactly analogous concept. A data set’s rows are essentially unlabeled, other than an implicit integer index that can be accessed during the DATA step (_N_).

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled Index or MultiIndex can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the Index and just treat the DataFrame as a collection of columns. Please see the indexing documentation for much more on how to use an Index effectively.
Copies vs. in place operations

Most pandas operations return copies of the `Series/DataFrame`. To make the changes “stick”, you’ll need to either assign to a new variable:

```python
sorted_df = df.sort_values("col1")
```

or overwrite the original one:

```python
df = df.sort_values("col1")
```

**Note:** You will see an `inplace=True` keyword argument available for some methods:

```python
df.sort_values("col1", inplace=True)
```

Its use is discouraged. *More information.*

Data input / output

Constructing a DataFrame from values

A SAS data set can be built from specified values by placing the data after a `datalines` statement and specifying the column names.

```plaintext
data df;
    input x y;
    datalines;
    1 2
    3 4
    5 6
; run;
```

A pandas DataFrame can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```python
In [1]: df = pd.DataFrame({"x": [1, 3, 5], "y": [2, 4, 6]})

In [2]: df  
Out[2]:
   x  y
0  1  2
1  3  4
2  5  6
```
Reading external data

Like SAS, pandas provides utilities for reading in data from many formats. The tips dataset, found within the pandas tests (csv) will be used in many of the following examples.

SAS provides PROC IMPORT to read csv data into a data set.

```sas
proc import datafile='tips.csv' dbms=csv out=tips replace;
    getnames=yes;
run;
```

The pandas method is `read_csv()`, which works similarly.

```python
In [3]: url = (
    ...:   "https://raw.github.com/pandas-dev/
    ...:   "pandas/master/pandas/tests/io/data/csv/tips.csv"
    ...: )
    ...:

In [4]: tips = pd.read_csv(url)

In [5]: tips
Out[5]:
   total_bill  tip  sex   smoker  day   time  size
0     16.99  1.01  Female    No     Sun  Dinner     2
1     10.34  1.66    Male     No     Sun  Dinner     3
2     21.01  3.50    Male     No     Sun  Dinner     3
3     23.68  3.31    Male     No     Sun  Dinner     2
4     24.59  3.61  Female    No     Sun  Dinner     4
   ...   ...   ...     ...    ...     ...     ...
239   29.03  5.92    Male     No     Sat  Dinner     3
240   27.18  2.00  Female     Yes     Sat  Dinner     2
241   22.67  2.00    Male     Yes     Sat  Dinner     2
242   17.82  1.75    Male     No     Sat  Dinner     2
243   18.78  3.00  Female     No  Thur  Dinner     2

[244 rows x 7 columns]
```

Like PROC IMPORT, read_csv can take a number of parameters to specify how the data should be parsed. For example, if the data was instead tab delimited, and did not have column names, the pandas command would be:

```python
tips = pd.read_csv("tips.csv", sep=\"\t\", header=None)
```

# alternatively, read_table is an alias to read_csv with tab delimiter
tips = pd.read_table("tips.csv", header=None)

In addition to text/csv, pandas supports a variety of other data formats such as Excel, HDF5, and SQL databases. These are all read via a pd.read_* function. See the IO documentation for more details.
Limiting output

By default, pandas will truncate output of large DataFrames to show the first and last rows. This can be overridden by changing the pandas options, or using `DataFrame.head()` or `DataFrame.tail()`.

```
In [1]: tips.head(5)
Out[1]:
         total_bill  tip    sex  smoker day  time  size
0      16.990000  1.01 Female    No  Sun  Dinner   2
1      10.340000  1.66    Male    No  Sun  Dinner   3
2      21.010000  3.50    Male    No  Sun  Dinner   3
3      23.680000  3.31    Male    No  Sun  Dinner   2
4      24.590000  3.61 Female    No  Sun  Dinner   4
```

The equivalent in SAS would be:

```
proc print data=df(obs=5);
run;
```

Exporting data

The inverse of PROC IMPORT in SAS is PROC EXPORT

```
proc export data=tips outfile='tips2.csv' dbms=csv;
run;
```

Similarly in pandas, the opposite of `read_csv` is `to_csv()`, and other data formats follow a similar api.

```
tips.to_csv("tips2.csv")
```

Data operations

Operations on columns

In the DATA step, arbitrary math expressions can be used on new or existing columns.

```
data tips;
  set tips;
  total_bill = total_bill - 2;
  new_bill = total_bill / 2;
run;
```

pandas provides vectorized operations by specifying the individual Series in the DataFrame. New columns can be assigned in the same way. The `DataFrame.drop()` method drops a column from the DataFrame.

```
In [1]: tips["total_bill"] = tips["total_bill"] - 2
In [2]: tips["new_bill"] = tips["total_bill"] / 2
In [3]: tips
Out[3]:
         total_bill  tip    sex  smoker day  time  size  new_bill
0      14.990000  1.01 Female    No  Sun  Dinner   2  7.495
(continues on next page)
Filtering

Filtering in SAS is done with an if or where statement, on one or more columns.

```plaintext
data tips;
  set tips;
  if total_bill > 10;
run;

data tips;
  set tips;
  where total_bill > 10;
  /* equivalent in this case - where happens before the
     DATA step begins and can also be used in PROC statements */
run;
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using boolean indexing.

```plaintext
In [1]: tips[tips["total_bill"] > 10]
Out[1]:
   total_bill  tip  sex  smoker  day  time  size  
0     14.99  1.01  Female  No   Sun  Dinner  2  
1     19.01  3.50    Male  No   Sun  Dinner  3  
2     21.68  3.31    Male  No   Sun  Dinner  2  
3     22.59  3.61  Female  No   Sun  Dinner  4  
4     23.29  4.71    Male  No   Sun  Dinner  4  
..     ...  ...     ...    ...    ...    ...  
239   27.03  5.92    Male  No    Sat  Dinner  3  
240   25.18  2.00  Female    Yes  Sat  Dinner  2  
241   20.67  2.00    Male    Yes  Sat  Dinner  2  
242   15.82  1.75    Male  No    Sat  Dinner  2  
243   16.78  3.00  Female  No    Thur  Dinner  2  
[204 rows x 7 columns]
```

The above statement is simply passing a Series of True/False objects to the DataFrame, returning all rows with True.

```plaintext
In [1]: is_dinner = tips["time"] == "Dinner"
```
If/then logic

In SAS, if/then logic can be used to create new columns.

```sas
data tips;
    set tips;
    format bucket $4.;
    if total_bill < 10 then bucket = 'low';
    else bucket = 'high';
run;
```

The same operation in pandas can be accomplished using the `where` method from `numpy`.

```python
In [1]: tips["bucket"] = np.where(tips["total_bill"] < 10, "low", "high")
In [2]: tips
```

(continues on next page)
Date functionality

SAS provides a variety of functions to do operations on date/datetime columns.

```sas
data tips;
  set tips;
  format date1 date2 date1_plusmonth mmdy10.;
  date1 = mdy(1, 15, 2013);
  date2 = mdy(2, 15, 2015);
  date1_year = year(date1);
  date2_month = month(date2);
  * shift date to beginning of next interval;
  date1_next = intnx('MONTH', date1, 1);
  * count intervals between dates;
  months_between = intck('MONTH', date1, date2);
run;
```

The equivalent pandas operations are shown below. In addition to these functions pandas supports other Time Series features not available in Base SAS (such as resampling and custom offsets) - see the `timeseries documentation` for more details.

```python
In [1]: tips["date1"] = pd.Timestamp("2013-01-15")

In [2]: tips["date2"] = pd.Timestamp("2015-02-15")

In [3]: tips["date1_year"] = tips["date1"].dt.year

In [4]: tips["date2_month"] = tips["date2"].dt.month

In [5]: tips["date1_next"] = tips["date1"] + pd.offsets.MonthBegin()

In [6]: tips["months_between"] = tips["date2"].dt.to_period("M") - tips["date1"].dt.to_period("M")

In [7]: tips["date1", "date2", "date1_year", "date2_month", "date1_next", "months_between"]
```

(continues on next page)
Selection of columns

SAS provides keywords in the DATA step to select, drop, and rename columns.

data tips;
   set tips;
   keep sex total_bill tip;
run;

data tips;
   set tips;
   drop sex;
run;

data tips;
   set tips;
   rename total_bill=total_bill_2;
run;

The same operations are expressed in pandas below.

Keep certain columns

In [1]: tips["sex", "total_bill", "tip"]

Out[1]:
    sex   total_bill  tip
   0 Female     14.99  1.01
   1  Male       8.34  1.66
   2  Male      19.01  3.50
   3  Male      21.68  3.31
   4 Female     22.59  3.61
...     ...     ...     ...
239  Male     27.03  5.92
240 Female    25.18  2.00
241  Male     20.67  2.00

[244 rows x 6 columns]
242 Male 15.82 1.75
243 Female 16.78 3.00

[244 rows x 3 columns]

Drop a column

```python
In [2]: tips.drop("sex", axis=1)
Out[2]:
                   total_bill  tip  smoker  day    time  size
0     14.990000  1.010000  No  Sun  Dinner  2
1      8.340000  1.660000  No  Sun  Dinner  3
2     19.010000  3.500000  No  Sun  Dinner  3
3     21.680000  3.310000  No  Sun  Dinner  2
4     22.590000  3.610000  No  Sun  Dinner  4
..       ...       ...    ...     ...    ...
239   27.030000  5.920000  No  Sat  Dinner  3
240   25.180000  2.000000  Yes  Sat  Dinner  2
241   20.670000  2.000000  Yes  Sat  Dinner  2
242   15.820000  1.750000  No  Sat  Dinner  2
243   16.780000  3.000000  No  Thur  Dinner  2
```

[244 rows x 6 columns]

Rename a column

```python
In [1]: tips.rename(columns={"total_bill": "total_bill_2"})
Out[1]:
                   total_bill_2  tip  sex  smoker  day    time  size
0   14.9900000000  1.01000000  Female  No  Sun  Dinner  2
1    8.3400000000  1.66000000  Male  No  Sun  Dinner  3
2   19.0100000000  3.50000000  Male  No  Sun  Dinner  3
3   21.6800000000  3.31000000  Male  No  Sun  Dinner  2
4   22.5900000000  3.61000000  Female  No  Sun  Dinner  4
..       ...       ...      ...     ...    ...
239  27.0300000000  5.92000000  Male  No  Sat  Dinner  3
240  25.1800000000  2.00000000  Female  Yes  Sat  Dinner  2
241  20.6700000000  2.00000000  Male  Yes  Sat  Dinner  2
242  15.8200000000  1.75000000  Male  No  Sat  Dinner  2
243  16.7800000000  3.00000000  Female  No  Thur  Dinner  2
```

[244 rows x 7 columns]
### Sorting by values

Sorting in SAS is accomplished via `PROC SORT`.

```sas
proc sort data=tips;
  by sex total_bill;
run;
```

Pandas has a `DataFrame.sort_values()` method, which takes a list of columns to sort by.

```python
In [1]: tips = tips.sort_values(['sex', 'total_bill'])
In [2]: tips
Out[2]:
```

```
<table>
<thead>
<tr>
<th></th>
<th>total_bill</th>
<th>tip</th>
<th>sex</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>67</td>

<td>No</td>
<td>Thur</td>
<td>Lunch</td>
<td>2</td>
</tr>
</tbody>
</table>
.. | ...         | ...  | ...   | ...    | ...  | ...    | ...  |
|182| 43.35       | 3.50 | Male  | Yes    | Sun  | Dinner | 3    |
|156| 46.17       | 5.00 | Male  | No     | Sun  | Dinner | 6    |
| 59| 46.27       | 6.73 | Male  | No     | Sat  | Dinner | 4    |
|212| 46.33       | 9.00 | Male  | No     | Sat  | Dinner | 4    |
|170| 48.81       | 10.00| Male  | Yes    | Sat  | Dinner | 3    |
```

[244 rows x 7 columns]

### String processing

#### Finding length of string

SAS determines the length of a character string with the `LENGTHN` and `LENGTHC` functions. `LENGTHN` excludes trailing blanks and `LENGTHC` includes trailing blanks.

```sas
data _null_;  
set tips;  
put (LENGTHN(time));  
put (LENGTHC(time));  
run;
```

You can find the length of a character string with `Series.str.len()`. In Python 3, all strings are Unicode strings. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```python
In [1]: tips['time'].str.len()
Out[1]:
```

```
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>67</td>
<td>6</td>
</tr>
<tr>
<td>92</td>
<td>6</td>
</tr>
<tr>
<td>111</td>
<td>6</td>
</tr>
<tr>
<td>145</td>
<td>5</td>
</tr>
<tr>
<td>135</td>
<td>5</td>
</tr>
</tbody>
</table>
.. |
|182| 6 |
|156| 6 |
```

(continues on next page)
Finding position of substring

SAS determines the position of a character in a string with the FINDW function. FINDW takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```plaintext
data _null_; set tips; put (FINDW(sex,'ale')); run;
```

You can find the position of a character in a column of strings with the Series.str.find() method. find searches for the first position of the substring. If the substring is found, the method returns its position. If not found, it returns -1. Keep in mind that Python indexes are zero-based.

```plaintext
In [1]: tips['sex'].str.find('ale')
Out[1]:
67    3
92    3
111   3
145   3
135   3
...
182   1
156   1
59    1
212   1
170   1
Name: sex, Length: 244, dtype: int64
```
Extracting substring by position

SAS extracts a substring from a string based on its position with the `SUBSTR` function.

```plaintext
data _null_;  
set tips;  
put(substr(sex,1,1));  
run;
```

With pandas you can use `[]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```plaintext
In [1]: tips["sex"].str[0:1]  
Out[1]:  
67   F  
92   F  
111  F  
145  F  
135  F  
   ...  
182  M  
156  M  
 59  M  
212  M  
170  M  
Name: sex, Length: 244, dtype: object
```

Extracting nth word

The SAS `SCAN` function returns the nth word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```plaintext
data firstlast;  
input String $60.;  
First_Name = scan(string, 1);  
Last_Name = scan(string, -1);  
datalines2;  
John Smith;  
Jane Cook;  
;;  
run;
```

The simplest way to extract words in pandas is to split the strings by spaces, then reference the word by index. Note there are more powerful approaches should you need them.

```plaintext
In [1]: firstlast = pd.DataFrame({"String": ["John Smith", "Jane Cook"]})  
In [2]: firstlast["First_Name"] = firstlast["String"].str.split( ",", expand=True)[0]  
In [3]: firstlast["Last_Name"] = firstlast["String"].str.rsplit( ",", expand=True)[0]  
In [4]: firstlast  
Out[4]:  
   String First_Name Last_Name  
0  John Smith       John        John  
1   Jane Cook       Jane         Jane
```
Changing case

The SAS UPCASE LOWCASE and PROPCASE functions change the case of the argument.

```plaintext
data firstlast;
input String $60.;
string_up = UPCASE(string);
string_low = LOWCASE(string);
string_prop = PROPCASE(string);
datalines2;
John Smith;
Jane Cook;
;
run;
```

The equivalent pandas methods are `Series.str.upper()`, `Series.str.lower()`, and `Series.str.title()`.

```plaintext
In [1]: firstlast = pd.DataFrame({"string": ["John Smith", "Jane Cook"]})
In [2]: firstlast["upper"] = firstlast["string"].str.upper()
In [3]: firstlast["lower"] = firstlast["string"].str.lower()
In [4]: firstlast["title"] = firstlast["string"].str.title()
In [5]: firstlast
```

<table>
<thead>
<tr>
<th></th>
<th>string</th>
<th>upper</th>
<th>lower</th>
<th>title</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>John Smith</td>
<td>JOHN SMITH</td>
<td>john smith</td>
<td>John Smith</td>
</tr>
<tr>
<td>1</td>
<td>Jane Cook</td>
<td>JANE COOK</td>
<td>jane cook</td>
<td>Jane Cook</td>
</tr>
</tbody>
</table>

Merging

The following tables will be used in the merge examples:

```plaintext
In [1]: df1 = pd.DataFrame({"key": ["A", "B", "C", "D"], "value": np.random.randn(4)})
In [2]: df1
```

```
key  value
0 A  0.469112
1 B -0.282863
2 C -1.509059
3 D -1.135632
```

```plaintext
In [3]: df2 = pd.DataFrame({"key": ["B", "D", "D", "E"], "value": np.random.randn(4)})
In [4]: df2
```

```
key  value
0 B  1.212112
1 D  0.173215
2 D  0.119209
3 E -1.044236
```
In SAS, data must be explicitly sorted before merging. Different types of joins are accomplished using the `in=` dummy variables to track whether a match was found in one or both input frames.

```sas
proc sort data=df1;
  by key;
run;
proc sort data=df2;
  by key;
run;
data left_join inner_join right_join outer_join;
merge df1( in=a) df2(in=b);
  if a and b then output inner_join;
  if a then output left_join;
  if b then output right_join;
  if a or b then output outer_join;
run;
```

pandas DataFrames have a `merge()` method, which provides similar functionality. The data does not have to be sorted ahead of time, and different join types are accomplished via the `how` keyword.

```python
In [1]: inner_join = df1.merge(df2, on="key", how="inner")
In [2]: inner_join
Out[2]:
   key  value_x  value_y
0  B   -0.282863  1.212112
1  D   -1.135632 -0.173215
2  D   -1.135632  0.119209

In [3]: left_join = df1.merge(df2, on="key", how="left")
In [4]: left_join
Out[4]:
   key  value_x  value_y
0  A    0.469112   NaN
1  B   -0.282863  1.212112
2  C  -1.509059   NaN
3  D  -1.135632 -0.173215
4  D  -1.135632  0.119209

In [5]: right_join = df1.merge(df2, on="key", how="right")
In [6]: right_join
Out[6]:
   key  value_x  value_y
0  B   -0.282863  1.212112
1  D  -1.135632 -0.173215
2  D  -1.135632  0.119209
3  E    NaN  -1.044236

In [7]: outer_join = df1.merge(df2, on="key", how="outer")
In [8]: outer_join
Out[8]:
   key  value_x  value_y
```

(continues on next page)
Both pandas and SAS have a representation for missing data.
pandas represents missing data with the special float value NaN (not a number). Many of the semantics are the same; for example missing data propagates through numeric operations, and is ignored by default for aggregations.

```python
In [1]: outer_join
Out[1]:
   key  value_x  value_y
  0   A    0.469112    NaN
  1   B  -0.282863  1.212112
  2   C  -1.509059    NaN
  3   D  -1.135632 -0.173215
  4   D  -1.135632  0.119209
  5   E     NaN     -1.044236

In [2]: outer_join["value_x"] + outer_join["value_y"]
Out[2]:
   0   NaN
  1   0.929249
  2   NaN
  3  -1.308847
  4  -1.016424
  5   NaN
dtype: float64

In [3]: outer_join["value_x"].sum()
Out[3]: -3.5940742896293765
```

One difference is that missing data cannot be compared to its sentinel value. For example, in SAS you could do this to filter missing values.

```sas
data outer_join_nulls;
   set outer_join;
   if value_x = .;
run;

data outer_join_no_nulls;
   set outer_join;
   if value_x ^= .;
run;
```

In pandas, `Series.isna()` and `Series.notna()` can be used to filter the rows.

```python
In [1]: outer_join[outer_join["value_x"].isna()]
Out[1]:
   key  value_x  value_y
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.1

(continued from previous page)

```
In [2]: outer_join[outer_join["value_x"].notna()]
Out[2]:
   key  value_x  value_y
0   A  0.469112    NaN
1   B -0.282863  1.212112
2   C -1.509059    NaN
3   D -1.135632 -0.173215
4   D -1.135632  0.119209
```

pandas provides *a variety of methods to work with missing data*. Here are some examples:

### Drop rows with missing values

```
In [3]: outer_join.dropna()
Out[3]:
   key  value_x  value_y
   0   A  0.469112    NaN
   1   B -0.282863  1.212112
   2   C -1.509059  1.212112
   3   D -1.135632 -0.173215
   4   D -1.135632  0.119209
```

### Forward fill from previous rows

```
In [4]: outer_join.fillna(method="ffill")
Out[4]:
   key  value_x  value_y
   0   A  0.469112    NaN
   1   B -0.282863  1.212112
   2   C -1.509059  1.212112
   3   D -1.135632 -0.173215
   4   D -1.135632  0.119209
   5   E -1.135632 -1.044236
```

### Replace missing values with a specified value

Using the mean:

```
In [1]: outer_join["value_x"].fillna(outer_join["value_x"].mean())
Out[1]:
0  0.469112
1 -0.282863
2 -1.509059
3 -1.135632
4 -1.135632
5 -0.718815
Name: value_x, dtype: float64
```

1.4. Tutorials
GroupBy

Aggregation

SAS’s PROC SUMMARY can be used to group by one or more key variables and compute aggregations on numeric columns.

```plaintext
proc summary data=tips nway;
    class sex smoker;
    var total_bill tip;
    output out=tips_summed sum=
run;
```

pandas provides a flexible groupby mechanism that allows similar aggregations. See the groupby documentation for more details and examples.

```
In [1]: tips_summed = tips.groupby(["sex", "smoker"])[["total_bill", "tip"]).sum()
```
```
In [2]: tips_summed
Out[2]:
     total_bill  tip
    sex smoker   
    Female No  869.68  149.77
     Yes         527.27  96.74
    Male No  1725.75  302.00
     Yes         1217.07  183.07
```

Transformation

In SAS, if the group aggregations need to be used with the original frame, it must be merged back together. For example, to subtract the mean for each observation by smoker group.

```plaintext
proc summary data=tips missing nway;
    class smoker;
    var total_bill;
    output out=smoker_means mean(total_bill)=group_bill;
run;
proc sort data=tips;
    by smoker;
run;
data tips;
    merge tips(in=a) smoker_means(in=b);
    by smoker;
    adj_total_bill = total_bill - group_bill;
    if a and b;
run;
```

pandas provides a Transformation mechanism that allows these type of operations to be succinctly expressed in one operation.

```
In [1]: gb = tips.groupby("smoker")["total_bill"]
In [2]: tips["adj_total_bill"] = tips["total_bill"] - gb.transform("mean")
```
In [3]: tips

Out[3]:

</table>

[244 rows x 8 columns]

By group processing

In addition to aggregation, pandas groupby can be used to replicate most other by group processing from SAS. For example, this DATA step reads the data by sex/smoker group and filters to the first entry for each.

```
proc sort data=tips;
  by sex smoker;
run;

data tips_first;
  set tips;
  by sex smoker;
  if FIRST.sex or FIRST.smoker then output;
run;
```

In pandas this would be written as:

```
In [4]: tips.groupby(['sex', 'smoker']).first()

Out[4]:

<table>
<thead>
<tr>
<th>sex</th>
<th>smoker</th>
<th>total_bill</th>
<th>tip</th>
<th>day</th>
<th>time</th>
<th>size</th>
<th>adj_total_bill</th>
</tr>
</thead>
<tbody>
<tr>
<td>Female</td>
<td>No</td>
<td>5.25</td>
<td>1.00</td>
<td>Sat</td>
<td>Dinner</td>
<td>1</td>
<td>-11.938278</td>
</tr>
<tr>
<td></td>
<td>Yes</td>
<td>3.75</td>
<td>1.00</td>
<td>Sat</td>
<td>Dinner</td>
<td>1</td>
<td>-17.686344</td>
</tr>
<tr>
<td>Male</td>
<td>No</td>
<td>5.51</td>
<td>2.00</td>
<td>Thur</td>
<td>Lunch</td>
<td>2</td>
<td>-11.678278</td>
</tr>
<tr>
<td></td>
<td>Yes</td>
<td>5.25</td>
<td>5.15</td>
<td>Sun</td>
<td>Dinner</td>
<td>2</td>
<td>-13.506344</td>
</tr>
</tbody>
</table>
Other considerations

Disk vs memory

pandas operates exclusively in memory, where a SAS data set exists on disk. This means that the size of data able to be loaded in pandas is limited by your machine’s memory, but also that the operations on that data may be faster.

If out of core processing is needed, one possibility is the dask.dataframe library (currently in development) which provides a subset of pandas functionality for an on-disk DataFrame.

Data interop

pandas provides a `read_sas()` method that can read SAS data saved in the XPORT or SAS7BDAT binary format.

```python
libname xportout xport 'transport-file.xpt';
data xportout.tips;
  set tips(rename=(total_bill=tbill));
  /* xport variable names limited to 6 characters; */
run;

df = pd.read_sas("transport-file.xpt")
df = pd.read_sas("binary-file.sas7bdat")
```

You can also specify the file format directly. By default, pandas will try to infer the file format based on its extension.

```python
df = pd.read_sas("transport-file.xpt", format="xport")
df = pd.read_sas("binary-file.sas7bdat", format="sas7bdat")
```

XPORT is a relatively limited format and the parsing of it is not as optimized as some of the other pandas readers. An alternative way to interop data between SAS and pandas is to serialize to csv.

```plaintext
# version 0.17, 10M rows
In [8]: %time df = pd.read_sas('big.xpt')
Wall time: 14.6 s

In [9]: %time df = pd.read_csv('big.csv')
Wall time: 4.86 s
```

Comparison with Stata

For potential users coming from Stata this page is meant to demonstrate how different Stata operations would be performed in pandas.

If you’re new to pandas, you might want to first read through *10 Minutes to pandas* to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```python
In [1]: import pandas as pd
In [2]: import numpy as np
```
Data structures

General terminology translation

**DataFrame**

A DataFrame in pandas is analogous to a Stata data set – a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set in Stata can also be accomplished in pandas.

**Series**

A Series is the data structure that represents one column of a DataFrame. Stata doesn’t have a separate data structure for a single column, but in general, working with a Series is analogous to referencing a column of a data set in Stata.

**Index**

Every DataFrame and Series has an Index – labels on the rows of the data. Stata does not have an exactly analogous concept. In Stata, a data set’s rows are essentially unlabeled, other than an implicit integer index that can be accessed with _n.

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled Index or MultiIndex can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the Index and just treat the DataFrame as a collection of columns. Please see the indexing documentation for much more on how to use an Index effectively.

**Copies vs. in place operations**

Most pandas operations return copies of the Series/DataFrame. To make the changes “stick”, you’ll need to either assign to a new variable:

```python
sorted_df = df.sort_values("coll")
```

or overwrite the original one:

```python
df = df.sort_values("coll")
```

**Note:** You will see an inplace=True keyword argument available for some methods:
df.sort_values("col1", inplace=True)

Its use is discouraged. More information.

Data input / output

Constructing a DataFrame from values

A Stata data set can be built from specified values by placing the data after an input statement and specifying the column names.

```
input x y
1 2
3 4
5 6
end
```

A pandas DataFrame can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```
In [3]: df = pd.DataFrame({"x": [1, 3, 5], "y": [2, 4, 6]})
In [4]: df
Out[4]:
x y
0 1 2
1 3 4
2 5 6
```

Reading external data

Like Stata, pandas provides utilities for reading in data from many formats. The tips data set, found within the pandas tests (csv) will be used in many of the following examples.

Stata provides import delimited to read csv data into a data set in memory. If the tips.csv file is in the current working directory, we can import it as follows.

```
import delimited tips.csv
```

The pandas method is read_csv(), which works similarly. Additionally, it will automatically download the data set if presented with a url.

```
In [5]: url = {
    ...:     "https://raw.github.com/pandas-dev"
    ...:     "/pandas/master/pandas/tests/io/data/csv/tips.csv"
    ...:     }
    ...:
In [6]: tips = pd.read_csv(url)
In [7]: tips
Out[7]:
```
Like `import delimited`, `read_csv()` can take a number of parameters to specify how the data should be parsed. For example, if the data were instead tab delimited, did not have column names, and existed in the current working directory, the pandas command would be:

```python
tips = pd.read_csv("tips.csv", sep="\t", header=None)
```

# alternatively, read_table is an alias to read_csv with tab delimiter
tips = pd.read_table("tips.csv", header=None)

pandas can also read Stata data sets in .dta format with the `read_stata()` function.

```python
df = pd.read_stata("data.dta")
```

In addition to text/csv and Stata files, pandas supports a variety of other data formats such as Excel, SAS, HDF5, Parquet, and SQL databases. These are all read via a `pd.read_*` function. See the IO documentation for more details.

### Limiting output

By default, pandas will truncate output of large DataFrames to show the first and last rows. This can be overridden by changing the pandas options, or using `DataFrame.head()` or `DataFrame.tail()`.

```
In [8]: tips.head(5)
Out[8]:
    total_bill  tip  sex  smoker day    time  size
0      16.99  1.01 Female   No  Sun  Dinner    2
1      10.34  1.66   Male    No  Sun  Dinner    3
2      21.01  3.50   Male    No  Sun  Dinner    3
3      23.68  3.31   Male    No  Sun  Dinner    2
4      24.59  3.61 Female   No  Sun  Dinner    4
```

The equivalent in Stata would be:

```
list in 1/5
```
Exporting data

The inverse of `import delimited` in Stata is `export delimited`.

```
export delimited tips2.csv
```

Similarly in pandas, the opposite of `read_csv` is `DataFrame.to_csv()`.

```
tips.to_csv("tips2.csv")
```

Pandas can also export to Stata file format with the `DataFrame.to_stata()` method.

```
tips.to_stata("tips2.dta")
```

Data operations

Operations on columns

In Stata, arbitrary math expressions can be used with the `generate` and `replace` commands on new or existing columns. The `drop` command drops the column from the data set.

```
replace total_bill = total_bill - 2
generate new_bill = total_bill / 2
drop new_bill
```

Pandas provides vectorized operations by specifying the individual `Series` in the `DataFrame`. New columns can be assigned in the same way. The `DataFrame.drop()` method drops a column from the `DataFrame`.

In [9]: tips["total_bill"] = tips["total_bill"] - 2
In [10]: tips["new_bill"] = tips["total_bill"] / 2
In [11]: tips

```
Out[11]:
   total_bill  tip  sex  smoker  day  time  size  new_bill
0     14.99  1.01  Female    No  Sun  Dinner   2     7.495
1      8.34  1.66    Male    No  Sun  Dinner   3     4.170
2     19.01  3.50    Male    No  Sun  Dinner   3     9.505
3     21.68  3.31    Male    No  Sun  Dinner   2   10.840
4     22.59  3.61  Female    No  Sun  Dinner   4    11.295
   ...   ...    ...    ...    ...    ...    ...    ...   ...
239   27.03  5.92    Male    No  Sat  Dinner   3   13.515
240   25.18  2.00  Female    Yes  Sat  Dinner   2   12.590
241   20.67  2.00    Male    Yes  Sat  Dinner   2   10.335
242   15.82  1.75    Male    No  Sat  Dinner   2     7.910
243   16.78  3.00  Female    No  Thur  Dinner   2     8.390
```

[244 rows x 8 columns]

In [12]: tips = tips.drop("new_bill", axis=1)
Filtering

Filtering in Stata is done with an *if* clause on one or more columns.

```stata
list if total_bill > 10
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using *boolean indexing*.

```python
In [13]: tips[tips["total_bill"] > 10]
Out[13]:
   total_bill  tip  sex  smoker  day  time  size
0      14.99  1.01  Female  No  Sun  Dinner  2
2      19.01  3.50    Male  No  Sun  Dinner  3
3      21.68  3.31    Male  No  Sun  Dinner  2
4      22.59  3.61  Female  No  Sun  Dinner  4
5      23.29  4.71    Male  No  Sun  Dinner  4
   ...    ...    ...    ...    ...    ...    ...
239   27.03  5.92    Male  No  Sat  Dinner  3
240   25.18  2.00  Female   Yes  Sat  Dinner  2
241   20.67  2.00    Male   Yes  Sat  Dinner  2
242   15.82  1.75    Male   Yes  Sat  Dinner  2
243   16.78  3.00  Female  No  Thur  Dinner  2
[204 rows x 7 columns]
```

The above statement is simply passing a *Series* of True/False objects to the DataFrame, returning all rows with True.

```python
In [14]: is_dinner = tips["time"] == "Dinner"
In [15]: is_dinner
Out[15]:
0    True
1    True
2    True
3    True
4    True
   ... 
239   True
240   True
241   True
242   True
243   True
Name: time, Length: 244, dtype: bool
In [16]: is_dinner.value_counts()
Out[16]:
   True   176
  False    68
Name: time, dtype: int64
In [17]: tips[is_dinner]
Out[17]:
   total_bill  tip  sex  smoker  day  time  size
0      14.99  1.01  Female  No  Sun  Dinner  2
1      8.34  1.66    Male  No  Sun  Dinner  3
2      19.01  3.50    Male  No  Sun  Dinner  3
```

(continues on next page)
If/then logic

In Stata, an if clause can also be used to create new columns.

```stata
generate bucket = "low" if total_bill < 10
replace bucket = "high" if total_bill >= 10
```

The same operation in pandas can be accomplished using the where method from numpy.

```python
In [18]: tips["bucket"] = np.where(tips["total_bill"] < 10, "low", "high")
```

```python
In [19]: tips
Out[19]:
    total_bill  tip  sex  smoker day  time  size  bucket
0  14.99   1.01  Female  No  Sun  Dinner  2  high
1   8.34   1.66   Male  No  Sun  Dinner  3  low
2  19.01   3.50   Male  No  Sun  Dinner  3  high
3  21.68   3.31   Male  No  Sun  Dinner  2  high
4  22.59   3.61  Female  No  Sun  Dinner  4  high
..  ..  ..  ..  ..  ..  ..  ..  ...
239 27.03   5.92  Male  No  Sat  Dinner  3  high
240 25.18   2.00  Female  Yes  Sat  Dinner  2  high
241 20.67   2.00   Male  Yes  Sat  Dinner  2  high
242 15.82   1.75  Male  No  Sat  Dinner  2  high
243 16.78   3.00  Female  No  Thur  Dinner  2  high
[244 rows x 8 columns]
```

Date functionality

Stata provides a variety of functions to do operations on date/datetime columns.

```stata
generate date1 = mdy(1, 15, 2013)
generate date2 = date("Feb152015", "MDY")
generate date1_year = year(date1)
generate date2_month = month(date2)
```

```stata
* shift date to beginning of next month
generate date1_next = mdy(month(date1) + 1, 1, year(date1)) if month(date1) != 12
replace date1_next = mdy(1, 1, year(date1) + 1) if month(date1) == 12
```

```stata
generate months_between = mofd(date2) - mofd(date1)
```

(continues on next page)
The equivalent pandas operations are shown below. In addition to these functions, pandas supports other Time Series features not available in Stata (such as time zone handling and custom offsets) – see the timeseries documentation for more details.

```
In [20]: tips["date1"] = pd.Timestamp("2013-01-15")
In [21]: tips["date2"] = pd.Timestamp("2015-02-15")
In [22]: tips["date1_year"] = tips["date1"].dt.year
In [23]: tips["date2_month"] = tips["date2"].dt.month
In [24]: tips["date1_next"] = tips["date1"] + pd.offsets.MonthBegin()
In [25]: tips["months_between"] = tips["date2"].dt.to_period("M") - tips["date1"].dt.to_period("M")
In [26]: tips["date1", "date2", "date1_year", "date2_month", "date1_next", "months_between"]
```

```
Out[26]:
   date1     date2  date1_year  date2_month  date1_next  months_between
0 2013-01-15 2015-02-15  2013      2  2013-02-01     <25 * MonthEnds>
...     ...      ...        ...        ...               ...
[244 rows x 6 columns]
```

### Selection of columns

Stata provides keywords to select, drop, and rename columns.

```plaintext
keep sex total_bill tip
drop sex
rename total_bill total_bill_2
```

The same operations are expressed in pandas below.
Keep certain columns

```python
In [27]: tips[['sex', 'total_bill', 'tip']]
```

```
Out[27]:
   sex  total_bill  tip
0   Female     14.99  1.01
1     Male       8.34  1.66
2     Male      19.01  3.50
3     Male      21.68  3.31
4   Female      22.59  3.61
..         ...     ... ...
239   Male      27.03  5.92
240  Female      25.18  2.00
241     Male      20.67  2.00
242     Male      15.82  1.75
243  Female      16.78  3.00
```

[244 rows x 3 columns]

Drop a column

```python
In [28]: tips.drop("sex", axis=1)
```

```
Out[28]:
   total_bill  tip  smoker  day  time  size
0      14.99  1.01    No     Sun  Dinner  2
1       8.34  1.66    No     Sun  Dinner  3
2      19.01  3.50    No     Sun  Dinner  3
3      21.68  3.31    No     Sun  Dinner  2
4      22.59  3.61    No     Sun  Dinner  4
..        ...     ...     ...    ...    ...
239     27.03  5.92    No      Sat  Dinner  3
240     25.18  2.00    Yes     Sat  Dinner  2
241     20.67  2.00    Yes     Sat  Dinner  2
242     15.82  1.75    No      Sat  Dinner  2
243     16.78  3.00    No     Thur  Dinner  2
```

[244 rows x 6 columns]

Rename a column

```python
In [29]: tips.rename(columns={"total_bill": "total_bill_2"})
```

```
Out[29]:
   total_bill_2  tip  sex  smoker  day  time  size
0      14.99  1.01   Female    No     Sun  Dinner  2
1       8.34  1.66     Male    No     Sun  Dinner  3
2      19.01  3.50     Male    No     Sun  Dinner  3
3      21.68  3.31     Male    No     Sun  Dinner  2
4      22.59  3.61   Female    No     Sun  Dinner  4
..        ...     ...     ...    ...    ...
239     27.03  5.92     Male    No      Sat  Dinner  3
240     25.18  2.00   Female    Yes     Sat  Dinner  2
241     20.67  2.00     Male    Yes     Sat  Dinner  2
242     15.82  1.75     Male    No      Sat  Dinner  2
```

(continues on next page)
pandas has a `DataFrame.sort_values()` method, which takes a list of columns to sort by.

```
In [30]: tips = tips.sort_values(["sex", "total_bill"])
In [31]: tips
```

```
Out[31]:
        total_bill  tip  sex  smoker  day  time  size
   67   1.07  1.00  Female   Yes  Sat  Dinner  1
   92   3.75  1.00  Female   Yes  Fri  Dinner  2
  111   5.25  1.00  Female  No   Sat  Dinner  1
  145   6.35  1.50  Female  No  Thur  Lunch  2
  135   6.51  1.25  Female  No  Thur  Lunch  2
  ...   ...   ...     ...     ...     ...  ...
 182  43.35  3.50   Male    Yes  Sun  Dinner  3
 156  46.17  5.00   Male  No    Sun  Dinner  6
  59  46.27  6.73   Male  No   Sat  Dinner  4
 212  46.33  9.00   Male  No   Sat  Dinner  4
 170  48.81 10.00   Male    Yes  Sat  Dinner  3
```

```
[244 rows x 7 columns]
```

String processing

Finding length of string

Stata determines the length of a character string with the `strlen()` and `ustrlen()` functions for ASCII and Unicode strings, respectively.

```
generate strlen_time = strlen(time)
generate ustrlen_time = ustrlen(time)
```

You can find the length of a character string with `Series.str.len()`. In Python 3, all strings are Unicode strings. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```
In [32]: tips["time"].str.len()
Out[32]:
   67   6
   92   6
  111   6
  145   5
  135   5
  ...   ...
```

(continues on next page)
Finding position of substring

Stata determines the position of a character in a string with the `strpos()` function. This takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```python
generate str_position = strpos(sex, "ale")
```

You can find the position of a character in a column of strings with the `Series.str.find()` method. `find` searches for the first position of the substring. If the substring is found, the method returns its position. If not found, it returns -1. Keep in mind that Python indexes are zero-based.

```python
In [34]: tips["sex"].str.find("ale")
Out[34]:
67  3
92  3
111 3
145 3
135 3
182 1
156 1
59  1
212 1
170 1
Name: sex, Length: 244, dtype: int64
```
**Extracting substring by position**

Stata extracts a substring from a string based on its position with the `substr()` function.

```plaintext
generate short_sex = substr(sex, 1, 1)
```

With pandas you can use `[ ]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```plaintext
In [35]: tips["sex"][0:1]
Out[35]:
67    F
92    F
111   F
145   F
135   F
   ...  
182   M
156   M
 59    M
212   M
170   M
Name: sex, Length: 244, dtype: object
```

**Extracting nth word**

The Stata `word()` function returns the nth word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```plaintext
clear
input str20 string
  "John Smith"
  "Jane Cook"
end
generate first_name = word(name, 1)
generate last_name = word(name, -1)
```

The simplest way to extract words in pandas is to split the strings by spaces, then reference the word by index. Note there are more powerful approaches should you need them.

```plaintext
In [36]: firstlast = pd.DataFrame({"String": ["John Smith", "Jane Cook"]})
In [37]: firstlast["First_Name"] = firstlast["String"][0].split(" ", expand=True)[0]
In [38]: firstlast["Last_Name"] = firstlast["String"][0].rsplit(" ", expand=True)[0]
In [39]: firstlast
Out[39]:
       String First_Name Last_Name
0  John Smith     John     John
1  Jane Cook   Jane   Jane
```
Changing case

The Stata `strupper()`, `strlower()`, `strproper()`, `ustrupper()`, `ustrlower()`, and `ustrtitle()` functions change the case of ASCII and Unicode strings, respectively.

```plaintext
clear
input str20 string
"John Smith"
"Jane Cook"
end
generate upper = strupper(string)
generate lower = strlower(string)
generate title = strproper(string)
list

The equivalent pandas methods are `Series.str.upper()`, `Series.str.lower()`, and `Series.str.title()`.

```
In [40]: firstlast = pd.DataFrame("
In [41]: firstlast["upper"] = firstlast["string"].str.upper()
In [42]: firstlast["lower"] = firstlast["string"].str.lower()
In [43]: firstlast["title"] = firstlast["string"].str.title()
In [44]: firstlast
Out[44]:
   string         upper          lower           title
0  John Smith  JOHN SMITH      john smith      John Smith
1  Jane Cook   JANE COOK       jane cook      Jane Cook
```

Merging

The following tables will be used in the merge examples:

```
In [45]: df1 = pd.DataFrame("
In [46]: df1
Out[46]:
   key    value
0   A   0.469112
1   B  -0.282863
2   C  -1.509059
3   D  -1.135632

In [47]: df2 = pd.DataFrame("
In [48]: df2
Out[48]:
   key    value
0   B   1.212112
```

(continues on next page)
In Stata, to perform a merge, one data set must be in memory and the other must be referenced as a file name on disk. In contrast, Python must have both DataFrames already in memory.

By default, Stata performs an outer join, where all observations from both data sets are left in memory after the merge. One can keep only observations from the initial data set, the merged data set, or the intersection of the two by using the values created in the _merge variable.

```stata
* First create df2 and save to disk
clear
input str1 key
B D E
end
generate value = rnormal()
save df2.dta

* Now create df1 in memory
clear
input str1 key
A B C D
end
generate value = rnormal()
preserve

* Left join
merge 1:n key using df2.dta
keep if _merge == 1

* Right join
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 2

* Inner join
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 3

* Outer join
restore
merge 1:n key using df2.dta
```

In Stata, to perform a merge, one data set must be in memory and the other must be referenced as a file name on disk. In contrast, Python must have both DataFrames already in memory.

By default, Stata performs an outer join, where all observations from both data sets are left in memory after the merge. One can keep only observations from the initial data set, the merged data set, or the intersection of the two by using the values created in the _merge variable.

```stata
* First create df2 and save to disk
clear
input str1 key
B D E
end
generate value = rnormal()
save df2.dta

* Now create df1 in memory
clear
input str1 key
A B C D
end
generate value = rnormal()
preserve

* Left join
merge 1:n key using df2.dta
keep if _merge == 1

* Right join
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 2

* Inner join
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 3

* Outer join
restore
merge 1:n key using df2.dta
```

pandas DataFrames have a `merge()` method, which provides similar functionality. The data does not have to be sorted ahead of time, and different join types are accomplished via the how keyword.

```
in [49]: inner_join = df1.merge(df2, on=['key'], how='inner')
```

1.4. Tutorials
In [50]: inner_join
Out[50]:
   key  value_x  value_y
0  B   -0.282863  1.212112
1  D   -1.135632 -0.173215
2  D   -1.135632  0.119209

In [51]: left_join = df1.merge(df2, on=['key'], how='left')
In [52]: left_join
Out[52]:
   key  value_x  value_y
0  A    0.469112  NaN
1  B  -0.282863  1.212112
2  C  -1.509059  NaN
3  D  -1.135632 -0.173215
4  D  -1.135632  0.119209
5  E    NaN     -1.044236

In [53]: right_join = df1.merge(df2, on=['key'], how='right')
In [54]: right_join
Out[54]:
   key  value_x  value_y
0  B  -0.282863  1.212112
1  D  -1.135632 -0.173215
2  D  -1.135632  0.119209
3  E    NaN     -1.044236

In [55]: outer_join = df1.merge(df2, on=['key'], how='outer')
In [56]: outer_join
Out[56]:
   key  value_x  value_y
0  A   0.469112  NaN
1  B  -0.282863  1.212112
2  C  -1.509059  NaN
3  D  -1.135632 -0.173215
4  D  -1.135632  0.119209
5  E    NaN     -1.044236

### Missing data

Both pandas and Stata have a representation for missing data.
pandas represents missing data with the special float value `NaN` (not a number). Many of the semantics are the same; for example missing data propagates through numeric operations, and is ignored by default for aggregations.
In [58]: outer_join["value_x"] + outer_join["value_y"]
Out[58]:
0  NaN
1  0.929249
2  NaN
3  -1.308847
4  -1.016424
5  NaN
dtype: float64

In [59]: outer_join["value_x"].sum()
Out[59]: -3.5940742896293765

One difference is that missing data cannot be compared to its sentinel value. For example, in Stata you could do this to filter missing values.

* Keep missing values
list if value_x == .
* Keep non-missing values
list if value_x != .

In pandas, `Series.isna()` and `Series.notna()` can be used to filter the rows.

In [60]: outer_join[outer_join["value_x"].isna()]
Out[60]:

<table>
<thead>
<tr>
<th>key</th>
<th>value_x</th>
<th>value_y</th>
</tr>
</thead>
<tbody>
<tr>
<td>E</td>
<td>NaN</td>
<td>-1.044236</td>
</tr>
</tbody>
</table>

In [61]: outer_join[outer_join["value_x"].notna()]
Out[61]:

<table>
<thead>
<tr>
<th>key</th>
<th>value_x</th>
<th>value_y</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>0.469112</td>
<td>NaN</td>
</tr>
<tr>
<td>B</td>
<td>-0.282863</td>
<td>1.212112</td>
</tr>
<tr>
<td>C</td>
<td>-1.509059</td>
<td>NaN</td>
</tr>
<tr>
<td>D</td>
<td>-1.135632</td>
<td>-0.173215</td>
</tr>
<tr>
<td>D</td>
<td>-1.135632</td>
<td>0.119209</td>
</tr>
</tbody>
</table>

pandas provides a variety of methods to work with missing data. Here are some examples:
Drop rows with missing values

```python
In [62]: outer_join.dropna()
Out[62]:
     key  value_x  value_y
1     B   -0.282863  1.212112
3     D   -1.135632 -0.173215
4     D   -1.135632  0.119209
```

Forward fill from previous rows

```python
In [63]: outer_join.fillna(method="ffill")
Out[63]:
     key  value_x  value_y
0     A    0.469112   NaN
1     B  -0.282863  1.212112
2     C  -1.509059  1.212112
3     D  -1.135632 -0.173215
4     D  -1.135632  0.119209
5     E  -1.135632 -1.044236
```

Replace missing values with a specified value

Using the mean:

```python
In [64]: outer_join["value_x"].fillna(outer_join["value_x"].mean())
Out[64]:
0    0.469112
1  -0.282863
2  -1.509059
3  -1.135632
4  -1.135632
5  -0.718815
Name: value_x, dtype: float64
```

**GroupBy**

**Aggregation**

Stata’s `collapse` can be used to group by one or more key variables and compute aggregations on numeric columns.

```bash
collapse (sum) total_bill tip, by(sex smoker)
```

pandas provides a flexible `groupby` mechanism that allows similar aggregations. See the `groupby documentation` for more details and examples.

```python
In [65]: tips_summed = tips.groupby(["sex", "smoker"])[["total_bill", "tip"]].sum()
In [66]: tips_summed
Out[66]:
```

(continues on next page)
Transformation

In Stata, if the group aggregations need to be used with the original data set, one would usually use `bysort` with `egen()`. For example, to subtract the mean for each observation by smoker group.

```plaintext
bysort sex smoker: egen group_bill = mean(total_bill)
generate adj_total_bill = total_bill - group_bill
```

pandas provides a `Transformation` mechanism that allows these type of operations to be succinctly expressed in one operation.

```plaintext
In [67]: gb = tips.groupby("smoker")["total_bill"]
In [68]: tips["adj_total_bill"] = tips["total_bill"] - gb.transform("mean")
```

```
Out[69]:
```

<table>
<thead>
<tr>
<th>total_bill</th>
<th>tip</th>
<th>sex</th>
<th>smoker</th>
<th>day</th>
<th>time</th>
<th>size</th>
<th>adj_total_bill</th>
</tr>
</thead>
<tbody>
<tr>
<td>67</td>
<td>1.07</td>
<td>1.00</td>
<td>Female</td>
<td>Yes</td>
<td>Sat</td>
<td>Dinner</td>
<td>-17.686344</td>
</tr>
<tr>
<td>92</td>
<td>3.75</td>
<td>1.00</td>

[244 rows x 8 columns]

By group processing

In addition to aggregation, pandas `groupby` can be used to replicate most other `bysort` processing from Stata. For example, the following example lists the first observation in the current sort order by sex/smoker group.

```plaintext
bysort sex smoker: list if _n == 1
```

In pandas this would be written as:

```
In [70]: tips.groupby(["sex", "smoker"]).first()
Out[70]:
```

```
total_bill tip day time size adj_total_bill
--- ----- --- ---- -- ---- ------------
Female No 5.25 1.00 Sat Dinner 1 -11.938278
```

(continues on next page)
Other considerations

Disk vs memory

pandas and Stata both operate exclusively in memory. This means that the size of data able to be loaded in pandas is limited by your machine’s memory. If out of core processing is needed, one possibility is the dask.dataframe library, which provides a subset of pandas functionality for an on-disk DataFrame.

1.4.5 Community tutorials

This is a guide to many pandas tutorials by the community, geared mainly for new users.

pandas cookbook by Julia Evans

The goal of this 2015 cookbook (by Julia Evans) is to give you some concrete examples for getting started with pandas. These are examples with real-world data, and all the bugs and weirdness that entails. For the table of contents, see the pandas-cookbook GitHub repository.

Learn pandas by Hernan Rojas

A set of lesson for new pandas users: https://bitbucket.org/hrojas/learn-pandas

Practical data analysis with Python

This guide is an introduction to the data analysis process using the Python data ecosystem and an interesting open dataset. There are four sections covering selected topics as munging data, aggregating data, visualizing data and time series.

Exercises for new users

Practice your skills with real data sets and exercises. For more resources, please visit the main repository.

Modern pandas

Tutorial series written in 2016 by Tom Augspurger. The source may be found in the GitHub repository TomAugspurger/effective-pandas.

Various tutorials

• Wes McKinney’s (pandas BDFL) blog
• Statistical analysis made easy in Python with SciPy and pandas DataFrames, by Randal Olson
• Statistical Data Analysis in Python, tutorial videos, by Christopher Fonnesbeck from SciPy 2013
• Financial analysis in Python, by Thomas Wiecki
• Intro to pandas data structures, by Greg Reda
• Pandas and Python: Top 10, by Manish Amde
• Pandas DataFrames Tutorial, by Karlijn Willems
• A concise tutorial with real life examples
The User Guide covers all of pandas by topic area. Each of the subsections introduces a topic (such as “working with missing data”), and discusses how pandas approaches the problem, with many examples throughout.

Users brand-new to pandas should start with 10 minutes to pandas.

For a high level summary of the pandas fundamentals, see Intro to data structures and Essential basic functionality.

Further information on any specific method can be obtained in the API reference.

2.1 10 minutes to pandas

This is a short introduction to pandas, geared mainly for new users. You can see more complex recipes in the Cookbook.

Customarily, we import as follows:

```python
In [1]: import numpy as np
In [2]: import pandas as pd
```

2.1.1 Object creation

See the Data Structure Intro section.

Creating a Series by passing a list of values, letting pandas create a default integer index:

```python
In [3]: s = pd.Series([1, 3, 5, np.nan, 6, 8])
In [4]: s
Out[4]:
0   1.0
1   3.0
2   5.0
3  NaN
4   6.0
5   8.0
dtype: float64
```

Creating a DataFrame by passing a NumPy array, with a datetime index and labeled columns:

```python
In [5]: dates = pd.date_range("20130101", periods=6)
In [6]: dates
```

(continues on next page)
Creating a `DataFrame` by passing a dict of objects that can be converted to series-like.

The columns of the resulting `DataFrame` have different dtypes.

If you’re using IPython, tab completion for column names (as well as public attributes) is automatically enabled. Here’s a subset of the attributes that will be completed:
As you can see, the columns A, B, C, and D are automatically tab completed. E and F are there as well; the rest of the attributes have been truncated for brevity.

### 2.1.2 Viewing data

See the Basics section.

Here is how to view the top and bottom rows of the frame:

```python
In [13]: df.head()
Out[13]:
   A     B     C     D
2013-01-01 0.469112 -0.282863 -1.509059 -1.135632
2013-01-02 1.212112 -0.173215  0.119209 -1.044236
2013-01-03 -0.861849 -2.104569 -0.494929  1.071804
2013-01-04  0.721555 -0.706771 -1.039575  0.271860
2013-01-05 -0.424972  0.567020  0.276232 -1.087401
```

```python
In [14]: df.tail(3)
Out[14]:
   A     B     C     D
2013-01-04 0.721555 -0.706771 -1.039575  0.271860
2013-01-05 -0.424972  0.567020  0.276232 -1.087401
2013-01-06 -0.673690  0.113648 -1.478427  0.524988
```

Display the index, columns:

```python
In [15]: df.index
Out[15]:
DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
               '2013-01-05', '2013-01-06'],
              dtype='datetime64[ns]', freq='D')
```

```python
In [16]: df.columns
Out[16]:
Index(['A', 'B', 'C', 'D'], dtype='object')
```

`DataFrame.to_numpy()` gives a NumPy representation of the underlying data. Note that this can be an expensive operation when your DataFrame has columns with different data types, which comes down to a fundamental difference between pandas and NumPy: NumPy arrays have one dtype for the entire array, while pandas DataFrames have one dtype per column. When you call `DataFrame.to_numpy()`, pandas will find the NumPy dtype that can hold all of the dtypes in the DataFrame. This may end up being object, which requires casting every value to a Python object.
For `df`, our `DataFrame` of all floating-point values, `DataFrame.to_numpy()` is fast and doesn’t require copying data.

```python
In [17]: df.to_numpy()
Out[17]:
array([[ 0.4691, -0.2829, -1.5091, -1.1356],
       [ 1.2121, -0.1732,  0.1192, -1.0442],
       [-0.8618, -2.1046, -0.4949,  1.0718],
       [ 0.7216, -0.7068, -1.0396,  0.2719],
       [-0.425 ,  0.567 ,  0.2762, -1.0874],
       [-0.6737,  0.1136, -1.4784,  0.525 ]])
```

For `df2`, the `DataFrame` with multiple dtypes, `DataFrame.to_numpy()` is relatively expensive.

```python
In [18]: df2.to_numpy()
Out[18]:
array([[1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'test', 'foo'],
       [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'train', 'foo'],
       [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'test', 'foo'],
       [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'train', 'foo']],
       dtype=object)
```

Note: `DataFrame.to_numpy()` does not include the index or column labels in the output.

describe() shows a quick statistic summary of your data:

```python
In [19]: df.describe()
Out[19]:
       A         B         C         D
count 6.000000 6.000000 6.000000 6.000000
mean  0.073711 -0.431125 -0.687758 -0.233103
std   0.843157 0.922818  0.779887  0.973118
min  -0.861849 -2.104569 -1.509059 -1.135632
25%  -0.611510 -0.600794 -1.368714 -1.076610
50%   0.022070 -0.228039 -0.767252 -0.386188
75%   0.658444  0.041933 -0.034326  0.461706
max   1.212112  0.567020  0.276232  1.071804
```

Transposing your data:

```python
In [20]: df.T
Out[20]:
A          0.469112  1.212112  -0.861849  0.721555  -0.424972  -0.673690
B          0.282863 -0.173215  -2.104569 -0.706771  0.567020   0.113648
C         -1.509059  0.119209  -0.494929 -1.039575  0.276232   1.478427
D         -1.135632 -1.044236  1.071804  0.271860  -1.087401   0.524988
```

Sorting by an axis:

```python
In [21]: df.sort_index(axis=1, ascending=False)
Out[21]:
          D         C         B         A
2013-01-01 -1.135632 -1.509059 0.469112
2013-01-02 -1.044236  0.119209 -1.73215  1.212112
2013-01-03  1.071804 -0.494929 -2.104569 -0.861849
```

(continues on next page)
2013-01-04  0.271860 -1.039575 -0.706771  0.721555
2013-01-05  -1.087401  0.276232  0.567020 -0.424972
2013-01-06  0.524988 -1.478427  0.113648 -0.673690

Sorting by values:

```
In [22]: df.sort_values(by="B")
Out[22]:
   A    B    C    D
2013-01-03 -0.861849 -2.104569 -0.494929  1.071804
2013-01-04  0.721555 -0.706771 -1.039575  0.271860
2013-01-01  0.469112 -0.282863 -1.509059 -1.135632
2013-01-02  1.212112 -0.173215  0.119209 -1.044236
2013-01-06 -0.673690  0.113648 -1.478427  0.524988
2013-01-05 -0.424972  0.567020  0.276232 -1.087401
```

### 2.1.3 Selection

**Note:** While standard Python / NumPy expressions for selecting and setting are intuitive and come in handy for interactive work, for production code, we recommend the optimized pandas data access methods, `.at`, `.iat`, `.loc` and `.iloc`.

See the indexing documentation *Indexing and Selecting Data* and *MultiIndex / Advanced Indexing*.

#### Getting

Selecting a single column, which yields a *Series*, equivalent to `df.A`:

```
In [23]: df["A"]
Out[23]:
   2013-01-01    0.469112
   2013-01-02    1.212112
   2013-01-03   -0.861849
   2013-01-04    0.721555
   2013-01-05   -0.424972
   2013-01-06   -0.673690
Freq: D, Name: A, dtype: float64
```

Selecting via [], which slices the rows.

```
In [24]: df[0:3]
Out[24]:
   A    B    C    D
2013-01-01  0.469112 -0.282863 -1.509059 -1.135632
2013-01-02  1.212112 -0.173215  0.119209 -1.044236
2013-01-03 -0.861849 -2.104569 -0.494929  1.071804
```

```
In [25]: df["20130102":"20130104"]
Out[25]:
   A    B    C    D
2013-01-02  1.212112 -0.173215  0.119209 -1.044236
```

(continues on next page)
Selection by label

See more in Selection by Label.

For getting a cross section using a label:

```python
In [26]: df.loc[dates[0]]
Out[26]:
A   0.469112
B  -0.282863
C  -1.509059
D  -1.135632
Name: 2013-01-01 00:00:00, dtype: float64
```

Selecting on a multi-axis by label:

```python
In [27]: df.loc[:, ["A", "B"]]
Out[27]:
      A     B
2013-01-01  0.469112 -0.282863
2013-01-02  1.212112 -0.173215
2013-01-03 -0.861849 -2.104569
2013-01-04  0.721555 -0.706771
2013-01-05 -0.424972  0.567020
2013-01-06 -0.673690  0.113648
```

Showing label slicing, both endpoints are included:

```python
In [28]: df.loc["20130102":"20130104", ["A", "B"]]
Out[28]:
          A     B
2013-01-02  1.212112 -0.173215
2013-01-03 -0.861849 -2.104569
2013-01-04  0.721555 -0.706771
```

Reduction in the dimensions of the returned object:

```python
In [29]: df.loc["20130102", ["A", "B"]]
Out[29]:
          A   B
2013-01-02  1.212112 -0.173215
Name: 2013-01-02 00:00:00, dtype: float64
```

For getting a scalar value:

```python
In [30]: df.loc[dates[0], "A"]
Out[30]:
0.4691122999071863
```

For getting fast access to a scalar (equivalent to the prior method):

```python
In [31]: df.at[dates[0], "A"]
Out[31]:
0.4691122999071863
```
Selection by position

See more in Selection by Position.

Select via the position of the passed integers:

```python
In [32]: df.iloc[3]
Out[32]:
A     0.721555
B    -0.706771
C    -1.039575
D     0.271860
Name: 2013-01-04 00:00:00, dtype: float64
```

By integer slices, acting similar to NumPy/Python:

```python
In [33]: df.iloc[3:5, 0:2]
Out[33]:
   A    B
2013-01-04  0.721555 -0.706771
2013-01-05  0.424972  0.567020
```

By lists of integer position locations, similar to the NumPy/Python style:

```python
In [34]: df.iloc[[1, 2, 4], [0, 2]]
Out[34]:
   A    C
2013-01-02  1.212112  0.119209
2013-01-03 -0.861849 -0.494929
2013-01-05 -0.424972  0.276232
```

For slicing rows explicitly:

```python
In [35]: df.iloc[1:3, :]
Out[35]:
   A    B    C    D
2013-01-02  1.212112 -0.173215  0.119209 -1.044236
2013-01-03 -0.861849 -2.104569 -0.494929  1.071804
```

For slicing columns explicitly:

```python
In [36]: df.iloc[:, 1:3]
Out[36]:
   B    C
2013-01-01  -0.282863 -1.509059
2013-01-02  -0.173215  0.119209
2013-01-03  -2.104569 -0.494929
2013-01-04  -0.706771 -1.039575
2013-01-05   0.567020  0.276232
2013-01-06   0.113648 -1.478427
```

For getting a value explicitly:

```python
In [37]: df.iloc[1, 1]
Out[37]:
-0.1732146490530858
```

For getting fast access to a scalar (equivalent to the prior method):

```
2.1. 10 minutes to pandas 151
```
In [38]: df.iat[1, 1]
Out[38]: -0.17321464905330858

Boolean indexing

Using a single column’s values to select data.

In [39]: df[df["A"] > 0]
Out[39]:
A     B     C     D
2013-01-01  0.469112 -0.282863 -1.509059 -1.135632
2013-01-02  1.212112 -0.173215  0.119209 -1.044236
2013-01-04  0.721555 -0.706771 -1.039575  0.271860

Selecting values from a DataFrame where a boolean condition is met.

In [40]: df[df > 0]
Out[40]:
A     B     C     D
2013-01-01  0.469112 NaN NaN NaN
2013-01-02  1.212112 NaN  0.119209 NaN
2013-01-03  NaN  NaN NaN  1.071804
2013-01-04  0.721555 NaN NaN  0.271860
2013-01-05  NaN  0.567020  0.276232 NaN
2013-01-06  NaN  0.113648 NaN  0.524988

Using the `isin()` method for filtering:

In [41]: df2 = df.copy()

In [42]: df2["E"] = ["one", "one", "two", "three", "four", "three"]

In [43]: df2
Out[43]:
A     B     C     D     E
2013-01-01  0.469112 -0.282863 -1.509059 -1.135632 one
2013-01-02  1.212112 -0.173215  0.119209 -1.044236 one
2013-01-03 -0.861849 -2.104569  0.119209  1.071804 two
2013-01-04  0.721555 -0.706771 -1.039575  0.271860 three
2013-01-05 -0.424972  0.567020  0.276232 -1.087401 four
2013-01-06 -0.673690  0.113648 -1.478427  0.524988 three

In [44]: df2[df2["E"].isin(["two", "four")]]
Out[44]:
A     B     C     D     E
2013-01-03 -0.861849 -2.104569 -0.494929  1.071804 two
2013-01-05 -0.424972  0.567020  0.276232 -1.087401 four
Setting

Setting a new column automatically aligns the data by the indexes.

```
In [45]: s1 = pd.Series([1, 2, 3, 4, 5, 6], index=pd.date_range("20130102", periods=6))
In [46]: s1
Out[46]:
2013-01-02  1
2013-01-03  2
2013-01-04  3
2013-01-05  4
2013-01-06  5
2013-01-07  6
Freq: D, dtype: int64
In [47]: df["F"] = s1
```

Setting values by label:

```
In [48]: df.at[dates[0], "A"] = 0
```

Setting values by position:

```
In [49]: df.iat[0, 1] = 0
```

Setting by assigning with a NumPy array:

```
In [50]: df.loc[:, "D"] = np.array([5] * len(df))
```

The result of the prior setting operations.

```
In [51]: df
Out[51]:
         A         B         C         D         F
   2013-01-01  0.000000  0.000000 -1.509059    5  NaN
   2013-01-02 -1.212112 -0.173215  0.119209    5  1.0
   2013-01-03 -0.861849 -2.104569 -0.494929    5  2.0
   2013-01-04  0.721555 -0.706771 -1.039575    5  3.0
   2013-01-05 -0.424972  0.567020  0.276232    5  4.0
   2013-01-06 -0.673690  0.113648 -1.478427    5  5.0
```

A where operation with setting.

```
In [52]: df2 = df.copy()
In [53]: df2[df2 > 0] = -df2
In [54]: df2
Out[54]:
         A         B         C         D         F
   2013-01-01  0.000000  0.000000 -1.509059  -5  NaN
   2013-01-02 -1.212112 -0.173215 -0.119209  -5 -1.0
   2013-01-03 -0.861849 -2.104569 -0.494929  -5 -2.0
   2013-01-04  0.721555 -0.706771 -1.039575  -5 -3.0
   2013-01-05 -0.424972  0.567020  0.276232  -5 -4.0
   2013-01-06 -0.673690 -0.113648 -1.478427  -5 -5.0
```
2.1.4 Missing data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the Missing Data section.

Reindexing allows you to change/add/delete the index on a specified axis. This returns a copy of the data.

```
In [55]: df1 = df.reindex(index=dates[0:4], columns=list(df.columns) + ["E"])

In [56]: df1.loc[dates[0] : dates[1], "E"] = 1

In [57]: df1
```

```
Out[57]:
A     B     C    D    F   E
2013-01-01 0.000000 0.000000 -1.509059 5  NaN 1.0
2013-01-02 1.212112 -0.173215  0.119209 5  1.0 1.0
2013-01-03 -0.861849 -2.104569 -0.494929 5  2.0 NaN
2013-01-04  0.721555 -0.706771 -1.039575 5  3.0 NaN
```

To drop any rows that have missing data.

```
In [58]: df1.dropna(how="any")
```

```
Out[58]:
A     B     C    D    F   E
2013-01-02 1.212112 -0.173215  0.119209 5  1.0 1.0
```

Filling missing data.

```
In [59]: df1.fillna(value=5)
```

```
Out[59]:
A     B     C    D    F   E
2013-01-01 0.000000 0.000000 -1.509059 5  5.0 1.0
2013-01-02 1.212112 -0.173215  0.119209 5  1.0 1.0
2013-01-03 -0.861849 -2.104569 -0.494929 5  2.0  5.0
2013-01-04  0.721555 -0.706771 -1.039575 5  3.0  5.0
```

To get the boolean mask where values are `nan`.

```
In [60]: pd.isna(df1)
```

```
Out[60]:
A     B     C    D    F   E
2013-01-01 False False False False True  False
2013-01-02 False False False False False  False
2013-01-03 False False False False False  False
2013-01-04 False False False False False  False
```

2.1.5 Operations

See the Basic section on Binary Ops.
Stats

Operations in general exclude missing data.

Performing a descriptive statistic:

```python
In [61]: df.mean()
Out[61]:
A   -0.004474
B   -0.383981
C   -0.687758
D    5.000000
F    3.000000
dtype: float64
```

Same operation on the other axis:

```python
In [62]: df.mean(1)
Out[62]:
2013-01-01  0.872735
2013-01-02  1.431621
2013-01-03  0.707731
2013-01-04  1.395042
2013-01-05  1.883656
2013-01-06  1.592306
Freq: D, dtype: float64
```

Operating with objects that have different dimensionality and need alignment. In addition, pandas automatically broadcasts along the specified dimension.

```python
In [63]: s = pd.Series([1, 3, 5, np.nan, 6, 8], index=dates).shift(2)
In [64]: s
Out[64]:
2013-01-01    NaN
2013-01-02    NaN
2013-01-03  1.0
2013-01-04  3.0
2013-01-05  5.0
2013-01-06    NaN
Freq: D, dtype: float64
```

```python
In [65]: df.sub(s, axis="index")
Out[65]:
     A     B     C     D     F
2013-01-01  NaN  NaN  NaN  NaN  NaN
2013-01-02  NaN  NaN  NaN  NaN  NaN
2013-01-03 -1.861849 -3.104569 -1.494929 4.0  1.0
2013-01-04 -2.278445 -3.706771 -4.039575 2.0  0.0
2013-01-05 -5.424972 -4.432980 -4.723768 0.0 -1.0
2013-01-06  NaN  NaN  NaN  NaN  NaN
```
Apply

Applying functions to the data:

```
In [66]: df.apply(np.cumsum)
Out[66]:
             A         B          C         D         F
2013-01-01  0.000000  0.000000 -1.509059  5.000000  NaN
2013-01-02  1.212112 -0.173215 -1.389850 10.000000  1.000000
2013-01-03  0.350263 -2.277784 -1.884779 15.000000  3.000000
2013-01-04  1.071818 -2.984555 -2.924354 20.000000  6.000000
2013-01-05  0.646846 -2.417535 -4.126549 30.000000  15.000000
In [67]: df.apply(lambda x: x.max() - x.min())
Out[67]:
          A    2.073961
          B    2.671590
          C    1.785291
          D  2.148779
          F    4.000000
dtype: float64
```

Histogramming

See more at `Histogramming and Discretization`

```
In [68]: s = pd.Series(np.random.randint(0, 7, size=10))
In [69]: s
Out[69]:
   0    4
   1    2
   2    1
   3    2
   4    6
   5    4
   6    4
   7    6
   8    4
   9    4
dtype: int64
In [70]: s.value_counts()
Out[70]:
4    5
2    2
6    2
1    1
dtype: int64
```
String Methods

Series is equipped with a set of string processing methods in the `str` attribute that make it easy to operate on each element of the array, as in the code snippet below. Note that pattern-matching in `str` generally uses regular expressions by default (and in some cases always uses them). See more at Vectorized String Methods.

```python
In [72]: s.str.lower()
Out[72]:
0    a
1    b
2    c
3   aaba
4   baca
5     NaN
6    caba
7    dog
8    cat
dtype: object
```

2.1.6 Merge

Concat

pandas provides various facilities for easily combining together Series and DataFrame objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

See the Merging section.

Concatenating pandas objects together with `concat()`:

```python
In [73]: df = pd.DataFrame(np.random.randn(10, 4))
In [74]: df
Out[74]:
     0         1         2         3
0 -0.548702  1.467327 -1.015962 -0.483075
1  1.637550 -1.217659 -0.291519 -1.745505
2 -0.263952  0.991460 -0.919069  0.266046
3 -0.709661  1.669052  1.037882 -1.705775
4 -0.919854 -0.042379  1.247642 -0.009920
5  0.290213  0.495767  0.362949  1.548106
6 -1.131345 -0.089329  0.337863 -0.945867
7 -0.932132  1.956030  0.017587 -0.016692
8 -0.575247  0.254161 -1.143704  0.215897
9  1.193555 -0.077118 -0.408530 -0.862495

# break it into pieces
In [75]: pieces = [df[:3], df[3:7], df[7:]]
In [76]: pd.concat(pieces)
Out[76]:
     0         1         2         3
0 -0.548702  1.467327 -1.015962 -0.483075
1  1.637550 -1.217659 -0.291519 -1.745505
(continues on next page)
```
2 -0.263952  0.991460 -0.919069  0.266046
3  0.709661  1.669052  1.037882 -1.705775
4 -0.919854 -0.042379  1.247642 -0.009920
5  0.292013  0.495767  0.362949  1.548106
6 -1.131345 -0.089329  0.337863 -0.945867
7 -0.932132  1.956030  0.017587 -0.016692
8 -0.575247  0.254161 -1.143704  0.215897
9  1.193555 -0.077118 -0.408530 -0.862495

Note: Adding a column to a DataFrame is relatively fast. However, adding a row requires a copy, and may be expensive. We recommend passing a pre-built list of records to the DataFrame constructor instead of building a DataFrame by iteratively appending records to it. See Appending to dataframe for more.

Join

SQL style merges. See the Database style joining section.

In [77]: left = pd.DataFrame({"key": ["foo", "foo"], "lval": [1, 2]})

In [78]: right = pd.DataFrame({"key": ["foo", "foo"], "rval": [4, 5]})

In [79]: left
Out[79]:
   key lval
0  foo   1
1  foo   2

In [80]: right
Out[80]:
   key rval
0  foo   4
1  foo   5

In [81]: pd.merge(left, right, on="key")
Out[81]:
   key  lval  rval
0  foo   1     4
1  foo   5
2  foo   1     5
3  foo   2

Another example that can be given is:

In [82]: left = pd.DataFrame({"key": ["foo", "bar"], "lval": [1, 2]})

In [83]: right = pd.DataFrame({"key": ["foo", "bar"], "rval": [4, 5]})

In [84]: left
Out[84]:
   key  lval
0  foo   1
1  bar   2
In [85]: right
Out[85]:
   key  rval
0  foo   4
1  bar   5

In [86]: pd.merge(left, right, on="key")
Out[86]:
   key  lval  rval
0  foo   1   4
1  bar   2   5

### 2.1.7 Grouping

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria
- **Applying** a function to each group independently
- **Combining** the results into a data structure

See the [Grouping section](#).

In [87]: df = pd.DataFrame(
       ....:     
       ....:     "A": ["foo", "bar", "foo", "bar", "foo", "bar", "foo", "foo"],
       ....:     "B": ["one", "one", "two", "three", "two", "one", "three"],
       ....:     "C": np.random.randn(8),
       ....:     "D": np.random.randn(8),
       ....:     )
       ....:  
In [88]: df
Out[88]:
   A     B         C         D
0  foo  one  1.346061 -1.577585
1  bar  one  1.511763  0.396823
2  foo  two  1.627081 -0.105381
3  bar  three -0.990582 -0.532532
4  foo  two -0.441652  1.453749
5  bar  two  1.211526  1.208843
6  foo  one  0.268520 -0.080952
7  foo  three  0.024580 -0.264610

Grouping and then applying the `sum()` function to the resulting groups.

In [89]: df.groupby("A").sum()
Out[89]:
   C         D
A
bar  1.732707  1.073134
foo  2.824590 -0.574779

Grouping by multiple columns forms a hierarchical index, and again we can apply the `sum()` function.

2.1. 10 minutes to pandas
2.1.8 Reshaping

See the sections on *Hierarchical Indexing* and *Reshaping*.

### Stack

```python
def groupby(
    df.groupby(["A", "B"]).sum()

Out[90]::
    C  D
A B
bar one 1.511763 0.396823
   three -0.990582 -0.532532
two 1.211526 1.208843
foo one 1.614581 -1.658537
   three 0.024580 -0.264610
two 1.185429 1.348368

In [91]: tuples = list(zip(*
                   *["bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"],
                     *["one", "two", "one", "two", "one", "two", "one", "two"],
                     )

In [92]: index = pd.MultiIndex.from_tuples(tuples, names=["first", "second"])

In [93]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=["A", "B"])  

In [94]: df2 = df[:4]

In [95]: df2
Out[95]::
    A  B
first second  
bar one -0.727965 -0.589346  
two 0.339969 -0.693205  
baz one -0.339355 0.593616  
two 0.884345 1.591431

The `stack()` method “compresses” a level in the DataFrame’s columns.

In [96]: stacked = df2.stack()

In [97]: stacked
Out[97]::
    first  second
    
bar one A -0.727965  
    B -0.589346  
two A 0.339969  
    B -0.693205  
baz one A -0.339355  
```

(continues on next page)
With a “stacked” DataFrame or Series (having a MultiIndex as the index), the inverse operation of `stack()` is `unstack()`, which by default unstacks the last level:

```python
In [98]: stacked.unstack()
Out[98]:
   A   B
first second
bar one -0.727965 -0.589346
two 0.339969 -0.693205
baz one -0.339355  0.593616
two  0.884345  1.591431
```

```python
In [99]: stacked.unstack(1)
Out[99]:
   second one two
first
bar   A -0.727965  0.339969
      B -0.589346 -0.693205
baz   A -0.339355  0.884345
      B  0.593616  1.591431
```

```python
In [100]: stacked.unstack(0)
Out[100]:
   first bar  baz
second
one   A -0.727965 -0.339355
      B -0.589346  0.593616
two   A  0.339969  0.884345
      B -0.693205  1.591431
```

Pivot tables

See the section on *Pivot Tables*.

```python
In [101]: df = pd.DataFrame(
   ....:      {  
   ....:          "A": ["one", "one", "two", "three"] * 3,
   ....:          "B": ["A", "B", "C"] * 4,
   ....:          "C": ["foo", "foo", "foo", "bar", "bar", "bar"] * 2,
   ....:          "D": np.random.randn(12),
   ....:          "E": np.random.randn(12),
   ....:      }
   ....:  )
   ....: 
In [102]: df
Out[102]:
   A  B  C  D  E
   0 one A  foo -1.202872 0.047609
   1 one B  foo -1.814470 -0.136473
```

(continues on next page)
We can produce pivot tables from this data very easily:

```
In [103]: pd.pivot_table(df, values="D", index=["A", "B"], columns=["C"])
Out[103]:
     C   bar   foo
    A   B
  one  A  2.395985 -1.202872
     B  1.395433 -1.814470
     C -0.392670  -0.055224
  three A -0.595447     NaN
       B      NaN  1.928123
       C  0.166599     NaN
  two  A     NaN  0.007207
     B  1.552825     NaN
     C     NaN  1.018601
```

### 2.1.9 Time series

pandas has simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications. See the Time Series section.

```
In [104]: rng = pd.date_range("1/1/2012", periods=100, freq="S")
In [105]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)
In [106]: ts.resample("5Min").sum()
Out[106]:

```

Time zone representation:

```
In [107]: rng = pd.date_range("3/6/2012 00:00", periods=5, freq="D")
In [108]: ts = pd.Series(np.random.randn(len(rng)), rng)
In [109]: ts
Out[109]:
2012-03-06  1.857704
2012-03-07  -1.193545
2012-03-08  0.677510
2012-03-09  -0.153931
2012-03-10  0.520091
```
Freq: D, dtype: float64

In [110]: ts_utc = ts.tz_localize("UTC")

In [111]: ts_utc
Out[111]:
2012-03-06 00:00:00+00:00  1.857704
2012-03-07 00:00:00+00:00 -1.193545
2012-03-08 00:00:00+00:00  0.677510
2012-03-09 00:00:00+00:00 -0.153931
2012-03-10 00:00:00+00:00  0.520091
Freq: D, dtype: float64

Converting to another time zone:

In [112]: ts_utc.tz_convert("US/Eastern")
Out[112]:
2012-03-05 19:00:00-05:00  1.857704
2012-03-06 19:00:00-05:00 -1.193545
2012-03-07 19:00:00-05:00  0.677510
2012-03-08 19:00:00-05:00 -0.153931
2012-03-09 19:00:00-05:00  0.520091
Freq: D, dtype: float64

Converting between time span representations:

In [113]: rng = pd.date_range("1/1/2012", periods=5, freq="M")

In [114]: ts = pd.Series(np.random.randn(len(rng)), index=rng)

In [115]: ts
Out[115]:
2012-01-31   -1.475051
2012-02-29    0.722570
2012-03-31   -0.322646
2012-04-30   -1.601631
2012-05-31    0.778033
Freq: M, dtype: float64

In [116]: ps = ts.to_period()

In [117]: ps
Out[117]:
2012-01   -1.475051
2012-02    0.722570
2012-03   -0.322646
2012-04   -1.601631
2012-05    0.778033
Freq: M, dtype: float64

In [118]: ps.to_timestamp()

Out[118]:
2012-01-01   -1.475051
2012-02-01    0.722570
2012-03-01   -0.322646
2012-04-01   -1.601631
2012-05-01    0.778033
Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```python
In [119]: prng = pd.period_range("1990Q1", "2000Q4", freq="Q-NOV")
In [120]: ts = pd.Series(np.random.randn(len(prng)), prng)
In [121]: ts.index = (prng.asfreq("M", "e") + 1).asfreq("H", "s") + 9
In [122]: ts.head()
Out[122]:
1990-03-01 09:00 -0.289342
1990-06-01 09:00 0.233141
1990-09-01 09:00 -0.223540
1990-12-01 09:00 0.542054
1991-03-01 09:00 -0.688585
Freq: H, dtype: float64
```

### 2.1.10 Categoricals

pandas can include categorical data in a `DataFrame`. For full docs, see the categorical introduction and the API documentation.

```python
In [123]: df = pd.DataFrame(
    .....:     {"id": [1, 2, 3, 4, 5, 6], "raw_grade": ["a", "b", "b", "a", "a", "e"]}
    .....: )
.....:
```

Convert the raw grades to a categorical data type.

```python
In [124]: df["grade"] = df["raw_grade"].astype("category")
In [125]: df["grade"]
Out[125]:
0    a
1    b
2    b
3    a
4    a
5    e
Name: grade, dtype: category
Categories (3, object): ['a', 'b', 'e']
```

Rename the categories to more meaningful names (assigning to `Series.cat.categories()` is in place!).

```python
In [126]: df["grade"].cat.categories = ["very good", "good", "very bad"]
```

Reorder the categories and simultaneously add the missing categories (methods under `Series.cat()` return a new `Series` by default).
In [127]: df["grade"] = df["grade"].cat.set_categories(    .....:       ["very bad", "bad", "medium", "good", "very good"]    .....: )
      .....:
In [128]: df["grade"]
Out[128]:
0   very good
1     good
2     good
3   very good
4   very good
5   very bad
Name: grade, dtype: category
Categories (5, object): ['very bad', 'bad', 'medium', 'good', 'very good']

Sorting is per order in the categories, not lexical order.

In [129]: df.sort_values(by="grade")
Out[129]:
   id raw_grade  grade
5   6       e    very bad
1   2       b      good
2   3       b      good
0   1       a    very good
3   4       a    very good
4   5       a    very good

Grouping by a categorical column also shows empty categories.

In [130]: df.groupby("grade").size()
Out[130]:
grade
very bad    1
bad         0
medium      0
good        2
very good   3
dtype: int64

2.1.11 Plotting

See the Plotting docs.

We use the standard convention for referencing the matplotlib API:

In [131]: import matplotlib.pyplot as plt
In [132]: plt.close("all")

The close() method is used to close a figure window.

In [133]: ts = pd.Series(np.random.randn(1000), index=pd.date_range("1/1/2000",-    ⎯periods=1000))
In [134]: ts = ts.cumsum()
In [135]: ts.plot();

On a DataFrame, the `plot()` method is a convenience to plot all of the columns with labels:

```python
In [136]: df = pd.DataFrame(
        ....:     np.random.randn(1000, 4), index=ts.index, columns=["A", "B", "C", "D"]
        ....:     )
        ....:

In [137]: df = df.cumsum()

In [138]: plt.figure();

In [139]: df.plot();

In [140]: plt.legend(loc='best');
```
2.1.12 Getting data in/out

CSV

Writing to a csv file.

```python
In [141]: df.to_csv("foo.csv")
```

Reading from a csv file.

```python
In [142]: pd.read_csv("foo.csv")
Out[142]:
    Unnamed: 0   A        B        C        D
 0  2000-01-01  0.350262  0.843315  1.798556  0.782234
 1  2000-01-02 -0.586873  0.034907  1.923792 -0.562651

[998 rows x 4 columns]
```

(continues on next page)

2.1.13 Gotchas

If you are attempting to perform an operation you might see an exception like:

```python
>>> if pd.Series([False, True, False]):
    ...    print("I was true")
Traceback
...
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

See Comparisons for an explanation and what to do.

See Gotchas as well.

2.2 Intro to data structures

We’ll start with a quick, non-comprehensive overview of the fundamental data structures in pandas to get you started. The fundamental behavior about data types, indexing, and axis labeling / alignment apply across all of the objects. To get started, import NumPy and load pandas into your namespace:

```python
In [1]: import numpy as np
In [2]: import pandas as pd
```

Here is a basic tenet to keep in mind: data alignment is intrinsic. The link between labels and data will not be broken unless done so explicitly by you.

We’ll give a brief intro to the data structures, then consider all of the broad categories of functionality and methods in separate sections.

2.2.1 Series

`Series` is a one-dimensional labeled array capable of holding any data type (integers, strings, floating point numbers, Python objects, etc.). The axis labels are collectively referred to as the index. The basic method to create a Series is to call:

```python
>>> s = pd.Series(data, index=index)
```

Here, data can be many different things:

- a Python dict
- an ndarray
- a scalar value (like 5)

The passed index is a list of axis labels. Thus, this separates into a few cases depending on what data is:

From ndarray
If `data` is an `ndarray`, `index` must be the same length as `data`. If no index is passed, one will be created having values `[0, ..., len(data) - 1]`.

```python
In [3]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e")

In [4]: s
Out[4]:
   a  0.469112
   b -0.282863
   c -1.509059
   d -1.135632
   e  1.212112
   dtype: float64

In [5]: s.index
Out[5]: Index(["a", "b", "c", "d", "e"], dtype='object')

In [6]: pd.Series(np.random.randn(5))
Out[6]:
   0  -0.173215
   1   0.119209
   2  -1.044236
   3  -0.861849
   4  -2.104569
   dtype: float64
```

**Note**: pandas supports non-unique index values. If an operation that does not support duplicate index values is attempted, an exception will be raised at that time. The reason for being lazy is nearly all performance-based (there are many instances in computations, like parts of GroupBy, where the index is not used).

### From dict

Series can be instantiated from dicts:

```python
In [7]: d = {"b": 1, "a": 0, "c": 2}

In [8]: pd.Series(d)
Out[8]:
   b  1
   a  0
   c  2
   dtype: int64
```

**Note**: When the data is a dict, and an index is not passed, the `Series` index will be ordered by the dict’s insertion order, if you’re using Python version >= 3.6 and pandas version >= 0.23. If you’re using Python < 3.6 or pandas < 0.23, and an index is not passed, the `Series` index will be the lexically ordered list of dict keys.

In the example above, if you were on a Python version lower than 3.6 or a pandas version lower than 0.23, the `Series` would be ordered by the lexical order of the dict keys (i.e. ['a', 'b', 'c'] rather than ['b', 'a', 'c']). If an index is passed, the values in data corresponding to the labels in the index will be pulled out.
In [9]: d = {"a": 0.0, "b": 1.0, "c": 2.0}

In [10]: pd.Series(d)
Out[10]:
a  0.0
b  1.0
c  2.0
dtype: float64

In [11]: pd.Series(d, index= ["b", "c", "d", "a")
Out[11]:
b  1.0
c  2.0
d  NaN
a  0.0
dtype: float64

Note: NaN (not a number) is the standard missing data marker used in pandas.

From scalar value

If data is a scalar value, an index must be provided. The value will be repeated to match the length of index.

In [12]: pd.Series(5.0, index= ["a", "b", "c", "d", "e")
Out[12]:
a  5.0
b  5.0
c  5.0
d  5.0
e  5.0
dtype: float64

Series is ndarray-like

Series acts very similarly to an ndarray, and is a valid argument to most NumPy functions. However, operations such as slicing will also slice the index.

In [13]: s[0]
Out[13]: 0.4691122999071863

In [14]: s[:3]
Out[14]:
a  0.469112
b -0.282863
c -1.509059
dtype: float64

In [15]: s[s > s.median()]
Out[15]:
a  0.469112
e  1.212112
dtype: float64

In [16]: s[[4, 3, 1]]
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
Out[16]:
e  1.212112
d  -1.135632
b  -0.282863
dtype: float64

In [17]: np.exp(s)
Out[17]:
a  1.598575
b  0.753623
c  0.221118
d  0.321219
e  3.360575
dtype: float64
```

Note: We will address array-based indexing like `s[[4, 3, 1]]` in section on indexing.

Like a NumPy array, a pandas Series has a `dtype`.

```python
In [18]: s.dtype
Out[18]: dtype('float64')
```

This is often a NumPy dtype. However, pandas and 3rd-party libraries extend NumPy’s type system in a few places, in which case the dtype would be an `ExtensionDtype`. Some examples within pandas are `Categorical data` and `Nullable integer data type`. See `dtypes` for more.

If you need the actual array backing a Series, use `Series.array`.

```python
In [19]: s.array
Out[19]: <PandasArray>
[ 0.4691122999071863, -0.2828633443286633, -1.5090585031735124, -1.1356323710171934, 1.2121120250208506]
Length: 5, dtype: float64
```

Accessing the array can be useful when you need to do some operation without the index (to disable automatic alignment, for example).

`Series.array` will always be an `ExtensionArray`. Briefly, an ExtensionArray is a thin wrapper around one or more concrete arrays like a `numpy.ndarray`, pandas knows how to take an `ExtensionArray` and store it in a Series or a column of a DataFrame. See `dtypes` for more.

While Series is ndarray-like, if you need an actual ndarray, then use `Series.to_numpy()`.

```python
In [20]: s.to_numpy()
Out[20]: array([ 0.4691, -0.2829, -1.5091, -1.1356, 1.2121])
```

Even if the Series is backed by a `ExtensionArray`, `Series.to_numpy()` will return a NumPy ndarray.
Series is dict-like

A Series is like a fixed-size dict in that you can get and set values by index label:

In [21]: s["a"]
Out [21]: 0.4691122999071863

In [22]: s["e"] = 12.0

In [23]: s
Out [23]:
a    0.469112
b   -0.282863
c   -1.509059
d   -1.135632
e     12.0000
dtype: float64

In [24]: "e" in s
Out [24]: True

In [25]: "f" in s
Out [25]: False

If a label is not contained, an exception is raised:

>>> s["f"]
KeyError: 'f'

Using the get method, a missing label will return None or specified default:

In [26]: s.get("f")

In [27]: s.get("f", np.nan)
Out [27]: nan

See also the section on attribute access.

Vectorized operations and label alignment with Series

When working with raw NumPy arrays, looping through value-by-value is usually not necessary. The same is true when working with Series in pandas. Series can also be passed into most NumPy methods expecting an ndarray.

In [28]: s + s
Out [28]:
a    0.938225
b   -0.565727
c   -3.018117
d   -2.271265
e    24.00000
dtype: float64

In [29]: s * 2
Out [29]:
a    0.938225
b   -0.565727

(continues on next page)
A key difference between Series and ndarray is that operations between Series automatically align the data based on label. Thus, you can write computations without giving consideration to whether the Series involved have the same labels.

The result of an operation between unaligned Series will have the **union** of the indexes involved. If a label is not found in one Series or the other, the result will be marked as missing NaN. Being able to write code without doing any explicit data alignment grants immense freedom and flexibility in interactive data analysis and research. The integrated data alignment features of the pandas data structures set pandas apart from the majority of related tools for working with labeled data.

**Note:** In general, we chose to make the default result of operations between differently indexed objects yield the **union** of the indexes in order to avoid loss of information. Having an index label, though the data is missing, is typically important information as part of a computation. You of course have the option of dropping labels with missing data via the **dropna** function.

**Name attribute**

Series can also have a name attribute:

```
In [32]: s = pd.Series(np.random.randn(5), name="something")
```

```
In [33]: s
Out[33]:
0   -0.494929
1    1.071804
2    0.721555
3   -0.706771
4   -1.039575
Name: something, dtype: float64
```
The Series name will be assigned automatically in many cases, in particular when taking 1D slices of DataFrame as you will see below.

You can rename a Series with the `pandas.Series.rename()` method.

Note that `s` and `s2` refer to different objects.

### 2.2.2 DataFrame

**DataFrame** is a 2-dimensional labeled data structure with columns of potentially different types. You can think of it like a spreadsheet or SQL table, or a dict of Series objects. It is generally the most commonly used pandas object. Like Series, DataFrame accepts many different kinds of input:

- Dict of 1D ndarrays, lists, dicts, or Series
- 2-D numpy.ndarray
- Structured or record ndarray
- A Series
- Another DataFrame

Along with the data, you can optionally pass **index** (row labels) and **columns** (column labels) arguments. If you pass an index and / or columns, you are guaranteeing the index and / or columns of the resulting DataFrame. Thus, a dict of Series plus a specific index will discard all data not matching up to the passed index.

If axis labels are not passed, they will be constructed from the input data based on common sense rules.

**Note:** When the data is a dict, and **columns** is not specified, the DataFrame columns will be ordered by the dict's insertion order, if you are using Python version >= 3.6 and pandas >= 0.23.

If you are using Python < 3.6 or pandas < 0.23, and **columns** is not specified, the DataFrame columns will be the lexically ordered list of dict keys.

#### From dict of Series or dicts

The resulting **index** will be the **union** of the indexes of the various Series. If there are any nested dicts, these will first be converted to Series. If no columns are passed, the columns will be the ordered list of dict keys.
The row and column labels can be accessed respectively by accessing the `index` and `columns` attributes:

```
In [42]: df.index
Out[42]: Index(['a', 'b', 'c', 'd'], dtype='object')
In [43]: df.columns
Out[43]: Index(['one', 'two'], dtype='object')
```

### From dict of ndarrays / lists

The ndarrays must all be the same length. If an index is passed, it must clearly also be the same length as the arrays. If no index is passed, the result will be `range(n)`, where `n` is the array length.

```
In [44]: d = {"one": [1.0, 2.0, 3.0, 4.0], "two": [4.0, 3.0, 2.0, 1.0]}
In [45]: pd.DataFrame(d)
Out[45]:
   one  two
0  1.0  4.0
1  2.0  3.0
2  3.0  2.0
3  4.0  1.0
In [46]: pd.DataFrame(d, index=["a", "b", "c", "d"])
Out[46]:
   one  two
a  1.0  4.0
```
### From structured or record array

This case is handled identically to a dict of arrays.

```python
In [47]: data = np.zeros((2,), dtype=[("A", "i4"), ("B", "f4"), ("C", "a10"))
In [48]: data[:] = [(1, 2.0, "Hello"), (2, 3.0, "World")]
In [49]: pd.DataFrame(data)
Out[49]:
   A     B        C
0  1  2.0  b'Hello'
1  2  3.0  b'World'

In [50]: pd.DataFrame(data, index=["first", "second"])
Out[50]:
     A     B        C
first 1  2.0  b'Hello'
second 2  3.0  b'World'

In [51]: pd.DataFrame(data, columns=["C", "A", "B"])
Out[51]:
   C  A  B
0  b'Hello'  1  2.0
1  b'World'  2  3.0
```

Note: DataFrame is not intended to work exactly like a 2-dimensional NumPy ndarray.

### From a list of dicts

```python
In [52]: data2 = [{"a": 1, "b": 2}, {"a": 5, "b": 10, "c": 20}]
In [53]: pd.DataFrame(data2)
Out[53]:
   a     b    c
0  1     2  NaN
1  5   10  20.0

In [54]: pd.DataFrame(data2, index=["first", "second"])
Out[54]:
   a     b    c
first 1     2  NaN
second 5   10  20.0

In [55]: pd.DataFrame(data2, columns=["a", "b"])
Out[55]:
   a  b
0  1  2
1  5 10
```
From a dict of tuples

You can automatically create a MultiIndexed frame by passing a tuples dictionary.

```
In [56]: pd.DataFrame(
       ....: { 
       ....:     ('a', 'b'): {('A', 'B'): 1, ('A', 'C'): 2}, 
       ....:     ('a', 'a'): {('A', 'C'): 3, ('A', 'B'): 4}, 
       ....:     ('b', 'c'): {('A', 'B'): 5, ('A', 'C'): 6}, 
       ....:     ('b', 'b'): {('A', 'D'): 9, ('A', 'B'): 10}, 
       ....:   }
       ....: )
```

```
Out[56]:
   a   b
  b  a  c  a  b
A 1.0  4.0 5.0 8.0 10.0
C 2.0  3.0 6.0 7.0 NaN
D  NaN NaN NaN NaN  9.0
```

From a Series

The result will be a DataFrame with the same index as the input Series, and with one column whose name is the original name of the Series (only if no other column name provided).

From a list of namedtuples

The field names of the first `namedtuple` in the list determine the columns of the DataFrame. The remaining namedtuples (or tuples) are simply unpacked and their values are fed into the rows of the DataFrame. If any of those tuples is shorter than the first `namedtuple` then the later columns in the corresponding row are marked as missing values. If any are longer than the first `namedtuple`, a `ValueError` is raised.

```
In [57]: from collections import namedtuple

In [58]: Point = namedtuple("Point", "x y")

In [59]: pd.DataFrame([Point(0, 0), Point(0, 3), (2, 3)])
```

```
Out[59]:
   x  y
0  0  0
1  0  3
2  2  3
```

```
In [60]: Point3D = namedtuple("Point3D", "x y z")

In [61]: pd.DataFrame([Point3D(0, 0, 0), Point3D(0, 3, 5), Point(2, 3)])
```

```
Out[61]:
   x  y  z
```

From a list of dataclasses

New in version 1.1.0.

Data Classes as introduced in PEP557, can be passed into the DataFrame constructor. Passing a list of dataclasses is equivalent to passing a list of dictionaries.

Please be aware, that all values in the list should be dataclasses, mixing types in the list would result in a TypeError.

```
In [62]: from dataclasses import make_dataclass
In [63]: Point = make_dataclass("Point", ["x", int], ["y", int])
In [64]: pd.DataFrame([Point(0, 0), Point(0, 3), Point(2, 3)])
Out[64]:
   x  y
0  0  0
1  0  3
2  2  3
```

Missing data

Much more will be said on this topic in the Missing data section. To construct a DataFrame with missing data, we use np.nan to represent missing values. Alternatively, you may pass a numpy.MaskedArray as the data argument to the DataFrame constructor, and its masked entries will be considered missing.

Alternate constructors

DataFrame.from_dict

DataFrame.from_dict takes a dict of dicts or a dict of array-like sequences and returns a DataFrame. It operates like the DataFrame constructor except for the orient parameter which is 'columns' by default, but which can be set to 'index' in order to use the dict keys as row labels.

```
In [65]: pd.DataFrame.from_dict(dict(["A", [1, 2, 3]], ["B", [4, 5, 6]]))
Out[65]:
   A  B
0  1  4
1  2  5
2  3  6
```

If you pass orient='index', the keys will be the row labels. In this case, you can also pass the desired column names:

```
In [66]: pd.DataFrame.from_dict(
       ....:     dict(["A", [1, 2, 3]], ["B", [4, 5, 6]]),
       ....:     orient="index",
       ....:     columns=["one", "two", "three"],
       ....: )
Out[66]:
```

2.2. Intro to data structures
DataFrame.from_records

`DataFrame.from_records` takes a list of tuples or an ndarray with structured dtype. It works analogously to the normal `DataFrame` constructor, except that the resulting DataFrame index may be a specific field of the structured dtype. For example:

```python
In [67]: data
Out[67]:
array([(1, 2., b'Hello'), (2, 3., b'World')],
     dtype=[('A', '<i4'), ('B', '<f4'), ('C', 'S10')])
```

```python
In [68]: pd.DataFrame.from_records(data, index="C")
Out[68]:
   A     B
C
b'Hello' 1 2.0
b'World' 2 3.0
```

Column selection, addition, deletion

You can treat a DataFrame semantically like a dict of like-indexed Series objects. Getting, setting, and deleting columns works with the same syntax as the analogous dict operations:

```python
In [69]: df['one']
Out[69]:
a    1.0
b    2.0
c    3.0
d   NaN
Name: one, dtype: float64
```

```python
In [70]: df['three'] = df['one'] * df['two']
In [71]: df['flag'] = df['one'] > 2
```

```python
In [72]: df
Out[72]:
   one      two      three   flag
a  1.00  1.000000  1.000000 False
b  2.00  2.000000  4.000000 False
c  3.00  3.000000  9.000000  True
d  NaN   4.000000   NaN0000 False
```

Columns can be deleted or popped like with a dict:

```python
In [73]: del df['two']
In [74]: three = df.pop('three')
In [75]: df
Out[75]:
   one      two      flag
a  1.00  1.000000  False
b  2.00  2.000000 False
c  3.00  3.000000  True
d  NaN   4.000000 False
```

(continues on next page)
When inserting a scalar value, it will naturally be propagated to fill the column:

```
In [76]: df["foo"] = "bar"

In [77]: df
Out[77]:
    one  flag  foo
   ---  ---  ---
    a  1.0  False  bar
    b  2.0  False  bar
    c  3.0   True  bar
    d  NaN   False  bar
```

When inserting a Series that does not have the same index as the DataFrame, it will be conformed to the DataFrame's index:

```
In [78]: df["one_trunc"] = df["one"][:2]

In [79]: df
Out[79]:
    one  flag  foo  one_trunc
   ---  ---  ---  -------
    a  1.0  False  bar  1.0
    b  2.0  False  bar  2.0
    c  3.0   True  bar  NaN
    d  NaN   False  bar  NaN
```

You can insert raw ndarrays but their length must match the length of the DataFrame’s index.

By default, columns get inserted at the end. The `insert` function is available to insert at a particular location in the columns:

```
In [80]: df.insert(1, "bar", df["one"])

In [81]: df
Out[81]:
    one  bar  flag  foo  one_trunc
   ---  ---  ---  ---  -------
    a  1.0  1.0  False  bar  1.0
    b  2.0  2.0  False  bar  2.0
    c  3.0  3.0   True  bar  NaN
    d  NaN  NaN   False  bar  NaN
```
Assigning new columns in method chains

Inspired by dplyr’s `mutate` verb, DataFrame has an `assign()` method that allows you to easily create new columns that are potentially derived from existing columns.

```python
In [82]: iris = pd.read_csv("data/iris.data")
In [83]: iris.head()
Out[83]:
<table>
<thead>
<tr>
<th>SepalLength</th>
<th>SepalWidth</th>
<th>PetalLength</th>
<th>PetalWidth</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1</td>
<td>3.5</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>4.9</td>
<td>3.0</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>4.7</td>
<td>3.2</td>
<td>1.3</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>4.6</td>
<td>3.1</td>
<td>1.5</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>5.0</td>
<td>3.6</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
</tbody>
</table>
In [84]: iris.assign(sepal_ratio=iris["SepalWidth"] / iris["SepalLength"]).head()
Out[84]:
<table>
<thead>
<tr>
<th>SepalLength</th>
<th>SepalWidth</th>
<th>PetalLength</th>
<th>PetalWidth</th>
<th>Name</th>
<th>sepal_ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1</td>
<td>3.5</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.686275</td>
</tr>
<tr>
<td>4.9</td>
<td>3.0</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.612245</td>
</tr>
<tr>
<td>4.7</td>
<td>3.2</td>
<td>1.3</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.680851</td>
</tr>
<tr>
<td>4.6</td>
<td>3.1</td>
<td>1.5</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.673913</td>
</tr>
<tr>
<td>5.0</td>
<td>3.6</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.720000</td>
</tr>
</tbody>
</table>
```

In the example above, we inserted a precomputed value. We can also pass in a function of one argument to be evaluated on the DataFrame being assigned to.

```python
In [85]: iris.assign(sepal_ratio=lambda x: (x["SepalWidth"] / x["SepalLength"])).head()
Out[85]:
<table>
<thead>
<tr>
<th>SepalLength</th>
<th>SepalWidth</th>
<th>PetalLength</th>
<th>PetalWidth</th>
<th>Name</th>
<th>sepal_ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1</td>
<td>3.5</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.686275</td>
</tr>
<tr>
<td>4.9</td>
<td>3.0</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.612245</td>
</tr>
<tr>
<td>4.7</td>
<td>3.2</td>
<td>1.3</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.680851</td>
</tr>
<tr>
<td>4.6</td>
<td>3.1</td>
<td>1.5</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.673913</td>
</tr>
<tr>
<td>5.0</td>
<td>3.6</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.720000</td>
</tr>
</tbody>
</table>
```

`assign` always returns a copy of the data, leaving the original DataFrame untouched.

Passing a callable, as opposed to an actual value to be inserted, is useful when you don’t have a reference to the DataFrame at hand. This is common when using `assign` in a chain of operations. For example, we can limit the DataFrame to just those observations with a Sepal Length greater than 5, calculate the ratio, and plot:

```python
In [86]: (    ....:     iris.query("SepalLength > 5")
    ....:         .assign(
    ....:             SepalRatio=lambda x: x.SepalWidth / x.SepalLength,
    ....:             PetalRatio=lambda x: x.PetalWidth / x.PetalLength,
    ....:         )
    ....:         .plot(kind="scatter", x="SepalRatio", y="PetalRatio")
    ....:     )
Out[86]: <AxesSubplot:xlabel='SepalRatio', ylabel='PetalRatio'>
Since a function is passed in, the function is computed on the DataFrame being assigned to. Importantly, this is the DataFrame that’s been filtered to those rows with sepal length greater than 5. The filtering happens first, and then the ratio calculations. This is an example where we didn’t have a reference to the filtered DataFrame available.

The function signature for \texttt{assign} is simply \texttt{**kwargs}. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a \texttt{Series} or NumPy array), or a function of one argument to be called on the DataFrame. A \textit{copy} of the original DataFrame is returned, with the new values inserted.

Starting with Python 3.6 the order of \texttt{**kwargs} is preserved. This allows for \textit{dependent} assignment, where an expression later in \texttt{**kwargs} can refer to a column created earlier in the same \texttt{assign()}.

\begin{Verbatim}
In [87]: dfa = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]})

In [88]: dfa.assign(C=lambda x: x['A'] + x['B'], D=lambda x: x['A'] + x['C'])
\end{Verbatim}

\begin{Verbatim}
Out[88]:
\begin{tabular}{cccc}
A & B & C & D \\
0 & 1 & 4 & 5 \\
1 & 2 & 5 & 7 \\
2 & 3 & 6 & 9 \\
\end{tabular}
\end{Verbatim}

In the second expression, \texttt{x['C']} will refer to the newly created column, that’s equal to \texttt{dfa['A']} + \texttt{dfa['B']}. 

\section{2.2. Intro to data structures}
Indexing / selection

The basics of indexing are as follows:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Syntax</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select column</td>
<td>df[col]</td>
<td>Series</td>
</tr>
<tr>
<td>Select row by label</td>
<td>df.loc[label]</td>
<td>Series</td>
</tr>
<tr>
<td>Select row by integer location</td>
<td>df.iloc[lo]</td>
<td>Series</td>
</tr>
<tr>
<td>Slice rows</td>
<td>df[5:10]</td>
<td>DataFrame</td>
</tr>
<tr>
<td>Select rows by boolean vector</td>
<td>df[bool_vec]</td>
<td>DataFrame</td>
</tr>
</tbody>
</table>

Row selection, for example, returns a Series whose index is the columns of the DataFrame:

```
In [89]: df.loc["b"]
Out[89]:
one   2.0
bar   2.0
flag  False
foo   bar
one_trunc  2.0
Name: b, dtype: object
```

```
In [90]: df.iloc[2]
Out[90]:
one   3.0
bar   3.0
flag  True
foo   bar
one_trunc  NaN
Name: c, dtype: object
```

For a more exhaustive treatment of sophisticated label-based indexing and slicing, see the section on indexing. We will address the fundamentals of reindexing / conforming to new sets of labels in the section on reindexing.

Data alignment and arithmetic

Data alignment between DataFrame objects automatically align on both the columns and the index (row labels). Again, the resulting object will have the union of the column and row labels.

```
In [91]: df = pd.DataFrame(np.random.randn(10, 4), columns=["A", "B", "C", "D"])
In [92]: df2 = pd.DataFrame(np.random.randn(7, 3), columns=["A", "B", "C"])
In [93]: df + df2
Out[93]:
          A       B       C     D
0  0.045691 -0.014138  1.380871 NaN
1 -0.955398 -1.501007  0.037181 NaN
2 -0.662690  1.534833 -0.859691 NaN
3 -2.452949  1.237274 -0.133712 NaN
4  1.414490  1.951676 -2.320422 NaN
5 -0.494922 -1.649727 -1.084601 NaN
6 -1.047551  0.748572 -0.805479 NaN
7   NaN       NaN       NaN  NaN
8   NaN       NaN       NaN  NaN
9   NaN       NaN       NaN  NaN
```
When doing an operation between DataFrame and Series, the default behavior is to align the Series index on the DataFrame columns, thus broadcasting row-wise. For example:

```
In [94]: df - df.iloc[0]
Out[94]:
   A    B    C    D
0 0.000000 0.000000 0.000000 0.000000
1 -1.359261 -0.248717 -0.453372 -1.754659
2 0.253128 0.829678 0.010026 -1.991234
3 -1.311128 0.054325 -1.724913 -1.620544
4 0.573025 1.500742 0.010026 -1.991234
5 -1.741248 0.781993 -1.241620 -2.053136
6 -1.240774 -0.869551 -0.153282 0.000430
7 -0.743894 0.411013 -0.929563 -0.282386
8 -1.194921 1.320690 0.238224 -1.482644
9 2.293786 1.856228 0.773289 -1.446531
```

For explicit control over the matching and broadcasting behavior, see the section on flexible binary operations. Operations with scalars are just as you would expect:

```
In [95]: df * 5 + 2
Out[95]:
   A    B    C    D
0 3.359299 -0.124862 4.835102 3.381160
1 -3.437003 -1.368449 2.568242 -5.392133
2 4.624938 4.023526 4.885230 -6.575010
3 -3.196342 0.146766 -3.789461 -4.721559
4 6.224426 7.378849 1.454750 10.217815
5 -5.346940 3.785103 -1.373001 -6.884519
6 -2.844569 -4.472618 4.068691 3.383309
7 -0.360173 1.930201 0.187285 1.969232
8 -2.615303 6.478587 6.026220 -4.032059
9 14.828230 9.156280 8.701544 -3.851494
```

```
In [96]: 1 / df
Out[96]:
   A    B    C    D
0 3.678365 -2.353094 1.763605 3.820145
1 -0.919624 -1.484363 8.799067 -0.676395
2 1.904807 2.470934 1.732964 -0.583090
3 -0.962215 -2.697986 -0.863638 -0.743875
4 1.183593 0.929567 -9.170108 0.608434
5 -0.680555 2.800959 -1.482360 -0.562777
6 -1.032084 -0.772485 2.416988 3.614523
7 -2.118489 -71.634509 -2.758294 -162.507295
8 -1.083352 1.116424 1.241860 -0.828904
9 0.389765 0.698687 0.746097 -0.854483
```

```
In [97]: df ** 4
Out[97]:
   A    B    C    D
0 0.000542 3.261689e-02 0.103370 5.822320e-03
1 1.398165 2.059869e-01 0.000167 4.777482e+00
```

(continues on next page)
Boolean operators work as well:

```
In [98]: df1 = pd.DataFrame(["a": [1, 0, 1], "b": [0, 1, 1]], dtype=bool)
In [99]: df2 = pd.DataFrame(["a": [0, 1, 1], "b": [1, 1, 0]], dtype=bool)
In [100]: df1 & df2
Out[100]:
   a   b
0  False  False
1    False    True
2   True  False

In [101]: df1 | df2
Out[101]:
   a   b
0  True   True
1  True   True
2  True   True

In [102]: df1 ^ df2
Out[102]:
   a   b
0  True  False
1  True  False
2  False  True

In [103]: -df1
Out[103]:
   a   b
0  False  True
1  True  False
2  False  False
```

Transposing

To transpose, access the $T$ attribute (also the `transpose` function), similar to an ndarray:

```
# only show the first 5 rows
In [104]: df[:5].T
Out[104]:
   0      1      2      3      4
A 0.271860 -1.087401  0.524988 -1.039268  0.844885
B -0.424972 -0.673690  0.404705  0.370647  1.075770
C  0.567020  0.113648  0.577046 -1.157892 -0.109050
D  0.276232 -1.478427 -1.715002 -1.344312  1.643563
```
DataFrame interoperability with NumPy functions

Elementwise NumPy ufuncs (log, exp, sqrt, ...) and various other NumPy functions can be used with no issues on Series and DataFrame, assuming the data within are numeric:

```
In [105]: np.exp(df)
Out[105]:
     A       B       C       D
0  1.3124  0.653788  1.763006  1.318154
1  0.337092  0.509824  1.120358  0.227996
2  1.690438  1.498861  1.780770  0.179963
3  0.353713  0.690288  0.314148  0.260719
4  2.327710  2.932249  0.896686  5.173571
5  0.230066  1.429065  0.509360  0.169161
6  0.379495  0.274028  1.512461  1.318720
7  0.623732  0.986137  0.695904  0.993865
8  0.397301  2.449092  2.237242  0.299269
9 13.009059  4.183951  3.820223  0.310274
```

```
In [106]: np.asarray(df)
Out[106]:
array([[ 0.2719, -0.4250,  0.5670,  0.2762],
       [-1.0874, -0.6737,  0.1136, -1.4784],
       [ 0.5250,  0.4047,  0.5770, -1.7150],
       [-1.0393, -0.3706, -1.1579, -1.3443],
       [ 0.8449,  1.0758, -0.1090,  1.6436],
       [-1.4694,  0.3570, -0.6746, -1.7769],
       [-0.9689, -1.2945,  0.4137,  0.2767],
       [-0.4720, -0.0140, -0.3625, -0.0062],
       [-0.9231,  0.8957,  0.8052, -1.2064],
       [ 2.5656,  1.4313,  1.3403, -1.1703]])
```

DataFrame is not intended to be a drop-in replacement for ndarray as its indexing semantics and data model are quite different in places from an n-dimensional array.

Series implements __array_ufunc__, which allows it to work with NumPy’s universal functions.

The ufunc is applied to the underlying array in a Series.

```
In [107]: ser = pd.Series([1, 2, 3, 4])
In [108]: np.exp(ser)
Out[108]:
0        2.718282
1        7.389056
2       20.085537
3       54.598150
dtype: float64
```

Changed in version 0.25.0: When multiple Series are passed to a ufunc, they are aligned before performing the operation.

Like other parts of the library, pandas will automatically align labeled inputs as part of a ufunc with multiple inputs. For example, using `numpy.remainder()` on two Series with differently ordered labels will align before the operation.

```
In [109]: ser1 = pd.Series([1, 2, 3], index=["a", "b", "c"])
```

(continues on next page)
In [110]: ser2 = pd.Series([1, 3, 5], index=["b", "a", "c"])

In [111]: ser1
Out[111]:
   a  1
   b  2
   c  3
   dtype: int64

In [112]: ser2
Out[112]:
   b  1
   a  3
   c  5
   dtype: int64

In [113]: np.remainder(ser1, ser2)
Out[113]:
   a  1
   b  0
   c  3
   dtype: int64

As usual, the union of the two indices is taken, and non-overlapping values are filled with missing values.

In [114]: ser3 = pd.Series([2, 4, 6], index=["b", "c", "d"])

In [115]: ser3
Out[115]:
   b  2
   c  4
   d  6
   dtype: int64

In [116]: np.remainder(ser1, ser3)
Out[116]:
   a   NaN
   b  0.0
   c  3.0
   d   NaN
   dtype: float64

When a binary ufunc is applied to a Series and Index, the Series implementation takes precedence and a Series is returned.

In [117]: ser = pd.Series([1, 2, 3])

In [118]: idx = pd.Index([4, 5, 6])

In [119]: np.maximum(ser, idx)
Out[119]:
   0  4
   1  5
   2  6
   dtype: int64

NumPy ufuncs are safe to apply to Series backed by non-ndarray arrays, for example arrays.SparseArray.
(see *Sparse calculation*). If possible, the ufunc is applied without converting the underlying data to an ndarray.

**Console display**

Very large DataFrames will be truncated to display them in the console. You can also get a summary using `info()`. (Here I am reading a CSV version of the `baseball` dataset from the `plyr` R package):

```python
In [120]: baseball = pd.read_csv("data/baseball.csv")

In [121]: print(baseball)
```

```
<table>

 98  89533  aloumo01  2007    1  NYN  NL  87328 51 112 19  1
 99  89534  alomasa02  2007    1  NYN  NL  822  1  3  1  0

Wide DataFrames will be printed across multiple rows by default:

```python
In [124]: pd.DataFrame(np.random.randn(3, 12))
Out[124]:
    0   1   2   3   4   5   6   7
0 -2.182937 0.380396 0.804844 0.432390 -0.493662 0.600178 0.274230
1 -1.226825 0.769804 -1.281247 -0.727707 -0.097883 0.695775 0.341734
2 -0.345352 1.314232 0.690579 0.995761 2.396780 0.014871 3.357427

You can change how much to print on a single row by setting the display.width option:

```python
In [125]: pd.set_option("display.width", 40)  # default is 80
In [126]: pd.DataFrame(np.random.randn(3, 12))
Out[126]:
    0   1   2   3   4   5   6   7
0 -2.182937 0.380396 0.804844 0.432390 -0.493662 0.600178 0.274230
1 -1.226825 0.769804 -1.281247 -0.727707 -0.097883 0.695775 0.341734
2 -0.345352 1.314232 0.690579 0.995761 2.396780 0.014871 3.357427

You can adjust the max width of the individual columns by setting display.max_colwidth

```python
In [127]: datafile = {
    .....:     "filename": ["filename_01", "filename_02"],
    .....:     "path": [}
```
You can also disable this feature via the `expand_frame_repr` option. This will print the table in one block.

### DataFrame column attribute access and IPython completion

If a DataFrame column label is a valid Python variable name, the column can be accessed like an attribute:

```python
In [132]: df = pd.DataFrame({"foo1": np.random.randn(5), "foo2": np.random.randn(5)})

In [133]: df
Out[133]:
       foo1    foo2
0  1.126203  0.781836
1 -0.977349 -1.071357
2  1.474071  0.441153
3 -0.064034  2.353925
4 -1.282782  0.583787
```

The columns are also connected to the IPython completion mechanism so they can be tab-completed:
2.3 Essential basic functionality

Here we discuss a lot of the essential functionality common to the pandas data structures. To begin, let’s create some example objects like we did in the 10 minutes to pandas section:

```
In [1]: index = pd.date_range("1/1/2000", periods=8)
In [2]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e")
In [3]: df = pd.DataFrame(np.random.randn(8, 3), index=index, columns=["A", "B", "C"])
```

2.3.1 Head and tail

To view a small sample of a Series or DataFrame object, use the `head()` and `tail()` methods. The default number of elements to display is five, but you may pass a custom number.

```
In [4]: long_series = pd.Series(np.random.randn(1000))
In [5]: long_series.head()
Out[5]:
    0   -1.157892
    1   -1.344312
    2    0.844885
    3    1.075770
    4   -0.109050
    dtype: float64
In [6]: long_series.tail(3)
Out[6]:
    997   -0.289388
    998   -1.020544
    999     0.589993
    dtype: float64
```

2.3.2 Attributes and underlying data

pandas objects have a number of attributes enabling you to access the metadata

- `shape`: gives the axis dimensions of the object, consistent with ndarray

- `Axis labels`
  - `Series`: `index` (only axis)
  - `DataFrame`: `index` (rows) and `columns`

Note, these attributes can be safely assigned to!

```
In [7]: df[:2]
Out[7]:
   A    B    C
2000-01-01 -0.173215  0.119209 -1.044236
2000-01-02 -0.861849 -2.104569  0.494929
In [8]: df.columns = [x.lower() for x in df.columns]
```
pandas objects (Index, Series, DataFrame) can be thought of as containers for arrays, which hold the actual data and do the actual computation. For many types, the underlying array is a numpy.ndarray. However, pandas and 3rd party libraries may extend NumPy’s type system to add support for custom arrays (see dtypes).

To get the actual data inside a Index or Series, use the .array property

array will always be an ExtensionArray. The exact details of what an ExtensionArray is and why pandas uses them are a bit beyond the scope of this introduction. See dtypes for more.

If you know you need a NumPy array, use to_numpy() or numpy.asarray().

When the Series or Index is backed by an ExtensionArray, to_numpy() may involve copying data and coercing values. See dtypes for more.

to_numpy() gives some control over the dtype of the resulting numpy.ndarray. For example, consider datetimes with timezones. NumPy doesn’t have a dtype to represent timezone-aware datetimes, so there are two possibly useful representations:

1. An object-dtype numpy.ndarray with Timestamp objects, each with the correct tz
2. A datetime64[ns] -dtype numpy.ndarray, where the values have been converted to UTC and the timezone discarded

Timezones may be preserved with dtype=object

2.3. Essential basic functionality
In [14]: ser = pd.Series(pd.date_range("2000", periods=2, tz="CET"))

In [15]: ser.to_numpy(dtype=object)
Out[15]:
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET')], dtype=object)

Or thrown away with dtype='datetime64[ns]'

In [16]: ser.to_numpy(dtype="datetime64[ns]"
Out[16]:
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
      dtype='datetime64[ns]')

Getting the "raw data" inside a DataFrame is possibly a bit more complex. When your DataFrame only has a single data type for all the columns, DataFrame.to_numpy() will return the underlying data:

In [17]: df.to_numpy()
Out[17]:
array([[-0.1732, 0.1192, -1.0442],
      [-0.8618, -2.1046, -0.4949],
      [ 1.0718, 0.7216, -0.7068],
      [-1.0396, 0.2719, -0.425 ],
      [ 0.567 , 0.2762, -1.0874],
      [-0.6737, 0.1136, -1.4784],
      [ 0.525 , 0.4047, 0.577 ],
      [-1.715 , -1.0393, -0.3706]])

If a DataFrame contains homogeneously-typed data, the ndarray can actually be modified in-place, and the changes will be reflected in the data structure. For heterogeneous data (e.g. some of the DataFrame’s columns are not all the same dtype), this will not be the case. The values attribute itself, unlike the axis labels, cannot be assigned to.

Note: When working with heterogeneous data, the dtype of the resulting ndarray will be chosen to accommodate all of the data involved. For example, if strings are involved, the result will be of object dtype. If there are only floats and integers, the resulting array will be of float dtype.

In the past, pandas recommended Series.values or DataFrame.values for extracting the data from a Series or DataFrame. You’ll still find references to these in old code bases and online. Going forward, we recommend avoiding .values and using .array or .to_numpy(). .values has the following drawbacks:

1. When your Series contains an extension type, it’s unclear whether Series.values returns a NumPy array or the extension array. Series.array will always return an ExtensionArray, and will never copy data. Series.to_numpy() will always return a NumPy array, potentially at the cost of copying / coercing values.

2. When your DataFrame contains a mixture of data types, DataFrame.values may involve copying data and coercing values to a common dtype, a relatively expensive operation. DataFrame.to_numpy(), being a method, makes it clearer that the returned NumPy array may not be a view on the same data in the DataFrame.
2.3.3 Accelerated operations

pandas has support for accelerating certain types of binary numerical and boolean operations using the `numexpr` library and the `bottleneck` libraries.

These libraries are especially useful when dealing with large data sets, and provide large speedups. `numexpr` uses smart chunking, caching, and multiple cores. `bottleneck` is a set of specialized cython routines that are especially fast when dealing with arrays that have nans.

Here is a sample (using 100 column x 100,000 row DataFrames):

<table>
<thead>
<tr>
<th>Operation</th>
<th>0.11.0 (ms)</th>
<th>Prior Version (ms)</th>
<th>Ratio to Prior</th>
</tr>
</thead>
<tbody>
<tr>
<td>df1 &gt; df2</td>
<td>13.32</td>
<td>125.35</td>
<td>0.1063</td>
</tr>
<tr>
<td>df1 * df2</td>
<td>21.71</td>
<td>36.63</td>
<td>0.5928</td>
</tr>
<tr>
<td>df1 + df2</td>
<td>22.04</td>
<td>36.50</td>
<td>0.6039</td>
</tr>
</tbody>
</table>

You are highly encouraged to install both libraries. See the section *Recommended Dependencies* for more installation info.

These are both enabled to be used by default, you can control this by setting the options:

```python
pd.set_option("compute.use_bottleneck", False)
pd.set_option("compute.use_numexpr", False)
```

2.3.4 Flexible binary operations

With binary operations between pandas data structures, there are two key points of interest:

- Broadcasting behavior between higher- (e.g. DataFrame) and lower-dimensional (e.g. Series) objects.
- Missing data in computations.

We will demonstrate how to manage these issues independently, though they can be handled simultaneously.

Matching / broadcasting behavior

Dataframe has the methods `add()`, `sub()`, `mul()`, `div()` and related functions `radd()`, `rsub()`, ... for carrying out binary operations. For broadcasting behavior, Series input is of primary interest. Using these functions, you can use to either match on the `index` or `columns` via the `axis` keyword:

```python
In [18]: df = pd.DataFrame(
......:   {  
......:     "one": pd.Series(np.random.randn(3), index=["a", "b", "c"]),  
......:     "two": pd.Series(np.random.randn(4), index=["a", "b", "c", "d"]),  
......:     "three": pd.Series(np.random.randn(3), index=["b", "c", "d"]),  
......:   }
......:)
......:
In [19]: df
Out[19]:
     one   two   three
a 1.394981 1.772517       NaN
b 0.343054 1.912123 -0.050390
c 0.695246 1.478369  1.227435
```

(continues on next page)
Furthermore you can align a level of a MultiIndexed DataFrame with a Series.

```python
In [26]: dfmi = df.copy()

In [27]: dfmi.index = pd.MultiIndex.from_tuples([((1, "a"), (1, "b"), (1, "c"), (2, "a")), names=["first", "second"]

In [28]: dfmi.sub(column, axis=0, level="second")
```

```
first second
<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>a</td>
<td>-0.377535</td>
<td>0.000000</td>
</tr>
<tr>
<td></td>
<td>b</td>
<td>-1.569069</td>
<td>0.000000</td>
</tr>
<tr>
<td></td>
<td>c</td>
<td>-0.783123</td>
<td>0.000000</td>
</tr>
<tr>
<td>2</td>
<td>a</td>
<td>NaN</td>
<td>-1.493173</td>
</tr>
</tbody>
</table>
```

Series and Index also support the `divmod()` builtin. This function takes the floor division and modulo operation at
the same time returning a two-tuple of the same type as the left hand side. For example:

```
In [29]: s = pd.Series(np.arange(10))
In [30]: s
Out[30]:
0 0
1 1
2 2
3 3
4 4
5 5
6 6
7 7
8 8
9 9
dtype: int64
In [31]: div, rem = divmod(s, 3)
In [32]: div
Out[32]:
0 0
1 0
2 0
3 1
4 1
5 1
6 2
7 2
8 2
9 3
dtype: int64
In [33]: rem
Out[33]:
0 0
1 1
2 2
3 0
4 1
5 2
6 0
7 1
8 2
9 0
dtype: int64
In [34]: idx = pd.Index(np.arange(10))
In [35]: idx
Out[35]: Int64Index([0, 1, 2, 3, 4, 5, 6, 7, 8, 9], dtype='int64')
In [36]: div, rem = divmod(idx, 3)
In [37]: div
Out[37]: Int64Index([0, 0, 0, 1, 1, 1, 2, 2, 2, 3], dtype='int64')
```
We can also do elementwise `divmod()`:

```python
In [39]: div, rem = divmod(s, [2, 2, 3, 3, 4, 4, 5, 5, 6, 6])

In [40]: div
Out[40]:
   0  0
   1  0
   2  0
   3  1
   4  1
   5  1
   6  1
   7  1
   8  1
   9  1

   dtype: int64

In [41]: rem
Out[41]:
   0  0
   1  1
   2  2
   3  0
   4  0
   5  1
   6  1
   7  2
   8  2
   9  3

   dtype: int64
```

**Missing data / operations with fill values**

In Series and DataFrame, the arithmetic functions have the option of inputting a `fill_value`, namely a value to substitute when at most one of the values at a location are missing. For example, when adding two DataFrame objects, you may wish to treat NaN as 0 unless both DataFrames are missing that value, in which case the result will be NaN (you can later replace NaN with some other value using `fillna` if you wish).

```python
In [42]: df
Out[42]:
   one  two  three
  a  1.394981  1.772517  NaN
  b  0.343054  1.912123 -0.050390
  c  0.695246  1.478369  1.227435
  d   NaN      0.279344 -0.613172

In [43]: df2
Out[43]:
   one  two  three
  a  1.394981  1.772517  1.000000
  b  0.343054  1.912123 -0.050390
```

(continues on next page)
Flexible comparisons

Series and DataFrame have the binary comparison methods `eq`, `ne`, `lt`, `gt`, `le`, and `ge` whose behavior is analogous to the binary arithmetic operations described above:

```
In [46]: df.gt(df2)
Out[46]:
     one  two  three
a   False False False
b   False False False
c   False False False
d   False False False
```

```
In [47]: df2.ne(df)
Out[47]:
     one  two  three
a   False False  True
b   False False False
c   False False False
d    True False False
```

These operations produce a pandas object of the same type as the left-hand-side input that is of dtype `bool`. These boolean objects can be used in indexing operations, see the section on Boolean indexing.

Boolean reductions

You can apply the reductions: `empty`, `any()`, `all()`, and `bool()` to provide a way to summarize a boolean result.

```
In [48]: (df > 0).all()
Out[48]:
     one  two  three
dtype: bool
     False True False
```

(continues on next page)
In [49]: (df > 0).any()
Out[49]:
one  True
two  True
three True
dtype: bool

You can reduce to a final boolean value.

In [50]: (df > 0).any().any()
Out[50]: True

You can test if a pandas object is empty, via the `empty` property.

In [51]: df.empty
Out[51]: False

In [52]: pd.DataFrame(columns=list("ABC")).empty
Out[52]: True

To evaluate single-element pandas objects in a boolean context, use the method `bool()`:

In [53]: pd.Series([True]).bool()
Out[53]: True

In [54]: pd.Series([False]).bool()
Out[54]: False

In [55]: pd.DataFrame([[True]]).bool()
Out[55]: True

In [56]: pd.DataFrame([[False]]).bool()
Out[56]: False

**Warning:** You might be tempted to do the following:

```python
>>> if df:
...    pass
```

Or

```python
>>> df and df2
```

These will both raise errors, as you are trying to compare multiple values.:  

```
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.
all().
```

See `gotchas` for a more detailed discussion.
Comparing if objects are equivalent

Often you may find that there is more than one way to compute the same result. As a simple example, consider \( \text{df} + \text{df} \) and \( \text{df} \times 2 \). To test that these two computations produce the same result, given the tools shown above, you might imagine using \((\text{df} + \text{df} == \text{df} \times 2).\text{all()}\). But in fact, this expression is False:

```
In [57]: df + df == df * 2
Out[57]:
   one  two  three
  a  True  True  False
  b  True  True  True
  c  True  True  True
  d  False  True  True

In [58]: (df + df == df * 2).all()
Out[58]:
   one  False
   two   True
  three  False
dtype: bool
```

Notice that the boolean DataFrame \( \text{df} + \text{df} == \text{df} \times 2 \) contains some False values! This is because NaNs do not compare as equals:

```
In [59]: np.nan == np.nan
Out[59]: False
```

So, NDFrames (such as Series and DataFrames) have an \textit{equals()}\ method for testing equality, with NaNs in corresponding locations treated as equal.

```
In [60]: (df + df).equals(df * 2)
Out[60]: True
```

Note that the Series or DataFrame index needs to be in the same order for equality to be True:

```
In [61]: df1 = pd.DataFrame({"col": ["foo", 0, np.nan]})
In [62]: df2 = pd.DataFrame({"col": [np.nan, 0, "foo"], index=[2, 1, 0]})
In [63]: df1.equals(df2)
Out[63]: False
In [64]: df1.equals(df2.sort_index())
Out[64]: True
```

Comparing array-like objects

You can conveniently perform element-wise comparisons when comparing a pandas data structure with a scalar value:

```
In [65]: pd.Series({"foo", "bar", "baz"}) == "foo"
Out[65]:
0   True
1  False
2  False
dtype: bool
```
(continues on next page)
pandas also handles element-wise comparisons between different array-like objects of the same length:

```python
In [67]: pd.Series(["foo", "bar", "baz"] == pd.Index(["foo", "bar", "qux"]
Out[67]:
0    True
1    True
2   False
dtype: bool
```
```
In [68]: pd.Series(["foo", "bar", "baz"] == np.array(["foo", "bar", "qux"]
Out[68]:
0    True
1    True
2   False
dtype: bool
```

Trying to compare Index or Series objects of different lengths will raise a ValueError:

```python
In [55]: pd.Series(["foo", "bar", "baz"] == pd.Series(["foo", "bar"]
   ...: )
ValueError: Series lengths must match to compare
```
```
In [56]: pd.Series(["foo", "bar", "baz"] == pd.Series(["foo"]
ValueError: Series lengths must match to compare
```

Note that this is different from the NumPy behavior where a comparison can be broadcast:

```python
In [69]: np.array([1, 2, 3]) == np.array([2])
Out[69]:
array([False, True, False])
```
or it can return False if broadcasting cannot be done:

```python
In [70]: np.array([1, 2, 3]) == np.array([1, 2])
Out[70]: False
```

### Combining overlapping data sets

A problem occasionally arising is the combination of two similar data sets where values in one are preferred over the other. An example would be two data series representing a particular economic indicator where one is considered to be of “higher quality”. However, the lower quality series might extend further back in history or have more complete data coverage. As such, we would like to combine two DataFrame objects where missing values in one DataFrame are conditionally filled with like-labeled values from the other DataFrame. The function implementing this operation is `combine_first()`, which we illustrate:

```python
In [71]: df1 = pd.DataFrame(
...:   {"A": [1.0, np.nan, 3.0, 5.0, np.nan], "B": [np.nan, 2.0, 3.0, np.nan, 6.0]}
...: )
In [72]: df2 = pd.DataFrame(
...:   {"A": [2.0, 3.0, np.nan, 5.0, 6.0]}
...: )
```
In [73]: df1
Out[73]:
   A    B
0  1.0  NaN
1  NaN  2.0
2  3.0  3.0
3  5.0  NaN
4  NaN  6.0

In [74]: df2
Out[74]:
   A    B
0  5.0  NaN
1  2.0  NaN
2  4.0  3.0
3  NaN  4.0
4  3.0  6.0
5  7.0  8.0

In [75]: df1.combine_first(df2)
Out[75]:
   A    B
0  1.0  NaN
1  2.0  2.0
2  3.0  3.0
3  5.0  4.0
4  3.0  6.0
5  7.0  8.0

General DataFrame combine

The `combine_first()` method above calls the more general DataFrame.combine(). This method takes another DataFrame and a combiner function, aligns the input DataFrame and then passes the combiner function pairs of Series (i.e., columns whose names are the same).

So, for instance, to reproduce `combine_first()` as above:

In [76]: def combiner(x, y):
    ...:     return np.where(pd.isna(x), y, x)
    ...:

In [77]: df1.combine(df2, combiner)
Out[77]:
   A    B
0  1.0  NaN
1  2.0  2.0
2  3.0  3.0
3  5.0  4.0
4  3.0  6.0
5  7.0  8.0

2.3. Essential basic functionality
2.3.5 Descriptive statistics

There exists a large number of methods for computing descriptive statistics and other related operations on `Series`, `DataFrame`. Most of these are aggregations (hence producing a lower-dimensional result) like `sum()`, `mean()`, and `quantile()`, but some of them, like `cumsum()` and `cumprod()`, produce an object of the same size. Generally speaking, these methods take an `axis` argument, just like `ndarray.{sum, std, ...}`, but the axis can be specified by name or integer:

- **Series**: no axis argument needed
- **DataFrame**: “index” (axis=0, default), “columns” (axis=1)

For example:

```python
In [78]: df
Out[78]:
     one   two   three
   a  1.394981  1.772517  NaN
   b  0.343054  1.912123 -0.050390
   c  0.695246  1.478369  1.227435
   d   NaN      0.279344 -0.613172

In [79]: df.mean(0)
Out[79]:
    one   two   three
   a  0.811094  1.360588  0.187958

In [80]: df.mean(1)
Out[80]:
   a  1.583749
   b  0.734929
   c  1.133683
   d -0.166914

dtype: float64
```

All such methods have a `skipna` option signaling whether to exclude missing data (True by default):

```python
In [81]: df.sum(0, skipna=False)
Out[81]:
   one   two   three
   a   NaN    NaN
   b  5.442353 NaN
   c   NaN    NaN
   d   NaN    NaN

dtype: float64
```

Combined with the broadcasting / arithmetic behavior, one can describe various statistical procedures, like standardization (rendering data zero mean and standard deviation of 1), very concisely:
In [83]: ts_stand = (df - df.mean()) / df.std()

In [84]: ts_stand.std()
Out[84]:
   one   two   three
0   1.0   1.0   1.0

dtype: float64

In [85]: xs_stand = df.sub(df.mean(1), axis=0).div(df.std(1), axis=0)

In [86]: xs_stand.std(1)
Out[86]:
   a   b   c   d
0  1.0  1.0  1.0  1.0

dtype: float64

Note that methods like `cumsum()` and `cumprod()` preserve the location of NaN values. This is somewhat different from `expanding()` and `rolling()` since NaN behavior is furthermore dictated by a `min_periods` parameter.

In [87]: df.cumsum()
Out[87]:
   one   two   three
 0  1.394981  1.772517   NaN
 1  1.738035  3.684640 -0.050390
 2  2.433281  5.163008  1.177045
 3   NaN   5.442353  0.563873

Here is a quick reference summary table of common functions. Each also takes an optional `level` parameter which applies only if the object has a `hierarchical index`.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>Number of non-NA observations</td>
</tr>
<tr>
<td>sum</td>
<td>Sum of values</td>
</tr>
<tr>
<td>mean</td>
<td>Mean of values</td>
</tr>
<tr>
<td>mad</td>
<td>Mean absolute deviation</td>
</tr>
<tr>
<td>median</td>
<td>Arithmetic median of values</td>
</tr>
<tr>
<td>min</td>
<td>Minimum</td>
</tr>
<tr>
<td>max</td>
<td>Maximum</td>
</tr>
<tr>
<td>mode</td>
<td>Mode</td>
</tr>
<tr>
<td>abs</td>
<td>Absolute Value</td>
</tr>
<tr>
<td>prod</td>
<td>Product of values</td>
</tr>
<tr>
<td>std</td>
<td>Bessel-corrected sample standard deviation</td>
</tr>
<tr>
<td>var</td>
<td>Unbiased variance</td>
</tr>
<tr>
<td>sem</td>
<td>Standard error of the mean</td>
</tr>
<tr>
<td>skew</td>
<td>Sample skewness (3rd moment)</td>
</tr>
<tr>
<td>kurt</td>
<td>Sample kurtosis (4th moment)</td>
</tr>
<tr>
<td>quantile</td>
<td>Sample quantile (value at %)</td>
</tr>
<tr>
<td>cumsum</td>
<td>Cumulative sum</td>
</tr>
<tr>
<td>cumprod</td>
<td>Cumulative product</td>
</tr>
<tr>
<td>cummax</td>
<td>Cumulative maximum</td>
</tr>
<tr>
<td>cummin</td>
<td>Cumulative minimum</td>
</tr>
</tbody>
</table>

2.3. Essential basic functionality
Note that by chance some NumPy methods, like `mean`, `std`, and `sum`, will exclude NAs on Series input by default:

```
In [88]: np.mean(df["one"],)  
Out[88]: 0.8110935116651192  
In [89]: np.mean(df["one"].to_numpy(),)  
Out[89]: nan  
```

`Series.nunique()` will return the number of unique non-NA values in a Series:

```
In [90]: series = pd.Series(np.random.randn(500))  
In [91]: series[20:500] = np.nan  
In [92]: series[10:20] = 5  
In [93]: series.nunique()  
Out[93]: 11  
```

### Summarizing data: `describe`

There is a convenient `describe()` function which computes a variety of summary statistics about a Series or the columns of a DataFrame (excluding NAs of course):

```
In [94]: series = pd.Series(np.random.randn(1000))  
In [95]: series[:2] = np.nan  
In [96]: series.describe()  
Out[96]:  
   count    500.000000  
   mean     -0.021292  
   std       1.015906  
   min      -2.683763  
   25%      -0.699070  
   50%      -0.069718  
   75%       0.714483  
   max       3.160915  
   dtype: float64  
In [97]: frame = pd.DataFrame(np.random.randn(1000, 5), columns=["a", "b", "c", "d", "e"])  
In [98]: frame.iloc[:2] = np.nan  
In [99]: frame.describe()  
Out[99]:  
<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
<th>e</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>500.000000</td>
<td>500.000000</td>
<td>500.000000</td>
<td>500.000000</td>
<td>500.000000</td>
</tr>
<tr>
<td>mean</td>
<td>0.033387</td>
<td>0.030045</td>
<td>-0.043719</td>
<td>-0.051686</td>
<td>0.005979</td>
</tr>
<tr>
<td>std</td>
<td>1.017152</td>
<td>0.978743</td>
<td>1.025270</td>
<td>1.015988</td>
<td>1.006695</td>
</tr>
<tr>
<td>25%</td>
<td>-0.647623</td>
<td>-0.576449</td>
<td>-0.712369</td>
<td>-0.691338</td>
<td>-0.691115</td>
</tr>
<tr>
<td>50%</td>
<td>0.047578</td>
<td>-0.021499</td>
<td>-0.023888</td>
<td>-0.032652</td>
<td>-0.025363</td>
</tr>
<tr>
<td>75%</td>
<td>0.714483</td>
<td>0.775880</td>
<td>0.618896</td>
<td>0.670047</td>
<td>0.649748</td>
</tr>
<tr>
<td>max</td>
<td>2.740139</td>
<td>2.752332</td>
<td>3.004229</td>
<td>2.728702</td>
<td>3.240991</td>
</tr>
</tbody>
</table>
```
You can select specific percentiles to include in the output:

```python
In [100]: series.describe(percentiles=[0.05, 0.25, 0.75, 0.95])
Out[100]:
count 500.000000
mean  -0.021292
std   1.015906
min   -2.683763
5%    -1.645423
25%   -0.699070
50%   -0.069718
75%   0.714483
95%   1.711409
max   3.160915
dtype: float64
```

By default, the median is always included.

For a non-numerical Series object, `describe()` will give a simple summary of the number of unique values and most frequently occurring values:

```python
In [101]: s = pd.Series(["a", "a", "b", "b", "a", "a", np.nan, "c", "d", "a"])
In [102]: s.describe()
Out[102]:
count 9
unique 4
top a
freq 5
dtype: object
```

Note that on a mixed-type DataFrame object, `describe()` will restrict the summary to include only numerical columns or, if none are, only categorical columns:

```python
In [103]: frame = pd.DataFrame({"a": ["Yes", "Yes", "No", "No"], "b": range(4)})
In [104]: frame.describe()
```

This behavior can be controlled by providing a list of types as `include/exclude` arguments. The special value `all` can also be used:

```python
In [105]: frame.describe(include=["object"])
```

(continues on next page)
That feature relies on `select_dtypes`. Refer to there for details about accepted inputs.

**Index of min/max values**

The `idxmin()` and `idxmax()` functions on Series and DataFrame compute the index labels with the minimum and maximum corresponding values:

```
In [108]: s1 = pd.Series(np.random.randn(5))

In [109]: s1
Out[109]:
   0    1.118076
   1   -0.352051
   2    0.124683
   3   -0.277455
   4    0.641184

Out[109]: float64

In [110]: s1.idxmin(), s1.idxmax()
Out[110]: (3, 0)

In [111]: df1 = pd.DataFrame(np.random.randn(5, 3), columns=['A', 'B', 'C'])

In [112]: df1
Out[112]:
    A         B         C
   0 -0.327863 -0.946180 -0.137570
```
When there are multiple rows (or columns) matching the minimum or maximum value, `idxmin()` and `idxmax()` return the first matching index:

```python
In [113]: df1.idxmin(axis=0)
Out[113]:
   A  2
   B  3
   C  1
   dtype: int64

In [114]: df1.idxmax(axis=1)
Out[114]:
   0  C
   1  A
   2  C
   3  A
   4  C
   dtype: object
```

Note: `idxmin` and `idxmax` are called `argmin` and `argmax` in NumPy.

**Value counts (histogramming) / mode**

The `value_counts()` Series method and top-level function computes a histogram of a 1D array of values. It can also be used as a function on regular arrays:

```python
In [118]: data = np.random.randint(0, 7, size=50)
In [119]: data
Out[119]:
array([6, 6, 2, 3, 5, 3, 2, 5, 4, 5, 3, 4, 5, 0, 2, 0, 4, 2, 0, 3, 2,
      2, 5, 6, 3, 5, 4, 2, 5, 6, 4, 3, 5, 6, 4, 3, 6, 2, 6, 6, 2, 3, 4,
      2, 1, 6, 2, 6, 4])
```

(continues on next page)
New in version 1.1.0.

The `value_counts()` method can be used to count combinations across multiple columns. By default all columns are used but a subset can be selected using the `subset` argument.

Similarly, you can get the most frequently occurring value(s), i.e. the mode, of the values in a Series or DataFrame:
Discretization and quantiling

Continuous values can be discretized using the \texttt{cut()} (bins based on values) and \texttt{qcut()} (bins based on sample quantiles) functions:

\begin{verbatim}
In [130]: arr = np.random.randn(20)
In [131]: factor = pd.cut(arr, 4)
In [132]: factor

Out[132]:
[(-0.251, 0.464], (-0.968, -0.251], (0.464, 1.179], (-0.251, 0.464], (-0.968, -0.251], ...
Length: 20
Categories (4, interval[float64, right]): 
(-0.968, -0.251] < (-0.251, 0.464] < (0.464, 1.179] < (1.179, 1.893]

In [133]: factor = pd.cut(arr, [-5, -1, 0, 1, 5])
In [134]: factor

Out[134]:
[(-1, 0], (-1, 0], (0, 1], (0, 1], (-1, 0], ..., (-1, 0], (-1, 0], (-1, 0], (-1, 0], (-1, 0]
Length: 20
Categories (4, interval[int64, right]): 
(-5, -1] < (-1, 0] < (0, 1] < (1, 5]
\end{verbatim}

\texttt{qcut()} computes sample quantiles. For example, we could slice up some normally distributed data into equal-size quartiles like so:

\begin{verbatim}
In [135]: arr = np.random.randn(30)
In [136]: factor = pd.qcut(arr, [0, 0.25, 0.5, 0.75, 1])
In [137]: factor

Out[137]:
[(0, 0.25], (0, 0.25], (0.25, 0.5], (0.25, 0.5], ..., (0.25, 0.5], (0.5, 0.75], (0.75, 1]
Length: 30
Categories (4, interval[float64, right]): 
(-0.301, 0.569] < (0.569, 1.184] < (1.184, 1.893] < (1.893, 2.346]
\end{verbatim}
In [138]: pd.value_counts(factor)
Out[138]:
(-2.278, -0.301]  8
(1.184, 2.346]  8
(-0.301, 0.569]  7
(0.569, 1.184]  7
dtype: int64

We can also pass infinite values to define the bins:

In [139]: arr = np.random.randn(20)
In [140]: factor = pd.cut(arr, [-np.inf, 0, np.inf])
In [141]: factor
Out[141]:
[(-inf, 0.0], (0.0, inf], (0.0, inf], (-inf, 0.0], (-inf, 0.0], ..., (-inf, 0.0], (-inf, 0.0], (0.0, inf], (0.0, inf]]
Length: 20
Categories (2, interval[float64, right]): [(-inf, 0.0] < (0.0, inf]]

2.3.6 Function application

To apply your own or another library’s functions to pandas objects, you should be aware of the three methods below. The appropriate method to use depends on whether your function expects to operate on an entire DataFrame or Series, row- or column-wise, or elementwise.

1. **Tablewise Function Application: pipe()**
2. **Row or Column-wise Function Application: apply()**
3. **Aggregation API: agg() and transform()**
4. **Applying Elementwise Functions: applymap()**

**Tablewise function application**

DataFrames and Series can be passed into functions. However, if the function needs to be called in a chain, consider using the `pipe()` method.

First some setup:

In [142]: def extract_city_name(df):
   ...:     
   ...:     "Chicago, IL -> Chicago for city_name column"
   ...:     ""
   ...:     df["city_name"] = df["city_and_code"].str.split(",").str.get(0)
   ...:     return df
   ...

In [143]: def add_country_name(df, country_name=\texttt{None}):
   ...:     """Chicago -> Chicago-US for city_name column"
   ...:     """
   ...:     col = "city_name"
extract_city_name and add_country_name are functions taking and returning DataFrames.

Now compare the following:

In [145]: add_country_name(extract_city_name(df_p), country_name="US")

Out[145]:

<table>
<thead>
<tr>
<th>city_and_code</th>
<th>city_name</th>
<th>city_and_country</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chicago, IL</td>
<td>Chicago</td>
<td>Chicago</td>
</tr>
</tbody>
</table>

Is equivalent to:

In [146]: df_p.pipe(extract_city_name).pipe(add_country_name, country_name="US")

Out[146]:

<table>
<thead>
<tr>
<th>city_and_code</th>
<th>city_name</th>
<th>city_and_country</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chicago, IL</td>
<td>Chicago</td>
<td>Chicago</td>
</tr>
</tbody>
</table>

pandas encourages the second style, which is known as method chaining. pipe makes it easy to use your own or another library’s functions in method chains, alongside pandas’ methods.

In the example above, the functions extract_city_name and add_country_name each expected a DataFrame as the first positional argument. What if the function you wish to apply takes its data as, say, the second argument? In this case, provide pipe with a tuple of (callable, data_keyword). .pipe will route the DataFrame to the argument specified in the tuple.

For example, we can fit a regression using statsmodels. Their API expects a formula first and a DataFrame as the second argument, data. We pass in the function, keyword pair (sm.ols, 'data') to pipe:

In [147]: import statsmodels.formula.api as sm

In [148]: bb = pd.read_csv("data/baseball.csv", index_col="id")

In [149]:

<p>| | | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>dep. variable</td>
<td>hr</td>
<td>r-squared:</td>
<td>0.685</td>
<td>model:</td>
<td>ols</td>
<td>0.665</td>
</tr>
<tr>
<td>method:</td>
<td>least squares</td>
<td>f-statistic:</td>
<td>34.28</td>
<td>date:</td>
<td>sun, 25 jul 2021</td>
<td>prob (f-statistic):</td>
</tr>
<tr>
<td>time:</td>
<td>09:38:02</td>
<td>log-likelihood:</td>
<td>-205.92</td>
<td>no. observations:</td>
<td>68</td>
<td>aic:</td>
</tr>
<tr>
<td>df residuals:</td>
<td>63</td>
<td>bic:</td>
<td>432.9</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Omnibus: 10.875 Durbin-Watson: 1.999
Prob(Omnibus): 0.004 Jarque-Bera (JB): 17.298
Skew: 0.537 Prob(JB): 0.000175
Kurtosis: 5.225 Cond. No. 1.49e+07

Notes:
[1] Standard Errors assume that the covariance matrix of the errors is correctly specified.
[2] The condition number is large, 1.49e+07. This might indicate that there are strong multicollinearity or other numerical problems.

The pipe method is inspired by unix pipes and more recently dplyr and magrittr, which have introduced the popular (read pipe) operator for R. The implementation of pipe here is quite clean and feels right at home in Python. We encourage you to view the source code of pipe().

Row or column-wise function application

Arbitrary functions can be applied along the axes of a DataFrame using the apply() method, which, like the descriptive statistics methods, takes an optional axis argument:

In [150]: df.apply(np.mean)
Out[150]:
one 0.811094
two 1.360588
three 0.187958
dtype: float64

In [151]: df.apply(np.mean, axis=1)
Out[151]:
a 1.583749
b 0.734929
c 1.133683
d -0.166914
dtype: float64

In [152]: df.apply(lambda x: x.max() - x.min())
Out[152]:
one 1.051928
two 1.632779
three 1.840607
dtype: float64
The `apply()` method will also dispatch on a string method name.

```
In [155]: df.apply("mean")
Out[155]:
          one     two     three
a  0.811094  1.360588     NaN
b  0.811094  1.360588     NaN
c   NaN      NaN       0.187958
d   NaN      NaN       0.187958
dtype: float64
```

The return type of the function passed to `apply()` affects the type of the final output from `DataFrame.apply` for the default behaviour:

- If the applied function returns a `Series`, the final output is a `DataFrame`. The columns match the index of the `Series` returned by the applied function.
- If the applied function returns any other type, the final output is a `Series`.

This default behaviour can be overridden using the `result_type`, which accepts three options: `reduce`, `broadcast`, and `expand`. These will determine how list-likes return values expand (or not) to a `DataFrame`.

`apply()` combined with some cleverness can be used to answer many questions about a data set. For example, suppose we wanted to extract the date where the maximum value for each column occurred:

```
In [157]: tsdf = pd.DataFrame(
.....:     np.random.randn(1000, 3),
.....:     columns=['A', 'B', 'C'],
.....:     index=pd.date_range("1/1/2000", periods=1000),
.....: )
.....: 
In [158]: tsdf.apply(lambda x: x.idxmax())
Out[158]:
A  2000-08-06
B  2001-01-18
```
You may also pass additional arguments and keyword arguments to the `apply()` method. For instance, consider the following function you would like to apply:

```python
def subtract_and_divide(x, sub, divide=1):
    return (x - sub) / divide
```

You may then apply this function as follows:

```python
df.apply(subtract_and_divide, args=(5,), divide=3)
```

Another useful feature is the ability to pass Series methods to carry out some Series operation on each column or row:

```python
In [159]: tsdf
Out[159]:
     A     B      C
2000-01-01 -0.158131 -0.232466  0.321604
2000-01-02 -1.810340 -3.105758  0.433834
2000-01-03 -1.209847 -1.156793 -0.136794
2000-01-04  NaN    NaN     NaN
2000-01-05  NaN    NaN     NaN
2000-01-06  NaN    NaN     NaN
2000-01-07  NaN    NaN     NaN
2000-01-08 -0.653602  0.178875  1.008298
2000-01-09  1.007996  0.462824  0.254472
2000-01-10  0.307473  0.600337  1.643950
```

```python
In [160]: tsdf.apply(pd.Series.interpolate)
Out[160]:
     A     B      C
2000-01-01 -0.158131 -0.232466  0.321604
2000-01-02 -1.810340 -3.105758  0.433834
2000-01-03 -1.209847 -1.156793 -0.136794
2000-01-04 -1.098598 -0.889659  0.092225
2000-01-05 -0.987349 -0.622526  0.321243
2000-01-06 -0.876100 -0.355392  0.550262
2000-01-07 -0.764851  0.088259  0.779280
2000-01-08 -0.653602  0.178875  1.008298
2000-01-09  1.007996  0.462824  0.254472
2000-01-10  0.307473  0.600337  1.643950
```

Finally, `apply()` takes an argument `raw` which is False by default, which converts each row or column into a Series before applying the function. When set to True, the passed function will instead receive an ndarray object, which has positive performance implications if you do not need the indexing functionality.
Aggregation API

The aggregation API allows one to express possibly multiple aggregation operations in a single concise way. This API is similar across pandas objects, see groupby API, the window API, and the resample API. The entry point for aggregation is DataFrame.aggregate(), or the alias DataFrame.agg().

We will use a similar starting frame from above:

```
In [161]: tsdf = pd.DataFrame(
       ....:     np.random.randn(10, 3),
       ....:     columns=['A', 'B', 'C'],
       ....:     index=pd.date_range("1/1/2000", periods=10),
       ....: )
       ...

In [162]: tsdf.iloc[3:7] = np.nan

In [163]: tsdf
Out[163]:
       A    B    C
2000-01-01  1.26  1.00  0.17
2000-01-02  0.75  0.29 -0.76
2000-01-03 -0.21 -0.30  0.12
2000-01-04  NaN  NaN  NaN
2000-01-05  NaN  NaN  NaN
2000-01-06  NaN  NaN  NaN
2000-01-07  NaN  NaN  NaN
2000-01-08  0.81 -0.26  0.87
2000-01-09 -0.25 -1.21  0.90
2000-01-10  2.17 -1.33  0.28
```

Using a single function is equivalent to apply(). You can also pass named methods as strings. These will return a Series of the aggregated output:

```
In [164]: tsdf.agg(np.sum)
Out[164]:
A    3.03
B   -1.80
C    1.58
dtype: float64

In [165]: tsdf.agg("sum")
Out[165]:
A    3.03
B   -1.80
C    1.58
dtype: float64
```

# these are equivalent to `\`.sum()` because we are aggregating # on a single function

```
In [166]: tsdf.sum()
Out[166]:
A    3.03
B   -1.80
C    1.58
dtype: float64
```

Single aggregations on a Series this will return a scalar value:
Aggregating with multiple functions

You can pass multiple aggregation arguments as a list. The results of each of the passed functions will be a row in the resulting DataFrame. These are naturally named from the aggregation function.

```
In [167]: tsdf["A"].agg("sum")
Out[167]: 3.033606102414146
```

Multiple functions yield multiple rows:

```
In [168]: tsdf.agg(["sum"])
Out[168]:
    A    B    C
sum 3.033606 -1.803879 1.57551
```

On a Series, multiple functions return a Series, indexed by the function names:

```
In [170]: tsdf["A"].agg(["sum", "mean"])
Out[170]:
    sum    mean
A  3.033606  0.505601
```

Passing a lambda function will yield a <lambda> named row:

```
In [171]: tsdf["A"].agg(["sum", lambda x: x.mean()])
Out[171]:
    sum  <lambda>
A  3.033606     0.505601
```

Passing a named function will yield that name for the row:

```
In [172]: def mymean(x):
       ....:     return x.mean()
       ....:
In [173]: tsdf["A"].agg(["sum", mymean])
Out[173]:
    sum  mymean
A  3.033606   0.505601
```
Aggregating with a dict

Passing a dictionary of column names to a scalar or a list of scalars, to `DataFrame.agg` allows you to customize which functions are applied to which columns. Note that the results are not in any particular order, you can use an `OrderedDict` instead to guarantee ordering.

```python
In [174]: tsdf.agg({"A": "mean", "B": "sum"})
Out[174]:
A   0.505601
B  -1.803879
dtype: float64
```

Passing a list-like will generate a `DataFrame` output. You will get a matrix-like output of all of the aggregators. The output will consist of all unique functions. Those that are not noted for a particular column will be NaN:

```python
In [175]: tsdf.agg({"A": ["mean", "min"], "B": "sum"})
Out[175]:
      A     B
mean 0.505601  NaN
min -0.749892  NaN
sum  NaN -1.803879
```

Mixed dtypes

When presented with mixed dtypes that cannot aggregate, `.agg` will only take the valid aggregations. This is similar to how `.groupby.agg` works.

```python
In [176]: mdf = pd.DataFrame({
    .....:     "A": [1, 2, 3],
    .....:     "B": [1.0, 2.0, 3.0],
    .....:     "C": ["foo", "bar", "baz"],
    .....:     "D": pd.date_range("20130101", periods=3),
    .....: })
In [177]: mdf.dtypes
Out[177]:
A    int64
B    float64
C    object
D  datetime64[ns]
dtype: object
```

```python
In [178]: mdf.agg(["min", "sum"])
Out[178]:
   A    B     C   D
min 1  1.0  bar  2013-01-01
sum 6  6.0  foobar baz   NaT
```
Custom describe

With `.agg()` it is possible to easily create a custom describe function, similar to the built in `describe` function.

```python
In [179]: from functools import partial

In [180]: q_25 = partial(pd.Series.quantile, q=0.25)

In [181]: q_25.__name__ = "25%"

In [182]: q_75 = partial(pd.Series.quantile, q=0.75)

In [183]: q_75.__name__ = "75%"

In [184]: tsdf.agg(['count', 'mean', 'std', 'min', q_25, 'median', q_75, 'max'])
```

```
Out[184]:
     A    B    C
count 6.000000 6.000000 6.000000
mean  0.505601 -0.300647  0.262585
std   1.103362 0.887508  0.606860
min  -0.749892 -1.333363 -0.757304
25%   -0.239885 -0.979600  0.128907
median 0.303398 -0.278111  0.225365
75%   1.146791  0.151678  0.722709
max   2.169758  1.004194  0.896839
```

Transform API

The `transform()` method returns an object that is indexed the same (same size) as the original. This API allows you to provide multiple operations at the same time rather than one-by-one. Its API is quite similar to the `.agg` API.

We create a frame similar to the one used in the above sections.

```python
In [185]: tsdf = pd.DataFrame(
    ...:     np.random.randn(10, 3),
    ...:     columns=['A', 'B', 'C'],
    ...:     index=pd.date_range("1/1/2000", periods=10),
    ...:     )

In [186]: tsdf.iloc[3:7] = np.nan

In [187]: tsdf
```

```
Out[187]:
       A    B    C
2000-01-01 -0.428759 -0.864890 -0.675341
2000-01-02 -0.168731  1.338144 -1.279321
2000-01-03 -1.621034  0.438107  0.903794
2000-01-04  NaN  NaN  NaN

```
Transform the entire frame. `.transform()` allows input functions as: a NumPy function, a string function name or a user defined function.

```
In [188]: tsdf.transform(np.abs)
Out[188]:
       A         B         C

```

(continues on next page)
Passing a single function to `transform()` with a `Series` will yield a single `Series` in return.

In [192]: tsdf[“A”].transform(np.abs)
Out[192]:
2000-01-01  0.428759
2000-01-02  0.168731
2000-01-03  1.621034
2000-01-04  NaN
2000-01-05  NaN
2000-01-06  NaN
2000-01-07  NaN
2000-01-08  0.254374
2000-01-09  0.157795
2000-01-10  0.030876
Freq: D, Name: A, dtype: float64

Transform with multiple functions

Passing multiple functions will yield a column MultiIndexed DataFrame. The first level will be the original frame column names; the second level will be the names of the transforming functions.

In [193]: tsdf.transform([np.abs, lambda x: x + 1])
Out[193]:
<table>
<thead>
<tr>
<th></th>
<th>absolute</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>absolute</td>
<td>&lt;lambda&gt;</td>
<td></td>
</tr>
<tr>
<td>2000-01-01</td>
<td>0.428759</td>
<td>0.571241</td>
<td></td>
</tr>
<tr>
<td>2000-01-02</td>
<td>0.168731</td>
<td>0.831269</td>
<td></td>
</tr>
<tr>
<td>2000-01-03</td>
<td>1.621034</td>
<td>-0.621034</td>
<td></td>
</tr>
<tr>
<td>2000-01-04</td>
<td>NaN</td>
<td>NaN</td>
<td></td>
</tr>
<tr>
<td>2000-01-05</td>
<td>NaN</td>
<td>NaN</td>
<td></td>
</tr>
<tr>
<td>2000-01-06</td>
<td>NaN</td>
<td>NaN</td>
<td></td>
</tr>
<tr>
<td>2000-01-07</td>
<td>NaN</td>
<td>NaN</td>
<td></td>
</tr>
<tr>
<td>2000-01-08</td>
<td>0.254374</td>
<td>1.254374</td>
<td></td>
</tr>
<tr>
<td>2000-01-09</td>
<td>0.157795</td>
<td>0.842205</td>
<td></td>
</tr>
<tr>
<td>2000-01-10</td>
<td>0.030876</td>
<td>0.969124</td>
<td></td>
</tr>
</tbody>
</table>

Passing multiple functions to a `Series` will yield a `DataFrame`. The resulting column names will be the transforming functions.

In [194]: tsdf[“A”].transform([np.abs, lambda x: x + 1])
Out[194]:
<table>
<thead>
<tr>
<th></th>
<th>absolute</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>absolute</td>
<td>&lt;lambda&gt;</td>
</tr>
<tr>
<td>2000-01-01</td>
<td>0.428759</td>
<td>0.571241</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>0.168731</td>
<td>0.831269</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>1.621034</td>
<td>-0.621034</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>NaN</td>
<td>NaN</td>

<tr>
<td>2000-01-05</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-06</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-07</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-08</td>
<td>0.254374</td>
<td>1.254374</td>
</tr>
<tr>
<td>2000-01-09</td>
<td>0.157795</td>
<td>0.842205</td>
</tr>
<tr>
<td>2000-01-10</td>
<td>0.030876</td>
<td>0.969124</td>
</tr>
</tbody>
</table>
Transforming with a dict

Passing a dict of functions will allow selective transforming per column.

```python
In [195]: tsdf.transform({"A": np.abs, "B": lambda x: x + 1})
Out[195]:
          A       B
2000-01-01 0.428759 0.135110
2000-01-02 0.168731 2.338144
2000-01-03 1.621034 1.438107
2000-01-04  NaN       NaN
2000-01-05  NaN       NaN
2000-01-06  NaN       NaN
2000-01-07  NaN       NaN
2000-01-08 0.254374 -0.240447
2000-01-09 0.157795  1.791197
2000-01-10 0.030876  1.371900
```

Passing a dict of lists will generate a MultiIndexed DataFrame with these selective transforms.

```python
In [196]: tsdf.transform({"A": np.abs, "B": [lambda x: x + 1, "sqrt"]})
Out[196]:
          A       B
absolute <lambda> sqrt
2000-01-01 0.428759 0.135110 NaN
2000-01-02 0.168731 2.338144  1.156782
2000-01-03 1.621034 1.438107  0.661897
2000-01-04  NaN       NaN       NaN
2000-01-05  NaN       NaN       NaN
2000-01-06  NaN       NaN       NaN
2000-01-07  NaN       NaN       NaN
2000-01-08 0.254374 -0.240447  NaN
2000-01-09 0.157795  1.791197  0.889493
2000-01-10 0.030876  1.371900  0.609836
```

Applying elementwise functions

Since not all functions can be vectorized (accept NumPy arrays and return another array or value), the methods `applymap()` on DataFrame and analogously `map()` on Series accept any Python function taking a single value and returning a single value. For example:

```python
In [197]: df4
Out[197]:
          one       two       three
   a  1.394981  1.772517       NaN
   b  0.343054  1.912123 -0.050390
   c  0.695246  1.478369  1.227435
   d    NaN   0.279344 -0.613172

In [198]: def f(x):
       ....:     return len(str(x))
       ....:
In [199]: df4["one"].map(f)
Out[199]:
a    18
(continues on next page)
Series.map() has an additional feature; it can be used to easily “link” or “map” values defined by a secondary series. This is closely related to merging/joining functionality:

In [201]: s = pd.Series(
    .....:     ["six", "seven", "six", "seven", "six"], index=["a", "b", "c", "d", "e"]
    .....: 
    .....:
In [202]: t = pd.Series({"six": 6.0, "seven": 7.0})

In [203]: s
Out[203]:
a six
b seven
c six
d seven
e six
dtype: object

In [204]: s.map(t)
Out[204]:
a 6.0
b 7.0
c 6.0
d 7.0
e 6.0
dtype: float64

2.3.7 Reindexing and altering labels

reindex() is the fundamental data alignment method in pandas. It is used to implement nearly all other features relying on label-alignment functionality. To reindex means to conform the data to match a given set of labels along a particular axis. This accomplishes several things:

- Reorders the existing data to match a new set of labels
- Inserts missing value (NA) markers in label locations where no data for that label existed
- If specified, fill data for missing labels using logic (highly relevant to working with time series data)

Here is a simple example:
In [205]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e")

In [206]: s
Out[206]:
 a  1.695148
 b  1.328614
 c  1.234686
d -0.385845
e -1.326508
dtype: float64

In [207]: s.reindex(["e", "b", "f", "d")
Out[207]:
e -1.326508
 b  1.328614
 f NaN
d -0.385845
dtype: float64

Here, the f label was not contained in the Series and hence appears as NaN in the result.

With a DataFrame, you can simultaneously reindex the index and columns:

In [208]: df
Out[208]:
<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1.394981</td>
<td>1.772517</td>
<td>NaN</td>
</tr>
<tr>
<td>b</td>
<td>0.343054</td>
<td>1.912123</td>
<td>-0.050390</td>
</tr>
<tr>
<td>c</td>
<td>0.695246</td>
<td>1.478369</td>
<td>1.227435</td>
</tr>
<tr>
<td>d</td>
<td>NaN</td>
<td>0.279344</td>
<td>-0.613172</td>
</tr>
</tbody>
</table>

In [209]: df.reindex(index=["c", "f", "b"], columns=["three", "two", "one")
Out[209]:
<table>
<thead>
<tr>
<th>three</th>
<th>two</th>
<th>one</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>1.227435</td>
<td>1.478369</td>
</tr>
<tr>
<td>f</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>b</td>
<td>-0.050390</td>
<td>1.912123</td>
</tr>
</tbody>
</table>

You may also use reindex with an axis keyword:

In [210]: df.reindex(["c", "f", "b"), axis="index")
Out[210]:
<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>0.695246</td>
<td>1.478369</td>
<td>1.227435</td>
</tr>
<tr>
<td>f</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>b</td>
<td>0.343054</td>
<td>1.912123</td>
<td>-0.050390</td>
</tr>
</tbody>
</table>

Note that the Index objects containing the actual axis labels can be shared between objects. So if we have a Series and a DataFrame, the following can be done:

In [211]: rs = s.reindex(df.index)

In [212]: rs
Out[212]:
 a  1.695148
 b  1.328614
c  1.234686
d -0.385845

(continues on next page)
dtype: float64

In [213]: rs.index is df.index
Out[213]: True

This means that the reindexed Series’s index is the same Python object as the DataFrame’s index. 

Dataframe.reindex() also supports an “axis-style” calling convention, where you specify a single labels argument and the axis it applies to.

In [214]: df.reindex(\["c", "f", "b"\], axis=\"index\")
Out[214]:
   one  two  three
  c 0.695246 1.478369 1.227435
  f  NaN  NaN  NaN
  b 0.343054 1.912123 -0.050390

In [215]: df.reindex(\["three", "two", "one"\], axis=\"columns\")
Out[215]:
    three  two  one
   a  NaN  1.772517  1.394981
   b -0.050390  1.912123  0.343054
   c  1.227435  1.478369  0.695246
d -0.613172  0.279344  NaN

See also:

MultiIndex / Advanced Indexing is an even more concise way of doing reindexing.

Note: When writing performance-sensitive code, there is a good reason to spend some time becoming a reindexing ninja: many operations are faster on pre-aligned data. Adding two unaligned DataFrames internally triggers a reindexing step. For exploratory analysis you will hardly notice the difference (because reindex has been heavily optimized), but when CPU cycles matter sprinkling a few explicit reindex calls here and there can have an impact.

Reindexing to align with another object

You may wish to take an object and reindex its axes to be labeled the same as another object. While the syntax for this is straightforward albeit verbose, it is a common enough operation that the reindex_like() method is available to make this simpler:

In [216]: df2
Out[216]:
   one  two
  a 1.394981  1.772517
  b 0.343054  1.912123
  c 0.695246  1.478369

In [217]: df3
Out[217]:
   one  two
  a 0.583888  0.051514
  b -0.468040  0.191120
c -0.115848 -0.242634

(continues on next page)
Aligning objects with each other with `align`

The `align()` method is the fastest way to simultaneously align two objects. It supports a `join` argument (related to *joining and merging*):

- `join='outer'`: take the union of the indexes (default)
- `join='left'`: use the calling object’s index
- `join='right'`: use the passed object’s index
- `join='inner'`: intersect the indexes

It returns a tuple with both of the reindexed Series:

```python
In [219]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
In [220]: s1 = s[:4]
In [221]: s2 = s[1:]
In [222]: s1.align(s2)
Out[222]:
(a -0.186646
 b -1.692424
c -0.303893
d -1.425662
e NaN
dtype: float64,
a NaN
 b -1.692424
c -0.303893
d -1.425662
e 1.114285
dtype: float64)
```

```
In [223]: s1.align(s2, join="inner")
Out[223]:
(b -1.692424
c -0.303893
d -1.425662
dtype: float64,
b -1.692424
c -0.303893
d -1.425662
dtype: float64)
```

```
In [224]: s1.align(s2, join="left")
Out[224]:
(a -0.186646
```
For DataFrames, the join method will be applied to both the index and the columns by default:

```
In [225]: df.align(df2, join="inner")
Out[225]:
( one  two
 a  1.394981  1.772517
 b  0.343054  1.912123
 c  0.695246  1.478369,
 one  two
 a  1.394981  1.772517
 b  0.343054  1.912123
 c  0.695246  1.478369)
```

You can also pass an `axis` option to only align on the specified axis:

```
In [226]: df.align(df2, join="inner", axis=0)
Out[226]:
( one  two  three
 a  1.394981  1.772517  NaN
 b  0.343054  1.912123 -0.050390
 c  0.695246  1.478369  1.227435,
 one  two  three
 a  1.394981  1.772517  NaN
 b  0.343054  1.912123  1.227435
 c  0.695246  1.478369  1.227435)
```

If you pass a Series to `DataFrame.align()`, you can choose to align both objects either on the DataFrame’s index or columns using the `axis` argument:

```
In [227]: df.align(df2.iloc[0], axis=1)
Out[227]:
( one  three  two
 a  1.394981  NaN  1.772517
 b  0.343054 -0.050390  1.912123
 c  0.695246  1.227435  1.478369
 d  NaN  0.279344 -0.613172,
 one  three  two
 a  1.394981  NaN  1.772517
 b  0.343054 -0.050390  1.912123
 c  0.695246  1.227435  1.478369
 d  NaN  0.279344  0.279344
Name: a, dtype: float64)
```
Filling while reindexing

`reindex()` takes an optional parameter `method` which is a filling method chosen from the following table:

<table>
<thead>
<tr>
<th>Method</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>pad / ffill</td>
<td>Fill values forward</td>
</tr>
<tr>
<td>bfill / backfill</td>
<td>Fill values backward</td>
</tr>
<tr>
<td>nearest</td>
<td>Fill from the nearest index value</td>
</tr>
</tbody>
</table>

We illustrate these fill methods on a simple Series:

```
In [228]: rng = pd.date_range("1/3/2000", periods=8)
In [229]: ts = pd.Series(np.random.randn(8), index=rng)
In [230]: ts2 = ts[[0, 3, 6]]
In [231]: ts
Out[231]:

2000-01-08  0.733639
2000-01-09  0.733639
2000-01-10  NaN
Freq: D, dtype: float64

In [236]: ts2.reindex(ts.index, method="nearest")
Out[236]:
2000-01-03  0.183051
2000-01-04  0.183051
2000-01-05  2.395489
2000-01-06  2.395489
2000-01-07  2.395489
2000-01-08  0.733639
2000-01-09  0.733639
2000-01-10  0.733639
Freq: D, dtype: float64

These methods require that the indexes are ordered increasing or decreasing.

Note that the same result could have been achieved using `fillna` (except for method='nearest') or `interpolate`:

In [237]: ts2.reindex(ts.index).fillna(method="ffill")
Out[237]:
2000-01-03  0.183051
2000-01-04  0.183051
2000-01-05  0.183051
2000-01-06  2.395489
2000-01-07  2.395489
2000-01-08  2.395489
2000-01-09  0.733639
2000-01-10  0.733639
Freq: D, dtype: float64

`reindex()` will raise a ValueError if the index is not monotonically increasing or decreasing. `fillna()` and `interpolate()` will not perform any checks on the order of the index.
Limits on filling while reindexing

The limit and tolerance arguments provide additional control over filling while reindexing. Limit specifies the maximum count of consecutive matches:

```
In [238]: ts2.reindex(ts.index, method="ffill", limit=1)
Out[238]:
2000-01-03  0.183051
2000-01-04  0.183051
2000-01-05  NaN
2000-01-06  2.395489
2000-01-07  2.395489
2000-01-08  NaN
2000-01-09  0.733639
2000-01-10  0.733639
Freq: D, dtype: float64
```

In contrast, tolerance specifies the maximum distance between the index and indexer values:

```
In [239]: ts2.reindex(ts.index, method="ffill", tolerance="1 day")
Out[239]:
2000-01-03  0.183051
2000-01-04  0.183051
2000-01-05  NaN
2000-01-06  2.395489
2000-01-07  2.395489
2000-01-08  NaN
2000-01-09  0.733639
2000-01-10  0.733639
Freq: D, dtype: float64
```

Notice that when used on a DatetimeIndex, TimedeltaIndex or PeriodIndex, tolerance will coerced into a Timedelta if possible. This allows you to specify tolerance with appropriate strings.

Dropping labels from an axis

A method closely related to reindex is the drop() function. It removes a set of labels from an axis:

```
In [240]: df
Out[240]:
   one    two    three
  a  1.394981  1.772517  NaN
  b  0.343054  1.912123 -0.050390
  c  0.695246  1.478369  1.227435
  d   NaN        0.279344 -0.613172

In [241]: df.drop(['a', 'd'], axis=0)
Out[241]:
   one    two    three
  b  0.343054  1.912123 -0.050390
  c  0.695246  1.478369  1.227435

In [242]: df.drop(['one'], axis=1)
Out[242]:
   two    three
  a  1.772517  NaN
```

(continues on next page)
b 1.912123 -0.050390
c 1.478369 1.227435
d 0.279344 -0.613172

Note that the following also works, but is a bit less obvious / clean:

```python
In [243]: df.reindex(df.index.difference(['a', 'd']))
Out[243]:
   one     two     three
b 0.343054 1.912123 -0.050390
c 0.695246 1.478369  1.227435
```

### Renaming / mapping labels

The `rename()` method allows you to relabel an axis based on some mapping (a dict or Series) or an arbitrary function.

```python
In [244]: s
Out[244]:
a -0.186646
b -1.692424
c -0.303893
d -1.425662
e  1.114285
dtype: float64
```

```python
In [245]: s.rename(str.upper)
Out[245]:
A -0.186646
B -1.692424
C -0.303893
D -1.425662
E  1.114285
dtype: float64
```

If you pass a function, it must return a value when called with any of the labels (and must produce a set of unique values). A dict or Series can also be used:

```python
In [246]: df.rename(
   .....: columns={"one": "foo", "two": "bar"},
   .....: index={"a": "apple", "b": "banana", "d": "durian"},
   .....: )
   .....:
Out[246]:
   foo  bar  three
apple  1.394981 1.772517  NaN
banana 0.343054 1.912123 -0.050390
c 0.695246 1.478369  1.227435
durian NaN  0.279344 -0.613172
```

If the mapping doesn’t include a column/index label, it isn’t renamed. Note that extra labels in the mapping don’t throw an error.

`DataFrame.rename()` also supports an “axis-style” calling convention, where you specify a single mapper and the axis to apply that mapping to.
In [247]: df.rename({"one": "foo", "two": "bar"}, axis="columns")
Out[247]:
    foo  bar  three
   a 1.394981 1.772517 NaN
   b 0.343054 1.912123 -0.050390
   c 0.695246 1.478369 1.227435
d  NaN 0.279344 -0.613172

In [248]: df.rename({"a": "apple", "b": "banana", "d": "durian"}, axis="index")
Out[248]:
    one  two  three
   apple 1.394981 1.772517 NaN
   banana 0.343054 1.912123 -0.050390
   c 0.695246 1.478369 1.227435
durian NaN 0.279344 -0.613172

The rename() method also provides an inplace named parameter that is by default False and copies the underlying data. Pass inplace=True to rename the data in place.

Finally, rename() also accepts a scalar or list-like for altering the Series.name attribute.

In [249]: s.rename("scalar-name")
Out[249]:
a -0.186646
b -1.692424
c -0.303893
d -1.425662
e 1.114285
Name: scalar-name, dtype: float64

The methods DataFrame.rename_axis() and Series.rename_axis() allow specific names of a MultiIndex to be changed (as opposed to the labels).

In [250]: df = pd.DataFrame(
    .....:     {"x": [1, 2, 3, 4, 5, 6], "y": [10, 20, 30, 40, 50, 60]},
    .....:     index=pd.MultiIndex.from_product(
    .....:         ["a", "b", "c"], [1, 2]), names=["let", "num"],
    .....:     )

In [251]: df
Out[251]:
x     y
let num
a 1  1 10
   2  2 20
b 1  3 30
   2  4 40
c 1  5 50
   2  6 60

In [252]: df.rename_axis(index={"let": "abc"})
Out[252]:
x     y
abc num
a 1  1 10
(continues on next page)
2.3.8 Iteration

The behavior of basic iteration over pandas objects depends on the type. When iterating over a Series, it is regarded as array-like, and basic iteration produces the values. DataFrames follow the dict-like convention of iterating over the “keys” of the objects.

In short, basic iteration (for i in object) produces:

- **Series**: values
- **DataFrame**: column labels

Thus, for example, iterating over a DataFrame gives you the column names:

```
In [254]: df = pd.DataFrame({
   ....:     "col1": np.random.randn(3), "col2": np.random.randn(3),
   ....:     index=["a", "b", "c"]
   ....: })

In [255]: for col in df:
   ....:     print(col)
   ....:     col1
   ....:     col2
```

Pandas objects also have the dict-like `items()` method to iterate over the (key, value) pairs.

To iterate over the rows of a DataFrame, you can use the following methods:

- **iterrows()**: Iterate over the rows of a DataFrame as (index, Series) pairs. This converts the rows to Series objects, which can change the dtypes and has some performance implications.
- **itertuples()**: Iterate over the rows of a DataFrame as namedtuples of the values. This is a lot faster than `iterrows()`, and is in most cases preferable to use to iterate over the values of a DataFrame.

**Warning**: Iterating through pandas objects is generally **slow**. In many cases, iterating manually over the rows is not needed and can be avoided with one of the following approaches:
• Look for a *vectorized* solution: many operations can be performed using built-in methods or NumPy functions, (boolean) indexing,…

• When you have a function that cannot work on the full DataFrame/Series at once, it is better to use `apply()` instead of iterating over the values. See the docs on *function application*.

• If you need to do iterative manipulations on the values but performance is important, consider writing the inner loop with cython or numba. See the *enhancing performance* section for some examples of this approach.

**Warning:** You should never modify something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect!

For example, in the following case setting the value has no effect:

```bash
In [256]: df = pd.DataFrame({"a": [1, 2, 3], "b": ["a", "b", "c"]})
In [257]: for index, row in df.iterrows():
......:    row["a"] = 10
......:
In [258]: df
Out[258]:
   a  b
0  1  a
1  2  b
2  3  c
```

**items**

Consistent with the dict-like interface, `items()` iterates through key-value pairs:

• **Series**: (index, scalar value) pairs

• **DataFrame**: (column, Series) pairs

For example:

```bash
In [259]: for label, ser in df.items():
......:    print(label)
......:    print(ser)
......:
a
0  1
1  2
2  3
Name: a, dtype: int64
b
0  a
1  b
2  c
Name: b, dtype: object
```
iterrows

*iterrows()* allows you to iterate through the rows of a DataFrame as Series objects. It returns an iterator yielding each index value along with a Series containing the data in each row:

```python
In [260]: for row_index, row in df.iterrows():
    ....:     print(row_index, row,
    ....:            sep="\n")
```

```
0  a  1
b  a
Name: 0, dtype: object
1  a  2
b  b
Name: 1, dtype: object
2  a  3
b  c
Name: 2, dtype: object
```

**Note:** Because *iterrows()* returns a Series for each row, it does not preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```python
In [261]: df_orig = pd.DataFrame([[1, 1.5]], columns=["int", "float"])

In [262]: df_orig.dtypes
Out[262]:
int    int64
float  float64
dtype: object

In [263]: row = next(df_orig.iterrows())[1]

In [264]: row
Out[264]:
int   1.0
float 1.5
Name: 0, dtype: float64
```

All values in *row*, returned as a Series, are now upcasted to floats, also the original integer value in column *x*:

```python
In [265]: row["int"].dtype
Out[265]: dtype('float64')

In [266]: df_orig["int"].dtype
Out[266]: dtype('int64')
```

To preserve dtypes while iterating over the rows, it is better to use *itertuples()* which returns namedtuples of the values and which is generally much faster than *iterrows()*.

For instance, a contrived way to transpose the DataFrame would be:

```python
In [267]: df2 = pd.DataFrame({"x": [1, 2, 3], "y": [4, 5, 6]})

In [268]: print(df2)
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

(continued from previous page)

<table>
<thead>
<tr>
<th></th>
<th>x</th>
<th>y</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>5</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>6</td>
</tr>
</tbody>
</table>

```
In [269]: print(df2.T)
   0 1 2
  x 1 2 3
  y 4 5 6
```

```
In [270]: df2_t = pd.DataFrame({idx: values for idx, values in df2.iterrows()})
```

```
In [271]: print(df2_t)
   0 1 2
  x 1 2 3
  y 4 5 6
```

### itertuples

The `itertuples()` method will return an iterator yielding a namedtuple for each row in the DataFrame. The first element of the tuple will be the row’s corresponding index value, while the remaining values are the row values.

For instance:

```
In [272]: for row in df.itertuples():
   ....:     print(row)
   ....:
     Pandas(Index=0, a=1, b='a')
     Pandas(Index=1, a=2, b='b')
     Pandas(Index=2, a=3, b='c')
```

This method does not convert the row to a Series object; it merely returns the values inside a namedtuple. Therefore, `itertuples()` preserves the data type of the values and is generally faster as `iterrows()`.

**Note:** The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. With a large number of columns (>255), regular tuples are returned.

### 2.3.9 .dt accessor

Series has an accessor to succinctly return datetime like properties for the `values` of the Series, if it is a datetime/period like Series. This will return a Series, indexed like the existing Series.

```
# datetime
In [273]: s = pd.Series(pd.date_range("20130101 09:10:12", periods=4))
```

```
In [274]: s
Out[274]:
0   2013-01-01 09:10:12
1   2013-01-02 09:10:12
2   2013-01-03 09:10:12
3   2013-01-04 09:10:12
dtype: datetime64[ns]
```

(continues on next page)
This enables nice expressions like this:

```python
In [278]: s[s.dt.day == 2]
Out[278]:
1  2013-01-02 09:10:12
```

dtype: datetime64[ns]

You can easily produces tz aware transformations:

```python
In [279]: stz = s.dt.tz_localize("US/Eastern")

In [280]: stz
Out[280]:
0  2013-01-01 09:10:12-05:00
1  2013-01-02 09:10:12-05:00
2  2013-01-03 09:10:12-05:00
3  2013-01-04 09:10:12-05:00
dtype: datetime64[ns, US/Eastern]
```

You can also chain these types of operations:

```python
In [282]: s.dt.tz_localize("UTC").dt.tz_convert("US/Eastern")
Out[282]:
0  2013-01-01 04:10:12-05:00
1  2013-01-02 04:10:12-05:00
2  2013-01-03 04:10:12-05:00
3  2013-01-04 04:10:12-05:00
dtype: datetime64[ns, US/Eastern]
```
You can also format datetime values as strings with `Series.dt.strftime()` which supports the same format as the standard `strftime()`.

```python
# DatetimeIndex
In [283]: s = pd.Series(pd.date_range("20130101", periods=4))

In [284]: s
Out[284]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
3 2013-01-04
dtype: datetime64[ns]

In [285]: s.dt.strftime("%Y/%m/%d")
Out[285]:
0 2013/01/01
1 2013/01/02
2 2013/01/03
3 2013/01/04
dtype: object
```

```python
# PeriodIndex
In [286]: s = pd.Series(pd.period_range("20130101", periods=4))

In [287]: s
Out[287]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
3 2013-01-04
dtype: period[D]

In [288]: s.dt.strftime("%Y/%m/%d")
Out[288]:
0 2013/01/01
1 2013/01/02
2 2013/01/03
3 2013/01/04
dtype: object
```

The `.dt` accessor works for period and timedelta dtypes.

```python
# period
In [289]: s = pd.Series(pd.period_range("20130101", periods=4, freq="D"))

In [290]: s
Out[290]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
3 2013-01-04
dtype: period[D]

In [291]: s.dt.year
Out[291]:
0 2013
1 2013
```

(continues on next page)
In [292]: s.dt.day
Out[292]:
0 1
1 2
2 3
3 4
dtype: int64

# timedelta
In [293]: s = pd.Series(pd.timedelta_range("1 day 00:00:05", periods=4, freq="s"))

In [294]: s
Out[294]:
0 1 days 00:00:05
1 1 days 00:00:06
2 1 days 00:00:07
3 1 days 00:00:08
dtype: timedelta64[ns]

In [295]: s.dt.days
Out[295]:
0 1
1 1
2 1
3 1
dtype: int64

In [296]: s.dt.seconds
Out[296]:
0 5
1 6
2 7
3 8
dtype: int64

In [297]: s.dt.components
Out[297]:
<table>
<thead>
<tr>
<th>days</th>
<th>hours</th>
<th>minutes</th>
<th>seconds</th>
<th>milliseconds</th>
<th>microseconds</th>
<th>nanoseconds</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>5</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
<td>6</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>0</td>
<td>7</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>3</td>
<td>0</td>
<td>0</td>
<td>8</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Note: Series.dt will raise a TypeError if you access with a non-datetime-like values.
2.3.10 Vectorized string methods

Series is equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the Series’s `str` attribute and generally have names matching the equivalent (scalar) built-in string methods. For example:

```
In [298]: s = pd.Series(
.....:     dtype="string"
.....: )
.....:
In [299]: s.str.lower()
Out[299]:
0    a
1    b
2    c
3  aaba
4    baca
5   <NA>
6    caba
7    dog
8    cat
dtype: string
```

Powerful pattern-matching methods are provided as well, but note that pattern-matching generally uses regular expressions by default (and in some cases always uses them).

**Note:** Prior to pandas 1.0, string methods were only available on `object`-dtype `Series`. pandas 1.0 added the `StringDtype` which is dedicated to strings. See Text data types for more.

Please see Vectorized String Methods for a complete description.

2.3.11 Sorting

pandas supports three kinds of sorting: sorting by index labels, sorting by column values, and sorting by a combination of both.

**By index**

The `Series.sort_index()` and `DataFrame.sort_index()` methods are used to sort a pandas object by its index levels.

```
In [300]: df = pd.DataFrame(
.....:     {                             
.....:         "one": pd.Series(np.random.randn(3), index=["a", "b", "c"]),
.....:         "two": pd.Series(np.random.randn(4), index=["a", "b", "c", "d"]),
.....:         "three": pd.Series(np.random.randn(3), index=["b", "c", "d"]),
.....:     }                         
.....: )                           
.....:
In [301]: unsorted_df = df.reindex(  
(continues on next page)
In [302]: unsorted_df
Out[302]:
      three   two   one
     a   NaN -1.152244  0.562973
     d -0.252916 -0.109597    NaN
c  1.273388 -0.167123  0.640382
b -0.098217  0.009797 -1.299504

# DataFrame
In [303]: unsorted_df.sort_index()
Out[303]:
      three   two   one
     a   NaN -1.152244  0.562973
     b -0.098217  0.009797 -1.299504
c  1.273388 -0.167123  0.640382
d -0.252916 -0.109597    NaN

In [304]: unsorted_df.sort_index(ascending=False)
Out[304]:
      three   two   one
     d -0.252916 -0.109597    NaN
c  1.273388 -0.167123  0.640382
b -0.098217  0.009797 -1.299504
a   NaN -1.152244  0.562973

In [305]: unsorted_df.sort_index(axis=1)
Out[305]:
     one   three   two
     a  0.562973   NaN -1.152244
d   NaN -0.252916 -0.109597
c  0.640382  1.273388 -0.167123
b -1.299504 -0.098217  0.009797

# Series
In [306]: unsorted_df["three"].sort_index()
Out[306]:
Name: three, dtype: float64

New in version 1.1.0.

Sorting by index also supports a key parameter that takes a callable function to apply to the index being sorted. For MultiIndex objects, the key is applied per-level to the levels specified by level.

In [307]: s1 = pd.DataFrame({"a": ["B", "a", "C"], "b": [1, 2, 3], "c": [2, 3, 4]}).set_index(
                         list(\"ab\")
                         )

(continues on next page)
In [308]: s1
Out[308]:
   a  b
B 1  2
a 2  3
C 3  4

In [309]: s1.sort_index(level="a")
Out[309]:
   a  b
B 1  2
C 3  4
a 2  3

In [310]: s1.sort_index(level="a", key=lambda idx: idx.str.lower())
Out[310]:
   a  b
a 2  3
B 1  2
C 3  4

For information on key sorting by value, see value sorting.

By values

The `Series.sort_values()` method is used to sort a Series by its values. The `DataFrame.sort_values()` method is used to sort a DataFrame by its column or row values. The optional `by` parameter to `DataFrame.sort_values()` may used to specify one or more columns to use to determine the sorted order.

In [311]: df1 = pd.DataFrame(
    .....:   {"one": [2, 1, 1, 1], "two": [1, 3, 2, 4], "three": [5, 4, 3, 2]})
In [312]: df1.sort_values(by="two")
Out[312]:
   one  two  three
0  2   1    5
2  1   2    3
1  1   3    4
3  1   4    2

The `by` parameter can take a list of column names, e.g.:

In [313]: df1["one", "two", "three"].sort_values(by=["one", "two"])
Out[313]:
   one  two  three
2  1   2    3
1  1   3    4
3  1   4    2
0  2   1    5

These methods have special treatment of NA values via the `na_position` argument:

2.3. Essential basic functionality
New in version 1.1.0.

Sorting also supports a `key` parameter that takes a callable function to apply to the values being sorted.

```python
In [316]: s1 = pd.Series(["B", "a", "C"])
In [317]: s1.sort_values()
Out[317]:
0   B
1   a
2   C
dtype: object
In [318]: s1.sort_values(key=lambda x: x.str.lower())
Out[318]:
1   a
0   B
2   C
dtype: object
```

`key` will be given the `Series` of values and should return a `Series` or array of the same shape with the transformed values. For `DataFrame` objects, the key is applied per column, so the key should still expect a `Series` and return a `Series`, e.g.

```python
In [320]: df = pd.DataFrame({"a": ["B", "a", "C"], "b": [1, 2, 3]})
In [321]: df.sort_values(by="a")
```

(continues on next page)
In [322]: df.sort_values(by="a", key=lambda col: col.str.lower())
Out[322]:
   a   b
0  B  1
1  a  2
2  C  3

The name or type of each column can be used to apply different functions to different columns.

By indexes and values

Strings passed as the `by` parameter to `DataFrame.sort_values()` may refer to either columns or index level names.

```python
# Build MultiIndex
In [323]: idx = pd.MultiIndex.from_tuples(
    ....:     [("a", 1), ("a", 2), ("a", 2), ("b", 2), ("b", 1), ("b", 1)]
    ....:     )
    ....:
In [324]: idx.names = ["first", "second"]

# Build DataFrame
In [325]: df_multi = pd.DataFrame({"A": np.arange(6, 0, -1)}, index=idx)

In [326]: df_multi
Out[326]:
   A
first second
a  1   6
   2   5
   2   4
b  2   3
   1   2
   1   1

Sort by `second` (index) and `A` (column)

```python
In [327]: df_multi.sort_values(by=["second", "A")
Out[327]:
   A
first second
b  1   1
   1   2
a  1   6
   2   3
b  2   4
   2   5
```

**Note:** If a string matches both a column name and an index level name then a warning is issued and the column takes
precedence. This will result in an ambiguity error in a future version.

**searchsorted**

Series has the `searchsorted()` method, which works similarly to `numpy.ndarray.searchsorted()`.

```python
In [328]: ser = pd.Series([1, 2, 3])
In [329]: ser.searchsorted([0, 3])
Out[329]: array([0, 2])
In [330]: ser.searchsorted([0, 4])
Out[330]: array([0, 3])
In [331]: ser.searchsorted([1, 3], side="right")
Out[331]: array([1, 3])
In [332]: ser.searchsorted([1, 3], side="left")
Out[332]: array([0, 2])
In [333]: ser = pd.Series([3, 1, 2])
In [334]: ser.searchsorted([0, 3], sorter=np.argsort(ser))
Out[334]: array([0, 2])
```

**smallest / largest values**

Series has the `nsmallest()` and `nlargest()` methods which return the smallest or largest $n$ values. For a large Series this can be much faster than sorting the entire Series and calling `head(n)` on the result.

```python
In [335]: s = pd.Series(np.random.permutation(10))
In [336]: s
Out[336]:
0   2
1   0
2   3
3   7
4   1
5   5
6   9
7   6
8   8
9   4
dtype: int64
In [337]: s.sort_values()
Out[337]:
1   0
4   1
0   2
2   3
9   4
5   5
```

(continues on next page)
Dataframe also has the `nlargest` and `nsmallest` methods.

```
In [340]: df = pd.DataFrame(
    .....:  
    .....:      "a": [-2, -1, 1, 10, 8, 11, -1],
    .....:      "b": list("abdcef"),
    .....:      "c": [1.0, 2.0, 4.0, 3.2, np.nan, 3.0, 4.0],
    .....:  }
Out[340]:
     a  b  c
0  -2  a  1.0
1  -1  b  2.0
2   f  c  NaN
```

```
In [341]: df.nlargest(3, "a")
Out[341]:
     a  b  c
4  11  f  3.0
3  10  c  3.2
6  11  f  4.0
```

```
In [342]: df.nlargest(5, ["a", "c"])
Out[342]:
     a  b  c
4  11  f  4.0
2   d  4.0
6  11  f  4.0
1   a  3.2
0   e  NaN
```

```
In [343]: df.nsmallest(3, "a")
Out[343]:
     a  b  c
0  -2  a  1.0
1  -1  b  2.0
2   f  c  NaN
```

```
In [344]: df.nsmallest(5, ["a", "c"])
Out[344]:
     a  b  c
```
```
Sorting by a MultiIndex column

You must be explicit about sorting when the column is a MultiIndex, and fully specify all levels to `by`.

```
In [345]: df1.columns = pd.MultiIndex.from_tuples(
    .....:     [("a", "one"), ("a", "two"), ("b", "three")]
    .....: )
    .....:

In [346]: df1.sort_values(by=("a", "two"))
Out[346]:
          a    b
one two three
0    2    1    5
2    1    2    3
1    1    3    4
3    1    4    2
```

2.3.12 Copying

The `copy()` method on pandas objects copies the underlying data (though not the axis indexes, since they are immutable) and returns a new object. Note that it is seldom necessary to copy objects. For example, there are only a handful of ways to alter a DataFrame *in-place*:

- Inserting, deleting, or modifying a column.
- Assigning to the `index` or `columns` attributes.
- For homogeneous data, directly modifying the values via the `values` attribute or advanced indexing.

To be clear, no pandas method has the side effect of modifying your data; almost every method returns a new object, leaving the original object untouched. If the data is modified, it is because you did so explicitly.

2.3.13 dtypes

For the most part, pandas uses NumPy arrays and dtypes for Series or individual columns of a DataFrame. NumPy provides support for `float`, `int`, `bool`, `timedelta64[ns]` and `datetime64[ns]` (note that NumPy does not support timezone-aware datetimes).

pandas and third-party libraries extend NumPy’s type system in a few places. This section describes the extensions pandas has made internally. See `Extension types` for how to write your own extension that works with pandas. See ecosystem.extensions for a list of third-party libraries that have implemented an extension.

The following table lists all of pandas extension types. For methods requiring `dtype` arguments, strings can be specified as indicated. See the respective documentation sections for more on each type.
## Data Types

<table>
<thead>
<tr>
<th>Kind of Data</th>
<th>Data Type</th>
<th>Scalar</th>
<th>Array</th>
<th>String Aliases</th>
<th>Documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>tz-aware date-time</td>
<td>Datetime64[ns, &lt;tz&gt;]</td>
<td>DatetimeArray</td>
<td>'datetime64[ns, &lt;tz&gt;]'</td>
<td>Time zone handling</td>
<td></td>
</tr>
<tr>
<td>Categorical</td>
<td>CategoricalDtype</td>
<td>Category</td>
<td>Categorical</td>
<td>Categorical data</td>
<td></td>
</tr>
<tr>
<td>period (time spans)</td>
<td>PeriodDtype</td>
<td>PeriodArray</td>
<td>'period[&lt;freq&gt;]', 'Period[&lt;freq&gt;]'</td>
<td>Time span representation</td>
<td></td>
</tr>
<tr>
<td>Sparse</td>
<td>SparseDtype</td>
<td>SparseArray</td>
<td>'Sparse', 'Sparse[int]', 'Sparse[float]'</td>
<td>Sparse data structures</td>
<td></td>
</tr>
<tr>
<td>Intervals</td>
<td>IntervalDtype</td>
<td>IntervalArray</td>
<td>'interval', 'Interval', 'Interval[&lt;numpy_dtype&gt;]', 'Interval[datetime64[ns, &lt;tz&gt;]]', 'Interval[timedelta64[&lt;freq&gt;]]'</td>
<td>IntervalIndex</td>
<td></td>
</tr>
<tr>
<td>Nullable integer</td>
<td>Int64Dtype</td>
<td>IntegerArray</td>
<td>'Int8', 'Int16', 'Int32', 'Int64', 'UInt8', 'UInt16', 'UInt32', 'UInt64'</td>
<td>Nullable integer data type</td>
<td></td>
</tr>
<tr>
<td>Strings</td>
<td>StringDtype</td>
<td>StringArray</td>
<td>'string'</td>
<td>Working with text data</td>
<td></td>
</tr>
<tr>
<td>Boolean (with NA)</td>
<td>BooleanDtype</td>
<td>BooleanArray</td>
<td>'boolean'</td>
<td>Boolean data with missing values</td>
<td></td>
</tr>
</tbody>
</table>

Pandas has two ways to store strings.

1. `object` dtype, which can hold any Python object, including strings.
2. `StringDtype`, which is dedicated to strings.

Generally, we recommend using `StringDtype`. See **Text data types** for more.

Finally, arbitrary objects may be stored using the `object` dtype, but should be avoided to the extent possible (for performance and interoperability with other libraries and methods. See **object conversion**).

A convenient `dtypes` attribute for DataFrame returns a Series with the data type of each column.

```python
In [347]: dft = pd.DataFrame(
......:     {......:         "A": np.random.rand(3),......:         "B": 1,......:         "C": "foo",......:         "D": pd.Timestamp("20010102"),......:         "E": pd.Series([1.0] * 3).astype("float32"),......:         "F": False,......:         "G": pd.Series([1] * 3, dtype="int8"),......:     }
```

(continues on next page)
In [348]: dft
Out[348]:
   A    B    C   D   E    F   G
0  0.035962  1  foo  2001-01-02  1.0  False  1
1  0.701379  1  foo  2001-01-02  1.0  False  1
2  0.281885  1  foo  2001-01-02  1.0  False  1

In [349]: dft.dtypes
Out[349]:
A  float64
B  int64
C  object
D  datetime64[ns]
E  float32
F  bool
G  int8
dtype: object

On a Series object, use the dtype attribute.

In [350]: dft['A'].dtype
Out[350]: dtype('float64')

If a pandas object contains data with multiple dtypes in a single column, the dtype of the column will be chosen to accommodate all of the data types (object is the most general).

# these ints are coerced to floats
In [351]: pd.Series([1, 2, 3, 4, 5, 6.0])
Out[351]:
0    1.0
1    2.0
2    3.0
3    4.0
4    5.0
5    6.0
dtype: float64

# string data forces an `object` dtype
In [352]: pd.Series([1, 2, 3, 6.0, "foo"])
Out[352]:
0     1
1     2
2     3
3    6.0
4    foo
dtype: object

The number of columns of each type in a DataFrame can be found by calling DataFrame.dtypes.value_counts().

In [353]: dft.dtypes.value_counts()
Out[353]:
float64    1
Numeric dtypes will propagate and can coexist in DataFrames. If a dtype is passed (either directly via the `dtype` keyword, a passed `ndarray`, or a passed `Series`), then it will be preserved in DataFrame operations. Furthermore, different numeric dtypes will **NOT** be combined. The following example will give you a taste.

```python
In [354]: df1 = pd.DataFrame(np.random.randn(8, 1), columns=['A'], dtype='float32')
In [355]: df1
Out[355]:
   A
0  0.224364
1  1.890546
2  0.182879
3  0.787847
4 -0.188449
5  0.667715
6 -0.011736
7 -0.399073

In [356]: df1.dtypes
Out[356]:
A float32
dtype: object

In [357]: df2 = pd.DataFrame(
       ...:     {  
       ...:         "A": pd.Series(np.random.randn(8), dtype="float16"),
       ...:         "B": pd.Series(np.random.randn(8)),
       ...:         "C": pd.Series(np.array(np.random.randn(8), dtype="uint8")),
       ...:     }
       ...: )  

In [358]: df2
Out[358]:
   A   B   C
0 0.823242 0.256090 0
1 1.607422 1.426469 0
2 -0.333740 -0.416203 255
3 -0.063477 1.139976 0
4 -1.014648 -1.193477 0
5  0.678711 0.096706 0
6 -0.040863 -1.956850 1
7 -0.357422 -0.714337 0

In [359]: df2.dtypes
Out[359]:
A  float16
B  float64
```

defaults

By default integer types are int64 and float types are float64, regardless of platform (32-bit or 64-bit). The following will all result in int64 dtypes.

```
In [360]: pd.DataFrame([1, 2], columns=["a"]).dtypes
Out[360]:
a   int64
dtype: object

In [361]: pd.DataFrame({"a": [1, 2]}).dtypes
Out[361]:
a   int64
dtype: object

In [362]: pd.DataFrame({"a": 1}, index=list(range(2))).dtypes
Out[362]:
a   int64
dtype: object
```

Note that Numpy will choose platform-dependent types when creating arrays. The following WILL result in int32 on 32-bit platform.

```
In [363]: frame = pd.DataFrame(np.array([1, 2]))
```

upcasting

Types can potentially be upcasted when combined with other types, meaning they are promoted from the current type (e.g. int to float).

```
In [364]: df3 = df1.reindex_like(df2).fillna(value=0.0) + df2

In [365]: df3
Out[365]:
   A      B      C
0  1.047606  0.256090  0.0
1  3.497968  1.426469  0.0
2 -0.150862 -0.416203 255.0
3  0.724370  1.139976  0.0
4 -1.203098 -1.193477  0.0
5  1.346426  0.096706  0.0
6 -0.052599 -1.956850  1.0
7 -0.756495 -0.714337  0.0

In [366]: df3.dtypes
Out[366]:
A    float32
B    float64
C    float64
dtype: object
```
DataFrame.to_numpy() will return the lower-common-denominator of the dtypes, meaning the dtype that can accommodate ALL of the types in the resulting homogeneous dtyped NumPy array. This can force some upcasting.

In [367]: df3.to_numpy().dtype
Out[367]: dtype('float64')

astype

You can use the astype() method to explicitly convert dtypes from one to another. These will by default return a copy, even if the dtype was unchanged (pass copy=False to change this behavior). In addition, they will raise an exception if the astype operation is invalid.

Upcasting is always according to the NumPy rules. If two different dtypes are involved in an operation, then the more general one will be used as the result of the operation.

In [368]: df3
Out[368]:
A   B   C
0 1.047606 0.256090 0.0
1 3.497968 1.426469 0.0
2 -0.150862 -0.416203 255.0
3 0.724370 1.139976 0.0
4 -1.203098 -1.193477 0.0
5 1.346426 0.096706 0.0
6 -0.052599 -1.956850 1.0
7 -0.756495 -0.714337 0.0

In [369]: df3.dtypes
Out[369]:
A float32
B float64
C float64
dtype: object
# conversion of dtypes
In [370]: df3.astype("float32").dtypes
Out[370]:
A float32
B float32
C float32
dtype: object

Convert a subset of columns to a specified type using astype().

In [371]: dft = pd.DataFrame({"a": [1, 2, 3], "b": [4, 5, 6], "c": [7, 8, 9]})

In [372]: dft["a", "b"] = dft["a", "b"].astype(np.uint8)

In [373]: dft
Out[373]:
a b c
0 1 4 7
1 2 5 8
2 3 6 9

In [374]: dft.dtypes

(continues on next page)
Convert certain columns to a specific dtype by passing a dict to `astype()`.

```python
In [375]: dft1 = pd.DataFrame({"a": [1, 0, 1], "b": [4, 5, 6], "c": [7, 8, 9]})

In [376]: dft1 = dft1.astype({"a": np.bool_, "c": np.float64})

In [377]: dft1
Out[377]:
   a  b  c
0  True  4  7.0
1  False  5  8.0
2  True  6  9.0

In [378]: dft1.dtypes
Out[378]:
       a    b    c
dtype: object
```

Note: When trying to convert a subset of columns to a specified type using `astype()` and `loc()`, upcasting occurs. `loc()` tries to fit in what we are assigning to the current dtypes, while [] will overwrite them taking the dtype from the right hand side. Therefore the following piece of code produces the unintended result.

```python
In [379]: dft = pd.DataFrame({"a": [1, 2, 3], "b": [4, 5, 6], "c": [7, 8, 9]})

In [380]: dft.loc[:, ["a", "b"]].astype(np.uint8).dtypes
Out[380]:
    a    b
dtype: object

In [381]: dft.loc[:, ["a", "b"]].astype(np.uint8)

In [382]: dft.dtypes
Out[382]:
       a    b    c
dtype: object
```
object conversion

pandas offers various functions to try to force conversion of types from the object dtype to other types. In cases where the data is already of the correct type, but stored in an object array, the `DataFrame.infer_objects()` and `Series.infer_objects()` methods can be used to soft convert to the correct type.

```python
In [383]: import datetime

In [384]: df = pd.DataFrame(
           .....:    [1, 2],
           .....:    ["a", "b"],
           .....:    [datetime.datetime(2016, 3, 2),
           .....:      "2")],
           .....:    )

In [385]: df = df.T

In [386]: df
Out[386]:
   0   1   2
0  1   a 2016-03-02
1  2   b 2016-03-02

In [387]: df.dtypes
Out[387]:
0     object
1     object
2  datetime64[ns]
dtype: object

Because the data was transposed the original inference stored all columns as object, which `infer_objects` will correct.

```python
In [388]: df.infer_objects().dtypes
Out[388]:
0     int64
1     object
2  datetime64[ns]
dtype: object
```

The following functions are available for one dimensional object arrays or scalars to perform hard conversion of objects to a specified type:

- `to_numeric()` (conversion to numeric dtypes)

```python
In [389]: m = ["1.1", 2, 3]

In [390]: pd.to_numeric(m)
Out[390]: array([1.1, 2. , 3. ])
```

- `to_datetime()` (conversion to datetime objects)

```python
In [391]: import datetime

In [392]: m = ["2016-07-09", datetime.datetime(2016, 3, 2)]
```
In [393]: pd.to_datetime(m)
Out[393]: DatetimeIndex(['2016-07-09', '2016-03-02'], dtype='datetime64[ns]',
                      freq=None)

- **to_timedelta()** (conversion to timedelta objects)

In [394]: m = ["5us", pd.Timedelta("1day")]
In [395]: pd.to_timedelta(m)
Out[395]: TimedeltaIndex([('0 days 00:00:00.000005', '1 days 00:00:00'),
                         ('timedelta64[ns]', 'freq=None')]

To force a conversion, we can pass in an errors argument, which specifies how pandas should deal with elements that cannot be converted to desired dtype or object. By default, errors='raise', meaning that any errors encountered will be raised during the conversion process. However, if errors='coerce', these errors will be ignored and pandas will convert problematic elements to pd.NaT (for datetime and timedelta) or np.nan (for numeric). This might be useful if you are reading in data which is mostly of the desired dtype (e.g. numeric, datetime), but occasionally has non-conforming elements intermixed that you want to represent as missing:

In [396]: import datetime
In [397]: m = ["apple", datetime.datetime(2016, 3, 2)]
In [398]: pd.to_datetime(m, errors="coerce")
Out[398]: DatetimeIndex([NaT, '2016-03-02'], dtype='datetime64[ns]', freq=None)
In [399]: m = ["apple", 2, 3]
In [400]: pd.to_numeric(m, errors="coerce")
Out[400]: array([nan, 2., 3.])
In [401]: m = ["apple", pd.Timedelta("1day")]
In [402]: pd.to_timedelta(m, errors="coerce")
Out[402]: TimedeltaIndex([NaT, '1 days'], dtype='timedelta64[ns]', freq=None)

The errors parameter has a third option of errors='ignore', which will simply return the passed in data if it encounters any errors with the conversion to a desired data type:

In [403]: import datetime
In [404]: m = ["apple", datetime.datetime(2016, 3, 2)]
In [405]: pd.to_datetime(m, errors="ignore")
Out[405]: Index(["apple", 2016-03-02 00:00:00], dtype='object')
In [406]: m = ["apple", 2, 3]
In [407]: pd.to_numeric(m, errors="ignore")
Out[407]: array(["apple", 2, 3], dtype=object)
In [408]: m = ["apple", pd.Timedelta("1day")]
In [409]: pd.to_timedelta(m, errors="ignore")
Out[409]: array(["apple", Timedelta('1 days 00:00:00')], dtype=object)
In addition to object conversion, `to_numeric()` provides another argument `downcast`, which gives the option of downcasting the newly (or already) numeric data to a smaller dtype, which can conserve memory:

```python
In [410]: m = ["1", 2, 3]
In [411]: pd.to_numeric(m, downcast="integer")  # smallest signed int dtype
Out[411]: array([1, 2, 3], dtype=int8)
In [412]: pd.to_numeric(m, downcast="signed")  # same as 'integer'
Out[412]: array([1, 2, 3], dtype=int8)
In [413]: pd.to_numeric(m, downcast="unsigned")  # smallest unsigned int dtype
Out[413]: array([1, 2, 3], dtype=uint8)
In [414]: pd.to_numeric(m, downcast="float")  # smallest float dtype
Out[414]: array([1., 2., 3.], dtype=float32)
```

As these methods apply only to one-dimensional arrays, lists or scalars; they cannot be used directly on multi-dimensional objects such as DataFrames. However, with `apply()`, we can “apply” the function over each column efficiently:

```python
In [415]: import datetime

In [416]: df = pd.DataFrame(["2016-07-09", datetime.datetime(2016, 3, 2)]) * 2,
   → dtype="O"

In [417]: df
Out[417]:
   0 1
0 2016-07-09 2016-03-02 00:00:00
1 2016-07-09 2016-03-02 00:00:00

In [418]: df.apply(pd.to_datetime)
Out[418]:
   0 1
0 2016-07-09 2016-03-02
1 2016-07-09 2016-03-02

In [419]: df = pd.DataFrame(["1.1", 2, 3]) * 2, dtype="O"

In [420]: df
Out[420]:
   0 1 2
0 1.1 2 3
1 1.1 2 3

In [421]: df.apply(pd.to_numeric)
Out[421]:
   0 1 2
0 1.1 2 3
1 1.1 2 3

In [422]: df = pd.DataFrame(["5us", pd.Timedelta("1day")]) * 2, dtype="O"

In [423]: df
Out[423]:
   0 1
0 5us 1 days 00:00:00
```
In [424]: df.apply(pd.to_timedelta)
Out[424]:
0 1 days 00:00:00
1 0 days 00:00:00.000005 1 days
1 0 days 00:00:00.000005 1 days

gotchias

Performing selection operations on integer type data can easily upcast the data to floating. The dtype of the input data will be preserved in cases where nans are not introduced. See also Support for integer NA.

In [425]: dfi = df3.astype("int32")
In [426]: dfi["E"] = 1
In [427]: dfi
Out[427]:
   A   B   C   E
0 1.0 NaN NaN NaN
1 3.0 1.0 NaN 1.0
2 NaN NaN 255.0 1.0
3 0.0 1.0 0.0 1.0
4 -1.0 -1.0 0.0 1.0
5 1.0 0.0 0.0 1.0
6 0.0 -1.0 1.0 1.0
7 0.0 0.0 0.0 1.0

In [428]: dfi.dtypes
Out[428]:
A  int32
B  int32
C  int32
E  int64
dtype: object

In [429]: casted = dfi[dfi > 0]
In [430]: casted
Out[430]:
   A   B   C   E
0 1.0 NaN NaN NaN
1 3.0 1.0 NaN 1.0
2 NaN NaN 255.0 1.0
3 NaN 1.0 NaN 1.0
4 NaN NaN NaN 1.0
5 1.0 NaN NaN 1.0
6 NaN NaN 1.0 1.0
7 NaN NaN NaN 1.0

In [431]: casted.dtypes
Out[431]:
A  float64
B  float64
While float dtypes are unchanged.

```python
In [432]: dfa = df3.copy()
In [433]: dfa["A"] = dfa["A"].astype("float32")
In [434]: dfa.dtypes
Out[434]:
A float32
B float64
C float64
dtype: object
```

```python
In [435]: casted = dfa[df2 > 0]
In [436]: casted
Out[436]:
   A    B    C
0  1.0  0.25  NaN
1  3.5  1.42  NaN
2  NaN  NaN  255
3  NaN  NaN  1.0
4  NaN  NaN  NaN
5  1.3  0.1  NaN
6  NaN  NaN  1.0
7  NaN  NaN  NaN
```

```python
In [437]: casted.dtypes
Out[437]:
A float32
B float64
C float64
dtype: object
```

### 2.3.14 Selecting columns based on dtype

The `select_dtypes()` method implements subsetting of columns based on their `dtype`.

First, let's create a `DataFrame` with a slew of different dtypes:

```python
In [438]: df = pd.DataFrame{
......:     "string": list("abc"),
......:     "int64": list(range(1, 4)),
......:     "uint8": np.arange(3, 6).astype("u1"),
......:     "float64": np.arange(4.0, 7.0),
......:     "bool1": [True, False, True],
......:     "bool2": [False, True, False],
......:     "dates": pd.date_range("now", periods=3),
......:     "category": pd.Series(list("ABC")).astype("category"),
......: }
```

(continues on next page)
In [439]: df["tdeltas"] = df.dates.diff()

In [440]: df["uint64"] = np.arange(3, 6).astype("u8")

In [441]: df["other_dates"] = pd.date_range("20130101", periods=3)

In [442]: df["tz_aware_dates"] = pd.date_range("20130101", periods=3, tz="US/Eastern")

In [443]: df

Out[443]:

<table>
<thead>
<tr>
<th></th>
<th>string</th>
<th>int64</th>
<th>uint8</th>
<th>float64</th>
<th>bool1</th>
<th>bool2</th>
<th>dates</th>
<th>category</th>
<th>tdeltas</th>
<th>uint64</th>
<th>other_dates</th>
<th>tz_aware_dates</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>a</td>
<td>1</td>
<td>3</td>
<td>4.0</td>
<td>True</td>
<td>False</td>
<td>2021-07-25 09:38:03.979698</td>
<td>A</td>
<td>NA</td>
<td>3</td>
<td>2013-01-01</td>
<td>2013-01-01 00:00:00-05:00</td>
</tr>
<tr>
<td>1</td>
<td>b</td>
<td>2</td>
<td>4</td>
<td>5.0</td>
<td>False</td>
<td>True</td>
<td>2021-07-26 09:38:03.979698</td>
<td>B</td>
<td>0</td>
<td>4</td>
<td>2013-01-02</td>
<td>2013-01-02 00:00:00-05:00</td>
</tr>
<tr>
<td>2</td>
<td>c</td>
<td>3</td>
<td>5</td>
<td>6.0</td>
<td>True</td>
<td>False</td>
<td>2021-07-27 09:38:03.979698</td>
<td>C</td>
<td>1</td>
<td>5</td>
<td>2013-01-03</td>
<td>2013-01-03 00:00:00-05:00</td>
</tr>
</tbody>
</table>

And the dtypes:

In [444]: df.dtypes

Out[444]:

<table>
<thead>
<tr>
<th>dtype</th>
<th>object</th>
<th>int64</th>
<th>uint8</th>
<th>float64</th>
<th>bool1</th>
<th>bool2</th>
<th>dates</th>
<th>category</th>
<th>tdeltas</th>
<th>uint64</th>
<th>other_dates</th>
<th>tz_aware_dates</th>
</tr>
</thead>
<tbody>

<td></td>
</tr>
<tr>
<td>other_dates</td>
<td>object</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>tz_aware_dates</td>
<td>object</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

dtype: object

`select_dtypes()` has two parameters `include` and `exclude` that allow you to say “give me the columns with these dtypes” (include) and/or “give the columns without these dtypes” (exclude).

For example, to select bool columns:

In [445]: df.select_dtypes(include=[bool])

Out[445]:

<table>
<thead>
<tr>
<th>bool1</th>
<th>bool2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>True</td>
</tr>
<tr>
<td>1</td>
<td>False</td>
</tr>
<tr>
<td>2</td>
<td>True</td>
</tr>
</tbody>
</table>

You can also pass the name of a dtype in the NumPy dtype hierarchy:
select_dtypes() also works with generic dtypes as well.

For example, to select all numeric and boolean columns while excluding unsigned integers:

```
In [447]: df.select_dtypes(include=['number', 'bool'], exclude=['unsignedinteger'])
Out[447]:
    int64  float64  bool1  bool2  tdeltas
   0  1 4.0  True  False  NaT
   1  2  5.0  False  True   1 days
   2  3  6.0  True  False   1 days
```

To select string columns you must use the object dtype:

```
In [448]: df.select_dtypes(include=['object'])
Out[448]:
    string
   0  a
   1  b
   2  c
```

To see all the child dtypes of a generic dtype like numpy.number you can define a function that returns a tree of child dtypes:

```
In [449]: def subdtypes(dtype):
   ....:     subs = dtype.__subclasses__()
   ....:     if not subs:
   ....:         return dtype
   ....:     return [dtype, [subdtypes(dt) for dt in subs]]
```

All NumPy dtypes are subclasses of numpy.generic:

```
In [450]: subdtypes(np.generic)
Out[450]:
[numpy.generic,
 [[numpy.integer,
   [[numpy.signedinteger,
     [numpy.int8,
     numpy.int16,
     numpy.int32,
     numpy.int64,
     numpy.longlong,
     numpy.timedelta64]],
     [numpy.unsignedinteger,
     [numpy.uint8,
     numpy.uint16,
     numpy.uint32,
     numpy.uint64,
     numpy.ulonglong]]],
     [numpy.inexact,
     [[numpy.floating,
       [numpy.float16, numpy.float32, numpy.float64, numpy.float128]]]]]]
```

(continues on next page)
Note: pandas also defines the types category, and datetime64[ns, tz], which are not integrated into the normal NumPy hierarchy and won’t show up with the above function.

2.4 IO tools (text, CSV, HDF5, …)

The pandas I/O API is a set of top level reader functions accessed like pandas.read_csv() that generally return a pandas object. The corresponding writer functions are object methods that are accessed like DataFrame.to_csv(). Below is a table containing available readers and writers.

<table>
<thead>
<tr>
<th>Format Type</th>
<th>Data Description</th>
<th>Reader</th>
<th>Writer</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>CSV</td>
<td>read_csv</td>
<td>to_csv</td>
</tr>
<tr>
<td>text</td>
<td>Fixed-Width Text File</td>
<td>read_fwf</td>
<td></td>
</tr>
<tr>
<td>text</td>
<td>JSON</td>
<td>read_json</td>
<td>to_json</td>
</tr>
<tr>
<td>text</td>
<td>HTML</td>
<td>read_html</td>
<td>to_html</td>
</tr>
<tr>

<td>Python Pickle Format</td>
<td>read_pickle</td>
<td>to_pickle</td>
</tr>
<tr>
<td>SQL</td>
<td>SQL</td>
<td>read_sql</td>
<td>to_sql</td>
</tr>
<tr>
<td>SQL</td>
<td>Google BigQuery</td>
<td>read_gbq</td>
<td>to_gbq</td>
</tr>
</tbody>
</table>

Here is an informal performance comparison for some of these IO methods.

Note: For examples that use the StringIO class, make sure you import it with from io import StringIO for Python 3.
2.4.1 CSV & text files

The workhorse function for reading text files (a.k.a. flat files) is `read_csv()`. See the cookbook for some advanced strategies.

Parsing options

`read_csv()` accepts the following common arguments:

**Basic**

- `filepath_or_buffer` [various] Either a path to a file (a `str`, `pathlib.Path`, or `py._path.local.LocalPath`), URL (including http, ftp, and S3 locations), or any object with a `read()` method (such as an open file or `StringIO`).

- `sep` [str, defaults to `,` for `read_csv()`, `\t` for `read_table()`] Delimiter to use. If `sep` is `None`, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python’s builtin sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from `\s+` will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: `'\\r\\t'`.

- `delimiter` [str, default `None`] Alternative argument name for `sep`.

- `delim_whitespace` [boolean, default `False`] Specifies whether or not whitespace (e.g. `' '` or `'\t'`) will be used as the delimiter. Equivalent to setting `sep='\s+'`. If this option is set to `True`, nothing should be passed in for the `delimiter` parameter.

**Column and index locations and names**

- `header` [int or list of ints, default `'infer'`] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to `header=None`. Explicitly pass `header=0` to be able to replace existing names.

  The header can be a list of ints that specify row locations for a MultiIndex on the columns e.g. `[0, 1, 3]`. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if `skip_blank_lines=True`, so `header=0` denotes the first line of data rather than the first line of the file.

- `names` [array-like, default `None`] List of column names to use. If file contains no header row, then you should explicitly pass `header=None`. Duplicates in this list are not allowed.

- `index_col` [int, str, sequence of int / str, or False, default `None`] Column(s) to use as the row labels of the `DataFrame`, either given as string name or column index. If a sequence of int / str is given, a MultiIndex is used.

  Note: `index_col=False` can be used to force pandas to not use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

  The default value of `None` instructs pandas to guess. If the number of fields in the column header row is equal to the number of fields in the body of the data file, then a default index is used. If it is larger, then the first columns are used as index so that the remaining number of fields in the body are equal to the number of fields in the header.

---

2.4. IO tools (text, CSV, HDF5, ...)
**usecols** [list-like or callable, default None] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in names or inferred from the document header row(s). For example, a valid list-like usecols parameter would be [0, 1, 2] or ['foo', 'bar', 'baz'].

Element order is ignored, so usecols=[0, 1] is the same as [1, 0]. To instantiate a DataFrame from data with element order preserved use `pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']]` for columns in ['foo', 'bar'] order or `pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']]` for ['bar', 'foo'] order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True:

```
In [1]: import pandas as pd
In [2]: from io import StringIO
In [3]: data = "col1,col2,col3\na,b,1\na,b,2\nc,d,3"
In [4]: pd.read_csv(StringIO(data))
Out[4]:
     col1  col2  col3
0    a    b    1
1    a    b    2
2    c    d    3
In [5]: pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ['COL1', 'COL3'])
Out[5]:
     col1  col3
0    a    1
1    a    2
2    c    3
```

Using this parameter results in much faster parsing time and lower memory usage.

**squeeze** [boolean, default False] If the parsed data only contains one column then return a Series.

**prefix** [str, default None] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1,…

**mangle_dupe_cols** [boolean, default True] Duplicate columns will be specified as ‘X’, ‘X.1’…’X.N’, rather than ‘X’…’X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

**General parsing configuration**

**dtype** [Type name or dict of column -> type, default None] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32} (unsupported with engine='python'). Use str or object together with suitable na_values settings to preserve and not interpret dtype.

**engine** [{'c', 'python'}] Parser engine to use. The C engine is faster while the Python engine is currently more feature-complete.

**converters** [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

**true_values** [list, default None] Values to consider as True.

**false_values** [list, default None] Values to consider as False.

**skipinitialspace** [boolean, default False] Skip spaces after delimiter.
skiprows [list-like or integer, default None] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise:

```
In [6]: data = "col1,col2,col3\na,b,1\na,b,2\nc,d,3"
In [7]: pd.read_csv(StringIO(data))
Out[7]:
   col1  col2  col3
0    a     b     1
1    a     b     2
2    c     d     3
```

```
In [8]: pd.read_csv(StringIO(data), skiprows=lambda x: x % 2 != 0)
Out[8]:
   col1  col2  col3
0    a     b     2
```

skipfooter [int, default 0] Number of lines at bottom of file to skip (unsupported with engine='c').
nrows [int, default None] Number of rows of file to read. Useful for reading pieces of large files.

low_memory [boolean, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the dtype parameter. Note that the entire file is read into a single DataFrame regardless, use the chunksize or iterator parameter to return the data in chunks. (Only valid with C parser)

memory_map [boolean, default False] If a filepath is provided for filepath_or_buffer, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

**NA and missing data handling**

na_values [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. See na values const below for a list of the values interpreted as NaN by default.

keep_default_na [boolean, default True] Whether or not to include the default NaN values when parsing the data.

Depending on whether na_values is passed in, the behavior is as follows:

- If keep_default_na is True, and na_values are specified, na_values is appended to the default NaN values used for parsing.
- If keep_default_na is True, and na_values are not specified, only the default NaN values are used for parsing.
- If keep_default_na is False, and na_values are specified, only the NaN values specified na_values are used for parsing.
- If keep_default_na is False, and na_values are not specified, no strings will be parsed as NaN.

Note that if na_filter is passed in as False, the keep_default_na and na_values parameters will be ignored.

na_filter [boolean, default True] Detect missing value markers (empty strings and the value of na_values). In data without any NAs, passing na_filter=False can improve the performance of reading a large file.

verbose [boolean, default False] Indicate number of NA values placed in non-numeric columns.

skip_blank_lines [boolean, default True] If True, skip over blank lines rather than interpreting as NaN values.
Datetime handling

**parse_dates** [boolean or list of ints or names or list of lists or dict, default **False**.]

- If **True** -> try parsing the index.
- If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- If {'foo': [1, 3]} -> parse columns 1, 3 as date and call result ‘foo’. A fast-path exists for iso8601-formatted dates.

**infer_datetime_format** [boolean, default **False**] If **True** and parse_dates is enabled for a column, attempt to infer the datetime format to speed up the processing.

**keep_date_col** [boolean, default **False**] If **True** and parse_dates specifies combining multiple columns then keep the original columns.

**date_parser** [function, default **None**] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses :mod:`dateutil.parser.parser` to do the conversion. pandas will try to call date_parser in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by parse_dates) as arguments; 2) concatenate (row-wise) the string values from the columns defined by parse_dates into a single array and pass that; and 3) call date_parser once for each row using one or more strings (corresponding to the columns defined by parse_dates) as arguments.

**dayfirst** [boolean, default **False**] DD/MM format dates, international and European format.

**cache_dates** [boolean, default **True**] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

Iteration

**iterator** [boolean, default **False**] Return :obj:`TextFileReader` object for iteration or getting chunks with :meth:`get_chunk`.

**chunksize** [int, default **None**] Return :obj:`TextFileReader` object for iteration. See iterating and chunking below.

Quoting, compression, and file format

**compression** [:obj:`{infer, gzip, bz2, zip, xz, None, dict}`, default 'infer'] For on-the-fly decompression of on-disk data. If ‘infer’, then use gzip, bz2, zip, or xz if filepath_or_buffer is path-like ending in ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’, respectively, and no decompression otherwise. If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression. Can also be a dict with key ‘method’ set to one of ‘zip’, ‘gzip’, ‘bz2’ and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile, or bz2.BZ2File. As an example, the following could be passed for faster compression and to create a reproducible gzip archive: compression={'method': 'gzip', 'compresslevel': 1, 'mtime': 1}.

Changed in version 1.1.0: dict option extended to support gzip and bz2.

Changed in version 1.2.0: Previous versions forwarded dict entries for ‘gzip’ to gzip.open.

**thousands** [str, default **None**] Thousands separator.

**decimal** [str, default ‘.’] Character to recognize as decimal point. E.g. use ‘,’ ‘,’ for European data.
**float_precision** [string, default None] Specifies which converter the C engine should use for floating-point values. The options are None for the ordinary converter, high for the high-precision converter, and round_trip for the round-trip converter.

**lineterminator** [str (length 1), default None] Character to break file into lines. Only valid with C parser.

**quotechar** [str (length 1)] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

**quoting** [int or csv.QUOTE_* instance, default 0] Control field quoting behavior per csv.QUOTE_* constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

**doublequote** [boolean, default True] When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements inside a field as a single quotechar element.

**escapechar** [str (length 1), default None] One-character string used to escape delimiter when quoting is QUOTE_NONE.

**comment** [str, default None] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as skip_blank_lines=True), fully commented lines are ignored by the parameter header but not by skiprows. For example, if comment='#', parsing '#empty
a,b,c
1,2,3' with header=0 will result in 'a,b,c' being treated as the header.

**encoding** [str, default None] Encoding to use for UTF when reading/writing (e.g. 'utf-8'). List of Python standard encodings.

**dialect** [str or csv.Dialect instance, default None] If provided, this parameter will override values (default or not) for the following parameters: delimiter, doublequote, escapechar, skipinitialspace, quotechar, and quoting. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

### Error handling

**error_bad_lines** [boolean, default None] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will dropped from the DataFrame that is returned. See bad lines below.

Deprecated since version 1.3.0: The on_bad_lines parameter should be used instead to specify behavior upon encountering a bad line instead.

**warn_bad_lines** [boolean, default None] If error_bad_lines is False, and warn_bad_lines is True, a warning for each “bad line” will be output.

Deprecated since version 1.3.0: The on_bad_lines parameter should be used instead to specify behavior upon encountering a bad line instead.

**on_bad_lines** [‘error’, ‘warn’, ‘skip’], default ‘error’) Specifies what to do upon encountering a bad line (a line with too many fields). Allowed values are:

- ‘error’, raise an ParserError when a bad line is encountered.
- ‘warn’, print a warning when a bad line is encountered and skip that line.
- ‘skip’, skip bad lines without raising or warning when they are encountered.

New in version 1.3.0.
Specifying column data types

You can indicate the data type for the whole DataFrame or individual columns:

```python
In [9]: import numpy as np

In [10]: data = "a,b,c,d\n1,2,3,4\n5,6,7,8\n9,10,11"

In [11]: print(data)
a,b,c,d
1,2,3,4
5,6,7,8
9,10,11

In [12]: df = pd.read_csv(StringIO(data), dtype=object)

In [13]: df
Out[13]:
a   b   c   d
0  1   2   3   4
1  5   6   7   8
2  9  10  11  NaN

In [14]: df["a"][0]
Out[14]: '1'

In [15]: df = pd.read_csv(StringIO(data), dtype={"b": object, "c": np.float64, "d": "Int64"})

In [16]: df.dtypes
Out[16]:
a    int64
b    object
c   float64
d    Int64
dtype: object
```

Fortunately, pandas offers more than one way to ensure that your column(s) contain only one dtype. If you’re unfamiliar with these concepts, you can see here to learn more about dtypes, and here to learn more about object conversion in pandas.

For instance, you can use the converters argument of `read_csv()`:

```python
In [17]: data = "col_1\n1\n2\n'A'\n4.22"

In [18]: df = pd.read_csv(StringIO(data), converters={"col_1": str})

In [19]: df
Out[19]:
<table>
<thead>
<tr>
<th></th>
<th>col_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>'A'</td>
</tr>
<tr>
<td>3</td>
<td>4.22</td>
</tr>
</tbody>
</table>

In [20]: df["col_1"].apply(type).value_counts()
Out[20]:
<class 'str'>    4
```

(continues on next page)
Or you can use the `to_numeric()` function to coerce the dtypes after reading in the data,

```python
In [21]: df2 = pd.read_csv(StringIO(data))
In [22]: df2["col_1"] = pd.to_numeric(df2["col_1"], errors="coerce")
In [23]: df2
Out[23]:
   col_1
0   1.00
1   2.00
2    NaN
3   4.22

In [24]: df2["col_1"].apply(type).value_counts()
Out[24]:
<class 'float'>    4
Name: col_1, dtype: int64
```

which will convert all valid parsing to floats, leaving the invalid parsing as NaN.

Ultimately, how you deal with reading in columns containing mixed dtypes depends on your specific needs. In the case above, if you wanted to NaN out the data anomalies, then `to_numeric()` is probably your best option. However, if you wanted for all the data to be coerced, no matter the type, then using the `converters` argument of `read_csv()` would certainly be worth trying.

**Note:** In some cases, reading in abnormal data with columns containing mixed dtypes will result in an inconsistent dataset. If you rely on pandas to infer the dtypes of your columns, the parsing engine will go and infer the dtypes for different chunks of the data, rather than the whole dataset at once. Consequently, you can end up with column(s) with mixed dtypes. For example,

```python
In [25]: col_1 = list(range(500000)) + ["a", "b"] + list(range(500000))
In [26]: df = pd.DataFrame({"col_1": col_1})
In [27]: df.to_csv("foo.csv")
In [28]: mixed_df = pd.read_csv("foo.csv")
In [29]: mixed_df["col_1"].apply(type).value_counts()
Out[29]:
<class 'int'>  737858
<class 'str'>  262144
Name: col_1, dtype: int64

In [30]: mixed_df["col_1"].dtype
Out[30]: dtype('O')
```

will result with `mixed_df` containing an `int` dtype for certain chunks of the column, and `str` for others due to the mixed dtypes from the data that was read in. It is important to note that the overall column will be marked with a `dtype` of `object`, which is used for columns with mixed dtypes.
Specifying categorical dtype

Categorical columns can be parsed directly by specifying dtype='category' or dtype=CategoricalDtype(categories, ordered).

```python
In [31]: data = "col1,col2,col3\na,b,1\na,b,2\nc,d,3"

In [32]: pd.read_csv(StringIO(data))
Out[32]:
coll  col2  col3
0     a     b   1
1     a     b   2
2     c     d   3

In [33]: pd.read_csv(StringIO(data)).dtypes
Out[33]:
coll  object
col2  object
col3  int64
dtype: object

In [34]: pd.read_csv(StringIO(data), dtype="category").dtypes
Out[34]:
coll  category
col2  object
col3  int64
dtype: object
```

Individual columns can be parsed as a Categorical using a dict specification:

```python
In [35]: pd.read_csv(StringIO(data), dtype={"coll": "category"}).dtypes
Out[35]:
coll  category
col2  object
col3  int64
dtype: object
```

Specifying dtype='category' will result in an unordered Categorical whose categories are the unique values observed in the data. For more control on the categories and order, create a CategoricalDtype ahead of time, and pass that for that column’s dtype.

```python
In [36]: from pandas.api.types import CategoricalDtype

In [37]: dtype = CategoricalDtype(["d", "c", "b", "a"], ordered=True)

In [38]: pd.read_csv(StringIO(data), dtype={"coll": dtype}).dtypes
Out[38]:
coll  category
col2  object
col3  int64
dtype: object
```

When using dtype=CategoricalDtype, “unexpected” values outside of dtype.categories are treated as missing values.

```python
In [39]: dtype = CategoricalDtype(["a", "b", "d"])  # No 'c'
```

(continues on next page)
This matches the behavior of `Categorical.set_categories()`.

**Note:** With `dtype='category'`, the resulting categories will always be parsed as strings (object dtype). If the categories are numeric they can be converted using the `to_numeric()` function, or as appropriate, another converter such as `to_datetime()`.

When `dtype` is a `CategoricalDtype` with homogeneous categories (all numeric, all datetimes, etc.), the conversion is done automatically.
Naming and using columns

Handling column names

A file may or may not have a header row. pandas assumes the first row should be used as the column names:

```python
In [46]: data = "a,b,c
1,2,3
4,5,6
7,8,9"

In [47]: print(data)
a,b,c
1,2,3
4,5,6
7,8,9

In [48]: pd.read_csv(StringIO(data))
Out[48]:
    a  b  c
0  1  2  3
1  4  5  6
2  7  8  9
```

By specifying the `names` argument in conjunction with `header` you can indicate other names to use and whether or not to throw away the header row (if any):

```python
In [49]: print(data)
a,b,c
1,2,3
4,5,6
7,8,9

In [50]: pd.read_csv(StringIO(data), names=["foo", "bar", "baz"], header=0)
Out[50]:
   foo  bar  baz
0   a   b   c
1   1   2   3
2   4   5   6
3   7   8   9

In [51]: pd.read_csv(StringIO(data), names=["foo", "bar", "baz"], header=None)
Out[51]:
   foo  bar  baz
0   a   b   c
1   1   2   3
2   4   5   6
3   7   8   9
```

If the header is in a row other than the first, pass the row number to `header`. This will skip the preceding rows:

```python
In [52]: data = "skip this skip it
a,b,c
1,2,3
4,5,6
7,8,9"

In [53]: pd.read_csv(StringIO(data), header=1)
Out[53]:
    a  b  c
0  1  2  3
1  4  5  6
2  7  8  9
```

**Note:** Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0`
and column names are inferred from the first non-blank line of the file, if column names are passed explicitly then the behavior is identical to header=None.

## Duplicate names parsing

If the file or header contains duplicate names, pandas will by default distinguish between them so as to prevent overwriting data:

```python
In [54]: data = "a,b,a\n0,1,2\n3,4,5"
In [55]: pd.read_csv(StringIO(data))
Out[55]:
   a  b  a.1
0  0  1  2
1  3  4  5
```

There is no more duplicate data because `mangle_dupe_cols=True` by default, which modifies a series of duplicate columns ‘X’, ‘X.1’, ‘X.2’ to become ‘X’, ‘X.1’, ‘X.2’. If `mangle_dupe_cols=False`, duplicate data can arise:

```python
In [2]: data = 'a,b,a\n0,1,2\n3,4,5'
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
Out[3]:
   a  b  a
0  2  1  2
1  5  4  5
```

To prevent users from encountering this problem with duplicate data, a `ValueError` exception is raised if `mangle_dupe_cols != True`:

```python
In [2]: data = 'a,b,a\n0,1,2\n3,4,5'
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
... 
ValueError: Setting mangle_dupe_cols=False is not supported yet
```

## Filtering columns (usecols)

The `usecols` argument allows you to select any subset of the columns in a file, either using the column names, position numbers or a callable:

```python
In [56]: data = "a,b,c,d\n1,2,3,foo\n4,5,6,bar\n7,8,9,baz"
In [57]: pd.read_csv(StringIO(data))
Out[57]:
   a  b  c  d
0  1  2  3  foo
1  4  5  6  bar
2  7  8  9  baz
In [58]: pd.read_csv(StringIO(data), usecols=['b', 'd'])
Out[58]:
   b  d
0  2  foo
```

(continues on next page)
The `usecols` argument can also be used to specify which columns not to use in the final result:

```python
In [61]: pd.read_csv(StringIO(data), usecols=lambda x: x not in ['a', 'c'])
Out[61]:
   b   d
0  2  foo
1  5  bar
2  8  baz
```

In this case, the callable is specifying that we exclude the “a” and “c” columns from the output.

### Comments and empty lines

#### Ignoring line comments and empty lines

If the `comment` parameter is specified, then completely commented lines will be ignored. By default, completely blank lines will be ignored as well.

```python
In [62]: data = "\na,b,c\n# commented line\n1,2,3\n4,5,6"

In [63]: print(data)
a,b,c
# commented line
1,2,3
4,5,6

In [64]: pd.read_csv(StringIO(data), comment="#")
Out[64]:
   a   b   c
0  1  2  3
1  4  5  6
```

If `skip_blank_lines=False`, then `read_csv` will not ignore blank lines:
In [65]: data = "a,b,c
1,2,3
4,5,6"

In [66]: pd.read_csv(StringIO(data), skip_blank_lines=False)
Out[66]:
 a  b  c
0  NaN NaN NaN
1  1.0  2.0  3.0
3  NaN NaN NaN
4  4.0  5.0  6.0

Warning: The presence of ignored lines might create ambiguities involving line numbers: the parameter header
uses row numbers (ignoring commented/empty lines), while skiprows uses line numbers (including commented/empty lines):

In [67]: data = "#comment
a,b,c
A,B,C
1,2,3"

In [68]: pd.read_csv(StringIO(data), comment="#", header=1)
Out[68]:
 A  B  C
0  1  2  3

In [69]: data = "A,B,C
#comment
a,b,c
1,2,3"

In [70]: pd.read_csv(StringIO(data), comment="#", skiprows=2)
Out[70]:
 a  b  c
0  1  2  3

If both header and skiprows are specified, header will be relative to the end of skiprows. For example:

In [71]: data = (  
..:  "# empty
..:  "# second empty line
..:  "# third emptyline
..:  "X,Y,Z
..:  "1,2,3
..:  "A,B,C
..:  "1,2.,4.
..:  "5.,NaN,10.0"  
..:  )  
..:  )

In [72]: print(data)
# empty
# second empty line
# third emptyline
X,Y,Z
1,2,3
A,B,C
1,2.,4.
5.,NaN,10.0

In [73]: pd.read_csv(StringIO(data), comment="#", skiprows=4, header=1)
(continues on next page)
Comments

Sometimes comments or meta data may be included in a file:

```python
In [74]: print(open("tmp.csv").read())
ID,level,category
Patient1,123000,x # really unpleasant
Patient2,23000,y # wouldn't take his medicine
Patient3,1234018,z # awesome
```

By default, the parser includes the comments in the output:

```python
In [75]: df = pd.read_csv("tmp.csv")
In [76]: df
Out[76]:
   ID     level category
0  Patient1  123000      x # really unpleasant
1  Patient2   23000      y # wouldn't take his medicine
2  Patient3 1234018      z # awesome
```

We can suppress the comments using the `comment` keyword:

```python
In [77]: df = pd.read_csv("tmp.csv", comment="#")
In [78]: df
Out[78]:
   ID     level category
0  Patient1   123000      x
1  Patient2   23000      y
2  Patient3 1234018      z
```

Dealing with Unicode data

The `encoding` argument should be used for encoded unicode data, which will result in byte strings being decoded to unicode in the result:

```python
In [79]: from io import BytesIO
In [80]: data = b"word,length\n\nTräumen,7\nGrüße,5"
In [81]: data = data.decode("utf8").encode("latin-1")
In [82]: df = pd.read_csv(BytesIO(data), encoding="latin-1")
In [83]: df
Out[83]:
   word  length
0    word    length
1    Träumen    7
2     Grüße    5
```

(continues on next page)
0  Träumen  7
1  Grüße     5

In [84]: df["word"][1]
Out[84]: 'Grüße'

Some formats which encode all characters as multiple bytes, like UTF-16, won’t parse correctly at all without specifying the encoding. Full list of Python standard encodings.

**Index columns and trailing delimiters**

If a file has one more column of data than the number of column names, the first column will be used as the DataFrame’s row names:

```python
In [85]: data = "a,b,c
4,apple,bat,5.7
8,orange,cow,10"

In [86]: pd.read_csv(StringIO(data))
Out[86]:
   a   b   c
0  4 apple bat 5.7
1  8 orange cow 10.0
```

```python
In [87]: data = "index,a,b,c
4,apple,bat,5.7
8,orange,cow,10"

In [88]: pd.read_csv(StringIO(data), index_col=0)
Out[88]:
   a   b   c
index
  4 apple bat  5.7
  8 orange cow  10.0
```

Ordinarily, you can achieve this behavior using the `index_col` option.

There are some exception cases when a file has been prepared with delimiters at the end of each data line, confusing the parser. To explicitly disable the index column inference and discard the last column, pass `index_col=False`:

```python
In [89]: data = "a,b,c
4,apple,bat,
8,orange,cow,"

In [90]: print(data)
a,b,c
4,apple,bat,
8,orange,cow,

In [91]: pd.read_csv(StringIO(data))
Out[91]:
   a   b   c
0  4 apple bat NaN
1  8 orange cow NaN

In [92]: pd.read_csv(StringIO(data), index_col=False)
Out[92]:
   a   b   c
0  4 apple bat
1  8 orange cow
```
If a subset of data is being parsed using the `usecols` option, the `index_col` specification is based on that subset, not the original data.

```
In [93]: data = "a,b,c\n4,apple,bat,\n8,orange,cow,"

In [94]: print(data)
a,b,c
4,apple,bat,
8,orange,cow,

In [95]: pd.read_csv(StringIO(data), usecols=['b', 'c'])
Out[95]:
b c
4 bat NaN
8 cow NaN

In [96]: pd.read_csv(StringIO(data), usecols=['b', 'c'], index_col=0)
Out[96]:
b c
4 bat NaN
8 cow NaN
```

**Date Handling**

**Specifying date columns**

To better facilitate working with datetime data, `read_csv()` uses the keyword arguments `parse_dates` and `date_parser` to allow users to specify a variety of columns and date/time formats to turn the input text data into `datetime` objects.

The simplest case is to just pass `parse_dates=True`:

```
# Use a column as an index, and parse it as dates.
In [97]: df = pd.read_csv("foo.csv", index_col=0, parse_dates=True)

In [98]: df
Out[98]:
          A  B  C
date
2009-01-01 a 1  2
2009-01-02 b 3  4
2009-01-03 c 4  5

# These are Python datetime objects
In [99]: df.index
Out[99]: DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype='datetime64[ns]', name='date', freq=None)
```

It is often the case that we may want to store date and time data separately, or store various date fields separately. the `parse_dates` keyword can be used to specify a combination of columns to parse the dates and/or times from.

You can specify a list of column lists to `parse_dates`, the resulting date columns will be prepended to the output (so as to not affect the existing column order) and the new column names will be the concatenation of the component column names:
In [100]: print(open("tmp.csv").read())
KORD, 19990127, 19:00:00, 18:56:00, 0.8100
KORD, 19990127, 20:00:00, 19:56:00, 0.0100
KORD, 19990127, 21:00:00, 20:56:00, -0.5900
KORD, 19990127, 21:00:00, 21:18:00, -0.9900
KORD, 19990127, 22:00:00, 21:56:00, -0.5900
KORD, 19990127, 23:00:00, 22:56:00, -0.5900

In [101]: df = pd.read_csv("tmp.csv", header=None, parse_dates=[[1, 2], [1, 3]])

In [102]: df
Out[102]:
   1_2      1_3     0    4
0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD 0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59

By default the parser removes the component date columns, but you can choose to retain them via the `keep_date_col` keyword:

In [103]: df = pd.read_csv("tmp.csv", header=None, parse_dates=[[1, 2], [1, 3]], keep_date_col=True)

In [104]: df
Out[104]:
   1_2      1_3     0    1    2    3    4
0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD 19990127 19:00:00 18:56:00 0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 19990127 20:00:00 19:56:00 0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD 19990127 21:00:00 20:56:00 -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD 19990127 21:00:00 21:18:00 -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD 19990127 22:00:00 21:56:00 -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD 19990127 23:00:00 22:56:00 -0.59

Note that if you wish to combine multiple columns into a single date column, a nested list must be used. In other words, `parse_dates=[1, 2]` indicates that the second and third columns should each be parsed as separate date columns while `parse_dates=[[1, 2]]` means the two columns should be parsed into a single column.

You can also use a dict to specify custom name columns:

In [105]: date_spec = {"nominal": [1, 2], "actual": [1, 3]}

In [106]: df = pd.read_csv("tmp.csv", header=None, parse_dates=date_spec)

In [107]: df
Out[107]:
   nominal      actual     0    4
0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD 0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59
It is important to remember that if multiple text columns are to be parsed into a single date column, then a new column is prepended to the data. The index_col specification is based off of this new set of columns rather than the original data columns:

```python
In [108]: date_spec = {"nominal": [1, 2], "actual": [1, 3]}

In [109]: df = pd.read_csv(
       ....:     "tmp.csv", header=None, parse_dates=date_spec, index_col=0
       ....: )  # index is the nominal column

In [110]: df
Out[110]:
          actual  
nominal  
1999-01-27 19:00:00 1999-01-27 18:56:00 KORD 0.81
1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 0.01
1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59
```

**Note:** If a column or index contains an unparsable date, the entire column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `to_datetime()` after `pd.read_csv`.

**Note:** `read_csv` has a fast_path for parsing datetime strings in iso8601 format, e.g. “2000-01-01T00:01:02+00:00” and similar variations. If you can arrange for your data to store datetimes in this format, load times will be significantly faster, ~20x has been observed.

### Date parsing functions

Finally, the parser allows you to specify a custom `date_parser` function to take full advantage of the flexibility of the date parsing API:

```python
In [111]: df = pd.read_csv(
       ....:     "tmp.csv", header=None, parse_dates=date_spec, date_parser=pd.to_
       "datetime"
       ....: )

In [112]: df
Out[112]:
          nominal     actual  
 0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD 0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59
```

pandas will try to call the `date_parser` function in three different ways. If an exception is raised, the next one is tried:
1. `date_parser` is first called with one or more arrays as arguments, as defined using `parse_dates` (e.g., `date_parser(["2013", '2013'], ['1', '2'])).

2. If #1 fails, `date_parser` is called with all the columns concatenated row-wise into a single array (e.g., `date_parser(['2013 1', '2013 2'])).

Note that performance-wise, you should try these methods of parsing dates in order:

1. Try to infer the format using `infer_datetime_format=True` (see section below).
2. If you know the format, use `pd.to_datetime()`: `date_parser=lambda x: pd.to_datetime(x, format=...)`.
3. If you have a really non-standard format, use a custom `date_parser` function. For optimal performance, this should be vectorized, i.e., it should accept arrays as arguments.

**Parsing a CSV with mixed timezones**

Pandas cannot natively represent a column or index with mixed timezones. If your CSV file contains columns with a mixture of timezones, the default result will be an object-dtype column with strings, even with `parse_dates`.

```python
In [113]: content = ""
......: a
......: 2000-01-01T00:00:00+05:00
......: 2000-01-01T00:00:00+06:00"
......:

In [114]: df = pd.read_csv(StringIO(content), parse_dates=['a'])

In [115]: df["a"]
Out[115]:
0 2000-01-01 00:00:00+05:00
1 2000-01-01 00:00:00+06:00
Name: a, dtype: object
```

To parse the mixed-timezone values as a datetime column, pass a partially-applied `to_datetime()` with `utc=True` as the `date_parser`.

```python
In [116]: df = pd.read_csv(
......:     StringIO(content),
......:     parse_dates=['a'],
......:     date_parser=lambda col: pd.to_datetime(col, utc=True),
......: )

In [117]: df["a"]
Out[117]:
0 1999-12-31 19:00:00+00:00
1 1999-12-31 18:00:00+00:00
Name: a, dtype: datetime64[ns, UTC]
```
Inferring datetime format

If you have `parse_dates` enabled for some or all of your columns, and your datetime strings are all formatted the same way, you may get a large speed up by setting `infer_datetime_format=True`. If set, pandas will attempt to guess the format of your datetime strings, and then use a faster means of parsing the strings. 5-10x parsing speeds have been observed. pandas will fallback to the usual parsing if either the format cannot be guessed or the format that was guessed cannot properly parse the entire column of strings. So in general, `infer_datetime_format` should not have any negative consequences if enabled.

Here are some examples of datetime strings that can be guessed (All representing December 30th, 2011 at 00:00:00):

- “20111230”
- “2011/12/30”
- “20111230 00:00:00”
- “12/30/2011 00:00:00”
- “30/Dec/2011 00:00:00”
- “30/December/2011 00:00:00”

Note that `infer_datetime_format` is sensitive to `dayfirst`. With `dayfirst=True`, it will guess “01/12/2011” to be December 1st. With `dayfirst=False` (default) it will guess “01/12/2011” to be January 12th.

```python
# Try to infer the format for the index column
In [118]: df = pd.read_csv(
    ....:     "foo.csv",
    ....:     index_col=0,
    ....:     parse_dates=True,
    ....:     infer_datetime_format=True,
    ....: )

In [119]: df
Out[119]:
          A   B  C
date
2009-01-01  a  1  2
2009-01-02  b  3  4
2009-01-03  c  4  5
```

International date formats

While US date formats tend to be MM/DD/YYYY, many international formats use DD/MM/YYYY instead. For convenience, a `dayfirst` keyword is provided:

```python
In [120]: print(open("tmp.csv").read())
date,value,cat
1/6/2000,5,a
2/6/2000,10,b
3/6/2000,15,c

In [121]: pd.read_csv("tmp.csv", parse_dates=[0])
Out[121]:
          date   value  cat
2000-06-01  5    a
2000-06-02  10   b
2000-06-03  15   c
```

(continues on next page)
Writing CSVs to binary file objects

New in version 1.2.0.

df.to_csv(..., mode="wb") allows writing a CSV to a file object opened binary mode. In most cases, it is not necessary to specify mode as Pandas will auto-detect whether the file object is opened in text or binary mode.

Specifying method for floating-point conversion

The parameter float_precision can be specified in order to use a specific floating-point converter during parsing with the C engine. The options are the ordinary converter, the high-precision converter, and the round-trip converter (which is guaranteed to round-trip values after writing to a file). For example:

```
In [127]: val = "0.3066101993807095471566981359501369297504425048828125"

In [128]: data = "a,b,c\n1,2,\n{0}".format(val)

In [129]: abs(pd.read_csv(StringIO(data), engine="c", float_precision=\nNone, \n)["c"][0] - float(val))

Out[129]: 5.551115123125783e-17

In [130]: abs(pd.read_csv(StringIO(data), engine="c", \nfloat_precision="high", \n)["c"][0] - float(val))

(continues on next page)
Out[130]: 5.551115123125783e-17

In [131]: abs(
   ...
   pd.read_csv(StringIO(data), engine="c", float_precision="round_trip")["c 
   ...
   - float(val)
   ...
   )
   ...
Out[131]: 0.0

**Thousand separators**

For large numbers that have been written with a thousands separator, you can set the thousands keyword to a string of length 1 so that integers will be parsed correctly:

By default, numbers with a thousands separator will be parsed as strings:

In [132]: print(open("tmp.csv").read())
ID|level|category
Patient1|123,000|x
Patient2|23,000|y
Patient3|1,234,018|z

In [133]: df = pd.read_csv("tmp.csv", sep="|")

In [134]: df
Out[134]:
   ID   level category
0 Patient1 123,000 x
1 Patient2 23,000 y
2 Patient3 1,234,018 z

In [135]: df.level.dtype
Out[135]: dtype('O')

The thousands keyword allows integers to be parsed correctly:

In [136]: print(open("tmp.csv").read())
ID|level|category
Patient1|123,000|x
Patient2|23,000|y
Patient3|1,234,018|z

In [137]: df = pd.read_csv("tmp.csv", sep="|", thousands=",",)

In [138]: df
Out[138]:
   ID   level category
0 Patient1 123000 x
1 Patient2 23000 y
2 Patient3 1234018 z

In [139]: df.level.dtype
Out[139]: dtype('int64')
NA values

To control which values are parsed as missing values (which are signified by NaN), specify a string in `na_values`. If you specify a list of strings, then all values in it are considered to be missing values. If you specify a number (a float, like 5.0 or an integer like 5), the corresponding equivalent values will also imply a missing value (in this case effectively [5.0, 5] are recognized as NaN).

To completely override the default values that are recognized as missing, specify `keep_default_na=False`.

The default NaN recognized values are `['-1.#IND', '1.#QNAN', '1.#IND', '-1.#QNAN', '#N/A', 'N/A', 'n/a', 'NA', '<NA>', '#NA', 'NULL', 'null', 'NaN', '-NaN', 'nan', '-nan', '']`.

Let us consider some examples:

```python
pd.read_csv("path_to_file.csv", na_values=[5])
```

In the example above 5 and 5.0 will be recognized as NaN, in addition to the defaults. A string will first be interpreted as a numerical 5, then as a NaN.

```python
pd.read_csv("path_to_file.csv", keep_default_na=False, na_values=[''])
```

Above, only an empty field will be recognized as NaN.

```python
pd.read_csv("path_to_file.csv", keep_default_na=False, na_values=['NA', '0'])
```

Above, both NA and 0 as strings are NaN.

```python
pd.read_csv("path_to_file.csv", na_values=['Nope'])
```

The default values, in addition to the string "Nope" are recognized as NaN.

Infinity

Inf like values will be parsed as `np.inf` (positive infinity), and `-inf` as `np.inf` (negative infinity). These will ignore the case of the value, meaning Inf will also be parsed as np.inf.

Returning Series

Using the `squeeze` keyword, the parser will return output with a single column as a Series:

```python
In [140]: print(open("tmp.csv").read())
level
Patient1,123000
Patient2,23000
Patient3,1234018
```

```python
In [141]: output = pd.read_csv("tmp.csv", squeeze=True)
```

```python
In [142]: output
Out[142]:
Patient1  123000
Patient2   23000
Patient3  1234018
Name: level, dtype: int64
```

(continues on next page)
In [143]: type(output)
Out[143]: pandas.core.series.Series

Boolean values

The common values `True`, `False`, `TRUE`, and `FALSE` are all recognized as boolean. Occasionally you might want to recognize other values as being boolean. To do this, use the `true_values` and `false_values` options as follows:

In [144]: data = "a,b,c\n1,Yes,2\n3,No,4"
In [145]: print(data)
a,b,c
1,Yes,2
3,No,4
In [146]: pd.read_csv(StringIO(data))
Out[146]:
   a  b  c
0  1  Yes  2
1  3  No  4
In [147]: pd.read_csv(StringIO(data), true_values=\"Yes\", false_values=\"No\")
Out[147]:
   a  b  c
0  1  True  2
1  3  False  4

Handling “bad” lines

Some files may have malformed lines with too few fields or too many. Lines with too few fields will have NA values filled in the trailing fields. Lines with too many fields will raise an error by default:

In [148]: data = "a,b,c\n1,2,3\n4,5,6,7\n8,9,10"
In [149]: pd.read_csv(StringIO(data))
---------------------------------------------------------------------------

      306     # Only do checks if the reader is not a fast (i.e., speedoptimized)
      305     if not fast_reader:
          ^
          File "...
You can elect to skip bad lines:

```python
In [29]: pd.read_csv(StringIO(data), on_bad_lines="warn")
Skipping line 3: expected 3 fields, saw 4
```
```
Out[29]:
a  b  c
0 1 2 3
1 8 9 10
```

You can also use the `usecols` parameter to eliminate extraneous column data that appear in some lines but not others:

```python
In [30]: pd.read_csv(StringIO(data), usecols=[0, 1, 2])
```
```
Out[30]:
a  b  c
0 1 2 3
1 4 5 6
2 8 9 10
```

2.4. IO tools (text, CSV, HDF5, …) 287
Dialect

The `dialect` keyword gives greater flexibility in specifying the file format. By default it uses the Excel dialect but you can specify either the dialect name or a `csv.Dialect` instance.

Suppose you had data with unenclosed quotes:

```
In [150]: print(data)
label1,label2,label3
index1,”a,c,e
index2,b,d,f
```

By default, `read_csv` uses the Excel dialect and treats the double quote as the quote character, which causes it to fail when it finds a newline before it finds the closing double quote.

We can get around this using `dialect`:

```
In [151]: import csv
In [152]: dia = csv.excel()
In [153]: dia.quoting = csv.QUOTE_NONE
In [154]: pd.read_csv(StringIO(data), dialect=dia)
Out[154]:
   label1  label2  label3
index1    "a  c  e
index2    b  d  f
```

All of the dialect options can be specified separately by keyword arguments:

```
In [155]: data = "a,b,c~1,2,3~4,5,6"
In [156]: pd.read_csv(StringIO(data), lineterminator="~")
Out[156]:
a  b  c
0  1  2  3
1  4  5  6
```

Another common dialect option is `skipinitialspace`, to skip any whitespace after a delimiter:

```
in [157]: data = "a, b, c\n1, 2, 3\n4, 5, 6"
In [158]: print(data)
a, b, c
1, 2, 3
4, 5, 6
In [159]: pd.read_csv(StringIO(data), skipinitialspace=True)
Out[159]:
a  b  c
0  1  2  3
1  4  5  6
```

The parsers make every attempt to “do the right thing” and not be fragile. Type inference is a pretty big deal. If a column can be coerced to integer dtype without altering the contents, the parser will do so. Any non-numeric columns will come through as object dtype as with the rest of pandas objects.
Quoting and Escape Characters

Quotes (and other escape characters) in embedded fields can be handled in any number of ways. One way is to use backslashes; to properly parse this data, you should pass the `escapechar` option:

```
In [160]: data = 'a,b

   "hello, \"Bob\", nice to see you\",5'

In [161]: print(data)
   a,b
   "hello, "Bob\", nice to see you\",5

In [162]: pd.read_csv(StringIO(data), escapechar="\\")
Out[162]:
   a  b
  0 hello, "Bob", nice to see you 5
```

Files with fixed width columns

While `read_csv()` reads delimited data, the `read_fwf()` function works with data files that have known and fixed column widths. The function parameters to `read_fwf` are largely the same as `read_csv` with two extra parameters, and a different usage of the `delimiter` parameter:

- `colspecs`: A list of pairs (tuples) giving the extents of the fixed-width fields of each line as half-open intervals (i.e., `[from, to[`). String value ‘infer’ can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data. Default behavior, if not specified, is to infer.

- `widths`: A list of field widths which can be used instead of `colspecs` if the intervals are contiguous.

- `delimiter`: Characters to consider as filler characters in the fixed-width file. Can be used to specify the filler character of the fields if it is not spaces (e.g., ‘~’).

Consider a typical fixed-width data file:

```
In [163]: print(open("bar.csv").read())
   id8141 360.242940 149.910199 11950.7
   id1594 444.953632 166.985655 11788.4
   id1849 364.136849 183.628767 11806.2
   id1230 413.836124 184.375703 11916.8
   id1948 502.953953 173.237159 12468.3
```

In order to parse this file into a DataFrame, we simply need to supply the column specifications to the `read_fwf` function along with the file name:

```
# Column specifications are a list of half-intervals
In [164]: colspecs = [(0, 6), (8, 20), (21, 33), (34, 43)]

In [165]: df = pd.read_fwf("bar.csv", colspecs=colspecs, header=None, index_col=0)

In [166]: df
Out[166]:
   1    2    3
  0 id8141 360.242940 149.910199 11950.7
   id1594 444.953632 166.985655 11788.4
   id1849 364.136849 183.628767 11806.2
   id1230 413.836124 184.375703 11916.8
   id1948 502.953953 173.237159 12468.3
```
Note how the parser automatically picks column names \texttt{X.<column number>} when \texttt{header=\text{None}} argument is specified. Alternatively, you can supply just the column widths for contiguous columns:

\begin{verbatim}
# Widths are a list of integers
In [167]: widths = [6, 14, 13, 10]

In [168]: df = pd.read_fwf("bar.csv", widths=widths, header=None)

In [169]: df
Out[169]:
   0  1  2  3
0  id8141 360.242940 149.910199 11950.7
1  id1594 444.953632 166.985655 11788.4
2  id1849 364.136849 183.628767 11806.2
3  id1230 413.836124 184.375703 11916.8
4  id1948 502.953953 173.237159 12468.3
\end{verbatim}

The parser will take care of extra white spaces around the columns so it’s ok to have extra separation between the columns in the file.

By default, \texttt{read_fwf} will try to infer the file’s \texttt{colspecs} by using the first 100 rows of the file. It can do it only in cases when the columns are aligned and correctly separated by the provided \texttt{delimiter} (default delimiter is whitespace).

\begin{verbatim}
In [170]: df = pd.read_fwf("bar.csv", header=None, index_col=0)

In [171]: df
Out[171]:
   1  2  3
  0 id8141 360.242940 149.910199 11950.7
  id1594 444.953632 166.985655 11788.4
  id1849 364.136849 183.628767 11806.2
  id1230 413.836124 184.375703 11916.8
  id1948 502.953953 173.237159 12468.3
\end{verbatim}

\texttt{read_fwf} supports the \texttt{dtype} parameter for specifying the types of parsed columns to be different from the inferred type.

\begin{verbatim}
In [172]: pd.read_fwf("bar.csv", header=None, index_col=0).dtypes
Out[172]:
0  object
1  float64
2  float64
3  float64
dtype: object

In [173]: pd.read_fwf("bar.csv", header=None, dtype={2: "object"}).dtypes
Out[173]:
0  object
1  float64
2  object
3  float64
dtype: object
\end{verbatim}
Indexes

Files with an “implicit” index column

Consider a file with one less entry in the header than the number of data column:

```python
In [174]: print(open("foo.csv").read())
A,B,C
20090101,a,1,2
20090102,b,3,4
20090103,c,4,5
```

In this special case, `read_csv` assumes that the first column is to be used as the index of the DataFrame:

```python
In [175]: pd.read_csv("foo.csv")
Out[175]:
   A  B  C
0 20090101  a  1  2
1 20090102  b  3  4
2 20090103  c  4  5
```

Note that the dates weren’t automatically parsed. In that case you would need to do as before:

```python
In [176]: df = pd.read_csv("foo.csv", parse_dates=True)
In [177]: df.index
Out[177]: DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype='datetime64[ns]', freq=None)
```

Reading an index with a MultiIndex

Suppose you have data indexed by two columns:

```python
In [178]: print(open("data/mindex_ex.csv").read())
year,indiv,zit,xit
1977,"A",1.2,.6
1977,"B",1.5,.5
1977,"C",1.7,.8
1978,"A",.2,.06
1978,"B",.7,.2
1978,"C",.8,.3
1978,"D",.9,.5
1978,"E",1.4,.9
1979,"C",.2,.15
1979,"D",.14,.05
1979,"E",.5,.15
1979,"F",1.2,.5
1979,"G",3.4,1.9
1979,"H",5.4,2.7
1979,"I",6.4,1.2
```

The `index_col` argument to `read_csv` can take a list of column numbers to turn multiple columns into a MultiIndex for the index of the returned object:
In [179]: df = pd.read_csv("data/mindex_ex.csv", index_col=[0, 1])

In [180]: df
Out[180]:
    zit  xit
year indiv
1977 A  1.20  0.60
    B  1.50  0.50
    C  1.70  0.80
1978 A  0.20  0.06
    B  0.70  0.20
    C  0.80  0.30
    D  0.90  0.50
    E  1.40  0.90
1979 C  0.20  0.15
    D  0.14  0.05
    E  0.50  0.15
    F  1.20  0.50
    G  3.40  1.90
    H  5.40  2.70
    I  6.40  1.20

In [181]: df.loc[1978]
Out[181]:
    zit  xit
indiv
A   0.20  0.06
B   0.70  0.20
C   0.80  0.30
D   0.90  0.50
E   1.40  0.90

Reading columns with a MultiIndex

By specifying list of row locations for the header argument, you can read in a MultiIndex for the columns. Specifying non-consecutive rows will skip the intervening rows.

In [182]: from pandas._testing import makeCustomDataframe as mkdf

In [183]: df = mkdf(5, 3, r_idx_nlevels=2, c_idx_nlevels=4)

In [184]: df.to_csv("mi.csv")

In [185]: print(open("mi.csv").read())
C0,,C_l0_g0,C_l0_g1,C_l0_g2
C1,,C_l1_g0,C_l1_g1,C_l1_g2
C2,,C_l2_g0,C_l2_g1,C_l2_g2
C3,,C_l3_g0,C_l3_g1,C_l3_g2
R0,R1,,,R_l0_g0,R_l1_g0,R0C0,R0C1,R0C2
R_l0_g1,R_l1_g1,R1C0,R1C1,R1C2
R_l0_g2,R_l1_g2,R2C0,R2C1,R2C2
R_l0_g3,R_l1_g3,R3C0,R3C1,R3C2
R_l0_g4,R_l1_g4,R4C0,R4C1,R4C2
**pandas: powerful Python data analysis toolkit, Release 1.3.1**

(continued from previous page)

```python
In [186]: pd.read_csv("mi.csv", header=[0, 1, 2, 3], index_col=[0, 1])
Out[186]:
C0          C_l0_g0          C_l0_g1          C_l0_g2
C1          C_l1_g0          C_l1_g1          C_l1_g2
C2          C_l2_g0          C_l2_g1          C_l2_g2
C3          C_l3_g0          C_l3_g1          C_l3_g2
R0          R1              R_l0_g0          R0C0          R0C1          R0C2
R_l0_g1          R_l1_g1          R1C0          R1C1          R1C2
R_l0_g2          R_l1_g2          R2C0          R2C1          R2C2
R_l0_g3          R_l1_g3          R3C0          R3C1          R3C2
R_l0_g4          R_l1_g4          R4C0          R4C1          R4C2
```

read_csv is also able to interpret a more common format of multi-columns indices.

```python
In [187]: print(open("mi2.csv").read())
```

```
, a, a, a, b, c, c
, q, r, s, t, u, v
one, 1, 2, 3, 4, 5, 6
two, 7, 8, 9, 10, 11, 12
```

```python
In [188]: pd.read_csv("mi2.csv", header=[0, 1], index_col=0)
Out[188]:
      a     b     c
q  1.0  2.0  3.0
r  4.0  5.0  6.0
```

Note: If an index_col is not specified (e.g. you don’t have an index, or wrote it with df.to_csv(..., index=False), then any names on the columns index will be lost.

**Automatically “sniffing” the delimiter**

read_csv is capable of inferring delimited (not necessarily comma-separated) files, as pandas uses the `csv.Sniffer` class of the csv module. For this, you have to specify sep=None.

```python
In [189]: print(open("tmp2.sv").read())
```

```

Reading multiple files to create a single DataFrame

It’s best to use `concat()` to combine multiple files. See the cookbook for an example.

Iterating through files chunk by chunk

Suppose you wish to iterate through a (potentially very large) file lazily rather than reading the entire file into memory, such as the following:

```python
In [191]: print(open("tmp.sv").read())
0|0.4691122999071863|-0.2828633443286633|-1.509058503308580|0.1136484096888855|-1.0392684835147725
1|1.211210250208506|0.17321464905330858|0.1920871129693428|0.442359662799567
2|-0.8618489633477999|-2.1045692188948086|-0.4949292740687813|1.071803807037338
3|0.72155162243669|-0.7067711336300845|1.1578922506419993|-1.344311812731667
4|-0.4249723297888375|0.2762320192777197|1.071803807037338
5|0.7636897808826706|0.1136484096888855|1.1578922506419993|-1.344311812731667
6|0.4047052186802365|0.5770459859204836|1.6435630703622064|1.4693879595399115
7|-0.3706468582364464|0.5770459859204836|1.6435630703622064|1.4693879595399115
8|1.075770 -0.109050 1.643563 -1.469388
9|0.35702056413309086|0.6746001037299882|1.776904 -0.968914
```

```
In [192]: table = pd.read_csv("tmp.sv", sep="|")
```

```
In [193]: table
Out[193]:
         0         1         2         3
0  0.469112 -0.282863 -1.509059 -1.135632
1  1.211211 -0.173215  0.119209  1.044236
2 -0.861849 -2.104569  0.494929  1.071804
3  0.721555 -0.706771 -1.039575  0.271860
4 -0.424972  0.567020  0.276232 -1.087401
5  0.763689  0.113648 -1.478427  0.524988
6  0.404705  0.577046 -1.715002 -1.039268
7 -0.370647 -1.157892 -1.344312  0.844885
8  1.075770 -0.109050  1.643563 -1.469388
9  0.357021 -0.674600 -1.776904 -0.968914
```

By specifying a `chunksize` to `read_csv`, the return value will be an iterable object of type `TextFileReader`:

```python
In [194]: with pd.read_csv("tmp.sv", sep="|", chunksize=4) as reader:
    for chunk in reader:
```

(continues on next page)
.. code-block:: python

    print(chunk)

.. code-block:: python

    Unnamed: 0 0 1 2 3
    0  0  0.469112 -0.282863 -1.509059 -1.135632

    7  7 -0.370647 -1.157892 -1.344312  0.844885
    8  8  1.075770 -0.10905  1.643563 -1.469388
    9  9  0.357021 -0.67460 -1.776904 -0.968914

Changed in version 1.2: read_csv/json/sas return a context-manager when iterating through a file.

Specifying `iterator=True` will also return the `TextFileReader` object:

```python
In [195]: with pd.read_csv("tmp.sv", sep="|", iterator=True) as reader:
......:     reader.get_chunk(5)
......:
```

### Specifying the parser engine

Under the hood pandas uses a fast and efficient parser implemented in C as well as a Python implementation which is currently more feature-complete. Where possible pandas uses the C parser (specified as `engine='c'`), but may fall back to Python if C-unsupported options are specified. Currently, C-unsupported options include:

- `sep` other than a single character (e.g. regex separators)
- `skipfooter`
- `sep=None` with `delim_whitespace=False`

Specifying any of the above options will produce a `ParserWarning` unless the python engine is selected explicitly using `engine='python'`.

### Reading/writing remote files

You can pass in a URL to read or write remote files to many of pandas’ IO functions - the following example shows reading a CSV file:

```python
def = pd.read_csv("https://download.bls.gov/pub/time.series/cu/cu.item", sep="\t")
```

New in version 1.3.0.

A custom header can be sent alongside HTTP(s) requests by passing a dictionary of header key value mappings to the `storage_options` keyword argument as shown below:

```python
def = pd.read_csv(
    "https://download.bls.gov/pub/time.series/cu/cu.item",
    sep="\t",
    headers={"User-Agent": "pandas"}
)
```
All URLs which are not local files or HTTP(s) are handled by fsspec, if installed, and its various filesystem implementations (including Amazon S3, Google Cloud, SSH, FTP, webHDFS...). Some of these implementations will require additional packages to be installed, for example S3 URLs require the s3fs library:

```python
df = pd.read_json("s3://pandas-test/adatafile.json")
```

When dealing with remote storage systems, you might need extra configuration with environment variables or config files in special locations. For example, to access data in your S3 bucket, you will need to define credentials in one of the several ways listed in the S3Fs documentation. The same is true for several of the storage backends, and you should follow the links at fsimpl1 for implementations built into fsspec and fsimpl2 for those not included in the main fsspec distribution.

You can also pass parameters directly to the backend driver. For example, if you do not have S3 credentials, you can still access public data by specifying an anonymous connection, such as

```python
df = pd.read_csv("s3://ncei-wcsd-archive/data/processed/SH1305/18kHz/SaKe2013-D20130523-T080854_to_SaKe2013-D20130523-T085643.csv", storage_options={"anon": True})
```

fsspec also allows complex URLs, for accessing data in compressed archives, local caching of files, and more. To locally cache the above example, you would modify the call to

```python
fs = pd.read_csv(
    "simplecache::s3://ncei-wcsd-archive/data/processed/SH1305/18kHz/
    "SaKe2013-D20130523-T080854_to_SaKe2013-D20130523-T085643.csv", storage_options={"s3": {"anon": True}})
```

where we specify that the “anon” parameter is meant for the “s3” part of the implementation, not to the caching implementation. Note that this caches to a temporary directory for the duration of the session only, but you can also specify a permanent store.

### Writing out data

#### Writing to CSV format

The `Series` and `DataFrame` objects have an instance method `to_csv` which allows storing the contents of the object as a comma-separated-values file. The function takes a number of arguments. Only the first is required.

- **path_or_buf**: A string path to the file to write or a file object. If a file object it must be opened with `newline=''`
- **sep**: Field delimiter for the output file (default ",")
- **na_rep**: A string representation of a missing value (default ")
- **float_format**: Format string for floating point numbers
- **columns**: Columns to write (default None)
- **header**: Whether to write out the column names (default True)
- **index**: whether to write row (index) names (default True)
- **index_label**: Column label(s) for index column(s) if desired. If None (default), and header and index are True, then the index names are used. (A sequence should be given if the DataFrame uses MultiIndex).
- **mode**: Python write mode, default ‘w’
- **encoding**: a string representing the encoding to use if the contents are non-ASCII, for Python versions prior to 3
- **line_terminator**: Character sequence denoting line end (default `os.linesep`)
- **quoting**: Set quoting rules as in csv module (default csv.QUOTE_MINIMAL). Note that if you have set a float_format then floats are converted to strings and csv.QUOTE_NONNUMERIC will treat them as non-numeric
- **quotechar**: Character used to quote fields (default ‘”’)
- **doublequote**: Control quoting of quotechar in fields (default True)
- **escapechar**: Character used to escape sep and quotechar when appropriate (default None)
- **chunksize**: Number of rows to write at a time
- **date_format**: Format string for datetime objects

### Writing a formatted string

The DataFrame object has an instance method `to_string` which allows control over the string representation of the object. All arguments are optional:

- **buf** default None, for example a StringIO object
- **columns** default None, which columns to write
- **col_space** default None, minimum width of each column.
- **na_rep** default NaN, representation of NA value
- **formatters** default None, a dictionary (by column) of functions each of which takes a single argument and returns a formatted string
- **float_format** default None, a function which takes a single (float) argument and returns a formatted string; to be applied to floats in the DataFrame.
- **sparsify** default True, set to False for a DataFrame with a hierarchical index to print every MultiIndex key at each row.
- **index_names** default True, will print the names of the indices
- **index** default True, will print the index (ie, row labels)
- **header** default True, will print the column labels
- **justify** default left, will print column headers left- or right-justified

The Series object also has a `to_string` method, but with only the buf, na_rep, float_format arguments. There is also a length argument which, if set to True, will additionally output the length of the Series.
2.4.2 JSON

Read and write JSON format files and strings.

Writing JSON

A Series or DataFrame can be converted to a valid JSON string. Use to_json with optional parameters:

- **path_or_buf**: the pathname or buffer to write the output. This can be None in which case a JSON string is returned.
- **orient**: Series:
  - default is index
  - allowed values are {split, records, index}
- **DataFrame**:
  - default is columns
  - allowed values are {split, records, index, columns, values, table}

The format of the JSON string

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>split</td>
<td>dict like {index -&gt; [index], columns -&gt; [columns], data -&gt; [values]}</td>
</tr>
<tr>
<td>records</td>
<td>list like [[column -&gt; value]...,{column -&gt; value}]</td>
</tr>
<tr>
<td>index</td>
<td>dict like {index -&gt; {column -&gt; value}}</td>
</tr>
<tr>
<td>columns</td>
<td>dict like {column -&gt; {index -&gt; value}}</td>
</tr>
<tr>
<td>values</td>
<td>just the values array</td>
</tr>
</tbody>
</table>

- **date_format**: string, type of date conversion, ‘epoch’ for timestamp, ‘iso’ for ISO8601.
- **double_precision**: The number of decimal places to use when encoding floating point values, default 10.
- **force_ascii**: force encoded string to be ASCII, default True.
- **date_unit**: The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’ or ‘ns’ for seconds, milliseconds, microseconds and nanoseconds respectively. Default ‘ms’.
- **default_handler**: The handler to call if an object cannot otherwise be converted to a suitable format for JSON. Takes a single argument, which is the object to convert, and returns a serializable object.
- **lines**: If records orient, then will write each record per line as json.

Note NaN’s, NaT’s and None will be converted to null and datetime objects will be converted based on the date_format and date_unit parameters.

```
In [196]: dfj = pd.DataFrame(np.random.randn(5, 2), columns=list("AB"))

In [197]: json = dfj.to_json()

In [198]: json
Out[198]: '{"A":{"0":-1.2945235903,"1":0.2766617129,"2":-0.0139597524,"3":-0.8006153699,"4":0.4137381054},"B":{"0":-0.472034511,"1":-0.923060654,"2":0.8052440254}}'
```
Orient options

There are a number of different options for the format of the resulting JSON file / string. Consider the following DataFrame and Series:

```
In [199]: dfjo = pd.DataFrame(
       ....:     dict(A=range(1, 4), B=range(4, 7), C=range(7, 10)),
       ....:     columns=list("ABC"),
       ....:     index=list("xyz"),
       ....:     )
```
```
In [200]: dfjo
Out[200]:
   A  B  C
  x 1  4  7
  y 2  5  8
  z 3  6  9
```
```
In [201]: sjo = pd.Series(dict(x=15, y=16, z=17), name="D")
```
```
In [202]: sjo
Out[202]:
   x  y  z
  15 16 17
Name: D, dtype: int64
```

Column oriented (the default for DataFrame) serializes the data as nested JSON objects with column labels acting as the primary index:
```
In [203]: dfjo.to_json(orient="columns")
Out[203]: '{"A":{"x":1, "y":2, "z":3}, "B":{"x":4, "y":5, "z":6}, "C":{"x":7, "y":8, "z":9}}'
```

Index oriented (the default for Series) similar to column oriented but the index labels are now primary:
```
In [204]: dfjo.to_json(orient="index")
Out[204]: '{"x":{"A":1, "B":4, "C":7}, "y":{"A":2, "B":5, "C":8}, "z":{"A":3, "B":6, "C":9}}'
```
```
In [205]: sjo.to_json(orient="index")
Out[205]: '{"x":15, "y":16, "z":17}'
```

Record oriented serializes the data to a JSON array of column -> value records, index labels are not included. This is useful for passing DataFrame data to plotting libraries, for example the JavaScript library d3.js:
```
In [206]: dfjo.to_json(orient="records")
Out[206]: '[["A":1,"B":4,"C":7], ["A":2,"B":5,"C":8], ["A":3,"B":6,"C":9]]'
```
```
In [207]: sjo.to_json(orient="records")
Out[207]: '[15,16,17]'
```

Value oriented is a bare-bones option which serializes to nested JSON arrays of values only, column and index labels are not included:
pandas: powerful Python data analysis toolkit, Release 1.3.1

In [208]: dfjo.to_json(orient="values")
Out[208]: '[[1,4,7],[2,5,8],[3,6,9]]'

# Not available for Series

Split oriented serializes to a JSON object containing separate entries for values, index and columns. Name is also included for Series:

In [209]: dfjo.to_json(orient="split")
Out[209]: '{"columns": ["A","B","C"], "index": ["x","y","z"], "data": [[1,4,7],[2,5,8],[3,6,9]]}'

In [210]: sjo.to_json(orient="split")
Out[210]: '{"name": "D", "index": ["x","y","z"], "data": [15,16,17]}'

Table oriented serializes to the JSON Table Schema, allowing for the preservation of metadata including but not limited to dtypes and index names.

Note: Any orient option that encodes to a JSON object will not preserve the ordering of index and column labels during round-trip serialization. If you wish to preserve label ordering use the split option as it uses ordered containers.

Date handling

Writing in ISO date format:

In [211]: dfd = pd.DataFrame(np.random.randn(5, 2), columns=list("AB"))
In [212]: dfd["date"] = pd.Timestamp("20130101")
In [213]: dfd = dfd.sort_index(axis=1, ascending=False)
In [214]: json = dfd.to_json(date_format="iso")
In [215]:
Out[215]: '{"date":{"0":"2013-01-01T00:00:00.000Z","1":"2013-01-01T00:00:00.000Z","2":...
"1":"2013-01-01T00:00:00.000Z","3":"2013-01-01T00:00:00.000Z","4":"2013-01-01T00:00.000Z"},"B":{"0":2.5656459463,"1":1.3403088498,"2":-0.2261692849,"3":0.8138502857,"4":-
0.8273169356},"A":{"0":-1.2064117817,"1":1.4312559863,"2":-1.702987971,"3":0.
4108345112,"4":0.1320031703}}'

Writing in ISO date format, with microseconds:

In [216]: json = dfd.to_json(date_format="iso", date_unit="us")
In [217]:
Out[217]: '{"date":{"0":"2013-01-01T00:00:00.000000Z","1":"2013-01-01T00:00:00.000000Z","2":...
"1":"2013-01-01T00:00:00.000000Z","3":"2013-01-01T00:00:00.000000Z","4":"2013-01-
01T00:00:00.000000Z"},"B":{"0":2.5656459463,"1":1.3403088498,"2":-0.2261692849,"3":0.
8138502857,"4":-0.8273169356},"A":{"0":-1.2064117817,"1":1.4312559863,"2":-1.702987971,"3":0.
4108345112,"4":0.1320031703}}'

Epoch timestamps, in seconds:

In [216]: json = dfd.to_json(date_format="iso", date_unit="us")
In [217]:
Out[217]: '{"date":{"0":1351699200,"1":1351699200,"2":1351699200,"3":1351699200,"4":1351699200}...
pandas: powerful Python data analysis toolkit, Release 1.3.1

In [218]: json = dfd.to_json(date_format="epoch", date_unit="s")
In [219]: json
Out[219]: '{"date":{"0":1356998400,"1":1356998400,"2":1356998400,"3":1356998400,"4":
˓→1356998400},"B":{"0":2.5656459463,"1":1.3403088498,"2":-0.2261692849,"3":0.
˓→8138502857,"4":-0.8273169356},"A":{"0":-1.2064117817,"1":1.4312559863,"2":-1.
˓→1702987971,"3":0.4108345112,"4":0.1320031703}}'

Writing to a file, with a date index and a date column:
In [220]: dfj2 = dfj.copy()
In [221]: dfj2["date"] = pd.Timestamp("20130101")
In [222]: dfj2["ints"] = list(range(5))
In [223]: dfj2["bools"] = True
In [224]: dfj2.index = pd.date_range("20130101", periods=5)
In [225]: dfj2.to_json("test.json")
In [226]: with open("test.json") as fh:
.....:
print(fh.read())
.....:
{"A":{"1356998400000":-1.2945235903,"1357084800000":0.2766617129,"1357171200000":-0.
˓→0139597524,"1357257600000":-0.0061535699,"1357344000000":0.8957173022},"B":{
˓→"1356998400000":0.4137381054,"1357084800000":-0.472034511,"1357171200000":-0.
˓→3625429925,"1357257600000":-0.923060654,"1357344000000":0.8052440254},"date":{
˓→"1356998400000":1356998400000,"1357084800000":1356998400000,"1357171200000":
˓→1356998400000,"1357257600000":1356998400000,"1357344000000":1356998400000},"ints":{
˓→"1356998400000":0,"1357084800000":1,"1357171200000":2,"1357257600000":3,
˓→"1357344000000":4},"bools":{"1356998400000":true,"1357084800000":true,"1357171200000
˓→":true,"1357257600000":true,"1357344000000":true}}

Fallback behavior
If the JSON serializer cannot handle the container contents directly it will fall back in the following manner:
• if the dtype is unsupported (e.g. np.complex_) then the default_handler, if provided, will be called for
each value, otherwise an exception is raised.
• if an object is unsupported it will attempt the following:
– check if the object has defined a toDict method and call it. A toDict method should return a dict
which will then be JSON serialized.
– invoke the default_handler if one was provided.
– convert the object to a dict by traversing its contents.
OverflowError or give unexpected results.

However this will often fail with an

In general the best approach for unsupported objects or dtypes is to provide a default_handler. For example:
>>> DataFrame([1.0, 2.0, complex(1.0, 2.0)]).to_json()
RuntimeError: Unhandled numpy dtype 15

# raises

can be dealt with by specifying a simple default_handler:

2.4. IO tools (text, CSV, HDF5, . . . )

301


Reading JSON

Reading a JSON string to pandas object can take a number of parameters. The parser will try to parse a DataFrame if `typ` is not supplied or is `None`. To explicitly force Series parsing, pass `typ=series`

- `filepath_or_buffer`: a VALID JSON string or file handle / StringIO. The string could be a URL. Valid URL schemes include http, ftp, S3, and file. For file URLs, a host is expected. For instance, a local file could be file:///localhost/path/to/table.json
- `typ`: type of object to recover (series or frame), default ‘frame’
- `orient`:
  - `Series`:
    - default is `index`
    - allowed values are `{split, records, index}`
  - `DataFrame`:
    - default is `columns`
    - allowed values are `{split, records, index, columns, values, table}`

The format of the JSON string

<table>
<thead>
<tr>
<th>split</th>
<th>dict like {index -&gt; [index], columns -&gt; [columns], data -&gt; [values]}</th>
</tr>
</thead>
<tbody>
<tr>
<td>records</td>
<td>list like [{column -&gt; value}, ..., {column -&gt; value}]</td>
</tr>
<tr>
<td>index</td>
<td>dict like {index -&gt; {column -&gt; value}}</td>
</tr>
<tr>
<td>columns</td>
<td>dict like {column -&gt; {index -&gt; value}}</td>
</tr>
<tr>
<td>values</td>
<td>just the values array</td>
</tr>
<tr>
<td>table</td>
<td>adhering to the JSON Table Schema</td>
</tr>
</tbody>
</table>

- `dtype`: if True, infer dtypes, if a dict of column to dtype, then use those, if False, then don’t infer dtypes at all, default is True, apply only to the data.
- `convert_axes`: boolean, try to convert the axes to the proper dtypes, default is True
- `convert_dates`: a list of columns to parse for dates; If True, then try to parse date-like columns, default is True.
- `keep_default_dates`: boolean, default True. If parsing dates, then parse the default date-like columns.
- `numpy`: direct decoding to NumPy arrays. default is False. Supports numeric data only, although labels may be non-numeric. Also note that the JSON ordering MUST be the same for each term if numpy=True.
- `precise_float`: boolean, default False. Set to enable usage of higher precision (strtod) function when decoding string to double values. Default (False) is to use fast but less precise built-in functionality.
- `date_unit`: string, the timestamp unit to detect if converting dates. Default None. By default the timestamp precision will be detected, if this is not desired then pass one of ‘s’, ‘ms’, ‘us’ or ‘ns’ to force timestamp precision to seconds, milliseconds, microseconds or nanoseconds respectively.
- `lines`: reads file as one json object per line.
- `encoding`: The encoding to use to decode py3 bytes.
• chunksize: when used in combination with lines=True, return a JsonReader which reads in chunksize lines per iteration.

The parser will raise one of ValueError/TypeError/AssertionError if the JSON is not parseable.

If a non-default orient was used when encoding to JSON be sure to pass the same option here so that decoding produces sensible results, see Orient Options for an overview.

Data conversion

The default of convert_axes=True, dtype=True, and convert_dates=True will try to parse the axes, and all of the data into appropriate types, including dates. If you need to override specific dtypes, pass a dict to dtype. convert_axes should only be set to False if you need to preserve string-like numbers (e.g. ‘1’, ‘2’) in an axes.

Note: Large integer values may be converted to dates if convert_dates=True and the data and / or column labels appear ‘date-like’. The exact threshold depends on the date_unit specified. ‘date-like’ means that the column label meets one of the following criteria:

• it ends with '_at'
• it ends with '_time'
• it begins with 'timestamp'
• it is 'modified'
• it is 'date'

Warning: When reading JSON data, automatic coercing into dtypes has some quirks:

• an index can be reconstructed in a different order from serialization, that is, the returned order is not guaranteed to be the same as before serialization
• a column that was float data will be converted to integer if it can be done safely, e.g. a column of 1.
• bool columns will be converted to integer on reconstruction

Thus there are times where you may want to specify specific dtypes via the dtype keyword argument.

Reading from a JSON string:

```
In [228]: pd.read_json(json)
Out[228]:
    date   B   A
0 2013-01-01  2.565646 -1.206412
1 2013-01-01  1.340309  1.431256
2 2013-01-01 -0.226169 -1.170299
3 2013-01-01  0.813850  0.410835
4 2013-01-01 -0.827317  0.132003
```

Reading from a file:

```
In [229]: pd.read_json("test.json")
Out[229]:
     A   B     date  ints  bools
0 2013-01-01 -1.294524  0.413738  2013-01-01     0 True
```

(continues on next page)
Don’t convert any data (but still convert axes and dates):

```
In [230]: pd.read_json("test.json", dtype=object).dtypes
Out[230]:
A   object
B   object
date object
ints object
bools object
dtype: object
```

Specify dtypes for conversion:

```
In [231]: pd.read_json("test.json", dtype={"A": "float32", "bools": "int8"}).dtypes
Out[231]:
A   float32
B   float64
date   datetime64[ns]
ints   int64
bools   int8
dtype: object
```

Preserve string indices:

```
In [232]: si = pd.DataFrame(
            ...
            np.zeros((4, 4)), columns=list(range(4)), index=[str(i) for i in
            ...
            range(4))
    ...
    ...
In [233]: si
Out[233]:
   0  1  2  3
0  0.0  0.0  0.0  0.0
1  0.0  0.0  0.0  0.0
2  0.0  0.0  0.0  0.0
3  0.0  0.0  0.0  0.0

In [234]: si.index
Out[234]: Index(['0', '1', '2', '3'], dtype='object')

In [235]: si.columns
Out[235]: Int64Index([0, 1, 2, 3], dtype='int64')

In [236]: json = si.to_json()

In [237]: sij = pd.read_json(json, convert_axes=False)
```
Dates written in nanoseconds need to be read back in nanoseconds:

```python
In [241]: json = dfj2.to_json(date_unit="ns")
# Try to parse timestamps as milliseconds -> Won't Work
In [242]: dfju = pd.read_json(json, date_unit="ms")
In [243]: dfju
Out[243]:
A    B    date    ints  bools
0  2013-01-01 -1.294524  0.413738 2013-01-01 0  True
1  2013-01-02  0.276662 -0.472035 2013-01-01 1  True
2  2013-01-03 -0.013960 -0.362543 2013-01-01 2  True
3  2013-01-04 -0.006154 -0.923061 2013-01-01 3  True
4   0.895717  0.805244 1356998400000000000 4  True

# Let pandas detect the correct precision
In [244]: dfju = pd.read_json(json)
In [245]: dfju
Out[245]:
A    B    date    ints  bools
0  2013-01-01 -1.294524  0.413738 2013-01-01 0  True
1  2013-01-02  0.276662 -0.472035 2013-01-01 1  True

4   0.895717  0.805244 1356998400000000000 4  True
```

2.4. IO tools (text, CSV, HDF5, ...)

---

In [239]: sij.index
Out[239]: Index(['0', '1', '2', '3'], dtype='object')

In [240]: sij.columns
Out[240]: Index(['0', '1', '2', '3'], dtype='object')
The Numpy parameter

**Note:** This param has been deprecated as of version 1.0.0 and will raise a `FutureWarning`. This supports numeric data only. Index and columns labels may be non-numeric, e.g. strings, dates etc.

If `numpy=True` is passed to `read_json` an attempt will be made to sniff an appropriate dtype during deserialization and to subsequently decode directly to NumPy arrays, bypassing the need for intermediate Python objects. This can provide speedups if you are deserialising a large amount of numeric data:

```python
In [248]: randfloats = np.random.uniform(-100, 1000, 10000)
In [249]: randfloats.shape = (1000, 10)
In [250]: dffloats = pd.DataFrame(randfloats, columns=list("ABCDEFGHIJ"))
In [251]: jsonfloats = dffloats.to_json()

In [252]: %timeit pd.read_json(jsonfloats)
7 ms +- 53 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [253]: %timeit pd.read_json(jsonfloats, numpy=True)
4.92 ms +- 71.7 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

The speedup is less noticeable for smaller datasets:

```python
In [254]: jsonfloats = dffloats.head(100).to_json()

In [255]: %timeit pd.read_json(jsonfloats)
4.4 ms +- 47.4 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [256]: %timeit pd.read_json(jsonfloats, numpy=True)
3.94 ms +- 16.6 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

**Warning:** Direct NumPy decoding makes a number of assumptions and may fail or produce unexpected output if these assumptions are not satisfied:

- data is numeric.
- data is uniform. The dtype is sniffed from the first value decoded. A `ValueError` may be raised, or incorrect output may be produced if this condition is not satisfied.
- labels are ordered. Labels are only read from the first container, it is assumed that each subsequent row / column has been encoded in the same order. This should be satisfied if the data was encoded using `to_json` but may not be the case if the JSON is from another source.
Normalization

pandas provides a utility function to take a dict or list of dicts and normalize this semi-structured data into a flat table.

```
In [257]: data = [
    ....:     {"id": 1, "name": {"first": "Coleen", "last": "Volk"}},
    ....:     {"name": {"given": "Mark", "family": "Regner"}},
    ....:     {"id": 2, "name": "Faye Raker"},
    ....: ]

In [258]: pd.json_normalize(data)
Out[258]:
   id   name.first   name.last   name.given   name.family
0  1.0       Coleen       Volk          NaN          NaN
1  NaN          NaN          NaN        Mark        Regner
2  2.0          NaN          NaN          NaN         Faye Raker
```

```
In [259]: data = [
    ....:     {
    ....:         "state": "Florida",
    ....:         "shortname": "FL",
    ....:         "info": {"governor": "Rick Scott"},
    ....:         "county": [
    ....:             {"name": "Dade", "population": 12345},
    ....:             {"name": "Broward", "population": 40000},
    ....:             {"name": "Palm Beach", "population": 60000},
    ....:         ],
    ....:     },
    ....:     {
    ....:         "state": "Ohio",
    ....:         "shortname": "OH",
    ....:         "info": {"governor": "John Kasich"},
    ....:         "county": [
    ....:             {"name": "Summit", "population": 1234},
    ....:             {"name": "Cuyahoga", "population": 1337},
    ....:         ],
    ....:     }
    ....: ]

In [260]: pd.json_normalize(data, "county", ["state", "shortname", ["info", "governor"]])
Out[260]:
    name population state  shortname   info.governor
0  Dade       12345 Florida   FL    Rick Scott
1  Broward     40000 Florida   FL    Rick Scott
2  Palm Beach  60000 Florida   FL    Rick Scott
3  Summit      1234  Ohio      OH    John Kasich
4  Cuyahoga    1337  Ohio      OH    John Kasich
```

The `max_level` parameter provides more control over which level to end normalization. With `max_level=1` the following snippet normalizes until 1st nesting level of the provided dict.

```
In [261]: data = [
    ....:     {
    ....:         "CreatedBy": {"Name": "User001"},
    ....:     }
    ....: ]

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.1

(continued from previous page)

```python
.....:
.....:  "Lookup": {  
.....:  "TextField": "Some text",  
.....:  "UserField": {"Id": "ID001", "Name": "Name001"},  
.....:  },  
.....:  "Image": {"a": "b"},  
.....: }  
.....:
In [262]: pd.json_normalize(data, max_level=1)  
Out[262]:  
  CreatedBy.Name Lookup.TextField Lookup.UserField Image.a  
  0  User001 Some text {'Id': 'ID001', 'Name': 'Name001'} b

Line delimited json

pandas is able to read and write line-delimited json files that are common in data processing pipelines using Hadoop or Spark.

For line-delimited json files, pandas can also return an iterator which reads in chunksize lines at a time. This can be useful for large files or to read from a stream.

```python
In [263]: jsonl = """  
.....:  {"a": 1, "b": 2}  
.....:  {"a": 3, "b": 4}  
.....: """  
.....:
In [264]: df = pd.read_json(jsonl, lines=True)  
In [265]: df  
Out[265]:  
  a  b  
  0  1  2  
  1  3  4  
In [266]: df.to_json(orient="records", lines=True)  
Out[266]:  '{"a":1,\"b":2}\n{"a":3,\"b":4}\n'

# reader is an iterator that returns `\chunksize` lines each iteration
In [267]: with pd.read_json(StringIO(jsonl), lines=True, chunksize=1) as reader:  
.....:  for chunk in reader:  
.....:      print(chunk)  
.....:  
Empty DataFrame
Columns: []
Index: []
  a  b  
  0  1  2  
  1  3  4
```

308 Chapter 2. User Guide
pandas: powerful Python data analysis toolkit, Release 1.3.1

Table schema
Table Schema is a spec for describing tabular datasets as a JSON object. The JSON includes information on the field
names, types, and other attributes. You can use the orient table to build a JSON string with two fields, schema and
data.
In [268]: df = pd.DataFrame(
.....:
{
.....:
"A": [1, 2, 3],
.....:
"B": ["a", "b", "c"],
.....:
"C": pd.date_range("2016-01-01", freq="d", periods=3),
.....:
},
.....:
index=pd.Index(range(3), name="idx"),
.....: )
.....:
In [269]:
Out[269]:
A B
idx
0
1 a
1
2 b
2
3 c

df
C
2016-01-01
2016-01-02
2016-01-03

In [270]: df.to_json(orient="table", date_format="iso")
Out[270]: '{"schema":{"fields":[{"name":"idx","type":"integer"},{"name":"A","type":
˓→"integer"},{"name":"B","type":"string"},{"name":"C","type":"datetime"}],"primaryKey
˓→":["idx"],"pandas_version":"0.20.0"},"data":[{"idx":0,"A":1,"B":"a","C":"2016-01˓→01T00:00:00.000Z"},{"idx":1,"A":2,"B":"b","C":"2016-01-02T00:00:00.000Z"},{"idx":2,
˓→"A":3,"B":"c","C":"2016-01-03T00:00:00.000Z"}]}'

The schema field contains the fields key, which itself contains a list of column name to type pairs, including the
Index or MultiIndex (see below for a list of types). The schema field also contains a primaryKey field if the
(Multi)index is unique.
The second field, data, contains the serialized data with the records orient. The index is included, and any
datetimes are ISO 8601 formatted, as required by the Table Schema spec.
The full list of types supported are described in the Table Schema spec. This table shows the mapping from pandas
types:
pandas type
int64
float64
bool
datetime64[ns]
timedelta64[ns]
categorical
object

Table Schema type
integer
number
boolean
datetime
duration
any
str

A few notes on the generated table schema:
• The schema object contains a pandas_version field. This contains the version of pandas’ dialect of the
schema, and will be incremented with each revision.
• All dates are converted to UTC when serializing. Even timezone naive values, which are treated as UTC with
an offset of 0.

2.4. IO tools (text, CSV, HDF5, . . . )

309


In [271]: from pandas.io.json import build_table_schema

In [272]: s = pd.Series(pd.date_range("2016", periods=4))

In [273]: build_table_schema(s)
Out[273]:
{'fields': [{'name': 'index', 'type': 'integer'},
            {'name': 'values', 'type': 'datetime'}],
     'primaryKey': ['index'],
     'pandas_version': '0.20.0'}

- datetimes with a timezone (before serializing), include an additional field `tz` with the time zone name (e.g. 'US/Central').

In [274]: s_tz = pd.Series(pd.date_range("2016", periods=12, tz="US/Central"))

In [275]: build_table_schema(s_tz)
Out[275]:
{'fields': [{'name': 'index', 'type': 'integer'},
            {'name': 'values', 'type': 'datetime', 'tz': 'US/Central'}],
     'primaryKey': ['index'],
     'pandas_version': '0.20.0'}

- Periods are converted to timestamps before serialization, and so have the same behavior of being converted to UTC. In addition, periods will contain and additional field `freq` with the period’s frequency, e.g. 'A-DEC'.

In [276]: s_per = pd.Series(1, index=pd.period_range("2016", freq="A-DEC", periods=4))

In [277]: build_table_schema(s_per)
Out[277]:
{'fields': [{'name': 'index', 'type': 'datetime', 'freq': 'A-DEC'},
            {'name': 'values', 'type': 'integer'}],
     'primaryKey': ['index'],
     'pandas_version': '0.20.0'}

- Categoricals use the any type and an enum constraint listing the set of possible values. Additionally, an ordered field is included:

In [278]: s_cat = pd.Series(pd.Categorical(['a', 'b', 'a']))

In [279]: build_table_schema(s_cat)
Out[279]:
{'fields': [{'name': 'index', 'type': 'integer'},
            {'name': 'values', 'type': 'any',
             'constraints': {'enum': ['a', 'b']},
             'ordered': False}],
     'primaryKey': ['index'],
     'pandas_version': '0.20.0'}

- A primaryKey field, containing an array of labels, is included if the index is unique:

In [280]: s_dupe = pd.Series([1, 2], index=[1, 1])

In [281]: build_table_schema(s_dupe)
Out[281]:
(continues on next page)
• The primaryKey behavior is the same with MultiIndexes, but in this case the primaryKey is an array:

```python
In [282]: s_multi = pd.Series(1, index=pd.MultiIndex.from_product([("a", "b"), (0, 1)])

In [283]: build_table_schema(s_multi)
Out[283]:
{'fields': [{'name': 'level_0', 'type': 'string'},
            {'name': 'level_1', 'type': 'integer'},
            {'name': 'values', 'type': 'integer'}],
   'primaryKey': FrozenList(["level_0", "level_1"],
   'pandas_version': '0.20.0'}
```

• The default naming roughly follows these rules:
  – For series, the object.name is used. If that’s none, then the name is values
  – For DataFrames, the stringified version of the column name is used
  – For Index (not MultiIndex), index.name is used, with a fallback to index if that is None.
  – For MultiIndex, mi.names is used. If any level has no name, then level_<i> is used.

`read_json` also accepts `orient='table'` as an argument. This allows for the preservation of metadata such as dtypes and index names in a round-trippable manner.

```python
In [284]: df = pd.DataFrame(
                   {.....: "foo": [1, 2, 3, 4],
                   "bar": ["a", "b", "c", "d"],
                   "baz": pd.date_range("2018-01-01", freq="d", periods=4),
                   "qux": pd.Categorical(["a", "b", "c", "c"]),
                   },
                  index=pd.Index(range(4), name="idx"),
                  )

In [285]: df
Out[285]:
foo  bar         baz     qux
idx
  0 1  a 2018-01-01  a
  1 2  b 2018-01-02  b
  2 3  c 2018-01-03  c
  3 4  d 2018-01-04  c

In [286]: df.dtypes
Out[286]:
foo       int64
bar      object
baz   datetime64[ns]
qux      category
dtype: object
```
In [287]: df.to_json("test.json", orient="table")

In [288]: new_df = pd.read_json("test.json", orient="table")

In [289]: new_df
Out[289]:
   foo  bar     baz
idx
0  1     a 2018-01-01 a
1  2     b 2018-01-02 b
2  3     c 2018-01-03 c
3  4     d 2018-01-04 c

In [290]: new_df.dtypes
Out[290]:
foo   int64
bar  object
baz  datetime64[ns]
qux   category
dtype: object

Please note that the literal string ‘index’ as the name of an Index is not round-trippable, nor are any names beginning with 'level_' within a MultiIndex. These are used by default in DataFrame.to_json() to indicate missing values and the subsequent read cannot distinguish the intent.

In [291]: df.index.name = "index"

In [292]: df.to_json("test.json", orient="table")

In [293]: new_df = pd.read_json("test.json", orient="table")

In [294]: print(new_df.index.name)
None

2.4.3 HTML

Reading HTML content

Warning: We highly encourage you to read the HTML Table Parsing gotchas below regarding the issues surrounding the BeautifulSoup4/html5lib/lxml parsers.

The top-level read_html() function can accept an HTML string/file/URL and will parse HTML tables into list of pandas DataFrames. Let’s look at a few examples.

Note: read_html returns a list of DataFrame objects, even if there is only a single table contained in the HTML content.

Read a URL with no options:
In [295]: url = {
......: "https://raw.githubusercontent.com/pandas-dev/pandas/master/
......: "pandas/tests/io/data/html/spam.html"
......: }
......:
In [296]: dfs = pd.read_html(url)

In [297]: dfs
Out[297]:
[ Nutrient Unit Value per 100.0g oz 1 NLEA
˓→ serving 56g Unnamed: 4 Unnamed: 5
0 Proximates Proximates Proximates Proximates
→ Proximates Proximates Proximates Proximates
1 Water g 51.70
2 Energy kcal 176
3 Protein g 7.50
4 Total lipid (fat) g 13.40
.. ... ... ...
32 Fatty acids, total monounsaturated g 13.505
33 Fatty acids, total polyunsaturated g 2.019
34 Cholesterol mg 71
35 Other Other Other
36 Caffeine mg 0
[37 rows x 6 columns]

Read in the content of the “banklist.html” file and pass it to read_html as a string:

In [298]: with open(file_path, "r") as f:
......: dfs = pd.read_html(f.read())
......:

In [299]: dfs
Out[299]:
[ Bank Name City ST CERT
˓→ Acquiring Institution Closing Date Updated Date
0 Banks of Wisconsin d/b/a Bank of Kenosha Kenosha WI 35386
1 Central Arizona Bank Scottsdale AZ 34527
→ Western State Bank May 14, 2013 May 20, 2013
2 Synovus Bank May 10, 2013 May 21, 2013
3 Pisgah Community Bank Asheville NC 58701
→ Capital Bank, N.A. May 10, 2013 May 14, 2013
4 Douglas County Bank Douglasville GA 21649
→ Hamilton State Bank April 26, 2013 May 16, 2013

(continues on next page)
You can even pass in an instance of `StringIO` if you so desire:

```
In [300]: with open(file_path, "r") as f:
    .....:
    sio = StringIO(f.read())
    .....:

In [301]: dfs = pd.read_html(sio)

In [302]: dfs
```

```
Out[302]:

```

Note: The following examples are not run by the IPython evaluator due to the fact that having so many network-accessing functions slows down the documentation build. If you spot an error or an example that doesn’t run, please do not hesitate to report it over on pandas GitHub issues page.
Read a URL and match a table that contains specific text:

```python
match = "Metcalf Bank"
df_list = pd.read_html(url, match=match)
```

Specify a header row (by default `<th>` or `<td>` elements located within a `<thead>` are used to form the column index, if multiple rows are contained within `<thead>` then a MultiIndex is created); if specified, the header row is taken from the data minus the parsed header elements (`<th>` elements).

```python
dfs = pd.read_html(url, header=0)
```

Specify an index column:

```python
dfs = pd.read_html(url, index_col=0)
```

Specify a number of rows to skip:

```python
dfs = pd.read_html(url, skiprows=0)
```

Specify a number of rows to skip using a list (range works as well):

```python
dfs = pd.read_html(url, skiprows=range(2))
```

Specify an HTML attribute:

```python
dfs1 = pd.read_html(url, attrs={"id": "table"})
dfs2 = pd.read_html(url, attrs={"class": "sortable"})
print(np.array_equal(dfs1[0], dfs2[0]))  # Should be True
```

Specify values that should be converted to NaN:

```python
dfs = pd.read_html(url, na_values="No Acquirer")
```

Specify whether to keep the default set of NaN values:

```python
dfs = pd.read_html(url, keep_default_na=False)
```

Specify converters for columns. This is useful for numerical text data that has leading zeros. By default columns that are numerical are cast to numeric types and the leading zeros are lost. To avoid this, we can convert these columns to strings.

```python
url_mcc = "https://en.wikipedia.org/wiki/Mobile_country_code"
dfs = pd.read_html(
    url_mcc,
    match="Telekom Albania",
    header=0,
    converters={"MNC": str},
)
```

Use some combination of the above:

```python
dfs = pd.read_html(url, match="Metcalf Bank", index_col=0)
```

Read in pandas `to_html` output (with some loss of floating point precision):

```python
df = pd.DataFrame(np.random.randn(2, 2))
s = df.to_html(float_format="{0:.40g}".format)
dfin = pd.read_html(s, index_col=0)
```
The *lxml* backend will raise an error on a failed parse if that is the only parser you provide. If you only have a single parser you can provide just a string, but it is considered good practice to pass a list with one string if, for example, the function expects a sequence of strings. You may use:

```python
dfs = pd.read_html(url, "Metcalf Bank", index_col=0, flavor=["lxml"])
```

Or you could pass `flavor='lxml'` without a list:

```python
dfs = pd.read_html(url, "Metcalf Bank", index_col=0, flavor="lxml")
```

However, if you have *bs4* and *html5lib* installed and pass *None* or `['lxml', 'bs4']` then the parse will most likely succeed. Note that *as soon as a parse succeeds, the function will return.*

```python
dfs = pd.read_html(url, "Metcalf Bank", index_col=0, flavor=["lxml", "bs4"])
```

**Writing to HTML files**

*DataFrame* objects have an instance method `to_html` which renders the contents of the *DataFrame* as an HTML table. The function arguments are as in the method `to_string` described above.

**Note:** Not all of the possible options for *DataFrame.to_html* are shown here for brevity’s sake. See `to_html()` for the full set of options.

```python
In [303]: df = pd.DataFrame(np.random.randn(2, 2))
In [304]: df
Out[304]:
      0       1
0 -0.184744  0.496971
1 -0.856240  1.857977

In [305]: print(df.to_html())  # raw html
<table border="1" class="dataframe">
  <thead>
    <tr style="text-align: right;">
      <th></th>
      <th>0</th>
      <th>1</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <th>0</th>
      <td>-0.184744</td>
      <td>0.496971</td>
    </tr>
    <tr>
      <th>1</th>
      <td>-0.856240</td>
      <td>1.857977</td>
    </tr>
  </tbody>
</table>
```

**HTML:**

```html
316 Chapter 2. User Guide
```
The `columns` argument will limit the columns shown:

```
In [306]: print(df.to_html(columns=[0]))

<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;"> 
<th></th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<th>0</th>
<td>-0.184744</td>
</tr>
<tr>
<th>1</th>
<td>-0.856240</td>
</tr>
</tbody>
</table>
```

**HTML:**

`float_format` takes a Python callable to control the precision of floating point values:

```
In [307]: print(df.to_html(float_format="{0:.10f}".format))

<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;"> 
<th></th>
<th>0</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<th>0</th>
<td>-0.1847438576</td>
<td>0.4969711327</td>
</tr>
<tr>
<th>1</th>
<td>-0.8562396763</td>
<td>1.8579766508</td>
</tr>
</tbody>
</table>
```

**HTML:**

`bold_rows` will make the row labels bold by default, but you can turn that off:

```
In [308]: print(df.to_html(bold_rows=False))

<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;"> 
<th></th>
<th>0</th>
</tr>
</thead>
```

(continues on next page)
The `classes` argument provides the ability to give the resulting HTML table CSS classes. Note that these classes are **appended** to the existing `'dataframe'` class.

```
In [309]: print(df.to_html(classes=["awesome_table_class", "even_more_awesome_class "]))
```
HTML:

Finally, the `escape` argument allows you to control whether the “<”, “>” and “&” characters escaped in the resulting HTML (by default it is `True`). So to get the HTML without escaped characters pass `escape=False`

```python
In [312]: df = pd.DataFrame({"a": list("&<>"), "b": np.random.randn(3)})
```

Escaped:

```python
In [313]: print(df.to_html())
```
Not escaped:

```python
In [314]: print(df.to_html(escape=False))

<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;">    
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<th>0</th>
<td>&</td>
<td>-0.474063</td>
</tr>
<tr>
<th>1</th>
<td><</td>
<td>-0.230305</td>
</tr>
<tr>
<th>2</th>
<td>></td>
<td>-0.400654</td>
</tr>
</tbody>
</table>
```

**Note:** Some browsers may not show a difference in the rendering of the previous two HTML tables.

### HTML Table Parsing Gotchas

There are some versioning issues surrounding the libraries that are used to parse HTML tables in the top-level pandas io function `read_html`.

**Issues with lxml**

- **Benefits**
  - lxml is very fast.
  - lxml requires Cython to install correctly.

- **Drawbacks**
  - lxml does not make any guarantees about the results of its parse unless it is given strictly valid markup.
  - In light of the above, we have chosen to allow you, the user, to use the lxml backend, but this backend will use html5lib if lxml fails to parse.
  - It is therefore highly recommended that you install both BeautifulSoup4 and html5lib, so that you will still get a valid result (provided everything else is valid) even if lxml fails.
Issues with Beautiful Soup 4 using lxml as a backend

- The above issues hold here as well since Beautiful Soup 4 is essentially just a wrapper around a parser backend.

Issues with Beautiful Soup 4 using html5lib as a backend

- Benefits
  - html5lib is far more lenient than lxml and consequently deals with real-life markup in a much saner way rather than just, e.g., dropping an element without notifying you.
  - html5lib generates valid HTML5 markup from invalid markup automatically. This is extremely important for parsing HTML tables, since it guarantees a valid document. However, that does NOT mean that it is “correct”, since the process of fixing markup does not have a single definition.
  - html5lib is pure Python and requires no additional build steps beyond its own installation.

- Drawbacks
  - The biggest drawback to using html5lib is that it is slow as molasses. However consider the fact that many tables on the web are not big enough for the parsing algorithm runtime to matter. It is more likely that the bottleneck will be in the process of reading the raw text from the URL over the web, i.e., IO (input-output). For very large tables, this might not be true.

2.4.4 LaTeX

New in version 1.3.0.

Currently there are no methods to read from LaTeX, only output methods.

Writing to LaTeX files

Note: DataFrame and Styler objects currently have a `to_latex` method. We recommend using the `Styler.to_latex()` method over `DataFrame.to_latex()` due to the former’s greater flexibility with conditional styling, and the latter’s possible future deprecation.

Review the documentation for `Styler.to_latex`, which gives examples of conditional styling and explains the operation of its keyword arguments.

For simple application the following pattern is sufficient.

```python
In [315]: df = pd.DataFrame([[1, 2], [3, 4]], index=["a", "b"], columns=["c", "d"])

In [316]: print(df.style.to_latex())
\begin{tabular}{lrr}
{} & {c} & {d} \\
\hline
a & 1 & 2 \\
b & 3 & 4 \\
\hline
\end{tabular}
```

To format values before output, chain the `Styler.format` method.

```python
In [317]: print(df.style.format("C {}").to_latex())
\begin{tabular}{lrr}
{} & {c} & {d} \\
\hline
a & C 1 & C 2 \\
\hline
\end{tabular}
```

(continues on next page)
2.4.5 XML

Reading XML

New in version 1.3.0.

The top-level `read_xml()` function can accept an XML string/file/URL and will parse nodes and attributes into a pandas DataFrame.

**Note:** Since there is no standard XML structure where design types can vary in many ways, `read_xml` works best with flatter, shallow versions. If an XML document is deeply nested, use the stylesheet feature to transform XML into a flatter version.

Let's look at a few examples.

Read an XML string:

```python
In [318]: xml = """"<?xml version="1.0" encoding="UTF-8"?>
......: <bookstore>
......:     <book category="cooking">
......:         <title lang="en">Everyday Italian</title>
......:         <author>Giada De Laurentiis</author>
......:         <year>2005</year>
......:         <price>30.00</price>
......:     </book>
......:     <book category="children">
......:         <title lang="en">Harry Potter</title>
......:         <author>J K. Rowling</author>
......:         <year>2005</year>
......:         <price>29.99</price>
......:     </book>
......:     <book category="web">
......:         <title lang="en">Learning XML</title>
......:         <author>Erik T. Ray</author>
......:         <year>2003</year>
......:         <price>39.95</price>
......:     </book>
......: </bookstore>"
```

```python
In [319]: df = pd.read_xml(xml)
```

```python
In [320]: df
Out[320]:
   category  title               author     year  price
0    cooking Everyday Italian Giada De Laurentiis 2005   30.00
2      web            Learning XML         Erik T. Ray 2003   39.95
```

Read a URL with no options:
In [321]: df = pd.read_xml("https://www.w3schools.com/xml/books.xml")

In [322]: df
Out[322]:
category   title            author       year    price  cover
0  cooking  Everyday Italian Giada De Laurentiis 2005  30.00  None
1   children Harry Potter         J K. Rowling 2005  29.99  None
2      web       XQuery Kick Start Vaidyanathan Nagarajan 2003  49.99  None
3      web            Learning XML           Erik T. Ray 2003  39.95  paperback

Read in the content of the “books.xml” file and pass it to read_xml as a string:

In [323]: with open(file_path, "r") as f:
.....:     df = pd.read_xml(f.read())
.....:

In [324]: df
Out[324]:
category        title            author       year    price
0  cooking  Everyday Italian Giada De Laurentiis 2005  30.00
2      web       XQuery Kick Start Vaidyanathan Nagarajan 2003  49.99
3      web            Learning XML           Erik T. Ray 2003  39.95

Read in the content of the “books.xml” as instance of StringIO or BytesIO and pass it to read_xml:

In [325]: with open(file_path, "r") as f:
.....:     sio = StringIO(f.read())
.....:

In [326]: df = pd.read_xml(sio)

In [327]: df
Out[327]:
category        title            author       year    price
0  cooking  Everyday Italian Giada De Laurentiis 2005  30.00
2      web       XQuery Kick Start Vaidyanathan Nagarajan 2003  49.99
3      web            Learning XML           Erik T. Ray 2003  39.95

In [328]: with open(file_path, "rb") as f:
.....:     bio = BytesIO(f.read())
.....:

In [329]: df = pd.read_xml(bio)

In [330]: df
Out[330]:
category        title            author       year    price
0  cooking  Everyday Italian Giada De Laurentiis 2005  30.00
2      web       XQuery Kick Start Vaidyanathan Nagarajan 2003  49.99
3      web            Learning XML           Erik T. Ray 2003  39.95

Even read XML from AWS S3 buckets such as Python Software Foundation’s IRS 990 Form:

In [331]: df = pd.read_xml(
.....:     "s3://irs-form-990/201923199349319487_public.xml",
.....:     xpath="//irs:Form990PartVIISectionAGrp",
.....:     namespaces={"irs": "http://www.irs.gov/efile"})

(continues on next page)
.....: )
.....:

In [332]: df
Out[332]:

<table>
<thead>

[21 rows x 10 columns]

With `lxml` as default parser, you access the full-featured XML library that extends Python’s `ElementTree` API. One powerful tool is ability to query nodes selectively or conditionally with more expressive XPath:

```python
In [333]: df = pd.read_xml(file_path, xpath="//book[year=2005]")
```

```python
In [334]: df
Out[334]:

<table>
<thead>
<tr>
<th>category</th>
<th>title</th>
<th>author</th>
<th>year</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>cooking</td>
<td>Everyday Italian</td>
<td>Giada De Laurentiis</td>
<td>2005</td>
<td>30.00</td>
</tr>
</tbody>
</table>
```

Specify only elements or only attributes to parse:

```python
In [335]: df = pd.read_xml(file_path, elems_only=True)
```

```python
In [336]: df
Out[336]:

<table>
<thead>
<tr>
<th>title</th>
<th>author</th>
<th>year</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>Everyday Italian</td>
<td>Giada De Laurentiis</td>
<td>2005</td>
<td>30.00</td>
</tr>
<tr>
<td>Harry Potter</td>
<td>J K. Rowling</td>
<td>2005</td>
<td>29.99</td>
</tr>
<tr>
<td>Learning XML</td>
<td>Erik T. Ray</td>
<td>2003</td>
<td>39.95</td>
</tr>
</tbody>
</table>
```

```python
In [337]: df = pd.read_xml(file_path, attrs_only=True)
```
XML documents can have namespaces with prefixes and default namespaces without prefixes both of which are denoted with a special attribute `xmlns`. In order to parse by node under a namespace context, `xpath` must reference a prefix.

For example, below XML contains a namespace with prefix, `doc`, and URI at `https://example.com`. In order to parse `doc:row` nodes, namespaces must be used.

```python
In [339]: xml = """<?xml version='1.0' encoding='utf-8'?>
.....: <doc:data xmlns:doc="https://example.com">
.....:   <doc:row>
.....:     <doc:shape>square</doc:shape>
.....:     <doc:degrees>360</doc:degrees>
.....:     <doc:sides>4.0</doc:sides>
.....:   </doc:row>
.....:   <doc:row>
.....:     <doc:shape>circle</doc:shape>
.....:     <doc:degrees>360</doc:degrees>
.....:     <doc:sides/>
.....:   </doc:row>
.....:   <doc:row>
.....:     <doc:shape>triangle</doc:shape>
.....:     <doc:degrees>180</doc:degrees>
.....:     <doc:sides>3.0</doc:sides>
.....:   </doc:row>
.....: </doc:data>""
.....:
```

```python
In [340]: df = pd.read_xml(xml,
.....:                    xpath="//doc:row",
.....:                    namespaces={"doc": "https://example.com"})
```

```python
In [341]: df
Out[341]:
       shape  degrees  sides
0     square   360    4.0
1      circle   360     NaN
2  triangle   180    3.0
```

Similarly, an XML document can have a default namespace without prefix. Failing to assign a temporary prefix will return no nodes and raise a `ValueError`. But assigning any temporary name to correct URI allows parsing by nodes.

```python
In [342]: xml = """<?xml version='1.0' encoding='utf-8'?>
.....: <data xmlns="https://example.com">
.....:   <row>
.....:     <shape>square</shape>
.....:     <degrees>360</degrees>
.....:     <sides>4.0</sides>
.....:   </row>
.....:   <row>
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.1

(continued from previous page)

.....:
<shape>circle</shape>
.....:
<degrees>360</degrees>
.....:
<sides/>
.....: </row>
.....: <row>
.....:
<shape>triangle</shape>
.....:
<degrees>180</degrees>
.....:
<sides>3.0</sides>
.....: </row>
.....: </data>"""
.....:
In [343]: df = pd.read_xml(xml,
.....:
xpath="//pandas:row",
.....:
namespaces={"pandas": "https://example.com"})
.....:
In [344]: df
Out[344]:
shape degrees
0
square
360
1
circle
360
2 triangle
180

sides
4.0
NaN
3.0

However, if XPath does not reference node names such as default, /*, then namespaces is not required.
With lxml as parser, you can flatten nested XML documents with an XSLT script which also can be string/file/URL
types. As background, XSLT is a special-purpose language written in a special XML file that can transform original
XML documents into other XML, HTML, even text (CSV, JSON, etc.) using an XSLT processor.
For example, consider this somewhat nested structure of Chicago “L” Rides where station and rides elements encapsulate data in their own sections. With below XSLT, lxml can transform original nested document into a flatter output
(as shown below for demonstration) for easier parse into DataFrame:
In [345]: xml = """<?xml version='1.0' encoding='utf-8'?>

Writing XML

New in version 1.3.0.

DataFrames have an instance method `to_xml` which renders the contents of the DataFrame as an XML document.

**Note:** This method does not support special properties of XML including DTD, CData, XSD schemas, processing instructions, comments, and others. Only namespaces at the root level is supported. However, `stylesheet` allows design changes after initial output.

Let's look at a few examples.

Write an XML without options:

**In [350]:** geom_df = pd.DataFrame(  
.....:   {  
.....:     "shape": ["square", "circle", "triangle"],  
.....:     "degrees": [360, 360, 180],  
.....:     "sides": [4, np.nan, 3],  
.....:   }  
.....: )  
.....:  

**In [351]:** print(geom_df.to_xml())

```xml
<?xml version='1.0' encoding='utf-8'?>
<data>
  <row>
    <index>0</index>
    <shape>square</shape>
    <degrees>360</degrees>
    <sides>4.0</sides>
  </row>
  <row>
    <index>1</index>
    <shape>circle</shape>
    <degrees>360</degrees>
    <sides/>
  </row>
  <row>
    <index>2</index>
  </row>
</data>
```
Write an XML with new root and row name:

```python
In [352]: print(geom_df.to_xml(root_name="geometry", row_name="objects"))
<?xml version='1.0' encoding='utf-8'?>
<geometry>
  <objects>
    <index>0</index>
    <shape>square</shape>
    <degrees>360</degrees>
    <sides>4.0</sides>
  </objects>
  <objects>
    <index>1</index>
    <shape>circle</shape>
    <degrees>360</degrees>
    <sides/>
  </objects>
  <objects>
    <index>2</index>
    <shape>triangle</shape>
    <degrees>180</degrees>
    <sides>3.0</sides>
  </objects>
</geometry>
```

Write an attribute-centric XML:

```python
In [353]: print(geom_df.to_xml(attr_cols=geom_df.columns.tolist()))
<?xml version='1.0' encoding='utf-8'?>
<data>
  <row index="0" shape="square" degrees="360" sides="4.0"/>
  <row index="1" shape="circle" degrees="360"/>
  <row index="2" shape="triangle" degrees="180" sides="3.0"/>
</data>
```

Write a mix of elements and attributes:

```python
In [354]: print(geom_df.to_xml(index=False, attr_cols=['shape'], elem_cols=['degrees', 'sides']))
<?xml version='1.0' encoding='utf-8'?>
<data>
  <row shape="square">
    <degrees>360</degrees>
    <sides>4.0</sides>
  </row>
  <row shape="circle">
```

(continues on next page)
Any DataFrames with hierarchical columns will be flattened for XML element names with levels delimited by underscores:

```python
In [355]: ext_geom_df = pd.DataFrame(
               .....:     
               .....:         "type": ["polygon", "other", "polygon"],
               .....:     "shape": ["square", "circle", "triangle"],
               .....:     "degrees": [360, 360, 180],
               .....:     "sides": [4, np.nan, 3],
               .....:     )
               .....:
In [356]: pvt_df = ext_geom_df.pivot_table(index='shape',
               .....:                 columns='type',
               .....:                 values=['degrees', 'sides'],
               .....:                 aggfunc='sum')
In [357]: pvt_df
Out[357]:
   degrees  sides
   type      other polygon other polygon
   shape    circle  360.0       NaN  0.0       NaN
            square  NaN  360.0       NaN  4.0
            triangle  NaN  180.0       NaN  3.0
In [358]: print(pvt_df.to_xml())
<?xml version='1.0' encoding='utf-8'?><data>
   <row>
      <shape>circle</shape>
      <degrees_other>360.0</degrees_other>
      <degrees_polygon/>
      <sides_other>0.0</sides_other>
      <sides_polygon/>
   </row>
   <row>
      <shape>square</shape>
      <degrees_other/>
      <degrees_polygon>360.0</degrees_polygon>
      <sides_other/>
      <sides_polygon>4.0</sides_polygon>
   </row>
   <row>
      <shape>triangle</shape>
```
Write an XML with default namespace:

```python
In [359]: print(geom_df.to_xml(namespaces={"": "https://example.com"}))
<?xml version='1.0' encoding='utf-8'?>
<data xmlns="https://example.com">
  <row>
    <index>0</index>
    <shape>square</shape>
    <degrees>360</degrees>
    <sides>4.0</sides>
  </row>
  <row>
    <index>1</index>
    <shape>circle</shape>
    <degrees>360</degrees>
    <sides/>
  </row>
  <row>
    <index>2</index>
    <shape>triangle</shape>
    <degrees>180</degrees>
    <sides>3.0</sides>
  </row>
</data>
```

Write an XML with namespace prefix:

```python
In [360]: print(
      .....: geom_df.to_xml(namespaces={"doc": "https://example.com"},
      .....: prefix="doc")
      .....: )
      .....: }
      .....: }
<?xml version='1.0' encoding='utf-8'?><doc:data xmlns:doc="https://example.com">
  <doc:row>
    <doc:index>0</doc:index>
    <doc:shape>square</doc:shape>
    <doc:degrees>360</doc:degrees>
    <doc:sides>4.0</doc:sides>
  </doc:row>
  <doc:row>
    <doc:index>1</doc:index>
    <doc:shape>circle</doc:shape>
    <doc:degrees>360</doc:degrees>
    <doc:sides/>
  </doc:row>
  <doc:row>
    <doc:index>2</doc:index>
    <doc:shape>triangle</doc:shape>
    <doc:degrees>180</doc:degrees>
    <doc:sides>3.0</doc:sides>
  </doc:row>
</doc:data>
```
Write an XML without declaration or pretty print:

```python
In [361]: print(geom_df.to_xml(xml_declaration=False, pretty_print=False))
```

```xml
<data><row><index>0</index><shape>square</shape><degrees>360</degrees><sides>4.0</sides></row><row><index>1</index><shape>circle</shape><degrees>360</degrees><sides/></row><row><index>2</index><shape>triangle</shape><degrees>180</degrees><sides>3.0</sides></row></data>
```

Write an XML and transform with stylesheet:

```python
In [362]: xsl = """"<xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
   .....:  <xsl:output method="xml" omit-xml-declaration="no" indent="yes"/>
   .....:  <xsl:strip-space elements="*"/>
   .....:  <xsl:template match="/data">
   .....:   <geometry>
   .....:    <xsl:apply-templates select="row"/>
   .....:   </geometry>
   .....:  </xsl:template>
   .....:  <xsl:template match="row">
   .....:   <object index="{index}">
   .....:    <xsl:if test="shape!='circle'">
   .....:     <xsl:attribute name="type">polygon</xsl:attribute>
   .....:    </xsl:if>
   .....:    <xsl:copy-of select="shape"/>
   .....:    <property>
   .....:     <xsl:copy-of select="degrees|sides"/>
   .....:    </property>
   .....:   </object>
   .....:  </xsl:template>
   .....: </xsl:stylesheet>"

In [363]: print(geom_df.to_xml(stylesheet=xsl))
```

```xml
<?xml version="1.0"?>
<geometry>
   <object index="0" type="polygon">
      <shape>square</shape>
      <property>
         <degrees>360</degrees>
         <sides>4.0</sides>
      </property>
   </object>
   <object index="1">
      <shape>circle</shape>
      <property>
         <degrees>360</degrees>
      </property>
   </object>
   <object index="2">
      <shape>triangle</shape>
      <property>
         <degrees>180</degrees>
         <sides>3.0</sides>
      </property>
   </object>
</geometry>
```
XML Final Notes

- All XML documents adhere to W3C specifications. Both etree and lxml parsers will fail to parse any markup document that is not well-formed or follows XML syntax rules. Do be aware HTML is not an XML document unless it follows XHTML specs. However, other popular markup types including KML, XAML, RSS, MusicML, MathML are compliant XML schemas.

- For above reason, if your application builds XML prior to pandas operations, use appropriate DOM libraries like etree and lxml to build the necessary document and not by string concatenation or regex adjustments. Always remember XML is a special text file with markup rules.

- With very large XML files (several hundred MBs to GBs), XPath and XSLT can become memory-intensive operations. Be sure to have enough available RAM for reading and writing to large XML files (roughly about 5 times the size of text).

- Because XSLT is a programming language, use it with caution since such scripts can pose a security risk in your environment and can run large or infinite recursive operations. Always test scripts on small fragments before full run.

- The etree parser supports all functionality of both read_xml and to_xml except for complex XPath and any XSLT. Though limited in features, etree is still a reliable and capable parser and tree builder. Its performance may trail lxml to a certain degree for larger files but relatively unnoticeable on small to medium size files.

2.4.6 Excel files

The read_excel() method can read Excel 2007+ (.xlsx) files using the openpyxl Python module. Excel 2003 (.xls) files can be read using xlrd. Binary Excel (.xlsb) files can be read using pyxlsb. The to_excel() instance method is used for saving a DataFrame to Excel. Generally the semantics are similar to working with csv data. See the cookbook for some advanced strategies.

**Warning:** The xlwt package for writing old-style .xls excel files is no longer maintained. The xlrd package is now only for reading old-style .xls files.

Before pandas 1.3.0, the default argument engine=None to read_excel() would result in using the xld engine in many cases, including new Excel 2007+ (.xlsx) files. pandas will now default to using the openpyxl engine.

It is strongly encouraged to install openpyxl to read Excel 2007+ (.xlsx) files. Please do not report issues when using "xlrd" to read "xlsx" files. This is no longer supported, switch to using openpyxl instead.

Attempting to use the the xlwt engine will raise a FutureWarning unless the option io.excel.xlswriter is set to "xlwt". While this option is now deprecated and will also raise a FutureWarning, it can
be globally set and the warning suppressed. Users are recommended to write .xlsx files using the openpyxl engine instead.

**Reading Excel files**

In the most basic use-case, `read_excel` takes a path to an Excel file, and the `sheet_name` indicating which sheet to parse.

```python
# Returns a DataFrame
pd.read_excel("path_to_file.xls", sheet_name="Sheet1")
```

**ExcelFile class**

To facilitate working with multiple sheets from the same file, the `ExcelFile` class can be used to wrap the file and can be passed into `read_excel` There will be a performance benefit for reading multiple sheets as the file is read into memory only once.

```python
xlsx = pd.ExcelFile("path_to_file.xls")
df = pd.read_excel(xlsx, "Sheet1")
```

The `ExcelFile` class can also be used as a context manager.

```python
with pd.ExcelFile("path_to_file.xls") as xls:
    df1 = pd.read_excel(xls, "Sheet1")
    df2 = pd.read_excel(xls, "Sheet2")
```

The `sheet_names` property will generate a list of the sheet names in the file.

The primary use-case for an `ExcelFile` is parsing multiple sheets with different parameters:

```python
data = {}
# For when Sheet1's format differs from Sheet2
with pd.ExcelFile("path_to_file.xls") as xls:
    data["Sheet1"] = pd.read_excel(xls, "Sheet1", index_col=None, na_values=["NA"])
    data["Sheet2"] = pd.read_excel(xls, "Sheet2", index_col=1)
```

Note that if the same parsing parameters are used for all sheets, a list of sheet names can simply be passed to `read_excel` with no loss in performance.

```python
# using the ExcelFile class
data = {}
with pd.ExcelFile("path_to_file.xls") as xls:
    data["Sheet1"] = pd.read_excel(xls, "Sheet1", index_col=None, na_values=["NA"])
    data["Sheet2"] = pd.read_excel(xls, "Sheet2", index_col=None, na_values=["NA"])

# equivalent using the read_excel function
data = pd.read_excel(
    "path_to_file.xls", ["Sheet1", "Sheet2"], index_col=None, na_values=["NA"])
```

ExcelFile can also be called with a `xlrd.book.Book` object as a parameter. This allows the user to control how the excel file is read. For example, sheets can be loaded on demand by calling `xlrd.open_workbook()` with `on_demand=True`. 

---

334 Chapter 2. User Guide
Specifying sheets

Note: The second argument is sheet_name, not to be confused with ExcelFile.sheet_names.

Note: An ExcelFile’s attribute sheet_names provides access to a list of sheets.

- The arguments sheet_name allows specifying the sheet or sheets to read.
- The default value for sheet_name is 0, indicating to read the first sheet
- Pass a string to refer to the name of a particular sheet in the workbook.
- Pass an integer to refer to the index of a sheet. Indices follow Python convention, beginning at 0.
- Pass a list of either strings or integers, to return a dictionary of specified sheets.
- Pass a None to return a dictionary of all available sheets.

```python
import pandas as pd
xlrd_book = xlrd.open_workbook("path_to_file.xls", on_demand=True)
with pd.ExcelFile(xlrd_book) as xls:
    df1 = pd.read_excel(xls, "Sheet1")
    df2 = pd.read_excel(xls, "Sheet2")
```

```python
# Returns a DataFrame
pd.read_excel("path_to_file.xls", "Sheet1", index_col=None, na_values=["NA"])  
```

Using the sheet index:

```python
# Returns a DataFrame
pd.read_excel("path_to_file.xls", 0, index_col=None, na_values=["NA"])  
```

Using all default values:

```python
# Returns a DataFrame
pd.read_excel("path_to_file.xls")  
```

Using None to get all sheets:

```python
# Returns a dictionary of DataFrames
pd.read_excel("path_to_file.xls", sheet_name=None)  
```

Using a list to get multiple sheets:

```python
# Returns the 1st and 4th sheet, as a dictionary of DataFrames.
pd.read_excel("path_to_file.xls", sheet_name=["Sheet1", 3])  
```

read_excel can read more than one sheet, by setting sheet_name to either a list of sheet names, a list of sheet positions, or None to read all sheets. Sheets can be specified by sheet index or sheet name, using an integer or string, respectively.
**Reading a MultiIndex**

`read_excel` can read a MultiIndex index, by passing a list of columns to `index_col` and a MultiIndex column by passing a list of rows to `header`. If either the index or columns have serialized level names those will be read in as well by specifying the rows/columns that make up the levels.

For example, to read in a MultiIndex index without names:

```python
In [364]: df = pd.DataFrame(
.....:    {"a": [1, 2, 3, 4], "b": [5, 6, 7, 8]},
.....:    index=pd.MultiIndex.from_product(["a", "b"], ["c", "d"]))
.....:
In [365]: df.to_excel("path_to_file.xlsx")
In [366]: df = pd.read_excel("path_to_file.xlsx", index_col=[0, 1])
In [367]: df
Out[367]:
   a  b
  a 1  5  
  d 2  6  
  b  c 3  7  
  d 4  8
```

If the index has level names, they will parsed as well, using the same parameters.

```python
In [368]: df.index = df.index.set_names(["lvl1", "lvl2"])
In [369]: df.to_excel("path_to_file.xlsx")
In [370]: df = pd.read_excel("path_to_file.xlsx", index_col=[0, 1])
In [371]: df
Out[371]:
   a  b
  lvl1 lvl2
  a  c 1  5  
  d 2  6  
  b  c 3  7  
  d 4  8
```

If the source file has both MultiIndex index and columns, lists specifying each should be passed to `index_col` and `header`:

```python
In [372]: df.columns = pd.MultiIndex.from_product(["a", "b", "d"], names=["c1", "c2"])
In [373]: df.to_excel("path_to_file.xlsx")
In [374]: df = pd.read_excel("path_to_file.xlsx", index_col=[0, 1], header=[0, 1])
In [375]: df
Out[375]:
   c1  a
   c2  b  d
  lvl1 lvl2
```

(continues on next page)
Parsing specific columns

It is often the case that users will insert columns to do temporary computations in Excel and you may not want to read in those columns. `read_excel` takes a `usecols` keyword to allow you to specify a subset of columns to parse.

Changed in version 1.0.0.

Passing in an integer for `usecols` will no longer work. Please pass in a list of ints from 0 to `usecols` inclusive instead.

You can specify a comma-delimited set of Excel columns and ranges as a string:

```python
def read_excel("path_to_file.xls", "Sheet1", usecols="A,C:E")
```

If `usecols` is a list of integers, then it is assumed to be the file column indices to be parsed.

```python
def read_excel("path_to_file.xls", "Sheet1", usecols=[0, 2, 3])
```

Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`.

If `usecols` is a list of strings, it is assumed that each string corresponds to a column name provided either by the user in `names` or inferred from the document header row(s). Those strings define which columns will be parsed:

```python
def read_excel("path_to_file.xls", "Sheet1", usecols=["foo", "bar"]
```

Element order is ignored, so `usecols=['baz', 'joe']` is the same as `['joe', 'baz']`.

If `usecols` is callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to `True`.

```python
def read_excel("path_to_file.xls", "Sheet1", usecols=\lambda x: x.isalpha())
```

Parsing dates

Datetime-like values are normally automatically converted to the appropriate dtype when reading the excel file. But if you have a column of strings that look like dates (but are not actually formatted as dates in excel), you can use the `parse_dates` keyword to parse those strings to datetimes:

```python
def read_excel("path_to_file.xls", "Sheet1", parse_dates=["date_strings"]
```
Cell converters

It is possible to transform the contents of Excel cells via the *converters* option. For instance, to convert a column to boolean:

```python
pd.read_excel("path_to_file.xls", "Sheet1", converters={"MyBools": bool})
```

This options handles missing values and treats exceptions in the converters as missing data. Transformations are applied cell by cell rather than to the column as a whole, so the array dtype is not guaranteed. For instance, a column of integers with missing values cannot be transformed to an array with integer dtype, because NaN is strictly a float. You can manually mask missing data to recover integer dtype:

```python
def cfun(x):
    return int(x) if x else -1

pd.read_excel("path_to_file.xls", "Sheet1", converters={"MyInts": cfun})
```

Dtype specifications

As an alternative to converters, the type for an entire column can be specified using the *dtype* keyword, which takes a dictionary mapping column names to types. To interpret data with no type inference, use the type *str* or *object*.

```python
pd.read_excel("path_to_file.xls", dtype={"MyInts": "int64", "MyText": str})
```

Writing Excel files

Writing Excel files to disk

To write a *DataFrame* object to a sheet of an Excel file, you can use the *to_excel* instance method. The arguments are largely the same as *to_csv* described above, the first argument being the name of the excel file, and the optional second argument the name of the sheet to which the *DataFrame* should be written. For example:

```python
df.to_excel("path_to_file.xlsx", sheet_name="Sheet1")
```

Files with a `.xls` extension will be written using *xlwt* and those with a `.xlsx` extension will be written using *xlsxwriter* (if available) or *openpyxl*.

The *DataFrame* will be written in a way that tries to mimic the REPL output. The *index_label* will be placed in the second row instead of the first. You can place it in the first row by setting the *merge_cells* option in *to_excel()* to *False*:

```python
df.to_excel("path_to_file.xlsx", index_label="label", merge_cells=False)
```

In order to write separate *DataFrames* to separate sheets in a single Excel file, one can pass an *ExcelWriter*.

```python
with pd.ExcelWriter("path_to_file.xlsx") as writer:
    df1.to_excel(writer, sheet_name="Sheet1")
    df2.to_excel(writer, sheet_name="Sheet2")
```
Writing Excel files to memory

pandas supports writing Excel files to buffer-like objects such as StringIO or BytesIO using ExcelWriter.

```python
from io import BytesIO

bio = BytesIO()

# By setting the 'engine' in the ExcelWriter constructor.
writer = pd.ExcelWriter(bio, engine="xlsxwriter")
df.to_excel(writer, sheet_name="Sheet1")

# Save the workbook
writer.save()

# Seek to the beginning and read to copy the workbook to a variable in memory
bio.seek(0)
workbook = bio.read()
```

**Note:** engine is optional but recommended. Setting the engine determines the version of workbook produced. Setting engine='xlrd' will produce an Excel 2003-format workbook (xls). Using either 'openpyxl' or 'xlsxwriter' will produce an Excel 2007-format workbook (xlsx). If omitted, an Excel 2007-formatted workbook is produced.

Excel writer engines

 Deprecated since version 1.2.0: As the xlwt package is no longer maintained, the xlwt engine will be removed from a future version of pandas. This is the only engine in pandas that supports writing to .xls files.

pandas chooses an Excel writer via two methods:

1. the engine keyword argument
2. the filename extension (via the default specified in config options)

By default, pandas uses the XlsxWriter for .xlsx, openpyxl for .xlsm, and xlwt for .xls files. If you have multiple engines installed, you can set the default engine through setting the config options `io.excel.xlsx.writer` and `io.excel.xls.writer`. pandas will fall back on openpyxl for .xlsx files if Xlsxwriter is not available.

To specify which writer you want to use, you can pass an engine keyword argument to `to_excel` and to `ExcelWriter`. The built-in engines are:

- openpyxl: version 2.4 or higher is required
- xlsxwriter
- xlwt

```python
# By setting the 'engine' in the DataFrame 'to_excel()' methods.
df.to_excel("path_to_file.xlsx", sheet_name="Sheet1", engine="xlsxwriter")

# By setting the 'engine' in the ExcelWriter constructor.
writer = pd.ExcelWriter("path_to_file.xlsx", engine="xlsxwriter")

# Or via pandas configuration.
from pandas import options # noqa: E402
```

(continues on next page)
options.io.excel.xlsx.writer = "xlsxwriter"
df.to_excel("path_to_file.xlsx", sheet_name="Sheet1")

Style and formatting

The look and feel of Excel worksheets created from pandas can be modified using the following parameters on the DataFrame’s `to_excel` method.

- `float_format`: Format string for floating point numbers (default `None`).
- `freeze_panes`: A tuple of two integers representing the bottommost row and rightmost column to freeze. Each of these parameters is one-based, so (1, 1) will freeze the first row and first column (default `None`).

Using the Xlsxwriter engine provides many options for controlling the format of an Excel worksheet created with the `to_excel` method. Excellent examples can be found in the Xlsxwriter documentation here: https://xlsxwriter.readthedocs.io/working_with_pandas.html

2.4.7 OpenDocument Spreadsheets

New in version 0.25.

The `read_excel()` method can also read OpenDocument spreadsheets using the odfpy module. The semantics and features for reading OpenDocument spreadsheets match what can be done for Excel files using `engine='odf'`.

```python
# Returns a DataFrame
pd.read_excel("path_to_file.ods", engine="odf")
```

**Note:** Currently pandas only supports reading OpenDocument spreadsheets. Writing is not implemented.

2.4.8 Binary Excel (.xlsb) files

New in version 1.0.0.

The `read_excel()` method can also read binary Excel files using the pyxlsb module. The semantics and features for reading binary Excel files mostly match what can be done for Excel files using `engine='pyxlsb'`. pyxlsb does not recognize datetime types in files and will return floats instead.

```python
# Returns a DataFrame
pd.read_excel("path_to_file.xlsb", engine="pyxlsb")
```

**Note:** Currently pandas only supports reading binary Excel files. Writing is not implemented.
2.4.9 Clipboard

A handy way to grab data is to use the `read_clipboard()` method, which takes the contents of the clipboard buffer and passes them to the `read_csv` method. For instance, you can copy the following text to the clipboard (CTRL-C on many operating systems):

```
A B C
x 1 4 p
y 2 5 q
z 3 6 r
```

And then import the data directly to a DataFrame by calling:

```
>>> clipdf = pd.read_clipboard()
>>> clipdf
   A  B  C
x 1  4  p
y 2  5  q
z 3  6  r
```

The `to_clipboard` method can be used to write the contents of a DataFrame to the clipboard. Following which you can paste the clipboard contents into other applications (CTRL-V on many operating systems). Here we illustrate writing a DataFrame into clipboard and reading it back.

```
>>> df = pd.DataFrame(...
            {"A": [1, 2, 3], "B": [4, 5, 6], "C": ["p", "q", "r"],
             index=["x", "y", "z"]
            }...
            )
>>> df
   A  B  C
x 1  4  p
y 2  5  q
z 3  6  r
>>> df.to_clipboard()
>>> pd.read_clipboard()
   A  B  C
x 1  4  p
y 2  5  q
z 3  6  r
```

We can see that we got the same content back, which we had earlier written to the clipboard.

**Note:** You may need to install xclip or xsel (with PyQt5, PyQt4 or qtpy) on Linux to use these methods.

2.4.10 Pickling

All pandas objects are equipped with `to_pickle` methods which use Python's `cPickle` module to save data structures to disk using the pickle format.

```
In [376]: df
Out[376]:
c1    a
c2    b  d
lvl1  lvl2
```

(continues on next page)
The `read_pickle` function in the pandas namespace can be used to load any pickled pandas object (or any other pickled object) from file:

```python
In [378]: pd.read_pickle("foo.pkl")
Out[378]:
   cl  a
   c2 b d
   lvl1 lvl2
   a c 1 5
d 2 6
   b c 3 7
d 4 8
```

**Warning:** Loading pickled data received from untrusted sources can be unsafe.

See: https://docs.python.org/3/library/pickle.html

**Warning:** `read_pickle()` is only guaranteed backwards compatible back to pandas version 0.20.3

### Compressed pickle files

`read_pickle()`, `DataFrame.to_pickle()` and `Series.to_pickle()` can read and write compressed pickle files. The compression types of gzip, bz2, xz are supported for reading and writing. The zip file format only supports reading and must contain only one data file to be read.

The compression type can be an explicit parameter or be inferred from the file extension. If 'infer', then use gzip, bz2, zip, or xz if filename ends in '.gz', '.bz2', '.zip', or '.xz', respectively.

The compression parameter can also be a `dict` in order to pass options to the compression protocol. It must have a 'method' key set to the name of the compression protocol, which must be one of {'zip', 'gzip', 'bz2'}. All other key-value pairs are passed to the underlying compression library.

```python
In [379]: df = pd.DataFrame({
    ...:     "A": np.random.randn(1000),
    ...:     "B": "foo",
    ...:     "C": pd.date_range("20130101", periods=1000, freq="s"),
    ...: )
In [380]: df
Out[380]:
     A     B         C
0 -0.288267 foo 2013-01-01 00:00:00
```
Using an explicit compression type:

```
In [381]: df.to_pickle("data.pkl.compress", compression="gzip")
In [382]: rt = pd.read_pickle("data.pkl.compress", compression="gzip")
In [383]: rt
Out[383]:
   A    B    C
0 -0.288267 foo 2013-01-01 00:00:00
1 -0.084905 foo 2013-01-01 00:00:01
2  0.004772 foo 2013-01-01 00:00:02
3  1.382989 foo 2013-01-01 00:00:03
4  0.343635 foo 2013-01-01 00:00:04
...     ...     ... ...
995 -0.220893 foo 2013-01-01 00:16:35
996  0.492996 foo 2013-01-01 00:16:36
997 -0.461625 foo 2013-01-01 00:16:37
998  1.361779 foo 2013-01-01 00:16:38
999 -1.197988 foo 2013-01-01 00:16:39
[1000 rows x 3 columns]
```

Inferring compression type from the extension:

```
In [384]: df.to_pickle("data.pkl.xz", compression="infer")
In [385]: rt = pd.read_pickle("data.pkl.xz", compression="infer")
In [386]: rt
Out[386]:
   A    B    C
0 -0.288267 foo 2013-01-01 00:00:00
1 -0.084905 foo 2013-01-01 00:00:01
2  0.004772 foo 2013-01-01 00:00:02
3  1.382989 foo 2013-01-01 00:00:03
4  0.343635 foo 2013-01-01 00:00:04
...     ...     ... ...
995 -0.220893 foo 2013-01-01 00:16:35
996  0.492996 foo 2013-01-01 00:16:36
997 -0.461625 foo 2013-01-01 00:16:37
998  1.361779 foo 2013-01-01 00:16:38
999 -1.197988 foo 2013-01-01 00:16:39
[1000 rows x 3 columns]
```
The default is to ‘infer’:

```
In [387]: df.to_pickle("data.pkl.gz")

In [388]: rt = pd.read_pickle("data.pkl.gz")

In [389]: rt
Out[389]:
      A         B             C
0  0.288267  foo 2013-01-01 00:00:00
1  0.084905  foo 2013-01-01 00:00:01
2  0.004772  foo 2013-01-01 00:00:02
3  1.382989  foo 2013-01-01 00:00:03
4  0.343635  foo 2013-01-01 00:00:04
   ... ... ... ... ...
995 -0.220893  foo 2013-01-01 00:16:35
996  0.492996  foo 2013-01-01 00:16:36
997 -0.461625  foo 2013-01-01 00:16:37
998  1.361779  foo 2013-01-01 00:16:38
999 -1.197988  foo 2013-01-01 00:16:39
[1000 rows x 3 columns]
```

```
In [390]: df["A"].to_pickle("s1.pkl.bz2")

In [391]: rt = pd.read_pickle("s1.pkl.bz2")

In [392]: rt
Out[392]:
            A
0  -0.288267
1  -0.084905
2   0.004772
3   1.382989
4   0.343635
   ... ...
995 -0.220893
996  0.492996
997 -0.461625
998  1.361779
999 -1.197988
Name: A, Length: 1000, dtype: float64
```

Passing options to the compression protocol in order to speed up compression:

```
In [393]: df.to_pickle("data.pkl.gz", compression={"method": "gzip", "compresslevel": 1})
```
2.4.11 msgpack

pandas support for msgpack has been removed in version 1.0.0. It is recommended to use pickle instead. Alternatively, you can also the Arrow IPC serialization format for on-the-wire transmission of pandas objects. For documentation on pyarrow, see here.

2.4.12 HDF5 (PyTables)

HDFStore is a dict-like object which reads and writes pandas using the high performance HDF5 format using the excellent PyTables library. See the cookbook for some advanced strategies.

**Warning:** pandas uses PyTables for reading and writing HDF5 files, which allows serializing object-dtype data with pickle. Loading pickled data received from untrusted sources can be unsafe.

See: https://docs.python.org/3/library/pickle.html for more.

In [394]: store = pd.HDFStore("store.h5")

In [395]: print(store)
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

Objects can be written to the file just like adding key-value pairs to a dict:

In [396]: index = pd.date_range("1/1/2000", periods=8)
In [397]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e"])
In [398]: df = pd.DataFrame(np.random.randn(8, 3), index=index, columns=["A", "B", "C"])

# store.put('s', s) is an equivalent method
In [399]: store["s"] = s
In [400]: store["df"] = df

In [401]: store
Out[401]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

In a current or later Python session, you can retrieve stored objects:

# store.get('df') is an equivalent method
In [402]: store["df"]

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>1.334065</td>
<td>0.521036</td>

</tbody>
</table>
Read/write API

HDFStore supports a top-level API using read_hdf for reading and to_hdf for writing, similar to how read_csv and to_csv work.

In [410]: df_tl = pd.DataFrame({'A': list(range(5)), 'B': list(range(5)))

In [411]: df_tl.to_hdf("store_tl.h5", "table", append=True)

In [412]: pd.read_hdf("store_tl.h5", "table", where=["index>2"])

Out[412]:
         A   B
2000-01-08  0.649464 -1.736427  0.197288
HDFStore will by default not drop rows that are all missing. This behavior can be changed by setting dropna=True.

```python
In [413]: df_with_missing = pd.DataFrame(
        .....:
        .....:
        "col1": [0, np.nan, 2],
        .....:
        "col2": [1, np.nan, np.nan],
        .....:
        )
        .....:
In [414]: df_with_missing
Out[414]:
   col1  col2
0   0.0   1.0
1   NaN   NaN
2   2.0   NaN
```

```python
In [415]: df_with_missing.to_hdf("file.h5", "df_with_missing", format="table", mode="w")
```

```python
In [416]: pd.read_hdf("file.h5", "df_with_missing")
Out[416]:
   col1  col2
0   0.0   1.0
1   NaN   NaN
2   2.0   NaN
```

```python
In [417]: df_with_missing.to_hdf(  .....:
In [418]: pd.read_hdf("file.h5", "df_with_missing")
```

**Fixed format**

The examples above show storing using put, which write the HDF5 to PyTables in a fixed array format, called the fixed format. These types of stores are not appendable once written (though you can simply remove them and rewrite). Nor are they *queryable*: they must be retrieved in their entirety. They also do not support dataframes with non-unique column names. The fixed format stores offer very fast writing and slightly faster reading than table stores. This format is specified by default when using put or to_hdf or by format='fixed' or format='f'.

**Warning:** A fixed format will raise a `TypeError` if you try to retrieve using a where:

```python
>>> pd.DataFrame(np.random.randn(10, 2)).to_hdf("test_fixed.h5", "df")
>>> pd.read_hdf("test_fixed.h5", "df", where="index>5")
TypeError: cannot pass a where specification when reading a fixed format.
this store must be selected in its entirety
```
Table format

HDFStore supports another PyTables format on disk, the table format. Conceptually a table is shaped very much like a DataFrame, with rows and columns. A table may be appended to in the same or other sessions. In addition, delete and query type operations are supported. This format is specified by format='table' or format='t' to append or put or to_hdf.

This format can be set as an option as well pd.set_option('io.hdf.default_format','table') to enable put/append/to_hdf to by default store in the table format.

In [419]: store = pd.HDFStore("store.h5")
In [420]: df1 = df[0:4]
In [421]: df2 = df[4:]
# append data (creates a table automatically)
In [422]: store.append("df", df1)
In [423]: store.append("df", df2)
In [424]: store
Out[424]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# select the entire object
In [425]: store.select("df")
Out[425]:
   A       B       C
0 2000-01-01 1.334065 0.521036 0.930384
1 2000-01-02 -1.613932 1.088104 -0.632963
2 2000-01-03 -0.585314 -0.275038 -0.937512
3 2000-01-04  0.632369 -1.249657  0.975593
4 2000-01-05  1.060617 -0.143682  0.218423
5 2000-01-06  3.050329  1.317933 -0.963725
6 2000-01-07 -0.539452 -0.771133  0.023751
7 2000-01-08  0.649464 -1.736427  0.197288

# the type of stored data
In [426]: store.root.df._v_attrs.pandas_type
Out[426]: 'frame_table'

Note: You can also create a table by passing format='table' or format='t' to a put operation.
Hierarchical keys

Keys to a store can be specified as a string. These can be in a hierarchical path-name like format (e.g. `foo/bar/bah`), which will generate a hierarchy of sub-stores (or Groups in PyTables parlance). Keys can be specified without the leading ‘/’ and are always absolute (e.g. ‘foo’ refers to ‘/foo’). Removal operations can remove everything in the sub-store and below, so be careful.

```
In [427]: store.put("foo/bar/bah", df)
In [428]: store.append("food/orange", df)
In [429]: store.append("food/apple", df)
In [430]: store
Out[430]: <class 'pandas.io.pytables.HDFStore'>
File path: store.h5
# a list of keys are returned
In [431]: store.keys()
Out[431]: ['/df', '/food/apple', '/food/orange', '/foo/bar/bah']
# remove all nodes under this level
In [432]: store.remove("food")
In [433]: store
Out[433]: <class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

You can walk through the group hierarchy using the `walk` method which will yield a tuple for each group key along with the relative keys of its contents.

```
In [434]: for (path, subgroups, subkeys) in store.walk():
    ....:     for subgroup in subgroups:
    ....:         print("GROUP: {}/{}").format(path, subgroup))
    ....:     for subkey in subkeys:
    ....:         key = "/".join([path, subkey])
    ....:         print("KEY: {}/{}").format(key))
    ....:         print(store.get(key))
GROUP: /foo
KEY: /df
   A     B     C
2000-01-01  1.334065  0.521036  0.930384
2000-01-02  1.613932  1.088104 -0.632963
2000-01-03  0.585314  0.275038  0.937512
2000-01-04  0.632369  1.249657  0.975593
2000-01-05  1.060617  0.143682  0.218423
2000-01-06  3.050329  1.317933 -0.963725
2000-01-07  0.539452  0.771133  0.023751
2000-01-08  0.649464  1.736427  0.197288
GROUP: /foo/bar
KEY: /foo/bar/bah
   A     B     C
2000-01-01  1.334065  0.521036  0.930384
2000-01-02  1.613932  1.088104 -0.632963
(continues on next page)```

2.4. IO tools (text, CSV, HDF5, …)
**Warning:** Hierarchical keys cannot be retrieved as dotted (attribute) access as described above for items stored under the root node.

```python
In [8]: store.foo.bar.bah
AttributeError: 'HDFStore' object has no attribute 'foo'
```

You can directly access the actual PyTables node but using the root node

```python
In [9]: store.root.foo.bar.bah
Out[9]:
/foo/bar/bah (Group) ''
    children := ['block0_items' (Array), 'block0_values' (Array), 'axis0' (Array),
      'axis1' (Array)]
```

Instead, use explicit string based keys:

```python
In [435]: store["foo/bar/bah"]
Out[435]:
     A         B         C
2000-01-01  1.334065  0.521036  0.930384
2000-01-02 -1.613932  1.088104 -0.632963
2000-01-03 -0.585314 -0.275038 -0.937512
2000-01-04  0.632369 -1.249657  0.975593
2000-01-05  1.060617 -0.143682  0.218423
2000-01-06  3.050329  1.317933 -0.963725
2000-01-07 -0.539452 -0.771133  0.023751
2000-01-08  0.649464 -1.736427  0.197288
```

### Storing types

#### Storing mixed types in a table

Storing mixed-dtype data is supported. Strings are stored as a fixed-width using the maximum size of the appended column. Subsequent attempts at appending longer strings will raise a `ValueError`.

Passing `min_itemsize={‘values’: size}` as a parameter to append will set a larger minimum for the string columns. Storing floats, strings, ints, bools, datetime64 are currently supported. For string columns, passing `nan_rep = ‘nan’` to append will change the default nan representation on disk (which converts to/from np.nan), this defaults to nan.

```python
In [436]: df_mixed = pd.DataFrame(  
    .....:     .....:
    .....:       "A": np.random.randn(8),  
    .....:       "B": np.random.randn(8),  
    .....:       "C": np.array(np.random.randn(8), dtype="float32"),  
    .....:       "string": "string",  
    .....:       "int": 1,
```

(continues on next page)
In [437]: df_mixed.loc[df_mixed.index[3:5], ["A", "B", "string", "datetime64"]] = np.nan

In [438]: store.append("df_mixed", df_mixed, min_itemsize={"values": 50})

In [439]: df_mixed1 = store.select("df_mixed")

In [440]: df_mixed1
Out[440]:
   A     B     C   string       int   bool     datetime64
0 -0.116008 0.743946 -0.398501  string   1   True 2001-01-02

   autoindex := True
   colindexes := {
    "index": Index(6, medium, shuffle, zlib(1)).is_csi=False}
Storing MultiIndex DataFrames

Storing MultiIndex DataFrames as tables is very similar to storing/selecting from homogeneous index DataFrames.

```python
In [443]: index = pd.MultiIndex(
    .....:     levels=["foo", "bar", "baz", "qux"], ["one", "two", "three"],
    .....:     codes=[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3], [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],
    .....:     names=["foo", "bar"],
    .....: )

In [444]: df_mi = pd.DataFrame(np.random.randn(10, 3), index=index, columns=["A", "B", "C"])

In [445]: df_mi
Out[445]:
         A          B          C
foo     bar
foo one  0.667450  0.169405 -1.358046
  two -0.105563  0.492195  0.076693
  three 0.213685 -0.285283 -1.210529
bar one -1.408386  0.941577 -0.342447
  two 0.222031  0.052607  2.093214
  three 1.064908  1.778161 -0.913867
baz one -0.030004 -0.399846 -1.234765
  two 0.081323 -0.268494  0.168016
  three  0.898283 -0.218499  1.408028
qux one  0.081323 -0.268494  0.168016
  two -0.898283 -0.218499  1.408028
  three -1.267828 -0.689263  0.520995

In [446]: store.append("df_mi", df_mi)

In [447]: store.select("df_mi")
Out[447]:
         A          B          C
foo     bar
foo one  0.667450  0.169405 -1.358046
  two -0.105563  0.492195  0.076693

  three 1.064908  1.778161 -0.913867
baz one -0.030004 -0.399846 -1.234765
  two 0.081323 -0.268494  0.168016
  three  0.898283 -0.218499  1.408028
qux one  0.081323 -0.268494  0.168016
  two -0.898283 -0.218499  1.408028
  three -1.267828 -0.689263  0.520995

Note: The index keyword is reserved and cannot be use as a level name.
Querying

Querying a table

select and delete operations have an optional criterion that can be specified to select/delete only a subset of the data. This allows one to have a very large on-disk table and retrieve only a portion of the data.

A query is specified using the Term class under the hood, as a boolean expression.

- index and columns are supported indexers of DataFrames.
- if data columns are specified, these can be used as additional indexers.
- level name in a MultiIndex, with default name level_0, level_1,... if not provided.

Valid comparison operators are:
=, ==, !=, >, >=, <, <=

Valid boolean expressions are combined with:

- |: or
- &: and
- ( and ) : for grouping

These rules are similar to how boolean expressions are used in pandas for indexing.

Note:

- = will be automatically expanded to the comparison operator ==
- ~ is the not operator, but can only be used in very limited circumstances
- If a list/tuple of expressions is passed they will be combined via &

The following are valid expressions:

- 'index >= date'
- "columns = ['A', 'D']"
- "columns in ['A', 'D']"
- 'columns == A'
- 'columns == A'
- "~(columns = ['A', 'B'])"
- 'index > df.index[3] & string = "bar"'
- '(index > df.index[3] & index <= df.index[6]) | string = "bar"'
- "ts >= Timestamp('2012-02-01')"
- "major_axis>=20130101"

The indexers are on the left-hand side of the sub-expression:

columns, major_axis, ts

The right-hand side of the sub-expression (after a comparison operator) can be:

- functions that will be evaluated, e.g. Timestamp('2012-02-01')
• strings, e.g. "bar"
• date-like, e.g. 20130101, or "20130101"
• lists, e.g. "['A', 'B']"
• variables that are defined in the local names space, e.g. date

Note: Passing a string to a query by interpolating it into the query expression is not recommended. Simply assign the string of interest to a variable and use that variable in an expression. For example, do this:

```python
string = "HolyMoly'"
store.select("df", "index == string")
```

instead of this

```python
string = "HolyMoly'"
store.select('df', f'index == {string}')
```

The latter will not work and will raise a SyntaxError. Note that there’s a single quote followed by a double quote in the string variable.

If you must interpolate, use the '%r' format specifier

```python
store.select("df", "index == $r $ string")
```

which will quote string.

Here are some examples:

```python
In [449]: dfq = pd.DataFrame(
.....: np.random.randn(10, 4),
.....: columns=list("ABCD"),
.....: index=pd.date_range("20130101", periods=10),
.....: )
.....:
In [450]: store.append("dfq", dfq, format="table", data_columns=True)
```

Use boolean expressions, with in-line function evaluation.

```python
In [451]: store.select("dfq", "index>pd.Timestamp('20130104') & columns=['A', 'B']")
Out[451]:
   A   B
0  2013-01-05  -1.083889  0.811865
1  2013-01-06   -0.402227  1.618922
2  2013-01-07    0.948196  0.183573
3  2013-01-08  -1.043530  -0.708145
4  2013-01-09    0.813949  1.508891
5  2013-01-10    1.176488 -1.246093
```

Use inline column reference.

```python
In [452]: store.select("dfq", where="A>0 or C>0")
Out[452]:
   A   B   C   D
0  2013-01-01  0.620028  0.159416  -0.263043  -0.639244
1  2013-01-04  0.536722  1.005707   0.296917   0.139796
```
(continues on next page)
The `columns` keyword can be supplied to select a list of columns to be returned, this is equivalent to passing a 'columns=list_of_columns_to_filter':

```python
In [453]: store.select("df", "columns=['A', 'B']")
Out [453]:
   A    B  
0 1.334065 0.521036
1 -1.613932 1.088104
2 -0.585314 -0.275038
3 0.632369 -1.249657
4 1.060617 -0.143682
5 3.050329 1.317933
6 -0.539452 -0.771133
7 0.649464 -1.736427
```

The `start` and `stop` parameters can be specified to limit the total search space. These are in terms of the total number of rows in a table.

**Note:** `select` will raise a `ValueError` if the query expression has an unknown variable reference. Usually this means that you are trying to select on a column that is not a data_column.

`select` will raise a `SyntaxError` if the query expression is not valid.

### Query timedelta64[ns]

You can store and query using the `timedelta64[ns]` type. Terms can be specified in the format: `<float>(<unit>)`, where float may be signed (and fractional), and unit can be D, s, ms, us, ns for the timedelta. Here's an example:

```python
In [454]: from datetime import timedelta

In [455]: dftd = pd.DataFrame({
    "A": pd.Timestamp("20130101"),
    "B": [pd.Timestamp("20130101") + timedelta(days=i, seconds=10) for i in range(10)],
})

In [456]: dftd["C"] = dftd["A"] - dftd["B"]

In [457]: dftd
Out [457]:
   A    B    C  
0 1.334065 0.521036  
1 -1.613932 1.088104  
2 -0.585314 -0.275038  
3 0.632369 -1.249657  
4 1.060617 -0.143682  
5 3.050329 1.317933  
6 -0.539452 -0.771133  
7 0.649464 -1.736427  
```

(continues on next page)
In [458]: store.append("dftd", dftd, data_columns=True)

In [459]: store.select("dftd", "C<'-3.5D'")
Out[459]:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>2013-01-01 2013-01-05 00:00:10 -5 days +23:59:50</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>2013-01-01 2013-01-06 00:00:10 -6 days +23:59:50</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>2013-01-01 2013-01-07 00:00:10 -7 days +23:59:50</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>2013-01-01 2013-01-08 00:00:10 -8 days +23:59:50</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td>2013-01-01 2013-01-09 00:00:10 -9 days +23:59:50</td>
<td></td>
</tr>
<tr>
<td>9</td>
<td>2013-01-01 2013-01-10 00:00:10 -10 days +23:59:50</td>
<td></td>
</tr>
</tbody>
</table>

Query MultiIndex

Selecting from a MultiIndex can be achieved by using the name of the level.

In [460]: df_mi.index.names
Out[460]: FrozenList(['foo', 'bar'])

In [461]: store.select("df_mi", "foo=baz and bar=two")
Out[461]:

<table>
<thead>
<tr>
<th>foo</th>
<th>bar</th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>baz</td>
<td>two</td>
<td>1.064908</td>
<td>1.778161</td>
<td>-0.913867</td>
</tr>
</tbody>
</table>

If the MultiIndex levels names are None, the levels are automatically made available via the level_n keyword with n the level of the MultiIndex you want to select from.

In [462]: index = pd.MultiIndex(  
    ...:     levels=["foo", "bar", "baz", "qux"], ["one", "two", "three"],  
    ...:     codes=[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3], [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],  
    ...: )  
In [463]: df_mi_2 = pd.DataFrame(np.random.randn(10, 3), index=index, columns=["A", "B", "C")

In [464]: df_mi_2
Out[464]:

<table>
<thead>
<tr>
<th>foo</th>
<th>bar</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>one</td>
<td>0.856838</td>
<td>0.661740</td>
</tr>
<tr>
<td>two</td>
<td>-0.459055</td>
<td>0.443531</td>
</tr>
<tr>
<td>three</td>
<td>0.701816</td>
<td>0.701816</td>
</tr>
<tr>
<td>qux</td>
<td>-0.058688</td>
<td>-0.058688</td>
</tr>
</tbody>
</table>
two  -0.781163  0.826204  -0.530057  
baz two  0.296135  1.366810  1.073372  
three  -0.994957  0.755314  2.119746  
qux one  -2.628174  -0.089460  -0.133636  
two  0.337920  -0.634027  0.421107  
three  0.604303  1.053434  1.109090

In [465]: store.append("df_mi_2", df_mi_2)

# the levels are automatically included as data columns with keyword level_n
In [466]: store.select("df_mi_2", "level_0=foo and level_1=two")
Out[466]:
   A     B     C
foo two -1.097917 0.102588

Indexing

You can create/modify an index for a table with create_table_index after data is already in the table (after and append/put operation). Creating a table index is highly encouraged. This will speed your queries a great deal when you use a select with the indexed dimension as the where.

Note: Indexes are automagically created on the indexables and any data columns you specify. This behavior can be turned off by passing index=False to append.

# we have automagically already created an index (in the first section)
In [467]: i = store.root.df.table.cols.index.index

In [468]: i.optlevel, i.kind
Out[468]: (6, 'medium')

# change an index by passing new parameters
In [469]: store.create_table_index("df", optlevel=9, kind="full")

In [470]: i = store.root.df.table.cols.index.index

In [471]: i.optlevel, i.kind
Out[471]: (9, 'full')

Oftentimes when appending large amounts of data to a store, it is useful to turn off index creation for each append, then recreate at the end.

In [472]: df_1 = pd.DataFrame(np.random.randn(10, 2), columns=list("AB"))

In [473]: df_2 = pd.DataFrame(np.random.randn(10, 2), columns=list("AB"))

In [474]: st = pd.HDFStore("appends.h5", mode="w")

In [475]: st.append("df", df_1, data_columns=["B"], index=False)

In [476]: st.append("df", df_2, data_columns=["B"], index=False)

In [477]: st.get_storer("df").table
Then create the index when finished appending.

```plaintext
In [478]: st.create_table_index("df", columns=["B"], optlevel=9, kind="full")
In [479]: st.get_storer("df").table
Out[479]:
/df/table (Table(20,))
  description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
    "B": Float64Col(shape=(), dflt=0.0, pos=2)}
  byteorder := 'little'
  chunkshape := (2730,)
  autoindex := True
  colindexes := {
    "B": Index(9, full, shuffle, zlib(1)).is_csi=True}
In [480]: st.close()
```

See here for how to create a completely-sorted-index (CSI) on an existing store.

**Query via data columns**

You can designate (and index) certain columns that you want to be able to perform queries (other than the indexable columns, which you can always query). For instance say you want to perform this common operation, on-disk, and return just the frame that matches this query. You can specify `data_columns = True` to force all columns to be `data_columns`.

```plaintext
In [481]: df_dc = df.copy()
In [482]: df_dc["string"] = "foo"
In [483]: df_dc.loc[df_dc.index[4:6], "string"] = np.nan
In [484]: df_dc.loc[df_dc.index[7:9], "string"] = "bar"
In [485]: df_dc["string2"] = "cool"
In [486]: df_dc.loc[df_dc.index[1:3], ["B", "C"]]) = 1.0
In [487]: df_dc
Out[487]:
   A   B          C  string  string2
0 2000-01-01  1.334065  0.521036  0.930384    foo     cool
1 2000-01-02 -1.613932   1.000000   1.000000    foo     cool
2 2000-01-03  0.585314   1.000000   1.000000    foo     cool
3 2000-01-04  0.632369 -1.249657  0.975593    foo     cool
```

(continues on previous page)
There is some performance degradation by making lots of columns into data columns, so it is up to the user to designate these. In addition, you cannot change data columns (nor indexables) after the first append/put operation (Of course you can simply read in the data and create a new table!).

2.4. IO tools (text, CSV, HDF5, ...)

```python
      1.334065  0.521036  0.930384  foo  cool
2000-01-02 -1.613932  1.000000  1.000000  foo  cool
2000-01-03 -0.585314  1.000000  1.000000  foo  cool
2000-01-06  3.050329  1.317933  -0.963725  NaN  cool

# getting creative
In [490]: store.select("df_dc", "B > 0 & C > 0 & string == foo")
Out[490]:
   A   B   C string string2
2000-01-01  1.334065  0.521036  0.930384  foo  cool
2000-01-02 -1.613932  1.000000  1.000000  foo  cool
2000-01-03 -0.585314  1.000000  1.000000  foo  cool

# this is in-memory version of this type of selection
In [491]: df_dc[(df_dc.B > 0) & (df_dc.C > 0) & (df_dc.string == "foo")]
Out[491]:
   A   B   C string string2
2000-01-01  1.334065  0.521036  0.930384  foo  cool
2000-01-02 -1.613932  1.000000  1.000000  foo  cool
2000-01-03 -0.585314  1.000000  1.000000  foo  cool

# we have automagically created this index and the B/C/string/string2
# columns are stored separately as ``PyTables`` columns
In [492]: store.root.df_dc.table
Out[492]:
   /df_dc/table (Table(8,)) ''
   description := {
   "index": Int64Col(shape=(), dflt=0, pos=0),
   "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
   "B": Float64Col(shape=(), dflt=0.0, pos=2),
   "C": Float64Col(shape=(), dflt=0.0, pos=3),
   "string": StringCol(itemsize=3, shape=(), dflt=b'', pos=4),
   "string2": StringCol(itemsize=4, shape=(), dflt=b'', pos=5)}
   byteorder := 'little'
   chunkshape := (1680,)
   autoindex := True
   colindexes := {
   "index": Index(6, medium, shuffle, zlib(1)).is_csi=False,
   "B": Index(6, medium, shuffle, zlib(1)).is_csi=False,
   "C": Index(6, medium, shuffle, zlib(1)).is_csi=False,
   "string": Index(6, medium, shuffle, zlib(1)).is_csi=False,
   "string2": Index(6, medium, shuffle, zlib(1)).is_csi=False}
Iterator

You can pass `iterator=True` or `chunksize=number_in_a_chunk` to `select` and `select_as_multiple` to return an iterator on the results. The default is 50,000 rows returned in a chunk.

```python
In [493]: for df in store.select("df", chunksize=3):
   ....:     print(df)
   ....:
   A   B   C
2000-01-01 1.334065 0.521036 0.930384
2000-01-02 -1.613932 1.088104 -0.632963
2000-01-03 -0.585314 -0.275038 -0.937512
   A   B   C
2000-01-04 0.632369 -1.249657 0.975593
2000-01-05 1.060617 -0.143682 0.218423
2000-01-06 3.050329 1.317933 -0.963725
   A   B   C
2000-01-07 -0.539452 -0.771133 0.023751
2000-01-08 0.649464 -1.736427 0.197288
```

**Note:** You can also use the iterator with `read_hdf` which will open, then automatically close the store when finished iterating.

```python
for df in pd.read_hdf("store.h5", "df", chunksize=3):
    print(df)
```

Note, that the chunksize keyword applies to the source rows. So if you are doing a query, then the chunksize will subdivide the total rows in the table and the query applied, returning an iterator on potentially unequal sized chunks.

Here is a recipe for generating a query and using it to create equal sized return chunks.

```python
In [494]: dfeq = pd.DataFrame({"number": np.arange(1, 11)})
In [495]: dfeq
Out[495]:
   number
0      1
1      2
2      3
3      4
4      5
5      6
6      7
7      8
8      9
9     10
In [496]: store.append("dfeq", dfeq, data_columns=["number"])  
In [497]: def chunks(l, n):
   ....:     return [l[i: i + n] for i in range(0, len(l), n)]
   ....:
In [498]: evens = [2, 4, 6, 8, 10]

(continues on next page)
Advanced queries

Select a single column

To retrieve a single indexable or data column, use the method `select_column`. This will, for example, enable you to get the index very quickly. These return a `Series` of the result, indexed by the row number. These do not currently accept the `where` selector.

```python
In [501]: store.select_column("df_dc", "index")
Out[501]:
0  2000-01-01
1  2000-01-02
2  2000-01-03
3  2000-01-04
4  2000-01-05
5  2000-01-06
6  2000-01-07
7  2000-01-08
Name: index, dtype: datetime64[ns]
```

```python
In [502]: store.select_column("df_dc", "string")
Out[502]:
0  foo
1  foo
2  foo
3  foo
4  NaN
5  NaN
6  foo
7  bar
Name: string, dtype: object
```
Selecting coordinates

Sometimes you want to get the coordinates (a.k.a the index locations) of your query. This returns an `Int64Index` of the resulting locations. These coordinates can also be passed to subsequent `where` operations.

```python
In [503]: df_coord = pd.DataFrame(
            .....: np.random.randn(1000, 2), index=pd.date_range("20000101", periods=1000)
            .....:)
            .....:
In [504]: store.append("df_coord", df_coord)
In [505]: c = store.select_as_coordinates("df_coord", "index > 20020101")
In [506]: c
Out[506]: Int64Index([732, 733, 734, 735, 736, 737, 738, 739, 740, 741,
        ... 990, 991, 992, 993, 994, 995, 996, 997, 998, 999],
        dtype='int64', length=268)
```

```python
In [507]: store.select("df_coord", where=c)
Out[507]:
        0     1
2002-01-02 -0.165548  0.646989
2002-01-03  0.782753 -0.123409
2002-01-04 -0.391932 -0.740915
2002-01-05  1.211070 -0.668715
2002-01-06  0.341987 -0.685867
        ...   ...
2002-09-22  1.788110 -0.405908
2002-09-23 -0.801912  0.768460
2002-09-24  0.466284  0.457411
2002-09-25  0.364060  0.785367
2002-09-26 -1.463093  1.187315
[268 rows x 2 columns]
```

Selecting using a where mask

Sometime your query can involve creating a list of rows to select. Usually this `mask` would be a resulting `index` from an indexing operation. This example selects the months of a `DatetimeIndex` which are 5.

```python
In [508]: df_mask = pd.DataFrame(
            .....: np.random.randn(1000, 2), index=pd.date_range("20000101", periods=1000)
            .....:)
            .....:
In [509]: store.append("df_mask", df_mask)
In [510]: c = store.select_column("df_mask", "index")
In [511]: where = c[pd.DatetimeIndex(c).month == 5].index
In [512]: store.select("df_mask", where=where)
```

(continues on next page)
Storer object

If you want to inspect the stored object, retrieve via `get_storer`. You could use this programatically to say get the number of rows in an object.

```
In [513]: store.get_storer("df_dc").nrows
Out[513]: 8
```

Multiple table queries

The methods `append_to_multiple` and `select_as_multiple` can perform appending/selecting from multiple tables at once. The idea is to have one table (call it the selector table) that you index most/all of the columns, and perform your queries. The other table(s) are data tables with an index matching the selector table’s index. You can then perform a very fast query on the selector table, yet get lots of data back. This method is similar to having a very wide table, but enables more efficient queries.

The `append_to_multiple` method splits a given single DataFrame into multiple tables according to `d`, a dictionary that maps the table names to a list of ‘columns’ you want in that table. If `None` is used in place of a list, that table will have the remaining unspecified columns of the given DataFrame. The argument `selector` defines which table is the selector table (which you can make queries from). The argument `dropna` will drop rows from the input DataFrame to ensure tables are synchronized. This means that if a row for one of the tables being written to is entirely `np.NaN`, that row will be dropped from all tables.

If `dropna` is False, **THE USER IS RESPONSIBLE FOR SYNCHRONIZING THE TABLES.** Remember that entirely `np.Nan` rows are not written to the HDFStore, so if you choose to call `dropna=False`, some tables may have more rows than others, and therefore `select_as_multiple` may not work or it may return unexpected results.

```
In [514]: df_mt = pd.DataFrame(  
.........:     np.random.randn(8, 6),  
.........:     index=pd.date_range("1/1/2000", periods=8),  
.........:     columns=['A', 'B', 'C', 'D', 'E', 'F'],  
.........: )  
.........: 
In [515]: df_mt['foo'] = "bar"
```

(continues on next page)
In [516]: df_mt.loc[df_mt.index[1], ("A", "B")].iloc[1] = np.nan

# you can also create the tables individually
In [517]: store.append_to_multiple(
    .....:   {"df1_mt": ["A", "B"], "df2_mt": None}, df_mt, selector="df1_mt"
    .....:   )

In [518]: store
Out[518]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# individual tables were created
In [519]: store.select("df1_mt")
Out[519]:

Delete from a table

You can delete from a table selectively by specifying a `where`. In deleting rows, it is important to understand the PyTables deletes rows by erasing the rows, then moving the following data. Thus deleting can potentially be a very expensive operation depending on the orientation of your data. To get optimal performance, it’s worthwhile to have the dimension you are deleting be the first of the indexables.

Data is ordered (on the disk) in terms of the indexables. Here’s a simple use case. You store panel-type data, with dates in the `major_axis` and ids in the `minor_axis`. The data is then interleaved like this:

- `date_1`
  - `id_1`
  - `id_2`
  - ...
  - `id_n`
- `date_2`
  - `id_1`
  - ...
  - `id_n`

It should be clear that a delete operation on the `major_axis` will be fairly quick, as one chunk is removed, then the following data moved. On the other hand a delete operation on the `minor_axis` will be very expensive. In this case it would almost certainly be faster to rewrite the table using a `where` that selects all but the missing data.

**Warning:** Please note that HDF5 DOES NOT RECLAIM SPACE in the h5 files automatically. Thus, repeatedly deleting (or removing nodes) and adding again, WILL TEND TO INCREASE THE FILE SIZE.

To repack and clean the file, use `ptrepack`.

Notes & caveats

Compression

PyTables allows the stored data to be compressed. This applies to all kinds of stores, not just tables. Two parameters are used to control compression: `complevel` and `complib`.

- `complevel` specifies if and how hard data is to be compressed. `complevel=0` and `complevel=None` disables compression and `0<complevel<10` enables compression.
- `complib` specifies which compression library to use. If nothing is specified the default library `zlib` is used. A compression library usually optimizes for either good compression rates or speed and the results will depend on the type of data. Which type of compression to choose depends on your specific needs and data. The list of supported compression libraries:
  - `zlib`: The default compression library. A classic in terms of compression, achieves good compression rates but is somewhat slow.
  - `lz4`: Fast compression and decompression.
  - `bzip2`: Good compression rates.
pandas: powerful Python data analysis toolkit, Release 1.3.1

- **blosc**: Fast compression and decompression.

Support for alternative blosc compressors:

- **blosc:blosclz**: This is the default compressor for blosc.
- **blosc:lz4**: A compact, very popular and fast compressor.
- **blosc:lz4hc**: A tweaked version of LZ4, produces better compression ratios at the expense of speed.
- **blosc:snappy**: A popular compressor used in many places.
- **blosc:zlib**: A classic; somewhat slower than the previous ones, but achieving better compression ratios.
- **blosc:zstd**: An extremely well balanced codec; it provides the best compression ratios among the others above, and at reasonably fast speed.

If `complib` is defined as something other than the listed libraries a `ValueError` exception is issued.

**Note**: If the library specified with the `complib` option is missing on your platform, compression defaults to `zlib` without further ado.

Enable compression for all objects within the file:

```python
store_compressed = pd.HDFStore(
    "store_compressed.h5", complevel=9, complib="blosc:blosclz"
)
```

Or on-the-fly compression (this only applies to tables) in stores where compression is not enabled:

```python
store.append("df", df, complib="zlib", complevel=5)
```

**ptrepack**

PyTables offers better write performance when tables are compressed after they are written, as opposed to turning on compression at the very beginning. You can use the supplied PyTables utility `ptrepack`. In addition, `ptrepack` can change compression levels after the fact.

```
ptrepack --chunkshape=auto --propindexes --complevel=9 --complib=blosc in.h5 out.h5
```

Furthermore `ptrepack in.h5 out.h5` will **repack** the file to allow you to reuse previously deleted space. Alternatively, one can simply remove the file and write again, or use the `copy` method.

**Caveats**

**Warning**: `HDFStore` is **not-threadsafe for writing**. The underlying PyTables only supports concurrent reads (via threading or processes). If you need reading and writing **at the same time**, you need to serialize these operations in a single thread in a single process. You will corrupt your data otherwise. See the (GH2397) for more information.

- If you use locks to manage write access between multiple processes, you may want to use `fsync()` before releasing write locks. For convenience you can use `store.flush(fsync=True)` to do this for you.
• Once a table is created columns (DataFrame) are fixed; only exactly the same columns can be appended

• Be aware that timezones (e.g., `pytz.timezone('US/Eastern')`) are not necessarily equal across timezone versions. So if data is localized to a specific timezone in the HDFStore using one version of a timezone library and that data is updated with another version, the data will be converted to UTC since these timezones are not considered equal. Either use the same version of timezone library or use `tz_convert` with the updated timezone definition.

**Warning:** PyTables will show a `NaturalNameWarning` if a column name cannot be used as an attribute selector. *Natural* identifiers contain only letters, numbers, and underscores, and may not begin with a number. Other identifiers cannot be used in a `where` clause and are generally a bad idea.

### DataTypes

HDFStore will map an object dtype to the PyTables underlying dtype. This means the following types are known to work:

<table>
<thead>
<tr>
<th>Type</th>
<th>Represents missing values</th>
</tr>
</thead>
<tbody>
<tr>
<td>floating: float64, float32, float16</td>
<td>np.nan</td>
</tr>
<tr>
<td>integer: int64, int32, int8, uint64,uint32, uint8</td>
<td></td>
</tr>
<tr>
<td>boolean</td>
<td>NaT</td>
</tr>
<tr>
<td>datetime64[ns]</td>
<td>NaT</td>
</tr>
<tr>
<td>timedelta64[ns]</td>
<td>NaT</td>
</tr>
<tr>
<td>categorical: see the section below</td>
<td></td>
</tr>
<tr>
<td>object: strings</td>
<td>np.nan</td>
</tr>
</tbody>
</table>

*unicode* columns are not supported, and WILL FAIL.

### Categorical data

You can write data that contains category dtypes to a HDFStore. Queries work the same as if it was an object array. However, the category dtyped data is stored in a more efficient manner.

```python
In [522]: dfcat = pd.DataFrame(
    .....:     "A": pd.Series(list("aabbcdba"))_.astype("category"), "B": np.random.
                 →randn(8))
    .....: )
    .....:

In [523]: dfcat
Out[523]:
     A    B
0   a  0.477849
1   a  0.283128
2   b -2.045700
3   b -0.338206
4   c -0.423113
5   d  2.314361
6   b  0.033100
7   a -0.965461

In [524]: dfcat.dtypes
```

(continues on next page)
String columns

`min_itemsize`

The underlying implementation of `HDFStore` uses a fixed column width (itemsize) for string columns. A string column itemsize is calculated as the maximum of the length of data (for that column) that is passed to the `HDFStore`, in the first append. Subsequent appends, may introduce a string for a column larger than the column can hold, an Exception will be raised (otherwise you could have a silent truncation of these columns, leading to loss of information). In the future we may relax this and allow a user-specified truncation to occur.

Pass `min_itemsize` on the first table creation to a-priori specify the minimum length of a particular string column. `min_itemsize` can be an integer, or a dict mapping a column name to an integer. You can pass `values` as a key to allow all `indexables` or `data_columns` to have this `min_itemsize`.

Passing a `min_itemsize` dict will cause all passed columns to be created as `data_columns` automatically.

**Note:** If you are not passing any `data_columns`, then the `min_itemsize` will be the maximum of the length of any string passed.
foo bar

# A and B have a size of 30
In [532]: store.append("dfs", dfs, min_itemsize=30)

In [533]: store.get_storer("dfs").table
Out[533]:
/dfs/table (Table(5,)) ''
description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": StringCol(itemsize=30, shape=(2,), dflt=b'', pos=1)
}
byteorder := 'little'
chunkshape := (963,)
autoindex := True
colindexes := {
    "index": Index(6, medium, shuffle, zlib(1)).is_csi=False
}

# A is created as a data_column with a size of 30
# B is size is calculated
In [534]: store.append("dfs2", dfs, min_itemsize={"A": 30})

In [535]: store.get_storer("dfs2").table
Out[535]:
/dfs2/table (Table(5,)) ''
description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": StringCol(itemsize=3, shape=(1,), dflt=b'', pos=1),
    "A": StringCol(itemsize=30, shape=(), dflt=b'', pos=2)
}
byteorder := 'little'
chunkshape := (1598,)
autoindex := True
colindexes := {
    "index": Index(6, medium, shuffle, zlib(1)).is_csi=False,
    "A": Index(6, medium, shuffle, zlib(1)).is_csi=False
}

---

nan_rep

String columns will serialize a np.nan (a missing value) with the nan_rep string representation. This defaults to the string value nan. You could inadvertently turn an actual nan value into a missing value.

In [536]: dfss = pd.DataFrame({"A": ["foo", "bar", nan]})

In [537]: dfss
Out[537]:
A
0 foo
1 bar
2 NaN

In [538]: store.append("dfss", dfss)

In [539]: store.select("dfss")
Out[539]:
A
0 foo
1 bar
2 NaN

(continues on next page)
# here you need to specify a different nan rep
In [540]: store.append("dfss2", dfss, nan_rep="_nan_")

In [541]: store.select("dfss2")
Out[541]:
   A
0  foo
1  bar
2  nan

### External compatibility

HDFStore writes table format objects in specific formats suitable for producing loss-less round trips to pandas objects. For external compatibility, HDFStore can read native PyTables format tables.

It is possible to write an HDFStore object that can easily be imported into R using the rhdf5 library (Package website). Create a table format store like this:

```
In [542]: df_for_r = pd.DataFrame(
        ...:     {
        ...:         "first": np.random.rand(100),
        ...:         "second": np.random.rand(100),
        ...:         "class": np.random.randint(0, 2, (100,)),
        ...:     },
        ...:     index=range(100),
        ...: )

In [543]: df_for_r.head()
Out[543]:
   first    second   class
0  0.864919  0.852910     0
1  0.030579  0.412962     1
2  0.015226  0.978410     0
3  0.498512  0.686761     0
4  0.232163  0.328185     1

In [544]: store_export = pd.HDFStore("export.h5")

In [545]: store_export.append("df_for_r", df_for_r, data_columns=df_dc.columns)

In [546]: store_export
Out[546]:
<class 'pandas.io.pytables.HDFStore'>
File path: export.h5
```

In R this file can be read into a data.frame object using the rhdf5 library. The following example function reads the corresponding column names and data values from the values and assembles them into a data.frame:

```
# Load values and column names for all datasets from corresponding nodes and
# insert them into one data.frame object.
library(rhdf5)
```

(continues on next page)
loadhdf5data <- function(h5File) {

listing <- h5ls(h5File)
# Find all data nodes, values are stored in *_values and corresponding column
# titles in *_items
data_nodes <- grep("_values", listing$name)
name_nodes <- grep("_items", listing$name)
data_paths = paste(listing$group[data_nodes], listing$name[data_nodes], sep = "/")
name_paths = paste(listing$group[name_nodes], listing$name[name_nodes], sep = "/")
columns = list()
for (idx in seq(data_paths)) {
  # NOTE: matrices returned by h5read have to be transposed to obtain
  # required Fortran order!
  data <- data.frame(t(h5read(h5File, data_paths[idx])))
  names <- t(h5read(h5File, name_paths[idx]))
  entry <- data.frame(data)
  colnames(entry) <- names
  columns <- append(columns, entry)
}
data <- data.frame(columns)
return(data)
}

Now you can import the DataFrame into R:

```r
> data = loadhdf5data("transfer.hdf5")
> head(data)
       first      second    class
   1 0.4170220047 0.32664490       0
   2 0.7203244934 0.52705810       0
   3 0.0001143748 0.88594210       1
   4 0.3023325726 0.35726980       1
   5 0.1467558908 0.90853520       1
   6 0.0923385948 0.62336010       1
```

**Note:** The R function lists the entire HDF5 file’s contents and assembles the `data.frame` object from all matching nodes, so use this only as a starting point if you have stored multiple `DataFrame` objects to a single HDF5 file.

**Performance**

- **tables** format come with a writing performance penalty as compared to `fixed` stores. The benefit is the ability to append/delete and query (potentially very large amounts of data). Write times are generally longer as compared with regular stores. Query times can be quite fast, especially on an indexed axis.

- You can pass `chunksize=<int>` to `append`, specifying the write chunksize (default is 50000). This will significantly lower your memory usage on writing.

- You can pass `expectedrows=<int>` to the first `append`, to set the TOTAL number of rows that PyTables will expect. This will optimize read/write performance.

- Duplicate rows can be written to tables, but are filtered out in selection (with the last items being selected; thus a table is unique on major, minor pairs)
• A `PerformanceWarning` will be raised if you are attempting to store types that will be pickled by PyTables (rather than stored as endemic types). See Here for more information and some solutions.

## 2.4.13 Feather

Feather provides binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy.

Feather is designed to faithfully serialize and de-serialize DataFrames, supporting all of the pandas dtypes, including extension dtypes such as categorical and date/time with tz.

Several caveats:

• The format will NOT write an `Index`, or `MultiIndex` for the `DataFrame` and will raise an error if a non-default one is provided. You can `.reset_index()` to store the index or `.reset_index(drop=True)` to ignore it.

• Duplicate column names and non-string column names are not supported.

• Actual Python objects in object dtype columns are not supported. These will raise a helpful error message on an attempt at serialization.

See the Full Documentation.

```python
In [547]: df = pd.DataFrame(
    .....:     { .....:
           "a": list("abc"),
           "b": list(range(1, 4)),
           "c": np.arange(3, 6).astype("uint8"),
           "d": np.arange(4.0, 7.0, dtype="float64"),
           "e": [True, False, True],
           "f": pd.Categorical(list("abc")),
           "g": pd.date_range("20130101", periods=3),
           "h": pd.date_range("20130101", periods=3, tz="US/Eastern"),
           "i": pd.date_range("20130101", periods=3, freq="ns"),
    .....:     })

In [548]: df
Out[548]:
   a     b    c      d       e       f                   g                  h
0  0  0  0  2013-01-01 00:00:00-05:00 00:00:00-05:00 2013-01-01 00:00:00.000000

```

**2.4.14 Parquet**

Apache Parquet provides a partitioned binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy. Parquet can use a variety of compression techniques to shrink the file size as much as possible while still maintaining good read performance.

Parquet is designed to faithfully serialize and de-serialize DataFrame s, supporting all of the pandas dtypes, including extension dtypes such as datetime with tz.

Several caveats.

- Duplicate column names and non-string columns names are not supported.
- The pyarrow engine always writes the index to the output, but fastparquet only writes non-default indexes. This extra column can cause problems for non-pandas consumers that are not expecting it. You can force including or omitting indexes with the index argument, regardless of the underlying engine.
- Index level names, if specified, must be strings.
In the **pyarrow** engine, categorical dtypes for non-string types can be serialized to parquet, but will de-serialize as their primitive dtype.

The **pyarrow** engine preserves the ordered flag of categorical dtypes with string types. **fastparquet** does not preserve the ordered flag.

Non supported types include `Interval` and actual Python object types. These will raise a helpful error message on an attempt at serialization. `Period` type is supported with pyarrow >= 0.16.0.

The **pyarrow** engine preserves extension data types such as the nullable integer and string data type (requiring pyarrow >= 0.16.0, and requiring the extension type to implement the needed protocols, see the extension types documentation).

You can specify an engine to direct the serialization. This can be one of **pyarrow**, or **fastparquet**, or **auto**. If the engine is NOT specified, then the `pd.options.io.parquet.engine` option is checked; if this is also auto, then pyarrow is tried, and falling back to fastparquet.

See the documentation for **pyarrow** and **fastparquet**.

**Note:** These engines are very similar and should read/write nearly identical parquet format files. Currently **pyarrow** does not support timedelta data. **fastparquet>=0.1.4** supports timezone aware datetimes. These libraries differ by having different underlying dependencies (fastparquet by using numba, while pyarrow uses a c-library).

```python
In [554]: df = pd.DataFrame(
   ....:   {
   ....:     "a": list("abc"),
   ....:     "b": list(range(1, 4)),
   ....:     "c": np.arange(3, 6).astype("u1"),
   ....:     "d": np.arange(4.0, 7.0, dtype="float64"),
   ....:     "e": [True, False, True],
   ....:     "f": pd.date_range(\"20130101\", periods=3),
   ....:     "g": pd.date_range(\"20130101\", periods=3, tz=\"US/Eastern\"),
   ....:     "h": pd.Categorical(list("abc")),
   ....:     "i": pd.Categorical(list("abc"), ordered=True),
   ....:   }
   ....: )
   ....: 

In [555]: df
Out[555]:
   a  b  c   d   e            f                   g           h               i
0  a  1  3 4.0  True  2013-01-01 00:00:00-05:00  a  a
1  b  2  4 5.0  False 2013-01-02 00:00:00-05:00  b  b
2  c  3  5 6.0  True  2013-01-03 00:00:00-05:00  c  c

In [556]: df.dtypes
Out[556]:
a object
b int64
c uint8
d float64
e bool
f datetime64[ns]
g datetime64[ns, US/Eastern]
h category
i category
dtype: object
```
Write to a parquet file.

```python
In [557]: df.to_parquet("example_pa.parquet", engine="pyarrow")
In [558]: df.to_parquet("example_fp.parquet", engine="fastparquet")
```

Read from a parquet file.

```python
In [559]: result = pd.read_parquet("example_fp.parquet", engine="fastparquet")
In [560]: result = pd.read_parquet("example_pa.parquet", engine="pyarrow")
In [561]: result.dtypes
Out[561]:
a     object
b    int64
c   uint8
d   float64
e     bool
f datetime64[ns]
g  datetime64[ns, US/Eastern]
h   category
i   category
dtype: object
```

Read only certain columns of a parquet file.

```python
In [562]: result = pd.read_parquet(
       ....: "example_fp.parquet",
       ....: engine="fastparquet",
       ....: columns=["a", "b"],
       ....: )

In [563]: result = pd.read_parquet(
       ....: "example_pa.parquet",
       ....: engine="pyarrow",
       ....: columns=["a", "b"],
       ....: )

In [564]: result.dtypes
Out[564]:
a     object
b    int64
dtype: object
```
Handling indexes

Serializing a DataFrame to parquet may include the implicit index as one or more columns in the output file. Thus, this code:

```python
In [565]: df = pd.DataFrame({"a": [1, 2], "b": [3, 4]})
In [566]: df.to_parquet("test.parquet", engine="pyarrow")
```

creates a parquet file with three columns if you use pyarrow for serialization: a, b, and __index_level_0__. If you’re using fastparquet, the index may or may not be written to the file.

This unexpected extra column causes some databases like Amazon Redshift to reject the file, because that column doesn’t exist in the target table.

If you want to omit a dataframe’s indexes when writing, pass index=False to `to_parquet()`:

```python
In [567]: df.to_parquet("test.parquet", index=False)
```

This creates a parquet file with just the two expected columns, a and b. If your DataFrame has a custom index, you won’t get it back when you load this file into a DataFrame.

Passing index=True will always write the index, even if that’s not the underlying engine’s default behavior.

Partitioning Parquet files

Parquet supports partitioning of data based on the values of one or more columns.

```python
In [568]: df = pd.DataFrame({"a": [0, 0, 1, 1], "b": [0, 1, 0, 1]})
In [569]: df.to_parquet(path="test", engine="pyarrow", partition_cols=["a"],
   compression=None)
```

The path specifies the parent directory to which data will be saved. The partition_cols are the column names by which the dataset will be partitioned. Columns are partitioned in the order they are given. The partition splits are determined by the unique values in the partition columns. The above example creates a partitioned dataset that may look like:

```
test
  | a=0
  | 0bac803e32dc42ae83fddfd029cbdebc.parquet
  |  ... 
  | a=1
  | e6ab24a4f45147b49b54a662f0c412a3.parquet
  |  ... 
```

2.4.15 ORC

New in version 1.0.0.

Similar to the parquet format, the ORC Format is a binary columnar serialization for data frames. It is designed to make reading data frames efficient. pandas provides only a reader for the ORC format, `read_orc()`. This requires the pyarrow library.
Warning:

- It is *highly recommended* to install pyarrow using conda due to some issues occurred by pyarrow.
- `read_orc()` is not supported on Windows yet, you can find valid environments on *install optional dependencies*.

### 2.4.16 SQL queries

The `pandas.io.sql` module provides a collection of query wrappers to both facilitate data retrieval and to reduce dependency on DB-specific API. Database abstraction is provided by SQLAlchemy if installed. In addition you will need a driver library for your database. Examples of such drivers are `psycopg2` for PostgreSQL or `pymysql` for MySQL. For SQLite this is included in Python's standard library by default. You can find an overview of supported drivers for each SQL dialect in the SQLAlchemy docs.

If SQLAlchemy is not installed, a fallback is only provided for sqlite (and for mysql for backwards compatibility, but this is deprecated and will be removed in a future version). This mode requires a Python database adapter which respect the Python DB-API.

See also some *cookbook examples* for some advanced strategies.

The key functions are:

- `read_sql_table(table_name, con[, schema, ...])` Read SQL database table into a DataFrame.
- `read_sql_query(sql, con[, index_col, ...])` Read SQL query into a DataFrame.
- `read_sql(sql, con[, index_col, ...])` Read SQL query or database table into a DataFrame.
- `DataFrame.to_sql(name, con[, schema, ...])` Write records stored in a DataFrame to a SQL database.

**Note:** The function `read_sql()` is a convenience wrapper around `read_sql_table()` and `read_sql_query()` (and for backward compatibility) and will delegate to specific function depending on the provided input (database table name or sql query). Table names do not need to be quoted if they have special characters.

In the following example, we use the SQLite SQL database engine. You can use a temporary SQLite database where data are stored in “memory”.

To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to. For more information on `create_engine()` and the URI formatting, see the examples below and the SQLAlchemy documentation.

```python
In [570]: from sqlalchemy import create_engine

# Create your engine.
In [571]: engine = create_engine("sqlite:///::memory:")
```

If you want to manage your own connections you can pass one of those instead. The example below opens a connection to the database using a Python context manager that automatically closes the connection after the block has completed. See the SQLAlchemy docs for an explanation of how the database connection is handled.

```python
with engine.connect() as conn, conn.begin():
    data = pd.read_sql_table("data", conn)
```

2.4. IO tools (text, CSV, HDF5, …)
Warning: When you open a connection to a database you are also responsible for closing it. Side effects of leaving a connection open may include locking the database or other breaking behaviour.

Writing DataFrames

Assuming the following data is in a DataFrame `data`, we can insert it into the database using `to_sql()`.

<table>
<thead>
<tr>
<th>id</th>
<th>Date</th>
<th>Col_1</th>
<th>Col_2</th>
<th>Col_3</th>
</tr>
</thead>
<tbody>
<tr>
<td>26</td>
<td>2012-10-18</td>
<td>X</td>
<td>25.7</td>
<td>True</td>
</tr>
<tr>
<td>42</td>
<td>2012-10-19</td>
<td>Y</td>
<td>-12.4</td>
<td>False</td>
</tr>
<tr>
<td>63</td>
<td>2012-10-20</td>
<td>Z</td>
<td>5.73</td>
<td>True</td>
</tr>
</tbody>
</table>

In [572]: data
Out[572]:

<table>
<thead>
<tr>
<th>id</th>
<th>Date</th>
<th>Col_1</th>
<th>Col_2</th>
<th>Col_3</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2010-10-18</td>
<td>X</td>
<td>27.50</td>
<td>True</td>
</tr>
<tr>
<td>1</td>
<td>2010-10-19</td>
<td>Y</td>
<td>-12.50</td>
<td>False</td>
</tr>
<tr>
<td>2</td>
<td>2010-10-20</td>
<td>Z</td>
<td>5.73</td>
<td>True</td>
</tr>
</tbody>
</table>

In [573]: data.to_sql("data", engine)

With some databases, writing large DataFrames can result in errors due to packet size limitations being exceeded. This can be avoided by setting the `chunksize` parameter when calling `to_sql`. For example, the following writes `data` to the database in batches of 1000 rows at a time:

In [574]: data.to_sql("data_chunked", engine, chunksize=1000)

SQL data types

to_sql() will try to map your data to an appropriate SQL data type based on the dtype of the data. When you have columns of dtype `object`, pandas will try to infer the data type.

You can always override the default type by specifying the desired SQL type of any of the columns by using the `dtype` argument. This argument needs a dictionary mapping column names to SQLAlchemy types (or strings for the sqlite3 fallback mode). For example, specifying to use the sqlalchemy `String` type instead of the default `Text` type for string columns:

In [575]: from sqlalchemy.types import String

In [576]: data.to_sql("data_dtype", engine, dtype={"Col_1": String})

Note: Due to the limited support for timedelta's in the different database flavors, columns with type `timedelta64` will be written as integer values as nanoseconds to the database and a warning will be raised.

Note: Columns of category dtype will be converted to the dense representation as you would get with np. asarray(categorical) (e.g. for string categories this gives an array of strings). Because of this, reading the database table back in does not generate a categorical.
Datetime data types

Using SQLAlchemy, `to_sql()` is capable of writing datetime data that is timezone naive or timezone aware. However, the resulting data stored in the database ultimately depends on the supported data type for datetime data of the database system being used.

The following table lists supported data types for datetime data for some common databases. Other database dialects may have different data types for datetime data.

<table>
<thead>
<tr>
<th>Database</th>
<th>SQL Datetime Types</th>
<th>Timezone Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLite</td>
<td>TEXT</td>
<td>No</td>
</tr>
<tr>
<td>MySQL</td>
<td>TIMESTAMP or DATETIME</td>
<td>No</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>TIMESTAMP or TIMESTAMP WITH TIME ZONE</td>
<td>Yes</td>
</tr>
</tbody>
</table>

When writing timezone aware data to databases that do not support timezones, the data will be written as timezone naive timestamps that are in local time with respect to the timezone.

`read_sql_table()` is also capable of reading datetime data that is timezone aware or naive. When reading `TIMESTAMP WITH TIME ZONE` types, pandas will convert the data to UTC.

Insertion method

The parameter `method` controls the SQL insertion clause used. Possible values are:

- None: Uses standard SQL INSERT clause (one per row).
- 'multi': Pass multiple values in a single INSERT clause. It uses a special SQL syntax not supported by all backends. This usually provides better performance for analytic databases like Presto and Redshift, but has worse performance for traditional SQL backend if the table contains many columns. For more information check the SQLAlchemy documentation.
- callable with signature `(pd_table, conn, keys, data_iter)`: This can be used to implement a more performant insertion method based on specific backend dialect features.

Example of a callable using PostgreSQL COPY clause:

```python
# Alternative to sql() *method* for DBs that support COPY FROM
import csv
from io import StringIO

def psql_insert_copy(table, conn, keys, data_iter):
    """
    Execute SQL statement inserting data
    Parameters
    ----------
    table : pandas.io.sql.SQLTable
    conn : sqlalchemy.engine.Engine or sqlalchemy.engine.Connection
    keys : list of str
        Column names
    data_iter : Iterable that iterates the values to be inserted
    """
    # gets a DBAPI connection that can provide a cursor
    dbapi_conn = conn.connection
    with dbapi_conn.cursor() as cur:
        sBuf = StringIO()
        cur.copy_to(sBuf, table.name, page_size=10000, 
```

(continues on next page)
Reading tables

`read_sql_table()` will read a database table given the table name and optionally a subset of columns to read.

**Note:** In order to use `read_sql_table()`, you must have the SQLAlchemy optional dependency installed.

```python
In [577]: pd.read_sql_table("data", engine)
Out[577]:
   index  id    Date  Col_1  Col_2  Col_3
0      0   26 2010-10-18    X  27.50   True
1      1   42 2010-10-19    Y -12.50  False
2      2   63 2010-10-20    Z  5.73   True
```

**Note:** Note that pandas infers column dtypes from query outputs, and not by looking up data types in the physical database schema. For example, assume `userid` is an integer column in a table. Then, intuitively, `select userid` ... will return integer-valued series, while `select cast(userid as text) ...` will return object-valued (str) series. Accordingly, if the query output is empty, then all resulting columns will be returned as object-valued (since they are most general). If you foresee that your query will sometimes generate an empty result, you may want to explicitly typecast afterwards to ensure dtype integrity.

You can also specify the name of the column as the `DataFrame` index, and specify a subset of columns to be read.

```python
In [578]: pd.read_sql_table("data", engine, index_col="id")
Out[578]:
    Date  Col_1  Col_2  Col_3
id
26 2010-10-18    X  27.50   True
42 2010-10-19    Y -12.50  False
63 2010-10-20    Z  5.73   True
```

```python
In [579]: pd.read_sql_table("data", engine, columns=["Col_1", "Col_2"])
Out[579]:
    Col_1  Col_2
0     X  27.50
1     Y -12.50
2     Z  5.73
```

And you can explicitly force columns to be parsed as dates:
In [580]: pd.read_sql_table("data", engine, parse_dates=["Date"])  
Out[580]:  
   index  id      Date  Col_1  Col_2  Col_3  
 0      0  26  2010-10-18     X  27.50   True  
 1      1  42  2010-10-19     Y -12.50   False  
 2      2  63  2010-10-20     Z   5.73   True  

If needed you can explicitly specify a format string, or a dict of arguments to pass to `pandas.to_datetime()`:

```python
pd.read_sql_table("data", engine, parse_dates={"Date": "%Y-%m-%d"})
pd.read_sql_table({
   "data",
   engine,
   parse_dates={"Date": {"format": "%Y-%m-%d %H:%M:%S"}},
})
```

You can check if a table exists using `has_table()`

**Schema support**

Reading from and writing to different schema’s is supported through the `schema` keyword in the `read_sql_table()` and `to_sql()` functions. Note however that this depends on the database flavor (sqlite does not have schema’s). For example:

```python
df.to_sql("table", engine, schema="other_schema")
pd.read_sql_table("table", engine, schema="other_schema")
```

**Querying**

You can query using raw SQL in the `read_sql_query()` function. In this case you must use the SQL variant appropriate for your database. When using SQLAlchemy, you can also pass SQLAlchemy Expression language constructs, which are database-agnostic.

In [581]: pd.read_sql_query("SELECT * FROM data", engine)  
Out[581]:  
   index  id      Date  Col_1  Col_2  Col_3  
 0      0  26  2010-10-18 00:00:00.000000     X  27.50   1  
 1      1  42  2010-10-19 00:00:00.000000     Y -12.50   0  
 2      2  63  2010-10-20 00:00:00.000000     Z   5.73   1  

Of course, you can specify a more “complex” query.

In [582]: pd.read_sql_query("SELECT id, Col_1, Col_2 FROM data WHERE id = 42;", engine)  
Out[582]:  
   id  Col_1  Col_2  
 0  42     Y  -12.5  

The `read_sql_query()` function supports a `chunksize` argument. Specifying this will return an iterator through chunks of the query result:

In [583]: df = pd.DataFrame(np.random.randn(20, 3), columns=list("abc"))  
In [584]: df.to_sql("data_chunks", engine, index=False)  

2.4. IO tools (text, CSV, HDF5, …)
In [585]: for chunk in pd.read_sql_query("SELECT * FROM data_chunks", engine, _
chunksize=5):
    .....:   print(chunk)
    .....:
       a    b    c
0   0.092961 -0.674003  1.104153
1  -0.092732 -0.156246 -0.585167
2  -0.358119 -0.862331 -1.672907
3   0.550313 -1.507513  -0.617232
4   0.650576  1.033221   0.492464
       a    b    c
0  -1.627786 -0.692062  1.039548
1  -1.802313 -0.890905  -0.881794
2   0.630492  0.016739   0.014500
3  -0.438358  0.647275  -0.052075
4   0.673137  1.227539   0.203534
       a    b    c
0   0.861658  0.867852  -0.465016
1   1.547012 -0.947189  -1.241043
2   0.070470  0.901320   0.937577
3   0.295770  1.420548   0.005283
4  -1.518598 -0.730065   0.226497
       a    b    c
0  -2.061465  0.632115   0.853619
1   2.719155  0.139018  -0.214557
2  -1.538924 -0.366973  -0.748801
3  -0.478137 -1.559153   3.097759
4  -2.320335 -0.221090   0.119763

You can also run a plain query without creating a DataFrame with execute(). This is useful for queries that don’t return values, such as INSERT. This is functionally equivalent to calling execute on the SQLAlchemy engine or db connection object. Again, you must use the SQL syntax variant appropriate for your database.

from pandas.io import sql
sql.execute("SELECT * FROM table_name", engine)
sql.execute("INSERT INTO table_name VALUES(?, ?, ?)", engine, params=[("id", 1, 12.2, True)]

Engine connection examples

To connect with SQLAlchemy you use the create_engine() function to create an engine object from database URI. You only need to create the engine once per database you are connecting to.

from sqlalchemy import create_engine

engine = create_engine("postgresql://scott:tiger@localhost:5432/mydatabase")
engine = create_engine("mysql+mysqldb://scott:tiger@localhost/foo")
engine = create_engine("oracle://scott:tiger@127.0.0.1:1521/sidname")
engine = create_engine("mssql+pyodbc://mydsn")
# sqlite://<nohostname>/<path>
For more information see the examples the SQLAlchemy documentation

Advanced SQLAlchemy queries

You can use SQLAlchemy constructs to describe your query.

Use `sqlalchemy.text()` to specify query parameters in a backend-neutral way

```
In [586]: import sqlalchemy as sa

In [587]: pd.read_sql(sa.text("SELECT * FROM data where Col_1=:col1"), engine, params={"col1": "X"})
Out[587]:
index id Date Col_1 Col_2 Col_3
0 0 26 2010-10-18 00:00:00.000000 X 27.5 1
```

If you have an SQLAlchemy description of your database you can express where conditions using SQLAlchemy expressions

```
In [588]: metadata = sa.MetaData()

In [589]: data_table = sa.Table(
    "data",
    metadata,
    sa.Column("index", sa.Integer),
    sa.Column("Date", sa.DateTime),
    sa.Column("Col_1", sa.String),
    sa.Column("Col_2", sa.Float),
    sa.Column("Col_3", sa.Boolean),
)

In [590]: pd.read_sql(sa.select([data_table]).where(data_table.c.Col_3.is_(True)), engine)
Out[590]:
Empty DataFrame
Columns: [index, Date, Col_1, Col_2, Col_3]
Index: []
```

You can combine SQLAlchemy expressions with parameters passed to `read_sql()` using `sqlalchemy.bindparam()`

```
In [591]: import datetime as dt

In [592]: expr = sa.select([data_table]).where(data_table.c.Date > sa.bindparam("date", dt.datetime(2010, 10, 31)))
```

(continues on next page)
In [593]: pd.read_sql(expr, engine, params={"date": dt.datetime(2010, 10, 18)})
Out[593]:
  index Date Col_1 Col_2 Col_3
0   1 2010-10-19   Y -12.50 False
1   2 2010-10-20   Z   5.73 True

**Sqlite fallback**

The use of sqlite is supported without using SQLAlchemy. This mode requires a Python database adapter which respect the Python DB-API.

You can create connections like so:

```python
import sqlite3
con = sqlite3.connect(":memory:"
```

And then issue the following queries:

```python
data.to_sql("data", con)
pd.read_sql_query("SELECT * FROM data", con)
```

### 2.4.17 Google BigQuery

**Warning:** Starting in 0.20.0, pandas has split off Google BigQuery support into the separate package `pandas-gbq`. You can pip install `pandas-gbq` to get it.

The `pandas-gbq` package provides functionality to read/write from Google BigQuery.

`pandas` integrates with this external package. if `pandas-gbq` is installed, you can use the `pandas` methods `pd.read_gbq` and `DataFrame.to_gbq`, which will call the respective functions from `pandas-gbq`.

Full documentation can be found [here](#).

### 2.4.18 Stata format

**Writing to stata format**

The method `to_stata()` will write a DataFrame into a .dta file. The format version of this file is always 115 (Stata 12).

```python
in [594]: df = pd.DataFrame(np.random.randn(10, 2), columns=list("AB"))
In [595]: df.to_stata("stata.dta")
```

*Stata* data files have limited data type support; only strings with 244 or fewer characters, int8, int16, int32, float32 and float64 can be stored in .dta files. Additionally, *Stata* reserves certain values to represent missing data. Exporting a non-missing value that is outside of the permitted range in *Stata* for a particular data type will retype the variable to the next larger size. For example, int8 values are restricted to lie between -127 and 100 in *Stata*, and so variables with values above 100 will trigger a conversion to int16. nan values in floating points data types are stored as the basic missing data type (. in *Stata*).
Note: It is not possible to export missing data values for integer data types.

The Stata writer gracefully handles other data types including int64, bool, uint8, uint16, uint32 by casting to the smallest supported type that can represent the data. For example, data with a type of uint8 will be cast to int8 if all values are less than 100 (the upper bound for non-missing int8 data in Stata), or, if values are outside of this range, the variable is cast to int16.

Warning: Conversion from int64 to float64 may result in a loss of precision if int64 values are larger than $2^{53}$.

Warning: StataWriter and to_stata() only support fixed width strings containing up to 244 characters, a limitation imposed by the version 115 dta file format. Attempting to write Stata dta files with strings longer than 244 characters raises a ValueError.

Reading from Stata format

The top-level function read_stata will read a dta file and return either a DataFrame or a StataReader that can be used to read the file incrementally.

```
In [596]: pd.read_stata("stata.dta")
Out[596]:
   index  A     B
0     0  0.608228  1.064810
1     1 -0.780506 -2.736887
2     2  0.143539  1.170191
3     3 -1.573076  0.075792
4     4 -1.722223 -0.774650
5     5  0.803627  0.221665
6     6  0.584637  0.147264
7     7  1.057825 -0.284136
8     8  0.912395  1.552808
9     9  0.189376 -0.109830
```

Specifying a chunksize yields a StataReader instance that can be used to read chunksize lines from the file at a time. The StataReader object can be used as an iterator.

```
In [597]: with pd.read_stata("stata.dta", chunksize=3) as reader:
   .....:
   .....: for df in reader:
   .....:
   .....: print(df.shape)
   .....:
   .....: (3, 3)
   .....: (3, 3)
   .....: (3, 3)
   .....: (1, 3)
```

For more fine-grained control, use iterator=True and specify chunksize with each call to read().

```
In [598]: with pd.read_stata("stata.dta", iterator=True) as reader:
   .....:
   .....: chunk1 = reader.read(5)
   .....:
   .....: chunk2 = reader.read(5)
   .....:
```
Currently the index is retrieved as a column.

The parameter `convert_categoricals` indicates whether value labels should be read and used to create a `Categorical` variable from them. Value labels can also be retrieved by the function `value_labels`, which requires `read()` to be called before use.

The parameter `convert_missing` indicates whether missing value representations in Stata should be preserved. If `False` (the default), missing values are represented as `np.nan`. If `True`, missing values are represented using `StataMissingValue` objects, and columns containing missing values will have `object` data type.

**Note:** `read_stata()` and `StataReader` support .dta formats 113-115 (Stata 10-12), 117 (Stata 13), and 118 (Stata 14).

**Note:** Setting `preserve_dtypes=False` will upcast to the standard pandas data types: `int64` for all integer types and `float64` for floating point data. By default, the Stata data types are preserved when importing.

### Categorical data

Categorical data can be exported to Stata data files as value labeled data. The exported data consists of the underlying category codes as integer data values and the categories as value labels. Stata does not have an explicit equivalent to a `Categorical` and information about whether the variable is ordered is lost when exporting.

**Warning:** Stata only supports string value labels, and so `str` is called on the categories when exporting data. Exporting Categorical variables with non-string categories produces a warning, and can result a loss of information if the `str` representations of the categories are not unique.

Labeled data can similarly be imported from Stata data files as `Categorical` variables using the keyword argument `convert_categoricals` (True by default). The keyword argument `order_categoricals` (True by default) determines whether imported `Categorical` variables are ordered.

**Note:** When importing categorical data, the values of the variables in the Stata data file are not preserved since `Categorical` variables always use integer data types between -1 and n-1 where n is the number of categories. If the original values in the Stata data file are required, these can be imported by setting `convert_categoricals=False`, which will import original data (but not the variable labels). The original values can be matched to the imported categorical data since there is a simple mapping between the original Stata data values and the category codes of imported Categorical variables: missing values are assigned code -1, and the smallest original value is assigned 0, the second smallest is assigned 1 and so on until the largest original value is assigned the code n-1.

**Note:** Stata supports partially labeled series. These series have value labels for some but not all data values. Importing a partially labeled series will produce a `Categorical` with string categories for the values that are labeled and numeric categories for values with no label.
2.4.19 SAS formats

The top-level function `read_sas()` can read (but not write) SAS XPORT (.xpt) and (since v0.18.0) SAS7BDAT (.sas7bdat) format files.

SAS files only contain two value types: ASCII text and floating point values (usually 8 bytes but sometimes truncated). For xport files, there is no automatic type conversion to integers, dates, or categoricals. For SAS7BDAT files, the format codes may allow date variables to be automatically converted to dates. By default the whole file is read and returned as a `DataFrame`.

Specify a `chunksize` or use `iterator=True` to obtain reader objects (`XportReader` or `SAS7BDATReader`) for incrementally reading the file. The reader objects also have attributes that contain additional information about the file and its variables.

Read a SAS7BDAT file:

```python
df = pd.read_sas("sas_data.sas7bdat")
```

Obtain an iterator and read an XPORT file 100,000 lines at a time:

```python
def do_something(chunk):
    pass

with pd.read_sas("sas_xport.xpt", chunk=100000) as rdr:
    for chunk in rdr:
        do_something(chunk)
```

The specification for the xport file format is available from the SAS web site.

No official documentation is available for the SAS7BDAT format.

2.4.20 SPSS formats

New in version 0.25.0.

The top-level function `read_spss()` can read (but not write) SPSS SAV (.sav) and ZSAV (.zsav) format files.

SPSS files contain column names. By default the whole file is read, categorical columns are converted into `pd.Categorical`, and a `DataFrame` with all columns is returned.

Specify the `usecols` parameter to obtain a subset of columns. Specify `convert_categoricals=False` to avoid converting categorical columns into `pd.Categorical`.

Read an SPSS file:

```python
df = pd.read_spss("spss_data.sav")
```

Extract a subset of columns contained in `usecols` from an SPSS file and avoid converting categorical columns into `pd.Categorical`:

```python
df = pd.read_spss(
    "spss_data.sav",
    usecols=["foo", "bar"],
    convert_categoricals=False
)
```

More information about the SAV and ZSAV file formats is available here.
2.4.21 Other file formats

pandas itself only supports IO with a limited set of file formats that map cleanly to its tabular data model. For reading and writing other file formats into and from pandas, we recommend these packages from the broader community.

netCDF

xarray provides data structures inspired by the pandas DataFrame for working with multi-dimensional datasets, with a focus on the netCDF file format and easy conversion to and from pandas.

2.4.22 Performance considerations

This is an informal comparison of various IO methods, using pandas 0.24.2. Timings are machine dependent and small differences should be ignored.

```python
In [1]: sz = 1000000

In [3]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 2 columns):
A 1000000 non-null float64
B 1000000 non-null int64
dtypes: float64(1), int64(1)
memory usage: 15.3 MB
```

The following test functions will be used below to compare the performance of several IO methods:

```python
import numpy as np
import os

sz = 1000000

sz = 1000000
np.random.seed(42)

def test_sql_write(df):
    if os.path.exists("test.sql"):
        os.remove("test.sql")
    sql_db = sqlite3.connect("test.sql")
df.to_sql(name="test_table", con=sql_db)
sql_db.close()

def test_sql_read():
    sql_db = sqlite3.connect("test.sql")
pd.read_sql_query("select * from test_table", sql_db)
sql_db.close()
```

(continues on next page)
```python
def test_hdf_fixed_write(df):
    df.to_hdf("test_fixed.hdf", "test", mode="w")

def test_hdf_fixed_read():
    pd.read_hdf("test_fixed.hdf", "test")

def test_hdf_fixed_write_compress(df):
    df.to_hdf("test_fixed_compress.hdf", "test", mode="w", complib="blosc")

def test_hdf_fixed_read_compress():
    pd.read_hdf("test_fixed_compress.hdf", "test")

def test_hdf_table_write(df):
    df.to_hdf("test_table.hdf", "test", mode="w", format="table")

def test_hdf_table_read():
    pd.read_hdf("test_table.hdf", "test")

def test_hdf_table_write_compress(df):
    df.to_hdf(
        "test_table_compress.hdf", "test", mode="w", complib="blosc", format="table"
    )

def test_hdf_table_read_compress():
    pd.read_hdf("test_table_compress.hdf", "test")

def test_csv_write(df):
    df.to_csv("test.csv", mode="w")

def test_csv_read():
    pd.read_csv("test.csv", index_col=0)

def test_feather_write(df):
    df.to_feather("test.feather")

def test_feather_read():
    pd.read_feather("test.feather")

def test_pickle_write(df):
    df.to_pickle("test.pkl")

def test_pickle_read():
    pd.read_pickle("test.pkl")
```

(continues on next page)
def test_pickle_write_compress(df):
    df.to_pickle("test.pkl.compress", compression="xz")

def test_pickle_read_compress():
    pd.read_pickle("test.pkl.compress", compression="xz")

def test_parquet_write(df):
    df.to_parquet("test.parquet")

def test_parquet_read():
    pd.read_parquet("test.parquet")

When writing, the top three functions in terms of speed are test_feather_write, test_hdf_fixed_write and test_hdf_fixed_write_compress.

In [4]: %timeit test_sql_write(df)
3.29 s ± 43.2 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [5]: %timeit test_hdf_fixed_write(df)
19.4 ms ± 560 µs per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [6]: %timeit test_hdf_fixed_write_compress(df)
19.6 ms ± 308 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [7]: %timeit test_hdf_table_write(df)
449 ms ± 5.61 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [8]: %timeit test_hdf_table_write_compress(df)
448 ms ± 11.9 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [9]: %timeit test_csv_write(df)
3.66 s ± 26.2 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [10]: %timeit test_feather_write(df)
9.75 ms ± 117 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

In [11]: %timeit test_pickle_write(df)
30.1 ms ± 229 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [12]: %timeit test_pickle_write_compress(df)
4.29 s ± 15.9 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [13]: %timeit test_parquet_write(df)
67.6 ms ± 706 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

When reading, the top three functions in terms of speed are test_feather_read, test_pickle_read and test_hdf_fixed_read.

In [14]: %timeit test_sql_read() 
1.77 s ± 17.7 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [15]: %timeit test_hdf_fixed_read() (continues on next page)
19.4 ms ± 436 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [16]: %timeit test_hdf_fixed_read_compress()
19.5 ms ± 222 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [17]: %timeit test_hdf_table_read()
38.6 ms ± 857 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [18]: %timeit test_hdf_table_read_compress()
38.8 ms ± 1.49 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [19]: %timeit test_csv_read()
452 ms ± 9.04 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [20]: %timeit test_feather_read()
12.4 ms ± 99.7 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

In [21]: %timeit test_pickle_read()
18.4 ms ± 191 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

In [22]: %timeit test_pickle_read_compress()
915 ms ± 7.48 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [23]: %timeit test_parquet_read()
24.4 ms ± 146 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

The files test.pkl.compress, test.parquet and test.feather took the least space on disk (in bytes).

29519500 Oct 10 06:45 test.csv
16000248 Oct 10 06:45 test.feather
8281983 Oct 10 06:49 test.parquet

24009288 Oct 10 06:43 test_fixed_compress.hdf
24458940 Oct 10 06:44 test_table.hdf
24458940 Oct 10 06:44 test_table_compress.hdf

2.5 Indexing and selecting data

The axis labeling information in pandas objects serves many purposes:

- Identifies data (i.e. provides metadata) using known indicators, important for analysis, visualization, and interactive console display.
- Enables automatic and explicit data alignment.
- Allows intuitive getting and setting of subsets of the data set.

In this section, we will focus on the final point: namely, how to slice, dice, and generally get and set subsets of pandas objects. The primary focus will be on Series and DataFrame as they have received more development attention in this area.

Note: The Python and NumPy indexing operators [ ] and attribute operator . provide quick and easy access to pandas
data structures across a wide range of use cases. This makes interactive work intuitive, as there’s little new to learn if you already know how to deal with Python dictionaries and NumPy arrays. However, since the type of the data to be accessed isn’t known in advance, directly using standard operators has some optimization limits. For production code, we recommended that you take advantage of the optimized pandas data access methods exposed in this chapter.

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See *Returning a View versus Copy*.

See the *MultiIndex / Advanced Indexing* for MultiIndex and more advanced indexing documentation.

See the *cookbook* for some advanced strategies.

### 2.5.1 Different choices for indexing

Object selection has had a number of user-requested additions in order to support more explicit location based indexing. pandas now supports three types of multi-axis indexing.

- **.loc** is primarily label based, but may also be used with a boolean array. `.loc` will raise `KeyError` when the items are not found. Allowed inputs are:
  - A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a *label* of the index. This use is **not** an integer position along the index.).
  - A list or array of labels `['a', 'b', 'c']`.
  - A slice object with labels 'a': 'f' (Note that contrary to usual Python slices, both the start and the stop are included, when present in the index! See *Slicing with labels* and *Endpoints are inclusive.*).
  - A boolean array (any NA values will be treated as `False`).
  - A **callable** function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above).

See more at *Selection by Label*.

- **.iloc** is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array. `.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except *slice* indexers which allow out-of-bounds indexing. (this conforms with Python/NumPy *slice* semantics). Allowed inputs are:
  - An integer e.g. 5.
  - A list or array of integers [4, 3, 0].
  - A slice object with ints 1:7.
  - A boolean array (any NA values will be treated as `False`).
  - A **callable** function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above).

See more at *Selection by Position, Advanced Indexing* and *Advanced Hierarchical*.

- **.loc, .iloc, and also []** indexing can accept a **callable** as indexer. See more at *Selection By Callable*.

Getting values from an object with multi-axes selection uses the following notation (using `.loc` as an example, but the following applies to `.iloc` as well). Any of the axes accessors may be the null slice `:`. Axes left out of the specification are assumed to be `:` e.g. `p.loc['a']` is equivalent to `p.loc['a', :, :]`. 

---

392 Chapter 2. User Guide
Object Type | Indexers
---|---
Series | s.loc[indexer]
DataFrame | df.loc[row_indexer, column_indexer]

### 2.5.2 Basics

As mentioned when introducing the data structures in the last section, the primary function of indexing with [] (a.k.a. `__getitem__` for those familiar with implementing class behavior in Python) is selecting out lower-dimensional slices. The following table shows return type values when indexing pandas objects with []:

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Selection</th>
<th>Return Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series</td>
<td>series[label]</td>
<td>scalar value</td>
</tr>
<tr>
<td>DataFrame</td>
<td>frame[colname]</td>
<td>Series corresponding to colname</td>
</tr>
</tbody>
</table>

Here we construct a simple time series data set to use for illustrating the indexing functionality:

```python
In [1]: dates = pd.date_range('1/1/2000', periods=8)
In [2]: df = pd.DataFrame(np.random.randn(8, 4),
                      index=dates, columns=['A', 'B', 'C', 'D'])
In [3]: df
Out[3]:
       A          B          C          D
2000-01-01 0.469112 -0.282863 -1.509059 -1.135632
2000-01-02 1.212112 -0.173215  0.119209 -1.044236
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
2000-01-04  0.721555 -0.706771 -1.039575  0.271860
2000-01-05 -0.424972  0.567020  0.276232 -1.087401
2000-01-06 -0.673690  0.113648 -1.478427  0.524988
2000-01-07  0.404705  0.577046 -1.715002 -1.039268
2000-01-08 -0.370647 -1.157892 -1.344312  0.844885
```

**Note:** None of the indexing functionality is time series specific unless specifically stated.

Thus, as per above, we have the most basic indexing using []:

```python
In [4]: s = df['A']
In [5]: s[dates[5]]
Out[5]: -0.6736897080883706
```

You can pass a list of columns to [] to select columns in that order. If a column is not contained in the DataFrame, an exception will be raised. Multiple columns can also be set in this manner:

```python
In [6]: df
Out[6]:
       A          B          C          D
2000-01-01 0.469112 -0.282863 -1.509059 -1.135632
2000-01-02 1.212112 -0.173215  0.119209 -1.044236
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
```

(continues on next page)
In [7]: df[['B', 'A']] = df[['A', 'B']]

In [8]: df

Out[8]:
A   B   C    D
000-01-01 -0.282863 0.469112 -1.509059 -1.135632
000-01-02 -0.173215 1.212112 0.119209 -1.044236
000-01-03 -2.104569 -0.861849 -0.494929 1.071804
000-01-04 -0.706771 0.721555 -1.039575 0.271860
000-01-05 0.567020 -0.424972 0.276232 -1.087401
000-01-06 0.113648 -0.673690 -1.478427 0.524988
000-01-07 0.577046 0.404705 -1.715002 -1.039268
000-01-08 -1.157892 -0.370647 -1.344312 0.844885

You may find this useful for applying a transform (in-place) to a subset of the columns.

**Warning:** pandas aligns all AXES when setting Series and DataFrame from .loc, and .iloc.

This will not modify df because the column alignment is before value assignment.

In [9]: df[['A', 'B']]  
Out[9]:
A   B
000-01-01 -0.282863 0.469112
000-01-02 -0.173215 1.212112
000-01-03 -2.104569 -0.861849
000-01-04 -0.706771 0.721555
000-01-05 0.567020 -0.424972
000-01-06 0.113648 -0.673690
000-01-07 0.577046 0.404705
000-01-08 -1.157892 -0.370647

In [10]: df.loc[:, ['B', 'A']] = df[['A', 'B']]

In [11]: df[['A', 'B']]  
Out[11]:
A   B
000-01-01 -0.282863 0.469112
000-01-02 -0.173215 1.212112
000-01-03 -2.104569 -0.861849
000-01-04 -0.706771 0.721555
000-01-05 0.567020 -0.424972
000-01-06 0.113648 -0.673690
000-01-07 0.577046 0.404705
000-01-08 -1.157892 -0.370647

The correct way to swap column values is by using raw values:
2.5.3 Attribute access

You may access an index on a `Series` or column on a `DataFrame` directly as an attribute:

```
In [14]: sa = pd.Series([1, 2, 3], index=list('abc'))
In [15]: dfa = df.copy()

In [16]: sa.b
Out[16]: 2

In [17]: dfa.A
Out[17]:
2000-01-01    0.469112
2000-01-02    1.212112
2000-01-03   -0.861849
2000-01-04    0.721555
2000-01-05   -0.424972
2000-01-06   -0.673690
2000-01-07    0.404705
2000-01-08   -0.370647
Freq: D, Name: A, dtype: float64
```

```
In [18]: sa.a = 5

In [19]: sa
Out[19]:
a    5
b    2
c    3
dtype: int64
```

```
In [20]: dfa.A = list(range(len(dfa.index)))  # ok if A already exists

In [21]: dfa
Out[21]:
   A  B       C       D
2000-01-01  0 -0.282863 -1.509059 -1.135632
2000-01-02  1 -0.173215  0.119209 -1.044236
2000-01-03  2 -2.104569 -0.494929  1.071804
```
In [22]: dfa['A'] = list(range(len(dfa.index)))  # use this form to create a new column

In [23]: dfa
Out[23]:
   A   B   C   D
0  0  -0.282863 -1.509059 -1.135632
1  1  -0.173215  0.119209 -1.044236
2  2  -2.104569  0.494929  1.071804
3  3  -0.706771 -1.039575  0.271860
4  4   0.567020  0.276232 -1.087401
5  5   0.113648 -1.478427  0.524988
6  6   0.577046 -1.715002 -1.039268
7  7  -1.157892 -1.344312  0.844885

Warning:

- You can use this access only if the index element is a valid Python identifier, e.g. s.1 is not allowed. See here for an explanation of valid identifiers.
- The attribute will not be available if it conflicts with an existing method name, e.g. s.min is not allowed, but s['min'] is possible.
- Similarly, the attribute will not be available if it conflicts with any of the following list: index, major_axis, minor_axis, items.
- In any of these cases, standard indexing will still work, e.g. s['1'], s['min'], and s['index'] will access the corresponding element or column.

If you are using the IPython environment, you may also use tab-completion to see these accessible attributes.

You can also assign a dict to a row of a DataFrame:

In [24]: x = pd.DataFrame({'x': [1, 2, 3], 'y': [3, 4, 5]})

In [25]: x.iloc[1] = {'x': 9, 'y': 99}

In [26]: x
Out[26]:
   x   y
0  1   3
1  9  99
2  3   5

You can use attribute access to modify an existing element of a Series or column of a DataFrame, but be careful; if you try to use attribute access to create a new column, it creates a new attribute rather than a new column. In 0.21.0 and later, this will raise a UserWarning:

In [1]: df = pd.DataFrame({'one': [1., 2., 3.]})
In [2]: df.two = [4, 5, 6]
2.5.4 Slicing ranges

The most robust and consistent way of slicing ranges along arbitrary axes is described in the Selection by Position section detailing the .iloc method. For now, we explain the semantics of slicing using the [ ] operator.

With Series, the syntax works exactly as with an ndarray, returning a slice of the values and the corresponding labels:

```python
In [27]: s[:5]
Out[27]:
2000-01-01  0.469112
2000-01-02  1.212112
2000-01-03 -0.861849
2000-01-04  0.721555
2000-01-05 -0.424972
Freq: D, Name: A, dtype: float64
```

```python
In [28]: s[::2]
Out[28]:
2000-01-01  0.469112
2000-01-03 -0.861849
2000-01-07  0.404705
Freq: 2D, Name: A, dtype: float64
```

```python
In [29]: s[::-1]
Out[29]:
2000-01-08 -0.370647
2000-01-07  0.404705
2000-01-06 -0.673690
2000-01-05 -0.424972
2000-01-04  0.721555
2000-01-03 -0.861849
2000-01-02  1.212112
2000-01-01  0.469112
Freq: -1D, Name: A, dtype: float64
```

Note that setting works as well:

```python
In [30]: s2 = s.copy()

In [31]: s2[:5] = 0

In [32]: s2
Out[32]:
2000-01-01  0.000000
2000-01-02  0.000000
```

(continues on next page)
With DataFrame, slicing inside of [] slices the rows. This is provided largely as a convenience since it is such a common operation.

```
In [33]: df[:3]
Out[33]:
   A    B    C    D
2000-01-01 0.469112 -0.282863 -1.509059 -1.135632
2000-01-02 1.212112 -0.173215 0.119209 -1.044236
2000-01-03 -0.861849 -2.104569 -0.494929 1.071804
```

```
In [34]: df[::-1]
Out[34]:
   A    B    C    D
2000-01-08 -0.370647 -1.157892 -1.344312 0.844885
2000-01-07 0.404705 0.577046 -1.715002 -1.039268
2000-01-06 -0.673690 0.113648 -1.478427 0.524988
2000-01-05 -0.424972 0.567020 0.276232 -1.087401
2000-01-04 0.721555 -0.706771 -1.039575 0.271860
2000-01-03 -0.861849 -2.104569 -0.494929 1.071804
2000-01-02 1.212112 -0.173215 0.119209 -1.044236
2000-01-01 0.469112 -0.282863 -1.509059 -1.135632
```

### 2.5.5 Selection by label

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See *Returning a View versus Copy*.

```
In [35]: dfl = pd.DataFrame(np.random.randn(5, 4),
                    columns=list('ABCD'),
                    index=pd.date_range('20130101', periods=5))
```

```
In [36]: dfl
Out[36]:
   A    B    C    D
2013-01-01 1.075770 -0.109050 1.643563 -1.469388
2013-01-02 0.357021 -0.674600 -1.715002 -1.039268
2013-01-03 -1.294524 0.413738 0.276232 -1.087401
2013-01-04 -0.013960 -0.362543 -0.006154 -0.923061
2013-01-05 0.895717 0.805244 -1.206412 2.565646
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

```
In [4]: df1.loc[2:3]
TypeError: cannot do slice indexing on <class 'pandas.tseries.index.DatetimeIndex'>

→ with these indexers [2] of <type 'int'>
```

String likes in slicing can be convertible to the type of the index and lead to natural slicing.

```
In [37]: df1.loc['20130102':'20130104']
Out[37]:
         A     B     C     D
2013-01-02  0.357021 -0.674600 -1.776904 -0.968914
2013-01-03 -1.294524  0.413738  0.276662 -0.472035
2013-01-04 -0.013960 -0.362543 -0.006154 -0.923061
```

**Warning:** Changed in version 1.0.0.

pandas will raise a `KeyError` if indexing with a list with missing labels. See *list-like Using loc with missing keys in a list is Deprecated.*

pandas provides a suite of methods in order to have **purely label based indexing**. This is a strict inclusion based protocol. Every label asked for must be in the index, or a `KeyError` will be raised. When slicing, both the start bound AND the stop bound are included, if present in the index. Integers are valid labels, but they refer to the label and not the position.

The `.loc` attribute is the primary access method. The following are valid inputs:

- A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a label of the index. This use is not an integer position along the index.).
- A list or array of labels ['a', 'b', 'c'].
- A slice object with labels 'a':'f' (Note that contrary to usual Python slices, both the start and the stop are included, when present in the index! See *Slicing with labels*).
- A boolean array.
- A callable, see *Selection By Callable*.

```
In [38]: s1 = pd.Series(np.random.randn(6), index=list('abcdef'))
In [39]: s1
Out[39]:
a   1.431256
b   1.340309
c -1.170299
d  -0.226169
e   0.410835
f   0.813850
dtype: float64
In [40]: s1.loc['c':]
Out[40]:
c  -1.170299
d  -0.226169
e   0.410835
f   0.813850
dtype: float64
```

(continues on next page)
In [41]: s1.loc['b']
Out[41]: 1.3403088497993827

Note that setting works as well:

In [42]: s1.loc['c'] = 0
In [43]: s1
Out[43]:
   a    1.431256
   b    1.340309
   c    0.000000
   d    0.000000
   e    0.000000
   f    0.000000
   dtype: float64

With a DataFrame:

In [44]: df1 = pd.DataFrame(np.random.randn(6, 4),
                      index=list('abcdef'),
                      columns=list('ABCD'))

In [45]: df1
Out[45]:
    A   B   C   D
  a 0.132003 -0.827317 -0.076467 -1.187678
  b 1.130127 -1.436737 -1.413681  1.607920
  c 1.024180  0.569605  0.875906 -2.211372
  d 0.974466 -2.006747 -0.410001 -0.078638
  e 0.545952 -1.219217 -1.226825  0.769804
  f -1.281247 -0.727707 -0.121306 -0.097883

In [46]: df1.loc[['a', 'b', 'd'], :]
Out[46]:
   A   B   C   D
  a 0.132003 -0.827317 -0.076467 -1.187678
  b 1.130127 -1.436737 -1.413681  1.607920
  d 0.974466 -2.006747 -0.410001 -0.078638

Accessing via label slices:

In [47]: df1.loc['a':'c', 'A':'C']
Out[47]:
    A  B  C
  a 0.132003 -0.827317 -0.076467
  b 1.130127 -1.436737 -1.413681
  c 1.024180  0.569605  0.875906
  d 0.974466 -2.006747 -0.410001
  e 0.545952 -1.219217 -1.226825
  f -1.281247 -0.727707 -0.121306

For getting a cross section using a label (equivalent to df.xs('a')):

In [48]: df1.loc['a']
Out[48]:
   A
  0  0.132003

(continues on next page)
For getting values with a boolean array:

```python
In [49]: df1.loc['a'] > 0
Out[49]:
   A   True
   B   False
   C   False
   D   False
Name: a, dtype: bool

In [50]: df1[:, df1.loc['a'] > 0]
Out[50]:
   a  b  c  d
   0.132003 1.130127 1.024180 0.974466
   e  -1.281247
```

NA values in a boolean array propagate as False:

Changed in version 1.0.2.

```python
In [51]: mask = pd.array([True, False, True, False, pd.NA, False], dtype="boolean")

In [52]: mask
Out[52]:
<BooleanArray>
[True, False, True, False, <NA>, False]
Length: 6, dtype: boolean

In [53]: df1[mask]
Out[53]:
   A  B  C  D
   a  0.132003 -0.827317 -0.076467 -1.187678
   c  1.024180 0.569605 0.875906 -2.211372
```

For getting a value explicitly:

```python
# this is also equivalent to `df1.at['a', 'A']`
In [54]: df1.loc['a', 'A']
Out[54]: 0.13200317033032932
```
Slicing with labels

When using `.loc` with slices, if both the start and the stop labels are present in the index, then elements *located* between the two (including them) are returned:

```
In [55]: s = pd.Series(list('abcde'), index=[0, 3, 2, 5, 4])
In [56]: s.loc[3:5]
Out[56]:
3  b
2  c
5  d
dtype: object
```

If at least one of the two is absent, but the index is sorted, and can be compared against start and stop labels, then slicing will still work as expected, by selecting labels which *rank* between the two:

```
In [57]: s.sort_index()
Out[57]:
  0  a
  2  c
  3  b
  4  e
  5  d
dtype: object
In [58]: s.sort_index().loc[1:6]
Out[58]:
  2  c
  3  b
  4  e
  5  d
dtype: object
```

However, if at least one of the two is absent *and* the index is not sorted, an error will be raised (since doing otherwise would be computationally expensive, as well as potentially ambiguous for mixed type indexes). For instance, in the above example, `s.loc[1:6]` would raise `KeyError`.

For the rationale behind this behavior, see *Endpoints are inclusive*.

```
In [59]: s = pd.Series(list('abcdef'), index=[0, 3, 2, 5, 4, 2])
In [60]: s.loc[3:5]
Out[60]:
  3  b
  2  c
  5  d
dtype: object
```

Also, if the index has duplicate labels *and* either the start or the stop label is duplicated, an error will be raised. For instance, in the above example, `s.loc[2:5]` would raise a `KeyError`.

For more information about duplicate labels, see *Duplicate Labels*.
2.5.6 Selection by position

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See [Returning a View versus Copy](#).

pandas provides a suite of methods in order to get purely integer based indexing. The semantics follow closely Python and NumPy slicing. These are 0-based indexing. When slicing, the start bound is included, while the upper bound is excluded. Trying to use a non-integer, even a valid label will raise an IndexError.

The `.iloc` attribute is the primary access method. The following are valid inputs:

- An integer e.g. 5.
- A list or array of integers [4, 3, 0].
- A slice object with ints 1:7.
- A boolean array.
- A callable, see [Selection By Callable](#).

```python
In [61]: s1 = pd.Series(np.random.randn(5), index=list(range(0, 10, 2))

In [62]: s1
Out[62]:
0    0.695775
2    0.341734
4    0.959726
6   -1.110336
8   -0.619976
dtype: float64

In [63]: s1.iloc[:3]
Out[63]:
0    0.695775
2    0.341734
4    0.959726
 dtype: float64

In [64]: s1.iloc[3]
Out[64]: -1.110336102891167
```

Note that setting works as well:

```python
In [65]: s1.iloc[3] = 0

In [66]: s1
Out[66]:
0    0.000000
2    0.000000
4    0.000000
6   -1.110336
8   -0.619976
dtype: float64
```

With a DataFrame:
In [67]: df1 = pd.DataFrame(np.random.randn(6, 4),
   ....:     index=list(range(0, 12, 2)),
   ....:     columns=list(range(0, 8, 2))
   ....:
In [68]: df1
Out[68]:
   0   2   4  
0 0.149748 -0.732339 0.687738 0.176444
2 0.403310 -0.154951 0.301624 -2.179861
4 -1.369849 -0.954208 1.462696 -1.743161
6 -0.826591 -0.345352 1.314232 0.690579
8 0.995761 2.396780 0.014871 3.357427
10 -0.317441 -1.236269 0.896171 -0.487602

Select via integer slicing:

In [69]: df1.iloc[:3]
Out[69]:
   0   2   4  
0 0.149748 -0.732339 0.687738 0.176444
2 0.403310 -0.154951 0.301624 -2.179861
4 -1.369849 -0.954208 1.462696 -1.743161

In [70]: df1.iloc[1:5, 2:4]
Out[70]:
   4  
 2 -0.154951 -2.179861
4 1.462696 -1.743161
6 0.690579
8 3.357427

Select via integer list:

In [71]: df1.iloc[[1, 3, 5], [1, 3]]
Out[71]:
   2  
2 -0.154951 -2.179861
6 -0.345352 0.690579
10 -1.236269 -0.487602

In [72]: df1.iloc[[1, 3], :]
Out[72]:
   0   2  
2 0.403310 -0.154951
4 -1.369849 -0.954208
   4  
 2 -0.732339 0.687738
4 -0.954208 1.462696
6 -0.345352 1.314232
8 2.396780 0.014871
10 -1.236269 0.896171
For getting a cross section using an integer position (equiv to `df.xs(1)`):

```py
In [75]: df1.iloc[1]
Out[75]:
0    0.403310
2    -0.154951
4     0.301624
6    -2.179861
Name: 2, dtype: float64
```

Out of range slice indexes are handled gracefully just as in Python/NumPy.

```py
# these are allowed in Python/NumPy.
In [76]: x = list('abcdef')
In [77]: x
Out[77]: ['a', 'b', 'c', 'd', 'e', 'f']
In [78]: x[4:10]
Out[78]: ['e', 'f']
In [79]: x[8:10]
Out[79]: []
In [80]: s = pd.Series(x)
In [81]: s
Out[81]:
0    a
1    b
2    c
3    d
4    e
5    f
dtype: object
In [82]: s.iloc[4:10]
Out[82]:
4    e
5    f
dtype: object
In [83]: s.iloc[8:10]
Out[83]: Series([], dtype: object)
```

Note that using slices that go out of bounds can result in an empty axis (e.g. an empty DataFrame being returned).

```py
In [84]: dfl = pd.DataFrame(np.random.randn(5, 2), columns=list('AB'))
In [85]: dfl
Out[85]:
   A         B
0  0.082240  2.182937
1 -0.154951 -0.872225
2 -0.154951 -0.872225
3 -0.154951 -0.872225
4 -0.154951 -0.872225
```
A single indexer that is out of bounds will raise an IndexError. A list of indexers where any element is out of bounds will raise an IndexError.

>>> df1.iloc[[4, 5, 6]]
IndexError: positional indexers are out-of-bounds

>>> df1.iloc[:, 4]
IndexError: single positional indexer is out-of-bounds

### 2.5.7 Selection by callable

.loc, .iloc, and also [] indexing can accept a callable as indexer. The callable must be a function with one argument (the calling Series or DataFrame) that returns valid output for indexing.

In [90]: df1 = pd.DataFrame(np.random.randn(6, 4),
                       index=list('abcdef'),
                       columns=list('ABCD'))

In [91]: df1.loc[lambda df: df['A'] > 0, :]
pandas: powerful Python data analysis toolkit, Release 1.3.1

You can use callable indexing in Series.

Using these methods / indexers, you can chain data selection operations without using a temporary variable.
### 2.5.8 Combining positional and label-based indexing

If you wish to get the 0th and the 2nd elements from the index in the ‘A’ column, you can do:

```py
In [98]: dfd = pd.DataFrame({'A': [1, 2, 3],
                         'B': [4, 5, 6],
                         index=list('abc'))

In [99]: dfd
Out[99]:
   A  B
a 1  4
b 2  5
c 3  6

In [100]: dfd.loc[dfd.index[[0, 2]], 'A']
Out[100]:
   Name: A, dtype: int64
   a  1
   c  3

This can also be expressed using `.iloc`, by explicitly getting locations on the indexers, and using *positional* indexing to select things.

```py
In [101]: dfd.iloc[[0, 2], dfd.columns.get_loc('A')]
Out[101]:
   Name: A, dtype: int64
   a  1
   c  3
```

For getting *multiple* indexers, using `.get_indexer`:

```py
In [102]: dfd.iloc[[0, 2], dfd.columns.get_indexer(['A', 'B'])]
Out[102]:
   A  B
   a  1  4
   c  3  6
```
### 2.5.9 Indexing with list with missing labels is deprecated

**Warning:** Changed in version 1.0.0.

Using `.loc` or `[]` with a list with one or more missing labels will no longer reindex, in favor of `.reindex`.

In prior versions, using `.loc[list-of-labels]` would work as long as at least 1 of the keys was found (otherwise it would raise a `KeyError`). This behavior was changed and will now raise a `KeyError` if at least one label is missing. The recommended alternative is to use `.reindex()`.

For example.

```
In [103]: s = pd.Series([1, 2, 3])
In [104]: s
Out[104]:
    0    1
   1    2
   2    3
   dtype: int64

Selection with all keys found is unchanged.

In [105]: s.loc[[1, 2]]
Out[105]:
    1    2
   2    3
   dtype: int64

Previous behavior

In [4]: s.loc[[1, 2, 3]]
Out[4]:
    1    2.0
    2    3.0
    3    NaN
   dtype: float64

Current behavior

In [4]: s.loc[[1, 2, 3]]
Passing list-likes to `.loc` with any non-matching elements will raise
KeyError in the future, you can use `.reindex()` as an alternative.

See the documentation here:
```

```
Reindexing

The idiomatic way to achieve selecting potentially not-found elements is via .reindex(). See also the section on reindexing.

```python
In [106]: s.reindex([1, 2, 3])
Out[106]:
1   2.0
2   3.0
3  NaN
dtype: float64
```

Alternatively, if you want to select only valid keys, the following is idiomatic and efficient; it is guaranteed to preserve the dtype of the selection.

```python
In [107]: labels = [1, 2, 3]
In [108]: s.loc[s.index.intersection(labels)]
Out[108]:
1   2
2   3
dtype: int64
```

Having a duplicated index will raise for a .reindex():

```python
In [109]: s = pd.Series(np.arange(4), index=['a', 'a', 'b', 'c'])
In [110]: labels = ['c', 'd']
```

```python
In [17]: s.reindex(labels)
ValueError: cannot reindex from a duplicate axis
```

Generally, you can intersect the desired labels with the current axis, and then reindex.

```python
In [111]: s.loc[s.index.intersection(labels)].reindex(labels)
Out[111]:
c   3.0
d  NaN
dtype: float64
```

However, this would still raise if your resulting index is duplicated.

```python
In [41]: labels = ['a', 'd']
In [42]: s.loc[s.index.intersection(labels)].reindex(labels)
ValueError: cannot reindex from a duplicate axis
```
2.5.10 Selecting random samples

A random selection of rows or columns from a Series or DataFrame with the `sample()` method. The method will sample rows by default, and accepts a specific number of rows/columns to return, or a fraction of rows.

```
In [112]: s = pd.Series([0, 1, 2, 3, 4, 5])

# When no arguments are passed, returns 1 row.
In [113]: s.sample()
Out[113]:
4 4
   dtype: int64

# One may specify either a number of rows:
In [114]: s.sample(n=3)
Out[114]:
0 0
4 4
1 1
   dtype: int64

# Or a fraction of the rows:
In [115]: s.sample(frac=0.5)
Out[115]:
5 5
3 3
1 1
   dtype: int64
```

By default, `sample` will return each row at most once, but one can also sample with replacement using the `replace` option:

```
In [116]: s = pd.Series([0, 1, 2, 3, 4, 5])

# Without replacement (default):
In [117]: s.sample(n=6, replace=False)
Out[117]:
0 0
1 1
5 5
3 3
2 2
4 4
   dtype: int64

# With replacement:
In [118]: s.sample(n=6, replace=True)
Out[118]:
0 0
4 4
3 3
2 2
4 4
4 4
   dtype: int64
```

By default, each row has an equal probability of being selected, but if you want rows to have different probabilities, you can pass the `sample` function sampling weights as `weights`. These weights can be a list, a NumPy array, or a
Series, but they must be of the same length as the object you are sampling. Missing values will be treated as a weight of zero, and inf values are not allowed. If weights do not sum to 1, they will be re-normalized by dividing all weights by the sum of the weights. For example:

```python
In [119]: s = pd.Series([0, 1, 2, 3, 4, 5])
In [120]: example_weights = [0, 0, 0.2, 0.2, 0.2, 0.4]
In [121]: s.sample(n=3, weights=example_weights)
Out[121]:
5 5
4 4
3 3
dtype: int64
# Weights will be re-normalized automatically
In [122]: example_weights2 = [0.5, 0, 0, 0, 0, 0]
In [123]: s.sample(n=1, weights=example_weights2)
Out[123]:
0 0
dtype: int64
```

When applied to a DataFrame, you can use a column of the DataFrame as sampling weights (provided you are sampling rows and not columns) by simply passing the name of the column as a string.

```python
In [124]: df2 = pd.DataFrame({'col1': [9, 8, 7, 6],
                       'weight_column': [0.5, 0.4, 0.1, 0]})
In [125]: df2.sample(n=3, weights='weight_column')
Out[125]:
   col1  weight_column
0   9       0.5
1   8       0.4
2   7       0.1
```

`sample` also allows users to sample columns instead of rows using the `axis` argument.

```python
In [126]: df3 = pd.DataFrame({'col1': [1, 2, 3], 'col2': [2, 3, 4]})
In [127]: df3.sample(n=1, axis=1)
Out[127]:
   col1
0   1
1   2
2   3
```

Finally, one can also set a seed for `sample`'s random number generator using the `random_state` argument, which will accept either an integer (as a seed) or a NumPy RandomState object.

```python
In [128]: df4 = pd.DataFrame({'col1': [1, 2, 3], 'col2': [2, 3, 4]})
# With a given seed, the sample will always draw the same rows.
In [129]: df4.sample(n=2, random_state=2)
Out[129]:
   col1  col2
0    1    2
1    3    4
```

(continues on next page)
2.5.11 Setting with enlargement

The .loc/[] operations can perform enlargement when setting a non-existent key for that axis.

In the Series case this is effectively an appending operation.

A DataFrame can be enlarged on either axis via .loc.

This is like an append operation on the DataFrame.
In [139]: dfi.loc[3] = 5

In [140]: dfi
Out[140]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
3  5  5  5

2.5.12 Fast scalar value getting and setting

Since indexing with [] must handle a lot of cases (single-label access, slicing, boolean indexing, etc.), it has a bit of overhead in order to figure out what you’re asking for. If you only want to access a scalar value, the fastest way is to use the at and iat methods, which are implemented on all of the data structures.

Similarly to loc, at provides label based scalar lookups, while, iat provides integer based lookups analogously to iloc

In [141]: s.iat[5]
Out[141]: 5

In [142]: df.at[dates[5], 'A']
Out[142]: -0.6736897080883706

In [143]: df.iat[3, 0]
Out[143]: 0.7215551622443669

You can also set using these same indexers.

In [144]: df.at[dates[5], 'E'] = 7
In [145]: df.iat[3, 0] = 7

at may enlarge the object in-place as above if the indexer is missing.

In [146]: df.at[dates[-1] + pd.Timedelta('1 day'), 0] = 7

In [147]: df
Out[147]:
   A      B      C      D      E
0 0.469112 -0.282863 -1.509059 -1.135632  NaN  NaN
1 1.212112  0.173215  0.119209  0.104426  NaN  NaN
2 0.861849  2.104569  0.494929  1.071804  NaN  NaN
3  7.000000  0.706771  2.39575  0.271860  NaN  NaN
4  0.424972  0.567020  0.276232  0.187401  NaN  NaN
5 -0.673690  0.113648 -1.478427  0.524988   7.0   NaN
6  0.404705  0.577046 -1.715002 -0.103926  NaN  NaN
7 -0.370647 -1.147892  1.344312  0.844885  NaN  NaN
8  NaN     NaN  NaN  NaN     NaN   7.0
2.5.13 Boolean indexing

Another common operation is the use of boolean vectors to filter the data. The operators are: | for or, & for and, and ~ for not. These must be grouped by using parentheses, since by default Python will evaluate an expression such as \( \text{df['A']} > 2 \& \text{df['B']} < 3 \) as \( \text{df['A']} > (2 \& \text{df['B']}) < 3 \), while the desired evaluation order is \( (\text{df['A']} > 2) \& (\text{df['B']} < 3) \).

Using a boolean vector to index a Series works exactly as in a NumPy ndarray:

```python
In [148]: s = pd.Series(range(-3, 4))

In [149]: s
Out[149]:
0   -3
1   -2
2   -1
3    0
4    1
5    2
6    3
dtype: int64

In [150]: s[s > 0]
Out[150]:
4    1
5    2
6    3
dtype: int64

In [151]: (s < -1) | (s > 0.5)
Out[151]:
0   -3
1   -2
4    1
5    2
6    3
dtype: int64

In [152]: ~s < 0]
Out[152]:
3    0
4    1
5    2
6    3
dtype: int64
```

You may select rows from a DataFrame using a boolean vector the same length as the DataFrame’s index (for example, something derived from one of the columns of the DataFrame):

```python
In [153]: df[df['A'] > 0]
Out[153]:
          A         B         C         D         E
2000-01-01 0.469112 -0.282863 -1.509059 -1.135632 NaN
2000-01-02 1.212112 -0.173215  0.119209 -1.044236 NaN
2000-01-04 7.000000 -0.706771 -1.039575  0.271860 NaN
2000-01-07 0.404705  0.577046 -1.715002 -1.039268 NaN
```

List comprehensions and the map method of Series can also be used to produce more complex criteria:
With the choice methods Selection by Label, Selection by Position, and Advanced Indexing you may select along more than one axis using boolean vectors combined with other indexing expressions.

```
In [159]: df2.loc[criterion & (df2['b'] == 'x'), 'b':'c']
Out[159]:
      b   c
   3  x  0.361719
```

**Warning:** `iloc` supports two kinds of boolean indexing. If the indexer is a boolean Series, an error will be raised. For instance, in the following example, `df.iloc[s.values, 1]` is ok. The boolean indexer is an array. But `df.iloc[s, 1]` would raise `ValueError`.

```
In [160]: df = pd.DataFrame([[1, 2], [3, 4], [5, 6]],
                      index=list('abc'),
                      columns=['A', 'B'])
In [161]: s = (df['A'] > 2)
In [162]: s
Out[162]:
a  False
b  True
c  True
Name: A, dtype: bool
In [163]: df.iloc[s, 'B']
```
2.5.14 Indexing with isin

Consider the `isin()` method of `Series`, which returns a boolean vector that is true wherever the `Series` elements exist in the passed list. This allows you to select rows where one or more columns have values you want:

```
In [165]: s = pd.Series(np.arange(5), index=np.arange(5)[::-1], dtype='int64')
In [166]: s
Out[166]:
        4
       3
       2
       1
       0
Name: 0, dtype: int64

In [167]: s.isin([2, 4, 6])
Out[167]:
       4  False
       3  False
       2   True
       1  False
       0   True
Name: 0, dtype: bool

In [168]: s[s.isin([2, 4, 6])]
Out[168]:
       2
       0
Name: 0, dtype: int64
```

The same method is available for `Index` objects and is useful for the cases when you don’t know which of the sought labels are in fact present:

```
In [169]: s[s.index.isin([2, 4, 6])]
Out[169]:
       2
       0
Name: 0, dtype: int64
```

# compare it to the following

```
In [170]: s.reindex([2, 4, 6])
Out[170]:
       2  2.0
Name: 0, dtype: float64
```
In addition to that, MultiIndex allows selecting a separate level to use in the membership check:

```python
In [171]: s_mi = pd.Series(np.arange(6),
                   index=pd.MultiIndex.from_product([0, 1], ['a', 'b', 'c']))

In [172]: s_mi
Out[172]:
0   a 0
   b 1
   c 2
1   a 3
   b 4
   c 5
dtype: int64

In [173]: s_mi.iloc[s_mi.index.isin([(1, 'a'), (2, 'b'), (0, 'c')])]
Out[173]:
0   c 2
1   a 3
dtype: int64

In [174]: s_mi.iloc[s_mi.index.isin(['a', 'c', 'e'], level=1)]
Out[174]:
0   a 0
   c 2
1   a 3
   c 5
dtype: int64
```

DataFrame also has an `isin()` method. When calling `isin`, pass a set of values as either an array or dict. If values is an array, `isin` returns a DataFrame of booleans that is the same shape as the original DataFrame, with True wherever the element is in the sequence of values.

```python
In [175]: df = pd.DataFrame({'vals': [1, 2, 3, 4], 'ids': ['a', 'b', 'c', 'n'],
                     'ids2': ['a', 'n', 'c', 'n']})

In [176]: values = ['a', 'b', 'n']

In [177]: df.isin(values)
Out[177]:
     vals  ids  ids2
0   True  True  True
1   False  True  False
2   True  False  False
3   False  False  False
```

Oftentimes you’ll want to match certain values with certain columns. Just make values a dict where the key is the column, and the value is a list of items you want to check for.

```python
In [178]: df = pd.DataFrame({'vals': [1, 2, 3, 4], 'ids': ['a', 'b', 'c', 'n'],
                     'ids2': ['a', 'n', 'c', 'n']})

In [179]: values = {'vals': ['a', 'b'], 'ids': [1, 3]}

In [180]: df.isin(values)
Out[180]:
     vals  ids  ids2
0   True  True  True
1   False  True  False
2   True  False  False
3   False  False  False
```
```
In [178]: values = {'ids': ['a', 'b'], 'vals': [1, 3]}
In [179]: df.isin(values)
Out[179]:
<table>
<thead>
<tr>
<th>vals</th>
<th>ids</th>
<th>ids2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>1</td>
<td>False</td>
<td>True</td>
</tr>
<tr>
<td>2</td>
<td>True</td>
<td>False</td>
</tr>
<tr>
<td>3</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>
```

Combine DataFrame’s `isin` with the `any()` and `all()` methods to quickly select subsets of your data that meet a given criteria. To select a row where each column meets its own criterion:

```
In [180]: values = {'ids': ['a', 'b'], 'ids2': ['a', 'c'], 'vals': [1, 3]}
In [181]: row_mask = df.isin(values).all(1)
In [182]: df[row_mask]
Out[182]:
<table>
<thead>
<tr>
<th>vals</th>
<th>ids</th>
<th>ids2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>a</td>
<td>a</td>
</tr>
</tbody>
</table>
```

### 2.5.15 The `where()` Method and Masking

Selecting values from a Series with a boolean vector generally returns a subset of the data. To guarantee that selection output has the same shape as the original data, you can use the `where` method in `Series` and `DataFrame`.

To return only the selected rows:

```
In [183]: s[s > 0]
Out[183]:
3  1
2  2
1  3
0  4
dtype: int64
```

To return a Series of the same shape as the original:

```
In [184]: s.where(s > 0)
Out[184]:
4  NaN
3  1.0
2  2.0
1  3.0
0  4.0
dtype: float64
```

Selecting values from a DataFrame with a boolean criterion now also preserves input data shape. `where` is used under the hood as the implementation. The code below is equivalent to `df.where(df < 0)`.

```
In [185]: df[df < 0]
Out[185]:
<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>2000-01-01</td>
<td>-2.104139</td>
<td>-1.309525</td>
<td>NaN</td>
</tr>
<tr>
<td></td>
<td>2000-01-02</td>
<td>-0.352480</td>
<td>NaN</td>
<td>-1.192319</td>
</tr>
</tbody>
</table>
```

(continues on next page)
In addition, `where` takes an optional `other` argument for replacement of values where the condition is False, in the returned copy.

In [186]: df.where(df < 0, -df)
Out[186]:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>-2.104139</td>
<td>-1.309525</td>
<td>-0.485855</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>-0.352480</td>
<td>-0.390389</td>
<td>-1.192319</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>-0.864883</td>
<td>-0.299674</td>
<td>-0.227870</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>-0.846958</td>
<td>-1.222082</td>
<td>-0.600705</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>-0.669692</td>
<td>-0.605656</td>
<td>-1.169184</td>
</tr>
<tr>
<td>2000-01-06</td>
<td>-0.868584</td>
<td>-0.948458</td>
<td>-2.297780</td>
</tr>
<tr>
<td>2000-01-07</td>
<td>-2.670153</td>
<td>-0.114722</td>
<td>-0.168904</td>
</tr>
<tr>
<td>2000-01-08</td>
<td>-0.801196</td>
<td>-1.392071</td>
<td>-0.048788</td>
</tr>
</tbody>
</table>

You may wish to set values based on some boolean criteria. This can be done intuitively like so:

In [187]: s2 = s.copy()
In [188]: s2[s2 < 0] = 0

Out[189]:

<p>| |</p>
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

dtype: int64

In [190]: df2 = df.copy()
In [191]: df2[df2 < 0] = 0

Out[192]:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>0.000000</td>
<td>0.000000</td>
<td>0.485855</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>0.000000</td>
<td>0.390389</td>
<td>0.000000</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>0.000000</td>
<td>0.299674</td>
<td>0.000000</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>0.846958</td>
<td>0.000000</td>
<td>0.600705</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>0.669692</td>
<td>0.000000</td>
<td>0.000000</td>
</tr>
<tr>
<td>2000-01-06</td>
<td>0.868584</td>
<td>0.000000</td>
<td>2.297780</td>
</tr>
<tr>
<td>2000-01-07</td>
<td>0.000000</td>
<td>0.000000</td>
<td>0.168904</td>
</tr>
<tr>
<td>2000-01-08</td>
<td>0.801196</td>
<td>1.392071</td>
<td>0.000000</td>
</tr>
</tbody>
</table>

By default, `where` returns a modified copy of the data. There is an optional parameter `inplace` so that the original data can be modified without creating a copy:
In [193]: df_orig = df.copy()

In [194]: df_orig.where(df > 0, -df, inplace=True)

In [195]: df_orig

Out[195]:
        A         B         C         D
2000-01-01 2.104139  1.309525  0.485855  0.245166
2000-01-02  0.352480  0.390389  1.192319  1.655824
2000-01-03  0.864883  0.299674  0.227870  0.281059
2000-01-04  0.846958  1.222082  0.600705  1.233203
2000-01-05  0.669692  0.605656  1.169184  0.342416
2000-01-06  0.868584  0.948458  2.297780  0.684718
2000-01-07  2.670153  0.114722  0.168904  0.048048
2000-01-08  0.801196  1.392071  0.048788  0.808838

Note: The signature for DataFrame.where() differs from numpy.where(). Roughly df1.where(m, df2) is equivalent to np.where(m, df1, df2).

In [196]: df.where(df < 0, -df) == np.where(df < 0, df, -df)

Out[196]:
        A         B         C         D
2000-01-01  True  True  True  True
2000-01-02  True  True  True  True
2000-01-03  True  True  True  True
2000-01-04  True  True  True  True
2000-01-05  True  True  True  True
2000-01-06  True  True  True  True
2000-01-07  True  True  True  True
2000-01-08  True  True  True  True

Alignment

Furthermore, where aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via .loc (but on the contents rather than the axis labels).

In [197]: df2 = df.copy()

In [198]: df2[df2[1:4] > 0] = 3

In [199]: df2

Out[199]:
        A         B         C         D
2000-01-01 -2.104139 -1.309525  0.485855  0.245166
2000-01-02 -0.352480  3.000000 -1.192319   3.000000
2000-01-03 -0.864883  3.000000 -0.227870   3.000000
2000-01-04  3.000000 -1.222082  3.000000 -1.233203
2000-01-05  0.669692 -0.605656 -1.169184  0.342416
2000-01-06  0.868584 -0.948458  2.297780 -0.684718
2000-01-07 -2.670153 -0.114722  0.168904 -0.048048
2000-01-08  0.801196  1.392071 -0.048788 -0.808838

Where can also accept axis and level parameters to align the input when performing the where.

In [200]: df2 = df.copy()

(continues on next page)
In [201]: df2.where(df2 > 0, df2['A'], axis='index')
Out[201]:
   A    B    C    D
2000-01-01 -2.104139 -2.104139 0.485855 0.245166
2000-01-02 -0.352480 0.390389 -0.352480 1.655824
2000-01-03 0.846958 0.846958 0.600705 0.846958
2000-01-04 0.669692 0.669692 0.669692 0.342416
2000-01-05 0.868584 0.868584 2.297780 0.868584
2000-01-06 -2.670153 -2.670153 0.168904 -2.670153
2000-01-07 0.801196 1.392071 0.801196 0.801196

This is equivalent to (but faster than) the following.

In [202]: df2 = df.copy()
In [203]: df.apply(lambda x, y: x.where(x > 0, y), y=df['A'])
Out[203]:
   A    B    C    D
2000-01-01 -2.104139 -2.104139 0.485855 0.245166
2000-01-02 -0.352480 0.390389 -0.352480 1.655824
2000-01-03 0.846958 0.846958 0.600705 0.846958
2000-01-04 0.669692 0.669692 0.669692 0.342416
2000-01-05 0.868584 0.868584 2.297780 0.868584
2000-01-06 -2.670153 -2.670153 0.168904 -2.670153
2000-01-07 0.801196 1.392071 0.801196 0.801196

where can accept a callable as condition and other arguments. The function must be with one argument (the calling Series or DataFrame) and that returns valid output as condition and other argument.

In [204]: df3 = pd.DataFrame({'A': [1, 2, 3],
                        'B': [4, 5, 6],
                        'C': [7, 8, 9]})
In [205]: df3.where(lambda x: x > 4, lambda x: x + 10)
Out[205]:
     A   B  C
0   11  14  7
1   12   5  8
2   13   6  9

**Mask**

`mask()` is the inverse boolean operation of `where`.

In [206]: s.mask(s >= 0)
Out[206]:
   0    NaN
   1    NaN
   2    NaN
   3    NaN
   4    NaN

In [207]: df.mask(df >= 0)
Out[207]:
   A          B         C          D
2000-01-01 -2.104139 -1.309525  NaN   NaN
2000-01-02  0.352480  NaN -1.192319  NaN
2000-01-03 -0.864883  NaN -0.227870  NaN
2000-01-04  NaN  1.222082  NaN -1.233203
2000-01-05  NaN -0.605656  NaN -1.169184
2000-01-06  NaN -0.948458  NaN -0.684718
2000-01-07  NaN -0.114722  NaN -0.048048
2000-01-08  NaN  NaN  NaN -0.808838

2.5.16 Setting with enlargement conditionally using numpy()

An alternative to where() is to use numpy.where(). Combined with setting a new column, you can use it to enlarge a DataFrame where the values are determined conditionally.

Consider you have two choices to choose from in the following DataFrame. And you want to set a new column color to ‘green’ when the second column has ‘Z’. You can do the following:

In [208]: df = pd.DataFrame({'col1': list('ABBC'), 'col2': list('ZZXY'))
In [209]: df['color'] = np.where(df['col2'] == 'Z', 'green', 'red')
In [210]: df
Out[210]:
   col1 col2 color
0    A    Z    green
1    B    Z    green
2    B    X    red
3    C    Y    red

If you have multiple conditions, you can use numpy.select() to achieve that. Say corresponding to three conditions there are three choice of colors, with a fourth color as a fallback, you can do the following.

In [211]: conditions = [
   ...: (df['col2'] == 'Z') & (df['col1'] == 'A'),
   ...: (df['col2'] == 'Z') & (df['col1'] == 'B'),
   ...: (df['col1'] == 'B')
   ...: ]
   ...
In [212]: choices = ['yellow', 'blue', 'purple']
In [213]: df['color'] = np.select(conditions, choices, default='black')
In [214]: df
Out[214]:
   col1 col2 color
0    A    Z    yellow
1    B    Z    blue
2    B    X    purple
3    C    Y    black

2.5. Indexing and selecting data
2.5.17 The \texttt{query()} Method

\texttt{DataFrame} objects have a \texttt{query()} method that allows selection using an expression.

You can get the value of the frame where column \texttt{b} has values between the values of columns \texttt{a} and \texttt{c}. For example:

\begin{verbatim}
In [215]: n = 10
In [216]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
In [217]: df
Out[217]:
   a     b     c
0  0.438921  0.118680  0.863670
1  0.138138  0.577363  0.686602
2  0.595307  0.564592  0.520630
3  0.913052  0.926075  0.616184
4  0.078718  0.854477  0.898725
5  0.076404  0.523211  0.591538
6  0.792342  0.216974  0.564056
7  0.397890  0.454131  0.915716
8  0.074315  0.437913  0.019794
9  0.559209  0.502065  0.026437

# pure python
In [218]: df[(df['a'] < df['b']) & (df['b'] < df['c'])]
Out[218]:
   a     b     c
1  0.138138  0.577363  0.686602
4  0.078718  0.854477  0.898725
5  0.076404  0.523211  0.591538
7  0.397890  0.454131  0.915716

# query
In [219]: df.query('(a < b) & (b < c)')
Out[219]:
   a     b     c
1  0.138138  0.577363  0.686602
4  0.078718  0.854477  0.898725
5  0.076404  0.523211  0.591538
7  0.397890  0.454131  0.915716

Do the same thing but fall back on a named index if there is no column with the name \texttt{a}.

In [220]: df = pd.DataFrame(np.random.randint(n / 2, size=(n, 2)), columns=list('bc'))
In [221]: df.index.name = 'a'
In [222]: df
Out[222]:
   b     c
a  0  4
  1  1
  2  3
  3  4
  4  3
  5  3
(continues on next page)
In [223]: df.query('a < b and b < c')
Out[223]:
   b  c
0  2  3
1  3  4

If instead you don’t want to or cannot name your index, you can use the name `index` in your query expression:

```
In [224]: df = pd.DataFrame(np.random.randint(n, size=(n, 2)), columns=list('bc'))
In [225]: df
Out[225]:
   b  c
0  3  1
1  3  0
2  5  6
3  5  2
4  7  4
5  0  1
6  2  5
7  0  1
8  6  0
9  7  9
In [226]: df.query('index < b < c')
Out[226]:
   b  c
2  5  6
```

**Note:** If the name of your index overlaps with a column name, the column name is given precedence. For example,

```
In [227]: df = pd.DataFrame({'a': np.random.randint(5, size=5)})
In [228]: df.index.name = 'a'
In [229]: df.query('a > 2')  # uses the column 'a', not the index
Out[229]:
   a
0  3
1  3
```

You can still use the index in a query expression by using the special identifier `index`:

```
In [230]: df.query('index > 2')
Out[230]:
   a
   a
0  3
1  3
2  4
```
If for some reason you have a column named index, then you can refer to the index as ilevel_0 as well, but at this point you should consider renaming your columns to something less ambiguous.

**MultiIndex query() Syntax**

You can also use the levels of a DataFrame with a MultiIndex as if they were columns in the frame:

```python
In [231]: n = 10
In [232]: colors = np.random.choice(['red', 'green'], size=n)
In [233]: foods = np.random.choice(['eggs', 'ham'], size=n)
In [234]: colors
Out[234]: array(['red', 'red', 'red', 'green', 'green', 'green', 'green', 'green', 'green', 'green'], dtype='<U5')
In [235]: foods
Out[235]: array(['ham', 'ham', 'eggs', 'eggs', 'eggs', 'ham', 'ham', 'eggs', 'eggs', 'eggs'], dtype='<U4')
In [236]: index = pd.MultiIndex.from_arrays([colors, foods], names=['color', 'food'])
In [237]: df = pd.DataFrame(np.random.randn(n, 2), index=index)
In [238]: df
Out[238]:
   0     1
color food
red  ham  0.194889 -0.381994
  ham  0.318587  2.089075
  eggs -0.728293 -0.090255
green eggs -0.748199  1.318931
  eggs -2.029766  0.792652
  ham  0.461007 -0.542749
  eggs -0.305384 -0.479195
  eggs  0.495031 -0.270099
  eggs -0.707140 -0.773882
  eggs  0.229453  0.304418
In [239]: df.query('color == "red"')
Out[239]:
   0     1
color food
red  ham  0.194889 -0.381994
  ham  0.318587  2.089075
  eggs -0.728293 -0.090255
```

If the levels of the MultiIndex are unnamed, you can refer to them using special names:

```python
In [240]: df.index.names = [None, None]
In [241]: df
Out[241]:
   0     1
color food
red  ham  0.194889 -0.381994
  ham  0.318587  2.089075
  eggs -0.728293 -0.090255
```

(continues on next page)
The convention is `ilevel_0`, which means “index level 0” for the 0th level of the index.

query() Use Cases

A use case for `query()` is when you have a collection of `DataFrame` objects that have a subset of column names (or index levels/names) in common. You can pass the same query to both frames without having to specify which frame you’re interested in querying.

```
In [243]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))

In [244]: df
Out[244]:
   a    b    c
0  0.224283  0.736107  0.139168
1  0.302827  0.657803  0.713897
2  0.611185  0.136624  0.984960
3  0.195246  0.123436  0.627712
4  0.618673  0.371660  0.047902
5  0.480088  0.062993  0.185760
6  0.568018  0.483467  0.445289
7  0.309040  0.274580  0.587101
8  0.258993  0.477769  0.370255
9  0.550459  0.840870  0.304611

In [245]: df2 = pd.DataFrame(np.random.rand(n + 2, 3), columns=df.columns)

In [246]: df2
Out[246]:
    a    b    c
0  0.357579  0.229800  0.596001
1  0.309059  0.957923  0.965663
2  0.123102  0.336914  0.318616
3  0.526506  0.323321  0.860813
4  0.518736  0.486514  0.384724
5  0.190804  0.505723  0.614533
6  0.891939  0.623977  0.676639
```
query()  Python versus pandas Syntax Comparison

Full numpy-like syntax:

```python
In [249]: df = pd.DataFrame(np.random.randint(10, size=(10, 3)), columns=list('abc'))

In [250]: df
Out[250]:
     a  b  c
0    7  8  9
1    1  0  7
2    2  7  2
3    3  2  2
4    4  6  3
5    5  8  2
6    6  7  2
7    7  1  5
8    8  8  0
9    9  1  5

In [251]: df.query('(a < b) & (b < c)')
Out[251]:
     a  b  c
0    7  8  9

In [252]: df[(df['a'] < df['b']) & (df['b'] < df['c'])]
Out[252]:
     a  b  c
0    7  8  9
```

Slightly nicer by removing the parentheses (comparison operators bind tighter than & and |):

```python
In [253]: df.query('a < b & b < c')
Out[253]:
     a  b  c
0    7  8  9
```

Use English instead of symbols:

```python
In [254]: df.query('a < b and b < c')
Out[254]:
     a  b  c
0    7  8  9
```

Pretty close to how you might write it on paper:
The `in` and `not in` operators

`query()` also supports special use of Python's `in` and `not in` comparison operators, providing a succinct syntax for calling the `isin` method of a `Series` or `DataFrame`.

```python
# get all rows where columns "a" and "b" have overlapping values
In [256]: df = pd.DataFrame({'a': list('aabbccddeeff'), 'b': list('aaaabbbbcccc'),
                          'c': np.random.randint(5, size=12),
                          'd': np.random.randint(9, size=12))

In [257]: df
Out[257]:
        a  b  c  d
   0  a  a  2  6
   1  a  a  4  7
   2  b  a  1  6
   3  b  a  2  1
   4  c  b  3  6
   5  c  b  0  2
   6  d  b  3  3
   7  d  b  2  1
   8  e  c  4  3
   9  e  c  2  0
  10  f  c  0  6
  11  f  c  1  2

In [258]: df.query('a in b')
Out[258]:
   a  b  c  d
  0  a  a  2  6
  1  a  a  4  7
  2  b  a  1  6
  3  b  a  2  1
  4  c  b  3  6
  5  c  b  0  2

# How you'd do it in pure Python
In [259]: df[df['a'].isin(df['b'])]
Out[259]:
   a  b  c  d
  0  a  a  2  6
  1  a  a  4  7
  2  b  a  1  6
  3  b  a  2  1
  4  c  b  3  6
  5  c  b  0  2

In [260]: df.query('a not in b')
Out[260]:
   a  b  c  d
```

(continues on next page)
You can combine this with other expressions for very succinct queries:

```python
# rows where cols a and b have overlapping values
# and col c's values are less than col d's
In [262]: df.query('a in b and c < d')
Out[262]:
      a  b  c  d
0    a  a  2  6
1    a  a  4  7
2    b  a  1  6
3    c  b  3  6
4    c  b  0  2
5    f  c  0  6
6    f  c  1  2
```

Note: Note that `in` and `not in` are evaluated in Python, since `numexpr` has no equivalent of this operation. However, **only the `in/not in` expression itself** is evaluated in vanilla Python. For example, in the expression

```python
df.query('a in b + c + d')
```

`(b + c + d)` is evaluated by `numexpr` and **then** the `in` operation is evaluated in plain Python. In general, any operations that can be evaluated using `numexpr` will be.
### Special use of the == operator with list objects

Comparing a list of values to a column using \( \sim \) works similarly to \( \text{in/not in} \).

```python
In [264]: df.query('b == ["a", "b", "c"]')
Out[264]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
7  d  b  2  1
8  e  c  4  3
9  e  c  2  0
10 f  c  0  6
11 f  c  1  2
```

# pure Python

```python
In [265]: df[df['b'].isin(['a', 'b', 'c'])]
Out[265]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
7  d  b  2  1
8  e  c  4  3
9  e  c  2  0
10 f  c  0  6
11 f  c  1  2
```

```python
In [266]: df.query('c == [1, 2]')
Out[266]:
   a  b  c  d
0  a  a  2  6
2  b  a  1  6
3  b  a  2  1
7  d  b  2  1
9  e  c  2  0
11 f  c  1  2
```

```python
In [267]: df.query('c != [1, 2]')
Out[267]:
   a  b  c  d
1  a  a  4  7
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
8  e  c  4  3
10 f  c  0  6
```

# using in/not in

(continues on next page)
In [268]: df.query('[1, 2] in c')
Out[268]:
<table>
<thead>
<tr>
<th></th>

**Boolean operators**

You can negate boolean expressions with the word not or the ~ operator.

In [271]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc')
In [272]: df['bools'] = np.random.rand(len(df)) > 0.5
In [273]: df.query('not bools')
Out[273]:
<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
<th>bools</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>0.697753</td>
<td>0.212799</td>
<td>0.329209</td>
<td>False</td>
</tr>
<tr>
<td>7</td>
<td>0.275396</td>
<td>0.691034</td>
<td>0.826619</td>
<td>False</td>
</tr>
<tr>
<td>8</td>
<td>0.190649</td>
<td>0.558748</td>
<td>0.262467</td>
<td>False</td>
</tr>
</tbody>
</table>

In [274]: df.query('not bools') == df[~df['bools']]
Out[275]:
<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
<th>bools</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>0.697753</td>
<td>0.212799</td>
<td>0.329209</td>
<td>False</td>
</tr>
<tr>
<td>7</td>
<td>0.275396</td>
<td>0.691034</td>
<td>0.826619</td>
<td>False</td>
</tr>
<tr>
<td>8</td>
<td>0.190649</td>
<td>0.558748</td>
<td>0.262467</td>
<td>False</td>
</tr>
</tbody>
</table>
Of course, expressions can be arbitrarily complex too:

```python
# short query syntax
In [276]: shorter = df.query('a < b < c and (not bools) or bools > 2')

# equivalent in pure Python
In [277]: longer = df[(df['a'] < df['b']) & (df['b'] < df['c']) & (~df['bools']) | (df['bools'] > 2)]

In [278]: shorter
Out[278]:
    a    b    c  bools
   7 0.2754 0.6910 0.8266  False

In [279]: longer
Out[279]:
    a    b    c  bools
   7 0.2754 0.6910 0.8266  False

In [280]: shorter == longer
Out[280]:
    a    b    c  bools
   7    True  True  True  True
```

Performance of `query()`

`DataFrame.query()` using `numexpr` is slightly faster than Python for large frames.

---

2.5. Indexing and selecting data 433
pandas: powerful Python data analysis toolkit, Release 1.3.1

Note: You will only see the performance benefits of using the `numexpr` engine with DataFrame.query() if your frame has more than approximately 200,000 rows.

This plot was created using a DataFrame with 3 columns each containing floating point values generated using `numpy.random.randn()`.

2.5.18 Duplicate data

If you want to identify and remove duplicate rows in a DataFrame, there are two methods that will help: `duplicated` and `drop_duplicates`. Each takes as an argument the columns to use to identify duplicated rows.

- `duplicated` returns a boolean vector whose length is the number of rows, and which indicates whether a row is duplicated.
- `drop_duplicates` removes duplicate rows.

By default, the first observed row of a duplicate set is considered unique, but each method has a `keep` parameter to specify targets to be kept.

- `keep='first'` (default): mark / drop duplicates except for the first occurrence.
- `keep='last'`: mark / drop duplicates except for the last occurrence.
- `keep=False`: mark / drop all duplicates.

```
In [281]: df2 = pd.DataFrame({'a': ['one', 'one', 'two', 'two', 'two', 'three', 'four'],
                          'b': ['x', 'y', 'x', 'y', 'x', 'x', 'x'],
                          'c': np.random.randn(7)})
```

```
In [282]: df2
Out[282]:
   a     b     c
0  one    x -1.067137
```

(continues on next page)
In [283]: df2.duplicated('a')
Out[283]:
0   False
1    True
2    False
3    True
4    True
5    False
6    False
dtype: bool

In [284]: df2.duplicated('a', keep='last')
Out[284]:
0    True
1    False
2    True
3    True
4    False
5    False
6    False
dtype: bool

In [285]: df2.duplicated('a', keep=False)
Out[285]:
0    True
1    True
2    True
3    True
4    True
5    False
6    False
dtype: bool

In [286]: df2.drop_duplicates('a')
Out[286]:
   a    b    c
0  one  -1.067137
2  two  -0.211056
5  three  -1.964475
6  four   1.298329

In [287]: df2.drop_duplicates('a', keep='last')
Out[287]:
   a    b    c
1  one   0.309500
4  two  -0.390820
5  three  -1.964475
6  four   1.298329

In [288]: df2.drop_duplicates('a', keep=False)
Also, you can pass a list of columns to identify duplications.

```
In [289]: df2.duplicated(['a', 'b'])
Out[289]:
0   False
1   False
2   False
3   False
4    True
5   False
6   False
dtype: bool
```

```
In [290]: df2.drop_duplicates(['a', 'b'])
Out[290]:
   a  b  c
0  one x  1.067137
1  one y  0.309500
2  two x -0.211056
3  two y -1.842023
5  three x -1.964475
6  four x  1.298329
```

To drop duplicates by index value, use `Index.duplicated` then perform slicing. The same set of options are available for the `keep` parameter.

```
In [291]: df3 = pd.DataFrame({'a': np.arange(6),
                        'b': np.random.randn(6)},
                        index=['a', 'a', 'b', 'c', 'b', 'a'])

In [292]: df3
Out[292]:
   a  b
0  0  1.440455
1  1  2.456086
2  2  1.038402
3  3 -0.894409
4  4  0.683536
5  5  3.082764

In [293]: df3.index.duplicated()
Out[293]: array([False, True, False, False, True, True])

In [294]: df3[~df3.index.duplicated()]
Out[294]:
   a  b
0  a  1.440455
1  b  2.456086
2  c  1.038402
3  b -0.894409
```
2.5.19 Dictionary-like `get()` method

Each of Series or DataFrame have a `get` method which can return a default value.

```python
In [297]: s = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
In [298]: s.get('a')  # equivalent to s['a']
Out[298]: 1
In [299]: s.get('x', default=-1)
Out[299]: -1
```

2.5.20 Looking up values by index/column labels

Sometimes you want to extract a set of values given a sequence of row labels and column labels, this can be achieved by `pandas.factorize` and NumPy indexing. For instance:

```python
In [300]: df = pd.DataFrame({'col': ['A', 'A', 'B', 'B'],
        'A': [80, 23, np.nan, 22],
        'B': [80, 55, 76, 67]})

In [301]: df
Out[301]:
   col  A  B
0    A  80 80
1    A  23 55
2    B  NaN 76
3    B  22 67

In [302]: idx, cols = pd.factorize(df['col'])
In [303]: df.reindex(cols, axis=1).to_numpy()[np.arange(len(df)), idx]
Out[303]: array([80., 23., 76., 67.])
```

Formerly this could be achieved with the dedicated `DataFrame.lookup` method which was deprecated in version 1.2.0.

2.5. Indexing and selecting data
2.5.21 Index objects

The pandas `Index` class and its subclasses can be viewed as implementing an ordered multiset. Duplicates are allowed. However, if you try to convert an `Index` object with duplicate entries into a set, an exception will be raised.

`Index` also provides the infrastructure necessary for lookups, data alignment, and reindexing. The easiest way to create an `Index` directly is to pass a list or other sequence to `Index`:

```python
In [304]: index = pd.Index(['e', 'd', 'a', 'b'])

In [305]: index
Out[305]: Index(['e', 'd', 'a', 'b'], dtype='object')

In [306]: 'd' in index
Out[306]: True
```

You can also pass a name to be stored in the index:

```python
In [307]: index = pd.Index(['e', 'd', 'a', 'b'], name='something')

In [308]: index.name
Out[308]: 'something'
```

The name, if set, will be shown in the console display:

```python
In [309]: index = pd.Index(list(range(5)), name='rows')

In [310]: columns = pd.Index(['A', 'B', 'C'], name='cols')

In [311]: df = pd.DataFrame(np.random.randn(5, 3), index=index, columns=columns)

In [312]: df
Out[312]:
     A         B         C
rows
0  1.295989 -1.051694  1.340429
1 -2.366110  0.428241  0.387275
2  0.433306  0.929548  0.278094
3  2.154730 -0.315628  0.264223
4  1.126818  1.132290 -0.353310

In [313]: df['A']
Out[313]:
     A
rows
0  1.295989
1 -2.366110
2  0.433306
3  2.154730
4  1.126818

Name: A, dtype: float64
```
Setting metadata

Indexes are “mostly immutable”, but it is possible to set and change their name attribute. You can use the rename, set_names to set these attributes directly, and they default to returning a copy.

See Advanced Indexing for usage of MultiIndexes.

```
In [314]: ind = pd.Index([1, 2, 3])
In [315]: ind.rename("apple")
Out[315]: Int64Index([1, 2, 3], dtype='int64', name='apple')
In [316]: ind
Out[316]: Int64Index([1, 2, 3], dtype='int64')
In [317]: ind.set_names(['apple'], inplace=True)
In [318]: ind.name = "bob"
In [319]: ind
Out[319]: Int64Index([1, 2, 3], dtype='int64', name='bob')
```

set_names, set_levels, and set_codes also take an optional level argument

```
In [320]: index = pd.MultiIndex.from_product([range(3), ['one', 'two']], names=['first', 'second'])
In [321]: index
Out[321]: MultiIndex([(0, 'one'),
                     (0, 'two'),
                     (1, 'one'),
                     (1, 'two'),
                     (2, 'one'),
                     (2, 'two')],
                      names=['first', 'second'])
In [322]: index.levels[1]
Out[322]: Index(['one', 'two'], dtype='object', name='second')
In [323]: index.set_levels(['a', 'b'], level=1)
Out[323]: MultiIndex([(0, 'a'),
                     (0, 'b'),
                     (1, 'a'),
                     (1, 'b'),
                     (2, 'a'),
                     (2, 'b')],
                      names=['first', 'second'])
```
Set operations on Index objects

The two main operations are union and intersection. Difference is provided via the .difference() method.

```python
In [324]: a = pd.Index(['c', 'b', 'a'])
In [325]: b = pd.Index(['c', 'e', 'd'])
In [326]: a.difference(b)
Out[326]: Index(['a', 'b'], dtype='object')
```

Also available is the symmetric_difference operation, which returns elements that appear in either idx1 or idx2, but not in both. This is equivalent to the Index created by idx1.difference(idx2).union(idx2.difference(idx1)), with duplicates dropped.

```python
In [327]: idx1 = pd.Index([1, 2, 3, 4])
In [328]: idx2 = pd.Index([2, 3, 4, 5])
In [329]: idx1.symmetric_difference(idx2)
Out[329]: Int64Index([1, 5], dtype='int64')
```

Note: The resulting index from a set operation will be sorted in ascending order.

When performing `Index.union()` between indexes with different dtypes, the indexes must be cast to a common dtype. Typically, though not always, this is object dtype. The exception is when performing a union between integer and float data. In this case, the integer values are converted to float.

```python
In [330]: idx1 = pd.Index([0, 1, 2])
In [331]: idx2 = pd.Index([0.5, 1.5])
In [332]: idx1.union(idx2)
Out[332]: Float64Index([0.0, 0.5, 1.0, 1.5, 2.0], dtype='float64')
```

Missing values

**Important**: Even though `Index` can hold missing values (NaN), it should be avoided if you do not want any unexpected results. For example, some operations exclude missing values implicitly.

`Index.fillna` fills missing values with specified scalar value.

```python
In [333]: idx1 = pd.Index([1, np.nan, 3, 4])
In [334]: idx1
Out[334]: Float64Index([1.0, nan, 3.0, 4.0], dtype='float64')
In [335]: idx1fillna(2)
Out[335]: Float64Index([1.0, 2.0, 3.0, 4.0], dtype='float64')
In [336]: idx2 = pd.DatetimeIndex([pd.Timestamp('2011-01-01'),
(continues on next page)
2.5.22 Set / reset index

Occasionally you will load or create a data set into a DataFrame and want to add an index after you’ve already done so. There are a couple of different ways.

Set an index

DataFrame has a `set_index()` method which takes a column name (for a regular Index) or a list of column names (for a MultiIndex). To create a new, re-indexed DataFrame:

```
In [339]: data
Out[339]:
  a  b  c  d
0  a  b  c  d
In [340]: indexed1 = data.set_index('c')
In [341]: indexed1
Out[341]:
  a  b  d
c  z  bar one 1.0
    y  bar two 2.0
    x  foo one 3.0
    w  foo two 4.0
In [342]: indexed2 = data.set_index(['a', 'b'])
In [343]: indexed2
Out[343]:
  c  d
a  b
  bar one 1.0
    two y 2.0
    foo one 3.0
    two w 4.0
```

The `append` keyword option allow you to keep the existing index and append the given columns to a MultiIndex:
In [344]: frame = data.set_index('c', drop=False)

In [345]: frame = frame.set_index(['a', 'b'], append=True)

In [346]: frame
Out[346]:
   c    d
   a  b  
   z bar one z 1.0
   y bar two y 2.0
   x foo one x 3.0
   w foo two w 4.0

Other options in set_index allow you not drop the index columns or to add the index in-place (without creating a new object):

In [347]: data.set_index('c', drop=False)
Out[347]:
   a    b    c    d
   c    z bar one z 1.0
   y bar two y 2.0
   x foo one x 3.0
   w foo two w 4.0

In [348]: data.set_index(['a', 'b'], inplace=True)

In [349]: data
Out[349]:
   c    d
   a  b  
   z bar one z 1.0
   y bar two y 2.0
   x foo one x 3.0
   w foo two w 4.0

Reset the index

As a convenience, there is a new function on DataFrame called reset_index() which transfers the index values into the DataFrame’s columns and sets a simple integer index. This is the inverse operation of set_index().

In [350]: data
Out[350]:
   a    b    c    d
   z bar one z 1.0
   y bar two y 2.0
   x foo one x 3.0
   w foo two w 4.0

In [351]: data.reset_index()
Out[351]:
   a    b    c    d
   0 bar one z 1.0
   1 bar two y 2.0

(continues on next page)
The output is more similar to a SQL table or a record array. The names for the columns derived from the index are the ones stored in the `names` attribute.

You can use the `level` keyword to remove only a portion of the index:

```
In [352]: frame
Out[352]:
   c   d
  a  b
c bar one  z  1.0
y bar two  y  2.0
x foo one  x  3.0
w foo two  w  4.0

In [353]: frame.reset_index(level=1)
Out[353]:
   a   c   d
  b  c  d
z one bar  z  1.0
y two bar  y  2.0
x one foo  x  3.0
w two foo  w  4.0
```

`reset_index` takes an optional parameter `drop` which if true simply discards the index, instead of putting index values in the DataFrame’s columns.

Adding an ad hoc index

If you create an index yourself, you can just assign it to the `index` field:

```python
data.index = index
```

### 2.5.23 Returning a view versus a copy

When setting values in a pandas object, care must be taken to avoid what is called chained indexing. Here is an example.

```
In [354]: dfmi = pd.DataFrame([list('abcd'),
                        ....: list('efgh'),
                        ....: list('ijkl'),
                        ....: list('mnop')],
                        ....: columns=pd.MultiIndex.from_product([['one', 'two'],
                        ....:                                      ['first', 'second']))

In [355]: dfmi
Out[355]:
   one two
first second first second
  0   a   b   c   d
```

(continues on next page)
Compare these two access methods:

```python
In [356]: dfmi['one']['second']
Out[356]:
0  b
1  f
2  j
3  n
Name: second, dtype: object
```

```python
In [357]: dfmi.loc[:, ('one', 'second')]
Out[357]:
0  b
1  f
2  j
3  n
Name: (one, second), dtype: object
```

These both yield the same results, so which should you use? It is instructive to understand the order of operations on these and why method 2 (.loc) is much preferred over method 1 (chained []).

dfmi['one'] selects the first level of the columns and returns a DataFrame that is singly-indexed. Then another Python operation dfmi_with_one['second'] selects the series indexed by 'second'. This is indicated by the variable dfmi_with_one because pandas sees these operations as separate events. e.g. separate calls to __getitem__, so it has to treat them as linear operations, they happen one after another.

Contrast this to df.loc[:,('one','second')] which passes a nested tuple of (slice(No), ('one', 'second')) to a single call to __getitem__. This allows pandas to deal with this as a single entity. Furthermore this order of operations can be significantly faster, and allows one to index both axes if so desired.

**Why does assignment fail when using chained indexing?**

The problem in the previous section is just a performance issue. What’s up with the SettingWithCopy warning? We don’t usually throw warnings around when you do something that might cost a few extra milliseconds!

But it turns out that assigning to the product of chained indexing has inherently unpredictable results. To see this, think about how the Python interpreter executes this code:

```python
dfmi.loc[:, ('one', 'second')] = value
# becomes
dfmi.loc.__setitem__((slice(None), ('one', 'second')), value)
```

But this code is handled differently:

```python
dfmi['one']['second'] = value
# becomes
dfmi.__getitem__('one').__setitem__('second', value)
```

See that __getitem__ in there? Outside of simple cases, it’s very hard to predict whether it will return a view or a copy (it depends on the memory layout of the array, about which pandas makes no guarantees), and therefore whether the __setitem__ will modify dfmi or a temporary object that gets thrown out immediately afterward. That’s what SettingWithCopy is warning you about!
Note: You may be wondering whether we should be concerned about the `loc` property in the first example. But `dfmi.loc` is guaranteed to be `dfmi` itself with modified indexing behavior, so `dfmi.loc.__getitem__ / dfmi.loc.__setitem__` operate on `dfmi` directly. Of course, `dfmi.loc.__getitem__(idx)` may be a view or a copy of `dfmi`.

Sometimes a `SettingWithCopy` warning will arise at times when there’s no obvious chained indexing going on. These are the bugs that `SettingWithCopy` is designed to catch! pandas is probably trying to warn you that you’ve done this:

```python
def do_something(df):
    foo = df[['bar', 'baz']]  # Is foo a view? A copy? Nobody knows!
    # ... many lines here ...
    # We don't know whether this will modify df or not!
    foo['quux'] = value
    return foo
```

Yikes!

**Evaluation order matters**

When you use chained indexing, the order and type of the indexing operation partially determine whether the result is a slice into the original object, or a copy of the slice.

Pandas has the `SettingWithCopyWarning` because assigning to a copy of a slice is frequently not intentional, but a mistake caused by chained indexing returning a copy where a slice was expected.

If you would like pandas to be more or less trusting about assignment to a chained indexing expression, you can set the `option mode.chained_assignment` to one of these values:

- `'warn'`, the default, means a `SettingWithCopyWarning` is printed.
- `'raise'` means pandas will raise a `SettingWithCopyException` you have to deal with.
- `None` will suppress the warnings entirely.

```python
In [358]: dfb = pd.DataFrame({'a': ['one', 'one', 'two', 'three', 'two', 'one', 'six'],
                         'b': np.arange(7)})

# This will show the SettingWithCopyWarning
# but the frame values will be set
In [359]: dfb['c'][dfb['a'].str.startswith('o')]['c'] = 42
```

This however is operating on a copy and will not work.

```python
>>> pd.set_option('mode.chained_assignment','warn')

# dfb is now a copy
>>> dfb['c'][dfb['a'].str.startswith('o')]['c'] = 42
Traceback (most recent call last)
 ... SettingWithCopyWarning:
   A value is trying to be set on a copy of a slice from a DataFrame.
   Try using .loc[row_index,col_indexer] = value instead
```

A chained assignment can also crop up in setting in a mixed dtype frame.
The following is the recommended access method using `.loc` for multiple items (using mask) and a single item using a fixed index:

```python
In [360]: dfc = pd.DataFrame({'a': ['one', 'one', 'two', ......: 'three', 'two', 'one', 'six'], ......: 'c': np.arange(7)})

In [361]: dfd = dfc.copy()

# Setting multiple items using a mask
In [362]: mask = dfd['a'].str.startswith('o')

In [363]: dfd.loc[mask, 'c'] = 42

In [364]: dfd
Out[364]:
   a   c
0  one  42
1  one  42
2  two  2
3  three  3
4  two  4
5  one  42
6  six  6

# Setting a single item
In [365]: dfd = dfc.copy()

In [366]: dfd.loc[2, 'a'] = 11

In [367]: dfd
Out[367]:
   a   c
0  one   0
1  one   1
2  11   2
3  three  3
4  two   4
5  one   5
6  six   6
```

The following *can* work at times, but it is not guaranteed to, and therefore should be avoided:

```python
In [368]: dfd = dfc.copy()

In [369]: dfd['a'][2] = 111

In [370]: dfd
Out[370]:
   a   c
0  one   0
1  one   1
2  111   2
```

(continues on next page)
Last, the subsequent example will **not** work at all, and so should be avoided:

```python
>>> pd.set_option('mode.chained_assignment','raise')
>>> dfd.loc[0]['a'] = 1111
Traceback (most recent call last)
...
SettingWithCopyException:
    A value is trying to be set on a copy of a slice from a DataFrame.
    Try using .loc[row_index,col_indexer] = value instead
```

**Warning:** The chained assignment warnings / exceptions are aiming to inform the user of a possibly invalid assignment. There may be false positives; situations where a chained assignment is inadvertently reported.

### 2.6 MultiIndex / advanced indexing

This section covers *indexing with a MultiIndex and other advanced indexing features.*

See the [Indexing and Selecting Data](#) for general indexing documentation.

**Warning:** Whether a copy or a reference is returned for a setting operation may depend on the context. This is sometimes called **chained assignment** and should be avoided. See [Returning a View versus Copy](#).

See the [cookbook](#) for some advanced strategies.

#### 2.6.1 Hierarchical indexing (MultiIndex)

Hierarchical / Multi-level indexing is very exciting as it opens the door to some quite sophisticated data analysis and manipulation, especially for working with higher dimensional data. In essence, it enables you to store and manipulate data with an arbitrary number of dimensions in lower dimensional data structures like `Series` (1d) and `DataFrame` (2d).

In this section, we will show what exactly we mean by “hierarchical” indexing and how it integrates with all of the pandas indexing functionality described above and in prior sections. Later, when discussing **group by** and **pivoting and reshaping data**, we’ll show non-trivial applications to illustrate how it aids in structuring data for analysis.

See the [cookbook](#) for some advanced strategies.
Creating a MultiIndex (hierarchical index) object

The MultiIndex object is the hierarchical analogue of the standard Index object which typically stores the axis labels in pandas objects. You can think of MultiIndex as an array of tuples where each tuple is unique. A MultiIndex can be created from a list of arrays (using MultiIndex.from_arrays()), an array of tuples (using MultiIndex.from_tuples()), a crossed set of iterables (using MultiIndex.from_product()), or a DataFrame (using MultiIndex.from_frame()). The Index constructor will attempt to return a MultiIndex when it is passed a list of tuples. The following examples demonstrate different ways to initialize MultiIndexes.

```
In [1]: arrays = [
    ...:   ['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
    ...:   ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'],
    ...:   ]
    ...:
In [2]: tuples = list(zip(*arrays))
In [3]: tuples
Out[3]: [('bar', 'one'), ('bar', 'two'), ('baz', 'one'), ('baz', 'two'), ('foo', 'one'), ('foo', 'two'), ('qux', 'one'), ('qux', 'two')]
In [4]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])
In [5]: index
Out[5]: MultiIndex([('bar', 'one'), ('bar', 'two'), ('baz', 'one'), ('baz', 'two'), ('foo', 'one'), ('foo', 'two'), ('qux', 'one'), ('qux', 'two')], names=['first', 'second'])
In [6]: s = pd.Series(np.random.randn(8), index=index)
In [7]: s
Out[7]:
first  second
bar    one    0.469112
        two   -0.282863
baz    one   -1.509059
        two   -1.135632
foo    one    1.212112
        two   -0.173215
qux    one    0.119209
        two  -1.044236
dtype: float64
```
When you want every pairing of the elements in two iterables, it can be easier to use the `MultiIndex.from_product()` method:

```python
In [8]: iterables = [['bar', 'baz', 'foo', 'qux'], ['one', 'two']]
In [9]: pd.MultiIndex.from_product(iterables, names=['first', 'second'])
Out[9]:
MultiIndex([('bar', 'one'),
            ('bar', 'two'),
            ('baz', 'one'),
            ('baz', 'two'),
            ('foo', 'one'),
            ('foo', 'two'),
            ('qux', 'one'),
            ('qux', 'two')],
           names=['first', 'second'])
```

You can also construct a `MultiIndex` from a `DataFrame` directly, using the method `MultiIndex.from_frame()`. This is a complementary method to `MultiIndex.to_frame()`.

```python
In [10]: df = pd.DataFrame(
            ...
            
            In [11]: pd.MultiIndex.from_frame(df)
Out[11]:
MultiIndex([('bar', 'one'),
            ('bar', 'two'),
            ('foo', 'one'),
            ('foo', 'two')],
           names=['first', 'second'])
```

As a convenience, you can pass a list of arrays directly into `Series` or `DataFrame` to construct a `MultiIndex` automatically:

```python
In [12]: arrays = [
            ...
            np.array(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'])],
            ...
            np.array(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'])],
            ...
            ]
            ...
In [13]: s = pd.Series(np.random.randn(8), index=arrays)
In [14]: s
Out[14]:
bar one -0.861849
   two -2.104569
baz one -0.494929
   two  1.071804
foo one  0.721555
   two -0.706771
qux one -1.039575
   two  0.271860
dtype: float64
In [15]: df = pd.DataFrame(np.random.randn(8, 4), index=arrays)
```

(continues on next page)
All of the MultiIndex constructors accept a names argument which stores string names for the levels themselves. If no names are provided, None will be assigned:

```
In [17]: df.index.names
Out[17]: FrozenList([None, None])
```

This index can back any axis of a pandas object, and the number of levels of the index is up to you:

```
In [18]: df = pd.DataFrame(np.random.randn(3, 8), index=["A", "B", "C"],
                        columns=index)
In [19]: df
Out[19]:
       bar  baz  foo  qux
first   one  two  one  two
A       0.895717  0.805244 -1.206412  2.565646
B       0.410835  0.813850  0.132003 -0.827317 -0.076467 -1.187678  1.130127 -1.436737
C      -1.413681  1.607920  1.024180  0.569605  0.875906 -2.211372  0.974466 -2.006747
```

We’ve “sparsified” the higher levels of the indexes to make the console output a bit easier on the eyes. Note that how the index is displayed can be controlled using the multi_sparse option in pandas.set_options():

```
In [21]: with pd.option_context("display.multi_sparse", False):
       ....:     df
       ....: 
```

It’s worth keeping in mind that there’s nothing preventing you from using tuples as atomic labels on an axis:

```
In [22]: pd.Series(np.random.randn(8), index=tuples)
Out[22]:
(bar, one) -1.236269
```

(continued from previous page)

The reason that the MultiIndex matters is that it can allow you to do grouping, selection, and reshaping operations as we will describe below and in subsequent areas of the documentation. As you will see in later sections, you can find yourself working with hierarchically-indexed data without creating a MultiIndex explicitly yourself. However, when loading data from a file, you may wish to generate your own MultiIndex when preparing the data set.

Reconstructing the level labels

The method `get_level_values()` will return a vector of the labels for each location at a particular level:

```
In [23]: index.get_level_values(0)
Out[23]: Index(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'], dtype='object', name='first')
```

```
In [24]: index.get_level_values("second")
Out[24]: Index(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'], dtype='object', name='second')
```

Basic indexing on axis with MultiIndex

One of the important features of hierarchical indexing is that you can select data by a “partial” label identifying a subgroup in the data. Partial selection “drops” levels of the hierarchical index in the result in a completely analogous way to selecting a column in a regular DataFrame:

```
In [25]: df["bar"]
Out[25]:
second one two
A  0.895717  0.805244
B  0.410835  0.813850
C -1.413681  1.607920
```

```
In [26]: df["bar", "one"]
Out[26]:
A   0.895717
B   0.410835
C  -1.413681
Name: (bar, one), dtype: float64
```

```
In [27]: df["bar"]["one"]
Out[27]:
A   0.895717
B   0.410835
C  -1.413681
Name: one, dtype: float64
```

(continues on next page)
See *Cross-section with hierarchical index* for how to select on a deeper level.

**Defined levels**

The `MultiIndex` keeps all the defined levels of an index, even if they are not actually used. When slicing an index, you may notice this. For example:

```python
In [29]: df.columns.levels  # original MultiIndex
Out[29]: FrozenList([["bar", "baz", "foo", "qux"], ["one", "two"]])

In [30]: df["foo", "qux"].columns.levels  # sliced
Out[30]: FrozenList([["bar", "baz", "foo", "qux"], ["one", "two"]])
```

This is done to avoid a recomputation of the levels in order to make slicing highly performant. If you want to see only the used levels, you can use the `get_level_values()` method.

```python
In [31]: df["foo", "qux"].columns.get_level_values(0)
Out[31]: Index(['foo', 'foo', 'qux', 'qux'], dtype='object', name='first')
```

To reconstruct the `MultiIndex` with only the used levels, the `remove_unused_levels()` method may be used.

```python
In [33]: new_mi = df["foo", "qux"].columns.remove_unused_levels()

In [34]: new_mi.levels
Out[34]: FrozenList([['foo', 'qux'], ['one', 'two']])
```

**Data alignment and using reindex**

Operations between differently-indexed objects having `MultiIndex` on the axes will work as you expect; data alignment will work the same as an Index of tuples:

```python
In [35]: s + s[:-2]
Out[35]:
bar one   -1.723698
      two   -4.209138
baz one   -0.989859
      two    2.143608
foo one    1.443110
      two  -1.413542
qux one     NaN
      two     NaN
dtype: float64
```

(continues on next page)
In [36]: s + s[[::2]]
Out[36]:
  bar one  -1.723698
        two  NaN
  baz one  -0.989859
        two  NaN
  foo one   1.443110
        two  NaN
  qux one  -2.079150
        two  NaN
dtype: float64

The `reindex()` method of Series/DataFrames can be called with another MultiIndex, or even a list or array of tuples:

In [37]: s.reindex(index[:3])
Out[37]:
  first  second
  bar one  -0.861849
        two  -2.104569
  baz one  -0.494929
dtype: float64

In [38]: s.reindex([("foo", "two"), ("bar", "one"), ("qux", "one"), ("baz", "one")])
Out[38]:
  foo two  -0.706771
  bar one  -0.861849
  qux one  -1.039575
  baz one  -0.494929
dtype: float64

2.6.2 Advanced indexing with hierarchical index

Syntactically integrating MultiIndex in advanced indexing with `.loc` is a bit challenging, but we’ve made every effort to do so. In general, MultiIndex keys take the form of tuples. For example, the following works as you would expect:

In [39]: df = df.T

In [40]: df
Out[40]:
   A   B   C
first second
  bar one  0.895717  0.410835 -1.413681
        two  0.805244  0.813850  1.607920
  baz one  1.206412  0.132003 -1.024180
        two  2.565646 -0.827317  0.569605
  foo one  1.431256 -0.076467  0.875906
        two  1.340309 -1.187678 -2.211372
  qux one  1.170299  1.130127  0.974466
        two  0.226169 -1.436737 -2.006747

In [41]: df.loc["bar", "two"]
Out[41]:
  A   B   C
  bar two  0.805244  0.813850  1.607920
  baz two  2.565646 -0.827317  0.569605
  foo two  1.340309 -1.187678 -2.211372
  qux two  0.226169 -1.436737 -2.006747

2.6. MultiIndex / advanced indexing
A 0.805244
B 0.813850
C 1.607920
Name: (bar, two), dtype: float64

Note that `df.loc['bar', 'two']` would also work in this example, but this shorthand notation can lead to ambiguity in general.

If you also want to index a specific column with `.loc`, you must use a tuple like this:

```
In [42]: df.loc[('bar',), 'A']
Out[42]:
0.8052440253863785
```

You don’t have to specify all levels of the MultiIndex by passing only the first elements of the tuple. For example, you can use “partial” indexing to get all elements with `bar` in the first level as follows:

```
In [43]: df.loc[('bar',), 'A']
Out[43]:
second
one 0.895717 0.410835 -1.413681
two 0.805244 0.813850 1.607920
```

This is a shortcut for the slightly more verbose notation `df.loc[['bar',], 'A']` (equivalent to `df.loc['bar',]` in this example).

“Partial” slicing also works quite nicely.

```
In [44]: df.loc[['baz':'foo'], 'A']
Out[44]:
first second
baz one -1.206412 0.132003 1.024180
two 2.565646 -0.827317 0.569605
foo one 1.431256 -0.076467 0.875906
two 1.340309 -1.187678 -2.211372
```

You can slice with a ‘range’ of values, by providing a slice of tuples.

```
In [45]: df.loc[['baz', 'two':'qux', 'one'], 'A']
Out[45]:
first second
baz two 2.565646 -0.827317 0.569605
foo one 1.431256 -0.076467 0.875906
two 1.340309 -1.187678 -2.211372
qux one -1.170299 1.130127 0.974466
```

```
In [46]: df.loc[['baz', 'two':'foo'], 'A']
Out[46]:
first second
baz two 2.565646 -0.827317 0.569605
foo one 1.431256 -0.076467 0.875906
two 1.340309 -1.187678 -2.211372
```

Passing a list of labels or tuples works similar to reindexing:
In [47]: df.loc[(["bar", "two"), ("qux", "one")]
Out[47]:
   A         B         C
first second
bar two  0.805244  0.813850  1.607920
qux one  -1.170299  1.130127  0.974466

Note: It is important to note that tuples and lists are not treated identically in pandas when it comes to indexing. Whereas a tuple is interpreted as one multi-level key, a list is used to specify several keys. Or in other words, tuples go horizontally (traversing levels), lists go vertically (scanning levels).

Importantly, a list of tuples indexes several complete MultiIndex keys, whereas a tuple of lists refer to several values within a level:

In [48]: s = pd.Series(
    ....:   [1, 2, 3, 4, 5, 6],
    ....:   index=pd.MultiIndex.from_product([["A", "B"], ["c", "d", "e"]]),
    ....:   )

In [49]: s.loc[(["A", "c"), ("B", "d")]
# list of tuples
Out[49]:
   A c 1
   d 5
dtype: int64

In [50]: s.loc[(["A", "B"], ["c", "d")]
# tuple of lists
Out[50]:
   A c 1
   d 2
   B c 4
   d 5
dtype: int64

Using slicers

You can slice a MultiIndex by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see Selection by Label, including slices, lists of labels, and boolean indexers.

You can use slice(Nothing) to select all the contents of that level. You do not need to specify all the deeper levels, they will be implied as slice(Nothing).

As usual, both sides of the slicers are included as this is label indexing.

Warning: You should specify all axes in the .loc specifier, meaning the indexer for the index and for the columns. There are some ambiguous cases where the passed indexer could be mis-interpreted as indexing both axes, rather than into say the MultiIndex for the rows.

You should do this:

df.loc([slice("A1", "A3"), ...), :] # noqa: E999

You should not do this:
Basic MultiIndex slicing using slices, lists, and labels.

```
In [51]: def mklbl(prefix, n):
   ....:     return ["%s%s" % (prefix, i) for i in range(n)]
   ....:
In [52]: miindex = pd.MultiIndex.from_product([mklbl("A", 4), mklbl("B", 2), mklbl("C", 4), mklbl("D", 2)])
   ....: 
In [53]: micolumns = pd.MultiIndex.from_tuples([("a", "foo"), ("a", "bar"), ("b", "foo"), ("b", "bah")], names=["lvl0", "lvl1"])
   ....:
In [54]: dfmi = (pd.DataFrame(np.arange(len(miindex) * len(micolumns)).reshape(len(miindex), len(micolumns)), index=miindex, columns=micolumns).sort_index().sort_index(axis=1))
   ....:
In [55]: dfmi
Out[55]:
lvl0     a     b
lvl1  bar  foo  bah  foo
A0  B0  C0  D0  1    0    3    2
   D1  5    4    7    6
   C1  D0  9    8   11   10
   D1  13   12   15   14
   C2  D0  17   16   19   18
   D1  245  244  247  246
   C3  D0  249  248  251  250
   D1  253  252  255  254
   ...  ...  ...  ...  ...
A3  B1  C1  D1  237  236  239  238
   C2  D0  241  240  243  242
   D1  245  244  247  246
   C3  D0  249  248  251  250
   D1  253  252  255  254
[64 rows x 4 columns]
```

```
In [56]: dfmi.loc[(slice("A1", "A3"), slice(None), ["C1", "C3")], :]
Out[56]:
lvl0   a   b
lvl1 bar foo bah foo
A1  B0  C0  D0  73   72   75   74
```
You can use `pandas.IndexSlice` to facilitate a more natural syntax using `:`., rather than using `slice(None)`.

```python
In [57]: idx = pd.IndexSlice

In [58]: dfmi.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]
Out[58]:
   lvl0  a  b
   lvl1  foo  foo
  A0  B0  C1  D0         8  10
     D1         12  14
  C3  D0         24  26
     D1         28  30
  B1  C1  D0         40  42
     ...      ...  ...
  A3  B0  C3  D1       220  222
  B1  C1  D0       232  234
     D1       236  238
  C3  D0       248  250
     D1       252  254
[32 rows x 2 columns]
```

It is possible to perform quite complicated selections using this method on multiple axes at the same time.

```python
In [59]: dfmi.loc[['A1', (slice(None), 'foo')]]
Out[59]:
   lvl0  a  b
   lvl1  foo  foo
  B0  C0  D0       64  66
     D1       68  70
  C1  D0       72  74
     D1       76  78
  C2  D0       80  82
     ...      ...  ...
  B1  C1  D1       108  110
  C2  D0       112  114
     D1       116  118
  C3  D0       120  122
     D1       124  126
[16 rows x 2 columns]
```

```python
In [60]: dfmi.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]  
```

(continues on next page)
Using a boolean indexer you can provide selection related to the `values`.

```python
In [61]: mask = dfmi[('a', 'foo')] > 200

In [62]: dfmi.loc[idx[mask, :, ['C1', 'C3']], idx[:, 'foo']]
```

You can also specify the `axis` argument to `.loc` to interpret the passed slicers on a single axis.

```python
In [63]: dfmi.loc(axis=0)[:, :, ['C1', 'C3']]
```

Furthermore, you can set the values using the following methods.

```python
In [64]: df2 = dfmi.copy()

In [65]: df2.loc(axis=0)[:, :, ['C1', 'C3']] = -10
```

(continues on next page)
In [66]: df2
Out[66]:
lvl0  a  b
lvl1  bar  foo  bah  foo
A0  B0  C0  D0  1  0  3  2
D1  5  4  7  6
C1  D0  -10 -10 -10 -10
D1  -10 -10 -10 -10
C2  D0  17  16  19  18
... ... ... ... ...
A3  B1  C1  D1  -10 -10 -10 -10
C2  D0  241  240  243  242
D1  245  244  247  246
C3  D0  -10 -10 -10 -10
D1  -10 -10 -10 -10
[64 rows x 4 columns]

You can use a right-hand-side of an alignable object as well.

In [67]: df2 = dfmi.copy()
In [68]: df2.loc[idx[:, :, ["C1", "C3"]], :] = df2 * 1000
In [69]: df2
Out[69]:
lvl0  a  b
lvl1  bar  foo  bah  foo
A0  B0  C0  D0  1  0  3  2
D1  5  4  7  6
C1  D0  9000  8000  11000  10000
D1  13000  12000  15000  14000
C2  D0  17  16  19  18
... ... ... ... ...
A3  B1  C1  D1  237000  236000  239000  238000
C2  D0  241  240  243  242
D1  245  244  247  246
C3  D0  249000  248000  251000  250000
D1  253000  252000  255000  254000
[64 rows x 4 columns]

Cross-section

The *xs()* method of DataFrame additionally takes a level argument to make selecting data at a particular level of a MultiIndex easier.

In [70]: df
Out[70]:
first  second  A    B    C
bar   one     0.895717 0.410835 -1.413681
       two     0.805244 0.813850  1.607920
       baz    -1.206412 0.132003  1.024180
(continues on next page)
two   2.565646  -0.827317  0.569605
foo one  1.431256  -0.076467  0.875906
two   1.340309  -1.187678  -2.211372
qux one  -1.170299  1.130127   0.974466
two   -0.226169  -1.436737  -2.006747

In [71]: df.xs("one", level="second")
Out[71]:
   A   B   C
first  
bar  0.895717  0.410835 -1.413681
baz  -1.206412  0.132003  1.024180
foo  1.431256  -0.076467  0.875906
qux -1.170299  1.130127   0.974466

# using the slicers
In [72]: df.loc[(slice(None), "one")), :]
Out[72]:
   A   B   C
first second  
bar one  0.895717  0.410835 -1.413681
baz one  -1.206412  0.132003  1.024180
foo one  1.431256  -0.076467  0.875906
qux one  -1.170299  1.130127   0.974466

You can also select on the columns with xs, by providing the axis argument.

In [73]: df = df.T

In [74]: df.xs("one", level="second", axis=1)
Out[74]:
   first bar baz foo qux
A   0.895717 -1.206412  1.431256 -1.170299
B   0.410835  0.132003 -0.076467  1.130127
C  -1.413681  1.024180  0.875906   0.974466

# using the slicers
In [75]: df.loc[:, (slice(None), "one")]
Out[75]:
   first bar baz foo qux
A   0.895717 -1.206412  1.431256 -1.170299
B   0.410835  0.132003 -0.076467  1.130127
C  -1.413681  1.024180  0.875906   0.974466

xs also allows selection with multiple keys.

In [76]: df.xs(("one", "bar"), level=("second", "first"), axis=1)
Out[76]:
   first bar
second one  
A   0.895717
B   0.410835
C  -1.413681
# using the slicers
In [77]: df.loc[:, ("bar", "one")]

Out[77]:
A  0.895717
B  0.410835
C -1.413681
Name: (bar, one), dtype: float64

You can pass drop_level=False to xs to retain the level that was selected.

In [78]: df.xs("one", level="second", axis=1, drop_level=False)

Out[78]:
  first  bar  baz  foo  qux
second  one  one  one  one
A      0.895717 -1.206412 1.431256 -1.170299
B      0.410835  0.132003 -0.076467  1.130127
C     -1.413681  1.024180  0.875906  0.974466

Compare the above with the result using drop_level=True (the default value).

In [79]: df.xs("one", level="second", axis=1, drop_level=True)

Out[79]:
  first  bar  baz  foo  qux
A      0.895717 -1.206412 1.431256 -1.170299
B      0.410835  0.132003 -0.076467  1.130127
C     -1.413681  1.024180  0.875906  0.974466

Advanced reindexing and alignment

Using the parameter level in the reindex() and align() methods of pandas objects is useful to broadcast values across a level. For instance:

In [80]: midx = pd.MultiIndex(
   ....:     levels=["zero", "one"], ["x", "y"],
   ....:     codes=[[1, 1, 0, 0], [1, 0, 1, 0]],
   ....:     )
   ....:
In [81]: df = pd.DataFrame(np.random.randn(4, 2), index=midx)

In [82]: df

Out[82]:
0  1
one y  1.519970 -0.493662
   x   0.600178  0.274230
zero y  0.132885 -0.023688
   x   2.410179  1.450520

In [83]: df2 = df.groupby(level=0).mean()

In [84]: df2

Out[84]:
0  1
one y  1.060074 -0.109716
   x   0.271532  0.713416
zero 1.271532  0.713416

In [85]: df2.reindex(df.index, level=0)
Swapping levels with `swaplevel`

The `swaplevel()` method can switch the order of two levels:

```python
In [89]: df[:5]
Out[89]:
    0     1
one  y  1.519970 -0.493662
    x  0.600178  0.274230
zero y  0.132885 -0.023688
    x  2.410179  1.450520

In [90]: df[:5].swaplevel(0, 1, axis=0)
Out[90]:
    0     1
    y one  1.519970 -0.493662
    x one  0.600178  0.274230
    y zero  0.132885 -0.023688
    x zero  2.410179  1.450520
```
Reordering levels with `reorder_levels`

The `reorder_levels()` method generalizes the `swaplevel` method, allowing you to permute the hierarchical index levels in one step:

```python
In [91]: df[:5].reorder_levels([1, 0], axis=0)
Out[91]:
   0    1
y one  1.519970 -0.493662
   x one  0.600178  0.274230
   y zero 0.132885 -0.023688
   x zero 2.410179  1.450520
```

Renaming names of an `Index` or `MultiIndex`

The `rename()` method is used to rename the labels of a `MultiIndex`, and is typically used to rename the columns of a `DataFrame`. The `columns` argument of `rename` allows a dictionary to be specified that includes only the columns you wish to rename.

```python
In [92]: df.rename(columns={0: "col0", 1: "col1"})
Out[92]:
    col0  col1
   one   y  1.519970 -0.493662
         x  0.600178  0.274230
   zero  y  0.132885 -0.023688
         x  2.410179  1.450520
```

This method can also be used to rename specific labels of the main index of the `DataFrame`.

```python
In [93]: df.rename(index={"one": "two", "y": "z"})
Out[93]:
    0    1
two z  1.519970 -0.493662
   x  0.600178  0.274230
zero z 0.132885 -0.023688
   x  2.410179  1.450520
```

The `rename_axis()` method is used to rename the name of a `Index` or `MultiIndex`. In particular, the names of the levels of a `MultiIndex` can be specified, which is useful if `reset_index()` is later used to move the values from the `MultiIndex` to a column.

```python
In [94]: df.rename_axis(index=["abc", "def"))
Out[94]:
    0    1
abc def
one  y  1.519970 -0.493662
   x  0.600178  0.274230
zero  y  0.132885 -0.023688
   x  2.410179  1.450520
```

Note that the columns of a `DataFrame` are an index, so that using `rename_axis` with the `columns` argument will change the name of that index.

```python
In [95]: df.rename_axis(columns="Cols").columns
Out[95]: RangeIndex(start=0, stop=2, step=1, name='Cols')
```
Both rename and rename_axis support specifying a dictionary, Series or a mapping function to map labels/names to new values.

When working with an Index object directly, rather than via a DataFrame, Index.set_names() can be used to change the names.

```
In [96]: mi = pd.MultiIndex.from_product([[1, 2], ["a", "b"]], names=["x", "y"])
In [97]: mi.names
Out[97]: FrozenList(['x', 'y'])
In [98]: mi2 = mi.rename("new name", level=0)
In [99]: mi2
Out[99]: MultiIndex([(1, 'a'),
  (1, 'b'),
  (2, 'a'),
  (2, 'b')],
  names=['new name', 'y'])
```

You cannot set the names of the MultiIndex via a level.

```
In [100]: mi.levels[0].name = "name via level"
---------------------------------------------------------------------------
RuntimeError                      Traceback (most recent call last)
<ipython-input-100-35d32a9a5218> in <module>
----> 1 mi.levels[0].name = "name via level"
/pandas/pandas/core/indexes/base.py in name(self, value)
    1458          # Used in MultiIndex.levels to avoid silently ignoring name
    1459          # updates.
>   1460      raise RuntimeError(
    1461          "Cannot set name on a level of a MultiIndex. Use 
    1462          "MultiIndex.set_names' instead."

RuntimeError: Cannot set name on a level of a MultiIndex. Use 'MultiIndex.set_names' instead.
```

Use Index.set_names() instead.

### 2.6.3 Sorting a MultiIndex

For MultiIndex-ed objects to be indexed and sliced effectively, they need to be sorted. As with any index, you can use sort_index().

```
In [101]: import random
In [102]: random.shuffle(tuples)
In [103]: s = pd.Series(np.random.randn(8), index=pd.MultiIndex.from_tuples(tuples))
In [104]: s
Out[104]:
foo    one   0.206053
       two  -0.251905
```
In [105]: s.sort_index()
Out[105]:
   bar one   -0.863838
   two   0.299368
   baz one  0.408204
   two   1.063327
   foo one  0.206053
   two  -0.251905
   qux one  1.266143
   two  -2.213588
   dtype: float64

In [106]: s.sort_index(level=0)
Out[106]:
   bar one   -0.863838
   two   0.299368
   baz one  0.408204
   two   1.063327
   foo one  0.206053
   two  -0.251905
   qux one  1.266143
   two  -2.213588
   dtype: float64

In [107]: s.sort_index(level=1)
Out[107]:
   bar one   -0.863838
   baz one  0.408204
   foo one  0.206053
   qux one  1.266143
   bar two   0.299368
   baz two  1.063327
   foo two  -0.251905
   qux two  -2.213588
   dtype: float64

You may also pass a level name to `sort_index` if the `MultiIndex` levels are named.

In [108]: s.index.set_names(["L1", "L2"], inplace=True)

In [109]: s.sort_index(level="L1")
Out[109]:
   L1  L2
   bar one   -0.863838
   two   0.299368
   baz one  0.408204
   two   1.063327
   foo one  0.206053
   two  -0.251905

(continues on next page)
qux  one  1.266143
two  -2.213588
dtype: float64

In [110]: s.sort_index(level="L2")
Out[110]:
   L1   L2
  bar one -0.863838
  baz one  0.408204
  foo one  0.206053
  qux one  1.266143
  bar two  0.299368
  baz two  1.063327
  foo two -0.251905
  qux two -2.213588
dtype: float64

On higher dimensional objects, you can sort any of the other axes by level if they have a MultiIndex:

In [111]: df.T.sort_index(level=1, axis=1)
Out[111]:
   one  zero  one  zero
     x   x   y   y
  0  0.600178  2.410179  1.519970  0.132885
  1  0.274230  1.450520 -0.493662 -0.023688

Indexing will work even if the data are not sorted, but will be rather inefficient (and show a PerformanceWarning). It will also return a copy of the data rather than a view:

In [112]: dfm = pd.DataFrame(
   ....:     {"jim": [0, 0, 1, 1], "joe": ["x", "x", "z", "y"], "jolie": np.random.
   ....:         rand(4)})
   ....:
In [113]: dfm = dfm.set_index(["jim", "joe"])

In [114]: dfm
Out[114]:
     jolie
    jim  joe
  0   x  0.490671
     x  0.120248
  1   z  0.537020
     y  0.110968

In [4]: dfm.loc[(1, 'z')]
PerformanceWarning: indexing past lexsort depth may impact performance.

Out[4]:
     jolie
    jim  joe
  0   x  0.490671
  1   z  0.64094

Furthermore, if you try to index something that is not fully lexsorted, this can raise:
The `is_monotonic_increasing()` method on a MultiIndex shows if the index is sorted:

```
In [115]: dfm.index.is_monotonic_increasing
Out[115]: False
```

```
In [116]: dfm = dfm.sort_index()
In [117]: dfm
Out[117]:
jolie
  jim
  joe
  0  x  0.490671
      x  0.120248
  1  y  0.110968
      z  0.537020
```

```
In [118]: dfm.index.is_monotonic_increasing
Out[118]: True
```

And now selection works as expected.

```
In [119]: dfm.loc[(0, "y"):(1, "z")]
Out[119]:
jolie
  jim
  joe
  1  y  0.110968
      z  0.537020
```

### 2.6.4 Take methods

Similar to NumPy ndarrays, pandas Index, Series, and DataFrame also provides the `take()` method that retrieves elements along a given axis at the given indices. The given indices must be either a list or an ndarray of integer index positions. `take` will also accept negative integers as relative positions to the end of the object.

```
In [120]: index = pd.Index(np.random.randint(0, 1000, 10))
In [121]: index
Out[121]: Int64Index([214, 502, 712, 567, 786, 175, 993, 133, 758, 329], dtype='int64')
In [122]: positions = [0, 9, 3]
In [123]: index[positions]
Out[123]: Int64Index([214, 329, 567], dtype='int64')
In [124]: index.take(positions)
Out[124]: Int64Index([214, 329, 567], dtype='int64')
In [125]: ser = pd.Series(np.random.randn(10))
In [126]: ser.iloc[positions]
Out[126]:
```
(continues on next page)
For DataFrames, the given indices should be a 1d list or ndarray that specifies row or column positions.

In [128]: frm = pd.DataFrame(np.random.randn(5, 3))

In [129]: frm.take([1, 4, 3])

Out[129]:
   0 1 2
0 -1.237881 0.106854 -1.276829
1 0.629675 -1.425966 1.857704
3 0.979542 -1.633678 0.615855

In [130]: frm.take([0, 2], axis=1)

Out[130]:
   0 2
0 0.595974 0.601544
1 -1.237881 -1.276829
2 -0.767101 1.499591
3 0.979542 0.615855
4 0.629675 1.857704

It is important to note that the `take` method on pandas objects are not intended to work on boolean indices and may return unexpected results.

In [131]: arr = np.random.randn(10)

In [132]: arr.take([False, False, True, True])

Out[132]: array([-1.1935, -1.1935, 0.6775, 0.6775])

In [133]: arr[[0, 1]]

Out[133]: array([-1.1935, 0.6775])

In [134]: ser = pd.Series(np.random.randn(10))

In [135]: ser.take([False, False, True, True])

Out[135]:
   0  0.233141
   0  0.233141
  201 -0.223540
  223 -0.223540
dtype: float64

In [136]: ser.iloc[[0, 1]]

Out[136]:
   0  0.233141

(continues on next page)
Finally, as a small note on performance, because the `take` method handles a narrower range of inputs, it can offer performance that is a good deal faster than fancy indexing.

In [137]: `arr = np.random.randn(10000, 5)`
In [138]: `indexer = np.arange(10000)`
In [139]: `random.shuffle(indexer)`
In [140]: `%timeit arr[indexer]`

```
......: %timeit arr.take(indexer, axis=0)
......:
148 us +- 6.89 us per loop (mean +- std. dev. of 7 runs, 10000 loops each)
37.9 us +- 2.1 us per loop (mean +- std. dev. of 7 runs, 10000 loops each)
```

In [141]: `ser = pd.Series(arr[:, 0])`
In [142]: `%timeit ser.iloc[indexer]`

```
.....: %timeit ser.take(indexer)
.....:
72.3 us +- 812 ns per loop (mean +- std. dev. of 7 runs, 10000 loops each)
62.9 us +- 1.04 us per loop (mean +- std. dev. of 7 runs, 10000 loops each)
```

### 2.6.5 Index types

We have discussed `MultiIndex` in the previous sections pretty extensively. Documentation about `DatetimeIndex` and `PeriodIndex` are shown [here](#), and documentation about `TimedeltaIndex` is found [here](#).

In the following sub-sections we will highlight some other index types.

**CategoricalIndex**

`CategoricalIndex` is a type of index that is useful for supporting indexing with duplicates. This is a container around a `Categorical` and allows efficient indexing and storage of an index with a large number of duplicated elements.

In [143]: `from pandas.api.types import CategoricalDtype`
In [144]: `df = pd.DataFrame({"A": np.arange(6), "B": list("aabbca"))}`
In [145]: `df["B"] = df["B"].astype(CategoricalDtype(list("cab")))`
In [146]: `df`

```
Out[146]:
   A  B
0  0  a
1  1  a
2  2  b
3  3  b
```
4 4  c  
5 5  a

In [147]: df.dtypes
Out[147]:
A  int64
B  category
dtype: object

In [148]: df["B"].cat.categories
Out[148]: Index(['c', 'a', 'b'], dtype='object')

Setting the index will create a CategoricalIndex.

In [149]: df2 = df.set_index("B")

In [150]: df2.index
Out[150]: CategoricalIndex(['a', 'a', 'b', 'b', 'c', 'a'], categories=['c', 'a', 'b'], ordered=False, dtype='category', name='B')

Indexing with __getitem__/.iloc/.loc works similarly to an Index with duplicates. The indexers must be in the category or the operation will raise a KeyError.

In [151]: df2.loc["a"]
Out[151]:
   A  B
0  a  a
1  a  1
2  a  5

The CategoricalIndex is preserved after indexing:

In [152]: df2.loc["a"].index
Out[152]: CategoricalIndex(['a', 'a', 'a'], categories=['c', 'a', 'b'], ordered=False, dtype='category', name='B')

Sorting the index will sort by the order of the categories (recall that we created the index with CategoricalDtype(list('cab')), so the sorted order is cab).

In [153]: df2.sort_index()
Out[153]:
   A  B
 c  4
 a  0
 a  1
 b  2
 b  3

Groupby operations on the index will preserve the index nature as well.

In [154]: df2.groupby(level=0).sum()
Out[154]:
   A
Reindexing operations will return a resulting index based on the type of the passed indexer. Passing a list will return a plain-old `Index`; indexing with a `Categorical` will return a `CategoricalIndex`, indexed according to the categories of the passed `Categorical` dtype. This allows one to arbitrarily index these even with values not in the categories, similarly to how you can reindex any pandas index.

```
In [156]: df3 = pd.DataFrame({
          .....:   "A": np.arange(3), 
          .....:   "B": pd.Series(list("abc")).astype("category")
          .....:   })
In [157]: df3 = df3.set_index("B")
In [158]: df3
Out[158]:
   A  B
a  0  a
b  1  b
a  2  a

In [159]: df3.reindex(["a", "e"])
Out[159]:
   A  B
   a  0.0
   e NaN

In [160]: df3.reindex(["a", "e"]).index
Out[160]: Index(["a", 
In [161]: df3.reindex(pd.Categorical(["a", "e"], categories=list("abe")))
Out[161]:
   A  B
   a  0.0
   e NaN

In [162]: df3.reindex(pd.Categorical(["a", "e"], categories=list("abe")))
Out[162]: CategoricalIndex(["a", 

**Warning:** Reshaping and Comparison operations on a `CategoricalIndex` must have the same categories or a `TypeError` will be raised.

```
In [163]: df4 = pd.DataFrame({
          .....:   "A": np.arange(2), 
          .....:   "B": list("ba")
          .....:   })
In [164]: df4["B"]=df4["B"].astype(CategoricalDtype(list("ab")))
```

---

2.6．MultiIndex / advanced indexing

471
Int64Index and RangelIndex

Int64Index is a fundamental basic index in pandas. This is an immutable array implementing an ordered, sliceable set.

RangelIndex is a sub-class of Int64Index that provides the default index for all NDFrame objects. RangelIndex is an optimized version of Int64Index that can represent a monotonic ordered set. These are analogous to Python range types.

Float64Index

By default a Float64Index will be automatically created when passing floating, or mixed-integer-floating values in index creation. This enables a pure label-based slicing paradigm that makes [],ix,loc for scalar indexing and slicing work exactly the same.

Scalar selection for [],.loc will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to 3.0).
In [175]: sf[3]
Out[175]: 2

In [176]: sf[3.0]
Out[176]: 2

In [177]: sf.loc[3]
Out[177]: 2

In [178]: sf.loc[3.0]
Out[178]: 2

The only positional indexing is via iloc.

In [179]: sf.iloc[3]
Out[179]: 3

A scalar index that is not found will raise a KeyError. Slicing is primarily on the values of the index when using [], ix, loc, and always positional when using iloc. The exception is when the slice is boolean, in which case it will always be positional.

In [180]: sf[2:4]
Out[180]:
   2.0  1
   3.0  2
   dtype: int64

In [181]: sf.loc[2:4]
Out[181]:
   2.0  1
   3.0  2
   dtype: int64

In [182]: sf.iloc[2:4]
Out[182]:
   3.0  2
   4.5  3
   dtype: int64

In float indexes, slicing using floats is allowed.

In [183]: sf[2.1:4.6]
Out[183]:
   3.0  2
   4.5  3
   dtype: int64

In [184]: sf.loc[2.1:4.6]
Out[184]:
   3.0  2
   4.5  3
   dtype: int64

In non-float indexes, slicing using floats will raise a TypeError.

In [1]: pd.Series(range(5))[3.5]
  TypeError: the label [3.5] is not a proper indexer for this index type (Int64Index)

2.6. MultiIndex / advanced indexing
In [1]: pd.Series(range(5))[3.5:4.5]
TypeError: the slice start [3.5] is not a proper indexer for this index type

Here is a typical use-case for using this type of indexing. Imagine that you have a somewhat irregular timedelta-like indexing scheme, but the data is recorded as floats. This could, for example, be millisecond offsets.

In [185]: dfir = pd.concat(
    .....:     [pd.DataFrame(
    .....:         np.random.randn(5, 2), index=np.arange(5) * 250.0, columns=list("AB")),
    .....:     pd.DataFrame(
    .....:         np.random.randn(6, 2),
    .....:         index=np.arange(4, 10) * 250.1,
    .....:         columns=list("AB")),
    .....:     ])  

In [186]: dfir
Out[186]:
   A      B
0 0.0  -0.435772  -1.188928
250.0  -0.808286  -0.284634
500.0  -1.815703   1.347213
750.0  -0.243487   0.514704
1000.0  1.162969  -0.287725
1000.4  0.179734   0.993962
1250.5  0.212673   0.909872
1500.6  0.733333  -0.349893
1750.7  0.456434  -0.307635
2000.8  0.553396   0.166221
2250.9 -0.101684  -0.734907

Selection operations then will always work on a value basis, for all selection operators.

In [187]: dfir[0:1000.4]
Out[187]:
   A      B
0 0.0  -0.435772  -1.188928
250.0  -0.808286  -0.284634
500.0  -1.815703   1.347213
750.0  -0.243487   0.514704
1000.0  1.162969  -0.287725
1000.4  0.179734   0.993962
1250.5  0.212673   0.909872
1500.6  0.733333  -0.349893
1750.7  0.456434  -0.307635
2000.8  0.553396   0.166221
2250.9 -0.101684  -0.734907

In [188]: dfir.loc[0:1001, "A"]
Out[188]:
   0.0  -0.435772
250.0  -0.808286
500.0  -1.815703
750.0  -0.243487
You could retrieve the first 1 second (1000 ms) of data as such:

```python
In [190]: dfir[0:1000]
Out[190]:
   A   B
0.0 -0.435772 -1.188928
250.0 -0.808286 -0.284634
500.0 -1.815703  1.347213
750.0 -0.243487  0.514704
1000.0  1.162969 -0.287725
```

If you need integer based selection, you should use `iloc`:

```python
In [191]: dfir.iloc[0:5]
Out[191]:
   A   B
0.0 -0.435772 -1.188928
250.0 -0.808286 -0.284634
500.0 -1.815703  1.347213
750.0 -0.243487  0.514704
1000.0  1.162969 -0.287725
```

### IntervalIndex

`IntervalIndex` together with its own dtype, `IntervalDtype` as well as the `Interval` scalar type, allow first-class support in pandas for interval notation.

The `IntervalIndex` allows some unique indexing and is also used as a return type for the categories in `cut()` and `qcut()`.

### Indexing with an IntervalIndex

An `IntervalIndex` can be used in `Series` and in `DataFrame` as the index.

```python
In [192]: df = pd.DataFrame(
           ....:     {"A": [1, 2, 3, 4]}, index=pd.IntervalIndex.from_breaks([0, 1, 2, 3, 4])
           ....:     )

In [193]: df
Out[193]:
   A
(0, 1]  1
(1, 2]  2
```

(continues on next page)
Label based indexing via \texttt{.loc} along the edges of an interval works as you would expect, selecting that particular interval.

\begin{verbatim}
In [194]: df.loc[2]
Out[194]:
A    2
Name: (1, 2], dtype: int64
In [195]: df.loc[[2, 3]]
Out[195]:
   A
(1, 2]  2
(2, 3]  3
\end{verbatim}

If you select a label \textit{contained} within an interval, this will also select the interval.

\begin{verbatim}
In [196]: df.loc[2.5]
Out[196]:
   A
(2, 3]  3
In [197]: df.loc[[2.5, 3.5]]
Out[197]:
  A
(2, 3]  3
(3, 4]  4
\end{verbatim}

Selecting using an \texttt{Interval} will only return exact matches (starting from pandas 0.25.0).

\begin{verbatim}
In [198]: df.loc[pd.Interval(1, 2)]
Out[198]:
   A
(1, 2]  2
Name: (1, 2], dtype: int64
\end{verbatim}

Trying to select an \texttt{Interval} that is not exactly contained in the \texttt{IntervalIndex} will raise a \texttt{KeyError}.

\begin{verbatim}
In [7]: df.loc[pd.Interval(0.5, 2.5)]
---------------------------------------------------------------------------
KeyError: Interval(0.5, 2.5, closed='right')
\end{verbatim}

Selecting all \texttt{Intervals} that overlap a given \texttt{Interval} can be performed using the \texttt{overlaps()} method to create a boolean indexer.

\begin{verbatim}
In [199]: idxr = df.index.overlaps(pd.Interval(0.5, 2.5))
In [200]: idxr
Out[200]: array([ True,  True,  True, False])
In [201]: df[idxr]
Out[201]:
   A
(0, 1]  1
(1, 2]  2
(2, 3]  3
\end{verbatim}
Binning data with `cut` and `qcut`

`cut()` and `qcut()` both return a `Categorical` object, and the bins they create are stored as an `IntervalIndex` in its `.categories` attribute.

```python
In [202]: c = pd.cut(range(4), bins=2)
In [203]: c
Out[203]: [(-0.003, 1.5], (-0.003, 1.5], (1.5, 3.0], (1.5, 3.0]]
Categories (2, interval[float64, right]): [(-0.003, 1.5] < (1.5, 3.0]]
```

`cut()` also accepts an `IntervalIndex` for its `bins` argument, which enables a useful pandas idiom. First, we call `cut()` with some data and `bins` set to a fixed number, to generate the bins. Then, we pass the values of `.categories` as the `bins` argument in subsequent calls to `cut()`, supplying new data which will be binned into the same bins.

```python
In [204]: c.categories
Out[204]: IntervalIndex([(-0.003, 1.5], (1.5, 3.0]], dtype='interval[float64, right]')
```

Any value which falls outside all bins will be assigned a NaN value.

Generating ranges of intervals

If we need intervals on a regular frequency, we can use the `interval_range()` function to create an `IntervalIndex` using various combinations of `start`, `end`, and `periods`. The default frequency for `interval_range` is a 1 for numeric intervals, and calendar day for datetime-like intervals:

```python
In [205]: pd.interval_range(start=0, end=5)
Out[205]: IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]], dtype='interval[int64, right]')
```

```python
In [206]: pd.interval_range(start=0, end=5)
Out[206]: IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]], dtype='interval[int64, right]')
```

```python
In [207]: pd.interval_range(start=pd.Timestamp("2017-01-01"), periods=4)
Out[207]: IntervalIndex([(2017-01-01, 2017-01-08], (2017-01-08, 2017-01-15],
           dtype='interval[datetime64[ns], right]')
```

The `freq` parameter can be used to specify non-default frequencies, and can utilize a variety of `frequency aliases` with datetime-like intervals:

```python
In [208]: pd.interval_range(start=pd.Timestamp("2017-01-01"), periods=3)
Out[208]: IntervalIndex([(0 days 00:00:00, 1 days 00:00:00],
           (1 days 00:00:00, 2 days 00:00:00],
           (2 days 00:00:00, 3 days 00:00:00]],
           dtype='interval[datetime64[ns], right]')
```

```python
In [209]: pd.interval_range(start=0, periods=5, freq=1.5)
Out[209]: IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0], (6.0, 7.5]],
           dtype='interval[float64, right]')
```

```python
In [210]: pd.interval_range(start=pd.Timestamp("2017-01-01"), periods=4, freq="W")
Out[210]: IntervalIndex([(2017-01-01, 2017-01-08],
           (2017-01-08, 2017-01-15],
           (2017-01-15, 2017-01-22],
           (2017-01-22, 2017-01-29]],
           dtype='interval[datetime64[ns], right]')
```
Additionally, the `closed` parameter can be used to specify which side(s) the intervals are closed on. Intervals are closed on the right side by default.

```python
In [212]: pd.interval_range(start=0, end=4, closed="both")
Out[212]: IntervalIndex([[0, 1], [1, 2], [2, 3], [3, 4]], dtype='interval[int64, both]')
```

```python
In [213]: pd.interval_range(start=0, end=4, closed="neither")
Out[213]: IntervalIndex([(0, 1), (1, 2), (2, 3), (3, 4)], dtype='interval[int64, neither]')
```

Specifying `start`, `end`, and `periods` will generate a range of evenly spaced intervals from `start` to `end` inclusively, with `periods` number of elements in the resulting `IntervalIndex`:

```python
In [214]: pd.interval_range(start=0, end=6, periods=4)
Out[214]: IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]], dtype='interval[float64, right]')
```

```python
In [215]: pd.interval_range(pd.Timestamp("2018-01-01"), pd.Timestamp("2018-02-28"), periods=3)
Out[215]: IntervalIndex([(2018-01-01, 2018-01-20 08:00:00], (2018-01-20 08:00:00, 2018-02-08 16:00:00], (2018-02-08 16:00:00, 2018-02-28]], dtype='interval[datetime64[ns], right]')
```

### 2.6.6 Miscellaneous indexing FAQ

**Integer indexing**

Label-based indexing with integer axis labels is a thorny topic. It has been discussed heavily on mailing lists and among various members of the scientific Python community. In pandas, our general viewpoint is that labels matter more than integer locations. Therefore, with an integer axis index only label-based indexing is possible with the standard tools like `.loc`. The following code will generate exceptions:

```python
In [216]: s = pd.Series(range(5))

In [217]: s[-1]
---------------------------------------------------------------------------
ValueError                                Traceback (most recent call last)
pandas/pandas/core/indexes/range.py in get_loc(self, key, method, tolerance) 384     try: 385         return self._range.index(new_key) 386     except ValueError as err:
ValueError: -1 is not in range

The above exception was the direct cause of the following exception:

KeyError                                Traceback (most recent call last)
(continues on next page)
This deliberate decision was made to prevent ambiguities and subtle bugs (many users reported finding bugs when the API change was made to stop “falling back” on position-based indexing).

2.6. MultiIndex / advanced indexing 479
Non-monotonic indexes require exact matches

If the index of a Series or DataFrame is monotonically increasing or decreasing, then the bounds of a label-based slice can be outside the range of the index, much like slice indexing a normal Python list. Monotonicity of an index can be tested with the `is_monotonic_increasing()` and `is_monotonic_decreasing()` attributes.

```
In [221]: df = pd.DataFrame(index=[2, 3, 3, 4, 5], columns=['data'],
                      data=list(range(5)))
In [222]: df.index.is_monotonic_increasing
Out[222]: True

# no rows 0 or 1, but still returns rows 2, 3 (both of them), and 4:
In [223]: df.loc[0:4, :]
Out[223]:
   data
2    0
3    1
3    2
4    3

# slice is are outside the index, so empty DataFrame is returned
In [224]: df.loc[13:15, :]
Out[224]:
Empty DataFrame
Columns: [data]
Index: []
```

On the other hand, if the index is not monotonic, then both slice bounds must be unique members of the index.

```
In [225]: df = pd.DataFrame(index=[2, 3, 1, 4, 3, 5], columns=['data'],
                      data=list(range(6)))
In [226]: df.index.is_monotonic_increasing
Out[226]: False

# OK because 2 and 4 are in the index
In [227]: df.loc[2:4, :]
Out[227]:
   data
2    0
3    1
3    2
4    3

# 0 is not in the index
In [9]: df.loc[0:4, :]
KeyError: 0

# 3 is not a unique label
In [11]: df.loc[2:3, :]
KeyError: 'Cannot get right slice bound for non-unique label: 3'
```

`Index.is_monotonic_increasing` and `Index.is_monotonic_decreasing` only check that an index is weakly monotonic. To check for strict monotonicity, you can combine one of those with the `is_unique()` attribute.
Endpoints are inclusive

Compared with standard Python sequence slicing in which the slice endpoint is not inclusive, label-based slicing in pandas is inclusive. The primary reason for this is that it is often not possible to easily determine the “successor” or next element after a particular label in an index. For example, consider the following Series:

```python
In [232]: s = pd.Series(np.random.randn(6), index=list("abcdef"))
In [233]: s
Out[233]:
a   0.301379
b   1.240445
c  -0.846068
d  -0.043312
e  -1.658747
f   -0.819549
dtype: float64
```

Suppose we wished to slice from c to e, using integers this would be accomplished as such:

```python
In [234]: s[2:5]
Out[234]:
c  -0.846068
d  -0.043312
e  -1.658747
dtype: float64
```

However, if you only had c and e, determining the next element in the index can be somewhat complicated. For example, the following does not work:

```python
s.loc['c':'e' + 1]
```

A very common use case is to limit a time series to start and end at two specific dates. To enable this, we made the design choice to make label-based slicing include both endpoints:

```python
In [235]: s.loc["c":"e"]
Out[235]:
c  -0.846068
d  -0.043312
e  -1.658747
dtype: float64
```

This is most definitely a “practicality beats purity” sort of thing, but it is something to watch out for if you expect label-based slicing to behave exactly in the way that standard Python integer slicing works.
Indexing potentially changes underlying Series dtype

The different indexing operation can potentially change the dtype of a Series.

```
In [236]: series1 = pd.Series([1, 2, 3])
In [237]: series1.dtype
Out[237]: dtype('int64')
In [238]: res = series1.reindex([0, 4])
In [239]: res.dtype
Out[239]: dtype('float64')
In [240]: res
Out[240]:
0  1.0
4  NaN
dtype: float64
```

```
In [241]: series2 = pd.Series([True])
In [242]: series2.dtype
Out[242]: dtype('bool')
In [243]: res = series2.reindex_like(series1)
In [244]: res.dtype
Out[244]: dtype('O')
In [245]: res
Out[245]:
0   True
1   NaN
2   NaN
dtype: object
```

This is because the (re)indexing operations above silently inserts NaNs and the dtype changes accordingly. This can cause some issues when using numpy ufuncs such as numpy.logical_and.

See the this old issue for a more detailed discussion.
2.7 Merge, join, concatenate and compare

pandas provides various facilities for easily combining together Series or DataFrame with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

In addition, pandas also provides utilities to compare two Series or DataFrame and summarize their differences.

2.7.1 Concatenating objects

The `concat()` function (in the main pandas namespace) does all of the heavy lifting of performing concatenation operations along an axis while performing optional set logic (union or intersection) of the indexes (if any) on the other axes. Note that I say “if any” because there is only a single possible axis of concatenation for Series.

Before diving into all of the details of `concat` and what it can do, here is a simple example:

```python
In [1]: df1 = pd.DataFrame(
   ...:     {
   ...:         "B": ["B0", "B1", "B2", "B3"],
   ...:         "C": ["C0", "C1", "C2", "C3"],
   ...:         "D": ["D0", "D1", "D2", "D3"],
   ...:     },
   ...:     index=[0, 1, 2, 3],
   ...: )
   ...

In [2]: df2 = pd.DataFrame(
   ...:     {
   ...:         "A": ["A4", "A5", "A6", "A7"],
   ...:         "B": ["B4", "B5", "B6", "B7"],
   ...:         "C": ["C4", "C5", "C6", "C7"],
   ...:         "D": ["D4", "D5", "D6", "D7"],
   ...:     },
   ...:     index=[4, 5, 6, 7],
   ...: )
   ...

In [3]: df3 = pd.DataFrame(
   ...:     {
   ...:         "B": ["B8", "B9", "B10", "B11"],
   ...:         "C": ["C8", "C9", "C10", "C11"],
   ...:         "D": ["D8", "D9", "D10", "D11"],
   ...:     },
   ...:     index=[8, 9, 10, 11],
   ...: )
   ...

In [4]: frames = [df1, df2, df3]
In [5]: result = pd.concat(frames)
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

Like its sibling function on ndarrays, `numpy.concatenate`, `pandas.concat` takes a list or dict of homogeneously-typed objects and concatenates them with some configurable handling of “what to do with the other axes”:

```python
pd.concat(
    obj,
    axis=0,
    join="outer",
    ignore_index=False,
    keys=None,
    levels=None,
    names=None,
    verify_integrity=False,
    copy=True,
)
```

- **objs**: a sequence or mapping of Series or DataFrame objects. If a dict is passed, the sorted keys will be used as the `keys` argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a ValueError will be raised.

- **axis**: {0, 1, ...}, default 0. The axis to concatenate along.

- **join**: {‘inner’, ‘outer’}, default ‘outer’. How to handle indexes on other axis(es). Outer for union and inner for intersection.

- **ignore_index**: boolean, default False. If True, do not use the index values on the concatenation axis. The resulting axis will be labeled 0, ..., n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.

- **keys**: sequence, default None. Construct hierarchical index using the passed keys as the outermost level. If multiple levels passed, should contain tuples.
levels: list of sequences, default None. Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys.

names: list, default None. Names for the levels in the resulting hierarchical index.

verify_integrity: boolean, default False. Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.

copy: boolean, default True. If False, do not copy data unnecessarily.

Without a little bit of context many of these arguments don’t make much sense. Let’s revisit the above example. Suppose we wanted to associate specific keys with each of the pieces of the chopped up DataFrame. We can do this using the keys argument:

\[
\text{In [6]: result = pd.concat(frames, keys=["x", "y", "z"])}
\]

As you can see (if you’ve read the rest of the documentation), the resulting object’s index has a **hierarchical index**. This means that we can now select out each chunk by key:

\[
\text{In [7]: result.loc["y"]}
\]

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>A4</td>
<td>B4</td>
<td>C4</td>
</tr>
<tr>
<td>5</td>
<td>A5</td>
<td>B5</td>
<td>C5</td>
</tr>
<tr>
<td>6</td>
<td>A6</td>
<td>B6</td>
<td>C6</td>
</tr>
<tr>
<td>7</td>
<td>A7</td>
<td>B7</td>
<td>C7</td>
</tr>
</tbody>
</table>

\[
\text{Out[7]:}
\]

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>A4</td>
<td>B4</td>
<td>C4</td>
</tr>
<tr>
<td>5</td>
<td>A5</td>
<td>B5</td>
<td>C5</td>
</tr>
<tr>
<td>6</td>
<td>A6</td>
<td>B6</td>
<td>C6</td>
</tr>
<tr>
<td>7</td>
<td>A7</td>
<td>B7</td>
<td>C7</td>
</tr>
</tbody>
</table>

It’s not a stretch to see how this can be very useful. More detail on this functionality below.

Note: It is worth noting that `concat()` (and therefore `append()`) makes a full copy of the data, and that constantly
reusing this function can create a significant performance hit. If you need to use the operation over several datasets, use a list comprehension.

```python
frames = [process_your_file(f) for f in files]
result = pd.concat(frames)
```

**Note:** When concatenating DataFrames with named axes, pandas will attempt to preserve these index/column names whenever possible. In the case where all inputs share a common name, this name will be assigned to the result. When the input names do not all agree, the result will be unnamed. The same is true for **MultiIndex**, but the logic is applied separately on a level-by-level basis.

### Set logic on the other axes

When gluing together multiple DataFrames, you have a choice of how to handle the other axes (other than the one being concatenated). This can be done in the following two ways:

- Take the union of them all, `join='outer'`. This is the default option as it results in zero information loss.
- Take the intersection, `join='inner'`.

Here is an example of each of these methods. First, the default `join='outer'` behavior:

```python
In [8]: df4 = pd.DataFrame({
    ...:     "B": ['B2', 'B3', 'B6', 'B7'],
    ...:     "D": ['D2', 'D3', 'D6', 'D7'],
    ...:     "F": ['F2', 'F3', 'F6', 'F7'],
    ...: },
    ...: index=[2, 3, 6, 7],
    ...: )
    ...

In [9]: result = pd.concat([df1, df4], axis=1)
```

<table>
<thead>
<tr>
<th>df1</th>
<th>df4</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>
</tr>
<tr>
<td>0</td>
<td>A0</td>
<td>B0</td>
</tr>
<tr>
<td>1</td>
<td>A1</td>
<td>B1</td>
</tr>
<tr>
<td>2</td>
<td>A2</td>
<td>B2</td>
</tr>
<tr>
<td>3</td>
<td>A3</td>
<td>B3</td>
</tr>
</tbody>
</table>

Here is the same thing with `join='inner'`:

```python
In [10]: result = pd.concat([df1, df4], axis=1, join="inner")
```
Lastly, suppose we just wanted to reuse the exact index from the original DataFrame:

In [11]: `result = pd.concat([df1, df4], axis=1).reindex(df1.index)`

Similarly, we could index before the concatenation:

In [12]: `pd.concat([df1, df4.reindex(df1.index)], axis=1)`

Out[12]:

<p>| | | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>A0</td>
<td>B0</td>
<td>C0</td>
<td>D0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>A1</td>
<td>B1</td>
<td>C1</td>
<td>D1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>A2</td>
<td>B2</td>
<td>C2</td>
<td>D2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>A3</td>
<td>B3</td>
<td>C3</td>
<td>D3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<p>| | | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>B2</td>
<td>D2</td>

<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>B3</td>
<td>D3</td>
<td>F3</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>B3</td>
<td>D3</td>
<td>F3</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>B7</td>
<td>D7</td>
<td>F7</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Concatenating using `append`

A useful shortcut to `concat()` are the `append()` instance methods on `Series` and `DataFrame`. These methods actually predated `concat`. They concatenate along `axis=0`, namely the index:

In [13]: `result = df1.append(df2)`
In the case of DataFrame, the indexes must be disjoint but the columns do not need to be:

```
In [14]: result = df1.append(df4, sort=False)
```

append may take multiple objects to concatenate:

```
In [15]: result = df1.append([df2, df3])
```
Note: Unlike the append() method, which appends to the original list and returns None, append() here does not modify df1 and returns its copy with df2 appended.

Ignoring indexes on the concatenation axis

For DataFrame objects which don’t have a meaningful index, you may wish to append them and ignore the fact that they may have overlapping indexes. To do this, use the ignore_index argument:

```python
In [16]: result = pd.concat([df1, df4], ignore_index=True, sort=False)
```
In [17]: result = df1.append(df4, ignore_index=True, sort=False)

Concatenating with mixed ndims

You can concatenate a mix of Series and DataFrame objects. The Series will be transformed to DataFrame with the column name as the name of the Series.

In [18]: s1 = pd.Series(["X0", "X1", "X2", "X3"], name="X")

In [19]: result = pd.concat([df1, s1], axis=1)
Note: Since we're concatenating a Series to a DataFrame, we could have achieved the same result with `DataFrame.assign()`. To concatenate an arbitrary number of pandas objects (DataFrame or Series), use `concat`.

If unnamed Series are passed they will be numbered consecutively.

```
In [20]: s2 = pd.Series(["_0", "_1", "_2", "_3"])
In [21]: result = pd.concat([df1, s2, s2, s2], axis=1)
```

Passing `ignore_index=True` will drop all name references.

```
In [22]: result = pd.concat([df1, s1], axis=1, ignore_index=True)
```
More concatenating with group keys

A fairly common use of the `keys` argument is to override the column names when creating a new `DataFrame` based on existing `Series`. Notice how the default behaviour consists on letting the resulting `DataFrame` inherit the parent `Series`' name, when these existed.

```python
In [23]: s3 = pd.Series([0, 1, 2, 3], name="foo")
In [24]: s4 = pd.Series([0, 1, 2, 3])
In [25]: s5 = pd.Series([0, 1, 4, 5])
In [26]: pd.concat([s3, s4, s5], axis=1)
Out[26]:
           foo  0  1
    0   0  0  0
    1   1  1  1
    2   2  2  4
    3   3  3  5
```

Through the `keys` argument we can override the existing column names.

```python
In [27]: pd.concat([s3, s4, s5], axis=1, keys=["red", "blue", "yellow")
Out[27]:
        red  blue  yellow
    0    0    0    0
    1    1    1    1
    2    2    2    4
    3    3    3    5
```

Let's consider a variation of the very first example presented:

```python
In [28]: result = pd.concat(frames, keys=["x", "y", "z")
```
You can also pass a dict to `concat` in which case the dict keys will be used for the `keys` argument (unless other keys are specified):

```
In [29]: pieces = {"x": df1, "y": df2, "z": df3}
In [30]: result = pd.concat(pieces)
```
The MultiIndex created has levels that are constructed from the passed keys and the index of the DataFrame pieces:

```python
In [31]: result = pd.concat(pieces, keys=['z', 'y'])
```
If you wish to specify other levels (as will occasionally be the case), you can do so using the `levels` argument:

```python
In [33]: result = pd.concat(
    ....:     pieces, keys=["x", "y", "z"], levels=[["z", "y", "x", "w"]], names=[
        "group_key"
    ]
    ....: )
```

This is fairly esoteric, but it is actually necessary for implementing things like GroupBy where the order of a categorical variable is meaningful.

### Appending rows to a DataFrame

While not especially efficient (since a new object must be created), you can append a single row to a `DataFrame` by passing a `Series` or dict to `append`, which returns a new `DataFrame` as above.

```python
In [35]: s2 = pd.Series(["X0", "X1", "X2", "X3"], index=["A", "B", "C", "D"])
In [36]: result = df1.append(s2, ignore_index=True)
```
You should use `ignore_index` with this method to instruct DataFrame to discard its index. If you wish to preserve the index, you should construct an appropriately-indexed DataFrame and append or concatenate those objects.

You can also pass a list of dicts or Series:

```
In [37]: dicts = ["A": 1, "B": 2, "C": 3, "X": 4}, {"A": 5, "B": 6, "C": 7, "Y": 8}]
In [38]: result = df1.append(dicts, ignore_index=True, sort=False)
```

### 2.7.2 Database-style DataFrame or named Series joining/merging

pandas has full-featured, high performance in-memory join operations idiomatically very similar to relational databases like SQL. These methods perform significantly better (in some cases well over an order of magnitude better) than other open source implementations (like base::merge.data.frame in R). The reason for this is careful algorithmic design and the internal layout of the data in DataFrame.

See the cookbook for some advanced strategies.

Users who are familiar with SQL but new to pandas might be interested in a comparison with SQL.
pandas provides a single function, `merge()`, as the entry point for all standard database join operations between DataFrame or named Series objects:

```python
pd.merge(
    left,
    right,
    how="inner",
    on=None,
    left_on=None,
    right_on=None,
    left_index=False,
    right_index=False,
    sort=True,
    suffixes=('_x', '_y'),
    copy=True,
    indicator=False,
    validate=None,
)
```

- **left**: A DataFrame or named Series object.
- **right**: Another DataFrame or named Series object.
- **on**: Column or index level names to join on. Must be found in both the left and right DataFrame and/or Series objects. If not passed and `left_index` and `right_index` are `False`, the intersection of the columns in the DataFrames and/or Series will be inferred to be the join keys.
- **left_on**: Columns or index levels from the left DataFrame or Series to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the DataFrame or Series.
- **right_on**: Columns or index levels from the right DataFrame or Series to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the DataFrame or Series.
- **left_index**: If `True`, use the index (row labels) from the left DataFrame or Series as its join key(s). In the case of a DataFrame or Series with a MultiIndex (hierarchical), the number of levels must match the number of join keys from the right DataFrame or Series.
- **right_index**: Same usage as `left_index` for the right DataFrame or Series.
- **how**: One of 'left', 'right', 'outer', 'inner'. Defaults to `inner`. See below for more detailed description of each method.
- **sort**: Sort the result DataFrame by the join keys in lexicographical order. Defaults to `True`, setting to `False` will improve performance substantially in many cases.
- **suffixes**: A tuple of string suffixes to apply to overlapping columns. Defaults to (`'_x'`, `'_y'`).
- **copy**: Always copy data (default `True`) from the passed DataFrame or named Series objects, even when reindexing is not necessary. Cannot be avoided in many cases but may improve performance / memory usage. The cases where copying can be avoided are somewhat pathological but this option is provided nonetheless.
- **indicator**: Add a column to the output DataFrame called `_merge` with information on the source of each row. `_merge` is Categorical-type and takes on a value of `left_only` for observations whose merge key only appears in 'left' DataFrame or Series, `right_only` for observations whose merge key only appears in 'right' DataFrame or Series, and `both` if the observation’s merge key is found in both.
- **validate**: string, default None. If specified, checks if merge is of specified type.
  - “one_to_one” or “1:1”: checks if merge keys are unique in both left and right datasets.
  - “one_to_many” or “1:m”: checks if merge keys are unique in left dataset.
  - “many_to_one” or “m:1”: checks if merge keys are unique in right dataset.
— “many_to_many” or “m:m”: allowed, but does not result in checks.

Note: Support for specifying index levels as the on, left_on, and right_on parameters was added in version 0.23.0. Support for merging named Series objects was added in version 0.24.0.

The return type will be the same as left. If left is a DataFrame or named Series and right is a subclass of DataFrame, the return type will still be DataFrame.

merge is a function in the pandas namespace, and it is also available as a DataFrame instance method `merge()`, with the calling DataFrame being implicitly considered the left object in the join.

The related `join()` method, uses `merge` internally for the index-on-index (by default) and column(s)-on-index join. If you are joining on index only, you may wish to use `DataFrame.join` to save yourself some typing.

**Brief primer on merge methods (relational algebra)**

Experienced users of relational databases like SQL will be familiar with the terminology used to describe join operations between two SQL-table like structures (DataFrame objects). There are several cases to consider which are very important to understand:

- **one-to-one** joins: for example when joining two DataFrame objects on their indexes (which must contain unique values).
- **many-to-one** joins: for example when joining an index (unique) to one or more columns in a different DataFrame.
- **many-to-many** joins: joining columns on columns.

Note: When joining columns on columns (potentially a many-to-many join), any indexes on the passed DataFrame objects will be discarded.

It is worth spending some time understanding the result of the **many-to-many** join case. In SQL / standard relational algebra, if a key combination appears more than once in both tables, the resulting table will have the **Cartesian product** of the associated data. Here is a very basic example with one unique key combination:

```python
In [39]: left = pd.DataFrame(
   ....:     {
   ....:       "key": ["K0", "K1", "K2", "K3"],
   ....:       "B": ["B0", "B1", "B2", "B3"],
   ....:     }
   ....: )
   ....:
In [40]: right = pd.DataFrame(
   ....:     {
   ....:       "key": ["K0", "K1", "K2", "K3"],
   ....:       "C": ["C0", "C1", "C2", "C3"],
   ....:       "D": ["D0", "D1", "D2", "D3"],
   ....:     }
   ....: )
   ....:
In [41]: result = pd.merge(left, right, on="key")
```

498 Chapter 2. User Guide
Here is a more complicated example with multiple join keys. Only the keys appearing in `left` and `right` are present (the intersection), since `how='inner'` by default.

```python
In [42]: left = pd.DataFrame(
    ....:     {
    ....:         "key1": ["K0", "K0", "K1", "K2"],
    ....:         "key2": ["K0", "K1", "K0", "K1"],
    ....:         "B": ["B0", "B1", "B2", "B3"],
    ....:     }
    ....: )

In [43]: right = pd.DataFrame(
    ....:     {
    ....:         "key1": ["K0", "K1", "K1", "K2"],
    ....:         "key2": ["K0", "K0", "K0", "K0"],
    ....:         "C": ["C0", "C1", "C2", "C3"],
    ....:         "D": ["D0", "D1", "D2", "D3"],
    ....:     }
    ....: )

In [44]: result = pd.merge(left, right, on=["key1", "key2"])
```

The `how` argument to `merge` specifies how to determine which keys are to be included in the resulting table. If a key combination does not appear in either the left or right tables, the values in the joined table will be `NA`. Here is a summary of the `how` options and their SQL equivalent names:
## Merge method | SQL Join Name | Description
---|---|---
left | LEFT OUTER JOIN | Use keys from left frame only
right | RIGHT OUTER JOIN | Use keys from right frame only
outer | FULL OUTER JOIN | Use union of keys from both frames
inner | INNER JOIN | Use intersection of keys from both frames

In [45]: result = pd.merge(left, right, how="left", on=["key1", "key2"])

<table>
<thead>
<tr>
<th>left</th>
<th>right</th>
<th>Result</th>
</tr>

</tbody>
</table>
In [48]: result = pd.merge(left, right, how="inner", on=["key1", "key2")

You can merge a mult-indexed Series and a DataFrame, if the names of the MultiIndex correspond to the columns from the DataFrame. Transform the Series to a DataFrame using `Series.reset_index()` before merging, as shown in the following example.

In [49]: df = pd.DataFrame({"Let": ["A", "B", "C"], "Num": [1, 2, 3]})

In [50]: df

Out[50]:
<table>
<thead>
<tr>
<th>Let</th>
<th>Num</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>1</td>
</tr>
<tr>
<td>B</td>
<td>2</td>
</tr>
<tr>
<td>C</td>
<td>3</td>
</tr>
</tbody>
</table>

In [51]: ser = pd.Series(
    ....: ["a", "b", "c", "d", "e", "f"],
    ....: index=pd.MultiIndex.from_arrays(
    ....:     [["A", "B", "C"] * 2, [1, 2, 3, 4, 5, 6]], names=["Let", "Num"]
    ....: ),
    ....: )

In [52]: ser

Out[52]:
<table>
<thead>
<tr>
<th>Let</th>
<th>Num</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>a</td>
</tr>
<tr>
<td>B</td>
<td>b</td>
</tr>
<tr>
<td>C</td>
<td>c</td>
</tr>
<tr>
<td>A</td>
<td>d</td>
</tr>
<tr>
<td>B</td>
<td>e</td>
</tr>
<tr>
<td>C</td>
<td>f</td>
</tr>
</tbody>
</table>

dtype: object

In [53]: pd.merge(df, ser.reset_index(), on=["Let", "Num")

Out[53]:
<table>
<thead>
<tr>
<th>Let</th>
<th>Num</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>1</td>
<td>a</td>
</tr>
<tr>
<td>B</td>
<td>2</td>
<td>b</td>
</tr>
<tr>
<td>C</td>
<td>3</td>
<td>c</td>
</tr>
</tbody>
</table>

Here is another example with duplicate join keys in DataFrames:

In [54]: left = pd.DataFrame({"A": [1, 2], "B": [2, 2]})

In [55]: right = pd.DataFrame({"A": [4, 5, 6], "B": [2, 2, 2]})

(continues on next page)
In [56]: result = pd.merge(left, right, on="B", how="outer")

Warning: Joining / merging on duplicate keys can cause a returned frame that is the multiplication of the row dimensions, which may result in memory overflow. It is the user’s responsibility to manage duplicate values in keys before joining large DataFrames.

Checking for duplicate keys

Users can use the validate argument to automatically check whether there are unexpected duplicates in their merge keys. Key uniqueness is checked before merge operations and so should protect against memory overflows. Checking key uniqueness is also a good way to ensure user data structures are as expected.

In the following example, there are duplicate values of B in the right DataFrame. As this is not a one-to-one merge – as specified in the validate argument – an exception will be raised.

In [57]: left = pd.DataFrame({"A": [1, 2], "B": [1, 2]})
In [58]: right = pd.DataFrame({"A": [4, 5, 6], "B": [2, 2, 2]})

In [53]: result = pd.merge(left, right, on="B", how="outer", validate="one_to_one")
... 
MergeError: Merge keys are not unique in right dataset; not a one-to-one merge

If the user is aware of the duplicates in the right DataFrame but wants to ensure there are no duplicates in the left DataFrame, one can use the validate='one_to_many' argument instead, which will not raise an exception.

In [59]: pd.merge(left, right, on="B", how="outer", validate="one_to_many")
Out[59]:
   A_x  B  A_y
0  1  1  NaN
1  2  2  4.0
2  2  2  5.0
3  2  2  6.0
The merge indicator

`merge()` accepts the argument `indicator`. If `True`, a Categorical-type column called `_merge` will be added to the output object that takes on values:

<table>
<thead>
<tr>
<th>Observation</th>
<th>Origin</th>
<th>_merge value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Merge key only in 'left' frame</td>
<td></td>
<td>left_only</td>
</tr>
<tr>
<td>Merge key only in 'right' frame</td>
<td></td>
<td>right_only</td>
</tr>
<tr>
<td>Merge key in both frames</td>
<td></td>
<td>both</td>
</tr>
</tbody>
</table>

In [60]: df1 = pd.DataFrame({"col1": [0, 1], "col_left": ["a", "b"]})

In [61]: df2 = pd.DataFrame({"col1": [1, 2, 2], "col_right": [2, 2, 2]})

In [62]: pd.merge(df1, df2, on="col1", how="outer", indicator=True)
Out[62]:

```
coll col_left col_right _merge
0 0 a NaN left_only
1 1 b 2.0 both
2 2 NaN 2.0 right_only
3 2 NaN 2.0 right_only
```

The `indicator` argument will also accept string arguments, in which case the indicator function will use the value of the passed string as the name for the indicator column.

In [63]: pd.merge(df1, df2, on="col1", how="outer", indicator="indicator_column")
Out[63]:

```
coll col_left col_right indicator_column
0 0 a NaN left_only
1 1 b 2.0 both
2 2 NaN 2.0 right_only
3 2 NaN 2.0 right_only
```

Merge dtypes

Merging will preserve the dtype of the join keys.

In [64]: left = pd.DataFrame({"key": [1], "v1": [10]})

In [65]: left
Out[65]:

```
key  v1
0  1 10
```

In [66]: right = pd.DataFrame({"key": [1, 2], "v1": [20, 30]})

In [67]: right
Out[67]:

```
key  v1
0  1 20
1  2 30
```

We are able to preserve the join keys:
In [68]: pd.merge(left, right, how="outer")
Out[68]:
   key  v1
0   1   10
1   1   20
2   2   30

In [69]: pd.merge(left, right, how="outer").dtypes
Out[69]:
   key     int64
   v1      int64
dtype: object

Of course if you have missing values that are introduced, then the resulting dtype will be upcast.

In [70]: pd.merge(left, right, how="outer", on="key")
Out[70]:
      key  v1_x  v1_y
0      1   10.0  20
1      2      NaN  30

In [71]: pd.merge(left, right, how="outer", on="key").dtypes
Out[71]:
   key     int64
   v1_x    float64
   v1_y    int64
dtype: object

Merging will preserve category dtypes of the mergands. See also the section on *categoricals*.

The left frame.

In [72]: from pandas.api.types import CategoricalDtype
In [73]: X = pd.Series(np.random.choice(["foo", "bar"], size=(10,)))
In [74]: X = X.astype(CategoricalDtype(categories=["foo", "bar"]))
In [75]: left = pd.DataFrame(
   ....:     {"X": X, "Y": np.random.choice(["one", "two", "three"], size=(10,))}
   ....: )
   ....:
In [76]: left
Out[76]:
   X   Y
  0 bar one
  1 foo one
  2 foo three
  3 bar three
  4 foo one
  5 bar one
  6 bar three
  7 bar three
  8 bar three
  9 foo three

In [77]: left.dtypes
(continues on next page)
The right frame.

```python
In [78]: right = pd.DataFrame(
              {"X": pd.Series(["foo", "bar"], dtype=CategoricalDtype(["foo", "bar"])),
               "Z": [1, 2],
            })

In [79]: right
dtype: object
```

The merged result:

```python
In [81]: result = pd.merge(left, right, how="outer")

In [82]: result
dtype: object
```

Note: The category dtypes must be exactly the same, meaning the same categories and the ordered attribute. Otherwise the result will coerce to the categories’ dtype.

2.7. Merge, join, concatenate and compare
Note: Merging on category dtypes that are the same can be quite performant compared to object dtype merging.

Joining on index

`DataFrame.join()` is a convenient method for combining the columns of two potentially differently-indexed DataFrames into a single result DataFrame. Here is a very basic example:

```python
In [84]: left = pd.DataFrame({
    ...:     "A": ["A0", "A1", "A2"],
    ...:     "B": ["B0", "B1", "B2"],
    ...:     }, index=["K0", "K1", "K2"]
    ...:    )
    ....:

In [85]: right = pd.DataFrame({
    ...:     "C": ["C0", "C2", "C3"],
    ...:     "D": ["D0", "D2", "D3"],
    ...:     }, index=["K0", "K2", "K3"]
    ...:    )
    ....:

In [86]: result = left.join(right)
```

<table>
<thead>
<tr>
<th>left</th>
<th>right</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>C</td>
<td>A</td>
</tr>
<tr>
<td>B</td>
<td>D</td>
<td>B</td>
</tr>
<tr>
<td>K0</td>
<td>K0</td>
<td>K0</td>
</tr>
<tr>
<td>A0</td>
<td>C0</td>
<td>A0</td>
</tr>
<tr>
<td>B0</td>
<td>D0</td>
<td>B0</td>
</tr>
<tr>
<td>K1</td>
<td>K2</td>
<td>K1</td>
</tr>
<tr>
<td>A1</td>
<td>C2</td>
<td>A1</td>
</tr>
<tr>
<td>B1</td>
<td>D2</td>
<td>B1</td>
</tr>
<tr>
<td>K2</td>
<td>K3</td>
<td>K2</td>
</tr>
<tr>
<td>A2</td>
<td>C3</td>
<td>A2</td>
</tr>
<tr>
<td>B2</td>
<td>D3</td>
<td>B2</td>
</tr>
</tbody>
</table>

In [87]: result = left.join(right, how="outer")

<table>
<thead>
<tr>
<th>left</th>
<th>right</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>C</td>
<td>A</td>
</tr>
<tr>
<td>B</td>
<td>D</td>
<td>B</td>
</tr>
<tr>
<td>K0</td>
<td>K0</td>
<td>K0</td>
</tr>
<tr>
<td>A0</td>
<td>C0</td>
<td>A0</td>
</tr>
<tr>
<td>B0</td>
<td>D0</td>
<td>B0</td>
</tr>
<tr>
<td>K1</td>
<td>K2</td>
<td>K1</td>
</tr>
<tr>
<td>A1</td>
<td>C2</td>
<td>A1</td>
</tr>
<tr>
<td>B1</td>
<td>D2</td>
<td>B1</td>
</tr>
<tr>
<td>K2</td>
<td>K3</td>
<td>K2</td>
</tr>
<tr>
<td>A2</td>
<td>C3</td>
<td>A2</td>
</tr>
<tr>
<td>B2</td>
<td>D3</td>
<td>B2</td>
</tr>
</tbody>
</table>

The same as above, but with how='inner'.

In [88]: result = left.join(right, how="inner")
The data alignment here is on the indexes (row labels). This same behavior can be achieved using `merge` plus additional arguments instructing it to use the indexes:

```python
In [89]: result = pd.merge(left, right, left_index=True, right_index=True, how="outer")
```

<table>
<thead>
<tr>
<th>left</th>
<th>right</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>
</tr>
<tr>
<td>K0 A0 B0</td>
<td>K0 C0 D0</td>
<td>K0 A0 B0 C0 D0</td>
</tr>
<tr>
<td>K1 A1 B1</td>
<td>K1 C2 D2</td>
<td>K1 A1 B1 NaN NaN</td>
</tr>
<tr>
<td>K3 NaN NaN</td>
<td>K3 C3 D3</td>
<td>K3 NaN NaN C3 D3</td>
</tr>
</tbody>
</table>

```python
In [90]: result = pd.merge(left, right, left_index=True, right_index=True, how="inner")
```

<table>
<thead>
<tr>
<th>left</th>
<th>right</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>
</tr>
<tr>
<td>K0 A0 B0</td>
<td>K0 C0 D0</td>
<td>K0 A0 B0 C0 D0</td>
</tr>
<tr>
<td>K1 A1 B1</td>
<td>K1 C2 D2</td>
<td>K1 A1 B1 NaN NaN</td>
</tr>
<tr>
<td>K3 NaN NaN</td>
<td>K3 C3 D3</td>
<td>K3 NaN NaN C3 D3</td>
</tr>
</tbody>
</table>

### Joining key columns on an index

`join()` takes an optional `on` argument which may be a column or multiple column names, which specifies that the passed DataFrame is to be aligned on that column in the DataFrame. These two function calls are completely equivalent:

```python
left.join(right, on=key_or_keys)
pd.merge(
    left, right, left_on=key_or_keys, right_index=True, how="left", sort=False
)
```

Obviously you can choose whichever form you find more convenient. For many-to-one joins (where one of the DataFrame's is already indexed by the join key), using `join` may be more convenient. Here is a simple example:

```python
In [91]: left = pd.DataFrame(
    ....:     {  
    ....:     "B": ["B0", "B1", "B2", "B3"],
    )
```

(continues on next page)
In [92]: right = pd.DataFrame({"C": ["C0", "C1"], "D": ["D0", "D1"]}, index=["K0", "K1"])

In [93]: result = left.join(right, on="key")

In [94]: result = pd.merge(
   ....:   left, right, left_on="key", right_index=True, how="left", sort=False
   ....: )
   ....:

The passed DataFrame must have a MultiIndex:

In [95]: left = pd.DataFrame(
   ....:   {
   ....:     "B": ["B0", "B1", "B2", "B3"],
   ....:     "key1": ["K0", "K0", "K1", "K2"],
   ....:     "key2": ["K0", "K1", "K0", "K1"],
   ....:   }
   ....: )
   ....:

In [96]: index = pd.MultiIndex.from_tuples(
   ....:   ["K0", "K0"], ("K1", "K0"), ("K2", "K0"), ("K2", "K1")
   ....: )
   ....:

In [97]: right = pd.DataFrame(
   ....:   {"C": ["C0", "C1", "C2", "C3"], "D": ["D0", "D1", "D2", "D3"]})
Now this can be joined by passing the two key column names:

```
In [98]: result = left.join(right, on=['key1', 'key2'])
```

The default for DataFrame.join is to perform a left join (essentially a “VLOOKUP” operation, for Excel users), which uses only the keys found in the calling DataFrame. Other join types, for example inner join, can be just as easily performed:

```
In [99]: result = left.join(right, on=['key1', 'key2'], how='inner')
```

As you can see, this drops any rows where there was no match.

### Joining a single Index to a MultiIndex

You can join a singly-indexed DataFrame with a level of a MultiIndexed DataFrame. The level will match on the name of the index of the singly-indexed frame against a level name of the MultiIndexed frame.

```
In [100]: left = pd.DataFrame(
          ....:     {'A': ['A0', 'A1', 'A2'], 'B': ['B0', 'B1', 'B2']},
          ....:     index=pd.Index(['K0', 'K1', 'K2'], name='key'),
          ....:     )
```

```
In [101]: index = pd.MultiIndex.from_tuples(
          ....:     [('K0', 'Y0'), ('K1', 'Y1'), ('K2', 'Y2'), ('K2', 'Y3')],
          ....:     names=['key', 'Y'],
          ....:     )
```

(continues on next page)
In [102]: right = pd.DataFrame(
......:     {
......:         "C": ["C0", "C1", "C2", "C3"],
......:         "D": ["D0", "D1", "D2", "D3"]},
......:     index=index,
......: )
......:
In [103]: result = left.join(right, how="inner")

This is equivalent but less verbose and more memory efficient / faster than this.

In [104]: result = pd.merge(
......:     left.reset_index(), right.reset_index(), on=["key"], how="inner"
......: ).set_index(["key","Y"])
......:

Joining with two MultiIndexes

This is supported in a limited way, provided that the index for the right argument is completely used in the join, and is a subset of the indices in the left argument, as in this example:

In [105]: leftindex = pd.MultiIndex.from_product(
......:     [list("abc"), list("xy"), [1, 2]], names=["abc", "xy", "num"]
......: )
......:
In [106]: left = pd.DataFrame({"v1": range(12)}, index=leftindex)
In [107]: left
Out[107]:
    abc  xy  num
  a x   1    0

(continues on next page)
In [108]: rightindex = pd.MultiIndex.from_product(
        .....:     [list("abc"), list("xy")], names="abc", "xy")
        .....:
        .....:

In [109]: right = pd.DataFrame({"v2": [100 * i for i in range(1, 7)]},
 indexes=rightindex)

In [110]: right
Out[110]:
   v2
  abc xy
 a x 1 100
 y 2 200
 b x 3 300
 y 4 400
 c x 5 500
 y 6 600

In [111]: left.join(right, on="abc", "xy", how="inner")
Out[111]:
   v1  v2
  abc xy num
 a x 1 0 100
 2 1 100
 y 1 2 200
 2 3 200
 b x 4 300
 2 5 300
 y 1 6 400
 2 7 400
 c x 8 500
 2 9 500
 y 1 10 600
 2 11 600

If that condition is not satisfied, a join with two multi-indexes can be done using the following code.

In [112]: leftindex = pd.MultiIndex.from_tuples(
        .....:     [("K0", "X0"), ("K0", "X1"), ("K1", "X2")], names="key", "X")
        .....:
        .....:

In [113]: left = pd.DataFrame(
        .....:     {"A": ["A0", "A1", "A2"], "B": ["B0", "B1", "B2"]}, index=leftindex
        .....: )

If that condition is not satisfied, a join with two multi-indexes can be done using the following code.
Merging on a combination of columns and index levels

Strings passed as the on, left_on, and right_on parameters may refer to either column names or index level names. This enables merging DataFrame instances on a combination of index levels and columns without resetting indexes.

In [117]: left_index = pd.Index(["K0", "K0", "K1", "K2"], name="key1")

In [118]: left = pd.DataFrame(
        ....:     {  
        ....:         "B": ["B0", "B1", "B2", "B3"],  
        ....:         "key2": ["K0", "K1", "K0", "K1"],  
        ....:     },  
        ....:     index=left_index,  
        ....: )  

In [119]: right_index = pd.Index(["K0", "K1", "K2", "K2"], name="key1")

In [120]: right = pd.DataFrame(
        ....:     {  
        ....:         "C": ["C0", "C1", "C2", "C3"],  
        ....:     })

(continues on next page)
The merge `suffixes` argument takes a tuple of list of strings to append to overlapping column names in the input DataFrames to disambiguate the result columns:

```python
In [122]: left = pd.DataFrame({"k": ["K0", "K1", "K2"], "v": [1, 2, 3]})
In [123]: right = pd.DataFrame({"k": ["K0", "K0", "K3"], "v": [4, 5, 6]})
In [124]: result = pd.merge(left, right, on="k")
```

### Overlapping value columns

The merge `suffixes` argument takes a tuple of list of strings to append to overlapping column names in the input DataFrames to disambiguate the result columns:
Joining multiple DataFrames

A list or tuple of DataFrames can also be passed to `join()` to join them together on their indexes.

In [129]: right2 = pd.DataFrame({"v": [7, 8, 9]}, index=["K1", "K1", "K2"])

In [130]: result = left.join([right, right2])
Merging together values within Series or DataFrame columns

Another fairly common situation is to have two like-indexed (or similarly indexed) Series or DataFrame objects and wanting to “patch” values in one object from values for matching indices in the other. Here is an example:

```
In [131]: df1 = pd.DataFrame(
            ....:     [[np.nan, 3.0, 5.0], [-4.6, np.nan, np.nan], [np.nan, 7.0, np.nan]],
            ....:     index=[1, 2])
```

```
In [132]: df2 = pd.DataFrame([[-42.6, np.nan, -8.2], [-5.0, 1.6, 4]], index=[1, 2])
```

For this, use the `combine_first()` method:

```
In [133]: result = df1.combine_first(df2)
```

```
<table>
<thead>
<tr>
<th></th>
<th>df1</th>
<th>df2</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NaN</td>
<td>3.0</td>
<td>3.0</td>
</tr>
<tr>
<td>1</td>
<td>-4.6</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2</td>
<td>2.0</td>
<td>NaN</td>
<td>4.0</td>
</tr>
</tbody>
</table>
```

Note that this method only takes values from the right DataFrame if they are missing in the left DataFrame. A related method, `update()`, alters non-NA values in place:

```
In [134]: df1.update(df2)
```

```
<table>
<thead>
<tr>
<th></th>
<th>df1</th>
<th>df2</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NaN</td>
<td>3.0</td>
<td>3.0</td>
</tr>
<tr>
<td>1</td>
<td>-4.6</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2</td>
<td>2.0</td>
<td>NaN</td>
<td>4.0</td>
</tr>
</tbody>
</table>
```
2.7.3 Timeseries friendly merging

Merging ordered data

A `merge_ordered()` function allows combining time series and other ordered data. In particular it has an optional `fill_method` keyword to fill/interpolate missing data:

```python
In [135]: left = pd.DataFrame(
    ....:     {"k": ["K0", "K1", "K1", "K2"], "lv": [1, 2, 3, 4], "s": ["a", "b", "c", "d"],
    ....:     }
    ....:     )
    ....: 
In [136]: right = pd.DataFrame({"k": ["K1", "K2", "K4"], "rv": [1, 2, 3]})
In [137]: pd.merge_ordered(left, right, fill_method="ffill", left_by="s")
Out[137]:
   k  lv  s  rv
0  K0  1.0  a  NaN
1  K1  1.0  a  1.0
2  K2  1.0  a  2.0
3  K4  1.0  a  3.0
4  K1  2.0  b  1.0
5  K2  2.0  b  2.0
6  K4  2.0  b  3.0
7  K1  3.0  c  1.0
8  K2  3.0  c  2.0
9  K4  3.0  c  3.0
10 K1  NaN  d  1.0
11 K2  4.0  d  2.0
12 K4  4.0  d  3.0
```

Merging asof

A `merge_asof()` is similar to an ordered left-join except that we match on nearest key rather than equal keys. For each row in the `left DataFrame`, we select the last row in the `right DataFrame` whose `on` key is less than the left’s key. Both DataFrames must be sorted by the key.

Optionally an asof merge can perform a group-wise merge. This matches the `by` key equally, in addition to the nearest match on the `on` key.

For example; we might have `trades` and `quotes` and we want to `asof` merge them.

```python
In [138]: trades = pd.DataFrame(
    ....:     {"time": pd.to_datetime([
    ....:         "20160525 13:30:00.023",
    ....:         "20160525 13:30:00.038",
    ....:         "20160525 13:30:00.048",
    ....:         "20160525 13:30:00.048",
    ....:         "20160525 13:30:00.048",
    ....:     ],
    ....:     "ticker": ["MSFT", "MSFT", "GOOG", "GOOG", "AAPL"],
    ....:     "price": [51.95, 51.95, 720.77, 720.92, 98.00],
    ....:     }
    ....:     )
    ....: 
```

(continues on next page)
In [139]: quotes = pd.DataFrame(
    ...:     {
    ...:       "time": pd.to_datetime(["20160525 13:30:00.023", "20160525 13:30:00.023", "20160525 13:30:00.030", "20160525 13:30:00.041", "20160525 13:30:00.048", "20160525 13:30:00.049", "20160525 13:30:00.072", "20160525 13:30:00.075"],
    ...:       "ticker": ["GOOG", "MSFT", "MSFT", "MSFT", "GOOG", "AAPL", "GOOG", "MSFT"],
    ...:       "bid": [720.50, 51.95, 51.97, 51.99, 720.50, 97.99, 720.50, 52.01],
    ...:       "ask": [720.93, 51.96, 51.98, 52.00, 720.93, 98.01, 720.88, 52.03],
    ...:     },
    ...:     columns=["time", "ticker", "bid", "ask"],
    ...: )

In [140]: trades
Out[140]:
   time       ticker  price  quantity
0 2016-05-25 13:30:00.023  MSFT    51.95       75
1 2016-05-25 13:30:00.038  MSFT    51.95      155
2 2016-05-25 13:30:00.048  GOOG   720.77      100
3 2016-05-25 13:30:00.048  GOOG   720.92      100
4 2016-05-25 13:30:00.048  AAPL    98.00      100

In [141]: quotes
Out[141]:
   time       ticker  bid   ask
0 2016-05-25 13:30:00.023  GOOG   720.50  720.93
1 2016-05-25 13:30:00.023  MSFT    51.95  51.96
2 2016-05-25 13:30:00.030  MSFT    51.97  51.98
3 2016-05-25 13:30:00.041  MSFT    51.99  52.00
4 2016-05-25 13:30:00.048  GOOG   720.50  720.93
5 2016-05-25 13:30:00.049  AAPL    97.99  98.01
6 2016-05-25 13:30:00.072  GOOG   720.50  720.88
7 2016-05-25 13:30:00.075  MSFT    52.01  52.03

By default we are taking the asof of the quotes.

In [142]: pd.merge_asof(trades, quotes, on="time", by="ticker")
Out[142]:
   time       ticker  price  quantity  bid   ask
0 2016-05-25 13:30:00.023  MSFT    51.95       75  51.95  51.96
We only asof within 2ms between the quote time and the trade time.

```
In [143]: pd.merge_asof(trades, quotes, on="time", by="ticker", tolerance=pd.Timedelta("2ms"))
Out[143]:
  time    ticker  price  quantity  bid  ask
0 2016-05-25 13:30:00.023 MSFT   51.95       75  51.95  51.96
1 2016-05-25 13:30:00.038 MSFT   51.95      155  NaN   NaN
2 2016-05-25 13:30:00.048 GOOG   720.77      100  720.50  720.93
3 2016-05-25 13:30:00.048 GOOG   720.92      100  720.50  720.93
4 2016-05-25 13:30:00.048 AAPL   98.00      100  NaN   NaN
```

We only asof within 10ms between the quote time and the trade time and we exclude exact matches on time. Note that though we exclude the exact matches (of the quotes), prior quotes do propagate to that point in time.

```
In [144]: pd.merge_asof(
      ....:   trades,
      ....:   quotes,
      ....:   on="time",
      ....:   by="ticker",
      ....:   tolerance=pd.Timedelta("10ms"),
      ....:   allow_exact_matches=False,
      ....:)
```

```
Out[144]:
  time    ticker  price  quantity  bid  ask
0 2016-05-25 13:30:00.023 MSFT   51.95       75  NaN   NaN
1 2016-05-25 13:30:00.038 MSFT   51.95      155  51.97  51.98
2 2016-05-25 13:30:00.048 GOOG   720.77      100  720.50  720.93
3 2016-05-25 13:30:00.048 GOOG   720.92      100  NaN   NaN
4 2016-05-25 13:30:00.048 AAPL   98.00      100  NaN   NaN
```

### 2.7.4 Comparing objects

The `compare()` and `compare()` methods allow you to compare two DataFrame or Series, respectively, and summarize their differences.

This feature was added in V1.1.0.

For example, you might want to compare two DataFrame and stack their differences side by side.
In [146]: df
Out[146]:
    col1  col2  col3
0    a    1.0  1.0
1    a    2.0  2.0
2    b    3.0  3.0
3    b    NaN  4.0
4    a    5.0  5.0

In [147]: df2 = df.copy()
In [148]: df2.loc[0, "col1"] = "c"
In [149]: df2.loc[2, "col3"] = 4.0
In [150]: df2
Out[150]:
    col1  col2  col3
0    c    1.0  1.0
1    a    2.0  2.0
2    b    3.0  4.0
3    b    NaN  4.0
4    a    5.0  5.0

In [151]: df.compare(df2)
Out[151]:
    col1  col3
     self  other  self  other
0    a    c  NaN    NaN
2    NaN  NaN  3.0    4.0

By default, if two corresponding values are equal, they will be shown as NaN. Furthermore, if all values in an entire row / column, the row / column will be omitted from the result. The remaining differences will be aligned on columns.

If you wish, you may choose to stack the differences on rows.

In [152]: df.compare(df2, align_axis=0)
Out[152]:
    col1  col2  col3
     self  other  self  other  self  other
0    a    NaN   NaN   NaN   NaN   NaN
2    NaN  NaN   NaN   NaN   NaN   NaN
3    NaN  NaN   NaN   NaN   NaN   NaN

If you wish to keep all original rows and columns, set keep_shape argument to True.

In [153]: df.compare(df2, keep_shape=True)
Out[153]:
    col1  col2  col3
     self  other  self  other  self  other
0    a    c    NaN    NaN    NaN    NaN
1    NaN  NaN    NaN    NaN    NaN    NaN
2    NaN  NaN    NaN    NaN    NaN    NaN
3    NaN  NaN    NaN    NaN    NaN    NaN
4    NaN  NaN    NaN    NaN    NaN    NaN

2.7. Merge, join, concatenate and compare 519
You may also keep all the original values even if they are equal.

```python
In [154]: df.compare(df2, keep_shape=True, keep_equal=True)
```

```
Out[154]:
      col1  col2  col3
    self other self other self other
 0  a     c  1.0  1.0  1.0  1.0
 1  a     a  2.0  2.0  2.0  2.0
 2  b     b  3.0  3.0  3.0  4.0
 3  b     b   NaN   NaN  4.0  4.0
 4  a     a  5.0  5.0  5.0  5.0
```

### 2.8 Reshaping and pivot tables

#### 2.8.1 Reshaping by pivoting DataFrame objects

**Pivot**

Data is often stored in so-called “stacked” or “record” format:

```python
In [1]: df
```

```
Out[1]:
          date variable  value
   0  2000-01-03          A  0.469112
   1  2000-01-04          A -0.282863
   2  2000-01-05          A -1.509059
   3  2000-01-03          B -1.135632
   4  2000-01-04          B  1.212112
   5  2000-01-03          C  0.119209
   6  2000-01-04          C -1.044236
   7  2000-01-05          C -0.861849
   8  2000-01-03          D -2.104569
   9  2000-01-04          D  2.894018
```

(continues on next page)
For the curious here is how the above DataFrame was created:

```python
import pandas._testing as tm
def unpivot(frame):
    N, K = frame.shape
    data = {
        "value": frame.to_numpy().ravel("F"),
        "variable": np.asarray(frame.columns).repeat(N),
        "date": np.tile(np.asarray(frame.index), K),
    }
    return pd.DataFrame(data, columns=["date", "variable", "value"])

df = unpivot(tm.makeTimeDataFrame(3))
```

To select out everything for variable A we could do:

```python
In [2]: df[df["variable"] == "A"]
Out[2]:
   date  variable  value
0  2000-01-03    A   0.469112
1  2000-01-04    A  -0.282863
2  2000-01-05    A  -1.509059
```

But suppose we wish to do time series operations with the variables. A better representation would be where the columns are the unique variables and an index of dates identifies individual observations. To reshape the data into this form, we use the `DataFrame.pivot()` method (also implemented as a top level function `pivot()`):

```python
In [3]: df.pivot(index="date", columns="variable", values="value")
Out[3]:
   variable  A   B   C   D
date       
2000-01-03  0.469112 -1.135632  0.119209 -2.104569
2000-01-04  -0.282863  1.212112 -1.044236  -0.494929
2000-01-05 -1.509059 -0.173215  -0.861849  1.071804
```

If the `values` argument is omitted, and the input DataFrame has more than one column of values which are not used as column or index inputs to `pivot`, then the resulting “pivoted” DataFrame will have hierarchical columns whose topmost level indicates the respective value column:

```python
In [4]: df["value2"] = df["value"] * 2
In [5]: pivoted = df.pivot(index="date", columns="variable")
In [6]: pivoted
Out[6]:
   variable  A   B   C   D
   value2     D   A   B   C
```

(continues on next page)
You can then select subsets from the pivoted DataFrame:

```python
In [7]: pivoted["value2"]
Out[7]:
   variable  A     B    C    D
date   
2000-01-03  0.938225 -2.271265 0.238417 -4.209138
2000-01-04  -0.565727  2.424224 -2.088472 -0.989859
2000-01-05  -3.018117 -0.346429 -1.723698  2.143608
```

Note that this returns a view on the underlying data in the case where the data are homogeneously-typed.

**Note:** `pivot()` will error with a `ValueError: Index contains duplicate entries, cannot reshape` if the index/column pair is not unique. In this case, consider using `pivot_table()` which is a generalization of pivot that can handle duplicate values for one index/column pair.

### 2.8.2 Reshaping by stacking and unstacking

**Stack**

```python
df2  
stacked = df2.stack()
```

Closely related to the `pivot()` method are the related `stack()` and `unstack()` methods available on Series and DataFrame. These methods are designed to work together with MultiIndex objects (see the section on
hierarchical indexing). Here are essentially what these methods do:

- **stack**: “pivot” a level of the (possibly hierarchical) column labels, returning a DataFrame with an index with a new inner-most level of row labels.

- **unstack**: (inverse operation of `stack`) “pivot” a level of the (possibly hierarchical) row index to the column axis, producing a reshaped DataFrame with a new inner-most level of column labels.

The clearest way to explain is by example. Let’s take a prior example data set from the hierarchical indexing section:

```
In [8]: tuples = list(zip(*[
        ...:     "bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"],
        ...:     "one", "two", "one", "two", "one", "two", "one", "two"],
        ...:     )
In [9]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])
In [10]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])
In [11]: df2 = df[:4]
```

```
Out[12]:

<table>
<thead>
<tr>
<th>first</th>
<th>second</th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td>one</td>
<td>0.721555</td>
<td>-0.706771</td>
</tr>
<tr>
<td>two</td>
<td>A</td>
<td>-1.039575</td>
<td>0.271860</td>
</tr>
<tr>
<td>baz</td>
<td>one</td>
<td>-0.424972</td>
<td>0.567020</td>
</tr>
<tr>
<td>two</td>
<td>B</td>
<td>2.865860</td>
<td>-1.039575</td>
</tr>
</tbody>
</table>
```

(continues on next page)
The `stack` function “compresses” a level in the DataFrame’s columns to produce either:

- A Series, in the case of a simple column Index.
- A DataFrame, in the case of a MultiIndex in the columns.

If the columns have a MultiIndex, you can choose which level to stack. The stacked level becomes the new lowest level in a MultiIndex on the columns:

```
In [13]: stacked = df2.stack()

In [14]: stacked
Out[14]:
first  second
bar    one  A   0.721555
       B   -0.706771
       two A  -1.039575
          B   0.271860
baz    one  A  -0.424972
       B   0.567020
       two A   0.276232
          B  -1.087401
dtype: float64
```

With a “stacked” DataFrame or Series (having a MultiIndex as the index), the inverse operation of `stack` is `unstack`, which by default unstacks the last level:

```
In [15]: stacked.unstack()
Out[15]:
   A      B
first
bar    one 0.721555 -0.706771
       two -1.039575  0.271860
baz    one -0.424972  0.567020
       two  0.276232 -1.087401

In [16]: stacked.unstack(1)
Out[16]:
   second
one    one  A  0.721555 -1.039575
       B -0.706771  0.271860
two    one -0.424972  0.276232
       B  0.567020 -1.087401

In [17]: stacked.unstack(0)
Out[17]:
   first
bar    bar  A  0.721555 -0.424972
       B -0.706771  0.567020
baz    bar  A -1.039575  0.276232
       B  0.271860 -1.087401
```
Unstack(1)

If the indexes have names, you can use the level names instead of specifying the level numbers:

```python
In [18]: stacked.unstack("second")
Out[18]:
                     one     two
    second         one     two
first
bar    A  0.721555 -1.039575
       B -0.706771  0.271860
baz    A -0.424972  0.276232
       B  0.567020 -1.087401
```

2.8. Reshaping and pivot tables
Unstack(0)

Notice that the stack and unstack methods implicitly sort the index levels involved. Hence a call to stack and then unstack, or vice versa, will result in a sorted copy of the original DataFrame or Series:

```
In [19]: index = pd.MultiIndex.from_product([[2, 1], ["a", "b"]])
In [20]: df = pd.DataFrame(np.random.randn(4), index=index, columns=["A"])
In [21]: df
Out[21]:
   A
0  2 a  -0.370647
   b  -1.157892
1  1 a  -1.344312
   b  0.844885
In [22]: all(df.unstack().stack() == df.sort_index())
Out[22]: True
```

The above code will raise a TypeError if the call to sort_index is removed.

Multiple levels

You may also stack or unstack more than one level at a time by passing a list of levels, in which case the end result is as if each level in the list were processed individually:

```
In [23]: columns = pd.MultiIndex.from_tuples(
   ....:     [("A", "cat", "long"),
   ....:      ("B", "cat", "long"),
   ....:      ("A", "dog", "short"),
   ....:      ("B", "dog", "short"),
   ....: ],
      )
```

(continues on next page)
In [24]: df = pd.DataFrame(np.random.randn(4, 4), columns=columns)

In [25]: df

Out[25]:
exp  A      B
animal    cat    cat    dog    dog
hair_length long  long  short  short
0  1.075770 -0.109050 1.643563 -1.469388
1  0.357021 -0.674600 -1.776904 0.968914
2 -1.294524 0.413738 0.276662 -0.472035
3 -0.013960 -0.362543 -0.006154 -0.923061

In [26]: df.stack(level=["animal", "hair_length"])

Out[26]:
exp  A      B
animal hair_length
0 cat   long  1.075770 -0.109050
dog  short 1.643563 -1.469388
1 cat  long  0.357021 -0.674600
dog  short -1.776904 0.968914
2 cat  long -1.294524 0.413738
dog  short 0.276662 -0.472035
3 cat  long -0.013960 -0.362543
dog  short -0.006154 -0.923061

The list of levels can contain either level names or level numbers (but not a mixture of the two).

# df.stack(level=['animal', 'hair_length'])
# from above is equivalent to:
In [27]: df.stack(level=[1, 2])

Out[27]:
exp  A      B
animal hair_length
0 cat  long  1.075770 -0.109050
dog  short 1.643563 -1.469388
1 cat  long  0.357021 -0.674600
dog  short -1.776904 0.968914
2 cat  long -1.294524 0.413738
dog  short 0.276662 -0.472035
3 cat  long -0.013960 -0.362543
dog  short -0.006154 -0.923061

2.8. Reshaping and pivot tables 527
These functions are intelligent about handling missing data and do not expect each subgroup within the hierarchical index to have the same set of labels. They also can handle the index being unsorted (but you can make it sorted by calling `sort_index`, of course). Here is a more complex example:

```python
In [28]: columns = pd.MultiIndex.from_tuples(
    ....:     [('A', 'cat'),
    ....:     ('B', 'dog'),
    ....:     ('B', 'cat'),
    ....:     ('A', 'dog'),
    ....:     ],
    ....:     names=['exp', 'animal'],
    ....:     )

In [29]: index = pd.MultiIndex.from_product(
    ....:     [('bar', 'baz', 'foo', 'qux'), ('one', 'two')],
    ....:     names=['first', 'second']
    ....:     )

In [30]: df = pd.DataFrame(np.random.randn(8, 4), index=index, columns=columns)

In [31]: df2 = df.iloc[[0, 1, 2, 4, 5, 7]]

In [32]: df2
```

<table>
<thead>
<tr>
<th>exp</th>
<th>A</th>
<th>B</th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td>animal</td>
<td>cat</td>
<td>dog</td>
<td>cat</td>
</tr>
<tr>
<td>first</td>
<td>second</td>
<td></td>
<td></td>
</tr>
<tr>
<td>bar one</td>
<td>0.895717</td>
<td>0.805244</td>
<td>-1.206412</td>
</tr>
<tr>
<td>two</td>
<td>1.431256</td>
<td>1.340309</td>
<td>-1.170299</td>
</tr>
<tr>
<td>baz one</td>
<td>0.410835</td>
<td>0.813850</td>
<td>0.132003</td>
</tr>
<tr>
<td>foo one</td>
<td>-1.413681</td>
<td>1.607920</td>
<td>1.024180</td>
</tr>
<tr>
<td>qux two</td>
<td>-1.226825</td>
<td>0.769804</td>
<td>-1.281247</td>
</tr>
</tbody>
</table>

As mentioned above, `stack` can be called with a `level` argument to select which level in the columns to stack:

```python
In [33]: df2.stack("exp")
```

<table>
<thead>
<tr>
<th>exp</th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>animal</td>
<td>cat</td>
<td>dog</td>
</tr>
<tr>
<td>first</td>
<td>second</td>
<td></td>
</tr>
<tr>
<td>bar one</td>
<td>0.895717</td>
<td>2.565646</td>
</tr>
<tr>
<td>two</td>
<td>-1.206412</td>
<td>0.805244</td>
</tr>
<tr>
<td>baz one</td>
<td>1.431256</td>
<td>-0.226169</td>
</tr>
<tr>
<td>foo one</td>
<td>-1.170299</td>
<td>1.340309</td>
</tr>
<tr>
<td>qux two</td>
<td>0.410835</td>
<td>-0.827317</td>
</tr>
</tbody>
</table>

(continues on next page)
Unstacking can result in missing values if subgroups do not have the same set of labels. By default, missing values will be replaced with the default fill value for that data type, `NaN` for float, `NaT` for datetimelike, etc. For integer types, by default data will converted to float and missing values will be set to `NaN`.

```
In [35]: df3 = df.iloc[[0, 1, 4, 7], [1, 2]]
```

```
In [36]: df3
Out[36]:
exp  B
animal dog cat
first second
bar one 0.805244 -1.206412
   dog 2.565646 0.805244
   two 1.431256 -1.170299
   baz one 0.410835 0.132003
   dog -0.827317 0.813850
   foo one -1.413681 1.024180
   dog 0.569605 1.607920
   two 0.875906 0.974466
   dog -2.006747 -2.211372
   qux two -1.226825 -1.281247
   dog -0.727707 0.769804
```

```
In [37]: df3.unstack()
Out[37]:
exp  B
animal dog  cat
second one  dog  cat
first
bar one  0.805244 -1.206412
   two  1.340309 -1.170299
   foo one  1.607920 1.024180
   qux two  0.769804 -1.281247
```

Alternatively, `unstack` takes an optional `fill_value` argument, for specifying the value of missing data.

```
In [38]: df3.unstack(fill_value=-1e9)
Out[38]:
exp  B
animal dog  cat
second one  dog  cat
first
bar one  0.805244 1.340309 -1.206412 -1.170299
   foo one  1.607920 NaN 1.024180 NaN
   qux one  NaN  0.769804 NaN -1.281247
```

2.8. Reshaping and pivot tables
With a MultiIndex

Unstacking when the columns are a MultiIndex is also careful about doing the right thing:

```
In [39]: df[:3].unstack(0)
Out[39]:
animal   A     B
         cat   dog
first    bar   baz   bar
         baz   bar   baz
second   one   two   one
two  0.895717  0.410835  0.805244  0.81385 -1.206412  0.132003  2.565646 -0.827317

In [40]: df2.unstack(1)
Out[40]:
animal   A
         cat   dog
second   one   two   one   two   one   two
first    bar    baz    bar    baz
baz  0.895717  1.431256  0.805244  1.340309 -1.206412 -1.170299  2.565646 -0.226169
foo -1.413681  0.875906  1.607920 -2.211372  1.024180  0.974466  0.569605 -2.006747
qux NaN  0.875906  NaN -2.211372 NaN  0.974466  NaN -0.727707
```

### 2.8.3 Reshaping by melt

#### Melt

The top-level `melt()` function and the corresponding `DataFrame.melt()` are useful to massage a DataFrame into a format where one or more columns are *identifier variables*, while all other columns, considered *measured variables*, are “unpivoted” to the row axis, leaving just two non-identifier columns, “variable” and “value”. The names of those columns can be customized by supplying the `var_name` and `value_name` parameters.

For instance,
When transforming a DataFrame using `melt()`, the index will be ignored. The original index values can be kept around by setting the `ignore_index` parameter to `False` (default is `True`). This will however duplicate them.

New in version 1.1.0.

```python
In [45]: index = pd.MultiIndex.from_tuples([("person", "A"), ("person", "B"))

In [46]: cheese = pd.DataFrame(
    ...:     {
    ...:         "first": ["John", "Mary"],
    ...:         "last": ["Doe", "Bo"],
    ...:         "height": [5.5, 6.0],
    ...:         "weight": [130, 150],
    ...:     },
    ...:     index=index,
    ...: )

In [47]: cheese
Out[47]:
first last height weight
person A John Doe 5.5 130
B Mary Bo 6.0 150

In [48]: cheese.melt(id_vars="first", "last")
Out[48]:
    first last quantity value
0  John Doe height 5.5
1  Mary Bo height 6.0
2  John Doe weight 130.0
3  Mary Bo weight 150.0
```
Another way to transform is to use the `wide_to_long()` panel data convenience function. It is less flexible than `melt()`, but more user-friendly.

```python
In [50]: dft = pd.DataFrame(
    ...:     {  
    ...:         "A1970": {0: "a", 1: "b", 2: "c"},  
    ...:         "A1980": {0: "d", 1: "e", 2: "f"},  
    ...:         "B1970": {0: 2.5, 1: 1.2, 2: 0.7},  
    ...:         "B1980": {0: 3.2, 1: 1.3, 2: 0.1},  
    ...:         "X": dict(zip(range(3), np.random.randn(3))),  
    ...:     }  
    ...: )
    ...:
    ...:

In [51]: dft["id"] = dft.index
In [52]: dft
Out[52]:
0     a     d  2.5    3.2  -0.121306  0
1     b     e  1.2    1.3 -0.097883  1
2     c     f  0.7    0.1  0.695775  2

In [53]: pd.wide_to_long(dft, ["A", "B"], i="id", j="year")
Out[53]:
     X  A  B  id year
0  0.121306  a  2.5  1970
1  0.097883  b  1.2  1970
2  0.695775  c  0.7  1970
0  0.121306  d  3.2  1980
1  0.097883  e  1.3  1980
2  0.695775  f  0.1  1980
```
2.8.4 Combining with stats and GroupBy

It should be no shock that combining `pivot`/`stack`/`unstack` with `GroupBy` and the basic `Series` and `DataFrame` statistical functions can produce some very expressive and fast data manipulations.

```
In [54]: df
Out[54]:
exp    A    B    A
animal  cat  dog  cat  dog

2.8.5 Pivot tables

While `pivot()` provides general purpose pivoting with various data types (strings, numerics, etc.), pandas also provides `pivot_table()` for pivoting with aggregation of numeric data.

The function `pivot_table()` can be used to create spreadsheet-style pivot tables. See the cookbook for some advanced strategies.

It takes a number of arguments:

- **data**: a DataFrame object.
- **values**: a column or a list of columns to aggregate.
- **index**: a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.
- **columns**: a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.
- **aggfunc**: function to use for aggregation, defaulting to `numpy.mean`.

Consider a data set like this:

```python
In [59]: import datetime
In [60]: df = pd.DataFrame(
   ....:   {
   ....:     "A": ["one", "one", "two", "three"] * 6,
   ....:     "B": ["A", "B", "C"] * 8,
   ....:     "C": ["foo", "foo", "foo", "bar", "bar", "bar"] * 4,
   ....:     "D": np.random.randn(24),
   ....:     "E": np.random.randn(24),
   ....:     "F": [datetime.datetime(2013, i, 1) for i in range(1, 13)] + 
   ....:        [datetime.datetime(2013, i, 15) for i in range(1, 13)],
   ....:   }
   ....:)
   ....:
In [61]: df
Out[61]:
   A  B  C  D  E        F
0  one  A  foo  0.341734 -0.317441 2013-01-01
1  one  B  foo  0.959726 -1.236269 2013-02-01
2  two  C  foo -1.110336  0.896171 2013-03-01
3  three A  bar -0.619976  0.487602 2013-04-01
4  one  B  bar  0.149748 -0.082240 2013-05-01
..     ..  ..    ...        ...      ...
19 three B  foo  0.690579 -2.213588 2013-08-15
20 one  C  foo  0.995761  1.063327 2013-09-15
21 one  A  bar  2.396780  1.266143 2013-10-15
22 two  B  bar  0.014871  0.299368 2013-11-15
23 three C  bar  3.357427 -0.863838 2013-12-15
[24 rows x 6 columns]
```
We can produce pivot tables from this data very easily:

```python
In [62]: pd.pivot_table(df, values="D", index=['A', 'B'], columns=['C'])
Out[62]:
C   bar   foo
A  
  one  A  1.120915 -0.514058
       B -0.338421  0.002759
       C -0.538846  0.699535
  three A -1.181568 NaN
       B   NaN  0.433512
       C   0.588783 NaN
  two   A   NaN  1.000985
       B  0.158248 NaN
       C   NaN  0.176180
In [63]: pd.pivot_table(df, values="D", index=['B'], columns=['A', 'C'], aggfunc=np.
   --> sum)
Out[63]:
  A   one   three  two
  C   bar   foo   bar   foo   bar   foo
B  
  A  2.241830 -1.028115 -2.363137   NaN   NaN  2.001971
  B -0.676843  0.005518   NaN  0.867024  0.316495   NaN
  C -1.077692  1.399070  1.177566   NaN   NaN  0.352360
In [64]: pd.pivot_table(
   --> ...
   --> df, values=['D', 'E'],
   -->   index=['B'],
   -->   columns=['A', 'C'],
   -->   aggfunc=np.sum,
   -->   )
   --> ...
Out[64]:
  D                   E
  A   one   three  two   one
  C   bar   foo   bar   foo   bar   foo
B  
  A  2.241830 -1.028115 -2.363137   NaN   NaN  2.001971  2.786113  0.043211  1.
  °922577   NaN   NaN  0.128491
  B -0.676843  0.005518   NaN  0.867024  0.316495   NaN  1.368280 -1.103384  
  °NaN -2.128743 -0.194294   NaN
  C -1.077692  1.399070  1.177566   NaN   NaN  0.352360 -1.976883  1.495717 -0.
  °263660   NaN   NaN  0.872482
```

The result object is a DataFrame having potentially hierarchical indexes on the rows and columns. If the values column name is not given, the pivot table will include all of the data that can be aggregated in an additional level of hierarchy in the columns:

```python
In [65]: pd.pivot_table(df, index=['A', 'B'], columns=['C'])
Out[65]:
  D                   E
  A   bar   foo   bar   foo
  B  
  A  
```

(continues on next page)
Also, you can use `Grouper` for `index` and `columns` keywords. For detail of `Grouper`, see *Grouping with a Grouper specification*.

In [66]: pd.pivot_table(df, values="D", index=pd.Grouper(freq="M", key="F"), columns="C")

Out[66]:

<table>
<thead>
<tr>
<th>F</th>
<th>bar</th>
<th>foo</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-31</td>
<td>NaN</td>
<td>-0.514058</td>
</tr>
<tr>
<td>2013-02-28</td>
<td>NaN</td>
<td>0.002759</td>
</tr>
<tr>
<td>2013-03-31</td>
<td>NaN</td>
<td>0.176180</td>
</tr>
<tr>
<td>2013-04-30</td>
<td>-1.181568</td>
<td>NaN</td>
</tr>
<tr>
<td>2013-05-31</td>
<td>-0.338421</td>
<td>NaN</td>
</tr>
<tr>
<td>2013-06-30</td>
<td>-0.538846</td>
<td>NaN</td>
</tr>
<tr>
<td>2013-07-31</td>
<td>NaN</td>
<td>1.000985</td>
</tr>
<tr>
<td>2013-08-31</td>
<td>NaN</td>
<td>0.433512</td>
</tr>
<tr>
<td>2013-09-30</td>
<td>NaN</td>
<td>0.699535</td>
</tr>
<tr>
<td>2013-10-31</td>
<td>1.120915</td>
<td>NaN</td>
</tr>
<tr>
<td>2013-11-30</td>
<td>0.158248</td>
<td>NaN</td>
</tr>
<tr>
<td>2013-12-31</td>
<td>0.588783</td>
<td>NaN</td>
</tr>
</tbody>
</table>

You can render a nice output of the table omitting the missing values by calling `to_string` if you wish:

In [67]: table = pd.pivot_table(df, index=["A", "B"], columns=["C"])

In [68]: print(table.to_string(na_rep=""))

<table>
<thead>
<tr>
<th></th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>bar</td>
<td>foo</td>
</tr>
<tr>
<td>A</td>
<td></td>
<td></td>
</tr>
<tr>
<td>one</td>
<td>A</td>
<td>1.120915</td>
</tr>
<tr>
<td></td>
<td>B</td>
<td>-0.338421</td>
</tr>
<tr>
<td></td>
<td>C</td>
<td>-0.538846</td>
</tr>
<tr>
<td>three</td>
<td>A</td>
<td>-1.181568</td>
</tr>
<tr>
<td></td>
<td>B</td>
<td>NaN</td>
</tr>
<tr>
<td></td>
<td>C</td>
<td>0.588783</td>
</tr>
<tr>
<td>two</td>
<td>A</td>
<td>NaN</td>
</tr>
<tr>
<td></td>
<td>B</td>
<td>0.158248</td>
</tr>
<tr>
<td></td>
<td>C</td>
<td>NaN</td>
</tr>
</tbody>
</table>

Note that `pivot_table` is also available as an instance method on DataFrame, i.e. `DataFrame.pivot_table()`.
Adding margins

If you pass margins=True to pivot_table, special All columns and rows will be added with partial group aggregates across the categories on the rows and columns:

```python
In [69]: df.pivot_table(index=["A", "B"], columns="C", margins=True, aggfunc=np.std)
Out[69]:
      D       E
  C  bar  foo  All  bar  foo  All
A  
one  1.804346  1.210272  1.569879  0.179483  0.418374  0.858005
  B  0.690376  1.353355  0.898998  1.083825  0.968138  1.101401
  C  0.273641  0.418926  0.771139  1.689271  0.446140  1.422136
three  0.794212  NaN  0.794212  2.049040  NaN  2.049040
  B  NaN  0.363548  0.363548  NaN  1.625237  1.625237
  C  3.915454  NaN  3.915454  1.035215  NaN  1.035215
two  0.442998  0.442998  NaN  0.447104  0.447104
  B  0.202765  NaN  0.202765  0.560757  NaN  0.560757
  C  NaN  1.819408  1.819408  NaN  0.650439  0.650439
All  1.556686  0.952552  1.246608  1.250924  0.899904  1.059389
```

2.8.6 Cross tabulations

Use `crosstab()` to compute a cross-tabulation of two (or more) factors. By default `crosstab` computes a frequency table of the factors unless an array of values and an aggregation function are passed.

It takes a number of arguments

- **index**: array-like, values to group by in the rows.
- **columns**: array-like, values to group by in the columns.
- **values**: array-like, optional, array of values to aggregate according to the factors.
- **aggfunc**: function, optional, If no values array is passed, computes a frequency table.
- **rownames**: sequence, default None, must match number of row arrays passed.
- **colnames**: sequence, default None, if passed, must match number of column arrays passed.
- **margins**: boolean, default False, Add row/column margins (subtotals)
- **normalize**: boolean, {‘all’, ‘index’, ‘columns’}, or {0,1}, default False. Normalize by dividing all values by the sum of values.

Any Series passed will have their name attributes used unless row or column names for the cross-tabulation are specified.

For example:

```python
In [70]: foo, bar, dull, shiny, one, two = "foo", "bar", "dull", "shiny", "one", "two"

In [71]: a = np.array([foo, foo, bar, bar, foo, foo], dtype=object)

In [72]: b = np.array([one, one, two, one, two, one], dtype=object)

In [73]: c = np.array([dull, dull, shiny, dull, dull, shiny], dtype=object)

In [74]: pd.crosstab(a, [b, c], rownames=["a"], colnames=["b", "c"], margins=True)
Out[74]:
```

(continues on next page)
If `crosstab` receives only two Series, it will provide a frequency table.

```python
In [75]: df = pd.DataFrame(
    ....:     {"A": [1, 2, 2, 2, 2], "B": [3, 3, 4, 4, 4], "C": [1, 1, np.nan, 1, 1]}
    ....: )

In [76]: df
Out[76]:
     A  B    C
0   1  3  1.0
1   2  3  1.0
2   2  4  NaN
3   2  4  1.0
4   2  4  1.0

In [77]: pd.crosstab(df["A"], df["B")
Out[77]:
     B  3  4
   A   1  0
   2  1  3
```

crosstab can also be implemented to Categorical data.

```python
In [78]: foo = pd.Categorical(["a", "b"], categories=["a", "b", "c")

In [79]: bar = pd.Categorical(["d", "e"], categories=["d", "e", "f")

In [80]: pd.crosstab(foo, bar)
Out[80]:
    col_0  d  e
row_0   a  1  0
        b  0  1
```

If you want to include all of data categories even if the actual data does not contain any instances of a particular category, you should set `dropna=False`.

For example:

```python
In [81]: pd.crosstab(foo, bar, dropna=False)
Out[81]:
     col_0  d  e  f
   row_0   a  1  0  0
       b  0  1  0
       c  0  0  0
```
Normalization

Frequency tables can also be normalized to show percentages rather than counts using the `normalize` argument:

```python
In [82]: pd.crosstab(df["A"], df["B"], normalize=True)
Out[82]:
   B 3 4
   A 1 0.2 0.0
      2 0.2 0.6
```

`normalize` can also normalize values within each row or within each column:

```python
In [83]: pd.crosstab(df["A"], df["B"], normalize="columns")
Out[83]:
   B 3 4
   A 1 0.5 0.0
      2 0.5 1.0
```

crosstab can also be passed a third `Series` and an aggregation function (`aggfunc`) that will be applied to the values of the third `Series` within each group defined by the first two `Series`:

```python
In [84]: pd.crosstab(df["A"], df["B"], values=df["C"], aggfunc=np.sum)
Out[84]:
   B 3 4
   A 1 1.0 NaN
      2 1.0 2.0
```

Adding margins

Finally, one can also add margins or normalize this output.

```python
In [85]: pd.crosstab(df["A"], df["B"], values=df["C"], aggfunc=np.sum, normalize=True,
                   margins=True)
Out[85]:
   B 3 4  All
   A 1 0.25 0.0  0.25
      2 0.25 0.5  0.75
     All 0.50 0.5  1.00
```
2.8.7 Tiling

The `cut()` function computes groupings for the values of the input array and is often used to transform continuous variables to discrete or categorical variables:

```
In [86]: ages = np.array([10, 15, 13, 12, 23, 25, 28, 59, 60])
In [87]: pd.cut(ages, bins=3)
Out[87]:
[(9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667],
   (26.667, 43.333], (43.333, 60.0], (43.333, 60.0]]
Categories (3, interval[float64, right]): [(9.95, 26.667] < (26.667, 43.333] < (43.333, 60.0]]
```

If the `bins` keyword is an integer, then equal-width bins are formed. Alternatively we can specify custom bin-edges:

```
In [88]: c = pd.cut(ages, bins=[0, 18, 35, 70])
In [89]: c
Out[89]:
[(0, 18], (0, 18], (0, 18], (0, 18], (18, 35], (18, 35], (18, 35], (35, 70], (35, 70]]
Categories (3, interval[int64, right]): [(0, 18] < (18, 35] < (35, 70]]
```

If the `bins` keyword is an `IntervalIndex`, then these will be used to bin the passed data:

```
pd.cut([25, 20, 50], bins=c.categories)
```

2.8.8 Computing indicator / dummy variables

To convert a categorical variable into a “dummy” or “indicator” DataFrame, for example a column in a DataFrame (a Series) which has k distinct values, can derive a DataFrame containing k columns of 1s and 0s using `get_dummies()`:

```
In [90]: df = pd.DataFrame({"key": list("bbacab"), "data1": range(6)})
In [91]: pd.get_dummies(df["key"])
Out[91]:
 a  b  c
0  0  1  0
1  0  1  0
2  1  0  0
3  0  0  1
4  1  0  0
5  0  1  0

Sometimes it’s useful to prefix the column names, for example when merging the result with the original DataFrame:

```
In [92]: dummies = pd.get_dummies(df["key"], prefix="key")
In [93]: dummies
Out[93]:
 key_a  key_b  key_c
0  0  1  0
1  0  1  0
2  1  0  0
3  0  0  1
(continues on next page)
This function is often used along with discretization functions like `cut`:

```
In [95]: values = np.random.randn(10)
In [96]: values
Out[96]: array([ 0.4082, -1.0481, -0.0257, -0.9884,  0.0941,  1.2627,  1.29 ,
        0.0824, -0.0558,  0.5366])
In [97]: bins = [0, 0.2, 0.4, 0.6, 0.8, 1]
In [98]: pd.get_dummies(pd.cut(values, bins))
Out[98]:
   (0.0, 0.2]  (0.2, 0.4]  (0.4, 0.6]  (0.6, 0.8]  (0.8, 1.0]
0          0          0          1          0          0
1          0          0          0          0          0
2          0          0          0          0          0
3          0          0          0          0          0
4          1          0          0          0          0
5          0          0          0          0          0
6          0          0          0          0          0
7          1          0          0          0          0
8          0          0          0          0          0
9          0          0          1          0          0
```

See also `Series.str.get_dummies`. `get_dummies()` also accepts a DataFrame. By default all categorical variables (categorical in the statistical sense, those with object or categorical dtype) are encoded as dummy variables.

```
In [99]: df = pd.DataFrame({"A": ["a", "b", "a"], "B": ["c", "c", "b"], "C": [1, 2, -3]})
In [100]: pd.get_dummies(df)
Out[100]:
   C  A_a  A_b  B_b  B_c
0  1  1  0  0  1
1  2  0  1  0  1
2  3  1  0  1  0
```

All non-object columns are included untouched in the output. You can control the columns that are encoded with the `columns` keyword.
Notice that the B column is still included in the output, it just hasn’t been encoded. You can drop B before calling get_dummies if you don’t want to include it in the output.

As with the Series version, you can pass values for the prefix and prefix_sep. By default the column name is used as the prefix, and ‘_’ as the prefix separator. You can specify prefix and prefix_sep in 3 ways:

- string: Use the same value for prefix or prefix_sep for each column to be encoded.
- list: Must be the same length as the number of columns being encoded.
- dict: Mapping column name to prefix.

Sometimes it will be useful to only keep k-1 levels of a categorical variable to avoid collinearity when feeding the result to statistical models. You can switch to this mode by turn on drop_first.

(continues on next page)
When a column contains only one level, it will be omitted in the result.

```
In [111]: df = pd.DataFrame({"A": list("aaaaa"), "B": list("ababc")})
In [112]: pd.get_dummies(df)
Out[112]:
     A_a  B_a  B_b  B_c
0     1    1    0    0
1     1    0    1    0
2     1    1    0    0
3     1    0    1    0
4     1    0    0    1
In [113]: pd.get_dummies(df, drop_first=True)
Out[113]:
    B_b  B_c
0    0    0
1    1    0
2    0    0
3    1    0
4    0    1
```

By default new columns will have np.uint8 dtype. To choose another dtype, use the dtype argument:

```
In [114]: df = pd.DataFrame({"A": list("abc"), "B": [1.1, 2.2, 3.3]})
In [115]: pd.get_dummies(df, dtype=bool).dtypes
Out[115]:
B        float64
A_a       bool
A_b       bool
A_c       bool
dtype: object
```

### 2.8.9 Factorizing values

To encode 1-d values as an enumerated type use `factorize()`:

```
In [117]: x
Out[117]:
0   A
1   A
```

(continues on next page)
Note that `factorize` is similar to `numpy.unique`, but differs in its handling of NaN:

```
In [1]: x = pd.Series(['A', 'A', np.nan, 'B', 3.14, np.inf])
In [2]: pd.factorize(x, sort=True)
Out[2]: (array([ 2, 2, -1, 3, 0, 1]),
    Index([3.14, inf, 'A', 'B'], dtype='object'))
In [3]: np.unique(x, return_inverse=True)[::-1]
Out[3]: (array([3, 3, 0, 4, 1, 2]), array([nan, 3.14, inf, 'A', 'B'], dtype=object))
```

**Note:** If you just want to handle one column as a categorical variable (like R’s factor), you can use `df['cat_col'] = pd.Categorical(df['col'])` or `df['cat_col'] = df['col'].astype('category')`. For full docs on `Categorical`, see the `Categorical introduction` and the `API documentation`.

### 2.8.10 Examples

In this section, we will review frequently asked questions and examples. The column names and relevant column values are named to correspond with how this DataFrame will be pivoted in the answers below.

```
In [121]: np.random.seed([3, 1415])
In [122]: n = 20
In [123]: cols = np.array(['key', 'row', 'item', 'col'])
In [124]: df = cols + pd.DataFrame(np.random.randint(5, size=(n, 4)) // [2, 1, 2, 1]).astype(str)
   .....:
In [125]: df.columns = cols
In [126]: df.columns = cols
```
Pivoting with single aggregations

Suppose we wanted to pivot `df` such that the `col` values are columns, `row` values are the index, and the mean of `val0` are the values? In particular, the resulting DataFrame should look like:

```
col  col0  col1  col2  col3  col4
row
row0  0.77  0.605  NaN  0.860  0.65
row2  0.13  NaN    0.395  0.500  0.25
row3  NaN  0.310  NaN  0.545  NaN
row4  NaN  0.100  0.395  0.760  0.24
```

This solution uses `pivot_table()`. Also note that `aggfunc='mean'` is the default. It is included here to be explicit.

```
In [128]: df.pivot_table(values="val0", index="row", columns="col", aggfunc="mean")
Out[128]:
col  col0  col1  col2  col3  col4
row
row0  0.77  0.605  NaN  0.860  0.65
row2  0.13  NaN    0.395  0.500  0.25
row3  NaN  0.310  NaN  0.545  NaN
row4  NaN  0.100  0.395  0.760  0.24
```

Note that we can also replace the missing values by using the `fill_value` parameter.

```
In [129]: df.pivot_table(
        .....:   values="val0",
        .....:   index="row",
        .....:   columns="col",
        .....:   aggfunc="mean",
        .....:   fill_value=0,
        .....: )
    .....:
Out[129]:
col  col0  col1  col2  col3  col4
row
row0  0.77  0.605  NaN  0.860  0.65
row2  0.13  NaN    0.395  0.500  0.25
row3  NaN  0.310  NaN  0.545  NaN
row4  NaN  0.100  0.395  0.760  0.24
```

(continues on next page)
Also note that we can pass in other aggregation functions as well. For example, we can also pass in **sum**.

```python
In [130]: df.pivot_table(
    ....:     values="val0",
    ....:     index="row",
    ....:     columns="col",
    ....:     aggfunc="sum",
    ....:     fill_value=0,
    ....: )

Out[130]:
    col  col0  col1  col2  col3  col4
row  row0  0.77  1.21  0.00  0.86  0.65
     row2  0.13  0.00  0.79  0.50  0.50
     row3  0.00  0.31  0.00  1.09  0.00
     row4  0.00  0.10  0.79  1.52  0.24
```

Another aggregation we can do is calculate the frequency in which the columns and rows occur together a.k.a. “cross tabulation”. To do this, we can pass **size** to the `aggfunc` parameter.

```python
In [131]: df.pivot_table(index="row", columns="col", fill_value=0, aggfunc="size")

Out[131]:
    col  col0  col1  col2  col3  col4
row  row0  1    2    0    1    1
     row2  1    0    2    1    2
     row3  0    1    0    2    0
     row4  0    1    2    2    1
```

### Pivoting with multiple aggregations

We can also perform multiple aggregations. For example, to perform both a **sum** and **mean**, we can pass in a list to the `aggfunc` argument.

```python
In [132]: df.pivot_table(
    ....:     values="val0",
    ....:     index="row",
    ....:     columns="col",
    ....:     aggfunc=["mean", "sum"],
    ....: )

Out[132]:
       mean       sum
    col  col0  col1  col2  col3  col4  col0  col1  col2  col3  col4
row  row0  0.77  0.605 NaN  0.860  0.65  0.77  1.21  NaN  0.86  0.65
     row2  0.13  0.000  0.395  0.500  0.25  0.13  NaN  0.79  0.50  0.50
     row3  NaN  0.310  NaN  0.545  NaN  NaN  0.31  NaN  1.09  NaN
     row4  NaN  0.100  0.395  0.760  0.24  NaN  0.10  0.79  1.52  0.24
```
Note to aggregate over multiple value columns, we can pass in a list to the `values` parameter.

```python
In [133]: df.pivot_table(  
.....:     values=["val0", "val1"],  
.....:     index="row",  
.....:     columns="col",  
.....:     aggfunc=["mean"],  
.....: )
...
Out[133]:
mean  
val0  
val1  
col  col0  col1  col2  col3  col4  col0  col1  col2  col3  col4
row  
row0  0.77  0.605  NaN  0.860  0.65  0.01  0.745  NaN  0.010  0.02
row2  0.13  NaN  0.395  0.500  0.25  0.45  NaN  0.34  0.440  0.79
row3  NaN  0.310  NaN  0.545  NaN  NaN  0.230  NaN  0.075  NaN
row4  NaN  0.100  0.395  0.760  0.24  NaN  0.070  0.42  0.300  0.46
```

Note to subdivide over multiple columns we can pass in a list to the `columns` parameter.

```python
In [134]: df.pivot_table(  
.....:     values=["val0"],  
.....:     index="row",  
.....:     columns=["item", "col"],  
.....:     aggfunc=["mean"],  
.....: )
```  
```
Out[134]:
mean  
val0  
item  item0  item1  item2  
col  col2  col3  col4  col0  col1  col2  col3  col4  col0  col1  col3  col4
row  
row0  NaN  NaN  NaN  0.77  NaN  NaN  NaN  NaN  NaN  NaN  0.605  0.86  0.65
row2  0.35  NaN  NaN  0.37  NaN  NaN  0.44  NaN  NaN  0.13  NaN  0.50  0.13
row3  NaN  NaN  NaN  0.31  NaN  NaN  0.81  NaN  NaN  NaN  NaN  0.28  NaN
row4  0.15  0.64  NaN  0.10  0.64  0.88  0.24  NaN  NaN  NaN  NaN  NaN  NaN
```

### 2.8.11 Exploding a list-like column

New in version 0.25.0.

Sometimes the values in a column are list-like.

```python
In [135]: keys = ["panda1", "panda2", "panda3"]

In [136]: values = [["eats", "shoots"], ["shoots", "leaves"], ["eats", "leaves"]]

In [137]: df = pd.DataFrame({"keys": keys, "values": values})

In [138]: df
Out[138]:
  keys     values
0 panda1 [eats, shoots]
1 panda2 [shoots, leaves]
2 panda3 [eats, leaves]
```
We can ‘explode’ the `values` column, transforming each list-like to a separate row, by using `explode()`. This will replicate the index values from the original row:

```python
In [139]: df["values"].explode()
Out[139]:
   0 eats
   0 shoots
   1 shoots
   1 leaves
   2 eats
   2 leaves
Name: values, dtype: object
```

You can also explode the column in the `DataFrame`.

```python
In [140]: df.explode("values")
Out[140]:
   keys values
   0 panda1 eats
   0 panda1 shoots
   1 panda2 shoots
   1 panda2 leaves
   2 panda3 eats
   2 panda3 leaves
```

`Series.explode()` will replace empty lists with `np.nan` and preserve scalar entries. The dtype of the resulting `Series` is always `object`.

```python
In [141]: s = pd.Series([[1, 2, 3], "foo", [], ["a", "b"]])
In [142]: s
Out[142]:
0   [1, 2, 3]
1     foo
2       []
3    [a, b]
dtype: object
In [143]: s.explode()
Out[143]:
   0  1
   0  2
   0  3
   1   foo
   2  NaN
   3    a
   3    b
dtype: object
```

Here is a typical usecase. You have comma separated strings in a column and want to expand this.

```python
In [144]: df = pd.DataFrame([{
   'var1': 'a,b,c',
   'var2': 1,
   'var1': 'd,e,f',
   'var2': 2}),
   ("var1": "d,e,f", "var2": 2))
In [145]: df
Out[145]:
   var1  var2
   d e f  2
```
Creating a long form DataFrame is now straightforward using explode and chained operations

```python
In [146]: df.assign(var1=df.var1.str.split(",")).explode("var1")
Out[146]:
   var1 var2
0    a   1
0    b   1
0    c   1
1    d   2
1    e   2
1    f   2
```

### 2.9 Working with text data

#### 2.9.1 Text data types

New in version 1.0.0.

There are two ways to store text data in pandas:

1. **object** - dtype NumPy array.
2. **StringDtype** extension type.

We recommend using `StringDtype` to store text data.

Prior to pandas 1.0, `object` dtype was the only option. This was unfortunate for many reasons:

1. You can accidentally store a mixture of strings and non-strings in an `object` dtype array. It’s better to have a dedicated dtype.
2. `object` dtype breaks dtype-specific operations like `DataFrame.select_dtypes()`. There isn’t a clear way to select just text while excluding non-text but still object-dtype columns.
3. When reading code, the contents of an `object` dtype array is less clear than 'string'.

Currently, the performance of `object` dtype arrays of strings and `arrays.StringArray` are about the same. We expect future enhancements to significantly increase the performance and lower the memory overhead of `StringArray`.

**Warning:** `StringArray` is currently considered experimental. The implementation and parts of the API may change without warning.

For backwards-compatibility, `object` dtype remains the default type we infer a list of strings to

```python
In [1]: pd.Series(["a", "b", "c"])
Out[1]:
0    a
1    b
2    c
dtype: object
```
To explicitly request string dtype, specify the dtype

```python
In [2]: pd.Series(["a", "b", "c"], dtype="string")
Out[2]:
0    a
1    b
2    c
dtype: string

In [3]: pd.Series(["a", "b", "c"], dtype=pd.StringDtype())
Out[3]:
0    a
1    b
2    c
dtype: string
```

Or `astype` after the Series or DataFrame is created

```python
In [4]: s = pd.Series(["a", "b", "c"])

In [5]: s
Out[5]:
0    a
1    b
2    c
dtype: object

In [6]: s.astype("string")
Out[6]:
0    a
1    b
2    c
dtype: string
```

Changed in version 1.1.0.

You can also use `StringDtype/"string"` as the dtype on non-string data and it will be converted to string dtype:

```python
In [7]: s = pd.Series(["a", 2, np.nan], dtype="string")

In [8]: s
Out[8]:
0    a
1    2
2  <NA>
dtype: string

In [9]: type(s[1])
Out[9]: str
```

or convert from existing pandas data:

```python
In [10]: s1 = pd.Series([1, 2, np.nan], dtype="Int64")

In [11]: s1
Out[11]:
0    1
```

(continues on next page)
Behavior differences

These are places where the behavior of `StringDtype` objects differ from `object` dtype:

1. For `StringDtype`, *string accessor methods* that return numeric output will always return a nullable integer dtype, rather than either int or float dtype, depending on the presence of NA values. Methods returning boolean output will return a nullable boolean dtype.

```
In [15]: s = pd.Series(['a', None, 'b'], dtype='string')

In [16]: s
Out[16]:
0   a
1  <NA>
2   b
dtype: string

In [17]: s.str.count("a")
Out[17]:
0    1
1    1
2    0
dtype: Int64

In [18]: s.dropna().str.count("a")
Out[18]:
0    1
2    0
dtype: Int64
```

Both outputs are `Int64` dtype. Compare that with object-dtype:

```
In [19]: s2 = pd.Series(['a', None, 'b'], dtype='object')

In [20]: s2.str.count("a")
Out[20]:
0    1.0
1   NaN
2    0.0
```

(continues on next page)
dtype: float64

In [21]: s2.dropna().str.count("a")
Out[21]:
0   1
2   0
dtype: int64

When NA values are present, the output dtype is float64. Similarly for methods returning boolean values.

In [22]: s.str.isdigit()
Out[22]:
0  False
1  <NA>
2  False
dtype: boolean

In [23]: s.str.match("a")
Out[23]:
0  True
1  <NA>
2  False
dtype: boolean

2. Some string methods, like Series.str.decode() are not available on StringArray because StringArray only holds strings, not bytes.

3. In comparison operations, arrays.StringArray and Series backed by a StringArray will return an object with BooleanDtype, rather than a bool dtype object. Missing values in a StringArray will propagate in comparison operations, rather than always comparing unequal like numpy.nan.

Everything else that follows in the rest of this document applies equally to string and object dtype.

2.9.2 String methods

Series and Index are equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the str attribute and generally have names matching the equivalent (scalar) built-in string methods:

In [24]: s = pd.Series(
    .....:   dtype="string"
    .....:)
    .....:

In [25]: s.str.lower()
Out[25]:
0  a
1  b
2  c
3  aaba
4  baca
5  <NA>
6  caba
7  dog
8 cat
dtype: string

In [26]: s.str.upper()
Out[26]:
0 A
1 B
2 C
3 AABA
4 BACA
5 <NA>
6 CABA
7 DOG
8 CAT
dtype: string

In [27]: s.str.len()
Out[27]:
0 1
1 1
2 1
3 4
4 4
5 <NA>
6 4
7 3
8 3
dtype: Int64

In [28]: idx = pd.Index(\[" jack", "jill ", " jesse ", "frank"])

In [29]: idx.str.strip()
Out[29]: Index(\['jack', 'jill', 'jesse', 'frank']\), dtype='object')

In [30]: idx.str.lstrip()
Out[30]: Index(\['jack', 'jill ', 'jesse ', 'frank']\), dtype='object')

In [31]: idx.str.rstrip()
Out[31]: Index(\[' jack', 'jill', ' jesse', 'frank']\), dtype='object')

The string methods on Index are especially useful for cleaning up or transforming DataFrame columns. For instance, you may have columns with leading or trailing whitespace:

In [32]: df = pd.DataFrame(........: np.random.randn(3, 2), columns=[" Column A ", " Column B "],
......: index=range(3)
......: )

In [33]: df
Out[33]:
   Column A     Column B
0   0.469112 -0.282863
1  -1.509059 -1.135632
2   1.212112 -0.173215

Since df.columns is an Index object, we can use the .str accessor
These string methods can then be used to clean up the columns as needed. Here we are removing leading and trailing whitespaces, lower casing all names, and replacing any remaining whitespaces with underscores:

```python
In [36]: df.columns = df.columns.str.strip().str.lower().str.replace(" ", ".")
In [37]: df
Out[37]:
column_a column_b
0 0.469112 -0.282863
1 -1.509059 -1.135632
2 1.212112 -0.173215
```

**Note:** If you have a `Series` where lots of elements are repeated (i.e. the number of unique elements in the `Series` is a lot smaller than the length of the `Series`), it can be faster to convert the original `Series` to one of type `category` and then use `.str.<method>` or `.dt.<property>` on that. The performance difference comes from the fact that, for `Series` of type `category`, the string operations are done on the `.categories` and not on each element of the `Series`.

Please note that a `Series` of type `category` with string `.categories` has some limitations in comparison to `Series` of type string (e.g. you can’t add strings to each other: `s + " " + s` won’t work if `s` is a `Series` of type `category`). Also, `.str` methods which operate on elements of type `list` are not available on such a `Series`.

**Warning:** Before v.0.25.0, the `.str`-accessor did only the most rudimentary type checks. Starting with v.0.25.0, the type of the Series is inferred and the allowed types (i.e. strings) are enforced more rigorously.

Generally speaking, the `.str` accessor is intended to work only on strings. With very few exceptions, other uses are not supported, and may be disabled at a later point.

### 2.9.3 Splitting and replacing strings

Methods like `split` return a `Series` of lists:

```python
In [38]: s2 = pd.Series(["a_b_c", "c_d_e", np.nan, "f_g_h"], dtype="string")
In [39]: s2.str.split("_")
Out[39]:
0  [a, b, c]
1  [c, d, e]
2    <NA>
3  [f, g, h]
dtype: object
```

Elements in the split lists can be accessed using `get` or `[]` notation:

```python
In [40]: s2.str.split("_"), str.get(1)
Out[40]:
```
It is easy to expand this to return a DataFrame using `expand`.

```python
In [42]: s2.str.split("_", expand=True)
Out[42]:
  0 1 2
0 a b c
1 c d e
2 <NA> <NA> <NA>
3 f g h
```

When original `Series` has `StringDtype`, the output columns will all be `StringDtype` as well.

It is also possible to limit the number of splits:

```python
In [43]: s2.str.split("_", expand=True, n=1)
Out[43]:
  0 1
0 a b c
1 c d e
2 <NA> <NA>
3 f g h
```

`rsplit` is similar to `split` except it works in the reverse direction, i.e., from the end of the string to the beginning of the string:

```python
In [44]: s2.str.rsplit("_", expand=True, n=1)
Out[44]:
  0 1
0 a_b c
1 c_d e
2 <NA> <NA>
3 f_g h
```

`replace` optionally uses regular expressions:

```python
In [45]: s3 = pd.Series(
.....: ['A', 'B', 'C', 'Aaba', 'Baca', '', np.nan, 'CABA', 'dog', 'cat'],
.....: dtype='string',
.....: )
In [46]: s3
Out[46]:
```

(continues on next page)
Warning: Some caution must be taken when dealing with regular expressions! The current behavior is to treat single character patterns as literal strings, even when `regex` is set to `True`. This behavior is deprecated and will be removed in a future version so that the `regex` keyword is always respected.

Changed in version 1.2.0.

If you want literal replacement of a string (equivalent to `str.replace()`), you can set the optional `regex` parameter to `False`, rather than escaping each character. In this case both `pat` and `repl` must be strings:

```
In [48]: dollars = pd.Series(['12', '-$10', '$10,000'], dtype='string')
# These lines are equivalent
In [49]: dollars.str.replace(r'^-$', '', regex=True)
Out[49]:
0    12
1    -10
2  $10,000
 dtype: string
```

The `replace` method can also take a callable as replacement. It is called on every `pat` using `re.sub()`. The callable should expect one positional argument (a regex object) and return a string.
# Reverse every lowercase alphabetic word

In [51]: pat = r"[a-z]+"

In [52]: def repl(m):
   ....:     return m.group(0)[::-1]
   ....:

In [53]: pd.Series(["foo 123", "bar baz", np.nan], dtype="string").str.replace(  
   ....:     pat, repl, regex=True  
   ....: )

Out[53]:
0 oof 123
1 rab zab
2 <NA>
dtype: string

# Using regex groups

In [54]: pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"

In [55]: def repl(m):
   ....:     return m.group("two").swapcase()
   ....:

In [56]: pd.Series(["Foo Bar Baz", np.nan], dtype="string").str.replace(  
   ....:     pat, repl, regex=True  
   ....: )

Out[56]:
0 bAR
1 <NA>
dtype: string

The \texttt{replace} method also accepts a compiled regular expression object from \texttt{re.compile()} as a pattern. All flags should be included in the compiled regular expression object.

In [57]: import re

In [58]: regex_pat = re.compile(r"^.a|dog", flags=re.IGNORECASE)

In [59]: s3.str.replace(regex_pat, "XX-XX ", regex=True)

Out[59]:
0 A
1 B
2 C
3 XX-XX ba
4 XX-XX ca
5 <NA>
6 XX-XX BA
7 XX-XX BA
8 XX-XX
9 XX-XX t
dtype: string

Including a \texttt{flags} argument when calling \texttt{replace} with a compiled regular expression object will raise a \texttt{ValueError}.  

2.9. Working with text data 557
2.9.4 Concatenation

There are several ways to concatenate a Series or Index, either with itself or others, all based on `cat()`, resp. `Index.str.cat`.

**Concatenating a single Series into a string**

The content of a Series (or Index) can be concatenated:

```
In [61]: s = pd.Series(["a", "b", "c", "d"], dtype="string")
In [62]: s.str.cat(sep=",")
Out[62]: 'a,b,c,d'
```

If not specified, the keyword `sep` for the separator defaults to the empty string, `sep=''`:

```
In [63]: s.str.cat()
Out[63]: 'abcd'
```

By default, missing values are ignored. Using `na_rep`, they can be given a representation:

```
In [64]: t = pd.Series(["a", "b", np.nan, "d"], dtype="string")
In [65]: t.str.cat(sep="")
Out[65]: 'a,b,d'

In [66]: t.str.cat(sep="", na_rep="-")
Out[66]: 'a,b,-,d'
```

**Concatenating a Series and something list-like into a Series**

The first argument to `cat()` can be a list-like object, provided that it matches the length of the calling Series (or Index).

```
In [67]: s.str.cat(["A", "B", "C", "D"])
Out[67]:
0  aA
1  bB
2  cC
3  dD
dtype: string
```

Missing values on either side will result in missing values in the result as well, unless `na_rep` is specified:

```
In [68]: s.str.cat(t)
Out[68]:
0  aa
1  bb
2  <NA>
```

(continues on next page)
Concatenating a Series and something array-like into a Series

The parameter others can also be two-dimensional. In this case, the number or rows must match the lengths of the calling Series (or Index).

```
In [70]: d = pd.concat([t, s], axis=1)
```

```
In [71]: d
Out[71]:
0 1
0 a a
1 b b
2 <NA> c
3 d d
dtype: string
```

```
In [72]: s.str.cat(d, na_rep="-")
Out[72]:
0 aaa
1 bbb
2 c-c
3 ddd
dtype: string
```

Concatenating a Series and an indexed object into a Series, with alignment

For concatenation with a Series or DataFrame, it is possible to align the indexes before concatenation by setting the join-keyword.

```
In [74]: u = pd.Series(["b", "d", "a", "c"], index=[1, 3, 0, 2], dtype="string")
```

```
In [75]: s
Out[75]:
0 a
1 b
```
Warning: If the `join` keyword is not passed, the method `cat()` will currently fall back to the behavior before version 0.23.0 (i.e. no alignment), but a `FutureWarning` will be raised if any of the involved indexes differ, since this default will change to `join='left'` in a future version.

The usual options are available for `join` (one of 'left', 'outer', 'inner', 'right'). In particular, alignment also means that the different lengths do not need to coincide anymore.

```python
In [79]: v = pd.Series(['z', 'a', 'b', 'd', 'e'], index=[-1, 0, 1, 3, 4], dtype='string')
In [80]: s
Out[80]:
0  a
1  b
2  c
3  d
dtype: string
In [81]: v
Out[81]:
-1  z
 0  a
 1  b
 3  d
 4  e
dtype: string
```
In [82]: s.str.cat(v, join="left", na_rep="-")
Out[82]:
0  aa
1  bb
2  c-
3  dd
dtype: string

In [83]: s.str.cat(v, join="outer", na_rep="-")
Out[83]:
-1  -z
  0  aa
  1  bb
  2  c-
  3  dd
  4  -e
dtype: string

The same alignment can be used when others is a DataFrame:

In [84]: f = d.loc[[3, 2, 1, 0], :]

In [85]: s
Out[85]:
0  a
1  b
2  c
3  d
dtype: string

In [86]: f
Out[86]:
0  l
3  d
2  <NA>  c
1  b
0  a

In [87]: s.str.cat(f, join="left", na_rep="-")
Out[87]:
0  aaa
1  bbb
2  c-c
3  ddd
dtype: string
Concatenating a Series and many objects into a Series

Several array-like items (specifically: Series, Index, and 1-dimensional variants of np.ndarray) can be combined in a list-like container (including iterators, dict-views, etc.).

```
In [88]: s
Out[88]:
0   a
1   b
2   c
3   d
dtype: string

In [89]: u
Out[89]:
1   b
2   d
0   a
2   c
dtype: string

In [90]: s.str.cat([u, u.to_numpy()], join="left")
Out[90]:
0   aab
1   bbd
2   cca
3   ddc
dtype: string
```

All elements without an index (e.g. np.ndarray) within the passed list-like must match in length to the calling Series (or Index), but Series and Index may have arbitrary length (as long as alignment is not disabled with join=None):  

```
In [91]: v
Out[91]:
-1  z
 0   a
1   b
3   d
4   e
dtype: string

In [92]: s.str.cat([v, u, u.to_numpy()], join="outer", na_rep="-")
Out[92]:
-1  -z--
 0  aaab
1  bbbd
2  c-cc
3  dddc
4  -e--
dtype: string
```

If using join='right' on a list-like of others that contains different indexes, the union of these indexes will be used as the basis for the final concatenation:

```
In [93]: u.loc[[3]]
Out[93]:
```

(continues on next page)
3  d

dtype: string

In [94]: v.loc[[-1, 0]]
Out[94]:
-1  z
  0  a

dtype: string

In [95]: s.str.cat([u.loc[[3]], v.loc[[-1, 0]]], join="right", na_rep="-")
Out[95]:
-1  --z
  0  a-a
  3  dd-

dtype: string

2.9.5 Indexing with .str

You can use [] notation to directly index by position locations. If you index past the end of the string, the result will be NaN.

In [96]: s = pd.Series(
       ....:     dtype="string"
       ....: )

In [97]: s.str[0]
Out[97]:
0  A
1  B
2  C
3  A
4  B
5  <NA>
6  C
7  d
8  c

dtype: string

In [98]: s.str[1]
Out[98]:
0  <NA>
1  <NA>
2  <NA>
3  a
4  a
5  <NA>
6  A
7  o
8  a

dtype: string
2.9.6 Extracting substrings

Extract first match in each subject (extract)

**Warning:** Before version 0.23, argument `expand` of the `extract` method defaulted to `False`. When `expand=False`, `expand` returns a `Series`, `Index`, or `DataFrame`, depending on the subject and regular expression pattern. When `expand=True`, it always returns a `DataFrame`, which is more consistent and less confusing from the perspective of a user. `expand=True` has been the default since version 0.23.0.

The `extract` method accepts a regular expression with at least one capture group.

Extracting a regular expression with more than one group returns a DataFrame with one column per group.

```python
In [99]: pd.Series(["a1", "b2", "c3"],
               dtype="string",
               ).str.extract(r"([ab])(\d)", expand=False)
```

```
Out[99]:
          0  1
0       a  1
1       b  2
2  <NA>  <NA>
```

Elements that do not match return a row filled with NaN. Thus, a Series of messy strings can be “converted” into a like-indexed Series or DataFrame of cleaned-up or more useful strings, without necessitating `get()` to access tuples or `re.match` objects. The dtype of the result is always object, even if no match is found and the result only contains NaN.

Named groups like

```python
In [100]: pd.Series(["a1", "b2", "c3"], dtype="string").str.extract(
               r"(?P<letter>[ab])(?P<digit>\d)", expand=False
               )
```

```
                        letter digit
0       a      1
1       b      2
2  <NA>  <NA>
```

and optional groups like

```python
In [101]: pd.Series(["a1", "b2", "3"],
               dtype="string",
               ).str.extract(r"([ab])?(\d)"amp;#34; expand=False amp;#34;
```

```
Out[101]:
          0  1
0  a  1
1  b  2
2 <NA> 3
```

can also be used. Note that any capture group names in the regular expression will be used for column names; otherwise capture group numbers will be used.
Extracting a regular expression with one group returns a DataFrame with one column if `expand=True`.

```python
In [102]: pd.Series(["a1", "b2", "c3"], dtype="string").str.extract(r"[ab](\d)\", expand=True)
Out[102]:
0   1
1   2
2  <NA>
```

It returns a Series if `expand=False`.

```python
In [103]: pd.Series(["a1", "b2", "c3"], dtype="string").str.extract(r"[ab](\d)\", expand=False)
Out[103]:
0   1
1   2
2  <NA>
dtype: string
```

Calling on an Index with a regex with exactly one capture group returns a DataFrame with one column if `expand=True`.

```python
In [104]: s = pd.Series(["a1", "b2", "c3"], ["A11", "B22", "C33"], dtype="string")
In [105]: s
Out[105]:
A11  a1
B22  b2
C33  c3
dtype: string
In [106]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=True)
Out[106]:
letter
0  A
1  B
2  C
```

It returns an Index if `expand=False`.

```python
In [107]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=False)
Out[107]: Index(["A", "B", "C"], dtype='object', name='letter')
```

Calling on an Index with a regex with more than one capture group returns a DataFrame if `expand=True`.

```python
In [108]: s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)\", expand=True)
Out[108]:
letter 1
0  A  11
1  B  22
2  C  33
```

It raises ValueError if `expand=False`.

```python
>>> s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)\", expand=False)
ValueError: only one regex group is supported with Index
```
The table below summarizes the behavior of `extract(expand=False)` (input subject in first column, number of groups in regex in first row)

<table>
<thead>
<tr>
<th>Index</th>
<th>1 group</th>
<th>&gt;1 group</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series</td>
<td>Index</td>
<td>Value</td>
</tr>
<tr>
<td></td>
<td>Series</td>
<td>DataFrame</td>
</tr>
</tbody>
</table>

**Extract all matches in each subject (extractall)**

Unlike `extract` (which returns only the first match),

```
In [109]: s = pd.Series(["ala2", "b1", "c1"], index=["A", "B", "C"], dtype="string")

In [110]: s
Out[110]:
A  ala2
B   b1
C   c1
dtype: string

In [111]: two_groups = "(?P<letter>[a-z])(?P<digit>[0-9])"

In [112]: s.str.extract(two_groups, expand=True)
Out[112]:
   letter digit
A    a  1
B    b  1
C    c  1

```

the `extractall` method returns every match. The result of `extractall` is always a `DataFrame` with a `MultiIndex` on its rows. The last level of the `MultiIndex` is named `match` and indicates the order in the subject.

```
In [113]: s.str.extractall(two_groups)
Out[113]:
   letter digit
   match
A    a  1
    1     a  2
B    b  1
C    c  1

```

When each subject string in the Series has exactly one match,

```
In [114]: s = pd.Series(["a3", "b3", "c2"], dtype="string")

In [115]: s
Out[115]:
0  a3
1  b3
2  c2
dtype: string

```

then `extractall(pat).xs(0, level='match')` gives the same result as `extract(pat)`. 

Index also supports `.str.extractall`. It returns a `DataFrame` which has the same result as a `Series.str.extractall` with a default index (starts from 0).

```python
In [121]: pd.Index(['a1a2', 'b1', 'c1']).str.extractall(two_groups)
Out[121]:
        letter digit
match            
0     a            3
1     b            3
2     c            2

In [122]: pd.Series(['a1a2', 'b1', 'c1'], dtype='string').str.extractall(two_groups)
Out[122]:
        letter digit
match            
0     a            1
1     a            2
1     b            1
2     c            1
```
2.9.7 Testing for strings that match or contain a pattern

You can check whether elements contain a pattern:

```
In [123]: pattern = r"[0-9][a-z]"

In [124]: pd.Series(["1", "2", "3a", "3b", "03c", "4dx"],
       ......:     dtype="string",
       ......:     ).str.contains(pattern)

Out[124]:
0    False
1    False
2     True
3     True
4     True
5     True
dtype: boolean
```

Or whether elements match a pattern:

```
In [125]: pd.Series(["1", "2", "3a", "3b", "03c", "4dx"],
       ......:     dtype="string",
       ......:     ).str.match(pattern)

Out[125]:
0    False
1    False
2     True
3     True
4    False
5     True
dtype: boolean
```

New in version 1.1.0.

```
In [126]: pd.Series(["1", "2", "3a", "3b", "03c", "4dx"],
       ......:     dtype="string",
       ......:     ).str.fullmatch(pattern)

Out[126]:
0    False
1    False
2     True
3     True
4    False
5    False
dtype: boolean
```

Note: The distinction between `match`, `fullmatch`, and `contains` is strictness: `fullmatch` tests whether the entire string matches the regular expression; `match` tests whether there is a match of the regular expression that begins at the first character of the string; and `contains` tests whether there is a match of the regular expression at any position within the string.
The corresponding functions in the `re` package for these three match modes are `re.fullmatch`, `re.match`, and `re.search`, respectively.

Methods like `match`, `fullmatch`, `contains`, `startswith`, and `endswith` take an extra `na` argument so missing values can be considered True or False:

```python
In [127]: s4 = pd.Series(
   .....:       "string"
   .....:       )
   .....:
In [128]: s4.str.contains("A", na=False)
Out[128]:
0    True
1    False
2    False
3     True
4    False
5    False
6     True
7    False
8    False
dtype: bool
```

### 2.9.8 Creating indicator variables

You can extract dummy variables from string columns. For example if they are separated by a `'|'`:

```python
In [129]: s = pd.Series(["a", "a|b", np.nan, "a|c"], dtype="string")
In [130]: s.str.get_dummies(sep="|")
Out[130]:
   a  b  c
0  1  0  0
1  1  1  0
2  0  0  0
3  1  0  1
```

String Index also supports `get_dummies` which returns a MultiIndex.

```python
In [131]: idx = pd.Index(["a", "a|b", np.nan, "a|c"])
In [132]: idx.str.get_dummies(sep="|")
Out[132]:
MultiIndex([(1, 0, 0),
            (1, 1, 0),
            (0, 0, 0),
            (1, 0, 1)],
           names=['a', 'b', 'c'])
```

See also `get_dummies()`.

---

2.9. Working with text data
## Method summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>

#### 2.10 Working with missing data

In this section, we will discuss missing (also referred to as NA) values in pandas.

**Note:** The choice of using NaN internally to denote missing data was largely for simplicity and performance reasons. Starting from pandas 1.0, some optional data types start experimenting with a native NA scalar using a mask-based approach. See [here](#) for more.

See the cookbook for some advanced strategies.

### 2.10.1 Values considered “missing”

As data comes in many shapes and forms, pandas aims to be flexible with regard to handling missing data. While NaN is the default missing value marker for reasons of computational speed and convenience, we need to be able to easily detect this value with data of different types: floating point, integer, boolean, and general object. In many cases, however, the Python None will arise and we wish to also consider that “missing” or “not available” or “NA”.

**Note:** If you want to consider inf and -inf to be “NA” in computations, you can set `pandas.options.mode.use_inf_as_na = True`.

```python
In [1]: df = pd.DataFrame(
...:     np.random.randn(5, 3),
...:     index=["a", "c", "e", "f", "h"],
...:     columns=["one", "two", "three"],
...: )

In [2]: df["four"] = "bar"

In [3]: df["five"] = df["one"] > 0

In [4]: df
```

```
Out[4]:
   one   two   three  four  five
  a 0.469112 -0.282863 -1.509059  bar True
  c -1.135632  1.212112 -0.173215  bar  False
  e  0.119209 -1.044236 -0.861849  bar True
  f -2.104569 -0.494929  1.071804  bar  False
  h  0.721555 -0.706771 -1.039575  bar True

In [5]: df2 = df.reindex(["a", "b", "c", "d", "e", "f", "g", "h"])
```

(continues on next page)
To make detecting missing values easier (and across different array dtypes), pandas provides the `isna()` and `notna()` functions, which are also methods on Series and DataFrame objects:

```
In [7]: df2["one"]
Out[7]:
a 0.469112
b NaN
c -1.135632
d NaN
e 0.119209
f -2.104569
g NaN
h 0.721555
Name: one, dtype: float64

In [8]: pd.isna(df2["one"])
Out[8]:
a False
b True
c False
d True
e False
f False
g True
h False
Name: one, dtype: bool

In [9]: df2["four"].notna()
Out[9]:
a True
b False
c True
d False
e True
f True
g False
h True
Name: four, dtype: bool
```

```
In [10]: df2.isna()
Out[10]:
   one  two  three  four  five
a   False  False  False  False
b    True    True    True    True
```
Warning: One has to be mindful that in Python (and NumPy), the `nan's` don’t compare equal, but `None's` do. Note that pandas/NumPy uses the fact that `np.nan != np.nan`, and treats `None` like `np.nan`.

```python
In [11]: None == None  # noqa: E711
Out[11]: True

In [12]: np.nan == np.nan
Out[12]: False
```

So as compared to above, a scalar equality comparison versus a `None/np.nan` doesn’t provide useful information.

```python
In [13]: df2["one"] == np.nan
Out[13]:
a  False
b  False
c  False
d  False
e  False
f  False
g  False
h  False
Name: one, dtype: bool
```

### Integer dtypes and missing data

Because `NaN` is a float, a column of integers with even one missing values is cast to floating-point dtype (see [Support for integer NA](#) for more). pandas provides a nullable integer array, which can be used by explicitly requesting the dtype:

```python
In [14]: pd.Series([1, 2, np.nan, 4], dtype=pd.Int64Dtype())
Out[14]:
0   1
1   2
2   <NA>
3   4
dtype: Int64
```

Alternatively, the string alias `dtype='Int64'` (note the capital "I") can be used.

See [Nullable integer data type](#) for more.
Datetimes

For datetime64[ns] types, NaT represents missing values. This is a pseudo-native sentinel value that can be represented by NumPy in a singular dtype (datetime64[ns]). pandas objects provide compatibility between NaT and NaN.

```
In [15]: df2 = df.copy()

In [16]: df2["timestamp"] = pd.Timestamp("20120101")

In [17]: df2
Out[17]:
   one    two    three    four    five  timestamp
  ---    ---    ---    ---    ---          ---
 a  0.469112 -0.282863 -1.509059   bar    True  2012-01-01
 c -1.135632  1.212112 -0.173215  bar    False  2012-01-01
 e  0.119209 -1.044236 -0.861849   bar    True  2012-01-01
 f -2.104569 -0.494929  1.071804  bar    False  2012-01-01
 h  0.721555 -0.706771 -1.039575   bar    True  2012-01-01

In [18]: df2.loc[\["a", "c", "h"\], ["one", "timestamp"]\] = np.nan

In [19]: df2
Out[19]:
   one    two    three    four    five  timestamp
  ---    ---    ---    ---    ---          ---
 a NaN   -0.282863 -1.509059  bar    True     NaT
 c NaN    1.212112 -0.173215  bar    False     NaT
 e  0.119209 -1.044236 -0.861849  bar    True  2012-01-01
 f -2.104569 -0.494929  1.071804  bar    False  2012-01-01
 h NaN  -0.706771 -1.039575  bar    True     NaT

In [20]: df2.dtypes.value_counts()
Out[20]:
float64    3
object      1
bool        1
datetime64[ns]  1
dtype: int64
```

2.10.2 Inserting missing data

You can insert missing values by simply assigning to containers. The actual missing value used will be chosen based on the dtype.

For example, numeric containers will always use NaN regardless of the missing value type chosen:

```
In [21]: s = pd.Series([1, 2, 3])

In [22]: s.loc[0] = None

In [23]: s
Out[23]:
0  NaN
1  2.0
2  3.0
dtype: float64
```

Likewise, datetime containers will always use NaT.
For object containers, pandas will use the value given:

```python
In [24]: s = pd.Series(['a', 'b', 'c'])
In [25]: s.loc[0] = None
In [26]: s.loc[1] = np.nan
In [27]: s
Out[27]:
0   None
1  NaN
2    c
dtype: object
```

2.10.3 Calculations with missing data

Missing values propagate naturally through arithmetic operations between pandas objects.

```python
In [28]: a
Out[28]:
   one  two
a  NaN -0.282863
   c  NaN 1.212112
   e  0.119209 -1.044236
   f -2.104569 -0.494929
   h -2.104569 -0.706771
In [29]: b
Out[29]:
   one  two  three
a  NaN -0.282863 -1.509059
   c  NaN 1.212112 -0.173215
   e  0.119209 -1.044236 -0.861849
   f -2.104569 -0.494929 1.071804
   h  NaN -0.706771 -1.039575
In [30]: a + b
Out[30]:
   one  three  two
a  NaN  NaN -0.565727
   c  NaN  NaN  2.424224
   e  0.238417  NaN -2.088472
   f -4.209138  NaN  1.071804
   h  NaN  NaN -1.413542
```

The descriptive statistics and computational methods discussed in the data structure overview (and listed here and here) are all written to account for missing data. For example:

- When summing data, NA (missing) values will be treated as zero.
- If the data are all NA, the result will be 0.
- Cumulative methods like `cumsum()` and `cumprod()` ignore NA values by default, but preserve them in the resulting arrays. To override this behaviour and include NA values, use `skipna=False`. 

2.10. Working with missing data
The sum of an empty or all-NA Series or column of a DataFrame is 0.

```python
In [36]: pd.Series([np.nan]).sum()
Out[36]: 0.0
```

The product of an empty or all-NA Series or column of a DataFrame is 1.

```python
In [37]: pd.Series([], dtype="float64").sum()
Out[37]: 0.0
```
2.10.5 NA values in GroupBy

NA groups in GroupBy are automatically excluded. This behavior is consistent with R, for example:

```
In [40]: df
Out[40]:
   one    two    three
a  NaN -0.282863  -1.509059
b  NaN    1.212112  -0.173215
c   0.119209 -1.044236  -0.861849
d -2.104569   -0.494929   1.071804
h  NaN   -0.706771  -1.039575
In [41]: df.groupby("one").mean()
Out[41]:
   two    three
one
  -2.104569   -0.494929   1.071804
  0.119209 -1.044236  -0.861849
```

See the groupby section [here](#) for more information.

**Cleaning / filling missing data**

pandas objects are equipped with various data manipulation methods for dealing with missing data.

2.10.6 Filling missing values: fillna

`fillna()` can “fill in” NA values with non-NA data in a couple of ways, which we illustrate:

Replace NA with a scalar value

```
In [42]: df2
Out[42]:
   one    two    three    four    five  timestamp
a  NaN -0.282863  -1.509059    bar   True   NaT
b  NaN    1.212112  -0.173215    bar  False   NaT
c   0.119209 -1.044236  -0.861849    bar  True  2012-01-01
d -2.104569   -0.494929   1.071804    bar  False  2012-01-01
h  NaN   -0.706771  -1.039575    bar   True   NaT
In [43]: df2.fillna(0)
Out[43]:
   one    two    three    four    five  timestamp
a  0.000000 -0.282863  -1.509059    bar   True    0
b  0.000000    1.212112  -0.173215    bar  False    0
c  0.119209 -1.044236  -0.861849    bar  True  2012-01-01  00:00:00
d -2.104569   -0.494929   1.071804    bar  False  2012-01-01  00:00:00
```
Fill gaps forward or backward

Using the same filling arguments as `reindexing`, we can propagate non-NA values forward or backward:

```python
In [45]: df
Out[45]:
   one    two    three
  a  NaN -0.282863 -1.509059
  c  NaN  1.212112 -0.173215
  e  0.119209 -1.044236 -0.861849
  f -2.104569 -0.494929  1.071804
  h  NaN  -0.706771 -1.039575

In [46]: df.fillna(method="pad")
Out[46]:
   one    two    three
  a  NaN -0.282863 -1.509059
  c  NaN  1.212112 -0.173215
  e  NaN  1.212112 -0.173215
  f  NaN  NaN   NaN
  h  NaN  -0.706771 -1.039575
```

Limit the amount of filling

If we only want consecutive gaps filled up to a certain number of data points, we can use the `limit` keyword:

```python
In [47]: df
Out[47]:
   one    two    three
  a  NaN -0.282863 -1.509059
  c  NaN  1.212112 -0.173215
  e  NaN   NaN  NaN
  f  NaN   NaN  NaN
  h  NaN  -0.706771 -1.039575

In [48]: df.fillna(method="pad", limit=1)
Out[48]:
   one    two    three
  a  NaN -0.282863 -1.509059
  c  NaN  1.212112 -0.173215
  e  NaN  1.212112 -0.173215
  f  NaN   NaN  NaN
  h  NaN  -0.706771 -1.039575
```

To remind you, these are the available filling methods:
With time series data, using pad/ffill is extremely common so that the “last known value” is available at every time point.

`ffill()` is equivalent to `fillna(method='ffill')` and `bfill()` is equivalent to `fillna(method='bfill')`

### 2.10.7 Filling with a PandasObject

You can also fillna using a dict or Series that is alignable. The labels of the dict or index of the Series must match the columns of the frame you wish to fill. The use case of this is to fill a DataFrame with the mean of that column.

```python
In [49]: dff = pd.DataFrame(np.random.randn(10, 3), columns=list("ABC"))
In [50]: dff.iloc[3:5, 0] = np.nan
In [51]: dff.iloc[4:6, 1] = np.nan
In [52]: dff.iloc[5:8, 2] = np.nan
In [53]: dff
Out[53]:
          A         B         C
0  0.271860 -0.424972  0.567020
1  0.276232 -1.087401 -0.673690
2  0.113648 -1.478427  0.524988
3     NaN       0.577046 -1.715002
4     NaN        NaN     NaN
5 -1.344312        NaN     NaN
6 -0.109050  1.643563     NaN
7  0.357021 -0.674600     NaN
8 -0.968914 -1.294524  0.413738
9  0.276662 -0.472035 -0.013960
In [54]: dff.fillna(dff.mean())
Out[54]:
          A         B         C
0  0.271860 -0.424972  0.567020
1  0.276232 -1.087401 -0.673690
2  0.113648 -1.478427  0.524988
3 -0.140857  0.577046 -1.715002
4 -0.140857 -0.401419 -0.293543
5 -1.344312 -0.401419 -0.293543
6 -0.109050  1.643563  0.413738
7  0.357021 -0.674600 -0.293543
8 -0.968914 -1.294524  0.413738
9  0.276662 -0.472035 -0.013960
In [55]: dff.fillna(dff.mean()["B":"C"])
Out[55]:
          A         B         C
0  0.271860 -0.424972  0.567020
(continues on next page)
Same result as above, but is aligning the ‘fill’ value which is a Series in this case.

```python
In [56]: dff.where(pd.notna(dff), dff.mean(), axis="columns")
Out[56]:
          A         B         C
0  0.271860 -0.424972  0.567020
1  0.276232 -1.087401 -0.673690
2  0.113648 -1.478427  0.524988
3 -0.140857  0.577046 -1.715002
4 -0.140857 -0.401419 -1.157892
5 -1.344312 -0.401419 -0.293543
6 -0.109050  1.643563 -0.293543
7  0.357021 -0.674600 -0.293543
8 -0.968914 -1.294524  0.413738
9  0.276662 -0.472035 -0.013960
```

### 2.10.8 Dropping axis labels with missing data: dropna

You may wish to simply exclude labels from a data set which refer to missing data. To do this, use `dropna()`:

```python
In [57]: df
Out[57]:
     one    two    three
a NaN  -0.282863 -1.509059
b NaN   1.212112  -0.173215
c NaN    0.000000    0.000000
d NaN    0.000000    0.000000
e NaN   -0.706771  -1.039575
f NaN    0.000000    0.000000
g NaN    0.000000    0.000000
h NaN   -0.706771  -1.039575

In [58]: df.dropna(axis=0)
Out[58]:
Empty DataFrame
Columns: [one, two, three]
Index: []
```

```python
In [59]: df.dropna(axis=1)
Out[59]:
     two    three
a -0.282863 -1.509059
c  1.212112  -0.173215
e  0.000000    0.000000
f  0.000000    0.000000
h -0.706771  -1.039575
```
An equivalent `dropna()` is available for Series. DataFrame.dropna has considerably more options than Series.dropna, which can be examined in the API.

### 2.10.9 Interpolation

Both Series and DataFrame objects have `interpolate()` that, by default, performs linear interpolation at missing data points.
In [64]: ts.interpolate()
Out[64]:
2000-01-31    0.469112
2000-02-29    0.434469
2000-03-31    0.399826
2000-04-28    0.365184
2000-05-31    0.330541
...            ...
2007-12-31   -6.950267
2008-01-31   -7.904475
2008-02-29   -6.441779
2008-03-31   -8.184940
2008-04-30   -9.011531
Freq: BM, Length: 100, dtype: float64

In [65]: ts.interpolate().count()
Out[65]: 100

In [66]: ts.interpolate().plot()
Out[66]: <AxesSubplot:>

In [64]: ts.interpolate()
Out[64]:
2000-01-31    0.469112
2000-02-29    0.434469
2000-03-31    0.399826
2000-04-28    0.365184
2000-05-31    0.330541
...            ...
2007-12-31   -6.950267
2008-01-31   -7.904475
2008-02-29   -6.441779
2008-03-31   -8.184940
2008-04-30   -9.011531
Freq: BM, Length: 100, dtype: float64

In [65]: ts.interpolate().count()
Out[65]: 100

In [66]: ts.interpolate().plot()
Index aware interpolation is available via the `method` keyword:

```
In [67]: ts2
Out[67]:
2000-01-31    0.469112
2000-02-29     NaN
2002-07-31   -5.785037
2005-01-31     NaN
2008-04-30   -9.011531
dtype: float64
```

```
In [68]: ts2.interpolate()
Out[68]:
2000-01-31    0.469112
2000-02-29  -2.657962
2002-07-31   -5.785037
2005-01-31   -7.398284
2008-04-30   -9.011531
dtype: float64
```

```
In [69]: ts2.interpolate(method="time")
Out[69]:
2000-01-31    0.469112
2000-02-29    0.270241
2002-07-31   -5.785037
```

(continues on next page)
For a floating-point index, use `method='values'`:

```python
In [70]: ser
Out[70]:
0.0  0.0
1.0  NaN
10.0 10.0
dtype: float64

In [71]: ser.interpolate()
Out[71]:
0.0  0.0
1.0  5.0
10.0 10.0
dtype: float64

In [72]: ser.interpolate(method="values")
Out[72]:
0.0  0.0
1.0  1.0
10.0 10.0
dtype: float64
```

You can also interpolate with a DataFrame:

```python
In [73]: df = pd.DataFrame(
    ....:     {               
    ....:         "A": [1, 2.1, np.nan, 4.7, 5.6, 6.8],
    ....:         "B": [0.25, np.nan, np.nan, 4, 12.2, 14.4],
    ....:     }
    ....: )
    ....: 

In [74]: df
Out[74]:
   A    B
0  1.0  0.25
1  2.1  NaN
2  NaN  NaN
3  4.7  4.00
4  5.6  12.20
5  6.8  14.40

In [75]: df.interpolate()
Out[75]:
   A    B
0  1.0  0.25
1  2.1  1.50
2  3.4  2.75
3  4.7  4.00
4  5.6  12.20
5  6.8  14.40
```
The `method` argument gives access to fancier interpolation methods. If you have `scipy` installed, you can pass the name of a 1-d interpolation routine to `method`. You’ll want to consult the full scipy interpolation documentation and reference guide for details. The appropriate interpolation method will depend on the type of data you are working with.

- If you are dealing with a time series that is growing at an increasing rate, `method='quadratic'` may be appropriate.
- If you have values approximating a cumulative distribution function, then `method='pchip'` should work well.
- To fill missing values with goal of smooth plotting, consider `method='akima'`.

**Warning:** These methods require `scipy`.

```python
In [76]: df.interpolate(method="barycentric")
Out[76]:
   A    B
0  1.0  0.25
1  2.1 -7.66
2  3.5 -4.51
3  4.7  4.00
4  5.6 12.20
5  6.8 14.40
```

```python
In [77]: df.interpolate(method="pchip")
Out[77]:
   A    B
0 1.00 0.25
1 2.10 0.67
2 3.43 1.93
3 4.70 4.00
4 5.60 12.20
5 6.80 14.40
```

```python
In [78]: df.interpolate(method="akima")
Out[78]:
   A    B
0 1.00 0.25
1 2.10 -0.90
2 3.41 1.21
3 4.70 4.00
4 5.60 12.20
5 6.80 14.40
```

When interpolating via a polynomial or spline approximation, you must also specify the degree or order of the approximation:

```python
In [79]: df.interpolate(method="spline", order=2)
Out[79]:
   A    B
0 1.00 0.25
1 2.10 -0.43
2 3.41 1.21
3 4.70 4.00
4 5.60 12.20
5 6.80 14.40
```

(continues on next page)
In [80]: df.interpolate(method="polynomial", order=2)
Out[80]:
   A    B
0  1.000000  0.250000
1  2.100000 -2.703846
2  3.451351 -1.453846
3  4.700000  4.000000
4  5.600000 12.200000
5  6.800000 14.400000

Compare several methods:

In [81]: np.random.seed(2)
In [82]: ser = pd.Series(np.arange(1, 10.1, 0.25) ** 2 + np.random.randn(37))
In [83]: missing = np.array([4, 13, 14, 15, 16, 17, 18, 20, 29])
In [84]: ser[missing] = np.nan
In [85]: methods = ["linear", "quadratic", "cubic"]
In [86]: df = pd.DataFrame({m: ser.interpolate(method=m) for m in methods})
In [87]: df.plot()
Another use case is interpolation at new values. Suppose you have 100 observations from some distribution. And let’s suppose that you’re particularly interested in what’s happening around the middle. You can mix pandas’ `reindex` and `interpolate` methods to interpolate at the new values.

```
in [88]: ser = pd.Series(np.sort(np.random.uniform(size=100)))

# interpolate at new_index
in [89]: new_index = ser.index.union(pd.Index([49.25, 49.5, 49.75, 50.25, 50.5, 50.75]))

in [90]: interp_s = ser.reindex(new_index).interpolate(method="pchip")

in [91]: interp_s[49:51]
```

```python
Out[91]:
49.00  0.471410
49.25  0.476841
49.50  0.481780
49.75  0.485998
50.00  0.489266
50.25  0.491814
50.50  0.493995
50.75  0.495763
51.00  0.497074
```

dtype: float64
Interpolation limits

Like other pandas fill methods, \texttt{interpolate()} accepts a \texttt{limit} keyword argument. Use this argument to limit the number of consecutive NaN values filled since the last valid observation:

\begin{verbatim}
In [92]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan, np.nan, 13, np.nan, np.nan])
In [93]: ser
Out[93]:
0    NaN
1    NaN
2     5.0
3    NaN
4    NaN
5    NaN
6    13.0
7    NaN
8    NaN
dtype: float64

# fill all consecutive values in a forward direction
In [94]: ser.interpolate()
Out[94]:
0    NaN
1    NaN
2    5.0
3    7.0
4    9.0
5    11.0
6    13.0
7    13.0
8    13.0

dtype: float64

# fill one consecutive value in a forward direction
In [95]: ser.interpolate(limit=1)
Out[95]:
0    NaN
1     5.0
2    NaN
3    NaN
4    NaN
5    NaN
6    13.0
7    13.0
8    NaN

dtype: float64
\end{verbatim}

By default, NaN values are filled in a forward direction. Use \texttt{limit\_direction} parameter to fill backward or from both directions.

\begin{verbatim}
# fill one consecutive value backwards
In [96]: ser.interpolate(limit=1, limit\_direction="backward")
Out[96]:
0    NaN
1     5.0
2     5.0
\end{verbatim}
# fill one consecutive value in both directions
In [97]: ser.interpolate(limit=1, limit_direction="both")
Out[97]:
0     NaN
1      5.0
2      5.0
3      7.0
4     NaN
5     11.0
6      13.0
7      13.0
8     NaN
dtype: float64

# fill all consecutive values in both directions
In [98]: ser.interpolate(limit_direction="both")
Out[98]:
0      5.0
1      5.0
2      5.0
3      7.0
4      9.0
5     11.0
6     13.0
7     13.0
8     13.0
dtype: float64

By default, NaN values are filled whether they are inside (surrounded by) existing valid values, or outside existing valid values. The limit_area parameter restricts filling to either inside or outside values.

# fill one consecutive inside value in both directions
In [99]: ser.interpolate(limit_direction="both", limit_area="inside", limit=1)
Out[99]:
0     NaN
1     NaN
2      5.0
3      7.0
4     NaN
5     11.0
6     13.0
7     13.0
8     NaN
dtype: float64

# fill all consecutive outside values backward
In [100]: ser.interpolate(limit_direction="backward", limit_area="outside")
Out[100]:
... (continues on next page)
# fill all consecutive outside values in both directions
In [101]: ser.interpolate(limit_direction="both", limit_area="outside")
Out[101]:
   0   5.0  
   1   5.0  
   2   5.0  
   3   NaN  
   4   NaN  
   5   NaN  
   6  13.0  
   7  13.0  
   8  13.0  

2.10.10 Replacing generic values

Often times we want to replace arbitrary values with other values.

replace() in Series and replace() in DataFrame provides an efficient yet flexible way to perform such replacements.

For a Series, you can replace a single value or a list of values by another value:

In [102]: ser = pd.Series([0.0, 1.0, 2.0, 3.0, 4.0])
In [103]: ser.replace(0, 5)
Out[103]:
   0   5.0  
   1   1.0  
   2   2.0  
   3   3.0  
   4   4.0  

dtype: float64

You can replace a list of values by a list of other values:

In [104]: ser.replace({0, 1, 2, 3, 4}, {4, 3, 2, 1, 0})
Out[104]:
   0   4.0  
   1   3.0  
   2   2.0  
   3   1.0  
   4   0.0  

dtype: float64
You can also specify a mapping dict:

```python
In [105]: ser.replace({0: 10, 1: 100})
Out[105]:
0  10.0
1  100.0
2   2.0
3   3.0
4   4.0
dtype: float64
```

For a DataFrame, you can specify individual values by column:

```python
In [106]: df = pd.DataFrame({"a": [0, 1, 2, 3, 4], "b": [5, 6, 7, 8, 9]})
In [107]: df.replace(\{"a": 0, "b": 5\}, 100)
Out[107]:
a b
0 100 100
1  1  6
2  2  7
3  3  8
4  4  9
```

Instead of replacing with specified values, you can treat all given values as missing and interpolate over them:

```python
In [108]: ser.replace([1, 2, 3], method="pad")
Out[108]:
0  0.0
1  0.0
2  0.0
3  0.0
4  4.0
dtype: float64
```

### 2.10.11 String/regular expression replacement

**Note:** Python strings prefixed with the `r` character such as `r'hello world'` are so-called “raw” strings. They have different semantics regarding backslashes than strings without this prefix. Backslashes in raw strings will be interpreted as an escaped backslash, e.g., `r\\` == `'`\`. You should read about them if this is unclear.

Replace the `'` with NaN (str -> str):

```python
In [109]: d = {"a": list(range(4)), "b": list("ab.."), "c": ["a", "b", np.nan, "d"]}
In [110]: df = pd.DataFrame(d)
In [111]: df.replace("\." , np.nan)
Out[111]:
a  b  c
0  a  a
1  b  b
2  NaN NaN
3  NaN d
```
Now do it with a regular expression that removes surrounding whitespace (regex -> regex):

```python
In [112]: df.replace(r"\s*\.\s*", np.nan, regex=True)
Out[112]:
    a  b  c
0  0  a  a
1  1  b  b
2  NaN NaN
3  NaN d
```

Replace a few different values (list -> list):

```python
In [113]: df.replace(['a', '.'], ['b', np.nan])
Out[113]:
    a  b  c
0  0  b  b
1  1  b  b
2  NaN NaN
3  NaN d
```

List of regex -> list of regex:

```python
In [114]: df.replace([r'\.', r'(a)' ], [ 'dot', r'\1stuff'], regex=True)
Out[114]:
    a  b  c
0  astuff astuff
1  b  b
2  dot  NaN
3  dot  d
```

Only search in column 'b' (dict -> dict):

```python
In [115]: df.replace( {"b": "."}, {"b": np.nan})
Out[115]:
    a  b  c
0  0  a  a
1  1  b  b
2  NaN NaN
3  NaN d
```

Same as the previous example, but use a regular expression for searching instead (dict of regex -> dict):

```python
In [116]: df.replace( {"b": r"\s*\.\s*"}, {"b": np.nan}, regex=True)
Out[116]:
    a  b  c
0  0  a  a
1  1  b  b
2  NaN NaN
3  NaN d
```

You can pass nested dictionaries of regular expressions that use regex=True:

```python
In [117]: df.replace( {"b": {"b": r"\s*\.\s*"}}, {"b": np.nan}, regex=True)
Out[117]:
    a  b  c
0  0  a  a
1  1  b
```

(continues on next page)
Alternatively, you can pass the nested dictionary like so:

```python
In [118]: df.replace({"b": {r"\s*\.(\s*)": np.nan}})
Out[118]:
a   b   c
0   0   a   a
1   1   b   b
2  NaN  NaN
3  NaN  d
```

You can also use the group of a regular expression match when replacing (dict of regex -> dict of regex), this works for lists as well.

```python
In [119]: df.replace({"b": r"\s*\.(\s*)"},{"b": r"\1ty"}, regex=True)
Out[119]:
a   b   c
0   0   a   a
1   1   b   b
2  .ty  NaN
3  .ty  d
```

You can pass a list of regular expressions, of which those that match will be replaced with a scalar (list of regex -> regex).

```python
In [120]: df.replace([r"\s*\.(\s*)", r"a|b"], np.nan, regex=True)
Out[120]:
a   b   c
0  NaN  NaN
1  NaN  NaN
2  NaN  NaN
3  NaN  d
```

All of the regular expression examples can also be passed with the `to_replace` argument as the `regex` argument. In this case the `value` argument must be passed explicitly by name or `regex` must be a nested dictionary. The previous example, in this case, would then be:

```python
In [121]: df.replace(regex=[r"\s*\.(\s*)", r"a|b"], value=np.nan)
Out[121]:
a   b   c
0  NaN  NaN
1  NaN  NaN
2  NaN  NaN
3  NaN  d
```

This can be convenient if you do not want to pass `regex=True` every time you want to use a regular expression.

**Note:** Anywhere in the above `replace` examples that you see a regular expression a compiled regular expression is valid as well.
### 2.10.12 Numeric replacement

`replace()` is similar to `fillna()`.

| In [122]: df = pd.DataFrame(np.random.randn(10, 2)) |
| In [123]: df[np.random.rand(df.shape[0]) > 0.5] = 1.5 |
| In [124]: df.replace(1.5, np.nan) |
| Out[124]: |
| 0 -0.844214 -1.021415 |
| 1 0.432396 -0.323580 |
| 2 0.423825 0.799180 |
| 3 1.262614 0.751965 |
| 4 NaN NaN |
| 5 NaN NaN |
| 6 -0.498174 -1.060799 |
| 7 0.591667 -0.183257 |
| 8 1.019855 -1.482465 |
| 9 NaN NaN |

Replacing more than one value is possible by passing a list.

| In [125]: df00 = df.iloc[0, 0] |
| In [126]: df.replace([1.5, df00], [np.nan, "a"]) |
| Out[126]: |
| 0 a -1.021415 |
| 1 0.432396 -0.323580 |
| 2 0.423825 0.799180 |
| 3 1.262614 0.751965 |
| 4 NaN NaN |
| 5 NaN NaN |
| 6 -0.498174 -1.060799 |
| 7 0.591667 -0.183257 |
| 8 1.019855 -1.482465 |
| 9 NaN NaN |

| In [127]: df[1].dtype |
| Out[127]: dtype('float64') |

You can also operate on the DataFrame in place:

| In [128]: df.replace(1.5, np.nan, inplace=True) |
Missing data casting rules and indexing

While pandas supports storing arrays of integer and boolean type, these types are not capable of storing missing data. Until we can switch to using a native NA type in NumPy, we’ve established some “casting rules”. When a reindexing operation introduces missing data, the Series will be cast according to the rules introduced in the table below.

<table>
<thead>
<tr>
<th>data type</th>
<th>Cast to</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>float</td>
</tr>
<tr>
<td>boolean</td>
<td>object</td>
</tr>
<tr>
<td>float</td>
<td>no cast</td>
</tr>
<tr>
<td>object</td>
<td>no cast</td>
</tr>
</tbody>
</table>

For example:

```python
In [129]: s = pd.Series(np.random.randn(5), index=[0, 2, 4, 6, 7])

In [130]: s > 0
Out[130]:
0   True
2   True
4   True
6   True
7   True
dtype: bool

In [131]: (s > 0).dtype
Out[131]: dtype('bool')

In [132]: crit = (s > 0).reindex(list(range(8)))

In [133]: crit
Out[133]:
0   True
1   NaN
2   True
3   NaN
4   True
5   NaN
6   True
7   True
dtype: object

In [134]: crit.dtype
Out[134]: dtype('O')
```

Ordinarily NumPy will complain if you try to use an object array (even if it contains boolean values) instead of a boolean array to get or set values from an ndarray (e.g. selecting values based on some criteria). If a boolean vector contains NAs, an exception will be generated:

```python
In [135]: reindexed = s.reindex(list(range(8))).fillna(0)

In [136]: reindexed[crit]
---------------------------------------------------------------------------
ValueError Traceback (most recent call last)
<ipython-input-136-0dac417a4890> in <module>
----> 1 reindexed[crit]

ValueError: could not convert string to float
```

(continues on next page)
However, these can be filled in using `fillna()` and it will work fine:

```
In [137]: reindexed[crit.fillna(False)]
Out[137]:
0   0.126504
1   0.000000
2   0.696198
3   0.000000
4   0.697416
5   0.000000
6   0.601516
7   0.003659
dtype: float64
```

```
In [138]: reindexed[crit.fillna(True)]
Out[138]:
0   0.126504
1   0.000000
2   0.696198
3   0.000000
4   0.697416
5   0.000000
6   0.601516
7   0.003659
dtype: float64
```

pandas provides a nullable integer dtype, but you must explicitly request it when creating the series or column. Notice that we use a capital “I” in the `dtype="Int64"`.

```
In [139]: s = pd.Series([0, 1, np.nan, 3, 4], dtype="Int64")
```

```
In [140]: s
Out[140]:
0    0
1    1
2   <NA>
3    3
4    4
dtype: Int64
```

See Nullable integer data type for more.
2.10.13 Experimental NA scalar to denote missing values

**Warning:** Experimental: the behaviour of `pd.NA` can still change without warning.

New in version 1.0.0.

Starting from pandas 1.0, an experimental `pd.NA` value (singleton) is available to represent scalar missing values. At this moment, it is used in the nullable `integer`, boolean and `dedicated string` data types as the missing value indicator.

The goal of `pd.NA` is provide a “missing” indicator that can be used consistently across data types (instead of `np.nan`, `None` or `pd.NaT` depending on the data type).

For example, when having missing values in a Series with the nullable integer dtype, it will use `pd.NA`:

```python
In [141]: s = pd.Series([1, 2, None], dtype="Int64")

In [142]: s
Out[142]:
0   1
1   2
2   <NA>
dtype: Int64

In [143]: s[2]
Out[143]: <NA>

In [144]: s[2] is pd.NA
Out[144]: True
```

Currently, pandas does not yet use those data types by default (when creating a DataFrame or Series, or when reading in data), so you need to specify the dtype explicitly. An easy way to convert to those dtypes is explained [here](#).

**Propagation in arithmetic and comparison operations**

In general, missing values *propagate* in operations involving `pd.NA`. When one of the operands is unknown, the outcome of the operation is also unknown.

For example, `pd.NA` propagates in arithmetic operations, similarly to `np.nan`:

```python
In [145]: pd.NA + 1
Out[145]: <NA>

In [146]: "a" * pd.NA
Out[146]: <NA>
```

There are a few special cases when the result is known, even when one of the operands is `NA`.

```python
In [147]: pd.NA ** 0
Out[147]: 1

In [148]: 1 ** pd.NA
Out[148]: 1
```

In equality and comparison operations, `pd.NA` also propagates. This deviates from the behaviour of `np.nan`, where comparisons with `np.nan` always return `False`. 
To check if a value is equal to `pd.NA`, the `isna()` function can be used:

```python
In [152]: pd.isna(pd.NA)
Out[152]: True
```

An exception on this basic propagation rule are reductions (such as the mean or the minimum), where pandas defaults to skipping missing values. See above for more.

### Logical operations

For logical operations, `pd.NA` follows the rules of the three-valued logic (or Kleene logic, similarly to R, SQL and Julia). This logic means to only propagate missing values when it is logically required.

For example, for the logical “or” operation (|), if one of the operands is `True`, we already know the result will be `True`, regardless of the other value (so regardless the missing value would be `True` or `False`). In this case, `pd.NA` does not propagate:

```python
In [153]: True | False
Out[153]: True

In [154]: True | pd.NA
Out[154]: True

In [155]: pd.NA | True
Out[155]: True
```

On the other hand, if one of the operands is `False`, the result depends on the value of the other operand. Therefore, in this case `pd.NA` propagates:

```python
In [156]: False | True
Out[156]: True

In [157]: False | False
Out[157]: False

In [158]: False | pd.NA
Out[158]: <NA>
```

The behaviour of the logical “and” operation (&) can be derived using similar logic (where now `pd.NA` will not propagate if one of the operands is already `False`):

```python
In [159]: False & True
Out[159]: False

In [160]: False & False
Out[160]: False
```

(continues on next page)
In [161]: False & pd.NA
Out[161]: False

In [162]: True & True
Out[162]: True

In [163]: True & False
Out[163]: False

In [164]: True & pd.NA
Out[164]: <NA>

NA in a boolean context

Since the actual value of an NA is unknown, it is ambiguous to convert NA to a boolean value. The following raises an error:

```
In [165]: bool(pd.NA)
---------------------------------------------------------------------------
TypeError                       Traceback (most recent call last)
<ipython-input-165-5477a57d5abb> in <module>
      1 bool(pd.NA)
/pandas/pandas/_libs/missing.pyx in pandas._libs.missing.NAType.__bool__()

TypeError: boolean value of NA is ambiguous
```

This also means that `pd.NA` cannot be used in a context where it is evaluated to a boolean, such as `if condition: ...` where `condition` can potentially be `pd.NA`. In such cases, `isna()` can be used to check for `pd.NA` or `condition` being `pd.NA` can be avoided, for example by filling missing values beforehand.

A similar situation occurs when using Series or DataFrame objects in `if` statements, see *Using if/truth statements with pandas*.

NumPy ufuncs

`pandas.NA` implements NumPy’s `__array_ufunc__` protocol. Most ufuncs work with NA, and generally return NA:

```
In [166]: np.log(pd.NA)
Out[166]: <NA>

In [167]: np.add(pd.NA, 1)
Out[167]: <NA>
```

**Warning:** Currently, ufuncs involving an ndarray and `NA` will return an object-dtype filled with `NA` values.

```
In [168]: a = np.array([1, 2, 3])
In [169]: np.greater(a, pd.NA)
Out[169]: array([<NA>, <NA>, <NA>], dtype=object)
```

The return type here may change to return a different array type in the future.
Conversion

If you have a DataFrame or Series using traditional types that have missing data represented using `np.nan`, there are convenience methods `convert_dtypes()` in Series and `convert_dtypes()` in DataFrame that can convert data to use the newer dtypes for integers, strings and booleans listed `here`. This is especially helpful after reading in data sets when letting the readers such as `read_csv()` and `read_excel()` infer default dtypes.

In this example, while the dtypes of all columns are changed, we show the results for the first 10 columns.

```
In [170]: bb = pd.read_csv("data/baseball.csv", index_col="id")
In [171]: bb[bb.columns[:10]].dtypes
Out[171]:
player  object
year    int64
stint   int64
team    object
lg      object
g       int64
ab      int64
r       int64
h       int64
X2b     int64
dtype: object

In [172]: bbn = bb.convert_dtypes()
In [173]: bbn[bbn.columns[:10]].dtypes
Out[173]:
player    string
year   Int64
stint   Int64
team    string
lg      string
g      Int64
ab     Int64
r      Int64
h      Int64
X2b    Int64
dtype: object
```

2.11 Duplicate Labels

Index objects are not required to be unique; you can have duplicate row or column labels. This may be a bit confusing at first. If you’re familiar with SQL, you know that row labels are similar to a primary key on a table, and you would never want duplicates in a SQL table. But one of pandas’ roles is to clean messy, real-world data before it goes to some downstream system. And real-world data has duplicates, even in fields that are supposed to be unique.

This section describes how duplicate labels change the behavior of certain operations, and how prevent duplicates from arising during operations, or to detect them if they do.
2.11.1 Consequences of Duplicate Labels

Some pandas methods (Series.reindex() for example) just don’t work with duplicates present. The output can’t be determined, and so pandas raises.

```
In [3]: s1 = pd.Series([0, 1, 2], index=["a", "b", "b")
In [4]: s1.reindex(["a", "b", "c")]
---------------------------------------------------------------------------
ValueError Traceback (most recent call last)
<ipython-input-4-18a38f6978fe> in
----> 1 s1.reindex(["a", "b", "c")]
pandas/pandas/core/series.py in reindex(self, index, **kwargs)
 4577     def reindex(self, index=None, **kwargs):
 4578         return super().reindex(index=index, **kwargs)
 4580     
 4581 @deprecate_nonkeyword_arguments(version=None, allowed_args=["self", ...
```

```
/pandas/pandas/core/generic.py in reindex(self, *args, **kwargs)
 4807     # perform the reindex on the axes
 4808     axes, level, limit, tolerance, method, fill_value, copy
 4809     return self._reindex_axes(axes, level, limit, tolerance, method, fill_value, copy)
 4811     ).__finalize__(self, method="reindex")
```

```
/pandas/pandas/core/generic.py in _reindex_axes(self, axes, level, limit, tolerance, method, fill_value, copy)
 4828     axis = self._get_axis_number(a)
 4829     obj = obj._reindex_with_indexers(axes, level, limit, tolerance, method, fill_value, copy)
 4830     fill_value=fill_value,
```

```
/pandas/pandas/core/generic.py in _reindex_with_indexers(self, reindexers, fill_value, copy, allow_dups)
 4872     new_data = new_data.reindex_indexer(index, indexer,
 4873     copy, consolidate, only_slice)
```

```
/pandas/pandas/core/internals/managers.py in reindex_indexer(self, new_axis, indexer, axis, fill_value, allow_dups, copy, consolidate, only_slice)
 664     if some axes don’t allow reindexing with dup
 665     if not allow_dups:
 666     self.axes[axis]._validate_can_reindex(indexer)
 667     if axis >= self.ndim:
```

(continues on next page)
Other methods, like indexing, can give very surprising results. Typically indexing with a scalar will reduce dimensionality. Slicing a DataFrame with a scalar will return a Series. Slicing a Series with a scalar will return a scalar. But with duplicates, this isn’t the case.

We have duplicates in the columns. If we slice 'B', we get back a Series

But slicing 'A' returns a DataFrame

This applies to row labels as well
2.11.2 Duplicate Label Detection

You can check whether an Index (storing the row or column labels) is unique with `Index.is_unique`:

```
In [13]: df2
Out[13]:
A
a 0
a 1
b 2

In [14]: df2.index.is_unique
Out[14]: False

In [15]: df2.columns.is_unique
Out[15]: True
```

**Note:** Checking whether an index is unique is somewhat expensive for large datasets. pandas does cache this result, so re-checking on the same index is very fast.

`Index.duplicated()` will return a boolean ndarray indicating whether a label is repeated.

```
In [16]: df2.index.duplicated()
Out[16]: array([False, True, False])
```

Which can be used as a boolean filter to drop duplicate rows.

```
In [17]: df2.loc[~df2.index.duplicated(), :]
Out[17]:
A
a 0
b 2
```

If you need additional logic to handle duplicate labels, rather than just dropping the repeats, using `groupby()` on the index is a common trick. For example, we’ll resolve duplicates by taking the average of all rows with the same label.

```
In [18]: df2.groupby(level=0).mean()
Out[18]:
A
a 0.5
b 2.0
```

2.11.3 Disallowing Duplicate Labels

New in version 1.2.0.

As noted above, handling duplicates is an important feature when reading in raw data. That said, you may want to avoid introducing duplicates as part of a data processing pipeline (from methods like `pandas.concat()`, `rename()`, etc.). Both Series and DataFrame disallow duplicate labels by calling `.set_flags(allows_duplicate_labels=False)` (the default is to allow them). If there are duplicate labels, an exception will be raised.
In [19]: pd.Series([0, 1, 2], index=['a', 'b', 'b']).set_flags(allows_duplicate_labels=False)

---------------------------------------------------------------------------
DuplicateLabelError Traceback (most recent call last)
<ipython-input-19-11af4ee9738e> in
----> 1 pd.Series([0, 1, 2], index=['a', 'b', 'b']).set_flags(allows_duplicate_labels=False)
/pandas/pandas/core/generic.py in set_flags(self, copy, allows_duplicate_labels)
429 df = self.copy(deep=copy)
430 if allows_duplicate_labels is not None:
--> 431 df.flags['allows_duplicate_labels'] = allows_duplicate_labels
432 return df
433
/pandas/pandas/core/flags.py in __setitem__(self, key, value)
103 if key not in self._keys:
104 raise ValueError(f"Unknown flag {key}. Must be one of {self._keys}"
--> 105 setattr(self, key, value)
106
107 def __repr__(self):
/pandas/pandas/core/flags.py in allows_duplicate_labels(self, value)
90 if not value:
91 for ax in obj.axes:
--> 92 ax._maybe_check_unique()
93 self._allows_duplicate_labels = value
94
/pandas/pandas/core/indexes/base.py in _maybe_check_unique(self)
649 msg += f"n/duplicates/"
650
--> 651 raise DuplicateLabelError(msg)
652
653 @final

DuplicateLabelError: Index has duplicates.

This applies to both row and column labels for a DataFrame

In [20]: pd.DataFrame([[0, 1, 2], [3, 4, 5]], columns=['A', 'B', 'C']).set_flags( ....: allows_duplicate_labels=False ....: )

Out[20]:
   A  B  C
0  0  1  2
1  3  4  5

This attribute can be checked or set with allows_duplicate_labels, which indicates whether that object can have duplicate labels.

In [21]: df = pd.DataFrame({'A': [0, 1, 2, 3], 'x': [4, 5, 6, 7], 'y': [8, 9, 10, 11], 'X': [12, 13, 14, 15], 'Y': [16, 17, 18, 19]}).set_flags(....: allows_duplicate_labels=True)

This applies to both row and column labels for a DataFrame.

In [22]: df = pd.DataFrame({'A': [0, 1, 2, 3], 'x': [4, 5, 6, 7], 'y': [8, 9, 10, 11], 'X': [12, 13, 14, 15], 'Y': [16, 17, 18, 19]}).set_flags(...: allows_duplicate_labels=False)

This attribute can be checked or set with allows_duplicate_labels, which indicates whether that object can have duplicate labels.
allows_duplicate_labels=True

In [22]: df
Out[22]:
   A  0
  y  1
  x  2
  y  3

In [23]: df.flags.allows_duplicate_labels
Out[23]: False

DataFrame.set_flags() can be used to return a new DataFrame with attributes like allows_duplicate_labels set to some value

In [24]: df2 = df.set_flags(allows_duplicate_labels=True)
In [25]: df2.flags.allows_duplicate_labels
Out[25]: True

The new DataFrame returned is a view on the same data as the old DataFrame. Or the property can just be set directly on the same object

In [26]: df2.flags.allows_duplicate_labels = False
In [27]: df2.flags.allows_duplicate_labels
Out[27]: False

When processing raw, messy data you might initially read in the messy data (which potentially has duplicate labels), deduplicate, and then disallow duplicates going forward, to ensure that your data pipeline doesn’t introduce duplicates.

```python
>>> raw = pd.read_csv("...")
>>> deduplicated = raw.groupby(level=0).first()  # remove duplicates
>>> deduplicated.flags.allows_duplicate_labels = False  # disallow going forward
```

Setting allows_duplicate_labels=True on a Series or DataFrame with duplicate labels or performing an operation that introduces duplicate labels on a Series or DataFrame that disallows duplicates will raise an errors.DuplicateLabelError.

```
In [28]: df.rename(str.upper)

    324     
    325     kind = inspect.Parameter.POSITIONAL_OR_KEYWORD
/pandas/pandas/core/frame.py in rename(self, mapper, index, columns, axis, copy,
`inplace, level, errors)
```

2.11. Duplicate Labels

(continues on next page)
This error message contains the labels that are duplicated, and the numeric positions of all the duplicates (including the “original”) in the Series or DataFrame.
Duplicate Label Propagation

In general, disallowing duplicates is “sticky”. It’s preserved through operations.

```python
In [29]: s1 = pd.Series(0, index=["a", "b"]).set_flags(allow_duplicate_labels=False)

In [30]: s1
Out[30]:
a 0
b 0
dtype: int64

In [31]: s1.head().rename{"a": "b"})
---------------------------------------------------------------------------
DuplicateLabelError Traceback (most recent call last)
<ipython-input-31-8f09bda3af1a> in <module>
----> 1 s1.head().rename{"a": "b"})
/pandas/pandas/core/series.py in rename(self, index, axis, copy, inplace, level,_
   4515     ""
   4516     if callable(index) or is_dict_like(index):
-> 4517         return super().rename(
   4518         index, copy=copy, inplace=inplace, level=level, errors=errors
   4519         )
/pandas/pandas/core/generic.py in rename(self, mapper, index, columns, axis, copy, _
   1159     return None
   1160     else:
-> 1161         return result.__finalize__(self, method="rename")
   1162     @rewrite_axis_style_signature("mapper", [("copy", True), ("inplace", _
   1163     False)])
/pandas/pandas/core/generic.py in __finalize__(self, other, method, **kwargs)
   5448         self.attrs[name] = other.attrs[name]
   5449     -> 5450         self.flags.allows_duplicate_labels = other.flags.allows_duplicate_labels
   5451     # For subclasses using _metadata.
   5452     for name in set(self._metadata) & set(other._metadata):
/pandas/pandas/core/flags.py in allows_duplicate_labels(self, value)
   90     if not value:
   91         for ax in obj.axes:
---> 92             ax._maybe_check_unique()
   93             self._allows_duplicate_labels = value
/pandas/pandas/core/indexes/base.py in _maybe_check_unique(self)
   649     msg += f"\n\n(duplicates)"
   650     --> 651         raise DuplicateLabelError(msg)
   652     653     @final
DuplicateLabelError: Index has duplicates.
```

(continues on next page)
2.12 Categorical data

This is an introduction to pandas categorical data type, including a short comparison with R’s `factor`.

Categoricals are a pandas data type corresponding to categorical variables in statistics. A categorical variable takes on a limited, and usually fixed, number of possible values (categories; levels in R). Examples are gender, social class, blood type, country affiliation, observation time or rating via Likert scales.

In contrast to statistical categorical variables, categorical data might have an order (e.g. ‘strongly agree’ vs ‘agree’ or ‘first observation’ vs. ‘second observation’), but numerical operations (additions, divisions, . . .) are not possible.

All values of categorical data are either in categories or np.nan. Order is defined by the order of categories, not lexical order of the values. Internally, the data structure consists of a categories array and an integer array of codes which point to the real value in the categories array.

The categorical data type is useful in the following cases:

- A string variable consisting of only a few different values. Converting such a string variable to a categorical variable will save some memory, see here.
- The lexical order of a variable is not the same as the logical order (“one”, “two”, “three”). By converting to a categorical and specifying an order on the categories, sorting and min/max will use the logical order instead of the lexical order, see here.
- As a signal to other Python libraries that this column should be treated as a categorical variable (e.g. to use suitable statistical methods or plot types).

See also the API docs on categoricals.

2.12.1 Object creation

Series creation

Categorical Series or columns in a DataFrame can be created in several ways:

By specifying dtype=category when constructing a Series:

```
In [1]: s = pd.Series(['a', 'b', 'c', 'a'], dtype='category')
In [2]: s
Out[2]:
0    a
1    b
2    c
3    a
```

Warning: This is an experimental feature. Currently, many methods fail to propagate the allows_duplicate_labels value. In future versions it is expected that every method taking or returning one or more DataFrame or Series objects will propagate allows_duplicate_labels.
By converting an existing Series or column to a category dtype:

In [3]: df = pd.DataFrame({"A": ["a", "b", "c", "a"]})
In [4]: df["B"] = df["A"].astype("category")
In [5]: df

```
   A  B
0  a  a
1  b  b
2  c  c
3  a  a
```

By using special functions, such as cut(), which groups data into discrete bins. See the example on tiling in the docs.

In [6]: df = pd.DataFrame({"value": np.random.randint(0, 100, 20)})
In [7]: labels = ["{0} - {1}".format(i, i + 9) for i in range(0, 100, 10)]
In [8]: df["group"] = pd.cut(df.value, range(0, 105, 10), right=False, labels=labels)
In [9]: df.head(10)

```
   value group
0   65  60 - 69
1   49  40 - 49
2   56  50 - 59
3   43  40 - 49
4   43  40 - 49
5   91  90 - 99
6   32  30 - 39
7   87  80 - 89
8   36  30 - 39
9    8  0 - 9
```

By passing a pandas.Categorical object to a Series or assigning it to a DataFrame.

In [10]: raw_cat = pd.Categorical(
      ....:     ["a", "b", "c", "a"], categories=["b", "c", "d"], ordered=False
      ....:     )
In [11]: s = pd.Series(raw_cat)
In [12]: s

```
0  NaN
1  b
2  c
3  NaN
```

dtype: category

(continued from previous page)
In [13]: df = pd.DataFrame(["A": ["a", "b", "c", "a"]])

In [14]: df["B"] = raw_cat

In [15]: df
Out[15]:
   A B
0  a NaN
1  b  b
2  c  c
3  a NaN

Categorical data has a specific category `dtype`:

```
In [16]: df.dtypes
Out[16]:
A    object
B  category
dtype: object
```

**Dataframe creation**

Similar to the previous section where a single column was converted to categorical, all columns in a DataFrame can be batch converted to categorical either during or after construction.

This can be done during construction by specifying `dtype="category"` in the DataFrame constructor:

```
In [17]: df = pd.DataFrame(["A": list("abca"), "B": list("bccd")], dtype="category")

In [18]: df.dtypes
Out[18]:
A    category
B  category
dtype: object
```

Note that the categories present in each column differ; the conversion is done column by column, so only labels present in a given column are categories:

```
In [19]: df["A"]
Out[19]:
0  a
1  b
2  c
3  a
Name: A, dtype: category
Categories (3, object): ['a', 'b', 'c']

In [20]: df["B"]
Out[20]:
0  b
1  c
2  c
3  d
```
Analogously, all columns in an existing DataFrame can be batch converted using `DataFrame.astype()`:

```python
In [21]: df = pd.DataFrame({"A": list("abca"), "B": list("bccd"))
In [22]: df_cat = df.astype("category")
In [23]: df_cat.dtypes
Out[23]:
A    category
B    category
dtype: object
```

This conversion is likewise done column by column:

```python
In [24]: df_cat["A"]
Out[24]:
0  a
1  b
2  c
3  a
Name: A, dtype: category
Categories (3, object): ['a', 'b', 'c']
```

```python
In [25]: df_cat["B"]
Out[25]:
0  b
1  c
2  c
3  d
Name: B, dtype: category
Categories (3, object): ['b', 'c', 'd']
```

### Controlling behavior

In the examples above where we passed `dtype='category'`, we used the default behavior:

1. Categories are inferred from the data.
2. Categories are unordered.

To control those behaviors, instead of passing `dtype='category'`, use an instance of `CategoricalDtype`.

```python
In [26]: from pandas.api.types import CategoricalDtype
In [27]: s = pd.Series(["a", "b", "c", "a")
In [28]: cat_type = CategoricalDtype(categories=["b", "c", "d"], ordered=True)
In [29]: s_cat = s.astype(cat_type)
In [30]: s_cat
Out[30]:
0  NaN
```

(continues on next page)
Similarly, a CategoricalDtype can be used with a DataFrame to ensure that categories are consistent among all columns.

```python
In [31]: from pandas.api.types import CategoricalDtype

In [32]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})

In [33]: cat_type = CategoricalDtype(categories=list('abcd'), ordered=True)

In [34]: df_cat = df.astype(cat_type)

In [35]: df_cat['A']
Out[35]:
0     a
1     b
2     c
3     a
Name: A, dtype: category
Categories (4, object): ['a' < 'b' < 'c' < 'd']

In [36]: df_cat['B']
Out[36]:
0     b
1     c
2     c
3     d
Name: B, dtype: category
Categories (4, object): ['a' < 'b' < 'c' < 'd']
```

**Note:** To perform table-wise conversion, where all labels in the entire DataFrame are used as categories for each column, the `categories` parameter can be determined programmatically by `categories = pd.unique(df.to_numpy().ravel())`.

If you already have codes and categories, you can use the `from_codes()` constructor to save the factorize step during normal constructor mode:

```python
In [37]: splitter = np.random.choice([0, 1], 5, p=[0.5, 0.5])

In [38]: s = pd.Series(pd.Categorical.from_codes(splitter, categories=['train', 'test']))
```
Regaining original data

To get back to the original `Series` or NumPy array, use `Series.astype(original_dtype)` or `np.asarray(categorical)`:  

```python
In [39]: s = pd.Series(["a", "b", "c", "a"])
In [40]: s
Out[40]:
0   a
1   b
2   c
3   a
dtype: object
In [41]: s2 = s.astype("category")
In [42]: s2
Out[42]:
0   a
1   b
2   c
3   a
dtype: category
Categories (3, object): [ 'a', 'b', 'c' ]
In [43]: s2.astype(str)
Out[43]:
0   a
1   b
2   c
3   a
dtype: object
In [44]: np.asarray(s2)
Out[44]: array([ 'a', 'b', 'c', 'a' ], dtype=object)
```

**Note:** In contrast to R’s `factor` function, categorical data is not converting input values to strings; categories will end up the same data type as the original values.

**Note:** In contrast to R’s `factor` function, there is currently no way to assign/change labels at creation time. Use `categories` to change the categories after creation time.
2.12.2 CategoricalDtype

A categorical’s type is fully described by

1. categories: a sequence of unique values and no missing values
2. ordered: a boolean

This information can be stored in a CategoricalDtype. The categories argument is optional, which implies that the actual categories should be inferred from whatever is present in the data when the pandas.Categorical is created. The categories are assumed to be unordered by default.

```python
In [45]: from pandas.api.types import CategoricalDtype

In [46]: CategoricalDtype(['a', 'b', 'c'])
Out[46]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=False)

In [47]: CategoricalDtype(['a', 'b', 'c'], ordered=True)
Out[47]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=True)

In [48]: CategoricalDtype()
Out[48]: CategoricalDtype(categories=None, ordered=False)
```

A CategoricalDtype can be used in any place pandas expects a dtype. For example pandas.read_csv(), pandas.DataFrame.astype(), or in the Series constructor.

Note: As a convenience, you can use the string 'category' in place of a CategoricalDtype when you want the default behavior of the categories being unordered, and equal to the set values present in the array. In other words, dtype='category' is equivalent to dtype=CategoricalDtype().

### Equality semantics

Two instances of CategoricalDtype compare equal whenever they have the same categories and order. When comparing two unordered categoricals, the order of the categories is not considered.

```python
In [49]: c1 = CategoricalDtype(['a', 'b', 'c'], ordered=False)

# Equal, since order is not considered when ordered=False
In [50]: c1 == CategoricalDtype(['b', 'c', 'a'], ordered=False)
Out[50]: True

# Unequal, since the second CategoricalDtype is ordered
In [51]: c1 == CategoricalDtype(['a', 'b', 'c'], ordered=True)
Out[51]: False
```

All instances of CategoricalDtype compare equal to the string 'category'.

```python
In [52]: c1 == "category"
Out[52]: True
```

Warning: Since dtype='category' is essentially CategoricalDtype(None, False), and since all instances CategoricalDtype compare equal to 'category', all instances of CategoricalDtype compare equal to a CategoricalDtype(None, False), regardless of categories or ordered.
2.12.3 Description

Using `describe()` on categorical data will produce similar output to a Series or DataFrame of type string.

```python
In [53]: cat = pd.Categorical(
    ...:     ['a', 'c', 'c', np.nan], categories=['b', 'a', 'c'])

In [54]: df = pd.DataFrame(
    ...:     {'cat': cat, 's': ['a', 'c', 'c', np.nan]})

In [55]: df.describe()
Out[55]:
   cat  s
  count 3 3
  unique 2 2
  top  c  c
  freq 2 2

In [56]: df['cat'].describe()
Out[56]:
   count 3
  unique 2
  top  c
  freq 2
Name: cat, dtype: object
```

2.12.4 Working with categories

Categorical data has a `categories` and a `ordered` property, which list their possible values and whether the ordering matters or not. These properties are exposed as `s.cat.categories` and `s.cat.ordered`. If you don’t manually specify categories and ordering, they are inferred from the passed arguments.

```python
In [57]: s = pd.Series(['a', 'b', 'c', 'a'], dtype='category')

In [58]: s.cat.categories
Out[58]: Index(['a', 'b', 'c'], dtype='object')

In [59]: s.cat.ordered
Out[59]: False
```

It’s also possible to pass in the categories in a specific order:

```python
In [60]: s = pd.Series(pd.Categorical(['a', 'b', 'c', 'a'], categories=['c', 'b', 'a']))

In [61]: s.cat.categories
Out[61]: Index(['c', 'b', 'a'], dtype='object')

In [62]: s.cat.ordered
Out[62]: False
```

**Note:** New categorical data are **not** automatically ordered. You must explicitly pass `ordered=True` to indicate an ordered `Categorical`.

**Note:** The result of `unique()` is not always the same as `Series.cat.categories`, because `Series.unique()` has a couple of guarantees, namely that it returns categories in the order of appearance, and it only
includes values that are actually present.

```python
In [63]: s = pd.Series(list("babc"), dtype(CategoricalDtype(list("abcd"))))

In [64]: s
Out[64]:
0 b
1 a
2 b
3 c
dtype: category
Categories (4, object): ['a', 'b', 'c', 'd']

# categories
In [65]: s.cat.categories
Out[65]: Index(['a', 'b', 'c', 'd'], dtype='object')

# uniques
In [66]: s.unique()
Out[66]:
['b', 'a', 'c']
Categories (4, object): ['a', 'b', 'c', 'd']

Renaming categories

Renaming categories is done by assigning new values to the `Series.cat.categories` property or by using the `rename_categories()` method:

```python
In [67]: s = pd.Series(["a", "b", "c", "a"], dtype="category")

In [68]: s
Out[68]:
0 a
1 b
2 c
3 a
dtype: category
Categories (3, object): ['a', 'b', 'c']

In [69]: s.cat.categories = ["Group %s" % g for g in s.cat.categories]

In [70]: s
Out[70]:
0  Group a
1  Group b
2  Group c
3  Group a
dtype: category
Categories (3, object): ['Group a', 'Group b', 'Group c']

In [71]: s = s.cat.rename_categories([1, 2, 3])

In [72]: s
Out[72]:
0  1
```

(continues on next page)
Note: In contrast to R’s `factor`, categorical data can have categories of other types than string.

Note: Be aware that assigning new categories is an inplace operation, while most other operations under `Series.cat` per default return a new `Series` of dtype `category`.

Categories must be unique or a `ValueError` is raised:

```python
In [75]: try:
    ....:     s.cat.categories = [1, 1, 1]
    ....: except ValueError as e:
    ....:     print("ValueError:", str(e))
    ....:
ValueError: Categorical categories must be unique
```

Categories must also not be `NaN` or a `ValueError` is raised:

```python
In [76]: try:
    ....:     s.cat.categories = [1, 2, np.nan]
    ....: except ValueError as e:
    ....:     print("ValueError:", str(e))
    ....:
ValueError: Categorical categories cannot be null
```

### Appending new categories

Appending categories can be done by using the `add_categories()` method:

```python
In [77]: s = s.cat.add_categories([4])
In [78]: s.cat.categories
Out[78]: Index(['x', 'y', 'z', 4], dtype='object')
In [79]: s
```

(continues on next page)
Removing categories

Removing categories can be done by using the `remove_categories()` method. Values which are removed are replaced by `np.nan`:

```python
In [80]: s = s.cat.remove_categories([4])
In [81]: s
Out[81]:
0  x
1  y
2  z
3  x
dtype: category
Categories (3, object): ['x', 'y', 'z']
```

Removing unused categories

Removing unused categories can also be done:

```python
In [82]: s = pd.Series(pd.Categorical(['a', 'b', 'a'], categories=['a', 'b', 'c', 'd']))
In [83]: s
Out[83]:
0  a
1  b
2  a
dtype: category
Categories (4, object): ['a', 'b', 'c', 'd']
In [84]: s.cat.remove_unused_categories()
Out[84]:
0  a
1  b
2  a
dtype: category
Categories (2, object): ['a', 'b']
```
Setting categories

If you want to do remove and add new categories in one step (which has some speed advantage), or simply set the categories to a predefined scale, use `set_categories()`.

```python
In [85]: s = pd.Series(["one", "two", "four", ","], dtype="category")

In [86]: s
Out[86]:
0 one
1 two
2 four
3 -
dtype: category
Categories (4, object): [',', 'four', 'one', 'two']

In [87]: s = s.cat.set_categories(["one", "two", "three", "four"])

In [88]: s
Out[88]:
0 one
1 two
2 four
3 NaN
dtype: category
Categories (4, object): ['one', 'two', 'three', 'four']
```

Note: Be aware that `Categorical.set_categories()` cannot know whether some category is omitted intentionally or because it is misspelled or (under Python3) due to a type difference (e.g., NumPy S1 dtype and Python strings). This can result in surprising behaviour!

2.12.5 Sorting and order

If categorical data is ordered (`s.cat.ordered == True`), then the order of the categories has a meaning and certain operations are possible. If the categorical is unordered, `.min()/.max()` will raise a `TypeError`.

```python
In [89]: s = pd.Series(pd.Categorical(["a", "b", "c", "a"], ordered=False))

In [90]: s.sort_values(inplace=True)

In [91]: s = pd.Series(["a", "b", "c", "a"]).astype(CategoricalDtype(ordered=True))

In [92]: s.sort_values(inplace=True)

In [93]: s
Out[93]:
0 a
3 a
1 b
2 c
dtype: category
Categories (3, object): ['a' < 'b' < 'c']
```

(continues on next page)
In [94]: s.min(), s.max()
Out[94]: ('a', 'c')

You can set categorical data to be ordered by using `as_ordered()` or unordered by using `as_unordered()`. These will by default return a new object.

In [95]: s.cat.as_ordered()
Out[95]:
0  a
1  b
2  c
dtype: category
Categories (3, object): ['a' < 'b' < 'c']

In [96]: s.cat.as_unordered()
Out[96]:
0  a
1  b
2  c
dtype: category
Categories (3, object): ['a', 'b', 'c']

Sorting will use the order defined by categories, not any lexical order present on the data type. This is even true for strings and numeric data:

In [97]: s = pd.Series([1, 2, 3, 1], dtype="category")
In [98]: s = s.cat.set_categories([2, 3, 1], ordered=True)
In [99]: s
Out[99]:
0  1
1  2
2  3
3  1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [100]: s.sort_values(inplace=True)
In [101]: s
Out[101]:
1  2
2  3
0  1
3  1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [102]: s.min(), s.max()
Out[102]: (2, 1)
Reordering

Reordering the categories is possible via the `Categorical.reorder_categories()` and the `Categorical.set_categories()` methods. For `Categorical.reorder_categories()`, all old categories must be included in the new categories and no new categories are allowed. This will necessarily make the sort order the same as the categories order.

```python
In [103]: s = pd.Series([1, 2, 3, 1], dtype="category")
In [104]: s = s.cat.reorder_categories([2, 3, 1], ordered=True)
In [105]: s
Out [105]:
0 1
1 2
2 3
3 1
dtype: category
Categories (3, int64): [2 < 3 < 1]
In [106]: s.sort_values(inplace=True)
In [107]: s
Out [107]:
1 2
2 3
0 1
3 1
dtype: category
Categories (3, int64): [2 < 3 < 1]
In [108]: s.min(), s.max()
Out [108]: (2, 1)
```

**Note:** Note the difference between assigning new categories and reordering the categories: the first renames categories and therefore the individual values in the `Series`, but if the first position was sorted last, the renamed value will still be sorted last. Reordering means that the way values are sorted is different afterwards, but not that individual values in the `Series` are changed.

**Note:** If the `Categorical` is not ordered, `Series.min()` and `Series.max()` will raise `TypeError`. Numeric operations like `+`, `-`, `*`, `/` and operations based on them (e.g. `Series.median()`, which would need to compute the mean between two values if the length of an array is even) do not work and raise a `TypeError`.

2.12. Categorical data
Multi column sorting

A categorical dtyped column will participate in a multi-column sort in a similar manner to other columns. The ordering of the categorical is determined by the categories of that column.

```
In [109]: dfs = pd.DataFrame(
    ....:     {  
    ....:         "A": pd.Categorical(
    ....:             list("bbeebbaa"),  
    ....:             categories=['e', 'a', 'b'],  
    ....:             ordered=True,  
    ....:         ),  
    ....:         "B": [1, 2, 1, 2, 2, 1, 2, 1],  
    ....:     })  
    ....:  
In [110]: dfs.sort_values(by=['A', 'B'])
```

```
Out[110]:  
   A B  
0  b 1  
1  b 2  
2  e 1  
3  e 2  
4  b 1  
5  b 1  
6  a 2  
7  a 1  
```

Reordering the categories changes a future sort.

```
In [111]: dfs["A"] = dfs["A"].cat.reorder_categories(['a', 'b', 'e'])
In [112]: dfs.sort_values(by=['A', 'B'])
```

```
Out[112]:  
   A B  
0  b 1  
1  b 2  
2  e 1  
3  e 2  
4  b 2  
5  b 1  
6  a 2  
7  a 1  
```

2.12.6 Comparisons

Comparing categorical data with other objects is possible in three cases:

- Comparing equality (== and !=) to a list-like object (list, Series, array, . . .) of the same length as the categorical data.
- All comparisons (==, ! =, >, >=, <, and <=) of categorical data to another categorical Series, when `ordered=True` and the categories are the same.
- All comparisons of a categorical data to a scalar.
All other comparisons, especially “non-equality” comparisons of two categoricals with different categories or a categorical with any list-like object, will raise a `TypeError`.

**Note:** Any “non-equality” comparisons of categorical data with a `Series`, `np.array`, `list` or categorical data with different categories or ordering will raise a `TypeError` because custom categories ordering could be interpreted in two ways: one with taking into account the ordering and one without.

```python
In [113]: cat = pd.Series([1, 2, 3]).astype(CategoricalDtype([3, 2, 1], ordered=True))
In [114]: cat_base = pd.Series([2, 2, 2]).astype(CategoricalDtype([3, 2, 1], ordered=True))
In [115]: cat_base2 = pd.Series([2, 2, 2]).astype(CategoricalDtype(ordered=True))

In [116]: cat
Out[116]:
0  1
1  2
2  3
dtype: category
Categories (3, int64): [3 < 2 < 1]
In [117]: cat_base
Out[117]:
0  2
1  2
2  2
dtype: category
Categories (3, int64): [3 < 2 < 1]
In [118]: cat_base2
Out[118]:
0  2
1  2
2  2
dtype: category
Categories (1, int64): [2]
```

Comparing to a categorical with the same categories and ordering or to a scalar works:

```python
In [119]: cat > cat_base
Out[119]:
0   True
1   False
2   False
dtype: bool
In [120]: cat > 2
Out[120]:
0   True
1   False
2   False
dtype: bool
```

Equality comparisons work with any list-like object of same length and scalars:

```python
In [121]: cat == [1, 2, 3]
Out[121]:
0  True
1 False
2 False
dtype: bool
In [122]: cat == [1, 2, 3]
Out[122]:
0  True
1 False
2 False
dtype: bool
```
This doesn’t work because the categories are not the same:

```
In [124]: try:
.....:    cat > cat_base2
.....: except TypeError as e:
.....:    print("TypeError:", str(e))
.....:
TypeError: Categoricals can only be compared if 'categories' are the same.
```

If you want to do a “non-equality” comparison of a categorical series with a list-like object which is not categorical data, you need to be explicit and convert the categorical data back to the original values:

```
In [125]: base = np.array([1, 2, 3])

In [126]: try:
.....:    cat > base
.....: except TypeError as e:
.....:    print("TypeError:", str(e))
.....:
TypeError: Cannot compare a Categorical for op __gt__ with type <class 'numpy.ndarray'>.
If you want to compare values, use 'np.asarray(cat) <op> other'.

In [127]: np.asarray(cat) > base
Out[127]: array([False, False, False])
```

When you compare two unordered categoricals with the same categories, the order is not considered:

```
In [128]: c1 = pd.Categorical(["a", "b"], categories=["a", "b"], ordered=False)

In [129]: c2 = pd.Categorical(["a", "b"], categories=["b", "a"], ordered=False)

In [130]: c1 == c2
Out[130]: array([ True, True])
```
2.12.7 Operations

Apart from \texttt{Series.min()}, \texttt{Series.max()} and \texttt{Series.mode()}, the following operations are possible with categorical data:

\textbf{Series} methods like \texttt{Series.value_counts()} will use all categories, even if some categories are not present in the data:

```
In [131]: s = pd.Series(pd.Categorical(["a", "b", "c", "c"], categories=["c", "a", "b", "d"]))
In [132]: s.value_counts()
Out[132]:
c    2
a    1
b    1
d    0
dtype: int64
```

\textbf{DataFrame} methods like \texttt{DataFrame.sum()} also show “unused” categories.

```
In [133]: columns = pd.Categorical(.....:
\   .....:  \["One", "One", "Two"], categories=["One", "Two", "Three"], ordered=True  \.......
\   .....:)

In [134]: df = pd.DataFrame(.....:
\   .....:  \[\[1, 2, 3\], \[4, 5, 6\]\],  \.......
\   .....:  \columns=pd.MultiIndex.from_arrays([["A", "B", "B"], columns]),  \.......
\   .....:)

In [135]: df.groupby(axis=1, level=1).sum()
Out[135]:
   One  Two  Three
0   3   3     0
1   9   6     0
```

\textbf{Groupby} will also show “unused” categories:

```
In [136]: cats = pd.Categorical(.....:
\   .....:  \["a", "b", "b", "b", "c", "c", "c"], categories=["a", "b", "c", "d"]  \.......
\   .....:)

In [137]: df = pd.DataFrame({"cats": cats, "values": \[1, 2, 2, 2, 3, 4, 5\]})
In [138]: df.groupby("cats").mean()
Out[138]:
   values
   cats
   a   1.0
   b   2.0
   c   4.0
   d   NaN

In [139]: cats2 = pd.Categorical(["a", "a", "b", "b"], categories=["a", "b", "c"])
```

(continues on next page)
In [140]: df2 = pd.DataFrame({
.....:
.....:   "cats": cats2,
.....:
.....:   "B": ["c", "d", "c", "d"],
.....:
.....:   "values": [1, 2, 3, 4],
.....:
.....: })
In [141]: df2.groupby(["cats", "B"]).mean()
Out[141]:
    values
   cats  B
   a  c   1.0
    d   2.0
   b  c   3.0
    d   4.0
   c  c   NaN
    d   NaN

Pivot tables:

In [142]: raw_cat = pd.Categorical(["a", "a", "b", "b"], categories=["a", "b", "c"])
In [143]: df = pd.DataFrame({"A": raw_cat, "B": ["c", "d", "c", "d"], "values": [1, 2, 3, 4]})
In [144]: pd.pivot_table(df, values="values", index=["A", "B"])
Out[144]:
    values
   A  B
   a  c   1
    d   2
   b  c   3
    d   4

2.12.8 Data munging

The optimized pandas data access methods .loc, .iloc, .at, and .iat, work as normal. The only difference is the return type (for getting) and that only values already in categories can be assigned.

Getting

If the slicing operation returns either a DataFrame or a column of type Series, the category dtype is preserved.

In [145]: idx = pd.Index(["h", "i", "j", "k", "l", "m", "n"])
In [146]: cats = pd.Series(["a", "b", "b", "b", "c", "c", "c"], dtype="category", index=idx)
In [147]: values = [1, 2, 2, 2, 3, 4, 5]
In [148]: df = pd.DataFrame({"cats": cats, "values": values}, index=idx)
In [149]: df.iloc[2:4, :]
Out[149]:
    cats  values
j   b    2
k   b    2

In [150]: df.iloc[2:4, :].dtypes
Out[150]:
    cats   category
values  int64
dtype: object

In [151]: df.loc["h":"j", "cats"]
Out[151]:
   h   a
   i   b
   j   b
Name: cats, dtype: category
Categories (3, object): ['a', 'b', 'c']

In [152]: df[df["cats"] == "b"]
Out[152]:
    cats  values
   i   b    2
   j   b    2
   k   b    2

An example where the category type is not preserved is if you take one single row: the resulting Series is of dtype object:

# get the complete "h" row as a Series
In [153]: df.loc["h", :]
Out[153]:
    cats  a
values  1
Name: h, dtype: object

Returning a single item from categorical data will also return the value, not a categorical of length “1”.

In [154]: df.iat[0, 0]
Out[154]: 'a'

In [155]: df["cats"]).cat.categories = ["x", "y", "z"]

In [156]: df.at["h", "cats"]  # returns a string
Out[156]: 'x'

Note: The is in contrast to R’s factor function, where factor(c(1,2,3))[1] returns a single value factor.

To get a single value Series of type category, you pass in a list with a single value:

In [157]: df.loc["h", "cats"]
Out[157]:
   h   x
String and datetime accessors

The accessors .dt and .str will work if the s.cat.categories are of an appropriate type:

```
In [158]: str_s = pd.Series(list("aabb"))
In [159]: str_cat = str_s.astype("category")
In [160]: str_cat
Out[160]:
0  a
1  a
2  b
3  b
dtype: category
Categories (2, object): ['a', 'b']
```

```
In [161]: str_cat.str.contains("a")
Out[161]:
0   True
1   True
2  False
3  False
dtype: bool
```

```
In [162]: date_s = pd.Series(pd.date_range("1/1/2015", periods=5))
In [163]: date_cat = date_s.astype("category")
In [164]: date_cat
Out[164]:
0  2015-01-01
1  2015-01-02
2  2015-01-03
3  2015-01-04
4  2015-01-05
dtype: category
```

```
In [165]: date_cat.dt.day
Out[165]:
0   1
1   2
2   3
3   4
4   5
dtype: int64
```

Note: The returned Series (or DataFrame) is of the same type as if you used the .str.<method> / .dt.<method> on a Series of that type (and not of type category!).
That means, that the returned values from methods and properties on the accessors of a Series and the returned values from methods and properties on the accessors of this Series transformed to one of type `category` will be equal:

```python
In [166]: ret_s = str_s.str.contains("a")
In [167]: ret_cat = str_cat.str.contains("a")
In [168]: ret_s.dtype == ret_cat.dtype
Out[168]: True
In [169]: ret_s == ret_cat
Out[169]:
0  True
1  True
2  True
3  True
dtype: bool
```

**Note:** The work is done on the categories and then a new Series is constructed. This has some performance implication if you have a Series of type `string`, where lots of elements are repeated (i.e. the number of unique elements in the Series is a lot smaller than the length of the Series). In this case it can be faster to convert the original Series to one of type `category` and use `.str.<method>` or `.dt.<property>` on that.

### Setting

Setting values in a categorical column (or Series) works as long as the value is included in the categories:

```python
In [170]: idx = pd.Index(["h", "i", "j", "k", "l", "m", "n")
In [171]: cats = pd.Categorical(["a", "a", "a", "a", "a", "a", "a"], categories=["a", ...
   ...: "b")
In [172]: values = [1, 1, 1, 1, 1, 1, 1]
In [173]: df = pd.DataFrame({"cats": cats, "values": values}, index=idx)
In [174]: df.iloc[2:4, :] = [["b", 2], ["b", 2]]
In [175]: df
Out[175]:
   cats  values
  h    a     1
  i    a     1
  j    b     2
  k    b     2
  l    a     1
  m    a     1
  n    a     1
In [176]: try:
......:   df.iloc[2:4, :] = [["c", 3], ["c", 3]]
......: except ValueError as e:
......:   print("ValueError:", str(e))
```

(continues on next page)
Setting values by assigning categorical data will also check that the categories match:

```python
In [177]: df.loc["j":"k", "cats"] = pd.Categorical(["a", "a"], categories=["a", "b"])
```

```python
In [178]: df
Out[178]:
   cats
  h   a
  i   a
  j   a
  k   a
  l   a
  m   a
  n   a
```

```python
In [179]: try:
    ....:     df.loc["j":"k", "cats"] = pd.Categorical(["b", "b"], categories=["a", "b", "c")
    ....: except ValueError as e:
    ....:     print("ValueError:", str(e))
```

```
ValueError: Cannot setitem on a Categorical with a new category, set the categories first
```

Assigning a Categorical to parts of a column of other types will use the values:

```python
In [180]: df = pd.DataFrame({"a": [1, 1, 1, 1, 1], "b": ["a", "a", "a", "a", "a"]})
```

```python
In [181]: df.loc[1:2, "a"] = pd.Categorical(["b", "b"], categories=["a", "b"])
```

```python
In [182]: df.loc[2:3, "b"] = pd.Categorical(["b", "b"], categories=["a", "b"])
```

```python
In [183]: df
Out[183]:
   a  b
  0  1  a
  1  1  a
  2  2  b
  3  1  b
  4  1  a
```

```python
In [184]: df.dtypes
Out[184]:
  a  object
  b  object
dtype: object
```
Merging / concatenation

By default, combining Series or DataFrames which contain the same categories results in category dtype, otherwise results will depend on the dtype of the underlying categories. Merges that result in non-categorical dtypes will likely have higher memory usage. Use .astype or union_categoricals to ensure category results.

```
In [185]: from pandas.api.types import union_categoricals

# same categories
In [186]: s1 = pd.Series(['a', 'b'], dtype='category')
In [187]: s2 = pd.Series(['a', 'b', 'a'], dtype='category')

In [188]: pd.concat([s1, s2])
Out[188]:
   0   a
   1   b
   2   a

dtype: category
Categories (2, object): ['a', 'b']

# different categories
In [189]: s3 = pd.Series(['b', 'c'], dtype='category')

In [190]: pd.concat([s1, s3])
Out[190]:
   0   a
   1   b
   2   b
   3   c

dtype: object

# Output dtype is inferred based on categories values
In [191]: int_cats = pd.Series([1, 2], dtype='category')

In [192]: float_cats = pd.Series([3.0, 4.0], dtype='category')

In [193]: pd.concat([int_cats, float_cats])
Out[193]:
   0  1.0
   1  2.0
   2  3.0
   3  4.0

dtype: float64

In [194]: pd.concat([s1, s3]).astype('category')
Out[194]:
   0   a
   1   b
   2   b
   3   c

dtype: category
Categories (3, object): ['a', 'b', 'c']

In [195]: union_categoricals([s1.array, s3.array])
```

(continues on next page)
The following table summarizes the results of merging Categoricals:

<table>
<thead>
<tr>
<th>arg1</th>
<th>arg2</th>
<th>identical</th>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>category</td>
<td>True</td>
<td>category</td>
</tr>
<tr>
<td>category (object)</td>
<td>category (object)</td>
<td>False</td>
<td>object (dtype is inferred)</td>
</tr>
<tr>
<td>category (int)</td>
<td>category (float)</td>
<td>False</td>
<td>float (dtype is inferred)</td>
</tr>
</tbody>
</table>

See also the section on `merge dtypes` for notes about preserving merge dtypes and performance.

**Unioning**

If you want to combine categoricals that do not necessarily have the same categories, the `union_categoricals()` function will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```
In [196]: from pandas.api.types import union_categoricals
In [197]: a = pd.Categorical(['b', 'c'])
In [198]: b = pd.Categorical(['a', 'b'])
In [199]: union_categoricals([a, b])
Out[199]:
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

By default, the resulting categories will be ordered as they appear in the data. If you want the categories to be lexsorted, use `sort_categories=True` argument.

```
In [200]: union_categoricals([a, b], sort_categories=True)
Out[200]:
['b', 'c', 'a', 'b']
Categories (3, object): ['a', 'b', 'c']
```

`union_categoricals` also works with the “easy” case of combining two categoricals of the same categories and order information (e.g. what you could also append for).

```
In [201]: a = pd.Categorical(['a', 'b'], ordered=True)
In [202]: b = pd.Categorical(['a', 'b', 'c'], ordered=True)
In [203]: union_categoricals([a, b])
Out[203]:
['a', 'b', 'a', 'b', 'a']
Categories (2, object): ['a' < 'b']
```

The below raises `TypeError` because the categories are ordered and not identical.

```
In [1]: a = pd.Categorical(['a', 'b'], ordered=True)
In [2]: b = pd.Categorical(['a', 'b', 'c'], ordered=True)
In [3]: union_categoricals([a, b])
(continues on next page)```
Out[3]:
TypeError: to union ordered Categoricals, all categories must be the same

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.

```python
In [204]: a = pd.Categorical(['a', 'b', 'c'], ordered=True)
In [205]: b = pd.Categorical(['c', 'b', 'a'], ordered=True)
In [206]: union_categoricals([a, b], ignore_order=True)
Out[206]: ['a', 'b', 'c', 'c', 'b', 'a']
Categories (3, object): ['a', 'b', 'c']
```

`union_categoricals()` also works with a `CategoricalIndex`, or `Series` containing categorical data, but note that the resulting array will always be a plain `Categorical`.

```python
In [207]: a = pd.Series(['b', 'c'], dtype="category")
In [208]: b = pd.Series(['a', 'b'], dtype="category")
In [209]: union_categoricals([a, b])
Out[209]: ['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

**Note:** `union_categoricals` may recode the integer codes for categories when combining categoricals. This is likely what you want, but if you are relying on the exact numbering of the categories, be aware.

```python
In [210]: c1 = pd.Categorical(['b', 'c'])
In [211]: c2 = pd.Categorical(['a', 'b'])
In [212]: c1
Out[212]: ['b', 'c']
Categories (2, object): ['b', 'c']

# "b" is coded to 0
In [213]: c1.codes
Out[213]: array([0, 1], dtype=int8)
In [214]: c2
Out[214]: ['a', 'b']
Categories (2, object): ['a', 'b']

# "b" is coded to 1
In [215]: c2.codes
Out[215]: array([0, 1], dtype=int8)
In [216]: c = union_categoricals([c1, c2])
In [217]: c
```
2.12.9 Getting data in/out

You can write data that contains category dtypes to a HDFStore. See here for an example and caveats.

It is also possible to write data to and reading data from Stata format files. See here for an example and caveats.

Writing to a CSV file will convert the data, effectively removing any information about the categorical (categories and ordering). So if you read back the CSV file you have to convert the relevant columns back to category and assign the right categories and categories ordering.

```python
In [219]: import io
In [220]: s = pd.Series(pd.Categorical(["a", "b", "b", "a", "a", "d"]))
    # rename the categories
In [221]: s.cat.categories = ["very good", "good", "bad"]
    # reorder the categories and add missing categories
In [222]: s = s.cat.set_categories(["very bad", "bad", "medium", "good", "very good"])
In [223]: df = pd.DataFrame({"cats": s, "vals": [1, 2, 3, 4, 5, 6]})
In [224]: csv = io.StringIO()
In [225]: df.to_csv(csv)
In [226]: df2 = pd.read_csv(io.StringIO(csv.getvalue()))
In [227]: df2.dtypes
Out[227]:
           cats     vals
Unnamed: 0 int64  int64
cats        object
vals        int64

dtype: object

In [228]: df2["cats"]
Out[228]:
0    very good
1      good
2      good
3    very good
4    very good
5      bad
Name: cats, dtype: object
    # Redo the category
```

In [229]: df2["cats"] = df2["cats"].astype("category")

In [230]: df2["cats"].cat.set_categories(
       ....:     ["very bad", "bad", "medium", "good", "very good"], inplace=True
       ....:     )
       ....:

In [231]: df2.dtypes
Out[231]:
    Unnamed: 0  int64
    cats        category
    vals        int64
dtype: object

In [232]: df2["cats"]
Out[232]:
    0   very good
    1      good
    2      good
    3   very good
    4   very good
    5      bad
Name: cats, dtype: category
Categories (5, object): ['very bad', 'bad', 'medium', 'good', 'very good']

The same holds for writing to a SQL database with `to_sql`.

### 2.12.10 Missing data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the [Missing Data section](#). Missing values should *not* be included in the Categorical’s `categories`, only in the `values`. Instead, it is understood that NaN is different, and is always a possibility. When working with the Categorical’s `codes`, missing values will always have a code of -1.

In [233]: s = pd.Series(["a", "b", np.nan, "a"], dtype="category")

# only two categories
In [234]: s
Out[234]:
    0   a
    1   b
    2   NaN
    3   a
dtype: category
Categories (2, object): ['a', 'b']

In [235]: s.cat.codes
Out[235]:
    0    0
    1    1
    2   -1
    3    0
dtype: int8
Methods for working with missing data, e.g. `isna()`, `fillna()`, `dropna()`, all work normally:

```python
In [236]: s = pd.Series(["a", "b", np.nan], dtype="category")

In [237]: s
Out[237]:
0    a
1    b
2  NaN
dtype: category
Categories (2, object): ['a', 'b']

In [238]: pd.isna(s)
Out[238]:
0   False
1   False
2    True
dtype: bool

In [239]: s.fillna("a")
Out[239]:
0    a
1    b
2    a
dtype: category
Categories (2, object): ['a', 'b']
```

### 2.12.11 Differences to R’s `factor`

The following differences to R’s `factor` functions can be observed:

- R’s `levels` are named categories.
- R’s `levels` are always of type string, while categories in pandas can be of any dtype.
- It’s not possible to specify labels at creation time. Use `s.cat.rename_categories(new_labels)` afterwards.
- In contrast to R’s `factor` function, using categorical data as the sole input to create a new categorical series will not remove unused categories but create a new categorical series which is equal to the passed in one!
- R allows for missing values to be included in its `levels` (pandas’ `categories`). pandas does not allow NaN categories, but missing values can still be in the `values`.

### 2.12.12 Gotchas

#### Memory usage

The memory usage of a `Categorical` is proportional to the number of categories plus the length of the data. In contrast, an `object` dtype is a constant times the length of the data.

```python
In [240]: s = pd.Series(["foo", "bar"] * 1000)
# object dtype

In [241]: s.nbytes
Out[241]: 16000
```
# category dtype
In [242]: s.astype("category").nbytes
Out[242]: 2016

Note: If the number of categories approaches the length of the data, the Categorical will use nearly the same or more memory than an equivalent object dtype representation.

In [243]: s = pd.Series(["foo%04d" % i for i in range(2000)])

# object dtype
In [244]: s.nbytes
Out[244]: 16000

# category dtype
In [245]: s.astype("category").nbytes
Out[245]: 20000

Categorical is not a numpy array

Currently, categorical data and the underlying Categorical is implemented as a Python object and not as a low-level NumPy array dtype. This leads to some problems.

NumPy itself doesn’t know about the new dtype:

In [246]: try:
   ....:     np.dtype("category")
   ....:     except TypeError as e:
   ....:         print("TypeError: ", str(e))
   ....:
TypeError: data type 'category' not understood

In [247]: dtype = pd.Categorical(["a"]).dtype

In [248]: try:
   ....:     np.dtype(dtype)
   ....:     except TypeError as e:
   ....:         print("TypeError: ", str(e))
   ....:
TypeError: Cannot interpret 'CategoricalDtype(categories=['a'], ordered=False)' as a data type

Dtype comparisons work:

In [249]: dtype == np.str_
Out[249]: False

In [250]: np.str_ == dtype
Out[250]: False

To check if a Series contains Categorical data, use hasattr(s, 'cat'):  

2.12. Categorical data
Using NumPy functions on a \texttt{Series} of type \texttt{category} should not work as \texttt{Categoricals} are not numeric data (even in the case that \texttt{.categories} is numeric).

\texttt{In [253]}: \texttt{s = pd.Series(pd.Categorical([1, 2, 3, 4]))}
\texttt{In [254]}: \texttt{try:}
\texttt{......: np.sum(s)}
\texttt{......: except TypeError as e:}
\texttt{......: print("TypeError:", str(e))}
\texttt{......:}
\texttt{TypeError: 'Categorical' does not implement reduction 'sum'}

\textbf{Note}: If such a function works, please file a bug at https://github.com/pandas-dev/pandas!

\textbf{dtype in apply}

\texttt{pandas} currently does not preserve the \texttt{dtype} in apply functions: If you apply along rows you get a \texttt{Series} of \texttt{object dtype} (same as getting a row -> getting one element will return a basic type) and applying along columns will also convert to \texttt{object}. NaN values are unaffected. You can use \texttt{fillna} to handle missing values before applying a function.

\texttt{In [255]}: \texttt{df = pd.DataFrame(}
\texttt{......: {}}
\texttt{......: "a": [1, 2, 3, 4],}
\texttt{......: "b": ["a", "b", "c", "d"],}
\texttt{......: "cats": pd.Categorical([1, 2, 3, 2]),}
\texttt{......: }}
\texttt{......: )}
\texttt{......:}
\texttt{In [256]}: \texttt{df.apply(\texttt{lambda row: type(row["cats"])}, axis=1)}
\texttt{Out[256]}:
\texttt{0 <class 'int'>}
\texttt{1 <class 'int'>}
\texttt{2 <class 'int'>}
\texttt{3 <class 'int'>}
\texttt{dtype: object}

\texttt{In [257]}: \texttt{df.apply(\texttt{lambda col: col.dtype}, axis=0)}
\texttt{Out[257]}:
\texttt{a int64}
\texttt{b object}
\texttt{cats category}
\texttt{dtype: object}
Categorical index

CategoricalIndex is a type of index that is useful for supporting indexing with duplicates. This is a container around a Categorical and allows efficient indexing and storage of an index with a large number of duplicated elements. See the advanced indexing docs for a more detailed explanation.

Setting the index will create a CategoricalIndex:

```
In [258]: cats = pd.Categorical([1, 2, 3, 4], categories=[4, 2, 3, 1])
In [259]: strings = ["a", "b", "c", "d"]
In [260]: values = [4, 2, 3, 1]
In [261]: df = pd.DataFrame({"strings": strings, "values": values}, index=cats)
In [262]: df.index
Out[262]: CategoricalIndex([1, 2, 3, 4], categories=[4, 2, 3, 1], ordered=False, dtype='category')
```

# This now sorts by the categories order
```
In [263]: df.sort_index()
Out[263]:
   strings  values
4       d       1
2       b       2
3       c       3
1       a       4
```

Side effects

Constructing a Series from a Categorical will not copy the input Categorical. This means that changes to the Series will in most cases change the original Categorical:

```
In [264]: cat = pd.Categorical([1, 2, 3, 10], categories=[1, 2, 3, 4, 10])
In [265]: s = pd.Series(cat, name="cat")
In [266]: cat
Out[266]:
[1, 2, 3, 10]  Categories (5, int64): [1, 2, 3, 4, 10]
In [267]: s.iloc[0:2] = 10
In [268]: cat
Out[268]:
[10, 10, 3, 10]  Categories (5, int64): [1, 2, 3, 4, 10]
In [269]: df = pd.DataFrame(s)
In [270]: df["cat"].cat.categories = [1, 2, 3, 4, 5]
In [271]: cat
Out[271]:
(continues on next page)
Use `copy=True` to prevent such a behaviour or simply don’t reuse Categoricals:

```
In [272]: cat = pd.Categorical([1, 2, 3, 10], categories=[1, 2, 3, 4, 10])
In [273]: s = pd.Series(cat, name="cat", copy=True)
In [274]: cat
Out[274]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
In [275]: s.iloc[0:2] = 10
In [276]: cat
Out[276]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
```

**Note:** This also happens in some cases when you supply a NumPy array instead of a `Categorical`: using an int array (e.g. `np.array([1, 2, 3, 4])`) will exhibit the same behavior, while using a string array (e.g. `np.array(["a", "b", "c", "a"])`) will not.

## 2.13 Nullable integer data type

**Note:** IntegerArray is currently experimental. Its API or implementation may change without warning.

Changed in version 1.0.0: Now uses `pandas.NA` as the missing value rather than `numpy.nan`.

In *Working with missing data*, we saw that pandas primarily uses NaN to represent missing data. Because NaN is a float, this forces an array of integers with any missing values to become floating point. In some cases, this may not matter much. But if your integer column is, say, an identifier, casting to float can be problematic. Some integers cannot even be represented as floating point numbers.

### 2.13.1 Construction

pandas can represent integer data with possibly missing values using `arrays.IntegerArray`. This is an extension types implemented within pandas.

```
In [1]: arr = pd.array([1, 2, None], dtype=pd.Int64Dtype())
In [2]: arr
Out[2]:
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64
```

Or the string alias "Int64" (note the capital "I", to differentiate from NumPy’s ‘int64’ dtype):
In [3]: pd.array([1, 2, np.nan], dtype="Int64")
Out[3]:
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64

All NA-like values are replaced with pandas.NA.

In [4]: pd.array([1, 2, np.nan, None, pd.NA], dtype="Int64")
Out[4]:
<IntegerArray>
[1, 2, <NA>, <NA>, <NA>]
Length: 5, dtype: Int64

This array can be stored in a DataFrame or Series like any NumPy array.

In [5]: pd.Series(arr)
Out[5]:
     0    1
   --- ---
      1   2
   2  <NA>
dtype: Int64

You can also pass the list-like object to the Series constructor with the dtype.

**Warning**: Currently pandas.array() and pandas.Series() use different rules for dtype inference. pandas.array() will infer a nullable-integer dtype

In [6]: pd.array([1, None])
Out[6]:
<IntegerArray>
[1, <NA>]
Length: 2, dtype: Int64

In [7]: pd.array([1, 2])
Out[7]:
<IntegerArray>
[1, 2]
Length: 2, dtype: Int64

For backwards-compatibility, Series infers these as either integer or float dtype

In [8]: pd.Series([1, None])
Out[8]:
   0 1.0
   1 NaN
dtype: float64

In [9]: pd.Series([1, 2])
Out[9]:
   0 1
   1 2
dtype: int64

We recommend explicitly providing the dtype to avoid confusion.
In [10]: pd.array([1, None], dtype="Int64")
Out[10]:
<IntegerArray>
[1, <NA>]
Length: 2, dtype: Int64

In [11]: pd.Series([1, None], dtype="Int64")
Out[11]:
0    1
1    <NA>
dtype: Int64

In the future, we may provide an option for Series to infer a nullable-integer dtype.

2.13.2 Operations

Operations involving an integer array will behave similar to NumPy arrays. Missing values will be propagated, and the data will be coerced to another dtype if needed.

In [12]: s = pd.Series([1, 2, None], dtype="Int64")
# arithmetic
In [13]: s + 1
Out[13]:
0    2
1    3
2    <NA>
dtype: Int64
# comparison
In [14]: s == 1
Out[14]:
0   True
1   False
2   <NA>
dtype: boolean
# indexing
In [15]: s.iloc[1:3]
Out[15]:
1    2
2    <NA>
dtype: Int64
# operate with other dtypes
In [16]: s + s.iloc[1:3].astype("Int8")
Out[16]:
0   <NA>
1    4
2    <NA>
dtype: Int64
# coerce when needed
In [17]: s + 0.01
Out[17]:
(continues on next page)
These dtypes can operate as part of DataFrame.

```python
In [18]: df = pd.DataFrame({"A": s, "B": [1, 1, 3], "C": list("aab")})

In [19]: df
Out[19]:
   A  B  C
0  1  1  a
1  2  1  a
2  <NA>  3  b

In [20]: df.dtypes
Out[20]:
A  Int64
B  int64
C  object
dtype: object
```

These dtypes can be merged & reshaped & casted.

```python
In [21]: pd.concat([df["A"], df["B", "C"]], axis=1).dtypes
Out[21]:
A  Int64
B  int64
C  object
dtype: object

In [22]: df["A"].astype(float)
Out[22]:
0   1.0
1   2.0
2  NaN
Name: A, dtype: float64
```

Reduction and groupby operations such as ‘sum’ work as well.

```python
In [23]: df.sum()
Out[23]:
   A  3
   B  5
   C  aab
dtype: object

In [24]: df.groupby("B").A.sum()
Out[24]:
   B
  1  3
  3  0
Name: A, dtype: Int64
```
2.13.3 Scalar NA Value

`arrays.IntegerArray` uses `pandas.NA` as its scalar missing value. Slicing a single element that’s missing will return `pandas.NA`.

```
In [25]: a = pd.array([1, None], dtype="Int64")
In [26]: a[1]
Out[26]: <NA>
```

2.14 Nullable Boolean data type

**Note:** BooleanArray is currently experimental. Its API or implementation may change without warning.

New in version 1.0.0.

2.14.1 Indexing with NA values

pandas allows indexing with NA values in a boolean array, which are treated as `False`.

Changed in version 1.0.2.

```
In [1]: s = pd.Series([1, 2, 3])
In [2]: mask = pd.array([True, False, pd.NA], dtype="boolean")
In [3]: s[mask]
Out[3]:
0  1
dtype: int64
```

If you would prefer to keep the NA values you can manually fill them with `fillna(True)`.

```
In [4]: s[mask.fillna(True)]
Out [4]:
0  1
2  3
dtype: int64
```

2.14.2 Kleene logical operations

`arrays.BooleanArray` implements Kleene Logic (sometimes called three-value logic) for logical operations like `&` (and), `|` (or) and `^` (exclusive-or).

This table demonstrates the results for every combination. These operations are symmetrical, so flipping the left- and right-hand side makes no difference in the result.
When an NA is present in an operation, the output value is NA only if the result cannot be determined solely based on the other input. For example, True | NA is True, because both True | True and True | False are True. In that case, we don’t actually need to consider the value of the NA.

On the other hand, True & NA is NA. The result depends on whether the NA really is True or False, since True & True is True, but True & False is False, so we can’t determine the output.

This differs from how np.nan behaves in logical operations. pandas treated np.nan is always false in the output.

In or

```
In [5]: pd.Series([True, False, np.nan], dtype="object") | True
Out[5]:
0    True
1    True
2    False
dtype: bool
```

```
In [6]: pd.Series([True, False, np.nan], dtype="boolean") | True
Out[6]:
0    True
1    True
2    True
dtype: boolean
```

In and

```
In [7]: pd.Series([True, False, np.nan], dtype="object") & True
Out[7]:
0    True
1    False
2    False
dtype: bool
```

```
In [8]: pd.Series([True, False, np.nan], dtype="boolean") & True
```

(continues on next page)
2.15 Chart Visualization

This section demonstrates visualization through charting. For information on visualization of tabular data please see the section on *Table Visualization*.

We use the standard convention for referencing the matplotlib API:

```python
In [1]: import matplotlib.pyplot as plt
In [2]: plt.close("all")
```

We provide the basics in pandas to easily create decent looking plots. See the ecosystem section for visualization libraries that go beyond the basics documented here.

**Note:** All calls to `np.random` are seeded with 123456.

2.15.1 Basic plotting: `plot`

We will demonstrate the basics, see the *cookbook* for some advanced strategies.

The `plot` method on Series and DataFrame is just a simple wrapper around `plt.plot()`:

```python
In [3]: ts = pd.Series(np.random.randn(1000), index=pd.date_range("1/1/2000", periods=1000))
In [4]: ts = ts.cumsum()
In [5]: ts.plot();
```
If the index consists of dates, it calls `gcf().autofmt_xdate()` to try to format the x-axis nicely as per above.

On DataFrame, `plot()` is a convenience to plot all of the columns with labels:

```python
In [6]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index, columns=list("ABCD"))

In [7]: df = df.cumsum()

In [8]: plt.figure();

In [9]: df.plot();
```
You can plot one column versus another using the \texttt{x} and \texttt{y} keywords in \texttt{plot()}:

\begin{verbatim}
In [10]: df3 = pd.DataFrame(np.random.randn(1000, 2), columns=["B", "C"]).cumsum()
In [11]: df3["A"] = pd.Series(list(range(len(df))))
In [12]: df3.plot(x="A", y="B");
\end{verbatim}
2.15.2 Other plots

Plotting methods allow for a handful of plot styles other than the default line plot. These methods can be provided as the `kind` keyword argument to `plot()`, and include:

- 'bar' or 'barh' for bar plots
- 'hist' for histogram
- 'box' for boxplot
- 'kde' or 'density' for density plots
- 'area' for area plots
- 'scatter' for scatter plots
- 'hexbin' for hexagonal bin plots
- 'pie' for pie plots

For example, a bar plot can be created the following way:
You can also create these other plots using the methods `DataFrame.plot.<kind>` instead of providing the `kind` keyword argument. This makes it easier to discover plot methods and the specific arguments they use:

```python
In [15]: df = pd.DataFrame()
In [16]: df.plot.<TAB>  # noqa: E225, E999
df.plot.area   df.plot.barh   df.plot.density df.plot.hist df.plot.line
   df.plot.scatter
   df.plot.bar   df.plot.box   df.plot.hexbin df.plot.kde df.plot.pie
```

In addition to these `kind`s, there are the `DataFrame.hist()` and `DataFrame.boxplot()` methods, which use a separate interface.

Finally, there are several `plotting functions` in `pandas.plotting` that take a `Series` or `DataFrame` as an argument. These include:

- `Scatter Matrix`
- `Andrews Curves`
- `Parallel Coordinates`
- `Lag Plot`
• *Autocorrelation Plot*

• *Bootstrap Plot*

• *RadViz*

Plots may also be adorned with *errorbars* or *tables*.

**Bar plots**

For labeled, non-time series data, you may wish to produce a bar plot:

```python
In [17]: plt.figure();
In [18]: df.iloc[5].plot.bar();
In [19]: plt.axhline(0, color="k");
```

Calling a DataFrame’s `plot.bar()` method produces a multiple bar plot:

```python
In [20]: df2 = pd.DataFrame(np.random.rand(10, 4), columns=["a", "b", "c", "d"])
In [21]: df2.plot.bar();
```
To produce a stacked bar plot, pass `stacked=True`:

```python
In [22]: df2.plot.bar(stacked=True);
```
To get horizontal bar plots, use the `barh` method:

```python
In [23]: df2.plot.barh(stacked=True);
```
Histograms

Histograms can be drawn by using the `DataFrame.plot.hist()` and `Series.plot.hist()` methods.

```python
In [24]: df4 = pd.DataFrame(
    ....:    {
    ....:        "a": np.random.randn(1000) + 1,
    ....:        "b": np.random.randn(1000),
    ....:        "c": np.random.randn(1000) - 1,
    ....:    },
    ....:    columns=['a', 'b', 'c'],
    ....:)

In [25]: plt.figure();

In [26]: df4.plot.hist(alpha=0.5);
```
A histogram can be stacked using `stacked=True`. Bin size can be changed using the `bins` keyword.

```python
In [27]: plt.figure();
In [28]: df4.plot.hist(stacked=True, bins=20);
```
You can pass other keywords supported by matplotlib `hist`. For example, horizontal and cumulative histograms can be drawn by `orientation='horizontal'` and `cumulative=True`.

```
In [29]: plt.figure();

In [30]: df4["a"].plot.hist(orientation="horizontal", cumulative=True);
```
See the `hist` method and the matplotlib `hist` documentation for more.

The existing interface `DataFrame.hist` to plot histogram still can be used.

```python
In [31]: plt.figure();

In [32]: df["A"].diff().hist();
```
DataFrame.hist() plots the histograms of the columns on multiple subplots:

In [33]: plt.figure();
In [34]: df.diff().hist(color="k", alpha=0.5, bins=50);
The `by` keyword can be specified to plot grouped histograms:

```python
In [35]: data = pd.Series(np.random.randn(1000))

In [36]: data.hist(by=np.random.randint(0, 4, 1000), figsize=(6, 4));
```
Box plots

Boxplot can be drawn calling `Series.plot.box()` and `Dataframe.plot.box()`, or `Dataframe.boxplot()` to visualize the distribution of values within each column.

For instance, here is a boxplot representing five trials of 10 observations of a uniform random variable on [0,1).

In [37]: df = pd.DataFrame(np.random.rand(10, 5), columns=['A', 'B', 'C', 'D', 'E'])

In [38]: df.plot.box();
Boxplot can be colorized by passing `color` keyword. You can pass a `dict` whose keys are `boxes`, `whiskers`, `medians` and `caps`. If some keys are missing in the `dict`, default colors are used for the corresponding artists. Also, boxplot has `sym` keyword to specify fliers style.

When you pass other type of arguments via `color` keyword, it will be directly passed to matplotlib for all the `boxes`, `whiskers`, `medians` and `caps` colorization.

The colors are applied to every boxes to be drawn. If you want more complicated colorization, you can get each drawn artists by passing `return_type`.

```python
In [39]: color = {
       ....:     "boxes": "DarkGreen",
       ....:     "whiskers": "DarkOrange",
       ....:     "medians": "DarkBlue",
       ....:     "caps": "Gray",
       ....: }
       ....:

In [40]: df.plot.box(color=color, sym="+");
```
Also, you can pass other keywords supported by matplotlib `boxplot`. For example, horizontal and custom-positioned boxplot can be drawn by `vert=False` and `positions` keywords.

```python
In [41]: df.plot.box(vert=False, positions=[1, 4, 5, 6, 8]);
```
See the `boxplot` method and the `matplotlib` boxplot documentation for more. The existing interface `DataFrame.boxplot` to plot boxplot still can be used.

```python
In [42]: df = pd.DataFrame(np.random.rand(10, 5))
In [43]: plt.figure();
In [44]: bp = df.boxplot()
```
You can create a stratified boxplot using the `by` keyword argument to create groupings. For instance,

```python
In [45]: df = pd.DataFrame(np.random.rand(10, 2), columns=['Col1', 'Col2'])
In [47]: plt.figure();
In [48]: bp = df.boxplot(by='X')
```
You can also pass a subset of columns to plot, as well as group by multiple columns:

In [49]: df = pd.DataFrame(np.random.rand(10, 3), columns=["Col1", "Col2", "Col3"])
In [52]: plt.figure();
In [53]: bp = df.boxplot(column=["Col1", "Col2"], by=["X", "Y"])
In `boxplot`, the return type can be controlled by the `return_type` keyword. The valid choices are {"axes", "dict", "both", None}. Faceting, created by `DataFrame.boxplot` with the `by` keyword, will affect the output type as well:

<table>
<thead>
<tr>
<th><code>return_type</code></th>
<th>Faceted</th>
<th>Output type</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>No</td>
<td>axes</td>
</tr>
<tr>
<td>None</td>
<td>Yes</td>
<td>2-D ndarray of axes</td>
</tr>
<tr>
<td>'axes'</td>
<td>No</td>
<td>axes</td>
</tr>
<tr>
<td>'axes'</td>
<td>Yes</td>
<td>Series of axes</td>
</tr>
<tr>
<td>'dict'</td>
<td>No</td>
<td>dict of artists</td>
</tr>
<tr>
<td>'dict'</td>
<td>Yes</td>
<td>Series of dicts of artists</td>
</tr>
<tr>
<td>'both'</td>
<td>No</td>
<td>namedtuple</td>
</tr>
<tr>
<td>'both'</td>
<td>Yes</td>
<td>Series of namedtuples</td>
</tr>
</tbody>
</table>

`Groupby.boxplot` always returns a Series of `return_type`.

```python
In [54]: np.random.seed(1234)
In [55]: df_box = pd.DataFrame(np.random.randn(50, 2))
In [56]: df_box["g"] = np.random.choice(["A", "B"], size=50)
In [57]: df_box.loc[df_box["g"] == "B", 1] += 3
```
In [58]: bp = df_box.boxplot(by="g")

The subplots above are split by the numeric columns first, then the value of the g column. Below the subplots are first split by the value of g, then by the numeric columns.

In [59]: bp = df_box.groupby("g").boxplot()
Area plot

You can create area plots with `Series.plot.area()` and `DataFrame.plot.area()`. Area plots are stacked by default. To produce stacked area plot, each column must be either all positive or all negative values.

When input data contains NaN, it will be automatically filled by 0. If you want to drop or fill by different values, use `dataframe.dropna()` or `dataframe.fillna()` before calling `plot`.

```python
In [60]: df = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])
In [61]: df.plot.area();
```
To produce an unstacked plot, pass `stacked=False`. Alpha value is set to 0.5 unless otherwise specified:

```python
In [62]: df.plot.area(stacked=False);
```
Scatter plot

Scatter plot can be drawn by using the `DataFrame.plot.scatter()` method. Scatter plot requires numeric columns for the x and y axes. These can be specified by the `x` and `y` keywords.

```python
In [63]: df = pd.DataFrame(np.random.rand(50, 4), columns=["a", "b", "c", "d"])

In [64]: df["species"] = pd.Categorical(
    .....:   ["setosa"] * 20 + ["versicolor"] * 20 + ["virginica"] * 10
    .....:)
    .....:

In [65]: df.plot.scatter(x="a", y="b");
```
To plot multiple column groups in a single axes, repeat `plot` method specifying target `ax`. It is recommended to specify `color` and `label` keywords to distinguish each groups.

```python
In [66]: ax = df.plot.scatter(x="a", y="b", color="DarkBlue", label="Group 1")
In [67]: df.plot.scatter(x="c", y="d", color="DarkGreen", label="Group 2", ax=ax);
```
The keyword `c` may be given as the name of a column to provide colors for each point:

```python
In [68]: df.plot.scatter(x="a", y="b", c="c", s=50);
```
If a categorical column is passed to `c`, then a discrete colorbar will be produced:

New in version 1.3.0.

```python
In [69]: df.plot.scatter(x="a", y="b", c="species", cmap="viridis", s=50);
```
You can pass other keywords supported by matplotlib `scatter`. The example below shows a bubble chart using a column of the DataFrame as the bubble size.

```python
In [70]: df.plot.scatter(x="a", y="b", s=df["c"] * 200);
```
See the `scatter` method and the `matplotlib` `scatter` documentation for more.

**Hexagonal bin plot**

You can create hexagonal bin plots with `DataFrame.plot.hexbin()`. Hexbin plots can be a useful alternative to scatter plots if your data are too dense to plot each point individually.

```python
In [71]: df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])
In [72]: df['b'] = df['b'] + np.arange(1000)
In [73]: df.plot.hexbin(x='a', y='b', gridsize=25);
```
A useful keyword argument is gridsize; it controls the number of hexagons in the x-direction, and defaults to 100. A larger gridsize means more, smaller bins.

By default, a histogram of the counts around each \((x, y)\) point is computed. You can specify alternative aggregations by passing values to the \(C\) and reduce\_C\_function arguments. \(C\) specifies the value at each \((x, y)\) point and reduce\_C\_function is a function of one argument that reduces all the values in a bin to a single number (e.g. mean, max, sum, std). In this example the positions are given by columns \(a\) and \(b\), while the value is given by column \(z\). The bins are aggregated with NumPy’s \texttt{max} function.

```python
In [74]: df = pd.DataFrame(np.random.randn(1000, 2), columns=["a", "b"])
In [75]: df["b"] = df["b"] + np.arange(1000)
In [76]: df["z"] = np.random.uniform(0, 3, 1000)
In [77]: df.plot.hexbin(x="a", y="b", C="z", reduce_C_function=np.max, gridsize=25);
```
See the `hexbin` method and the `matplotlib` hexbin documentation for more.

**Pie plot**

You can create a pie plot with `DataFrame.plot.pie()` or `Series.plot.pie()`. If your data includes any NaN, they will be automatically filled with 0. A `ValueError` will be raised if there are any negative values in your data.

```
In [78]: series = pd.Series(3 * np.random.rand(4), index=["a", "b", "c", "d"], name="series")
In [79]: series.plot.pie(figsize=(6, 6));
```
For pie plots it’s best to use square figures, i.e. a figure aspect ratio 1. You can create the figure with equal width and height, or force the aspect ratio to be equal after plotting by calling `ax.set_aspect('equal')` on the returned axes object.

Note that pie plot with `DataFrame` requires that you either specify a target column by the `y` argument or `subplots=True`. When `y` is specified, pie plot of selected column will be drawn. If `subplots=True` is specified, pie plots for each column are drawn as subplots. A legend will be drawn in each pie plots by default; specify `legend=False` to hide it.

```python
In [80]: df = pd.DataFrame(
    ....:     3 * np.random.rand(4, 2), index=['a', 'b', 'c', 'd'], columns=['x', 'y']
    ....: )
    ....:
In [81]: df.plot.pie(subplots=True, figsize=(8, 4));
```
You can use the `labels` and `colors` keywords to specify the labels and colors of each wedge.

**Warning:** Most pandas plots use the `label` and `color` arguments (note the lack of “s” on those). To be consistent with `matplotlib.pyplot.pie()` you must use `labels` and `colors`.

If you want to hide wedge labels, specify `labels=None`. If `fontsize` is specified, the value will be applied to wedge labels. Also, other keywords supported by `matplotlib.pyplot.pie()` can be used.

```python
In [82]: series.plot.pie(
    ....:     labels=['AA', 'BB', 'CC', 'DD'],
    ....:     colors=['r', 'g', 'b', 'c'],
    ....:     autopct='%.2f',
    ....:     fontsize=20,
    ....:     figsize=(6, 6),
    ....: );
```
If you pass values whose sum total is less than 1.0, matplotlib draws a semicircle.

```python
In [83]: series = pd.Series([0.1] * 4, index=['a', 'b', 'c', 'd'], name='series2')
In [84]: series.plot.pie(figsize=(6, 6));
```
2.15.3 Plotting with missing data

pandas tries to be pragmatic about plotting DataFrame or Series that contain missing data. Missing values are dropped, left out, or filled depending on the plot type.
If any of these defaults are not what you want, or if you want to be explicit about how missing values are handled, consider using `fillna()` or `dropna()` before plotting.

### 2.15.4 Plotting tools

These functions can be imported from `pandas.plotting` and take a `Series` or `DataFrame` as an argument.

**Scatter matrix plot**

You can create a scatter plot matrix using the `scatter_matrix` method in `pandas.plotting`:

```python
In [85]: from pandas.plotting import scatter_matrix
In [86]: df = pd.DataFrame(np.random.randn(1000, 4), columns=['a', 'b', 'c', 'd'])
In [87]: scatter_matrix(df, alpha=0.2, figsize=(6, 6), diagonal='kde');```
Density plot

You can create density plots using the `Series.plot.kde()` and `DataFrame.plot.kde()` methods.

```
In [88]: ser = pd.Series(np.random.randn(1000))
In [89]: ser.plot.kde();
```
Andrews curves

Andrews curves allow one to plot multivariate data as a large number of curves that are created using the attributes of samples as coefficients for Fourier series, see the Wikipedia entry for more information. By coloring these curves differently for each class it is possible to visualize data clustering. Curves belonging to samples of the same class will usually be closer together and form larger structures.

**Note:** The “Iris” dataset is available here.

```python
In [90]: from pandas.plotting import andrews_curves

In [91]: data = pd.read_csv("data/iris.data")

In [92]: plt.figure();

In [93]: andrews_curves(data, "Name");
```
Parallel coordinates

Parallel coordinates is a plotting technique for plotting multivariate data, see the Wikipedia entry for an introduction. Parallel coordinates allows one to see clusters in data and to estimate other statistics visually. Using parallel coordinates points are represented as connected line segments. Each vertical line represents one attribute. One set of connected line segments represents one data point. Points that tend to cluster will appear closer together.

```
In [94]: from pandas.plotting import parallel_coordinates

In [95]: data = pd.read_csv("data/iris.data")

In [96]: plt.figure();

In [97]: parallel_coordinates(data, "Name");
```
Lag plots are used to check if a data set or time series is random. Random data should not exhibit any structure in the lag plot. Non-random structure implies that the underlying data are not random. The lag argument may be passed, and when lag=1 the plot is essentially \texttt{data[:-1]} vs. \texttt{data[1:]}. 

```
In [98]: from pandas.plotting import lag_plot
In [99]: plt.figure();
In [100]: spacing = np.linspace(-99 * np.pi, 99 * np.pi, num=1000)
In [101]: data = pd.Series(0.1 * np.random.rand(1000) + 0.9 * np.sin(spacing))
In [102]: lag_plot(data);
```
Autocorrelation plot

Autocorrelation plots are often used for checking randomness in time series. This is done by computing autocorrelations for data values at varying time lags. If time series is random, such autocorrelations should be near zero for any and all time-lag separations. If time series is non-random then one or more of the autocorrelations will be significantly non-zero. The horizontal lines displayed in the plot correspond to 95% and 99% confidence bands. The dashed line is 99% confidence band. See the Wikipedia entry for more about autocorrelation plots.

```
In [103]: from pandas.plotting import autocorrelation_plot

In [104]: plt.figure();

In [105]: spacing = np.linspace(-9 * np.pi, 9 * np.pi, num=1000)

In [106]: data = pd.Series(0.7 * np.random.rand(1000) + 0.3 * np.sin(spacing))

In [107]: autocorrelation_plot(data);
```
Bootstrap plots are used to visually assess the uncertainty of a statistic, such as mean, median, midrange, etc. A random subset of a specified size is selected from a data set, the statistic in question is computed for this subset and the process is repeated a specified number of times. Resulting plots and histograms are what constitutes the bootstrap plot.

```python
In [108]: from pandas.plotting import bootstrap_plot

In [109]: data = pd.Series(np.random.rand(1000))

In [110]: bootstrap_plot(data, size=50, samples=500, color="grey");
```
RadViz

RadViz is a way of visualizing multi-variate data. It is based on a simple spring tension minimization algorithm. Basically you set up a bunch of points in a plane. In our case they are equally spaced on a unit circle. Each point represents a single attribute. You then pretend that each sample in the data set is attached to each of these points by a spring, the stiffness of which is proportional to the numerical value of that attribute (they are normalized to unit interval). The point in the plane, where our sample settles to (where the forces acting on our sample are at an equilibrium) is where a dot representing our sample will be drawn. Depending on which class that sample belongs it will be colored differently. See the R package Radviz for more information.

Note: The “Iris” dataset is available here.

In [111]: from pandas.plotting import radviz

In [112]: data = pd.read_csv("data/iris.data")

In [113]: plt.figure();

In [114]: radviz(data, "Name");
2.15.5 Plot formatting

Setting the plot style

From version 1.5 and up, matplotlib offers a range of pre-configured plotting styles. Setting the style can be used to easily give plots the general look that you want. Setting the style is as easy as calling `matplotlib.style.use('my_plot_style')` before creating your plot. For example you could write `matplotlib.style.use('ggplot')` for ggplot-style plots.

You can see the various available style names at `matplotlib.style.available` and it’s very easy to try them out.

General plot style arguments

Most plotting methods have a set of keyword arguments that control the layout and formatting of the returned plot:

```
In [115]: plt.figure();
In [116]: ts.plot(style="k--", label="Series");
```
For each kind of plot (e.g. line, bar, scatter) any additional arguments keywords are passed along to the corresponding matplotlib function (ax.plot(), ax.bar(), ax.scatter()). These can be used to control additional styling, beyond what pandas provides.

**Controlling the legend**

You may set the `legend` argument to `False` to hide the legend, which is shown by default.

```
In [117]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index, columns=list("ABCD"))
In [118]: df = df.cumsum()
In [119]: df.plot(legend=False);
```
Controlling the labels

New in version 1.1.0.

You may set the `xlabel` and `ylabel` arguments to give the plot custom labels for x and y axis. By default, pandas will pick up index name as `xlabel`, while leaving it empty for `ylabel`.

```
In [120]: df.plot();

In [121]: df.plot(xlabel="new x", ylabel="new y");
```
Scales

You may pass `logy` to get a log-scale Y axis.

```
In [122]: ts = pd.Series(np.random.randn(1000), index=pd.date_range("1/1/2000", periods=1000))
In [123]: ts = np.exp(ts.cumsum())
In [124]: ts.plot(logy=True);
```
See also the `logx` and `loglog` keyword arguments.

**Plotting on a secondary y-axis**

To plot data on a secondary y-axis, use the `secondary_y` keyword:

```python
In [125]: df["A"].plot();
In [126]: df["B"].plot(secondary_y=True, style="g");
```
To plot some columns in a DataFrame, give the column names to the `secondary_y` keyword:

```python
In [127]: plt.figure();
In [128]: ax = df.plot(secondary_y=["A", "B"],)
In [129]: ax.set_ylabel("CD scale");
In [130]: ax.right_ax.set_ylabel("AB scale");
```
Note that the columns plotted on the secondary y-axis is automatically marked with “(right)” in the legend. To turn off the automatic marking, use the mark_right=False keyword:

```python
In [131]: plt.figure();

In [132]: df.plot(secondary_y=["A", "B"], mark_right=False);
```
Custom formatters for timeseries plots

Changed in version 1.0.0.

pandas provides custom formatters for timeseries plots. These change the formatting of the axis labels for dates and times. By default, the custom formatters are applied only to plots created by pandas with DataFrame.plot() or Series.plot(). To have them apply to all plots, including those made by matplotlib, set the option pd.options.plotting.matplotlib.register_converters = True or use pandas.plotting.register_matplotlib_converters().

Suppressing tick resolution adjustment

pandas includes automatic tick resolution adjustment for regular frequency time-series data. For limited cases where pandas cannot infer the frequency information (e.g., in an externally created twinx), you can choose to suppress this behavior for alignment purposes.

Here is the default behavior, notice how the x-axis tick labeling is performed:

```
In [133]: plt.figure();
In [134]: df["A").plot();
```
Using the `x_compat` parameter, you can suppress this behavior:

```python
In [135]: plt.figure();
In [136]: df["A"].plot(x_compat=True);
```
If you have more than one plot that needs to be suppressed, the `use` method in `pandas.plotting.plot_params` can be used in a `with` statement:

```python
In [137]: plt.figure();
In [138]: with pd.plotting.plot_params.use("x_compat", True):
    ....:     df["A"].plot(color="r")
    ....:     df["B"].plot(color="g")
    ....:     df["C"].plot(color="b")
    ....:
```
Automatic date tick adjustment

TimedeltaIndex now uses the native matplotlib tick locator methods, it is useful to call the automatic date tick adjustment from matplotlib for figures whose ticklabels overlap.

See the autofmt_xdate method and the matplotlib documentation for more.
Subplots

Each Series in a DataFrame can be plotted on a different axis with the `subplots` keyword:

```python
In [139]: df.plot(subplots=True, figsize=(6, 6));
```
Using layout and targeting multiple axes

The layout of subplots can be specified by the `layout` keyword. It can accept `(rows, columns)`. The `layout` keyword can be used in `hist` and `boxplot` also. If the input is invalid, a `ValueError` will be raised.

The number of axes which can be contained by rows x columns specified by `layout` must be larger than the number of required subplots. If layout can contain more axes than required, blank axes are not drawn. Similar to a NumPy array’s `reshape` method, you can use `-1` for one dimension to automatically calculate the number of rows or columns needed, given the other.

```python
In [140]: df.plot(subplots=True, layout=(2, 3), figsize=(6, 6), sharex=False);
```

The above example is identical to using:

```python
In [141]: df.plot(subplots=True, layout=(2, -1), figsize=(6, 6), sharex=False);
```

The required number of columns (3) is inferred from the number of series to plot and the given number of rows (2).
You can pass multiple axes created beforehand as list-like via `ax` keyword. This allows more complicated layouts. The passed axes must be the same number as the subplots being drawn.

When multiple axes are passed via the `ax` keyword, `layout`, `sharex` and `sharey` keywords don’t affect to the output. You should explicitly pass `sharex=False` and `sharey=False`, otherwise you will see a warning.

```python
In [142]: fig, axes = plt.subplots(4, 4, figsize=(9, 9))
In [143]: plt.subplots_adjust(wspace=0.5, hspace=0.5)
In [144]: target1 = [axes[0][0], axes[1][1], axes[2][2], axes[3][3]]
In [145]: target2 = [axes[3][0], axes[2][1], axes[1][2], axes[0][3]]
In [146]: df.plot(subplots=True, ax=target1, legend=False, sharex=False, sharey=False);
In [147]: (-df).plot(subplots=True, ax=target2, legend=False, sharex=False, sharey=False);
```
Another option is passing an `ax` argument to `Series.plot()` to plot on a particular axis:

```python
In [148]: fig, axes = plt.subplots(nrows=2, ncols=2)
In [149]: plt.subplots_adjust(wspace=0.2, hspace=0.5)
In [150]: df["A"].plot(ax=axes[0, 0]);
In [151]: axes[0, 0].set_title("A");
In [152]: df["B"].plot(ax=axes[0, 1]);
In [153]: axes[0, 1].set_title("B");
In [154]: df["C"].plot(ax=axes[1, 0]);
(continues on next page)
```
Plotting with error bars

Plotting with error bars is supported in `DataFrame.plot()` and `Series.plot()`.

Horizontal and vertical error bars can be supplied to the `xerr` and `yerr` keyword arguments to `plot()`. The error values can be specified using a variety of formats:

- As a `DataFrame` or dict of errors with column names matching the `columns` attribute of the plotting `DataFrame` or matching the `name` attribute of the `Series`.
- As a `str` indicating which of the columns of plotting `DataFrame` contain the error values.
- As raw values (`list`, `tuple`, or `np.ndarray`). Must be the same length as the plotting `DataFrame/Series`.

Here is an example of one way to easily plot group means with standard deviations from the raw data.
# Generate the data
In [158]: ix3 = pd.MultiIndex.from_arrays(  
......:     [  
......:         ["a", "a", "a", "a", "b", "b", "b", "b", "b"],  
......:         ["foo", "foo", "foo", "bar", "bar", "foo", "foo", "bar", "bar"]  
......:     ],  
......:     names=["letter", "word"],  
......: )  
......:

In [159]: df3 = pd.DataFrame(  
......:     {  
......:         "data1": [9, 3, 2, 4, 3, 2, 4, 6, 3, 2],  
......:         "data2": [9, 6, 5, 7, 5, 4, 5, 6, 5, 1],  
......:     },  
......:     index=ix3,  
......: )  
......:

# Group by index labels and take the means and standard deviations  
# for each group
In [160]: gp3 = df3.groupby(level=("letter", "word"))
In [161]: means = gp3.mean()
In [162]: errors = gp3.std()

In [163]: means
Out[163]:
<table>
<thead>
<tr>
<th>letter</th>
<th>word</th>
<th>data1</th>
<th>data2</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>bar</td>
<td>3.500000</td>
<td>6.000000</td>
</tr>
<tr>
<td></td>
<td>foo</td>
<td>4.666667</td>
<td>6.666667</td>
</tr>
<tr>
<td>b</td>
<td>bar</td>
<td>3.666667</td>
<td>4.000000</td>
</tr>
<tr>
<td></td>
<td>foo</td>
<td>3.000000</td>
<td>4.500000</td>
</tr>
</tbody>
</table>

In [164]: errors
Out[164]:
<table>
<thead>
<tr>
<th>letter</th>
<th>word</th>
<th>data1</th>
<th>data2</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>bar</td>
<td>0.707107</td>
<td>1.414214</td>
</tr>
<tr>
<td></td>
<td>foo</td>
<td>3.785939</td>
<td>2.081666</td>
</tr>
<tr>
<td>b</td>
<td>bar</td>
<td>2.081666</td>
<td>2.645751</td>
</tr>
<tr>
<td></td>
<td>foo</td>
<td>1.414214</td>
<td>0.707107</td>
</tr>
</tbody>
</table>

# Plot
In [165]: fig, ax = plt.subplots()

In [166]: means.plot.bar(yerr=errors, ax=ax, capsize=4, rot=0);
Asymmetrical error bars are also supported, however raw error values must be provided in this case. For a $N$ length *Series*, a $2xN$ array should be provided indicating lower and upper (or left and right) errors. For a $MxN$ *DataFrame*, asymmetrical errors should be in a $Mx2xN$ array.

Here is an example of one way to plot the min/max range using asymmetrical error bars.

```python
In [167]: mins = gp3.min()
In [168]: maxs = gp3.max()
# errors should be positive, and defined in the order of lower, upper
In [169]: errors = [[means[c] - mins[c], maxs[c] - means[c]] for c in df3.columns]
# Plot
In [170]: fig, ax = plt.subplots()
In [171]: means.plot.bar(yerr=errors, ax=ax, capsize=4, rot=0);
```
Plotting tables

Plotting with matplotlib table is now supported in DataFrame.plot() and Series.plot() with a table keyword. The table keyword can accept bool, DataFrame or Series. The simple way to draw a table is to specify table=True. Data will be transposed to meet matplotlib’s default layout.

```python
In [172]: fig, ax = plt.subplots(1, 1, figsize=(7, 6.5))

In [173]: df = pd.DataFrame(np.random.rand(5, 3), columns=['a', 'b', 'c'])

In [174]: ax.xaxis.tick_top()  # Display x-axis ticks on top.

In [175]: df.plot(table=True, ax=ax);
```
Also, you can pass a different `DataFrame` or `Series` to the `table` keyword. The data will be drawn as displayed in print method (not transposed automatically). If required, it should be transposed manually as seen in the example below.

```python
In [176]: fig, ax = plt.subplots(1, 1, figsize=(7, 6.75))

In [177]: ax.xaxis.tick_top()  # Display x-axis ticks on top.

In [178]: df.plot(table=np.round(df.T, 2), ax=ax);
```
There also exists a helper function pandas.plotting.table, which creates a table from DataFrame or Series, and adds it to an matplotlib.Axes instance. This function can accept keywords which the matplotlib table has.

```
In [179]: from pandas.plotting import table

In [180]: fig, ax = plt.subplots(1, 1)

In [181]: table(ax, np.round(df.describe(), 2), loc="upper right", colWidths=[0.2, 0.2, 0.2]);

In [182]: df.plot(ax=ax, ylim=(0, 2), legend=None);
```
Note: You can get table instances on the axes using `axes.tables` property for further decorations. See the matplotlib table documentation for more.

Colormaps

A potential issue when plotting a large number of columns is that it can be difficult to distinguish some series due to repetition in the default colors. To remedy this, `DataFrame` plotting supports the use of the `colormap` argument, which accepts either a Matplotlib colormap or a string that is a name of a colormap registered with Matplotlib. A visualization of the default matplotlib colormaps is available here.

As matplotlib does not directly support colormaps for line-based plots, the colors are selected based on an even spacing determined by the number of columns in the `DataFrame`. There is no consideration made for background color, so some colormaps will produce lines that are not easily visible.

To use the cubehelix colormap, we can pass `colormap='cubehelix'`.

```python
In [183]: df = pd.DataFrame(np.random.randn(1000, 10), index=ts.index)
In [184]: df = df.cumsum()
In [185]: plt.figure();
In [186]: df.plot(colormap="cubehelix");
```
Alternatively, we can pass the colormap itself:

```python
In [187]: from matplotlib import cm
In [188]: plt.figure();
In [189]: df.plot(colormap=cm.cubehelix);
```
Colormaps can also be used other plot types, like bar charts:

```python
In [190]: dd = pd.DataFrame(np.random.randn(10, 10)).applymap(abs)
In [191]: dd = dd.cumsum()
In [192]: plt.figure();
In [193]: dd.plot.bar(colormap="Greens");
```
Parallel coordinates charts:

```python
In [194]: plt.figure();

In [195]: parallel_coordinates(data, "Name", colormap="gist_rainbow");
```
Andrews curves charts:

```python
In [196]: plt.figure();

In [197]: andrews_curves(data, "Name", colormap="winter");
```
2.15.6 Plotting directly with matplotlib

In some situations it may still be preferable or necessary to prepare plots directly with matplotlib, for instance when a certain type of plot or customization is not (yet) supported by pandas. Series and DataFrame objects behave like arrays and can therefore be passed directly to matplotlib functions without explicit casts.

pandas also automatically registers formatters and locators that recognize date indices, thereby extending date and time support to practically all plot types available in matplotlib. Although this formatting does not provide the same level of refinement you would get when plotting via pandas, it can be faster when plotting a large number of points.

```python
In [198]: price = pd.Series(
   ....:     np.random.randn(150).cumsum(),
   ....:     index=pd.date_range("2000-1-1", periods=150, freq="B"),
   ....: )
   ....:
In [199]: ma = price.rolling(20).mean()
In [200]: mstd = price.rolling(20).std()
In [201]: plt.figure();
In [202]: plt.plot(price.index, price, "k");
```

(continues on next page)
2.15.7 Plotting backends

Starting in version 0.25, pandas can be extended with third-party plotting backends. The main idea is letting users select a plotting backend different than the provided one based on Matplotlib.

This can be done by passing `backend.module` as the argument `backend` in `plot` function. For example:

```python
>>> Series([1, 2, 3]).plot(backend="backend.module")
```

Alternatively, you can also set this option globally, do you don’t need to specify the keyword in each `plot` call. For example:

```python
>>> pd.set_option("plotting.backend", "backend.module")

>>> pd.Series([1, 2, 3]).plot()
```

Or:
This would be more or less equivalent to:

```python
>>> import backend.module
>>> backend.module.plot(pd.Series([1, 2, 3]))
```

The backend module can then use other visualization tools (Bokeh, Altair, hvplot,...) to generate the plots. Some libraries implementing a backend for pandas are listed on the ecosystem ecosystem.visualization page.

Developers guide can be found at https://pandas.pydata.org/docs/dev/development/extending.html#plotting-backends

## 2.16 Table Visualization

This section demonstrates visualization of tabular data using the `Styler` class. For information on visualization with charting please see *Chart Visualization*. This document is written as a Jupyter Notebook, and can be viewed or downloaded here.

### 2.16.1 Styler Object and HTML

Styling should be performed after the data in a DataFrame has been processed. The `Styler` creates an HTML `<table>` and leverages CSS styling language to manipulate many parameters including colors, fonts, borders, background, etc. See here for more information on styling HTML tables. This allows a lot of flexibility out of the box, and even enables web developers to integrate DataFrames into their exiting user interface designs.

The DataFrame.style attribute is a property that returns a `Styler` object. It has a `_repr_html_` method defined on it so they are rendered automatically in Jupyter Notebook.

```python
[2]: import pandas as pd
    import numpy as np

df = pd.DataFrame([[38.0, 2.0, 18.0, 22.0, 21, np.nan],
                  [19, 439, 6, 452, 226,232]],
              index=pd.Index(['Tumour (Positive)', 'Non-Tumour (Negative)'], name='Actual Label:'),
              columns=pd.MultiIndex.from_product([['Decision Tree', 'Regression', 'Random'],['Tumour', 'Non-Tumour']], names=['Model:', 'Predicted:']))

df.style
```

The above output looks very similar to the standard DataFrame HTML representation. But the HTML here has already attached some CSS classes to each cell, even if we haven’t yet created any styles. We can view these by calling the `.render()` method, which returns the raw HTML as string, which is useful for further processing or adding to a file - read on in *More about CSS and HTML*. Below we will show how we can use these to format the DataFrame to be more communicative. For example how we can build `s`:

```python
[4]: s
```

```python
[4]: <pandas.io.formats.style.Styler at 0x7f16f3e4c1c0>
```
2.16.2 Formatting the Display

Formatting Values

Before adding styles it is useful to show that the *Styler* can distinguish the *display* value from the *actual* value. To control the display value, the text is printed in each cell, and we can use the *format* method to manipulate this according to a *format spec string* or a callable that takes a single value and returns a string. It is possible to define this for the whole table or for individual columns.

Additionally, the format function has a *precision* argument to specifically help formatting floats, as well as *decimal* and *thousands* separators to support other locales, an *na_rep* argument to display missing data, and an *escape* argument to help displaying safe-HTML or safe-LaTeX. The default formatter is configured to adopt pandas’ regular *display.precision* option, controllable using `pd.option_context('display.precision', 2)`.

Here is an example of using the multiple options to control the formatting generally and with specific column formats.

```python
[5]: df.style.format(precision=0, na_rep='MISSING', thousands=' ',
                  formatter={('Decision Tree', 'Tumour'): '{:.2f}',
                             ('Regression', 'Non-Tumour'): lambda x: '$ {:.1f}.'
                              →format(x*-1e6)

                  })
```

Hiding Data

The index and column headers can be completely hidden, as well subselecting rows or columns that one wishes to exclude. Both these options are performed using the same methods.

The index can be hidden from rendering by calling `.hide_index()` without any arguments, which might be useful if your index is integer based. Similarly column headers can be hidden by calling `.hide_columns()` without any arguments.

Specific rows or columns can be hidden from rendering by calling the same `.hide_index()` or `.hide_columns()` methods and passing in a row/column label, a list-like or a slice of row/column labels to for the *subset* argument.

Hiding does not change the integer arrangement of CSS classes, e.g. hiding the first two columns of a DataFrame means the column class indexing will start at *col2*, since *col0* and *col1* are simply ignored.

We can update our *Styler* object to hide some data and format the values.

```python
[6]: s = df.style.format('{:.0f}').hide_columns([('Random', 'Tumour'), ('Random', 'Non-
‹→Tumour')])
```

```
[6]: <pandas.io.formats.style.Styler at 0x7f16b87aee80>
```
2.16.3 Methods to Add Styles

There are 3 primary methods of adding custom CSS styles to Styler:

- Using `set_table_styles()` to control broader areas of the table with specified internal CSS. Although table styles allow the flexibility to add CSS selectors and properties controlling all individual parts of the table, they are unwieldy for individual cell specifications. Also, note that table styles cannot be exported to Excel.

- Using `set_td_classes()` to directly link either external CSS classes to your data cells or link the internal CSS classes created by `set_table_styles()`. See here. These cannot be used on column header rows or indexes, and also won’t export to Excel.

- Using the `apply()` and `applymap()` functions to add direct internal CSS to specific data cells. See here. These cannot be used on column header rows or indexes, but only these methods add styles that will export to Excel. These methods work in a similar way to `DataFrame.apply()` and `DataFrame.applymap()`.

2.16.4 Table Styles

Table styles are flexible enough to control all individual parts of the table, including column headers and indexes. However, they can be unwieldy to type for individual data cells or for any kind of conditional formatting, so we recommend that table styles are used for broad styling, such as entire rows or columns at a time.

Table styles are also used to control features which can apply to the whole table at once such as creating a generic hover functionality. The :hover pseudo-selector, as well as other pseudo-selectors, can only be used this way.

To replicate the normal format of CSS selectors and properties (attribute value pairs), e.g.

```tr:hover {
    background-color: #fff99b;
}
```

the necessary format to pass styles to `set_table_styles()` is as a list of dicts, each with a CSS-selector tag and CSS-properties. Properties can either be a list of 2-tuples, or a regular CSS-string, for example:

```python
[8]: cell_hover = {  # for row hover use <tr> instead of <td>
    'selector': 'td:hover',
    'props': [('background-color', '#fff99b')]
}
index_names = {
    'selector': '.index_name',
    'props': 'font-style: italic; color: darkgrey; font-weight:normal;'}
headers = {
    'selector': 'th:not(.index_name)',
    'props': 'background-color: #000066; color: white;'}
s.set_table_styles([cell_hover, index_names, headers])
```

Next we just add a couple more styling artifacts targeting specific parts of the table. Be careful here, since we are chaining methods we need to explicitly instruct the method not to overwrite the existing styles.

```python
[10]: s.set_table_styles(
        [{'selector': 'th.col_heading', 'props': 'text-align: center;'},
         {'selector': 'th.col_heading.level0', 'props': 'font-size: 1.5em;'},
         {'selector': 'td', 'props': 'text-align: center; font-weight: bold;'},
        ], overwrite=False)
```
As a convenience method (since version 1.2.0) we can also pass a dict to `.set_table_styles()` which contains row or column keys. Behind the scenes Styler just indexes the keys and adds relevant `.col<m>` or `.row<n>` classes as necessary to the given CSS selectors.

```python
s.set_table_styles(
    ('Regression', 'Tumour'): [{'selector': 'th', 'props': 'border-left: 1px solid white'},
     {'selector': 'td', 'props': 'border-left: 1px solid #000066'}], overwrite=False, axis=0)
```

### 2.16.5 Setting Classes and Linking to External CSS

If you have designed a website then it is likely you will already have an external CSS file that controls the styling of table and cell objects within it. You may want to use these native files rather than duplicate all the CSS in python (and duplicate any maintenance work).

**Table Attributes**

It is very easy to add a class to the main `<table>` using `.set_table_attributes()`. This method can also attach inline styles - read more in CSS Hierarchies.

```python
out = s.set_table_attributes('class="my-table-cls"').render()
print(out[out.find('<table'):][:109])
```

```html
<table id="T_xyz01" class="my-table-cls">
<thead>
<tr>
<th class="index_name level0" >Model:</th>
</tr>
</thead>
</table>
```

**Data Cell CSS Classes**

*New in version 1.2.0*

The `.set_td_classes()` method accepts a DataFrame with matching indices and columns to the underlying Styler’s DataFrame. That DataFrame will contain strings as css-classes to add to individual data cells: the `<td>` elements of the `<table>`. Rather than use external CSS we will create our classes internally and add them to table style. We will save adding the borders until the section on tooltips.

```python
s.set_table_styles([  # create internal CSS classes
    {'selector': '.true', 'props': 'background-color: #e6ffe6;'},
    {'selector': '.false', 'props': 'background-color: #ffe6e6;'},
], overwrite=False)
cell_color = pd.DataFrame([[true ', 'false ', 'true ', 'false '],
     ['false ', 'true ', 'false ', 'true ']],
    index=df.index,
    columns=df.columns[:4])
s.set_td_classes(cell_color)
```
2.16.6 Styler Functions

We use the following methods to pass your style functions. Both of those methods take a function (and some other keyword arguments) and apply it to the DataFrame in a certain way, rendering CSS styles.

- `.applymap()` (elementwise): accepts a function that takes a single value and returns a string with the CSS attribute-value pair.

- `.apply()` (column-/row-/table-wise): accepts a function that takes a Series or DataFrame and returns a Series, DataFrame, or numpy array with an identical shape where each element is a string with a CSS attribute-value pair. This method passes each column or row of your DataFrame one-at-a-time or the entire table at once, depending on the `axis` keyword argument. For columnwise use `axis=0`, rowwise use `axis=1`, and for the entire table at once use `axis=None`.

This method is powerful for applying multiple, complex logic to data cells. We create a new DataFrame to demonstrate this.

```python
np.random.seed(0)
df2 = pd.DataFrame(np.random.randn(10,4), columns=['A','B','C','D'])
df2.style
```

For example we can build a function that colors text if it is negative, and chain this with a function that partially fades cells of negligible value. Since this looks at each element in turn we use `applymap`.

```python
def style_negative(v, props=''):    
    return props if v < 0 else None
s2 = df2.style.applymap(style_negative, props='color:red;')
    .applymap(lambda v: 'opacity: 20%;' if (v < 0.3) and (v > -0.3) else None)
s2
```

We can also build a function that highlights the maximum value across rows, cols, and the DataFrame all at once. In this case we use `apply`. Below we highlight the maximum in a column.

```python
def highlight_max(s, props=''):    
    return np.where(s == np.nanmax(s.values), props, '')
s2.apply(highlight_max, props='color:white;background-color:darkblue', axis=0)
```

We can use the same function across the different axes, highlighting here the DataFrame maximum in purple, and row maximums in pink.

```python
.s2.apply(highlight_max, props='color:white;background-color:pink;', axis=1)\n    .apply(highlight_max, props='color:white;background-color:purple', axis=None)
```

This last example shows how some styles have been overwritten by others. In general the most recent style applied is active but you can read more in the section on CSS hierarchies. You can also apply these styles to more granular parts of the DataFrame - read more in section on subset slicing.
It is possible to replicate some of this functionality using just classes but it can be more cumbersome. See item 3) of Optimization

Debugging Tip: If you’re having trouble writing your style function, try just passing it into DataFrame.apply. Internally, Styler.apply uses DataFrame.apply so the result should be the same, and with DataFrame.apply you will be able to inspect the CSS string output of your intended function in each cell.

### 2.16.7 Tooltips and Captions

Table captions can be added with the `.set_caption()` method. You can use table styles to control the CSS relevant to the caption.

```python
[23]: s.set_caption("Confusion matrix for multiple cancer prediction models.")
   .set_table_styles([{
       'selector': 'caption',
       'props': 'caption-side: bottom; font-size:1.25em;'  
      }, overwrite=False])

[23]: <pandas.io.formats.style.Styler at 0x7f1693e4c310>
```

Adding tooltips (since version 1.3.0) can be done using the `.set_tooltips()` method in the same way you can add CSS classes to data cells by providing a string based DataFrame with intersecting indices and columns. You don’t have to specify a `css_class` name or any css props for the tooltips, since there are standard defaults, but the option is there if you want more visual control.

```python
[25]: tt = pd.DataFrame([["This model has a very strong true positive rate",
                        "This model's total number of false negatives is too high"],
                       index=['Tumour (Positive)'], columns=df.columns[[0,3]])
   s.set_tooltips(tt, props='visibility: hidden; position: absolute; z-index: 1; border: 1px solid #000066;'
                  'background-color: white; color: #000066; font-size: 0.8em;'                  'transform: translate(0px, -24px); padding: 0.6em; border-radius: 0.5em;')

[25]: <pandas.io.formats.style.Styler at 0x7f1693e4c310>
```

The only thing left to do for our table is to add the highlighting borders to draw the audience attention to the tooltips. We will create internal CSS classes as before using table styles. Setting classes always overwrites so we need to make sure we add the previous classes.

```python
[27]: s.set_table_styles([ # create internal CSS classes
       {'selector': '.border-red', 'props': 'border: 2px dashed red;'},
       {'selector': '.border-green', 'props': 'border: 2px dashed green;'},
      ], overwrite=False)
   cell_border = pd.DataFrame([['border-green ', ' ', ' ', 'border-red '],
                            [' ', ' ', ' ', ' '],
                            index=df.index,
                            columns=df.columns[:4])
   s.set_td_classes(cell_color + cell_border)

[27]: <pandas.io.formats.style.Styler at 0x7f1693e4c310>
```
2.16.8 Finer Control with Slicing

The examples we have shown so far for the `Styler.apply` and `Styler.applymap` functions have not demonstrated the use of the `subset` argument. This is a useful argument which permits a lot of flexibility: it allows you to apply styles to specific rows or columns, without having to code that logic into your `style` function.

The value passed to `subset` behaves similar to slicing a DataFrame:

- A scalar is treated as a column label
- A list (or Series or NumPy array) is treated as multiple column labels
- A tuple is treated as `(row_indexer, column_indexer)`

Consider using `pd.IndexSlice` to construct the tuple for the last one. We will create a MultiIndexed DataFrame to demonstrate the functionality.

```
[29]: df3 = pd.DataFrame(np.random.randn(4,4),
                      pd.MultiIndex.from_product([['A', 'B'], ['r1', 'r2']]),
                      columns=['c1','c2','c3','c4'])
df3
```

<table>
<thead>
<tr>
<th></th>
<th>c1</th>
<th>c2</th>
<th>c3</th>
<th>c4</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>-1.048553</td>
<td>-1.420018</td>
<td>-1.706270</td>
<td>1.950775</td>
</tr>
<tr>
<td></td>
<td>-0.509652</td>
<td>-0.438074</td>
<td>-1.252795</td>
<td>0.777490</td>
</tr>
<tr>
<td>B</td>
<td>-1.613898</td>
<td>-0.212740</td>
<td>-0.895467</td>
<td>0.386902</td>
</tr>
<tr>
<td></td>
<td>-0.510805</td>
<td>-1.180632</td>
<td>-0.028182</td>
<td>0.428332</td>
</tr>
</tbody>
</table>

We will use `subset` to highlight the maximum in the third and fourth columns with red text. We will highlight the subset sliced region in yellow.

```
[30]: slice_ = ['c3', 'c4']
df3.style.apply(highlight_max, props='color:red;', axis=0, subset=slice_)
          .set_properties(**{'background-color': '#ffffb3'}, subset=slice_)
```

```
<font color='red'>pandas.io.formats.style.Styler at 0x7f1693e62700</font>
```

If combined with the `IndexSlice` as suggested then it can index across both dimensions with greater flexibility.

```
[31]: idx = pd.IndexSlice
slice_ = idx[idx[:, 'r1'], idx['c2':'c4']] 
df3.style.apply(highlight_max, props='color:red;', axis=0, subset=slice_)
          .set_properties(**{'background-color': '#ffffb3'}, subset=slice_)
```

```
<font color='red'>pandas.io.formats.style.Styler at 0x7f1693e62f10</font>
```

This also provides the flexibility to sub select rows when used with the `axis=1`.

```
[32]: slice_ = idx[idx[:, 'r2'], :]
df3.style.apply(highlight_max, props='color:red;', axis=1, subset=slice_)
          .set_properties(**{'background-color': '#ffffb3'}, subset=slice_)
```

```
<font color='red'>pandas.io.formats.style.Styler at 0x7f1693e62820</font>
```

There is also scope to provide **conditional filtering**.

Suppose we want to highlight the maximum across columns 2 and 4 only in the case that the sum of columns 1 and 3 is less than -2.0 (essentially excluding rows `(:, 'r2')`).

```
[33]: slice_ = idx[idx[(df3['c1'] + df3['c3']) < -2.0], ['c2', 'c4']] 
df3.style.apply(highlight_max, props='color:red;', axis=1, subset=slice_)
          .set_properties(**{'background-color': '#ffffb3'}, subset=slice_)
```

```
<font color='red'>pandas.io.formats.style.Styler at 0x7f1693e62820</font>
```
Only label-based slicing is supported right now, not positional, and not callables.

If your style function uses a `subset` or `axis` keyword argument, consider wrapping your function in a `functools.partial`, partialing out that keyword.

```python
my_func2 = functools.partial(my_func, subset=42)
```

### 2.16.9 Optimization

Generally, for smaller tables and most cases, the rendered HTML does not need to be optimized, and we don’t really recommend it. There are two cases where it is worth considering:

- If you are rendering and styling a very large HTML table, certain browsers have performance issues.
- If you are using `Styler` to dynamically create part of online user interfaces and want to improve network performance.

Here we recommend the following steps to implement:

1. **Remove UUID and cell_ids**

Ignore the `uuid` and set `cell_ids` to False. This will prevent unnecessary HTML.

This is sub-optimal:

```python
df4 = pd.DataFrame([[[1, 2], [3, 4]]])
s4 = df4.style
```

This is better:

```python
from pandas.io.formats.style import Styler
s4 = Styler(df4, uuid_len=0, cell_ids=False)
```

2. **Use table styles**

Use table styles where possible (e.g. for all cells or rows or columns at a time) since the CSS is nearly always more efficient than other formats.

This is sub-optimal:

```python
props = 'font-family: "Times New Roman", Times, serif; color: #e83e8c; font-size:1.3em;'
df4.style.applymap(lambda x: props, subset=[1])
```

2.16. Table Visualization
3. Set classes instead of using Styler functions

For large DataFrames where the same style is applied to many cells it can be more efficient to declare the styles as classes and then apply those classes to data cells, rather than directly applying styles to cells. It is, however, probably still easier to use the Styler function api when you are not concerned about optimization.

This is better:

```python
[37]: df4.style.set_table_styles([{'selector': 'td.col1', 'props': props}])
[37]: <pandas.io.formats.style.Styler at 0x7f1693e1ef40>
```

This is sub-optimal:

```python
[38]: df2.style.apply(highlight_max, props='color:white;background-color:darkblue;', axis=0)\ .apply(highlight_max, props='color:white;background-color:pink;', axis=1)\ .apply(highlight_max, props='color:white;background-color:purple', axis=None)
```

This is better:

```python
[39]: build = lambda x: pd.DataFrame(x, index=df2.index, columns=df2.columns) cls1 = build(df2.apply(highlight_max, props='cls-1 ', axis=0)) cls2 = build(df2.apply(highlight_max, props='cls-2 ', axis=1, result_type='expand').values) cls3 = build(highlight_max(df2, props='cls-3 ')) df2.style.set_table_styles([\ {'selector': '.cls-1', 'props': 'color:white;background-color:darkblue;'},\ {'selector': '.cls-2', 'props': 'color:white;background-color:pink;'},\ {'selector': '.cls-3', 'props': 'color:white;background-color:purple;'}\ ]).set_td_classes(cls1 + cls2 + cls3)
```

[39]: <pandas.io.formats.style.Styler at 0x7f1693dba6a0>
4. Don’t use tooltips

Tooltips require cell_ids to work and they generate extra HTML elements for every data cell.

5. If every byte counts use string replacement

You can remove unnecessary HTML, or shorten the default class names with string replace functions.

```python
import re
html = re.sub(r'col\[0-9\]+', lambda x: x.group().replace('col', 'c'), html)
html = re.sub(r'row\[0-9\]+', lambda x: x.group().replace('row', 'r'), html)
print(html)
```

```
<style type="text/css">
#T__ td {
    font-family: "Times New Roman", Times, serif;
    color: #e83e8c;
    font-size: 1.3em;
}
#T__ .c1 {
    color: green;
}
#T__ .l0 {
    color: blue;
}
</style>
<table id="T__">
<thead>
<tr>
<th id="T__l0_r0" class=" l0 r0" >0</th>
<td class=" r0 c0" >1</td>
<td class=" r0 c1" >2</td>
</tr>
</thead>
<tbody>
<tr>
<th id="T__l0_r1" class=" l0 r1" >1</th>
<td class=" r1 c0" >3</td>
<td class=" r1 c1" >4</td>
</tr>
</tbody>
</table>
```
2.16.10 Builtin Styles

Some styling functions are common enough that we’ve “built them in” to the Styler, so you don’t have to write them and apply them yourself. The current list of such functions is:

- `.highlight_null`: for use with identifying missing data.
- `.highlight_min` and `.highlight_max`: for use with identifying extremeties in data.
- `.highlight_between` and `.highlight_quantile`: for use with identifying classes within data.
- `.background_gradient`: a flexible method for highlighting cells based or their, or other, values on a numeric scale.
- `.text_gradient`: similar method for highlighting text based on their, or other, values on a numeric scale.
- `.bar`: to display mini-charts within cell backgrounds.

The individual documentation on each function often gives more examples of their arguments.

**Highlight Null**

```python
[42]: df2.iloc[0,2] = np.nan
df2.iloc[4,3] = np.nan
df2.loc[:4].style.highlight_null(null_color='yellow')
```

**Highlight Min or Max**

```python
[43]: df2.loc[:4].style.highlight_max(axis=1, props='color:white, font-weight:bold, background-color:darkblue;')
```

**Highlight Between**

This method accepts ranges as float, or NumPy arrays or Series provided the indexes match.

```python
[44]: left = pd.Series([1.0, 0.0, 1.0], index=['A', 'B', 'D'])
df2.loc[:4].style.highlight_between(left=left, right=1.5, axis=1, props='color:white, background-color:purple;')
```

Highlight Quantile

Useful for detecting the highest or lowest percentile values

```python
[45]: df2.loc[:4].style.highlight_quantile(q_left=0.85, axis=None, color='yellow')
```

```python
[45]: <pandas.io.formats.style.Styler at 0x7f1693e4c5e0>
```

Background Gradient and Text Gradient

You can create “heatmaps” with the `background_gradient` and `text_gradient` methods. These require `matplotlib`, and we’ll use `Seaborn` to get a nice colormap.

```python
[46]: import seaborn as sns
    cm = sns.light_palette("green", as_cmap=True)
    df2.style.background_gradient(cmap=cm)
```

```python
[46]: <pandas.io.formats.style.Styler at 0x7f1693dbaca0>
```

```python
[47]: df2.style.text_gradient(cmap=cm)
```

```python
[47]: <pandas.io.formats.style.Styler at 0x7f1693e4cd00>
```

`.background_gradient` and `.text_gradient` have a number of keyword arguments to customise the gradients and colors. See the documentation.

Set properties

Use `Styler.set_properties` when the style doesn’t actually depend on the values. This is just a simple wrapper for `.applymap` where the function returns the same properties for all cells.

```python
[48]: df2.loc[:4].style.set_properties(**{'background-color': 'black',
                                         'color': 'lawngreen',
                                         'border-color': 'white'})
```

```python
[48]: <pandas.io.formats.style.Styler at 0x7f16895d5d00>
```

Bar charts

You can include “bar charts” in your DataFrame.

```python
[49]: df2.style.bar(subset=['A', 'B'], color="#d65f5f")
```

```python
[49]: <pandas.io.formats.style.Styler at 0x7f16895f60a0>
```

In version 0.20.0 the ability to customize the bar chart further was given. You can now have the `df.style.bar` be centered on zero or midpoint value (in addition to the already existing way of having the min value at the left side of the cell), and you can pass a list of `[color_negative, color_positive]`.

Here’s how you can change the above with the new `align='mid'` option:

```python
[50]: df2.style.bar(subset=['A', 'B'], align='mid', color=['#d65f5f', '#5fba7d'])
```

```python
[50]: <pandas.io.formats.style.Styler at 0x7f16895e70d0>
```
The following example aims to give a highlight of the behavior of the new align options:

```
> HTML(head)
> <IPython.core.display.HTML object>
```

### 2.16.11 Sharing styles

Say you have a lovely style built up for a DataFrame, and now you want to apply the same style to a second DataFrame. Export the style with `df1.style.export`, and import it on the second DataFrame with `df1.style.set`.

```
> style1 = df2.style.applymap(style_negative, props='color:red;')
> .applymap(lambda v: 'opacity: 20%;' if (v < 0.3) and (v > -0.3) else None)
> style2 = df3.style
> style2.use(style1.export())
> style2
> <pandas.io.formats.style.Styler at 0x7f16895e7bb0>
```

Notice that you’re able to share the styles even though they’re data aware. The styles are re-evaluated on the new DataFrame they’ve been used upon.

### 2.16.12 Limitations

- DataFrame only (use `Series.to_frame().style`)
- The index and columns must be unique
- No large repr, and construction performance isn’t great; although we have some HTML optimizations
- You can only style the values, not the index or columns (except with `table_styles` above)
- You can only apply styles, you can’t insert new HTML entities

Some of these might be addressed in the future.

### 2.16.13 Other Fun and Useful Stuff

Here are a few interesting examples.

**Widgets**

Styler interacts pretty well with widgets. If you’re viewing this online instead of running the notebook yourself, you’re missing out on interactively adjusting the color palette.

```
> from ipywidgets import widgets
> @widgets.interact
> def f(h_neg=(0, 359, 1), h_pos=(0, 359), s=(0., 99.9), l=(0., 99.9)):
>     return df2.style.background_gradient(
>         cmap=sns.palettes.diverging_palette(h_neg=h_neg, h_pos=h_pos, s=s, l=l,
>             as_cmap=True)
>     )
> interactive(children=(IntSlider(value=179, description='h_neg', max=359),
>              IntSlider(value=179, description='h_pos'))
```

Magnify

```python
[56]: def magnify():
    return [
        dict(selector="th",
             props=[("font-size", "4pt")]),
        dict(selector="td",
             props=[('padding', '0em 0em')]),
        dict(selector="th:hover",
             props=[("font-size", "12pt")]),
        dict(selector="tr:hover td:hover",
             props=[('max-width', '200px'),
                    ('font-size', '12pt')])
    ]
```

```python
[57]: np.random.seed(25)
cmap = cmap=sns.diverging_palette(5, 250, as_cmap=True)
bigdf = pd.DataFrame(np.random.randn(20, 25)).cumsum()
bigdf.style.background_gradient(cmap, axis=1)\n        .set_properties(**{'max-width': '80px', 'font-size': '1pt'})\n        .set_caption("Hover to magnify")\n        .format(precision=2)\n        .set_table_styles(magnify())
```

Sticky Headers

If you display a large matrix or DataFrame in a notebook, but you want to always see the column and row headers you can use the `.set_sticky` method which manipulates the table styles CSS.

```python
[58]: bigdf = pd.DataFrame(np.random.randn(16, 100))
bigdf.style.set_sticky(axis="index")
```

```python
[59]: bigdf.index = pd.MultiIndex.from_product([["A","B"],[0,1],[0,1,2,3]])
bigdf.style.set_sticky(axis="index", pixel_size=18, levels=[1,2])
```

HTML Escaping

Suppose you have to display HTML within HTML, that can be a bit of pain when the renderer can’t distinguish. You can use the `escape` formatting option to handle this, and even use it within a formatter that contains HTML itself.

```python
[60]: df4 = pd.DataFrame([['<div></div>', '"&other"', '<span></span>']])
df4.style
```

```python
[61]: df4.style.format(escape="html")
```
2.16.14 Export to Excel

Some support (since version 0.20.0) is available for exporting styled DataFrames to Excel worksheets using the OpenPyXL or XlsxWriter engines. CSS2.2 properties handled include:

- background-color
- color
- font-family
- font-style
- font-weight
- text-align
- text-decoration
- vertical-align
- white-space: nowrap
- Currently broken: border-style, border-width, border-color and their {top, right, bottom, left} variants
- Only CSS2 named colors and hex colors of the form #rgb or #rrggbb are currently supported.
- The following pseudo CSS properties are also available to set excel specific style properties:
  - number-format

Table level styles, and data cell CSS-classes are not included in the export to Excel: individual cells must have their properties mapped by the Styler.apply and/or Styler.applymap methods.

```python
[63]: df2.style.applymap(style_negative, props='color:red;').highlight_max(axis=0).to_excel('styled.xlsx', engine='openpyxl')
```

A screenshot of the output:
2.16.15 Export to LaTeX

There is support (since version 1.3.0) to export Styler to LaTeX. The documentation for the .to_latex method gives further detail and numerous examples.

2.16.16 More About CSS and HTML

Cascading Style Sheet (CSS) language, which is designed to influence how a browser renders HTML elements, has its own peculiarities. It never reports errors: it just silently ignores them and doesn’t render your objects how you intend so can sometimes be frustrating. Here is a very brief primer on how Styler creates HTML and interacts with CSS, with advice on common pitfalls to avoid.

CSS Classes and Ids

The precise structure of the CSS class attached to each cell is as follows.

- Cells with Index and Column names include index_name and level<k> where k is its level in a MultiIndex
- Index label cells include
  - row_heading
  - level<k> where k is the level in a MultiIndex
  - row<m> where m is the numeric position of the row
- Column label cells include
  - col_heading
  - level<k> where k is the level in a MultiIndex
  - col<n> where n is the numeric position of the column
- Data cells include
  - data
  - row<m>, where m is the numeric position of the cell.
  - col<n>, where n is the numeric position of the cell.
• Blank cells include `blank`

The structure of the `id` is `T_uuid_level<k>_row<m>_col<n>` where `level<k>` is used only on headings, and headings will only have either `row<m>` or `col<n>` whichever is needed. By default we’ve also prepended each row/column identifier with a UUID unique to each DataFrame so that the style from one doesn’t collide with the styling from another within the same notebook or page. You can read more about the use of UUIDs in *Optimization*.

We can see example of the HTML by calling the `.render()` method.

```python
[64]: print(pd.DataFrame([[[1,2],[3,4]], index=['i1', 'i2'], columns=['c1', 'c2']]).style.
    → render())

<html><head></head>
<body>
<style type="text/css">
</style>
<table id="T_dc5bd_">
<thead>
<tr>
<th class="blank level0" >&nbsp;</th>
<th class="col_heading level0 col0" >c1</th>
<th class="col_heading level0 col1" >c2</th>
</tr>
</thead>
<tbody>
<tr>
<th id="T_dc5bd_level0_row0" class="row_heading level0 row0" >i1</th>
<td id="T_dc5bd_row0_col0" class="data row0 col0" >1</td>
<td id="T_dc5bd_row0_col1" class="data row0 col1" >2</td>
</tr>
<tr>
<th id="T_dc5bd_level0_row1" class="row_heading level0 row1" >i2</th>
<td id="T_dc5bd_row1_col0" class="data row1 col0" >3</td>
<td id="T_dc5bd_row1_col1" class="data row1 col1" >4</td>
</tr>
</tbody>
</table>
</body></html>
```

**CSS Hierarchies**

The examples have shown that when CSS styles overlap, the one that comes last in the HTML render, takes precedence. So the following yield different results:

```python
[65]: df4 = pd.DataFrame([['text']])
df4.style.applymap(lambda x: 'color:green;')
    .applymap(lambda x: 'color:red;')

[65]: <pandas.io.formats.style.Styler at 0x7f16868fe700>

[66]: df4.style.applymap(lambda x: 'color:red;')
    .applymap(lambda x: 'color:green;')

[66]: <pandas.io.formats.style.Styler at 0x7f16868fe280>
```

This is only true for CSS rules that are equivalent in hierarchy, or importance. You can read more about CSS specificity [here](#) but for our purposes it suffices to summarize the key points:

A CSS importance score for each HTML element is derived by starting at zero and adding:

- 1000 for an inline style attribute
• 100 for each ID
• 10 for each attribute, class or pseudo-class
• 1 for each element name or pseudo-element

Let’s use this to describe the action of the following configurations

```python
[67]: df4.style.set_uuid('a_')
   .set_table_styles(["selector": 'td', 'props': 'color:red;'])
   .applymap(lambda x: 'color:green;')

[67]: <pandas.io.formats.style.Styler at 0x7f1686917160>
```

This text is red because the generated selector #T_a_ td is worth 101 (ID plus element), whereas #T_a_row0_col0 is only worth 100 (ID), so is considered inferior even though in the HTML it comes after the previous.

```python
[68]: df4.style.set_uuid('b_')
   .set_table_styles(["selector": 'td', 'props': 'color:red;'},
   {'selector': '.cls-1', 'props': 'color:blue;'}
   .applymap(lambda x: 'color:green;')
   .set_td_classes(pd.DataFrame([['cls-1']])

[68]: <pandas.io.formats.style.Styler at 0x7f1686917820>
```

In the above case the text is blue because the selector #T_b_ .cls-1 is worth 110 (ID plus class), which takes precedence.

```python
[69]: df4.style.set_uuid('c_')
   .set_table_styles(["selector": 'td', 'props': 'color:red;'},
   {'selector': '.cls-1', 'props': 'color:blue;'},
   {'selector': 'td.data', 'props': 'color:yellow;'}
   .applymap(lambda x: 'color:green;')
   .set_td_classes(pd.DataFrame([['cls-1']])

[69]: <pandas.io.formats.style.Styler at 0x7f16868fe130>
```

Now we have created another table style this time the selector T_c_ td.data (ID plus element plus class) gets bumped up to 111.

If your style fails to be applied, and its really frustrating, try the !important trump card.

```python
[70]: df4.style.set_uuid('d_')
   .set_table_styles(["selector": 'td', 'props': 'color:red;'},
   {'selector': '.cls-1', 'props': 'color:blue;'},
   {'selector': 'td.data', 'props': 'color:yellow;'}
   .applymap(lambda x: 'color:green !important;')
   .set_td_classes(pd.DataFrame([['cls-1']])

[70]: <pandas.io.formats.style.Styler at 0x7f16868f07f0>
```

Finally got that green text after all!
2.16.17 Extensibility

The core of pandas is, and will remain, its “high-performance, easy-to-use data structures”. With that in mind, we hope that DataFrame.style accomplishes two goals

- Provide an API that is pleasing to use interactively and is “good enough” for many tasks
- Provide the foundations for dedicated libraries to build on

If you build a great library on top of this, let us know and we’ll link to it.

Subclassing

If the default template doesn’t quite suit your needs, you can subclass Styler and extend or override the template. We’ll show an example of extending the default template to insert a custom header before each table.

```python
from jinja2 import Environment, ChoiceLoader, FileSystemLoader
from IPython.display import HTML
from pandas.io.formats.style import Styler
```

We’ll use the following template:

```python
with open("templates/myhtml.tpl") as f:
    print(f.read())

{% extends "html_table.tpl" %}
{% block table %}
<h1>{{ table_title|default("My Table") }}</h1>
{{ super() }}
{% endblock table %}
```

Now that we’ve created a template, we need to set up a subclass of Styler that knows about it.

```python
class MyStyler(Styler):
    env = Environment(
        loader=ChoiceLoader(
            [FileSystemLoader("templates"),  # contains ours
             Styler.loader,  # the default
           ])
    )
    template_html_table = env.get_template("myhtml.tpl")
```

Notice that we include the original loader in our environment’s loader. That’s because we extend the original template, so the Jinja environment needs to be able to find it.

Now we can use that custom styler. It’s __init__ takes a DataFrame.

```python
MyStyler(df3)
```

```
<__main__.MyStyler at 0x7f16868f02e0>
```

Our custom template accepts a table_title keyword. We can provide the value in the .render method.

```python
HTML(MyStyler(df3).render(table_title="Extending Example"))
```

```
<IPython.core.display.HTML object>
```

For convenience, we provide the Styler.from_custom_template method that does the same as the custom subclass.
Template Structure

Here’s the template structure for both the style generation template and the table generation template:

Style template:

```python
[78]: HTML(style_structure)
[78]: <IPython.core.display.HTML object>
```

Table template:

```python
[80]: HTML(table_structure)
[80]: <IPython.core.display.HTML object>
```

See the template in the GitHub repo for more details.

## 2.17 Computational tools

### 2.17.1 Statistical functions

**Percent change**

Series and DataFrame have a method `pct_change()` to compute the percent change over a given number of periods (using `fill_method` to fill NA/null values `before` computing the percent change).

```python
In [1]: ser = pd.Series(np.random.randn(8))

In [2]: ser.pct_change()
Out[2]:
   0   NaN
   1 -1.602976
   2  4.334938
   3 -0.247456
   4 -2.067345
   5 -1.142903
   6 -1.688214
   7 -9.759729
dtype: float64

In [3]: df = pd.DataFrame(np.random.randn(10, 4))

In [4]: df.pct_change(periods=3)
Out[4]:
   0  1  2   3
0   NaN NaN NaN NaN
1   NaN NaN NaN NaN
```

(continues on next page)
Covariance

`Series.cov()` can be used to compute covariance between series (excluding missing values).

In [5]: s1 = pd.Series(np.random.randn(1000))
In [6]: s2 = pd.Series(np.random.randn(1000))
In [7]: s1.cov(s2)
Out[7]:

Analogously, `DataFrame.cov()` to compute pairwise covariances among the series in the DataFrame, also excluding NA/null values.

**Note:** Assuming the missing data are missing at random this results in an estimate for the covariance matrix which is unbiased. However, for many applications this estimate may not be acceptable because the estimated covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimated correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.

In [8]: frame = pd.DataFrame(np.random.randn(1000, 5), columns=
   ['a', 'b', 'c', 'd', 'e'])
In [9]: frame.cov()
Out[9]:

Dataframe.cov also supports an optional `min_periods` keyword that specifies the required minimum number of observations for each column pair in order to have a valid result.

In [10]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])
In [11]: frame.loc[frame.index[:5], 'a'] = np.nan
In [12]: frame.loc[frame.index[5:10], 'b'] = np.nan
In [13]: frame.cov()
Out[13]:

(continues on next page)
Correlation

Correlation may be computed using the \texttt{corr()} method. Using the \texttt{method} parameter, several methods for computing correlations are provided:

<table>
<thead>
<tr>
<th>Method name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pearson</td>
<td>Standard correlation coefficient</td>
</tr>
<tr>
<td>kendall</td>
<td>Kendall Tau correlation coefficient</td>
</tr>
<tr>
<td>spearman</td>
<td>Spearman rank correlation coefficient</td>
</tr>
</tbody>
</table>

All of these are currently computed using pairwise complete observations. Wikipedia has articles covering the above correlation coefficients:

- Pearson correlation coefficient
- Kendall rank correlation coefficient
- Spearman’s rank correlation coefficient

\textbf{Note:} Please see the \textit{caveats} associated with this method of calculating correlation matrices in the \textit{covariance section}.

```
In [15]: frame = pd.DataFrame(np.random.randn(1000, 5), columns=["a", "b", "c", "d", "e"])
In [16]: frame.iloc[::2] = np.nan
# Series with Series
In [17]: frame["a"].corr(frame["b"])  
Out[17]: 0.013479040400098775
In [18]: frame["a"].corr(frame["b"], method="spearman")  
Out[18]: -0.007289885159540637
# Pairwise correlation of DataFrame columns
In [19]: frame.corr()  
Out[19]:
   a    b    c    d    e
a 1.000000 -0.049269 -0.042239 -0.028525 0.013479
b -0.049269 1.000000 -0.020433 -0.011139 0.005654
```
Note that non-numeric columns will be automatically excluded from the correlation calculation.

Like `cov`, `corr` also supports the optional `min_periods` keyword:

```python
In [20]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])
In [21]: frame.loc[frame.index[:5], 'a'] = np.nan
In [22]: frame.loc[frame.index[5:10], 'b'] = np.nan
In [23]: frame.corr()
Out[23]:
    a     b     c
a  1.000000 -0.121111  0.069544
b -0.121111  1.000000  0.051742
c  0.069544  0.051742  1.000000
```

The `method` argument can also be a callable for a generic correlation calculation. In this case, it should be a single function that produces a single value from two ndarray inputs. Suppose we wanted to compute the correlation based on histogram intersection:

```python
# histogram intersection
In [25]: def histogram_intersection(a, b):
    ....:     return np.minimum(np.true_divide(a, a.sum()), np.true_divide(b, b.sum())).sum()
    ....:
In [26]: frame.corr(method=histogram_intersection)
Out[26]:
    a    b    c
a  1.000000 NaN  0.069544
b  NaN  1.000000  0.051742
c  0.069544  0.051742  1.000000
```

A related method `corrwith()` is implemented on DataFrame to compute the correlation between like-labeled Series contained in different DataFrame objects.

```python
In [27]: index = ['a', 'b', 'c', 'd', 'e']
In [28]: columns = ['one', 'two', 'three', 'four']
In [29]: df1 = pd.DataFrame(np.random.randn(5, 4), index=index, columns=columns)
In [30]: df2 = pd.DataFrame(np.random.randn(4, 4), index=index[:4], columns=columns)
In [31]: df1.corrwith(df2)
```

(continues on next page)
In [32]: df2.corrwith(df1, axis=1)
Out[32]:
a -0.675817
b  0.458296
c  0.190809
d -0.186275
e   NaN
dtype: float64

Data ranking

The `rank()` method produces a data ranking with ties being assigned the mean of the ranks (by default) for the group:

In [33]: s = pd.Series(np.random.randn(5), index=list("abcde"))
In [34]: s["d"] = s["b"]  # so there's a tie
In [35]: s.rank()
Out[35]:
a  5.0
b  2.5
c  1.0
d  2.5
e  4.0
dtype: float64

`rank()` is also a DataFrame method and can rank either the rows (`axis=0`) or the columns (`axis=1`). NaN values are excluded from the ranking.

In [36]: df = pd.DataFrame(np.random.randn(10, 6))
In [38]: df
Out[38]:
   0        1        2        3        4        5
0 -0.904948 -1.163537 -1.457187  0.135463 -1.457187  0.294650
1 -0.976288 -0.244652 -0.748406 -0.999601 -0.748406 -0.800809
2  0.401965  1.460840  1.256057  1.308127  1.256057  0.876004
3  0.205954  0.369552 -0.669304  0.038378 -0.669304  1.140296
4 -0.477586 -0.730705 -1.129149 -0.601463 -1.129149 -0.211196
5 -1.092970 -0.689246  0.908114  0.204848     NaN    0.463347
6  0.376892  0.959292  0.095572 -0.593740     NaN    0.469180
7 -1.002601  1.957794 -0.120708  0.094214     NaN    1.467422
8 -0.547231  0.664402 -0.519424 -0.073254     NaN    1.263544
9 -0.250277 -0.237428 -1.056443  0.419477     NaN    1.375064

In [39]: df.rank(1)
Out[39]: (continues on next page)
rank optionally takes a parameter `ascending` which by default is true; when false, data is reverse-ranked, with larger values assigned a smaller rank.

`rank` supports different tie-breaking methods, specified with the `method` parameter:

- average: average rank of tied group
- min: lowest rank in the group
- max: highest rank in the group
- first: ranks assigned in the order they appear in the array

Windowing functions

See the window operations user guide for an overview of windowing functions.

### 2.18 Group by: split-apply-combine

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria.
- **Applying** a function to each group independently.
- **Combining** the results into a data structure.

Out of these, the split step is the most straightforward. In fact, in many situations we may wish to split the data set into groups and do something with those groups. In the apply step, we might wish to do one of the following:

- **Aggregation**: compute a summary statistic (or statistics) for each group. Some examples:
  - Compute group sums or means.
  - Compute group sizes / counts.
- **Transformation**: perform some group-specific computations and return a like-indexed object. Some examples:
  - Standardize data (zscore) within a group.
  - Filling NAs within groups with a value derived from each group.
- **Filtration**: discard some groups, according to a group-wise computation that evaluates True or False. Some examples:
  - Discard data that belongs to groups with only a few members.
  - Filter out data based on the group sum or mean.
• Some combination of the above: GroupBy will examine the results of the apply step and try to return a sensibly combined result if it doesn’t fit into either of the above two categories.

Since the set of object instance methods on pandas data structures are generally rich and expressive, we often simply want to invoke, say, a DataFrame function on each group. The name GroupBy should be quite familiar to those who have used a SQL-based tool (or itertools), in which you can write code like:

```sql
SELECT Column1, Column2, mean(Column3), sum(Column4)
FROM SomeTable
GROUP BY Column1, Column2
```

We aim to make operations like this natural and easy to express using pandas. We’ll address each area of GroupBy functionality then provide some non-trivial examples / use cases.

See the cookbook for some advanced strategies.

## 2.18.1 Splitting an object into groups

pandas objects can be split on any of their axes. The abstract definition of grouping is to provide a mapping of labels to group names. To create a GroupBy object (more on what the GroupBy object is later), you may do the following:

```python
In [1]: df = pd.DataFrame(
   ...: [(
   ...:   "bird", "Falconiformes", 389.0),
   ...:   "bird", "Psittaciformes", 24.0),
   ...:   "mammal", "Carnivora", 80.2),
   ...:   "mammal", "Primates", np.nan),
   ...:   "mammal", "Carnivora", 58),
   ...: ]),
   ...: index=["falcon", "parrot", "lion", "monkey", "leopard"],
   ...: columns=("class", "order", "max_speed"),
   ...: )
   ...

In [2]: df
Out[2]:
          class     order      max_speed
falcon    bird  Falconiformes   389.0
parrot    bird  Psittaciformes  24.0
lion      mammal  Carnivora    80.2
monkey    mammal  Primates    NaN
leopard   mammal  Carnivora    58.0

# default is axis=0
In [3]: grouped = df.groupby("class")

In [4]: grouped = df.groupby("order", axis="columns")

In [5]: grouped = df.groupby(["class", "order"])
```

The mapping can be specified many different ways:

- A Python function, to be called on each of the axis labels.
- A list or NumPy array of the same length as the selected axis.
- A dict or Series, providing a label -> group name mapping.
- For DataFrame objects, a string indicating either a column name or an index level name to be used to group.
• df.groupby('A') is just syntactic sugar for df.groupby(df['A']).

• A list of any of the above things.

Collectively we refer to the grouping objects as the keys. For example, consider the following DataFrame:

Note: A string passed to groupby may refer to either a column or an index level. If a string matches both a column name and an index level name, a ValueError will be raised.

```python
In [6]: df = pd.DataFrame(
    ...:     {
    ...:         "A": ["foo", "bar", "foo", "bar", "foo", "foo"],
    ...:         "B": ["one", "one", "two", "three", "two", "one"],
    ...:         "C": np.random.randn(8),
    ...:         "D": np.random.randn(8),
    ...:     }
    ...: )

In [7]: df
Out[7]:
   A    B        C         D
0  foo  one  0.469112 -0.861849
1  bar  one -0.282863 -2.104569
2  foo  two -1.509059 -0.494929
3  bar  three -1.135632  1.071804
4  foo  two  1.212112  0.721555
5  bar  two -0.173215 -0.706771
6  foo  one  0.119209 -1.039575
7  foo  three -1.044236  0.271860
```

On a DataFrame, we obtain a GroupBy object by calling `groupby()`. We could naturally group by either the A or B columns, or both:

```python
In [8]: grouped = df.groupby("A")
In [9]: grouped = df.groupby(["A", "B"])
```

If we also have a MultiIndex on columns A and B, we can group by all but the specified columns:

```python
In [10]: df2 = df.set_index(["A", "B"])
In [11]: grouped = df2.groupby(level=df2.index.names.difference(["B"]))
In [12]: grouped.sum()
Out[12]:
   C         D
A  bar -1.591710 -1.739537
   foo -0.752861 -1.402938
```

These will split the DataFrame on its index (rows). We could also split by the columns:

```python
In [13]: def get_letter_type(letter):
    ...:     if letter.lower() in 'aeiou':
    ...:         return 'vowel'
    ...:     else:
```

(continues on next page)
....:    return 'consonant'
....:
In [14]: grouped = df.groupby(get_letter_type, axis=1)

pandas `Index` objects support duplicate values. If a non-unique index is used as the group key in a groupby operation, all values for the same index value will be considered to be in one group and thus the output of aggregation functions will only contain unique index values:

In [15]: lst = [1, 2, 3, 1, 2, 3]
In [16]: s = pd.Series([1, 2, 3, 10, 20, 30], lst)
In [17]: grouped = s.groupby(level=0)
In [18]: grouped.first()
Out[18]:
  1  1
  2  2
  3  3

dtype: int64

In [19]: grouped.last()
Out[19]:
  1  10
  2  20
  3  30

dtype: int64

In [20]: grouped.sum()
Out[20]:
  1  11
  2  22
  3  33

dtype: int64

Note that **no splitting occurs** until it’s needed. Creating the GroupBy object only verifies that you’ve passed a valid mapping.

**Note:** Many kinds of complicated data manipulations can be expressed in terms of GroupBy operations (though can’t be guaranteed to be the most efficient). You can get quite creative with the label mapping functions.

**GroupBy sorting**

By default the group keys are sorted during the groupby operation. You may however pass `sort=False` for potential speedups:

In [21]: df2 = pd.DataFrame({"X": ["B", "B", "A", "A"], "Y": [1, 2, 3, 4]})
In [22]: df2.groupby(["X"]).sum()
Out[22]:
   X   Y
0  A   6
1  B   5
2  B   4
3  A   3
A 7
B 3

In [23]: df2.groupby(["X"], sort=False).sum()
Out[23]:
   Y
  X
B 3
A 7

Note that `groupby` will preserve the order in which `observations` are sorted within each group. For example, the groups created by `groupby()` below are in the order they appeared in the original DataFrame:

In [24]: df3 = pd.DataFrame({"X": ["A", "B", "A", "B"], "Y": [1, 4, 3, 2]})
In [25]: df3.groupby(["X"]).get_group("A")
Out[25]:
   X  Y
0  A  1
2  A  3
In [26]: df3.groupby(["X"]).get_group("B")
Out[26]:
   X  Y
1  B  4
3  B  2

New in version 1.1.0.

**GroupBy dropna**

By default `NA` values are excluded from group keys during the `groupby` operation. However, in case you want to include `NA` values in group keys, you could pass `dropna=False` to achieve it.

In [27]: df_list = [[1, 2, 3], [1, None, 4], [2, 1, 3], [1, 2, 2]]
In [28]: df_dropna = pd.DataFrame(df_list, columns=["a", "b", "c"])
In [29]: df_dropna
Out[29]:
   a   b   c
0  1  2.0  3
1  1   NaN  4
2  2  1.0  3
3  1  2.0  2

# Default `dropna` is set to True, which will exclude NaNs in keys
In [30]: df_dropna.groupby(by=["b"], dropna=True).sum()
Out[30]:
   a  c
   b
1.0  2  3
2.0  2  5

# In order to allow NaN in keys, set `dropna` to False
In [31]: df_dropna.groupby(by=["b"], dropna=False).sum()
Out[31]:
    a  c  
b 1.0 2 3
   2.0 2 5
  NaN 1 4

The default setting of dropna argument is True which means NA are not included in group keys.

**GroupBy object attributes**

The groups attribute is a dict whose keys are the computed unique groups and corresponding values being the axis labels belonging to each group. In the above example we have:

In [32]: df.groupby("A").groups
Out[32]: {'bar': [1, 3, 5], 'foo': [0, 2, 4, 6, 7]}

In [33]: df.groupby(get_letter_type, axis=1).groups
Out[33]: {'consonant': ['B', 'C', 'D'], 'vowel': ['A']}

Calling the standard Python len function on the GroupBy object just returns the length of the groups dict, so it is largely just a convenience:

In [34]: grouped = df.groupby(['A', 'B'])
In [35]: grouped.groups
Out[35]: {('bar', 'one'): [1], ('bar', 'three'): [3], ('bar', 'two'): [5], ('foo', 'one'): [0, 6], ('foo', 'three'): [7], ('foo', 'two'): [2, 4]}

In [36]: len(grouped)
Out[36]: 6

GroupBy will tab complete column names (and other attributes):

In [37]: df
Out[37]:
   height  weight  gender
0 2000-01-01 42.849980 157.500553  male
1 2000-01-02 49.607315 177.340407  male
2 2000-01-03 56.293531 171.524640  male
3 2000-01-04 48.421077 144.251986  female
4 2000-01-05 46.556882 152.526206  male
5 2000-01-06 68.448851 168.272968  female
6 2000-01-07 70.757698 136.431469  male
7 2000-01-08 58.909500 176.499753  female
8 2000-01-09 76.435631 174.094104  female
9 2000-01-10 45.306120 177.540920  male

In [38]: gb = df.groupby("gender")

In [39]: gb.<TAB>  # noqa: E225, E999
gb.agg  gb.boxplot  gb.cummin  gb.describe  gb.filter  gb.get_group  gb.height  gb.last  gb.median  gb.ngroups  gb.plot  gb.rank  gb.std  gb.transform
(continues on next page)
**GroupBy with MultiIndex**

With *hierarchically-indexed data*, it’s quite natural to group by one of the levels of the hierarchy. Let’s create a Series with a two-level MultiIndex.

```
In [40]: arrays = [
    ....:   ["bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"],
    ....:   ["one", "two", "one", "two", "one", "two", "one", "two"],
    ....:   ]
    ....:
In [41]: index = pd.MultiIndex.from_arrays(arrays, names=["first", "second"])
In [42]: s = pd.Series(np.random.randn(8), index=index)
In [43]: s
Out[43]:
first  second
bar   one    -0.919854
       two    -0.042379
baz   one    1.247642
       two    -0.009920
foo   one    0.290213
       two     0.495767
qux   one    0.362949
       two    1.548106
dtype: float64
```

We can then group by one of the levels in `s`.

```
In [44]: grouped = s.groupby(level=0)
In [45]: grouped.sum()
Out[45]:
first
bar   -0.962232
baz    1.237723
foo    0.785980
qux    1.911055
dtype: float64
```

If the MultiIndex has names specified, these can be passed instead of the level number:

```
In [46]: s.groupby(level="second").sum()
Out[46]:
second
  one    0.980950
```

(continues on next page)
Grouping with multiple levels is supported.

```python
In [47]: s
Out[47]:
first second third
bar  doo  one  -1.31345
      two  -0.089329
baz  bee  one  0.337863
      two  -0.945867
foo  bop  one  -0.932132
      two   1.956030
qux  bop  one   0.17587
      two  -0.016692
dtype: float64

In [48]: s.groupby(level=["first", "second"]).sum()
Out[48]:
first second
bar  doo  -1.220674
baz  bee  -0.608004
foo  bop   1.023898
qux  bop   0.000895
dtype: float64
```

Index level names may be supplied as keys.

```python
In [49]: s.groupby(["first", "second"]).sum()
Out[49]:
first second
bar  doo  -1.220674
baz  bee  -0.608004
foo  bop   1.023898
qux  bop   0.000895
dtype: float64
```

More on the `sum` function and aggregation later.

### Grouping DataFrame with Index levels and columns

A DataFrame may be grouped by a combination of columns and index levels by specifying the column names as strings and the index levels as `pd.Grouper` objects.

```python
In [50]: arrays = [
       ...:     ["bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"],
       ...:     ["one", "two", "one", "two", "one", "two", "one", "two"],
       ...: ]
       ...

In [51]: index = pd.MultiIndex.from_arrays(arrays, names=["first", "second"])

In [52]: df = pd.DataFrame({"A": [1, 1, 1, 2, 2, 3, 3], "B": np.arange(8)},
                      index=index)
```

(continues on next page)
The following example groups `df` by the second index level and the A column.

```python
In [54]: df.groupby([pd.Grouper(level=1), "A"]).sum()
Out[54]:
          B
    second A
  one  1  2
      2  4
      3  6
  two  1  4
      2  5
      3  7
```

Index levels may also be specified by name.

```python
In [55]: df.groupby([pd.Grouper(level="second"), "A"]).sum()
Out[55]:
          B
    second A
  one  1  2
      2  4
      3  6
  two  1  4
      2  5
      3  7
```

Index level names may be specified as keys directly to `groupby`.

```python
In [56]: df.groupby(["second", "A"]).sum()
Out[56]:
          B
    second A
  one  1  2
      2  4
      3  6
  two  1  4
      2  5
      3  7
```
DataFrame column selection in GroupBy

Once you have created the GroupBy object from a DataFrame, you might want to do something different for each of the columns. Thus, using [] similar to getting a column from a DataFrame, you can do:

```python
In [57]: grouped = df.groupby(['A'])
In [58]: grouped_C = grouped['C']
In [59]: grouped_D = grouped['D']
```

This is mainly syntactic sugar for the alternative and much more verbose:

```python
In [60]: df['C'].groupby(df['A'])
Out[60]: <pandas.core.groupby.generic.SeriesGroupBy object at 0x7f1e0ae46580>
```

Additionally this method avoids recomputing the internal grouping information derived from the passed key.

2.18.2 Iterating through groups

With the GroupBy object in hand, iterating through the grouped data is very natural and functions similarly to itertools.groupby():
See Iterating through groups.

### 2.18.3 Selecting a group

A single group can be selected using `get_group()`:

```python
In [64]: grouped.get_group("bar")
Out[64]:
   A  B  C  D
0  bar one  0.254161 1.511763
1  bar   two -0.077118 1.211526
3  bar three  0.215897 -0.990582
5  bar two  -0.077118 1.211526
```

Or for an object grouped on multiple columns:

```python
In [65]: df.groupby(["A", "B"]).get_group(("bar", "one"))
Out[65]:
   A  B  C  D
0 bar one  0.254161 1.511763
```

### 2.18.4 Aggregation

Once the GroupBy object has been created, several methods are available to perform a computation on the grouped data. These operations are similar to the aggregating API, window API, and resample API.

An obvious one is aggregation via the `aggregate()` or equivalently `agg()` method:

```python
In [66]: grouped = df.groupby("A")

In [67]: grouped.aggregate(np.sum)
Out[67]:
   C  D
A  
bar  0.392940 1.732707
foo -1.796421 2.824590

In [68]: grouped = df.groupby(["A", "B"]) 

In [69]: grouped.aggregate(np.sum)
Out[69]:
   C  D
```

(continues on next page)
As you can see, the result of the aggregation will have the group names as the new index along the grouped axis. In the case of multiple keys, the result is a MultiIndex by default, though this can be changed by using the as_index option:

```
In [70]: grouped = df.groupby(["A", "B"], as_index=False)
In [71]: grouped.aggregate(np.sum)
Out[71]:
   A  B  C   D
0  bar one 0.254161 1.511763
1  bar three 0.215897 -0.990582
2  bar two -0.077118 1.211526
3  foo one -0.983776 1.614581
4  foo three -0.862495 0.024580
5  foo two 0.049851 1.185429
```

```
In [72]: df.groupby("A", as_index=False).sum()
Out[72]:
   A   C   D
0  bar 0.392940 1.732707
1  foo -1.796421 2.824590
```

Note that you could use the reset_index DataFrame function to achieve the same result as the column names are stored in the resulting MultiIndex:

```
In [73]: df.groupby(["A", "B"]).sum().reset_index()
Out[73]:
   A  B  C   D
0  bar one 0.254161 1.511763
1  bar three 0.215897 -0.990582
2  bar two -0.077118 1.211526
3  foo one -0.983776 1.614581
4  foo three -0.862495 0.024580
5  foo two 0.049851 1.185429
```

Another simple aggregation example is to compute the size of each group. This is included in GroupBy as the size method. It returns a Series whose index are the group names and whose values are the sizes of each group.

```
In [74]: grouped.size()
Out[74]:
   A  B  size
0  bar one   1
1  bar three  1
2  bar two   1
3  foo one   2
4  foo three  1
5  foo two   2
```
Another aggregation example is to compute the number of unique values of each group. This is similar to the \texttt{value_counts} function, except that it only counts unique values.

```python
In [76]: ll = [['foo', 1], ['foo', 2], ['foo', 2], ['bar', 1], ['bar', 1]]

In [77]: df4 = pd.DataFrame(ll, columns=['A', 'B'])

In [78]: df4
Out[78]:
    A  B
0  foo  1
1  foo  2
2  foo  2
3  bar  1
4  bar  1

In [79]: df4.groupby("A")["B"].nunique()
Out[79]:
     B
A  
bar 1
foo 2
Name: B, dtype: int64
```

**Note:** Aggregation functions \textbf{will not} return the groups that you are aggregating over if they are named \textit{columns}, when \texttt{as_index=True}, the default. The grouped columns will be the \textit{indices} of the returned object.

Passing \texttt{as_index=False} \textbf{will} return the groups that you are aggregating over, if they are named \textit{columns}.

Aggregating functions are the ones that reduce the dimension of the returned objects. Some common aggregating functions are tabulated below:
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mean()</td>
<td>Compute mean of groups</td>
</tr>
<tr>
<td>sum()</td>
<td>Compute sum of group values</td>
</tr>
<tr>
<td>size()</td>
<td>Compute group sizes</td>
</tr>
<tr>
<td>count()</td>
<td>Compute count of group</td>
</tr>
<tr>
<td>std()</td>
<td>Standard deviation of groups</td>
</tr>
<tr>
<td>var()</td>
<td>Compute variance of groups</td>
</tr>
<tr>
<td>sem()</td>
<td>Standard error of the mean</td>
</tr>
<tr>
<td>describe()</td>
<td>Generates descriptive</td>
</tr>
<tr>
<td>first()</td>
<td>Compute first of group values</td>
</tr>
<tr>
<td>last()</td>
<td>Compute last of group values</td>
</tr>
<tr>
<td>nth()</td>
<td>Take nth value, or a subset</td>
</tr>
<tr>
<td>min()</td>
<td>Compute min of group values</td>
</tr>
<tr>
<td>max()</td>
<td>Compute max of group values</td>
</tr>
</tbody>
</table>

The aggregating functions above will exclude NA values. Any function which reduces a `Series` to a scalar value is an aggregation function and will work, a trivial example is `df.groupby('A').agg(lambda ser: 1)`. Note that `nth()` can act as a reducer or a filter, see here.

### Applying multiple functions at once

With grouped `Series` you can also pass a list or dict of functions to do aggregation with, outputting a DataFrame:

```python
In [80]: grouped = df.groupby("A")

In [81]: grouped["C"].agg([np.sum, np.mean, np.std])
Out[81]:
   sum    mean   std
A       
bar   0.392940 0.130980 0.181231  
foo  -1.796421 -0.359284  0.912265
```

On a grouped `DataFrame`, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```python
In [82]: grouped.agg([np.sum, np.mean, np.std])
Out[82]:
   C         D
  sum   mean   std  sum   mean   std
A      
bar   0.392940 0.130980 0.181231  1.732707 0.577569 1.366330
foo  -1.796421 -0.359284  0.912265  2.824590 0.564918 0.884785
```

The resulting aggregations are named for the functions themselves. If you need to rename, then you can add in a chained operation for a `Series` like this:

```python
In [83]:
   ...: grouped["C"]
   ...: .agg([np.sum, np.mean, np.std])
   ...: .rename(columns={"sum": "foo", "mean": "bar", "std": "baz")
   ...: )
   ...:
Out[83]:
   foo  bar  baz
```

(continues on next page)
For a grouped DataFrame, you can rename in a similar manner:

```python
In [84]:
----
.....: grouped.agg([np.sum, np.mean, np.std]).rename(
.....:     columns={"sum": "foo", "mean": "bar", "std": "baz"})
.....: )
Out[84]:

<table>
<thead>
<tr>
<th></th>
<th>C</th>
<th>D</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>foo</td>
<td>bar</td>
<td>baz</td>
</tr>
<tr>
<td>A</td>
<td>0.392940</td>
<td>0.130980</td>
<td>0.181231</td>
</tr>
<tr>
<td>foo</td>
<td>-1.796421</td>
<td>-0.359284</td>
<td>0.912265</td>
</tr>
</tbody>
</table>
```

Note: In general, the output column names should be unique. You can’t apply the same function (or two functions with the same name) to the same column.

```python
In [85]: grouped["C"].agg(["sum", "sum"])
Out[85]:

<table>
<thead>
<tr>
<th></th>
<th>sum</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>0.392940</td>
<td>0.392940</td>
</tr>
<tr>
<td>foo</td>
<td>-1.796421</td>
<td>-1.796421</td>
</tr>
</tbody>
</table>
```

pandas does allow you to provide multiple lambdas. In this case, pandas will mangle the name of the (nameless) lambda functions, appending _<i>_ to each subsequent lambda.

```python
In [86]: grouped["C"].agg([lambda x: x.max() - x.min(), lambda x: x.median() - x.
.....:     -mean()])
Out[86]:

<table>
<thead>
<tr>
<th></th>
<th>&lt;lambda_0&gt;</th>
<th>&lt;lambda_1&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>0.331279</td>
<td>0.084917</td>
</tr>
<tr>
<td>foo</td>
<td>2.337259</td>
<td>-0.215962</td>
</tr>
</tbody>
</table>
```

**Named aggregation**

New in version 0.25.0.

To support column-specific aggregation with control over the output column names, pandas accepts the special syntax in `GroupBy.agg()`, known as “named aggregation”, where

- The keywords are the output column names
- The values are tuples whose first element is the column to select and the second element is the aggregation to apply to that column. pandas provides the `pandas.NamedAgg` namedtuple with the fields ['column', 'aggfunc'] to make it clearer what the arguments are. As usual, the aggregation can be a callable or a string alias.
```python
In [87]: animals = pd.DataFrame(
        ...:     {
        ...:         "kind": ["cat", "dog", "cat", "dog"],
        ...:         "height": [9.1, 6.0, 9.5, 34.0],
        ...:         "weight": [7.9, 7.5, 9.9, 198.0],
        ...:     }
        ...: )
        ...:
In [88]: animals
Out[88]:
        kind height  weight
    0    cat   9.1      7.9
    1    dog   6.0      7.5
    2    cat   9.5      9.9
    3    dog  34.0    198.0

In [89]: animals.groupby("kind").agg(
        ...:     **{
        ...:         "min_height": pd.NamedAgg(column="height", aggfunc="min"),
        ...:         "max_height": pd.NamedAgg(column="height", aggfunc="max"),
        ...:         "average_weight": pd.NamedAgg(column="weight", aggfunc=np.mean),
        ...:     }
        ...: )
        ...:
Out[89]:
        min_height  max_height  average_weight
        kind
        cat        9.1          9.5           8.90
        dog        6.0         34.0         102.75

pandas.NamedAgg is just a namedtuple. Plain tuples are allowed as well.

In [90]: animals.groupby("kind").agg(
        ...:     **{
        ...:         "min_height": ("height", "min"),
        ...:         "max_height": ("height", "max"),
        ...:         "average_weight": ("weight", np.mean),
        ...:     }
        ...: )
        ...:
Out[90]:
        min_height  max_height  average_weight
        kind
        cat        9.1          9.5           8.90
        dog        6.0         34.0         102.75

If your desired output column names are not valid Python keywords, construct a dictionary and unpack the keyword arguments

In [91]: animals.groupby("kind").agg(
        ...:     **{
        ...:         "total weight": pd.NamedAgg(column="weight", aggfunc=sum)
        ...:     }
        ...: )
        ...:
Out[91]:
        total weight
        kind
        cat      17.8
        dog     205.5
```

2.18. Group by: split-apply-combine 757
Additional keyword arguments are not passed through to the aggregation functions. Only pairs of (column, aggfunc) should be passed as **kwargs. If your aggregation functions requires additional arguments, partially apply them with functools.partial().

**Note:** For Python 3.5 and earlier, the order of **kwargs in a function was not preserved. This means that the output column ordering would not be consistent. To ensure consistent ordering, the keys (and so output columns) will always be sorted for Python 3.5.

Named aggregation is also valid for Series groupby aggregations. In this case there’s no column selection, so the values are just the functions.

```
In [92]: animals.groupby("kind").height.agg({
    ....:     min_height="min",
    ....:     max_height="max",
                ....: })
Out[92]:

    min_height  max_height
  kind
    cat      9.1       9.5
    dog      6.0      34.0
```

### Applying different functions to DataFrame columns

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a DataFrame:

```
In [93]: grouped.agg({"C": np.sum, "D": lambda x: np.std(x, ddof=1)})
Out[93]:

    C     D
  A
  bar  0.392940  1.366330
  foo -1.796421  0.884785
```

The function names can also be strings. In order for a string to be valid it must be either implemented on GroupBy or available via `dispatching`:

```
In [94]: grouped.agg({"C": "sum", "D": "std"})
Out[94]:

    C     D
  A
  bar  0.392940  1.366330
  foo -1.796421  0.884785
```

### Cython-optimized aggregation functions

Some common aggregations, currently only sum, mean, std, and sem, have optimized Cython implementations:

```
In [95]: df.groupby("A").sum()
Out[95]:

    C     D
  A
  bar  0.392940  1.732707
  foo -1.796421  2.824590
```

(continues on next page)
Of course `sum` and `mean` are implemented on pandas objects, so the above code would work even without the special versions via dispatching (see below).

### Aggregations with User-Defined Functions

Users can also provide their own functions for custom aggregations. When aggregating with a User-Defined Function (UDF), the UDF should not mutate the provided `Series`, see Mutating with User Defined Function (UDF) methods for more information.

```python
In [97]: animals.groupby("kind")["height"].agg(lambda x: set(x))
Out[97]:
   height
   kind
  cat   {9.1, 9.5}
  dog   {34.0, 6.0}
```

The resulting dtype will reflect that of the aggregating function. If the results from different groups have different dtypes, then a common dtype will be determined in the same way as `DataFrame` construction.

```python
In [98]: animals.groupby("kind")["height"].agg(lambda x: x.astype(int).sum())
Out[98]:
   height
   kind
  cat   18
  dog   40
```

### 2.18.5 Transformation

The `transform` method returns an object that is indexed the same (same size) as the one being grouped. The transform function must:

- Return a result that is either the same size as the group chunk or broadcastable to the size of the group chunk (e.g., a scalar, `grouped.transform(lambda x: x.iloc[-1])`).
- Operate column-by-column on the group chunk. The transform is applied to the first group chunk using `chunk.apply`.
- Not perform in-place operations on the group chunk. Group chunks should be treated as immutable, and changes to a group chunk may produce unexpected results. For example, when using `fillna`, `inplace` must be `False` (`grouped.transform(lambda x: x.fillna(inplace=False))`).
- (Optionally) operates on the entire group chunk. If this is supported, a fast path is used starting from the second chunk.
Similar to *Aggregations with User-Defined Functions*, the resulting dtype will reflect that of the transformation function. If the results from different groups have different dtypes, then a common dtype will be determined in the same way as DataFrame construction.

Suppose we wished to standardize the data within each group:

```
In [99]: index = pd.date_range("10/1/1999", periods=1100)
In [100]: ts = pd.Series(np.random.normal(0.5, 2, 1100), index)
In [101]: ts = ts.rolling(window=100, min_periods=100).mean().dropna()
In [102]: ts.head()
Out[102]:
time       0.779333
           0.778852
           0.786476
           0.782797
           0.798110
Freq: D, dtype: float64
In [103]: ts.tail()
Out[103]:
time       0.660294
           0.631095
           0.673601
           0.709213
           0.719369
Freq: D, dtype: float64
In [104]: transformed = ts.groupby(lambda x: x.year).transform(lambda x: (x - x.mean()) / x.std())
```

We would expect the result to now have mean 0 and standard deviation 1 within each group, which we can easily check:

```
# Original Data
In [105]: grouped = ts.groupby(lambda x: x.year)
In [106]: grouped.mean()
Out[106]:
2000 0.442441
2001 0.526246
2002 0.459365
dtype: float64
In [107]: grouped.std()
Out[107]:
2000 0.131752
2001 0.210945
2002 0.128753
dtype: float64
# Transformed Data
In [108]: grouped_trans = transformed.groupby(lambda x: x.year)
(continues on next page)
In [109]: grouped_trans.mean()
Out[109]:
2000   1.193722e-15
2001   1.945476e-15
2002   1.272949e-15
dtype: float64

In [110]: grouped_trans.std()
Out[110]:
2000   1.0
2001   1.0
2002   1.0
dtype: float64

We can also visually compare the original and transformed data sets.

In [111]: compare = pd.DataFrame({"Original": ts, "Transformed": transformed})

In [112]: compare.plot()
Out[112]: <AxesSubplot:>

Transformation functions that have lower dimension outputs are broadcast to match the shape of the input array.
In [113]: ts.groupby(lambda x: x.year).transform(lambda x: x.max() - x.min())
Out[113]:
2000-01-08 0.623893
2000-01-09 0.623893
2000-01-10 0.623893
2000-01-11 0.623893
2000-01-12 0.623893
...  
2002-09-30 0.558275
2002-10-01 0.558275
2002-10-02 0.558275
2002-10-03 0.558275
2002-10-04 0.558275
Freq: D, Length: 1001, dtype: float64

Alternatively, the built-in methods could be used to produce the same outputs.

In [114]: max = ts.groupby(lambda x: x.year).transform("max")
In [115]: min = ts.groupby(lambda x: x.year).transform("min")
In [116]: max - min
Out[116]:
2000-01-08 0.623893
2000-01-09 0.623893
2000-01-10 0.623893
2000-01-11 0.623893

3 -1.309622  1.118697 -1.161657
4 -1.924296  0.396437  0.812436
...     ...     ...     ...
995 -0.093110  0.683847 -0.774753
996 -0.185043  1.438572   NaN
997 -0.394469  0.642343  0.011374
998 -1.174126  1.857148   NaN
999  0.234564  0.517098  0.393534
[1000 rows x 3 columns]
In [118]: countries = np.array(["US", "UK", "GR", "JP"])

(continues on next page)
We can verify that the group means have not changed in the transformed data and that the transformed data contains no NAs.

In [123]: grouped_trans = transformed.groupby(key)

In [124]: grouped.mean()  # original group means
Out[124]:
          A      B      C
    GR  -0.098371 -0.015420  0.068053
    JP   0.069025  0.023100 -0.077324
    UK   0.034069 -0.052580 -0.116525
    US   0.058664 -0.020399  0.028603

In [125]: grouped_trans.mean()  # transformation did not change group means
Out[125]:
          A      B      C
    GR  -0.098371 -0.015420  0.068053
    JP   0.069025  0.023100 -0.077324
    UK   0.034069 -0.052580 -0.116525
    US   0.058664 -0.020399  0.028603

In [126]: grouped.count()  # original has some missing data points
Out[126]:
          A      B      C
    GR   209  217   189
    JP   240  255   217
    UK   216  231   193
    US   239  250   217

In [127]: grouped_trans.count()  # counts after transformation
Out[127]:
          A      B      C
    GR   228  228   228
    JP   267  267   267
    UK   247  247   247
    US   258  258   258

In [128]: grouped_trans.size()  # Verify non-NA count equals group size
Out[128]:
    GR   228
    JP   267
Some functions will automatically transform the input when applied to a GroupBy object, but returning an object of the same shape as the original. Passing `as_index=False` will not affect these transformation methods.

For example: `fillna, ffill, bfill, shift`.

```python
In [129]: grouped.fillna()
Out[129]:
   A    B    C
0  0  1.54  2.54
1  0  1.54  2.54
2  0  1.54  2.54
3  0  1.54  2.54
4  0  1.54  2.54
5  0  1.54  2.54
6  0  1.54  2.54
7  0  1.54  2.54
8  0  1.54  2.54
9  0  1.54  2.54
10 0  1.54  2.54
11 0  1.54  2.54
12 0  1.54  2.54
13 0  1.54  2.54
14 0  1.54  2.54
```

## Window and resample operations

It is possible to use `resample()`, `expanding()` and `rolling()` as methods on groupbys.

The example below will apply the `rolling()` method on the samples of the column B based on the groups of column A.

```python
In [131]: df_re.groupby('A').rolling(4).B.mean()
```

```python
In [132]: df_re
```

```python
Out[131]:
   A    B
0  0  1.00
1  1  1.00
2  1  1.00
3  1  1.00
4  1  1.00
5  1  1.00
6  1  1.00
7  1  1.00
8  1  1.00
9  1  1.00
10 1  1.00
11 1  1.00
12 1  1.00
13 1  1.00
14 1  1.00
15 1  1.00
16 1  1.00
17 1  1.00
18 1  1.00
19 1  1.00
20 1  1.00
...
```
The `expanding()` method will accumulate a given operation (sum() in the example) for all the members of each particular group.

```python
In [133]: df_re.groupby("A").expanding().sum()
Out[133]:
               B
A
1  0  0.0
1  1  1.0
2  2  3.0
3  3  6.0
4  4 10.0
...    ...
5 15 75.0
16  91.0
17 108.0
18 126.0
19 145.0
```

[20 rows x 1 columns]

Suppose you want to use the `resample()` method to get a daily frequency in each group of your dataframe and wish to complete the missing values with the `ffill()` method.

```python
In [134]: df_re = pd.DataFrame(.....:
    .....:
    .....:
    .....:
    .....:
    .....:
    .....:
    .....:
    ) . set_index("date")
    .....:
In [135]: df_re
Out[135]:
          group  val
date
2016-01-03    1  5
2016-01-10    1  6
2016-01-17    2  7
2016-01-24    2  8
```

(continues on next page)
In [136]: df_re.groupby("group").resample("1D").ffill()
Out[136]:
<table>
<thead>
<tr>
<th>group</th>
<th>val</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>5</td>
</tr>
<tr>
<td>2016-01-03</td>
<td>1</td>
</tr>
<tr>
<td>2016-01-04</td>
<td>1</td>
</tr>
<tr>
<td>2016-01-05</td>
<td>1</td>
</tr>
<tr>
<td>2016-01-06</td>
<td>1</td>
</tr>
<tr>
<td>2016-01-07</td>
<td>1</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>2</td>
<td>7</td>
</tr>
<tr>
<td>2016-01-20</td>
<td>2</td>
</tr>
<tr>
<td>2016-01-21</td>
<td>2</td>
</tr>
<tr>
<td>2016-01-22</td>
<td>2</td>
</tr>
<tr>
<td>2016-01-23</td>
<td>2</td>
</tr>
<tr>
<td>2016-01-24</td>
<td>2</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>
[16 rows x 2 columns]

2.18.6 Filtration

The `filter` method returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

In [137]: sf = pd.Series([1, 1, 2, 3, 3, 3])
In [138]: sf.groupby(sf).filter(lambda x: x.sum() > 2)
Out[138]:
| 3   |
| 4   |
| 5   |
| dtype: int64 |

The argument of `filter` must be a function that, applied to the group as a whole, returns True or False. Another useful operation is filtering out elements that belong to groups with only a couple members.

In [139]: dff = pd.DataFrame({"A": np.arange(8), "B": list("aabbbccc")})
In [140]: dff.groupby("B").filter(lambda x: len(x) > 2)
Out[140]:
<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>b</td>
</tr>
<tr>
<td>3</td>
<td>b</td>
</tr>
<tr>
<td>4</td>
<td>b</td>
</tr>
<tr>
<td>5</td>
<td>b</td>
</tr>
</tbody>
</table>

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with NaNs.

In [141]: dff.groupby("B").filter(lambda x: len(x) > 2, dropna=False)
Out[141]:
<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NaN</td>
</tr>
<tr>
<td>1</td>
<td>NaN</td>
</tr>
</tbody>
</table>

(continues on next page)
For DataFrames with multiple columns, filters should explicitly specify a column as the filter criterion.

```
In [142]: dff["C"] = np.arange(8)

In [143]: dff.groupby("B").filter(lambda x: len(x["C"]) > 2)
Out[143]:
   A  B  C
 2  2  b  2
 3  3  b  3
 4  4  b  4
 5  5  b  5
```

**Note:** Some functions when applied to a groupby object will act as a filter on the input, returning a reduced shape of the original (and potentially eliminating groups), but with the index unchanged. Passing `as_index=False` will not affect these transformation methods.

For example: `head`, `tail`.

```
In [144]: dff.groupby("B").head(2)
Out[144]:
    A  B  C
 0  0  a  0
 1  1  a  1
 2  2  b  2
 3  3  b  3
 6  6  c  6
 7  7  c  7
```

### 2.18.7 Dispatching to instance methods

When doing an aggregation or transformation, you might just want to call an instance method on each data group. This is pretty easy to do by passing lambda functions:

```
In [145]: grouped = df.groupby("A")

In [146]: grouped.agg(lambda x: x.std())
Out[146]:
   C    D
  A bar 0.181231 1.366330
     foo 0.912265 0.884785
```

But, it’s rather verbose and can be untidy if you need to pass additional arguments. Using a bit of metaprogramming cleverness, GroupBy now has the ability to “dispatch” method calls to the groups:
In [147]: grouped.std()
Out[147]:
     C     D
A bar  0.181231  1.366330
foo  0.912265  0.884785

What is actually happening here is that a function wrapper is being generated. When invoked, it takes any passed arguments and invokes the function with any arguments on each group (in the above example, the std function). The results are then combined together much in the style of agg and transform (it actually uses apply to infer the gluing, documented next). This enables some operations to be carried out rather succinctly:

In [148]: tsdf = pd.DataFrame(
        .....:     np.random.randn(1000, 3),
        .....:     index=pd.date_range("1/1/2000", periods=1000),
        .....:     columns=["A", "B", "C"],
        .....: )

In [149]: tsdf.iloc[::2] = np.nan

In [150]: grouped = tsdf.groupby(lambda x: x.year)

In [151]: grouped.fillna(method="pad")
Out[151]:
     A     B     C
2000-01-01 NaN   NaN   NaN
2000-01-02 -0.353501 -0.080957 -0.876864
2000-01-03 -0.353501 -0.080957 -0.876864
2000-01-04  0.050976  0.044273 -0.559849
2000-01-05  0.050976  0.044273 -0.559849
         ... ... ... ...
2002-09-22  0.005011  0.053897 -1.026922
2002-09-23  0.005011  0.053897 -1.026922
2002-09-24 -0.456542 -1.849051  1.559856
2002-09-25 -0.456542 -1.849051  1.559856
2002-09-26  1.123162  0.354660  1.128135
[1000 rows x 3 columns]

In this example, we chopped the collection of time series into yearly chunks then independently called fillna on the groups.

The nlargest and nsmallest methods work on Series style groupbys:

In [152]: s = pd.Series([9, 8, 7, 5, 19, 1, 4.2, 3.3])

In [153]: g = pd.Series(list("abababab"))

In [154]: gb = s.groupby(g)

In [155]: gb.nlargest(3)
Out[155]:
a      4  19.0
    0  9.0
    2  7.0
b      1  8.0

(continues on next page)
2.18.8 Flexible apply

Some operations on the grouped data might not fit into either the aggregate or transform categories. Or, you may simply want GroupBy to infer how to combine the results. For these, use the `apply` function, which can be substituted for both `aggregate` and `transform` in many standard use cases. However, `apply` can handle some exceptional use cases, for example:

```
In [157]: df
Out[157]:
   A    B      C      D
0  foo  one  -0.575247  1.346061
1  bar  one   0.254161  1.511763
2  foo  two  -1.143704  1.627081
3  bar  three  0.215897 -0.990582
4  foo  two   1.193555 -0.441652
5  bar  two  -0.077118  1.211526
6  foo  one  -0.408530  0.268520
7  foo  three  0.862495  0.024580

In [158]: grouped = df.groupby("A")
   # could also just call .describe()
In [159]: grouped["C"].apply(lambda x: x.describe())
Out[159]:
   A
   bar count 3.000000
         mean  0.130980
         std  0.181231
         min -0.077118
        25%  0.069390
         50% -0.575247
         75% -0.408530
         max  1.193555
Name: C, Length: 16, dtype: float64
```

The dimension of the returned result can also change:
apply on a Series can operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a DataFrame:

apply can act as a reducer, transformer, or filter function, depending on exactly what is passed to it. So depending on the path taken, and exactly what you are grouping. Thus the grouped columns(s) may be included in the output as well as set the indices.

Similar to Aggregations with User-Defined Functions, the resulting dtype will reflect that of the apply function. If the results from different groups have different dtypes, then a common dtype will be determined in the same way as DataFrame construction.
2.18.9 Numba Accelerated Routines

New in version 1.1.

If Numba is installed as an optional dependency, the transform and aggregate methods support engine='numba' and engine_kwargs arguments. See enhancing performance with Numba for general usage of the arguments and performance considerations.

The function signature must start with values, index exactly as the data belonging to each group will be passed into values, and the group index will be passed into index.

**Warning:** When using engine='numba', there will be no “fall back” behavior internally. The group data and group index will be passed as NumPy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

2.18.10 Other useful features

Automatic exclusion of “nuisance” columns

Again consider the example DataFrame we’ve been looking at:

```python
In [167]: df
Out[167]:
   A   B    C      D
0  foo  one -0.575247  1.346061
1   bar  one  0.254161  1.511763
2    foo  two -1.143704  1.627081
3    bar  three  0.215897 -0.990582
4    foo  two  1.193555  0.441652
5    bar  two  0.077118  1.211526
6    foo  one  0.408530  0.268520
7    foo  three -0.862495  0.024580
```

Suppose we wish to compute the standard deviation grouped by the A column. There is a slight problem, namely that we don’t care about the data in column B. We refer to this as a “nuisance” column. If the passed aggregation function can’t be applied to some columns, the troublesome columns will be (silently) dropped. Thus, this does not pose any problems:

```python
In [168]: df.groupby("A").std()
Out[168]:
   C      D
A
bar  0.181231  1.366330
foo  0.912265  0.884785
```

Note that df.groupby('A').colname.std(). is more efficient than df.groupby('A').std().colname, so if the result of an aggregation function is only interesting over one column (here colname), it may be filtered before applying the aggregation function.

Note: Any object column, also if it contains numerical values such as Decimal objects, is considered as a “nuisance” columns. They are excluded from aggregate functions automatically in groupby.
If you do wish to include decimal or object columns in an aggregation with other non-nuisance data types, you must do so explicitly.

```python
In [169]: from decimal import Decimal

In [170]: df_dec = pd.DataFrame(
        .....:     {  
        .....:         "id": [1, 2, 1, 2],  
        .....:         "int_column": [1, 2, 3, 4],  
        .....:         "dec_column": [  
        .....:             Decimal("0.50"),  
        .....:             Decimal("0.15"),  
        .....:             Decimal("0.25"),  
        .....:             Decimal("0.40"),  
        .....:         ],  
        .....:     }
        .....:     )

# Decimal columns can be sum'd explicitly by themselves...
In [171]: df_dec.groupby("id")["dec_column"].sum()
Out[171]:
Empty DataFrame
Columns: []
Index: [1, 2]

# ...but cannot be combined with standard data types or they will be excluded
In [172]: df_dec.groupby("id")["int_column", "dec_column"].sum()
Out[172]:
   int_column  dec_column
  id
  1     4     0.75
  2     6     0.55

Handling of (un)observed Categorical values

When using a Categorical grouper (as a single grouper, or as part of multiple groupers), the observed keyword controls whether to return a cartesian product of all possible groupers values (observed=False) or only those that are observed groupers (observed=True).

Show all values:

```python
In [174]: pd.Series([1, 1, 1]).groupby(
        .....:     pd.Categorical(["a", "a", "a"], categories=["a", "b"], observed=False)
        .....:     ).count()
        .....:     )
Out[174]:
```

(continues on next page)
Show only the observed values:

```python
In [175]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'], categories=['a', 'b']), observed=True).count()
Out[175]:
       a
dtype: int64
```

The returned dtype of the grouped will *always* include *all* of the categories that were grouped.

```python
In [176]: s = (pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'], categories=['a', 'b']), observed=False).count())
In [177]: s.index.dtype
Out[177]: CategoricalDtype(categories=['a', 'b'], ordered=False)
```

### NA and NaT group handling

If there are any NaN or NaT values in the grouping key, these will be automatically excluded. In other words, there will never be an “NA group” or “NaT group”. This was not the case in older versions of pandas, but users were generally discarding the NA group anyway (and supporting it was an implementation headache).

### Grouping with ordered factors

Categorical variables represented as instance of pandas’s `Categorical` class can be used as group keys. If so, the order of the levels will be preserved:

```python
In [178]: data = pd.Series(np.random.randn(100))
In [179]: factor = pd.qcut(data, [0, 0.25, 0.5, 0.75, 1.0])
In [180]: data.groupby(factor).mean()
Out[180]:
       (-2.645, -0.523] -1.362896
       (-0.523, 0.0296] -0.260266
        (0.0296, 0.654]  0.361802
        (0.654, 2.21]   1.073801
       dtype: float64
```
Grouping with a grouper specification

You may need to specify a bit more data to properly group. You can use the pd.Grouper to provide this local control.

In [181]: import datetime
In [182]: df = pd.DataFrame(
    .....:     
    .....:       "Branch": "A A A A A A A B".split(),
    .....:       "Buyer": "Carl Mark Carl Joe Joe Joe Carl".split(),
    .....:       "Quantity": [1, 3, 5, 1, 8, 1, 9, 3],
    .....:       "Date": [
    .....:         datetime.datetime(2013, 1, 1, 13, 0),
    .....:         datetime.datetime(2013, 1, 1, 13, 5),
    .....:         datetime.datetime(2013, 10, 1, 20, 0),
    .....:         datetime.datetime(2013, 10, 2, 10, 0),
    .....:         datetime.datetime(2013, 10, 2, 10, 0),
    .....:         datetime.datetime(2013, 12, 2, 14, 0),
    .....:         datetime.datetime(2013, 12, 2, 12, 0),
    .....:         datetime.datetime(2013, 12, 12, 12, 0),
    .....:     ],
    .....:   }
In [183]: df
Out[183]:

<table>
<thead>
<tr>
<th>Branch</th>
<th>Buyer</th>
<th>Quantity</th>
<th>Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>Carl</td>
<td>1</td>
<td>2013-01-01 13:00:00</td>
</tr>
<tr>
<td>A</td>
<td>Mark</td>
<td>3</td>
<td>2013-01-01 13:05:00</td>
</tr>
<tr>
<td>A</td>
<td>Carl</td>
<td>5</td>
<td>2013-10-01 20:00:00</td>
</tr>
<tr>
<td>A</td>
<td>Carl</td>
<td>1</td>
<td>2013-10-02 10:00:00</td>
</tr>
<tr>
<td>A</td>
<td>Joe</td>
<td>8</td>
<td>2013-10-01 20:00:00</td>
</tr>
<tr>
<td>A</td>
<td>Joe</td>
<td>1</td>
<td>2013-10-02 10:00:00</td>
</tr>
<tr>
<td>A</td>
<td>Joe</td>
<td>9</td>
<td>2013-12-02 12:00:00</td>
</tr>
<tr>
<td>B</td>
<td>Carl</td>
<td>3</td>
<td>2013-12-02 14:00:00</td>
</tr>
</tbody>
</table>

Groupby a specific column with the desired frequency. This is like resampling.

In [184]: df.groupby([pd.Grouper(freq="1M", key="Date"), "Buyer"]).sum()
Out[184]:

<table>
<thead>
<tr>
<th>Date</th>
<th>Buyer</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-31</td>
<td>Carl</td>
<td>1</td>
</tr>
<tr>
<td>2013-10-31</td>
<td>Carl</td>
<td>6</td>
</tr>
<tr>
<td>2013-12-31</td>
<td>Carl</td>
<td>3</td>
</tr>
</tbody>
</table>

You have an ambiguous specification in that you have a named index and a column that could be potential groupers.

In [185]: df = df.set_index("Date")
In [186]: df["Date"] = df.index + pd.offsets.MonthEnd(2)
In [187]: df.groupby([pd.Grouper(freq="6M", key="Date"), "Buyer"]).sum()
Out[187]:

<table>
<thead>
<tr>
<th>Date</th>
<th>Buyer</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-02-28</td>
<td>Carl</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Mark</td>
<td>3</td>
</tr>
<tr>
<td>2014-02-28</td>
<td>Carl</td>
<td>9</td>
</tr>
<tr>
<td></td>
<td>Joe</td>
<td>18</td>
</tr>
</tbody>
</table>

In[188]: df.groupby([pd.Grouper(freq="6M", level="Date"), "Buyer"]).sum()

Out[188]:

<table>
<thead>
<tr>
<th>Date</th>
<th>Buyer</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-31</td>
<td>Carl</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>Mark</td>
<td>3</td>
</tr>
<tr>
<td>2014-01-31</td>
<td>Carl</td>
<td>9</td>
</tr>
<tr>
<td></td>
<td>Joe</td>
<td>18</td>
</tr>
</tbody>
</table>

**Taking the first rows of each group**

Just like for a DataFrame or Series you can call head and tail on a groupby:

In[189]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=["A", "B"])

In[190]: df

Out[190]:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
</tr>
</tbody>
</table>

In[191]: g = df.groupby("A")

In[192]: g.head(1)

Out[192]:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
</tr>
</tbody>
</table>

In[193]: g.tail(1)

Out[193]:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
</tr>
</tbody>
</table>

This shows the first or last n rows from each group.
Taking the nth row of each group

To select from a DataFrame or Series the nth item, use `nth()`. This is a reduction method, and will return a single row (or no row) per group if you pass an int for n:

```python
In [194]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])
In [195]: g = df.groupby('A')
In [196]: g.nth(0)
Out[196]:
   A  B  
0  1  NaN
1  5  6.0
In [197]: g.nth(-1)
Out[197]:
   A  B  
0  1  4.0
1  5  6.0
In [198]: g.nth(1)
Out[198]:
   A  B  
0  1  4.0
1  5  6.0
```

If you want to select the nth not-null item, use the `dropna` kwarg. For a DataFrame this should be either 'any' or 'all' just like you would pass to `dropna`:

```python
# nth(0) is the same as g.first()
In [199]: g.nth(0, dropna='any')
Out[199]:
   A  B  
0  1  4.0
1  5  6.0

# nth(-1) is the same as g.last()
In [200]: g.first()
Out[200]:
   A  B  
0  1  4.0
1  5  6.0
```

(continues on next page)
As with other methods, passing `as_index=False`, will achieve a filtration, which returns the grouped row.

You can also select multiple rows from each group by specifying multiple `nth` values as a list of ints.
Enumerate group items

To see the order in which each row appears within its group, use the `cumcount` method:

```
In [211]: dfg = pd.DataFrame(list("aaabba"), columns=["A"))

In [212]: dfg
Out[212]:
   A
0  a
1  a
2  a
3  b
4  b
5  a

In [213]: dfg.groupby("A").cumcount()
Out[213]:
   0  0
   1  1
   2  2
   3  0
   4  1
   5  3
dtype: int64

In [214]: dfg.groupby("A").cumcount(ascending=False)
Out[214]:
   0  3
   1  2
   2  1
   3  1
   4  0
   5  0
dtype: int64
```

Enumerate groups

To see the ordering of the groups (as opposed to the order of rows within a group given by `cumcount`) you can use `ngroup()`.

Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the `groupby` object, not the order they are first observed.

```
In [215]: dfg = pd.DataFrame(list("aaabba"), columns=["A")

In [216]: dfg
Out[216]:
   A
0  a
1  a
2  a
3  b
4  b
5  a
```

(continues on next page)
Plotting

Groupby also works with some plotting methods. For example, suppose we suspect that some features in a DataFrame may differ by group, in this case, the values in column 1 where the group is “B” are 3 higher on average.

```python
In [219]: np.random.seed(1234)

In [220]: df = pd.DataFrame(np.random.randn(50, 2))

In [221]: df["g"] = np.random.choice(['A', 'B'], size=50)

In [222]: df.loc[df["g"] == "B", 1] += 3
```

We can easily visualize this with a boxplot:

```python
In [223]: df.groupby("g").boxplot()
Out [223]:
A AxesSubplot(0.1,0.15;0.363636x0.75)
B AxesSubplot(0.536364,0.15;0.363636x0.75)
dtype: object
```
The result of calling `boxplot` is a dictionary whose keys are the values of our grouping column `g` ("A" and "B"). The values of the resulting dictionary can be controlled by the `return_type` keyword of `boxplot`. See the visualization documentation for more.

**Warning:** For historical reasons, `df.groupby("g").boxplot()` is not equivalent to `df.boxplot(by="g")`. See here for an explanation.

### Piping function calls

Similar to the functionality provided by DataFrame and Series, functions that take GroupBy objects can be chained together using a pipe method to allow for a cleaner, more readable syntax. To read about `.pipe` in general terms, see here.

Combining `.groupby` and `.pipe` is often useful when you need to reuse GroupBy objects.

As an example, imagine having a DataFrame with columns for stores, products, revenue and quantity sold. We’d like to do a groupwise calculation of `prices` (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable. First we set the data:

```python
In [224]: n = 1000
In [225]: df = pd.DataFrame(
```
In [226]: df.head(2)
Out[226]:
   Store  Product  Revenue  Quantity
0  Store_2  Product_1      26.12       1
1  Store_2  Product_1      28.86       1

Now, to find prices per store/product, we can simply do:

In [227]:
   (  
   ...:  df.groupby(["Store", "Product"])
   ...:     .pipe(lambda grp: grp.Revenue.sum() / grp.Quantity.sum())
   ...:     .unstack()
   ...:     .round(2)
   ...: )
   ...

Out[227]:
   Product  Product_1  Product_2
   Store
   Store_1   6.82      7.05
   Store_2   6.30      6.64

Piping can also be expressive when you want to deliver a grouped object to some arbitrary function, for example:

In [228]:
   def mean(groupby):
       ...
       return groupby.mean()
   ...

In [229]: df.groupby(["Store", "Product"]).pipe(mean)
Out[229]:
   Revenue  Quantity
   Store Product
   Store_1 Product_1  34.622727  5.075758
                Product_2  35.482815  5.029630
   Store_2 Product_1  32.972837  5.237589
                Product_2  34.684360  5.224000

where mean takes a GroupBy object and finds the mean of the Revenue and Quantity columns respectively for each Store-Product combination. The mean function can be any function that takes in a GroupBy object; the .pipe will pass the GroupBy object as a parameter into the function you specify.
2.18.11 Examples

Regrouping by factor

Regroup columns of a DataFrame according to their sum, and sum the aggregated ones.

In [230]: df = pd.DataFrame({"a": [1, 0, 0], "b": [0, 1, 0], "c": [1, 0, 0], "d": [2, 3, 4]})

In [231]: df
Out[231]:
   a  b  c  d
0  1  0  1  2
1  0  1  0  3
2  0  0  0  4

In [232]: df.groupby(df.sum(), axis=1).sum()
Out[232]:
   0  1
0  2  2
1  1  3
2  0  4

Multi-column factorization

By using ngroup(), we can extract information about the groups in a way similar to factorize() (as described further in the reshaping API) but which applies naturally to multiple columns of mixed type and different sources. This can be useful as an intermediate categorical-like step in processing, when the relationships between the group rows are more important than their content, or as input to an algorithm which only accepts the integer encoding. (For more information about support in pandas for full categorical data, see the Categorical introduction and the API documentation.)

In [233]: dfg = pd.DataFrame({"A": [1, 1, 2, 3, 2], "B": list("aaaba")})

In [234]: dfg
Out[234]:
   A  B
0  1  a
1  1  a
2  2  a
3  3  b
4  2  a

In [235]: dfg.groupby(["A", "B"]).ngroup()
Out[235]:
   0  0
1  0
2  1
3  2
4  1
dtype: int64

In [236]: dfg.groupby(["A", [0, 0, 0, 1, 1]]).ngroup()
Out[236]:
   0  0
(continues on next page)
Groupby by indexer to ‘resample’ data

Resampling produces new hypothetical samples (resamples) from already existing observed data or from a model that generates data. These new samples are similar to the pre-existing samples.

In order to resample to work on indices that are non-datetimelike, the following procedure can be utilized.

In the following examples, `df.index // 5` returns a binary array which is used to determine what gets selected for the groupby operation.

**Note:** The below example shows how we can downsample by consolidation of samples into fewer samples. Here by using `df.index // 5`, we are aggregating the samples in bins. By applying `std()` function, we aggregate the information contained in many samples into a small subset of values which is their standard deviation thereby reducing the number of samples.

```python
In [237]: df = pd.DataFrame(np.random.randn(10, 2))
In [238]: df
Out[238]:
   0    1
0 -0.793893  0.321153
1  0.342250  1.618906
2 -0.975807  1.918201
3 -0.810847 -1.405919
4 -1.977759  0.461659
5  0.730057 -1.316938
6 -0.751328  0.528290
7 -0.257759 -1.081009
8  0.505895 -1.701948
9 -1.006349  0.020208

In [239]: df.index // 5
Out[239]: Int64Index([0, 0, 0, 0, 0, 1, 1, 1, 1, 1], dtype='int64')

In [240]: df.groupby(df.index // 5).std()
Out[240]:
   0     1
0  0.823647  1.312912
1  0.760109  0.942941
```
Returning a Series to propagate names

Group DataFrame columns, compute a set of metrics and return a named Series. The Series name is used as the name for the column index. This is especially useful in conjunction with reshaping operations such as stacking in which the column index name will be used as the name of the inserted column:

In [241]: df = pd.DataFrame(
        .....:     {
        .....:         "a": [0, 0, 0, 0, 1, 1, 1, 1, 2, 2, 2, 2],
        .....:         "b": [0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1],
        .....:         "c": [1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0],
        .....:         "d": [0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1],
        .....:     })

In [242]: def compute_metrics(x):
        .....:     result = {"b_sum": x["b"].sum(), "c_mean": x["c"].mean()}
        .....:     return pd.Series(result, name="metrics")

In [243]: result = df.groupby("a").apply(compute_metrics)

In [244]: result
Out[244]:
        metrics  b_sum  c_mean
        a
        0     2.0  0.5
        1     2.0  0.5
        2     2.0  0.5

In [245]: result.stack()
Out[245]:
        a metrics
        0  b_sum  2.0
        c_mean  0.5
        1  b_sum  2.0
        c_mean  0.5
        2  b_sum  2.0
        c_mean  0.5
dtype: float64

2.19 Windowing Operations

pandas contains a compact set of APIs for performing windowing operations - an operation that performs an aggregation over a sliding partition of values. The API functions similarly to the groupby API in that Series and DataFrame call the windowing method with necessary parameters and then subsequently call the aggregation function.

In [1]: s = pd.Series(range(5))

In [2]: s.rolling(window=2).sum()
Out[2]:
        0  NaN
        1  1.0
The windows are comprised by looking back the length of the window from the current observation. The result above can be derived by taking the sum of the following windowed partitions of data:

```python
In [3]: for window in s.rolling(window=2):
    ...:     print(window)
    ...:
0    0
     dtype: int64
0    0
     dtype: int64
1    1
     dtype: int64
1    1
     dtype: int64
2    2
     dtype: int64
2    2
     dtype: int64
3    3
     dtype: int64
3    3
     dtype: int64
4    4
     dtype: int64
```

2.19.1 Overview

pandas supports 4 types of windowing operations:

1. Rolling window: Generic fixed or variable sliding window over the values.
2. Weighted window: Weighted, non-rectangular window supplied by the `scipy.signal` library.
3. Expanding window: Accumulating window over the values.
4. Exponentially Weighted window: Accumulating and exponentially weighted window over the values.

<table>
<thead>
<tr>
<th>Concept</th>
<th>Method</th>
<th>Returned Object</th>
<th>Supports time-based windows</th>
<th>Supports chained groupby</th>
<th>Supports table method</th>
<th>Supports online operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rolling window</td>
<td>rolling</td>
<td>rolling</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Weighted window</td>
<td>rolling</td>
<td>Window</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Expanding window</td>
<td>expanding</td>
<td>Expanding</td>
<td>No</td>
<td>Yes</td>
<td>Yes (as of version 1.3)</td>
<td>No</td>
</tr>
<tr>

<td>ewm</td>
<td>ExponentialMovingWindow</td>
<td>Yes (as of version 1.2)</td>
<td>No</td>
<td>Yes (as of version 1.3)</td>
<td>No</td>
</tr>
</tbody>
</table>

As noted above, some operations support specifying a window based on a time offset:
Additionally, some methods support chaining a `groupby` operation with a windowing operation which will first group the data by the specified keys and then perform a windowing operation per group.

```python
In [6]: df = pd.DataFrame({'A': ['a', 'b', 'a', 'b', 'a'], 'B': range(5)})

In [7]: df.groupby('A').expanding().sum()
Out[7]:
   B
A  
a  0  0.0
   2  2.0
   4  6.0
b  1  1.0
   3  4.0
```

**Note:** Windowing operations currently only support numeric data (integer and float) and will always return float64 values.

**Warning:** Some windowing aggregation, mean, sum, var and std methods may suffer from numerical imprecision due to the underlying windowing algorithms accumulating sums. When values differ with magnitude \(1/\text{np.finfo(np.double).eps}\) this results in truncation. It must be noted, that large values may have an impact on windows, which do not include these values. **Kahan summation** is used to compute the rolling sums to preserve accuracy as much as possible.

New in version 1.3.0.

Some windowing operations also support the `method='table'` option in the constructor which performs the windowing operation over an entire DataFrame instead of a single column or row at a time. This can provide a useful performance benefit for a DataFrame with many columns or rows (with the corresponding axis argument) or the ability to utilize other columns during the windowing operation. The `method='table'` option can only be used if `engine='numba'` is specified in the corresponding method call.

For example, a weighted mean calculation can be calculated with `apply()` by specifying a separate column of weights.

```python
In [8]: def weighted_mean(x):
    ...:     arr = np.ones((1, x.shape[1]))
    ...:     arr[:, :2] = (x[:, :2] * x[:, 2]).sum(axis=0) / x[:, 2].sum()
    ...:     return arr
    ...:
```

(continues on next page)
New in version 1.3.

Some windowing operations also support an online method after constructing a windowing object which returns a new object that supports passing in new DataFrame or Series objects to continue the windowing calculation with the new values (i.e. online calculations).

The methods on this new windowing objects must call the aggregation method first to “prime” the initial state of the online calculation. Then, new DataFrame or Series objects can be passed in the update argument to continue the windowing calculation.

All windowing operations support a min_periods argument that dictates the minimum amount of non-np.nan values a window must have; otherwise, the resulting value is np.nan. min_periods defaults to 1 for time-based windows and window for fixed windows.
Additionally, all windowing operations support the `aggregate` method for returning a result of multiple aggregations applied to a window.

```python
In [20]: df = pd.DataFrame({"A": range(5), "B": range(10, 15)})
In [21]: df.expanding().agg([np.sum, np.mean, np.std])
```

```
   A     B
   sum  mean  std   sum  mean  std
   0.0  0.0  NaN   10.0 10.0  NaN
   1.0  0.5  0.71   21.0 10.5  0.71
   3.0  1.0  1.0    33.0 11.0  1.0
   6.0  1.5  1.29   46.0 11.5  1.29
   10.0 2.0  1.58   60.0 12.0  1.58
```

### 2.19.2 Rolling window

Generic rolling windows support specifying windows as a fixed number of observations or variable number of observations based on an offset. If a time based offset is provided, the corresponding time based index must be monotonic.

```python
In [22]: times = ['2020-01-01', '2020-01-03', '2020-01-04', '2020-01-05', '2020-01-29']
In [23]: s = pd.Series(range(5), index=pd.DatetimeIndex(times))
In [24]: s
```

```
2020-01-01  0
2020-01-03  1
2020-01-04  2
```
2020-01-05  3
2020-01-29  4
dtype: int64

# Window with 2 observations
In [25]: s.rolling(window=2).sum()

Out[25]:
2020-01-01    NaN
2020-01-03    1.0
2020-01-04    3.0
2020-01-05    5.0
2020-01-29    7.0
dtype: float64

# Window with 2 days worth of observations
In [26]: s.rolling(window='2D').sum()

Out[26]:
2020-01-01    0.0
2020-01-03    1.0
2020-01-04    3.0
2020-01-05    5.0
2020-01-29    4.0
dtype: float64

For all supported aggregation functions, see [Rolling window functions](#).

### Centering windows

By default the labels are set to the right edge of the window, but a `center` keyword is available so the labels can be set at the center.

In [27]: s = pd.Series(range(10))

In [28]: s.rolling(window=5).mean()

Out[28]:
0    NaN
1    NaN
2    NaN
3    NaN
4    2.0
5    3.0
6    4.0
7    5.0
8    6.0
9    7.0
dtype: float64

In [29]: s.rolling(window=5, center=True).mean()

Out[29]:
0    NaN
1    NaN
2    2.0
3    3.0
4    4.0
5    5.0

(continues on next page)
This can also be applied to datetime-like indices.

New in version 1.3.0.

```python
>>> df = pd.DataFrame(
    ...:     {"A": [0, 1, 2, 3, 4]}, index=pd.date_range("2020", periods=5, freq="1D")
    ...: )

>>> df
   A
2020-01-01  0
2020-01-02  1
2020-01-03  2
2020-01-04  3
2020-01-05  4

>>> df.rolling("2D", center=False).mean()
   A
2020-01-01  0.0
2020-01-02  0.5
2020-01-03  1.5
2020-01-04  2.5
2020-01-05  3.5

>>> df.rolling("2D", center=True).mean()
   A
2020-01-01  0.5
2020-01-02  1.5
2020-01-03  2.5
2020-01-04  3.5
2020-01-05  4.0
```

**Rolling window endpoints**

The inclusion of the interval endpoints in rolling window calculations can be specified with the `closed` parameter:

<table>
<thead>
<tr>
<th>Value</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>'right'</td>
<td>close right endpoint</td>
</tr>
<tr>
<td>'left'</td>
<td>close left endpoint</td>
</tr>
<tr>
<td>'both'</td>
<td>close both endpoints</td>
</tr>
<tr>
<td>'neither'</td>
<td>open endpoints</td>
</tr>
</tbody>
</table>

For example, having the right endpoint open is useful in many problems that require that there is no contamination from present information back to past information. This allows the rolling window to compute statistics “up to that point in time”, but not including that point in time.
In [34]: df = pd.DataFrame(
    .....:     {"x": 1},
    .....:     index=[
    .....:         pd.Timestamp("20130101 09:00:01"),
    .....:         pd.Timestamp("20130101 09:00:02"),
    .....:         pd.Timestamp("20130101 09:00:03"),
    .....:         pd.Timestamp("20130101 09:00:04"),
    .....:         pd.Timestamp("20130101 09:00:06"),
    .....:     ],
    .....: )
In [35]: df["right"] = df.rolling("2s", closed="right").x.sum()  # default
In [36]: df["both"] = df.rolling("2s", closed="both").x.sum()
In [37]: df["left"] = df.rolling("2s", closed="left").x.sum()
In [38]: df["neither"] = df.rolling("2s", closed="neither").x.sum()
In [39]: df
Out[39]:
     x  right  both  left  neither
2013-01-01 09:00:01 1   1.0 1.0  NaN   NaN
2013-01-01 09:00:02 1   2.0 2.0   1.0  1.0
2013-01-01 09:00:03 1   2.0 3.0   2.0  1.0
2013-01-01 09:00:04 1   2.0 3.0   2.0  1.0
2013-01-01 09:00:06 1   1.0 2.0   1.0   NaN

Custom window rolling

New in version 1.0.

In addition to accepting an integer or offset as a window argument, rolling also accepts a BaseIndexer subclass that allows a user to define a custom method for calculating window bounds. The BaseIndexer subclass will need to define a get_window_bounds method that returns a tuple of two arrays, the first being the starting indices of the windows and second being the ending indices of the windows. Additionally, num_values, min_periods, center, closed and will automatically be passed to get_window_bounds and the defined method must always accept these arguments.

For example, if we have the following DataFrame

In [40]: use_expanding = [True, False, True, False, True]
In [41]: use_expanding
Out[41]: [True, False, True, False, True]
In [42]: df = pd.DataFrame({"values": range(5)})
In [43]: df
Out[43]:
   values
0    0
1    1
2    2
3    3

(continues on next page)
and we want to use an expanding window where `use_expanding` is `True` otherwise a window of size 1, we can create the following `BaseIndexer` subclass:

```python
In [2]: from pandas.api.indexers import BaseIndexer
In [3]: class CustomIndexer(BaseIndexer):
   ...:     def get_window_bounds(self, num_values, min_periods, center, closed):
   ...:         start = np.empty(num_values, dtype=np.int64)
   ...:         end = np.empty(num_values, dtype=np.int64)
   ...:         for i in range(num_values):
   ...:             if self.use_expanding[i]:
   ...:                 start[i] = 0
   ...:                 end[i] = i + 1
   ...:             else:
   ...:                 start[i] = i
   ...:                 end[i] = i + self.window_size
   ...:         return start, end
In [4]: indexer = CustomIndexer(window_size=1, use_expanding=use_expanding)
In [5]: df.rolling(indexer).sum()
Out[5]:
   values
0     0.0
1     1.0
2     3.0
3     3.0
4    10.0
```

You can view other examples of `BaseIndexer` subclasses [here](#).

New in version 1.1.

One subclass of note within those examples is the `VariableOffsetWindowIndexer` that allows rolling operations over a non-fixed offset like a `BusinessDay`.

```python
In [44]: from pandas.api.indexers import VariableOffsetWindowIndexer
In [45]: df = pd.DataFrame(range(10), index=pd.date_range("2020", periods=10))
In [46]: offset = pd.offsets.BDay(1)
In [47]: indexer = VariableOffsetWindowIndexer(index=df.index, offset=offset)
In [48]: df
Out[48]:
   0
2020-01-01  0
2020-01-02  1
2020-01-03  2
2020-01-04  3
2020-01-05  4
2020-01-06  5
2020-01-07  6
2020-01-08  7
```
For some problems knowledge of the future is available for analysis. For example, this occurs when each data point is a full time series read from an experiment, and the task is to extract underlying conditions. In these cases it can be useful to perform forward-looking rolling window computations. `FixedForwardWindowIndexer` class is available for this purpose. This `BaseIndexer` subclass implements a closed fixed-width forward-looking rolling window, and we can use it as follows:

```python
In [50]: from pandas.api.indexers import FixedForwardWindowIndexer

In [51]: indexer = FixedForwardWindowIndexer(window_size=2)

In [52]: df.rolling(indexer, min_periods=1).sum()
```

We can also achieve this by using slicing, applying rolling aggregation, and then flipping the result as shown in example below:

```python
In [53]: df = pd.DataFrame(
        ....:     data=[
        ....:         [pd.Timestamp("2018-01-01 00:00:00"), 100],
        ....:         [pd.Timestamp("2018-01-01 00:00:01"), 101],
        ....:         [pd.Timestamp("2018-01-01 00:00:03"), 103],
        ....:         [pd.Timestamp("2018-01-01 00:00:04"), 111],
        ....:     ],
        ....:     columns=["time", "value"],
        ....: ).set_index("time")

In [54]: df
```
Rolling apply

The apply() function takes an extra func argument and performs generic rolling computations. The func argument should be a single function that produces a single value from an ndarray input. raw specifies whether the windows are cast as Series objects (raw=False) or ndarray objects (raw=True).

```python
In [57]: def mad(x):
    ....:     return np.fabs(x - x.mean()).mean()
    ....:

In [58]: s = pd.Series(range(10))

In [59]: s.rolling(window=4).apply(mad, raw=True)
Out[59]:
        0    NaN
        1    NaN
        2    NaN
        3     1.0
        4     1.0
        5     1.0
        6     1.0
        7     1.0
        8     1.0
        9     1.0
dtype: float64
```
Numba engine

New in version 1.0.

Additionally, apply() can leverage Numba if installed as an optional dependency. The apply aggregation can be executed using Numba by specifying engine='numba' and engine_kwargs arguments (raw must also be set to True). See enhancing performance with Numba for general usage of the arguments and performance considerations.

Numba will be applied in potentially two routines:

1. If func is a standard Python function, the engine will JIT the passed function. func can also be a JITed function in which case the engine will not JIT the function again.

2. The engine will JIT the for loop where the apply function is applied to each window.

The engine_kwargs argument is a dictionary of keyword arguments that will be passed into the numba.jit decorator. These keyword arguments will be applied to both the passed function (if a standard Python function) and the apply for loop over each window.

New in version 1.3.0.

mean, median, max, min, and sum also support the engine and engine_kwargs arguments.

Binary window functions

cov() and corr() can compute moving window statistics about two Series or any combination of DataFrame/Series or DataFrame/DataFrame. Here is the behavior in each case:

- two Series: compute the statistic for the pairing.
- DataFrame/Series: compute the statistics for each column of the DataFrame with the passed Series, thus returning a DataFrame.
- DataFrame/DataFrame: by default compute the statistic for matching column names, returning a DataFrame. If the keyword argument pairwise=True is passed then computes the statistic for each pair of columns, returning a DataFrame with a MultiIndex whose values are the dates in question (see the next section).

For example:

```
In [60]: df = pd.DataFrame(
          ....:     np.random.randn(10, 4),
          ....:     index=pd.date_range("2020-01-01", periods=10),
          ....:     columns=["A", "B", "C", "D"],
          ....:     )
      ....:

In [61]: df = df.cumsum()

In [62]: df2 = df[:4]

In [63]: df2.rolling(window=2).corr(df2["B"])
Out[63]:
   A    B  C    D
2020-01-01 NaN  NaN  NaN  NaN
2020-01-02 -1.0  1.0 -1.0  1.0
2020-01-03  1.0  1.0  1.0 -1.0
2020-01-04 -1.0  1.0  1.0 -1.0
```
Computing rolling pairwise covariances and correlations

In financial data analysis and other fields it’s common to compute covariance and correlation matrices for a collection of time series. Often one is also interested in moving-window covariance and correlation matrices. This can be done by passing the pairwise keyword argument, which in the case of DataFrame inputs will yield a MultiIndexed DataFrame whose index are the dates in question. In the case of a single DataFrame argument the pairwise argument can even be omitted:

Note: Missing values are ignored and each entry is computed using the pairwise complete observations. Please see the covariance section for caveats associated with this method of calculating covariance and correlation matrices.

```
In [64]: covs = (  
      ...:     df["B", "C", "D"]  
      ...:     .rolling(window=4)  
      ...:     .cov(df["A", "B", "C"], pairwise=True)  
      ...: )  
      ...:

In [65]: covs
Out[65]:
          B         C         D
2020-01-01 A  NaN     NaN     NaN
      B  NaN     NaN     NaN
      C  NaN     NaN     NaN

[30 rows x 3 columns]
```

2.19.3 Weighted window

The win_type argument in .rolling generates a weighted windows that are commonly used in filtering and spectral estimation. win_type must be string that corresponds to a scipy.signal window function. Scipy must be installed in order to use these windows, and supplementary arguments that the Scipy window methods take must be specified in the aggregation function.

```
In [66]: s = pd.Series(range(10))  

In [67]: s.rolling(window=5).mean()  
Out[67]:
       0  NaN
       1  NaN
       2  NaN
       3  NaN
       4  2.0
       5  3.0
       6  4.0
       7  5.0
       8  6.0
       9  7.0
(continues on next page)
```
In [68]: s.rolling(window=5, win_type="triang").mean()
Out[68]:
0  NaN
1  NaN
2  NaN
3  NaN
4  2.0
5  3.0
6  4.0
7  5.0
8  6.0
9  7.0
dtype: float64

# Supplementary Scipy arguments passed in the aggregation function
In [69]: s.rolling(window=5, win_type="gaussian").mean(std=0.1)
Out[69]:
0  NaN
1  NaN
2  NaN
3  NaN
4  2.0
5  3.0
6  4.0
7  5.0
8  6.0
9  7.0
dtype: float64

For all supported aggregation functions, see Weighted window functions.

2.19.4 Expanding window

An expanding window yields the value of an aggregation statistic with all the data available up to that point in time. Since these calculations are a special case of rolling statistics, they are implemented in pandas such that the following two calls are equivalent:

In [70]: df = pd.DataFrame(range(5))

In [71]: df.rolling(window=len(df), min_periods=1).mean()
Out[71]:
       0
0  0.0
1  0.5
2  1.0
3  1.5
4  2.0

In [72]: df.expanding(min_periods=1).mean()
Out[72]:
      0
0  0.0

(continues on next page)
For all supported aggregation functions, see *Expanding window functions*.

### 2.19.5 Exponentially Weighted window

An exponentially weighted window is similar to an expanding window but with each prior point being exponentially weighted down relative to the current point.

In general, a weighted moving average is calculated as

\[ y_t = \frac{\sum_{i=0}^{t} w_i x_{t-i}}{\sum_{i=0}^{t} w_i}, \]

where \( x_t \) is the input, \( y_t \) is the result and the \( w_i \) are the weights.

For all supported aggregation functions, see *Exponentially-weighted window functions*.

The EW functions support two variants of exponential weights. The default, `adjust=True`, uses the weights \( w_i = (1 - \alpha)^i \) which gives

\[ y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + ... + (1 - \alpha)^t x_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + ... + (1 - \alpha)^t} \]

When `adjust=False` is specified, moving averages are calculated as

\[
\begin{align*}
y_0 &= x_0 \\
y_t &= (1 - \alpha)y_{t-1} + \alpha x_t,
\end{align*}
\]

which is equivalent to using weights

\[
\begin{align*}
w_i &= \begin{cases} 
\alpha(1 - \alpha)^i & \text{if } i < t \\
(1 - \alpha)^i & \text{if } i = t.
\end{cases}
\end{align*}
\]

**Note:** These equations are sometimes written in terms of \( \alpha' = 1 - \alpha \), e.g.

\[ y_t = \alpha' y_{t-1} + (1 - \alpha') x_t. \]

The difference between the above two variants arises because we are dealing with series which have finite history. Consider a series of infinite history, with `adjust=True`:

\[ y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + ...}{1 + (1 - \alpha) + (1 - \alpha)^2 + ...} \]

Noting that the denominator is a geometric series with initial term equal to 1 and a ratio of \( 1 - \alpha \) we have

\[
\begin{align*}
y_t &= \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + ...}{1 - (1 - \alpha)} \\
&= \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + ...}{1 - \alpha} \alpha \\
&= \alpha x_t + \frac{(1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + ...}{1 - \alpha} \alpha \\
&= \alpha x_t + (1 - \alpha)[x_{t-1} + (1 - \alpha)x_{t-2} + ...] \alpha \\
&= \alpha x_t + (1 - \alpha)y_{t-1}
\end{align*}
\]
which is the same expression as adjust=False above and therefore shows the equivalence of the two variants for infinite series. When adjust=False, we have \( y_0 = x_0 \) and \( y_t = \alpha x_t + (1 - \alpha)y_{t-1} \). Therefore, there is an assumption that \( x_0 \) is not an ordinary value but rather an exponentially weighted moment of the infinite series up to that point.

One must have \( 0 < \alpha \leq 1 \), and while it is possible to pass \( \alpha \) directly, it’s often easier to think about either the span, center of mass (com) or half-life of an EW moment:

\[
\alpha = \begin{cases} 
\frac{2}{s+1}, & \text{for span } s \geq 1 \\
\frac{1}{1+c}, & \text{for center of mass } c \geq 0 \\
1 - \exp^{-0.5}, & \text{for half-life } h > 0
\end{cases}
\]

One must specify precisely one of span, center of mass, half-life and alpha to the EW functions:

- **Span** corresponds to what is commonly called an “N-day EW moving average”.
- **Center of mass** has a more physical interpretation and can be thought of in terms of span: \( c = (s - 1)/2 \).
- **Half-life** is the period of time for the exponential weight to reduce to one half.
- **Alpha** specifies the smoothing factor directly.

New in version 1.1.0.

You can also specify halflife in terms of a timedelta convertible unit to specify the amount of time it takes for an observation to decay to half its value when also specifying a sequence of times.

```python
In [73]: df = pd.DataFrame( { "B": [0, 1, 2, np.nan, 4] } )
```

```python
In [74]: df
Out[74]:
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```

```python
In [75]: times = ["2020-01-01", "2020-01-03", "2020-01-10", "2020-01-15", "2020-01-17"]
```

```python
In [76]: df.ewm(halflife="4 days", times=pd.DatetimeIndex(times)).mean()
Out[76]:
   B
0  0.000000
1  0.585786
2  1.523889
3  1.523889
4  3.233686
```

The following formula is used to compute exponentially weighted mean with an input vector of times:

\[
y_t = \frac{\sum_{i=0}^{t} 0.5^{\frac{i}{s+1}} x_{t-i}}{\sum_{i=0}^{t} 0.5^{\frac{i}{s+1}}},
\]

ExponentialMovingWindow also has an ignore_na argument, which determines how intermediate null values affect the calculation of the weights. When ignore_na=False (the default), weights are calculated based on absolute positions, so that intermediate null values affect the result. When ignore_na=True, weights are calculated by

2.19. Windowing Operations 799
ignoring intermediate null values. For example, assuming adjust=True, if ignore_na=False, the weighted average of 3, NaN, 5 would be calculated as

\[
\frac{(1 - \alpha)^2 \cdot 3 + 1 \cdot 5}{(1 - \alpha)^2 + 1}.
\]

Whereas if ignore_na=True, the weighted average would be calculated as

\[
\frac{(1 - \alpha) \cdot 3 + 1 \cdot 5}{(1 - \alpha) + 1}.
\]

The var(), std(), and cov() functions have a bias argument, specifying whether the result should contain biased or unbiased statistics. For example, if bias=True, ewmvar(x) is calculated as \(\text{ewmvar}(x) = \text{ewma}(x^2) - \text{ewma}(x)^2\); whereas if bias=False (the default), the biased variance statistics are scaled by debiasing factors

\[
\frac{\left(\sum_{i=0}^{t} w_i\right)^2}{\left(\sum_{i=0}^{t} w_i^2\right)} - \sum_{i=0}^{t} w_i^2.
\]

(For \(w_i = 1\), this reduces to the usual \(N/(N - 1)\) factor, with \(N = t + 1\).) See Weighted Sample Variance on Wikipedia for further details.

### 2.20 Time series / date functionality

pandas contains extensive capabilities and features for working with time series data for all domains. Using the NumPy datetime64 and timedelta64 dtypes, pandas has consolidated a large number of features from other Python libraries like scikits.timeseries as well as created a tremendous amount of new functionality for manipulating time series data.

For example, pandas supports:

- Parsing time series information from various sources and formats

```python
In [1]: import datetime

In [2]: dti = pd.to_datetime(
    ...:    ["1/1/2018", np.datetime64("2018-01-01"), datetime.datetime(2018, 1, 1)],
    ...:    )

In [3]: dti
    ...:    "datetime64[ns]", freq=None)
```

- Generate sequences of fixed-frequency dates and time spans

```python
In [4]: dti = pd.date_range("2018-01-01", periods=3, freq="H")

In [5]: dti
Out[5]: DatetimeIndex(["2018-01-01 00:00:00", "2018-01-01 01:00:00",
    ...:    "2018-01-01 02:00:00"],
    dtype='datetime64[ns]'")
```

- Manipulating and converting date times with timezone information
In [6]: dti = dti.tz_localize("UTC")

In [7]: dti
Out[7]:
DatetimeIndex(['2018-01-01 00:00:00+00:00', '2018-01-01 01:00:00+00:00',
              '2018-01-01 02:00:00+00:00'],
            dtype='datetime64[ns, UTC]', freq='H')

In [8]: dti.tz_convert("US/Pacific")
Out[8]:
DatetimeIndex(['2017-12-31 16:00:00-08:00', '2017-12-31 17:00:00-08:00',
               '2017-12-31 18:00:00-08:00'],
            dtype='datetime64[ns, US/Pacific]', freq='H')

Resampling or converting a time series to a particular frequency

In [9]: idx = pd.date_range("2018-01-01", periods=5, freq="H")

In [10]: ts = pd.Series(range(len(idx)), index=idx)

In [11]: ts
Out[11]:
2018-01-01 00:00:00    0
2018-01-01 01:00:00    1
2018-01-01 02:00:00    2
2018-01-01 03:00:00    3
2018-01-01 04:00:00    4
Freq: H, dtype: int64

In [12]: ts.resample("2H").mean()
Out[12]:
2018-01-01 00:00:00    0.5
2018-01-01 02:00:00    2.5
2018-01-01 04:00:00    4.0
Freq: 2H, dtype: float64

Performing date and time arithmetic with absolute or relative time increments

In [13]: friday = pd.Timestamp("2018-01-05")

In [14]: friday.day_name()
Out[14]: 'Friday'

# Add 1 day
In [15]: saturday = friday + pd.Timedelta("1 day")

In [16]: saturday.day_name()
Out[16]: 'Saturday'

# Add 1 business day (Friday --> Monday)
In [17]: monday = friday + pd.offsets.BDay()

In [18]: monday.day_name()
Out[18]: 'Monday'

pandas provides a relatively compact and self-contained set of tools for performing the above tasks and more.
2.20.1 Overview

pandas captures 4 general time related concepts:

1. Date times: A specific date and time with timezone support. Similar to `datetime.datetime` from the standard library.
2. Time deltas: An absolute time duration. Similar to `datetime.timedelta` from the standard library.
3. Time spans: A span of time defined by a point in time and its associated frequency.
4. Date offsets: A relative time duration that respects calendar arithmetic. Similar to `dateutil.relativedelta.relativedelta` from the `dateutil` package.

<table>
<thead>
<tr>
<th>Concept</th>
<th>Scalar Class</th>
<th>Array Class</th>
<th>pandas Data Type</th>
<th>Primary Creation Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date times</td>
<td>Timestamp</td>
<td>DatetimeIndex</td>
<td>datetime64[ns]</td>
<td>or to_datetime or date_range</td>
</tr>
<tr>
<td>Time deltas</td>
<td>Timedelta</td>
<td>TimedeltaIndex</td>
<td>timedelta64[ns]</td>
<td>or to_timedelta or timedelta_range</td>
</tr>
<tr>

<td>period[freq]</td>
<td>Period or period_range</td>
</tr>
<tr>
<td>Date offsets</td>
<td>DateOffset</td>
<td>None</td>
<td>None</td>
<td>DateOffset</td>
</tr>
</tbody>
</table>

For time series data, it’s conventional to represent the time component in the index of a `Series` or `DataFrame` so manipulations can be performed with respect to the time element.

```python
In [19]: pd.Series(range(3), index=pd.date_range("2000", freq="D", periods=3))
Out[19]:
2000-01-01  0
2000-01-02  1
2000-01-03  2
Freq: D, dtype: int64
```

However, `Series` and `DataFrame` can directly also support the time component as data itself.

```python
In [20]: pd.Series(pd.date_range("2000", freq="D", periods=3))
Out[20]:
0    2000-01-01
1    2000-01-02
2    2000-01-03
dtype: datetime64[ns]
```

`Series` and `DataFrame` have extended data type support and functionality for `datetime`, `timedelta` and `Period` data when passed into those constructors. `DateOffset` data however will be stored as object data.

```python
In [21]: pd.Series(pd.period_range("1/1/2011", freq="M", periods=3))
Out[21]:
0  2011-01
1  2011-02
2  2011-03
dtype: period[M]
```

```python
In [22]: pd.Series([pd.DateOffset(1), pd.DateOffset(2)])
Out[22]:
0  <DateOffset>
```

(continues on next page)
Lastly, pandas represents null date times, time deltas, and time spans as `NaT` which is useful for representing missing or null date like values and behaves similar as `np.nan` does for float data.

```
In [24]: pd.Timestamp(pd.NaT)
Out[24]: NaT

In [25]: pd.Timedelta(pd.NaT)
Out[25]: NaT

In [26]: pd.Period(pd.NaT)
Out[26]: NaT

# Equality acts as np.nan would
In [27]: pd.NaT == pd.NaT
Out[27]: False
```

### 2.20.2 Timestamps vs. time spans

Timestamped data is the most basic type of time series data that associates values with points in time. For pandas objects it means using the points in time.

```
In [28]: pd.Timestamp(datetime.datetime(2012, 5, 1))
Out[28]: Timestamp('2012-05-01 00:00:00')

In [29]: pd.Timestamp("2012-05-01")
Out[29]: Timestamp('2012-05-01 00:00:00')

In [30]: pd.Timestamp(2012, 5, 1)
Out[30]: Timestamp('2012-05-01 00:00:00')
```

However, in many cases it is more natural to associate things like change variables with a time span instead. The span represented by `Period` can be specified explicitly, or inferred from datetime string format.

For example:

```
In [31]: pd.Period("2011-01")
Out[31]: Period('2011-01', 'M')

In [32]: pd.Period("2012-05", freq="D")
Out[32]: Period('2012-05-01', 'D')
```

`Timestamp` and `Period` can serve as an index. Lists of `Timestamp` and `Period` are automatically coerced to `DatetimeIndex` and `PeriodIndex` respectively.
In [33]: dates = [
......:    pd.Timestamp("2012-05-01"),
......:    pd.Timestamp("2012-05-02"),
......:    pd.Timestamp("2012-05-03"),
......: ]
......:
In [34]: ts = pd.Series(np.random.randn(3), dates)
In [35]: type(ts.index)
Out[35]: pandas.core.indexes.datetimes.DatetimeIndex
In [36]: ts.index
Out[36]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]', freq=None)
In [37]: ts
Out[37]:
2012-05-01    0.469112
2012-05-02   -0.282863
2012-05-03   -1.509059
dtype: float64
In [38]: periods = [pd.Period("2012-01"), pd.Period("2012-02"), pd.Period("2012-03")]
In [39]: ts = pd.Series(np.random.randn(3), periods)
In [40]: type(ts.index)
Out[40]: pandas.core.indexes.period.PeriodIndex
In [41]: ts.index
Out[41]: PeriodIndex(['2012-01', '2012-02', '2012-03'], dtype='period[M]')
In [42]: ts
Out[42]:
2012-01    -1.135632
2012-02     1.212112
2012-03   -0.173215
Freq: M, dtype: float64

pandas allows you to capture both representations and convert between them. Under the hood, pandas represents timestamps using instances of Timestamp and sequences of timestamps using instances of DatetimeIndex. For regular time spans, pandas uses Period objects for scalar values and PeriodIndex for sequences of spans. Better support for irregular intervals with arbitrary start and end points are forth-coming in future releases.

### 2.20.3 Converting to timestamps

To convert a Series or list-like object of date-like objects e.g. strings, epochs, or a mixture, you can use the to_datetime function. When passed a Series, this returns a Series (with the same index), while a list-like is converted to a DatetimeIndex:

In [43]: pd.to_datetime(pd.Series(["Jul 31, 2009", "2010-01-10", None]))
Out[43]:
0    2009-07-31
1    2010-01-10
2      NaT

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.1

(continued from previous page)

dtype: datetime64[ns]

In [44]: pd.to_datetime(["2005/11/23", "2010.12.31"])
Out[44]: DatetimeIndex(['2005-11-23', '2010-12-31'], dtype='datetime64[ns]',
→ freq=None)

If you use dates which start with the day first (i.e. European style), you can pass the `dayfirst` flag:

In [45]: pd.to_datetime(["04-01-2012 10:00"], dayfirst=True)
Out[45]: DatetimeIndex(['2012-01-04 10:00:00'], dtype='datetime64[ns]',
→ freq=None)

In [46]: pd.to_datetime(["14-01-2012", "01-14-2012"], dayfirst=True)
Out[46]: DatetimeIndex(['2012-01-14', '2012-01-14'], dtype='datetime64[ns]',
→ freq=None)

Warning: You see in the above example that `dayfirst` isn’t strict, so if a date can’t be parsed with the day being first it will be parsed as if `dayfirst` were False.

If you pass a single string to `to_datetime`, it returns a single `Timestamp`. `Timestamp` can also accept string input, but it doesn’t accept string parsing options like `dayfirst` or `format`, so use `to_datetime` if these are required.

In [47]: pd.to_datetime("2010/11/12")
Out[47]: Timestamp('2010-11-12 00:00:00')

In [48]: pd.Timestamp("2010/11/12")
Out[48]: Timestamp('2010-11-12 00:00:00')

You can also use the `DatetimeIndex` constructor directly:

In [49]: pd.DatetimeIndex(["2018-01-01", "2018-01-03", "2018-01-05"])
Out[49]: DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'],
→ dtype='datetime64[ns]', freq=None)

The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation:

In [50]: pd.DatetimeIndex(["2018-01-01", "2018-01-03", "2018-01-05"], freq="infer")
Out[50]: DatetimeIndex(["2018-01-01", '2018-01-03', '2018-01-05'],
→ dtype='datetime64[ns]', freq='2D')

Providing a format argument

In addition to the required datetime string, a `format` argument can be passed to ensure specific parsing. This could also potentially speed up the conversion considerably.

In [51]: pd.to_datetime("2010/11/12", format="%Y/%m/%d")
Out[51]: Timestamp('2010-11-12 00:00:00')

In [52]: pd.to_datetime("12-11-2010 00:00", format="%d-%m-%Y %H:%M")
Out[52]: Timestamp('2010-11-12 00:00:00')

For more information on the choices available when specifying the `format` option, see the Python `datetime` documentation.

2.20. Time series / date functionality
Assembling datetime from multiple DataFrame columns

You can also pass a DataFrame of integer or string columns to assemble into a Series of Timestamps.

In [53]: df = pd.DataFrame(
    ....:    {"year": [2015, 2016], "month": [2, 3], "day": [4, 5], "hour": [2, 3]}
    ....: )
    ....:

In [54]: pd.to_datetime(df)
Out[54]:
0 2015-02-04 02:00:00
1 2016-03-05 03:00:00
dtype: datetime64[ns]

You can pass only the columns that you need to assemble.

In [55]: pd.to_datetime(df["year", "month", "day"])
Out[55]:
0 2015-02-04
1 2016-03-05
dtype: datetime64[ns]

d.to_datetime looks for standard designations of the datetime component in the column names, including:

- required: year, month, day
- optional: hour, minute, second, millisecond, microsecond, nanosecond

Invalid data

The default behavior, errors='raise', is to raise when unparsable:

In [2]: pd.to_datetime(["2009/07/31", 'asd'], errors='raise')
ValueError: Unknown string format

Pass errors='ignore' to return the original input when unparsable:

In [56]: pd.to_datetime(["2009/07/31", 'asd'], errors='ignore')
Out[56]: Index(["2009/07/31", 'asd'], dtype='object')

Pass errors='coerce' to convert unparsable data to NaT (not a time):

In [57]: pd.to_datetime(["2009/07/31", 'asd'], errors='coerce')
Out[57]: DatetimeIndex(["2009-07-31", 'NaT'], dtype='datetime64[ns]', freq=None)

Epoch timestamps

pandas supports converting integer or float epoch times to Timestamp and DatetimeIndex. The default unit is nanoseconds, since that is how Timestamp objects are stored internally. However, epochs are often stored in another unit which can be specified. These are computed from the starting point specified by the origin parameter.

In [58]: pd.to_datetime(
    ....:    [1349720105, 1349806505, 1349892905, 1349979305, 1350065705], unit="s"
    ....: )
(continues on next page)
....:
Out[58]:
DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05',
               '2012-10-10 18:15:05', '2012-10-11 18:15:05',
               '2012-10-12 18:15:05'],
dtype='datetime64[ns]', freq=None)

In [59]: pd.to_datetime(
   ....: [1349720105100, 1349720105200, 1349720105300, 1349720105400,
   ---> 1349720105500],
   ....: unit="ms",
   ....: )
   ....:
Out[59]:
DatetimeIndex(['2012-10-08 18:15:05.100000', '2012-10-08 18:15:05.200000',
               '2012-10-08 18:15:05.300000', '2012-10-08 18:15:05.400000',
               '2012-10-08 18:15:05.500000'],
dtype='datetime64[ns]', freq=None)

Note: The unit parameter does not use the same strings as the format parameter that was discussed above). The available units are listed on the documentation for pandas.to_datetime().

Changed in version 1.0.0.

Constructing a Timestamp or DatetimeIndex with an epoch timestamp with the tz argument specified will raise a ValueError. If you have epochs in wall time in another timezone, you can read the epochs as timezone-naive timestamps and then localize to the appropriate timezone:

In [60]: pd.Timestamp(1262347200000000000).tz_localize("US/Pacific")
Out[60]:
Timestamp('2010-01-01 12:00:00-0800', tz='US/Pacific')

In [61]: pd.DatetimeIndex([1262347200000000000]).tz_localize("US/Pacific")
Out[61]: DatetimeIndex(['2010-01-01 12:00:00-08:00'], dtype='datetime64[ns, US/Pacific]', freq=None)

Note: Epoch times will be rounded to the nearest nanosecond.

Warning: Conversion of float epoch times can lead to inaccurate and unexpected results. Python floats have about 15 digits precision in decimal. Rounding during conversion from float to high precision Timestamp is unavoidable. The only way to achieve exact precision is to use a fixed-width types (e.g. an int64).

In [62]: pd.to_datetime([1490195805.433, 1490195805.433502912], unit="s")
Out[62]:
DatetimeIndex(['2017-03-22 15:16:45.433000088', '2017-03-22 15:16:45.433502913'],
               dtype='datetime64[ns]', freq=None)

In [63]: pd.to_datetime(1490195805433502912, unit="ns")
Out[63]:
Timestamp('2017-03-22 15:16:45.433502912')

See also:
Using the origin Parameter
From timestamps to epoch

To invert the operation from above, namely, to convert from a Timestamp to a ‘unix’ epoch:

```
In [64]: stamps = pd.date_range("2012-10-08 18:15:05", periods=4, freq="D")
In [65]: stamps
Out[65]: DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05', '2012-10-10 18:15:05', '2012-10-11 18:15:05'], dtype='datetime64[ns]', freq='D')
```

We subtract the epoch (midnight at January 1, 1970 UTC) and then floor divide by the “unit” (1 second).

```
In [66]: (stamps - pd.Timestamp("1970-01-01")) // pd.Timedelta("1s")
Out[66]: Int64Index([1349720105, 1349806505, 1349892905, 1349979305], dtype='int64')
```

Using the origin Parameter

Using the origin parameter, one can specify an alternative starting point for creation of a DatetimeIndex. For example, to use 1960-01-01 as the starting date:

```
In [67]: pd.to_datetime([1, 2, 3], unit="D", origin=pd.Timestamp("1960-01-01"))
Out[67]: DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype='datetime64[ns]', freq=None)
```

The default is set at origin='unix', which defaults to 1970-01-01 00:00:00. Commonly called ‘unix epoch’ or POSIX time.

```
In [68]: pd.to_datetime([1, 2, 3], unit="D")
Out[68]: DatetimeIndex(['1970-01-02', '1970-01-03', '1970-01-04'], dtype='datetime64[ns]', freq=None)
```

2.20.4 Generating ranges of timestamps

To generate an index with timestamps, you can use either the DatetimeIndex or Index constructor and pass in a list of datetime objects:

```
In [69]: dates = [
        datetime.datetime(2012, 5, 1),
        datetime.datetime(2012, 5, 2),
        datetime.datetime(2012, 5, 3),
    ]

# Note the frequency information
In [70]: index = pd.DatetimeIndex(dates)
In [71]: index
Out[71]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]', freq=None)

# Automatically converted to DatetimeIndex
In [72]: index = pd.Index(dates)
```
In practice this becomes very cumbersome because we often need a very long index with a large number of timestamps. If we need timestamps on a regular frequency, we can use the `date_range()` and `bdate_range()` functions to create a `DatetimeIndex`. The default frequency for `date_range` is a **calendar day** while the default for `bdate_range` is a **business day**:

```python
In [73]: index
Out[73]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]', freq=None)
```

```python
In [74]: start = datetime.datetime(2011, 1, 1)
In [75]: end = datetime.datetime(2012, 1, 1)
In [76]: index = pd.date_range(start, end)
In [77]: index
  ... '2011-12-23', '2011-12-24', '2011-12-25', '2011-12-26', '2011-12-27', '2011-12-28', '2011-12-29', '2011-12-30',
  '2012-01-01'],
     dtype='datetime64[ns]', length=366, freq='D')
```

```python
In [78]: index = pd.bdate_range(start, end)
In [79]: index
  '2012-01-01'],
     dtype='datetime64[ns]', length=260, freq='B')
```

Convenience functions like `date_range` and `bdate_range` can utilize a variety of **frequency aliases**:

```python
In [80]: pd.date_range(start, periods=1000, freq="M")
  '2011-09-30', '2011-10-31',
  ... '2093-07-31', '2093-08-31', '2093-09-30', '2093-10-31', '2093-11-30', '2094-01-31', '2094-02-28', '2094-03-31', '2094-04-30'],
     dtype='datetime64[ns]', length=1000, freq='M')
```

```python
In [81]: pd.bdate_range(start, periods=250, freq="BQS")
  ... '2011-10-30', '2011-11-30', '2011-12-30'],
     dtype='datetime64[ns]', length=250, freq='B')
```
date_range and bdate_range make it easy to generate a range of dates using various combinations of parameters like start, end, periods, and freq. The start and end dates are strictly inclusive, so dates outside of those specified will not be generated:

```
In [82]: pd.date_range(start, end, freq="BM")
Out[82]:
            dtype='datetime64[ns]', freq='BM')
```

```
In [83]: pd.date_range(start, end, freq="W")
Out[83]:
               '2011-08-14', '2011-08-21', '2011-08-28', '2011-09-04',
               '2011-12-04', '2011-12-11', '2011-12-18', '2011-12-25',
               '2012-01-01'],
            dtype='datetime64[ns]', freq='W-SUN')
```

```
In [84]: pd.bdate_range(end=end, periods=20)
Out[84]:
DatetimeIndex(['2011-12-05', '2011-12-06', '2011-12-07', '2011-12-08',
               '2011-12-09', '2011-12-12', '2011-12-13', '2011-12-14',
               '2011-12-15', '2011-12-16', '2011-12-19', '2011-12-20',
               '2011-12-21', '2011-12-22', '2011-12-23', '2011-12-26',
               '2011-12-27', '2011-12-28', '2011-12-29', '2011-12-30'],
            dtype='datetime64[ns]', freq='B')
```

```
In [85]: pd.bdate_range(start=start, periods=20)
Out[85]:
            dtype='datetime64[ns]', freq='B')
```

Specifying start, end, and periods will generate a range of evenly spaced dates from start to end inclusively, with periods number of elements in the resulting DatetimeIndex:
Custom frequency ranges

`bdate_range` can also generate a range of custom frequency dates by using the `weekmask` and `holidays` parameters. These parameters will only be used if a custom frequency string is passed.

```
In [88]: weekmask = "Mon Wed Fri"
In [89]: holidays = [datetime.datetime(2011, 1, 5), datetime.datetime(2011, 3, 14)]
In [90]: pd.bdate_range(start, end, freq="C", weekmask=weekmask, holidays=holidays)
Out[90]:
         '2011-01-24', '2011-01-26',
         ...]
         dtype='datetime64[ns]', length=154, freq='C')
```

```
In [91]: pd.bdate_range(start, end, freq="CBMS", weekmask=weekmask)
Out[91]:
DatetimeIndex(['2011-01-03', '2011-02-02', '2011-03-02', '2011-04-01',
         '2011-09-02', '2011-10-03', '2011-11-02', '2011-12-02'],
         dtype='datetime64[ns]', freq='CBMS')
```

`Custom business days`
2.20.5 Timestamp limitations

Since pandas represents timestamps in nanosecond resolution, the time span that can be represented using a 64-bit integer is limited to approximately 584 years:

```
In [92]: pd.Timestamp.min
Out[92]: Timestamp('1677-09-21 00:12:43.145224193')

In [93]: pd.Timestamp.max
Out[93]: Timestamp('2262-04-11 23:47:16.854775807')
```

See also:

*Representing out-of-bounds spans*

2.20.6 Indexing

One of the main uses for DatetimeIndex is as an index for pandas objects. The DatetimeIndex class contains many time series related optimizations:

- A large range of dates for various offsets are pre-computed and cached under the hood in order to make generating subsequent date ranges very fast (just have to grab a slice).
- Fast shifting using the shift method on pandas objects.
- Unioning of overlapping DatetimeIndex objects with the same frequency is very fast (important for fast data alignment).
- Quick access to date fields via properties such as year, month, etc.
- Regularization functions like snap and very fast asof logic.

DatetimeIndex objects have all the basic functionality of regular Index objects, and a smorgasbord of advanced time series specific methods for easy frequency processing.

See also:

*Reindexing methods*

**Note:** While pandas does not force you to have a sorted date index, some of these methods may have unexpected or incorrect behavior if the dates are unsorted.

DatetimeIndex can be used like a regular index and offers all of its intelligent functionality like selection, slicing, etc.

```
In [94]: rng = pd.date_range(start, end, freq="BM")

In [95]: ts = pd.Series(np.random.randn(len(rng)), index=rng)

In [96]: ts.index
   dtype='datetime64[ns]', freq='BM')

In [97]: ts[:5].index
Out[97]:
```

(continues on next page)
Partial string indexing

Dates and strings that parse to timestamps can be passed as indexing parameters:

```
In [99]: ts["1/31/2011"]
Out[99]: 0.11920871129693428

In [100]: ts[datetime.datetime(2011, 12, 25):]
Out[100]:
2011-12-30  0.56702
Freq: BM, dtype: float64

In [101]: ts["10/31/2011":"12/31/2011"]
Out[101]:
2011-10-31  0.271860
2011-11-30 -0.424972
2011-12-30  0.567020
Freq: BM, dtype: float64
```

To provide convenience for accessing longer time series, you can also pass in the year or year and month as strings:

```
In [102]: ts["2011"]
Out[102]:
2011-01-31  0.119209
2011-02-28  -1.044236
2011-03-31  -0.861849
2011-04-29  -2.104569
2011-05-31  -0.494929
2011-06-30  1.071804
2011-07-29  0.721555
2011-08-31  -0.706771
2011-09-30  -1.039575
2011-10-31  0.271860
2011-11-30  -0.424972
2011-12-30  0.567020
Freq: BM, dtype: float64

In [103]: ts["2011-6"]
Out[103]:
2011-06-30  1.071804
Freq: BM, dtype: float64
```

This type of slicing will work on a DataFrame with a DatetimeIndex as well. Since the partial string selection is a form of label slicing, the endpoints will be included. This would include matching times on an included date:
Warning: Indexing DataFrame rows with a single string with getitem (e.g. frame[dtstring]) is deprecated starting with pandas 1.2.0 (given the ambiguity whether it is indexing the rows or selecting a column) and will be removed in a future version. The equivalent with .loc (e.g. frame.loc[dtstring]) is still supported.

In [104]: dft = pd.DataFrame(
       ....:     np.random.randn(100000, 1),
       ....:     columns=['A'],
       ....:     index=pd.date_range("20130101", periods=100000, freq="T"),
       ....:     )
       ...

In [105]: dft
Out[105]:
   A
2013-01-01 00:00:00  0.276232

2013-03-11 10:38:00  -1.509067
2013-03-11 10:39:00  -1.693043
[100000 rows x 1 columns]

This starts on the very first time in the month, and includes the last date and time for the month:

In [107]: dft["2013-1":"2013-2"]
Out[107]:
   A
2013-01-01 00:00:00  0.276232
2013-01-01 00:01:00  -1.087401
2013-01-01 00:02:00  -0.673690
2013-01-01 00:03:00  0.113648
2013-01-01 00:04:00  -1.478427
   ...
   ...
2013-03-11 10:35:00  -0.747967
2013-03-11 10:36:00  -0.034523
2013-03-11 10:37:00  -0.201754
2013-03-11 10:38:00  -1.509067
2013-03-11 10:39:00  -1.693043
(continues on next page)
This specifies a stop time that includes all of the times on the last day:

```
In [108]: dft["2013-1":"2013-2-28"]
Out[108]:
    A
2013-01-01 00:00:00   0.276232
2013-01-01 00:01:00  -1.087401
2013-01-01 00:02:00  -0.673690
2013-01-01 00:03:00   0.113648
2013-01-01 00:04:00  -1.478427
     ...
2013-02-28 23:55:00   0.850929
2013-02-28 23:56:00   0.976712
2013-02-28 23:57:00  -2.693884
2013-02-28 23:58:00  -1.575535
2013-02-28 23:59:00  -1.573517
[84960 rows x 1 columns]
```

This specifies an exact stop time (and is not the same as the above):

```
In [109]: dft["2013-1-15":"2013-1-15 12:30:00"]
Out[109]:
    A
2013-01-15 00:00:00   -0.984810
2013-01-15 00:01:00    0.941451
2013-01-15 00:02:00    1.559365
2013-01-15 00:03:00    1.034374
2013-01-15 00:04:00   -1.480656
     ...
2013-02-27 23:56:00    1.197749
2013-02-27 23:57:00    0.720521
2013-02-27 23:58:00   -0.072718
2013-02-27 23:59:00   -0.681192
2013-02-28 00:00:00   -0.557501
[83521 rows x 1 columns]
```

We are stopping on the included end-point as it is part of the index:

```
In [110]: dft["2013-1-15":"2013-1-15 12:30:00"]
Out[110]:
    A
2013-01-15 00:00:00    -0.984810
2013-01-15 00:01:00    0.941451
2013-01-15 00:02:00    1.559365
2013-01-15 00:03:00    1.034374
2013-01-15 00:04:00   -1.480656
     ...
2013-01-15 00:00:00    -0.984810
2013-01-15 00:01:00    0.941451
2013-01-15 00:02:00    1.559365
2013-01-15 00:03:00    1.034374
2013-01-15 00:04:00   -1.480656
[256 rows x 1 columns]
```

(continues on next page)
Partial string indexing also works on a DataFrame with a MultiIndex:

```python
In [111]:
   ...: dft2 = pd.DataFrame(
   ...:     
   ...:     np.random.randn(20, 1),
   ...:     columns=["A"],
   ...:     index=pd.MultiIndex.from_product(
   ...:         [pd.date_range("20130101", periods=10, freq="12H"), ["a", "b"]
   ...:         ),
   ...:     )
   ...
   ...

In [112]:
   ...
   ...

In [113]:
   ...
   ...

In [114]:
   ...
   ...

In [115]:
   ...
   ...

In [116]:
   ...
   ...
```

New in version 0.25.0.
Slicing with string indexing also honors UTC offset.

```
In [117]: df = pd.DataFrame([0], index=pd.DatetimeIndex(["2019-01-01"], tz="US/Pacific"))
In [118]: df
Out[118]:
0  2019-01-01 00:00:00-08:00   0
In [119]: df["2019-01-01 12:00:00+04:00":"2019-01-01 13:00:00+04:00"]
Out[119]:
0  2019-01-01 00:00:00-08:00   0
```

**Slice vs. exact match**

The same string used as an indexing parameter can be treated either as a slice or as an exact match depending on the resolution of the index. If the string is less accurate than the index, it will be treated as a slice, otherwise as an exact match.

Consider a `Series` object with a minute resolution index:

```
In [120]: series_minute = pd.Series([1, 2, 3],
   ....:     pd.DatetimeIndex(["2011-12-31 23:59:00", "2012-01-01 00:00:00", "2012-01-01 00:02:00"],
   ....: )
   ....: )
   ....: )
In [121]: series_minute.index.resolution
Out[121]: 'minute'
```

A timestamp string less accurate than a minute gives a `Series` object.

```
In [122]: series_minute["2011-12-31 23"]
Out[122]:
2011-12-31 23:59:00   1
dtype: int64
```

A timestamp string with minute resolution (or more accurate), gives a scalar instead, i.e. it is not casted to a slice.

```
In [123]: series_minute["2011-12-31 23:59"]
Out[123]: 1
In [124]: series_minute["2011-12-31 23:59:00"]
Out[124]: 1
```

If index resolution is second, then the minute-accurate timestamp gives a `Series`.

```
In [125]: series_second = pd.Series([1, 2, 3],
   ....:     pd.DatetimeIndex(["2011-12-31 23:59:59", "2012-01-01 00:00:00", "2012-01-01 00:00:1"],
   ....: )
   ....: )
   ....: )
```

(continues on next page)
If the timestamp string is treated as a slice, it can be used to index DataFrame with `.loc[]` as well.

```python
In [128]: dft_minute = pd.DataFrame(
    """
    {'a': [1, 2, 3], 'b': [4, 5, 6]}, index=series_minute.index
    ""
)

In [129]: dft_minute.loc['2011-12-31 23']
```

```
Out[129]:
    a  b
2011-12-31 23:59:00 1 4
```

**Warning:** However, if the string is treated as an exact match, the selection in DataFrame's [] will be column-wise and not row-wise, see Indexing Basics. For example `dft_minute['2012-12-31 23:59']` will raise KeyError as '2012-12-31 23:59' has the same resolution as the index and there is no column with such name:

To *always* have unambiguous selection, whether the row is treated as a slice or a single selection, use `.loc`.

```python
In [130]: dft_minute.loc['2011-12-31 23:59']
```

```
Out[130]:
a  1
b  4
Name: 2011-12-31 23:59:00, dtype: int64
```

Note also that DatetimeIndex resolution cannot be less precise than day.

```python
In [131]: series_monthly = pd.Series(
    """
    [1, 2, 3], pd.DatetimeIndex(['2011-12', '2012-01', '2012-02'])
    ""
)
```

```
In [132]: series_monthly.index.resolution
Out[132]: 'day'
```

```python
In [133]: series_monthly['2011-12']  # returns Series
```

```
Out[133]:
2011-12-01  1
```

dtype: int64
Exact indexing

As discussed in previous section, indexing a DatetimeIndex with a partial string depends on the “accuracy” of the period, in other words how specific the interval is in relation to the resolution of the index. In contrast, indexing with Timestamp or datetime objects is exact, because the objects have exact meaning. These also follow the semantics of including both endpoints.

These Timestamp and datetime objects have exact hours, minutes, and seconds, even though they were not explicitly specified (they are 0).

```python
In [134]: dft[datetime.datetime(2013, 1, 1): datetime.datetime(2013, 2, 28)]
Out[134]:
   2013-01-01 00:00:00    0.276232
   2013-01-01 00:01:00   -1.087401
   2013-01-01 00:02:00    -0.673690
   2013-01-01 00:03:00    0.113648
   2013-01-01 00:04:00   -1.478427
   ...
   2013-02-27 23:56:00    1.197749
   2013-02-27 23:57:00    0.720521
   2013-02-27 23:58:00   -0.072718
   2013-02-27 23:59:00   -0.681192
   2013-02-28 00:00:00   -0.557501
[83521 rows x 1 columns]
```

With no defaults.

```python
In [135]: dft[
       ....:    : datetime.datetime(2013, 1, 1, 10, 12, 0): datetime.datetime(2013, 2, 28, 10, 12, 0)
       ....:    : ]
Out[135]:
   2013-01-01 10:12:00    0.565375
   2013-01-01 10:13:00    0.068184
   2013-01-01 10:14:00    0.788871
   2013-01-01 10:15:00   -0.280343
   2013-01-01 10:16:00    0.931536
   ...
   2013-02-28 10:08:00   -0.148098
   2013-02-28 10:09:00   -0.388138
   2013-02-28 10:10:00    0.139348
   2013-02-28 10:11:00    0.085288
   2013-02-28 10:12:00    0.950146
[83521 rows x 1 columns]
```
Truncating & fancy indexing

A `truncate()` convenience function is provided that is similar to slicing. Note that `truncate` assumes a 0 value for any unspecified date component in a `DatetimeIndex` in contrast to slicing which returns any partially matching dates:

```python
In [136]: rng2 = pd.date_range("2011-01-01", "2012-01-01", freq="W")
In [137]: ts2 = pd.Series(np.random.randn(len(rng2)), index=rng2)
In [138]: ts2.truncate(before="2011-11", after="2011-12")
Out[138]:
2011-11-06  0.437823
2011-11-13  0.293083
2011-11-20  0.059881
2011-11-27  1.252450
Freq: W-SUN, dtype: float64

In [139]: ts2["2011-11":"2011-12"]
Out[139]:
2011-11-06  0.437823
2011-11-13  0.293083
2011-11-20  0.059881
2011-11-27  1.252450
2011-12-04  0.046611
2011-12-11  0.059478
2011-12-18  0.286539
2011-12-25  0.841669
Freq: W-SUN, dtype: float64
```

Even complicated fancy indexing that breaks the `DatetimeIndex` frequency regularity will result in a `DatetimeIndex`, although frequency is lost:

```python
In [140]: ts2[[0, 2, 6]].index
Out[140]: DatetimeIndex(['2011-01-02', '2011-01-16', '2011-02-13'], dtype='datetime64[ns]', freq=None)
```

2.20.7 Time/date components

There are several time/date properties that one can access from `Timestamp` or a collection of timestamps like a `DatetimeIndex`. 

---

820 Chapter 2. User Guide
### pandas: powerful Python data analysis toolkit, Release 1.3.1

</tbody>
</table>

Furthermore, if you have a `Series` with datetimelike values, then you can access these properties via the `.dt` accessor, as detailed in the section on `.dt accessors`.

New in version 1.1.0.

You may obtain the year, week and day components of the ISO year from the ISO 8601 standard:

```python
In [141]: idx = pd.date_range(start="2019-12-29", freq="D", periods=4)
In [142]: idx.isocalendar()
Out[142]:
<table>
<thead>
<tr>
<th>year</th>
<th>week</th>
<th>day</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019</td>
<td>52</td>
<td>7</td>
</tr>
<tr>
<td>2019</td>
<td>52</td>
<td>1</td>
</tr>
<tr>
<td>2019</td>
<td>52</td>
<td>2</td>
</tr>
<tr>
<td>2020</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>

In [143]: idx.to_series().dt.isocalendar()
Out[143]:
<table>
<thead>
<tr>
<th>year</th>
<th>week</th>
<th>day</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019</td>
<td>52</td>
<td>7</td>
</tr>
<tr>
<td>2019</td>
<td>52</td>
<td>1</td>
</tr>
<tr>
<td>2019</td>
<td>52</td>
<td>2</td>
</tr>
<tr>
<td>2020</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>
```

2.20. Time series / date functionality
2.20.8 DateOffset objects

In the preceding examples, frequency strings (e.g. 'D') were used to specify a frequency that defined:

- how the date times in DatetimeIndex were spaced when using date_range()
- the frequency of a Period or PeriodIndex

These frequency strings map to a DateOffset object and its subclasses. A DateOffset is similar to a Timedelta that represents a duration of time but follows specific calendar duration rules. For example, a Timedelta day will always increment datetimes by 24 hours, while a DateOffset day will increment datetimes to the same time the next day whether a day represents 23, 24 or 25 hours due to daylight savings time. However, all DateOffset subclasses that are an hour or smaller (Hour, Minute, Second, Milli, Micro, Nano) behave like Timedelta and respect absolute time.

The basic DateOffset acts similar to dateutil.relativedelta (relativedelta documentation) that shifts a date time by the corresponding calendar duration specified. The arithmetic operator (+) or the apply method can be used to perform the shift.

```
# This particular day contains a day light savings time transition
In [144]: ts = pd.Timestamp("2016-10-30 00:00:00", tz="Europe/Helsinki")

# Respects absolute time
In [145]: ts + pd.Timedelta(days=1)
Out[145]: Timestamp('2016-10-30 23:00:00+0200', tz='Europe/Helsinki')

# Respects calendar time
In [146]: ts + pd.DateOffset(days=1)
Out[146]: Timestamp('2016-10-31 00:00:00+0200', tz='Europe/Helsinki')

In [147]: friday = pd.Timestamp("2018-01-05")

In [148]: friday.day_name()
Out[148]: 'Friday'

# Add 2 business days (Friday --> Tuesday)
In [149]: two_business_days = 2 * pd.offsets.BDay()

In [150]: two_business_days.apply(friday)
Out[150]: Timestamp('2018-01-09 00:00:00')

In [151]: friday + two_business_days
Out[151]: Timestamp('2018-01-09 00:00:00')

In [152]: (friday + two_business_days).day_name()
Out[152]: 'Tuesday'
```

Most DateOffsets have associated frequencies strings, or offset aliases, that can be passed into freq keyword arguments. The available date offsets and associated frequency strings can be found below:

<table>
<thead>
<tr>
<th>Date Offset</th>
<th>Frequency String</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DateOffset</td>
<td>None</td>
<td>Generic offset class, defaults to absolute 24 hours</td>

</tbody>
</table>

DateOffsets additionally have rollforward() and rollback() methods for moving a date forward or backward respectively to a valid offset date relative to the offset. For example, business offsets will roll dates that land on the weekends (Saturday and Sunday) forward to Monday since business offsets operate on the weekdays.

In [153]: ts = pd.Timestamp("2018-01-06 00:00:00")

In [154]: ts.day_name()
Out[154]: 'Saturday'

(continues on next page)
# BusinessHour's valid offset dates are Monday through Friday

```python
In [155]: offset = pd.offsets.BusinessHour(start="09:00")
```

# Bring the date to the closest offset date (Monday)

```python
In [156]: offset.rollforward(ts)
Out[156]: Timestamp('2018-01-08 09:00:00')
```

# Date is brought to the closest offset date first and then the hour is added

```python
In [157]: ts + offset
Out[157]: Timestamp('2018-01-08 10:00:00')
```

These operations preserve time (hour, minute, etc) information by default. To reset time to midnight, use `normalize()` before or after applying the operation (depending on whether you want the time information included in the operation).

```python
In [158]: ts = pd.Timestamp("2014-01-01 09:00")
In [159]: day = pd.offsets.Day()
In [160]: day.apply(ts)
Out[160]: Timestamp('2014-01-02 09:00:00')
In [161]: day.apply(ts).normalize()
Out[161]: Timestamp('2014-01-02 00:00:00')
In [162]: ts = pd.Timestamp("2014-01-01 22:00")
In [163]: hour = pd.offsets.Hour()
In [164]: hour.apply(ts)
Out[164]: Timestamp('2014-01-01 23:00:00')
In [165]: hour.apply(ts).normalize()
Out[165]: Timestamp('2014-01-01 00:00:00')
In [166]: hour.apply(pd.Timestamp("2014-01-01 23:30")).normalize()
Out[166]: Timestamp('2014-01-02 00:00:00')
```

## Parametric offsets

Some of the offsets can be “parameterized” when created to result in different behaviors. For example, the `Week` offset for generating weekly data accepts a `weekday` parameter which results in the generated dates always lying on a particular day of the week:

```python
In [167]: d = datetime.datetime(2008, 8, 18, 9, 0)
In [168]: d
Out[168]: datetime.datetime(2008, 8, 18, 9, 0)
In [169]: d + pd.offsets.Week()
Out[169]: Timestamp('2008-08-25 09:00:00')
In [170]: d + pd.offsets.Week(weekday=4)
Out[170]: Timestamp('2008-08-22 09:00:00')
```
The `normalize` option will be effective for addition and subtraction.

```
In [173]: d + pd.offsets.Week(normalize=True)
Out[173]: Timestamp('2008-08-25 00:00:00')
In [174]: d - pd.offsets.Week(normalize=True)
Out[174]: Timestamp('2008-08-11 00:00:00')
```

Another example is parameterizing `YearEnd` with the specific ending month:

```
In [175]: d + pd.offsets.YearEnd()
Out[175]: Timestamp('2008-12-31 09:00:00')
In [176]: d + pd.offsets.YearEnd(month=6)
Out[176]: Timestamp('2009-06-30 09:00:00')
```

### Using offsets with `Series` / `DatetimeIndex`

Offsets can be used with either a `Series` or `DatetimeIndex` to apply the offset to each element.

```
In [177]: rng = pd.date_range("2012-01-01", "2012-01-03")
In [178]: s = pd.Series(rng)
In [179]: rng
Out[179]: DatetimeIndex(['2012-01-01', '2012-01-02', '2012-01-03'], dtype='datetime64[ns]', freq='D')
In [180]: rng + pd.DateOffset(months=2)
Out[180]: DatetimeIndex(['2012-03-01', '2012-03-02', '2012-03-03'], dtype='datetime64[ns]', freq=None)
In [181]: s + pd.DateOffset(months=2)
Out[181]:
   0  2012-03-01
   1  2012-03-02
   2  2012-03-03
   dtype: datetime64[ns]
In [182]: s - pd.DateOffset(months=2)
Out[182]:
   0  2011-11-01
   1  2011-11-02
   2  2011-11-03
   dtype: datetime64[ns]
```

If the offset class maps directly to a `Timedelta` (Day, Hour, Minute, Second, Micro, Milli, Nano) it can be used exactly like a `Timedelta` - see the `Timedelta section` for more examples.
### Custom business days

The `CDay` or `CustomBusinessDay` class provides a parametric `BusinessDay` class which can be used to create customized business day calendars which account for local holidays and local weekend conventions.

As an interesting example, let's look at Egypt where a Friday-Saturday weekend is observed.

```python
In [188]: weekmask_egypt = "Sun Mon Tue Wed Thu"

# They also observe International Workers' Day so let's
# add that for a couple of years
In [189]: holidays = [  
....:     "2012-05-01",  
....:     datetime.datetime(2013, 5, 1),  
....:     np.datetime64("2014-05-01"),  
....: ]

In [190]: bday_egypt = pd.offsets.CustomBusinessDay(  
....:     holidays=holidays,  
....:     weekmask=weekmask_egypt,  
....: )

In [191]: dt = datetime.datetime(2013, 4, 30)
```

(continues on next page)
Let’s map to the weekday names:

```python
In [193]: dts = pd.date_range(dt, periods=5, freq=bday_egypt)
In [194]: pd.Series(dts.weekday, dts).map(pd.Series("Mon Tue Wed Thu Fri Sat Sun".split()))
```

```
Out[194]:
2013-04-30 Tue
2013-05-02 Thu
2013-05-05 Sun
2013-05-06 Mon
2013-05-07 Tue
Freq: C, dtype: object
```

Holiday calendars can be used to provide the list of holidays. See the holiday calendar section for more information.

```python
In [195]: from pandas.tseries.holiday import USFederalHolidayCalendar
In [196]: bday_us = pd.offsets.CustomBusinessDay(calendar=USFederalHolidayCalendar())
# Friday before MLK Day
In [197]: dt = datetime.datetime(2014, 1, 17)
# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [198]: dt + bday_us
```

```
Out[198]:
Timestamp('2014-01-21 00:00:00')
```

Monthly offsets that respect a certain holiday calendar can be defined in the usual way.

```python
In [199]: bmth_us = pd.offsets.
    
    CustomBusinessMonthBegin(calendar=USFederalHolidayCalendar())
# Skip new years
In [200]: dt = datetime.datetime(2013, 12, 17)
In [201]: dt + bmth_us
```

```
Out[201]:
Timestamp('2014-01-02 00:00:00')
```

```python
# Define date index with custom offset
In [202]: pd.date_range(start="20100101", end="20120101", freq=bmth_us)
```

```
Out[202]:
```

**Note:** The frequency string ‘C’ is used to indicate that a CustomBusinessDay DateOffset is used, it is important to note that since CustomBusinessDay is a parameterised type, instances of CustomBusinessDay may differ and this is not detectable from the ‘C’ frequency string. The user therefore needs to ensure that the ‘C’ frequency string is used
consistent within the user’s application.

Business hour

The BusinessHour class provides a business hour representation on BusinessDay, allowing to use specific start and end times.

By default, BusinessHour uses 9:00 - 17:00 as business hours. Adding BusinessHour will increment Timestamp by hourly frequency. If target Timestamp is out of business hours, move to the next business hour then increment it. If the result exceeds the business hours end, the remaining hours are added to the next business day.

```python
In [203]: bh = pd.offsets.BusinessHour()

In [204]: bh
Out[204]: <BusinessHour: BH=09:00-17:00>

# 2014-08-01 is Friday
In [205]: pd.Timestamp("2014-08-01 10:00").weekday()
Out[205]: 4

In [206]: pd.Timestamp("2014-08-01 10:00") + bh
Out[206]: Timestamp('2014-08-01 11:00:00')

# Below example is the same as: pd.Timestamp('2014-08-01 09:00') + bh
In [207]: pd.Timestamp("2014-08-01 08:00") + bh
Out[207]: Timestamp('2014-08-01 10:00:00')

# If the results is on the end time, move to the next business day
In [208]: pd.Timestamp("2014-08-01 16:00") + bh
Out[208]: Timestamp('2014-08-04 09:00:00')

# Remainings are added to the next day
In [209]: pd.Timestamp("2014-08-01 16:30") + bh
Out[209]: Timestamp('2014-08-04 09:30:00')

# Adding 2 business hours
In [210]: pd.Timestamp("2014-08-01 10:00") + pd.offsets.BusinessHour(2)
Out[210]: Timestamp('2014-08-01 12:00:00')

# Subtracting 3 business hours
In [211]: pd.Timestamp("2014-08-01 10:00") + pd.offsets.BusinessHour(-3)
Out[211]: Timestamp('2014-07-31 15:00:00')
```

You can also specify start and end time by keywords. The argument must be a str with an hour:minute representation or a datetime.time instance. Specifying seconds, microseconds and nanoseconds as business hour results in ValueError.

```python
In [212]: bh = pd.offsets.BusinessHour(start="11:00", end=datetime.time(20, 0))

In [213]: bh
Out[213]: <BusinessHour: BH=11:00-20:00>

In [214]: pd.Timestamp("2014-08-01 13:00") + bh
Out[214]: Timestamp('2014-08-01 14:00:00')

In [215]: pd.Timestamp("2014-08-01 09:00") + bh
```

(continues on next page)
Passing \texttt{start} time later than \texttt{end} represents midnight business hour. In this case, business hour exceeds midnight and overlap to the next day. Valid business hours are distinguished by whether it started from valid \texttt{BusinessDay}.

Applying \texttt{BusinessHour.rollforward} and \texttt{rollback} to out of business hours results in the next business hour start or previous day’s end. Different from other offsets, \texttt{BusinessHour.rollforward} may output different results from \texttt{apply} by definition.

This is because one day’s business hour end is equal to next day’s business hour start. For example, under the default business hours (9:00 - 17:00), there is no gap (0 minutes) between 2014-08-01 17:00 and 2014-08-04 09:00.

# This adjusts a Timestamp to business hour edge
\begin{Verbatim}
In [223]: pd.offsets.BusinessHour().rollback(pd.Timestamp("2014-08-02 15:00"))
Out[223]: Timestamp('2014-08-01 17:00:00')
\end{Verbatim}

\begin{Verbatim}
In [224]: pd.offsets.BusinessHour().rollforward(pd.Timestamp("2014-08-02 15:00"))
Out[224]: Timestamp('2014-08-04 09:00:00')
\end{Verbatim}

# It is the same as BusinessHour().apply(pd.Timestamp('2014-08-01 17:00')). # And it is the same as BusinessHour().apply(pd.Timestamp('2014-08-04 09:00'))
\begin{Verbatim}
In [225]: pd.offsets.BusinessHour().apply(pd.Timestamp("2014-08-02 15:00"))
Out[225]: Timestamp('2014-08-04 10:00:00')
\end{Verbatim}

# BusinessDay results (for reference)
\begin{Verbatim}
In [226]: pd.offsets.BusinessHour().rollforward(pd.Timestamp("2014-08-02"))
Out[226]: Timestamp('2014-08-04 09:00:00')
\end{Verbatim}

# It is the same as BusinessDay().apply(pd.Timestamp('2014-08-01'))
\begin{Verbatim}
In [227]: pd.offsets.BusinessHour().apply(pd.Timestamp("2014-08-02"))
Out[227]: Timestamp('2014-08-04 10:00:00')
\end{Verbatim}
BusinessHour regards Saturday and Sunday as holidays. To use arbitrary holidays, you can use CustomBusinessHour offset, as explained in the following subsection.

**Custom business hour**

The CustomBusinessHour is a mixture of BusinessHour and CustomBusinessDay which allows you to specify arbitrary holidays. CustomBusinessHour works as the same as BusinessHour except that it skips specified custom holidays.

```python
from pandas.tseries.holiday import USFederalHolidayCalendar

bhour_us = pd.offsets.CustomBusinessHour(calendar=USFederalHolidayCalendar())

# Friday before MLK Day
In [230]: dt = datetime.datetime(2014, 1, 17, 15)
Out[230]: Timestamp('2014-01-17 16:00:00')

# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [231]: dt + bhour_us
Out[231]: Timestamp('2014-01-21 09:00:00')

In [232]: dt + bhour_us * 2
Out[232]: Timestamp('2014-01-21 10:00:00')
```

You can use keyword arguments supported by either BusinessHour and CustomBusinessDay.

```python
bhour_mon = pd.offsets.CustomBusinessHour(start="10:00", weekmask="Tue Wed Thu Fri")

# Monday is skipped because it's a holiday, business hour starts from 10:00
In [234]: dt + bhour_mon * 2
Out[234]: Timestamp('2014-01-21 10:00:00')
```

**Offset aliases**

A number of string aliases are given to useful common time series frequencies. We will refer to these aliases as offset aliases.
<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>business day frequency</td>
</tr>
<tr>
<td>C</td>
<td>custom business day frequency</td>
</tr>
<tr>
<td>D</td>
<td>calendar day frequency</td>
</tr>
<tr>
<td>W</td>
<td>weekly frequency</td>
</tr>
<tr>
<td>M</td>
<td>month end frequency</td>
</tr>
<tr>
<td>SM</td>
<td>semi-month end frequency (15th and end of month)</td>
</tr>
<tr>
<td>BM</td>
<td>business month end frequency</td>
</tr>
<tr>
<td>CBM</td>
<td>custom business month end frequency</td>
</tr>
<tr>
<td>MS</td>
<td>month start frequency</td>
</tr>
<tr>
<td>SMS</td>
<td>semi-month start frequency (1st and 15th)</td>
</tr>
<tr>
<td>BMS</td>
<td>business month start frequency</td>
</tr>
<tr>
<td>CBMS</td>
<td>custom business month start frequency</td>
</tr>
<tr>
<td>Q</td>
<td>quarter end frequency</td>
</tr>
<tr>
<td>BQ</td>
<td>business quarter end frequency</td>
</tr>
<tr>
<td>QS</td>
<td>quarter start frequency</td>
</tr>
<tr>
<td>BQS</td>
<td>business quarter start frequency</td>
</tr>
<tr>
<td>A, Y</td>
<td>year end frequency</td>
</tr>
<tr>
<td>BA, BY</td>
<td>business year end frequency</td>
</tr>
<tr>
<td>AS, YS</td>
<td>year start frequency</td>
</tr>
<tr>
<td>BAS, BYS</td>
<td>business year start frequency</td>
</tr>
<tr>
<td>BH</td>
<td>business hour frequency</td>
</tr>
<tr>
<td>H</td>
<td>hourly frequency</td>
</tr>
<tr>
<td>T, min</td>
<td>minutely frequency</td>
</tr>
<tr>
<td>S</td>
<td>secondly frequency</td>
</tr>
<tr>
<td>L, ms</td>
<td>milliseconds</td>
</tr>
<tr>
<td>U, us</td>
<td>microseconds</td>
</tr>
<tr>
<td>N</td>
<td>nanoseconds</td>
</tr>
</tbody>
</table>

**Combining aliases**

As we have seen previously, the alias and the offset instance are fungible in most functions:

```python
In [235]: pd.date_range(start, periods=5, freq="B")
Out[235]:
               '2011-01-07'],
              dtype='datetime64[ns]', freq='B')
```

```python
In [236]: pd.date_range(start, periods=5, freq=pd.offsets.BDay())
Out[236]:
               '2011-01-07'],
              dtype='datetime64[ns]', freq='B')
```

You can combine together day and intraday offsets:

```python
In [237]: pd.date_range(start, periods=10, freq="2h20min")
Out[237]:
DatetimeIndex(['2011-01-01 00:00:00', '2011-01-01 02:20:00',
               '2011-01-01 04:40:00', '2011-01-01 07:00:00',
               '2011-01-01 09:20:00', '2011-01-01 11:40:00',
               '2011-01-01 14:00:00', '2011-01-01 16:20:00',
               '2011-01-01 18:40:00', '2011-01-01 21:00:00'],
              dtype='datetime64[ns]', freq='2h20min')
```

(continues on next page)
Anchored offsets

For some frequencies you can specify an anchoring suffix:

<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>W-SUN</td>
<td>weekly frequency (Sundays). Same as ‘W’</td>
</tr>
<tr>
<td>W-MON</td>
<td>weekly frequency (Mondays)</td>
</tr>
<tr>
<td>W-TUE</td>
<td>weekly frequency (Tuesdays)</td>
</tr>
<tr>
<td>W-WED</td>
<td>weekly frequency (Wednesdays)</td>
</tr>
<tr>
<td>W-THU</td>
<td>weekly frequency (Thursdays)</td>
</tr>
<tr>
<td>W-FRI</td>
<td>weekly frequency (Fridays)</td>
</tr>
<tr>
<td>W-SAT</td>
<td>weekly frequency (Saturdays)</td>
</tr>
<tr>
<td>(B)Q(S)-DEC</td>
<td>quarterly frequency, year ends in December. Same as ‘Q’</td>
</tr>
<tr>
<td>(B)Q(S)-JAN</td>
<td>quarterly frequency, year ends in January</td>
</tr>
<tr>
<td>(B)Q(S)-FEB</td>
<td>quarterly frequency, year ends in February</td>
</tr>
<tr>
<td>(B)Q(S)-MAR</td>
<td>quarterly frequency, year ends in March</td>
</tr>
<tr>
<td>(B)Q(S)-APR</td>
<td>quarterly frequency, year ends in April</td>
</tr>
<tr>
<td>(B)Q(S)-MAY</td>
<td>quarterly frequency, year ends in May</td>
</tr>
<tr>
<td>(B)Q(S)-JUN</td>
<td>quarterly frequency, year ends in June</td>
</tr>
<tr>
<td>(B)Q(S)-JUL</td>
<td>quarterly frequency, year ends in July</td>
</tr>
<tr>
<td>(B)Q(S)-AUG</td>
<td>quarterly frequency, year ends in August</td>
</tr>
<tr>
<td>(B)Q(S)-SEP</td>
<td>quarterly frequency, year ends in September</td>
</tr>
<tr>
<td>(B)Q(S)-OCT</td>
<td>quarterly frequency, year ends in October</td>
</tr>
<tr>
<td>(B)Q(S)-NOV</td>
<td>quarterly frequency, year ends in November</td>
</tr>
<tr>
<td>(B)A(S)-DEC</td>
<td>annual frequency, anchored end of December. Same as ‘A’</td>
</tr>
</tbody>
</table>
Table 4 – continued from previous page

<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(B)A(S)-JAN</td>
<td>annual frequency, anchored end of January</td>
</tr>
<tr>
<td>(B)A(S)-FEB</td>
<td>annual frequency, anchored end of February</td>
</tr>
<tr>
<td>(B)A(S)-MAR</td>
<td>annual frequency, anchored end of March</td>
</tr>
<tr>
<td>(B)A(S)-APR</td>
<td>annual frequency, anchored end of April</td>
</tr>
<tr>
<td>(B)A(S)-MAY</td>
<td>annual frequency, anchored end of May</td>
</tr>
<tr>
<td>(B)A(S)-JUN</td>
<td>annual frequency, anchored end of June</td>
</tr>
<tr>
<td>(B)A(S)-JUL</td>
<td>annual frequency, anchored end of July</td>
</tr>
<tr>
<td>(B)A(S)-AUG</td>
<td>annual frequency, anchored end of August</td>
</tr>
<tr>
<td>(B)A(S)-SEP</td>
<td>annual frequency, anchored end of September</td>
</tr>
<tr>
<td>(B)A(S)-OCT</td>
<td>annual frequency, anchored end of October</td>
</tr>
<tr>
<td>(B)A(S)-NOV</td>
<td>annual frequency, anchored end of November</td>
</tr>
</tbody>
</table>

These can be used as arguments to date_range, bdate_range, constructors for DatetimeIndex, as well as various other timeseries-related functions in pandas.

**Anchored offset semantics**

For those offsets that are anchored to the start or end of specific frequency (MonthEnd, MonthBegin, WeekEnd, etc), the following rules apply to rolling forward and backwards.

When \( n \) is not 0, if the given date is not on an anchor point, it snapped to the next(previous) anchor point, and moved \(|n| - 1\) additional steps forwards or backwards.

```python
In [239]: pd.Timestamp("2014-01-02") + pd.offsets.MonthBegin(n=1)
Out[239]: Timestamp('2014-02-01 00:00:00')

In [240]: pd.Timestamp("2014-01-02") + pd.offsets.MonthEnd(n=1)
Out[240]: Timestamp('2014-01-31 00:00:00')

In [241]: pd.Timestamp("2014-01-02") - pd.offsets.MonthBegin(n=1)
Out[241]: Timestamp('2014-01-01 00:00:00')

In [242]: pd.Timestamp("2014-01-02") - pd.offsets.MonthEnd(n=1)
Out[242]: Timestamp('2013-12-31 00:00:00')

In [243]: pd.Timestamp("2014-01-02") + pd.offsets.MonthBegin(n=4)
Out[243]: Timestamp('2014-05-01 00:00:00')

In [244]: pd.Timestamp("2014-01-02") - pd.offsets.MonthBegin(n=4)
Out[244]: Timestamp('2013-10-01 00:00:00')
```

If the given date is on an anchor point, it is moved \(|n|\) points forwards or backwards.
For the case when \( n=0 \), the date is not moved if on an anchor point, otherwise it is rolled forward to the next anchor point.

### Holidays / holiday calendars

Holidays and calendars provide a simple way to define holiday rules to be used with `CustomBusinessDay` or in other analysis that requires a predefined set of holidays. The `AbstractHolidayCalendar` class provides all the necessary methods to return a list of holidays and only rules need to be defined in a specific holiday calendar class. Furthermore, the `start_date` and `end_date` class attributes determine over what date range holidays are generated. These should be overwritten on the `AbstractHolidayCalendar` class to have the range apply to all calendar subclasses. `USFederalHolidayCalendar` is the only calendar that exists and primarily serves as an example for developing other calendars.

For holidays that occur on fixed dates (e.g., US Memorial Day or July 4th) an observance rule determines when that holiday is observed if it falls on a weekend or some other non-observed day. Defined observance rules are:

<table>
<thead>
<tr>
<th>Rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nearest_workday</td>
<td>move Saturday to Friday and Sunday to Monday</td>
</tr>
<tr>
<td>sunday_to_monday</td>
<td>move Sunday to following Monday</td>
</tr>
<tr>
<td>next_monday_or_tuesday</td>
<td>Saturday to Monday and Sunday/Monday to Tuesday</td>
</tr>
<tr>
<td>previous_friday</td>
<td>move Saturday and Sunday to previous Friday</td>
</tr>
<tr>
<td>next_monday</td>
<td>move Saturday and Sunday to following Monday</td>
</tr>
</tbody>
</table>

An example of how holidays and holiday calendars are defined:
pandas: powerful Python data analysis toolkit, Release 1.3.1

In [255]: from pandas.tseries.holiday import (Holiday, USMemorialDay, AbstractHolidayCalendar, nearest_workday, MO, )

In [256]: class ExampleCalendar (AbstractHolidayCalendar):
   rules = [USMemorialDay,
   Holiday("July 4th", month=7, day=4, observance=nearest_workday),
   Holiday("Columbus Day", month=10, day=1, offset=pd.DateOffset(weekday=MO(2))),
   ]

In [257]: cal = ExampleCalendar()

In [258]: cal.holidays(datetime.datetime(2012, 1, 1), datetime.datetime(2012, 12, 31))
   Out[258]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype='datetime64[ns]', freq=None)

hint weekday=MO(2) is same as 2 * Week(weekday=2)

Using this calendar, creating an index or doing offset arithmetic skips weekends and holidays (i.e., Memorial Day/July 4th). For example, the below defines a custom business day offset using the ExampleCalendar. Like any other offset, it can be used to create a DatetimeIndex or added to datetime or Timestamp objects.

In [259]: pd.date_range(start="7/1/2012", end="7/10/2012", freq=pd.offsets.CDay(calendar=cal)).to_pydatetime()
   Out[259]: array([datetime.datetime(2012, 7, 2, 0, 0),
   datetime.datetime(2012, 7, 3, 0, 0),
   datetime.datetime(2012, 7, 5, 0, 0),
   datetime.datetime(2012, 7, 6, 0, 0),
   datetime.datetime(2012, 7, 9, 0, 0),
   datetime.datetime(2012, 7, 10, 0, 0)], dtype=object)

In [260]: offset = pd.offsets.CustomBusinessDay(calendar=cal)

In [261]: datetime.datetime(2012, 5, 25) + offset
   Out[261]: Timestamp('2012-05-29 00:00:00')

In [262]: datetime.datetime(2012, 7, 3) + offset
   Out[262]: Timestamp('2012-07-05 00:00:00')

In [263]: datetime.datetime(2012, 7, 3) + 2 * offset
   Out[263]: Timestamp('2012-07-06 00:00:00')

(continues on next page)
Ranges are defined by the start_date and end_date class attributes of AbstractHolidayCalendar. The defaults are shown below.

```
In [265]: AbstractHolidayCalendar.start_date
Out [265]: Timestamp('1970-01-01 00:00:00')
In [266]: AbstractHolidayCalendar.end_date
Out [266]: Timestamp('2200-12-31 00:00:00')
```

These dates can be overwritten by setting the attributes as datetime/Timestamp/string.

```
In [267]: AbstractHolidayCalendar.start_date = datetime.datetime(2012, 1, 1)
In [268]: AbstractHolidayCalendar.end_date = datetime.datetime(2012, 12, 31)
In [269]: cal.holidays()
Out [269]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype='datetime64[ns]', freq=None)
```

Every calendar class is accessible by name using the get_calendar function which returns a holiday class instance. Any imported calendar class will automatically be available by this function. Also, HolidayCalendarFactory provides an easy interface to create calendars that are combinations of calendars or calendars with additional rules.

```
In [270]: from pandas.tseries.holiday import get_calendar, HolidayCalendarFactory, USLaborDay
In [271]: cal = get_calendar("ExampleCalendar")
In [272]: cal.rules
Out [272]: 
[Holiday: Memorial Day (month=5, day=31, offset=<DateOffset: weekday=MO(-1)>),
 Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at 0x7f1e9314de50>),
 Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=MO(+2)>)]
In [273]: new_cal = HolidayCalendarFactory("NewExampleCalendar", cal, USLaborDay)
In [274]: new_cal.rules
Out [274]: 
[Holiday: Labor Day (month=9, day=1, offset=<DateOffset: weekday=MO(+1)>),
 Holiday: Memorial Day (month=5, day=31, offset=<DateOffset: weekday=MO(-1)>),
 Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at 0x7f1e9314de50>),
 Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=MO(+2)>)]
```
2.20.9 Time series-related instance methods

Shifting / lagging

One may want to shift or lag the values in a time series back and forward in time. The method for this is `shift()`, which is available on all of the pandas objects.

```python
In [275]: ts = pd.Series(range(len(rng)), index=rng)
In [276]: ts = ts[:5]
In [277]: ts.shift(1)
Out[277]:
2012-01-01    NaN
2012-01-02    0.0
2012-01-03    1.0
Freq: D, dtype: float64
```

The `shift` method accepts an `freq` argument which can accept a `DateOffset` class or other `timedelta`-like object or also an `offset alias`.

When `freq` is specified, `shift` method changes all the dates in the index rather than changing the alignment of the data and the index:

```python
In [278]: ts.shift(5, freq="D")
Out[278]:
2012-01-06    0
2012-01-07    1
2012-01-08    2
Freq: D, dtype: int64
```

```python
In [279]: ts.shift(5, freq=pd.offsets.BDay())
Out[279]:
2012-01-06    0
2012-01-09    1
2012-01-10    2
dtype: int64
```

```python
In [280]: ts.shift(5, freq="BM")
Out[280]:
2012-05-31    0
2012-05-31    1
2012-05-31    2
dtype: int64
```

Note that with when `freq` is specified, the leading entry is no longer NaN because the data is not being realigned.
Frequency conversion

The primary function for changing frequencies is the `asfreq()` method. For a `DatetimeIndex`, this is basically just a thin, but convenient wrapper around `reindex()` which generates a `date_range` and calls `reindex`.

```
In [281]: dr = pd.date_range("1/1/2010", periods=3, freq=3 * pd.offsets.BDay())
In [282]: ts = pd.Series(np.random.randn(3), index=dr)
In [283]: ts
Out[283]:
2010-01-01  1.494522
2010-01-06 -0.778425
2010-01-11 -0.253355
Freq: 3B, dtype: float64
```

`asfreq` provides a further convenience so you can specify an interpolation method for any gaps that may appear after the frequency conversion.

```
In [284]: ts.asfreq(pd.offsets.BDay(), method="pad")
Out[284]:
2010-01-01  1.494522
2010-01-04  1.494522
2010-01-05  1.494522
2010-01-06 -0.778425
2010-01-07 -0.778425
2010-01-08 -0.778425
2010-01-11 -0.253355
Freq: B, dtype: float64
```

Filling forward / backward

Related to `asfreq` and `reindex` is `fillna()`, which is documented in the `missing data section`.

Converting to Python datetimes

`DatetimeIndex` can be converted to an array of Python native `datetime.datetime` objects using the `to_pydatetime` method.
2.20.10 Resampling

pandas has a simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications.

`resample()` is a time-based groupby, followed by a reduction method on each of its groups. See some cookbook examples for some advanced strategies.

The `resample()` method can be used directly from DataFrameGroupBy objects, see the `groupby docs`.

Basics

```python
In [286]: rng = pd.date_range("1/1/2012", periods=100, freq="S")
In [287]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)
In [288]: ts.resample("5Min").sum()
Out[288]:
2012-01-01  25103
Freq: 5T, dtype: int64
```

The `resample` function is very flexible and allows you to specify many different parameters to control the frequency conversion and resampling operation.

Any function available via dispatching is available as a method of the returned object, including `sum`, `mean`, `std`, `sem`, `max`, `min`, `median`, `first`, `last`, `ohlc`:

```python
In [289]: ts.resample("5Min").mean()
Out[289]:
2012-01-01    251.03
Freq: 5T, dtype: float64
```

```python
In [290]: ts.resample("5Min").ohlc()
Out[290]:
                        open  high  low  close
2012-01-01             308   460    9  205
```

```python
In [291]: ts.resample("5Min").max()
Out[291]:
2012-01-01    460
Freq: 5T, dtype: int64
```

For downsampling, `closed` can be set to ‘left’ or ‘right’ to specify which end of the interval is closed:

```python
In [292]: ts.resample("5Min", closed="right").mean()
Out[292]:
2011-12-31 23:55:00    308.000000
2012-01-01  00:00:00  250.454545
Freq: 5T, dtype: float64
```

```python
In [293]: ts.resample("5Min", closed="left").mean()
Out[293]:
2012-01-01    251.03
Freq: 5T, dtype: float64
```

Parameters like `label` are used to manipulate the resulting labels. `label` specifies whether the result is labeled with the beginning or the end of the interval.
In [294]: ts.resample("5Min").mean()  # by default label='left'
Out[294]:
2012-01-01  251.03
Freq: 5T, dtype: float64

In [295]: ts.resample("5Min", label="left").mean()
Out[295]:
2012-01-01  251.03
Freq: 5T, dtype: float64

Warning: The default values for label and closed is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

This might unintendly lead to looking ahead, where the value for a later time is pulled back to a previous time as in the following example with the BusinessDay frequency:

In [296]: s = pd.date_range("2000-01-01", "2000-01-05").to_series()
In [297]: s.iloc[2] = pd.NaT
In [298]: s.dt.day_name()
Out[298]:
2000-01-01 Saturday
2000-01-02 Sunday
2000-01-03 NaN
2000-01-04 Tuesday
2000-01-05 Wednesday
Freq: D, dtype: object

# default: label='left', closed='left'
In [299]: s.resample("B").last().dt.day_name()
Out[299]:
1999-12-31 Sunday
2000-01-03 NaN
2000-01-04 Tuesday
2000-01-05 Wednesday
Freq: B, dtype: object

Notice how the value for Sunday got pulled back to the previous Friday. To get the behavior where the value for Sunday is pushed to Monday, use instead

In [300]: s.resample("B", label="right", closed="right").last().dt.day_name()
Out[300]:
2000-01-03 Sunday
2000-01-04 Tuesday
2000-01-05 Wednesday
Freq: B, dtype: object

The axis parameter can be set to 0 or 1 and allows you to resample the specified axis for a DataFrame.

kind can be set to ‘timestamp’ or ‘period’ to convert the resulting index to/from timestamp and time span representations. By default resample retains the input representation.

convention can be set to ‘start’ or ‘end’ when resampling period data (detail below). It specifies how low frequency periods are converted to higher frequency periods.
Upsampling

For upsampling, you can specify a way to upsample and the limit parameter to interpolate over the gaps that are created:

```python
# from secondly to every 250 milliseconds
In [301]: ts[:2].resample("250L").asfreq()
Out[301]:
2012-01-01 00:00:00.000 308.0
2012-01-01 00:00:00.250 NaN
2012-01-01 00:00:00.500 NaN
2012-01-01 00:00:00.750 NaN
2012-01-01 00:00:01.000 204.0
Freq: 250L, dtype: float64

In [302]: ts[:2].resample("250L").ffill()
Out[302]:
2012-01-01 00:00:00.000 308
2012-01-01 00:00:00.250 308
2012-01-01 00:00:00.500 308
2012-01-01 00:00:00.750 308
2012-01-01 00:00:01.000 204
Freq: 250L, dtype: int64

In [303]: ts[:2].resample("250L").ffill(limit=2)
Out[303]:
2012-01-01 00:00:00.000 308.0
2012-01-01 00:00:00.250 308.0
2012-01-01 00:00:00.500 308.0
2012-01-01 00:00:00.750 NaN
2012-01-01 00:00:01.000 204.0
Freq: 250L, dtype: float64
```

Sparse resampling

Sparse timeseries are the ones where you have a lot fewer points relative to the amount of time you are looking to resample. Naively upsampling a sparse series can potentially generate lots of intermediate values. When you don’t want to use a method to fill these values, e.g. fill_method is None, then intermediate values will be filled with NaN.

Since resample is a time-based groupby, the following is a method to efficiently resample only the groups that are not all NaN.

```python
In [304]: rng = pd.date_range("2014-1-1", periods=100, freq="D") + pd.Timedelta("1s")
In [305]: ts = pd.Series(range(100), index=rng)

If we want to resample to the full range of the series:

```python
In [306]: ts.resample("3T").sum()
Out[306]:
2014-01-01 00:00:00 0
2014-01-01 00:03:00 0
2014-01-01 00:06:00 0

Freq: 3T, dtype: int64
```
Aggregation

Similar to the aggregating API, groupby API, and the window API, a Resampler can be selectively resampled. Resampling a DataFrame, the default will be to act on all columns with the same function.

The resampled DataFrame looks like this:

```
In [311]: df = pd.DataFrame(
    ...:     np.random.randn(1000, 3),
    ...:     index=pd.date_range("1/1/2012", freq="S", periods=1000),
    ...:     columns=["A", "B", "C"],
    ...: )
In [312]: r = df.resample("3T")
In [313]: r.mean()
Out[313]:
         A         B         C
2012-01-01 00:00:00 -0.033823 -0.121514 -0.081447
2012-01-01 00:03:00  0.056909  0.146731 -0.024320
2012-01-01 00:06:00 -0.058837  0.047046 -0.052021
```

(continues on next page)
We can select a specific column or columns using standard getitem.

```
In [314]: r["A"]).mean()
Out[314]:
   2012-01-01 00:00:00 -0.033823
   2012-01-01 00:03:00  0.056909
   2012-01-01 00:06:00 -0.058837
   2012-01-01 00:09:00  0.063123
   2012-01-01 00:12:00  0.186340
   2012-01-01 00:15:00 -0.085954
Freq: 3T, Name: A, dtype: float64
```

```
In [315]: r["A", "B"]').mean()
Out[315]:
   A B
   2012-01-01 00:00:00 -0.033823 -0.121514
   2012-01-01 00:03:00  0.056909  0.146731
   2012-01-01 00:06:00 -0.058837  0.047046
   2012-01-01 00:09:00  0.063123 -0.026158
   2012-01-01 00:12:00  0.186340 -0.003144
   2012-01-01 00:15:00 -0.085954 -0.016287
```

You can pass a list or dict of functions to do aggregation with, outputting a DataFrame:

```
In [316]: r["A"]').agg([np.sum, np.mean, np.std])
Out[316]:
   sum  mean    std
   2012-01-01 00:00:00 -6.088060 -0.033823  1.043263
   2012-01-01 00:03:00 10.243678  0.056909  1.058534
   2012-01-01 00:06:00 -10.590584 -0.058837  0.949264
   2012-01-01 00:09:00 11.362228  0.063123  1.028096
   2012-01-01 00:12:00 33.541257  0.186340  0.884586
   2012-01-01 00:15:00 -8.595393 -0.085954  1.035476
```

On a resampled DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [317]: r.agg([np.sum, np.mean])
Out[317]:
   A B C
   sum mean sum mean sum mean
   2012-01-01 00:00:00 -6.088060 -0.033823 -21.872530 -0.121514 -14.660515 -0.081447
   2012-01-01 00:03:00 10.243678  0.056909  26.411633  0.146731 -4.377642 -0.024320
   2012-01-01 00:06:00 -10.590584 -0.058837  8.468289  0.047046 -9.363825 -0.052021
   2012-01-01 00:09:00 33.541257  0.186340  13.455299  0.074752
   2012-01-01 00:12:00 -8.595393 -0.085954 -1.628689 -0.016287 -5.004580 -0.050046
```

By passing a dict to aggregate you can apply a different aggregation to the columns of a DataFrame:

```
In [318]: r.agg({"A": np.sum, "B": lambda x: np.std(x, ddof=1)})
Out[318]:
   A  B  C
   sum mean  sum mean  sum mean
   2012-01-01 00:00:00 -6.088060 -0.033823 -21.872530 -0.121514 -14.660515 -0.081447
   2012-01-01 00:03:00 10.243678  0.056909  26.411633  0.146731 -4.377642 -0.024320
   2012-01-01 00:06:00 -10.590584 -0.058837  8.468289  0.047046 -9.363825 -0.052021
   2012-01-01 00:09:00 11.362228  0.063123  13.455299  0.074752
   2012-01-01 00:12:00 33.541257  0.186340  13.455299  0.074752
   2012-01-01 00:15:00 -8.595393 -0.085954 -1.628689 -0.016287 -5.004580 -0.050046
```

(continues on next page)
The function names can also be strings. In order for a string to be valid it must be implemented on the resampled object:

```
In [319]: r.agg({"A": "sum", "B": "std"})
```

```
A    B
2012-01-01 00:00:00 -6.088060 1.001294
2012-01-01 00:03:00 10.243678 1.074597
2012-01-01 00:06:00 -10.590584 0.987309
2012-01-01 00:09:00 11.362228 0.944953
2012-01-01 00:12:00 33.541257 1.095025
2012-01-01 00:15:00 -8.595393 1.035312
```

Furthermore, you can also specify multiple aggregation functions for each column separately.

```
In [320]: r.agg({"A": ["sum", "std"], "B": ["mean", "std"]})
```

```
A       B
      sum    std  mean    std
2012-01-01 00:00:00 -6.088060 1.043263 -0.121514 1.001294
2012-01-01 00:03:00 10.243678 1.058534 0.146731 1.074597
2012-01-01 00:06:00 -10.590584 0.949264 0.047046 0.987309
2012-01-01 00:09:00 11.362228 1.028096 -0.026158 0.944953
2012-01-01 00:12:00 33.541257 0.884586 -0.003144 1.095025
2012-01-01 00:15:00 -8.595393 1.035476 -0.016287 1.035312
```

If a DataFrame does not have a datetimelike index, but instead you want to resample based on datetimelike column in the frame, it can passed to the `on` keyword.

```
In [321]: df = pd.DataFrame(
       ....:     {"date": pd.date_range("2015-01-01", freq="W", periods=5), "a": np.
       ....:         arange(5),
       ....:     index=pd.MultiIndex.from_arrays(
       ....:         [[1, 2, 3, 4, 5], pd.date_range("2015-01-01", freq="W", periods=5)],
       ....:         names=["v", "d"],
       ....:     ),
       ....: )
```

```
In [322]: df
```

```
      date      a  
      v  d
1 2015-01-04 2015-01-04 0
2 2015-01-11 2015-01-11 1
3 2015-01-18 2015-01-18 2
4 2015-01-25 2015-01-25 3
5 2015-02-01 2015-02-01 4
```
Similarly, if you instead want to resample by a datetimelike level of `MultiIndex`, its name or location can be passed to the `level` keyword.

```python
In [324]: df.resample("M", level="d").sum()
Out[324]:
            a
     date       
2015-01-31  6
2015-02-28  4
```

### Iterating through groups

With the `Resampler` object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

```python
In [325]: small = pd.Series(
    ...:     range(6),
    ...:     index=pd.to_datetime(
    ...:         ["2017-01-01T00:00:00",
    ...:         "2017-01-01T00:30:00",
    ...:         "2017-01-01T00:31:00",
    ...:         "2017-01-01T01:00:00",
    ...:         "2017-01-01T03:00:00",
    ...:         "2017-01-01T03:05:00",
    ...:     ],
    ...: ),
    ...
    ...
    ...
)

In [326]: resampled = small.resample("H")

In [327]: for name, group in resampled:
    ...:     print("Group: ", name)
    ...:     print("-" * 27)
    ...:     print(group, end="\n\n")
    ...
```

(continues on next page)
See *Iterating through groups* or `Resampler.__iter__` for more.

**Use origin or offset to adjust the start of the bins**

New in version 1.1.0.

The bins of the grouping are adjusted based on the beginning of the day of the time series starting point. This works well with frequencies that are multiples of a day (like `30D`) or that divide a day evenly (like `90s` or `1min`). This can create inconsistencies with some frequencies that do not meet this criteria. To change this behavior you can specify a fixed Timestamp with the argument `origin`.

For example:

```
In [328]: start, end = "2000-10-01 23:30:00", "2000-10-02 00:30:00"
In [329]: middle = "2000-10-02 00:00:00"
In [330]: rng = pd.date_range(start, end, freq="7min")
In [331]: ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
In [332]: ts
Out[332]:
2000-10-01 23:30:00    0
2000-10-01 23:37:00    3
2000-10-01 23:44:00    6
2000-10-01 23:51:00    9
2000-10-01 23:58:00   12
2000-10-02 00:05:00   15
2000-10-02 00:12:00   18
2000-10-02 00:19:00   21
2000-10-02 00:26:00   24
Freq: 7T, dtype: int64
```

Here we can see that, when using `origin` with its default value ('*start_day*'), the result after '2000-10-02 00:00:00' are not identical depending on the start of time series:

```
In [333]: ts.resample("17min", origin="start_day").sum()
Out[333]:
2000-10-01 23:14:00    0
2000-10-01 23:31:00    9
2000-10-01 23:48:00   21
2000-10-02 00:05:00   54
2000-10-02 00:22:00   24
```
Here we can see that, when setting `origin` to 'epoch', the result after '2000-10-02 00:00:00' are identical depending on the start of time series:

If needed you can use a custom timestamp for `origin`:

If needed you can just adjust the bins with an `offset` `Timedelta` that would be added to the default `origin`. Those two examples are equivalent for this time series:
2000-10-01 23:30:00 9
2000-10-01 23:47:00 21
2000-10-02 00:04:00 54
2000-10-02 00:21:00 24
Freq: 17T, dtype: int64

Note the use of 'start' for origin on the last example. In that case, origin will be set to the first value of the timeseries.

**Backward resample**

New in version 1.3.0.

Instead of adjusting the beginning of bins, sometimes we need to fix the end of the bins to make a backward resample with a given freq. The backward resample sets closed to 'right' by default since the last value should be considered as the edge point for the last bin.

We can set origin to 'end'. The value for a specific Timestamp index stands for the resample result from the current Timestamp minus freq to the current Timestamp with a right close.

```
In [341]: ts.resample('17min', origin='end').sum()
Out[341]:
2000-10-01 23:35:00 0
2000-10-01 23:52:00 18
2000-10-02 00:09:00 27
2000-10-02 00:26:00 63
Freq: 17T, dtype: int64
```

Besides, in contrast with the 'start_day' option, end_day is supported. This will set the origin as the ceiling midnight of the largest Timestamp.

```
In [342]: ts.resample('17min', origin='end_day').sum()
Out[342]:
2000-10-01 23:38:00 3
2000-10-01 23:55:00 15
2000-10-02 00:12:00 45
2000-10-02 00:29:00 45
Freq: 17T, dtype: int64
```

The above result uses 2000-10-02 00:29:00 as the last bin’s right edge since the following computation.

```
In [343]: ceil_mid = rng.max().ceil('D')
In [344]: freq = pd.offsets.Minute(17)
In [345]: bin_res = ceil_mid - freq * ((ceil_mid - rng.max()) // freq)
In [346]: bin_res
Out[346]: Timestamp('2000-10-02 00:29:00')
```
2.20.11 Time span representation

Regular intervals of time are represented by `Period` objects in pandas while sequences of `Period` objects are collected in a `PeriodIndex`, which can be created with the convenience function `period_range`.

**Period**

A `Period` represents a span of time (e.g., a day, a month, a quarter, etc). You can specify the span via `freq` keyword using a frequency alias like below. Because `freq` represents a span of `Period`, it cannot be negative like “-3D”.

```python
In [347]: pd.Period("2012", freq="A-DEC")
Out[347]: Period('2012', 'A-DEC')

In [348]: pd.Period("2012-1-1", freq="D")
Out[348]: Period('2012-01-01', 'D')

In [349]: pd.Period("2012-1-1 19:00", freq="H")
Out[349]: Period('2012-01-01 19:00', 'H')

In [350]: pd.Period("2012-1-1 19:00", freq="5H")
Out[350]: Period('2012-01-01 19:00', '5H')
```

Adding and subtracting integers from periods shifts the period by its own frequency. Arithmetic is not allowed between `Period` with different `freq` (span).

```python
In [351]: p = pd.Period("2012", freq="A-DEC")
In [352]: p + 1
Out[352]: Period('2013', 'A-DEC')
In [353]: p - 3
Out[353]: Period('2009', 'A-DEC')
In [354]: p = pd.Period("2012-01", freq="2M")
In [355]: p + 2
Out[355]: Period('2012-05', '2M')
In [356]: p - 1
Out[356]: Period('2011-11', '2M')
In [357]: p == pd.Period("2012-01", freq="3M")
Out[357]: False
```

If `Period freq` is daily or higher (D, H, T, S, L, U, N), offsets and timedelta-like can be added if the result can have the same freq. Otherwise, `ValueError` will be raised.

```python
In [358]: p = pd.Period("2014-07-01 09:00", freq="H")
In [359]: p + pd.offsets.Hour(2)
Out[359]: Period('2014-07-01 11:00', 'H')
In [360]: p + datetime.timedelta(minutes=120)
Out[360]: Period('2014-07-01 11:00', 'H')
In [361]: p + np.timedelta64(7200, "s")
Out[361]: Period('2014-07-01 11:00', 'H')
```
In [1]: p + pd.offsets.Minute(5)
Traceback
...
ValueError: Input has different freq from Period(freq=H)

If `Period` has other frequencies, only the same offsets can be added. Otherwise, `ValueError` will be raised.

In [362]: p = pd.Period("2014-07", freq="M")
In [363]: p + pd.offsets.MonthEnd(3)
Out[363]: Period('2014-10', 'M')

In [1]: p + pd.offsets.MonthBegin(3)
Traceback
...
ValueError: Input has different freq from Period(freq=M)

Taking the difference of `Period` instances with the same frequency will return the number of frequency units between them:

Out[364]: <10 * YearEnds: month=12>

**PeriodIndex and period_range**

Regular sequences of `Period` objects can be collected in a `PeriodIndex`, which can be constructed using the `period_range` convenience function:

In [365]: prng = pd.period_range("1/1/2011", "1/1/2012", freq="M")
In [366]: prng
                   '2012-01'], dtype='period[M]')

The `PeriodIndex` constructor can also be used directly:

In [367]: pd.PeriodIndex(['2011-1', '2011-2', '2011-3'], freq="M")
Out[367]: PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]')

Passing multiplied frequency outputs a sequence of `Period` which has multiplied span.

In [368]: pd.period_range(start="2014-01", freq="3M", periods=4)
˓→')

If `start` or `end` are `Period` objects, they will be used as anchor endpoints for a `PeriodIndex` with frequency matching that of the `PeriodIndex` constructor.

In [369]: pd.period_range(
       ....: start=pd.Period("2017Q1", freq="Q"), end=pd.Period("2017Q2", freq="Q"),
       ....: ˓→freq="M"
       ....: )
(continues on next page)
Just like `DatetimeIndex`, a `PeriodIndex` can also be used to index pandas objects:

```python
In [370]: ps = pd.Series(np.random.randn(len(prng)), prng)
In [371]: ps
Out[371]:
2011-01 -2.916901
2011-02  0.514474
2011-03  1.346470
2011-04  0.816397
2011-05  2.258648
2011-06  0.494789
2011-07  0.301239
2011-08  0.464776
2011-09 -1.393581
2011-10  0.056780
Freq: M, dtype: float64
```

`PeriodIndex` supports addition and subtraction with the same rule as `Period`.

```python
In [372]: idx = pd.period_range("2014-07-01 09:00", periods=5, freq="H")
In [373]: idx
Out[373]:
PeriodIndex(['2014-07-01 09:00', '2014-07-01 10:00', '2014-07-01 11:00',
             '2014-07-01 12:00', '2014-07-01 13:00'],
            dtype='period[H]')
In [374]: idx + pd.offsets.Hour(2)
Out[374]:
PeriodIndex(['2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00',
             '2014-07-01 14:00', '2014-07-01 15:00'],
            dtype='period[H]')
```

`PeriodIndex` has its own `dtype` named `period`, refer to `Period Dtypes`.

2.20. Time series / date functionality
**Period dtypes**

PeriodIndex has a custom period dtype. This is a pandas extension dtype similar to the timezone aware dtype (datetime64[ns, tz]).

The period dtype holds the freq attribute and is represented with period[freq] like period[D] or period[M], using frequency strings.

```python
In [378]: pi = pd.period_range("2016-01-01", periods=3, freq="M")

In [379]: pi
Out[379]: PeriodIndex(["2016-01", '2016-02', '2016-03'], dtype='period[M]')

In [380]: pi.dtype
Out[380]: period[M]
```

The period dtype can be used in .astype(...). It allows one to change the freq of a PeriodIndex like .asfreq() and convert a DatetimeIndex to PeriodIndex like .to_period():

```python
# change monthly freq to daily freq
In [381]: pi.astype("period[D]"")
Out[381]: PeriodIndex(["2016-01-31", '2016-02-29', '2016-03-31'], dtype='period[D]')

# convert to DatetimeIndex
In [382]: pi.astype("datetime64[ns]"")
Out[382]: DatetimeIndex(["2016-01-01", '2016-02-01', '2016-03-01'], dtype="datetime64[ns]", freq='M')

# convert to PeriodIndex
In [383]: dti = pd.date_range("2011-01-01", freq="M", periods=3)

In [384]: dti
Out[384]: DatetimeIndex(["2011-01-31", '2011-02-28', '2011-03-31'], dtype="datetime64[ns]", freq='M')

In [385]: dti.astype("period[M]"")
Out[385]: PeriodIndex(["2011-01", '2011-02', '2011-03'], dtype='period[M]')
```

**PeriodIndex partial string indexing**

PeriodIndex now supports partial string slicing with non-monotonic indexes.

New in version 1.1.0.

You can pass in dates and strings to Series and DataFrame with PeriodIndex, in the same manner as DatetimeIndex. For details, refer to DatetimeIndex Partial String Indexing.

```python
In [386]: ps["2011-01"]
Out[386]: -2.9169013294054507

In [387]: ps[datetime.datetime(2011, 12, 25):]
Out[387]:
2011-12  2.261385
2012-01 -0.329583
Freq: M, dtype: float64

In [388]: ps["10/31/2011":"12/31/2011"]
```
Passing a string representing a lower frequency than PeriodIndex returns partial sliced data.

```
In [389]: ps["2011"]
Out[389]:
2011-01 -2.916901
2011-02  0.514474
2011-03  1.346470
2011-04  0.816397
2011-05  2.258648
2011-06  0.494789
2011-07  0.301239
2011-08  0.464776
2011-09 -1.393581
2011-10  0.056780
2011-11  0.197035
2011-12  2.261385
Freq: M, dtype: float64
```

```
In [390]: dfp = pd.DataFrame(np.random.randn(600, 1), columns=["A"],
                       index=pd.period_range("2013-01-01 9:00", periods=600, freq="T"),
                       )
```

```
In [391]: dfp.loc["2013-01-01 10H"]
Out[391]:
A
2013-01-01 09:00  -0.538468
2013-01-01 09:01  -1.365819
2013-01-01 09:02  -0.969051
2013-01-01 09:03  -0.331152
2013-01-01 09:04  -0.245334
...    ...
2013-01-01 18:55   0.522460
2013-01-01 18:56   0.118710
2013-01-01 18:57   0.167517
2013-01-01 18:58   0.922883
2013-01-01 18:59   1.721104
[600 rows x 1 columns]
```

(continues on next page)
As with `DatetimeIndex`, the endpoints will be included in the result. The example below slices data starting from 10:00 to 11:59.

```
In [393]: dfp["2013-01-01 10H":"2013-01-01 11H"]
Out[393]:
    A
2013-01-01 10:00 -0.308975
2013-01-01 10:01  0.542520
2013-01-01 10:02  1.061068
2013-01-01 10:03  0.754005
2013-01-01 10:04  0.352933
... ...  
2013-01-01 11:55 -0.590204
2013-01-01 11:56  1.539990
2013-01-01 11:57 -1.224826
2013-01-01 11:58  0.578798
2013-01-01 11:59 -0.685496
[120 rows x 1 columns]
```

**Frequency conversion and resampling with `PeriodIndex`**

The frequency of `Period` and `PeriodIndex` can be converted via the `asfreq` method. Let's start with the fiscal year 2011, ending in December:

```
In [394]: p = pd.Period("2011", freq="A-DEC")
In [395]: p
Out[395]: Period('2011', 'A-DEC')
```

We can convert it to a monthly frequency. Using the `how` parameter, we can specify whether to return the starting or ending month:

```
In [396]: p.asfreq("M", how="start")
Out[396]: Period('2011-01', 'M')
In [397]: p.asfreq("M", how="end")
Out[397]: Period('2011-12', 'M')
```

The shorthands ‘s’ and ‘e’ are provided for convenience:

```
In [398]: p.asfreq("M", "s")
Out[398]: Period('2011-01', 'M')
In [399]: p.asfreq("M", "e")
Out[399]: Period('2011-12', 'M')
```
Converting to a “super-period” (e.g., annual frequency is a super-period of quarterly frequency) automatically returns the super-period that includes the input period:

```python
In [400]: p = pd.Period("2011-12", freq="M")
In [401]: p.asfreq("A-NOV")
Out[401]: Period('2012', 'A-NOV')
```

Note that since we converted to an annual frequency that ends the year in November, the monthly period of December 2011 is actually in the 2012 A-NOV period.

Period conversions with anchored frequencies are particularly useful for working with various quarterly data common to economics, business, and other fields. Many organizations define quarters relative to the month in which their fiscal year starts and ends. Thus, first quarter of 2011 could start in 2010 or a few months into 2011. Via anchored frequencies, pandas works for all quarterly frequencies Q-JAN through Q-DEC.

Q-DEC define regular calendar quarters:

```python
In [402]: p = pd.Period("2012Q1", freq="Q-DEC")
In [403]: p.asfreq("D", "s")
Out[403]: Period('2012-01-01', 'D')
In [404]: p.asfreq("D", "e")
Out[404]: Period('2012-03-31', 'D')
```

Q-MAR defines fiscal year end in March:

```python
In [405]: p = pd.Period("2011Q4", freq="Q-MAR")
In [406]: p.asfreq("D", "s")
Out[406]: Period('2011-01-01', 'D')
In [407]: p.asfreq("D", "e")
Out[407]: Period('2011-03-31', 'D')
```

### 2.20.12 Converting between representations

Timestamped data can be converted to PeriodIndex-ed data using `to_period` and vice-versa using `to_timestamp`:

```python
In [408]: rng = pd.date_range("1/1/2012", periods=5, freq="M")
In [409]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
In [410]: ps = ts.to_period()
```

(continues on next page)
In [412]: ps
Out[412]:
2012-01  1.931253
2012-02 -0.184594
2012-03  0.249656
2012-04 -0.978151
2012-05 -0.873389
Freq: M, dtype: float64

In [413]: ps.to_timestamp()
Out[413]:
2012-01-01  1.931253
2012-02-01 -0.184594
2012-03-01  0.249656
2012-04-01 -0.978151
2012-05-01 -0.873389
Freq: MS, dtype: float64

Remember that ‘s’ and ‘e’ can be used to return the timestamps at the start or end of the period:

In [414]: ps.to_timestamp("D", how="s")
Out[414]:
2012-01-01  1.931253
2012-02-01 -0.184594
2012-03-01  0.249656
2012-04-01 -0.978151
2012-05-01 -0.873389
Freq: MS, dtype: float64

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

In [415]: prng = pd.period_range("1990Q1", "2000Q4", freq="Q-NOV")
In [416]: ts = pd.Series(np.random.randn(len(prng)), prng)
In [417]: ts.index = (prng.asfreq("M", "e") + 1).asfreq("H", "s") + 9
In [418]: ts.head()
Out[418]:
1990-03-01 09:00 -0.109291
1990-06-01 09:00 -0.637235
1990-09-01 09:00 -1.735925
1990-12-01 09:00  2.096946
1991-03-01 09:00 -1.039926
Freq: H, dtype: float64
2.20.13 Representing out-of-bounds spans

If you have data that is outside of the Timestamp bounds, see Timestamp limitations, then you can use a PeriodIndex and/or Series of Periods to do computations.

```
In [419]: span = pd.period_range("1215-01-01", "1381-01-01", freq="D")

In [420]: span
Out[420]:
PeriodIndex(['1215-01-01', '1215-01-02', '1215-01-03', '1215-01-04',
           '1215-01-05', '1215-01-06', '1215-01-07', '1215-01-08',
           '1215-01-09', '1215-01-10',
           ...
           '1380-12-23', '1380-12-24', '1380-12-25', '1380-12-26',
           '1380-12-27', '1380-12-28', '1380-12-29', '1380-12-30',
           '1380-12-31', '1381-01-01'],
dtype='period[D]', length=60632)
```

To convert from an int64 based YYYYMMDD representation.

```
In [421]: s = pd.Series([20121231, 20141130, 99991231])

In [422]: s
Out[422]:
0   20121231
1   20141130
2   99991231
dtype: int64

In [423]: def conv(x):
       .....: return pd.Period(year=x // 10000, month=x // 100 % 100, day=x % 100,
       .....:        freq="D")
       .....:

In [424]: s.apply(conv)
Out[424]:
0   2012-12-31
1   2014-11-30
2   9999-12-31
dtype: period[D]

In [425]: s.apply(conv)[2]
Out[425]: Period('9999-12-31', 'D')
```

These can easily be converted to a PeriodIndex:

```
In [426]: span = pd.PeriodIndex(s.apply(conv))

In [427]: span
Out[427]: PeriodIndex(['2012-12-31', '2014-11-30', '9999-12-31'],
dtype='period[D]')
```
2.20.14 Time zone handling

pandas provides rich support for working with timestamps in different time zones using the pytz and dateutil libraries or datetime.timezone objects from the standard library.

Working with time zones

By default, pandas objects are time zone unaware:

```python
In [428]: rng = pd.date_range("3/6/2012 00:00", periods=15, freq="D")
In [429]: rng.tz
Out[429]: None
```

To localize these dates to a time zone (assign a particular time zone to a naive date), you can use the `tz_localize` method or the `tz` keyword argument in `date_range()`, `Timestamp`, or `DatetimeIndex`. You can either pass `pytz` or `dateutil` time zone objects or Olson time zone database strings. Olson time zone strings will return `pytz` time zone objects by default. To return `dateutil` time zone objects, append `dateutil/` before the string.

- In `pytz` you can find a list of common (and less common) time zones using `from pytz import common_timezones, all_timezones`.
- `dateutil` uses the OS time zones so there isn’t a fixed list available. For common zones, the names are the same as `pytz`.

```python
In [430]: import dateutil
# pytz
In [431]: rng_pytz = pd.date_range("3/6/2012 00:00", periods=3, freq="D", tz="Europe/London")
In [432]: rng_pytz.tz
Out[432]: <DstTzInfo 'Europe/London' LMT-1 day, 23:59:00 STD>
# dateutil
In [433]: rng_dateutil = pd.date_range("3/6/2012 00:00", periods=3, freq="D")
In [434]: rng_dateutil = rng_dateutil.tz_localize("dateutil/Europe/London")
In [435]: rng_dateutil.tz
Out[435]: tzfile('/usr/share/zoneinfo/Europe/London')
# dateutil - utc special case
In [436]: rng_utc = pd.date_range(
    ....:     "3/6/2012 00:00",
    ....:     periods=3,
    ....:     freq="D",
    ....:     tz=dateutil.tz.tzutc(),
    ....: )
In [437]: rng_utc.tz
Out[437]: tzutc()
```

New in version 0.25.0.
Note that the UTC time zone is a special case in dateutil and should be constructed explicitly as an instance of dateutil.tz.tzutc. You can also construct other time zones objects explicitly first.

To convert a time zone aware pandas object from one time zone to another, you can use the `tz_convert` method.

Note: When using pytz time zones, `DatetimeIndex` will construct a different time zone object than a `Timestamp` for the same time zone input. A `DatetimeIndex` can hold a collection of `Timestamp` objects that may have different UTC offsets and cannot be succinctly represented by one `pytz` time zone instance while one `Timestamp` represents one point in time with a specific UTC offset.
**Warning:** Be wary of conversions between libraries. For some time zones, `pytz` and `dateutil` have different definitions of the zone. This is more of a problem for unusual time zones than for ‘standard’ zones like US/Eastern.

**Warning:** Be aware that a time zone definition across versions of time zone libraries may not be considered equal. This may cause problems when working with stored data that is localized using one version and operated on with a different version. See [here](#) for how to handle such a situation.

**Warning:** For `pytz` time zones, it is incorrect to pass a time zone object directly into the `datetime.datetime` constructor (e.g., `datetime.datetime(2011, 1, 1, tz=pytz.timezone('US/Eastern'))`). Instead, the datetime needs to be localized using the `localize` method on the `pytz` time zone object.

**Warning:** Be aware that for times in the future, correct conversion between time zones (and UTC) cannot be guaranteed by any time zone library because a timezone’s offset from UTC may be changed by the respective government.

**Warning:** If you are using dates beyond 2038-01-18, due to current deficiencies in the underlying libraries caused by the year 2038 problem, daylight saving time (DST) adjustments to timezone aware dates will not be applied. If and when the underlying libraries are fixed, the DST transitions will be applied.

For example, for two dates that are in British Summer Time (and so would normally be GMT+1), both the following asserts evaluate as true:

```python
In [453]: d_2037 = "2037-03-31T010101"
In [454]: d_2038 = "2038-03-31T010101"
In [455]: DST = "Europe/London"
In [456]: assert pd.Timestamp(d_2037, tz=DST) != pd.Timestamp(d_2037, tz="GMT")
In [457]: assert pd.Timestamp(d_2038, tz=DST) == pd.Timestamp(d_2038, tz="GMT")
```

Under the hood, all timestamps are stored in UTC. Values from a time zone aware `DatetimeIndex` or `Timestamp` will have their fields (day, hour, minute, etc.) localized to the time zone. However, timestamps with the same UTC value are still considered to be equal even if they are in different time zones:

```python
In [458]: rng_eastern = rng_utc.tz_convert("US/Eastern")
In [459]: rng_germany = rng_utc.tz_convert("Europe/Berlin")
```
Operations between \textit{Series} in different time zones will yield UTC \textit{Series}, aligning the data on the UTC timestamps:

\begin{verbatim}
In [463]: ts_utc = pd.Series(range(3), pd.date_range("20130101", periods=3, tz="UTC"))
In [464]: eastern = ts_utc.tz_convert("US/Eastern")
In [465]: berlin = ts_utc.tz_convert("Europe/Berlin")
In [466]: result = eastern + berlin
In [467]: result
Out[467]:
2013-01-01 00:00:00+00:00    0
2013-01-02 00:00:00+00:00    2
2013-01-03 00:00:00+00:00    4
Freq: D, dtype: int64

In [468]: result.index
Out[468]:
DatetimeIndex(['2013-01-01 00:00:00', '2013-01-02 00:00:00', '2013-01-03 00:00:00'],
dtype='datetime64[ns, UTC]', freq='D')
\end{verbatim}

To remove time zone information, use \texttt{tz\_localize(\textit{None})} or \texttt{tz\_convert(\textit{None})}. \texttt{tz\_localize(\textit{None})} will remove the time zone yielding the local time representation. \texttt{tz\_convert(\textit{None})} will remove the time zone after converting to UTC time.

\begin{verbatim}
In [469]: didx = pd.date_range(start="2014-08-01 09:00", freq="H", periods=3, tz="US/Eastern")
In [470]: didx
Out[470]:
DatetimeIndex(['2014-08-01 09:00:00+04:00', '2014-08-01 10:00:00+04:00',
              '2014-08-01 11:00:00+04:00'],
dtype='datetime64[ns, US/Eastern]', freq='H')
In [471]: didx.tz_localize(\textit{None})
Out[471]:
DatetimeIndex(['2014-08-01 09:00:00', '2014-08-01 10:00:00',
              '2014-08-01 11:00:00'],
dtype='datetime64[ns]', freq=None)
In [472]: didx.tz_convert(\textit{None})
Out[472]:
DatetimeIndex(['2014-08-01 13:00:00', '2014-08-01 14:00:00',
\end{verbatim}
Fold

New in version 1.1.0.

For ambiguous times, pandas supports explicitly specifying the keyword-only fold argument. Due to daylight saving time, one wall clock time can occur twice when shifting from summer to winter time; fold describes whether the datetime-like corresponds to the first (0) or the second time (1) the wall clock hits the ambiguous time. Fold is supported only for constructing from naive datetime.datetime (see datetime documentation for details) or from Timestamp or for constructing from components (see below). Only dateutil timezones are supported (see dateutil documentation for dateutil methods that deal with ambiguous datetimes) as pytz timezones do not support fold (see pytz documentation for details on how pytz deals with ambiguous datetimes). To localize an ambiguous datetime with pytz, please use Timestamp.tz_localize(). In general, we recommend to rely on Timestamp.tz_localize() when localizing ambiguous datetimes if you need direct control over how they are handled.

In [474]: pd.Timestamp(  ......:     datetime.datetime(2019, 10, 27, 1, 30, 0, 0),  ......:     tz="dateutil/Europe/London",  ......:     fold=0,  ......: )  ......:
Out[474]: Timestamp('2019-10-27 01:30:00+0100', tz='dateutil/\usr/share/zoneinfo/Europe/London')

In [475]: pd.Timestamp(  ......:     year=2019,  ......:     month=10,  ......:     day=27,  ......:     hour=1,  ......:     minute=30,  ......:     tz="dateutil/Europe/London",  ......:     fold=1,  ......: )  ......:
Out[475]: Timestamp('2019-10-27 01:30:00+0000', tz='dateutil/\usr/share/zoneinfo/Europe/London')
Ambiguous times when localizing

tz_localize may not be able to determine the UTC offset of a timestamp because daylight savings time (DST) in a local time zone causes some times to occur twice within one day (“clocks fall back”). The following options are available:

- 'raise': Raises a pytz.AmbiguousTimeError (the default behavior)
- 'infer': Attempt to determine the correct offset base on the monotonicity of the timestamps
- 'NaT': Replaces ambiguous times with NaT
- 'bool': True represents a DST time, False represents non-DST time. An array-like of bool values is supported for a sequence of times.

```
In [476]: rng_hourly = pd.DatetimeIndex(
          ['11/06/2011 00:00', '11/06/2011 01:00', '11/06/2011 01:00', '11/06/2011 02:00'])

In [2]: rng_hourly.tz_localize('US/Eastern')
AmbiguousTimeError: Cannot infer dst time from Timestamp('2011-11-06 01:00:00'), try using the 'ambiguous' argument
```

Handle these ambiguous times by specifying the following.

```
In [477]: rng_hourly.tz_localize("US/Eastern", ambiguous="infer")
Out[477]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', '2011-11-06 01:00:00-04:00',
              '2011-11-06 01:00:00-05:00', '2011-11-06 02:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)
```

```
In [478]: rng_hourly.tz_localize("US/Eastern", ambiguous="NaT")
Out[478]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', 'NaT', 'NaT',
              '2011-11-06 02:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)
```

```
In [479]: rng_hourly.tz_localize("US/Eastern", ambiguous=[True, True, False, False])
Out[479]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', '2011-11-06 01:00:00-04:00',
              '2011-11-06 01:00:00-05:00', '2011-11-06 02:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)
```

Nonexistent times when localizing

A DST transition may also shift the local time ahead by 1 hour creating nonexistent local times (“clocks spring forward”). The behavior of localizing timeseries with nonexistent times can be controlled by the nonexistent argument. The following options are available:

- 'raise': Raises a pytz.NonExistentTimeError (the default behavior)
- 'NaT': Replaces nonexistent times with NaT
- 'shift_forward': Shifts nonexistent times forward to the closest real time

2.20. Time series / date functionality
• 'shift_backward': Shifts nonexistent times backward to the closest real time
• timedelta object: Shifts nonexistent times by the timedelta duration

In [480]: dti = pd.date_range(start="2015-03-29 02:30:00", periods=3, freq="H")
# 2:30 is a nonexistent time

Localization of nonexistent times will raise an error by default.

In [2]: dti.tz_localize('Europe/Warsaw')
NonExistentTimeError: 2015-03-29 02:30:00

Transform nonexistent times to NaT or shift the times.

In [481]: dti
Out[481]:
DatetimeIndex(['2015-03-29 02:30:00', '2015-03-29 03:30:00',
                '2015-03-29 04:30:00'],
dtype='datetime64[ns]', freq='H')

In [482]: dti.tz_localize("Europe/Warsaw", nonexistent="shift_forward")
Out[482]:
DatetimeIndex(['2015-03-29 03:00:00+02:00', '2015-03-29 03:30:00+02:00',
                '2015-03-29 04:30:00+02:00'],
dtype='datetime64[ns, Europe/Warsaw]', freq=None)

In [483]: dti.tz_localize("Europe/Warsaw", nonexistent="shift_backward")
Out[483]:
DatetimeIndex(['2015-03-29 01:59:59.999999999+01:00',
                '2015-03-29 03:30:00+02:00',
                '2015-03-29 04:30:00+02:00'],
dtype='datetime64[ns, Europe/Warsaw]', freq=None)

In [484]: dti.tz_localize("Europe/Warsaw", nonexistent=pd.Timedelta(1, unit="H"))
Out[484]:
DatetimeIndex(['2015-03-29 03:30:00+02:00', '2015-03-29 03:30:00+02:00',
                '2015-03-29 04:30:00+02:00'],
dtype='datetime64[ns, Europe/Warsaw]', freq=None)

In [485]: dti.tz_localize("Europe/Warsaw", nonexistent="NaT")
Out[485]:
DatetimeIndex(['NaT', '2015-03-29 03:30:00+02:00',
                '2015-03-29 04:30:00+02:00'],
dtype='datetime64[ns, Europe/Warsaw]', freq=None)

Time zone series operations

A Series with time zone naive values is represented with a dtype of datetime64[ns].

In [486]: s_naive = pd.Series(pd.date_range("20130101", periods=3))

In [487]: s_naive
Out[487]:
0   2013-01-01
1   2013-01-02

(continues on next page)
A Series with a time zone aware values is represented with a dtype of `datetime64[ns, tz]` where `tz` is the time zone.

```python
In [488]: s_aware = pd.Series(pd.date_range("20130101", periods=3, tz="US/Eastern"))

In [489]: s_aware
Out[489]:
0  2013-01-01 00:00:00-05:00
1  2013-01-02 00:00:00-05:00
2  2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

Both of these Series time zone information can be manipulated via the `.dt` accessor, see the dt accessor section.

For example, to localize and convert a naive stamp to time zone aware.

```python
In [490]: s_naive.dt.tz_localize("UTC").dt.tz_convert("US/Eastern")
Out[490]:
0  2012-12-31 19:00:00-05:00
1  2013-01-01 19:00:00-05:00
2  2013-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

Time zone information can also be manipulated using the `astype` method. This method can convert between different timezone-aware dtypes.

```python
# convert to a new time zone
In [491]: s_aware.astype("datetime64[ns, CET]"")
Out[491]:
0  2013-01-01 06:00:00+01:00
1  2013-01-02 06:00:00+01:00
2  2013-01-03 06:00:00+01:00
dtype: datetime64[ns, CET]
```

**Note:** Using `Series.to_numpy()` on a Series, returns a NumPy array of the data. NumPy does not currently support time zones (even though it is printing in the local time zone!), therefore an object array of Timestamps is returned for time zone aware data:

```python
In [492]: s_naive.to_numpy()
Out[492]:
array(['2013-01-01T00:00:00.000000000', '2013-01-02T00:00:00.000000000',
      '2013-01-03T00:00:00.000000000'], dtype='datetime64[ns]')

In [493]: s_aware.to_numpy()
Out[493]:
array([Timestamp('2013-01-01 00:00:00-0500', tz='US/Eastern'),
      Timestamp('2013-01-02 00:00:00-0500', tz='US/Eastern'),
      Timestamp('2013-01-03 00:00:00-0500', tz='US/Eastern')],
      dtype=object)
```

By converting to an object array of Timestamps, it preserves the time zone information. For example, when converting back to a Series:
However, if you want an actual NumPy `datetime64[ns]` array (with the values converted to UTC) instead of an array of objects, you can specify the `dtype` argument:

```python
In [495]: s_aware.to_numpy(dtype="datetime64[ns"]
Out[495]:
array(['2013-01-01T05:00:00.000000000', '2013-01-02T05:00:00.000000000',
       '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')
```

### 2.21 Time deltas

Timedeltas are differences in times, expressed in difference units, e.g. days, hours, minutes, seconds. They can be both positive and negative.

`Timedelta` is a subclass of `datetime.timedelta`, and behaves in a similar manner, but allows compatibility with `np.timedelta64` types as well as a host of custom representation, parsing, and attributes.

#### 2.21.1 Parsing

You can construct a `Timedelta` scalar through various arguments, including ISO 8601 Duration strings.

```python
In [1]: import datetime

# strings
In [2]: pd.Timedelta("1 days")
Out[2]: Timedelta('1 days 00:00:00')

In [3]: pd.Timedelta("1 days 00:00:00")
Out[3]: Timedelta('1 days 00:00:00')

In [4]: pd.Timedelta("1 days 2 hours")
Out[4]: Timedelta('1 days 02:00:00')

In [5]: pd.Timedelta("-1 days 2 min 3us")
Out[5]: Timedelta('-2 days +23:57:59.999997')

# like datetime.timedelta
# note: these MUST be specified as keyword arguments
In [6]: pd.Timedelta(days=1, seconds=1)
Out[6]: Timedelta('1 days 00:00:01')

# integers with a unit
In [7]: pd.Timedelta(1, unit="d")
Out[7]: Timedelta('1 days 00:00:00')

# from a datetime.timedelta/np.timedelta64
```

(continues on next page)
In [8]: pd.Timedelta(datetime.timedelta(days=1, seconds=1))
Out[8]: Timedelta('1 days 00:00:01')

In [9]: pd.Timedelta(np.timedelta64(1, "ms"))
Out[9]: Timedelta('0 days 00:00:00.001000')

# negative Timedeltas have this string repr
# to be more consistent with datetime.timedelta conventions
In [10]: pd.Timedelta("-1us")
Out[10]: Timedelta('-1 days +23:59:59.999999')

# a NaT
In [11]: pd.Timedelta("nan")
Out[11]: NaT

In [12]: pd.Timedelta("nat")
Out[12]: NaT

# ISO 8601 Duration strings
In [13]: pd.Timedelta("P0DT0H1M0S")
Out[13]: Timedelta('0 days 00:01:00')

In [14]: pd.Timedelta("P0DT0H0M0.000000123S")
Out[14]: Timedelta('0 days 00:00:00.000000123')

DateOffsets (Day, Hour, Minute, Second, Milli, Micro, Nano) can also be used in construction.

In [15]: pd.Timedelta(pd.offsets.Second(2))
Out[15]: Timedelta('0 days 00:00:02')

Further, operations among the scalars yield another scalar Timedelta.

        ─Timedelta(
            ....: "00:00:00.000123"
            ....: )
            ....:
Out[16]: Timedelta('2 days 00:00:02.000123')

to_timedelta

Using the top-level pd.to_timedelta, you can convert a scalar, array, list, or Series from a recognized timedelta format / value into a Timedelta type. It will construct Series if the input is a Series, a scalar if the input is scalar-like, otherwise it will output a TimedeltaIndex.

You can parse a single string to a Timedelta:

In [17]: pd.to_timedelta("1 days 06:05:01.00003")
Out[17]: Timedelta('1 days 06:05:01.000030')

In [18]: pd.to_timedelta("15.5us")
Out[18]: Timedelta('0 days 00:00:00.000015500')

or a list/array of strings:
In [19]: pd.to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
Out[19]: TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015500', NaT],
                        dtype='timedelta64[ns]', freq=None)

The unit keyword argument specifies the unit of the Timedelta:

In [20]: pd.to_timedelta(np.arange(5), unit="s")
Out[20]: TimedeltaIndex(['0 days 00:00:00', '0 days 00:00:01', '0 days 00:00:02',
                         '0 days 00:00:03', '0 days 00:00:04'],
                        dtype='timedelta64[ns]', freq=None)

In [21]: pd.to_timedelta(np.arange(5), unit="d")
Out[21]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
                        dtype='timedelta64[ns]', freq=None)

Timedelta limitations

pandas represents Timedeltas in nanosecond resolution using 64 bit integers. As such, the 64 bit integer limits determine the Timedelta limits.

In [22]: pd.Timedelta.min
Out[22]: Timedelta('-106752 days +00:12:43.145224193')

In [23]: pd.Timedelta.max
Out[23]: Timedelta('106751 days 23:47:16.854775807')

2.21.2 Operations

You can operate on Series/DataFrames and construct timedelta64[ns] Series through subtraction operations on datetime64[ns] Series, or Timestamps.

In [24]: s = pd.Series(pd.date_range("2012-1-1", periods=3, freq="D"))
In [25]: td = pd.Series([pd.Timedelta(days=i) for i in range(3)])
In [26]: df = pd.DataFrame({"A": s, "B": td})
In [27]: df
Out[27]:
     A     B
0 2012-01-01 0 days
1 2012-01-02 1 days
2 2012-01-03 2 days

In [28]: df["C"] = df["A"] + df["B"]
In [29]: df
Out[29]:
     A     B     C
0 2012-01-01 0 days 2012-01-01
1 2012-01-02 1 days 2012-01-03
2 2012-01-03 2 days 2012-01-05
In [30]: df.dtypes
Out[30]:
A    datetime64[ns]
B    timedelta64[ns]
C    datetime64[ns]
dtype: object

In [31]: s - s.max()
Out[31]:
0    -2 days
1    -1 days
2     0 days
dtype: timedelta64[ns]

In [32]: s - datetime.datetime(2011, 1, 1, 3, 5)
Out[32]:
0    364 days 20:55:00
1    365 days 20:55:00
2    366 days 20:55:00
dtype: timedelta64[ns]

In [33]: s + datetime.timedelta(minutes=5)
Out[33]:
0    2012-01-01 00:05:00
1    2012-01-02 00:05:00
2    2012-01-03 00:05:00
dtype: datetime64[ns]

In [34]: s + pd.offsets.Minute(5)
Out[34]:
0    2012-01-01 00:05:00
1    2012-01-02 00:05:00
2    2012-01-03 00:05:00
dtype: datetime64[ns]

In [35]: s + pd.offsets.Minute(5) + pd.offsets.Milli(5)
Out[35]:
0    2012-01-01 00:05:00.005
1    2012-01-02 00:05:00.005
2    2012-01-03 00:05:00.005
dtype: datetime64[ns]

Operations with scalars from a timedelta64[ns] series:

In [36]: y = s - s[0]

In [37]: y
Out[37]:
0    0 days
1    1 days
2    2 days
dtype: timedelta64[ns]

Series of timedeltas with NaT values are supported:

In [38]: y = s - s.shift()
In [39]: y
Out[39]:
0    NaT
1    1 days
2    1 days
dtype: timedelta64[ns]

Elements can be set to `NaT` using `np.nan` analogously to datetimes:

In [40]: y[1] = np.nan

In [41]: y
Out[41]:
0    NaT
1    NaT
2    1 days
dtype: timedelta64[ns]

Operands can also appear in a reversed order (a singular object operated with a Series):

In [42]: s.max() - s
Out[42]:
0   2 days
1   1 days
2   0 days
dtype: timedelta64[ns]

In [43]: datetime.datetime(2011, 1, 1, 3, 5) - s
Out[43]:
0  -365 days +03:05:00
1  -366 days +03:05:00
2  -367 days +03:05:00
dtype: timedelta64[ns]

In [44]: datetime.timedelta(minutes=5) + s
Out[44]:
0 2012-01-01 00:05:00
1 2012-01-02 00:05:00
2 2012-01-03 00:05:00
dtype: datetime64[ns]

`min`, `max` and the corresponding `idxmin`, `idxmax` operations are supported on frames:

In [45]: A = s - pd.Timestamp("20120101") - pd.Timedelta("00:05:05")

In [46]: B = s - pd.Series(pd.date_range("2012-1-2", periods=3, freq="D"))

In [47]: df = pd.DataFrame({"A": A, "B": B})

In [48]: df
Out[48]:
     A      B
0 -1 days +23:54:55 -1 days
1   0 days 23:54:55 -1 days
2   1 days 23:54:55 -1 days

In [49]: df.min()
min, max, idxmin, idxmax operations are supported on Series as well. A scalar result will be a Timedelta.

You can fillna on timedeltas, passing a timedelta to get a particular value.
1 -1 days +00:00:05
2 1 days 00:00:00
dtype: timedelta64[ns]

You can also negate, multiply and use abs on Timedeltas:

```
In [60]: tdl = pd.Timedelta("-1 days 2 hours 3 seconds")
In [61]: tdl
Out[61]: Timedelta('-2 days +21:59:57')
In [62]: -1 * tdl
Out[62]: Timedelta('1 days 02:00:03')
In [63]: -tdl
Out[63]: Timedelta('1 days 02:00:03')
In [64]: abs(tdl)
Out[64]: Timedelta('1 days 02:00:03')
```

### 2.21.3 Reductions

Numeric reduction operation for timedelta64[ns] will return Timedelta objects. As usual NaT are skipped during evaluation.

```
In [65]: y2 = pd.Series(
       ...:     pd.to_timedelta(["-1 days +00:00:05", "nat", "-1 days +00:00:05", "1 days -"]))
       ...: )
       ...
In [66]: y2
Out[66]:
0  -1 days +00:00:05
1     NaT
2  -1 days +00:00:05
3     1 days
      dtype: timedelta64[ns]
In [67]: y2.mean()
Out[67]: Timedelta('-1 days +16:00:03.333333334')
In [68]: y2.median()
Out[68]: Timedelta('-1 days +00:00:05')
In [69]: y2.quantile(0.1)
Out[69]: Timedelta('-1 days +00:00:05')
In [70]: y2.sum()
Out[70]: Timedelta('-1 days +00:00:10')
```
2.21.4 Frequency conversion

Timedelta Series, TimedeltaIndex, and Timedelta scalars can be converted to other ‘frequencies’ by dividing by another timedelta, or by astyping to a specific timedelta type. These operations yield Series and propagate NaT -> nan. Note that division by the NumPy scalar is true division, while astyping is equivalent of floor division.

```
In [71]: december = pd.Series(pd.date_range("20121201", periods=4))
In [72]: january = pd.Series(pd.date_range("20130101", periods=4))
In [73]: td = january - december
In [74]: td[2] += datetime.timedelta(minutes=5, seconds=3)
In [75]: td[3] = np.nan
In [76]: td
Out[76]:
0  31 days 00:00:00
1  31 days 00:00:00
2  31 days 00:05:03
3   NaT
dtype: timedelta64[ns]

# to days
In [77]: td / np.timedelta64(1, "D")
Out[77]:
0  31.000000
1  31.000000
2  31.003507
3    NaN
dtype: float64

In [78]: td.astype("timedelta64[D]")
Out[78]:
0  31.0
1  31.0
2  31.0
3    NaN
dtype: float64

# to seconds
In [79]: td / np.timedelta64(1, "s")
Out[79]:
0  2678400.0
1  2678400.0
2  2678703.0
3    NaN
dtype: float64

In [80]: td.astype("timedelta64[s]")
Out[80]:
0  2678400.0
1  2678400.0
2  2678703.0
3    NaN
dtype: float64
```
Dividing or multiplying a `timedelta64[ns]` Series by an integer or integer Series yields another `timedelta64[ns]` dtypes Series.

Rounded division (floor-division) of a `timedelta64[ns]` Series by a scalar `Timedelta` gives a series of integers.

The mod (%) and divmod operations are defined for `Timedelta` when operating with another timedelta-like or with a numeric argument.
2.21.5 Attributes

You can access various components of the Timedelta or TimedeltaIndex directly using the attributes `days, seconds, microseconds, nanoseconds`. These are identical to the values returned by `datetime.timedelta`, in that, for example, the `.seconds` attribute represents the number of seconds >= 0 and < 1 day. These are signed according to whether the Timedelta is signed.

These operations can also be directly accessed via the `.dt` property of the Series as well.

Note: Note that the attributes are NOT the displayed values of the Timedelta. Use `.components` to retrieve the displayed values.

For a Series:

```python
In [89]: td.dt.days
Out[89]:
0    31.0
1    31.0
2    31.0
3    NaN
dtype: float64

In [90]: td.dt.seconds
Out[90]:
0    0.0
1    0.0
2   303.0
3    NaN
dtype: float64
```

You can access the value of the fields for a scalar Timedelta directly.

```python
In [91]: tds = pd.Timedelta("31 days 5 min 3 sec")
In [92]: tds.days
Out[92]: 31
In [93]: tds.seconds
Out[93]: 303
In [94]: (-tds).seconds
Out[94]: 86097
```

You can use the `.components` property to access a reduced form of the timedelta. This returns a DataFrame indexed similarly to the Series. These are the displayed values of the Timedelta.

```python
In [95]: td.dt.components
Out[95]:
          days  hours  minutes  seconds  milliseconds  microseconds
0  32.000000  0.000    0.000    0.000000    0.000000
```

2.21. Time deltas 875
You can convert a Timedelta to an ISO 8601 Duration string with the .isoformat method

```python
In [97]: pd.Timedelta(
    ...:     days=6, minutes=50, seconds=3, milliseconds=10, microseconds=10, nanoseconds=12
    ...: ).isoformat()
```

```text
Out[97]: 'P6DT0H50M3.010010012S'
```

## 2.21.6 TimedeltaIndex

To generate an index with time delta, you can use either the `TimedeltaIndex` or the `timedelta_range()` constructor.

Using `TimedeltaIndex` you can pass string-like, Timedelta, timedelta, or np.timedelta64 objects. Passing `np.nan/pd.NaT/nat` will represent missing values.

```python
In [98]: pd.TimedeltaIndex(
    ...:     ['1 days', '1 days, 00:00:05', np.timedelta64(2, 'D'),
    ...:      datetime.timedelta(days=2, seconds=2)],
    ...:     dtype='timedelta64[ns]', freq=None)
```

```text
Out[98]: TimedeltaIndex(['1 days 00:00:00', '1 days 00:00:05', '2 days 00:00:02'],
                           dtype='timedelta64[ns]', freq=None)
```

The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation:

```python
In [99]: pd.TimedeltaIndex(['0 days', '10 days', '20 days'], freq="infer")
```

```text
Out[99]: TimedeltaIndex(['0 days', '10 days', '20 days'], dtype='timedelta64[ns]',
                           freq='10D')
```
Generating ranges of time deltas

Similar to `date_range()`, you can construct regular ranges of a TimedeltaIndex using `timedelta_range()`. The default frequency for `timedelta_range` is calendar day:

```python
In [100]: pd.timedelta_range(start="1 days", periods=5)
Out[100]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'], dtype='timedelta64[ns]', freq='D')
```

Variations of `start`, `end`, and `periods` can be used with `timedelta_range`:

```python
In [101]: pd.timedelta_range(start="1 days", end="5 days")
Out[101]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'], dtype='timedelta64[ns]', freq='D')

In [102]: pd.timedelta_range(end="10 days", periods=4)
Out[102]: TimedeltaIndex(['7 days', '8 days', '9 days', '10 days'], dtype='timedelta64[ns]', freq='D')
```

The `freq` parameter can pass a variety of frequency aliases:

```python
In [103]: pd.timedelta_range(start="1 days", end="2 days", freq="30T")
Out[103]:
TimedeltaIndex(['1 days 00:00:00', '1 days 00:30:00', '1 days 01:00:00',
                '1 days 01:30:00', '1 days 02:00:00', '1 days 02:30:00',
                '1 days 03:00:00', '1 days 03:30:00', '1 days 04:00:00',
                '1 days 04:30:00', '1 days 05:00:00', '1 days 05:30:00',
                '1 days 06:00:00', '1 days 06:30:00', '1 days 07:00:00',
                '1 days 07:30:00', '1 days 08:00:00', '1 days 08:30:00',
                '1 days 09:00:00', '1 days 09:30:00', '1 days 10:00:00',
                '1 days 10:30:00', '1 days 11:00:00', '1 days 11:30:00',
                '1 days 12:00:00', '1 days 12:30:00', '1 days 13:00:00',
                '1 days 13:30:00', '1 days 14:00:00', '1 days 14:30:00',
                '1 days 15:00:00', '1 days 15:30:00', '1 days 16:00:00',
                '1 days 16:30:00', '1 days 17:00:00', '1 days 17:30:00',
                '1 days 18:00:00', '1 days 18:30:00', '1 days 19:00:00',
                '1 days 19:30:00', '1 days 20:00:00', '1 days 20:30:00',
                '1 days 21:00:00', '1 days 21:30:00', '1 days 22:00:00',
                '1 days 22:30:00', '1 days 23:00:00', '1 days 23:30:00',
                '2 days 00:00:00'],
dtype='timedelta64[ns]', freq='30T')

In [104]: pd.timedelta_range(start="1 days", periods=5, freq="2D5H")
Out[104]:
TimedeltaIndex(['1 days 00:00:00', '3 days 05:00:00', '5 days 10:00:00',
                '7 days 15:00:00', '9 days 20:00:00'],
dtype='timedelta64[ns]', freq='53H')
```

Specifying `start`, `end`, and `periods` will generate a range of evenly spaced timedeltas from `start` to `end` inclusively, with `periods` number of elements in the resulting TimedeltaIndex:

```python
In [105]: pd.timedelta_range("0 days", "4 days", periods=5)
Out[105]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'], dtype='timedelta64[ns]', freq=None)

In [106]: pd.timedelta_range("0 days", "4 days", periods=10)
Out[106]: TimedeltaIndex(['0 days 00:00:00', '0 days 10:40:00', '0 days 21:20:00','0 days 32:00:00'])
```
Using the TimedeltaIndex

Similarly to other of the datetime-like indices, DatetimeIndex and PeriodIndex, you can use TimedeltaIndex as the index of pandas objects.

```
In [107]: s = pd.Series(
       ....:     np.arange(100),
       ....:     index=pd.timedelta_range("1 days", periods=100, freq="h"),
       ....:     )
       ....:

In [108]: s
Out[108]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
    ...
4 days 23:00:00    95
5 days 00:00:00    96
5 days 01:00:00    97
5 days 02:00:00    98
5 days 03:00:00    99
Freq: H, Length: 100, dtype: int64

In [109]: s["1 day":"2 day"]
Out[109]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
    ...
2 days 19:00:00    43
2 days 20:00:00    44
2 days 21:00:00    45
2 days 22:00:00    46
2 days 23:00:00    47
Freq: H, Length: 48, dtype: int64

In [110]: s["1 day 01:00:00"]
Out[110]: 1

In [111]: s[pd.Timedelta("1 day 1h")]
Out[111]: 1
```

Furthermore you can use partial string selection and the range will be inferred:
In [112]: s["1 day":"1 day 5 hours"]
Out[112]:
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>5</td>
</tr>
</tbody>
</table>
Freq: H, dtype: int64

Operations

Finally, the combination of TimedeltaIndex with DatetimeIndex allow certain combination operations that are NaT preserving:

In [113]: tdi = pd.TimedeltaIndex(['1 days', pd.NaT, '2 days'])

In [114]: tdi.to_list()  
Out[114]: [Timedelta('1 days 00:00:00'), NaT, Timedelta('2 days 00:00:00')]

In [115]: dti = pd.date_range("20130101", periods=3)

In [116]: dti.to_list()  
Out[116]: [Timestamp('2013-01-01 00:00:00', freq='D'),
          Timestamp('2013-01-02 00:00:00', freq='D'),
          Timestamp('2013-01-03 00:00:00', freq='D')]

In [117]: (dti + tdi).to_list()  
Out[117]: [Timestamp('2013-01-02 00:00:00'), NaT, Timestamp('2013-01-05 00:00:00')]

In [118]: (dti - tdi).to_list()  
Out[118]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2013-01-01 00:00:00')]

Conversions

Similarly to frequency conversion on a Series above, you can convert these indices to yield another Index.

In [119]: tdi / np.timedelta64(1, "s")  
Out[119]: Float64Index([86400.0, nan, 172800.0], dtype='float64')

In [120]: tdi.astype("timedelta64[s]")  
Out[120]: Float64Index([86400.0, nan, 172800.0], dtype='float64')

Scalars type ops work as well. These can potentially return a different type of index.

# adding or timedelta and date -> datelike
In [121]: tdi + pd.Timestamp("20130101")  
Out[121]: DatetimeIndex(['2013-01-02', 'NaT', '2013-01-03'], dtype='datetime64[ns]',
                       freq=None)

# subtraction of a date and a timedelta -> datelike
# note that trying to subtract a date from a Timedelta will raise an exception
In [122]: (pd.Timestamp("20130101") - tdi).to_list()  

(continues on next page)
2.21.7 Resampling

Similar to `timeseries resampling`, we can resample with a `TimedeltaIndex`.

```python
In [126]: s.resample("D").mean()
Out[126]:
    1 days    11.5
    2 days    35.5
    3 days    59.5
    4 days    83.5
    5 days    97.5
Freq: D, dtype: float64
```

2.22 Options and settings

2.22.1 Overview

pandas has an options system that lets you customize some aspects of its behaviour, display-related options being those the user is most likely to adjust.

Options have a full “dotted-style”, case-insensitive name (e.g. `display.max_rows`). You can get/set options directly as attributes of the top-level `options` attribute:

```python
In [1]: import pandas as pd
In [2]: pd.options.display.max_rows
Out[2]: 15
In [3]: pd.options.display.max_rows = 999
In [4]: pd.options.display.max_rows
Out[4]: 999
```

The API is composed of 5 relevant functions, available directly from the `pandas` namespace:

- `get_option()` / `set_option()` - get/set the value of a single option.
- `reset_option()` - reset one or more options to their default value.
- `describe_option()` - print the descriptions of one or more options.
- `option_context()` - execute a codeblock with a set of options that revert to prior settings after execution.

Note: Developers can check out pandas/core/config_init.py for more information.

All of the functions above accept a regexp pattern (re.search style) as an argument, and so passing in a substring will work - as long as it is unambiguous:

```python
In [5]: pd.get_option("display.max_rows")
Out[5]: 999

In [6]: pd.set_option("display.max_rows", 101)

In [7]: pd.get_option("display.max_rows")
Out[7]: 101

In [8]: pd.set_option("max_r", 102)

In [9]: pd.get_option("display.max_rows")
Out[9]: 102
```

The following will **not work** because it matches multiple option names, e.g. display.max_colwidth, display.max_rows,display.max_columns:

```python
In [10]: try:
.....:     pd.get_option("column")
.....: except KeyError as e:
.....:     print(e)
.....: 'Pattern matched multiple keys'
```

Note: Using this form of shorthand may cause your code to break if new options with similar names are added in future versions.

You can get a list of available options and their descriptions with `describe_option`. When called with no argument `describe_option` will print out the descriptions for all available options.

### 2.22.2 Getting and setting options

As described above, `get_option()` and `set_option()` are available from the pandas namespace. To change an option, call `set_option('option regex', new_value)`. 

```python
In [11]: pd.get_option("mode.sim_interactive")
Out[11]: False

In [12]: pd.set_option("mode.sim_interactive", True)

In [13]: pd.get_option("mode.sim_interactive")
Out[13]: True
```

Note: The option ‘mode.sim_interactive’ is mostly used for debugging purposes.

All options also have a default value, and you can use `reset_option` to do just that:
**2.22.3 Setting startup options in Python/IPython environment**

Using startup scripts for the Python/IPython environment to import pandas and set options makes working with pandas more efficient. To do this, create a .py or .ipy script in the startup directory of the desired profile. An example where the startup folder is in a default IPython profile can be found at:

```
$IPYTHONDIR/profile_default/startup
```

More information can be found in the IPython documentation. An example startup script for pandas is displayed below:

```python
import pandas as pd

pd.set_option("display.max_rows", 999)
pd.set_option("precision", 5)
```
2.22.4 Frequently used options

The following is a walk-through of the more frequently used display options.

display.max_rows and display.max_columns sets the maximum number of rows and columns displayed when a frame is pretty-printed. Truncated lines are replaced by an ellipsis.

```
In [23]: df = pd.DataFrame(np.random.randn(7, 2))
In [24]: pd.set_option("max_rows", 7)
In [25]: df
Out[25]:
   0   1
0  0.469112 -0.282863
1 -1.509059 -1.135632
2  1.212112 -0.173215
3  0.119209 -1.044236
4 -0.861849 -2.104569
5 -0.494929  1.071804
6  0.721555 -0.706771

In [26]: pd.set_option("max_rows", 5)
In [27]: df
Out[27]:
   0   1
0  0.469112 -0.282863
1 -1.509059 -1.135632
2  1.212112 -0.173215
3  0.119209 -1.044236
4 -0.861849 -2.104569
5 -0.494929  1.071804
6  0.721555 -0.706771
[7 rows x 2 columns]

In [28]: pd.reset_option("max_rows")
```

Once the display.max_rows is exceeded, the display.min_rows options determines how many rows are shown in the truncated repr.

```
In [29]: pd.set_option("max_rows", 8)
In [30]: pd.set_option("min_rows", 4)
# below max_rows -> all rows shown
In [31]: df = pd.DataFrame(np.random.randn(7, 2))
In [32]: df
Out[32]:
   0   1
0 -1.039575  0.271860
1 -0.424972  0.567020
2  0.276232 -1.087401
3 -0.673690  0.113648
4 -1.478427  0.524988
5  0.404705  0.577046
6 -1.715002 -1.039268
(continues on next page)
```
# above max_rows \rightarrow only min_rows (4) rows shown

```
In [33]: df = pd.DataFrame(np.random.randn(9, 2))

In [34]: df
Out[34]:
   0    1
0 -0.370647 -1.157892
1 -1.344312  0.844885
2    ...    ...
7  0.276662 -0.472035
8 -0.013960 -0.362543
[9 rows x 2 columns]
```

```
In [35]: pd.reset_option("max_rows")

In [36]: pd.reset_option("min_rows")
```

display.expand_frame_repr allows for the representation of dataframes to stretch across pages, wrapped over the full column vs row-wise.

```
In [37]: df = pd.DataFrame(np.random.randn(5, 10))

In [38]: pd.set_option("expand_frame_repr", True)

In [39]: df
Out[39]:
   0      1      2      3      4      5      6      7      8      9
0 -0.006154 -0.923061  0.895717  0.805244 -1.206412  2.565646  1.431256  1.340309 -1.170299 -0.226169
1  0.410835  0.813850 -0.132003 -0.827317 -0.076467 -1.187678  1.130127 -1.436373 -1.941368  1.607920
2  1.024180  0.569605  0.875906 -2.211372  0.974466 -2.006747 -0.410001 -0.078638  0.545952 -1.219217
3 -1.226825  0.769804 -1.281247 -0.727707 -0.121306 -0.097883  0.695775  0.341734  0.959726 -1.110336
4 -0.619976  0.149748 -0.732339  0.687738  0.176444  0.403310 -0.154951  0.301624 -1.798611 -1.369849
```

```
In [40]: pd.set_option("expand_frame_repr", False)

In [41]: df
Out[41]:
   0      1      2      3      4      5      6      7      8      9
0 -0.006154 -0.923061  0.895717  0.805244 -1.206412  2.565646  1.431256  1.340309 -1.170299 -0.226169
1  0.410835  0.813850 -0.132003 -0.827317 -0.076467 -1.187678  1.130127 -1.436373 -1.941368  1.607920
2  1.024180  0.569605  0.875906 -2.211372  0.974466 -2.006747 -0.410001 -0.078638  0.545952 -1.219217
3 -1.226825  0.769804 -1.281247 -0.727707 -0.121306 -0.097883  0.695775  0.341734  0.959726 -1.110336

```

In [42]: `pd.reset_option("expand_frame_repr")`

display.large_repr lets you select whether to display dataframes that exceed max_columns or max_rows as a truncated frame, or as a summary.

In [43]: `df = pd.DataFrame(np.random.randn(10, 10))`
In [44]: `pd.set_option("max_rows", 5)`
In [45]: `pd.set_option("large_repr", "truncate")`

In [46]: `df`
Out[46]:
```
   0  1  2  3  4  5  6  7...
  0 -0.9542 1.4627 -1.7432 -0.8266 -0.3454 0.6906 0.9960
  7...
  8 -0.3034 -0.8584 0.3069 -0.0287 0.3843 1.5742 1.5889
  9 -0.0148 -0.2843 0.6508 -1.4617 -1.1377 -0.8911 1.6136
[10 rows x 10 columns]
```

In [47]: `pd.set_option("large_repr", "info")`

In [48]: `df`
Out[48]:
```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10 entries, 0 to 9
Data columns (total 10 columns):
   # Column Non-Null Count  Dtype
  --- ------ -------------- ------
     0      10 non-null   float64
     1      10 non-null   float64
     2      10 non-null   float64
     3      10 non-null   float64
     4      10 non-null   float64
     5      10 non-null   float64
     6      10 non-null   float64
     7      10 non-null   float64
     8      10 non-null   float64
     9      10 non-null   float64
dtypes: float64(10)
memory usage: 928.0 bytes
```

In [49]: `pd.reset_option("large_repr")`

In [50]: `pd.reset_option("max_rows")`

display.max_colwidth sets the maximum width of columns. Cells of this length or longer will be truncated with an ellipsis.

2.22. Options and settings
In [51]: df = pd.DataFrame(
    ....:     np.array(
    ....:         [
    ....:             ['foo', 'bar', 'bim', 'uncomfortably long string'],
    ....:             ['horse', 'cow', 'banana', 'apple'],
    ....:         ]
    ....:     )
    ....: )
    ....: 
In [52]: pd.set_option("max_colwidth", 40)
In [53]: df
Out[53]:
          0    1    2    3
0  foo  bar  bim  uncomfortably long string
1  horse  cow  banana  apple
In [54]: pd.set_option("max_colwidth", 6)
In [55]: df
Out[55]:
          0    1    2    3
0  foo  bar  bim  un...  
1  horse  cow  ba...  apple
In [56]: pd.reset_option("max_colwidth")

display.max_info_columns sets a threshold for when by-column info will be given.

In [57]: df = pd.DataFrame(np.random.randn(10, 10))
In [58]: pd.set_option("max_info_columns", 11)
In [59]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10 entries, 0 to 9
Data columns (total 10 columns):

In [62]: pd.reset_option("max_info_columns")

display.max_info_rows: df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions then specified. Note that you can specify the option df.info(null_counts=True) to override on showing a particular frame.

In [63]: df = pd.DataFrame(np.random.choice([0, 1, np.nan], size=(10, 10)))

In [64]: df
Out[64]:

</tr>
</tbody>
</table>

### 2.22.6 Number formatting

pandas also allows you to set how numbers are displayed in the console. This option is not set through the `set_options` API.

Use the `set_eng_float_format` function to alter the floating-point formatting of pandas objects to produce a particular format.

For instance:

```python
In [87]: import numpy as np

In [88]: pd.set_eng_float_format(accuracy=3, use_eng_prefix=True)

In [89]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [90]: s / 1.0e3
Out[90]:
   a  303.638u
   b -721.084u
   c -622.696u
   d  648.250u
   e  -1.945m
dtype: float64

In [91]: s / 1.0e6
Out[91]:
   a  303.638n
   b -721.084n
   c -622.696n
   d  648.250n
   e  -1.945u
dtype: float64
```
To round floats on a case-by-case basis, you can also use `round()` and `round()`.

### 2.22.7 Unicode formatting

**Warning:** Enabling this option will affect the performance for printing of DataFrame and Series (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters whose width corresponds to two Latin characters. If a DataFrame or Series contains these characters, the default output mode may not align them properly.

**Note:** Screen captures are attached for each output to show the actual results.

```
In [92]: df = pd.DataFrame({"": ["UK", ""], "": ["Alice", ""]})
In [93]: df
Out[93]:
    0  UK  Alice
    1
```

Enabling `display.unicode.east_asian_width` allows pandas to check each character’s “East Asian Width” property. These characters can be aligned properly by setting this option to `True`. However, this will result in longer render times than the standard `len` function.

```
In [94]: pd.set_option("display.unicode.east_asian_width", True)
In [95]: df
Out[95]:
    0  UK  Alice
    1
```

```
>>> pd.set_option('display.unicode.east_asian_width', True)
>>> df
   名前  国籍
0  Alice  UK
1    しのぶ  日本
```

In addition, Unicode characters whose width is “Ambiguous” can either be 1 or 2 characters wide depending on the terminal setting or encoding. The option `display.unicode.ambiguous_as_wide` can be used to handle the ambiguity.

By default, an “Ambiguous” character’s width, such as “¡” (inverted exclamation) in the example below, is taken to be 1.

```
In [96]: df = pd.DataFrame({"a": ["xxx", "¡"], "b": ["yyy", "¡"]})
```

(continues on next page)
In 

```python
In [97]: df
Out[97]:
   a  b
0 xxx  yyy
1 ii ii
```

```python
>>> df = pd.DataFrame({'a': ['xxx', 'u'+'i'+'i'], 'b': ['yyy', 'u'+'i'+'i']})
```

```python
In [98]: df
Out[98]:
   a  b
0 xxx  yyy
1 ii ii
```

Enabling display.unicode.ambiguous_as_wide makes pandas interpret these characters’ widths to be 2. (Note that this option will only be effective when display.unicode.east_asian_width is enabled.)

However, setting this option incorrectly for your terminal will cause these characters to be aligned incorrectly:

```python
In [99]: pd.set_option("display.unicode.ambiguous_as_wide", True)
```

```python
In [100]: df
Out[100]:
   a  b
0 xxx  yyy
1 ii ii
```

2.22.8 Table schema display

DataFrame and Series will publish a Table Schema representation by default. False by default, this can be enabled globally with the display.html.table_schema option:

```python
In [100]: pd.set_option("display.html.table_schema", True)
```

Only 'display.max_rows' are serialized and published.

2.23 Enhancing performance

In this part of the tutorial, we will investigate how to speed up certain functions operating on pandas DataFrames using three different techniques: Cython, Numba and pandas.eval(). We will see a speed improvement of ~200 when we use Cython and Numba on a test function operating row-wise on the DataFrame. Using pandas.eval() we will speed up a sum by an order of ~2.

Note: In addition to following the steps in this tutorial, users interested in enhancing performance are highly encouraged to install the recommended dependencies for pandas. These dependencies are often not installed by default, but will offer speed improvements if present.
2.23.1 Cython (writing C extensions for pandas)

For many use cases writing pandas in pure Python and NumPy is sufficient. In some computationally heavy applications however, it can be possible to achieve sizable speed-ups by offloading work to cython.

This tutorial assumes you have refactored as much as possible in Python, for example by trying to remove for-loops and making use of NumPy vectorization. It’s always worth optimising in Python first.

This tutorial walks through a “typical” process of cythonizing a slow computation. We use an example from the Cython documentation but in the context of pandas. Our final cythonized solution is around 100 times faster than the pure Python solution.

Pure Python

We have a DataFrame to which we want to apply a function row-wise.

```
In [1]: df = pd.DataFrame(
    ...:     {
    ...:         "a": np.random.randn(1000),
    ...:         "b": np.random.randn(1000),
    ...:         "N": np.random.randint(100, 1000, (1000)),
    ...:         "x": "x",
    ...:     }
    ...:
)

In [2]: df
Out[2]:
          a          b          N        x
         0   0.469112  -0.218470   585   x
         1  -0.282863   -0.061645   841   x
         2  -1.509059   -0.723780   251   x
         3  -1.135632   0.551225   972   x
         4   1.212112   -0.497767   181   x
         ..         ..          ..     ..
        995 -1.512743    0.874737   374   x
        996   0.933753   1.120790   246   x
        997 -0.308013   0.198768   157   x
        998 -0.079915   1.757555   977   x
        999 -1.010589  -1.115680   770   x
[1000 rows x 4 columns]
```

Here’s the function in pure Python:

```
In [3]: def f(x):
    ...:     return x * (x - 1)
    ...:

In [4]: def integrate_f(a, b, N):
    ...:     s = 0
    ...:     dx = (b - a) / N
    ...:     for i in range(N):
    ...:         s += f(a + i * dx)
    ...:     return s * dx
    ...:
```

We achieve our result by using apply (row-wise):
In [7]: %timeit df.apply(lambda x: integrate_f(x["a"], x["b"], x["N"]), axis=1)
10 loops, best of 3: 174 ms per loop

But clearly this isn’t fast enough for us. Let’s take a look and see where the time is spent during this operation (limited to the most time consuming four calls) using the `prun` ipython magic function:

In [5]: %prun -l 4 df.apply(lambda x: integrate_f(x["a"], x["b"], x["N"]), axis=1) #
   → noqa E999
626349 function calls (626331 primitive calls) in 0.147 seconds

Ordered by: internal time
List reduced from 205 to 4 due to restriction <4>

</tbody>
</table>

By far the majority of time is spend inside either `integrate_f` or `f`, hence we’ll concentrate our efforts cythonizing these two functions.

### Plain Cython

First we’re going to need to import the Cython magic function to IPython:

In [6]: %load_ext Cython

Now, let’s simply copy our functions over to Cython as is (the suffix is here to distinguish between function versions):

In [7]: %%cython
   ...: def f_plain(x):
   ...:     return x * (x - 1)
   ...: def integrate_f_plain(a, b, N):
   ...:     s = 0
   ...:     dx = (b - a) / N
   ...:     for i in range(N):
   ...:         s += f_plain(a + i * dx)
   ...:     return s * dx

Note: If you’re having trouble pasting the above into your ipython, you may need to be using bleeding edge IPython for paste to play well with cell magics.

In [4]: %timeit df.apply(lambda x: integrate_f_plain(x["a"], x["b"], x["N"]), axis=1)
10 loops, best of 3: 85.5 ms per loop

Already this has shaved a third off, not too bad for a simple copy and paste.
Adding type

We get another huge improvement simply by providing type information:

```python
In [8]: %cython
cdef double f_typed(double x) except? -2:
   ...:     return x * (x - 1)
   ...:
cdef double integrate_f_typed(double a, double b, int N):
   ...:     cdef int i
   ...:     cdef double s, dx
   ...:     s = 0
   ...:     dx = (b - a) / N
   ...:     for i in range(N):
   ...:         s += f_typed(a + i * dx)
   ...:     return s * dx
   ...

In [4]: %timeit
df.apply(lambda x: integrate_f_typed(x["a"], x["b"], x["N"]), axis=1)
   10 loops, best of 3: 20.3 ms per loop
```

Now, we're talking! It's now over ten times faster than the original Python implementation, and we haven't really modified the code. Let's have another look at what's eating up time:

```plaintext
In [9]: %prun
df.apply(lambda x: integrate_f_typed(x["a"], x["b"], x["N"]), axis=1)
73919 function calls (73901 primitive calls) in 0.027 seconds
Ordered by: internal time
List reduced from 198 to 4 due to restriction <4>
ncalls  tottime  percall  cumtime  percall filename:lineno(function)
   3000  0.003   0.000   0.016   0.000  series.py:928(__getitem__)
   3000  0.002   0.000   0.011   0.000  series.py:1034(_get_value)
   3000  0.001   0.000   0.005   0.000  base.py:3317(get_loc)
   3000  0.001   0.000   0.004   0.000  base.py:5175(_get_values_for_loc)
```

Using ndarray

It's calling series... a lot! It's creating a Series from each row, and getting from both the index and the series (three times for each row). Function calls are expensive in Python, so maybe we could minimize these by cythonizing the apply part.

**Note:** We are now passing ndarrays into the Cython function, fortunately Cython plays very nicely with NumPy.

```python
In [10]: %cython
   ...: cimport numpy as np
   ...: import numpy as np
   ...: cdef double f_typed(double x) except? -2:
   ...:     return x * (x - 1)
   ...:
cdef double integrate_f_typed(double a, double b, int N):
   ...:     cdef int i
   ...:     cdef double s, dx
   ...:     s = 0
   ...:     dx = (b - a) / N
   ...
```

(continues on next page)
The implementation is simple, it creates an array of zeros and loops over the rows, applying our `integrate_f_typed`, and putting this in the zeros array.

**Warning:** You can not pass a Series directly as a ndarray typed parameter to a Cython function. Instead pass the actual ndarray using the `Series.to_numpy()`. The reason is that the Cython definition is specific to an ndarray and not the passed Series.

So, do not do this:

```
apply_integrate_f(df["a"], df["b"], df["N"])
```

But rather, use `Series.to_numpy()` to get the underlying ndarray:

```
apply_integrate_f(df["a"].to_numpy(), df["b"].to_numpy(), df["N"].to_numpy())
```

**Note:** Loops like this would be extremely slow in Python, but in Cython looping over NumPy arrays is fast.

```
In [4]: %timeit apply_integrate_f(df["a"].to_numpy(), df["b"].to_numpy(), df["N"].to_numpy())
1000 loops, best of 3: 1.25 ms per loop
```

We’ve gotten another big improvement. Let’s check again where the time is spent:

```
In [11]: %prun -l 4 apply_integrate_f(df["a"].to_numpy(), df["b"].to_numpy(), df["N"].to_numpy())
260 function calls in 0.001 seconds

Ordered by: internal time
List reduced from 63 to 4 due to restriction <4>
ncalls  tottime  percall  cumtime  percall filename:lineno(function)
1  0.001    0.001  0.001    0.001 {built-in method _cython_magic_
˓→5bf25023a10e325a5ec22d3662e5e732.apply_integrate_f}  
3  0.000    0.000  0.000    0.000 frame.py:3418(__getitem__)   
3  0.000    0.000  0.000    0.000 managers.py:973(iget)      
1  0.000    0.000  0.001    0.001 (built-in method builtins.exec)
```

As one might expect, the majority of the time is now spent in `apply_integrate_f`, so if we wanted to make
anymore efficiencies we must continue to concentrate our efforts here.

More advanced techniques

There is still hope for improvement. Here’s an example of using some more advanced Cython techniques:

```
In [12]: %%cython
   ....: cimport cython
   ....: cimport numpy as np
   ....: import numpy as np
   ....: cdef double f_typed(double x) except? -2:
   ....:     return x * (x - 1)
   ....: cpdef double integrate_f_typed(double a, double b, int N):
   ....:     cdef int i
   ....:     cdef double s, dx
   ....:     s = 0
   ....:     dx = (b - a) / N
   ....:     for i in range(N):
   ....:         s += f_typed(a + i * dx)
   ....:     return s * dx
   ....: @cython.boundscheck(False)
   ....: @cython.wraparound(False)
   ....: cpdef np.ndarray[double] apply_integrate_f_wrap(np.ndarray[double] col_a,
   ....: np.ndarray[double] col_b,
   ....: np.ndarray[int] col_N):
   ....:     cdef int i, n = len(col_N)
   ....:     assert len(col_a) == len(col_b) == n
   ....:     cdef np.ndarray[double] res = np.empty(n)
   ....:     for i in range(n):
   ....:         res[i] = integrate_f_typed(col_a[i], col_b[i], col_N[i])
   ....:     return res

In [4]: %timeit apply_integrate_f_wrap(df["a"].to_numpy(), df["b"].to_numpy(), df["N →"].to_numpy())
1000 loops, best of 3: 987 us per loop
```

Even faster, with the caveat that a bug in our Cython code (an off-by-one error, for example) might cause a segfault because memory access isn’t checked. For more about boundscheck and wraparound, see the Cython docs on compiler directives.

2.23.2 Numba (JIT compilation)

An alternative to statically compiling Cython code is to use a dynamic just-in-time (JIT) compiler with Numba.

Numba allows you to write a pure Python function which can be JIT compiled to native machine instructions, similar in performance to C, C++ and Fortran, by decorating your function with `@jit`.

Numba works by generating optimized machine code using the LLVM compiler infrastructure at import time, runtime, or statically (using the included pycc tool). Numba supports compilation of Python to run on either CPU or GPU hardware and is designed to integrate with the Python scientific software stack.

Note: The `@jit` compilation will add overhead to the runtime of the function, so performance benefits may not be realized especially when using small data sets. Consider caching your function to avoid compilation overhead each.
time your function is run.

Numba can be used in 2 ways with pandas:

1. Specify the `engine="numba"` keyword in select pandas methods

2. Define your own Python function decorated with `@jit` and pass the underlying NumPy array of `Series` or `Dataframe` (using `to_numpy()`) into the function

**pandas Numba Engine**

If Numba is installed, one can specify `engine="numba"` in select pandas methods to execute the method using Numba. Methods that support `engine="numba"` will also have an `engine_kwargs` keyword that accepts a dictionary that allows one to specify "nogil", "nopython" and "parallel" keys with boolean values to pass into the `@jit` decorator. If `engine_kwargs` is not specified, it defaults to `{"nogil": False, "nopython": True, "parallel": False}` unless otherwise specified.

In terms of performance, the first time a function is run using the Numba engine will be slow as Numba will have some function compilation overhead. However, the JIT compiled functions are cached, and subsequent calls will be fast. In general, the Numba engine is performant with a larger amount of data points (e.g. 1+ million).

```python
In [1]: data = pd.Series(range(1_000_000))  # noqa: E225
In [2]: roll = data.rolling(10)
In [3]: def f(x):
   ...:     return np.sum(x) + 5
   ...:
# Run the first time, compilation time will affect performance
In [4]: %timeit -r 1 -n 1 roll.apply(f, engine='numba', raw=True)
    1.23 s ± 0 ns per loop (mean ± std. dev. of 1 run, 1 loop each)
    # Function is cached and performance will improve
In [5]: %timeit roll.apply(f, engine='numba', raw=True)
    188 ms ± 1.93 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)
In [6]: %timeit roll.apply(f, engine='cython', raw=True)
    3.92 s ± 59 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)
```

**Custom Function Examples**

A custom Python function decorated with `@jit` can be used with pandas objects by passing their NumPy array representations with `to_numpy()`.

```python
import numba

@numba.jit
def f_plain(x):
    return x * (x - 1)

@numba.jit
def integrate_f_numba(a, b, N):
    s = 0
    dx = (b - a) / N
    for i in range(N):
```
(continues on next page)
s += f_plain(a + i * dx)
return s * dx

@numba.jit
def apply_integrate_f_numba(col_a, col_b, col_N):
    n = len(col_N)
    result = np.empty(n, dtype="float64")
    assert len(col_a) == len(col_b) == n
    for i in range(n):
        result[i] = integrate_f_numba(col_a[i], col_b[i], col_N[i])
    return result

def compute_numba(df):
    result = apply_integrate_f_numba(
        df["a"].to_numpy(), df["b"].to_numpy(), df["N"].to_numpy()
    )
    return pd.Series(result, index=df.index, name="result")

In [4]: %timeit compute_numba(df)
1000 loops, best of 3: 798 us per loop

In this example, using Numba was faster than Cython.
Numba can also be used to write vectorized functions that do not require the user to explicitly loop over the observations of a vector; a vectorized function will be applied to each row automatically. Consider the following example of doubling each observation:

```python
import numba
def double_every_value_nonumba(x):
    return x * 2
@numba.vectorize
def double_every_value_withnumba(x):  # noqa E501
    return x * 2
# Custom function without numba
In [5]: %timeit df["coll_doubled"] = df["a"].apply(double_every_value_nonumba)  # noqa E501
1000 loops, best of 3: 797 us per loop
# Standard implementation (faster than a custom function)
In [6]: %timeit df["coll_doubled"] = df["a"] * 2
1000 loops, best of 3: 233 us per loop
# Custom function with numba
In [7]: %timeit df["coll_doubled"] = double_every_value_withnumba(df["a"].to_numpy())
1000 loops, best of 3: 145 us per loop
```
Caveats

Numba is best at accelerating functions that apply numerical functions to NumPy arrays. If you try to @jit a function that contains unsupported Python or NumPy code, compilation will revert object mode which will mostly likely not speed up your function. If you would prefer that Numba throw an error if it cannot compile a function in a way that speeds up your code, pass Numba the argument nopython=True (e.g. @jit(nopython=True)). For more on troubleshooting Numba modes, see the Numba troubleshooting page.

Using parallel=True (e.g. @jit(parallel=True)) may result in a SIGABRT if the threading layer leads to unsafe behavior. You can first specify a safe threading layer before running a JIT function with parallel=True.

Generally if the you encounter a segfault (SIGSEGV) while using Numba, please report the issue to the Numba issue tracker.

2.23.3 Expression evaluation via eval()

The top-level function pandas.eval() implements expression evaluation of Series and DataFrame objects.

Note: To benefit from using eval() you need to install numexpr. See the recommended dependencies section for more details.

The point of using eval() for expression evaluation rather than plain Python is two-fold: 1) large DataFrame objects are evaluated more efficiently and 2) large arithmetic and boolean expressions are evaluated all at once by the underlying engine (by default numexpr is used for evaluation).

Note: You should not use eval() for simple expressions or for expressions involving small DataFrames. In fact, eval() is many orders of magnitude slower for smaller expressions/objects than plain ol’ Python. A good rule of thumb is to only use eval() when you have a DataFrame with more than 10,000 rows.

eval() supports all arithmetic expressions supported by the engine in addition to some extensions available only in pandas.

Note: The larger the frame and the larger the expression the more speedup you will see from using eval().

Supported syntax

These operations are supported by pandas.eval():

- Arithmetic operations except for the left shift (<<) and right shift (>>) operators, e.g., df + 2 * pi / s ** 4 % 42 - the_golden_ratio
- Comparison operations, including chained comparisons, e.g., 2 < df < df2
- Boolean operations, e.g., df < df2 and df3 < df4 or not df_bool
- list and tuple literals, e.g., [1, 2] or (1, 2)
- Attribute access, e.g., df.a
- Subscript expressions, e.g., df[0]
- Simple variable evaluation, e.g., pd.eval("df") (this is not very useful)
- Math functions: \texttt{sin, cos, exp, log, expm1, log1p, sqrt, sinh, cosh, tanh, arcsin, arccos, arctan, arccosh, arcsinh, arctanh, abs, arctan2 and log10}.

This Python syntax is \textbf{not} allowed:

- Expressions
  - Function calls other than math functions.
  - \texttt{is/is not} operations
  - \texttt{if} expressions
  - \texttt{lambda} expressions
  - \texttt{list/set/dict} comprehensions
  - \texttt{Literal dict and set} expressions
  - \texttt{yield} expressions
  - Generator expressions
  - Boolean expressions consisting of only scalar values

- Statements
  - Neither simple nor compound statements are allowed. This includes things like \texttt{for}, \texttt{while}, and \texttt{if}.

\texttt{eval()} \textbf{examples}

\texttt{pandas.eval()} works well with expressions containing large arrays.

First let’s create a few decent-sized arrays to play with:

```
In [13]: nrows, ncols = 20000, 100
In [14]: df1, df2, df3, df4 = [pd.DataFrame(np.random.randn(nrows, ncols)) for _ in \˓→range(4)]
```

Now let’s compare adding them together using plain ol’ Python versus \texttt{eval()}:

```
In [15]: %timeit df1 + df2 + df3 + df4
5.74 ms +- 64.7 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [16]: %timeit pd.eval("df1 + df2 + df3 + df4")
3.98 ms +- 44.9 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

Now let’s do the same thing but with comparisons:

```
In [17]: %timeit (df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)
5.24 ms +- 63.9 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [18]: %timeit pd.eval("(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)")
4.36 ms +- 64.7 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

\texttt{eval()} also works with unaligned pandas objects:

```
In [19]: s = pd.Series(np.random.randn(50))
In [20]: %timeit df1 + df2 + df3 + df4 + s
19.2 ms +- 89.4 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

\textbf{2.23. Enhancing performance}
In [21]: %timeit pd.eval("df1 + df2 + df3 + df4 + s")
5.01 ms +- 28.9 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

Note: Operations such as

1 and 2  # would parse to 1 & 2, but should evaluate to 2
3 or 4   # would parse to 3 | 4, but should evaluate to 3
~1      # this is okay, but slower when using eval

should be performed in Python. An exception will be raised if you try to perform any boolean/bitwise operations with scalar operands that are not of type bool or np.bool_. Again, you should perform these kinds of operations in plain Python.

The DataFrame.eval method

In addition to the top level pandas.eval() function you can also evaluate an expression in the “context” of a DataFrame.

In [22]: df = pd.DataFrame(np.random.randn(5, 2), columns=["a", "b"])
In [23]: df.eval("a + b")
Out[23]:
   0   1
0 -0.246747
1  0.867786
2 -1.626063
3 -1.134978
4 -1.027798
dtype: float64

Any expression that is a valid pandas.eval() expression is also a valid DataFrame.eval() expression, with the added benefit that you don’t have to prefix the name of the DataFrame to the column(s) you’re interested in evaluating.

In addition, you can perform assignment of columns within an expression. This allows for formulaic evaluation. The assignment target can be a new column name or an existing column name, and it must be a valid Python identifier.

The inplace keyword determines whether this assignment will performed on the original DataFrame or return a copy with the new column.

In [24]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
In [25]: df.eval("c = a + b", inplace=True)
In [26]: df.eval("d = a + b + c", inplace=True)
In [27]: df.eval("a = 1", inplace=True)
In [28]: df
Out[28]:
a   b   c   d
0  1   5   5  10
1  1   6   7  14
2  1   7   9  18
(continues on next page)
When `inplace` is set to `False`, the default, a copy of the DataFrame with the new or modified columns is returned and the original frame is unchanged.

```
In [29]: df
Out[29]:
     a  b  c  d
0  1  5  5  10
1  1  6  7  14
2  1  7  9  18
3  1  8 11  22
4  1  9 13  26

In [30]: df.eval("e = a - c", inplace=False)
Out[30]:
     a  b  c  d  e
0  1  5  5  10 -4
1  1  6  7  14 -6
2  1  7  9  18 -8
3  1  8 11  22 -10
4  1  9 13  26 -12

In [31]: df
Out[31]:
     a  b  c  d
0  1  5  5  10
1  1  6  7  14
2  1  7  9  18
3  1  8 11  22
4  1  9 13  26
```

As a convenience, multiple assignments can be performed by using a multi-line string.

```
In [32]: df.eval(....:"""
.....: c = a + b
.....: d = a + b + c
.....: e = 1""",
.....: inplace=False,
.....: )
....:
Out[32]:
     a  b  c  d
0  1  5  6  12
1  1  6  7  14
2  1  7  8  16
3  1  8  9  18
4  1  9 10  20
```

The equivalent in standard Python would be

```
In [33]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
In [34]: df["c"] = df["a"] + df["b"]
```
In [35]: df["d"] = df["a"] + df["b"] + df["c"]
In [36]: df["a"] = 1
In [37]: df
Out[37]:
   a  b  c  d
0  1  5  5  10
1  1  6  7  14
2  1  7  9  18
3  1  8 11  22
4  1  9 13  26

The query method has a inplace keyword which determines whether the query modifies the original frame.

In [38]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
In [39]: df.query("a > 2")
Out[39]:
   a  b
3  3  8
4  4  9
In [40]: df.query("a > 2", inplace=True)
In [41]: df
Out[41]:
   a  b
3  3  8
4  4  9

Local variables

You must explicitly reference any local variable that you want to use in an expression by placing the @ character in front of the name. For example,

In [42]: df = pd.DataFrame(np.random.randn(5, 2), columns=list("ab"))
In [43]: newcol = np.random.randn(len(df))
In [44]: df.eval("b + @newcol")
Out[44]:
   0  -0.173926
   1   2.493083
   2  -0.881831
   3  -0.691045
   4   1.334703
dtype: float64
In [45]: df.query("b < @newcol")
Out[45]:
   a  b
 0  0.863987  -0.115998
 2 -2.621419  -1.297879
If you don’t prefix the local variable with @, pandas will raise an exception telling you the variable is undefined.

When using DataFrame.eval() and DataFrame.query(), this allows you to have a local variable and a DataFrame column with the same name in an expression.

```
In [46]: a = np.random.randn()
In [47]: df.query("@a < a")
Out[47]:
   a     b
0  0.863987 -0.115998
In [48]: df.loc[a < df["a"]]
In [48]:
   a     b
0  0.863987 -0.115998
```

With pandas.eval() you cannot use the @ prefix at all, because it isn’t defined in that context. pandas will let you know this if you try to use @ in a top-level call to pandas.eval(). For example,

```
In [49]: a, b = 1, 2
In [50]: pd.eval("@a + b")
```

```
Traceback (most recent call last):
  File "/opt/conda/envs/pandas/lib/python3.8/site-packages/IPython/core/interactiveshell.py", line 3441, in run_code
    exec(code_obj, self.user_global_ns, self.user_ns)
  File "<ipython-input-50-f23f43311349>"", line 1, in <module>
    pd.eval("@a + b")
  File "/pandas/pandas/core/computation/eval.py", line 337, in eval
    _check_for_locals(expr, level, parser)
  File "/pandas/pandas/core/computation/eval.py", line 161, in _check_for_locals
    raise SyntaxError(msg)
  File "<string>", line unknown
SyntaxError: The '@' prefix is not allowed in top-level eval calls. Please refer to your variables by name without the '@' prefix.
```

In this case, you should simply refer to the variables like you would in standard Python.

```
In [51]: pd.eval("a + b")
Out[51]: 3
```

**pandas.eval() parsers**

There are two different parsers and two different engines you can use as the backend.

The default 'pandas' parser allows a more intuitive syntax for expressing query-like operations (comparisons, conjunctions and disjunctions). In particular, the precedence of the & and | operators is made equal to the precedence of the corresponding boolean operations and and or.

For example, the above conjunction can be written without parentheses. Alternatively, you can use the 'python' parser to enforce strict Python semantics.
In [52]: expr = "(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)"

In [53]: x = pd.eval(expr, parser="python")

In [54]: expr_no_parens = "df1 > 0 & df2 > 0 & df3 > 0 & df4 > 0"

In [55]: y = pd.eval(expr_no_parens, parser="pandas")

In [56]: np.all(x == y)
Out[56]: True

The same expression can be “anded” together with the word and as well:

In [57]: expr = "(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)"

In [58]: x = pd.eval(expr, parser="python")

In [59]: expr_with_ands = "df1 > 0 and df2 > 0 and df3 > 0 and df4 > 0"

In [60]: y = pd.eval(expr_with_ands, parser="pandas")

In [61]: np.all(x == y)
Out[61]: True

The and and or operators here have the same precedence that they would in vanilla Python.

**pandas.eval() backends**

There’s also the option to make eval() operate identical to plain ol’ Python.

**Note:** Using the 'python' engine is generally not useful, except for testing other evaluation engines against it. You will achieve no performance benefits using eval() with engine='python' and in fact may incur a performance hit.

You can see this by using pandas.eval() with the 'python' engine. It is a bit slower (not by much) than evaluating the same expression in Python

```python
In [62]: %timeit df1 + df2 + df3 + df4
5.77 ms +- 94.3 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```python
In [63]: %timeit pd.eval("df1 + df2 + df3 + df4", engine="python")
6.4 ms +- 66.2 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

**pandas.eval() performance**

eval() is intended to speed up certain kinds of operations. In particular, those operations involving complex expressions with large DataFrame/Series objects should see a significant performance benefit. Here is a plot showing the running time of pandas.eval() as function of the size of the frame involved in the computation. The two lines are two different engines.
Note: Operations with smallish objects (around 15k-20k rows) are faster using plain Python:

This plot was created using a DataFrame with 3 columns each containing floating point values generated using `numpy.random.randn()`.
Technical minutia regarding expression evaluation

Expressions that would result in an object dtype or involve datetime operations (because of NaT) must be evaluated in Python space. The main reason for this behavior is to maintain backwards compatibility with versions of NumPy < 1.7. In those versions of NumPy a call to ndarray.astype(str) will truncate any strings that are more than 60 characters in length. Second, we can’t pass object arrays to numexpr thus string comparisons must be evaluated in Python space.

The upshot is that this only applies to object-dtype expressions. So, if you have an expression—for example

```python
In [64]: df = pd.DataFrame(  
....:     {"strings": np.repeat(list("cba"), 3), "nums": np.repeat(range(3), 3)}  
....: )  
....:

In [65]: df
Out[65]:
strings  nums
0       c      0
1       c      0
2       c      0
3       b      1
4       b      1
5       b      1
6       a      2
7       a      2
8       a      2
```

The numeric part of the comparison (nums == 1) will be evaluated by numexpr.

In general, DataFrame.query() / pandas.eval() will evaluate the subexpressions that can be evaluated by numexpr and those that must be evaluated in Python space transparently to the user. This is done by inferring the result type of an expression from its arguments and operators.

2.24 Scaling to large datasets

pandas provides data structures for in-memory analytics, which makes using pandas to analyze datasets that are larger than memory datasets somewhat tricky. Even datasets that are a sizable fraction of memory become unwieldy, as some pandas operations need to make intermediate copies.

This document provides a few recommendations for scaling your analysis to larger datasets. It’s a complement to Enhancing performance, which focuses on speeding up analysis for datasets that fit in memory.

But first, it’s worth considering not using pandas. pandas isn’t the right tool for all situations. If you’re working with very large datasets and a tool like PostgreSQL fits your needs, then you should probably be using that. Assuming you want or need the expressiveness and power of pandas, let’s carry on.

```python
In [1]: import pandas as pd
In [2]: import numpy as np
```
### 2.24.1 Load less data

Suppose our raw dataset on disk has many columns:

<table>
<thead>
<tr>
<th>timestamp</th>
<th>id_0</th>
<th>name_0</th>
<th>x_0</th>
<th>y_0</th>
<th>id_1</th>
<th>name_1</th>
<th>x_1</th>
<th>y_1</th>
</tr>
</thead>
<tbody>

<td>0.776424</td>
<td>0.783392</td>
<td></td>
</tr>
</tbody>
</table>

To load the columns we want, we have two options. Option 1 loads in all the data and then filters to what we need.

**In [3]:**
```
columns = ["id_0", "name_0", "x_0", "y_0"]
```

**In [4]:**
```
pd.read_parquet("timeseries_wide.parquet")[columns]
```

**Out [4]:**
```
    timestamp       id_0   name_0   x_0   y_0
2000-01-01 00:00:00 1015 Michael -0.399453 0.095427
2000-01-01 00:01:00 969 Patricia -0.650773 -0.874275
2000-01-01 00:02:00 1016 Victor -0.721465 -0.584710
2000-01-01 00:03:00 939 Alice -0.746004 -0.908008
2000-01-01 00:04:00 1017 Dan 0.919451 -0.803504
2000-12-30 23:56:00 999 Tim 0.162578 0.512817
2000-12-30 23:57:00 970 Laura -0.433586 -0.600289
2000-12-30 23:58:00 1065 Edith 0.232211 -0.454540
2000-12-30 23:59:00 1019 Ingrid 0.322208 -0.615974
2000-12-31 00:00:00 937 Ursula -0.906523 0.943178
2000-12-31 00:01:00 973 Kevin -0.403352
```

Option 2 only loads the columns we request.

**In [5]:**
```
pd.read_parquet("timeseries_wide.parquet", columns=columns)
```

**Out [5]:**
```
    timestamp       id_0   name_0   x_0   y_0
2000-01-01 00:00:00 1015 Michael -0.399453 0.095427
2000-01-01 00:01:00 969 Patricia -0.650773 -0.874275
2000-01-01 00:02:00 1016 Victor -0.721465 -0.584710
2000-01-01 00:03:00 939 Alice -0.746004 -0.908008
2000-01-01 00:04:00 1017 Dan 0.919451 -0.803504
2000-12-30 23:56:00 999 Tim 0.162578 0.512817
2000-12-30 23:57:00 970 Laura -0.433586 -0.600289
2000-12-30 23:58:00 1065 Edith 0.232211 -0.454540
2000-12-30 23:59:00 1019 Ingrid 0.322208 -0.615974
2000-12-31 00:00:00 937 Ursula -0.906523 0.943178
```

(continues on next page)
If we were to measure the memory usage of the two calls, we’d see that specifying columns uses about 1/10th the memory in this case.

With pandas.read_csv(), you can specify usecols to limit the columns read into memory. Not all file formats that can be read by pandas provide an option to read a subset of columns.

### 2.24.2 Use efficient datatypes

The default pandas data types are not the most memory efficient. This is especially true for text data columns with relatively few unique values (commonly referred to as “low-cardinality” data). By using more efficient data types, you can store larger datasets in memory.

```
In [6]: ts = pd.read_parquet("timeseries.parquet")
In [7]: ts
Out[7]:
   id  name   x   y
0  1029  Michael  0.278837  0.247932
1  1010  Patricia  0.077144  0.490260
2  1001  Victor  0.214525  0.258635
3  1018  Alice  -0.646866  0.822104
4   991    Dan  0.902389  0.466665
... ... ...     ...
999   921  Sarah  0.721155  0.944118
1000 1007  Ursula  0.409277  0.133227
```

Now, let’s inspect the data types and memory usage to see where we should focus our attention.

```
In [8]: ts.dtypes
Out[8]:
        id     name      x     y
int64   int64   float64  float64
```
The `name` column is taking up much more memory than any other. It has just a few unique values, so it’s a good candidate for converting to a `Categorical`. With a Categorical, we store each unique name once and use space-efficient integers to know which specific name is used in each row.

```python
In [10]: ts2 = ts.copy()
In [11]: ts2["name"] = ts2["name"].astype("category")
In [12]: ts2.memory_usage(deep=True)
```

```
Out[12]:
Index 8409608  
id 8409608
name 1053894  
x 8409608  
y 8409608  
dtype: int64
```

We can go a bit further and downcast the numeric columns to their smallest types using `pandas.to_numeric()`.

```python
In [13]: ts2["id"] = pd.to_numeric(ts2["id"], downcast="unsigned")
In [14]: ts2[["x", "y"]].apply(pd.to_numeric, downcast="float")
In [15]: ts2.dtypes
```

```
Out[15]:
id   uint16
name  category
x     float32
y     float32
```

```python
In [16]: ts2.memory_usage(deep=True)
```

```
Out[16]:
Index 8409608  
id 2102402
name 1053894  
x 4204804
y 4204804
```

```python
In [17]: reduction = ts2.memory_usage(deep=True).sum() / ts.memory_usage(deep=True).sum()
```

(continues on next page)
In all, we’ve reduced the in-memory footprint of this dataset to 1/5 of its original size.

See *Categorical data* for more on *Categorical* and *dtypes* for an overview of all of pandas’ dtypes.

### 2.24.3 Use chunking

Some workloads can be achieved with chunking: splitting a large problem like “convert this directory of CSVs to parquet” into a bunch of small problems (“convert this individual CSV file into a Parquet file. Now repeat that for each file in this directory.”). As long as each chunk fits in memory, you can work with datasets that are much larger than memory.

**Note:** Chunking works well when the operation you’re performing requires zero or minimal coordination between chunks. For more complicated workflows, you’re better off using another library.

Suppose we have an even larger “logical dataset” on disk that’s a directory of parquet files. Each file in the directory represents a different year of the entire dataset.

```python
data
timeseries
ts-00.parquet
ts-01.parquet
ts-02.parquet
ts-03.parquet
ts-04.parquet
ts-05.parquet
ts-06.parquet
ts-07.parquet
ts-08.parquet
ts-09.parquet
ts-10.parquet
ts-11.parquet
```

Now we’ll implement an out-of-core `value_counts`. The peak memory usage of this workflow is the single largest chunk, plus a small series storing the unique value counts up to this point. As long as each individual file fits in memory, this will work for arbitrary-sized datasets.

```python
In [19]: %time
   ....: files = pathlib.Path("data/timeseries/").glob("ts*.parquet")
   ....: counts = pd.Series(dtype=int)
   ....: for path in files:
   ....:     df = pd.read_parquet(path)
   ....:     counts = counts.add(df["name"].value_counts(), fill_value=0)
   ....:     counts.astype(int)
CPU times: user 605 ms, sys: 41.1 ms, total: 646 ms
Wall time: 458 ms
Out[19]:
   Alice    229802
   Bob      229211
   Charlie  229303
```
Some readers, like `pandas.read_csv()`, offer parameters to control the `chunksize` when reading a single file. Manually chunking is an OK option for workflows that don’t require too sophisticated of operations. Some operations, like `groupby`, are much harder to do chunkwise. In these cases, you may be better switching to a different library that implements these out-of-core algorithms for you.

### 2.24.4 Use other libraries

pandas is just one library offering a DataFrame API. Because of its popularity, pandas’ API has become something of a standard that other libraries implement. The pandas documentation maintains a list of libraries implementing a DataFrame API in our ecosystem page.

For example, Dask, a parallel computing library, has `dask.dataframe`, a pandas-like API for working with larger than memory datasets in parallel. Dask can use multiple threads or processes on a single machine, or a cluster of machines to process data in parallel.

We’ll import `dask.dataframe` and notice that the API feels similar to pandas. We can use Dask’s `read_parquet` function, but provide a globstring of files to read in.

```python
In [20]: import dask.dataframe as dd
In [21]: ddf = dd.read_parquet("data/timeseries/ts*.parquet", engine="pyarrow")
In [22]: ddf
```

```
Dask DataFrame Structure:
    id  name  x   y
npartitions=12
   int64  object  float64  float64
...  ...  ...  ...  

Inspecting the `ddf` object, we see a few things

- There are familiar attributes like `.columns` and `.dtypes`
- There are familiar methods like `.groupby`, `.sum`, etc.
- There are new attributes like `.npartitions` and `.divisions`

The partitions and divisions are how Dask parallelizes computation. A Dask DataFrame is made up of many pandas DataFrames. A single method call on a Dask DataFrame ends up making many pandas method calls, and Dask knows how to coordinate everything to get the result.

2.24. Scaling to large datasets
One major difference: the `dask.dataframe` API is lazy. If you look at the repr above, you’ll notice that the values aren’t actually printed out; just the column names and dtypes. That’s because Dask hasn’t actually read the data yet. Rather than executing immediately, doing operations build up a task graph.

Each of these calls is instant because the result isn’t being computed yet. We’re just building up a list of computation to do when someone needs the result. Dask knows that the return type of a `pandas.Series.value_counts` is a pandas Series with a certain dtype and a certain name. So the Dask version returns a Dask Series with the same dtype and the same name.

To get the actual result you can call `.compute()`.
In [29]: %time ddf["name"].value_counts().compute()
CPU times: user 772 ms, sys: 214 ms, total: 986 ms
Wall time: 462 ms
Out[29]:
Laura 230906
Ingrid 230838
Kevin 230698
Dan 230621
Frank 230595
...  
Ray 229603
Xavier 229553
Charlie 229303
Bob 229211
Yvonne 228766
Name: name, Length: 26, dtype: int64

At that point, you get back the same thing you’d get with pandas, in this case a concrete pandas Series with the count of each name.

Calling .compute causes the full task graph to be executed. This includes reading the data, selecting the columns, and doing the value_counts. The execution is done in parallel where possible, and Dask tries to keep the overall memory footprint small. You can work with datasets that are much larger than memory, as long as each partition (a regular pandas DataFrame) fits in memory.

By default, dask.dataframe operations use a threadpool to do operations in parallel. We can also connect to a cluster to distribute the work on many machines. In this case we’ll connect to a local “cluster” made up of several processes on this single machine.

```python
>>> from dask.distributed import Client, LocalCluster
>>> cluster = LocalCluster()
>>> client = Client(cluster)
>>> client
<Client: 'tcp://127.0.0.1:53349' processes=4 threads=8, memory=17.18 GB>
```

Once this client is created, all of Dask’s computation will take place on the cluster (which is just processes in this case).

Dask implements the most used parts of the pandas API. For example, we can do a familiar groupby aggregation.

```python
In [30]: %time ddf.groupby("name")["x", "y"].mean().compute().head()
CPU times: user 1.54 s, sys: 422 ms, total: 1.97 s
Wall time: 819 ms
Out[30]:
       x        y
name  
Alice 0.000086 -0.001170
Bob   -0.000843 -0.000799
Charlie 0.000564 -0.000038
Dan    0.000584  0.000818
Edith -0.000116 -0.000044
```

The grouping and aggregation is done out-of-core and in parallel.

When Dask knows the divisions of a dataset, certain optimizations are possible. When reading parquet datasets written by dask, the divisions will be known automatically. In this case, since we created the parquet files manually, we need to supply the divisions manually.
Now we can do things like fast random access with .loc.

```python
In [37]: ddf.loc['2002-01-01 12:01':'2002-01-01 12:05'].compute()
```

```
id   name    x            y
2002-01-01 12:01:00 983 Laura 0.243985 -0.079392
2002-01-01 12:02:00 1001 Laura -0.523119 -0.226026
2002-01-01 12:03:00 1059 Oliver 0.612886 0.405680
2002-01-01 12:04:00 993 Kevin 0.451977 0.332947
2002-01-01 12:05:00 1014 Yvonne -0.948681 0.361748
```
These Dask examples have all been done using multiple processes on a single machine. Dask can be deployed on a cluster to scale up to even larger datasets.

You see more dask examples at https://examples.dask.org.

### 2.25 Sparse data structures

pandas provides data structures for efficiently storing sparse data. These are not necessarily sparse in the typical “mostly 0”. Rather, you can view these objects as being “compressed” where any data matching a specific value (NaN / missing value, though any value can be chosen, including 0) is omitted. The compressed values are not actually stored in the array.

```
In [1]: arr = np.random.randn(10)
In [2]: arr[2:-2] = np.nan
In [3]: ts = pd.Series(pd.arrays.SparseArray(arr))
In [4]: ts
Out[4]:
   0    0.469112
   1  -0.282863
   2    NaN
```
Notice the dtype, Sparse[float64, nan]. The nan means that elements in the array that are nan aren’t actually stored, only the non-nan elements are. Those non-nan elements have a float64 dtype.

The sparse objects exist for memory efficiency reasons. Suppose you had a large, mostly NA DataFrame:

```python
In [5]: df = pd.DataFrame(np.random.randn(10000, 4))
In [6]: df.iloc[:9998] = np.nan
In [7]: sdf = df.astype(pd.SparseDtype("float", np.nan))
In [8]: sdf.head()
Out[8]:
   0  1  2  3
0  NaN NaN NaN NaN
1  NaN NaN NaN NaN
2  NaN NaN NaN NaN
3  NaN NaN NaN NaN
4  NaN NaN NaN NaN
In [9]: sdf.dtypes
Out[9]:
0    Sparse[float64, nan]
1    Sparse[float64, nan]
2    Sparse[float64, nan]
3    Sparse[float64, nan]
dtype: object
In [10]: sdf.sparse.density
Out[10]: 0.0002
```

As you can see, the density (% of values that have not been “compressed”) is extremely low. This sparse object takes up much less memory on disk (pickled) and in the Python interpreter.

```python
In [11]: 'dense : {:0.2f} bytes'.format(df.memory_usage().sum() / 1e3)
Out[11]: 'dense : 320.13 bytes'
In [12]: 'sparse: {:0.2f} bytes'.format(sdf.memory_usage().sum() / 1e3)
Out[12]: 'sparse: 0.22 bytes'
```

Functionally, their behavior should be nearly identical to their dense counterparts.
2.25.1 SparseArray

arrays.SparseArray is a ExtensionArray for storing an array of sparse values (see dtypes for more on extension arrays). It is a 1-dimensional ndarray-like object storing only values distinct from the fill_value:

```python
In [13]: arr = np.random.randn(10)
In [14]: arr[2:5] = np.nan
In [15]: arr[7:8] = np.nan
In [16]: sparr = pd.arrays.SparseArray(arr)
In [17]: sparr
Out[17]:
[-1.9556635297215477, -1.6588664275960427, nan, nan, nan, 1.1589328886422277, 0.,
 1.14529711373305043, nan, 0.6060271905134522, 1.3342113401317768]
Fill: nan
IntIndex
Indices: array([0, 1, 5, 6, 8, 9], dtype=int32)
```

A sparse array can be converted to a regular (dense) ndarray with numpy.asarray()

```python
In [18]: np.asarray(sparr)
Out[18]:
array([-1.9557, -1.6589, nan, nan, nan, 1.1589, 0.1453,
       nan, 0.606, 1.3342])
```

2.25.2 SparseDtype

The SparseArray.dtype property stores two pieces of information

1. The dtype of the non-sparse values
2. The scalar fill value

```python
In [19]: sparr.dtype
Out[19]: Sparse[float64, nan]
```

A SparseDtype may be constructed by passing only a dtype

```python
In [20]: pd.SparseDtype(np.dtype('datetime64[ns]'))
Out[20]: Sparse[datetime64[ns], numpy.datetime64('NaT')]
```

in which case a default fill value will be used (for NumPy dtypes this is often the “missing” value for that dtype). To override this default an explicit fill value may be passed instead

```python
In [21]: pd.SparseDtype(np.dtype('datetime64[ns]'),
                  fill_value=pd.Timestamp('2017-01-01'))
Out[21]: Sparse[datetime64[ns], Timestamp('2017-01-01 00:00:00')]
```

Finally, the string alias 'Sparse[dtype]' may be used to specify a sparse dtype in many places

```python
In [22]: pd.array([1, 0, 0, 2], dtype='Sparse[int]')
Out[22]:
```

(continues on next page)
2.25.3 Sparse accessor

pandas provides a .sparse accessor, similar to .str for string data, .cat for categorical data, and .dt for datetime-like data. This namespace provides attributes and methods that are specific to sparse data.

```
In [23]: s = pd.Series([0, 0, 1, 2], dtype="Sparse[int"]")
In [24]: s.sparse.density
Out [24]: 0.5
In [25]: s.sparse.fill_value
Out [25]: 0
```

This accessor is available only on data with SparseDtype, and on the Series class itself for creating a Series with sparse data from a scipy COO matrix with.

New in version 0.25.0.

A .sparse accessor has been added for DataFrame as well. See Sparse accessor for more.

2.25.4 Sparse calculation

You can apply NumPy ufuncs to SparseArray and get a SparseArray as a result.

```
In [26]: arr = pd.arrays.SparseArray([1., np.nan, np.nan, -2., np.nan])
In [27]: np.abs(arr)
Out [27]:
[1.0, nan, nan, 2.0, nan]
Fill: nan
IntIndex
Indices: array([0, 3], dtype=int32)
```

The ufunc is also applied to fill_value. This is needed to get the correct dense result.

```
In [28]: arr = pd.arrays.SparseArray([1., -1, -1, -2., -1], fill_value=-1)
In [29]: np.abs(arr)
Out [29]:
[1.0, 1, 1, 2.0, 1]
Fill: 1
IntIndex
Indices: array([0, 3], dtype=int32)
In [30]: np.abs(arr).to_dense()
Out [30]: array([1., 1., 1., 2., 1.])
```
2.25.5 Migrating

**Note:** SparseSeries and SparseDataFrame were removed in pandas 1.0.0. This migration guide is present to aid in migrating from previous versions.

In older versions of pandas, the SparseSeries and SparseDataFrame classes (documented below) were the preferred way to work with sparse data. With the advent of extension arrays, these subclasses are no longer needed. Their purpose is better served by using a regular Series or DataFrame with sparse values instead.

**Note:** There’s no performance or memory penalty to using a Series or DataFrame with sparse values, rather than a SparseSeries or SparseDataFrame.

This section provides some guidance on migrating your code to the new style. As a reminder, you can use the Python warnings module to control warnings. But we recommend modifying your code, rather than ignoring the warning.

**Construction**

From an array-like, use the regular `Series` or `DataFrame` constructors with `SparseArray` values.

```python
# Previous way
>>> pd.SparseDataFrame({"A": [0, 1]})
```

```python
# New way
In [31]: pd.DataFrame({"A": pd.arrays.SparseArray([0, 1])})
```

```
Out[31]:
     A
0  0
1  1
```

From a SciPy sparse matrix, use `DataFrame.sparse.from_spmatrix()`.

```python
# Previous way
>>> from scipy import sparse
>>> mat = sparse.eye(3)
>>> df = pd.SparseDataFrame(mat, columns=["A", "B", "C"])
```

```python
# New way
In [32]: from scipy import sparse

In [33]: mat = sparse.eye(3)

In [34]: df = pd.DataFrame.sparse.from_spmatrix(mat, columns=["A", "B", "C"])

In [35]: df.dtypes
```

```
Out[35]:
A  Sparse[float64, 0]
B  Sparse[float64, 0]
C  Sparse[float64, 0]
dtype: object
```

**Conversion**

From sparse to dense, use the `.sparse accessors`
From dense to sparse, use `DataFrame.astype()` with a `SparseDtype`.

General differences

In a `SparseDataFrame`, all columns were sparse. A `DataFrame` can have a mixture of sparse and dense columns. As a consequence, assigning new columns to a `DataFrame` with sparse values will not automatically convert the input to be sparse.

Instead, you’ll need to ensure that the values being assigned are sparse
The `SparseDataFrame.default_kind` and `SparseDataFrame.default_fill_value` attributes have no replacement.

### 2.25.6 Interaction with scipy.sparse

Use `DataFrame.sparse.from_spmatrix()` to create a DataFrame with sparse values from a sparse matrix. New in version 0.25.0.

```python
In [47]: from scipy.sparse import csr_matrix

In [48]: arr = np.random.random(size=(1000, 5))

In [49]: arr[arr < .9] = 0

In [50]: sp_arr = csr_matrix(arr)

In [51]: sp_arr
Out[51]:
<1000x5 sparse matrix of type '<class 'numpy.float64'>'
    with 517 stored elements in Compressed Sparse Row format>

In [52]: sdf = pd.DataFrame.sparse.from_spmatrix(sp_arr)

In [53]: sdf.head()
Out[53]:
   0    1    2    3    4
0 0.956380 0.0 0.0 0.000000 0.0
1 0.000000 0.0 0.0 0.000000 0.0
2 0.000000 0.0 0.0 0.000000 0.0
3 0.000000 0.0 0.0 0.000000 0.0
4 0.999552 0.0 0.0 0.956153 0.0

In [54]: sdf.dtypes
Out[54]:
0  Sparse[float64, 0]
1  Sparse[float64, 0]
2  Sparse[float64, 0]
3  Sparse[float64, 0]
4  Sparse[float64, 0]
dtype: object
```

All sparse formats are supported, but matrices that are not in COOrdinate format will be converted, copying data as needed. To convert back to sparse SciPy matrix in COO format, you can use the `DataFrame.sparse.to_coo()` method:

```python
In [55]: sdf.sparse.to_coo()
Out[55]:
<1000x5 sparse matrix of type '<class 'numpy.float64'>'
    with 517 stored elements in COOrdinate format>
```

`Series.sparse.to_coo` is implemented for transforming a Series with sparse values indexed by a `MultiIndex` to a `scipy.sparse.coo_matrix`.

The method requires a `MultiIndex` with two or more levels.
In [56]: s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])

In [57]: s.index = pd.MultiIndex.from_tuples(
   ....:   [(1, 2, "a", 0),
   ....:    (1, 2, "a", 1),
   ....:    (1, 1, "b", 0),
   ....:    (1, 1, "b", 1),
   ....:    (2, 1, "b", 0),
   ....:    (2, 1, "b", 1),
   ....:   ],
   ....:   names=["A", "B", "C", "D"],
   ....: )

In [58]: ss = s.astype('Sparse')

In [59]: ss
Out[59]:
A B C D
1 2 a 0 3.0
1 NaN
1 b 0 1.0
1 3.0
2 1 b 0 NaN
1 NaN
dtype: Sparse[float64, nan]

In the example below, we transform the Series to a sparse representation of a 2-d array by specifying that the first and second MultiIndex levels define labels for the rows and the third and fourth levels define labels for the columns. We also specify that the column and row labels should be sorted in the final sparse representation.

In [60]: A, rows, columns = ss.sparse.to_coo(
   ....:   row_levels=["A", "B"], column_levels=["C", "D"], sort_labels=True
   ....: )

In [61]: A
Out[61]:
<3x4 sparse matrix of type '<class 'numpy.float64'>'
   with 3 stored elements in COOrdinate format>

In [62]: A.todense()
Out[62]:
matrix([[0., 0., 1., 3.],
        [3., 0., 0., 0.],
        [0., 0., 0., 0.]])

In [63]: rows
Out[63]: [(1, 1), (1, 2), (2, 1)]

In [64]: columns
Out[64]: [('a', 0), ('a', 1), ('b', 0), ('b', 1)]

Specifying different row and column labels (and not sorting them) yields a different sparse matrix:

In [65]: A, rows, columns = ss.sparse.to_coo(
   ....:   row_levels=["a", "b"], column_levels=["c", "d"], sort_labels=False
   ....: )

(continues on next page)
row_levels=['A', 'B', 'C'], column_levels=['D'], sort_labels=False

In [66]: A
Out[66]:
<3x2 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>

In [67]: A.todense()
Out[67]:
matrix([[3., 0.],
        [1., 3.],
        [0., 0.]])

In [68]: rows
Out[68]: [(1, 2, 'a'), (1, 1, 'b'), (2, 1, 'b')]

In [69]: columns
Out[69]: [0, 1]

A convenience method `Series.sparse.from_coo()` is implemented for creating a Series with sparse values from a `scipy.sparse.coo_matrix`.

In [70]: from scipy import sparse

In [71]: A = sparse.coo_matrix(((3.0, 1.0, 2.0), ([1, 0, 0], [0, 2, 3])), shape=(3, 4))

In [72]: A
Out[72]:
<3x4 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>

In [73]: A.todense()
Out[73]:
matrix([[0., 0., 1., 2.],
        [3., 0., 0., 0.],
        [0., 0., 0., 0.]])

The default behaviour (with `dense_index=False`) simply returns a Series containing only the non-null entries.

In [74]: ss = pd.Series.sparse.from_coo(A)

In [75]: ss
Out[75]:
0  2   1.0
  3   2.0
  0   3.0
dtype: Sparse[float64, nan]

Specifying `dense_index=True` will result in an index that is the Cartesian product of the row and columns coordinates of the matrix. Note that this will consume a significant amount of memory (relative to `dense_index=False`) if the sparse matrix is large (and sparse) enough.

In [76]: ss_dense = pd.Series.sparse.from_coo(A, dense_index=True)
2.26 Frequently Asked Questions (FAQ)

2.26.1 DataFrame memory usage

The memory usage of a DataFrame (including the index) is shown when calling the `info()` method. A configuration option, `display.memory_usage` (see the list of options), specifies if the DataFrame’s memory usage will be displayed when invoking the `df.info()` method.

For example, the memory usage of the DataFrame below is shown when calling `info()`:

```
In [1]: dtypes = [
   ...:   "int64",
   ...:   "float64",
   ...:   "datetime64[ns]",
   ...:   "timedelta64[ns]",
   ...:   "complex128",
   ...:   "object",
   ...:   "bool",
   ...: ]
   ...

In [2]: n = 5000

In [3]: data = {t: np.random.randint(100, size=n).astype(t) for t in dtypes}

In [4]: df = pd.DataFrame(data)

In [5]: df["categorical"] = df["object"].astype("category")

In [6]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
#  Column     Non-Null Count  Dtype
---  ------     --------------  -----  
   0  int64      5000 non-null  int64  
   1  float64    5000 non-null  float64  
```
The + symbol indicates that the true memory usage could be higher, because pandas does not count the memory used by values in columns with `dtype=object`.

Passing `memory_usage='deep'` will enable a more accurate memory usage report, accounting for the full usage of the contained objects. This is optional as it can be expensive to do this deeper introspection.

By default the display option is set to `True` but can be explicitly overridden by passing the `memory_usage` argument when invoking `df.info()`.

The memory usage of each column can be found by calling the `memory_usage()` method. This returns a `Series` with an index represented by column names and memory usage of each column shown in bytes. For the `DataFrame` above, the memory usage of each column and the total memory usage can be found with the `memory_usage` method:

```
In [8]: df.memory_usage()
Out[8]:
Index   128
int64   40000
float64 40000
datetime64[ns] 40000
timedelta64[ns] 40000
complex128 80000
object   40000
bool     5000
categorical 9968
dtype: int64

# total memory usage of dataframe
In [9]: df.memory_usage().sum()
Out[9]: 295096
```
By default the memory usage of the DataFrame’s index is shown in the returned Series, the memory usage of the index can be suppressed by passing the `index=False` argument:

```python
In [10]: df.memory_usage(index=False)
Out[10]:
int64 40000
float64 40000
datetime64[ns] 40000
timedelta64[ns] 40000
complex128 80000
object 40000
bool 5000
categorical 9968
dtype: int64
```

The memory usage displayed by the `info()` method utilizes the `memory_usage()` method to determine the memory usage of a DataFrame while also formatting the output in human-readable units (base-2 representation; i.e. 1KB = 1024 bytes).

See also *Categorical Memory Usage*.

### 2.26.2 Using if/truth statements with pandas

pandas follows the NumPy convention of raising an error when you try to convert something to a `bool`. This happens in an `if`-statement or when using the boolean operations: `and`, `or`, and `not`. It is not clear what the result of the following code should be:

```python
>>> if pd.Series([False, True, False]):
...    pass
```

Should it be `True` because it’s not zero-length, or `False` because there are `False` values? It is unclear, so instead, pandas raises a `ValueError`:

```python
>>> if pd.Series([False, True, False]):
...    print("I was true")
Traceback...
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

You need to explicitly choose what you want to do with the DataFrame, e.g. use `any()`, `all()` or `empty()`. Alternatively, you might want to compare if the pandas object is `None`:

```python
>>> if pd.Series([False, True, False]) is not None:
...    print("I was not None")
I was not None
```

Below is how to check if any of the values are `True`:

```python
>>> if pd.Series([False, True, False]).any():
...    print("I am any")
I am any
```

To evaluate single-element pandas objects in a boolean context, use the method `bool()`:

```python
In [11]: pd.Series([True]).bool()
Out[11]: True
```
Bitwise boolean

Bitwise boolean operators like == and != return a boolean Series, which is almost always what you want anyways.

```python
>>> s = pd.Series(range(5))
>>> s == 4
0    False
1    False
2    False
3    False
4     True
dtype: bool
```

See boolean comparisons for more examples.

Using the in operator

Using the Python in operator on a Series tests for membership in the index, not membership among the values.

```python
In [15]: s = pd.Series(range(5), index=list("abcde"))
In [16]: 2 in s
Out[16]: False
In [17]: 'b' in s
Out[17]: True
```

If this behavior is surprising, keep in mind that using in on a Python dictionary tests keys, not values, and Series are dict-like. To test for membership in the values, use the method isin():

```python
In [18]: s.isin([2])
Out[18]:
a    False
b    False
c     True
d    False
e    False
dtype: bool
In [19]: s.isin([2]).any()
Out[19]: True
```

For DataFrames, likewise, in applies to the column axis, testing for membership in the list of column names.
### 2.26.3 Mutating with User Defined Function (UDF) methods

This section applies to pandas methods that take a UDF. In particular, the methods `.apply`, `.aggregate`, `.transform`, and `.filter`.

It is a general rule in programming that one should not mutate a container while it is being iterated over. Mutation will invalidate the iterator, causing unexpected behavior. Consider the example:

```python
In [20]: values = [0, 1, 2, 3, 4, 5]
In [21]: n_removed = 0
In [22]: for k, value in enumerate(values):
   ....:     idx = k - n_removed
   ....:     if value % 2 == 1:
   ....:         del values[idx]
   ....:         n_removed += 1
   ....:     else:
   ....:         values[idx] = value + 1
In [23]: values
Out[23]: [1, 4, 5]
```

One probably would have expected that the result would be `[1, 3, 5]`. When using a pandas method that takes a UDF, internally pandas is often iterating over the `DataFrame` or other pandas object. Therefore, if the UDF mutates (changes) the `DataFrame`, unexpected behavior can arise.

Here is a similar example with `DataFrame.apply()`:

```python
In [24]: def f(s):
   ....:     s.pop("a")
   ....:     return s
   ....:
In [25]: df = pd.DataFrame({"a": [1, 2, 3], "b": [4, 5, 6]})
In [26]: try:
   ....:     df.apply(f, axis="columns")
   ....: except Exception as err:
   ....:     print(repr(err))
   ....: KeyError('a')
```

To resolve this issue, one can make a copy so that the mutation does not apply to the container being iterated over.

```python
In [27]: values = [0, 1, 2, 3, 4, 5]
In [28]: n_removed = 0
In [29]: for k, value in enumerate(values.copy()):
   ....:     idx = k - n_removed
   ....:     if value % 2 == 1:
   ....:         del values[idx]
   ....:         n_removed += 1
   ....:     else:
   ....:         values[idx] = value + 1
   ....:
```

2.26.4 NaN, Integer NA values and NA type promotions

Choice of NA representation

For lack of NA (missing) support from the ground up in NumPy and Python in general, we were given the difficult choice between either:

- A masked array solution: an array of data and an array of boolean values indicating whether a value is there or is missing.

- Using a special sentinel value, bit pattern, or set of sentinel values to denote NA across the dtypes.

For many reasons we chose the latter. After years of production use it has proven, at least in my opinion, to be the best decision given the state of affairs in NumPy and Python in general. The special value NaN (Not-A-Number) is used everywhere as the NA value, and there are API functions `isna` and `notna` which can be used across the dtypes to detect NA values.

However, it comes with it a couple of trade-offs which I most certainly have not ignored.

Support for integer NA

In the absence of high performance NA support being built into NumPy from the ground up, the primary casualty is the ability to represent NAs in integer arrays. For example:

```
In [34]: s = pd.Series([1, 2, 3, 4, 5], index=list("abcde"))

In [35]: s
Out[35]:
    a  1
    b  2
    c  3
    d  4
    e  5
dtype: int64
```
In [36]: s.dtype
Out[36]: dtype('int64')

In [37]: s2 = s.reindex(['a', 'b', 'c', 'f', 'u'])

In [38]: s2
Out[38]:
     a  1.0
     b  2.0
     c  3.0
     f  NaN
     u  NaN

dtype: float64

In [39]: s2.dtype
Out[39]: dtype('float64')

This trade-off is made largely for memory and performance reasons, and also so that the resulting Series continues to be “numeric”.

If you need to represent integers with possibly missing values, use one of the nullable-integer extension dtypes provided by pandas

- Int8Dtype
- Int16Dtype
- Int32Dtype
- Int64Dtype

In [40]: s_int = pd.Series([1, 2, 3, 4, 5], index=list('abcde'), dtype=pd.Int64Dtype())

In [41]: s_int
Out[41]:
     a  1
     b  2
     c  3
     d  4
     e  5

dtype: Int64

In [42]: s_int.dtype
Out[42]: Int64Dtype()

In [43]: s2_int = s_int.reindex(['a', 'b', 'c', 'f', 'u'])

In [44]: s2_int
Out[44]:
     a  1
     b  2
     c  3
     f <NA>
     u <NA>

dtype: Int64
See Nullable integer data type for more.

**NA type promotions**

When introducing NAs into an existing Series or DataFrame via `reindex()` or some other means, boolean and integer types will be promoted to a different dtype in order to store the NAs. The promotions are summarized in this table:

<table>
<thead>
<tr>
<th>Typeclass</th>
<th>Promotion dtype for storing NAs</th>
</tr>
</thead>
<tbody>
<tr>
<td>floating</td>
<td>no change</td>
</tr>
<tr>
<td>object</td>
<td>no change</td>
</tr>
<tr>
<td>integer</td>
<td>cast to float64</td>
</tr>
<tr>
<td>boolean</td>
<td>cast to object</td>
</tr>
</tbody>
</table>

While this may seem like a heavy trade-off, I have found very few cases where this is an issue in practice i.e. storing values greater than $2^{53}$. Some explanation for the motivation is in the next section.

**Why not make NumPy like R?**

Many people have suggested that NumPy should simply emulate the NA support present in the more domain-specific statistical programming language R. Part of the reason is the NumPy type hierarchy:

<table>
<thead>
<tr>
<th>Typeclass</th>
<th>Dtypes</th>
</tr>
</thead>
<tbody>
<tr>
<td>numpy.floating</td>
<td>float16, float32, float64, float128</td>
</tr>
<tr>
<td>numpy.integer</td>
<td>int8, int16, int32, int64</td>
</tr>
<tr>
<td>numpy.unsignedinteger</td>
<td>uint8, uint16, uint32, uint64</td>
</tr>
<tr>
<td>numpy.object_</td>
<td>object_</td>
</tr>
<tr>
<td>numpy.bool_</td>
<td>bool_</td>
</tr>
<tr>
<td>numpy.character</td>
<td>string_, unicode_</td>
</tr>
</tbody>
</table>

The R language, by contrast, only has a handful of built-in data types: integer, numeric (floating-point), character, and boolean. NA types are implemented by reserving special bit patterns for each type to be used as the missing value. While doing this with the full NumPy type hierarchy would be possible, it would be a more substantial trade-off (especially for the 8- and 16-bit data types) and implementation undertaking.

An alternate approach is that of using masked arrays. A masked array is an array of data with an associated boolean mask denoting whether each value should be considered NA or not. I am personally not in love with this approach as I feel that overall it places a fairly heavy burden on the user and the library implementer. Additionally, it exacts a fairly high performance cost when working with numerical data compared with the simple approach of using NaN. Thus, I have chosen the Pythonic “practicality beats purity” approach and traded integer NA capability for a much simpler approach of using a special value in float and object arrays to denote NA, and promoting integer arrays to floating when NAs must be introduced.
2.26.5 Differences with NumPy

For Series and DataFrame objects, var() normalizes by $N-1$ to produce unbiased estimates of the sample variance, while NumPy’s var normalizes by $N$, which measures the variance of the sample. Note that cov() normalizes by $N-1$ in both pandas and NumPy.

2.26.6 Thread-safety

As of pandas 0.11, pandas is not 100% thread safe. The known issues relate to the copy() method. If you are doing a lot of copying of DataFrame objects shared among threads, we recommend holding locks inside the threads where the data copying occurs.

See this link for more information.

2.26.7 Byte-ordering issues

Occasionally you may have to deal with data that were created on a machine with a different byte order than the one on which you are running Python. A common symptom of this issue is an error like:

```
Traceback
...
ValueError: Big-endian buffer not supported on little-endian compiler
```

To deal with this issue you should convert the underlying NumPy array to the native system byte order before passing it to Series or DataFrame constructors using something similar to the following:

```
In [46]: x = np.array(list(range(10)), ">i4")  # big endian
In [47]: newx = x.byteswap().newbyteorder()  # force native byteorder
In [48]: s = pd.Series(newx)
```

See the NumPy documentation on byte order for more details.

2.27 Cookbook

This is a repository for short and sweet examples and links for useful pandas recipes. We encourage users to add to this documentation.

Adding interesting links and/or inline examples to this section is a great First Pull Request.

Simplified, condensed, new-user friendly, in-line examples have been inserted where possible to augment the StackOverflow and GitHub links. Many of the links contain expanded information, above what the in-line examples offer.

pandas (pd) and NumPy (np) are the only two abbreviated imported modules. The rest are kept explicitly imported for newer users.
2.27.1 Idioms

These are some neat pandas idioms

if-then/if-then-else on one column, and assignment to another one or more columns:

```
In [1]: df = pd.DataFrame(
    ...:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
    ...: )
    ...

In [2]: df
Out[2]:
AAA  BBB   CCC
0  4    10    100
1  5     20     50
2  6     30    -30
3  7     40    -50

if-then...

An if-then on one column

```

```
In [3]: df.loc[df.AAA >= 5, "BBB"] = -1

In [4]: df
Out[4]:
AAA  BBB   CCC
0  4    10  100
1  5   -1    50
2  6   -1   -30
3  7   -1   -50

An if-then with assignment to 2 columns:

```

```

```
In [5]: df.loc[df.AAA >= 5, ["BBB", "CCC"]]
Out[5]:
AAA  BBB   CCC
0  4    10    100
1  5  555   555
2  6  555   555
3  7  555   555

Add another line with different logic, to do the -else

```

```

```
In [7]: df.loc[df.AAA < 5, ["BBB", "CCC"]]
Out[7]:
AAA  BBB   CCC
0  4  2000  2000
1  5  555   555
2  6  555   555
3  7  555   555

2.27. Cookbook
Or use pandas where after you’ve set up a mask

```
In [9]: df_mask = pd.DataFrame(
    ...:     {"AAA": [True] * 4, "BBB": [False] * 4, "CCC": [True, False] * 2}
    ...:
    ...
)

In [10]: df.where(df_mask, -1000)
Out[10]:
   AAA  BBB  CCC
0 4  1000 -1000
1 5  -1000  555
2 6  -1000 -1000
3 7  -1000 -1000
```

if-then-else using NumPy’s where()

```
In [11]: df = pd.DataFrame(
    ...:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
    ...:
    ...
)

In [12]: df
Out[12]:
   AAA  BBB  CCC
0 4  10  100
1 5  20  50
2 6  30 -30
3 7  40 -50

In [13]: df["logic"] = np.where(df["AAA"] > 5, "high", "low")

In [14]: df
Out[14]:
   AAA  BBB  CCC  logic
0 4  10  100  low
1 5  20  50  low
2 6  30 -30  high
3 7  40 -50  high
```

**Splitting**

Split a frame with a boolean criterion

```
In [15]: df = pd.DataFrame(
    ...:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
    ...:
    ...
)

In [16]: df
Out[16]:
   AAA  BBB  CCC
0 4  10  100
1 5  20  50
```

(continues on next page)
Building criteria

Select with multi-column criteria

```
In [19]: df = pd.DataFrame(
    .....:   {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
    .....: )
In [20]: df
Out[20]:
   AAA  BBB  CCC
  0   4   10  100
  1   5   20   50
  2   6   30  -30
  3   7   40  -50
```

... and (without assignment returns a Series)

```
In [21]: df.loc[(df["BBB"] < 25) & (df["CCC"] >= -40), "AAA"]
Out[21]:
     0
    4
   Name: AAA, dtype: int64
```

... or (without assignment returns a Series)

```
In [22]: df.loc[(df["BBB"] > 25) | (df["CCC"] >= -40), "AAA"]
Out[22]:
     0
    4
     1
    5
   Name: AAA, dtype: int64
```

... or (with assignment modifies the DataFrame.)

```
In [23]: df.loc[(df["BBB"] > 25) | (df["CCC"] >= 75), "AAA"] = 0.1
```
Select rows with data closest to certain value using argsort

```python
In [24]: df
Out[24]:
   AAA  BBB  CCC
0   0.1  10  100
1   5.0  20   50
2   0.1  30  -30
3   0.1  40  -50
```

```python
In [25]: df = pd.DataFrame(
    ....:
    .....:
    .....:
    In [26]: df
Out[26]:
   AAA  BBB  CCC
0   4   10  100
1   5   20   50
2   6   30  -30
3   7   40  -50
```

```python
In [27]: aValue = 43.0
In [28]: df.loc[(df.CCC - aValue).abs().argsort()]
Out[28]:
   AAA  BBB  CCC
0   4   10  100
1   5   20   50
2   6   30  -30
3   7   40  -50
```

Dynamically reduce a list of criteria using a binary operators

```python
In [29]: df = pd.DataFrame(
    ....:
    "AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50])
    ....:
    ....:
In [30]: df
Out[30]:
   AAA  BBB  CCC
0   4   10  100
1   5   20   50
2   6   30  -30
3   7   40  -50
```

```python
In [31]: Crit1 = df.AAA <= 5.5
In [32]: Crit2 = df.BBB == 10.0
In [33]: Crit3 = df.CCC > -40.0
```

One could hard code:
...Or it can be done with a list of dynamically built criteria

```python
In [35]: import functools
In [36]: CritList = [Crit1, Crit2, Crit3]
In [37]: AllCrit = functools.reduce(lambda x, y: x & y, CritList)
In [38]: df[AllCrit]
```

### 2.27.2 Selection

**Dataframes**

The *indexing* docs.

Using both row labels and value conditionals

```python
In [39]: df = pd.DataFrame(
   .....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
   .....: )
   .....:
In [40]: df
```

```python
Out[40]:
AAA  BBB  CCC
0   4    10   100
1   5    20    50
2   6    30   -30
3   7    40   -50
```

```python
In [41]: df[(df.AAA <= 6) & (df.index.isin([0, 2, 4]))]
```

```python
Out[41]:
AAA  BBB  CCC
0   4    10   100
2   6    30   -30
```

Use `loc` for label-oriented slicing and `iloc` positional slicing

```python
In [42]: df = pd.DataFrame(
   .....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]},
   .....:     index=['foo', 'bar', 'boo', 'kar'],
   .....:     )
   .....:
```

There are 2 explicit slicing methods, with a third general case

1. Positional-oriented (Python slicing style : exclusive of end)
2. Label-oriented (Non-Python slicing style : inclusive of end)
3. General (Either slicing style : depends on if the slice contains labels or positions)

```python
In [43]: df.loc["bar":"kar"]  # Label
Out[43]:
      AAA  BBB  CCC
bar  5.00  20.0  50.0
boo  6.00  30.0 -30.0
kar  7.00  40.0 -50.0

# Generic
In [44]: df[0:3]
Out[44]:
      AAA  BBB  CCC
foo  4.00  10.0 100.0
bar  5.00  20.0  50.0
boo  6.00  30.0 -30.0

In [45]: df["bar":"kar"]
Out[45]:
      AAA  BBB  CCC
bar  5.00  20.0  50.0
boo  6.00  30.0 -30.0
kar  7.00  40.0 -50.0
```

Ambiguity arises when an index consists of integers with a non-zero start or non-unit increment.

```python
In [46]: data = {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
In [47]: df2 = pd.DataFrame(data=data, index=[1, 2, 3, 4])  # Note index starts at 1.
In [48]: df2.iloc[1:3]  # Position-oriented
Out[48]:
      AAA  BBB  CCC
2  5.00  20.0  50.0
3  6.00  30.0 -30.0

In [49]: df2.loc[1:3]  # Label-oriented
Out[49]:
      AAA  BBB  CCC
1  4.00  10.0 100.0
2  5.00  20.0  50.0
3  6.00  30.0 -30.0
```

Using inverse operator (~) to take the complement of a mask

```python
In [50]: df = pd.DataFrame(
    ....:   {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
    ....: )
    ....: 
In [51]: df
Out[51]:
      AAA  BBB  CCC
0  4.00  10.0 100.0
1  5.00  20.0  50.0
2  6.00  30.0 -30.0
```

(continues on next page)
New columns

Efficiently and dynamically creating new columns using applymap

```
In [53]: df = pd.DataFrame({"AAA": [1, 2, 1, 3], "BBB": [1, 1, 2, 2], "CCC": [2, 1, 3, 1]})

In [54]: df
Out[54]:
      AAA  BBB  CCC
 0     1     1     2
 1     2     1     1
 2     1     2     3
 3     3     2     1
```

```
In [55]: source_cols = df.columns  # Or some subset would work too

In [56]: new_cols = [str(x) + "_cat" for x in source_cols]

In [57]: categories = {1: "Alpha", 2: "Beta", 3: "Charlie"}

In [58]: df[new_cols] = df[source_cols].applymap(categories.get)

In [59]: df
Out[59]:
      AAA  BBB  CCC       AAA_cat  BBB_cat  CCC_cat
 0     1     1     2       Alpha    Alpha     Beta
 1     2     1     1       Beta     Alpha    Alpha
 2     1     2     3       Alpha     Beta    Charlie
 3     3     2     1     Charlie    Beta     Alpha
```

Keep other columns when using min() with groupby

```
In [60]: df = pd.DataFrame(...
                        {"AAA": [1, 1, 1, 2, 2, 2, 3, 3], "BBB": [2, 1, 3, 4, 5, 1, 2, 3]})
                        ...

In [61]: df
Out[61]:
      AAA  BBB
 0     1  2  
 1     1  1  
 2     1  3  
 3     2  4  
 4     2  5  
 5     2  1  
```

(continues on next page)
Method 1 : idxmin() to get the index of the minimums

```
In [62]: df.loc[df.groupby("AAA")["BBB"]).idxmin()  
Out[62]:  
   AAA  BBB  
1  1  1  1  
5  2  1  1  
6  3  2  2  
```

Method 2 : sort then take first of each

```
In [63]: df.sort_values(by="BBB").groupby("AAA", as_index=False).first()  
Out[63]:  
   AAA  BBB  
0  1  1  1  
1  2  1  1  
2  3  2  2  
```

Notice the same results, with the exception of the index.

### 2.27.3 Multiindexing

The `multindexing` docs.

Creating a MultiIndex from a labeled frame

```
In [64]: df = pd.DataFrame(  
        "row": [0, 1, 2],  
        "One_X": [1.1, 1.1, 1.1],  
        "One_Y": [1.2, 1.2, 1.2],  
        "Two_X": [1.11, 1.11, 1.11],  
        "Two_Y": [1.22, 1.22, 1.22],  
    }  
In [65]: df  
Out[65]:  
   row  One_X  One_Y  Two_X  Two_Y  
0  0    1.1    1.2    1.11    1.22  
1  1    1.1    1.2    1.11    1.22  
2  2    1.1    1.2    1.11    1.22  
```

# As Labelled Index

```
In [66]: df = df.set_index("row")  
In [67]: df  
Out[67]:  
   One_X  One_Y  Two_X  Two_Y  
row  
0  1.1    1.2    1.11    1.22  
1  1.1    1.2    1.11    1.22  
2  1.1    1.2    1.11    1.22  
```

(continues on next page)
# With Hierarchical Columns

```python
In [68]: df.columns = pd.MultiIndex.from_tuples([tuple(c.split('_')) for c in df.columns])
```

```python
Out[69]:
```

<table>
<thead>
<tr>
<th>row</th>
<th>One</th>
<th>Two</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>X</td>
<td>Y</td>
</tr>
<tr>
<td>0</td>
<td>1.1</td>
<td>1.2</td>
</tr>
<tr>
<td>1</td>
<td>1.1</td>
<td>1.2</td>
</tr>
<tr>
<td>2</td>
<td>1.1</td>
<td>1.1</td>
</tr>
</tbody>
</table>

# Now stack & Reset

```python
In [70]: df = df.stack(0).reset_index(1)
```

```python
Out[71]:
```

<table>
<thead>
<tr>
<th>level_1</th>
<th>X</th>
<th>Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>One</td>
<td>1.1</td>
<td>1.2</td>
</tr>
<tr>
<td>Two</td>
<td>1.1</td>
<td>1.2</td>
</tr>
<tr>
<td>One</td>
<td>1.1</td>
<td>1.2</td>
</tr>
<tr>
<td>Two</td>
<td>1.1</td>
<td>1.1</td>
</tr>
<tr>
<td>One</td>
<td>1.1</td>
<td>1.2</td>
</tr>
<tr>
<td>Two</td>
<td>1.1</td>
<td>1.1</td>
</tr>
</tbody>
</table>

# And fix the labels (Notice the label 'level_1' got added automatically)

```python
In [72]: df.columns = ['Sample', 'All_X', 'All_Y']
```

```python
Out[73]:
```

<table>
<thead>
<tr>
<th>Sample</th>
<th>All_X</th>
<th>All_Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>One</td>
<td>1.10</td>
<td>1.20</td>
</tr>
<tr>
<td>Two</td>
<td>1.11</td>
<td>1.22</td>
</tr>
<tr>
<td>One</td>
<td>1.10</td>
<td>1.20</td>
</tr>
<tr>
<td>Two</td>
<td>1.11</td>
<td>1.22</td>
</tr>
<tr>
<td>One</td>
<td>1.10</td>
<td>1.20</td>
</tr>
<tr>
<td>Two</td>
<td>1.11</td>

</tr>
</tbody>
</table>

## Arithmetic

Performing arithmetic with a MultiIndex that needs broadcasting

```python
In [74]: cols = pd.MultiIndex.from_tuples(
.....:     [(x, y) for x in ['A', 'B', 'C'] for y in ['O', 'I']]
.....: )
.....:
```

```python
In [75]: df = pd.DataFrame(np.random.randn(2, 6), index=["n", "m"], columns=cols)
```

```python
In [76]: df
```

(continues on next page)
Slicing

Slicing a MultiIndex with xs

```python
In [79]: coords = ["AA", "one"], ["AA", "six"], ["BB", "one"], ["BB", "two"], ["BB", "six"]

In [80]: index = pd.MultiIndex.from_tuples(coords)

In [81]: df = pd.DataFrame([11, 22, 33, 44, 55], index, ["MyData"])

In [82]: df
Out[82]:
   MyData
AA   one  11
     six  22
BB   one  33
     two  44
     six  55

To take the cross section of the 1st level and 1st axis the index:

```python
# Note : level and axis are optional, and default to zero
In [83]: df.xs("BB", level=0, axis=0)
Out[83]:
   MyData
one  33
two  44
six  55

...and now the 2nd level of the 1st axis.

```python
In [84]: df.xs("six", level=1, axis=0)
Out[84]:
   MyData
AA   22
BB   55
```

Slicing a MultiIndex with xs, method #2
```python
In [85]: import itertools
In [86]: index = list(itertools.product(["Ada", "Quinn", "Violet"], ["Comp", "Math", "Sci"]))
In [87]: headr = list(itertools.product(["Exams", "Labs"], ["I", "II"]))
In [88]: indx = pd.MultiIndex.from_tuples(index, names=["Student", "Course"])
In [89]: cols = pd.MultiIndex.from_tuples(headr)  # Notice these are un-named
In [90]: data = [[70 + x + y + (x * y) % 3 for x in range(4)] for y in range(9)]
In [91]: df = pd.DataFrame(data, indx, cols)
In [92]: df
Out[92]:
<table>

</tr>
</tbody>
</table>

(continues on next page)```
Setting portions of a MultiIndex with `xs`

**Sorting**

Sort by specific column or an ordered list of columns, with a MultiIndex

```python
In [99]: df.sort_values(by=("Labs", "II"), ascending=False)
Out[99]:
```

<table>
<thead>
<tr>
<th>Student</th>
<th>Course</th>
<th>Exams</th>
<th>Labs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Violet</td>
<td>Sci</td>
<td>78 71</td>
<td>81 74</td>
</tr>
<tr>
<td></td>
<td>Math</td>
<td>77 73</td>
<td>81 77</td>
</tr>
<tr>
<td></td>
<td>Comp</td>
<td>76 70</td>
<td>78 72</td>
</tr>
<tr>
<td>Quinn</td>
<td>Sci</td>
<td>75 71</td>
<td>78 74</td>
</tr>
<tr>
<td></td>
<td>Math</td>
<td>74 72</td>
<td>78 76</td>
</tr>
<tr>
<td></td>
<td>Comp</td>
<td>73 71</td>
<td>75 74</td>
</tr>
<tr>
<td>Ada</td>
<td>Sci</td>
<td>72 70</td>
<td>75 73</td>
</tr>
<tr>
<td></td>
<td>Math</td>
<td>71 71</td>
<td>75 72</td>
</tr>
<tr>
<td></td>
<td>Comp</td>
<td>70 70</td>
<td>72 73</td>
</tr>
</tbody>
</table>
```

Partial selection, the need for sortedness;

**Levels**

Prepending a level to a multiindex

Flatten Hierarchical columns
2.27.4 Missing data

The *missing data* docs.

Fill forward a reversed timeseries

```
In [100]: df = pd.DataFrame(
    ....:     np.random.randn(6, 1),
    ....:     index=pd.date_range("2013-08-01", periods=6, freq="B"),
    ....:     columns=list("A"),
    ....:     )

In [101]: df.loc[df.index[3], "A"] = np.nan

In [102]: df
Out[102]:
   A
0  0.721555
1 -0.706771
2 -1.039575
3 NaN
4 -0.424972
5  0.567020

In [103]: df.reindex(df.index[::-1]).ffill()
Out[103]:
   A
0  0.567020
1 -0.424972
2 -0.424972
3 -1.039575
4 -0.706771
5  0.721555
```

cumsum reset at NaN values

**Replace**

Using replace with backrefs

2.27.5 Grouping

The *grouping* docs.

Basic grouping with apply

Unlike agg, apply’s callable is passed a sub-DataFrame which gives you access to all the columns

```
In [104]: df = pd.DataFrame(
    ....:     {
    ....:         "animal": "cat dog cat fish dog cat cat".split(),
    ....:         "size": list("SSMMMLL"),
    ....:         "weight": [8, 10, 11, 1, 20, 12, 12],
    ....:         "adult": [False] * 5 + [True] * 2,
    ....:     }
    ....: )
```

(continues on next page)
In [105]: df
Out[105]:
<table>
<thead>
<tr>
<th>animal</th>
<th>size</th>
<th>weight</th>
<th>adult</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat</td>
<td>S</td>
<td>8</td>
<td>False</td>
</tr>
<tr>
<td>dog</td>
<td>S</td>
<td>10</td>
<td>False</td>
</tr>
<tr>
<td>cat</td>
<td>M</td>
<td>11</td>
<td>False</td>
</tr>
<tr>
<td>fish</td>
<td>M</td>
<td>1</td>
<td>False</td>
</tr>
<tr>
<td>dog</td>
<td>M</td>
<td>20</td>
<td>False</td>
</tr>
<tr>
<td>cat</td>
<td>L</td>
<td>12</td>
<td>True</td>
</tr>
<tr>
<td>cat</td>
<td>L</td>
<td>12</td>
<td>True</td>
</tr>
</tbody>
</table>

# List the size of the animals with the highest weight.
In [106]: df.groupby("animal").apply(lambda subf: subf["size"][subf["weight"].idxmax()])
Out[106]:
<table>
<thead>
<tr>
<th>animal</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat L</td>
</tr>
<tr>
<td>dog M</td>
</tr>
<tr>
<td>fish M</td>
</tr>
</tbody>
</table>

dtype: object

Using get_group

In [107]: gb = df.groupby(["animal"])
In [108]: gb.get_group("cat")
Out[108]:
<table>
<thead>
<tr>
<th>animal</th>
<th>size</th>
<th>weight</th>
<th>adult</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat</td>
<td>S</td>
<td>8</td>
<td>False</td>
</tr>
<tr>
<td>cat</td>
<td>M</td>
<td>11</td>
<td>False</td>
</tr>
<tr>
<td>cat</td>
<td>L</td>
<td>12</td>
<td>True</td>
</tr>
<tr>
<td>cat</td>
<td>L</td>
<td>12</td>
<td>True</td>
</tr>
</tbody>
</table>

Apply to different items in a group

In [109]: def GrowUp(x):
   .....:     avg_weight = sum(x[x["size"] == "S"].weight * 1.5)
   .....:     avg_weight += sum(x[x["size"] == "M"].weight * 1.25)
   .....:     avg_weight += sum(x[x["size"] == "L"].weight)
   .....:     avg_weight /= len(x)
   .....:     return pd.Series(["L", avg_weight, True], index=["size", "weight", "adult"])
   .....:
In [110]: expected_df = gb.apply(GrowUp)
In [111]: expected_df
Out[111]:
<table>
<thead>
<tr>
<th>size</th>
<th>weight</th>
<th>adult</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat</td>
<td>L 12.4375</td>
<td>True</td>
</tr>
<tr>
<td>dog</td>
<td>L 20.0000</td>
<td>True</td>
</tr>
<tr>
<td>fish</td>
<td>L 1.2500</td>
<td>True</td>
</tr>
</tbody>
</table>
Expanding apply

```python
In [112]: S = pd.Series([i / 100.0 for i in range(1, 11)]

In [113]: def cum_ret(x, y):
    ....:     return x * (1 + y)
    ....:

In [114]: def red(x):
    ....:     return functools.reduce(cum_ret, x, 1.0)
    ....:

In [115]: S.expanding().apply(red, raw=True)
Out[115]:
          0  1.010000
          1  1.030200
          2  1.061106
          3  1.103550
          4  1.158728
          5  1.228251
          6  1.314229
          7  1.419367
          8  1.547110
          9  1.701821
       dtype: float64
```

Replacing some values with mean of the rest of a group

```python
In [116]: df = pd.DataFrame({"A": [1, 1, 2, 2], "B": [1, -1, 1, 2]})

In [117]: gb = df.groupby("A")

In [118]: def replace(g):
    ....:     mask = g < 0
    ....:     return g.where(mask, g[~mask].mean())
    ....:

In [119]: gb.transform(replace)
Out[119]:
          B
          0  1.0
          1 -1.0
          2  1.5
          3  1.5
```

Sort groups by aggregated data

```python
In [120]: df = pd.DataFrame(
    ....:     "code": ["foo", "bar", "baz"] * 2,
    ....:     "data": [0.16, -0.21, 0.33, 0.45, -0.59, 0.62],
    ....:     "flag": [False, True] * 3,
    ....:     )

In [121]: code_groups = df.groupby("code")

(continues on next page)
Create multiple aggregated columns

In [125]: rng = pd.date_range(start="2014-10-07", periods=10, freq="2min")

In [126]: ts = pd.Series(data=list(range(10)), index=rng)

In [127]: def MyCust(x):
   ...:     if len(x) > 2:
   ...:         return x[1] * 1.234
   ...:     return pd.NaT
   ...:

In [128]: mhc = {"Mean": np.mean, "Max": np.max, "Custom": MyCust}

In [129]: ts.resample("5min").apply(mhc)

Out[129]:
          Mean  Max    Custom
2014-10-07  00:00:00  1.0  2.0     1.234
2014-10-07  00:05:00  3.5  4.0     NaT

```

Grouping like Python’s itertools.groupby

```
In [143]: df = pd.DataFrame([0, 1, 0, 1, 1, 1, 0, 1, 1], columns=["A"])

In [144]: df["A"].groupby((df["A"] != df["A"].shift()).cumsum()).groups
Out[144]: {1: [0], 2: [1], 3: [2], 4: [3, 4, 5], 5: [6], 6: [7, 8]}

In [145]: df["A"].groupby((df["A"] != df["A"].shift()).cumsum()).cumsum()
Out[145]:
0  0
1  1
2  0
3  1
4  2
5  3
6  0
7  1
8  2
Name: A, dtype: int64
```

**Expanding data**

Alignment and to-date

Rolling Computation window based on values instead of counts

Rolling Mean by Time Interval
**Splitting**

**Splitting a frame**

Create a list of dataframes, split using a delineation based on logic included in rows.

```python
In [146]: df = pd.DataFrame(
     ........:     data={
     ........:         "Data": np.random.randn(9),
     ........:     }
     ........: )
     ........:

In [147]: dfs = list(
     ........:     zip(
     ........:         *df.groupby(
     ........:             (1 * (df["Case"] == "B"))
     ........:             .cumsum()
     ........:             .rolling(window=3, min_periods=1)
     ........:             .median()
     ........:         )
     ........:     )[-1]
     ........: )
     ........:

In [148]: dfs[0]
Out[148]:
     Case  Data
     0   A   0.276232
     1   A  -1.087401
     2   A  -0.673690
     3   B   0.113648

In [149]: dfs[1]
Out[149]:
     Case  Data
     4   A  -1.478427
     5   A   0.524988
     6   B   0.404705

In [150]: dfs[2]
Out[150]:
     Case  Data
     7   A   0.577046
     8   A  -1.715002
```
Pivot

The Pivot docs.

Partial sums and subtotals

```
In [151]: df = pd.DataFrame(
    ..........: data={
    ..........:     "Province": ["ON", "QC", "BC", "AL", "AL", "MN", "ON"],
    ..........:     "City": [
    ..........:         "Toronto",
    ..........:         "Montreal",
    ..........:         "Vancouver",
    ..........:         "Calgary",
    ..........:         "Edmonton",
    ..........:         "Winnipeg",
    ..........:         "Windsor",
    ..........:     ],
    ..........:     "Sales": [13, 6, 16, 8, 4, 3, 1],
    ..........:     }
    ..........: }
    ..........: )
    ..........:

In [152]: table = pd.pivot_table(
    ..........: df,
    ..........:     values=["Sales"],

2.27.9 Data in/out

Performance comparison of SQL vs HDF5

CSV

The CSV docs
read_csv in action
appending to a csv
Reading a csv chunk-by-chunk
Reading only certain rows of a csv chunk-by-chunk
Reading the first few lines of a frame
Reading a file that is compressed but not by gzip/bz2 (the native compressed formats which read_csv understands). This example shows a WinZipped file, but is a general application of opening the file within a context manager and using that handle to read. See here
Inferring dtypes from a file
Dealing with bad lines
Dealing with bad lines II
Reading CSV with Unix timestamps and converting to local timezone
Write a multi-row index CSV without writing duplicates

Reading multiple files to create a single DataFrame

The best way to combine multiple files into a single DataFrame is to read the individual frames one by one, put all of the individual frames into a list, and then combine the frames in the list using pd.concat():

```python
In [189]: for i in range(3):
    .....:    data = pd.DataFrame(np.random.randn(10, 4))
    .....:    data.to_csv("file_{i}.csv".format(i))
    .....:
In [190]: files = ["file_0.csv", "file_1.csv", "file_2.csv"]
In [191]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

You can use the same approach to read all files matching a pattern. Here is an example using glob:

```python
In [192]: import glob
In [193]: import os
In [194]: files = glob.glob("file_*\.csv")
In [195]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

Finally, this strategy will work with the other pd.read_*(...) functions described in the io docs.
Parsing date components in multi-columns

Parsing date components in multi-columns is faster with a format

```
In [196]: i = pd.date_range("20000101", periods=10000)
In [197]: df = pd.DataFrame({"year": i.year, "month": i.month, "day": i.day})
In [198]: df.head()
Out[198]:
      year  month  day
0     2000     1     1
1     2000     1     2
2     2000     1     3
3     2000     1     4
4     2000     1     5
```

```
In [199]: %timeit pd.to_datetime(df.year * 10000 + df.month * 100 + df.day, format='%Y-%m-%d')
     3.76 ms +- 103 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
     943 us +- 4.3 us per loop (mean +- std. dev. of 7 runs, 1000 loops each)
```

Skip row between header and data

```
In [200]: data = """;
   ....: ;
   ....: ;
   ....: ;
   ....: ;
   ....: ;
   ....: ;
   ....: ;
   ....: ;
   ....: ;
   ....: ;
   ....: ;
   ....: ;
   ....: date;Param1;Param2;Param4;Param5
   ....: m;°C;m;m;m
   ....: ;
   ....: 01.01.1990 00:00;1;1;2;3
   ....: 01.01.1990 01:00;5;3;4;5
   ....: 01.01.1990 02:00;9;5;6;7
   ....: 01.01.1990 03:00;13;7;8;9
   ....: 01.01.1990 04:00;17;9;10;11
   ....: 01.01.1990 05:00;21;11;12;13
   ....: ""
   ....: 
   ````
### Option 1: pass rows explicitly to skip rows

```python
In [201]: from io import StringIO
In [202]: pd.read_csv(StringIO(data),
   ....:     sep=';',
   ....:     skiprows=[11, 12],
   ....:     index_col=0,
   ....:     parse_dates=True,
   ....:     header=10,
   ....: )
```

```
Out[202]:
          Param1  Param2  Param4  Param5
date
1990-01-01 00:00:00     1      1      2      3
1990-01-01 01:00:00     5      3      4      5
1990-01-01 02:00:00     9      5      6      7
1990-01-01 03:00:00    13      7      8      9
1990-01-01 04:00:00    17      9     10     11
1990-01-01 05:00:00    21     11     12     13
```

### Option 2: read column names and then data

```python
In [203]: pd.read_csv(StringIO(data), sep=';', header=10, nrows=10).columns
Out[203]: Index(['date', 'Param1', 'Param2', 'Param4', 'Param5'], dtype='object')
```
```
In [204]: columns = pd.read_csv(StringIO(data), sep=';', header=10, nrows=10).columns
In [205]: pd.read_csv(StringIO(data), sep=';', index_col=0, parse_dates=True,
   ....:     names=columns
   ....: )
```

```
Out[205]:
          Param1  Param2  Param4  Param5
date
1990-01-01 00:00:00     1      1      2      3

Troubleshoot HDFStore exceptions  
Setting min_itemsize with strings  
Using ptrepack to create a completely-sorted-index on a store

Storing Attributes to a group node

```
In [206]: df = pd.DataFrame(np.random.randn(8, 3))

In [207]: store = pd.HDFStore("test.h5")

In [208]: store.put("df", df)
```
# you can store an arbitrary Python object via pickle
In [209]: store.get_storer("df").attrs.my_attribute = {"A": 10}

In [210]: store.get_storer("df").attrs.my_attribute
Out[210]: {'A': 10}

You can create or load a HDFStore in-memory by passing the `driver` parameter to PyTables. Changes are only written to disk when the HDFStore is closed.

In [211]: store = pd.HDFStore("test.h5", "w", driver="H5FD_CORE")

In [212]: df = pd.DataFrame(np.random.randn(8, 3))

In [213]: store["test"] = df

# only after closing the store, data is written to disk:
In [214]: store.close()

**Binary files**

pandas readily accepts NumPy record arrays, if you need to read in a binary file consisting of an array of C structs. For example, given this C program in a file called `main.c` compiled with `gcc main.c -std=gnu99` on a 64-bit machine,

```c
#include <stdio.h>
#include <stdint.h>

typedef struct _Data
{
    int32_t count;
    double avg;
    float scale;
} Data;

int main(int argc, const char *argv[])
{
    size_t n = 10;
    Data d[n];

    for (int i = 0; i < n; ++i)
    {
        d[i].count = i;
        d[i].avg = i + 1.0;
        d[i].scale = (float) i + 2.0f;
    }

    FILE *file = fopen("binary.dat", "wb");
    fwrite(d, sizeof(Data), n, file);
    fclose(file);

    return 0;
}
```

the following Python code will read the binary file 'binary.dat' into a pandas DataFrame, where each element of the struct corresponds to a column in the frame:
names = "count", "avg", "scale"

# note that the offsets are larger than the size of the type because of
# struct padding
offsets = 0, 8, 16
formats = "i4", "f8", "f4"
dt = np.dtype(("names": names, "offsets": offsets, "formats": formats), align=True)
df = pd.DataFrame(np.fromfile("binary.dat", dt))

Note: The offsets of the structure elements may be different depending on the architecture of the machine on which
the file was created. Using a raw binary file format like this for general data storage is not recommended, as it is not
cross platform. We recommended either HDF5 or parquet, both of which are supported by pandas’ IO facilities.

2.27.10 Computation

Numerical integration (sample-based) of a time series

Correlation

Often it’s useful to obtain the lower (or upper) triangular form of a correlation matrix calculated from DataFrame.
corr(). This can be achieved by passing a boolean mask to where as follows:

In [215]: df = pd.DataFrame(np.random.random(size=(100, 5)))
In [216]: corr_mat = df.corr()
In [217]: mask = np.tril(np.ones_like(corr_mat, dtype=np.bool_), k=-1)
In [218]: corr_mat.where(mask)
Out[218]:
       0     1     2     3     4
0 NaN  NaN  NaN  NaN  NaN
1 -0.079861  NaN  NaN  NaN  NaN
2 -0.236573 -0.051975  NaN  NaN  NaN
3 -0.013795 -0.051975 0.037235  NaN  NaN
4 -0.031974 0.118342 -0.073499 -0.02063  NaN

The method argument within DataFrame.corr can accept a callable in addition to the named correlation types.
Here we compute the distance correlation matrix for a DataFrame object.

In [219]: def distcorr(x, y):
   ....:     n = len(x)
   ....:     a = np.zeros(shape=(n, n))
   ....:     b = np.zeros(shape=(n, n))
   ....:     for i in range(n):
   ....:         for j in range(i + 1, n):
   ....:             a[i, j] = abs(x[i] - x[j])
   ....:             b[i, j] = abs(y[i] - y[j])
   ....:     a += a.T
   ....:     b += b.T
   ....:     a_bar = np.vstack([np.nanmean(a, axis=0)] * n)
   ....:     b_bar = np.vstack([np.nanmean(b, axis=0)] * n)

(continues on next page)
2.27.11 Timedeltas

The Timedeltas docs.

Using timedeltas

In [222]: import datetime

In [223]: s = pd.Series(pd.date_range("2012-1-1", periods=3, freq="D"))

In [224]: s - s.max()
Out[224]:
0   2 days
1   1 days
2    0 days
dtype: timedelta64[ns]

In [225]: s.max() - s
Out[225]:
0   2 days
1   1 days
2    0 days
dtype: timedelta64[ns]

In [226]: s - datetime.datetime(2011, 1, 1, 3, 5)
Out[226]:
0   364 days 20:55:00
1   365 days 20:55:00
2   366 days 20:55:00
dtype: timedelta64[ns]

In [227]: s + datetime.timedelta(minutes=5)
Out[227]:
0 2012-01-01 05:05:00
1 2012-01-02 05:05:00
2 2012-01-03 05:05:00
dtype: datetime64[ns]
Adding and subtracting deltas and dates

Adding and subtracting deltas and dates

Another example

Values can be set to NaT using np.nan, similar to datetime
In [239]: y[1] = np.nan

In [240]: y
Out[240]:
0  NaT
1  NaT
2  1 days
dtype: timedelta64[ns]

2.27.12 Creating example data

To create a dataframe from every combination of some given values, like R’s `expand.grid()` function, we can create a dict where the keys are column names and the values are lists of the data values:

```python
In [241]: def expand_grid(data_dict):
    ...:     rows = itertools.product(*data_dict.values())
    ...:     return pd.DataFrame.from_records(rows, columns=data_dict.keys())
    ...:

In [242]: df = expand_grid(
    ...:     {"height": [60, 70], "weight": [100, 140, 180], "sex": ["Male", "Female"]}
    ...: )
    ...:

In [243]: df
Out[243]:
height  weight  sex
0       60      100  Male
1       60      100  Female
2       60      140  Male
3       60      140  Female
4       60      180  Male
5       60      180  Female
6       70      100  Male
7       70      100  Female
8       70      140  Male
9       70      140  Female
10      70      180  Male
11      70      180  Female
```
This page gives an overview of all public pandas objects, functions and methods. All classes and functions exposed in pandas.* namespace are public.

Some subpackages are public which include pandas.errors, pandas.plotting, and pandas.testing. Public functions in pandas.io and pandas.tseries submodules are mentioned in the documentation. pandas.api.types subpackage holds some public functions related to data types in pandas.

Warning: The pandas.core, pandas.compat, and pandas.util top-level modules are PRIVATE. Stable functionality in such modules is not guaranteed.

### 3.1 Input/output

#### 3.1.1 Pickling

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>read_pickle(filepath_or_buffer[,...])</code></td>
<td>Loadpickledpandasobject(oranyobject)fromfile.</td>
</tr>
<tr>
<td><code>DataFrame.to_pickle(path[, compression,...])</code></td>
<td>Pickle(serializ)objecttofile.</td>
</tr>
</tbody>
</table>

**pandas.read_pickle**

- **pandas.read_pickle (filepath_or_buffer, compression='infer', storage_options=None)**
  - Load pickled pandas object (or any object) from file.

  Warning: Loading pickled data received from untrusted sources can be unsafe. See here.

**Parameters**

- **filepath_or_buffer** [str, path object or file-like object] File path, URL, or buffer where the pickled object will be loaded from.
  - Changed in version 1.0.0: Accept URL. URL is not limited to S3 and GCS.

- **compression** [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] If ‘infer’ and ‘path_or_url’ is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’ (otherwise no compression) If ‘infer’ and ‘path_or_url’ is not path-like, then use None (= no decompression).
storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

Returns

unpickled [same type as object stored in file]

See also:

DataFrame.to_pickle Pickle (serialize) DataFrame object to file.
Series.to_pickle Pickle (serialize) Series object to file.
read_hdf Read HDF5 file into a DataFrame.
read_sql Read SQL query or database table into a DataFrame.
read_parquet Load a parquet object, returning a DataFrame.

Notes

read_pickle is only guaranteed to be backwards compatible to pandas 0.20.3.

Examples

```python
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0   0   5
1   1   6
2   2   7
3   3   8
4   4   9

>>> pd.to_pickle(original_df, ".\dummy.pkl")

>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0   0   5
1   1   6
2   2   7
3   3   8
4   4   9

>>> import os
>>> os.remove("./dummy.pkl")
```
pandas.DataFrame.to_pickle

DataFrame.to_pickle(path, compression=’infer’, protocol=5, storage_options=None)

Pickle (serialize) object to file.

Parameters

path [str] File path where the pickled object will be stored.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] A string representing the compression to use in the output file. By default, infers from the file extension in specified path. Compression mode may be any of the following possible values: {‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}. If compression mode is ‘infer’ and path_or_buf is path-like, then detect compression mode from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’ or ‘.xz’. (otherwise no compression). If dict given and mode is ‘zip’ or inferred as ‘zip’, other entries passed as additional compression options.

protocol [int] Int which indicates which protocol should be used by the pickler, default HIGHEST_PROTOCOL (see [1] paragraph 12.1.2). The possible values are 0, 1, 2, 3, 4, 5. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST_PROTOCOL.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

See also:

read_pickle Load pickled pandas object (or any object) from file.

DataFrame.to_hdf Write DataFrame to an HDF5 file.

DataFrame.to_sql Write DataFrame to a SQL database.

DataFrame.to_parquet Write a DataFrame to the binary parquet format.

Examples

```python
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0    0   5
1    1   6
2    2   7
3    3   8
4    4   9
>>> original_df.to_pickle("./dummy.pkl")

>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0    0   5
1    1   6
2    2   7
```

(continues on next page)
>>> import os
>>> os.remove("./dummy.pkl")

3.1.2 Flat file

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>read_table(filepath_or_buffer[, sep, ...])</code></td>
<td>Read general delimited file into DataFrame.</td>
</tr>
<tr>
<td><code>read_csv(filepath_or_buffer[, sep, ...])</code></td>
<td>Read a comma-separated values (csv) file into DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.to_csv([path_or_buf, sep, na_rep, ...])</code></td>
<td>Write object to a comma-separated values (csv) file.</td>
</tr>
<tr>
<td><code>read_fwf(filepath_or_buffer[, colspecs, ...])</code></td>
<td>Read a table of fixed-width formatted lines into DataFrame.</td>
</tr>
</tbody>
</table>

**pandas.read_table**

Read general delimited file into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for IO Tools.

**Parameters**

- **filepath_or_buffer** [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, gs, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.csv.

  If you want to pass in a path object, pandas accepts any `os.PathLike`.

  By file-like object, we refer to objects with a `read()` method, such as a file handle (e.g. via `builtin open function`) or `StringIO`.

- **sep** [str, default ‘\t’ (tab-stop)] Delimiter to use. If sep is None, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python’s builtin sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from ‘\s+’ will be interpreted as
regular expressions and will also force the use of the Python parsing engine. Note that regex
delimiters are prone to ignoring quoted data. Regex example: '\r\t'.

delimiter [str, default None] Alias for sep.

header [int, list of int, default ‘infer’] Row number(s) to use as the column names, and the
start of the data. Default behavior is to infer the column names: if no names are passed the
behavior is identical to header=0 and column names are inferred from the first line of the
file, if column names are passed explicitly then the behavior is identical to header=None. Explicitly pass header=0 to be able to replace existing names. The header can be a list of
integers that specify row locations for a multi-index on the columns e.g. [0,1,3]. Intervening
rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this
parameter ignores commented lines and empty lines if skip_blank_lines=True, so
header=0 denotes the first line of data rather than the first line of the file.

names [array-like, optional] List of column names to use. If the file contains a header row, then
you should explicitly pass header=0 to override the column names. Duplicates in this list
are not allowed.

index_col [int, str, sequence of int / str, or False, default None] Column(s) to use as the row
labels of the DataFrame, either given as string name or column index. If a sequence of int
/ str is given, a MultiIndex is used.

Note: index_col=False can be used to force pandas to not use the first column as the
index, e.g. when you have a malformed file with delimiters at the end of each line.

usecols [list-like or callable, optional] Return a subset of the columns. If list-like, all elements
must either be positional (i.e. integer indices into the document columns) or strings that
correspond to column names provided either by the user in names or inferred from the
document header row(s). For example, a valid list-like usecols parameter would be [0, 1, 2] or ['foo', 'bar', 'baz']. Element order is ignored, so usecols=[0, 1] is the same as [1, 0]. To instantiate a DataFrame from data with element or-
der preserved use pd.read_csv(data, usecols=['foo', 'bar'])[[‘foo’,
‘bar’]] for columns in [‘foo’, ‘bar’] order or pd.read_csv(data,
usecols=['foo', 'bar'])[[‘bar’, ‘foo’]] for [‘bar’, ‘foo’] order.

If callable, the callable function will be evaluated against the column names, returning
names where the callable function evaluates to True. An example of a valid callable ar-
gument would be lambda x: x.upper() in [‘AAA’, ‘BBB’, ‘DDD’]. Using
this parameter results in much faster parsing time and lower memory usage.

squeeze [bool, default False] If the parsed data only contains one column then return a Series.

prefix [str, optional] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1, …

mangle_dupe_cols [bool, default True] Duplicate columns will be specified as ‘X’, ‘X.1’,
… ‘X.N’, rather than ‘X’…’X’. Passing in False will cause data to be overwritten if there
are duplicate names in the columns.

dtype [Type name or dict of column -> type, optional] Data type for data or columns. E.g. {‘a’:
np.float64, ‘b’: np.int32, ‘c’: ‘Int64’} Use str or object together with suitable na_values
settings to preserve and not interpret dtype. If converters are specified, they will be applied
INSTEAD of dtype conversion.

engine [(‘c’, ‘python’), optional] Parser engine to use. The C engine is faster while the python
engine is currently more feature-complete.

converters [dict, optional] Dict of functions for converting values in certain columns. Keys can
either be integers or column labels.

true_values [list, optional] Values to consider as True.
false_values [list, optional] Values to consider as False.

skipinitialspace [bool, default False] Skip spaces after delimiter.

skiprows [list-like, int or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

skipfooter [int, default 0] Number of lines at bottom of file to skip (Unsupported with engine='c').

nrows [int, optional] Number of rows of file to read. Useful for reading pieces of large files.

na_values [scalar, str, list-like, or dict, optional] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: `'`, '#N/A', '#N/A #NAME?', '-1.#IND', '-1.#QNAN', '-NaN', '-nan', '1.#IND', '1.#QNAN', '<Na>', 'N/A', 'NA', 'NULL', 'NaN', 'n/a', 'nan', 'null'.

keep_default_na [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether na_values is passed in, the behavior is as follows:

- If keep_default_na is True, and na_values are specified, na_values is appended to the default NaN values used for parsing.
- If keep_default_na is True, and na_values are not specified, only the default NaN values are used for parsing.
- If keep_default_na is False, and na_values are specified, only the NaN values specified na_values are used for parsing.
- If keep_default_na is False, and na_values are not specified, no strings will be parsed as NaN.

Note that if na_filter is passed in as False, the keep_default_na and na_values parameters will be ignored.

na_filter [bool, default True] Detect missing value markers (empty strings and the value of na_values). In data without any NAs, passing na_filter=False can improve the performance of reading a large file.

verbose [bool, default False] Indicate number of NA values placed in non-numeric columns.

skip_blank_lines [bool, default True] If True, skip over blank lines rather than interpreting as NaN values.

parse_dates [bool or list of int or names or list of lists or dict, default False] The behavior is as follows:

- boolean. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. {'foo': [1, 3]} -> parse columns 1, 3 as date and call result ‘foo’

If a column or index cannot be represented as an array of datetimes, say because of an unparsable value or a mixture of timezones, the column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use pd.to_datetime after pd.read_csv. To parse an index or column with a mixture of timezones, specify
date_parser to be a partially-applied pandas.to_datetime() with utc=True. See Parsing a CSV with mixed timezones for more.

Note: A fast-path exists for iso8601-formatted dates.

infer_datetime_format [bool, default False] If True and parse_dates is enabled, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

keep_date_col [bool, default False] If True and parse_dates specifies combining multiple columns then keep the original columns.

date_parser [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses dateutil.parser.parser to do the conversion. Pandas will try to call date_parser in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by parse_dates) as arguments; 2) concatenate (row-wise) the string values from the columns defined by parse_dates into a single array and pass that; and 3) call date_parser once for each row using one or more strings (corresponding to the columns defined by parse_dates) as arguments.

dayfirst [bool, default False] DD/MM format dates, international and European format.

cache_dates [bool, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

iterator [bool, default False] Return TextFileReader object for iteration or getting chunks with get_chunk().

Changed in version 1.2: TextFileReader is a context manager.

chunksize [int, optional] Return TextFileReader object for iteration. See the IO Tools docs for more information on iterator and chunksize.

Changed in version 1.2: TextFileReader is a context manager.

compression [['infer', 'gzip', 'bzip2', 'zip', 'xz', None], default 'infer'] For on-the-fly decompression of on-disk data. If ‘infer’ and filepath_or_buffer is path-like, then detect compression from the following extensions: .gz, .bzip2, .zip, or .xz (otherwise no decompression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

thousands [str, optional] Thousands separator.

decimal [str, default ‘.’] Character to recognize as decimal point (e.g. use ‘,’ for European data).

lineterminator [str (length 1), optional] Character to break file into lines. Only valid with C parser.

quotechar [str (length 1), optional] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

quoting [int or csv.QUOTE_* instance, default 0] Control field quoting behavior per csv.QUOTE_* constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

doublequote [bool, default True] When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements INSIDE a field as a single quotechar element.
escapechar  [str (length 1), optional] One-character string used to escape other characters.

comment  [str, optional] Indicates remainder of line should not be parsed. If found at the begin-
ing of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as skip_blank_lines=True), fully commented lines are ignored by the parameter header but not by skiprows. For example, if comment='#', parsing #empty\n a,b,c
1,2,3 with header=0 will result in 'a,b,c' being treated as the header.

encoding  [str, optional] Encoding to use for UTF when reading/writing (ex. ‘utf-8’). List of Python standard encodings.

  Changed in version 1.2: When encoding is None, errors="replace" is passed to open(). Otherwise, errors="strict" is passed to open(). This behavior was pre-
viously only the case for engine="python".

  Changed in version 1.3.0: encoding_errors is a new argument. encoding has no
longer an influence on how encoding errors are handled.

encoding_errors  [str, optional, default "strict"] How encoding errors are treated. List of possible values.

  New in version 1.3.0.

dialect  [str or csv.Dialect, optional] If provided, this parameter will override values (default or not) for the following parameters: delimiter, doublequote, escapechar, skipinitialspace, quotechar, and quoting. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

error_bad_lines  [bool, default None] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will be dropped from the DataFrame that is returned.

  Deprecated since version 1.3.0: The on_bad_lines parameter should be used instead to specify behavior upon encountering a bad line instead.

warn_bad_lines  [bool, default None] If error_bad_lines is False, and warn_bad_lines is True, a warning for each “bad line” will be output.

  Deprecated since version 1.3.0: The on_bad_lines parameter should be used instead to specify behavior upon encountering a bad line instead.

on_bad_lines  [{'error', 'warn', 'skip'}, default 'error'] Specifies what to do upon encountering a bad line (a line with too many fields). Allowed values are:

  • ’error’, raise an Exception when a bad line is encountered.
  • ’warn’, raise a warning when a bad line is encountered and skip that line.
  • ’skip’, skip bad lines without raising or warning when they are encountered.

  New in version 1.3.0.

delim_whitespace  [bool, default False] Specifies whether or not whitespace (e.g. ' ' or '
') will be used as the sep. Equivalent to setting sep='\s+'. If this option is set to True, nothing should be passed in for the delimiter parameter.

low_memory  [bool, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the dtype parameter. Note that the entire file is read into a single DataFrame regardless, use the chunksize or iterator parameter to return the data in chunks. (Only valid with C parser).
**memory_map** [bool, default False] If a filepath is provided for `filepath_or_buffer`, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

**float_precision** [str, optional] Specifies which converter the C engine should use for floating-point values. The options are None or ‘high’ for the ordinary converter, ‘legacy’ for the original lower precision pandas converter, and ‘round_trip’ for the round-trip converter. Changed in version 1.2.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details. New in version 1.2.

**Returns**

DataFrame or TextParser A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

`DataFrame.to_csv` Write DataFrame to a comma-separated values (csv) file.

`read_csv` Read a comma-separated values (csv) file into DataFrame.

`read_fwf` Read a table of fixed-width formatted lines into DataFrame.

**Examples**

```python
>>> pd.read_table('data.csv')
```

**pandas.read_csv**

Read a comma-separated values (csv) file into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for IO Tools.

**Parameters**
filepath_or_buffer [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, gs, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.csv.

If you want to pass in a path object, pandas accepts any os.PathLike.

By file-like object, we refer to objects with a read() method, such as a file handle (e.g. via built-in open function) or StringIO.

sep [str, default ‘,’] Delimiter to use. If sep is None, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python’s built-in sniffer tool, csv.Sniffer. In addition, separators longer than 1 character and different from ‘\s+’ will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: ‘\r\t’.

delimiter [str, default None] Alias for sep.

header [int, list of int, default ‘infer’] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to header=0 and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to header=None. Explicitly pass header=0 to be able to replace existing names. The header can be a list of integers that specify row locations for a multi-index on the columns e.g. [0,1,3]. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if skip_blank_lines=True, so header=0 denotes the first line of data rather than the first line of the file.

names [array-like, optional] List of column names to use. If the file contains a header row, then you should explicitly pass header=0 to override the column names. Duplicates in this list are not allowed.

index_col [int, str, sequence of int / str, or False, default None] Column(s) to use as the row labels of the DataFrame, either given as string name or column index. If a sequence of int / str is given, a MultiIndex is used.

Note: index_col=False can be used to force pandas to not use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

usecols [list-like or callable, optional] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in names or inferred from the document header row(s). For example, a valid list-like usecols parameter would be [0, 1, 2] or ['foo', 'bar', 'baz']. Element order is ignored, so usecols=[0, 1] is the same as [1, 0]. To instantiate a DataFrame from data with element order preserved use pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']][['foo', 'bar']] for columns in ['foo', 'bar'] order or pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']] for ['bar', 'foo'] order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True. An example of a valid callable argument would be lambda x: x.upper() in ['AAA', 'BBB', 'DDD']. Using this parameter results in much faster parsing time and lower memory usage.

squeeze [bool, default False] If the parsed data only contains one column then return a Series.

prefix [str, optional] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1,…

mangle_dupe_cols [bool, default True] Duplicate columns will be specified as ‘X’, ‘X.1’, … ‘X.N’, rather than ‘X’… ‘X’. Passing in False will cause data to be overwritten if there
are duplicate names in the columns.

dtype [Type name or dict of column -> type, optional] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32, ‘c’: ‘Int64’} Use str or object together with suitable na_values settings to preserve and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

dtype [{'c', 'python'}, optional] Parser engine to use. The C engine is faster while the python engine is currently more feature-complete.

converters [dict, optional] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

true_values [list, optional] Values to consider as True.

false_values [list, optional] Values to consider as False.

skipinitialspace [bool, default False] Skip spaces after delimiter.

skiprows [list-like, int or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be lambda x: x in [0, 2].

skipfooter [int, default 0] Number of lines at bottom of file to skip (Unsupported with engine='c').

nrows [int, optional] Number of rows of file to read. Useful for reading pieces of large files.

na_values [scalar, str, list-like, or dict, optional] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘’, ‘#N/A’, ‘#N/A N/A’, ‘#NA’, ‘-1.#IND’, ‘-1.#QNAN’, ‘-NaN’, ‘-nan’, ‘1.#IND’, ‘1.#QNAN’, ‘<NA>’, ‘N/A’, ‘NA’, ‘NULL’, ‘NaN’, ‘n/a’, ‘nan’, ‘null’.

keep_default_na [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether na_values is passed in, the behavior is as follows:

• If keep_default_na is True, and na_values are specified, na_values is appended to the default NaN values used for parsing.

• If keep_default_na is True, and na_values are not specified, only the default NaN values are used for parsing.

• If keep_default_na is False, and na_values are specified, only the NaN values specified na_values are used for parsing.

• If keep_default_na is False, and na_values are not specified, no strings will be parsed as NaN.

Note that if na_filter is passed in as False, the keep_default_na and na_values parameters will be ignored.

na_filter [bool, default True] Detect missing value markers (empty strings and the value of na_values). In data without any NAs, passing na_filter=False can improve the performance of reading a large file.

verbose [bool, default False] Indicate number of NA values placed in non-numeric columns.

skip_blank_lines [bool, default True] If True, skip over blank lines rather than interpreting as NaN values.

3.1. Input/output 987
**parse_dates** [bool or list of int or names or list of lists or dict, default False] The behavior is as follows:

- boolean. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict. e.g. {'foo' : [1, 3]} -> parse columns 1, 3 as date and call result ‘foo’

If a column or index cannot be represented as an array of datetimes, say because of an unparsable value or a mixture of timezones, the column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`. To parse an index or column with a mixture of timezones, specify `date_parser` to be a partially-applied `pandas.to_datetime()` with `utc=True`. See [Parsing a CSV with mixed timezones](#) for more.

Note: A fast-path exists for iso8601-formatted dates.

**infer_datetime_format** [bool, default False] If True and `parse_dates` is enabled, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

**keep_date_col** [bool, default False] If True and `parse_dates` specifies combining multiple columns then keep the original columns.

**date_parser** [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

**dayfirst** [bool, default False] DD/MM format dates, international and European format.

**cache_dates** [bool, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

**iterator** [bool, default False] Return TextFileReader object for iteration or getting chunks with `get_chunk()`.

Changed in version 1.2: `TextFileReader` is a context manager.

**chunksize** [int, optional] Return TextFileReader object for iteration. See the IO Tools docs for more information on `iterator` and `chunksize`.

Changed in version 1.2: `TextFileReader` is a context manager.

**compression** ['infer', 'gzip', 'bz2', 'zip', 'xz', None], default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’ and `filepath_or_buffer` is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’ (otherwise no decompression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

**thousands** [str, optional] Thousands separator.
decimal [str, default ‘.’] Character to recognize as decimal point (e.g. use ‘,’ for European data).
lineterminator [str (length 1), optional] Character to break file into lines. Only valid with C parser.
quotechar [str (length 1), optional] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.
quoting [int or csv.QUOTE_* instance, default 0] Control field quoting behavior per csv.QUOTE_* constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).
doublequote [bool, default True] When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements INSIDE a field as a single quotechar element.
escapechar [str (length 1), optional] One-character string used to escape other characters.
comment [str, optional] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as skip_blank_lines=True), fully commented lines are ignored by the parameter header but not by skiprows. For example, if comment='!', parsing #empty
a,b,c
1,2,3 with header=0 will result in ‘a,b,c’ being treated as the header.
encoding [str, optional] Encoding to use for UTF when reading/writing (ex. ‘utf-8’). List of Python standard encodings.

Changed in version 1.2: When encoding is None, errors="replace" is passed to open(). Otherwise, errors="strict" is passed to open(). This behavior was previously only the case for engine="python".

Changed in version 1.3.0: encoding_errors is a new argument. encoding has no longer an influence on how encoding errors are handled.

encoding_errors [str, optional, default “strict”] How encoding errors are treated. List of possible values.

New in version 1.3.0.
dialect [str or csv.Dialect, optional] If provided, this parameter will override values (default or not) for the following parameters: delimiter, doublequote, escapechar, skipinitialspace, quotechar, and quoting. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

error_bad_lines [bool, default None] Lines with too many fields (e.g. a csv line with too many commas) will be dropped by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will be dropped from the DataFrame that is returned.

Deprecated since version 1.3.0: The on_bad_lines parameter should be used instead to specify behavior upon encountering a bad line instead.

warn_bad_lines [bool, default None] If error_bad_lines is False, and warn_bad_lines is True, a warning for each “bad line” will be output.

Deprecated since version 1.3.0: The on_bad_lines parameter should be used instead to specify behavior upon encountering a bad line instead.

on_bad_lines [‘error’, ‘warn’, ‘skip’], default ‘error’] Specifies what to do upon encountering a bad line (a line with too many fields). Allowed values are:

- ‘error’, raise an Exception when a bad line is encountered.
pandas: powerful Python data analysis toolkit, Release 1.3.1

- ‘warn’, raise a warning when a bad line is encountered and skip that line.
- 'skip', skip bad lines without raising or warning when they are encountered.

New in version 1.3.0.

**delim_whitespace** [bool, default False] Specifies whether or not whitespace (e.g. ' ' or '
') will be used as the sep. Equivalent to setting `sep='\s+'`. If this option is set to True, nothing should be passed in for the `delimiter` parameter.

**low_memory** [bool, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the `dtype` parameter. Note that the entire file is read into a single DataFrame regardless, use the `chunksize` or `iterator` parameter to return the data in chunks. (Only valid with C parser).

**memory_map** [bool, default False] If a filepath is provided for `filepath_or_buffer`, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

**float_precision** [str, optional] Specifies which converter the C engine should use for floating-point values. The options are `None` or ‘high’ for the ordinary converter, ‘legacy’ for the original lower precision pandas converter, and ‘round_trip’ for the round-trip converter.

Changed in version 1.2.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.

**Returns**

- **DataFrame** or **TextParser** A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

- **DataFrame.to_csv** Write DataFrame to a comma-separated values (csv) file.
- **read_csv** Read a comma-separated values (csv) file into DataFrame.
- **read_fwf** Read a table of fixed-width formatted lines into DataFrame.

**Examples**

```python
>>> pd.read_csv('data.csv')
```
**pandas.DataFrame.to_csv**

```python
DataFrame.to_csv(path_or_buf=None, sep=',', na_rep='', float_format=None, columns=None, header=True, index=True, index_label=None, mode='w', encoding=None, compression='infer', quoting=None, quotechar='', line_terminator=None, chunksize=None, date_format=None, doublequote=True, escapechar=None, decimal='.', errors='strict', storage_options=None)
```

Write object to a comma-separated values (csv) file.

**Parameters**

- `path_or_buf` [str or file handle, default None] File path or object, if None is provided the result is returned as a string. If a non-binary file object is passed, it should be opened with `newline='\n'`, disabling universal newlines. If a binary file object is passed, `mode` might need to contain a `b`.

  Changed in version 1.2.0: Support for binary file objects was introduced.

- `float_format` [str, default None] Format string for floating point numbers.

- `columns` [sequence, optional] Columns to write.

- `header` [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

- `index` [bool, default True] Write row names (index).

- `index_label` [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and `header` and `index` are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use `index_label=False` for easier importing in R.

- `mode` [str] Python write mode, default `w`.

- `encoding` [str, optional] A string representing the encoding to use in the output file, defaults to `utf-8`. `encoding` is not supported if `path_or_buf` is a non-binary file object.

- `compression` [str or dict, default `infer`] If str, represents compression mode. If dict, value at `method` is the compression mode. Compression mode may be any of the following possible values: `{'infer', 'gzip', 'bz2', 'zip', 'xz', None}`. If compression mode is `infer` and `path_or_buf` is path-like, then detect compression mode from the following extensions: `'.gz'`, `'.bz2'`, `'.zip'` or `'.xz'`. (otherwise no compression). If dict given and mode is one of `{'zip', 'gzip', 'bz2'}`, or inferred as one of the above, other entries passed as additional compression options.

  Changed in version 1.0.0: May now be a dict with key `method` as compression mode and other entries as additional compression options if compression mode is `zip`.

  Changed in version 1.1.0: Passing compression options as keys in dict is supported for compression modes `gzip` and `bz2` as well as `zip`.

  Changed in version 1.2.0: Compression is supported for binary file objects.

  Changed in version 1.2.0: Previous versions forwarded dict entries for `gzip` to `gzip.open` instead of `gzip.GzipFile` which prevented setting `mtime`.

- `quoting` [optional constant from csv module] Defaults to `csv.QUOTE_MINIMAL`. If you have set a `float_format` then floats are converted to strings and thus `csv.QUOTE_NONNUMERIC` will treat them as non-numeric.

3.1. Input/output
quotechar [str, default ‘”’] String of length 1. Character used to quote fields.

line_terminator [str, optional] The newline character or character sequence to use in the output file. Defaults to os.linesep, which depends on the OS in which this method is called (‘\n’ for linux, ‘\r\n’ for Windows, i.e.).

chunksize [int or None] Rows to write at a time.

date_format [str, default None] Format string for datetime objects.

doublequote [bool, default True] Control quoting of quotechar inside a field.

escapechar [str, default None] String of length 1. Character used to escape sep and quotechar when appropriate.

decimal [str, default ‘.’] Character recognized as decimal separator. E.g. use ‘,’ for European data.

errors [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for open() for a full list of options.

New in version 1.1.0.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

Returns

None or str If path_or_buf is None, returns the resulting csv format as a string. Otherwise returns None.

See also:

read_csv Load a CSV file into a DataFrame.

to_excel Write DataFrame to an Excel file.

Examples

```python
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                    'mask': ['red', 'purple'],
...                    'weapon': ['sai', 'bo staff']})
>>> df.to_csv(index=False)
'name,mask,weapon
Raphael,red,sai
Donatello,purple,bo staff'
```

Create ‘out.zip’ containing ‘out.csv’

```python
>>> compression_opts = dict(method='zip',
...                        archive_name='out.csv')
>>> df.to_csv('out.zip', index=False,
...           ... compression=compression_opts)
```
pandas.read_fwf

`pandas.read_fwf(filepath_or_buffer, colspecs='infer', widths=None, infer_nrows=100, **kwds)`

Read a table of fixed-width formatted lines into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for IO Tools.

**Parameters**

- `filepath_or_buffer` [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.csv`.

  If you want to pass in a path object, pandas accepts any `os.PathLike`.

  By file-like object, we refer to objects with a `read()` method, such as a file handle (e.g. via built in `open` function) or `StringIO`.

- `colspecs` [list of tuple (int, int) or ‘infer’. optional] A list of tuples giving the extents of the fixed-width fields of each line as half-open intervals (i.e., [from, to[). String value ‘infer’ can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data which are not being skipped via skiprows (default='infer').

- `widths` [list of int, optional] A list of field widths which can be used instead of ‘colspecs’ if the intervals are contiguous.

- `infer_nrows` [int, default 100] The number of rows to consider when letting the parser determine the `colspecs`.

- `**kwds` [optional] Optional keyword arguments can be passed to `TextFileReader`.

**Returns**

- `DataFrame` or `TextParser` A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

- `DataFrame.to_csv` Write DataFrame to a comma-separated values (csv) file.
- `read_csv` Read a comma-separated values (csv) file into DataFrame.

**Examples**

```python
def pd.read_fwf(filepath):
    return pd.read_fwf(filepath)
```

3.1.3 Clipboard

- `read_clipboard([sep])` Read text from clipboard and pass to read_csv.
- `DataFrame.to_clipboard([excel, sep])` Copy object to the system clipboard.

3.1. Input/output
pandas: powerful Python data analysis toolkit, Release 1.3.1

**pandas.read_clipboard**

```python
pandas.read_clipboard(sep='\s+', **kwargs)
```

Read text from clipboard and pass to read_csv.

**Parameters**

- `sep` [str, default 's+'] A string or regex delimiter. The default of 's+' denotes one or more whitespace characters.
- **kwargs** See read_csv for the full argument list.

**Returns**

DataFrame A parsed DataFrame object.

**pandas.DataFrame.to_clipboard**

```python
DataFrame.to_clipboard(excel=True, sep=None, **kwargs)
```

Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

**Parameters**

- `excel` [bool, default True] Produce output in a csv format for easy pasting into excel.
  - True, use the provided separator for csv pasting.
  - False, write a string representation of the object to the clipboard.
- `sep` [str, default '\t'] Field delimiter.
- **kwargs** These parameters will be passed to DataFrame.to_csv.

**See also:**

- **DataFrame.to_csv** Write a DataFrame to a comma-separated values (csv) file.
- **read_clipboard** Read text from clipboard and pass to read_table.

**Notes**

Requirements for your platform.

- Linux: xclip, or xsel (with PyQt4 modules)
- Windows: none
- OS X: none
Examples

Copy the contents of a DataFrame to the clipboard.

```python
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])

>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the index by passing the keyword `index` and setting it to false.

```python
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

3.1.4 Excel

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>read_excel</code></td>
<td>Read an Excel file into a pandas DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.to_excel</code></td>
<td>Write object to an Excel sheet.</td>
</tr>
<tr>

**pandas.read_excel**

```python
pandas.read_excel(io, sheet_name=0, header=0, names=None, index_col=None, usecols=None, squeeze=False, dtype=None, engine=None, converters=None, true_values=None, false_values=None, skiprows=None, nrows=None, na_values=None, keep_default_na=True, na_filter=True, verbose=False, parse_dates=False, date_parser=None, thousands=None, comment=None, skipfooter=0, convert_float=None, mangle_dupe_cols=True, storage_options=None)
```

Read an Excel file into a pandas DataFrame.

Supports *xls, xlsx, xslm, xlsb, odf, ods* and *odt* file extensions read from a local filesystem or URL. Supports an option to read a single sheet or a list of sheets.

**Parameters**

- **io** [str, bytes, ExcelFile, xld.Book, path object, or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.xlsx`.

  If you want to pass in a path object, pandas accepts any `os.PathLike`.

  By file-like object, we refer to objects with a `read()` method, such as a file handle (e.g. via `builtin open` function) or `StringIO`.

- **sheet_name** [str, int, list, or None, default 0] Strings are used for sheet names. Integers are used in zero-indexed sheet positions. Lists of strings/integers are used to request multiple sheets. Specify None to get all sheets.
Available cases:

- Defaults to 0: 1st sheet as a DataFrame
- 1: 2nd sheet as a DataFrame
- "Sheet1": Load sheet with name “Sheet1”
- [0, 1, "Sheet5"]: Load first, second and sheet named “Sheet5” as a dict of DataFrame
- None: All sheets.

**header** [int, list of int, default 0] Row (0-indexed) to use for the column labels of the parsed DataFrame. If a list of integers is passed those row positions will be combined into a MultiIndex. Use None if there is no header.

**names** [array-like, default None] List of column names to use. If file contains no header row, then you should explicitly pass header=None.

**index_col** [int, list of int, default None] Column (0-indexed) to use as the row labels of the DataFrame. Pass None if there is no such column. If a list is passed, those columns will be combined into a MultiIndex. If a subset of data is selected with usecols, index_col is based on the subset.

**usecols** [int, str, list-like, or callable default None]

- If None, then parse all columns.
- If str, then indicates comma separated list of Excel column letters and column ranges (e.g. “A:E” or “A,C,E:F”). Ranges are inclusive of both sides.
- If list of int, then indicates list of column numbers to be parsed.
- If list of string, then indicates list of column names to be parsed.
- If callable, then evaluate each column name against it and parse the column if the callable returns True.

Returns a subset of the columns according to behavior above.

**squeeze** [bool, default False] If the parsed data only contains one column then return a Series.

**dtype** [Type name or dict of column -> type, default None] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32} Use object to preserve data as stored in Excel and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

**engine** [str, default None] If io is not a buffer or path, this must be set to identify io. Supported engines: “xlrd”, “openpyxl”, “odf”, “pyxlsb”. Engine compatibility :

- “xlrd” supports old-style Excel files (.xls).
- “openpyxl” supports newer Excel file formats.
- “odf” supports OpenDocument file formats (.odf, .ods, .odt).
- “pyxlsb” supports Binary Excel files.

Changed in version 1.2.0: The engine xlrd now only supports old-style .xls files. When engine=None, the following logic will be used to determine the engine:

- If path_or_buffer is an OpenDocument format (.odf, .ods, .odt), then odf will be used.
- Otherwise if path_or_buffer is an xls format, xlrd will be used.
• Otherwise if `path_or_buffer` is in xlsb format, `pyxlsb` will be used.
  New in version 1.3.0.
• Otherwise `openpyxl` will be used.
  Changed in version 1.3.0.

**converters** [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels, values are functions that take one input argument, the Excel cell content, and return the transformed content.

**true_values** [list, default None] Values to consider as True.

**false_values** [list, default None] Values to consider as False.

**skiprows** [list-like, int, or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file. If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

**nrows** [int, default None] Number of rows to parse.

**na_values** [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘’, ‘#N/A’, ‘#N/A #N/A’, ‘#NA’, ‘-1.#IND’, ‘-1.#QNAN’, ‘-NaN’, ‘-nan’, ‘1.#IND’, ‘1.#QNAN’, ‘<NA>’, ‘N/A’, ‘NA’, ‘NULL’, ‘NaN’, ‘n/a’, ‘nan’, ‘null’.

**keep_default_na** [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether `na_values` is passed in, the behavior is as follows:
• If `keep_default_na` is True, and `na_values` are specified, `na_values` is appended to the default NaN values used for parsing.
• If `keep_default_na` is True, and `na_values` are not specified, only the default NaN values are used for parsing.
• If `keep_default_na` is False, and `na_values` are specified, only the NaN values specified `na_values` are used for parsing.
• If `keep_default_na` is False, and `na_values` are not specified, no strings will be parsed as NaN.

Note that if `na_filter` is passed in as False, the `keep_default_na` and `na_values` parameters will be ignored.

**na_filter** [bool, default True] Detect missing value markers (empty strings and the value of `na_values`). In data without any NAs, passing `na_filter=False` can improve the performance of reading a large file.

**verbose** [bool, default False] Indicate number of NA values placed in non-numeric columns.

**parse_dates** [bool, list-like, or dict, default False] The behavior is as follows:
• bool. If True - try parsing the index.
• list of int or names. e.g. If [1, 2, 3] - try parsing columns 1, 2, 3 each as a separate date column.
• list of lists. e.g. If [[1, 3]] - combine columns 1 and 3 and parse as a single date column.
• dict, e.g. {'foo': [1, 3]} - parse columns 1, 3 as date and call result ‘foo’

If a column or index contains an unparsable date, the entire column or index will be returned unaltered as an object data type. If you don’t want to parse some cells as date just change...
their type in Excel to “Text”. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_excel`.

Note: A fast-path exists for iso8601-formatted dates.

**date_parser** [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

**thousands** [str, default None] Thousands separator for parsing string columns to numeric. Note that this parameter is only necessary for columns stored as TEXT in Excel, any numeric columns will automatically be parsed, regardless of display format.

**comment** [str, default None] Comments out remainder of line. Pass a character or characters to this argument to indicate comments in the input file. Any data between the comment string and the end of the current line is ignored.

**skipfooter** [int, default 0] Rows at the end to skip (0-indexed).

**convert_float** [bool, default True] Convert integral floats to int (i.e., 1.0 -> 1). If False, all numeric data will be read in as floats: Excel stores all numbers as floats internally.

Deprecated since version 1.3.0: `convert_float` will be removed in a future version

**mangle_dupe_cols** [bool, default True] Duplicate columns will be specified as ‘X’, ‘X.1’, … ‘X.N’, rather than ‘X’…’X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc., if using a URL that will be parsed by `fsspec`, e.g., starting “s3://”, “gcs://”. An error will be raised if providing this argument with a local path or a file-like buffer. See the `fsspec` and backend storage implementation docs for the set of allowed keys and values.

New in version 1.2.0.

**Returns**

DataFrame or dict of DataFrames DataFrame from the passed in Excel file. See notes in `sheet_name` argument for more information on when a dict of DataFrames is returned.

See also:

* DataFrame.to_excel* Write DataFrame to an Excel file.

* DataFrame.to_csv* Write DataFrame to a comma-separated values (csv) file.

* read_csv* Read a comma-separated values (csv) file into DataFrame.

* read_fwf* Read a table of fixed-width formatted lines into DataFrame.
Examples

The file can be read using the file name as string or an open file object:

```python
>>> pd.read_excel('tmp.xlsx', index_col=0)
   Name  Value
0  string1   1
1   string2   2
2      #Comment   3

>>> pd.read_excel(open('tmp.xlsx', 'rb'), ...
                sheet_name='Sheet3')
     Unnamed: 0     Name  Value
0           0   string1   1
1           1   string2   2
2           2      #Comment   3

Index and header can be specified via the index_col and header arguments

```python
>>> pd.read_excel('tmp.xlsx', index_col=None, header=None)
     0  1  2
0  NaN  1  2
1  0.0 1.0 2.0
2  1.0 2.0 #Comment 3.0

Column types are inferred but can be explicitly specified

```python
>>> pd.read_excel('tmp.xlsx', index_col=0, ...
                dtype={'Name': str, 'Value': float})
      Name  Value
0  string1  1.0
1   string2  2.0
2      #Comment 3.0

```

True, False, and NA values, and thousands separators have defaults, but can be explicitly specified, too. Supply the values you would like as strings or lists of strings!

```python
>>> pd.read_excel('tmp.xlsx', index_col=0, ...
                na_values=['string1', 'string2'])
      Name  Value
0        NaN   1
1        NaN   2
2      #Comment   3

Comment lines in the excel input file can be skipped using the comment kwarg

```python
>>> pd.read_excel('tmp.xlsx', index_col=0, comment='#')
      Name  Value
0  string1  1.0
1   string2  2.0
2      None  NaN
```

3.1. Input/output
DataFrame.to_excel

DataFrame.to_excel(excel_writer, sheet_name='Sheet1', na_rep='', float_format=None, columns=None, header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf', verbose=True, freeze_panes=None, storage_options=None)

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an ExcelWriter object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique sheet_name. With all data written to the file it is necessary to save the changes. Note that creating an ExcelWriter object with a file name that already exists will result in the contents of the existing file being erased.

**Parameters**

- **excel_writer** [path-like, file-like, or ExcelWriter object] File path or existing ExcelWriter.
- **sheet_name** [str, default ‘Sheet1’] Name of sheet which will contain DataFrame.
- **na_rep** [str, default ‘’] Missing data representation.
- **float_format** [str, optional] Format string for floating point numbers. For example `float_format="%.2f"` will format 0.1234 to 0.12.
- **columns** [sequence or list of str, optional] Columns to write.
- **header** [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.
- **index** [bool, default True] Write row names (index).
- **index_label** [str or sequence, optional] Column label for index column(s) if desired. If not specified, and header and index are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- **startrow** [int, default 0] Upper left cell row to dump data frame.
- **startcol** [int, default 0] Upper left cell column to dump data frame.

Deprecated since version 1.2.0: As the xlwt package is no longer maintained, the xlwt engine will be removed in a future version of pandas.
- **merge_cells** [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.
- **encoding** [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.
- **inf_rep** [str, default ‘inf’] Representation for infinity (there is no native representation for infinity in Excel).
- **verbose** [bool, default True] Display more information in the error logs.
- **freeze_panes** [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.
- **storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and
“gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib
for more details.

New in version 1.2.0.

See also:

to_csv Write DataFrame to a comma-separated values (csv) file.
ExcelWriter Class for writing DataFrame objects into excel sheets.
read_excel Read an Excel file into a pandas DataFrame.
read_csv Read a comma-separated values (csv) file into DataFrame.

Notes

For compatibility with to_csv(), to_excel serializes lists and dicts to strings before writing.
Once a workbook has been saved it is not possible to write further data without rewriting the whole workbook.

Examples

Create, write to and save a workbook:

```python
>>> df1 = pd.DataFrame([['a', 'b'], ['c', 'd']],
...                      index=['row 1', 'row 2'],
...                      columns=['col 1', 'col 2'])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```python
>>> df1.to_excel("output.xlsx",
...               sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:

```python
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

ExcelWriter can also be used to append to an existing Excel file:

```python
>>> with pd.ExcelWriter('output.xlsx',
...                      mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the engine keyword (the default engine is automatically chosen depending on the file extension):

```python
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```
ExcelFile.parse

ExcelFile.parse(sheet_name=0, header=0, names=None, index_col=None, usecols=None, squeeze=False, converters=None, true_values=None, false_values=None, skiprows=None, nrows=None, na_values=None, parse_dates=False, date_parser=None, thousands=None, comment=None, skipfooter=0, convert_float=None, mangle_dupe_cols=True, **kwds)

Parse specified sheet(s) into a DataFrame.

Equivalent to read_excel(ExcelFile, . . . ) See the read_excel docstring for more info on accepted parameters.

Returns

- DataFrame or dict of DataFrames
  - DataFrame from the passed in Excel file.

Styler.to_excel

Styler.to_excel(excel_writer[, sheet_name, . . . ]) Write Styler to an Excel sheet.

Parameters

- excel_writer [path-like, file-like, or ExcelWriter object] File path or existing ExcelWriter.
- sheet_name [str, default ‘Sheet1’] Name of sheet which will contain DataFrame.
- na_rep [str, default ‘’] Missing data representation.
- float_format [str, optional] Format string for floating point numbers. For example float_format="%.2f" will format 0.1234 to 0.12.
- columns [sequence or list of str, optional] Columns to write.
- header [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.
- index [bool, default True] Write row names (index).
- index_label [str or sequence, optional] Column label for index column(s) if desired. If not specified, and header and index are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- startrow [int, default 0] Upper left cell row to dump data frame.
- startcol [int, default 0] Upper left cell column to dump data frame.
Deprecation of xlwt from pandas: As of version 1.2.0 of pandas, the `xlwt` package is no longer maintained, and the `xlwt` engine will be removed in a future version of pandas.

- **merge_cells** [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.

- **encoding** [str, optional] Encoding of the resulting excel file. Only necessary for `xlwt`, other writers support unicode natively.

- **inf_rep** [str, default ‘inf’] Representation for infinity (there is no native representation for infinity in Excel).

- **verbose** [bool, default True] Display more information in the error logs.

- **freeze_panes** [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

- **storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

See also:

- **to_csv** Write DataFrame to a comma-separated values (csv) file.

- **ExcelWriter** Class for writing DataFrame objects into excel sheets.

- **read_excel** Read an Excel file into a pandas DataFrame.

- **read_csv** Read a comma-separated values (csv) file into DataFrame.

Notes

For compatibility with `to_csv()`, `to_excel` serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible to write further data without rewriting the whole workbook.

Examples

Create, write to and save a workbook:

```python
>>> df1 = pd.DataFrame([['a', 'b'], ['c', 'd']],
                    index=['row 1', 'row 2'],
                    columns=['col 1', 'col 2'])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```python
>>> df1.to_excel("output.xlsx",
               sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:

```python
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...    df1.to_excel(writer, sheet_name='Sheet_name_1')
...    df2.to_excel(writer, sheet_name='Sheet_name_2')
```
ExcelWriter can also be used to append to an existing Excel file:

```python
>>> with pd.ExcelWriter('output.xlsx',
...     mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the `engine` keyword (the default engine is automatically chosen depending on the file extension):

```python
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```

ExcelWriter(path[, engine, date_format,...]) Class for writing DataFrame objects into excel sheets.

pandas.ExcelWriter

class pandas.ExcelWriter(path, engine=None, date_format=None, datetime_format=None, mode='w', storage_options=None, if_sheet_exists=None, engine_kwargs=None, **kwargs)

Class for writing DataFrame objects into excel sheets.

Default is to use xlwt for xls, openpyxl for xlsx, odf for ods. See DataFrame.to_excel for typical usage.

The writer should be used as a context manager. Otherwise, call close() to save and close any opened file handles.

Parameters

- **path** [str or typing.BinaryIO] Path to xls or xlsx or ods file.
- **engine** [str (optional)] Engine to use for writing. If None, defaults to io.excel.<extension>.writer. NOTE: can only be passed as a keyword argument. Deprecation since version 1.2.0: As the xlwt package is no longer maintained, the xlwt engine will be removed in a future version of pandas.
- **date_format** [str, default None] Format string for dates written into Excel files (e.g. ‘YYYY-MM-DD’).
- **datetime_format** [str, default None] Format string for datetime objects written into Excel files. (e.g. ‘YYYY-MM-DD HH:MM:SS’).
- **mode** [‘w’, ‘a’], default ‘w’] File mode to use (write or append). Append does not work with fsspec URLs.
- **storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc., if using a URL that will be parsed by fsspec, e.g., starting “s3://”, “gcs://”.
  
  New in version 1.2.0.
- **if_sheet_exists** [‘error’, ‘new’, ‘replace’], default ‘error’] How to behave when trying to write to a sheet that already exists (append mode only).
  
  • error: raise a ValueError.
  
  • new: Create a new sheet, with a name determined by the engine.
  
  • replace: Delete the contents of the sheet before writing to it.

New in version 1.3.0.
**engine_kwargs**  [dict, optional] Keyword arguments to be passed into the engine.

New in version 1.3.0.

**kwargs**  [dict, optional] Keyword arguments to be passed into the engine.

Depreciated since version 1.3.0: Use engine_kwargs instead.

**Notes**

None of the methods and properties are considered public.

For compatibility with CSV writers, ExcelWriter serializes lists and dicts to strings before writing.

**Examples**

Default usage:

```python
>>> df = pd.DataFrame(["ABC", "XYZ"], columns=["Foo", "Bar"])
>>> with ExcelWriter("path_to_file.xlsx") as writer:
...     df.to_excel(writer)
```

To write to separate sheets in a single file:

```python
>>> df1 = pd.DataFrame(["AAA", "BBB"], columns=["Spam", "Egg"])
>>> df2 = pd.DataFrame(["ABC", "XYZ"], columns=["Foo", "Bar"])
>>> with ExcelWriter("path_to_file.xlsx") as writer:
...     df1.to_excel(writer, sheet_name="Sheet1")
...     df2.to_excel(writer, sheet_name="Sheet2")
```

You can set the date format or datetime format:

```python
>>> from datetime import date, datetime
>>> df = pd.DataFrame(
...     [  
...         [date(2014, 1, 31), date(1999, 9, 24)],
...         [datetime(1998, 5, 26, 23, 33, 4), datetime(2014, 2, 28, 13, 5, 13)],
...     ],
...     index=["Date", "Datetime"],
...     columns=["X", "Y"],
... )
>>> with ExcelWriter(
...     "path_to_file.xlsx",
...     date_format="YYYY-MM-DD",
...     datetime_format="YYYY-MM-DD HH:MM:SS"
... ) as writer:
...     df.to_excel(writer)
```

You can also append to an existing Excel file:

```python
>>> with ExcelWriter("path_to_file.xlsx", mode="a", engine="openpyxl") as writer:
...     df.to_excel(writer, sheet_name="Sheet3")
```

You can store Excel file in RAM:
You can pack Excel file into zip archive:

```python
>>> import zipfile
>>> df = pd.DataFrame([['ABC', 'XYZ']], columns=['Foo', 'Bar'])
>>> with zipfile.ZipFile("path_to_file.zip", "w") as zf:
...     with zf.open("filename.xlsx", "w") as buffer:
...         with pd.ExcelWriter(buffer) as writer:
...             df.to_excel(writer)
```

#### pandas.io.json.read_json

```python
pd.read_json(path_or_buf=None, orient=None, typ='frame', dtype=None, convert_axes=None, convert_dates=..., numpy=..., convert_float=..., date_unit=..., keep_default_dates=..., encoding=..., encoding_errors=..., error_bad_lines=..., lines=..., keep_default_na=..., storage_options=None, ...)```

Convert a JSON string to pandas object.

**Parameters**

- `path_or_buf` [a valid JSON str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.json`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handle (e.g. via `builtin open()` function) or `StringIO`. 

---

1006 Chapter 3. API reference
orient [str] Indication of expected JSON string format. Compatible JSON strings can be produced by to_json() with a corresponding orient value. The set of possible orients is:
- 'split': dict like {index -> [index], columns -> [columns], data -> [values]}
- 'records': list like [{column -> value}, ..., {column -> value}]
- 'index': dict like {index -> {column -> value}}
- 'columns': dict like {column -> {index -> value}}
- 'values': just the values array

The allowed and default values depend on the value of the typ parameter.
- when typ == 'series',
  - allowed orients are {'split', 'records', 'index'}
  - default is 'index'
  - The Series index must be unique for orient 'index'.
- when typ == 'frame',
  - allowed orients are {'split', 'records', 'index', 'columns', 'values', 'table'}
  - default is 'columns'
  - The DataFrame index must be unique for orients 'index' and 'columns'.
  - The DataFrame columns must be unique for orients 'index', 'columns', and 'records'.

typ [{‘frame’, ‘series’}, default ‘frame’] The type of object to recover.
dtype [bool or dict, default None] If True, infer dtypes; if a dict of column to dtype, then use those; if False, then don’t infer dtypes at all, applies only to the data.

For all orient values except 'table', default is True.

Changed in version 0.25.0: Not applicable for orient='table'.

convert_axes [bool, default None] Try to convert the axes to the proper dtypes.

For all orient values except 'table', default is True.

Changed in version 0.25.0: Not applicable for orient='table'.

convert_dates [bool or list of str, default True] If True then default datelike columns may be converted (depending on keep_default_dates). If False, no dates will be converted. If a list of column names, then those columns will be converted and default datelike columns may also be converted (depending on keep_default_dates).

keep_default_dates [bool, default True] If parsing dates (convert_dates is not False), then try to parse the default datelike columns. A column label is datelike if
- it ends with '_at',
- it ends with '_time',
- it begins with 'timestamp',
- it is 'modified', or
• it is 'date'.

**numpy** [bool, default False] Direct decoding to numpy arrays. Supports numeric data only, but non-numeric column and index labels are supported. Note also that the JSON ordering MUST be the same for each term if numpy=True.

Deprecated since version 1.0.0.

**precise_float** [bool, default False] Set to enable usage of higher precision (strtod) function when decoding string to double values. Default (False) is to use fast but less precise builtin functionality.

**date_unit** [str, default None] The timestamp unit to detect if converting dates. The default behaviour is to try and detect the correct precision, but if this is not desired then pass one of ‘s’, ‘ms’, ‘us’ or ‘ns’ to force parsing only seconds, milliseconds, microseconds or nanoseconds respectively.

**encoding** [str, default is ‘utf-8’] The encoding to use to decode py3 bytes.

**encoding_errors** [str, optional, default “strict”] How encoding errors are treated. List of possible values .

New in version 1.3.0.

**lines** [bool, default False] Read the file as a json object per line.

**chunksize** [int, optional] Return JsonReader object for iteration. See the line-delimited json docs for more information on chunksize. This can only be passed if lines=True. If this is None, the file will be read into memory all at once.

Changed in version 1.2: JsonReader is a context manager.

**compression** [‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None], default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’, then use gzip, bz2, zip or xz if path_or_buf is a string ending in `.gz`, `.bz2`, `.zip`, or `.xz`, respectively, and no decompression otherwise. If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

**nrows** [int, optional] The number of lines from the line-delimited jsonfile that has to be read. This can only be passed if lines=True. If this is None, all the rows will be returned.

New in version 1.1.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

**Returns**

**Series or DataFrame** The type returned depends on the value of typ.

**See also:**

- **DataFrame.to_json** Convert a DataFrame to a JSON string.
- **Series.to_json** Convert a Series to a JSON string.
pandas: powerful Python data analysis toolkit, Release 1.3.1

Notes
Specific to orient='table', if a DataFrame with a literal Index name of index gets written with
to_json(), the subsequent read operation will incorrectly set the Index name to None. This is because
index is also used by DataFrame.to_json() to denote a missing Index name, and the subsequent
read_json() operation cannot distinguish between the two. The same limitation is encountered with a
MultiIndex and any names beginning with 'level_'.
Examples
>>> df = pd.DataFrame([['a', 'b'], ['c', 'd']],
...
index=['row 1', 'row 2'],
...
columns=['col 1', 'col 2'])

Encoding/decoding a Dataframe using 'split' formatted JSON:
>>> df.to_json(orient='split')
'{"columns":["col 1","col 2"],"index":["row 1","row 2"],"data":[["a","b"],["c
˓→","d"]]}'
>>> pd.read_json(_, orient='split')
col 1 col 2
row 1
a
b
row 2
c
d

Encoding/decoding a Dataframe using 'index' formatted JSON:
>>> df.to_json(orient='index')
'{"row 1":{"col 1":"a","col 2":"b"},"row 2":{"col 1":"c","col 2":"d"}}'
>>> pd.read_json(_, orient='index')
col 1 col 2
row 1
a
b
row 2
c
d

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved
with this encoding.
>>> df.to_json(orient='records')
'[{"col 1":"a","col 2":"b"},{"col 1":"c","col 2":"d"}]'
>>> pd.read_json(_, orient='records')
col 1 col 2
0
a
b
1
c
d

Encoding with Table Schema
>>> df.to_json(orient='table')
'{"schema":{"fields":[{"name":"index","type":"string"},{"name":"col 1","type":
˓→"string"},{"name":"col 2","type":"string"}],"primaryKey":["index"],"pandas_
˓→version":"0.20.0"},"data":[{"index":"row 1","col 1":"a","col 2":"b"},{"index":
˓→"row 2","col 1":"c","col 2":"d"}]}'

3.1. Input/output

1009


pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.io.json.to_json

**pandas.io.json.to_json** *(path_or_buf, obj, orient=None, date_format='epoch', double_precision=10, force_ascii=True, date_unit='ms', default_handler=None, lines=False, compression='infer', index=True, indent=0, storage_options=None)*

Create a Table schema from data.

**pandas.io.json.build_table_schema**

**pandas.io.json.build_table_schema** *(data, index=True, primary_key=None, version=True)*

Create a Table schema from data.

**Parameters**

- **data**  [Series, DataFrame]  Whether to include data.index in the schema.
- **index**  [bool, default True]  Whether to include data.index in the schema.
- **primary_key**  [bool or None, default True]  Column names to designate as the primary key. The default None will set 'primaryKey' to the index level or levels if the index is unique.
- **version**  [bool, default True]  Whether to include a field pandas_version with the version of pandas that generated the schema.

**Returns**

- **schema**  [dict]

**Notes**

See Table Schema for conversion types. Timedeltas as converted to ISO8601 duration format with 9 decimal places after the seconds field for nanosecond precision.

Categoricals are converted to the any dtype, and use the enum field constraint to list the allowed values. The ordered attribute is included in an ordered field.

**Examples**

```python
>>> df = pd.DataFrame(
...     {'A': [1, 2, 3],
...      'B': ['a', 'b', 'c'],
...      'C': pd.date_range('2016-01-01', freq='d', periods=3),
...     }, index=pd.Index(range(3), name='idx'))
>>> build_table_schema(df)
{'fields': [{'name': 'idx', 'type': 'integer'}, {'name': 'A', 'type': 'integer'},
            {'name': 'B', 'type': 'string'}, {'name': 'C', 'type': 'datetime'}], 'primaryKey': ['idx'], 'pandas_version': '0.20.0'}
```
3.1.6 HTML

```python
pandas.read_html
```

Read HTML tables into a list of DataFrame objects.

```python
DataFrame.to_html
```

Render a DataFrame as an HTML table.

**pandas.read_html**

```python
pandas.read_html(io[, match, flavor, header, ...])
```

Read HTML tables into a list of DataFrame objects.

**Parameters**

- **io** [str, path object or file-like object] A URL, a file-like object, or a raw string containing HTML. Note that lxml only accepts the http, ftp and file url protocols. If you have a URL that starts with 'https' you might try removing the 's'.

- **match** [str or compiled regular expression, optional] The set of tables containing text matching this regex or string will be returned. Unless the HTML is extremely simple you will probably need to pass a non-empty string here. Defaults to '.+' (match any non-empty string). The default value will return all tables contained on a page. This value is converted to a regular expression so that there is consistent behavior between Beautiful Soup and lxml.

- **flavor** [str, optional] The parsing engine to use. 'bs4' and 'html5lib' are synonymous with each other, they are both there for backwards compatibility. The default of None tries to use lxml to parse and if that fails it falls back on bs4 + html5lib.

- **header** [int or list-like, optional] The row (or list of rows for a MultiIndex) to use to make the columns headers.

- **index_col** [int or list-like, optional] The column (or list of columns) to use to create the index.

- **skiprows** [int, list-like or slice, optional] Number of rows to skip after parsing the column integer. 0-based. If a sequence of integers or a slice is given, will skip the rows indexed by that sequence. Note that a single element sequence means ‘skip the nth row’ whereas an integer means ‘skip n rows’.

- **attrs** [dict, optional] This is a dictionary of attributes that you can pass to use to identify the table in the HTML. These are not checked for validity before being passed to lxml or Beautiful Soup. However, these attributes must be valid HTML table attributes to work correctly. For example,

```python
attrs = {'id': 'table'}
```

is a valid attribute dictionary because the ‘id’ HTML tag attribute is a valid HTML attribute for any HTML tag as per this document.

```python
attrs = {'asdf': 'table'}
```

is not a valid attribute dictionary because ‘asdf’ is not a valid HTML attribute even if it is a valid XML attribute. Valid HTML 4.01 table attributes can be found here. A working draft of the HTML 5 spec can be found here. It contains the latest information on table attributes for the modern web.
parse_dates [bool, optional] See read_csv() for more details.

thousands [str, optional] Separator to use to parse thousands. Defaults to ','.

can either be integers or column labels, values are functions that take one input argument, the cell (not column) content, and return the transformed content.

na_values [iterable, default None] Custom NA values.

keep_default_na [bool, default True] If na_values are specified and keep_default_na is False the default NaN values are overridden, otherwise they’re appended to.

displayed_only [bool, default True] Whether elements with “display: none” should be parsed.

Returns
dfs A list of DataFrames.

See also:

read_csv Read a comma-separated values (csv) file into DataFrame.

Notes

Before using this function you should read the gotchas about the HTML parsing libraries.

Expect to do some cleanup after you call this function. For example, you might need to manually assign column names if the column names are converted to NaN when you pass the header=0 argument. We try to assume as little as possible about the structure of the table and push the idiosyncrasies of the HTML contained in the table to the user.

This function searches for <table> elements and only for <tr> and <th> rows and <td> elements within each <tr> or <th> element in the table. <td> stands for “table data”. This function attempts to properly handle colspan and rowspan attributes. If the function has a <thead> argument, it is used to construct the header, otherwise the function attempts to find the header within the body (by putting rows with only <th> elements into the header).

Similar to read_csv() the header argument is applied after skiprows is applied.

This function will always return a list of DataFrame or it will fail, e.g., it will not return an empty list.

Examples

See the read_html documentation in the IO section of the docs for some examples of reading in HTML tables.
**DataFrame.to_html**

`DataFrame.to_html(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, justify=None, max_rows=None, max_cols=None, show_dimensions=False, decimal='.', bold_rows=True, notebook=False, border=None, table_id=None, render_links=False, encoding=None)

Render a DataFrame as an HTML table.

**Parameters**

- **buf** [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

- **columns** [sequence, optional, default None] The subset of columns to write. Writes all columns by default.

- **col_space** [str or list or dict of int or str, optional] The minimum width of each column in CSS length units. An int is assumed to be px units.
  
  New in version 0.25.0: Ability to use str.

- **header** [bool, optional] Whether to print column labels, default True.

- **index** [bool, optional, default True] Whether to print index (row) labels.

- **na_rep** [str, optional, default 'NaN'] String representation of NaN to use.

- **formatters** [list, tuple or dict of one-param. functions, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List/tuple must be of length equal to the number of columns.

- **float_format** [one-parameter function, optional, default None] Formatter function to apply to columns’ elements if they are floats. This function must return a unicode string and will be applied only to the non-NaN elements, with NaN being handled by `na_rep`.
  
  Changed in version 1.2.0.

- **sparsify** [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.

- **index_names** [bool, optional, default True] Prints the names of the indexes.

- **justify** [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by set_option), ‘right’ out of the box. Valid values are
  
  - left
  - right
  - center
  - justify
  - justify-all
  - start
  - end
  - inherit
  - match-parent
  - initial
- unset.

**max_rows** [int, optional] Maximum number of rows to display in the console.

**min_rows** [int, optional] The number of rows to display in the console in a truncated repr (when number of rows is above max_rows).

**max_cols** [int, optional] Maximum number of columns to display in the console.

**show_dimensions** [bool, default False] Display DataFrame dimensions (number of rows by number of columns).

**decimal** [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

**bold_rows** [bool, default True] Make the row labels bold in the output.

**classes** [str or list or tuple, default None] CSS class(es) to apply to the resulting html table.

**escape** [bool, default True] Convert the characters <, >, and & to HTML-safe sequences.

**notebook** [{True, False}, default False] Whether the generated HTML is for IPython Notebook.

**border** [int] A border=border attribute is included in the opening <table> tag. Default pd.options.display.html.border.

**encoding** [str, default “utf-8”] Set character encoding.

New in version 1.0.

**table_id** [str, optional] A css id is included in the opening <table> tag if specified.

**render_links** [bool, default False] Convert URLs to HTML links.

Returns

str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:

to_string Convert DataFrame to a string.

```python
Styler.to_html([buf, table_uuid, ...]) Write Styler to a file, buffer or string in HTML-CSS format.
```

**pandas.io.formats.style.Styler.to_html**

Styler.to_html(buf=None, *, table_uuid=None, table_attributes=None, encoding=None, doc-type_html=False, exclude_styles=False)

Write Styler to a file, buffer or string in HTML-CSS format.

New in version 1.3.0.

Parameters

buf [str, Path, or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

table_uuid [str, optional] Id attribute assigned to the <table> HTML element in the format:

```html
<table id="T_<table_uuid>" ..>
```

If not given uses Styler’s initially assigned value.
table_attributes [str, optional] Attributes to assign within the <table> HTML element in the format:

<table .. <table_attributes> >

If not given defaults to Styler’s preexisting value.

encoding [str, optional] Character encoding setting for file output, and HTML meta tags, defaults to “utf-8” if None.

doctype_html [bool, default False] Whether to output a fully structured HTML file including all HTML elements, or just the core <style> and <table> elements.

exclude_styles [bool, default False] Whether to include the <style> element and all associated element class and id identifiers, or solely the <table> element without styling identifiers.

Returns

str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:

Dataframe.to_html Write a DataFrame to a file, buffer or string in HTML format.

3.1.7 XML

read_xml(path_or_buffer[, xpath, ...]) Read XML document into a DataFrame object.

DataFrame.to_xml([path_or_buffer, index, ...]) Render a DataFrame to an XML document.

pandas.read_xml

pandas.read_xml (path_or_buffer, xpath='/*', namespaces=None, elems_only=False, attrs_only=False, names=None, encoding='utf-8', parser='lxml', stylesheet=None, compression='infer', storage_options=None)

Read XML document into a DataFrame object.

New in version 1.3.0.

Parameters

path_or_buffer [str, path object, or file-like object] Any valid XML string or path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file.

xpath [str, optional, default ‘/’] The XPath to parse required set of nodes for migration to DataFrame. XPath should return a collection of elements and not a single element. Note: The etree parser supports limited XPath expressions. For more complex XPath, use lxml which requires installation.

namespaces [dict, optional] The namespaces defined in XML document as dicts with key being namespace prefix and value the URI. There is no need to include all namespaces in XML, only the ones used in xpath expression. Note: if XML document uses default namespace denoted as xmlns='<URI>' without a prefix, you must assign any temporary namespace prefix such as ‘doc’ to the URI in order to parse underlying nodes and/or attributes. For example,

```python
    namespaces = {"doc": "https://example.com"}
```

3.1. Input/output 1015
**elems_only** [bool, optional, default False] Parse only the child elements at the specified `xpath`. By default, all child elements and non-empty text nodes are returned.

**attrs_only** [bool, optional, default False] Parse only the attributes at the specified `xpath`. By default, all attributes are returned.

**names** [list-like, optional] Column names for DataFrame of parsed XML data. Use this parameter to rename original element names and distinguish same named elements.

**encoding** [str, optional, default ‘utf-8’] Encoding of XML document.

**parser** [{‘lxml’, ‘etree’}, default ‘lxml’] Parser module to use for retrieval of data. Only ‘lxml’ and ‘etree’ are supported. With ‘lxml’ more complex XPath searches and ability to use XSLT stylesheet are supported.

**stylesheet** [str, path object or file-like object] A URL, file-like object, or a raw string containing an XSLT script. This stylesheet should flatten complex, deeply nested XML documents for easier parsing. To use this feature you must have lxml module installed and specify ‘lxml’ as parser. The `xpath` must reference nodes of transformed XML document generated after XSLT transformation and not the original XML document. Only XSLT 1.0 scripts and not later versions is currently supported.

**compression** [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’, then use gzip, bz2, zip or xz if path_or_buffer is a string ending in ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’, respectively, and no decompression otherwise. If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

**Returns**

df A DataFrame.

**See also:**

- `read_json` Convert a JSON string to pandas object.
- `read_html` Read HTML tables into a list of DataFrame objects.

**Notes**

This method is best designed to import shallow XML documents in following format which is the ideal fit for the two-dimensions of a DataFrame (row by column).

```
<root>
  <row>
    <column1>data</column1>
    <column2>data</column2>
    <column3>data</column3>
    ...
  </row>
  ...
</root>
```
As a file format, XML documents can be designed any way including layout of elements and attributes as long as it conforms to W3C specifications. Therefore, this method is a convenience handler for a specific flatter design and not all possible XML structures.

However, for more complex XML documents, stylesheet allows you to temporarily redesign original document with XSLT (a special purpose language) for a flatter version for migration to a DataFrame.

This function will always return a single DataFrame or raise exceptions due to issues with XML document, xpath, or other parameters.

Examples

```python
>>> xml = '''<?xml version='1.0' encoding='utf-8'?>
... <data xmlns="http://example.com">
... <row>
...   <shape>square</shape>
...   <degrees>360</degrees>
...   <sides>4.0</sides>
... </row>
... <row>
...   <shape>circle</shape>
...   <degrees>360</degrees>
... </row>
... <row>
...   <shape>triangle</shape>
...   <degrees>180</degrees>
...   <sides>3.0</sides>
... </row>
... </data>'''

>>> df = pd.read_xml(xml)

>>> df
shape  degrees  sides
0  square       360   4.0
1   circle      360  NaN
2 triangle     180   3.0
```

```python
>>> xml = '''<?xml version='1.0' encoding='utf-8'?>
... <data>
... <row shape="square" degrees="360" sides="4.0"/>
... <row shape="circle" degrees="360"/>
... <row shape="triangle" degrees="180" sides="3.0"/>
... </data>'''

>>> df = pd.read_xml(xml, xpath=".//row")

>>> df
shape  degrees  sides
0  square       360   4.0
1   circle      360  NaN
2 triangle     180   3.0
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

>>> xml = '''<?xml version='1.0' encoding='utf-8'?>
... <doc:data xmlns:doc="https://example.com">
...
<doc:row>
...
<doc:shape>square</doc:shape>
...

pandas.DataFrame.to_xml
DataFrame.to_xml(path_or_buffer=None,
index=True,
root_name='data',
row_name='row',
na_rep=None, attr_cols=None, elem_cols=None, namespaces=None, prefix=None, encoding='utf-8', xml_declaration=True, pretty_print=True, parser='lxml',
stylesheet=None, compression='infer', storage_options=None)
Render a DataFrame to an XML document.
New in version 1.3.0.
Parameters
path_or_buffer [str, path object or file-like object, optional] File to write output to. If None,
the output is returned as a string.
index [bool, default True] Whether to include index in XML document.
root_name [str, default ‘data’] The name of root element in XML document.
row_name [str, default ‘row’] The name of row element in XML document.
attr_cols [list-like, optional] List of columns to write as attributes in row element. Hierarchical
columns will be flattened with underscore delimiting the different levels.
elem_cols [list-like, optional] List of columns to write as children in row element. By default,
all columns output as children of row element. Hierarchical columns will be flattened with
underscore delimiting the different levels.

1018

Chapter 3. API reference


namespaces [dict, optional] All namespaces to be defined in root element. Keys of dict should be prefix names and values of dict corresponding URLs. Default namespaces should be given empty string key. For example,

```python
namespaces = {"": "https://example.com"}
```

prefix [str, optional] Namespace prefix to be used for every element and/or attribute in document. This should be one of the keys in namespaces dict.

encoding [str, default ‘utf-8’] Encoding of the resulting document.

xml_declaration [bool, default True] Whether to include the XML declaration at start of document.

pretty_print [bool, default True] Whether output should be pretty printed with indentation and line breaks.

parser [{‘lxml’, ‘etree’}, default ‘lxml’] Parser module to use for building of tree. Only ‘lxml’ and ‘etree’ are supported. With ‘lxml’, the ability to use XSLT stylesheet is supported.

stylesheet [str, path object or file-like object, optional] A URL, file-like object, or a raw string containing an XSLT script used to transform the raw XML output. Script should use layout of elements and attributes from original output. This argument requires lxml to be installed. Only XSLT 1.0 scripts and not later versions is currently supported.

compression [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’, then use gzip, bz2, zip or xz if path_or_buffer is a string ending in ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’, respectively, and no decompression otherwise. If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

Returns

None or str If io is None, returns the resulting XML format as a string. Otherwise returns None.

See also:

to_json Convert the pandas object to a JSON string.

to_html Convert DataFrame to a html.

Examples

```python
>>> df = pd.DataFrame({'shape': ['square', 'circle', 'triangle'],
...                    'degrees': [360, 360, 180],
...                    'sides': [4, np.nan, 3]})

>>> df.to_xml()
<?xml version='1.0' encoding='utf-8'?><data>
  <row>
    <shape>square</shape>
    <degrees>360</degrees>
    <sides>4</sides>
  </row>
  <row>
    <shape>circle</shape>
    <degrees>360</degrees>
    <sides>0</sides>
  </row>
  <row>
    <shape>triangle</shape>
    <degrees>180</degrees>
    <sides>3</sides>

3.1.8 Latex

DataFrame.to_latex([buf, columns, ...])  
Render object to a LaTeX tabular, longtable, or nested table/tabular.

pandas.DataFrame.to_latex

DataFrame.to_latex(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, bold_rows=False, column_format=None, longtable=None, escape=None, encoding=None, decimal='.', multicolumn=None, multicolumn_format=None, multirow=None, caption=None, label=None, position=None)

Render object to a LaTeX tabular, longtable, or nested table/tabular.

Requires \usepackage{booktabs}. The output can be copy/pasted into a main LaTeX document or read from an external file with \input{table.tex}.

Changed in version 1.0.0: Added caption and label arguments.

Changed in version 1.2.0: Added position argument, changed meaning of caption argument.

Parameters

buf  [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

columns  [list of label, optional] The subset of columns to write. Writes all columns by default.

col_space  [int, optional] The minimum width of each column.

header  [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

index  [bool, default True] Write row names (index).

na_rep  [str, default ‘NaN’] Missing data representation.

formatters  [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.

float_format  [one-parameter function or str, optional, default None] Formatter for floating point numbers. For example float_format="%.2f" and float_format="{:0.2f}".format will both result in 0.1234 being formatted as 0.12.

sparsify  [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.

index_names  [bool, default True] Prints the names of the indexes.

bold_rows  [bool, default False] Make the row labels bold in the output.

column_format  [str, optional] The columns format as specified in \LaTeX\ table format e.g. ‘rcl’ for 3 columns. By default, ‘l’ will be used for all columns except columns of numbers, which default to ‘r’.

longtable  [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a usepackage{longtable} to your \LaTeX\ preamble.
escape [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to "utf-8".

decimal [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

multicolumn [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.

multicolumn_format [str, default ‘l’] The alignment for multicolumns, similar to column_format. The default will be read from the config module.

multirow [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a usepackage{multirow} to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

caption [str or tuple, optional] Tuple (full_caption, short_caption), which results in \caption[short_caption]{full_caption}; if a single string is passed, no short caption will be set.

New in version 1.0.0.

Changed in version 1.2.0: Optionally allow caption to be a tuple (full_caption, short_caption).

label [str, optional] The LaTeX label to be placed inside \label{} in the output. This is used with \ref{} in the main .tex file.

New in version 1.0.0.

position [str, optional] The LaTeX positional argument for tables, to be placed after \begin{} in the output.

New in version 1.2.0.

Returns

str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:

DataFrame.to_string Render a DataFrame to a console-friendly tabular output.

DataFrame.to_html Render a DataFrame as an HTML table.

Examples

```python
>>> df = pd.DataFrame(dict(name=['Raphael', 'Donatello'],
                        mask=['red', 'purple'],
                        weapon=['sai', 'bo staff']))
>>> print(df.to_latex(index=False))
\begin{tabular}{lll}
\toprule
name & mask & weapon \\
\midrule
Raphael & red & sai \\
Donatello & purple & bo staff \\
\bottomrule
\end{tabular}
```

(continues on next page)
\bottomrule
\end{tabular}

\texttt{Styler.to\_latex}([\texttt{buf}, \texttt{column\_format}, \ldots]) \hspace{1em} Write Styler to a file, buffer or string in LaTeX format.

\texttt{pandas.io.formats.style.Styler.to\_latex}

\texttt{Styler.to\_latex}(\texttt{buf=None, \*, \texttt{column\_format=None, \texttt{position=None, \texttt{position\_float=None, \texttt{hrules=False, \texttt{label=None, \texttt{caption=None, \texttt{sparse\_index=None, \texttt{sparse\_columns=None, \texttt{multirow\_align='c', \texttt{multicol\_align='r', \texttt{siunitx=False, \texttt{encoding=None, convert\_css=False)}}}}}}}}}})

Write Styler to a file, buffer or string in LaTeX format.

New in version 1.3.0.

\textbf{Parameters}

- **\texttt{buf}** [str, Path, or StringIO-like, optional, default None] Buffer to write to. If \texttt{None}, the output is returned as a string.

- **\texttt{column\_format}** [str, optional] The LaTeX column specification placed in location:
  \begin{tabular}{<column\_format>}
  \end{tabular}
  Defaults to ‘l’ for index and non-numeric data columns, and, for numeric data columns, to ‘r’ by default, or ‘S’ if \texttt{siunitx} is \texttt{True}.

- **\texttt{position}** [str, optional] The LaTeX positional argument (e.g. ‘h!’) for tables, placed in location:
  \begin{table} [<position>]
  \end{table}

- **\texttt{position\_float}** ["centering", “raggedleft”, “raggedright"], optional] The LaTeX float command placed in location:
  \begin{table} [<position>]
  \end{table}

- **\texttt{hrules}** [bool, default \texttt{False}] Set to \texttt{True} to add \texttt{toprule}, \texttt{midrule} and \texttt{bottomrule} from the \{booktabs\} LaTeX package.

- **\texttt{label}** [str, optional] The LaTeX label included as: \label{<label>}. This is used with \ref{<label>} in the main .tex file.

- **\texttt{caption}** [str, tuple, optional] If string, the LaTeX table caption included as: \caption{<caption>}. If tuple, i.e (“full caption”, “short caption”), the caption included as: \caption[<caption[1]>][<caption[0]>].

- **\texttt{sparse\_index}** [bool, optional] Whether to sparsify the display of a hierarchical index. Setting to \texttt{False} will display each explicit level element in a hierarchical key for each row. Defaults to \texttt{pandas.options.styler.sparse.index value}.

- **\texttt{sparse\_columns}** [bool, optional] Whether to sparsify the display of a hierarchical index. Setting to \texttt{False} will display each explicit level element in a hierarchical key for each row. Defaults to \texttt{pandas.options.styler.sparse.columns value}.

- **\texttt{multirow\_align}** ["c", “t”, “b"] If sparsifying hierarchical MultiIndexes whether to align text centrally, at the top or bottom.
multicol_align ["r", "c", "l"] If sparsifying hierarchical MultiIndex columns whether to align text at the left, centrally, or at the right.

siunitx [bool, default False] Set to True to structure LaTeX compatible with the {siunitx} package.

encoding [str, default “utf-8”] Character encoding setting.

convert_css [bool, default False] Convert simple cell-styles from CSS to LaTeX format. Any CSS not found in conversion table is dropped. A style can be forced by adding option --latex. See notes.

Returns

str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:

Styler.format Format the text display value of cells.

Notes

Latex Packages

For the following features we recommend the following LaTeX inclusions:

<table>
<thead>
<tr>
<th>Feature</th>
<th>Inclusion</th>
</tr>
</thead>
<tbody>
<tr>
<td>sparse columns</td>
<td>none: included within default {tabular} environment</td>
</tr>
<tr>
<td>sparse rows</td>
<td>\usepackage{multirow}</td>
</tr>
<tr>
<td>hrules</td>
<td>\usepackage{booktabs}</td>
</tr>
<tr>
<td>colors</td>
<td>\usepackage{table}{xcolor}</td>
</tr>
<tr>
<td>siunitx</td>
<td>\usepackage{siunitx}</td>
</tr>
<tr>
<td>bold (with siunitx)</td>
<td>\usepackage{etoolbox} \robustify\bfseries \sisetup{detect-all = true} (within \document)</td>
</tr>
<tr>
<td>italic (with siunitx)</td>
<td>\usepackage{etoolbox} \robustify\itshape \sisetup{detect-all = true} (within \document)</td>
</tr>
</tbody>
</table>

Cell Styles

LaTeX styling can only be rendered if the accompanying styling functions have been constructed with appropriate LaTeX commands. All styling functionality is built around the concept of a CSS (<attribute>, <value>) pair (see Table Visualization), and this should be replaced by a LaTeX (<command>, <options>) approach. Each cell will be styled individually using nested LaTeX commands with their accompanied options.

For example the following code will highlight and bold a cell in HTML-CSS:
```python
>>> df = pd.DataFrame([[1, 2], [3, 4]])
>>> s = df.style.highlight_max(axis=0,
...                           props='background-color:red; font-weight:bold;')
>>> s.render()
```

The equivalent using LaTeX only commands is the following:

```python
>>> s = df.style.highlight_max(axis=0,
...                           props='cellcolor:red; bfseries:')
>>> s.to_latex()
```

Internally these structured LaTeX (<command>, <options>) pairs are translated to the `display_value` with the default structure: \(<command><options><display_value>. Where there are multiple commands the latter is nested recursively, so that the above example highlighted cell is rendered as \cellcolor{red} \bfseries 4.

Occasionally this format does not suit the applied command, or combination of LaTeX packages that is in use, so additional flags can be added to the <options>, within the tuple, to result in different positions of required braces (the default being the same as --nowrap):

<table>
<thead>
<tr>
<th>Tuple Format</th>
<th>Output Structure</th>
</tr>
</thead>
<tbody>
<tr>
<td>(&lt;command&gt;,&lt;options&gt;)</td>
<td>&lt;command&gt;&lt;options&gt;&lt;display_value&gt;</td>
</tr>
<tr>
<td>(&lt;command&gt;,&lt;options&gt;--nowrap)</td>
<td>&lt;command&gt;&lt;options&gt;&lt;display_value&gt;</td>
</tr>
<tr>
<td>(&lt;command&gt;,&lt;options&gt;--rwrap)</td>
<td>&lt;command&gt;&lt;options&gt;&lt;display_value&gt;</td>
</tr>
<tr>
<td>(&lt;command&gt;,&lt;options&gt;--lwrap)</td>
<td>&lt;command&gt;&lt;options&gt;&lt;display_value&gt;</td>
</tr>
<tr>
<td>(&lt;command&gt;,&lt;options&gt;--dwrap)</td>
<td>{&lt;command&gt;&lt;options&gt;&lt;display_value&gt;</td>
</tr>
</tbody>
</table>

For example the `textbf` command for font-weight should always be used with --rwrap so ('textbf', '--rwrap') will render a working cell, wrapped with braces, as `\textbf{<display_value>}`.

A more comprehensive example is as follows:

```python
>>> df = pd.DataFrame([[1.1, 2.2, "dogs"], [3.3, 4.4, "cats"], [2.2, 6.6, "cows"]],
...                    index=["ix1", "ix2", "ix3"],
...                    columns=["Integers", "Floats", "Strings"])
>>> s = df.style.highlight_max(
...                           props="cellcolor:HTML(FFFF00); color:red;"
...                           'textit:--rwrap; textbf:--rwrap;')
>>> s.to_latex()
```

```
<table>
<thead>
<tr>
<th>Integers</th>
<th>Floats</th>
<th>Strings</th>
</tr>
</thead>
<tbody>
<tr>
<td>ix1</td>
<td>1</td>
<td>2.200000 dogs</td>
</tr>
<tr>
<td>ix2</td>
<td>3</td>
<td>4.400000 cats</td>
</tr>
<tr>
<td>ix3</td>
<td>2</td>
<td>6.600000 cows</td>
</tr>
</tbody>
</table>
```

**Table Styles**

Internally Styler uses its `table_styles` object to parse the `column_format`, `position`, `position_float`, and `label` input arguments. These arguments are added to table styles in the format:

```
set_table_styles({
    "selector": "column_format",
    "props": f":{column_format};",
})
```
Exception is made for the `hrules` argument which, in fact, controls all three commands: `toprule`, `bottomrule` and `midrule` simultaneously. Instead of setting `hrules` to `True`, it is also possible to set each individual rule definition, by manually setting the `table_styles`, for example below we set a regular `toprule`, set an `hline` for `bottomrule` and exclude the `midrule`:

```python
set_table_styles([{
    'selector': 'toprule', 'props': ':toprule;'},
    {'selector': 'bottomrule', 'props': ':hline;'},
], overwrite=False)
```

If other commands are added to table styles they will be detected, and positioned immediately above the `\begin{tabular}` command. For example to add odd and even row coloring, from the `{colortbl}` package, in format `\rowcolors{1}{pink}{red}`, use:

```python
set_table_styles([{
    'selector': 'rowcolors', 'props': ':{1}{pink}{red};'}], overwrite=False)
```

A more comprehensive example using these arguments is as follows:

```python
>>> df.columns = pd.MultiIndex.from_tuples([
    ...
    ('Numeric', 'Integers'),
    ...
    ('Numeric', 'Floats'),
    ...
    ('Non-Numeric', 'Strings')
    ...
])
>>> df.index = pd.MultiIndex.from_tuples([
    ...
    ('L0', 'ix1'), ('L0', 'ix2'), ('L1', 'ix3')
    ...
])
>>> s = df.style.highlight_max(
    ...
    props='cellcolor:[HTML]{FFFF00}; color:{red}; itshape:; bfseries:'
    ...
)  
>>> s.to_latex(
    ...
    column_format="rrrrr", position="h", position_float="centering",
    ...
    hrules=True, label="table:5", caption="Styled \LaTeX\ Table",
    ...
    multirow_align="t", multicolumn_align="r"
    ...
)
```

### Table 1: Styled \LaTeX\ Table

<table>
<thead>
<tr>
<th></th>
<th>Numeric</th>
<th>Non-Numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Integers</td>
<td>Floats</td>
</tr>
<tr>
<td>L0</td>
<td>ix1</td>
<td>2.200000</td>
</tr>
<tr>
<td></td>
<td>ix2</td>
<td>4.400000</td>
</tr>
<tr>
<td>L1</td>
<td>ix3</td>
<td>6.600000</td>
</tr>
</tbody>
</table>

#### Formatting

To format values `Styler.format()` should be used prior to calling `Styler.to_latex`, as well as other methods such as `Styler.hide_index()` or `Styler.hide_columns()`, for example:
>>> s.clear()
>>> s.table_styles = []
>>> s.caption = None
>>> s.format(
    ...
    ("Numeric", "Integers"): '{:0.0f}',
    ...
    ("Numeric", "Floats"): '{:.3f}',
    ...
    ("Non-Numeric", "Strings"): str.upper
    ...
)
>>> s.to_latex()
\begin{tabular}{llrrl}
{} & {} & \multicolumn{2}{r}{Numeric} & {Non-Numeric} \\
{} & {} & {Integers} & {Floats} & {Strings} \\
\multirow[2]{*}{{L0}} & ix1 & \$1 & 2.200 & DOGS \\
& ix2 & \$3 & 4.400 & CATS \\
L1 & ix3 & \$2 & 6.600 & COWS \\
\end{tabular}

CSS Conversion

This method can convert a Styler constructed with HTML-CSS to LaTeX using the following limited conversions.

<table>
<thead>
<tr>
<th>CSS Attribute</th>
<th>CSS value</th>
<th>LaTeX Command</th>
<th>LaTeX Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>font-weight</td>
<td>bold</td>
<td>bfseries</td>
<td></td>
</tr>
<tr>
<td></td>
<td>bolder</td>
<td>bfseries</td>
<td></td>
</tr>
<tr>
<td>font-style</td>
<td>italic</td>
<td>itshape</td>
<td></td>
</tr>
<tr>
<td></td>
<td>oblique</td>
<td>slshape</td>
<td></td>
</tr>
<tr>
<td>background-color</td>
<td>red</td>
<td>cellcolor</td>
<td></td>
</tr>
<tr>
<td></td>
<td>#fe01ea</td>
<td></td>
<td>{red}–lwrap</td>
</tr>
<tr>
<td></td>
<td>#0f0e</td>
<td></td>
<td>[HTML]{FE01EA}–lwrap</td>
</tr>
<tr>
<td></td>
<td>rgb(128,255,0)</td>
<td></td>
<td>[HTML]{FF00EE}–lwrap</td>
</tr>
<tr>
<td></td>
<td>rgb(128,0,0,0.5)</td>
<td></td>
<td>[rgb]{0.5,1,0}–lwrap</td>
</tr>
<tr>
<td></td>
<td>rgb(25%,255,50%)</td>
<td></td>
<td>[rgb]{0.5,0,0}–lwrap</td>
</tr>
<tr>
<td>color</td>
<td>red</td>
<td>color</td>
<td></td>
</tr>
<tr>
<td></td>
<td>#fe01ea</td>
<td></td>
<td>[red]</td>
</tr>
<tr>
<td></td>
<td>#0f0e</td>
<td></td>
<td>[HTML]{FE01EA}</td>
</tr>
<tr>
<td></td>
<td>rgb(128,255,0)</td>
<td></td>
<td>[HTML]{FF00EE}</td>
</tr>
<tr>
<td></td>
<td>rgb(128,0,0,0.5)</td>
<td></td>
<td>[rgb]{0.5,1,0}</td>
</tr>
<tr>
<td></td>
<td>rgb(25%,255,50%)</td>
<td></td>
<td>[rgb]{0.5,0,0}</td>
</tr>
</tbody>
</table>

It is also possible to add user-defined LaTeX only styles to a HTML-CSS Styler using the \--latex flag, and
to add LaTeX parsing options that the converter will detect within a CSS-comment.

```python
>>> df = pd.DataFrame([[1]])
>>> df.style.set_properties({
...   **"font-weight": "bold /* --dwrap */", "Huge": "--latex--rwrap"}
... ).to_latex(convert_css=True)
\begin{tabular}{lr}
{} & {0} \\
0 & {'bfseries}{$\Huge{1}$} \\
\end{tabular}
```

### 3.1.9 HDFStore: PyTables (HDF5)

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>read_hdf(path_or_buf[, key, mode, errors, ...])</code></td>
<td>Read from the store, close it if we opened it.</td>
</tr>
<tr>
<td><code>HDFStore.put(key, value[, format, index, ...])</code></td>
<td>Store object in HDFStore.</td>
</tr>
<tr>
<td><code>HDFStore.append(key, value[, format, axes, ...])</code></td>
<td>Append object to Table in file.</td>
</tr>
<tr>
<td><code>HDFStore.get(key)</code></td>
<td>Retrieve pandas object stored in file.</td>
</tr>
<tr>
<td><code>HDFStore.select(key[, where, start, stop, ...])</code></td>
<td>Retrieve pandas object stored in file, optionally based on where criteria.</td>
</tr>
<tr>
<td><code>HDFStore.info()</code></td>
<td>Print detailed information on the store.</td>
</tr>
<tr>
<td><code>HDFStore.keys([include])</code></td>
<td>Return a list of keys corresponding to objects stored in HDFStore.</td>
</tr>
<tr>
<td><code>HDFStore.groups()</code></td>
<td>Return a list of all the top-level nodes.</td>
</tr>
<tr>
<td><code>HDFStore.walk([where])</code></td>
<td>Walk the pytables group hierarchy for pandas objects.</td>
</tr>
</tbody>
</table>

**pandas.read_hdf**

`pandas.read_hdf(path_or_buf, key=None, mode='r', errors='strict', where=None, start=None, stop=None, columns=None, iterator=False, chunksize=None, **kwargs)`

Read from the store, close it if we opened it.

Retrieve pandas object stored in file, optionally based on where criteria.

**Warning:** Pandas uses PyTables for reading and writing HDF5 files, which allows serializing object-dtype data with pickle when using the “fixed” format. Loading pickled data received from untrusted sources can be unsafe.

See: [https://docs.python.org/3/library/pickle.html](https://docs.python.org/3/library/pickle.html) for more.

**Parameters**

- `path_or_buf` [str, path object, pandas.HDFStore] Any valid string path is acceptable. Only supports the local file system, remote URLs and file-like objects are not supported.
  
  If you want to pass in a path object, pandas accepts any `os.PathLike`.
  
  Alternatively, pandas accepts an open `pandas.HDFStore` object.

- `key` [object, optional] The group identifier in the store. Can be omitted if the HDF file contains a single pandas object.

- `mode` [{'r', 'r+', 'a'}, default ‘r’] Mode to use when opening the file. Ignored if `path_or_buf` is a `pandas.HDFStore` object. Defaults is ‘r’.
errors [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

where [list, optional] A list of Term (or convertible) objects.

start [int, optional] Row number to start selection.

stop [int, optional] Row number to stop selection.

columns [list, optional] A list of columns names to return.

iterator [bool, optional] Return an iterator object.

chunksize [int, optional] Number of rows to include in an iteration when using an iterator.

**kwargs Additional keyword arguments passed to HDFStore.

Returns

item [object] The selected object. Return type depends on the object stored.

See also:

DataFrames.to_hdf Write a HDF file from a DataFrame.

HDFStore Low-level access to HDF files.

Examples

```python
>>> df = pd.DataFrame([[1, 1.0, 'a']], columns=['x', 'y', 'z'])
>>> df.to_hdf('./store.h5', 'data')
>>> reread = pd.read_hdf('./store.h5')
```

pandas.HDFStore.put

HDFStore.put(key, value, format=None, index=True, append=False, complib=None, complevel=None, min_itemsize=None, nan_rep=None, data_columns=None, encoding=None, errors='strict', track_times=True, dropna=False)

Store object in HDFStore.

Parameters

key [str]

value [[Series, DataFrame]]

format [‘fixed(f)|table(t)’, default is ‘fixed’] Format to use when storing object in HDFStore. Value can be one of:

'fixed' Fixed format. Fast writing/reading. Not-appendable, nor searchable.

'table' Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.

append [bool, default False] This will force Table format, append the input data to the existing.

data_columns [list, default None] List of columns to create as data columns, or True to use all columns. See here.

encoding [str, default None] Provide an encoding for strings.
track_times [bool, default True] Parameter is propagated to ‘create_table’ method of ‘PyTables’. If set to False it enables to have the same h5 files (same hashes) independent on creation time.

New in version 1.1.0.

pandas.HDFStore.append

HDFStore.append (key, value, format=None, axes=None, index=True, append=True, complib=None, complevel=None, columns=None, min_itemsize=None, nan_rep=None, chunksize=None, expectedrows=None, dropna=None, data_columns=None, encoding=None, errors='strict')

Append to Table in file. Node must already exist and be Table format.

Parameters

key [str]
value [{Series, DataFrame}]
format ['table' is the default] Format to use when storing object in HDFStore. Value can be one of:
'table' Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
append [bool, default True] Append the input data to the existing.
data_columns [list of columns, or True, default None] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See here.
min_itemsize [dict of columns that specify minimum str sizes]
nan_rep [str to use as str nan representation]
chunksize [size to chunk the writing]
expectedrows [expected TOTAL row size of this table]
encoding [default None, provide an encoding for str]
dropna [bool, default False] Do not write an ALL nan row to the store settable by the option ‘io.hdf.dropna_table’.

Notes

Does not check if data being appended overlaps with existing data in the table, so be careful

pandas.HDFStore.get

HDFStore.get (key)

Retrieve pandas object stored in file.

Parameters

key [str]

Returns

object Same type as object stored in file.
pandas.HDFStore.select

HDFStore.select(key, where=None, start=None, stop=None, columns=None, iterator=False, chunksize=None, auto_close=False)

Retrieve pandas object stored in file, optionally based on where criteria.

Warning: Pandas uses PyTables for reading and writing HDF5 files, which allows serializing object-dtype data with pickle when using the “fixed” format. Loading pickled data received from untrusted sources can be unsafe.
See: https://docs.python.org/3/library/pickle.html for more.

Parameters

- key [str] Object being retrieved from file.
- where [list or None] List of Term (or convertible) objects, optional.
- start [int or None] Row number to start selection.
- stop [int, default None] Row number to stop selection.
- columns [list or None] A list of columns that if not None, will limit the return columns.
- iterator [bool or False] Returns an iterator.
- chunksize [int or None] Number or rows to include in iteration, return an iterator.
- auto_close [bool or False] Should automatically close the store when finished.

Returns

- object Retrieved object from file.

pandas.HDFStore.info

HDFStore.info()

Print detailed information on the store.

Returns

- str

pandas.HDFStore.keys

HDFStore.keys(include='pandas')

Return a list of keys corresponding to objects stored in HDFStore.

Parameters

- include [str, default ‘pandas’] When kind equals ‘pandas’ return pandas objects. When kind equals ‘native’ return native HDF5 Table objects.

New in version 1.1.0.

Returns

- list List of ABSOLUTE path-names (e.g. have the leading ‘/’).

Raises
raises ValueError if kind has an illegal value

**pandas.HDFStore.groups**

HDFStore.groups()  
Return a list of all the top-level nodes.  
Each node returned is not a pandas storage object.  

**Returns**  
- list: List of objects.

**pandas.HDFStore.walk**

HDFStore.walk(where='/')  
Walk the PyTables group hierarchy for pandas objects.  
This generator will yield the group path, subgroups and pandas object names for each group.  
Any non-pandas PyTables objects that are not a group will be ignored.  
The where group itself is listed first (preorder), then each of its child groups (following an alphanumerical order) is also traversed, following the same procedure.  

**Parameters**  
- where: [str, default ‘/’] Group where to start walking.  

**Yields**  
- path: [str] Full path to a group (without trailing ‘/’).  
- groups: [list] Names (strings) of the groups contained in path.  
- leaves: [list] Names (strings) of the pandas objects contained in path.

**Warning:** One can store a subclass of DataFrame or Series to HDF5, but the type of the subclass is lost upon storing.

### 3.1.10 Feather

read_feather(path[, columns, use_threads, ...])  
Load a feather-format object from the file path.

DataFrame.to_feather(path, **kwargs)  
Write a DataFrame to the binary Feather format.
pandas.read_feather

pandas.read_feather(path, columns=None, use_threads=True, storage_options=None)
Load a feather-format object from the file path.

Parameters

path [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.feather.

If you want to pass in a path object, pandas accepts any os.PathLike.

By file-like object, we refer to objects with a read() method, such as a file handle (e.g. via builtin open function) or StringIO.

columns [sequence, default None] If not provided, all columns are read.

use_threads [bool, default True] Whether to parallelize reading using multiple threads.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

Returns
type of object stored in file

pandas.DataFrame.to_feather

DataFrame.to_feather(path, **kwargs)
Write a DataFrame to the binary Feather format.

Parameters

path [str or file-like object] If a string, it will be used as Root Directory path.

**kwargs : Additional keywords passed to pyarrow.feather.write_feather().
Starting with pyarrow 0.17, this includes the compression, compression_level, chunksize and version keywords.

New in version 1.1.0.

3.1.11 Parquet

read_parquet(path[, engine, columns, ...])
Load a parquet object from the file path, returning a DataFrame.

DataFrame.to_parquet([path, engine, ...])
Write a DataFrame to the binary parquet format.
pandas.read_parquet

`pandas.read_parquet(path, engine='auto', columns=None, storage_options=None, use_nullable_dtypes=False, **kwargs)`

Load a parquet object from the file path, returning a DataFrame.

**Parameters**

- `path` [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, gs, and file. For file URLs, a host is expected. A local file could be: file://localhost/path/to/table.parquet. A file URL can also be a path to a directory that contains multiple partitioned parquet files. Both pyarrow and fastparquet support paths to directories as well as file URLs. A directory path could be: file://localhost/path/to/tables or s3://bucket/partition_dir

  If you want to pass in a path object, pandas accepts any os.PathLike.

  By file-like object, we refer to objects with a `read()` method, such as a file handle (e.g. via builtin `open` function) or `StringIO`.

- `engine` [{'auto', 'pyarrow', 'fastparquet'}, default 'auto'] Parquet library to use. If `auto`, then the option `io.parquet.engine` is used. The default `io.parquet.engine` behavior is to try `pyarrow`, falling back to `fastparquet` if `pyarrow` is unavailable.

- `columns` [list, default=None] If not None, only these columns will be read from the file.

- `storage_options` [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://” and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

  New in version 1.3.0.

- `use_nullable_dtypes` [bool, default False] If True, use dtypes that use `pd.NA` as missing value indicator for the resulting DataFrame (only applicable for engine="pyarrow"). As new dtypes are added that support `pd.NA` in the future, the output with this option will change to use those dtypes. Note: this is an experimental option, and behaviour (e.g. additional support dtypes) may change without notice.

  New in version 1.2.0.

- `**kwargs` Any additional kwargs are passed to the engine.

**Returns**

- `DataFrame`

pandas.DataFrame.to_parquet

`DataFrame.to_parquet(path=None, engine='auto', compression='snappy', index=None, partition_cols=None, storage_options=None, **kwargs)`

Write a DataFrame to the binary parquet format.

This function writes the dataframe as a parquet file. You can choose different parquet backends, and have the option of compression. See the user guide for more details.

**Parameters**
**path**  [str or file-like object, default None] If a string, it will be used as Root Directory path when writing a partitioned dataset. By file-like object, we refer to objects with a write() method, such as a file handle (e.g. via builtin open function) or io.BytesIO. The engine fastparquet does not accept file-like objects. If path is None, a bytes object is returned.

Changed in version 1.2.0.

Previously this was “fname”

**engine**  [{‘auto’, ‘pyarrow’, ‘fastparquet’}, default ‘auto’] Parquet library to use. If ‘auto’, then the option io.parquet.engine is used. The default io.parquet.engine behavior is to try ‘pyarrow’, falling back to ‘fastparquet’ if ‘pyarrow’ is unavailable.

**compression**  [{‘snappy’, ‘gzip’, ‘brotli’, None}, default ‘snappy’] Name of the compression to use. Use None for no compression.

**index**  [bool, default None] If True, include the dataframe’s index(es) in the file output. If False, they will not be written to the file. If None, similar to True the dataframe’s index(es) will be saved. However, instead of being saved as values, the RangeIndex will be stored as a range in the metadata so it doesn’t require much space and is faster. Other indexes will be included as columns in the file output.

**partition_cols**  [list, optional, default None] Column names by which to partition the dataset. Columns are partitioned in the order they are given. Must be None if path is not a string.

**storage_options**  [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

**kwargs**  Additional arguments passed to the parquet library. See pandas io for more details.

**Returns**

bytes if no path argument is provided else None

See also:

read_parquet  Read a parquet file.

DataFrame.to_csv  Write a csv file.

DataFrame.to_sql  Write to a sql table.

DataFrame.to_hdf  Write to hdf.

**Notes**

This function requires either the fastparquet or pyarrow library.
Examples

```python
>>> df = pd.DataFrame(data={'col1': [1, 2], 'col2': [3, 4]})
>>> df.to_parquet('df.parquet.gzip',
...               compression='gzip')
>>> pd.read_parquet('df.parquet.gzip')
   col1  col2
0    1    3
1    2    4
```

If you want to get a buffer to the parquet content you can use a `io.BytesIO` object, as long as you don’t use `partition_cols`, which creates multiple files.

```python
>>> import io

>>> f = io.BytesIO()
>>> df.to_parquet(f)
>>> f.seek(0)
0
>>> content = f.read()
```

3.1.12 ORC

```python
read_orc(path[, columns])
```

Load an ORC object from the file path, returning a DataFrame.

**pandas.read_orc**

pandas.read_orc(*path*, *columns=None*, **kwargs)

Load an ORC object from the file path, returning a DataFrame.

New in version 1.0.0.

**Parameters**

- `path` [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.orc`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handle (e.g. via builtin `open` function) or `StringIO`.

- `columns` [list, default None] If not None, only these columns will be read from the file.

**kwargs Any additional kwargs are passed to pyarrow.

**Returns**

- `DataFrame`
3.1.13 SAS

3.1. Input/output
3.1.14 SPSS

read_spss(path[, usecols, convert_categoricals])
Load an SPSS file from the file path, returning a DataFrame.

New in version 0.25.0.

Parameters

path [str or Path] File path.
usecols [list-like, optional] Return a subset of the columns. If None, return all columns.
convert_categoricals [bool, default is True] Convert categorical columns into pd.Categorical.

Returns
DataFrame

3.1.15 SQL

read_sql_table(table_name, con[, schema,...])
Read SQL database table into a DataFrame.

given a table name and a SQLAlchemy connectable, returns a DataFrame. This function does not support DBAPI connections.

Parameters

table_name [str] Name of SQL table in database.
con [SQLAlchemy connectable or str] A database URI could be provided as str. SQLite DBAPI connection mode not supported.
schema [str, default None] Name of SQL schema in database to query (if database flavor supports this). Uses default schema if None (default).
index_col [str or list of str, optional, default: None] Column(s) to set as index(MultiIndex).
coerce_float [bool, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Can result in loss of Precision.
parse_dates [list or dict, default None]
• List of column names to parse as dates.
• Dict of \{column_name: format string\} where format string is strftime compatible in case of parsing string times or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
• Dict of \{column_name: arg dict\}, where the arg dict corresponds to the keyword arguments of pandas.to_datetime() Especially useful with databases without native Datetime support, such as SQLite.

columns  [list, default None] List of column names to select from SQL table.
chunksize  [int, default None] If specified, returns an iterator where chunksize is the number of rows to include in each chunk.

Returns

DataFrame or Iterator[DataFrame] A SQL table is returned as two-dimensional data structure with labeled axes.

See also:

read_sql_query Read SQL query into a DataFrame.
read_sql Read SQL query or database table into a DataFrame.

Notes

Any datetime values with time zone information will be converted to UTC.

Examples

```python
>>> pd.read_sql_table('table_name', 'postgres:///db_name')
```

pandas.read_sql_query

pandas.read_sql_query(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None, chunksize=None, dtype=None)

Read SQL query into a DataFrame.

Returns a DataFrame corresponding to the result set of the query string. Optionally provide an index_col parameter to use one of the columns as the index, otherwise default integer index will be used.

Parameters

sql  [str SQL query or SQLAlchemy Selectable (select or text object)] SQL query to be executed.
con  [SQLAlchemy connectable, str, or sqlite3 connection] Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported.
index_col  [str or list of str, optional, default: None] Column(s) to set as index(MultiIndex).
coerce_float  [bool, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Useful for SQL result sets.
params  [list, tuple or dict, optional, default: None] List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249’s
paramstyle, is supported. Eg. for psycopg2, uses %\(name\)s so use \params=\{'name': 'value'\}.

**parse_dates** [list or dict, default: None]

- List of column names to parse as dates.
- Dict of {\textit{column\_name}: \textit{format\_string}} where \textit{format\_string} is strftime compatible in case of parsing string times, or is one of \{D, s, ns, ms, us\} in case of parsing integer timestamps.
- Dict of {\textit{column\_name}: \textit{arg\_dict}}, where the \textit{arg\_dict} corresponds to the keyword arguments of \texttt{pandas.to\_datetime()} Especially useful with databases without native Datetime support, such as SQLite.

**chunksize** [int, default None] If specified, return an iterator where \textit{chunksize} is the number of rows to include in each chunk.

**dtype** [Type name or dict of columns] Data type for data or columns. E.g. np.float64 or \{'a': np.float64, 'b': np.int32, 'c': 'Int64'\}

New in version 1.3.0.

**Returns**

DataFrame or Iterator[DataFrame]

See also:

- \texttt{read\_sql\_table} Read SQL database table into a DataFrame.
- \texttt{read\_sql} Read SQL query or database table into a DataFrame.

**Notes**

Any datetime values with time zone information parsed via the \textit{parse\_dates} parameter will be converted to UTC.

**pandas.read_sql**

\texttt{pandas.read\_sql} \(sql\text{	exttt{, con=None, index\_col=None, coerce\_float=True, params=None, parse\_dates=None, columns=None, chunksize=None}}\)

Read SQL query or database table into a DataFrame.

This function is a convenience wrapper around \texttt{read\_sql\_table} and \texttt{read\_sql\_query} (for backward compatibility). It will delegate to the specific function depending on the provided input. A SQL query will be routed to \texttt{read\_sql\_query}, while a database table name will be routed to \texttt{read\_sql\_table}. Note that the delegated function might have more specific notes about their functionality not listed here.

**Parameters**

- \texttt{sql} [str or SQLAlchemy Selectable (\texttt{select} or \texttt{text} object)] SQL query to be executed or a table name.
- \texttt{con} [SQLAlchemy connectable, str, or sqlite3 connection] Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable; str connections are closed automatically. See \texttt{here}.
- \texttt{index\_col} [str or list of str, optional, default: None] Column(s) to set as index(MultiIndex).
coerce_float [bool, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets.

params [list, tuple or dict, optional, default: None] List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249’s paramstyle, is supported. Eg. for psyco2, uses %(name)s so use params={'name': ‘value’}.

parse_dates [list or dict, default: None]
  • List of column names to parse as dates.
  • Dict of {column_name: format string} where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
  • Dict of {column_name: arg dict}, where the arg dict corresponds to the keyword arguments of pandas.to_datetime() Especially useful with databases without native Datetime support, such as SQLite.

columns [list, default: None] List of column names to select from SQL table (only used when reading a table).

chunksize [int, default None] If specified, return an iterator where chunksize is the number of rows to include in each chunk.

Returns
DataFrame or Iterator[DataFrame]

See also:
read_sql_table Read SQL database table into a DataFrame.
read_sql_query Read SQL query into a DataFrame.

Examples

Read data from SQL via either a SQL query or a SQL tablename. When using a SQLite database only SQL queries are accepted, providing only the SQL tablename will result in an error.

```python
>>> from sqlite3 import connect
>>> conn = connect(':memory:)
>>> df = pd.DataFrame(data=[[0, '10/11/12'], [1, '12/11/10']],
... columns=['int_column', 'date_column'])
>>> df.to_sql('test_data', conn)

>>> pd.read_sql('SELECT int_column, date_column FROM test_data', conn)
   int_column  date_column
0          0  10/11/12
1          1  12/11/10

>>> pd.read_sql('test_data', 'postgres:///db_name')
```

Apply date parsing to columns through the parse_dates argument
```python
>>> pd.read_sql('SELECT int_column, date_column FROM test_data',
...             conn,
...             parse_dates=['date_column'])
   int_column  date_column
0       0   2012-10-11
1       1   2010-12-11
```

The `parse_dates` argument calls `pd.to_datetime` on the provided columns. Custom argument values for applying `pd.to_datetime` on a column are specified via a dictionary format: 1. Ignore errors while parsing the values of “date_column”

```python
>>> pd.read_sql('SELECT int_column, date_column FROM test_data',
...             conn,
...             parse_dates={'date_column': {'errors': 'ignore'}})
   int_column  date_column
0       0   2012-10-11
1       1   2010-12-11
```

2. Apply a dayfirst date parsing order on the values of “date_column”

```python
>>> pd.read_sql('SELECT int_column, date_column FROM test_data',
...             conn,
...             parse_dates={'date_column': {'dayfirst': True}})
   int_column  date_column
0       0   2012-11-10
1       1   2010-11-12
```

3. Apply custom formatting when date parsing the values of “date_column”

```python
>>> pd.read_sql('SELECT int_column, date_column FROM test_data',
...             conn,
...             parse_dates={'date_column': {'format': '%d/%m/%y'}})
   int_column  date_column
0       0   2012-11-10
1       1   2010-11-12
```

### pandas.DataFrame.to_sql

`DataFrame.to_sql` writes records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [1] are supported. Tables can be newly created, appended to, or overwritten.

**Parameters**

- `name` [str] Name of SQL table.
- `con` [sqlalchemy.engine.(Engine or Connection) or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable. See here.
- `schema` [str, optional] Specify the schema (if database flavor supports this). If None, use default schema.
if_exists  [['fail', 'replace', 'append'], default 'fail'] How to behave if the table already exists.
  • fail: Raise a ValueError.
  • replace: Drop the table before inserting new values.
  • append: Insert new values to the existing table.
index  [bool, default True] Write DataFrame index as a column. Uses index_label as the column name in the table.
index_label  [str or sequence, default None] Column label for index column(s). If None is given (default) and index is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
chunksize  [int, optional] Specify the number of rows in each batch to be written at a time. By default, all rows will be written at once.
dtype  [dict or scalar, optional] Specifying the datatype for columns. If a dictionary is used, the keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode. If a scalar is provided, it will be applied to all columns.
method  [{None, 'multi', callable}, optional] Controls the SQL insertion clause used:
  • None : Uses standard SQL INSERT clause (one per row).
  • ‘multi’: Pass multiple values in a single INSERT clause.
  • callable with signature (pd_table, conn, keys, data_iter).
Details and a sample callable implementation can be found in the section insert method.
Raises
  ValueError When the table already exists and if_exists is ‘fail’ (the default).
See also:
  read_sql  Read a DataFrame from a table.

Notes
Timerzone aware datetime columns will be written as Timestamp with timezone type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

References
[1], [2]
Examples

Create an in-memory SQLite database.

```python
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```python
>>> df = pd.DataFrame({'name': ['User 1', 'User 2', 'User 3']})
>>> df
   name
0  User 1
1  User 2
2  User 3
```

```python
>>> df.to_sql('users', con=engine)

>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

An `sqlalchemy.engine.Connection` can also be passed to `con`:

```python
>>> with engine.begin() as connection:
...     df1 = pd.DataFrame({'name': ['User 4', 'User 5']})
...     df1.to_sql('users', con=connection, if_exists='append')
```

This is allowed to support operations that require that the same DBAPI connection is used for the entire operation.

```python
>>> df2 = pd.DataFrame({'name': ['User 6', 'User 7']})
>>> df2.to_sql('users', con=engine, if_exists='append')
```

```python
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'),
 (0, 'User 4'), (1, 'User 5'), (0, 'User 6'),
 (1, 'User 7')]
```

Overwrite the table with just `df2`.

```python
>>> df2.to_sql('users', con=engine, if_exists='replace',
...     index_label='id')

>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 6'), (1, 'User 7')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```python
>>> df = pd.DataFrame({'A': [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0
```

```python
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...     dtype={'A': Integer()})
```
3.1.16 Google BigQuery

```python
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

**pandas: powerful Python data analysis toolkit, Release 1.3.1**

### 3.1.16 Google BigQuery

`read_gbq(query[, project_id, index_col, ...])` Load data from Google BigQuery.

`pandas.read_gbq`

This function requires the `pandas-gbq` package. See the How to authenticate with Google BigQuery guide for authentication instructions.

**Parameters**

- **query** [str] SQL-Like Query to return data values.
- **project_id** [str, optional] Google BigQuery Account project ID. Optional when available from the environment.
- **index_col** [str, optional] Name of result column to use for index in results DataFrame.
- **col_order** [list(str), optional] List of BigQuery column names in the desired order for results DataFrame.
- **reauth** [bool, default False] Force Google BigQuery to re-authenticate the user. This is useful if multiple accounts are used.
- **auth_local_webserver** [bool, default False] Use the local webserver flow instead of the console flow when getting user credentials.

  *New in version 0.2.0 of pandas-gbq.*

- **dialect** [str, default ‘legacy’] Note: The default value is changing to ‘standard’ in a future version.

  SQL syntax dialect to use. Value can be one of:

  - ‘legacy’ Use BigQuery’s legacy SQL dialect. For more information see BigQuery Legacy SQL Reference.
  - ‘standard’ Use BigQuery’s standard SQL, which is compliant with the SQL 2011 standard. For more information see BigQuery Standard SQL Reference.

- **location** [str, optional] Location where the query job should run. See the BigQuery locations documentation for a list of available locations. The location must match that of any datasets used in the query.

  *New in version 0.5.0 of pandas-gbq.*

- **configuration** [dict, optional] Query config parameters for job processing. For example:

  ```python
  configuration = {'query': {'useQueryCache': False}}
  ```
For more information see BigQuery REST API Reference.

**credentials** [google.auth.credentials.Credentials, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine google.auth.compute_engine.Credentials or Service Account google.oauth2.service_account.Credentials directly.

*New in version 0.8.0 of pandas-gbq.*

**use_bqstorage_api** [bool, default False] Use the BigQuery Storage API to download query results quickly, but at an increased cost. To use this API, first enable it in the Cloud Console. You must also have the bigquery.readsessions.create permission on the project you are billing queries to.

This feature requires version 0.10.0 or later of the pandas-gbq package. It also requires the google-cloud-bigquery-storage and fastavro packages.

*New in version 0.25.0.*

**max_results** [int, optional] If set, limit the maximum number of rows to fetch from the query results.

*New in version 0.12.0 of pandas-gbq.*

*New in version 1.1.0.*

**progress_bar_type** [Optional, str] If set, use the tqdm library to display a progress bar while the data downloads. Install the tqdm package to use this feature.

Possible values of **progress_bar_type** include:

**None** No progress bar.

'**tqdm**' Use the tqdm.tqdm() function to print a progress bar to sys.stderr.

'**tqdm_notebook**' Use the tqdm.tqdm_notebook() function to display a progress bar as a Jupyter notebook widget.

'**tqdm_gui**' Use the tqdm.tqdm_gui() function to display a progress bar as a graphical dialog box.

Note that this feature requires version 0.12.0 or later of the pandas-gbq package. And it requires the tqdm package. Slightly different than pandas-gbq, here the default is **None**.

*New in version 1.0.0.*

**Returns**

**df:** DataFrame DataFrame representing results of query.

**See also:**

**pandas_gbq.read_gbq** This function in the pandas-gbq library.

**DataFrame.to_gbq** Write a DataFrame to Google BigQuery.
3.1.17 STATA

```
pandas.read_stata(filepath_or_buffer[, ...])
```
Read Stata file into DataFrame.

```
DataFrame.to_stata(path[, convert_dates, ...])
```
Export DataFrame object to Stata dta format.

**pandas.read_stata**

```python
def pandas.read_stata(filepath_or_buffer, convert_dates=True, convert_categoricals=True, index_col=None, convert_missing=False, preserve_dtypes=True, columns=None, order_categoricals=True, chunksize=None, iterator=False, compression='infer', storage_options=None):
    Read Stata file into DataFrame.
```

**Parameters**

- **filepath_or_buffer** [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.dta`. If you want to pass in a path object, pandas accepts any `os.PathLike`. By file-like object, we refer to objects with a `read()` method, such as a file handle (e.g. via built-in `open` function) or `StringIO`.

- **convert_dates** [bool, default True] Convert date variables to DataFrame time values.

- **convert_categoricals** [bool, default True] Read value labels and convert columns to Categorical/Factor variables.

- **index_col** [str, optional] Column to set as index.

- **convert_missing** [bool, default False] Flag indicating whether to convert missing values to their Stata representations. If False, missing values are replaced with `nan`. If True, columns containing missing values are returned with object data types and missing values are represented by `StataMissingValue` objects.

- **preserve_dtypes** [bool, default True] Preserve Stata datatypes. If False, numeric data are upcast to pandas default types for foreign data (float64 or int64).

- **columns** [list or None] Columns to retain. Columns will be returned in the given order. None returns all columns.

- **order_categoricals** [bool, default True] Flag indicating whether converted categorical data are ordered.

- **chunksize** [int, default None] Return StataReader object for iterations, returns chunks with given number of lines.

- **iterator** [bool, default False] Return StataReader object.

- **compression** [str or dict, default None] If string, specifies compression mode. If dict, value at key `method` specifies compression mode. Compression mode must be one of {'infer', 'gzip', 'bz2', 'zip', 'xz', None}. If compression mode is `infer` and `filepath_or_buffer` is path-like, then detect compression from the following extensions: `.gz`, `.bz2`, `.zip`, or `.xz` (otherwise no compression). If dict and compression mode is one of {'zip', 'gzip', 'bz2'}, or inferred as one of the above, other entries passed as additional compression options.

- **storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are
forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

Returns

DataFrame or StataReader

See also:

io stata.StataReader Low-level reader for Stata data files.

DataFrame.to_stata Export Stata data files.

Notes

Categorical variables read through an iterator may not have the same categories and dtype. This occurs when a variable stored in a DTA file is associated to an incomplete set of value labels that only label a strict subset of the values.

Examples

Read a Stata dta file:

```python
>>> df = pd.read_stata('filename.dta')
```

Read a Stata dta file in 10,000 line chunks:

```python
>>> itr = pd.read_stata('filename.dta', chunksize=10000)
>>> for chunk in itr:
...     do_something(chunk)
```

pandas.DataFrame.to_stata

DataFrame.to_stata(path, convert_dates=None, write_index=True, byteorder=None, time_stamp=None, data_label=None, variable_labels=None, version=114, convert_strl=None, compression='infer', storage_options=None)

Export DataFrame object to Stata dta format.

Writes the DataFrame to a Stata dataset file. “dta” files contain a Stata dataset.

Parameters

- **path** [str, buffer or path object] String, path object (pathlib.Path or py._path.local.LocalPath) or object implementing a binary write() function. If using a buffer then the buffer will not be automatically closed after the file data has been written.

- **convert_dates** [dict] Dictionary mapping columns containing datetime types to stata internal format to use when writing the dates. Options are ‘tc’, ‘td’, ‘tm’, ‘tw’, ‘th’, ‘tq’, ‘ty’. Column can be either an integer or a name. Datetime columns that do not have a conversion type specified will be converted to ‘tc’. Raises NotImplementedError if a datetime column has timezone information.

- **write_index** [bool] Write the index to Stata dataset.
byteorder  [str] Can be “>”, “<”, “little”, or “big”. default is sys.byteorder.

time_stamp  [datetime] A datetime to use as file creation date. Default is the current time.

data_label  [str, optional] A label for the data set. Must be 80 characters or smaller.

variable_labels  [dict] Dictionary containing columns as keys and variable labels as values. Each label must be 80 characters or smaller.

version  [[114, 117, 118, 119, None], default 114] Version to use in the output dta file. Set to None to let pandas decide between 118 or 119 formats depending on the number of columns in the frame. Version 114 can be read by Stata 10 and later. Version 117 can be read by Stata 13 or later. Version 118 is supported in Stata 14 and later. Version 119 is supported in Stata 15 and later. Version 114 limits string variables to 244 characters or fewer while versions 117 and later allow strings with lengths up to 2,000,000 characters. Versions 118 and 119 support Unicode characters, and version 119 supports more than 32,767 variables.

Version 119 should usually only be used when the number of variables exceeds the capacity of dta format 118. Exporting smaller datasets in format 119 may have unintended consequences, and, as of November 2020, Stata SE cannot read version 119 files.

Changed in version 1.0.0: Added support for formats 118 and 119.

convert_strl  [list, optional] List of column names to convert to string columns to Stata StrL format. Only available if version is 117. Storing strings in the StrL format can produce smaller dta files if strings have more than 8 characters and values are repeated.

compression  [str or dict, default ‘infer’] For on-the-fly compression of the output dta. If string, specifies compression mode. If dict, value at key ‘method’ specifies compression mode. Compression mode must be one of {'infer', ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}. If compression mode is ‘infer’ and fnam is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’ (otherwise no compression). If dict and compression mode is one of {'zip', ‘gzip’, ‘bz2’}, or inferred as one of the above, other entries passed as additional compression options.

New in version 1.1.0.

storage_options  [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

Raises

NotImplementedError

• If datetimes contain timezone information
• Column dtype is not representable in Stata

ValueError

• Columns listed in convert_dates are neither datetime64[ns] or datetime.datetime
• Column listed in convert_dates is not in DataFrame
• Categorical label contains more than 32,000 characters

See also:

read_stata  Import Stata data files.
io.stata.StataWriter  Low-level writer for Stata data files.

io.stata.StataWriter117  Low-level writer for version 117 files.

Examples

```python
>>> df = pd.DataFrame({'animal': ['falcon', 'parrot', 'falcon',
...     'parrot'],
...     'speed': [350, 18, 361, 15]})
```

```python
>>> df.to_stata('animals.dta')
```

### pandas.melt

`pandas.melt(frame[, id_vars=None, value_vars=None, var_name=None, value_name='value', col_level=None, ignore_index=True])`

Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (`id_vars`), while all other columns, considered measured variables (`value_vars`), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’.

**Parameters**

- **id_vars** [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.
- **value_vars** [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as `id_vars`.
- **var_name** [scalar] Name to use for the ‘variable’ column. If None it uses `frame.columns.name` or ‘variable’.
- **value_name** [scalar, default ‘value’] Name to use for the ‘value’ column.
- **col_level** [int or str, optional] If columns are a MultiIndex then use this level to melt.
- **ignore_index** [bool, default True] If True, original index is ignored. If False, the original index is retained. Index labels will be repeated as necessary.

**Returns**

New in version 1.1.0.
DataFrame | Unpivoted DataFrame.

See also:

DataFrame.melt | Identical method.
pivot_table | Create a spreadsheet-style pivot table as a DataFrame.
DataFrame.pivot | Return reshaped DataFrame organized by given index / column values.
DataFrame.explode | Explode a DataFrame from list-like columns to long format.

Examples

```python
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
...                     'B': {0: 1, 1: 3, 2: 5},
...                     'C': {0: 2, 1: 4, 2: 6}})
>>> df
   A  B  C
0  a  1  2
1  b  3  4
2  c  5  6

>>> pd.melt(df, id_vars=['A'], value_vars=['B'])
   A  variable  value
0  a          B  1
1  b          B  3
2  c          B  5

>>> pd.melt(df, id_vars=['A'], value_vars=['B', 'C'])
   A  variable  value
0  a          B  1
1  b          B  3
2  c          B  5
3  a          C  2
4  b          C  4
5  c          C  6

The names of ‘variable’ and ‘value’ columns can be customized:

```python
>>> pd.melt(df, id_vars=['A'], value_vars=['B', 'C'],
...          var_name='myVarname', value_name='myValname')
   A  myVarname  myValname
0  a          B  1
1  b          B  3
2  c          B  5

Original index values can be kept around:

```python
>>> pd.melt(df, id_vars=['A'], value_vars=['B', 'C'], ignore_index=False)
   A  variable  value
0  a          B  1
1  b          B  3
2  c          B  5
0  a          C  2
1  b          C  4
2  c          C  6
```
If you have multi-index columns:

```python
>>> df.columns = [list('ABC'), list('DEF')]
>>> df
   A  B  C  D  E  F
0  a  1  2
1  b  3  4
2  c  5  6

>>> pd.melt(df, col_level=0, id_vars=['A'], value_vars=['B'])
   A  variable value
0  a     B    1
1  b     B    3
2  c     B    5

>>> pd.melt(df, id_vars=[('A', 'D')], value_vars=[('B', 'E')])
   (A, D) variable_0 variable_1 value
0  a         B     E    1
1  b         B     E    3
2  c         B     E    5
```

### pandas.pivot

**pandas.pivot** *(data, index=None, columns=None, values=None)*

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified *index* / *columns* to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the *User Guide* for more on reshaping.

**Parameters**

- **data** [DataFrame]

- **index** [str or object or a list of str, optional] Column to use to make new frame’s index. If None, uses existing index.

  Changed in version 1.1.0: Also accept list of index names.

- **columns** [str or object or a list of str] Column to use to make new frame’s columns.

  Changed in version 1.1.0: Also accept list of columns names.

- **values** [str, object or a list of the previous, optional] Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.

**Returns**

- **DataFrame** Returns reshaped DataFrame.

**Raises**

- **ValueError**: When there are any *index*, *columns* combinations with multiple values. *DataFrame.pivot_table* when you need to aggregate.

**See also:**

3.2. General functions
**DataFrame.pivot_table** Generalization of pivot that can handle duplicate values for one index/column pair.

**DataFrame.unstack** Pivot based on the index values instead of a column.

**wide_to_long** Wide panel to long format. Less flexible but more user-friendly than melt.

**Notes**

For finer-tuned control, see hierarchical indexing documentation along with the related stack/unstack methods.

**Examples**

```python
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two', 'two'],
...                    'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
...                    'baz': [1, 2, 3, 4, 5, 6],
...                    'zoo': ['x', 'y', 'z', 'q', 'w', 't']})
>>> df
    foo  bar  baz  zoo
 0   one   A   1    x
 1   one   B   2    y
 2   one   C   3    z
 3   two   A   4    q
 4   two   B   5    w
 5   two   C   6    t

>>> df.pivot(index='foo', columns='bar', values='baz')
bar   A  B  C
foo
one  1  2  3
two  4  5  6

>>> df.pivot(index='foo', columns='bar')['baz']
bar   A  B  C
foo
one  1  2  3
two  4  5  6

>>> df.pivot(index='foo', columns='bar', values=['baz', 'zoo'])
baz  zoo
bar   A  B  C   A  B  C
foo
one  1  2  3  x  y  z
two  4  5  6  q  w  t

You could also assign a list of column names or a list of index names.

```
lev1  lev2  lev3  lev4  values
0   1   1   1   1   0
1   1   1   2   2   1
2   1   2   1   3   2
3   2   1   2   4   3
4   2   1   1   5   4
5   2   2   2   6   5

```python
>>> df.pivot(index="lev1", columns=["lev2", "lev3"], values="values")
lev2 1 2
lev3 1 2 1 2
lev1
1     0.0 1.0 2.0 NaN
2     4.0 3.0 NaN 5.0
```

```python
>>> df.pivot(index=["lev1", "lev2"], columns=["lev3"], values="values")
lev3 1 2
lev1 lev2
1 1 0.0 1.0
2 2.0 NaN
2 1 4.0 3.0
2 NaN 5.0
```

A ValueError is raised if there are any duplicates.

```python
>>> df = pd.DataFrame({"foo": ["one", "one", "two", "two"], ...
...                       "bar": ["A", "A", "B", "C"], ...
...                       "baz": [1, 2, 3, 4]})
```

```python
>>> df.pivot(index='foo', columns='bar', values='baz')
```

```
Traceback (most recent call last):
...
ValueError: Index contains duplicate entries, cannot reshape
```

**pandas.pivot_table**

pandas.pivot_table(data, values=None, index=None, columns=None, aggfunc='mean', fill_value=None, margins=False, dropna=True, margins_name='All', observed=False, sort=True)

Create a spreadsheet-style pivot table as a DataFrame.

The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

Parameters

data  [DataFrame]
values [column to aggregate, optional]

index [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.

columns [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.

aggfunc [function, list of functions, dict, default numpy.mean] If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions.

fill_value [scalar, default None] Value to replace missing values with (in the resulting pivot table, after aggregation).

margins [bool, default False] Add all row / columns (e.g. for subtotal / grand totals).

dropna [bool, default True] Do not include columns whose entries are all NaN.

margins_name [str, default ‘All’] Name of the row / column that will contain the totals when margins is True.

observed [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

Changed in version 0.25.0.

sort [bool, default True] Specifies if the result should be sorted.

New in version 1.3.0.

Returns

DataFrame An Excel style pivot table.

See also:

DataFrame.pivot Pivot without aggregation that can handle non-numeric data.

DataFrame.melt Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

wide_to_long Wide panel to long format. Less flexible but more user-friendly than melt.

Examples

```python
>>> df = pd.DataFrame({"A": ["foo", "foo", "foo", "foo", "foo"],
...     "bar", "bar", "bar", "bar"],
...     "B": ["one", "one", "one", "two", "two"],
...     "one", "one", "two", "two"],
...     "C": ["small", "large", "large", "small",
...     "small", "large", "small", "small",
...     "large"],
...     "D": [1, 2, 2, 3, 3, 4, 5, 6, 7],
...     "E": [2, 4, 5, 5, 6, 6, 8, 9, 9]})
>>> df
```

(continues on next page)
This first example aggregates values by taking the sum.

```python
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
                        columns=['C'], aggfunc=np.sum)
```

```
A  B  C  D  E
0 foo one small 1 2
1 foo one large 2 4
2 foo one large 2 5
3 foo two small 3 5
4 foo two small 3 6
5 bar one large 4 6
6 bar one small 5 8
7 bar two small 6 9
8 bar two large 7 9
```

We can also fill missing values using the `fill_value` parameter.

```python
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
                        columns=['C'], aggfunc=np.sum, fill_value=0)
```

```
A  B  C  D  E
0 foo one small 1 2
1 foo one large 2 4
2 foo one large 2 5
3 foo two small 3 5
4 foo two small 3 6
5 bar one large 4 6
6 bar one small 5 8
7 bar two small 6 9
8 bar two large 7 9
```

The next example aggregates by taking the mean across multiple columns.

```python
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
                        aggfunc={'D': np.mean, 'E': np.mean})
```

```
A  C  D  E
0 bar large 5.500000 7.500000
   small 5.500000 8.500000
1 foo large 2.000000 4.500000
   small 2.333333 4.333333
```

We can also calculate multiple types of aggregations for any given value column.

```python
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
                        aggfunc={'D': np.mean, 'E': [min, max, np.mean]})
```

```
A  C  D  E
0 mean 5.0 2.5
   max 7.5 4.5
   min 2.0 2.0
1 mean 5.0 2.0
   max 8.5 4.5
   min 2.333333 2.333333
```
Computes a simple cross tabulation of two (or more) factors. By default computes a frequency table of the factors unless an array of values and an aggregation function are passed.

**Parameters**

- **index** [array-like, Series, or list of arrays/Series] Values to group by in the rows.
- **columns** [array-like, Series, or list of arrays/Series] Values to group by in the columns.
- **values** [array-like, optional] Array of values to aggregate according to the factors. Requires **aggfunc** to be specified.
- **rownames** [sequence, default None] If passed, must match number of row arrays passed.
- **colnames** [sequence, default None] If passed, must match number of column arrays passed.
- **aggfunc** [function, optional] If specified, requires **values** to be specified as well.
- **margins** [bool, default False] Add row/column margins (subtotals).
- **margins_name** [str, default ‘All’] Name of the row/column that will contain the totals when margins is True.
- **dropna** [bool, default True] Do not include columns whose entries are all NaN.
- **normalize** [bool, {‘all’, ‘index’, ‘columns’}, or {0,1}, default False] Normalize by dividing all values by the sum of values.
  - If passed ‘all’ or True, will normalize over all values.
  - If passed ‘index’ will normalize over each row.
  - If passed ‘columns’ will normalize over each column.
  - If margins is True, will also normalize margin values.

**Returns**

**DataFrame** Cross tabulation of the data.

**See also:**

- **DataFrame.pivot** Reshape data based on column values.
- **pivot_table** Create a pivot table as a DataFrame.
Notes

Any Series passed will have their name attributes used unless row or column names for the cross-tabulation are specified.

Any input passed containing Categorical data will have all of its categories included in the cross-tabulation, even if the actual data does not contain any instances of a particular category.

In the event that there aren’t overlapping indexes an empty DataFrame will be returned.

Examples

```python
>>> a = np.array(['foo', 'foo', 'foo', 'foo', 'bar', 'bar',
    ... 'bar', 'bar', 'foo', 'foo', 'foo'], dtype=object)
>>> b = np.array(['one', 'one', 'one', 'two', 'one', 'one',
    ... 'one', 'two', 'two', 'two', 'one'], dtype=object)
>>> c = np.array(['dull', 'dull', 'shiny', 'dull', 'dull', 'shiny',
    ... 'shiny', 'dull', 'shiny', 'shiny', 'shiny'],
    ... dtype=object)
>>> pd.crosstab(a, [b, c], rownames=['a'], colnames=['b', 'c'])
     b     c
    dull   shiny
da  1  2  1  0
   bar  2  2  1  2
```

Here ‘c’ and ‘f’ are not represented in the data and will not be shown in the output because dropna is True by default. Set dropna=False to preserve categories with no data.

```python
>>> foo = pd.Categorical(['a', 'b'], categories=['a', 'b', 'c'])
>>> bar = pd.Categorical(['d', 'e'], categories=['d', 'e', 'f'])
>>> pd.crosstab(foo, bar)
    col_0  d  e
   row_0
   a    1  0
   b    0  1
>>> pd.crosstab(foo, bar, dropna=False)
    col_0  d  e  f
   row_0
   a    1  0  0
   b    0  1  0
   c    0  0  0
```

**pandas.cut**

The `pandas.cut` function is used to bin values into discrete intervals. It can be used when you need to segment and sort data values into bins. This function is also useful for going from a continuous variable to a categorical variable. For example, `cut` could convert ages to groups of age ranges. Supports binning into an equal number of bins, or a pre-specified array of bins.

**Parameters**

- `x` [array-like] The input array to be binned. Must be 1-dimensional.
**bins** [int, sequence of scalars, or IntervalIndex] The criteria to bin by.

- int: Defines the number of equal-width bins in the range of \( x \). The range of \( x \) is extended by .1% on each side to include the minimum and maximum values of \( x \).
- sequence of scalars: Defines the bin edges allowing for non-uniform width. No extension of the range of \( x \) is done.
- IntervalIndex: Defines the exact bins to be used. Note that IntervalIndex for bins must be non-overlapping.

**right** [bool, default True] Indicates whether bins includes the rightmost edge or not. If right == True (the default), then the bins [1, 2, 3, 4] indicate (1,2], (2,3], (3,4]. This argument is ignored when bins is an IntervalIndex.

**labels** [array or False, default None] Specifies the labels for the returned bins. Must be the same length as the resulting bins. If False, returns only integer indicators of the bins. This affects the type of the output container (see below). This argument is ignored when bins is an IntervalIndex. If True, raises an error. When ordered=False, labels must be provided.

**retbins** [bool, default False] Whether to return the bins or not. Useful when bins is provided as a scalar.

**precision** [int, default 3] The precision at which to store and display the bins labels.

**include_lowest** [bool, default False] Whether the first interval should be left-inclusive or not.

**duplicates** [(default ‘raise’, ‘drop’), optional] If bin edges are not unique, raise ValueError or drop non-uniques.

**ordered** [bool, default True] Whether the labels are ordered or not. Applies to returned types Categorical and Series (with Categorical dtype). If True, the resulting categorical will be ordered. If False, the resulting categorical will be unordered (labels must be provided).

New in version 1.1.0.

**Returns**

**out** [Categorical, Series, or ndarray] An array-like object representing the respective bin for each value of \( x \). The type depends on the value of labels.

- True (default): returns a Series for Series \( x \) or a Categorical for all other inputs. The values stored within are Interval dtype.
- sequence of scalars: returns a Series for Series \( x \) or a Categorical for all other inputs. The values stored within are whatever the type in the sequence is.
- False: returns an ndarray of integers.

**bins** [numpy.ndarray or IntervalIndex.] The computed or specified bins. Only returned when retbins=True. For scalar or sequence bins, this is an ndarray with the computed bins. If set duplicates=drop, bins will drop non-unique bin. For an IntervalIndex bins, this is equal to bins.

**See also:**

- **qcut** Discretize variable into equal-sized buckets based on rank or based on sample quantiles.
- **Categorical** Array type for storing data that come from a fixed set of values.
- **Series** One-dimensional array with axis labels (including time series).
- **IntervalIndex** Immutable Index implementing an ordered, sliceable set.
Notes

Any NA values will be NA in the result. Out of bounds values will be NA in the resulting Series or Categorical object.

Examples

Discretize into three equal-sized bins.

```python
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3)
...[(0.994, 3.0], (5.0, 7.0], (3.0, 5.0], (3.0, 5.0], (5.0, 7.0], ...
Categories (3, interval[float64, right]): [(0.994, 3.0] < (3.0, 5.0] ...]
```

```python
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3, retbins=True)
...[(0.994, 3.0], (5.0, 7.0], (3.0, 5.0], (3.0, 5.0], (5.0, 7.0], ...
Categories (3, interval[float64, right]): [(0.994, 3.0] < (3.0, 5.0] ...
array([0.994, 3. , 5. , 7. ]))
```

DisCOVERs the same bins, but assign them specific labels. Notice that the returned Categorical’s categories are labels and is ordered.

```python
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3, labels=['bad', 'medium', 'good'])
['bad', 'good', 'medium', 'medium', 'good', 'bad']
Categories (3, object): ['bad' < 'medium' < 'good']
```

`ordered=False` will result in unordered categories when labels are passed. This parameter can be used to allow non-unique labels:

```python
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3, labels=['B', 'A', 'B', 'A', 'B', 'B'], ordered=False)
['B', 'B', 'A', 'A', 'B', 'B']
Categories (2, object): ['A' 'B']
```

`labels=False` implies you just want the bins back.

```python
>>> pd.cut([0, 1, 1, 2], bins=4, labels=False)
array([0, 1, 1, 3])
```

Passing a Series as an input returns a Series with categorical dtype:

```python
>>> s = pd.Series(np.array([2, 4, 6, 8, 10]),
... index=['a', 'b', 'c', 'd', 'e'])
>>> pd.cut(s, 3)
... a  (1.992, 4.667]
b  (1.992, 4.667]  
c  (4.667, 7.333]
d  (7.333, 10.0]  
e  (7.333, 10.0]
dtype: category
Categories (3, interval[float64, right]): [(1.992, 4.667] < (4.667, ...
```

Passing a Series as an input returns a Series with mapping value. It is used to map numerically to intervals based on bins.
```python
>>> s = pd.Series(np.array([2, 4, 6, 8, 10]),
                 index=['a', 'b', 'c', 'd', 'e'])
>>> pd.cut(s, [0, 2, 4, 6, 8, 10], labels=False, retbins=True, right=False)
...  
  (a 1.0
d 4.0
e NaN
dtype: float64,
array([ 0,  2,  4,  6, 10]))

Use drop optional when bins is not unique

```python
>>> pd.cut(s, [0, 2, 4, 6, 10, 10], labels=False, retbins=True, 
          right=False, duplicates='drop')
...
(a 1.0
b 2.0
c 3.0
d 3.0
e NaN
dtype: float64,
array([ 0,  2,  4,  6, 10]))
```

Passing an IntervalIndex for bins results in those categories exactly. Notice that values not covered by the IntervalIndex are set to NaN. 0 is to the left of the first bin (which is closed on the right), and 1.5 falls between two bins.

```python
>>> bins = pd.IntervalIndex.from_tuples([(0, 1), (2, 3), (4, 5)])
...  
>>> pd.cut([0, 0.5, 1.5, 2.5, 4.5], bins)
[NaN, (0.0, 1.0], NaN, (2.0, 3.0], (4.0, 5.0]

Categories (3, interval[int64, right]): 
[0, 1] < (2, 3) < (4, 5]
```

**pandas.qcut**

`pandas.qcut(x, q, labels=None, retbins=False, precision=3, duplicates='raise')`

Quantile-based discretization function.

Discretize variable into equal-sized buckets based on rank or based on sample quantiles. For example 1000 values for 10 quantiles would produce a Categorical object indicating quantile membership for each data point.

**Parameters**

- `x` [1d ndarray or Series] 
- `q` [int or list-like of float] Number of quantiles. 10 for deciles, 4 for quartiles, etc. Alternately array of quantiles, e.g. [0, .25, .5, .75, 1.] for quartiles.
- `labels` [array or False, default None] Used as labels for the resulting bins. Must be of the same length as the resulting bins. If False, return only integer indicators of the bins. If True, raises an error.
- `retbins` [bool, optional] Whether to return the (bins, labels) or not. Can be useful if bins is given as a scalar.
- `precision` [int, optional] The precision at which to store and display the bins labels.
**duplicates**  [[default ‘raise’, ‘drop’], optional] If bin edges are not unique, raise ValueError or drop non-uniques.

**Returns**

**out**  [Categorical or Series or array of integers if labels is False] The return type (Categorical or Series) depends on the input: a Series of type category if input is a Series else Categorical. Bins are represented as categories when categorical data is returned.

**bins**  [ndarray of floats] Returned only if retbins is True.

**Notes**

Out of bounds values will be NA in the resulting Categorical object

**Examples**

```python
>>> pd.qcut(range(5), 4)
...
[(-0.001, 1.0], (-0.001, 1.0], (1.0, 2.0], (2.0, 3.0], (3.0, 4.0]]
Categories (4, interval[float64, right]): [(-0.001, 1.0] < (1.0, 2.0] ...
```

```python
>>> pd.qcut(range(5), 3, labels=["good", "medium", "bad")
...
[good, good, medium, bad, bad]
Categories (3, object): [good < medium < bad]
```

```python
>>> pd.qcut(range(5), 4, labels=False)
array([0, 0, 1, 2, 3])
```

---

**pandas.merge**

**pandas.merge** *(left, right, how='inner', on=None, left_on=None, right_on=None, left_index=False, right_index=False, sort=False, suffixes=('x', '_y'), copy=True, indicator=False, validate=None)*

Merge DataFrame or named Series objects with a database-style join.

A named Series object is treated as a DataFrame with a single named column.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes will be ignored. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on. When performing a cross merge, no column specifications to merge on are allowed.

**Parameters**

**left**  [DataFrame]

**right**  [DataFrame or named Series] Object to merge with.

**how**  [['left', 'right', 'outer', 'inner', 'cross'], default ‘inner’] Type of merge to be performed.

- left: use only keys from left frame, similar to a SQL left outer join; preserve key order.
- right: use only keys from right frame, similar to a SQL right outer join; preserve key order.
- outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
• inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.
• cross: creates the cartesian product from both frames, preserves the order of the left keys.

New in version 1.2.0.

**on** [label or list] Column or index level names to join on. These must be found in both DataFrames. If **on** is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

**left_on** [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

**right_on** [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

**left_index** [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

**right_index** [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as **left_index**.

**sort** [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword).

**suffixes** [list-like, default is (“_x”, “_y”) ] A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in **left** and **right** respectively. Pass a value of **None** instead of a string to indicate that the column name from **left** or **right** should be left as-is, with no suffix. At least one of the values must not be **None**.

**copy** [bool, default True] If False, avoid copy if possible.

**indicator** [bool or str, default False] If True, adds a column to the output DataFrame called “_merge” with information on the source of each row. The column can be given a different name by providing a string argument. The column will have a Categorical type with the value of “left_only” for observations whose merge key only appears in the left DataFrame, “right_only” for observations whose merge key only appears in the right DataFrame, and “both” if the observation’s merge key is found in both DataFrames.

**validate** [str, optional] If specified, checks if merge is of specified type.

- “one_to_one” or “1:1”: check if merge keys are unique in both left and right datasets.
- “one_to_many” or “1:m”: check if merge keys are unique in left dataset.
- “many_to_one” or “m:1”: check if merge keys are unique in right dataset.
- “many_to_many” or “m:m”: allowed, but does not result in checks.

**Returns**

**DataFrame** A DataFrame of the two merged objects.

**See also:**

- **merge_ordered** Merge with optional filling/interpolation.
- **merge_asof** Merge on nearest keys.
- **DataFrame.join** Similar method using indices.
Notes

Support for specifying index levels as the on, left_on, and right_on parameters was added in version 0.23.0
Support for merging named Series objects was added in version 0.24.0

Examples

```python
def1 = pd.DataFrame({'lkey': ['foo', 'bar', 'baz', 'foo'], 
                    'value': [1, 2, 3, 5]})

def2 = pd.DataFrame({'rkey': ['foo', 'bar', 'baz', 'foo'], 
                    'value': [5, 6, 7, 8]})

def1.merge(df2, left_on='lkey', right_on='rkey')
```

Merge df1 and df2 on the lkey and rkey columns. The value columns have the default suffixes, _x and _y, appended.

```python
def1.merge(df2, left_on='lkey', right_on='rkey')
                    lkey value_x rkey value_y
                0  foo    1  foo    5
                1  foo    1  foo    8
                2  foo    5  foo    5
                3  foo    5  foo    8
                4  bar    2  bar    6
                5  baz    3  baz    7
```

Merge DataFrames df1 and df2 with specified left and right suffixes appended to any overlapping columns.

```python
def1.merge(df2, left_on='lkey', right_on='rkey', 
           suffixes=('_left', '_right'))
                    lkey value_left rkey value_right
                0  foo    1  foo    5
                1  foo    1  foo    8
                2  foo    5  foo    5
                3  foo    5  foo    8
                4  bar    2  bar    6
                5  baz    3  baz    7
```

Merge DataFrames df1 and df2, but raise an exception if the DataFrames have any overlapping columns.

```python
def1.merge(df2, left_on='lkey', right_on='rkey', suffixes=(False, False))
Traceback (most recent call last):
  ...
ValueError: columns overlap but no suffix specified:
    Index(['value'], dtype='object')
```
```python
>>> df1 = pd.DataFrame({'a': ['foo', 'bar'], 'b': [1, 2]})

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo</td>
<td>1</td>
</tr>
<tr>
<td>bar</td>
<td>2</td>
</tr>
</tbody>
</table>

>>> df2 = pd.DataFrame({'a': ['foo', 'baz'], 'c': [3, 4]})

<table>
<thead>
<tr>
<th>a</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo</td>
<td>3</td>
</tr>
<tr>
<td>baz</td>
<td>4</td>
</tr>
</tbody>
</table>

>>> df1.merge(df2, how='inner', on='a')

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>

>>> df1.merge(df2, how='left', on='a')

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo</td>
<td>1</td>
<td>3.0</td>
</tr>
<tr>
<td>bar</td>
<td>2</td>
<td>NaN</td>
</tr>
</tbody>
</table>

>>> df1 = pd.DataFrame({'left': ['foo', 'bar']})

<table>

</tbody>
</table>
```

### pandas.merge_ordered

**pandas.merge_ordered**(left, right, on=None, left_on=None, right_on=None, left_by=None, right_by=None, fill_method=None, suffixes=('_x', '_y'), how='outer')

Perform merge with optional filling/interpolation.

Designed for ordered data like time series data. Optionally perform group-wise merge (see examples).

**Parameters**

- **left** [DataFrame]
- **right** [DataFrame]
- **on** [label or list] Field names to join on. Must be found in both DataFrames.
- **left_on** [label or list, or array-like] Field names to join on in left DataFrame. Can be a vector or list of vectors of the length of the DataFrame to use a particular vector as the join key instead of columns.
right_on [label or list, or array-like] Field names to join on in right DataFrame or vector/list of vectors per left_on docs.

left_by [column name or list of column names] Group left DataFrame by group columns and merge piece by piece with right DataFrame.

right_by [column name or list of column names] Group right DataFrame by group columns and merge piece by piece with left DataFrame.

fill_method [{‘ffill’, None}, default None] Interpolation method for data.

suffixes [list-like, default is ("_x", "_y") A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in left and right respectively. Pass a value of None instead of a string to indicate that the column name from left or right should be left as-is, with no suffix. At least one of the values must not be None.

Changed in version 0.25.0.

how [{‘left’, ‘right’, ‘outer’, ‘inner’}, default ‘outer’]
  • left: use only keys from left frame (SQL: left outer join)
  • right: use only keys from right frame (SQL: right outer join)
  • outer: use union of keys from both frames (SQL: full outer join)
  • inner: use intersection of keys from both frames (SQL: inner join).

Returns

DataFrame The merged DataFrame output type will be same as ‘left’, if it is a subclass of DataFrame.

See also:

merge Merge with a database-style join.
merge_asof Merge on nearest keys.

Examples

```python
>>> df1 = pd.DataFrame(
...     {  
...         "key": ["a", "c", "e", "a", "c", "e"],  
...         "lvalue": [1, 2, 3, 1, 2, 3],  
...         "group": ["a", "a", "a", "b", "b", "b"]  
...     }
... )
>>> df1  
key  lvalue  group
0   a      1      a
1   c      2      a
2   e      3      a
3   a      1      b
4   c      2      b
5   e      3      b
```

```python
>>> df2 = pd.DataFrame({"key": ["b", "c", "d"], "rvalue": [1, 2, 3]})
>>> df2  
key  rvalue
0   b      1
1   c      2
2   d      3
```

(continues on next page)
merge_ordered(df1, df2, fill_method="ffill", left_by="group")

<table>
<thead>
<tr>
<th>key</th>
<th>lvalue</th>
<th>group</th>
<th>rvalue</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>b</td>
<td>1</td>
<td>NaN</td>
</tr>

pandas.merge_asof

pandas.merge_asof(left, right, on=None, left_on=None, right_on=None, left_index=False, right_index=False, by=None, left_by=None, right_by=None, suffixes=('_x', '_y'), tolerance=None, allow_exact_matches=True, direction='backward')

Perform an asof merge.

This is similar to a left-join except that we match on nearest key rather than equal keys. Both DataFrames must be sorted by the key.

For each row in the left DataFrame:

- A “backward” search selects the last row in the right DataFrame whose ‘on’ key is less than or equal to the left’s key.
- A “forward” search selects the first row in the right DataFrame whose ‘on’ key is greater than or equal to the left’s key.
- A “nearest” search selects the row in the right DataFrame whose ‘on’ key is closest in absolute distance to the left’s key.

The default is “backward” and is compatible in versions below 0.20.0. The direction parameter was added in version 0.20.0 and introduces “forward” and “nearest”.

Optionally match on equivalent keys with ‘by’ before searching with ‘on’.

Parameters

left [DataFrame or named Series]
right [DataFrame or named Series]
on [label] Field name to join on. Must be found in both DataFrames. The data MUST be ordered. Furthermore this must be a numeric column, such as datetimelike, integer, or float. On or left_on/right_on must be given.
left_on [label] Field name to join on in left DataFrame.
right_on [label] Field name to join on in right DataFrame.
left_index [bool] Use the index of the left DataFrame as the join key.
right_index [bool] Use the index of the right DataFrame as the join key.
by  [column name or list of column names] Match on these columns before performing merge operation.

left_by  [column name] Field names to match on in the left DataFrame.

right_by  [column name] Field names to match on in the right DataFrame.

suffixes  [2-length sequence (tuple, list, …)] Suffix to apply to overlapping column names in the left and right side, respectively.

tolerance  [int or Timedelta, optional, default None] Select asof tolerance within this range; must be compatible with the merge index.

allow_exact_matches  [bool, default True]
  • If True, allow matching with the same ‘on’ value (i.e. less-than-or-equal-to / greater-than-or-equal-to)
  • If False, don’t match the same ‘on’ value (i.e., strictly less-than / strictly greater-than).

direction  ['backward' (default), ‘forward’, or ‘nearest’] Whether to search for prior, subsequent, or closest matches.

Returns
  merged  [DataFrame]

See also:

merge  Merge with a database-style join.

merge_ordered  Merge with optional filling/interpolation.

Examples

```python
>>> left = pd.DataFrame({'a': [1, 5, 10], 'left_val': ['a', 'b', 'c']})
>>> left
   a   left_val
0  1       a
1  5       b
2 10      c

>>> right = pd.DataFrame({'a': [1, 2, 3, 6, 7], 'right_val': [1, 2, 3, 6, 7]})
>>> right
   a   right_val
0  1         1
1  2         2
2  3         3
3  6         6
4  7         7

>>> pd.merge_asof(left, right, on='a')
   a   left_val   right_val
0  1       a       1
1  5       b       3
2 10      c       7
```
>>> pd.merge_asof(left, right, on="a", allow_exact_matches=False)
   a   left_val  right_val
0  1        a       NaN
1  5        b      3.0
2 10       c      7.0

>>> pd.merge_asof(left, right, on="a", direction="forward")
   a   left_val  right_val
0  1        a       1.0
1  5        b      6.0
2 10       c       NaN

>>> pd.merge_asof(left, right, on="a", direction="nearest")
   a   left_val  right_val
0  1        a       1
1  5        b       6
2 10       c       7

We can use indexed DataFrames as well.

>>> left = pd.DataFrame({"left_val": ["a", "b", "c"], index=[1, 5, 10]})
>>> left
   left_val
1    a
5    b
10   c

>>> right = pd.DataFrame({"right_val": [1, 2, 3, 6, 7], index=[1, 2, 3, 6, 7]})
>>> right
   right_val
1      1
2      2
3      3
6      6
7      7

>>> pd.merge_asof(left, right, left_index=True, right_index=True)
   left_val  right_val
1        a        1
5        b        3
10       c        7

Here is a real-world times-series example

>>> quotes = pd.DataFrame({
...   "time": [
...     pd.Timestamp("2016-05-25 13:30:00.023"),
...     pd.Timestamp("2016-05-25 13:30:00.023"),
...     pd.Timestamp("2016-05-25 13:30:00.030"),
...     pd.Timestamp("2016-05-25 13:30:00.041"),
...     pd.Timestamp("2016-05-25 13:30:00.048"),
...     pd.Timestamp("2016-05-25 13:30:00.049"),
...     pd.Timestamp("2016-05-25 13:30:00.072"),
...     pd.Timestamp("2016-05-25 13:30:00.075")
...   ],
...   "value": [100, 105, 110, 115, 120, 125, 130, 135]
... })
(continues on next page)
...     "ticker": [  
...         "GOOG",  
...         "MSFT",  
...         "MSFT",  
...         "MSFT",  
...         "GOOG",  
...         "AAPL",  
...         "GOOG",  
...         "MSFT"  
...     ],  
...     "bid": [720.50, 51.95, 51.97, 51.99, 720.50, 97.99, 720.50, 52.01],  
...     "ask": [720.93, 51.96, 51.98, 52.00, 720.93, 98.01, 720.88, 52.03]  
... ]
...
}

</table>
```

By default we are taking the asof of the quotes

```python
>>> pd.merge_asof(trades, quotes, on="time", by="ticker")

<table>
<thead>
<tr>
<th>time</th>
<th>ticker</th>
<th>price</th>
<th>quantity</th>
<th>bid</th>
<th>ask</th>
</tr>
</thead>
<tbody>
<tr>
<td>2016-05-25 13:30:00.023</td>
<td>MSFT</td>
<td>51.95</td>
<td>75</td>
<td>51.95</td>
<td>51.96</td>
</tr>
<tr>
<td>2016-05-25 13:30:00.030</td>
<td>MSFT</td>
<td>51.95</td>
<td>155</td>
<td>51.97</td>
<td>51.98</td>
</tr>
<tr>
<td>2016-05-25 13:30:00.038</td>
<td>MSFT</td>
<td>51.97</td>
<td>100</td>
<td>720.50</td>
<td>720.93</td>
</tr>
<tr>
<td>2016-05-25 13:30:00.041</td>
<td>MSFT</td>
<td>51.99</td>
<td>100</td>
<td>720.50</td>
<td>720.93</td>
</tr>
<tr>
<td>2016-05-25 13:30:00.048</td>
<td>GOOG</td>
<td>720.77</td>
<td>100</td>
<td>720.50</td>
<td>720.93</td>
</tr>
<tr>
<td>2016-05-25 13:30:00.049</td>
<td>AAPL</td>
<td>98.00</td>
<td>100</td>
<td>NaN</td>
<td>NaN</td>
</tr>
</tbody>
</table>
```
We only asof within 2ms between the quote time and the trade time

```python
>>> pd.merge_asof(
...     trades, quotes, on="time", by="ticker", tolerance=pd.Timedelta("2ms")
... )
```

<table>
<thead>
<tr>
<th>time</th>
<th>ticker</th>
<th>price</th>
<th>quantity</th>
<th>bid</th>
<th>ask</th>
</tr>
</thead>
<tbody>
<tr>
<td>2016-05-25 13:30:00.023</td>
<td>MSFT</td>
<td>51.95</td>
<td>75</td>
<td>51.95</td>
<td>51.96</td>

<td>100</td>
<td>NaN</td>
<td>NaN</td>
</tr>
</tbody>
</table>

We only asof within 10ms between the quote time and the trade time and we exclude exact matches on time. However prior data will propagate forward

```python
>>> pd.merge_asof(
...     trades, quotes, on="time", by="ticker", tolerance=pd.Timedelta("10ms"),
...     allow_exact_matches=False
... )
```

<table>
<thead>
<tr>
<th>time</th>
<th>ticker</th>
<th>price</th>
<th>quantity</th>
<th>bid</th>
<th>ask</th>
</tr>
</thead>
<tbody>
<tr>
<td>2016-05-25 13:30:00.023</td>
<td>MSFT</td>
<td>51.95</td>
<td>75</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>

</tr>
</tbody>
</table>

**pandas.concat**

*pandas.concat (objs, axis=0, join='outer', ignore_index=False, keys=None, levels=None, names=None, verify_integrity=False, sort=False, copy=True)*

Concatenate pandas objects along a particular axis with optional set logic along the other axes.

Can also add a layer of hierarchical indexing on the concatenation axis, which may be useful if the labels are the same (or overlapping) on the passed axis number.

**Parameters**

- **objs** [a sequence or mapping of Series or DataFrame objects] If a mapping is passed, the sorted keys will be used as the keys argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a ValueError will be raised.

- **axis** [{0/’index’, 1/’columns’}, default 0] The axis to concatenate along.

- **join** [{‘inner’, ‘outer’}, default ‘outer’] How to handle indexes on other axis (or axes).

- **ignore_index** [bool, default False] If True, do not use the index values along the concatenation axis. The resulting axis will be labeled 0, ..., n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.

- **keys** [sequence, default None] If multiple levels passed, should contain tuples. Construct hierarchical index using the passed keys as the outermost level.
levels [list of sequences, default None] Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys.

names [list, default None] Names for the levels in the resulting hierarchical index.

verify_integrity [bool, default False] Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.

sort [bool, default False] Sort non-concatenation axis if it is not already aligned when join is 'outer'. This has no effect when join='inner', which already preserves the order of the non-concatenation axis.

Changed in version 1.0.0: Changed to not sort by default.

copy [bool, default True] If False, do not copy data unnecessarily.

Returns

object, type of objs When concatenating all Series along the index (axis=0), a Series is returned. When objs contains at least one DataFrame, a DataFrame is returned. When concatenating along the columns (axis=1), a DataFrame is returned.

See also:

Series.append Concatenate Series.
DataFrame.append Concatenate DataFrames.
DataFrame.join Join DataFrames using indexes.
DataFrame.merge Merge DataFrames by indexes or columns.

Notes

The keys, levels, and names arguments are all optional.
A walkthrough of how this method fits in with other tools for combining pandas objects can be found here.

Examples

Combine two Series.

```python
>>> s1 = pd.Series(['a', 'b'])
>>> s2 = pd.Series(['c', 'd'])
>>> pd.concat([s1, s2])
0    a
1    b
0    c
1    d
dtype: object
```

Clear the existing index and reset it in the result by setting the ignore_index option to True.

```python
>>> pd.concat([s1, s2], ignore_index=True)
0    a
1    b
2    c
3    d
dtype: object
```
Add a hierarchical index at the outermost level of the data with the keys option.

```python
>>> pd.concat([s1, s2], keys=['s1', 's2'])
s1 0  a
   1  b
s2 0  c
   1  d
dtype: object
```

Label the index keys you create with the names option.

```python
>>> pd.concat([s1, s2], keys=['s1', 's2'],
            names=['Series name', 'Row ID'])
Series name  Row ID
s1 0  a
    1  b
s2 0  c
    1  d
dtype: object
```

Combine two DataFrame objects with identical columns.

```python
>>> df1 = pd.DataFrame([[a, 1], [b, 2]],
                     columns=['letter', 'number'])
>>> df1
   letter number
0   a        1
1   b        2

>>> df2 = pd.DataFrame([[c, 3], [d, 4]],
                     columns=['letter', 'number'])
>>> df2
   letter number
0   c        3
1   d        4

>>> pd.concat([df1, df2])
   letter number
0   a        1
1   b        2
0   c        3
1   d        4
```

Combine DataFrame objects with overlapping columns and return everything. Columns outside the intersection will be filled with NaN values.

```python
>>> df3 = pd.DataFrame([[c, 3, 'cat'], [d, 4, 'dog']],
                     columns=['letter', 'number', 'animal'])
>>> df3
   letter number animal
0   c        3  cat
1   d        4  dog

>>> pd.concat([df1, df3], sort=False)
   letter number animal
0   a        1   NaN
1   b        2   NaN
0   c        3  cat
1   d        4  dog
```

Combine DataFrame objects with overlapping columns and return only those that are shared by passing inner to the join keyword argument.

```python
>>> pd.concat([df1, df3], sort=False, join='inner')
   letter number animal
0   a        1  NaN
1   b        2  NaN
```
```python
>>> pd.concat([df1, df3], join="inner")
letter number
0  a  1
1  b  2
0  c  3
1  d  4

Combine DataFrame objects horizontally along the x axis by passing in axis=1.

```python
>>> df4 = pd.DataFrame([['bird', 'polly'], ['monkey', 'george']],
...                     columns=['animal', 'name'])
>>> pd.concat([df1, df4], axis=1)
letter number animal name
0  a  1  bird  polly
1  b  2  monkey  george

Prevent the result from including duplicate index values with the verify_integrity option.

```python
>>> df5 = pd.DataFrame([1], index=['a'])
>>> df5
0
a 1
>>> df6 = pd.DataFrame([2], index=['a'])
>>> df6
0
a 2
>>> pd.concat([df5, df6], verify_integrity=True)
Traceback (most recent call last):
  ...  
ValueError: Indexes have overlapping values: ['a']
```

**pandas.get_dummies**

`pandas.get_dummies(data, prefix=None, prefix_sep='__', dummy_na=False, columns=None, sparse=False, drop_first=False, dtype=None)`

Convert categorical variable into dummy/indicator variables.

**Parameters**

- **data** [array-like, Series, or DataFrame] Data of which to get dummy indicators.
- **prefix** [str, list of str, or dict of str, default None] String to append DataFrame column names. Pass a list with length equal to the number of columns when calling get_dummies on a DataFrame. Alternatively, prefix can be a dictionary mapping column names to prefixes.
- **prefix_sep** [str, default '__'] If appending prefix, separator/delimiter to use. Or pass a list or dictionary as with prefix.
- **dummy_na** [bool, default False] Add a column to indicate NaNs, if False NaNs are ignored.
- **columns** [list-like, default None] Column names in the DataFrame to be encoded. If columns is None then all the columns with object or category dtype will be converted.
- **sparse** [bool, default False] Whether the dummy-encoded columns should be backed by a SparseArray (True) or a regular NumPy array (False).
- **drop_first** [bool, default False] Whether to get k-1 dummies out of k categorical levels by removing the first level.
**dtype** [dtype, default np.uint8] Data type for new columns. Only a single dtype is allowed.

**Returns**

- **DataFrame** Dummy-coded data.

**See also:**

- *Series.str.get_dummies* Convert Series to dummy codes.

**Examples**

```python
>>> s = pd.Series(list('abca'))

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>

**pandas.factorize**

`pandas.factorize(values, sort=False, na_sentinel=-1, size_hint=None)`

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. `factorize` is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

**Parameters**

- **values** [sequence] A 1-D sequence. Sequences that aren’t pandas objects are coerced to ndarrays before factorization.
- **sort** [bool, default False] Sort `uniques` and shuffle `codes` to maintain the relationship.
- **na_sentinel** [int or None, default -1] Value to mark “not found”. If None, will not drop the NaN from the uniques of the values.
  
  Changed in version 1.1.2.
- **size_hint** [int, optional] Hint to the hashtable sizer.

**Returns**

- **codes** [ndarray] An integer ndarray that’s an indexer into `uniques`. `uniques.take(codes)` will have the same values as `values`.
- **uniques** [ndarray, Index, or Categorical] The unique valid values. When `values` is Categorical, `uniques` is a Categorical. When `values` is some other pandas object, an `Index` is returned. Otherwise, a 1-D ndarray is returned.

**Note:** Even if there’s a missing value in `values`, `uniques` will not contain an entry for it.

**See also:**

- `cut` Discretize continuous-valued array.
- `unique` Find the unique value in an array.
Examples

These examples all show factorize as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> codes
array([0, 0, 1, 2, 0]...)
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the `uniques` will be sorted, and `codes` will be shuffled so that the relationship is maintained.

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> codes
array([1, 1, 0, 2, 1]...)
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in `codes` with `na_sentinel` (-1 by default). Note that missing values are never included in `uniques`.

```python
>>> codes, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> codes
array([ 0, -1, 1, 2, 0]...)
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we’ve only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of `uniques` will differ. For Categoricals, a `Categorical` is returned.

```python
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1]...)
>>> uniques
['a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```python
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1]...)
>>> uniques
Index(['a', 'c'], dtype='object')
```

If NaN is in the values, and we want to include NaN in the uniques of the values, it can be achieved by setting `na_sentinel=None`.

```python
>>> values = np.array([1, 2, 1, np.nan])
>>> codes, uniques = pd.factorize(values)  # default: na_sentinel=-1
>>> codes
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.1

array([ 0, 1, 0, -1])
>>> uniques
array([1., 2.])

>>> codes, uniques = pd.factorize(values, na_sentinel=None)
>>> codes
array([0, 1, 0, 2])
>>> uniques
array([ 1., 2., nan])

pandas.unique

pandas.unique(values)
Hash table-based unique. Uniques are returned in order of appearance. This does NOT sort.
Significantly faster than numpy.unique for long enough sequences. Includes NA values.

Parameters
values [1d array-like]

Returns
numpy.ndarray or ExtensionArray The return can be:
• Index : when the input is an Index
• Categorical : when the input is a Categorical dtype
• ndarray : when the input is a Series/ndarray

Return numpy.ndarray or ExtensionArray.

See also:

Index.unique Return unique values from an Index.
Series.unique Return unique values of Series object.

Examples

>>> pd.unique(pd.Series([2, 1, 3, 3]))
array([2, 1, 3])

>>> pd.unique(pd.Series([2] + [1] * 5))
array([2, 1])

>>> pd.unique(pd.Series([pd.Timestamp("20160101"), pd.Timestamp("20160101")]))
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')

>>> pd.unique(
...   pd.Series(
...       [pd.Timestamp("20160101", tz="US/Eastern"),
...        pd.Timestamp("20160101", tz="US/Eastern"),
...        pd.Timestamp("20160101", tz="US/Eastern"),
...        pd.Timestamp("20160101", tz="US/Eastern")])
...)
(continues on next page)
... )
... }
DatetimeArray
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]

>>> pd.unique(
...     pd.Index(
...         [pd.Timestamp("20160101", tz="US/Eastern"),
...          pd.Timestamp("20160101", tz="US/Eastern"),
...          ]
...     )
... )
DatetimeIndex(['2016-01-01 00:00:00-05:00'],
dtype='datetime64[ns, US/Eastern'],
freq=None)

>>> pd.unique(list("baabc"))
array(['b', 'a', 'c'], dtype=object)

An unordered Categorical will return categories in the order of appearance.

>>> pd.unique(pd.Series(pd.Categorical(list("baabc"))))
['b', 'a', 'c']
Categories (3, object): ['a', 'b', 'c']

>>> pd.unique(pd.Series(pd.Categorical(list("baabc"), categories=list("abc"))))
['b', 'a', 'c']
Categories (3, object): ['a', 'b', 'c']

An ordered Categorical preserves the category ordering.

>>> pd.unique(
...     pd.Series(
...         pd.Categorical(list("baabc"), categories=list("abc"), ordered=True)
...     )
... )
['b', 'a', 'c']
Categories (3, object): ['a' < 'b' < 'c']

An array of tuples

>>> pd.unique([("a", "b"), ("b", "a"), ("a", "c"), ("b", "a")])
array([(a', 'b'), ('b', 'a'), ('a', 'c')], dtype=object)
### pandas.wide_to_long

**pandas.wide_to_long**(df, stubnames, i, j, sep='', suffix='\d+')

Wide panel to long format. Less flexible but more user-friendly than melt.

With stubnames ['A', 'B'], this function expects to find one or more group of columns with format A-suffix1, A-suffix2..., B-suffix1, B-suffix2... You specify what you want to call this suffix in the resulting long format with j (for example j='year')

Each row of these wide variables are assumed to be uniquely identified by i (can be a single column name or a list of column names)

All remaining variables in the data frame are left intact.

**Parameters**

- **df** [DataFrame] The wide-format DataFrame.
- **stubnames** [str or list-like] The stub name(s). The wide format variables are assumed to start with the stub names.
- **i** [str or list-like] Column(s) to use as id variable(s).
- **j** [str] The name of the sub-observation variable. What you wish to name your suffix in the long format.
- **sep** [str, default ''] A character indicating the separation of the variable names in the wide format, to be stripped from the names in the long format. For example, if your column names are A-suffix1, A-suffix2, you can strip the hyphen by specifying sep='\-'.
- **suffix** [str, default '\d+'] A regular expression capturing the wanted suffixes. '\d+' captures numeric suffixes. Suffixes with no numbers could be specified with the negated character class '\D+'. You can also further disambiguate suffixes, for example, if your wide variables are of the form A-one, B-two,..., and you have an unrelated column A-rating, you can ignore the last one by specifying suffix='(!?one|two)'. When all suffixes are numeric, they are cast to int64/float64.

**Returns**

- **DataFrame** A DataFrame that contains each stub name as a variable, with new index (i, j).

**See also:**

- **melt** Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.
- **pivot** Create a spreadsheet-style pivot table as a DataFrame.
- **DataFrame.pivot** Pivot without aggregation that can handle non-numeric data.
- **DataFrame.pivot_table** Generalization of pivot that can handle duplicate values for one index/column pair.
- **DataFrame.unstack** Pivot based on the index values instead of a column.
Notes

All extra variables are left untouched. This simply uses pandas.melt under the hood, but is hard-coded to “do the right thing” in a typical case.

Examples

```python
>>> np.random.seed(123)
>>> df = pd.DataFrame({"A1970": {0: "a", 1: "b", 2: "c"},
... "A1980": {0: "d", 1: "e", 2: "f"},
... "B1970": {0: 2.5, 1: 1.2, 2: .7},
... "B1980": {0: 3.2, 1: 1.3, 2: .1},
... "X": dict(zip(range(3), np.random.randn(3)))
... })
>>> df["id"] = df.index
>>> df
0 a d 2.5 3.2 -1.085631 0
1 b e 1.2 1.3 0.997345 1
2 c f 0.7 0.1 0.282978 2
>>> pd.wide_to_long(df, ["A", "B"], i="id", j="year")
... X A B
id year
0 1970 -1.085631 a 2.5
1 1970 0.997345 b 1.2
2 1970 0.282978 c 0.7
0 1980 -1.085631 d 3.2
1 1980 0.997345 e 1.3
2 1980 0.282978 f 0.1
```

With multiple id columns

```python
>>> df = pd.DataFrame({
... 'famid': [1, 1, 1, 2, 2, 2, 3, 3, 3],
... 'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],
... 'ht1': [2.8, 2.9, 2.2, 2, 1.8, 2.8, 2.2, 2.3, 2.1],
... 'ht2': [3.4, 3.8, 2.9, 3.2, 2.8, 3.4, 2.3, 3.4, 2.9]
... })
>>> df
famid birth ht1 ht2
0 1 1 2.8 3.4
1 1 2 2.9 3.8
2 1 3 2.2 2.9
3 2 1 2.0 3.2
4 2 2 1.8 2.8
5 2 3 1.9 2.4
6 3 1 2.2 3.3
7 3 2 2.3 3.4
8 3 3 2.1 2.9
>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age')
>>> l
... famid birth age
0 1 1 2.8
1 1 2 2.9
(continues on next page)
Going from long back to wide just takes some creative use of `unstack`

```python
>>> w = l.unstack()
>>> w.columns = w.columns.map('0[0][0]1').format
>>> w.reset_index()
  famid birth ht1 ht2
0  1   1    2.8  3.4
1  1   2    2.9  3.8
2  1   3    2.2  2.9
3  2   1    2.0  2.3
4  2   2    2.8  1.8
5  2   3    2.4  2.4
6  3   1    2.2  3.3
7  3   2    2.3  3.4
8  3   3    2.1  2.9
```

Less wieldy column names are also handled

```python
>>> np.random.seed(0)
>>> df = pd.DataFrame({'A(weekly)-2010': np.random.rand(3),
...                    'A(weekly)-2011': np.random.rand(3),
...                    'B(weekly)-2010': np.random.rand(3),
...                    'B(weekly)-2011': np.random.rand(3),
...                    'X' : np.random.randint(3, size=3)})
>>> df['id'] = df.index
>>> df
  A(weekly)-2010  A(weekly)-2011  B(weekly)-2010  B(weekly)-2011  X  id
0  0.548814       0.544883       0.437587       0.383442     0  0
1  0.715189       0.423655       0.891773       0.791725     1  1
2  0.602763       0.645894       0.963663       0.528895     1  2

>>> pd.wide_to_long(df, ['A(weekly)', 'B(weekly)'], i='id',
...                  j='year', sep='-')
...                  X  A(weekly)  B(weekly)
id year
0  2010 0  0.548814  0.437587
1  2010 1  0.715189  0.891773
```

(continues on next page)
If we have many columns, we could also use a regex to find our stubnames and pass that list on to wide_to_long

```python
>>> stubnames = sorted(set([match[0] for match in df.columns.str.findall(r'[A-B]\.(.*\)')].values if match != []])
...]
>>> list(stubnames)
['A(weekly)', 'B(weekly)']
```

All of the above examples have integers as suffixes. It is possible to have non-integers as suffixes.

```python
>>> df = pd.DataFrame({
... 'famid': [1, 1, 1, 2, 2, 2, 3, 3, 3],
... 'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],
... 'ht_one': [2.8, 2.9, 2.2, 1.8, 1.9, 2.2, 2.3, 2.1],
... 'ht_two': [3.4, 3.8, 3.2, 2.8, 2.4, 3.3, 3.4, 2.9]
... })
>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age', sep='_', suffix=r'\w+')
```

(continues on next page)
3.2.2 Top-level missing data

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pandas.isna(obj)</td>
<td>Detect missing values for an array-like object.</td>
</tr>
<tr>
<td>pandas.isnull(obj)</td>
<td>Detect missing values for an array-like object.</td>
</tr>
<tr>
<td>pandas.notna(obj)</td>
<td>Detect non-missing values for an array-like object.</td>
</tr>
<tr>
<td>pandas.notnull(obj)</td>
<td>Detect non-missing values for an array-like object.</td>
</tr>
</tbody>
</table>

**pandas.isna**

**pandas.isna** *(obj)*

Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

**Parameters**

- **obj** [scalar or array-like] Object to check for null or missing values.

**Returns**

- **bool or array-like of bool** For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

**See also:**

- **notna** Boolean inverse of pandas.isna.
- **Series.isna** Detect missing values in a Series.
- **DataFrame.isna** Detect missing values in a DataFrame.
- **Index.isna** Detect missing values in an Index.

**Examples**

Scalar arguments (including strings) result in a scalar boolean.

```python
>>> pd.isna('dog')
False
```

```python
>>> pd.isna(pd.NA)
True
```

```python
>>> pd.isna(np.nan)
True
```

ndarrays result in an ndarray of booleans.
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan, 3.],
       [ 4., 5., nan]])
>>> pd.isna(array)
array([[False, True, False],
       [False, False, True]])

For indexes, an ndarray of booleans is returned.

```python
>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None, ...
                           '2017-07-08'])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
>>> pd.isna(index)
array([False, False, True, False])
```

For Series and DataFrame, the same type is returned, containing booleans.

```python
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
  0 1 2
0 ant bee cat
1 dog None fly
>>> pd.isna(df)
  0 1 2
0 False False False
1 False True False
```

```python
>>> pd.isna(df[1])
0   False
1   True
Name: 1, dtype: bool
```

### pandas.isnull

**pandas.isnull** *(obj)*

Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

**Parameters**

- **obj** [scalar or array-like] Object to check for null or missing values.

**Returns**

- **bool or array-like of bool** For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

**See also:**

- **notna** Boolean inverse of pandas.isna.
- **Series.isna** Detect missing values in a Series.
- **DataFrame.isna** Detect missing values in a DataFrame.
**Index.isna** Detect missing values in an Index.

**Examples**

Scalar arguments (including strings) result in a scalar boolean.

```python
>>> pd.isna('dog')
False

>>> pd.isna(pd.NA)
True

>>> pd.isna(np.nan)
True
```

ndarrays result in an ndarray of booleans.

```python
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.isna(array)
array([[False, True, False],
       [False, False, True]])
```

For indexes, an ndarray of booleans is returned.

```python
>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None, ...
"2017-07-08'])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', NaT', '2017-07-08'],
dtype='datetime64[ns]', freq=None)
>>> pd.isna(index)
array([False, False, True, False])
```

For Series and DataFrame, the same type is returned, containing booleans.

```python
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
     0   1   2
0  ant  bee cat
1   dog None  fly
>>> pd.isna(df)
   0  1  2
0 False False False
1 False True False
```

```python
>>> pd.isna(df[1])
0  False
1  True
Name: 1, dtype: bool
```
**pandas: powerful Python data analysis toolkit, Release 1.3.1**

### pandas.notna

**pandas.notna(obj)**

Detect non-missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

**Parameters**

- **obj** [array-like or object value] Object to check for not null or non-missing values.

**Returns**

- **bool or array-like of bool** For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

**See also:**

- **isna** Boolean inverse of pandas.notna.
- **Series.notna** Detect valid values in a Series.
- **DataFrame.notna** Detect valid values in a DataFrame.
- **Index.notna** Detect valid values in an Index.

**Examples**

Scalar arguments (including strings) result in a scalar boolean.

```python
>>> pd.notna('dog')
True
```

```python
>>> pd.notna(pd.NA)
False
```

```python
>>> pd.notna(np.nan)
False
```

ndarrays result in an ndarray of booleans.

```python
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan, 3.],
       [ 4., 5., nan]])
```

```python
>>> pd.notna(array)
array([[ True, False, True],
       [ True, True, False]])
```

For indexes, an ndarray of booleans is returned.

```python
>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None, ...
                                  '2017-07-08'])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
              dtype='datetime64[ns]', freq=None)
```

```python
>>> pd.notna(index)
array([ True, True, False, True])
```
For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
   0  1  2
0  ant bee cat
1  dog None fly
```

```
>>> pd.notna(df)
   0  1  2
0  True True True
1  True False True
```

```
>>> pd.notna(df[1])
0  True
1  False
Name: 1, dtype: bool
```

**pandas.notnull**

`pandas.notnull(obj)`

Detect non-missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

**Parameters**

- **obj** [array-like or object value] Object to check for not null or non-missing values.

**Returns**

- **bool or array-like of bool** For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

See also:

- **isna** Boolean inverse of pandas.notna.
- **Series.notna** Detect valid values in a Series.
- **DataFrame.notna** Detect valid values in a DataFrame.
- **Index.notna** Detect valid values in an Index.

**Examples**

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.notna('dog')
True
```

```
>>> pd.notna(pd.NA)
False
```

```
>>> pd.notna(np.nan)
False
```

ndarrays result in an ndarray of bools.
```python
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan, 3.],
       [ 4.,  5., nan]])
>>> pd.notna(array)
array([[ True, False, True],
       [ True, True, False]])

For indexes, an ndarray of booleans is returned.
```  
```python
>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
               dtype='datetime64[ns]', freq=None)
>>> pd.notna(index)
array([[ True, True, False, True]])
```

For Series and DataFrame, the same type is returned, containing booleans.
```python
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
   0 1 2
0 ant bee cat
1 dog None fly
>>> pd.notna(df)
   0 1 2
0 True True True
1 True False True
```
```python
>>> pd.notna(df[1])
0 True
1 False
Name: 1, dtype: bool
```

## 3.2.3 Top-level conversions

### to_numeric(arg[, errors, downcast])
Convert argument to a numeric type.

**pandas.to_numeric**

pandas.to_numeric (arg, errors='raise', downcast=None)
Convert argument to a numeric type.

The default return dtype is float64 or int64 depending on the data supplied. Use the downcast parameter to obtain other dtypes.

Please note that precision loss may occur if really large numbers are passed in. Due to the internal limitations of ndarray, if numbers smaller than -9223372036854775808 (np.iinfo(np.int64).min) or larger than 18446744073709551615 (np.iinfo(np.uint64).max) are passed in, it is very likely they will be converted to float so that they can stored in an ndarray. These warnings apply similarly to Series since it internally leverages ndarray.

**Parameters**
arg [scalar, list, tuple, 1-d array, or Series] Argument to be converted.

errors [{'ignore', 'raise', 'coerce'}, default 'raise']
  • If 'raise', then invalid parsing will raise an exception.
  • If 'coerce', then invalid parsing will be set as NaN.
  • If 'ignore', then invalid parsing will return the input.

downcast [{‘integer’, ‘signed’, ‘unsigned’, ‘float’}, default None] If not None, and if the data has been successfully cast to a numerical dtype (or if the data was numeric to begin with), downcast that resulting data to the smallest numerical dtype possible according to the following rules:
  • ‘integer’ or ‘signed’: smallest signed int dtype (min.: np.int8)
  • ‘unsigned’: smallest unsigned int dtype (min.: np.uint8)
  • ‘float’: smallest float dtype (min.: np.float32)

As this behaviour is separate from the core conversion to numeric values, any errors raised during the downcasting will be surfaced regardless of the value of the ‘errors’ input.

In addition, downcasting will only occur if the size of the resulting data's dtype is strictly larger than the dtype it is to be cast to, so if none of the dtypes checked satisfy that specification, no downcasting will be performed on the data.

Returns

ret Numeric if parsing succeeded. Return type depends on input. Series if Series, otherwise ndarray.

See also:

DataFrame.astype Cast argument to a specified dtype.
to_datetime Convert argument to datetime.
to_timedelta Convert argument to timedelta.
numpy.ndarray.astype Cast a numpy array to a specified type.

DataFrame.convert_dtypes Convert dtypes.

Examples

Take separate series and convert to numeric, coercing when told to

```python
>>> s = pd.Series(['1.0', '2', -3])
>>> pd.to_numeric(s)
    0    1.0
    1    2.0
    2   -3.0
dtype: float64
>>> pd.to_numeric(s, downcast='float')
    0    1.0
    1    2.0
    2   -3.0
dtype: float32
>>> pd.to_numeric(s, downcast='signed')
    0    1
```
(continues on next page)
1  2
2  -3
dtype: int8
>>> s = pd.Series(['apple', '1.0', '2', -3])
>>> pd.to_numeric(s, errors='ignore')
  0    apple
  1    1.0
  2      2
  3      3
dtype: object
>>> pd.to_numeric(s, errors='coerce')
  0     NaN
  1    1.0
  2    2.0
  3    3.0
dtype: float64

Downcasting of nullable integer and floating dtypes is supported:

>>> s = pd.Series([1, 2, 3], dtype="Int64")
>>> pd.to_numeric(s, downcast="integer")
  0    1
  1    2
  2    3
dtype: Int8
>>> s = pd.Series([1.0, 2.1, 3.0], dtype="Float64")
>>> pd.to_numeric(s, downcast="float")
  0  1.0
  1  2.1
  2  3.0
dtype: Float32

3.2.4 Top-level dealing with datetimelike

<table>

pandas.to_datetime

```
pandas.to_datetime(arg, errors='raise', dayfirst=False, yearfirst=False, utc=None, format=None, exact=True, unit=None, infer_datetime_format=False, origin='unix', cache=True)
```

Convert argument to datetime.

**Parameters**

- **arg** [int, float, str, datetime, list, tuple, 1-d array, Series, DataFrame/dict-like] The object to convert to a datetime.
- **errors** [{'ignore', 'raise', 'coerce'}, default 'raise']
  - If 'raise', then invalid parsing will raise an exception.
  - If 'coerce', then invalid parsing will be set as NaT.
  - If 'ignore', then invalid parsing will return the input.
- **dayfirst** [bool, default False] Specify a date parse order if arg is str or its list-likes. If True, parses dates with the day first, eg 10/11/12 is parsed as 2012-11-10. Warning: dayfirst=True is not strict, but will prefer to parse with day first (this is a known bug, based on dateutil behavior).
- **yearfirst** [bool, default False] Specify a date parse order if arg is str or its list-likes.
  - If True parses dates with the year first, eg 10/11/12 is parsed as 2010-11-12.
  - If both dayfirst and yearfirst are True, yearfirst is preceded (same as dateutil).
  Warning: yearfirst=True is not strict, but will prefer to parse with year first (this is a known bug, based on dateutil behavior).
- **utc** [bool, default None] Return UTC DatetimeIndex if True (converting any tz-aware datetime objects as well).
- **format** [str, default None] The strftime to parse time, eg “%d/%m/%Y”, note that “%f” will parse all the way up to nanoseconds. See strftime documentation for more information on choices: https://docs.python.org/3/library/datetime.html#strftime-and-strptime-behavior.
- **exact** [bool, True by default] Behaves as: - If True, require an exact format match. - If False, allow the format to match anywhere in the target string.
- **unit** [str, default 'ns'] The unit of the arg (D,s,ms,us,ns) denote the unit, which is an integer or float number. This will be based off the origin. Example, with unit=’ms’ and origin=’unix’ (the default), this would calculate the number of milliseconds to the unix epoch start.
- **infer_datetime_format** [bool, default False] If True and no format is given, attempt to infer the format of the datetime strings based on the first non-NaN element, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by ~5-10x.
- **origin** [scalar, default ‘unix’] Define the reference date. The numeric values would be parsed as number of units (defined by unit) since this reference date.
  - If ‘unix’ (or POSIX) time; origin is set to 1970-01-01.
  - If ‘julian’, unit must be ‘D’, and origin is set to beginning of Julian Calendar. Julian day number 0 is assigned to the day starting at noon on January 1, 4713 BC.
  - If Timestamp convertible, origin is set to Timestamp identified by origin.
- **cache** [bool, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets. The cache is only used when there are at least 50 values.
The presence of out-of-bounds values will render the cache unusable and may slow down parsing.

Changed in version 0.25.0: changed default value from False to True.

Returns

- **datetime** If parsing succeeded. Return type depends on input:
  - list-like: DatetimeIndex
  - Series: Series of datetime64 dtype
  - scalar: Timestamp

In case when it is not possible to return designated types (e.g. when any element of input is before Timestamp.min or after Timestamp.max) return will have datetime.datetime type (or corresponding array/Series).

See also:

- **DataFrame.astype** Cast argument to a specified dtype.
- **to_timedelta** Convert argument to timedelta.
- **convert_dtypes** Convert dtypes.

Examples

Assembling a datetime from multiple columns of a DataFrame. The keys can be common abbreviations like [
'yyear', 'month', 'day', 'minute', 'second', 'ms', 'us', 'ns']) or plurals of the same

```python
>>> df = pd.DataFrame({'year': [2015, 2016],
... 'month': [2, 3],
... 'day': [4, 5]})
>>> pd.to_datetime(df)
0 2015-02-04
1 2016-03-05
dtype: datetime64[ns]
```

If a date does not meet the timestamp limitations, passing errors='ignore' will return the original input instead of raising any exception.

Passing errors='coerce' will force an out-of-bounds date to NaT, in addition to forcing non-dates (or non-parseable dates) to NaT.

```python
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='ignore')
datetime(1300, 1, 1, 0, 0)
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='coerce')
NaT
```

Passing infer_datetime_format=True can often-times speedup a parsing if its not an ISO8601 format exactly, but in a regular format.

```python
>>> s.head()
0 3/11/2000
1 3/12/2000
2 3/13/2000
3 3/11/2000
```
Using a unix epoch time

```python
>>> pd.to_datetime(1490195805, unit='s')
Timestamp('2017-03-22 15:16:45')

>>> pd.to_datetime(1490195805433502912, unit='ns')
Timestamp('2017-03-22 15:16:45.433502912')
```

**Warning:** For float arg, precision rounding might happen. To prevent unexpected behavior use a fixed-width exact type.

Using a non-unix epoch origin

```python
>>> pd.to_datetime([1, 2, 3], unit='D', origin=pd.Timestamp('1960-01-01'))
DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype='datetime64[ns]', freq=None)
```

In case input is list-like and the elements of input are of mixed timezones, return will have object type Index if utc=False.

```python
>>> pd.to_datetime(['2018-10-26 12:00 -0530', '2018-10-26 12:00 -0500'])
Index(['2018-10-26 12:00:00-05:30', '2018-10-26 12:00:00-05:00'], dtype='object')

>>> pd.to_datetime(['2018-10-26 12:00 -0530', '2018-10-26 12:00 -0500'], utc=True)
DatetimeIndex(['2018-10-26 17:30:00+00:00', '2018-10-26 17:00:00+00:00'], dtype='datetime64[ns, UTC]', freq=None)
```

**pandas.to_timedelta**

Convert argument to timedelta.

Timedeltas are absolute differences in times, expressed in difference units (e.g. days, hours, minutes, seconds). This method converts an argument from a recognized timedelta format / value into a Timedelta type.

**Parameters**

- **arg** [str, timedelta, list-like or Series] The data to be converted to timedelta.

  Deprecated since version 1.2: Strings with units ‘M’, ‘Y’ and ‘y’ do not represent unambiguous timedelta values and will be removed in a future version

- **unit** [str, optional] Denotes the unit of the arg for numeric arg. Defaults to "ns".

Possible values:
- ‘W’
- ‘D’ / ‘days’ / ‘day’
- ‘hours’ / ‘hour’ / ‘hr’ / ‘h’
- ‘m’ / ‘minute’ / ‘min’ / ‘minutes’ / ‘T’
- ‘S’ / ‘seconds’ / ‘sec’ / ‘second’
- ‘ms’ / ‘milliseconds’ / ‘millisecond’ / ‘milli’ / ‘millis’ / ‘L’
- ‘us’ / ‘microseconds’ / ‘microsecond’ / ‘micro’ / ‘micros’ / ‘U’
- ‘ns’ / ‘nanoseconds’ / ‘nano’ / ‘nanos’ / ‘nanosecond’ / ‘N’

Changed in version 1.1.0: Must not be specified when arg context strings and errors= "raise".

**errors** [{‘ignore’, ‘raise’, ‘coerce’}, default ‘raise’]
- If ‘raise’, then invalid parsing will raise an exception.
- If ‘coerce’, then invalid parsing will be set as NaT.
- If ‘ignore’, then invalid parsing will return the input.

**Returns**
- **timedelta64 or numpy.array of timedelta64** Output type returned if parsing succeeded.

**See also:**
- **DataFrame.astype** Cast argument to a specified dtype.
- **to_datetime** Convert argument to datetime.
- **convert_dtypes** Convert dtypes.

**Notes**

If the precision is higher than nanoseconds, the precision of the duration is truncated to nanoseconds for string inputs.

**Examples**

Parsing a single string to a Timedelta:

```python
>>> pd.to_timedelta('1 days 06:05:01.00003')
Timedelta('1 days 06:05:01.000030')

>>> pd.to_timedelta('15.5us')
Timedelta('0 days 00:00:00.000015500')
```

Parsing a list or array of strings:

```python
>>> pd.to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015500', NaT],
                dtype='timedelta64[ns]', freq=None)
```

Converting numbers by specifying the **unit** keyword argument:
pandas: powerful Python data analysis toolkit, Release 1.3.1

```
>>> pd.to_timedelta(np.arange(5), unit='s')
TimedeltaIndex(['0 days 00:00:00', '0 days 00:00:01', '0 days 00:00:02',
                 '0 days 00:00:03', '0 days 00:00:04'],
                dtype='timedelta64[ns]', freq=None)
```
```
>>> pd.to_timedelta(np.arange(5), unit='d')
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
                dtype='timedelta64[ns]', freq=None)
```

**pandas.date_range**

`pandas.date_range(start=None, end=None, periods=None, freq=None, tz=None, normalize=False, name=None, closed=None, **kwargs)`

Return a fixed frequency DatetimeIndex.

Returns the range of equally spaced time points (where the difference between any two adjacent points is specified by the given frequency) such that they all satisfy `start <= x <= end`, where the first one and the last one are, resp., the first and last time points in that range that fall on the boundary of `freq` (if given as a frequency string) or that are valid for `freq` (if given as a `pandas.tseries.offsets.DateOffset`). (If exactly one of `start`, `end`, or `freq` is not specified, this missing parameter can be computed given `periods`, the number of timesteps in the range. See the note below.)

**Parameters**

- `start` [str or datetime-like, optional] Left bound for generating dates.
- `end` [str or datetime-like, optional] Right bound for generating dates.
- `periods` [int, optional] Number of periods to generate.
- `freq` [str or DateOffset, default ‘D’] Frequency strings can have multiples, e.g. ‘5H’. See [here](https://pandas.pydata.org/pandas-docs/stable/user_guide/timeseries.html#frequency-strings) for a list of frequency aliases.
- `tz` [str or tzinfo, optional] Time zone name for returning localized DatetimeIndex, for example ‘Asia/Hong_Kong’. By default, the resulting DatetimeIndex is timezone-naive.
- `normalize` [bool, default False] Normalize start/end dates to midnight before generating date range.
- `name` [str, default None] Name of the resulting DatetimeIndex.
- `closed` [[None, ‘left’, ‘right’], optional] Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None, the default).

**kwargs For compatibility. Has no effect on the result.

**Returns**

- `rng` [DatetimeIndex]

See also:

- `DatetimeIndex` An immutable container for datetimes.
- `timedelta_range` Return a fixed frequency TimedeltaIndex.
- `period_range` Return a fixed frequency PeriodIndex.
- `interval_range` Return a fixed frequency IntervalIndex.
Notes

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting `DatetimeIndex` will have periods linearly spaced elements between `start` and `end` (closed on both sides).

To learn more about the frequency strings, please see this link.

Examples

Specifying the values

The next four examples generate the same `DatetimeIndex`, but vary the combination of `start`, `end` and `periods`.

Specify `start` and `end`, with the default daily frequency.

```python
>>> pd.date_range(start='1/1/2018', end='1/08/2018')
              dtype='datetime64[ns]', freq='D')
```

Specify `start` and `periods`, the number of periods (days).

```python
>>> pd.date_range(start='1/1/2018', periods=8)
              dtype='datetime64[ns]', freq='D')
```

Specify `end` and `periods`, the number of periods (days).

```python
>>> pd.date_range(end='1/1/2018', periods=8)
DatetimeIndex(['2017-12-25', '2017-12-26', '2017-12-27', '2017-12-28',
               '2017-12-29', '2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```python
>>> pd.date_range(start='2018-04-24', end='2018-04-27', periods=3)
DatetimeIndex(['2018-04-24 00:00:00', '2018-04-25 12:00:00',
               '2018-04-27 00:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Other Parameters

Changed the `freq` (frequency) to 'M' (month end frequency).

```python
>>> pd.date_range(start='1/1/2018', periods=5, freq='M')
               '2018-05-31'],
              dtype='datetime64[ns]', freq='M')
```

Multiples are allowed

```python
>>> pd.date_range(start='1/1/2018', periods=5, freq='3M')
               '2019-01-31'],
              dtype='datetime64[ns]', freq='3M')
```
freq can also be specified as an Offset object.

```python
>>> pd.date_range(start='1/1/2018', periods=5, freq=pd.offsets.MonthEnd(3))
              '2019-01-31'],
       dtype='datetime64[ns]', freq='3M')
```

Specify tz to set the timezone.

```python
>>> pd.date_range(start='1/1/2018', periods=5, tz='Asia/Tokyo')
DatetimeIndex(['2018-01-01 00:00:00+09:00', '2018-01-02 00:00:00+09:00',
              '2018-01-03 00:00:00+09:00', '2018-01-04 00:00:00+09:00',
              '2018-01-05 00:00:00+09:00'],
       dtype='datetime64[ns, Asia/Tokyo]', freq='D')
```

closed controls whether to include start and end that are on the boundary. The default includes boundary points on either end.

```python
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed=None)
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03', '2017-01-04'],
       dtype='datetime64[ns]', freq='D')
```

Use closed='left' to exclude end if it falls on the boundary.

```python
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed='left')
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03'],
       dtype='datetime64[ns]', freq='D')
```

Use closed='right' to exclude start if it falls on the boundary.

```python
>>> pd.date_range(start='2017-01-01', end='2017-01-04', closed='right')
DatetimeIndex(['2017-01-02', '2017-01-03', '2017-01-04'],
       dtype='datetime64[ns]', freq='D')
```

### pandas.bdate_range

**pandas.bdate_range**

```
pandas.bdate_range(start=None, end=None, periods=None, freq='B', tz=None, normalize=True, name=None, weekmask=None, holidays=None, closed=None, **kwargs)
```

Return a fixed frequency DatetimeIndex, with business day as the default frequency.

**Parameters**

- **start** [str or datetime-like, default None] Left bound for generating dates.
- **end** [str or datetime-like, default None] Right bound for generating dates.
- **periods** [int, default None] Number of periods to generate.
- **freq** [str or DateOffset, default ‘B’ (business daily)] Frequency strings can have multiples, e.g. ‘5H’.
- **tz** [str or None] Time zone name for returning localized DatetimeIndex, for example Asia/Beijing.
- **normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.
- **name** [str, default None] Name of the resulting DatetimeIndex.
**weekmask** [str or None, default None] Weekmask of valid business days, passed to numpy.
busdaycalendar, only used when custom frequency strings are passed. The default value None is equivalent to ‘Mon Tue Wed Thu Fri’.

**holidays** [list-like or None, default None] Dates to exclude from the set of valid business days, passed to numpy.busdaycalendar, only used when custom frequency strings are passed.

**closed** [str, default None] Make the interval closed with respect to the given frequency to the 'left', ‘right’, or both sides (None).

****kwargs For compatibility. Has no effect on the result.

**Returns**

**DatetimeIndex**

**Notes**

Of the four parameters: start, end, periods, and freq, exactly three must be specified. Specifying freq is a requirement for bdate_range. Use date_range if specifying freq is not desired.

To learn more about the frequency strings, please see this link.

**Examples**

Note how the two weekend days are skipped in the result.

```python
>>> pd.bdate_range(start='1/1/2018', end='1/08/2018')
               '2018-01-05', '2018-01-08'],
dtype='datetime64[ns]', freq='B')
```

**pandas.period_range**

pandas.*period_range*(start=None, end=None, periods=None, freq=None, name=None)

Return a fixed frequency PeriodIndex.

The day (calendar) is the default frequency.

**Parameters**

start [str or period-like, default None] Left bound for generating periods.

end [str or period-like, default None] Right bound for generating periods.

periods [int, default None] Number of periods to generate.

freq [str or DateOffset, optional] Frequency alias. By default the freq is taken from start or end if those are Period objects. Otherwise, the default is "D" for daily frequency.

name [str, default None] Name of the resulting PeriodIndex.

**Returns**

**PeriodIndex**
Notes

Of the three parameters: `start`, `end`, and `periods`, exactly two must be specified.

To learn more about the frequency strings, please see this link.

Examples

```python
>>> pd.period_range(start='2017-01-01', end='2018-01-01', freq='M')
```

If `start` or `end` are `Period` objects, they will be used as anchor endpoints for a `PeriodIndex` with frequency matching that of the `period_range` constructor.

```python
>>> pd.period_range(start=pd.Period('2017Q1', freq='Q'),
                  end=pd.Period('2017Q2', freq='Q'), freq='M')
PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'],
            dtype='period[M]')
```

`pandas.timedelta_range`

`pandas.timedelta_range(start=None, end=None, periods=None, freq=None, name=None, closed=None)`

Return a fixed frequency TimedeltaIndex, with day as the default frequency.

**Parameters**

- `start` [str or timedelta-like, default None] Left bound for generating timedeltas.
- `end` [str or timedelta-like, default None] Right bound for generating timedeltas.
- `periods` [int, default None] Number of periods to generate.
- `freq` [str or DateOffset, default ‘D’] Frequency strings can have multiples, e.g. ‘5H’.
- `name` [str, default None] Name of the resulting TimedeltaIndex.
- `closed` [str, default None] Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None).

**Returns**

TimedeltaIndex

**Notes**

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting TimedeltaIndex will have `periods` linearly spaced elements between `start` and `end` (closed on both sides).

To learn more about the frequency strings, please see this link.
Examples

```python
>>> pd.timedelta_range(start='1 day', periods=4)
TimedeltaIndex(['1 days', '2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq='D')
```

The `closed` parameter specifies which endpoint is included. The default behavior is to include both endpoints.

```python
>>> pd.timedelta_range(start='1 day', periods=4, closed='right')
TimedeltaIndex(['2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq='D')
```

The `freq` parameter specifies the frequency of the TimedeltaIndex. Only fixed frequencies can be passed, non-fixed frequencies such as ‘M’ (month end) will raise.

```python
>>> pd.timedelta_range(start='1 day', end='2 days', freq='6H')
TimedeltaIndex(['1 days 00:00:00', '1 days 06:00:00', '1 days 12:00:00',
                 '1 days 18:00:00', '2 days 00:00:00'],
               dtype='timedelta64[ns]', freq='6H')
```

Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```python
>>> pd.timedelta_range(start='1 day', end='5 days', periods=4)
TimedeltaIndex(['1 days 00:00:00', '2 days 08:00:00', '3 days 16:00:00',
                 '5 days 00:00:00'],
               dtype='timedelta64[ns]', freq=None)
```

`pandas.infer_freq`

`pandas.infer_freq(index, warn=True)`

Infer the most likely frequency given the input index. If the frequency is uncertain, a warning will be printed.

Parameters

- `index` [DatetimeIndex or TimedeltaIndex] If passed a Series will use the values of the series (NOT THE INDEX).
- `warn` [bool, default True]

Returns

- `str` or `None` None if no discernible frequency.

Raises

- `TypeError` If the index is not datetime-like.
- `ValueError` If there are fewer than three values.
Examples

```python
>>> idx = pd.date_range(start='2020/12/01', end='2020/12/30', periods=30)
>>> pd.infer_freq(idx)
'D'
```

3.2.5 Top-level dealing with intervals

```
interval_range([start, end, periods, freq, ...])  Return a fixed frequency IntervalIndex.
```

**pandas.interval_range**

`pandas.interval_range` *(start=None, end=None, periods=None, freq=None, name=None, closed='right')*

Return a fixed frequency IntervalIndex.

**Parameters**

- `start` [numeric or datetime-like, default None] Left bound for generating intervals.
- `end` [numeric or datetime-like, default None] Right bound for generating intervals.
- `periods` [int, default None] Number of periods to generate.
- `freq` [numeric, str, or DateOffset, default None] The length of each interval. Must be consistent with the type of start and end, e.g. 2 for numeric, or ‘5H’ for datetime-like. Default is 1 for numeric and ‘D’ for datetime-like.
- `name` [str, default None] Name of the resulting IntervalIndex.
- `closed` [[‘left’, ‘right’, ‘both’, ‘neither’], default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.

**Returns**

IntervalIndex

**See also:**

`IntervalIndex` An Index of intervals that are all closed on the same side.

**Notes**

Of the four parameters start, end, periods, and freq, exactly three must be specified. If freq is omitted, the resulting IntervalIndex will have periods linearly spaced elements between start and end, inclusively.

To learn more about datetime-like frequency strings, please see this link.

3.2. General functions 1103
Examples

Numeric start and end is supported.

```python
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]),
dtype='interval[int64, right]')
```

Additionally, datetime-like input is also supported.

```python
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
... end=pd.Timestamp('2017-01-04'))
IntervalIndex([(2017-01-01, 2017-01-02], (2017-01-02, 2017-01-03],
... (2017-01-03, 2017-01-04]),
dtype='interval[datetime64[ns], right]')
```

The `freq` parameter specifies the frequency between the left and right endpoints of the individual intervals within the `IntervalIndex`. For numeric `start` and `end`, the frequency must also be numeric.

```python
>>> pd.interval_range(start=0, periods=4, freq=1.5)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]),
dtype='interval[float64, right]')
```

Similarly, for datetime-like `start` and `end`, the frequency must be convertible to a DateOffset.

```python
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
... ... end=pd.Timestamp('2017-01-04'),
... ... periods=3, freq='MS')
IntervalIndex([(2017-01-01, 2017-02-01], (2017-02-01, 2017-03-01],
... (2017-03-01, 2017-04-01]),
dtype='interval[datetime64[ns], right]')
```

Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```python
>>> pd.interval_range(start=0, end=6, periods=4)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]),
dtype='interval[float64, right]')
```

The `closed` parameter specifies which endpoints of the individual intervals within the `IntervalIndex` are closed.

```python
>>> pd.interval_range(end=5, periods=4, closed='both')
IntervalIndex([(1, 2], [2, 3], [3, 4], [4, 5]),
dtype='interval[int64, both]')
```

3.2.6 Top-level evaluation

```
eval(expr[, parser, engine, truediv, ...])
```

Evaluate a Python expression as a string using various backends.
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.eval

```python
pandas.eval(expr, parser='pandas', engine=None, truediv=<no_default>, local_dict=None, global_dict=None, resolvers=(), level=0, target=None, inplace=False)
```

Evaluate a Python expression as a string using various backends.

The following arithmetic operations are supported: `+`, `-`, `/`, `*`, `**`, `%`, `//` (python engine only) along with the following boolean operations: `|` (or), `&` (and), and `~` (not). Additionally, the 'pandas' parser allows the use of `and`, `or`, and `not` with the same semantics as the corresponding bitwise operators. Series and DataFrame objects are supported and behave as they would with plain ol’ Python evaluation.

**Parameters**

- **expr** [str] The expression to evaluate. This string cannot contain any Python statements, only Python expressions.
- **parser** [{'pandas', 'python'}, default 'pandas'] The parser to use to construct the syntax tree from the expression. The default of 'pandas' parses code slightly different than standard Python. Alternatively, you can parse an expression using the 'python' parser to retain strict Python semantics. See the enhancing performance documentation for more details.
- **engine** [{'python', 'numexpr'}, default 'numexpr'] The engine used to evaluate the expression. Supported engines are
  - None: tries to use numexpr, falls back to python
  - 'numexpr': This default engine evaluates pandas objects using numexpr for large speed ups in complex expressions with large frames.
  - 'python': Performs operations as if you had eval’d in top level python. This engine is generally not that useful.

More backends may be available in the future.

- **truediv** [bool, optional] Whether to use true division, like in Python >= 3.

  Deprecated since version 1.0.0.

- **local_dict** [dict or None, optional] A dictionary of local variables, taken from locals() by default.

- **global_dict** [dict or None, optional] A dictionary of global variables, taken from globals() by default.

- **resolvers** [list of dict-like or None, optional] A list of objects implementing the `__getitem__` special method that you can use to inject an additional collection of namespaces to use for variable lookup. For example, this is used in the `query()` method to inject the `DataFrame.index` and `DataFrame.columns` variables that refer to their respective `DataFrame` instance attributes.

- **level** [int, optional] The number of prior stack frames to traverse and add to the current scope. Most users will not need to change this parameter.

- **target** [object, optional, default None] This is the target object for assignment. It is used when there is variable assignment in the expression. If so, then target must support item assignment with string keys, and if a copy is being returned, it must also support .copy().

- **inplace** [bool, default False] If target is provided, and the expression mutates target, whether to modify target inplace. Otherwise, return a copy of target with the mutation.

**Returns**

ndarray, numeric scalar, DataFrame, Series, or None The completion value of evaluating the given code or None if inplace=True.
Raises

**ValueError**  There are many instances where such an error can be raised:

- `target=None`, but the expression is multiline.
- The expression is multiline, but not all them have item assignment. An example of such an arrangement is this:
  
  \[
  a = b + 1 \\
  a + 2
  \]

  Here, there are expressions on different lines, making it multiline, but the last line has no variable assigned to the output of `a + 2`.
- `inplace=True`, but the expression is missing item assignment.
- Item assignment is provided, but the `target` does not support string item assignment.
- Item assignment is provided and `inplace=False`, but the `target` does not support the `.copy()` method.

See also:

- `DataFrame.query` Evaluates a boolean expression to query the columns of a frame.
- `DataFrame.eval` Evaluate a string describing operations on DataFrame columns.

Notes

The `dtype` of any objects involved in an arithmetic `%` operation are recursively cast to `float64`.

See the *enhancing performance* documentation for more details.

Examples

```python
>>> df = pd.DataFrame({"animal": ["dog", "pig"], "age": [10, 20]})
>>> df
animal  age
0  dog  10
1  pig  20
```

We can add a new column using `pd.eval`:

```python
>>> pd.eval("double_age = df.age * 2", target=df)
animal  age  double_age
0  dog  10       20
1  pig  20       40
```
3.2.7 Hashing

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>util.hash_array(vals[, encoding, hash_key, ...])</code></td>
<td>Given a 1d array, return an array of deterministic integers.</td>
</tr>
<tr>
<td><code>util.hash_pandas_object(obj[, index, ...])</code></td>
<td>Return a data hash of the Index/Series/DataFrame.</td>
</tr>
</tbody>
</table>

pandas.util.hash_array

Given a 1d array, return an array of deterministic integers.

**Parameters**
- `vals` [ndarray or ExtensionArray]
- `encoding` [str, default 'utf8'] Encoding for data & key when strings.
- `hash_key` [str, default `_default_hash_key`] Hash_key for string key to encode.
- `categorize` [bool, default True] Whether to first categorize object arrays before hashing. This is more efficient when the array contains duplicate values.

**Returns**
- `ndarray[np.uint64, ndim=1]` Hashed values, same length as the vals.

pandas.util.hash_pandas_object

Return a data hash of the Index/Series/DataFrame.

**Parameters**
- `obj` [Index, Series, or DataFrame]
- `index` [bool, default True] Include the index in the hash (if Series/DataFrame).
- `encoding` [str, default ‘utf8’] Encoding for data & key when strings.
- `hash_key` [str, default `_default_hash_key`] Hash_key for string key to encode.
- `categorize` [bool, default True] Whether to first categorize object arrays before hashing. This is more efficient when the array contains duplicate values.

**Returns**
- Series of uint64, same length as the object
### 3.2.8 Testing

```python
test([extra_args])
```

`pandas.test`

`pandas.test(extra_args=None)`

### 3.3 Series

#### 3.3.1 Constructor

<table>
<thead>
<tr>
<th><strong>Series</strong>([data, index, dtype, name, copy, ...])</th>
<th>One-dimensional ndarray with axis labels (including time series).</th>
</tr>
</thead>
</table>

`pandas.Series`

```python
class pandas.Series(data=None, index=None, dtype=None, name=None, copy=False, fast-path=False)
```

One-dimensional ndarray with axis labels (including time series).

Labels need not be unique but must be a hashable type. The object supports both integer- and label-based indexing and provides a host of methods for performing operations involving the index. Statistical methods from ndarray have been overridden to automatically exclude missing data (currently represented as NaN).

Operations between Series (+, -, /, *) align values based on their associated index values— they need not be the same length. The result index will be the sorted union of the two indexes.

**Parameters**

- **data** [array-like, Iterable, dict, or scalar value] Contains data stored in Series. If data is a dict, argument order is maintained.

- **index** [array-like or Index (1d)] Values must be hashable and have the same length as data. Non-unique index values are allowed. Will default to RangeIndex (0, 1, 2, ..., n) if not provided. If data is dict-like and index is None, then the keys in the data are used as the index. If the index is not None, the resulting Series is reindexed with the index values.

- **dtype** [str, numpy.dtype, or ExtensionDtype, optional] Data type for the output Series. If not specified, this will be inferred from data. See the user guide for more usages.

- **name** [str, optional] The name to give to the Series.

- **copy** [bool, default False] Copy input data. Only affects Series or 1d ndarray input. See examples.
Examples

Constructing Series from a dictionary with an Index specified

```python
>>> d = {'a': 1, 'b': 2, 'c': 3}
>>> ser = pd.Series(data=d, index=['a', 'b', 'c'])
>>> ser
a 1
b 2
c 3
dtype: int64
```

The keys of the dictionary match with the Index values, hence the Index values have no effect.

```python
>>> d = {'a': 1, 'b': 2, 'c': 3}
>>> ser = pd.Series(data=d, index=['x', 'y', 'z'])
>>> ser
x NaN
y NaN
z NaN
dtype: float64
```

Note that the Index is first build with the keys from the dictionary. After this the Series is reindexed with the given Index values, hence we get all NaN as a result.

Constructing Series from a list with `copy=False`.

```python
>>> r = [1, 2]
>>> ser = pd.Series(r, copy=False)
>>> ser.iloc[0] = 999
>>> r
[1, 2]
>>> ser
0 999
1 2
dtype: int64
```

Due to input data type the Series has a `copy` of the original data even though `copy=False`, so the data is unchanged.

Constructing Series from a 1d ndarray with `copy=False`.

```python
>>> r = np.array([1, 2])
>>> ser = pd.Series(r, copy=False)
>>> r.iloc[0] = 999
>>> r
array([999, 2])
>>> ser
0 999
1 2
dtype: int64
```

Due to input data type the Series has a `view` on the original data, so the data is changed as well.
### Attributes

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>T</strong></td>
<td>Return the transpose, which is by definition self.</td>
</tr>
<tr>

<td><strong>shape</strong></td>
<td>Return a tuple of the shape of the underlying data.</td>
</tr>
<tr>
<td><strong>size</strong></td>
<td>Return the number of elements in the underlying data.</td>
</tr>
<tr>
<td><strong>values</strong></td>
<td>Return Series as ndarray or ndarray-like depending on the dtype.</td>
</tr>
</tbody>
</table>

#### pandas.Series.T

**property** `Series.T`

Return the transpose, which is by definition self.
pandas.Series.array

**property Series.array**
The ExtensionArray of the data backing this Series or Index.

**Returns**

ExtensionArray An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around numpy.ndarray.

differs .values which may require converting the data to a different form.

**See also:**

Index.to_numpy Similar method that always returns a NumPy array.
Series.to_numpy Similar method that always returns a NumPy array.

**Notes**

This table lays out the different array types for each extension dtype within pandas.

<table>
<thead>
<tr>
<th>dtype</th>
<th>array type</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>Categorical</td>
</tr>
<tr>
<td>period</td>
<td>PeriodArray</td>
</tr>
<tr>
<td>interval</td>
<td>IntervalArray</td>
</tr>
<tr>
<td>IntegerNA</td>
<td>IntegerArray</td>
</tr>
<tr>
<td>string</td>
<td>StringArray</td>
</tr>
<tr>
<td>boolean</td>
<td>BooleanArray</td>
</tr>
<tr>
<td>datetime64[ns, tz]</td>
<td>DatetimeArray</td>
</tr>
</tbody>
</table>

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes .array will be a arrays.NumpyExtensionArray wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use Series.to_numpy() instead.

**Examples**

For regular NumPy types like int, and float, a PandasArray is returned.

```python
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

For extension types, like Categorical, the actual ExtensionArray is returned

```python
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
['a', 'b', 'a']
Categories (2, object): ['a', 'b']
```
**pandas.Series.at**

**Property Series.at**

Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

**Raises**

`KeyError` If ‘label’ does not exist in DataFrame.

**See also:**

- `DataFrame.iat` Access a single value for a row/column pair by integer position.
- `DataFrame.loc` Access a group of rows and columns by label(s).
- `Series.at` Access a single value using a label.

**Examples**

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                    index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
   A  B  C
4  0  2  3
5  0  4  1
6 10 20 30
Get value at specified row/column pair

>>> df.at[4, 'B']
2
Set value at specified row/column pair

>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
Get value within a Series

>>> df.loc[5].at['B']
4
```

**pandas.Series.attrs**

**Property Series.attrs**

Dictionary of global attributes of this dataset.

**Warning:** attrs is experimental and may change without warning.

**See also:**
DataFrame.flags Global flags applying to this object.

pandas.Series.axes

property Series.axes
Return a list of the row axis labels.

pandas.Series.dtype

property Series.dtype
Return the dtype object of the underlying data.

pandas.Series.dtypes

property Series.dtypes
Return the dtype object of the underlying data.

pandas.Series.flags

property Series.flags
Get the properties associated with this pandas object.

The available flags are

- Flags.allows_duplicate_labels

See also:

Flags Flags that apply to pandas objects.

DataFrame.attrs Global metadata applying to this dataset.

Notes

“Flags” differ from “metadata”. Flags reflect properties of the pandas object (the Series or DataFrame). Metadata refer to properties of the dataset, and should be stored in DataFrame.attrs.

Examples

```python
>>> df = pd.DataFrame({"A": [1, 2]})
>>> df.flags
<Flags(allows_duplicate_labels=True)>
```

Flags can be get or set using .

```python
>>> df.flags.allows_duplicate_labels
True
>>> df.flags.allows_duplicate_labels = False
```

Or by slicing with a key
>>> df.flags["allows_duplicate_labels"]
False
>>> df.flags["allows_duplicate_labels"] = True

pandas.Series.hasnans

**property** Series.hasnans

Return if I have any nans; enables various perf speedups.

pandas.Series.iat

**property** Series.iat

Access a single value for a row/column pair by integer position.

Similar to `iloc`, in that both provide integer-based lookups. Use `iat` if you only need to get or set a single value in a DataFrame or Series.

**Raises**

`IndexError` When integer position is out of bounds.

**See also:**

*DataFrame.at* Access a single value for a row/column label pair.

*DataFrame.loc* Access a group of rows and columns by label(s).

*DataFrame.iloc* Access a group of rows and columns by integer position(s).

**Examples**

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
                      columns=['A', 'B', 'C'])

0   A   B   C
0  0   2   3
1  0   4   1
2 10  20  30
```

Get value at specified row/column pair

```python
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair

```python
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series

```python
>>> df.loc[0].iat[1]
2
```
pandas.Series.iloc

**property** Series.iloc

Purely integer-location based indexing for selection by position.

.iloc[] is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. [4, 3, 0].
- A slice object with ints, e.g. 1:7.
- A boolean array.
- A **callable** function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don’t have a reference to the calling object, but would like to base your selection on some value.

.iloc will raise IndexError if a requested indexer is out-of-bounds, except slice indexers which allow out-of-bounds indexing (this conforms with python/numpy slice semantics).

See more at *Selection by Position*.

See also:

- **DataFrame.iat** Fast integer location scalar accessor.
- **DataFrame.loc** Purely label-location based indexer for selection by label.
- **Series.iloc** Purely integer-location based indexing for selection by position.

**Examples**

```python
>>> mydict = [{'a': 1, 'b': 2, 'c': 3, 'd': 4},
            {'a': 100, 'b': 200, 'c': 300, 'd': 400},
            {'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000}]

>>> df = pd.DataFrame(mydict)
>>> df
          a     b     c     d
0     1  100  200  300  400
1  1000 2000 3000 4000

Indexing just the rows

With a scalar integer.

```python
>>> type(df.iloc[0])
<class 'pandas.core.series.Series'>

```python
>>> df.iloc[0]
a  1
b  2
c  3
d  4
Name: 0, dtype: int64
```

With a list of integers.
>>> df.iloc[[0]]
    a  b  c  d
0  1  2  3  4
>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>

>>> df.iloc[[0, 1]]
    a  b  c  d
0  1  2  3  4
1 100 200 300 400
With a slice object.

>>> df.iloc[:3]
    a  b  c  d
0  1  2  3  4
1 100 200 300 400
2 1000 2000 3000 4000
With a boolean mask the same length as the index.

>>> df.iloc[[True, False, True]]
    a  b  c  d
0  1  2  3  4
2 1000 2000 3000 4000
With a callable, useful in method chains. The x passed to the lambda is the DataFrame being sliced. This selects the rows whose index label even.

>>> df.iloc[lambda x: x.index % 2 == 0]
    a  b  c  d
0  1  2  3  4
2 1000 2000 3000 4000

Indexing both axes
You can mix the indexer types for the index and columns. Use : to select the entire axis.

With scalar integers.

>>> df.iloc[0, 1]
2
With lists of integers.

>>> df.iloc[[0, 2], [1, 3]]
    b  d
0  2  4
2 2000 4000
With slice objects.

>>> df.iloc[1:3, 0:3]
    a  b  c
1 100 200 300
2 1000 2000 3000
With a boolean array whose length matches the columns.
>>> df.iloc[:, [True, False, True, False]]
   a   c
0  1   3
1 100 300
2 1000 3000

With a callable function that expects the Series or DataFrame.

>>> df.iloc[:, lambda df: [0, 2]]
   a   c
0  1   3
1 100 300
2 1000 3000

**pandas.Series.index**

*Series.index: Index*

The index (axis labels) of the Series.

**pandas.Series.is_monotonic**

*property Series.is_monotonic*

Return boolean if values in the object are monotonic_increasing.

Returns

bool

**pandas.Series.is_monotonic_decreasing**

*property Series.is_monotonic_decreasing*

Return boolean if values in the object are monotonic_decreasing.

Returns

bool

**pandas.Series.is_monotonic_increasing**

*property Series.is_monotonic_increasing*

Alias for is_monotonic.
**pandas.Series.is_unique**

**property Series.is_unique**
Return boolean if values in the object are unique.

Returns

bool

**pandas.Series.loc**

**property Series.loc**
Access a group of rows and columns by label(s) or a boolean array.

.loc[] is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a label of the index, and **never** as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a':'f'.

**Warning:** Note that contrary to usual python slices, **both** the start and the stop are included

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- An alignable boolean Series. The index of the key will be aligned before masking.
- An alignable Index. The Index of the returned selection will be the input.
- A **callable** function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above)

See more at *Selection by Label*.

**Raises**

**KeyError** If any items are not found.

**IndexingError** If an indexed key is passed and its index is unalignable to the frame index.

**See also:**

- **DataFrame.at** Access a single value for a row/column label pair.
- **DataFrame.iloc** Access group of rows and columns by integer position(s).
- **DataFrame.xs** Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.
- **Series.loc** Access group of values using labels.
Examples

Getting values

```python
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
                    index=['cobra', 'viper', 'sidewinder'],
                    columns=['max_speed', 'shield'])
>>> df
       max_speed  shield
    cobra       1       2
    viper       4       5
   sidewinder   7       8

Single label. Note this returns the row as a Series.

```python
>>> df.loc['viper']
max_speed  4
shield    5
Name: viper, dtype: int64
```

List of labels. Note using `[]` returns a DataFrame.

```python
>>> df.loc[['viper', 'sidewinder']]
       max_speed  shield
    viper       4       5
   sidewinder   7       8
```

Single label for row and column

```python
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```python
>>> df.loc['cobra':'viper', 'max_speed']
    cobra 1
    viper 4
Name: max_speed, dtype: int64
```

Boolean list with the same length as the row axis

```python
>>> df.loc[[False, False, True]]
       max_speed  shield
   sidewinder   7       8
```

Alignable boolean Series:

```python
>>> df.loc[pd.Series([False, True, False],
                    index=['viper', 'sidewinder', 'cobra'])]
       max_speed  shield
   sidewinder   7       8
```

Index (same behavior as df.reindex)

```python
>>> df.loc[pd.Index(['cobra', 'viper'], name='foo')]
       max_speed  shield
    cobra       1       2
    viper       4       5
   sidewinder   7       8
```
foo
cobra   1   2
viper    4   5

Conditional that returns a boolean Series

```python
>>> df.loc[df['shield'] > 6]
max_speed shield
sidewinder 7   8
```

Conditional that returns a boolean Series with column labels specified

```python
>>> df.loc[df['shield'] > 6, ['max_speed']]
max_speed
sidewinder 7
```

Callable that returns a boolean Series

```python
>>> df.loc[lambda df: df['shield'] == 8]
max_speed shield
sidewinder 7   8
```

**Setting values**

Set value for all items matching the list of labels

```python
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
```

```python
def:
    max_speed shield
cobra    1   2
viper    4   50
sidewinder 7   50
```

Set value for an entire row

```python
>>> df.loc['cobra'] = 10
```

```python
def:
    max_speed shield
cobra    10  10
viper    4   50
sidewinder 7   50
```

Set value for an entire column

```python
>>> df.loc[:, 'max_speed'] = 30
```

```python
def:
    max_speed shield
cobra    30  10
viper    30  50
sidewinder 30  50
```

Set value for rows matching callable condition

```python
>>> df.loc[df['shield'] > 35] = 0
```

```python
def:
    max_speed shield
cobra    30  10
```
Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```python
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
                     index=[7, 8, 9], columns=['max_speed', 'shield'])
```

```python
>>> df
    max_speed  shield
   7          1  2
   8          4  5
   9          7  8
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```python
>>> df.loc[7:9]
    max_speed  shield
   7          1  2
   8          4  5
   9          7  8
```

Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```python
tuples = [  
    ('cobra', 'mark i'), ('cobra', 'mark ii'),  
    ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),  
    ('viper', 'mark ii'), ('viper', 'mark iii')  
]
```

```python
index = pd.MultiIndex.from_tuples(tuples)
```

```python
values = [[12, 2], [0, 4], [10, 20],
          [1, 4], [7, 1], [16, 36]]
```

```python
df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
```

```python
>>> df
    max_speed  shield
  cobra   mark i  12  2
      mark ii  0  4
  sidewinder   mark i 10  20
      mark ii  1  4
    viper   mark ii  7  1
           mark iii 16 36
```

Single label. Note this returns a DataFrame with a single index.

```python
>>> df.loc['cobra']
    max_speed  shield
   mark i  12  2
   mark ii  0  4
```

Single index tuple. Note this returns a Series.

```python
>>> df.loc[('cobra', 'mark ii')]
    max_speed
mark ii  0
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

(continued from previous page)

<table>
<thead>
<tr>
<th>shield</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name:</td>
<td>(cobra, mark ii), dtype: int64</td>
</tr>
</tbody>
</table>

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```python
>>> df.loc['cobra', 'mark i']
max_speed 12
shield 2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using [[]] returns a DataFrame.

```python
>>> df.loc[('cobra', 'mark ii')]
max_speed   shield
cobra mark ii 0    4
```

Single tuple for the index with a single label for the column

```python
>>> df.loc[('cobra', 'mark i'), 'shield']
2
```

Slice from index tuple to single label

```python
>>> df.loc[('cobra', 'mark i'):'viper']
max_speed   shield
cobra mark i 12    2
mark ii      0   4
sidewinder mark i 10  20
mark ii      1   4
viper mark ii 7   1
mark iii     16  36
```

Slice from index tuple to index tuple

```python
>>> df.loc[('cobra', 'mark i'):('viper', 'mark ii')]
max_speed   shield
cobra mark i 12    2
mark ii      0   4
sidewinder mark i 10  20
mark ii      1   4
viper mark ii 7   1
```

```
pandas.Series.name
```

**property** `Series.name`

Return the name of the Series.

The name of a Series becomes its index or column name if it is used to form a DataFrame. It is also used whenever displaying the Series using the interpreter.

**Returns**

- `label` *(hashable object)* The name of the Series, also the column name if part of a DataFrame.

**See also:**
**Series.rename** Sets the Series name when given a scalar input.

**Index.name** Corresponding Index property.

**Examples**

The Series name can be set initially when calling the constructor.

```python
>>> s = pd.Series([1, 2, 3], dtype=np.int64, name='Numbers')
>>> s
0   1
1   2
2   3
Name: Numbers, dtype: int64
>>> s.name = "Integers"
>>> s
0   1
1   2
2   3
Name: Integers, dtype: int64
```

The name of a Series within a DataFrame is its column name.

```python
>>> df = pd.DataFrame([[1, 2], [3, 4], [5, 6]],
                     columns=["Odd Numbers", "Even Numbers"])
>>> df
   Odd Numbers  Even Numbers
0         1        2
1         3        4
2         5        6
>>> df["Even Numbers"].name
'Even Numbers'
```

**pandas.Series.nbytes**

**property** Series.nbytes

Return the number of bytes in the underlying data.

**pandas.Series.ndim**

**property** Series.ndim

Number of dimensions of the underlying data, by definition 1.

**pandas.Series.shape**

**property** Series.shape

Return a tuple of the shape of the underlying data.
pandas.Series.size

property Series.size
Return the number of elements in the underlying data.

pandas.Series.values

property Series.values
Return Series as ndarray or ndarray-like depending on the dtype.

Warning: We recommend using Series.array or Series.to_numpy(), depending on whether you need a reference to the underlying data or a NumPy array.

Returns
numpy.ndarray or ndarray-like

See also:

Series.array Reference to the underlying data.
Series.to_numpy A NumPy array representing the underlying data.

Examples

>>> pd.Series([1, 2, 3]).values
array([1, 2, 3])

>>> pd.Series(list('aabc')).values
array(['a', 'a', 'b', 'c'], dtype=object)

>>> pd.Series(list('aabc')).astype('category').values
['a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']

Timezone aware datetime data is converted to UTC:

>>> pd.Series(pd.date_range('20130101', periods=3, tz='US/Eastern')).values
array(['2013-01-01T05:00:00.000000000',
   '2013-01-02T05:00:00.000000000',
   '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')
### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>abs()</td>
<td>Return a Series/DataFrame with absolute numeric value of each element.</td>
</tr>
<tr>
<td>add(other[, level, fill_value, axis])</td>
<td>Return Addition of series and other, element-wise (binary operator add).</td>
</tr>
<tr>
<td>add_prefix(prefix)</td>
<td>Prefix labels with string prefix.</td>
</tr>
<tr>
<td>add_suffix(suffix)</td>
<td>Suffix labels with string suffix.</td>
</tr>
<tr>
<td>agg([func, axis])</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>aggregate([func, axis])</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>align(other[, join, axis, level, copy, . . .])</td>
<td>Align two objects on their axes with the specified join method.</td>
</tr>
<tr>
<td>all([axis, bool_only, skipna, level])</td>
<td>Return whether all elements are True, potentially over an axis.</td>
</tr>
<tr>
<td>any([axis, bool_only, skipna, level])</td>
<td>Return whether any element is True, potentially over an axis.</td>
</tr>
<tr>
<td>append(to_append[, ignore_index, . . .])</td>
<td>Concatenate two or more Series.</td>
</tr>
<tr>
<td>apply(func[, convert_dtype, args])</td>
<td>Invoke function on values of Series.</td>
</tr>
<tr>
<td>argmax([axis, skipna])</td>
<td>Return int position of the largest value in the Series.</td>
</tr>
<tr>
<td>argmin([axis, skipna])</td>
<td>Return int position of the smallest value in the Series.</td>
</tr>
<tr>
<td>argsort([axis, kind, order])</td>
<td>Return the integer indices that would sort the Series values.</td>
</tr>
<tr>
<td>asfreq(freq[, method, how, normalize, . . .])</td>
<td>Convert time series to specified frequency.</td>
</tr>
<tr>
<td>asof(where[, subset])</td>
<td>Return the last row(s) without any NaNs before where.</td>
</tr>
<tr>
<td>asstr(dtype[, copy, errors])</td>
<td>Cast a pandas object to a specified dtype dtype.</td>
</tr>
<tr>
<td>at_time(time[, asof, axis])</td>
<td>Select values at particular time of day (e.g., 9:30AM).</td>
</tr>
<tr>
<td>autocorr([lag])</td>
<td>Compute the lag-N autocorrelation.</td>
</tr>
<tr>
<td>backfill([axis, inplace, limit, downcast])</td>
<td>Synonym for DataFrame.fillna() with method='bfill'.</td>
</tr>
<tr>
<td>between(left, right[, inclusive])</td>
<td>Return boolean Series equivalent to left &lt;= series &lt;= right.</td>
</tr>
<tr>
<td>between_time(start_time, end_time[, . . .])</td>
<td>Select values between particular times of the day (e.g., 9:00-9:30 AM).</td>
</tr>
<tr>
<td>bfill([axis, inplace, limit, downcast])</td>
<td>Synonym for DataFrame.fillna() with method='bfill'.</td>
</tr>
<tr>
<td>bool()</td>
<td>Return the bool of a single element Series or DataFrame.</td>
</tr>
<tr>
<td>cat</td>
<td>alias of pandas.core.arrays.categorical.CategoricalAccessor</td>
</tr>
<tr>
<td>clip([lower, upper, axis, inplace])</td>
<td>Trim values at input threshold(s).</td>
</tr>
<tr>
<td>combine(other, func[, fill_value])</td>
<td>Combine the Series with a Series or scalar according to func.</td>
</tr>
<tr>
<td>combine_first(other)</td>
<td>Update null elements with value in the same location in ‘other’.</td>
</tr>
<tr>
<td>compare(other[, align_axis, keep_shape, . . .])</td>
<td>Compare to another Series and show the differences.</td>
</tr>
<tr>
<td>convert_dtypes([infer_objects, . . .])</td>
<td>Convert columns to best possible dtypes using dtypes supporting pd.NA.</td>
</tr>
</tbody>
</table>

### Table 34 – continued from previous page

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>copy([deep])</code></td>
<td>Make a copy of this object’s indices and data.</td>
</tr>
<tr>
<td><code>corr(other[, method, min_periods])</code></td>
<td>Compute correlation with other Series, excluding missing values.</td>
</tr>
<tr>
<td><code>count([level])</code></td>
<td>Return number of non-NA/null observations in the Series.</td>
</tr>
<tr>
<td><code>cov(other[, min_periods, ddof])</code></td>
<td>Compute covariance with Series, excluding missing values.</td>
</tr>
<tr>
<td><code>cummax([axis, skipna])</code></td>
<td>Return cumulative maximum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>cummin([axis, skipna])</code></td>
<td>Return cumulative minimum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>cumprod([axis, skipna])</code></td>
<td>Return cumulative product over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>cumsum([axis, skipna])</code></td>
<td>Return cumulative sum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>describe([percentiles, include, exclude, ...])</code></td>
<td>Generate descriptive statistics.</td>
</tr>
<tr>
<td><code>diff([periods])</code></td>
<td>First discrete difference of element.</td>
</tr>
<tr>
<td><code>div(other[, level, fill_value, axis])</code></td>
<td>Return Floating division of series and other, element-wise (binary operator <code>truediv</code>).</td>
</tr>
<tr>
<td><code>divide(other[, level, fill_value, axis])</code></td>
<td>Return Floating division of series and other, element-wise (binary operator <code>truediv</code>).</td>
</tr>
<tr>
<td><code>divmod(other[, level, fill_value, axis])</code></td>
<td>Return Integer division and modulo of series and other, element-wise (binary operator <code>divmod</code>).</td>
</tr>
<tr>
<td><code>dot(other)</code></td>
<td>Compute the dot product between the Series and the columns of other.</td>
</tr>
<tr>
<td><code>drop([labels, axis, index, columns, level, ...])</code></td>
<td>Return Series with specified index labels removed.</td>
</tr>
<tr>
<td><code>drop_duplicates([keep, inplace])</code></td>
<td>Return Series with duplicate values removed.</td>
</tr>
<tr>
<td><code>droplevel([level[, axis]])</code></td>
<td>Return Series/DataFrame with requested index / column level(s) removed.</td>
</tr>
<tr>
<td><code>dropna([axis, inplace, how])</code></td>
<td>Return a new Series with missing values removed.</td>
</tr>
<tr>
<td><code>dt</code></td>
<td>alias of pandas.core.indexes.accessors. CombinedDatetimelikeProperties</td>
</tr>
<tr>
<td><code>duplicated([keep])</code></td>
<td>Indicate duplicate Series values.</td>
</tr>
<tr>
<td><code>eq(other[, level, fill_value, axis])</code></td>
<td>Return Equal to of series and other, element-wise (binary operator <code>eq</code>).</td>
</tr>
<tr>
<td><code>equals(other)</code></td>
<td>Test whether two objects contain the same elements.</td>
</tr>
<tr>
<td><code>ewm([com, span, halflife, alpha, ...])</code></td>
<td>Provide exponential weighted (EW) functions.</td>
</tr>
<tr>
<td><code>expanding([min_periods, center, axis, method])</code></td>
<td>Provide expanding transformations.</td>
</tr>
<tr>
<td><code>explode([ignore_index])</code></td>
<td>Transform each element of a list-like to a row.</td>
</tr>
<tr>
<td><code>factorize([sort, na_sentinel])</code></td>
<td>Encode the object as an enumerated type or categorical variable.</td>
</tr>
<tr>
<td><code>ffill([axis, inplace, limit, downcast])</code></td>
<td>Synonym for DataFrame.fillna() with method='ffill'.</td>
</tr>
<tr>
<td><code>fillna(value, method, axis, inplace, ...)</code></td>
<td>Fill NA/NaN values using the specified method.</td>
</tr>
<tr>
<td><code>filter([items, like, regex, axis])</code></td>
<td>Subset the dataframe rows or columns according to the specified index labels.</td>
</tr>
<tr>
<td><code>first(offset)</code></td>
<td>Select initial periods of time series data based on a date offset.</td>
</tr>
<tr>
<td><code>first_valid_index()</code></td>
<td>Return index for first non-NA value or None, if no NA value is found.</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------</td>

<td>Return the row label of the maximum value.</td>
</tr>
<tr>
<td>idamin</td>
<td>Return the row label of the minimum value.</td>
</tr>
<tr>
<td>infer_objects</td>
<td>Attempt to infer better dtypes for object columns.</td>
</tr>
<tr>
<td>isin</td>
<td>Whether elements in Series are contained in <code>values</code>.</td>
</tr>
<tr>
<td>isnan</td>
<td>Detect missing values.</td>
</tr>
<tr>
<td>isnull</td>
<td>Detect missing values.</td>
</tr>
<tr>
<td>item</td>
<td>Return the first element of the underlying data as a Python scalar.</td>
</tr>
<tr>
<td>items</td>
<td>Lazily iterate over (index, value) tuples.</td>
</tr>
<tr>
<td>iteritems</td>
<td>Lazily iterate over (index, value) tuples.</td>
</tr>
<tr>
<td>keys</td>
<td>Return alias for index.</td>
</tr>
<tr>
<td>kurt</td>
<td>Return unbiased kurtosis over requested axis.</td>
</tr>
<tr>
<td>kurtosis</td>
<td>Return unbiased kurtosis over requested axis.</td>
</tr>
<tr>
<td>last</td>
<td>Select final periods of time series data based on a date offset.</td>
</tr>
<tr>
<td>last_valid_index</td>
<td>Return index for last non-NA value or None, if no NA value is found.</td>
</tr>
<tr>
<td>le</td>
<td>Return Less than or equal to of series and other, element-wise (binary operator <code>le</code>).</td>
</tr>
<tr>
<td>lt</td>
<td>Return Less than of series and other, element-wise (binary operator <code>lt</code>).</td>
</tr>
<tr>
<td>mad</td>
<td>Return the mean absolute deviation of the values over the requested axis.</td>
</tr>
<tr>
<td>map</td>
<td>Map values of Series according to input correspondence.</td>
</tr>
<tr>
<td>mask</td>
<td>Replace values where the condition is True.</td>
</tr>
<tr>
<td>max</td>
<td>Return the maximum of the values over the requested axis.</td>
</tr>
<tr>
<td>mean</td>
<td>Return the mean of the values over the requested axis.</td>
</tr>
<tr>
<td>median</td>
<td>Return the median of the values over the requested axis.</td>
</tr>
<tr>
<td>memory_usage</td>
<td>Return the memory usage of the Series.</td>
</tr>
<tr>
<td>min</td>
<td>Return the minimum of the values over the requested axis.</td>
</tr>
<tr>
<td>mod</td>
<td>Return Modulo of series and other, element-wise (binary operator <code>mod</code>).</td>
</tr>
<tr>
<td>mode</td>
<td>Return the mode(s) of the Series.</td>
</tr>
</tbody>

<td><code>notna</code></td>
<td>Detect existing (non-missing) values.</td>
</tr>
<tr>
<td><code>notnull</code></td>
<td>Detect existing (non-missing) values.</td>
</tr>
<tr>
<td><code>nunique</code></td>
<td>Return number of unique elements in the object.</td>
</tr>
<tr>
<td><code>pad</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with method='ffill'.</td>
</tr>
<tr>
<td><code>pct_change</code></td>
<td>Percentage change between the current and a prior element.</td>
</tr>
<tr>
<td><code>pipe</code></td>
<td>Apply <code>func(self, *args, **kwargs)</code>.</td>
</tr>
<tr>
<td><code>plot</code></td>
<td>Alias of <code>pandas.plotting._core.PlotAccessor</code>.</td>
</tr>
<tr>
<td><code>pop</code></td>
<td>Return item and drops from series.</td>
</tr>
<tr>
<td><code>pow</code></td>
<td>Return Exponential power of series and other, element-wise (binary operator <code>pow</code>).</td>
</tr>
<tr>
<td><code>prod</code></td>
<td>Return the product of the values over the requested axis.</td>
</tr>
<tr>
<td><code>product</code></td>
<td>Return the product of the values over the requested axis.</td>
</tr>
<tr>
<td><code>quantile</code></td>
<td>Return value at the given quantile.</td>
</tr>
<tr>
<td><code>radd</code></td>
<td>Return Addition of series and other, element-wise (binary operator <code>radd</code>).</td>
</tr>
<tr>
<td><code>rank</code></td>
<td>Compute numerical data ranks (1 through n) along axis.</td>
</tr>
<tr>
<td><code>ravel</code></td>
<td>Return the flattened underlying data as an ndarray.</td>
</tr>
<tr>
<td><code>rdiv</code></td>
<td>Return Floating division of series and other, element-wise (binary operator <code>rdiv</code>).</td>
</tr>
<tr>
<td><code>rdivmod</code></td>
<td>Return Integer division and modulo of series and other, element-wise (binary operator <code>rdivmod</code>).</td>
</tr>
<tr>
<td><code>reindex</code></td>
<td>Conform Series to new index with optional filling logic.</td>
</tr>
<tr>
<td><code>reindex_like</code></td>
<td>Return an object with matching indices as other object.</td>
</tr>
<tr>
<td><code>rename</code></td>
<td>Alter Series index labels or name.</td>
</tr>
<tr>
<td><code>rename_axis</code></td>
<td>Set the name of the axis for the index or columns.</td>
</tr>
<tr>
<td><code>reorder_levels</code></td>
<td>Rearrange index levels using input order.</td>
</tr>
<tr>
<td><code>repeat</code></td>
<td>Repeat elements of a Series.</td>
</tr>
<tr>
<td><code>replace</code></td>
<td>Replace values given in <code>to_replace</code> with <code>value</code>.</td>
</tr>
<tr>
<td><code>resample</code></td>
<td>Resample time-series data.</td>
</tr>
<tr>
<td><code>reset_index</code></td>
<td>Generate a new DataFrame or Series with the index reset.</td>
</tr>
<tr>
<td><code>rfloordiv</code></td>
<td>Return Integer division of series and other, element-wise (binary operator <code>rfloordiv</code>).</td>

<tr>
<td><code>rmod</code></td>
<td>Return Modulo of series and other, element-wise (binary operator <code>rmod</code>).</td>
</tr>
<tr>
<td><code>rmul</code></td>
<td>Return Multiplication of series and other, element-wise (binary operator <code>rmul</code>).</td>
</tr>
<tr>
<td><code>rolling</code></td>
<td>Provide rolling window calculations.</td>
</tr>
<tr>
<td><code>round</code></td>
<td>Round each value in a Series to the given number of decimals.</td>
</tr>
<tr>
<td><code>rpow</code></td>
<td>Return Exponential power of series and other, element-wise (binary operator <code>rpow</code>).</td>
</tr>
<tr>
<td><code>rsub</code></td>
<td>Return Subtraction of series and other, element-wise (binary operator <code>rsub</code>).</td>
</tr>
<tr>
<td><code>rtruediv</code></td>
<td>Return Floating division of series and other, element-wise (binary operator <code>rtruediv</code>).</td>
</tr>
<tr>
<td><code>sample</code></td>
<td>Return a random sample of items from an axis of object.</td>
</tr>
<tr>
<td><code>searchsorted</code></td>
<td>Find indices where elements should be inserted to maintain order.</td>
</tr>
<tr>
<td><code>sem</code></td>
<td>Return unbiased standard error of the mean over requested axis.</td>
</tr>
<tr>
<td><code>set_axis</code></td>
<td>Assign desired index to given axis.</td>
</tr>
<tr>
<td><code>set_flags</code></td>
<td>Return a new object with updated flags.</td>
</tr>
<tr>
<td><code>shift</code></td>
<td>Shift index by desired number of periods with an optional time <code>freq</code>.</td>
</tr>
<tr>
<td><code>skew</code></td>
<td>Return unbiased skew over requested axis.</td>
</tr>
<tr>
<td><code>slice_shift</code></td>
<td>(DEPRECATED) Equivalent to <code>shift</code> without copying data.</td>
</tr>
<tr>
<td><code>sort_index</code></td>
<td>Sort Series by index labels.</td>
</tr>
<tr>
<td><code>sort_values</code></td>
<td>Sort by the values.</td>
</tr>
<tr>
<td><code>squeeze</code></td>
<td>Squeeze 1 dimensional axis objects into scalars.</td>
</tr>
<tr>
<td><code>std</code></td>
<td>Return sample standard deviation over requested axis.</td>
</tr>
<tr>
<td><code>str</code></td>
<td>Alias of pandas.core.strings.accessor.StringMethods</td>
</tr>
<tr>
<td><code>sub</code></td>
<td>Return Subtraction of series and other, element-wise (binary operator <code>sub</code>).</td>
</tr>
<tr>
<td><code>subtract</code></td>
<td>Return Subtraction of series and other, element-wise (binary operator <code>subtract</code>).</td>
</tr>
<tr>
<td><code>sum</code></td>
<td>Return the sum of the values over the requested axis.</td>
</tr>
<tr>
<td><code>swapaxes</code></td>
<td>Interchange axes and swap values axes appropriately.</td>
</tr>
<tr>
<td><code>swaplevel</code></td>
<td>Swap levels i and j in a <code>Multiindex</code>.</td>
</tr>
<tr>
<td><code>tail</code></td>
<td>Return the last n rows.</td>
</tr>
<tr>
<td><code>take</code></td>
<td>Return the elements in the given <code>positional</code> indices along an axis.</td>
</tr>
<tr>
<td><code>to_clipboard</code></td>
<td>Copy object to the system clipboard.</td>
</tr>
<tr>
<td><code>to_csv</code></td>
<td>Write object to a comma-separated values (csv) file.</td>
</tr>
<tr>
<td><code>to_dict</code></td>
<td>Convert Series to {label -&gt; value} dict or dict-like object.</td>
</tr>
<tr>
<td><code>to_excel</code></td>
<td>Write object to an Excel sheet.</td>
</tr>

<td><code>xs(key[, axis, level, drop_level])</code></td>
<td>Return cross-section from the Series/DataFrame.</td>
</tr>
</tbody>
</table>
pandas.Series.abs

Series.abs()

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

Returns

abs  Series/DataFrame containing the absolute value of each element.

See also:

numpy.absolute  Calculate the absolute value element-wise.

Notes

For complex inputs, 1.2 + 1j, the absolute value is $\sqrt{a^2 + b^2}$.

Examples

Absolute numeric values in a Series.

```python
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1    2.00
2    3.33
3    4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```python
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```python
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0    1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using argsort (from StackOverflow).

```python
>>> df = pd.DataFrame(
...     ...
...     'a': [4, 5, 6, 7],
...     'b': [10, 20, 30, 40],
...     'c': [100, 50, -30, -50]
...     ...
... )
>>> df
   a  b  c
0  4  10 100
1  5  20  50
(continues on next page)
pandas.Series.add

Series.add(other, level=None, fill_value=None, axis=0)

Return Addition of series and other, element-wise (binary operator add).

Equivalent to series + other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

- other [Series or scalar value]
- fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

- Series.radd Reverse of the Addition operator, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d  NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b  NaN
c    1.0
d    1.0
e  NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
```

(continues on next page)
pandas.Series.add_prefix

Series.add_prefix(prefix)

Prefix labels with string prefix.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

Parameters

prefix [str] The string to add before each label.

Returns

Series or DataFrame New Series or DataFrame with updated labels.

See also:

Series.add_suffix Suffix row labels with string suffix.

DataFrame.add_suffix Suffix column labels with string suffix.

Examples

```python
c1.0
c1.0
d1.0
eNaN
dtype: float64

>>> s = pd.Series([1, 2, 3, 4])
>>> s
0 1
1 2
2 3
3 4
dtype: int64

>>> s.add_prefix('item_')
item_0 1
item_1 2
item_2 3
item_3 4
dtype: int64

>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0 1  3
1 2  4
2 3  5
3 4  6

>>> df.add_prefix('col_')
   col_A  col_B
0     1     3
1     2     4
2     3     5
3     4     6
```
pandas.Series.add_suffix

Series.add_suffix(suffix)
Suffix labels with string suffix.
For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

Parameters

suffix [str] The string to add after each label.

Returns

Series or DataFrame New Series or DataFrame with updated labels.

See also:

Series.add_prefix Prefix row labels with string prefix.
DataFrame.add_prefix Prefix column labels with string prefix.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0   1
1   2
2   3
3   4
dtype: int64

>>> s.add_suffix('_item')
0_item 1
1_item 2
2_item 3
3_item 4
dtype: int64

>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6

>>> df.add_suffix('_col')
    A_col  B_col
0     1     3
(continues on next page)```
pandas.Series.agg

Series.agg (func=None, axis=0, *args, **kwargs)
Aggregate using one or more operations over the specified axis.

Parameters

func  [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.

Accepted combinations are:
• function
• string function name
• list of functions and/or function names, e.g. [np.sum, 'mean']
• dict of axis labels -> functions, function names or list of such.

axis  [[0 or ‘index’]] Parameter needed for compatibility with DataFrame.

*args  Positional arguments to pass to func.

**kwargs  Keyword arguments to pass to func.

Returns

scalar, Series or DataFrame  The return can be:
• scalar : when Series.agg is called with single function
• Series : when DataFrame.agg is called with a single function
• DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

Series.apply  Invoke function on a Series.

Series.transform  Transform function producing a Series with like indexes.

Notes

agg is an alias for aggregate. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

A passed user-defined-function will be passed a Series for evaluation.
### Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64

>>> s.agg('min')
1

>>> s.agg(['min', 'max'])
min     1
max     4
dtype: int64
```

### pandas.Series.aggregate

`Series.aggregate(func=None, axis=0, *args, **kwargs)`

Aggregate using one or more operations over the specified axis.

**Parameters**

- **func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.
  
  Accepted combinations are:
  
  - function
  - string function name
  - list of functions and/or function names, e.g. `[np.sum, 'mean']`
  - dict of axis labels -> functions, function names or list of such.

- **axis** [{0 or ‘index’}] Parameter needed for compatibility with DataFrame.

- **args** Positional arguments to pass to `func`.

- **kwargs** Keyword arguments to pass to `func`.

**Returns**

- scalar, Series or DataFrame The return can be:
  
  - scalar : when Series.agg is called with single function
  - Series : when DataFrame.agg is called with a single function
  - DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

**See also:**

- `Series.apply` Invoke function on a Series.
- `Series.transform` Transform function producing a Series with like indexes.
Notes

`agg` is an alias for `aggregate`. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0   1
1   2
2   3
3   4
dtype: int64

>>> s.agg('min')
1

>>> s.agg(['min', 'max'])
min 1
max 4
dtype: int64
```

`pandas.Series.align`

Series.**align**(other, join='outer', axis=None, level=None, copy=True, fill_value=None, method=None, limit=None, fill_axis=0, broadcast_axis=None)

Align two objects on their axes with the specified join method.

Join method is specified for each axis Index.

Parameters

- `other` [DataFrame or Series]
- `join` [‘outer’, ‘inner’, ‘left’, ‘right’], default ‘outer’
- `axis` [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None).
- `level` [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level.
- `copy` [bool, default True] Always returns new objects. If `copy=False` and no reindexing is required then original objects are returned.
- `fill_value` [scalar, default NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.
- `method` [‘backfill’, ‘bfill’, ‘pad’, ‘ffill’, None], default None] Method to use for filling holes in reindexed Series:
  - pad / ffill: propagate last valid observation forward to next valid.
  - backfill / bfill: use NEXT valid observation to fill gap.
**limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

**fill_axis** [{0 or ‘index’}, default 0] Filling axis, method and limit.

**broadcast_axis** [{0 or ‘index’}, default None] Broadcast values along this axis, if aligning two objects of different dimensions.

Returns

(left, right) [(Series, type of other)] Aligned objects.

### pandas.Series.all

**Series.all** (axis=0, bool_only=None, skipna=True, level=None, **kwargs)

Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

#### Parameters

**axis** [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Indicate which axis or axes should be reduced.

- 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
- 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

**bool_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

**skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

#### Returns

scalar or Series If level is specified, then, Series is returned; otherwise, scalar is returned.

#### See also:

**Series.all** Return True if all elements are True.

**DataFrame.any** Return True if one (or more) elements are True.
Examples

Series

```python
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([], dtype="float64").all()
True
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

DataFrames

Create a dataframe from a dictionary.

```python
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
   col1  col2
0   True  True
1   True  False
```

Default behaviour checks if column-wise values all return True.

```python
>>> df.all()
   col1  col2
0   True  True
dtype: bool
```

Specify `axis='columns'` to check if row-wise values all return True.

```python
>>> df.all(axis='columns')
0   True
1   False
dtype: bool
```

Or `axis=None` for whether every value is True.

```python
>>> df.all(axis=None)
False
```

**pandas.Series.any**

Series.any (axis=0, bool_only=None, skipna=True, level=None, **kwargs)

Return whether any element is True, potentially over an axis.

Returns False unless there is at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

Parameters

- **axis** [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Indicate which axis or axes should be reduced.
  - 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
• 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
• None : reduce all axes, return a scalar.

bool_only [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

skipna [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**kwargs [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series  If level is specified, then, Series is returned; otherwise, scalar is returned.

See also:

numpy.any  Numpy version of this method.
Series.any  Return whether any element is True.
Series.all  Return whether all elements are True.
DataFrame.any  Return whether any element is True over requested axis.
DataFrame.all  Return whether all elements are True over requested axis.

Examples

Series

For Series input, the output is a scalar indicating whether any element is True.

```
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([], dtype="float64").any()
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True
```

DataFrame

Whether each column contains at least one True element (the default).

```
>>> df = pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
>>> df
   A  B  C
0  1  0  0
1  2  2  0
```
Aggregating over the columns.

```python
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
   A  B
0  True 1
1  False 2

>>> df.any(axis='columns')
0  True
1  True
dtype: bool
```

```python
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})
>>> df
   A  B
0  True 1
1  False 0

>>> df.any(axis='columns')
0  True
1  False
dtype: bool
```

Aggregating over the entire DataFrame with axis=None.

```python
>>> df.any(axis=None)
True
```

`any` for an empty DataFrame is an empty Series.

```python
>>> pd.DataFrame([]).any()
Series([], dtype: bool)
```

### pandas.Series.append

`Series.append` *(to_append, ignore_index=False, verify_integrity=False)*

Concatenate two or more Series.

**Parameters**

- **to_append** [Series or list/tuple of Series] Series to append with self.
- **ignore_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.
- **verify_integrity** [bool, default False] If True, raise Exception on creating index with duplicates.

**Returns**

- **Series** Concatenated Series.
See also:

**concat** General function to concatenate DataFrame or Series objects.

**Notes**

Iteratively appending to a Series can be more computationally intensive than a single concatenate. A better solution is to append values to a list and then concatenate the list with the original Series all at once.

**Examples**

```python
>>> s1 = pd.Series([1, 2, 3])
>>> s2 = pd.Series([4, 5, 6])
>>> s3 = pd.Series([4, 5, 6], index=[3, 4, 5])
>>> s1.append(s2)
0  1
1  2
2  3
0  4
1  5
2  6
dtype: int64

>>> s1.append(s3)
0  1
1  2
2  3
3  4
4  5
5  6
dtype: int64

With **ignore_index** set to True:

```python
>>> s1.append(s2, ignore_index=True)
0  1
1  2
2  3
3  4
4  5
5  6
dtype: int64
```

With **verify_integrity** set to True:

```python
>>> s1.append(s2, verify_integrity=True)
Traceback (most recent call last):
...
ValueError: Indexes have overlapping values: [0, 1, 2]
```
pandas.Series.apply

Series.apply (func, convert_dtype=True, args=(), **kwargs)
Invoke function on values of Series.
Can be ufunc (a NumPy function that applies to the entire Series) or a Python function that only works on single values.

Parameters

func [function] Python function or NumPy ufunc to apply.
convert_dtype [bool, default True] Try to find better dtype for elementwise function results.
If False, leave as dtype=object. Note that the dtype is always preserved for some extension array dtypes, such as Categorical.
args [tuple] Positional arguments passed to func after the series value.
**kwargs Additional keyword arguments passed to func.

Returns

Series or DataFrame If func returns a Series object the result will be a DataFrame.

See also:
Series.map For element-wise operations.
Series.agg Only perform aggregating type operations.
Series.transform Only perform transforming type operations.

Notes

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

Examples

Create a series with typical summer temperatures for each city.

```python
g <!-- 2013 -->
>>> s = pd.Series([20, 21, 12],
...                   index=['London', 'New York', 'Helsinki'])
>>> s
London 20
New York 21
Helsinki 12
dtype: int64
```

Square the values by defining a function and passing it as an argument to apply().

```python
g <!-- 2013 -->
>>> def square(x):
...         return x ** 2
>>> s.apply(square)
London 400
New York 441
Helsinki 144
dtype: int64
```
Square the values by passing an anonymous function as an argument to `apply()`.

```python
>>> s.apply(lambda x: x ** 2)
London  400
New York 441
Helsinki 144
dtype: int64
```

Define a custom function that needs additional positional arguments and pass these additional arguments using the `args` keyword.

```python
>>> def subtract_custom_value(x, custom_value):
...     return x - custom_value

>>> s.apply(subtract_custom_value, args=(5,))
London  15
New York 16
Helsinki  7
dtype: int64
```

Define a custom function that takes keyword arguments and pass these arguments to `apply`.

```python
>>> def add_custom_values(x, **kwargs):
...     for month in kwargs:
...         x += kwargs[month]
...     return x

>>> s.apply(add_custom_values, june=30, july=20, august=25)
London  95
New York 96
Helsinki 87
dtype: int64
```

Use a function from the Numpy library.

```python
>>> s.apply(np.log)
London  2.995732
New York 3.044522
Helsinki 2.484907
dtype: float64
```

**pandas.Series.argmax**

`Series.argmax(axis=None, skipna=True, *args, **kwargs)`

Return int position of the largest value in the Series.

If the maximum is achieved in multiple locations, the first row position is returned.

**Parameters**

- `axis` ([None]) Dummy argument for consistency with Series.
- `skipna` [bool, default True] Exclude NA/null values when showing the result.
- `*args, **kwargs` Additional arguments and keywords for compatibility with NumPy.

**Returns**
**pandas**: powerful Python data analysis toolkit, Release 1.3.1

int Row position of the maximum value.

See also:

*Series.argmax* Return position of the maximum value.

*Series.argmin* Return position of the minimum value.

*numpy.ndarray.argmax* Equivalent method for numpy arrays.

*Series.idxmax* Return index label of the maximum values.

*Series.idxmin* Return index label of the minimum values.

**Examples**

Consider dataset containing cereal calories

```
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,
...                  'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
```

```
>>> s
Corn Flakes     100.0
Almond Delight  110.0
Cinnamon Toast Crunch  120.0
Cocoa Puff      110.0
dtype: float64
```

```
>>> s.argmax()
2
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.

**pandas.Series.argmin**

*Series.argmin*(axis=None, skipna=True, *args, **kwargs)

Return int position of the smallest value in the Series.

If the minimum is achieved in multiple locations, the first row position is returned.

Parameters

- **axis** [{None}] Dummy argument for consistency with Series.
- **skipna** [bool, default True] Exclude NA/null values when showing the result.
- ***args, **kwargs** Additional arguments and keywords for compatibility with NumPy.

Returns

int Row position of the minimum value.

See also:

*Series.argmin* Return position of the minimum value.

*Series.argmax* Return position of the maximum value.

*numpy.ndarray.argmin* Equivalent method for numpy arrays.
Series.idxmax  Return index label of the maximum values.
Series.idxmin  Return index label of the minimum values.

Examples

Consider dataset containing cereal calories

```python
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0, ...
                 'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
>>> s
Corn Flakes    100.0
Almond Delight 110.0
Cinnamon Toast Crunch  120.0
Cocoa Puff    110.0
dtype: float64
```

```python
>>> s.argmax()
2
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.

pandas.Series.argsort

Series.argsort (axis=0, kind='quicksort', order=None)

Return the integer indices that would sort the Series values.

Override ndarray.argsort. Argsorts the value, omitting NA/null values, and places the result in the same locations as the non-NA values.

Parameters

- axis  [{0 or “index”}] Has no effect but is accepted for compatibility with numpy.
- kind  [{‘mergesort’, ‘quicksort’, ‘heapsort’, ‘stable’}, default ‘quicksort’] Choice of sorting algorithm. See numpy.sort() for more information. ‘mergesort’ and ‘stable’ are the only stable algorithms.
- order  [None] Has no effect but is accepted for compatibility with numpy.

Returns

- Series[np.intp] Positions of values within the sort order with -1 indicating nan values.

See also:

numpy.ndarray.argsort  Returns the indices that would sort this array.
pandas.Series.asfreq

Series.asfreq(freq=\text{None}, method=\text{None}, how=\text{None}, normalize=\text{False}, fill_value=\text{None})

Convert time series to specified frequency.

Returns the original data conformed to a new index with the specified frequency.

If the index of this Series is a PeriodIndex, the new index is the result of transforming the original index with PeriodIndex.asfreq (so the original index will map one-to-one to the new index).

Otherwise, the new index will be equivalent to pd.date_range(start, end, freq=freq) where start and end are, respectively, the first and last entries in the original index (see pandas.date_range()). The values corresponding to any timesteps in the new index which were not present in the original index will be null (NaN), unless a method for filling such unknowns is provided (see the method parameter below).

The resample() method is more appropriate if an operation on each group of timesteps (such as an aggregate) is necessary to represent the data at the new frequency.

Parameters

freq [DateOffset or str] Frequency DateOffset or string.
method [{'backfill'/'bfill', 'pad'/'ffill'}, default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):

• 'pad' / 'fill': propagate last valid observation forward to next valid
• 'backfill' / 'bfill': use NEXT valid observation to fill.
how [{'start', 'end'}, default end] For PeriodIndex only (see PeriodIndex.asfreq).
normalize [bool, default False] Whether to reset output index to midnight.
fill_value [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

Returns

Series Series object reindexed to the specified frequency.

See also:

reindex Conform DataFrame to new index with optional filling logic.

Notes

To learn more about the frequency strings, please see this link.

Examples

Start by creating a series with 4 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s': series})
>>> df
     s
2000-01-01  00:00:00  0.0
2000-01-01  00:01:00  NaN
```
Upsample the series into 30 second bins.

```python
>>> df.asfreq(freq='30S')

2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  NaN
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  NaN
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  NaN
2000-01-01 00:03:00  3.0
```

Upsample again, providing a `fill` value.

```python
>>> df.asfreq(freq='30S', fill_value=9.0)

2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  9.0
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  9.0
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  9.0
2000-01-01 00:03:00  3.0
```

Upsample again, providing a `method`.

```python
>>> df.asfreq(freq='30S', method='bfill')

2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  NaN
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  2.0
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  3.0
2000-01-01 00:03:00  3.0
```

**pandas.Series.asof**

```python
Series.asof( where, subset=None)
```

Return the last row(s) without any NaNs before `where`.

The last row (for each element in `where`, if list) without any NaN is taken. In case of a `DataFrame`, the last row without NaN considering only the subset of columns (if not `None`)

If there is no good value, NaN is returned for a Series or a Series of NaN values for a DataFrame

**Parameters**

- **where** [date or array-like of dates] Date(s) before which the last row(s) are returned.
- **subset** [str or array-like of str, default `None`] For DataFrame, if not `None`, only use these columns to check for NaNs.

**Returns**
scalar, Series, or DataFrame  The return can be:

- scalar : when self is a Series and where is a scalar
- Series: when self is a Series and where is an array-like, or when self is a DataFrame and where is a scalar
- DataFrame : when self is a DataFrame and where is an array-like

Return scalar, Series, or DataFrame.

See also:

merge_asof  Perform an asof merge. Similar to left join.

Notes

Dates are assumed to be sorted. Raises if this is not the case.

Examples

A Series and a scalar where.

```python
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10  1.0
20  2.0
30  NaN
40  4.0
dtype: float64
```

```python
>>> s.asof(20)
2.0
```

For a sequence where, a Series is returned. The first value is NaN, because the first element of where is before the first index value.

```python
>>> s.asof([5, 20])
5   NaN
20  2.0
dtype: float64
```

Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

```python
>>> s.asof(30)
2.0
```

Take all columns into consideration

```python
>>> df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
...                     'b': [None, None, None, None, 500],
...                     index=pd.DatetimeIndex(['2018-02-27 09:01:00',
...                                              '2018-02-27 09:02:00',
...                                              '2018-02-27 09:03:00',
...                                              '2018-02-27 09:04:00',
...                                              '2018-02-27 09:05:00'])})
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.1

>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30', ...
    '2018-02-27 09:04:30']))
   a    b
2018-02-27 09:03:30 NaN NaN
2018-02-27 09:04:30 NaN NaN

Take a single column into consideration

>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30', ...
    '2018-02-27 09:04:30']),
    subset=['a'])
   a    b
2018-02-27 09:03:30 30.0 NaN
2018-02-27 09:04:30 40.0 NaN

pandas.Series.astype

Series.astype (dtype, copy=True, errors='raise')
Cast a pandas object to a specified dtype dtype.

Parameters

dtype [data type, or dict of column name -> data type] Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use {col: dtype, ...}, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame’s columns to column-specific types.

copy [bool, default True] Return a copy when copy=True (be very careful setting copy=False as changes to values then may propagate to other pandas objects).

errors ['raise', 'ignore'], default ‘raise’] Control raising of exceptions on invalid data for provided dtype.

• raise: allow exceptions to be raised

• ignore: suppress exceptions. On error return original object.

Returns

casted [same type as caller]

See also:

to_datetime Convert argument to datetime.
to_timedelta Convert argument to timedelta.
to_numeric Convert argument to a numeric type.
numpy.ndarray.astype Cast a numpy array to a specified type.
Notes

Deprecated since version 1.3.0: Using astype to convert from timezone-naive dtype to timezone-aware dtype is deprecated and will raise in a future version. Use Series.dt.tz_localize() instead.

Examples

Create a DataFrame:

```python
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df.dtypes
col1 int64
col2 int64
dtype: object
```

Cast all columns to int32:

```python
>>> df.astype('int32').dtypes
col1 int32
col2 int32
dtype: object
```

Cast col1 to int32 using a dictionary:

```python
>>> df.astype({'col1': 'int32'}).dtypes
col1 int32
col2 int64
dtype: object
```

Create a series:

```python
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0 1
1 2
dtype: int32
```

Convert to categorical type:

```python
>>> ser.astype('category')
0 1
1 2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```python
>>> from pandas.api.types import CategoricalDtype
>>> cat_dtype = CategoricalDtype(
...     categories=[2, 1], ordered=True)
>>> ser.astype(cat_dtype)
```

(continues on next page)
Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```python
>>> s1 = pd.Series([1, 2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1  # note that s1[0] has changed too
0 10
1 2
dtype: int64
```

Create a series of dates:

```python
>>> ser_date = pd.Series(pd.date_range('20200101', periods=3))
>>> ser_date
0 2020-01-01
1 2020-01-02
2 2020-01-03
dtype: datetime64[ns]
```

### pandas.Series.at_time

`Series.at_time(time, asof=False, axis=None)`

Select values at particular time of day (e.g., 9:30AM).

**Parameters**

- `time` [datetime.time or str]
- `axis` [{0 or ‘index’, 1 or ‘columns’}, default 0]

**Returns**

Series or DataFrame

**Raises**

- `TypeError` If the index is not a `DatetimeIndex`

**See also:**

- `between_time` Select values between particular times of the day.
- `first` Select initial periods of time series based on a date offset.
- `last` Select final periods of time series based on a date offset.
- `DatetimeIndex.indexer_at_time` Get just the index locations for values at particular time of the day.
Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
   A
2018-04-09 00:00:00    1
2018-04-09 12:00:00    2
2018-04-10 00:00:00    3
2018-04-10 12:00:00    4
```

```python
>>> ts.at_time('12:00')
   A
2018-04-09 12:00:00    2
2018-04-10 12:00:00    4
```

**pandas.Series.autocorr**

Series.autocorr(lag=1)

Compute the lag-N autocorrelation.

This method computes the Pearson correlation between the Series and its shifted self.

**Parameters**

- **lag** [int, default 1] Number of lags to apply before performing autocorrelation.

**Returns**

- **float** The Pearson correlation between self and self.shift(lag).

**See also:**

- `Series.corr` Compute the correlation between two Series.
- `Series.shift` Shift index by desired number of periods.
- `DataFrame.corr` Compute pairwise correlation of columns.
- `DataFrame.corrwith` Compute pairwise correlation between rows or columns of two DataFrame objects.

**Notes**

If the Pearson correlation is not well defined return ‘NaN’.

**Examples**

```python
>>> s = pd.Series([0.25, 0.5, 0.2, -0.05])
>>> s.autocorr()
0.10355...
>>> s.autocorr(lag=2)
-0.99999...
```

If the Pearson correlation is not well defined, then ‘NaN’ is returned.
```python
>>> s = pd.Series([1, 0, 0, 0])
>>> s.autocorr()
nan
```

**pandas.Series.backfill**

`Series.backfill(axis=None, inplace=False, limit=None, downcast=None)`

Synonym for `DataFrame.fillna()` with `method='bfill'`.

Returns

Series/DataFrame or None Object with missing values filled or None if `inplace=True`.

**pandas.Series.between**

`Series.between(left, right, inclusive='both')`

Return boolean Series equivalent to `left <= series <= right`. This function returns a boolean vector containing `True` wherever the corresponding Series element is between the boundary values `left` and `right`. NA values are treated as `False`.

Parameters

- `left` [scalar or list-like] Left boundary.
- `right` [scalar or list-like] Right boundary.
- `inclusive` ["both", "neither", "left", "right"]] Include boundaries. Whether to set each bound as closed or open.

Returns

Series Series representing whether each element is between left and right (inclusive).

See also:

- `Series.gt` Greater than of series and other.
- `Series.lt` Less than of series and other.

Notes

This function is equivalent to `(left <= ser) & (ser <= right)`
Examples

```python
>>> s = pd.Series([2, 0, 4, 8, np.nan])
Boundary values are included by default:
```n
```python
>>> s.between(1, 4)
0   True
1   False
2   True
3   False
4   False
dtype: bool
```

With *inclusive* set to "neither" boundary values are excluded:

```python
>>> s.between(1, 4, inclusive="neither")
0   True
1   False
2   False
3   False
4   False
dtype: bool
```

*left* and *right* can be any scalar value:

```python
>>> s = pd.Series(['Alice', 'Bob', 'Carol', 'Eve'])
>>> s.between('Anna', 'Daniel')
0   False
1   True
2   True
3   False
dtype: bool
```

*pandas.Series.between_time*

*Series.between_time*(start_time, end_time, include_start=True, include_end=True, axis=None)
Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting *start_time* to be later than *end_time*, you can get the times that are *not* between the two times.

**Parameters**

- **start_time** [datetime.time or str] Initial time as a time filter limit.
- **end_time** [datetime.time or str] End time as a time filter limit.
- **include_start** [bool, default True] Whether the start time needs to be included in the result.
- **include_end** [bool, default True] Whether the end time needs to be included in the result.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Determine range time on index or columns value.

**Returns**

*Series or DataFrame* Data from the original object filtered to the specified dates range.

**Raises**
TypeError If the index is not a `DatetimeIndex`.

See also:

- `at_time` Select values at a particular time of the day.
- `first` Select initial periods of time series based on a date offset.
- `last` Select final periods of time series based on a date offset.
- `DatetimeIndex.indexer_between_time` Get just the index locations for values between particular times of the day.

**Examples**

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
       A
2018-04-09 00:00:00 1
2018-04-10 00:20:00 2
2018-04-11 00:40:00 3
2018-04-12 01:00:00 4

>>> ts.between_time('0:15', '0:45')
       A
2018-04-10 00:20:00 2
2018-04-11 00:40:00 3
```

You get the times that are *not* between two times by setting `start_time` later than `end_time`:

```python
>>> ts.between_time('0:45', '0:15')
       A
2018-04-09 00:00:00 1
2018-04-12 01:00:00 4
```

**pandas.Series.bfill**

- `Series.bfill(axis=None, inplace=False, limit=None, downcast=None)`
  - Synonym for `DataFrame.fillna()` with method='bfill'.
  - Returns `Series/DataFrame or None` Object with missing values filled or None if `inplace=True`.

**pandas.Series.bool**

- `Series.bool()`
  - Return the bool of a single element Series or DataFrame.
  - This must be a boolean scalar value, either True or False. It will raise a ValueError if the Series or DataFrame does not have exactly 1 element, or that element is not boolean (integer values 0 and 1 will also raise an exception).
  - Returns
bool  The value in the Series or DataFrame.

See also:

Series.astype  Change the data type of a Series, including to boolean.

DataFrame.astype  Change the data type of a DataFrame, including to boolean.

numpy.bool_  NumPy boolean data type, used by pandas for boolean values.

Examples

The method will only work for single element objects with a boolean value:

```python
>>> pd.Series([True]).bool()
True
>>> pd.Series([False]).bool()
False

>>> pd.DataFrame({'col': [True]}).bool()
True
>>> pd.DataFrame({'col': [False]}).bool()
False
```

pandas.Series.cat

Series.cat()
Accessor object for categorical properties of the Series values.

Be aware that assigning to categories is a inplace operation, while all methods return new categorical data per default (but can be called with inplace=True).

Parameters

data  [Series or CategoricalIndex]

Examples

```python
>>> s = pd.Series(list("abbccc")).astype("category")
>>> s
0   a
1   b

(continues on next page)
pandas.Series.clip

Series.clip(lower=None, upper=None, axis=None, inplace=False, *args, **kwargs)

Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

Parameters

lower [float or array-like, default None] Minimum threshold value. All values below this threshold will be set to it. A missing threshold (e.g NA) will not clip the value.

upper [float or array-like, default None] Maximum threshold value. All values above this threshold will be set to it. A missing threshold (e.g NA) will not clip the value.

axis [int or str axis name, optional] Align object with lower and upper along the given axis.

inplace [bool, default False] Whether to perform the operation in place on the data.

*args, **kwargs Additional keywords have no effect but might be accepted for compatibility with numpy.

Returns

Series or DataFrame or None Same type as calling object with the values outside the clip boundaries replaced or None if inplace=True.

See also:

Series.clip Trim values at input threshold in series.
**DataFrame.clip** Trim values at input threshold in dataframe.

**numpy.clip** Clip (limit) the values in an array.

**Examples**

```python
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0  col_1
0      9    -2
1     -3     -7
2      0      6
3     -1      8
4      5    -5
```

Clips per column using lower and upper thresholds:

```python
>>> df.clip(-4, 6)
   col_0  col_1
0      6    -2
1     -3     -4
2      0      6
3     -1      6
4      5     -4
```

Clips using specific lower and upper thresholds per column element:

```python
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0    2
1   -4
2   -1
3    6
4    3
dtype: int64

>>> df.clip(t, t + 4, axis=0)
   col_0  col_1
0      6     2
1     -3     -4
2      0      3
3      6      8
4      5      3
```

Clips using specific lower threshold per column element, with missing values:

```python
>>> t = pd.Series([2, -4, np.NaN, 6, 3])
>>> t
0   2.0
1  -4.0
2   NaN
3   6.0
4   3.0
dtype: float64
```
```python
>>> df.clip(t, axis=0)
   col_0  col_1
0     9     2
1    -3    -4
2     0     6
3     6     8
4     5     3
```

**pandas.Series.combine**

Series.combine(other, func, fill_value=None)

Combine the Series with a Series or scalar according to `func`.

Combine the Series and `other` using `func` to perform elementwise selection for combined Series. `fill_value` is assumed when value is missing at some index from one of the two objects being combined.

**Parameters**

- **other** [Series or scalar] The value(s) to be combined with the Series.
- **func** [function] Function that takes two scalars as inputs and returns an element.
- **fill_value** [scalar, optional] The value to assume when an index is missing from one Series or the other. The default specifies to use the appropriate NaN value for the underlying `dtype` of the Series.

**Returns**

Series The result of combining the Series with the other object.

**See also:**

Series.combine_first Combine Series values, choosing the calling Series’ values first.

**Examples**

Consider 2 Datasets `s1` and `s2` containing highest clocked speeds of different birds.

```python
>>> s1 = pd.Series({'falcon': 330.0, 'eagle': 160.0})
>>> s1
falcon    330.0
eagle    160.0
dtype: float64
>>> s2 = pd.Series({'falcon': 345.0, 'eagle': 200.0, 'duck': 30.0})
>>> s2
falcon    345.0
eagle    200.0
duck     30.0
dtype: float64
```

Now, to combine the two datasets and view the highest speeds of the birds across the two datasets:

```python
>>> s1.combine(s2, max)
duck      NaN
eagle    200.0
falcon    345.0
dtype: float64
```
In the previous example, the resulting value for duck is missing, because the maximum of a NaN and a float is a NaN. So, in the example, we set \texttt{fill_value=0}, so the maximum value returned will be the value from some dataset.

\begin{verbatim}
>>> s1.combine(s2, max, fill_value=0)
duck  30.0
eagle 200.0
falcon 345.0
dtype: float64
\end{verbatim}

\textbf{pandas.Series.combine\_first}

\texttt{Series\.combine\_first}(\texttt{other})

Update null elements with value in the same location in ‘other’.

Combine two Series objects by filling null values in one Series with non-null values from the other Series. Result index will be the union of the two indexes.

\begin{description}
\item[Parameters] \texttt{other} [Series] The value(s) to be used for filling null values.
\end{description}

\begin{description}
\item[Returns] \texttt{Series} The result of combining the provided Series with the other object.
\end{description}

\begin{description}
\item[See also:] \texttt{Series.combine} Perform element-wise operation on two Series using a given function.
\end{description}

\textbf{Examples}

\begin{verbatim}
>>> s1 = pd.Series([1, np.nan])
>>> s2 = pd.Series([3, 4, 5])
>>> s1.combine_first(s2)
0  1.0
1  4.0
2  5.0
dtype: float64
\end{verbatim}

Null values still persist if the location of that null value does not exist in \texttt{other}

\begin{verbatim}
>>> s1 = pd.Series({'falcon': np.nan, 'eagle': 160.0})
>>> s2 = pd.Series({'eagle': 200.0, 'duck': 30.0})
>>> s1.combine_first(s2)
duck  30.0
eagle 160.0
falcon NaN
dtype: float64
\end{verbatim}
**pandas.Series.compare**

Series.compare(other, align_axis=1, keep_shape=False, keep_equal=False)

Compare to another Series and show the differences.

New in version 1.1.0.

Parameters

- **other** [Series] Object to compare with.
- **align_axis** [{0 or ‘index’, 1 or ‘columns’}, default 1] Determine which axis to align the comparison on.
  - 0, or ‘index’ [Resulting differences are stacked vertically] with rows drawn alternately from self and other.
  - 1, or ‘columns’ [Resulting differences are aligned horizontally] with columns drawn alternately from self and other.
- **keep_shape** [bool, default False] If true, all rows and columns are kept. Otherwise, only the ones with different values are kept.
- **keep_equal** [bool, default False] If true, the result keeps values that are equal. Otherwise, equal values are shown as NaNs.

Returns

Series or DataFrame If axis is 0 or ‘index’ the result will be a Series. The resulting index will be a MultiIndex with ‘self’ and ‘other’ stacked alternately at the inner level.

If axis is 1 or ‘columns’ the result will be a DataFrame. It will have two columns namely ‘self’ and ‘other’.

See also:

**DataFrame.compare** Compare with another DataFrame and show differences.

Notes

Matching NaNs will not appear as a difference.

Examples

```python
>>> s1 = pd.Series(['a', 'b', 'c', 'd', 'e'])
>>> s2 = pd.Series(['a', 'a', 'c', 'b', 'e'])
```

Align the differences on columns

```python
>>> s1.compare(s2)
   self other
1   b   a
3   d   b
```

Stack the differences on indices
```python
>>> s1.compare(s2, align_axis=0)
  0   self b
     other a
  3   self d
     other b
dtype: object

Keep all original rows

```py
>>> s1.compare(s2, keep_shape=True)
     self  other
   0  NaN   NaN
   1   b   a
   2  NaN   NaN
   3   d   b
   4  NaN   NaN

Keep all original rows and also all original values

```py
>>> s1.compare(s2, keep_shape=True, keep_equal=True)
     self  other
   0   a   a
   1   b   a
   2  NaN  NaN
   3   d   b
   4   e   e
```

### pandas.Series.convert_dtypes

`Series.convert_dtypes(infer_objects=True, convert_string=True, convert_integer=True, convert_boolean=True, convert_floating=True)`

Convert columns to best possible dtypes using dtypes supporting `pd.NA`.

New in version 1.0.0.

**Parameters**

- `infer_objects` [bool, default True] Whether object dtypes should be converted to the best possible types.
- `convert_string` [bool, default True] Whether object dtypes should be converted to `StringDtype()`.
- `convert_integer` [bool, default True] Whether, if possible, conversion can be done to integer extension types.
- `convert_boolean` [bool, defaults True] Whether object dtypes should be converted to `BooleanDtypes()`.
- `convert_floating` [bool, defaults True] Whether, if possible, conversion can be done to floating extension types. If `convert_integer` is also True, preference will be given to integer dtypes if the floats can be faithfully casted to integers.

New in version 1.2.0.

**Returns**

`Series or DataFrame` Copy of input object with new dtype.

See also:
**infer_objects**  Infer dtypes of objects.

**to_datetime**  Convert argument to datetime.

**to_timedelta**  Convert argument to timedelta.

**to_numeric**  Convert argument to a numeric type.

**Notes**

By default, `convert_dtypes` will attempt to convert a Series (or each Series in a DataFrame) to dtypes that support `pd.NA`. By using the options `convert_string`, `convert_integer`, `convert_boolean` and `convert_boolean`, it is possible to turn off individual conversions to `StringDtype`, the integer extension types, `BooleanDtype` or floating extension types, respectively.

For object-dtyped columns, if `infer_objects` is `True`, use the inference rules as during normal Series/DataFrame construction. Then, if possible, convert to `StringDtype`, `BooleanDtype` or an appropriate integer or floating extension type, otherwise leave as `object`.

If the dtype is integer, convert to an appropriate integer extension type.

If the dtype is numeric, and consists of all integers, convert to an appropriate integer extension type. Otherwise, convert to an appropriate floating extension type.

Changed in version 1.2: Starting with pandas 1.2, this method also converts float columns to the nullable floating extension type.

In the future, as new dtypes are added that support `pd.NA`, the results of this method will change to support those new dtypes.

**Examples**

```python
>>> df = pd.DataFrame(
...     {  
...         "a": pd.Series([1, 2, 3], dtype=np.dtype("int32")),  
...         "b": pd.Series(["x", "y", "z"], dtype=np.dtype("O")),  
...         "c": pd.Series([True, False, np.nan], dtype=np.dtype("O")),  
...         "d": pd.Series(["h", "i", np.nan], dtype=np.dtype("O")),  
...         "e": pd.Series([10, np.nan, 20], dtype=np.dtype("float")),  
...         "f": pd.Series([np.nan, 100.5, 200], dtype=np.dtype("float")),  
...     }
... )
```

Start with a DataFrame with default dtypes.

```python
>>> df
   a  b        c   d        e  f
0  1  x    True  10.0    NaN
1  2  y  False   i  NaN  100.5
2  3  z     NaN  NaN  20.0  200.0
```

```python
>>> df.dtypes
a    int32
b    object
c    object
d    object
e  float64
```

(continues on next page)
Convert the DataFrame to use best possible dtypes.

```python
>>> dfn = df.convert_dtypes()
>>> dfn
   a  b  c  d  e  f
0  1  x  True  h  10 <NA>
1  2  y  False  i  <NA>  100.5
2  3  z  <NA>  <NA>  20  200.0
```

```python
>>> dfn.dtypes
a  Int32
b  string
c  boolean
d  string
e  Int64
f  Float64
dtype: object
```

Start with a Series of strings and missing data represented by `np.nan`.

```python
>>> s = pd.Series(["a", "b", np.nan])
>>> s
0  a
1  b
2  NaN
dtype: object
```

Obtain a Series with dtype `StringDtype`.

```python
>>> s.convert_dtypes()
0   a
1   b
2  <NA>
dtype: string
```

**pandas.Series.copy**

**Series.copy**(deep=True)

Make a copy of this object’s indices and data.

When `deep=True` (default), a new object will be created with a copy of the calling object’s data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When `deep=False`, a new object will be created without copying the calling object’s data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

**Parameters**

- **deep** [bool, default True] Make a deep copy, including a copy of the data and the indices.
  With `deep=False` neither the indices nor the data are copied.
Returns

**copy** [Series or DataFrame] Object type matches caller.

Notes

When `deep=True`, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to `copy.deepcopy` in the Standard Library, which recursively copies object data (see examples below).

While `Index` objects are copied when `deep=True`, the underlying numpy array is not copied for performance reasons. Since `Index` is immutable, the underlying data can be safely shared and a copy is not needed.

Examples

```python
>>> s = pd.Series([1, 2], index=['a', 'b'])
```

```python
>>> s
a    1
b    2
dtype: int64
```

```python
>>> s_copy = s.copy()
```

```python
>>> s_copy
a    1
b    2
dtype: int64
```

**Shallow copy versus default (deep) copy:**

```python
>>> s = pd.Series([1, 2], index=['a', 'b'])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)
```

Shallow copy shares data and index with original.

```python
>>> s is shallow
False
```

```python
>>> s.values is shallow.values and s.index is shallow.index
True
```

```python
>>> s is deep
False
```

```python
>>> s.values is deep.values or s.index is deep.index
False
```

Deep copy has own copy of data and index.

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```python
>>> s[0] = 3
```

```python
>>> shallow[1] = 4
```

```python
>>> s
a    3
b    4
```
Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```python
>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
```
**DataFrame.corr**  Compute pairwise correlation between columns.

**DataFrame.corrwith**  Compute pairwise correlation with another DataFrame or Series.

**Examples**

```python
def histogram_intersection(a, b):
    v = np.minimum(a, b).sum().round(decimals=1)
    return v

s1 = pd.Series([.2, .0, .6, .2])
s2 = pd.Series([.3, .6, .0, .1])
s1.corr(s2, method=histogram_intersection)
```

**pandas.Series.count**

**Series.count** *(level=None)*  
Return number of non-NA/null observations in the Series.

**Parameters**

- **level**  [int or level name, default None]  If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a smaller Series.

**Returns**

- **int or Series (if level specified)**  Number of non-null values in the Series.

**See also:**

- **DataFrame.count**  Count non-NA cells for each column or row.

**Examples**

```python
s = pd.Series([0.0, 1.0, np.nan])
s.count()
```

**pandas.Series.cov**

**Series.cov** *(other, min_periods=None, ddof=1)*  
Compute covariance with Series, excluding missing values.

**Parameters**

- **other**  [Series]  Series with which to compute the covariance.

- **min_periods**  [int, optional]  Minimum number of observations needed to have a valid result.

- **ddof**  [int, default 1]  Delta degrees of freedom. The divisor used in calculations is $N - ddof$, where $N$ represents the number of elements.

**New in version 1.1.0.**

**Returns**
float  Covariance between Series and other normalized by N-1 (unbiased estimator).

See also:

DataFrame.cov  Compute pairwise covariance of columns.

Examples

```python
>>> s1 = pd.Series([0.90010907, 0.13484424, 0.62036035])
>>> s2 = pd.Series([0.12528585, 0.26962463, 0.51111198])
>>> s1.cov(s2)
-0.01685762652715874
```

pandas.Series.cummax

Series.cummax (axis=None, skipna=True, *args, **kwargs)

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

Parameters

axis {[0 or ‘index’, 1 or ‘columns’], default 0] The index or the name of the axis. 0 is
equivalent to None or ‘index’.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the
result will be NA.

*args, **kwargs Additional keywords have no effect but might be accepted for compat-
ibility with NumPy.

Returns

scalar or Series  Return cumulative maximum of scalar or Series.

See also:

core.window.Expanding.max  Similar functionality but ignores NaN values.

Series.max  Return the maximum over Series axis.

Series.cummax  Return cumulative maximum over Series axis.

Series.cummin  Return cumulative minimum over Series axis.

Series.cumsum  Return cumulative sum over Series axis.

Series.cumprod  Return cumulative product over Series axis.
Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1   NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cummax()
0    2.0
1   NaN
2    5.0
3    5.0
4    5.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cummax(skipna=False)
0    2.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64
```

DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0],
                     ...                    [3.0, np.nan],
                     ...                    [1.0, 0.0]],
                     ...                   columns=list('AB'))
>>> df
   A  B
0  2.0 1.0
1  3.0 NaN
2  1.0 0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cummax()
   A  B
0  2.0 1.0
1  3.0 NaN
2  3.0 1.0
```

To iterate over columns and find the maximum in each row, use `axis=1`

```python
>>> df.cummax(axis=1)
   A  B
0  2.0 1.0
1  3.0 NaN
2  3.0 1.0
```

(continues on next page)
pandas.Series.cummin

Series.cummin (axis=None, skipna=True, *args, **kwargs)

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

Parameters

- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- ***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

- **scalar or Series** Return cumulative minimum of scalar or Series.

See also:

core.window.Expanding.min Similar functionality but ignores NaN values.

Series.min Return the minimum over Series axis.

Series.cummax Return cumulative maximum over Series axis.

Series.cummin Return cumulative minimum over Series axis.

Series.cumsum Return cumulative sum over Series axis.

Series.cumprod Return cumulative product over Series axis.

Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4     0.0
dtype: float64
```

By default, NA values are ignored.
>>> s.cummin()
0  2.0
1  NaN
2  2.0
3 -1.0
4 -1.0
dtype: float64

To include NA values in the operation, use skipna=False

>>> s.cummin(skipna=False)
0  2.0
1  NaN
2  NaN
3  NaN
4  NaN
dtype: float64

DataFrame

>>> df = pd.DataFrame([[2.0, 1.0],
                      ...                     [3.0, np.nan],
                      ...                     [1.0, 0.0]],
                      ...                     columns=list('AB'))
>>> df
   A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0

By default, iterates over rows and finds the minimum in each column. This is equivalent to axis=None or axis='index'.

>>> df.cummin()
   A  B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0

To iterate over columns and find the minimum in each row, use axis=1

>>> df.cummin(axis=1)
   A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
pandas.Series.cumprod

Series.cumprod(axis=None, skipna=True, *args, **kwargs)
Return cumulative product over a DataFrame or Series axis.
Returns a DataFrame or Series of the same size containing the cumulative product.

Parameters

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

*args, **kwargs Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series  Return cumulative product of scalar or Series.

See also:

core.window.Expanding.prod  Similar functionality but ignores NaN values.

Series.prod  Return the product over Series axis.

Series.cummax  Return cumulative maximum over Series axis.

Series.cummin  Return cumulative minimum over Series axis.

Series.cumsum  Return cumulative sum over Series axis.

Series.cumprod  Return cumulative product over Series axis.

Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1   NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cumprod()
0    2.0
1   NaN
2   10.0
3  -10.0
4    -0.0
dtype: float64
```

To include NA values in the operation, use skipna=False
>>> s.cumprod(skipna=False)
0   2.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64

DataFrame

>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A  B
0  2.0 1.0
1  3.0  NaN
2  1.0  0.0

By default, iterates over rows and finds the product in each column. This is equivalent to axis=None or axis='index'.

>>> df.cumprod()
   A  B
0  2.0  1.0
1  6.0  NaN
2  6.0  0.0

To iterate over columns and find the product in each row, use axis=1.

>>> df.cumprod(axis=1)
   A  B
0  2.0  2.0
1  3.0  NaN
2  1.0  0.0

pandas.Series.cumsum

Series.cumsum(axis=None, skipna=True, *args, **kwargs)

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

Parameters

axis [0 or ‘index’, 1 or ‘columns’], default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

*args, **kwargs Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series Return cumulative sum of scalar or Series.
See also:

- `core.window.Expanding.sum` Similar functionality but ignores NaN values.
- `Series.sum` Return the sum over Series axis.
- `Series.cummax` Return cumulative maximum over Series axis.
- `Series.cummin` Return cumulative minimum over Series axis.
- `Series.cumsum` Return cumulative sum over Series axis.
- `Series.cumprod` Return cumulative product over Series axis.

**Examples**

**Series**

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1   NaN
2    5.0
3   -1.0
4     0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cumsum()
0    2.0
1   NaN
2    7.0
3    6.0
4    6.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cumsum(skipna=False)
0    2.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64
```

**DataFrame**

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
    A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```
By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
df.cumsum()
```

```
A  B
0 2.0 1.0
1 5.0 NaN
2 6.0 1.0
```

To iterate over columns and find the sum in each row, use `axis=1`

```python
df.cumsum(axis=1)
```

```
A  B
0 2.0 3.0
1 3.0 NaN
2 1.0 1.0
```

### pandas.Series.describe

`Series.describe(percentiles=None, include=None, exclude=None, datetime_is_numeric=False)`

Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset’s distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

**Parameters**

- **percentiles** [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is `[.25,.5,.75]`, which returns the 25th, 50th, and 75th percentiles.

- **include** ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for Series. Here are the options:
  - 'all': All columns of the input will be included in the output.
  - A list-like of dtypes: Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use 'category'
  - None (default): The result will include all numeric columns.

- **exclude** [list-like of dtypes or None (default), optional] A black list of data types to omit from the result. Ignored for Series. Here are the options:
  - A list-like of dtypes: Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To exclude pandas categorical columns, use 'category'
  - None (default): The result will exclude nothing.
**datetime_is_numeric** [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

New in version 1.1.0.

**Returns**

*Series or DataFrame*  Summary statistics of the Series or Dataframe provided.

**See also:**

*DataFrame.count*  Count number of non-NA/null observations.

*DataFrame.max*  Maximum of the values in the object.

*DataFrame.min*  Minimum of the values in the object.

*DataFrame.mean*  Mean of the values.

*DataFrame.std*  Standard deviation of the observations.

*DataFrame.select_dtypes*  Subset of a DataFrame including/excluding columns based on their dtype.

**Notes**

For numeric data, the result’s index will include count, mean, std, min, max as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result’s index will include count, unique, top, and freq. The top is the most common value. The freq is the most common value’s frequency. Timestamps also include the first and last items.

If multiple object values have the highest count, then the count and top results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a DataFrame, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If include='all' is provided as an option, the result will include a union of attributes of each type.

The include and exclude parameters can be used to limit which columns in a DataFrame are analyzed for the output. The parameters are ignored when analyzing a Series.

**Examples**

Describing a numeric Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count   3.0
mean    2.0
std     1.0
min     1.0
25%     1.5
50%     2.0
75%     2.5
```

(continues on next page)
Describing a categorical Series.

```python
s = pd.Series(['a', 'a', 'b', 'c'])
s.describe()
count  4
unique  3
top    a
dtype: object
```

Describing a timestamp Series.

```python
s = pd.Series([...
    ... np.datetime64("2000-01-01"),
    ... np.datetime64("2010-01-01"),
    ... np.datetime64("2010-01-01")
    ... ])
s.describe(datetime_is_numeric=True)
count  3
mean  2006-09-01 08:00:00
min  2000-01-01 00:00:00
25%  2004-12-31 12:00:00
50%  2010-01-01 00:00:00
75%  2010-01-01 00:00:00
max  2010-01-01 00:00:00
dtype: object
```

Describing a DataFrame. By default only numeric fields are returned.

```python
df = pd.DataFrame({'categorical': pd.Categorical(['d','e','f']),
    ... 'numeric': [1, 2, 3],
    ... 'object': ['a', 'b', 'c']
    ... })
df.describe()
count   numeric
numeric  3.0
mean     2.0
std      1.0
min      1.0
25%      1.5
50%      2.0
75%      2.5
max      3.0
```

Describing all columns of a DataFrame regardless of data type.

```python
df.describe(include='all')
categorical numeric object
count  3  3.0  3
unique 3  NaN  3
top    f  NaN  a
dtype: object
```

(continues on next page)
Describing a column from a DataFrame by accessing it as an attribute.

```python
>>> df.numeric.describe()
count    3.0
mean     2.0
std      1.0
min      1.0
25%      1.5
50%      2.0
75%      2.5
max      3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a DataFrame description.

```python
>>> df.describe(include=[np.number])
numeric
count    3.0
mean     2.0
std      1.0
min      1.0
25%      1.5
50%      2.0
75%      2.5
max      3.0
```

Including only string columns in a DataFrame description.

```python
>>> df.describe(include=[object])
object
count    3
unique   3
top      a
freq     1
```

Including only categorical columns from a DataFrame description.

```python
>>> df.describe(include=['category'])
categorical
count    3
unique   3
top      d
freq     1
```

Excluding numeric columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.number])
categorical object
count    3   3
```
Excluding object columns from a DataFrame description.

```python
>>> df.describe(exclude=[object])

<table>
<thead>
<tr>
<th></th>
<th>categorical</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>3</td>
<td>3.0</td>
</tr>
<tr>
<td>unique</td>
<td>3</td>
<td>NaN</td>
</tr>
<tr>

</tr>
</tbody>
</table>
```

**pandas.Series.diff**

`Series.diff(periods=1)`

First discrete difference of element.

Calculates the difference of a Series element compared with another element in the Series (default is element in previous row).

**Parameters**

- `periods` [int, default 1] Periods to shift for calculating difference, accepts negative values.

**Returns**

- `Series` First differences of the Series.

**See also:**

- `Series.pct_change` Percent change over given number of periods.
- `Series.shift` Shift index by desired number of periods with an optional time freq.
- `DataFrame.diff` First discrete difference of object.

**Notes**

For boolean dtypes, this uses `operator.xor()` rather than `operator.sub()`. The result is calculated according to current dtype in Series, however dtype of the result is always float64.
Examples

Difference with previous row

```python
>>> s = pd.Series([1, 1, 2, 3, 5, 8])
>>> s.diff()
0    NaN
1     0.0
2     1.0
3     1.0
4     2.0
5     3.0
dtype: float64
```

Difference with 3rd previous row

```python
>>> s.diff(periods=3)
0    NaN
1    NaN
2    NaN
3     2.0
4     4.0
5     6.0
dtype: float64
```

Difference with following row

```python
>>> s.diff(periods=-1)
0     0.0
1    -1.0
2    -1.0
3    -2.0
4    -3.0
5    NaN
dtype: float64
```

Overflow in input dtype

```python
>>> s = pd.Series([1, 0], dtype=np.uint8)
>>> s.diff()
0    NaN
1   255.0
dtype: float64
```

`pandas.Series.div`

Series.div(\text{other}, level=None, fill_value=None, axis=0)  
Return Floating division of series and other, element-wise (binary operator truediv).  
Equivalent to \text{series} / \text{other}, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

- **other** [Series or scalar value]  
  - fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before
computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

**level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

**Series** The result of the operation.

**See also:**

*Series.rtruediv* Reverse of the Floating division operator, see Python documentation for more details.

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
d    0.0
e    NaN
dtype: float64
```

**pandas.Series.divide**

*Series.divide* *(other, level=None, fill_value=None, axis=0)*

Return Floating division of series and other, element-wise (binary operator *truediv*).

Equivalent to *series / other*, but with support to substitute a *fill_value* for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]

- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.
Returns

Series  The result of the operation.

See also:

Series.rtruediv  Reverse of the Floating division operator, see Python documentation for more
details.

Examples

```python
ged> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
ged> a
a    1.0
ged> b    1.0
ged> c    1.0
ged> d   NaN
dtype: float64
ged> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
ged> b
a    1.0
ged> b   NaN
ged> d    1.0
ged> e   NaN
dtype: float64
ged> a.divide(b, fill_value=0)
     a    1.0
     b  inf
     c  inf
     d   0.0
     e   NaN
dtype: float64
```

pandas.Series.divmod

Series.divmod(other, level=None, fill_value=None, axis=0)
Return integer division and modulo of series and other, element-wise (binary operator divmod).
Equivalent to divmod(series, other), but with support to substitute a fill_value for missing data
in either one of the inputs.

Parameters

other  [Series or scalar value]

fill_value  [None or float value, default None (NaN)] Fill existing missing (NaN) values,
and any new element needed for successful Series alignment, with this value before
computation. If data in both corresponding Series locations is missing the result of
filling (at that location) will be missing.

level  [int or name] Broadcast across a level, matching Index values on the passed Multi-
Index level.

Returns

2-Tuple of Series  The result of the operation.

See also:
Series.rdivmod  Reverse of the Integer division and modulo operator, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divmod(b, fill_value=0)
(a 1.0
b NaN
c NaN
d 0.0
e NaN
dtype: float64,
(a 0.0
b NaN
c NaN
d 0.0
e NaN
dtype: float64)
```

pandas.Series.dot

Series.dot (other)

Compute the dot product between the Series and the columns of other.

This method computes the dot product between the Series and another one, or the Series and each columns of a DataFrame, or the Series and each columns of an array.

It can also be called using self @ other in Python >= 3.5.

Parameters

- **other** [Series, DataFrame or array-like] The other object to compute the dot product with its columns.

Returns

- **scalar, Series or numpy.ndarray** Return the dot product of the Series and other if other is a Series, the Series of the dot product of Series and each rows of other if other is a DataFrame or a numpy.ndarray between the Series and each columns of the numpy array.

See also:
**DataFrame.dot**  Compute the matrix product with the DataFrame.

**Series.mul**  Multiplication of series and other, element-wise.

**Notes**

The Series and other has to share the same index if other is a Series or a DataFrame.

**Examples**

```python
>>> s = pd.Series([0, 1, 2, 3])
>>> other = pd.Series([-1, 2, -3, 4])
>>> s.dot(other)
8
>>> s @ other
8
>>> df = pd.DataFrame([[0, 1], [-2, 3], [4, -5], [6, 7]])
>>> s.dot(df)
0   24
1   14
dtype: int64
>>> arr = np.array([[0, 1], [-2, 3], [4, -5], [6, 7]])
>>> s.dot(arr)
array([24, 14])
```

**pandas.Series.drop**

Series.drop(labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise')

Return Series with specified index labels removed.

Remove elements of a Series based on specifying the index labels. When using a multi-index, labels on different levels can be removed by specifying the level.

**Parameters**

- **labels**  [single label or list-like] Index labels to drop.
- **axis**  [0, default 0] Redundant for application on Series.
- **index**  [single label or list-like] Redundant for application on Series, but ‘index’ can be used instead of ‘labels’.
- **columns**  [single label or list-like] No change is made to the Series; use ‘index’ or ‘labels’ instead.
- **level**  [int or level name, optional] For MultiIndex, level for which the labels will be removed.
- **inplace**  [bool, default False] If True, do operation inplace and return None.
- **errors**  [‘ignore’, ‘raise’], default ‘raise’) If ‘ignore’, suppress error and only existing labels are dropped.

**Returns**

- **Series or None**  Series with specified index labels removed or None if inplace=True.

**Raises**
**KeyError** If none of the labels are found in the index.

See also:

*Series.reindex* Return only specified index labels of Series.

*Series.dropna* Return series without null values.

*Series.drop_duplicates* Return Series with duplicate values removed.

*DataFrame.drop* Drop specified labels from rows or columns.

**Examples**

```python
def s = pd.Series(data=np.arange(3), index=['A', 'B', 'C'])
>>> s
A 0
B 1
C 2
dtype: int64

Drop labels B en C

```python
>>> s.drop(labels=['B', 'C'])
A 0
dtype: int64
```

Drop 2nd level label in MultiIndex Series

```python
>>> midx = pd.MultiIndex(levels=[['lama', 'cow', 'falcon'],
... ['speed', 'weight', 'length']],
... codes=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
... [0, 1, 2, 0, 1, 2, 0, 1, 2]])
>>> s = pd.Series([45, 200, 1.2, 30, 250, 1.5, 320, 1, 0.3],
... index=midx)
>>> s
lama speed 45.0
weight 200.0
length 1.2
cow speed 30.0
weight 250.0
length 1.5
falcon speed 320.0
weight 1.0
length 0.3
dtype: float64

```python
>>> s.drop(labels='weight', level=1)
lama speed 45.0
length 1.2
cow speed 30.0
length 1.5
falcon speed 320.0
length 0.3
dtype: float64
```
pandas.Series.drop_duplicates

Series.drop_duplicates(keep='first', inplace=False)

Return Series with duplicate values removed.

Parameters

keep [{'first', 'last', False}, default 'first'] Method to handle dropping duplicates:
  • 'first': Drop duplicates except for the first occurrence.
  • 'last': Drop duplicates except for the last occurrence.
  • False: Drop all duplicates.

inplace [bool, default False] If True, performs operation inplace and returns None.

Returns

Series or None Series with duplicates dropped or None if inplace=True.

See also:

Index.drop_duplicates Equivalent method on Index.
DataFrame.drop_duplicates Equivalent method on DataFrame.
Series.duplicated Related method on Series, indicating duplicate Series values.

Examples

Generate a Series with duplicated entries.

```python
>>> s = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'],
...                   name='animal')
>>> s
0   lama
1   cow
2   lama
3  beetle
4   lama
5  hippo
Name: animal, dtype: object
```

With the 'keep' parameter, the selection behaviour of duplicated values can be changed. The value 'first' keeps the first occurrence for each set of duplicated entries. The default value of keep is 'first'.

```python
>>> s.drop_duplicates()
0   lama
1   cow
3  beetle
5  hippo
Name: animal, dtype: object
```

The value 'last' for parameter 'keep' keeps the last occurrence for each set of duplicated entries.

```python
>>> s.drop_duplicates(keep='last')
1   cow
3  beetle
4   lama
```

(continues on next page)
The value `False` for parameter ‘keep’ discards all sets of duplicated entries. Setting the value of ‘inplace’ to `True` performs the operation inplace and returns None.

```python
>>> s.drop_duplicates(keep=False, inplace=True)
>>> s
1 cow
3 beetle
5 hippo
Name: animal, dtype: object
```

**pandas.Series.droplevel**

```python
Series.droplevel(level, axis=0)
```

Return Series/DataFrame with requested index / column level(s) removed.

**Parameters**

- `level` [int, str, or list-like] If a string is given, must be the name of a level If list-like, elements must be names or positional indexes of levels.

- `axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis along which the level(s) is removed:
  - 0 or ‘index’: remove level(s) in column.
  - 1 or ‘columns’: remove level(s) in row.

**Returns**

Series/DataFrame  Series/DataFrame with requested index / column level(s) removed.

**Examples**

```python
>>> df = pd.DataFrame([...
... [1, 2, 3, 4],
... [5, 6, 7, 8],
... [9, 10, 11, 12]
... ]).set_index([0, 1]).rename_axis(["a", "b"])
```

```python
>>> df.columns = pd.MultiIndex.from_tuples([...
... ("c", "e"), ("d", "f")
... ], names=["level_1", "level_2"])```

```python
>>> df
level_1  c  d
level_2  e  f
  a  b
1  2  3  4
5  6  7  8
9 10 11 12
```
```python
>>> df.droplevel('a')
level_1  c  d
    level_2  e  f
b  
   2  3  4
   6  7  8
10 11 12

>>> df.droplevel('level_2', axis=1)
level_1  c  d
a  b
   1  2  3  4
   5  6  7  8
   9 10 11 12
```

### pandas.Series.dropna

`Series.dropna(axis=0, inplace=False, how=None)`

Return a new Series with missing values removed.

See the User Guide for more on which values are considered missing, and how to work with missing data.

**Parameters**

- `axis` ([0 or ‘index’], default 0] There is only one axis to drop values from.
- `inplace` [bool, default False] If True, do operation inplace and return None.

**Returns**

Series or None Series with NA entries dropped from it or None if `inplace=True`.

See also:

- `Series.isna` Indicate missing values.
- `Series.notna` Indicate existing (non-missing) values.
- `Series.fillna` Replace missing values.
- `DataFrame.dropna` Drop rows or columns which contain NA values.
- `Index.dropna` Drop missing indices.

**Examples**

```python
>>> ser = pd.Series([1., 2., np.nan])
>>> ser
0  1.0
1  2.0
2  NaN
dtype: float64

Drop NA values from a Series.
```
Keep the Series with valid entries in the same variable.

```python
>>> ser.dropna()
0  1.0
1  2.0
dtype: float64
```

Empty strings are not considered NA values. None is considered an NA value.

```python
>>> ser = pd.Series([np.NaN, 2, pd.NaT, '', None, 'I stay'])
>>> ser
0    NaN
1     2
2    NaT
3     
4    None
5    I stay
dtype: object
>>> ser.dropna()
1     2
2    NaT
5    I stay
dtype: object
```

**pandas.Series.dt**

Series.dt()  
Accessor object for datetimelike properties of the Series values.

**Examples**

```python
>>> seconds_series = pd.Series(pd.date_range("2000-01-01", periods=3, freq="s"))
>>> seconds_series
0  2000-01-01 00:00:00
1  2000-01-01 00:00:01
2  2000-01-01 00:00:02
dtype: datetime64[ns]
>>> seconds_series.dt.second
0    0
1    1
2    2
dtype: int64
```

```python
>>> hours_series = pd.Series(pd.date_range("2000-01-01", periods=3, freq="h"))
>>> hours_series
(continues on next page)
0  2000-01-01 00:00:00
1  2000-01-01 01:00:00
2  2000-01-01 02:00:00
dtype: datetime64[ns]

```python
>>> hours_series.dt.hour
0  0
1  1
2  2
dtype: int64
```

```python
>>> quarters_series = pd.Series(pd.date_range("2000-01-01", periods=3, freq="q"))
```

```python
>>> quarters_series
0 2000-03-31
1 2000-06-30
2 2000-09-30
dtype: datetime64[ns]
```

```python
>>> quarters_series.dt.quarter
0 1
1 2
2 3
dtype: int64
```

Returns a Series indexed like the original Series. Raises TypeError if the Series does not contain datetimelike values.

**pandas.Series.duplicated**

**Series.duplicated** *(keep='first')*

Indicate duplicate Series values.

Duplicated values are indicated as True values in the resulting Series. Either all duplicates, all except the first or all except the last occurrence of duplicates can be indicated.

**Parameters**

- **keep** ['first', 'last', False], default 'first' Method to handle dropping duplicates:
  - 'first': Mark duplicates as True except for the first occurrence.
  - 'last': Mark duplicates as True except for the last occurrence.
  - False: Mark all duplicates as True.

**Returns**

**Series[bool]** Series indicating whether each value has occurred in the preceding values.

**See also:**

- **Index.duplicated** Equivalent method on pandas.Index.
- **DataFrame.duplicated** Equivalent method on pandas.DataFrame.
- **Series.drop_duplicates** Remove duplicate values from Series.
Examples

By default, for each set of duplicated values, the first occurrence is set on False and all others on True:

```python
>>> animals = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> animals.duplicated()
0    False
1    False
2     True
3    False
4     True
dtype: bool
```

which is equivalent to

```python
>>> animals.duplicated(keep='first')
0    False
1    False
2     True
3    False
4     True
dtype: bool
```

By using ‘last’, the last occurrence of each set of duplicated values is set on False and all others on True:

```python
>>> animals.duplicated(keep='last')
0     True
1    False
2     True
3    False
4    False
dtype: bool
```

By setting keep on False, all duplicates are True:

```python
>>> animals.duplicated(keep=False)
0     True
1    False
2     True
3    False
4     True
dtype: bool
```

pandas.Series.eq

Series\[other, level=None, fill_value=None, axis=0\]

Return Equal to of series and other, element-wise (binary operator eq).

Equivalent to series == other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before
computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.eq(b, fill_value=0)
a True
b False
c False
d False
e False
dtype: bool
```

**pandas.Series.equals**

Series.equals(other)

Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the same shape and elements. NaNs in the same location are considered equal.

The row/column index do not need to have the same type, as long as the values are considered equal. Corresponding columns must be of the same dtype.

Parameters

other [Series or DataFrame] The other Series or DataFrame to be compared with the first.

Returns

bool True if all elements are the same in both objects, False otherwise.

See also:

Series.eq Compare two Series objects of the same length and return a Series where each element is True if the element in each Series is equal, False otherwise.
**DataFrame.eq** Compare two DataFrame objects of the same shape and return a DataFrame where each element is True if the respective element in each DataFrame is equal, False otherwise.

**testing.assert_series_equal** Raises an AssertionError if left and right are not equal. Provides an easy interface to ignore inequality in dtypes, indexes and precision among others.

**testing.assert_frame_equal** Like assert_series_equal, but targets DataFrames.

**numpy.array_equal** Return True if two arrays have the same shape and elements, False otherwise.

**Examples**

```python
def = pd.DataFrame({1: [10], 2: [20]})
def
d
0   10  20

DataFrames df and exactly_equal have the same types and values for their elements and column labels, which will return True.

```python
eaxtly_equal = pd.DataFrame({1: [10], 2: [20]})
exactly_equal
ddf = exactly_equal
df.equals(exactly_equal)
True
```

DataFrames df and different_column_type have the same element types and values, but have different types for the column labels, which will still return True.

```python
different_column_type = pd.DataFrame({1.0: [10], 2.0: [20]})
different_column_type
different_column_type
donf = different_column_type
df.equals(different_column_type)
True
```

DataFrames df and different_data_type have different types for the same values for their elements, and will return False even though their column labels are the same values and types.

```python
different_data_type = pd.DataFrame({1: [10.0], 2: [20.0]})
different_data_type
different_data_type
donf = different_data_type
df.equals(different_data_type)
False
```
pandas.Series.ewm

Series.ewm(com=None, span=None, halflife=None, alpha=None, min_periods=0, adjust=True, ignore_na=False, axis=0, times=None)

Provide exponential weighted (EW) functions.

Available EW functions: mean(), var(), std(), corr(), cov().

Exactly one parameter: com, span, halflife, or alpha must be provided.

Parameters

com [float, optional] Specify decay in terms of center of mass, \(\alpha = \frac{1}{1 + \text{com}}\), for \(\text{com} \geq 0\).

span [float, optional] Specify decay in terms of span, \(\alpha = \frac{2}{\text{span} + 1}\), for \(\text{span} \geq 1\).

halflife [float, str, timedelta, optional] Specify decay in terms of half-life, \(\alpha = 1 - \exp\left(-\frac{\ln(2)}{\text{halflife}}\right)\), for \(\text{halflife} > 0\).

If times is specified, the time unit (str or timedelta) over which an observation decays to half its value. Only applicable to mean() and halflife value will not apply to the other functions.

New in version 1.1.0.

alpha [float, optional] Specify smoothing factor \(\alpha\) directly, \(0 < \alpha \leq 1\).

min_periods [int, default 0] Minimum number of observations in window required to have a value (otherwise result is NA).

adjust [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average).

• When adjust=True (default), the EW function is calculated using weights \(w_i = (1 - \alpha)^i\). For example, the EW moving average of the series \([x_0, x_1, \ldots, x_t]\) would be:

\[
y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \ldots + (1 - \alpha)^tx_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + \ldots + (1 - \alpha)^t}
\]

• When adjust=False, the exponentially weighted function is calculated recursively:

\[
y_0 = x_0 \\
y_t = (1 - \alpha)y_{t-1} + \alpha x_t,
\]

ignore_na [bool, default False] Ignore missing values when calculating weights; specify True to reproduce pre-0.15.0 behavior.

• When ignore_na=False (default), weights are based on absolute positions. For example, the weights of \(x_0\) and \(x_2\) used in calculating the final weighted average of \([x_0, \text{None}, x_2]\) are \((1 - \alpha)^2\) and 1 if adjust=True, and \((1 - \alpha)^2\) and \(\alpha\) if adjust=False.

• When ignore_na=True (reproducing pre-0.15.0 behavior), weights are based on relative positions. For example, the weights of \(x_0\) and \(x_2\) used in calculating the final weighted average of \([x_0, \text{None}, x_2]\) are \(1 - \alpha\) and 1 if adjust=True, and \(1 - \alpha\) and \(\alpha\) if adjust=False.

axis [[0, 1], default 0] The axis to use. The value 0 identifies the rows, and 1 identifies the columns.
times [str, np.ndarray, Series, default None] New in version 1.1.0.

    Times corresponding to the observations. Must be monotonically increasing and
datetime64[ns] dtype.

    If str, the name of the column in the DataFrame representing the times.
    If 1-D array like, a sequence with the same shape as the observations.
    Only applicable to mean().

Returns

    DataFrame  A Window sub-classed for the particular operation.

See also:

    rolling  Provides rolling window calculations.
    expanding  Provides expanding transformations.

Notes

More details can be found at: Exponentially weighted windows.

Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})

>>> df
   B
0  0
1  1
2  2
3  NaN
4  4

>>> df.ewm(com=0.5).mean()
   B
0  0
1  0.75
2  1.615
3  1.615
4  3.67

Specifying times with a timedelta halflife when computing mean.

```python
>>> times = ['2020-01-01', '2020-01-03', '2020-01-10', '2020-01-15', '2020-01-17']

>>> df.ewm(halflife='4 days', times=pd.DatetimeIndex(times)).mean()
   B
0  0.0
1  0.59
2  1.53
3  1.53
4  3.24
```
pandas.Series.expanding

Series.expanding(min_periods=1, center=None, axis=0, method='single')

Provide expanding transformations.

Parameters

- **min_periods** [int, default 1] Minimum number of observations in window required to have a value (otherwise result is NA).
- **center** [bool, default False] Set the labels at the center of the window.
- **axis** [int or str, default 0]
- **method** [str {'single', 'table'}, default 'single'] Execute the rolling operation per single column or row ('single') or over the entire object ('table').

This argument is only implemented when specifying engine='numba' in the method call.

New in version 1.3.0.

Returns

- a Window sub-classed for the particular operation

See also:

rolling Provides rolling window calculations.

ewm Provides exponential weighted functions.

Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting center=True.

Examples

```python
>>> df = pd.DataFrame({"B": [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0

>>> df.expanding(2).sum()
   B
0  NaN
1  1.0
2  3.0
3  3.0
4  7.0
```
**pandas.Series.explode**

Series.\texttt{explode}(ignore\_index=False)  
Transform each element of a list-like to a row.

New in version 0.25.0.

**Parameters**

**ignore\_index** [bool, default False] If True, the resulting index will be labeled 0, 1, ..., n - 1.

New in version 1.1.0.

**Returns**

Series Exploded lists to rows; index will be duplicated for these rows.

See also:

\texttt{Series.str.split} Split string values on specified separator.  
\texttt{Series.unstack} Unstack, a.k.a. pivot, Series with MultiIndex to produce DataFrame.  
\texttt{DataFrame.melt} Unpivot a DataFrame from wide format to long format.  
\texttt{DataFrame.explode} Explode a DataFrame from list-like columns to long format.

**Notes**

This routine will explode list-likes including lists, tuples, sets, Series, and np.ndarray. The result dtype of the subset rows will be object. Scalars will be returned unchanged, and empty list-likes will result in a np.nan for that row. In addition, the ordering of elements in the output will be non-deterministic when exploding sets.

**Examples**

```python
>>> s = pd.Series([[1, 2, 3], 'foo', [], [3, 4]])
>>> s
0   [1, 2, 3]
1     foo
2     []
3    [3, 4]
dtype: object

>>> s.explode()
0    1
0    2
0    3
1    foo
2   NaN
3    3
3    4
dtype: object
```
**pandas.Series.factorize**

$pandas.Series.factorize\left(\text{sort=False, na sentinel=-1}\right)$

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. `factorize` is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

**Parameters**

- `sort` [bool, default False] Sort `uniques` and shuffle `codes` to maintain the relationship.
- `na_sentinel` [int or None, default -1] Value to mark “not found”. If None, will not drop the NaN from the uniques of the values.

  Changed in version 1.1.2.

**Returns**

- `codes` [ndarray] An integer ndarray that’s an indexer into `uniques`. `uniques.take(codes)` will have the same values as `values`.
- `uniques` [ndarray, Index, or Categorical] The unique valid values. When `values` is Categorical, `uniques` is a Categorical. When `values` is some other pandas object, an Index is returned. Otherwise, a 1-D ndarray is returned.

  **Note:** Even if there’s a missing value in `values`, `uniques` will not contain an entry for it.

**See also:**

- `cut` Discretize continuous-valued array.
- `unique` Find the unique value in an array.

**Examples**

These examples all show `factorize` as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```python
>>> codes, uniques = pd.factorize(["b", "b", "a", "c", "b")
>>> codes
array([0, 0, 1, 2, 0]...)
>>> uniques
array(["b", "a", "c"], dtype=object)
```

With `sort=True`, the `uniques` will be sorted, and `codes` will be shuffled so that the relationship is maintained.

```python
>>> codes, uniques = pd.factorize(["b", "b", "a", "c", "b")], sort=True)
>>> codes
array([1, 1, 0, 2, 1]...)
>>> uniques
array(["a", "b", "c"], dtype=object)
```

Missing values are indicated in `codes` with `na_sentinel` (-1 by default). Note that missing values are never included in `uniques`. 
Thus far, we've only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of `uniques` will differ. For Categoricals, a `Categorical` is returned.

```python
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1]...)
>>> uniques
['a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```python
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1]...)
>>> uniques
Index(['a', 'c'], dtype='object')
```

If NaN is in the values, and we want to include NaN in the uniques of the values, it can be achieved by setting `na_sentinel=None`.

```python
>>> values = np.array([1, 2, 1, np.nan])
>>> codes, uniques = pd.factorize(values)  # default: na_sentinel=-1
>>> codes
array([ 0, 1, 0, -1])
>>> uniques
array([ 1., 2.])
```

```python
>>> codes, uniques = pd.factorize(values, na_sentinel=None)
>>> codes
array([0, 1, 0, 2])
>>> uniques
array([ 1., 2., nan])
```

### pandas.Series.ffill

`Series.ffill` is a synonym for `DataFrame.fillna()` with method='ffill'.

**Returns**

- **Series/DataFrame or None** Object with missing values filled or None if `inplace=True`. 

---

3.3. Series
pandas.Series.fillna

Series.fillna(value=None, method=None, axis=None, inplace=False, limit=None, downcast=None)

Fill NA/NaN values using the specified method.

Parameters

- **value**: [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

- **method**: [{'backfill', 'bfill', 'pad', 'ffill', None}, default None] Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use next valid observation to fill gap.

- **axis**: [0 or 'index'] Axis along which to fill missing values.

- **inplace**: [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

- **limit**: [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

- **downcast**: [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns

Series or None Object with missing values filled or None if inplace=True.

See also:

- **interpolate** Fill NaN values using interpolation.
- **reindex** Conform object to new index.
- **asfreq** Convert TimeSeries to specified frequency.

Examples

```python
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                     [3, 4, np.nan, 1],
...                     [np.nan, np.nan, np.nan, 5],
...                     [np.nan, 3, np.nan, 4]],
...                    columns=list("ABCD"))
>>> df
   A  B  C  D
0  NaN 2.0 NaN 0
1    3.0 4.0 NaN 1
2  NaN NaN NaN 5
3  NaN  3.0 NaN 4
```

Replace all NaN elements with 0s.
```python
>>> df.fillna(0)
   A   B   C   D
0 0.0 2.0 0.0 0.0
1 3.0 4.0 0.0 1.0
2 0.0 0.0 0.0 5.0
3 0.0 3.0 0.0 4.0
```

We can also propagate non-null values forward or backward.

```python
>>> df.fillna(method="ffill")
   A   B   C   D
0  NaN 2.0  NaN 0.0
1  3.0 4.0  NaN 1.0
2  3.0 4.0  NaN 5.0
3  3.0 3.0  NaN 4.0
```

Replace all NaN elements in column ‘A’, ‘B’, ‘C’, and ‘D’, with 0, 1, 2, and 3 respectively.

```python
>>> values = {"A": 0, "B": 1, "C": 2, "D": 3}

>>> df.fillna(value=values)
   A   B   C   D
0 0.0 2.0 2.0 0.0
1 3.0 4.0 2.0 1.0
2 0.0 1.0 2.0 5.0
3 0.0 3.0 2.0 4.0
```

Only replace the first NaN element.

```python
>>> df.fillna(value=values, limit=1)
   A   B   C   D
0 0.0 2.0 2.0 0.0
1 3.0 4.0 NaN 1.0
2 NaN 1.0 NaN 5.0
3 NaN 3.0 NaN 4.0
```

When filling using a DataFrame, replacement happens along the same column names and same indices.

```python
>>> df2 = pd.DataFrame(np.zeros((4, 4)), columns=list("ABCE"))

>>> df.fillna(df2)
   A   B   C   D
0 0.0 2.0 0.0 0.0
1 3.0 4.0 0.0 1.0
2 0.0 0.0 0.0 5.0
3 0.0 3.0 0.0 4.0
```

**pandas.Series.filter**

*Series.filter(items=None, like=None, regex=None, axis=None)*

Subset the dataframe rows or columns according to the specified index labels.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

**Parameters**

- **items** [list-like] Keep labels from axis which are in items.
like  [str] Keep labels from axis for which “like in label == True”.

regex  [str (regular expression)] Keep labels from axis for which re.search(regex, label) == True.

axis  [{0 or ‘index’, 1 or ‘columns’, None}, default None] The axis to filter on, expressed either as an index (int) or axis name (str). By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame.

Returns
    same type as input object

See also:

**DataFrame.loc**  Access a group of rows and columns by label(s) or a boolean array.

Notes

The items, like, and regex parameters are enforced to be mutually exclusive.

axis defaults to the info axis that is used when indexing with [].

Examples

```python
>>> df = pd.DataFrame(np.array(([[1, 2, 3], [4, 5, 6]]),
... index=['mouse', 'rabbit'],
... columns=['one', 'two', 'three'])
>>> df
one   two  three
mouse   1   2   3
rabbit   4   5   6
>>> # select columns by name
>>> df.filter(items=['one', 'three'])
    one  three
mouse   1   3
rabbit   4   6
>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
    one  three
mouse   1   3
rabbit   4   6
>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
    one   two  three
mouse   1   2   3
rabbit   4   5   6
```
pandas.Series.first

Series.first(offset)
Select initial periods of time series data based on a date offset.
When having a DataFrame with dates as index, this function can select the first few rows based on a date offset.

Parameters

offset [str, DateOffset or dateutil.relativedelta] The offset length of the data that will be selected. For instance, ‘1M’ will display all the rows having their index within the first month.

Returns

Series or DataFrame A subset of the caller.

Raises

TypeError If the index is not a DatetimeIndex

See also:

last Select final periods of time series based on a date offset.
at_time Select values at a particular time of the day.
between_time Select values between particular times of the day.

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
   A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4

Get the rows for the first 3 days:

```python
>>> ts.first('3D')
   A
2018-04-09  1
2018-04-11  2
```

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.
pandas.Series.first_valid_index

Series.first_valid_index()
Return index for first non-NA value or None, if no NA value is found.

Returns
scalar [type of index]

Notes
If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.Series.floordiv

Series.floordiv(other, level=None, fill_value=None, axis=0)
Return Integer division of series and other, element-wise (binary operator floordiv).
Equivalent to series // other, but with support to substitute a fill_value for missing data in either
one of the inputs.

Parameters
other [Series or scalar value]
fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values,
and any new element needed for successful Series alignment, with this value before
computation. If data in both corresponding Series locations is missing the result of
filling (at that location) will be missing.
level [int or name] Broadcast across a level, matching Index values on the passed Multi-
Index level.

Returns
Series The result of the operation.

See also:
Series.rfloordiv Reverse of the Integer division operator, see Python documentation for more
details.

Examples

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0  
b  1.0   
c  1.0   
d  NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b  NaN
d  1.0
(continues on next page)
pandas.Series.ge

Series.ge(other, level=None, fill_value=None, axis=0)

Return Greater than or equal to of series and other, element-wise (binary operator ge).

Equivalent to series >= other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

- other [Series or scalar value]
- fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
>>> a
a    1.0
b    1.0
c    1.0
d   NaN
e    1.0
dtype: float64
>>> b = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
>>> b
a    0.0
b    1.0
c    2.0
d   NaN
f    1.0
dtype: float64
>>> a.ge(b, fill_value=0)
a    True
b    True
```

(continues on next page)
pandas.Series.get

Series.get(key, default=None)

Get item from object for given key (ex: DataFrame column).

Returns default value if not found.

Parameters

key [object]

Returns

value [same type as items contained in object]

pandas.Series.groupby

Series.groupby(by=None, axis=0, level=None, as_index=True, sort=True, group_keys=True, squeeze=<no_default>, observed=False, dropna=True)

Group Series using a mapper or by a Series of columns.

A groupby operation involves some combination of splitting the object, applying a function, and combining the results. This can be used to group large amounts of data and compute operations on these groups.

Parameters

by [mapping, function, label, or list of labels] Used to determine the groups for the groupby. If by is a function, it’s called on each value of the object’s index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the groups (the Series’ values are first aligned; see .align() method). If an ndarray is passed, the values are used as-is to determine the groups. A label or list of labels may be passed to group by the columns in self. Notice that a tuple is interpreted as a (single) key.

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Split along rows (0) or columns (1).

level [int, level name, or sequence of such, default None] If the axis is a MultiIndex (hierarchical), group by a particular level or levels.

as_index [bool, default True] For aggregated output, return object with group labels as the index. Only relevant for DataFrame input. as_index=False is effectively “SQL-style” grouped output.

sort [bool, default True] Sort group keys. Get better performance by turning this off. Note this does not influence the order of observations within each group. Groupby preserves the order of rows within each group.

group_keys [bool, default True] When calling apply, add group keys to index to identify pieces.
**squeeze** [bool, default False] Reduce the dimensionality of the return type if possible, otherwise return a consistent type.

Deprecated since version 1.1.0.

**observed** [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

**dropna** [bool, default True] If True, and if group keys contain NA values, NA values together with row/column will be dropped. If False, NA values will also be treated as the key in groups.

New in version 1.1.0.

**Returns**

**SeriesGroupBy** Returns a groupby object that contains information about the groups.

**See also:**

**resample** Convenience method for frequency conversion and resampling of time series.

**Notes**

See the user guide for more.

**Examples**

```python
>>> ser = pd.Series([390., 350., 30., 20.],
                   index=['Falcon', 'Falcon', 'Parrot', 'Parrot'], name='Max Speed')
>>> ser
Falcon 390.0
Falcon 350.0
Parrot 30.0
Parrot 20.0
Name: Max Speed, dtype: float64

>>> ser.groupby(['a', 'b', 'a', 'b']).mean()
a  210.0
b  185.0
Name: Max Speed, dtype: float64

>>> ser.groupby(level=0).mean()
Falcon 370.0
Parrot 25.0
Name: Max Speed, dtype: float64

>>> ser.groupby(ser > 100).mean()
Max Speed
False 25.0
True 370.0
Name: Max Speed, dtype: float64
```

**Grouping by Indexes**

We can groupby different levels of a hierarchical index using the `level` parameter:
arrays = [['Falcon', 'Falcon', 'Parrot', 'Parrot'],
          ['Captive', 'Wild', 'Captive', 'Wild']]
index = pd.MultiIndex.from_arrays(arrays, names=('Animal', 'Type'))
ser = pd.Series([390., 350., 30., 20.], index=index, name="Max Speed")
ser
Animal   Type
Falcon  Captive  390.0
         Wild  350.0
Parrot  Captive  30.0
         Wild  20.0
Name: Max Speed, dtype: float64
ser.groupby(level=0).mean()
Animal
Falcon  370.0
Parrot  25.0
Name: Max Speed, dtype: float64
ser.groupby(level="Type").mean()
Type
Captive  210.0
Wild  185.0
Name: Max Speed, dtype: float64
We can also choose to include NA in group keys or not by defining dropna parameter, the default setting is True:

ser = pd.Series([1, 2, 3, 3], index=['a', 'a', 'b', np.nan])
ser.groupby(level=0).sum()
a  3
b  3
dtype: int64
ser.groupby(level=0, dropna=False).sum()
a  3
b  3
NaN  3
dtype: int64
arrays = ['Falcon', 'Falcon', 'Parrot', 'Parrot']
ser = pd.Series([390., 350., 30., 20.], index=arrays, name="Max Speed")
ser.groupby("a", "b", "a", np.nan).mean()
a  210.0
b  350.0
Name: Max Speed, dtype: float64
ser.groupby(\"a", \"b", \"a\", np.nan, dropna=False).mean()
a  210.0
b  350.0
NaN  20.0
Name: Max Speed, dtype: float64
**pandas.Series.gt**

Series.gt (other, level=None, fill_value=None, axis=0)

Return Greater than of series and other, element-wise (binary operator gt).

Equivalent to series > other, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

Series The result of the operation.

**Examples**

```python
gt = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
gt = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
gt = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
```

```python
gt = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
gt = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
gt = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
```

```python
gt = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
gt = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
gt = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
```

```python
gt = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
gt = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
gt = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
```
**pandas.Series.head**

Series.head(n=5)

Return the first $n$ rows.

This function returns the first $n$ rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

For negative values of $n$, this function returns all rows except the last $n$ rows, equivalent to `df[:-n]`.

**Parameters**

- $n$ [int, default 5] Number of rows to select.

**Returns**

- same type as caller The first $n$ rows of the caller object.

See also:

- `DataFrame.tail` Returns the last $n$ rows.

**Examples**

```python
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
... 'monkey', 'parrot', 'shark', 'whale', 'zebra']})

>>> df
animal
0  alligator
1    bee
2  falcon
3    lion
4  monkey
5   parrot
6   shark
7   whale
8    zebra
```

Viewing the first 5 lines

```python
>>> df.head()
animal
0  alligator
1    bee
2  falcon
3    lion
4  monkey
```

Viewing the first $n$ lines (three in this case)

```python
>>> df.head(3)
animal
0  alligator
1    bee
2  falcon
```

For negative values of $n
```
>>> df.head(-3)
animal
0   alligator
1     bee
2   falcon
3     lion
4   monkey
5  parrot
```

**pandas.Series.hist**

`Series.hist(by=None, ax=None, grid=True, xlabelsize=None, xrot=None, ylabelsize=None, yrot=None, figsize=None, bins=10, backend=None, legend=False, **kwargs)`

Draw histogram of the input series using matplotlib.

**Parameters**

- `by` [object, optional] If passed, then used to form histograms for separate groups.
- `ax` [matplotlib axis object] If not passed, uses gca().
- `grid` [bool, default True] Whether to show axis grid lines.
- `xlabelsize` [int, default None] If specified changes the x-axis label size.
- `xrot` [float, default None] Rotation of x axis labels.
- `ylabelsize` [int, default None] If specified changes the y-axis label size.
- `yrot` [float, default None] Rotation of y axis labels.
- `figsize` [tuple, default None] Figure size in inches by default.
- `bins` [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.
- `backend` [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, `matplotlib`. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

- `legend` [bool, default False] Whether to show the legend.

New in version 1.1.0.

**kwargs To be passed to the actual plotting function.

**Returns**

`matplotlib.AxesSubplot` A histogram plot.

**See also:**

- `matplotlib.axes.Axes.hist` Plot a histogram using matplotlib.
Series.idxmax

Return the row label of the maximum value.

If multiple values equal the maximum, the first row label with that value is returned.

Parameters

axis [int, default 0] For compatibility with DataFrame.idxmax. Redundant for application
on Series.

skipna [bool, default True] Exclude NA/null values. If the entire Series is NA, the result
will be NA.

*args, **kwargs Additional arguments and keywords have no effect but might be ac-
cepted for compatibility with NumPy.

Returns

Index Label of the maximum value.

Raises

ValueError If the Series is empty.

See also:

numpy.argmax Return indices of the maximum values along the given axis.
(DataFrame.idxmax Return index of first occurrence of maximum over requested axis.
Series.idxmin Return index label of the first occurrence of minimum of values.

Notes

This method is the Series version of ndarray.argmax. This method returns the label of the maximum,
while ndarray.argmax returns the position. To get the position, use series.values.argmax().

Examples

```python
>>> s = pd.Series(data=[1, None, 4, 3, 4],
...                index=['A', 'B', 'C', 'D', 'E'])
>>> s
A    1.0
B   NaN
C    4.0
D    3.0
E    4.0
dtype: float64

>>> s.idxmax()
'C'
```

If skipna is False and there is an NA value in the data, the function returns nan.

```python
>>> s.idxmax(skipna=False)
nan
```
**pandas.Series.idxmin**

Series.idxmin(axis=0, skipna=True, *args, **kwargs)
Return the row label of the minimum value.
If multiple values equal the minimum, the first row label with that value is returned.

**Parameters**

- **axis** [int, default 0] For compatibility with DataFrame.idxmin. Redundant for application on Series.
- **skipna** [bool, default True] Exclude NA/null values. If the entire Series is NA, the result will be NA.
- ***args, **kwargs** Additional arguments and keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- **Index**  Label of the minimum value.

**Raises**

- **ValueError** If the Series is empty.

**See also:**

- numpy.argmin Return indices of the minimum values along the given axis.
- DataFrame.idxmin Return index of first occurrence of minimum over requested axis.
- Series.idxmax Return index label of the first occurrence of maximum of values.

**Notes**

This method is the Series version of ndarray.argmin. This method returns the label of the minimum, while ndarray.argmin returns the position. To get the position, use series.values.argmin().

**Examples**

```python
>>> s = pd.Series(data=[1, None, 4, 1],
                  index=['A', 'B', 'C', 'D'])
>>> s
A    1.0
B   NaN
C    4.0
D    1.0
dtype: float64

>>> s.idxmin()
'A'

If skipna is False and there is an NA value in the data, the function returns nan.

>>> s.idxmin(skipna=False)
nan
```
pandas.Series.infer_objects

Series.infer_objects()

Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

Returns

converted [same type as input object]

See also:

to_datetime  Convert argument to datetime.
to_timedelta Convert argument to timedelta.
to_numeric  Convert argument to numeric type.
convert_dtypes  Convert argument to best possible dtype.

Examples

```python
>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
      A
1  1  1
2  2  2
3  3  3
```

```python
>>> df.dtypes
A object
dtype: object
```

```python
>>> df.infer_objects().dtypes
A int64
dtype: object
```

pandas.Series.interpolate

Series.interpolate(method='linear', axis=0, limit=None, inplace=False, limit_direction=None, limit_area=None, downcast=None, **kwargs)

Fill NaN values using an interpolation method.

Please note that only method='linear' is supported for DataFrame/Series with a MultiIndex.

Parameters

method  [str, default ‘linear’] Interpolation technique to use. One of:

- ‘linear’: Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
- ‘time’: Works on daily and higher resolution data to interpolate given length of interval.
• ‘index’, ‘values’: use the actual numerical values of the index.
• ‘pad’: Fill in NaNs using existing values.
• ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘spline’, ‘barycentric’, ‘polynomial’: Passed to `scipy.interpolate.interp1d`. These methods use the numerical values of the index. Both ‘polynomial’ and ‘spline’ require that you also specify an order (int), e.g. `df.interpolate(method='polynomial', order=5)`.
• ‘from_derivatives’: Refers to `scipy.interpolate.BPoly.from_derivatives` which replaces ‘piecewise_polynomial’ interpolation method in scipy 0.18.

**axis** [(0 or ‘index’, 1 or ‘columns’, None), default None] Axis to interpolate along.

**limit** [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

**inplace** [bool, default False] Update the data in place if possible.

**limit_direction** [{‘forward’, ‘backward’, ‘both’}, Optional] Consecutive NaNs will be filled in this direction.

**If limit is specified:**
• If ‘method’ is ‘pad’ or ‘ffill’, ‘limit_direction’ must be ‘forward’.
• If ‘method’ is ‘backfill’ or ‘bfill’, ‘limit_direction’ must be ‘backwards’.

**If ‘limit’ is not specified:**
• If ‘method’ is ‘backfill’ or ‘bfill’, the default is ‘backward’
• else the default is ‘forward’

Changed in version 1.1.0: raises ValueError if `limit_direction` is ‘forward’ or ‘both’ and method is ‘backfill’ or ‘bfill’. raises ValueError if `limit_direction` is ‘backward’ or ‘both’ and method is ‘pad’ or ‘ffill’.

**limit_area** [{None, ‘inside’, ‘outside’}, default None] If limit is specified, consecutive NaNs will be filled with this restriction.
• None: No fill restriction.
• ‘inside’: Only fill NaNs surrounded by valid values (interpolate).
• ‘outside’: Only fill NaNs outside valid values (extrapolate).

**downcast** [optional, ‘infer’ or None, defaults to None] Downcast dtypes if possible.

**\*\*kwargs** [optional] Keyword arguments to pass on to the interpolating function.

Returns

Series or DataFrame or None Returns the same object type as the caller, interpolated at some or all NaN values or None if inplace=True.

See also:

fillna Fill missing values using different methods.

scipy.interpolate.Akima1DInterpolator Piecewise cubic polynomials (Akima interpolator).
**scipy.interpolate.BPoly.from_derivatives** Piecewise polynomial in the Bernstein basis.

**scipy.interpolate.interp1d** Interpolate a 1-D function.

**scipy.interpolate.KroghInterpolator** Interpolate polynomial (Krogh interpolator).

**scipy.interpolate.PchipInterpolator** PCHIP 1-d monotonic cubic interpolation.

**scipy.interpolate.CubicSpline** Cubic spline data interpolator.

**Notes**

The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the SciPy documentation and SciPy tutorial.

**Examples**

**Filling in NaN in a Series via linear interpolation.**

```python
>>> s = pd.Series([0, 1, np.nan, 3])

>>> s.interpolate()
0    0.0
1    1.0
2    NaN
3    3.0
dtype: float64
```

**Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.**

```python
>>> s = pd.Series([np.nan, "single_one", np.nan, ...  "fill_two_more", np.nan, np.nan, np.nan, ...  4.71, np.nan])

>>> s.interpolate(method='pad', limit=2)
0    NaN
1  single_one
2    NaN
3  fill_two_more
4    NaN
5    NaN
6    NaN
7    4.71
8    NaN
dtype: object
```

(continues on next page)
Filling in NaN in a Series via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an order (int).

```python
>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64
```

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it to use for interpolation.

```python
>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
... (np.nan, 2.0, np.nan, np.nan),
... (2.0, 3.0, np.nan, 9.0),
... (np.nan, 4.0, -4.0, 16.0)],
... columns=list('abcd'))
>>> df.interpolate(method='linear', limit_direction='forward', axis=0)
a  b  c  d
0  0.0 NaN -1.0  1.0
1  NaN  2.0 NaN NaN
2  2.0  3.0 NaN  9.0
3  NaN  4.0 -4.0 16.0
```

Using polynomial interpolation.

```python
>>> df['d'].interpolate(method='polynomial', order=2)
0   1.0
1   4.0
2   9.0
3  16.0
Name: d, dtype: float64
```
pandas.Series.isin

Series.isin(values)
Whether elements in Series are contained in values.
Return a boolean Series showing whether each element in the Series matches an element in the passed sequence of values exactly.

Parameters
values [set or list-like] The sequence of values to test. Passing in a single string will raise a TypeError. Instead, turn a single string into a list of one element.

Returns
Series Series of booleans indicating if each element is in values.

Raises
TypeError
• If values is a string

See also:

DataFrame.isin Equivalent method on DataFrame.

Examples

```python
>>> s = pd.Series(['lama', 'cow', 'lama', 'beetle', 'lama',
... 'hippo'], name='animal')
>>> s.isin(['cow', 'lama'])
0    True
1    True
2    True
3   False
4    True
5   False
Name: animal, dtype: bool
```

Passing a single string as s.isin('lama') will raise an error. Use a list of one element instead:

```python
>>> s.isin(['lama'])
0    True
1   False
2    True
3   False
4    True
5   False
Name: animal, dtype: bool
```

Strings and integers are distinct and are therefore not comparable:

```python
>>> pd.Series([1]).isin(['1'])
0   False
dtype: bool
>>> pd.Series([1.1]).isin(['1.1'])
0   False
dtype: bool
```
pandas.Series.isna

Series.isna()
Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy.nan, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

Returns

Series Mask of bool values for each element in Series that indicates whether an element is an NA value.

See also:

Series.isnull Alias of isna.
Series.notna Boolean inverse of isna.
Series.dropna Omit axes labels with missing values.

Examples

Show which entries in a DataFrame are NA.

```python
>>> df = pd.DataFrame(dict(age=[5, 6, np.nan],
                             pd.Timestamp('1940-04-25')],
                      name=['Alfred', 'Batman', ''],
                      toy=[None, 'Batmobile', 'Joker']))
>>> df
   age   born                name         toy
0   5.0      NaT          Alfred        None
1   6.0 1939-05-27        Batman  Batmobile
2  NaN   1940-04-25  Joker
```

```python
>>> df.isna()
   age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2  True  False  False  False
```

Show which entries in a Series are NA.

```python
>>> ser = pd.Series([5, 6, np.nan])
>>> ser
0    5.0
1    6.0
2   NaN
dtype: float64
```

```python
>>> ser.isna()
0  False
```

(continues on next page)
pandas.Series.isnull

Series.isnull()
Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy. NaN, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

Returns
Series Mask of bool values for each element in Series that indicates whether an element is an NA value.
See also:

 Series.isnull Alias of isna.
 Series.notna Boolean inverse of isna.
 Series.dropna Omit axes labels with missing values.
 isna Top-level isna.

Examples
Show which entries in a DataFrame are NA.

```python
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
... born=[pd.NaT, pd.Timestamp('1939-05-27'),
... pd.Timestamp('1940-04-25')],
... name=['Alfred', 'Batman', ''],
... toy=[None, 'Batmobile', 'Joker']))
```

```plain
age born name toy
0 5.0 NaT Alfred None
1 6.0 1939-05-27 Batman Batmobile
2 NaN 1940-04-25 Joker
```

```python
>>> df.isna()
age born name toy
0 False True False True
1 False False False False
2 True False False False
```

Show which entries in a Series are NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0 5.0
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
1  6.0
2  NaN
dtype: float64
```

```python
>>> ser.isna()
0  False
1  False
2  True
dtype: bool
```

### pandas.Series.item

**Series.item()**

Return the first element of the underlying data as a Python scalar.

**Returns**

- `scalar` The first element of `%(klass)s`.

**Raises**

- `ValueError` If the data is not length-1.

### pandas.Series.items

**Series.items()**

Lazily iterate over (index, value) tuples.

This method returns an iterable tuple (index, value). This is convenient if you want to create a lazy iterator.

**Returns**

- `iterable` Iterable of tuples containing the (index, value) pairs from a Series.

**See also:**

- `DataFrame.items` Iterate over (column name, Series) pairs.
- `DataFrame.iterrows` Iterate over DataFrame rows as (index, Series) pairs.

### Examples

```python
>>> s = pd.Series(['A', 'B', 'C'])
>>> for index, value in s.items():
...     print(f"Index : {index}, Value : {value}" )
Index : 0, Value : A
Index : 1, Value : B
Index : 2, Value : C
```
**pandas.Series.iteritems**

Series.iteritems() Lazily iterate over (index, value) tuples.

This method returns an iterable tuple (index, value). This is convenient if you want to create a lazy iterator.

**Returns**

iterable Iterable of tuples containing the (index, value) pairs from a Series.

**See also:**

- **DataFrame.items** Iterate over (column name, Series) pairs.
- **DataFrame.iterrows** Iterate over DataFrame rows as (index, Series) pairs.

**Examples**

```python
>>> s = pd.Series(['A', 'B', 'C'])
>>> for index, value in s.items():
...     print(f"Index : {index}, Value : {value}"
Index : 0, Value : A
Index : 1, Value : B
Index : 2, Value : C
```

**pandas.Series.keys**

Series.keys() Return alias for index.

**Returns**

Index Index of the Series.

**pandas.Series.kurt**

Series.kurt(axis=None, skipna=None, level=None, numeric_only=None, **kwargs) Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

**Parameters**

- **axis** ([index (0)]) Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- ****kwargs Additional keyword arguments to be passed to the function.

**Returns**
scalar or Series (if level specified)

**pandas.Series.kurtosis**

Series.kurtosis (axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher's definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

**Parameters**
- **axis** [index (0)] Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs** Additional keyword arguments to be passed to the function.

**Returns**
scalar or Series (if level specified)

**pandas.Series.last**

Series.last (offset)
Select final periods of time series data based on a date offset.

For a DataFrame with a sorted DatetimeIndex, this function selects the last few rows based on a date offset.

**Parameters**
- **offset** [str, DateOffset, dateutil.relativedelta] The offset length of the data that will be selected. For instance, ‘3D’ will display all the rows having their index within the last 3 days.

**Returns**
Series or DataFrame A subset of the caller.

**Raises**
TypeError If the index is not a DatetimeIndex

**See also:**
- **first** Select initial periods of time series based on a date offset.
- **at_time** Select values at a particular time of the day.
- **between_time** Select values between particular times of the day.
Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
   A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4
```

Get the rows for the last 3 days:

```python
>>> ts.last('3D')
   A
2018-04-13  3
2018-04-15  4
```

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

**pandas.Series.last_valid_index**

Series.last_valid_index()

Return index for last non-NA value or None, if no NA value is found.

**Returns**

```
scalar  [type of index]
```

**Notes**

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

**pandas.Series.le**

Series.le(other, level=None, fill_value=None, axis=0)

Return Less than or equal to of series and other, element-wise (binary operator \(le\)).

Equivalent to `series <= other`, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

```
other  [Series or scalar value]
fill_value  [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
level  [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.
```

**Returns**

```
Series  The result of the operation.
```
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
e 1.0
dtype: float64
>>> b = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
>>> b
a 0.0
b 1.0
c 2.0
d NaN
f 1.0
dtype: float64
>>> a.le(b, fill_value=0)
a False
b True
c True
d False
e False
f True
dtype: bool
```

### pandas.Series.lt

**Series.lt**(other, level=None, fill_value=None, axis=0)

Return Less than of series and other, element-wise (binary operator lt).

Equivalent to `series < other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

**Returns**

- **Series** The result of the operation.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan, 1], index=['a', 'b', 'c', 'd', 'e'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
e    1.0
dtype: float64
>>> b = pd.Series([0, 1, 2, np.nan, 1], index=['a', 'b', 'c', 'd', 'f'])
>>> b
a    0.0
b    1.0
c    2.0
d    NaN
f    1.0
dtype: float64
>>> a.lt(b, fill_value=0)
a   False
b   False
c   True
d   False
e   False
f   True
dtype: bool
```

**pandas.Series.mad**

Series.mad(axis=None, skipna=None, level=None)

Return the mean absolute deviation of the values over the requested axis.

**Parameters**

- **axis** [{index (0)] Axis for the function to be applied on.
- **skipna** [bool, default None] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

**Returns**

- scalar or Series (if level specified)

**pandas.Series.map**

Series.map(arg, na_action=None)

Map values of Series according to input correspondence.

Used for substituting each value in a Series with another value, that may be derived from a function, a dict or a Series.

**Parameters**

- **arg** [function, collections.abc.Mapping subclass or Series] Mapping correspondence.
na_action  [{None, ‘ignore’}, default None] If ‘ignore’, propagate NaN values, without
passing them to the mapping correspondence.

Returns
Series  Same index as caller.

See also:

Series.apply  For applying more complex functions on a Series.

Dataframe.apply  Apply a function row-/column-wise.

Dataframe.applymap  Apply a function elementwise on a whole DataFrame.

Notes

When **arg** is a dictionary, values in Series that are not in the dictionary (as keys) are converted to NaN. However, if the dictionary is a dict subclass that defines **__missing__** (i.e. provides a method for default values), then this default is used rather than NaN.

Examples

```python
>>> s = pd.Series(['cat', 'dog', np.nan, 'rabbit'])
>>> s
0    cat
1    dog
2    NaN
3   rabbit
dtype: object
```

map accepts a dict or a Series. Values that are not found in the dict are converted to NaN, unless the dict has a default value (e.g. defaultdict):

```python
>>> s.map({'cat': 'kitten', 'dog': 'puppy'})
0     kitten
1    puppy
2      NaN
3      NaN
dtype: object
```

It also accepts a function:

```python
>>> s.map('I am a {0}'.format)
0    I am a cat
1    I am a dog
2    I am a nan
3    I am a rabbit
dtype: object
```

To avoid applying the function to missing values (and keep them as NaN) **na_action='ignore'** can be used:

```python
>>> s.map('I am a {0}'.format, na_action='ignore')
0    I am a cat
1    I am a dog
```

(continues on next page)
pandas.Series.mask

Series.mask(cond, other=nan, inplace=False, axis=None, level=None, errors='raise',
try_cast=<no_default>)

Replace values where the condition is True.

Parameters

cond [bool Series/DataFrame, array-like, or callable] Where cond is False, keep the original value. Where True, replace with corresponding value from other. If cond is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

other [scalar, Series/DataFrame, or callable] Entries where cond is True are replaced with corresponding value from other. If other is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {‘raise’, ‘ignore’}, default ‘raise’] Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.

• ‘raise’ : allow exceptions to be raised.
• ‘ignore’ : suppress exceptions. On error return original object.

try_cast [bool, default None] Try to cast the result back to the input type (if possible).

Returns

Same type as caller or None if inplace=True.

See also:

DataFrame.where() Return an object of same shape as self.

Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if cond is False the element is used; otherwise the corresponding element from the DataFrame other is used.

The signature for DataFrame.where() differs from numpy.where(). Roughly df1.where(m, df2) is equivalent to np.where(m, df1, df2).

For further details and examples see the mask documentation in indexing.
Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```python
>>> s.where(s > 1, 10)
0   10
1   10
2    2
3    3
4    4
dtype: int64
>>> s.mask(s > 1, 10)
0    0
1    1
2   10
3   10
4   10
dtype: int64
```

```python
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
>>> m = df % 3 == 0
>>> df.where(m, -df)
   A  B
0  0 -1
1 -2  3
2 -4 -5
3  6 -7
4 -8  9
```

```python
>>> df.where(m, -df) == np.where(m, df, -df)
   A  B
0  True True
1  True True
2  True True
3  True True
4  True True
```

**pandas.Series.max**

Series.max(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return the maximum of the values over the requested axis.

If you want the index of the maximum, use idxmax. This is the equivalent of the numpy.ndarray method argmax.

**Parameters**

- **axis** ([index (0)]) Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs** Additional keyword arguments to be passed to the function.

**Returns**

scalar or Series (if level specified)

**See also:**

- **Series.sum** Return the sum.
- **Series.min** Return the minimum.
- **Series.max** Return the maximum.
- **Series.idxmin** Return the index of the minimum.
- **Series.idxmax** Return the index of the maximum.
- **DataFrame.sum** Return the sum over the requested axis.
- **DataFrame.min** Return the minimum over the requested axis.
- **DataFrame.max** Return the maximum over the requested axis.
- **DataFrame.idxmin** Return the index of the minimum over the requested axis.
- **DataFrame.idxmax** Return the index of the maximum over the requested axis.
Examples

```python
>>> idx = pd.MultiIndex.from_arrays(
...     [['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded animal
    warm  dog  4
    falcon  2
cold    fish   0
    spider   8
Name: legs, dtype: int64

>>> s.max()
8
```

**pandas.Series.mean**

`Series.mean(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return the mean of the values over the requested axis.

**Parameters**

- **axis** ([index (0)]) Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs** Additional keyword arguments to be passed to the function.

**Returns**

- scalar or Series (if level specified)

**pandas.Series.median**

`Series.median(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)`

Return the median of the values over the requested axis.

**Parameters**

- **axis** ([index (0)]) Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
**kwargs Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

**pandas.Series.memory_usage**

Series.memory_usage (index=True, deep=False)

Return the memory usage of the Series.

The memory usage can optionally include the contribution of the index and of elements of `object` dtype.

Parameters

index [bool, default True] Specifies whether to include the memory usage of the Series index.

depth [bool, default False] If True, introspect the data deeply by interrogating `object` dtypes for system-level memory consumption, and include it in the returned value.

Returns

int Bytes of memory consumed.

See also:

numpy.ndarray.nbytes Total bytes consumed by the elements of the array.

DataFrame.memory_usage Bytes consumed by a DataFrame.

Examples

```python
>>> s = pd.Series(range(3))
>>> s.memory_usage()
152
```

Not including the index gives the size of the rest of the data, which is necessarily smaller:

```python
>>> s.memory_usage(index=False)
24
```

The memory footprint of `object` values is ignored by default:

```python
>>> s = pd.Series(['a', 'b'])
>>> s.values
array(['a', 'b'], dtype=object)
>>> s.memory_usage()
144
>>> s.memory_usage(deep=True)
244
```
pandas.Series.min

Series.min(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return the minimum of the values over the requested axis.

If you want the index of the minimum, use idxmin. This is the equivalent of the numpy.ndarray method argmin.

Parameters

axis [index (0)] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

See also:

Series.sum Return the sum.
Series.min Return the minimum.
Series.max Return the maximum.
Series.idxmin Return the index of the minimum.
Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.
DataFrame.min Return the minimum over the requested axis.
DataFrame.max Return the maximum over the requested axis.
DataFrame.idxmin Return the index of the minimum over the requested axis.
DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

```python
>>> idx = pd.MultiIndex.from_arrays([
... ['warm', 'warm', 'cold', 'cold'],
... ['dog', 'falcon', 'fish', 'spider'],
... names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
        warm  dog  4
        falcon  2
        cold  fish  0
        spider  8
Name: legs, dtype: int64
```
pandas.Series.mod

Series.mod(other, level=None, fill_value=None, axis=0)

Return Modulo of series and other, element-wise (binary operator mod).

Equivalent to series % other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

See also:

Series.rmod Reverse of the Modulo operator, see Python documentation for more details.

Examples

```python
ts1 = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
ts2 = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> ts1 % ts2
a    0.0
b     NaN
c     NaN
d    0.0
Name: a, dtype: float64
```
pandas.Series.mode

Series.mode (dropna=True)
Return the mode(s) of the Series.
The mode is the value that appears most often. There can be multiple modes.
Always returns Series even if only one value is returned.

Parameters

dropna [bool, default True] Don’t consider counts of NaN/NaT.

Returns

Series  Modes of the Series in sorted order.

pandas.Series.mul

Series.mul (other, level=None, fill_value=None, axis=0)
Return Multiplication of series and other, element-wise (binary operator mul).
Equivalent to series * other, but with support to substitute a fill_value for missing data in either
one of the inputs.

Parameters

other [Series or scalar value]
fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values,
and any new element needed for successful Series alignment, with this value before
computation. If data in both corresponding Series locations is missing the result of
filling (at that location) will be missing.
level [int or name] Broadcast across a level, matching Index values on the passed Multi-
Index level.

Returns

Series  The result of the operation.

See also:

Series.rmul  Reverse of the Multiplication operator, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0
b  1.0
c  1.0
d  NaN
dtype: float64
```

```python
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b  NaN
d  1.0
```

(continues on next page)
e  NaN
dtype: float64
>>> a.multiply(b, fill_value=0)
a  1.0
b  0.0
c  0.0
d  0.0
e  NaN
dtype: float64

pandas.Series.multiply

Series.multiply(other, level=None, fill_value=None, axis=0)

Return Multiplication of series and other, element-wise (binary operator mul).

Equivalent to series * other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.rmul Reverse of the Multiplication operator, see Python documentation for more details.

Examples

>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])

>>> a
a  1.0
b  1.0
c  1.0
d  NaN
dtype: float64

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])

>>> b
a  1.0
b  NaN
d  1.0
e  NaN
dtype: float64

>>> a.multiply(b, fill_value=0)
pandas.Series.ne

Series.ne(other, level=None, fill_value=None, axis=0)
Return Not equal to of series and other, element-wise (binary operator ne).
Equivalent to series != other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters
other [Series or scalar value]
fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns
Series The result of the operation.

Examples
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0
b  1.0
c  1.0
d  NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b  NaN
d  1.0
e  NaN
dtype: float64
>>> a.ne(b, fill_value=0)
a  False
b  True
c  True
d  True
e  True
dtype: bool
pandas.Series.nlargest

Series.nlargest \(n=5\), \texttt{keep='first'}

Return the largest \(n\) elements.

Parameters

- **n** [int, default 5] Return this many descending sorted values.
- **keep** ['first', 'last', 'all'], default 'first' When there are duplicate values that cannot all fit in a Series of \(n\) elements:
  - **first** [return the first \(n\) occurrences in order] of appearance.
  - **last** [return the last \(n\) occurrences in reverse] order of appearance.
  - **all** [keep all occurrences. This can result in a Series of] size larger than \(n\).

Returns

Series The \(n\) largest values in the Series, sorted in decreasing order.

See also:

- **Series.nsmallest** Get the \(n\) smallest elements.
- **Series.sort_values** Sort Series by values.
- **Series.head** Return the first \(n\) rows.

Notes

Faster than .sort_values(ascending=False).head(n) for small \(n\) relative to the size of the Series object.

Examples

```python
>>> countries_population = {
    "Italy": 59000000,  "France": 65000000,
    ...  "Malta": 434000,  "Maldives": 434000,
    ...  "Brunei": 434000,  "Iceland": 337000,
    ...  "Nauru": 11300,    "Tuvalu": 11300,
    ...  "Anguilla": 11300, "Montserrat": 5200
}
>>> s = pd.Series(countries_population)
>>> s
Italy    59000000
France   65000000
Malta    434000
Maldives 434000
Brunei   434000
Iceland  337000
Nauru    11300
Tuvalu   11300
Anguilla 11300
Montserrat 5200
dtype: int64
```

The \(n\) largest elements where \(n=5\) by default.
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
>>> s.nlargest()
France  65000000
Italy   59000000
Malta   434000
Maldives 434000
Brunei  434000
dtype: int64
```

The n largest elements where n=3. Default keep value is ‘first’ so Malta will be kept.

```python
>>> s.nlargest(3)
France  65000000
Italy   59000000
Malta   434000
dtype: int64
```

The n largest elements where n=3 and keeping the last duplicates. Brunei will be kept since it is the last with value 434000 based on the index order.

```python
>>> s.nlargest(3, keep='last')
France  65000000
Italy   59000000
Brunei  434000
dtype: int64
```

The n largest elements where n=3 with all duplicates kept. Note that the returned Series has five elements due to the three duplicates.

```python
>>> s.nlargest(3, keep='all')
France  65000000
Italy   59000000
Malta   434000
Maldives 434000
Brunei  434000
dtype: int64
```

**pandas.Series.notna**

Series. **notna()**

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

**Returns**

Series Mask of bool values for each element in Series that indicates whether an element is not an NA value.

**See also:**

*Series.notnull* Alias of notna.

*Series.isna* Boolean inverse of notna.

*Series.dropna* Omit axes labels with missing values.

3.3. Series 1241
notna: Top-level notna.

Examples

Show which entries in a DataFrame are not NA.

```python
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
                      pd.Timestamp('1940-04-25')],
                      name=['Alfred', 'Batman', ''],
                      toy=[None, 'Batmobile', 'Joker']))

>>> df
   age  born      name      toy
0   5.0    NaT   Alfred       None
1   6.0 1939-05-27   Batman  Batmobile
2  NaN 1940-04-25    Joker
```

```python
>>> df.notna()
   age  born      name      toy
0  True  False  True    False
1  True   True  True    True
2 False  True  True    True
```

Show which entries in a Series are not NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])

>>> ser
0   5.0
1   6.0
2   NaN
dtype: float64
```

```python
>>> ser.notna()
0   True
1   True
2  False
dtype: bool
```

pandas.Series.notnull

Series.notnull()

Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

Returns

Series Mask of bool values for each element in Series that indicates whether an element is not an NA value.

See also:

Series.notnull Alias of notna.
Series.isna  Boolean inverse of notna.
Series.dropna  Omit axes labels with missing values.
notna  Top-level notna.

Examples

Show which entries in a DataFrame are not NA.

```python
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
                           pd.Timestamp('1940-04-25')],
                      name=['Alfred', 'Batman', ''],
                      toy=[None, 'Batmobile', 'Joker']))
```
```
  age  born    name  toy
0  5.0  NaT  Alfred  None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25  Joker
```

```python
>>> df.notna()
```
```
      age   born   name  toy
0  True  False  True  False
1  True   True  True  True
2 False  True  True  True
```

Show which entries in a Series are not NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
```
```
  0   5.0
  1   6.0
  2  NaN
```

```python
>>> ser.notna()
```
```
0   True
1   True
2  False
```

pandas.Series.nsmallest

Series.nsmallest \((n=5, \text{keep}='\text{first}')\)
Return the smallest \(n\) elements.

Parameters

\(n\) [int, default 5] Return this many ascending sorted values.

\(\text{keep}\) ['first', 'last', 'all'], default 'first' When there are duplicate values that cannot all fit in a Series of \(n\) elements:

- **first** [return the first \(n\) occurrences in order] of appearance.
- **last** [return the last \(n\) occurrences in reverse] order of appearance.
• **all** [keep all occurrences. This can result in a Series of] size larger than $n$.

**Returns**

**Series** The $n$ smallest values in the Series, sorted in increasing order.

**See also:**

*Series.nlargest* Get the $n$ largest elements.

*Series.sort_values* Sort Series by values.

*Series.head* Return the first $n$ rows.

**Notes**

Faster than `.sort_values().head(n)` for small $n$ relative to the size of the Series object.

**Examples**

```python
>>> countries_population = {
    "Italy": 590000000, "France": 650000000,
    "Brunei": 434000, "Malta": 434000,
    "Maldives": 434000, "Iceland": 337000,
    "Nauru": 11300, "Tuvalu": 11300,
    "Anguilla": 11300, "Montserrat": 5200
}

>>> s = pd.Series(countries_population)

>>> s
Italy     590000000
France    650000000
Brunei    434000
Malta     434000
Maldives  434000
Iceland   337000
Nauru     11300
Tuvalu    11300
Anguilla  11300
Montserrat 5200
dtype: int64

The $n$ smallest elements where $n=5$ by default.

```python
>>> s.nsmallest()
Montserrat     5200
Nauru          11300
Tuvalu         11300
Anguilla       11300
Iceland        337000
dtype: int64
```

The $n$ smallest elements where $n=3$. Default *keep* value is ‘first’ so Nauru and Tuvalu will be kept.

```python
>>> s.nsmallest(3)
Montserrat     5200
Nauru          11300
Tuvalu         11300
dtype: int64
```
The \( n \) smallest elements where \( n=3 \) and keeping the last duplicates. Anguilla and Tuvalu will be kept since they are the last with value 11300 based on the index order.

```python
>>> s.nsmallest(3, keep='last')
Montserrat  5200
Anguilla   11300
Tuvalu     11300
dtype: int64
```

The \( n \) smallest elements where \( n=3 \) with all duplicates kept. Note that the returned Series has four elements due to the three duplicates.

```python
>>> s.nsmallest(3, keep='all')
Montserrat  5200
Nauru       11300
Tuvalu      11300
Anguilla    11300
dtype: int64
```

### pandas.Series.nunique

Series.nunique\((\text{dropna}=\text{True})\)

Return number of unique elements in the object.

Excludes NA values by default.

**Parameters**

- **dropna** [bool, default True] Don’t include NaN in the count.

**Returns**

- int

**See also:**

- **DataFrame.nunique** Method nunique for DataFrame.
- **Series.count** Count non-NA/null observations in the Series.

**Examples**

```python
>>> s = pd.Series([1, 3, 5, 7, 7])
>>> s
0  1
1  3
2  5
3  7
4  7
dtype: int64

>>> s.nunique()
4
```
**pandas.Series.pad**

`Series.pad(axis=None, inplace=False, limit=None, downcast=None)`

Synonym for `DataFrame.fillna()` with method='ffill'.

**Returns**

`Series/DataFrame` or `None` Object with missing values filled or `None` if

`inplace=True`.

**pandas.Series.pct_change**

`Series.pct_change(periods=1, fill_method='pad', limit=None, freq=None, **kwargs)`

Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

**Parameters**

- `periods` [int, default 1] Periods to shift for forming percent change.
- `fill_method` [str, default ‘pad’] How to handle NAs before computing percent changes.
- `limit` [int, default None] The number of consecutive NAs to fill before stopping.
- `freq` [DateOffset, timedelta, or str, optional] Increment to use from time series API (e.g. ‘M’ or BDay()).
- `**kwargs` Additional keyword arguments are passed into `DataFrame.shift` or `Series.shift`.

**Returns**

`chg` [Series or DataFrame] The same type as the calling object.

**See also:**

- `Series.diff` Compute the difference of two elements in a Series.
- `DataFrame.diff` Compute the difference of two elements in a DataFrame.
- `Series.shift` Shift the index by some number of periods.
- `DataFrame.shift` Shift the index by some number of periods.

**Examples**

**Series**

```python
>>> s = pd.Series([90, 91, 85])
>>> s
0   90
1   91
2   85
dtype: int64

>>> s.pct_change()
0    NaN
1  0.011111
```

(continues on next page)
See the percentage change in a Series where filling NAs with last valid observation forward to next valid.

```python
>>> s = pd.Series([90, 91, None, 85])
>>> s
0 90.0
1 91.0
2 NaN
3 85.0
dtype: float64
```

```python
>>> s.pct_change(fill_method='ffill')
0 NaN
1 0.011111
2 0.000000
3 -0.065934
dtype: float64
```

**DataFrame**

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```python
>>> df = pd.DataFrame({
...     'FR': [4.0405, 4.0963, 4.3149],
...     'GR': [1.7246, 1.7482, 1.8519],
...     'IT': [804.74, 810.01, 860.13],
...     'index': ['1980-01-01', '1980-02-01', '1980-03-01']
... })
>>> df
     FR   GR   IT
1980-01-01  4.0405  1.7246  804.74
1980-02-01  4.0963  1.7482  810.01
1980-03-01  4.3149  1.8519  860.13
```

```python
>>> df.pct_change()
     FR   GR   IT
1980-01-01   NaN   NaN   NaN
1980-02-01  0.013810 0.013684 0.006549
1980-03-01  0.053365 0.059318 0.061876
```

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

```python
>>> df = pd.DataFrame({
...     '2016': [1769950, 30586265],
...     '2015': [1500923, 40912316],
...     '2014': [1371819, 41403351],
...     'index': ['GOOG', 'APPL']
... })
>>> df
```

(continues on next page)
2016 2015 2014
GOOG 1769950 1500923 1371819
APPL 30586265 40912316 41403351

```python
>>> df.pct_change(axis='columns', periods=-1)
     2016  2015    2014
GOOG  0.179241  0.094112   NaN
APPL -0.252395 -0.011860   NaN
```

**pandas.Series.pipe**

Series.pipe(func, *args, **kwargs)

Apply func(self, *args, **kwargs).

**Parameters**

- **func** [function] Function to apply to the Series/DataFrame. *args* and **kwargs* are passed into func. Alternatively a (callable, data_keyword) tuple where data_keyword is a string indicating the keyword of callable that expects the Series/DataFrame.

- **args** [iterable, optional] Positional arguments passed into func.

- **kwargs** [mapping, optional] A dictionary of keyword arguments passed into func.

**Returns**

- **object** [the return type of func.]

**See also:**

- DataFrame.apply Apply a function along input axis of DataFrame.
- DataFrame.applymap Apply a function elementwise on a whole DataFrame.
- Series.map Apply a mapping correspondence on a Series.

**Notes**

Use .pipe when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```python
>>> func(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```python
>>> (df.pipe(h)
...     .pipe(g, arg1=a)
...     .pipe(func, arg2=b, arg3=c)
... )
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose \( f \) takes its data as `arg2`:
pandas.Series.plot

Series.plot (*args, **kwargs)
Make plots of Series or DataFrame.

Uses the backend specified by the option plotting.backend. By default, matplotlib is used.

Parameters

- **data** [Series or DataFrame] The object for which the method is called.
- **x** [label or position, default None] Only used if data is a DataFrame.
- **y** [label, position or list of label, positions, default None] Allows plotting of one column versus another. Only used if data is a DataFrame.

- **kind** [str] The kind of plot to produce:
  - ‘line’: line plot (default)
  - ‘bar’: vertical bar plot
  - ‘barh’: horizontal bar plot
  - ‘hist’: histogram
  - ‘box’: boxplot
  - ‘kde’: Kernel Density Estimation plot
  - ‘density’: same as ‘kde’
  - ‘area’: area plot
  - ‘pie’: pie plot
  - ‘scatter’: scatter plot (DataFrame only)
  - ‘hexbin’: hexbin plot (DataFrame only)

- **ax** [matplotlib axes object, default None] An axes of the current figure.
- **subplots** [bool, default False] Make separate subplots for each column.

- **sharex** [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in; Be aware, that passing in both an ax and sharex=True will alter all x axis labels for all axis in a figure.

- **sharey** [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.

- **layout** [tuple, optional] (rows, columns) for the layout of subplots.

- **figsize** [a tuple (width, height) in inches] Size of a figure object.

- **use_index** [bool, default True] Use index as ticks for x axis.
**title** [str or list] Title to use for the plot. If a string is passed, print the string at the top of the figure. If a list is passed and `subplots` is True, print each item in the list above the corresponding subplot.

**grid** [bool, default None (matlab style default)] Axis grid lines.

**legend** [bool or {'reverse'}] Place legend on axis subplots.

**style** [list or dict] The matplotlib line style per column.

**logx** [bool or ‘sym’, default False] Use log scaling or symlog scaling on x axis. .. versionchanged:: 0.25.0

**logy** [bool or ‘sym’ default False] Use log scaling or symlog scaling on y axis. .. versionchanged:: 0.25.0

**loglog** [bool or ‘sym’, default False] Use log scaling or symlog scaling on both x and y axes. .. versionchanged:: 0.25.0

**xticks** [sequence] Values to use for the xticks.

**yticks** [sequence] Values to use for the yticks.

**xlim** [2-tuple/list] Set the x limits of the current axes.

**ylim** [2-tuple/list] Set the y limits of the current axes.

**xlabel** [label, optional] Name to use for the xlabel on x-axis. Default uses index name as xlabel, or the x-column name for planar plots.

New in version 1.1.0.

Changed in version 1.2.0: Now applicable to planar plots (scatter, hexbin).

**ylabel** [label, optional] Name to use for the ylabel on y-axis. Default will show no ylabel, or the y-column name for planar plots.

New in version 1.1.0.

Changed in version 1.2.0: Now applicable to planar plots (scatter, hexbin).

**rot** [int, default None] Rotation for ticks (xticks for vertical, yticks for horizontal plots).

**fontsize** [int, default None] Font size for xticks and yticks.

**colormap** [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

**colorbar** [bool, optional] If True, plot colorbar (only relevant for ‘scatter’ and ‘hexbin’ plots).

**position** [float] Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center).

**table** [bool, Series or DataFrame, default False] If True, draw a table using the data in the DataFrame and the data will be transposed to meet matplotlib’s default layout. If a Series or DataFrame is passed, use passed data to draw a table.

**yerr** [DataFrame, Series, array-like, dict and str] See *Plotting with Error Bars* for detail.

**xerr** [DataFrame, Series, array-like, dict and str] Equivalent to yerr.

**stacked** [bool, default False in line and bar plots, and True in area plot] If True, create stacked plot.

**sort_columns** [bool, default False] Sort column names to determine plot ordering.
**secondary_y** [bool or sequence, default False] Whether to plot on the secondary y-axis if a list/tuple, which columns to plot on secondary y-axis.

**mark_right** [bool, default True] When using a secondary_y axis, automatically mark the column labels with “(right)” in the legend.

**include_bool** [bool, default is False] If True, boolean values can be plotted.

**backend** [str, default None] Backend to use instead of the backend specified in the option plotting.backend. For instance, ‘matplotlib’. Alternatively, to specify the plotting.backend for the whole session, set pd.options.plotting.backend.

  New in version 1.0.0.

**kwargs** Options to pass to matplotlib plotting method.

**Returns**

* *matplotlib.axes.Axes or numpy.ndarray of them* If the backend is not the default matplotlib one, the return value will be the object returned by the backend.

**Notes**

  - See matplotlib documentation online for more on this subject
  - If kind = ‘bar’ or ‘barh’, you can specify relative alignments for bar plot layout by position keyword. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

**pandas.Series.pop**

* *Series.pop(item)*
  Return item and drops from series. Raise KeyError if not found.

  **Parameters**

  * *item* [label] Index of the element that needs to be removed.

  **Returns**

  * Value that is popped from series.

**Examples**

```python
>>> ser = pd.Series([1,2,3])
```

```python
>>> ser.pop(0)
1
```

```python
>>> ser
1  2
2  3
dtype: int64
```
pandas.Series.pow

Series.pow(other, level=None, fill_value=None, axis=0)
Return Exponential power of series and other, element-wise (binary operator pow).
Equivalent to series ** other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]
fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

See also:

Series.rpow Reverse of the Exponential power operator, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d   NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b   NaN
d    1.0
e   NaN
dtype: float64
>>> a.pow(b, fill_value=0)
0    1.0
d    1.0
c    1.0
d   0.0
e   NaN
dtype: float64
```
pandas.Series.prod

Series.prod(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)

Return the product of the values over the requested axis.

Parameters

axis [(index (0))] Axis for the function to be applied on.
skipna [bool, default True] Exclude NA/null values when computing the result.
level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
min_count [int, default 0] The required number of valid values to perform the operation.
If fewer than min_count non-NA values are present the result will be NA.
**kwargs Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

See also:

Series.sum Return the sum.
Series.min Return the minimum.
Series.max Return the maximum.
Series.idxmin Return the index of the minimum.
Series.idxmax Return the index of the maximum.
DataFrame.sum Return the sum over the requested axis.
DataFrame.min Return the minimum over the requested axis.
DataFrame.max Return the maximum over the requested axis.
DataFrame.idxmin Return the index of the minimum over the requested axis.
DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

By default, the product of an empty or all-NA Series is 1

>>> pd.Series([], dtype="float64").prod()
1.0

This can be controlled with the min_count parameter

>>> pd.Series([], dtype="float64").prod(min_count=1)
nan

Thanks to the skipna parameter, min_count handles all-NA and empty series identically.
pandas.Series.product

Series.product(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)

Return the product of the values over the requested axis.

Parameters

- **axis** [{index (0)}] Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **min_count** [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.
- ****kwargs Additional keyword arguments to be passed to the function.

Returns

scalar or Series (if level specified)

See also:

Series.sum Return the sum.
Series.min Return the minimum.
Series.max Return the maximum.
Series.idxmin Return the index of the minimum.
Series.idxmax Return the index of the maximum.
DataFrame.sum Return the sum over the requested axis.
DataFrame.min Return the minimum over the requested axis.
DataFrame.max Return the maximum over the requested axis.
DataFrame.idxmin Return the index of the minimum over the requested axis.
DataFrame.idxmax Return the index of the maximum over the requested axis.
Examples

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([], dtype="float64").prod()
1.0
```

This can be controlled with the `min_count` parameter

```python
>>> pd.Series([], dtype="float64").prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0
```

```python
>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

### pandas.Series.quantile

**Series.quantile** *(q=0.5, interpolation='linear')*

Return value at the given quantile.

**Parameters**

- `q` [float or array-like, default 0.5 (50% quantile)] The quantile(s) to compute, which can lie in range: 0 <= q <= 1.
  
- interpolation [[‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’]] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j:
  
  - linear: \( i + (j - i) \times fraction \), where `fraction` is the fractional part of the index surrounded by `i` and `j`.
  
  - lower: `i`.
  
  - higher: `j`.
  
  - nearest: `i` or `j` whichever is nearest.
  
  - midpoint: \( (i + j) / 2 \).

**Returns**

- float or Series If `q` is an array, a Series will be returned where the index is `q` and the values are the quantiles, otherwise a float will be returned.

**See also:**

- `core.window.Rolling.quantile` Calculate the rolling quantile.

- `numpy.percentile` Returns the q-th percentile(s) of the array elements.
Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.quantile(.5)
2.5
>>> s.quantile([.25, .5, .75])
0.25 1.75
0.50 2.50
0.75 3.25
dtype: float64
```

```python
pandas.Series.radd
Series.radd(other, level=None, fill_value=None, axis=0)

Return Addition of series and other, element-wise (binary operator radd).
Equivalent to other + series, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

Series The result of the operation.

See also:

Series.add Element-wise Addition, see Python documentation for more details.
```

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.add(b, fill_value=0)
```

(continues on next page)
pandas.Series.rank

Series.rank (axis=0, method='average', numeric_only=None, na_option='keep', ascending=True, pct=False)

Compute numerical data ranks (1 through n) along axis.

By default, equal values are assigned a rank that is the average of the ranks of those values.

Parameters

- axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Index to direct ranking.
- method [{‘average’, ‘min’, ‘max’, ‘first’, ‘dense’}, default ‘average’] How to rank the group of records that have the same value (i.e. ties):
  - average: average rank of the group
  - min: lowest rank in the group
  - max: highest rank in the group
  - first: ranks assigned in order they appear in the array
  - dense: like ‘min’, but rank always increases by 1 between groups.
- numeric_only [bool, optional] For DataFrame objects, rank only numeric columns if set to True.
- na_option [{‘keep’, ‘top’, ‘bottom’}, default ‘keep’] How to rank NaN values:
  - keep: assign NaN rank to NaN values
  - top: assign lowest rank to NaN values
  - bottom: assign highest rank to NaN values
- ascending [bool, default True] Whether or not the elements should be ranked in ascending order.
- pct [bool, default False] Whether or not to display the returned rankings in percentile form.

Returns

same type as caller Return a Series or DataFrame with data ranks as values.

See also:

core.groupby.GroupBy.rank Rank of values within each group.
### Examples

```python
>>> df = pd.DataFrame(data={'Animal': ['cat', 'penguin', 'dog', 'spider', 'snake'],
                         'Number_legs': [4, 2, 4, 8, np.nan]})

>>> df
    Animal  Number_legs
0      cat          4.0
1   penguin         2.0
2      dog          4.0
3    spider          8.0
4     snake         nan

The following example shows how the method behaves with the above parameters:

- **default_rank**: this is the default behaviour obtained without using any parameter.

- **max_rank**: setting method = 'max' the records that have the same values are ranked using the highest rank (e.g.: since ‘cat’ and ‘dog’ are both in the 2nd and 3rd position, rank 3 is assigned.)

- **NA_bottom**: choosing na_option = 'bottom', if there are records with NaN values they are placed at the bottom of the ranking.

- **pct_rank**: when setting pct = True, the ranking is expressed as percentile rank.
```
```python
>>> df['default_rank'] = df['Number_legs'].rank()
>>> df['max_rank'] = df['Number_legs'].rank(method='max')
>>> df['NA_bottom'] = df['Number_legs'].rank(na_option='bottom')
>>> df['pct_rank'] = df['Number_legs'].rank(pct=True)

>>> df
    Animal  Number_legs  default_rank  max_rank  NA_bottom  pct_rank
0      cat          4.0          2.5        3.0       2.5       0.625
1   penguin         2.0          1.0        1.0       1.0       0.250
2      dog          4.0          2.5        3.0       2.5       0.625
3    spider          8.0          4.0        4.0       4.0       1.000
4     snake         nan          nan        nan       nan
```

### pandas.Series.ravel

Series.ravel (order='C')

Return the flattened underlying data as an ndarray.

**Returns**

- numpy.ndarray or ndarray-like Flattened data of the Series.

**See also**

- numpy.ndarray.ravel Return a flattened array.
**pandas.Series.rdiv**

`Series.rdiv(other, level=None, fill_value=None, axis=0)`

Return Floating division of series and other, element-wise (binary operator `rtruediv`).

Equivalent to `other / series`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- `other` [Series or scalar value]
- `fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- `level` [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

- `Series` The result of the operation.

**See also:**

- `Series.truediv` Element-wise Floating division, see Python documentation for more details.

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d   NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b   NaN
d    1.0
e   NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
d   0.0
e   NaN
dtype: float64
```
pandas.Series.rdivmod

Series.rdivmod(other, level=None, fill_value=None, axis=0)

Return integer division and modulo of series and other, element-wise (binary operator rdivmod).

Equivalent to other divmod series, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

2-Tuple of Series The result of the operation.

See also:

Series.divmod Element-wise Integer division and modulo, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.divmod(b, fill_value=0)
(a 1.0
b NaN
c NaN
d 0.0
e NaN
dtype: float64,
a 0.0
b NaN
c NaN
d 0.0
e NaN
dtype: float64)
```
**pandas.Series.reindex**

`Series.reindex(index=None, **kwargs)`

Conform Series to new index with optional filling logic. Places NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and `copy=False`.

**Parameters**

- **index** [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data.

- **method** [[None, ‘backfill’/’bfill’, ‘pad’/’ffill’, ‘nearest’]] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.
  - None (default): don’t fill gaps
  - pad / ffill: Propagate last valid observation forward to next valid.
  - backfill / bfill: Use next valid observation to fill gap.
  - nearest: Use nearest valid observations to fill gap.

- **copy** [bool, default True] Return a new object, even if the passed indexes are the same.

- **level** [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

- **fill_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.

- **limit** [int, default None] Maximum number of consecutive elements to forward or backward fill.

- **tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation

  \[
  \text{abs}(\text{index[indexer]} - \text{target}) \leq \text{tolerance}.
  \]

  Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

**Returns**

Series with changed index.

See also:

- `DataFrame.set_index` Set row labels.
- `DataFrame.reset_index` Remove row labels or move them to new columns.
- `DataFrame.reindex_like` Change to same indices as other DataFrame.
Examples

DataFrame.reindex supports two calling conventions

- (index=index_labels, columns=column_labels, ...)
- (labels, axis={'index', 'columns'}, ...)

We highly recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```python
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']
>>> df = pd.DataFrame({'http_status': [200, 200, 404, 404, 301],
...    'response_time': [0.04, 0.02, 0.07, 0.08, 1.0]},
...    index=index)
>>> df
    http_status  response_time
Firefox      200          0.04
Chrome      200          0.02
Safari      404          0.07
IE10        404          0.08
Konqueror   301          1.00
```

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```python
>>> new_index = ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10', 'Chrome']
>>> df.reindex(new_index)
    http_status  response_time
Safari      404.0        0.07
Iceweasel   NaN          NaN
Comodo Dragon NaN         NaN
IE10        404.0        0.08
Chrome      200.0        0.02
```

We can fill in the missing values by passing a value to the keyword fill_value. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword method to fill the NaN values.

```python
>>> df.reindex(new_index, fill_value=0)
    http_status  response_time
Safari      404          0.07
Iceweasel   0           0.00
Comodo Dragon 0          0.00
IE10        404          0.08
Chrome      200          0.02
```

We can also reindex the columns.
>>> df.reindex(columns=['http_status', 'user_agent'])

  http_status  user_agent
Firefox       200  NaN
Chrome        200  NaN
Safari        404  NaN
IE10          404  NaN
Konqueror     301  NaN

Or we can use “axis-style” keyword arguments

>>> df.reindex(['http_status', 'user_agent'], axis="columns")

  http_status  user_agent
Firefox       200  NaN
Chrome        200  NaN
Safari        404  NaN
IE10          404  NaN
Konqueror     301  NaN

To further illustrate the filling functionality in reindex, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

>>> date_index = pd.date_range('1/1/2010', periods=6, freq='D')

>>> df2 = pd.DataFrame({'prices': [100, 101, np.nan, 100, 89, 88]},
...                    index=date_index)

>>> df2

   prices
2010-01-01  100.0
2010-01-02  101.0
2010-01-03   NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0

Suppose we decide to expand the dataframe to cover a wider date range.

>>> date_index2 = pd.date_range('12/29/2009', periods=10, freq='D')

>>> df2.reindex(date_index2)

   prices
2009-12-29      NaN
2009-12-30      NaN
2009-12-31      NaN
2010-01-01  100.0
2010-01-02  101.0
2010-01-03     NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
2010-01-07     NaN

The index entries that did not have a value in the original data frame (for example, ‘2009-12-29’) are by default filled with NaN. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the NaN values, pass bfill as an argument to the method keyword.

>>> df2.reindex(date_index2, method='bfill')

   prices
2009-12-29      NaN
2009-12-30      NaN
2009-12-31      NaN
2010-01-01  100.0
2010-01-02  101.0
2010-01-03     NaN
2010-01-04  100.0
2010-01-05   89.0
2010-01-06   88.0
2010-01-07   88.0
(continues on next page)
Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the fillna() method.

See the user guide for more.

**pandas.Series.reindex_like**

Series.reindex_like(other, method=None, copy=True, limit=None, tolerance=None)

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

**Parameters**

other [Object of the same data type] Its row and column indices are used to define the new indices of this object.

method [{None, ‘backfill’/’bfill’, ‘pad’/’ffill’, ‘nearest’}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.

- None (default): don’t fill gaps
- pad / ffill: propagate last valid observation forward to next valid
- backfill / bfill: use next valid observation to fill gap
- nearest: use nearest valid observations to fill gap.

copy [bool, default True] Return a new object, even if the passed indexes are the same.

limit [int, default None] Maximum number of consecutive labels to fill for inexact matches.

tolerance [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation \( \text{abs} \text{index[indexer]} - \text{target} \leq \text{tolerance} \).

Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

**Returns**
Series or DataFrame  Same type as caller, but with changed indices on each axis.

See also:

Dataframe.set_index  Set row labels.

Dataframe.reset_index  Remove row labels or move them to new columns.

Dataframe.reindex  Change to new indices or expand indices.

Notes

Same as calling .reindex(index=other.index, columns=other.columns,...).

Examples

```python
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
...                      [31, 87.8, 'high'],
...                      [22, 71.6, 'medium'],
...                      [35, 95, 'medium']],
...                     columns=['temp_celsius', 'temp_fahrenheit',
...                          'windspeed'],
...                     index=pd.date_range(start='2014-02-12',
...                             end='2014-02-15', freq='D'))

>>> df1
   temp_celsius  temp_fahrenheit  windspeed
2014-02-12       24.3           75.7      high
2014-02-13       31.0           87.8      high
2014-02-14       22.0           71.6   medium
2014-02-15       35.0           95.0   medium

>>> df2 = pd.DataFrame([[28, 'low'],
...                      [30, 'low'],
...                      [35.1, 'medium']],
...                     columns=['temp_celsius', 'windspeed'],
...                     index=pd.DatetimeIndex(['2014-02-12', '2014-02-13',
...                                              '2014-02-15']))

>>> df2
   temp_celsius  windspeed
2014-02-12       28.0      low
2014-02-13       30.0      low
2014-02-15      35.1  medium

>>> df2.reindex_like(df1)
   temp_celsius  temp_fahrenheit  windspeed
2014-02-12       28.0           NaN      low

3.3. Series 1265
pandas.Series.rename

Series.rename(index=None, *, axis=None, copy=True, inplace=False, level=None, errors='ignore')

Alter Series index labels or name.

Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is. Extra labels listed don’t throw an error.

Alternatively, change Series.name with a scalar value.

See the user guide for more.

Parameters

axis [[0 or “index”]] Unused. Accepted for compatibility with DataFrame method only.

index [scalar, hashable sequence, dict-like or function, optional] Functions or dict-like are transformations to apply to the index. Scalar or hashable sequence-like will alter the Series.name attribute.

**kwargs Additional keyword arguments passed to the function. Only the “inplace” keyword is used.

Returns

Series or None Series with index labels or name altered or None if inplace=True.

See also:

Dataframe.rename Corresponding DataFrame method.

Series.rename_axis Set the name of the axis.

Examples

```python
>>> s = pd.Series([1, 2, 3])
>>> s
0  1  
1  2  
2  3  
dtype: int64

>>> s.rename("my_name")  # scalar, changes Series.name
0  1  
1  2  
2  3  
Name: my_name, dtype: int64

>>> s.rename(lambda x: x ** 2)  # function, changes labels
0  1  
1  2  
4  3  
dtype: int64

>>> s.rename({1: 3, 2: 5})  # mapping, changes labels
0  1  
3  2  
5  3  
dtype: int64
```
**pandas.Series.rename_axis**

`Series.rename_axis(mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False)`

Set the name of the axis for the index or columns.

**Parameters**

- **mapper** [scalar, list-like, optional] Value to set the axis name attribute.
- **index, columns** [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis' values. Note that the `columns` parameter is not allowed if the object is a Series. This parameter only apply for DataFrame type objects.
  
  Use either `mapper` and `axis` to specify the axis to target with `mapper`, or `index` and/or `columns`.

- **axis** `{0 or ‘index’, 1 or ‘columns’}, default 0` The axis to rename.
- **copy** [bool, default True] Also copy underlying data.
- **inplace** [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

**Returns**

- **Series, DataFrame, or None** The same type as the caller or None if `inplace=True`.

**See also:**

- `Series.rename` Alter Series index labels or name.
- `DataFrame.rename` Alter DataFrame index labels or name.
- `Index.rename` Set new names on index.

**Notes**

`DataFrame.rename_axis` supports two calling conventions

- `(index=index_mapper, columns=columns_mapper, ...)
- `(mapper, axis={'index', 'columns'}, ...)

The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter `copy` is ignored.

The second calling convention will modify the names of the corresponding index if mapper is a list or a scalar. However, if mapper is dict-like or a function, it will use the deprecated behavior of modifying the axis `labels`.

We **highly** recommend using keyword arguments to clarify your intent.
### Examples

#### Series

```python
def = pd.DataFrame(
    {
        "num_legs": [4, 4, 2],
        "num_arms": [0, 0, 2]
    },
    index= pd.MultiIndex.from_product([['mammal'], ['dog', 'cat', 'monkey']], names=['type', 'name'])
)
```

#### MultiIndex

```python
def = pd.DataFrame(
    {
        "num_legs": [4, 4, 2],
        "num_arms": [0, 0, 2]
    },
    index= pd.MultiIndex.from_product([['mammal'], ['dog', 'cat', 'monkey']], names=['type', 'name'])
)
```
mammal  dog  4  0
  cat            4  0
monkey         2  2

```python
>>> df.rename_axis(columns=str.upper)
LIMBS        num_legs  num_arms
type   name
mammal  dog       4  0
  cat            4  0
monkey         2  2
```

**pandas.Series.reorder_levels**

Series.reorder_levels(order)

Rearrange index levels using input order.

May not drop or duplicate levels.

**Parameters**

- **order** [list of int representing new level order] Reference level by number or key.

**Returns**

- type of caller (new object)

**pandas.Series.repeat**

Series.repeat(repeats, axis=None)

Repeat elements of a Series.

Returns a new Series where each element of the current Series is repeated consecutively a given number of times.

**Parameters**

- **repeats** [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Series.

- **axis** [None] Must be None. Has no effect but is accepted for compatibility with numpy.

**Returns**

- Series Newly created Series with repeated elements.

**See also:**

- Index.repeat Equivalent function for Index.

- numpy.repeat Similar method for numpy.ndarray.
Examples

```python
>>> s = pd.Series(['a', 'b', 'c'])
>>> s
0  a
1  b
2  c
dtype: object

>>> s.repeat(2)
0  a
0  a
1  b
1  b
2  c
2  c
dtype: object

>>> s.repeat([1, 2, 3])
0  a
1  b
1  b
2  c
2  c
2  c
dtype: object
```

**pandas.Series.replace**

```
pandas.Series.replace(to_replace=None, value=None, inplace=False, limit=None, regex=False, method='pad')
```

Replace values given in `to_replace` with `value`.

Values of the Series are replaced with other values dynamically.

This differs from updating with `.loc` or `.iloc`, which require you to specify a location to update with some value.

**Parameters**

- **to_replace** [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.
  - numeric, str or regex:
    - numeric: numeric values equal to `to_replace` will be replaced with `value`
    - str: string exactly matching `to_replace` will be replaced with `value`
    - regex: regexs matching `to_replace` will be replaced with `value`
  - list of str, regex, or numeric:
    - First, if `to_replace` and `value` are both lists, they must be the same length.
    - Second, if `regex=True` then all of the strings in both lists will be interpreted as regexes otherwise they will match directly. This doesn’t matter much for `value` since there are only a few possible substitution regexes you can use.
  - str, regex and numeric rules apply as above.
  - dict:
- **Dicts can be used to specify different replacement values** for different existing values. For example, `{'a': 'b', 'y': 'z'}` replaces the value ‘a’ with ‘b’ and ‘y’ with ‘z’. To use a dict in this way the `value` parameter should be `None`.

- **For a DataFrame a dict can specify that different values** should be replaced in different columns. For example, `{'a': 1, 'b': 'z'}` looks for the value 1 in column ‘a’ and the value ‘z’ in column ‘b’ and replaces these values with whatever is specified in `value`. The `value` parameter should not be `None` in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.

- **For a DataFrame nested dictionaries, e.g.,** `{a: {b: np.nan}}`, are read as follows: look in column ‘a’ for the value ‘b’ and replace it with NaN. The `value` parameter should be `None` to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) **cannot** be regular expressions.

  - None:

  - **This means that the `regex` argument must be a string**, compiled regular expression, or list, dict, ndarray or Series of such elements. If `value` is also `None` then this **must** be a nested dictionary or Series.

See the examples section for examples of each of these.

**value** [scalar, dict, list, str, regex, default None] Value to replace any values matching `to_replace` with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

**inplace** [bool, default False] If True, performs operation inplace and returns None.

**limit** [int, default None] Maximum size gap to forward or backward fill.

**regex** [bool or same types as `to_replace`, default False] Whether to interpret `to_replace` and/or `value` as regular expressions. If this is True then `to_replace` must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case `to_replace` must be `None`.

**method** [{‘pad’, ‘ffill’, ‘bfill’}, None] The method to use when for replacement, when `to_replace` is a scalar, list or tuple and `value` is `None`.

Changed in version 0.23.0: Added to DataFrame.

**Returns**

- **Series** Object after replacement.

**Raises**

- **AssertionError**

  - If `regex` is not a bool and `to_replace` is not None.

- **TypeError**

  - If `to_replace` is not a scalar, array-like, dict, or `None`.

  - If `to_replace` is a dict and `value` is not a list, dict, ndarray, or Series

  - If `to_replace` is `None` and `regex` is not compilable into a regular expression or is a list, dict, ndarray, or Series.
• When replacing multiple bool or datetime64 objects and the arguments to to_replace does not match the type of the value being replaced

ValueError

• If a list or an ndarray is passed to to_replace and value but they are not the same length.

See also:

Series.fillna Fill NA values.
Series.where Replace values based on boolean condition.
Series.str.replace Simple string replacement.

Notes

• Regex substitution is performed under the hood with re.sub. The rules for substitution for re.sub are the same.

• Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers are strings, then you can do this.

• This method has a lot of options. You are encouraged to experiment and play with this method to gain intuition about how it works.

• When dict is used as the to_replace value, it is like key(s) in the dict are the to_replace part and value(s) in the dict are the value parameter.

Examples

Scalar `to_replace` and `value`

```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0   5
1   1
2   2
3   3
4   4
 dtype: int64
```

```python
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
...                   'B': [5, 6, 7, 8, 9],
...                   'C': ['a', 'b', 'c', 'd', 'e']})
>>> df.replace(0, 5)
         A   B   C
0     5   5   a
1     1   6   b
2     2   7   c
3     3   8   d
4     4   9   e
```

List-like `to_replace`
```python
df.replace([0, 1, 2, 3], 4)
A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e
```

```python
df.replace([0, 1, 2, 3], [4, 3, 2, 1])
A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e
```

```python
s.replace([1, 2], method='bfill')
0  0
1  3
2  3
3  3
4  4
dtype: int64
```

```
dict-like `to_replace`
```

```python
df.replace({0: 10, 1: 100})
A  B  C
0 10  5  a
1 100  6  b
2 2  7  c
3 3  8  d
4 4  9  e
```

```python
df.replace({'A': 0, 'B': 5}, 100)
A  B  C
0 100 100  a
1 1  6  b
2 2  7  c
3 3  8  d
4 4  9  e
```

```python
df.replace({'A': {0: 100, 4: 400}})
A  B  C
0 100  5  a
1 1  6  b
2 2  7  c
3 3  8  d
4 400  9  e
```

```
Regular expression `to_replace`
```

```python
df = pd.DataFrame({'A': ['bat', 'foo', 'bait'],
                  'B': ['abc', 'bar', 'xyz']})
>>> df.replace(to_replace=r'^ba.', value='new', regex=True)
A  B
```

(continues on next page)
```
0    new  abc
1    foo  new
2    bait xyz

>>> df.replace({'A': r'^ba.$'}, {'A': 'new'}, regex=True)
   A   B
0  new abc
1   foo  bar
2    bait xyz

>>> df.replace(regex=r'^ba.$', value='new')
   A   B
0  new abc
1    foo  new
2    bait xyz

>>> df.replace(regex={r'^ba.$': 'new', 'foo': 'xyz'})
   A  B
0  new abc
1   xyz  new
2    bait xyz

>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
   A  B
0  new abc
1    new  new
2    bait xyz

```

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the to_replace parameter:

```
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])

When one uses a dict as the to_replace value, it is like the value(s) in the dict are equal to the value parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None):

```
>>> s.replace({'a': None})
0    10
1   None
2   None
3    b
4   None
dtype: object

When `value=None` and to_replace is a scalar, list or tuple, replace uses the method parameter (default 'pad') to do the replacement. So this is why the ‘a’ values are being replaced by 10 in rows 1 and 2 and ‘b’ in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad'):

```
>>> s.replace('a', None)
0    10
1    10
2    10

(continues on next page)
pandas.Series.resample

Series.resample(rule, axis=0, closed=None, label=None, convention='start', kind=None, loffset=None, base=None, on=None, level=None, origin='start_day', offset=None)

Resample time-series data.

Convenience method for frequency conversion and resampling of time series. The object must have a datetime-like index (DatetimeIndex, PeriodIndex, or TimedeltaIndex), or the caller must pass the label of a datetime-like series/index to the `on/level` keyword parameter.

**Parameters**

- **rule** [DateOffset, Timedelta or str] The offset string or object representing target conversion.

- **axis** [{0 or 'index', 1 or 'columns'}, default 0] Which axis to use for up- or down-sampling. For Series this will default to 0, i.e. along the rows. Must be DateTimeIndex, TimedeltaIndex or PeriodIndex.

- **closed** [ {'right', 'left'}, default None] Which side of bin interval is closed. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

- **label** [ {'right', 'left'}, default None] Which bin edge label to label bucket with. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

- **convention** [{‘start’, ‘end’, ‘s’, ‘e’}, default ‘start’] For PeriodIndex only, controls whether to use the start or end of rule.

- **kind** [{‘timestamp’, ‘period’}, optional, default None] Pass ‘timestamp’ to convert the resulting index to a DateTimeIndex or ‘period’ to convert it to a PeriodIndex. By default the input representation is retained.

- **loffset** [timedelta, default None] Adjust the resampled time labels.

  Deprecated since version 1.1.0: You should add the loffset to the df.index after the resample. See below.

- **base** [int, default 0] For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0.

  Deprecated since version 1.1.0: The new arguments that you should use are ‘offset’ or ‘origin’.

- **on** [str, optional] For a DataFrame, column to use instead of index for resampling. Column must be datetime-like.

- **level** [str or int, optional] For a MultiIndex, level (name or number) to use for resampling. level must be datetime-like.

- **origin** [{‘epoch’, ‘start’, ‘start_day’, ‘end’, ‘end_day’}, Timestamp] or str, default ‘start_day’ The timestamp on which to adjust the grouping. The timezone of origin
must match the timezone of the index. If a timestamp is not used, these values are also supported:

- ‘epoch’: origin is 1970-01-01
- ‘start’: origin is the first value of the timeseries
- ‘start_day’: origin is the first day at midnight of the timeseries

New in version 1.1.0.

- ‘end’: origin is the last value of the timeseries
- ‘end_day’: origin is the ceiling midnight of the last day

New in version 1.3.0.

offset [Timedelta or str, default is None] An offset timedelta added to the origin.

New in version 1.1.0.

Returns

pandas.core.Resampler Resampler object.

See also:

Series.resample Resample a Series.

DataFrame.resample Resample a DataFrame.

groupby Group Series by mapping, function, label, or list of labels.

asfreq Reindex a Series with the given frequency without grouping.

Notes

See the user guide for more.

To learn more about the offset strings, please see this link.

Examples

Start by creating a series with 9 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
2000-01-01 00:00:00    0
2000-01-01 00:01:00    1
2000-01-01 00:02:00    2
2000-01-01 00:03:00    3
2000-01-01 00:04:00    4
2000-01-01 00:05:00    5
2000-01-01 00:06:00    6
2000-01-01 00:07:00    7
2000-01-01 00:08:00    8
Freq: T, dtype: int64
```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.
Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket 2000-01-01 00:03:00 contains the value 3, but the summed value in the resampled bucket with the label 2000-01-01 00:03:00 does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00 3
2000-01-01 00:06:00 12
2000-01-01 00:09:00 21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00 0
2000-01-01 00:03:00 6
2000-01-01 00:06:00 15
2000-01-01 00:09:00 15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.

```
>>> series.resample('30S').asfreq()[0:5]  # Select first 5 rows
2000-01-01 00:00:00   0
2000-01-01 00:00:30  NaN
2000-01-01 00:01:00  1.0
2000-01-01 00:01:30  NaN
2000-01-01 00:02:00  2.0
Freq: 30S, dtype: float64
```

Upsample the series into 30 second bins and fill the NaN values using the pad method.

```
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00   0
2000-01-01 00:00:30   0
2000-01-01 00:01:00   1
2000-01-01 00:01:30   1
2000-01-01 00:02:00   2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the bfill method.

```
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00   0
2000-01-01 00:00:30   1
2000-01-01 00:01:00   1
2000-01-01 00:01:30   2
2000-01-01 00:02:00   2
Freq: 30S, dtype: int64
```
Pass a custom function via `apply`.

```python
>>> def custom_resampler(arraylike):
...     return np.sum(arraylike) + 5
...
>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00    8
2000-01-01 00:03:00   17
2000-01-01 00:06:00   26
Freq: 3T, dtype: int64
```

For a Series with a PeriodIndex, the keyword `convention` can be used to control whether to use the start or end of `rule`.

Resample a year by quarter using 'start' `convention`. Values are assigned to the first quarter of the period.

```python
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
...               freq='A',
...               periods=2))
>>> s
2012 1
2013 2
Freq: A-DEC, dtype: int64
>>> s.resample('Q', convention='start').asfreq()
2012Q1 1.0
2012Q2 NaN
2012Q3 NaN
2012Q4 NaN
2013Q1 2.0
2013Q2 NaN
2013Q3 NaN
2013Q4 NaN
Freq: Q-DEC, dtype: float64
```

Resample quarters by month using 'end' `convention`. Values are assigned to the last month of the period.

```python
>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01',
...               freq='Q',
...               periods=4))
>>> q
2018Q1 1
2018Q2 2
2018Q3 3
2018Q4 4
Freq: Q-DEC, dtype: int64
>>> q.resample('M', convention='end').asfreq()
2018-03 1.0
2018-04 NaN
2018-05 NaN
2018-06 2.0
2018-07 NaN
2018-08 NaN
2018-09 3.0
2018-10 NaN
2018-11 NaN
2018-12 4.0
Freq: M, dtype: float64
```

For DataFrame objects, the keyword `on` can be used to specify the column instead of the index for resam-
pling.

```python
>>> d = {'price': [10, 11, 9, 13, 14, 18, 17, 19],
...     'volume': [50, 60, 40, 100, 50, 100, 40, 50]}
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018',
...       periods=8,
...       freq='W')
>>> df
   price  volume week_starting
0    10     50 2018-01-07
1    11     60 2018-01-14
2     9     40 2018-01-21
3    13    100 2018-01-28
4    14      50 2018-02-04
5    18    100 2018-02-11
6    17     40 2018-02-18
7    19      50 2018-02-25
>>> df.resample('M', on='week_starting').mean()
   price  volume
week_starting
2018-01-31  10.75  62.5
2018-02-28  17.00  60.0
```

For a DataFrame with MultiIndex, the keyword `level` can be used to specify on which level the resampling needs to take place.

```python
>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = {'price': [10, 11, 9, 13, 14, 18, 17, 19],
...       'volume': [50, 60, 40, 100, 50, 100, 40, 50]}
>>> df2 = pd.DataFrame(
...     d2,
...     index=pd.MultiIndex.from_product(
...         [days, ['morning', 'afternoon']] ) )
>>> df2
   price  volume
2000-01-01 morning 10  50
          afternoon 11  60
2000-01-02 morning  9  40
          afternoon 13 100
2000-01-03 morning 14  50
          afternoon 18 100
2000-01-04 morning 17  40
          afternoon 19  50
>>> df2.resample('D', level=0).sum()
   price  volume
2000-01-01  21  110
2000-01-02  22  140
2000-01-03  32  150
2000-01-04  36   90
```

If you want to adjust the start of the bins based on a fixed timestamp:

```python
>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
(continues on next page)
```python
>>> ts
2000-10-01 23:30:00 0
2000-10-01 23:37:00 3
2000-10-01 23:44:00 6
2000-10-01 23:51:00 9
2000-10-01 23:58:00 12
2000-10-02 00:05:00 15
2000-10-02 00:12:00 18
2000-10-02 00:19:00 21
2000-10-02 00:26:00 24
Freq: 7T, dtype: int64
```

```python
>>> ts.resample('17min').sum()
2000-10-01 23:14:00 0
2000-10-01 23:31:00 9
2000-10-01 23:48:00 21
2000-10-02 00:05:00 54
2000-10-02 00:22:00 24
Freq: 17T, dtype: int64
```

```python
>>> ts.resample('17min', origin='epoch').sum()
2000-10-01 23:18:00 0
2000-10-01 23:35:00 18
2000-10-01 23:52:00 27
2000-10-02 00:09:00 39
2000-10-02 00:26:00 24
Freq: 17T, dtype: int64
```

```python
>>> ts.resample('17min', origin='2000-01-01').sum()
2000-10-01 23:24:00 3
2000-10-01 23:41:00 15
2000-10-01 23:58:00 45
2000-10-02 00:15:00 45
Freq: 17T, dtype: int64
```

If you want to adjust the start of the bins with an offset Timedelta, the two following lines are equivalent:

```python
>>> ts.resample('17min', origin='start').sum()
2000-10-01 23:30:00 9
2000-10-01 23:47:00 21
2000-10-02 00:04:00 54
2000-10-02 00:21:00 24
Freq: 17T, dtype: int64
```

```python
>>> ts.resample('17min', offset='23h30min').sum()
2000-10-01 23:30:00 9
2000-10-01 23:47:00 21
2000-10-02 00:04:00 54
2000-10-02 00:21:00 24
Freq: 17T, dtype: int64
```

If you want to take the largest Timestamp as the end of the bins:

```python
>>> ts.resample('17min', origin='end').sum()
2000-10-01 23:35:00 0
```
In contrast with the `start_day`, you can use `end_day` to take the ceiling midnight of the largest Timestamp as the end of the bins and drop the bins not containing data:

```python
>>> ts.resample('17min', origin='end_day').sum()
2000-10-01 23:38:00    3
2000-10-01 23:55:00    15
2000-10-02 00:12:00    45
2000-10-02 00:29:00    45
Freq: 17T, dtype: int64
```

To replace the use of the deprecated `base` argument, you can now use `offset`, in this example it is equivalent to have `base=2`:

```python
>>> ts.resample('17min', offset='2min').sum()
2000-10-01 23:16:00    0
2000-10-01 23:33:00    9
2000-10-01 23:50:00    36
2000-10-02 00:07:00    39
2000-10-02 00:24:00    24
Freq: 17T, dtype: int64
```

To replace the use of the deprecated `loffset` argument:

```python
>>> from pandas.tseries.frequencies import to_offset
>>> loffset = '19min'
>>> ts_out = ts.resample('17min').sum()
>>> ts_out.index = ts_out.index + to_offset(loffset)
```

### pandas.Series.reset_index

`Series.reset_index(level=None, drop=False, name=None, inplace=False)`

Generate a new DataFrame or Series with the index reset.

This is useful when the index needs to be treated as a column, or when the index is meaningless and needs to be reset to the default before another operation.

**Parameters**

- **level** [int, str, tuple, or list, default optional] For a Series with a MultiIndex, only remove the specified levels from the index. Removes all levels by default.

- **drop** [bool, default False] Just reset the index, without inserting it as a column in the new DataFrame.
name [object, optional] The name to use for the column containing the original Series values. Uses self.name by default. This argument is ignored when drop is True.

Returns

Series or DataFrame or None When drop is False (the default), a DataFrame is returned. The newly created columns will come first in the DataFrame, followed by the original Series values. When drop is True, a Series is returned. In either case, if inplace=True, no value is returned.

See also:

DataFrame.reset_index Analogous function for DataFrame.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4], name='foo',
                 index=pd.Index(['a', 'b', 'c', 'd'], name='idx'))
Generate a DataFrame with default index.

>>> s.reset_index()
    idx  foo
   0  a   1
   1  b   2
   2  c   3
   3  d   4
To specify the name of the new column use name.

>>> s.reset_index(name='values')
    idx  values
   0  a    1
   1  b    2
   2  c    3
   3  d    4
To generate a new Series with the default set drop to True.

>>> s.reset_index(drop=True)
   0   1
   1   2
   2   3
   3   4
Name: foo, dtype: int64
To update the Series in place, without generating a new one set inplace to True. Note that it also requires drop=True.

>>> s.reset_index(inplace=True, drop=True)
>>> s
   0   1
   1   2
   2   3
   3   4
Name: foo, dtype: int64
```
The `level` parameter is interesting for Series with a multi-level index.

```python
>>> arrays = [np.array(['bar', 'bar', 'baz', 'baz']),
            np.array(['one', 'two', 'one', 'two'])]
>>> s2 = pd.Series(
    ... range(4), name='foo',
    ... index=pd.MultiIndex.from_arrays(arrays,
    ... names=['a', 'b']))
```

To remove a specific level from the Index, use `level`.

```python
>>> s2.reset_index(level='a')
   a   foo  
  b
one   bar   0
two   bar   1
one   baz   2
two   baz   3
```

If `level` is not set, all levels are removed from the Index.

```python
>>> s2.reset_index()
   a  b   foo  
  0  bar  one   0
  1  bar  two   1
  2  baz  one   2
  3  baz  two   3
```

**pandas.Series.rfloordiv**

`Series.rfloordiv(other, level=None, fill_value=None, axis=0)`

Return integer division of series and other, element-wise (binary operator `rfloordiv`). Equivalent to `other // series`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- `other` [Series or scalar value]
- `fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- `level` [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

- `Series` The result of the operation.

**See also:**

- `Series.floordiv` Element-wise Integer division, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0  
b 1.0  
c 1.0  
d NaN  
dtype: float64
```

```python
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0  
b NaN  
d 1.0  
e NaN  
dtype: float64
```

```python
>>> a.floordiv(b, fill_value=0)
```

```python
a 1.0  
b NaN  
c NaN  
d 0.0  
e NaN  
dtype: float64
```

**pandas.Series.rmod**

`Series.rmod(other, level=None, fill_value=None, axis=0)`

Return Modulo of series and other, element-wise (binary operator rmod).

Equivalent to `other % series`, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- `other` [Series or scalar value]
- `fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- `level` [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

- `Series` The result of the operation.

**See also:**

- `Series.mod` Element-wise Modulo, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.mod(b, fill_value=0)
a    0.0
b    NaN
c    NaN
d    0.0
e    NaN
dtype: float64
```

**pandas.Series.rmul**

```
Series.rmul(other, level=None, fill_value=None, axis=0)
```

Return Multiplication of series and other, element-wise (binary operator `rmul`).

Equivalent to `other * series`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- `other` [Series or scalar value]
- `fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- `level` [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

- `Series` The result of the operation.

**See also:**

- `Series.mul` Element-wise Multiplication, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64

>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64

>>> a.multiply(b, fill_value=0)
a 1.0
b 0.0
c 0.0
d 0.0
e NaN
dtype: float64
```

**pandas.Series.rolling**

Series.rolling(*window*, *min_periods=None*, *center=False*, *win_type=None*, *on=None*, *axis=0*, *closed=None*, *method='single'*)

Provide rolling window calculations.

**Parameters**

- **window** [int, offset, or BaseIndexer subclass] Size of the moving window. This is the number of observations used for calculating the statistic. Each window will be a fixed size.

  If its an offset then this will be the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes.

  If a BaseIndexer subclass is passed, calculates the window boundaries based on the defined `get_window_bounds` method. Additional rolling keyword arguments, namely `min_periods`, `center`, and `closed` will be passed to `get_window_bounds`.

- **min_periods** [int, default None] Minimum number of observations in window required to have a value (otherwise result is NA). For a window that is specified by an offset, `min_periods` will default to 1. Otherwise, `min_periods` will default to the size of the window.

- **center** [bool, default False] Set the labels at the center of the window.

- **win_type** [str, default None] Provide a window type. If `None`, all points are evenly weighted. See the notes below for further information.

- **on** [str, optional] For a DataFrame, a datetimelike column or Index level on which to calculate the rolling window, rather than the DataFrame’s index. Provided integer column is ignored and excluded from result since an integer index is not used to calculate the rolling window.
axis [int or str, default 0]

closed [str, default None] Make the interval closed on the ‘right’, ‘left’, ‘both’ or ‘neither’ endpoints. Defaults to ‘right’.

   Changed in version 1.2.0: The closed parameter with fixed windows is now supported.

method [str {'single', 'table'}, default 'single'] Execute the rolling operation per single column or row ('single') or over the entire object ('table').

   This argument is only implemented when specifying engine='numba' in the method call.

   New in version 1.3.0.

Returns

   a Window or Rolling sub-classed for the particular operation

See also:

expanding Provides expanding transformations.

ewm Provides exponential weighted functions.

Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting center=True.

To learn more about the offsets & frequency strings, please see this link.

If win_type=None, all points are evenly weighted; otherwise, win_type can accept a string of any scipy.signal window function.

Certain Scipy window types require additional parameters to be passed in the aggregation function. The additional parameters must match the keywords specified in the Scipy window type method signature. Please see the third example below on how to add the additional parameters.

Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0

Rolling sum with a window length of 2, using the 'triang' window type.

>>> df.rolling(2, win_type='triang').sum()
   B
0  NaN
1  0.5
2  1.5
```

(continues on next page)
Rolling sum with a window length of 2, using the ‘gaussian’ window type (note how we need to specify std).

```python
>>> df.rolling(2, win_type='gaussian').sum(std=3)
   B
0  NaN
1  0.986207
2  2.958621
3  NaN
4  NaN
```

Rolling sum with a window length of 2, min_periods defaults to the window length.

```python
>>> df.rolling(2).sum()
   B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN
```

Same as above, but explicitly set the min_periods

```python
>>> df.rolling(2, min_periods=1).sum()
   B
0  0.0
1  1.0
2  3.0
3  2.0
4  4.0
```

Same as above, but with forward-looking windows

```python
>>> indexer = pd.api.indexers.FixedForwardWindowIndexer(window_size=2)
>>> df.rolling(window=indexer, min_periods=1).sum()
   B
0  1.0
1  3.0
2  2.0
3  4.0
4  4.0
```

A ragged (meaning not-a-regular frequency), time-indexed DataFrame

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
...                   index=[pd.Timestamp('20130101 09:00:00'),
...                          pd.Timestamp('20130101 09:00:02'),
...                          pd.Timestamp('20130101 09:00:03'),
...                          pd.Timestamp('20130101 09:00:05'),
...                          pd.Timestamp('20130101 09:00:06')])
```

```python
>>> df
   B
0  0
1  1
2  2
3  NaN
4  4
```
Contrasting to an integer rolling window, this will roll a variable length window corresponding to the time period. The default for min_periods is 1.

```python
>>> df.rolling('2s').sum()
 2013-01-01 09:00:00    0.0
2013-01-01 09:00:02    1.0
2013-01-01 09:00:03    2.0
2013-01-01 09:00:05   NaN
2013-01-01 09:00:06    4.0
```

**pandas.Series.round**

Series.round(decimals=0, *args, **kwargs)

Round each value in a Series to the given number of decimals.

**Parameters**

- **decimals** [int, default 0] Number of decimal places to round to. If decimals is negative, it specifies the number of positions to the left of the decimal point.
- **args, **kwargs** Additional arguments and keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

Series  Rounded values of the Series.

**See also:**

- `numpy.around`  Round values of an np.array.
- `DataFrame.round`  Round values of a DataFrame.

**Examples**

```python
>>> s = pd.Series([0.1, 1.3, 2.7])
>>> s.round()
0   0.0
1   1.0
2   2.0
dtype: float64
```
**pandas.Series.rpow**

Series.rpow(other, level=None, fill_value=None, axis=0)

Return Exponential power of series and other, element-wise (binary operator rpow).

Equivalent to other ** series, but with support to substitute a fill_value for missing data in either one of the inputs.

**Parameters**

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

Series The result of the operation.

**See also:**

Series.pow Element-wise Exponential power, see Python documentation for more details.

**Examples**

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.pow(b, fill_value=0)
a 1.0
b 1.0
c 1.0
d 0.0
e NaN
dtype: float64
```
pandas.Series.rsub

Series.rsub(other, level=None, fill_value=None, axis=0)

Return Subtraction of series and other, element-wise (binary operator rsub).

Equivalent to other - series, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.sub Element-wise Subtraction, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0
b  1.0
c  1.0
d  NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b  NaN
d  1.0
e  NaN
dtype: float64
>>> a.subtract(b, fill_value=0)
a  0.0
b  1.0
c  1.0
d -1.0
e  NaN
dtype: float64
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.Series.rtruediv

Series.rtruediv(other, level=None, fill_value=None, axis=0)

Return Floating division of series and other, element-wise (binary operator rtruediv).

Equivalent to other / series, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.truediv Element-wise Floating division, see Python documentation for more details.

Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a  1.0
b  1.0
c  1.0
d  NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a  1.0
b  NaN
d  1.0
e  NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a  1.0
b  inf
c  inf
d  0.0
e  NaN
dtype: float64
```
**pandas.Series.sample**

Series.sample(n=None, frac=None, replace=False, weights=None, random_state=None, axis=None, ignore_index=False)

Return a random sample of items from an axis of object.

You can use random_state for reproducibility.

**Parameters**

- **n** [int, optional] Number of items from axis to return. Cannot be used with frac. Default = 1 if frac = None.
- **frac** [float, optional] Fraction of axis items to return. Cannot be used with n.
- **replace** [bool, default False] Allow or disallow sampling of the same row more than once.
- **weights** [str or ndarray-like, optional] Default ‘None’ results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when axis = 0. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.
- **random_state** [int, array-like, BitGenerator, np.random.RandomState, optional] If int, array-like, or BitGenerator (NumPy>=1.17), seed for random number generator If np.random.RandomState, use as numpy RandomState object. Changed in version 1.1.0: array-like and BitGenerator (for NumPy>=1.17) object now passed to np.random.RandomState() as seed
- **axis** [[0 or ‘index’, 1 or ‘columns’, None], default None] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames).
- **ignore_index** [bool, default False] If True, the resulting index will be labeled 0, 1, ..., n - 1. New in version 1.3.0.

**Returns**

- **Series or DataFrame** A new object of same type as caller containing n items randomly sampled from the caller object.

**See also:**

- **DataFrameGroupBy.sample** Generates random samples from each group of a DataFrame object.
- **SeriesGroupBy.sample** Generates random samples from each group of a Series object.
- **numpy.random.choice** Generates a random sample from a given 1-D numpy array.
Notes

If $\text{frac} > 1$, replacement should be set to True.

Examples

```python
>>> df = pd.DataFrame({'num_legs': [2, 4, 8, 0],
...                    'num_wings': [2, 0, 0, 0],
...                    'num_specimen_seen': [10, 2, 1, 8]},
...                   index=['falcon', 'dog', 'spider', 'fish'])
```

Extract 3 random elements from the Series df['num_legs']: Note that we use random_state to ensure the reproducibility of the examples.

```python
>>> df['num_legs'].sample(n=3, random_state=1)
fish 0
spider 8
falcon 2
Name: num_legs, dtype: int64
```

A random 50% sample of the DataFrame with replacement:

```python
>>> df.sample(frac=0.5, replace=True, random_state=1)
```

An upsample sample of the DataFrame with replacement: Note that replace parameter has to be True for frac parameter > 1.

```python
>>> df.sample(frac=2, replace=True, random_state=1)
```

Using a DataFrame column as weights. Rows with larger value in the num_specimen_seen column are more likely to be sampled.

```python
>>> df.sample(n=2, weights='num_specimen_seen', random_state=1)
```
pandas.Series.searchsorted

Series.searchsorted(value, side='left', sorter=None)

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted Series self such that, if the corresponding elements in value were inserted before the indices, the order of self would be preserved.

**Note:** The Series must be monotonically sorted, otherwise wrong locations will likely be returned. Pandas does not check this for you.

**Parameters**

value [array-like] Values to insert into self.

side [{'left', 'right'}, optional] If ‘left’, the index of the first suitable location found is given. If ‘right’, return the last such index. If there is no suitable index, return either 0 or N (where N is the length of self).

sorter [1-D array-like, optional] Optional array of integer indices that sort self into ascending order. They are typically the result of np.argsort.

**Returns**

int or array of int A scalar or array of insertion points with the same shape as value.

**See also:**

sort_values Sort by the values along either axis.
numpy.searchsorted Similar method from NumPy.

**Notes**

Binary search is used to find the required insertion points.

**Examples**

```python
>>> ser = pd.Series([1, 2, 3])
>>> ser
0    1
1    2
2    3
dtype: int64

>>> ser.searchsorted(4)
3

>>> ser.searchsorted([0, 4])
array([0, 3])

>>> ser.searchsorted([1, 3], side='left')
array([0, 2])
```
```python
>>> ser.searchsorted([1, 3], side='right')
array([1, 3])

>>> ser.searchsorted('3/14/2000')
3

>>> ser.searchsorted(['bread'])
1

array(['bread'], side='right')
```

If the values are not monotonically sorted, wrong locations may be returned:

```python
>>> ser = pd.Series([2, 1, 3])
>>> ser
0  2
1  1
2  3
dtype: int64

>>> ser.searchsorted(1)
0  # wrong result, correct would be 1
```

### pandas.Series.sem

**Series.sem (axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)**

Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument.

**Parameters**

- **axis** ([index (0)])
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns
scalar or Series (if level specified)

Notes
To have the same behaviour as numpy.std, use ddof=0 (instead of the default ddof=1)

pandas.Series.set_axis

Series.set_axis (labels, axis=0, inplace=False)
Assign desired index to given axis.
Indexes for row labels can be changed by assigning a list-like or Index.

Parameters
labels [list-like, Index] The values for the new index.
axis [{0 or 'index'}, default 0] The axis to update. The value 0 identifies the rows.
inplace [bool, default False] Whether to return a new Series instance.

Returns
