renamed [Series or None] An object of type Series or None if inplace=True.

See also:
Series.rename_axis Alter the name of the index.

Examples

```python
g = pd.Series([1, 2, 3])
g = [0, 1, 2]
2 3
```

g.set_axis(['a', 'b', 'c'], axis=0)
a b c
a 1
b 2
c 3
dtype: int64
**pandas.Series.set_flags**

```
Series.set_flags(*, copy=False, allows_duplicate_labels=None)
```

Return a new object with updated flags.

**Parameters**

- `allows_duplicate_labels` [bool, optional] Whether the returned object allows duplicate labels.

**Returns**

- Series or DataFrame The same type as the caller.

**See also:**

- `DataFrame.attrs` Global metadata applying to this dataset.
- `DataFrame.flags` Global flags applying to this object.

**Notes**

This method returns a new object that’s a view on the same data as the input. Mutating the input or the output values will be reflected in the other.

This method is intended to be used in method chains.

“Flags” differ from “metadata”. Flags reflect properties of the pandas object (the Series or DataFrame). Metadata refer to properties of the dataset, and should be stored in `DataFrame.attrs`.

**Examples**

```python
gp.user='example_user'
gp.set_flags(copy=False,allows_duplicate_labels=None)
```

**pandas.Series.shift**

```
Series.shift(periods=1, freq=None, axis=0, fill_value=None)
```

Shift index by desired number of periods with an optional time `freq`.

When `freq` is not passed, shift the index without realigning the data. If `freq` is passed (in this case, the index must be date or datetime, or it will raise a `NotImplementedError`), the index will be increased using the periods and the `freq`. `freq` can be inferred when specified as “infer” as long as either `freq` or `inferred_freq` attribute is set in the index.

**Parameters**

- `periods` [int] Number of periods to shift. Can be positive or negative.
- `freq` [DateOffset, tseries.offsets, timedelta, or str, optional] Offset to use from the tseries module or time rule (e.g. ‘EOM’). If `freq` is specified then the index values are shifted but the data is not realigned. That is, use `freq` if you would like to extend the index when shifting and preserve the original data. If `freq` is specified as
“infer” then it will be inferred from the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown.

axis [{0 or ‘index’, 1 or ‘columns’, None}, default None] Shift direction.

fill_value [object, optional] The scalar value to use for newly introduced missing values. the default depends on the dtype of self. For numeric data, np.nan is used. For datetime, timedelta, or period data, etc. NaT is used. For extension dtypes, self.dtype.na_value is used.

Changed in version 1.1.0.

Returns

Series Copy of input object, shifted.

See also:

Index.shift Shift values of Index.

DatetimeIndex.shift Shift values of DatetimeIndex.

PeriodIndex.shift Shift values of PeriodIndex.

tshift Shift the time index, using the index’s frequency if available.

Examples

```
>>> df = pd.DataFrame({"Col1": [10, 20, 15, 30, 45],
...                     "Col2": [13, 23, 18, 33, 48],
...                     "Col3": [17, 27, 22, 37, 52]},
...                    index=pd.date_range("2020-01-01", "2020-01-05"))

```

```
>>> df
       Col1  Col2  Col3
2020-01-01 10    13    17

**pandas.Series.skew**

*Series.skew (axis=None, skipna=None, level=None, numeric_only=None, **kwags)*

Return unbiased skew over requested axis. Normalized by N-1.

**Parameters**

- **axis** [{index (0)]] Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

- **scalar or Series (if level specified)**
pandas.Series.slice_shift

Series.slice_shift(periods=1, axis=0)

Equivalent to shift without copying data. The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

Deprecated since version 1.2.0: slice_shift is deprecated, use DataFrame/Series.shift instead.

Parameters

- **periods** [int] Number of periods to move, can be positive or negative.

Returns

- **shifted** [same type as caller]

Notes

While the slice_shift is faster than shift, you may pay for it later during alignment.

pandas.Series.sort_index

Series.sort_index(axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na_position='last', sort_remaining=True, ignore_index=False, key=None)

Sort Series by index labels.

Returns a new Series sorted by label if inplace argument is False, otherwise updates the original series and returns None.

Parameters

- **axis** [int, default 0] Axis to direct sorting. This can only be 0 for Series.
- **level** [int, optional] If not None, sort on values in specified index level(s).
- **ascending** [bool or list-like of bools, default True] Sort ascending vs. descending. When the index is a MultiIndex the sort direction can be controlled for each level individually.
- **inplace** [bool, default False] If True, perform operation in-place.
- **kind** [{‘quicksort’, ‘mergesort’, ‘heapsort’, ‘stable’}, default ‘quicksort’] Choice of sorting algorithm. See also numpy.sort() for more information. ‘mergesort’ and ‘stable’ are the only stable algorithms. For DataFrames, this option is only applied when sorting on a single column or label.
- **na_position** [{‘first’, ‘last’}, default ‘last’] If ‘first’ puts NaNs at the beginning, ‘last’ puts NaNs at the end. Not implemented for MultiIndex.
- **sort_remaining** [bool, default True] If True and sorting by level and index is multi-level, sort by other levels too (in order) after sorting by specified level.
- **ignore_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

- **key** [callable, optional] If not None, apply the key function to the index values before sorting. This is similar to the key argument in the builtin sorted() function, with the notable difference that this key function should be vectorized. It should expect an Index and return an Index of the same shape.
New in version 1.1.0.

**Returns**

Series or None  The original Series sorted by the labels or None if inplace=True.

See also:

- `DataFrame.sort_index`  Sort DataFrame by the index.
- `DataFrame.sort_values`  Sort DataFrame by the value.
- `Series.sort_values`  Sort Series by the value.

**Examples**

```python
>>> s = pd.Series(['a', 'b', 'c', 'd'], index=[3, 2, 1, 4])
>>> s.sort_index()
1 c
2 b
3 a
4 d
dtype: object
```

Sort Descending

```python
>>> s.sort_index(ascending=False)
4 d
3 a
2 b
1 c
dtype: object
```

Sort Inplace

```python
>>> s.sort_index(inplace=True)
>>> s
1 c
2 b
3 a
4 d
dtype: object
```

By default NaNs are put at the end, but use `na_position` to place them at the beginning

```python
>>> s = pd.Series(['a', 'b', 'c', 'd'], index=[3, 2, 1, np.nan])
>>> s.sort_index(na_position='first')
NaN d
1.0 c
2.0 b
3.0 a
dtype: object
```

Specify index level to sort

```python
>>> arrays = [np.array(['qux', 'qux', 'foo', 'foo',
... 'baz', 'baz', 'bar', 'bar']),
... np.array(['two', 'one', 'two', 'one',
... 'two', 'one', 'two'])]
```

(continues on next page)
...  
[1 2 3 4 5 6 7 8]

```python
>>> s = pd.Series([1, 2, 3, 4, 5, 6, 7, 8], index=arrays)
>>> s.sort_index(level=1)
bar one  8
baz one  6
foo one  4
qux one  2
bar two  7
baz two  5
foo two  3
qux two  1
dtype: int64
Does not sort by remaining levels when sorting by levels
```  
```python
>>> s.sort_index(level=1, sort_remaining=False)
qux one  2
foo one  4
baz one  6
bar one  8
qux two  1
foo two  3
baz two  5
bar two  7
dtype: int64
```  
Apply a key function before sorting
```python
>>> s = pd.Series([1, 2, 3, 4], index=['A', 'b', 'C', 'd'])
```  
```python
>>> s.sort_index(key=lambda x : x.str.lower())
A    1
b    2
C    3
d    4
dtype: int64
```

**pandas.Series.sort_values**

`Series.sort_values(axis=0, ascending=True, inplace=False, kind='quicksort', na_position='last', ignore_index=False, key=None)`

Sort by the values.
Sort a Series in ascending or descending order by some criterion.

**Parameters**

- `axis` [{0 or ‘index’}, default 0] Axis to direct sorting. The value ‘index’ is accepted for compatibility with DataFrame.sort_values.
- `ascending` [bool or list of bools, default True] If True, sort values in ascending order, otherwise descending.
- `inplace` [bool, default False] If True, perform operation in-place.
- `kind` [{‘quicksort’, ‘mergesort’, ‘heapsort’, ‘stable’}, default ‘quicksort’] Choice of sorting algorithm. See also `numpy.sort()` for more information. ‘mergesort’ and ‘stable’ are the only stable algorithms.

---

**3.3. Series**

1303
**na_position** 
[‘first’ or ‘last’], default ‘last’] Argument ‘first’ puts NaNs at thebeginning, ‘last’ puts NaNs at the end.

**ignore_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

**key** [callable, optional] If not None, apply the key function to the series values before sorting. This is similar to the key argument in the builtin sorted() function, with the notable difference that this key function should be vectorized. It should expect a Series and return an array-like.

New in version 1.1.0.

**Returns**

Series or None Series ordered by values or None if inplace=True.

**See also:**

*Series.sort_index* Sort by the Series indices.

*Dataframe.sort_values* Sort DataFrame by the values along either axis.

*Dataframe.sort_index* Sort DataFrame by indices.

**Examples**

```python
>>> s = pd.Series([np.nan, 1, 3, 10, 5])
>>> s
0   NaN
1    1
2    3
3   10
4    5
dtype: float64

Sort values ascending order (default behaviour)

```python
>>> s.sort_values(ascending=True)
1    1
2    3
4    5
3   10
0   NaN
dtype: float64

Sort values descending order

```python
>>> s.sort_values(ascending=False)
3   10
4    5
2    3
1    1
0   NaN
dtype: float64

Sort values inplace
```
Sort values putting NAs first

```python
>>> s.sort_values(na_position='first')
0  NaN
1   1.0
2   3.0
3   5.0
4  10.0
dtype: float64
```

Sort a series of strings

```python
>>> s = pd.Series(['z', 'b', 'd', 'a', 'c'])
```

```python
>>> s.sort_values()
3  a
1  b
4  c
2  d
0  z
dtype: object
```

Sort using a key function. Your key function will be given the Series of values and should return an array-like.

```python
>>> s = pd.Series(['a', 'B', 'c', 'D', 'e'])
```

```python
>>> s.sort_values()
1  B
3  D
0  a
2  c
4  e
dtype: object
```

```python
>>> s.sort_values(key=lambda x: x.str.lower())
0  a
1  B
2  c
3  D
4  e
dtype: object
```

NumPy ufuncs work well here. For example, we can sort by the sin of the value.
```python
>>> s = pd.Series([-4, -2, 0, 2, 4])
>>> s.sort_values(key=np.sin)
  1  -2
  4   4
  2   0
  0  -4
  3   2
dtype: int64
```

More complicated user-defined functions can be used, as long as they expect a Series and return an array-like

```python
>>> s.sort_values(key=lambda x: (np.tan(x.cumsum())))
  0  -4
  3   2
  4   4
  1  -2
  2   0
dtype: int64
```

---

**pandas.Series.sparse**

*Series.sparse()*  
Accessor for Sparse from other sparse matrix data types.

**pandas.Series.squeeze**

*Series.squeeze(axis=None)*  
Squeeze 1 dimensional axis objects into scalars.

Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.

This method is most useful when you don’t know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call `squeeze` to ensure you have a Series.

**Parameters**

- **axis**  
  [{0 or ‘index’, 1 or ‘columns’, None}, default None] A specific axis to squeeze. By default, all length-1 axes are squeezed.

**Returns**

- **DataFrame, Series, or scalar**  
  The projection after squeezing `axis` or all the axes.

See also:

- *Series.iloc* Integer-location based indexing for selecting scalars.
- *DataFrame.iloc* Integer-location based indexing for selecting Series.
- *Series.to_frame* Inverse of DataFrame.squeeze for a single-column DataFrame.
Examples

```python
>>> primes = pd.Series([2, 3, 5, 7])

Slicing might produce a Series with a single value:

```python
define_expr(even_primes = primes[primes % 2 == 0])
define_expr(even_primes)
   0  2
dtype: int64
```

```python
define_expr(even_primes.squeeze())
   2
```

Squeezing objects with more than one value in every axis does nothing:

```python
>>> odd_primes = primes[primes % 2 == 1]
>>> odd_primes
   1  3
   2  5
   3  7
dtype: int64
```

```python
define_expr(odd_primes.squeeze())
   1  3
   2  5
   3  7
dtype: int64
```

Squeezing is even more effective when used with DataFrames.

```python
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
>>> df
   a  b
  0 1  2
  1 3  4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```python
>>> df_a = df[['a']]  
>>> df_a
   a
  0 1
  1 3
```

So the columns can be squeezed down, resulting in a Series:

```python
define_expr(df_a.squeeze('columns'))
   0  1
   1  3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```python
>>> df_0a = df.loc[df.index < 1, ['a']] 
>>> df_0a
```

(continues on next page)
Squeezing the rows produces a single scalar Series:

```
>>> df_0a.squeeze('rows')
a  1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```
>>> df_0a.squeeze()
1
```

**pandas.Series.std**

*Series.std*(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)  
Return sample standard deviation over requested axis.  
Normalized by N-1 by default. This can be changed using the ddof argument  

**Parameters**

- **axis** ([index (0)])
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

scalar or Series (if level specified)

**Notes**

To have the same behaviour as *numpy.std*, use *ddof=0* (instead of the default *ddof=1*)
pandas.Series.str

Series.str()
Vectorized string functions for Series and Index.
NAs stay NA unless handled otherwise by a particular method. Patterned after Python’s string methods, with some inspiration from R’s stringr package.

Examples

```python
>>> s = pd.Series(["A_Str_Series"])
>>> s
0   A_Str_Series
dtype: object

>>> s.str.split("_")
0   [A, Str, Series]
dtype: object

>>> s.str.replace("_", "")
0   AStrSeries
dtype: object
```

pandas.Series.sub

Series.sub(other, level=None, fill_value=None, axis=0)
Return Subtraction of series and other, element-wise (binary operator sub).
Equivalent to series - other, but with support to substitute a fill_value for missing data in either one of the inputs.

Parameters

- **other** [Series or scalar value]
- **fill_value** [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.
- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

Series The result of the operation.

See also:

Series.rsub Reverse of the Subtraction operator, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.subtract(b, fill_value=0)
a 0.0
b 1.0
c 1.0
d -1.0
e NaN
dtype: float64
```

**pandas.Series.subtract**

`Series.subtract(other, level=None, fill_value=None, axis=0)`

Return Subtraction of series and other, element-wise (binary operator `sub`).

Equivalent to `series - other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- `other` [Series or scalar value]

- `fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

- `level` [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

- `Series` The result of the operation.

**See also:**

- `Series.rsub` Reverse of the Subtraction operator, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a 1.0
b 1.0
c 1.0
d NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a 1.0
b NaN
d 1.0
e NaN
dtype: float64
>>> a.subtract(b, fill_value=0)
a 0.0
b 1.0
c 1.0
d -1.0
e NaN
dtype: float64
```

### pandas.Series.sum

`Series.sum(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)`  
Return the sum of the values over the requested axis.  
This is equivalent to the method `numpy.sum`.

**Parameters**

- **axis**  
  [[index (0)]] Axis for the function to be applied on.

- **skipna**  
  [bool, default True] Exclude NA/null values when computing the result.

- **level**  
  [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

- **numeric_only**  
  [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

- **min_count**  
  [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

- **kwargs**  
  Additional keyword arguments to be passed to the function.

**Returns**

- scalar or Series (if level specified)

**See also:**

- `Series.sum` Return the sum.
- `Series.min` Return the minimum.
Series.max  Return the maximum.
Series.idxmin  Return the index of the minimum.
Series.idxmax  Return the index of the maximum.
DataFrame.sum  Return the sum over the requested axis.
DataFrame.min  Return the minimum over the requested axis.
DataFrame.max  Return the maximum over the requested axis.
DataFrame.idxmin  Return the index of the minimum over the requested axis.
DataFrame.idxmax  Return the index of the maximum over the requested axis.

Examples

```python
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider'],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
  warm  dog 4
     falcon  2
  cold  fish  0
     spider  8
Name: legs, dtype: int64

>>> s.sum()
14
```

By default, the sum of an empty or all-NA Series is 0.

```python
>>> pd.Series([], dtype="float64").sum()  # min_count=0 is the default
0.0
```

This can be controlled with the min_count parameter. For example, if you’d like the sum of an empty series to be NaN, pass min_count=1.

```python
>>> pd.Series([], dtype="float64").sum(min_count=1)
nan
```

Thanks to the skipna parameter, min_count handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).sum()
0.0

>>> pd.Series([np.nan]).sum(min_count=1)
nan
```
pandas.Series.swapaxes

Series.swapaxes(axis1, axis2, copy=True)
Interchange axes and swap values axes appropriately.

Returns
y [same as input]

pandas.Series.swaplevel

Series.swaplevel(i=-2, j=-1, copy=True)
Swap levels i and j in a MultiIndex.

Default is to swap the two innermost levels of the index.

Parameters
i, j [int or str] Levels of the indices to be swapped. Can pass level name as string.
copy [bool, default True] Whether to copy underlying data.

Returns
Series Series with levels swapped in MultiIndex.

Examples

```python
>>> s = pd.Series(
...     ['A', 'B', 'A', 'C'],
...     index=[
...         ['Final exam', 'Final exam', 'Coursework', 'Coursework'],
...         ['History', 'Geography', 'History', 'Geography'],
...         ['January', 'February', 'March', 'April'],
...     ],
... )
```

```
Final exam History January A
Geography February B
Coursework History March A
Geography April C
dtype: object
```

In the following example, we will swap the levels of the indices. Here, we will swap the levels column-wise, but levels can be swapped row-wise in a similar manner. Note that column-wise is the default behaviour. By not supplying any arguments for i and j, we swap the last and second to last indices.

```python
>>> s.swaplevel()
```

```
Final exam January History A
February Geography B
Coursework March History A
April Geography C
dtype: object
```

By supplying one argument, we can choose which index to swap the last index with. We can for example swap the first index with the last one as follows.
We can also define explicitly which indices we want to swap by supplying values for both i and j. Here, we for example swap the first and second indices.

```python
>>> s.swaplevel(0, 1)
History Final exam January A
Geography Final exam February B
History Coursework March A
Geography Coursework April C
dtype: object
```

### pandas.Series.tail

**Series.tail(n=5)**

Return the last n rows.

This function returns last n rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

For negative values of n, this function returns all rows except the first n rows, equivalent to `df[n:]`.

**Parameters**

- **n** [int, default 5] Number of rows to select.

**Returns**

- `type of caller` The last n rows of the caller object.

**See also:**

- `DataFrame.head` The first n rows of the caller object.

**Examples**

```python
>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...                         'monkey', 'parrot', 'shark', 'whale', 'zebra']})
```

Viewing the last 5 lines

```python
>>> df.tail(5)  # Viewing the last 5 lines
            animal
0  alligator
1       bee
2  falcon
3      lion
4  monkey
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
>>> df.tail()
animal
4 monkey
5 parrot
6 shark
7 whale
8 zebra
```

Viewing the last $n$ lines (three in this case)

```python
>>> df.tail(3)
animal
6 shark
7 whale
8 zebra
```

For negative values of $n$

```python
>>> df.tail(-3)
animal
3 lion
4 monkey
5 parrot
6 shark
7 whale
8 zebra
```

**pandas.Series.take**

`Series.take(indices, axis=0, is_copy=None, **kwargs)`

Return the elements in the given positional indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

**Parameters**

- `indices` [array-like] An array of ints indicating which positions to take.
- `axis` [[0 or ‘index’, 1 or ‘columns’, None], default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.
- `is_copy` [bool] Before pandas 1.0, `is_copy=False` can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, `take` always returns a copy, and the keyword is therefore deprecated.

Deprecation since version 1.0.0.

- **kwargs For compatibility with `numpy.take()` Has no effect on the output.

**Returns**

- `taken` [same type as caller] An array-like containing the elements taken from the object.

**See also:**

- `DataFrame.loc` Select a subset of a DataFrame by labels.
- `DataFrame.iloc` Select a subset of a DataFrame by positions.
**numpy.take** Take elements from an array along an axis.

**Examples**

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                     ('parrot', 'bird', 24.0),
...                     ('lion', 'mammal', 80.5),
...                     ('monkey', 'mammal', np.nan)],
...                    columns=['name', 'class', 'max_speed'],
...                    index=[0, 2, 3, 1])

>>> df
   name class  max_speed
0  falcon  bird     389.0
2   parrot  bird      24.0
3     lion  mammal     80.5
1  monkey  mammal      NaN

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That's because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```python
>>> df.take([0, 3])
   name class  max_speed
0  falcon  bird     389.0
1  monkey  mammal      NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```python
>>> df.take([1, 2], axis=1)
    class  max_speed
0    bird     389.0
2    bird      24.0
3  mammal      80.5
1  mammal      NaN
```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```python
>>> df.take([-1, -2])
   name class  max_speed
1  monkey  mammal      NaN
3     lion  mammal     80.5
```

**pandas.Series.to_clipboard**

```python
Series.to_clipboard(excel=True, sep=None, **kwargs)
```

Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

**Parameters**

- **excel** [bool, default True] Produce output in a csv format for easy pasting into excel.
  - True, use the provided separator for csv pasting.
• False, write a string representation of the object to the clipboard.

**kwargs These parameters will be passed to DataFrame.to_csv.

See also:

*DataFrame.to_csv* Write a DataFrame to a comma-separated values (csv) file.

*read_clipboard* Read text from clipboard and pass to read_table.

**Notes**

Requirements for your platform.

* Linux : *xclip*, or *xsel* (with *PyQt4* modules)
* Windows : none
* OS X : none

**Examples**

Copy the contents of a DataFrame to the clipboard.

```python
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
```

```python
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the index by passing the keyword *index* and setting it to false.

```python
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

**pandas.Series.to_csv**

*Series.to_csv*(path_or_buf=None, sep=",", na_rep='', float_format=None, columns=None, header=True, index=True, index_label=None, mode='w', encoding=None, compression='infer', quoting=None, quotechar='"', line_terminator=None, chunksize=None, date_format=None, doublequote=True, escapechar=None, errors='strict', storage_options=None)

Write object to a comma-separated values (csv) file.

**Parameters**

*path_or_buf* [str or file handle, default None] File path or object, if None is provided the result is returned as a string. If a non-binary file object is passed, it should be opened with *newlines*=''`, disabling universal newlines. If a binary file object is passed, *mode* might need to contain a ‘b’.
Changed in version 1.2.0: Support for binary file objects was introduced.

**sep** [str, default ‘,’] String of length 1. Field delimiter for the output file.

**na_rep** [str, default ‘’] Missing data representation.

**float_format** [str, default None] Format string for floating point numbers.

**columns** [sequence, optional] Columns to write.

**header** [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

**index** [bool, default True] Write row names (index).

**index_label** [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and header and index are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use index_label=False for easier importing in R.

**mode** [str] Python write mode, default ‘w’.

**encoding** [str, optional] A string representing the encoding to use in the output file, defaults to ‘utf-8’. encoding is not supported if path_or_buf is a non-binary file object.

**compression** [str or dict, default ‘infer’] If str, represents compression mode. If dict, value at ‘method’ is the compression mode. Compression mode may be any of the following possible values: {‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}. If compression mode is ‘infer’ and path_or_buf is path-like, then detect compression mode from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’ or ‘.xz’. (otherwise no compression). If dict given and mode is one of {‘zip’, ‘gzip’, ‘bz2’}, or inferred as one of the above, other entries passed as additional compression options.

Changed in version 1.0.0: May now be a dict with key ‘method’ as compression mode and other entries as additional compression options if compression mode is ‘zip’.

Changed in version 1.1.0: Passing compression options as keys in dict is supported for compression modes ‘gzip’ and ‘bz2’ as well as ‘zip’.

Changed in version 1.2.0: Compression is supported for binary file objects.

Changed in version 1.2.0: Previous versions forwarded dict entries for ‘gzip’ to gzip.open instead of gzip.GzipFile which prevented setting mtimes.

**quoting** [optional constant from csv module] Defaults to csv.QUOTE_MINIMAL. If you have set a float_format then floats are converted to strings and thus csv.QUOTE_NONNUMERIC will treat them as non-numeric.

**quotechar** [str, default ‘’] String of length 1. Character used to quote fields.

**line_terminator** [str, optional] The newline character or character sequence to use in the output file. Defaults to os.linesep, which depends on the OS in which this method is called (‘
’ for linux, ‘\n\n’ for Windows, i.e.).

**chunksize** [int or None] Rows to write at a time.

**date_format** [str, default None] Format string for datetime objects.

**doublequote** [bool, default True] Control quoting of quotechar inside a field.

**escapechar** [str, default None] String of length 1. Character used to escape sep and quotechar when appropriate.
decimal [str, default ‘.’] Character recognized as decimal separator. E.g. use ‘,’ for European data.

errors [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for open() for a full list of options.

New in version 1.1.0.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

Returns

None or str If path_or_buf is None, returns the resulting csv format as a string. Otherwise returns None.

See also:

read_csv Load a CSV file into a DataFrame.

to_excel Write DataFrame to an Excel file.

Examples

```python
>>> df = pd.DataFrame({"name": ['Raphael', 'Donatello'],
...                   "mask": ['red', 'purple'],
...                   "weapon": ['sai', 'bo staff']})
>>> df.to_csv(index=False)
'name,mask,weapon
Raphael,red,sai
Donatello,purple,bo staff
'
Create ‘out.zip’ containing ‘out.csv’

```python
>>> compression_opts = dict(method='zip',
...                           archive_name='out.csv')
>>> df.to_csv('out.zip', index=False,
...           compression=compression_opts)

pandas.Series.to_dict

Series.to_dict (into=<class 'dict'>)
Convert Series to {label -> value} dict or dict-like object.

Parameters

into [class, default dict] The collections.abc.Mapping subclass to use as the return object. Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

Returns

collections.abc.Mapping Key-value representation of Series.
Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_dict()
{0: 1, 1: 2, 2: 3, 3: 4}
>>> from collections import OrderedDict, defaultdict
>>> s.to_dict(OrderedDict)
OrderedDict([(0, 1), (1, 2), (2, 3), (3, 4)])
>>> dd = defaultdict(list)
>>> s.to_dict(dd)
defaultdict(<class 'list'>, {0: 1, 1: 2, 2: 3, 3: 4})
```

**pandas.Series.to_excel**

```python
Series.to_excel(excel_writer, sheet_name='Sheet1', na_rep='', float_format=None, columns=None, header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None, merge_cells=True, encoding=None, inf_rep='inf', verbose=True, freeze_panes=None, storage_options=None)
```

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an ExcelWriter object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique sheet name. With all data written to the file it is necessary to save the changes. Note that creating an ExcelWriter object with a file name that already exists will result in the contents of the existing file being erased.

**Parameters**

- **excel_writer** [path-like, file-like, or ExcelWriter object] File path or existing ExcelWriter.
- **sheet_name** [str, default ‘Sheet1’] Name of sheet which will contain DataFrame.
- **na_rep** [str, default ‘ ’] Missing data representation.
- **float_format** [str, optional] Format string for floating point numbers. For example float_format="%.2f" will format 0.1234 to 0.12.
- **columns** [sequence or list of str, optional] Columns to write.
- **header** [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.
- **index** [bool, default True] Write row names (index).
- **index_label** [str or sequence, optional] Column label for index column(s) if desired. If not specified, and header and index are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- **startrow** [int, default 0] Upper left cell row to dump data frame.
- **startcol** [int, default 0] Upper left cell column to dump data frame.
- **engine** [str, optional] Write engine to use, ‘openpyxl’ or ‘xlsxwriter’. You can also set this via the options io.excel.xlsx.writer, io.excel.xls.writer, and io.excel.xlsm.writer.

Deprecation since version 1.2.0: As the xlwt package is no longer maintained, the xlwt engine will be removed in a future version of pandas.
merge_cells [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.

encoding [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.

inf_rep [str, default ‘inf’] Representation for infinity (there is no native representation for infinity in Excel).

verbose [bool, default True] Display more information in the error logs.

freeze_panes [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

See also:

to_csv Write DataFrame to a comma-separated values (csv) file.

ExcelWriter Class for writing DataFrame objects into excel sheets.

read_excel Read an Excel file into a pandas DataFrame.

read_csv Read a comma-separated values (csv) file into DataFrame.

Notes

For compatibility with to_csv(), to_excel serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible to write further data without rewriting the whole workbook.

Examples

Create, write to and save a workbook:

```python
>>> df1 = pd.DataFrame([[a, b], [c, d]],
...                      index=['row 1', 'row 2'],
...                      columns=['col 1', 'col 2'])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```python
>>> df1.to_excel("output.xlsx",
...                  sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an ExcelWriter object:
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

ExcelWriter can also be used to append to an existing Excel file:

```python
>>> with pd.ExcelWriter('output.xlsx', mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the `engine` keyword (the default engine is automatically chosen depending on the file extension):

```python
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```

### pandas.Series.to_frame

**Series.to_frame** *(name=None)*  
Convert Series to DataFrame.

**Parameters**

- **name** [object, default None] The passed name should substitute for the series name (if it has one).

**Returns**

- **DataFrame** DataFrame representation of Series.

**Examples**

```python
>>> s = pd.Series(['a', 'b', 'c'], name='vals')
>>> s.to_frame()

<table>
<thead>
<tr>
<th>vals</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
</tr>
<tr>
<td>b</td>
</tr>
<tr>
<td>c</td>
</tr>
</tbody>
</table>
```

### pandas.Series.to_hdf

**Series.to_hdf** *(path_or_buf, key, mode='a', complevel=None, complib=None, append=False, format=None, index=True, min_itemsize=None, nan_rep=None, dropna=None, data_columns=None, errors='strict', encoding='UTF-8')*

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different a key.
Warning: One can store a subclass of `DataFrame` or `Series` to HDF5, but the type of the subclass is lost upon storing.

For more information see the *user guide*.

**Parameters**

- **path_or_buf** [str or pandas.HDFStore] File path or HDFStore object.
- **key** [str] Identifier for the group in the store.
- **mode** [{‘a’, ‘w’, ‘r+’}, default ‘a’] Mode to open file:
  - ‘w’: write, a new file is created (an existing file with the same name would be deleted).
  - ‘a’: append, an existing file is opened for reading and writing, and if the file does not exist it is created.
  - ‘r+’: similar to ‘a’, but the file must already exist.
- **complevel** [{0-9}, optional] Specifies a compression level for data. A value of 0 disables compression.
- **append** [bool, default False] For Table formats, append the input data to the existing.
- **format** [{‘fixed’, ‘table’, None}, default ‘fixed’] Possible values:
  - ‘table’: Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.
  - If None, pd.get_option(‘io.hdf.default_format’) is checked, followed by fallback to “fixed”
- **errors** [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.
- **encoding** [str, default “UTF-8”]
- **min_itemsize** [dict or int, optional] Map column names to minimum string sizes for columns.
- **nan_rep** [Any, optional] How to represent null values as str. Not allowed with append=True.
- **data_columns** [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See *Query via data columns*. Applicable only to format=‘table’.

See also:

- `read_hdf` Read from HDF file.
**DataFrame.to_parquet**  Write a DataFrame to the binary parquet format.

**DataFrame.to_sql**  Write to a SQL table.

**DataFrame.to_feather**  Write out feather-format for DataFrames.

**DataFrame.to_csv**  Write out to a csv file.

**Examples**

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
...                   index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')
```

We can add another object to the same file:

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```python
>>> pd.read_hdf('data.h5', 'df')
A  B
a 1 4
b 2 5
c 3 6
```

Deleting file with data:

```python
>>> import os
>>> os.remove('data.h5')
```

**Series.to_json**

Series.to_json(path_or_buf=None, orient=None, date_format=None, double_precision=10, force_ascii=True, date_unit='ms', default_handler=None, lines=False, compression='infer', index=True, indent=None, storage_options=None)

Convert the object to a JSON string.

Note NaN’s and None will be converted to null and datetime objects will be converted to UNIX timestamps.

**Parameters**

- **path_or_buf**  [str or file handle, optional] File path or object. If not specified, the result is returned as a string.

- **orient**  [str] Indication of expected JSON string format.
  - **Series**:
    - default is ‘index’
- allowed values are: {'split', 'records', 'index', 'table'}.

- DataFrame:
  - default is 'columns'
  - allowed values are: {'split', 'records', 'index', 'columns', 'values', 'table'}.

- The format of the JSON string:
  - 'split': dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
  - 'records': list like [{column -> value}, . . . , {column -> value}]
  - 'index': dict like {index -> {column -> value}}
  - 'columns': dict like {column -> {index -> value}}
  - 'values': just the values array
  - 'table': dict like {'schema': {schema}, 'data': {data}}

Describing the data, where data component is like `orient='records'`.

**Date format** {
[None, 'epoch', 'iso']] Type of date conversion. 'epoch' = epoch milliseconds, 'iso' = ISO8601. The default depends on the `orient`. For `orient='table'`, the default is 'iso'. For all other orients, the default is 'epoch'.

**Double precision** [int, default 10] The number of decimal places to use when encoding floating point values.

**Force ascii** [bool, default True] Force encoded string to be ASCII.

**Date unit** [str, default 'ms' (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of 's', 'ms', 'us', 'ns' for second, millisecond, microsecond, and nanosecond respectively.

**Default handler** [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

**Lines** [bool, default False] If 'orient' is 'records' write out line-delimited json format. Will throw ValueError if incorrect 'orient' since others are not list-like.

**Compression** [{'infer', 'gzip', 'bz2', 'zip', 'xz', None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

**Index** [bool, default True] Whether to include the index values in the JSON string. Not including the index (index=False) is only supported when orient is 'split' or 'table'.

**Indent** [int, optional] Length of whitespace used to indent each record.

New in version 1.0.0.

**Storage options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with `s3://`, and `gcs://`) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.
New in version 1.2.0.

Returns

None or str
If path_or_buf is None, returns the resulting json format as a string. Otherwise returns None.

See also:

read_json
Convert a JSON string to pandas object.

Notes

The behavior of indent=0 varies from the stdlib, which does not indent the output but does insert newlines. Currently, indent=0 and the default indent=None are equivalent in pandas, though this may change in a future release.

orient='table' contains a 'pandas_version' field under 'schema'. This stores the version of pandas used in the latest revision of the schema.

Examples

```python
>>> import json
>>> df = pd.DataFrame(  
...   [["a", "b"], ["c", "d"],  
...   index=["row 1", "row 2"],  
...   columns=["col 1", "col 2"],  
... )

>>> result = df.to_json(orient="split")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)  
{
    "columns": [
        "col 1",
        "col 2"
    ],
    "index": [
        "row 1",
        "row 2"
    ],
    "data": [
        [
            "a",
            "b"
        ],
        [
            "c",
            "d"
        ]
    ]
}
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.
>>> result = df.to_json(orient="records")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[
    {
        "col 1": "a",
        "col 2": "b"
    },
    {
        "col 1": "c",
        "col 2": "d"
    }
]

Encoding/decoding a DataFrame using 'index' formatted JSON:

```python
>>> result = df.to_json(orient="index")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "row 1": {
        "col 1": "a",
        "col 2": "b"
    },
    "row 2": {
        "col 1": "c",
        "col 2": "d"
    }
}
```

Encoding/decoding a DataFrame using 'columns' formatted JSON:

```python
>>> result = df.to_json(orient="columns")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "col 1": {
        "row 1": "a",
        "row 2": "c"
    },
    "col 2": {
        "row 1": "b",
        "row 2": "d"
    }
}
```

Encoding/decoding a DataFrame using 'values' formatted JSON:

```python
>>> result = df.to_json(orient="values")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[
    ["a","b"],
    ["c","d"
]
(continues on next page)```
Encoding with Table Schema:

```python
>>> result = df.to_json(orient="table")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "schema": {
        "fields": [
            {
                "name": "index",
                "type": "string"
            },
            {
                "name": "col 1",
                "type": "string"
            },
            {
                "name": "col 2",
                "type": "string"
            }
        ],
        "primaryKey": [
            "index"
        ],
        "pandas_version": "0.20.0"
    },
    "data": [
        {
            "index": "row 1",
            "col 1": "a",
            "col 2": "b"
        },
        {
            "index": "row 2",
            "col 1": "c",
            "col 2": "d"
        }
    ]
}
```

*pandas.Series.to_latex*

`Series.to_latex` *(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, bold_rows=False, column_format=None, longtable=None, escape=None, encoding=None, decimal='.', multicolumn=None, multicolumn_format=None, multirow=None, caption=None, label=None, position=None)*

Render object to a LaTeX tabular, longtable, or nested table/tabular.

Requires `\usepackage{booktabs}`. The output can be copy/pasted into a main LaTeX document or
read from an external file with `\input{table.tex}`.

Changed in version 1.0.0: Added caption and label arguments.

Changed in version 1.2.0: Added position argument, changed meaning of caption argument.

**Parameters**

- **buf** [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

- **columns** [list of label, optional] The subset of columns to write. Writes all columns by default.

- **col_space** [int, optional] The minimum width of each column.

- **header** [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

- **index** [bool, default True] Write row names (index).

- **na_rep** [str, default ‘NaN’] Missing data representation.

- **formatters** [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.

- **float_format** [one-parameter function or str, optional, default None] Formatter for floating point numbers. For example `float_format="%.2f"` and `float_format="{:0.2f}".format` will both result in 0.1234 being formatted as 0.12.

- **sparsify** [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.

- **index_names** [bool, default True] Prints the names of the indexes.

- **bold_rows** [bool, default False] Make the row labels bold in the output.

- **column_format** [str, optional] The columns format as specified in LaTeX table format e.g. ‘rcl’ for 3 columns. By default, ‘l’ will be used for all columns except columns of numbers, which default to ‘r’.

- **longtable** [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a usepackage{longtable} to your LaTeX preamble.

- **escape** [bool, optional] By default, the value will be read from the pandas config module. When set to False prevents from escaping latex special characters in column names.

- **encoding** [str, optional] A string representing the encoding to use in the output file, defaults to ‘utf-8’.

- **decimal** [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

- **multicolumn** [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.

- **multicolumn_format** [str, default ‘l’] The alignment for multicolumns, similar to column_format. The default will be read from the config module.

- **multirow** [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a usepackage{multirow} to your LaTeX preamble. Will print centered
labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

**caption** [str or tuple, optional] Tuple (full_caption, short_caption), which results in `\caption{short_caption}{full_caption}`; if a single string is passed, no short caption will be set.

New in version 1.0.0.

Changed in version 1.2.0: Optionally allow caption to be a tuple (full_caption, short_caption).

**label** [str, optional] The LaTeX label to be placed inside `\label{}` in the output. This is used with `\ref{}` in the main `.tex` file.

New in version 1.0.0.

**position** [str, optional] The LaTeX positional argument for tables, to be placed after `\begin{}` in the output.

New in version 1.2.0.

**Returns**

- **str or None** If buf is None, returns the result as a string. Otherwise returns None.

**See also:**

*DataFrame.to_string* Render a DataFrame to a console-friendly tabular output.

*DataFrame.to_html* Render a DataFrame as an HTML table.

**Examples**

```python
>>> df = pd.DataFrame(dict(name=['Raphael', 'Donatello'],
...                      mask=['red', 'purple'],
...                      weapon=['sai', 'bo staff']))
>>> print(df.to_latex(index=False))
\begin{tabular}{lll}
\toprule
name & mask & weapon \\
\midrule
Raphael & red & sai \\
Donatello & purple & bo staff \\
\bottomrule
\end{tabular}
```

*pandas.Series.to_list*

**Series.to_list()**

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

**Returns**

- **list**

**See also:**
numpy.ndarray.tolist  Return the array as an a.ndim-levels deep nested list of Python scalars.

pandas.Series.to_markdown

Series.to_markdown(buf=None, mode='wt', index=True, storage_options=None, **kwargs)
Print Series in Markdown-friendly format.
New in version 1.0.0.

Parameters

buf [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.
mode [str, optional] Mode in which file is opened, “wt” by default.
index [bool, optional, default True] Add index (row) labels.
New in version 1.1.0.
storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.
New in version 1.2.0.
**kwargs These parameters will be passed to tabulate.

Returns

str Series in Markdown-friendly format.

Notes
Requires the tabulate package.

Examples

```python
>>> s = pd.Series(["elk", "pig", "dog", "quetzal"], name="animal")
>>> print(s.to_markdown())
<table>
<thead>
<tr>
<th></th>
<th>animal</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>elk</td>
</tr>
<tr>
<td>1</td>
<td>pig</td>
</tr>
<tr>
<td>2</td>
<td>dog</td>
</tr>
<tr>
<td>3</td>
<td>quetzal</td>
</tr>
</tbody>
</table>
```
Output markdown with a tabulate option.

```python
>>> print(s.to_markdown(tablefmt="grid"))
+-----+----------+
|     | animal    |
+-----+----------+
| 0   | elk      |
+-----+----------+
```
pandas.Series.to_numpy

Series.to_numpy (dtype=None, copy=False, na_value=<no_default>, **kwargs)
A NumPy ndarray representing the values in this Series or Index.

Parameters

dtype [str or numpy.dtype, optional] The dtype to pass to numpy.asarray().
copy [bool, default False] Whether to ensure that the returned value is not a view on another array. Note that copy=False does not ensure that to_numpy() is no-copy. Rather, copy=True ensure that a copy is made, even if not strictly necessary.
na_value [Any, optional] The value to use for missing values. The default value depends on dtype and the type of the array.

New in version 1.0.0.

**kwargs Additional keywords passed through to the to_numpy method of the underlying array (for extension arrays).

New in version 1.0.0.

Returns

numpy.ndarray

See also:

Series.array Get the actual data stored within.
Index.array Get the actual data stored within.
DataFrame.to_numpy Similar method for DataFrame.

Notes

The returned array will be the same up to equality (values equal in self will be equal in the returned array; likewise for values that are not equal). When self contains an ExtensionArray, the dtype may be different. For example, for a category-dtype Series, to_numpy() will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming copy=False). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, to_numpy() may require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, Series.array should be used instead.
This table lays out the different dtypes and default return types of `to_numpy()` for various dtypes within pandas.

<table>
<thead>
<tr>
<th>dtype</th>
<th>array type</th>
</tr>
</thead>
<tbody>
<tr>
<td>category[T]</td>
<td>ndarray[T] (same dtype as input)</td>
</tr>
<tr>
<td>period</td>
<td>ndarray[object] (Periods)</td>
</tr>
<tr>
<td>interval</td>
<td>ndarray[object] (Intervals)</td>
</tr>
<tr>
<td>IntegerNA</td>
<td>ndarray[object]</td>
</tr>
<tr>
<td>datetime64[ns]</td>
<td>datetime64[ns]</td>
</tr>
<tr>
<td>datetime64[ns, tz]</td>
<td>ndarray[object] (Timestamps)</td>
</tr>
</tbody>
</table>

**Examples**

```python
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.to_numpy()
array(['a', 'b', 'a'], dtype=object)
```

Specify the `dtype` to control how datetime-aware data is represented. Use `dtype=object` to return an ndarray of pandas `Timestamp` objects, each with the correct `tz`.

```python
>>> ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> ser.to_numpy(dtype=object)
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET')],
       dtype=object)
```

Or `dtype='datetime64[ns]'` to return an ndarray of native datetime64 values. The values are converted to UTC and the timezone info is dropped.

```python
>>> ser.to_numpy(dtype="datetime64[ns]"
...array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00...'],
       dtype='datetime64[ns]')
```

**pandas.Series.to_period**

`Series.to_period(freq=None, copy=True)`

Convert Series from DatetimeIndex to PeriodIndex.

- **Parameters**
  - `freq` [str, default None] Frequency associated with the PeriodIndex.
  - `copy` [bool, default True] Whether or not to return a copy.

- **Returns**
  - `Series` Series with index converted to PeriodIndex.
### pandas.Series.to_pickle

`Series.to_pickle(path, compression='infer', protocol=5, storage_options=None)`

Pickle (serialize) object to file.

**Parameters**

- **path** [str] File path where the pickled object will be stored.
- **compression** [{'infer', 'gzip', 'bz2', 'zip', 'xz', None}, default 'infer'] A string representing the compression to use in the output file. By default, infers from the file extension in specified path. Compression mode may be any of the following possible values: {'infer', 'gzip', 'bz2', 'zip', 'xz', None}. If compression mode is 'infer' and path_or_buf is path-like, then detect compression mode from the following extensions: '.gz', '.bz2', '.zip' or '.xz'. (otherwise no compression). If dict given and mode is 'zip' or inferred as 'zip', other entries passed as additional compression options.
- **protocol** [int] Int which indicates which protocol should be used by the pickler, default HIGHEST_PROTOCOL (see [1] paragraph 12.1.2). The possible values are 0, 1, 2, 3, 4, 5. A negative value for the protocol parameter is equivalent to setting its value to HIGHEST_PROTOCOL.
- **storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

**See also:**

- `read_pickle` Load pickled pandas object (or any object) from file.
- `DataFrame.to_hdf` Write DataFrame to an HDF5 file.
- `DataFrame.to_sql` Write DataFrame to a SQL database.
- `DataFrame.to_parquet` Write a DataFrame to the binary parquet format.

**Examples**

```python
>>> original_df = pd.DataFrame({"foo": range(5), "bar": range(5, 10)})
>>> original_df
   foo  bar
0   0   5
1   1   6
2   2   7
3   3   8
4   4   9
>>> original_df.to_pickle("./Dummy.pkl")

>>> unpickled_df = pd.read_pickle("./Dummy.pkl")
>>> unpickled_df
   foo  bar
0   0   5
1   1   6
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.1

>>> import os
>>> os.remove("./dummy.pkl")

pandas.Series.to_sql

Series.to_sql (name, con, schema=None, if_exists='fail', index=True, index_label=None, chunksize=None, dtype=None, method=None)

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [1] are supported. Tables can be newly created, appended to, or overwritten.

Parameters

- **name** [str] Name of SQL table.
- **con** [sqlalchemy.engine.Engine or Connection or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable See here.
- **schema** [str, optional] Specify the schema (if database flavor supports this). If None, use default schema.
- **if_exists** [{'fail', 'replace', 'append'}, default 'fail'] How to behave if the table already exists.
  - fail: Raise a ValueError.
  - replace: Drop the table before inserting new values.
  - append: Insert new values to the existing table.
- **index** [bool, default True] Write DataFrame index as a column. Uses index_label as the column name in the table.
- **index_label** [str or sequence, default None] Column label for index column(s). If None is given (default) and index is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- **chunksize** [int, optional] Specify the number of rows in each batch to be written at a time. By default, all rows will be written at once.
- **dtype** [dict or scalar, optional] Specifying the datatype for columns. If a dictionary is used, the keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode. If a scalar is provided, it will be applied to all columns.
- **method** [{None, 'multi', callable}, optional] Controls the SQL insertion clause used:
  - None: Uses standard SQL INSERT clause (one per row).
  - multi: Pass multiple values in a single INSERT clause.
  - callable with signature (pd_table, conn, keys, data_iter).
Details and a sample callable implementation can be found in the section *insert method*.

**Raises**

`ValueError` When the table already exists and `if_exists` is ‘fail’ (the default).

**See also:**

*read_sql* Read a DataFrame from a table.

**Notes**

Timezone aware datetime columns will be written as `Timestamp with timezone` type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

**References**

[1], [2]

**Examples**

Create an in-memory SQLite database.

```python
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```python
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
    name
0  User 1
1  User 2
2  User 3
```

```python
>>> df.to_sql('users', con=engine)
```

```python
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

An `sqlalchemy.engine.Connection` can also be passed to `con`:

```python
>>> with engine.begin() as connection:
...     df1 = pd.DataFrame({'name' : ['User 4', 'User 5']})
...     df1.to_sql('users', con=connection, if_exists='append')
```

This is allowed to support operations that require that the same DBAPI connection is used for the entire operation.

```python
>>> df2 = pd.DataFrame({'name' : ['User 6', 'User 7']})
>>> df2.to_sql('users', con=engine, if_exists='append')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'), (3, 'User 4'), (4, 'User 5'), (5, 'User 6'), (6, 'User 7')]
```
Overwrite the table with just df2.

```python
>>> df2.to_sql('users', con=engine, if_exists='replace',
...            index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 6'), (1, 'User 7')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```python
>>> df = pd.DataFrame({"A": [1, None, 2]})
>>> df
   A
0  1.0
1 NaN
2  2.0
```

```python
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...           dtype={"A": Integer()})
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

**pandas.Series.to_string**

series.to_string(buf=None, na_rep='NaN', float_format=None, header=True, index=True, length=False, dtype=False, name=False, max_rows=None, min_rows=None)

Render a string representation of the Series.

**Parameters**

- **buf** [StringIO-like, optional] Buffer to write to.
- **na_rep** [str, optional] String representation of NaN to use, default ‘NaN’.
- **float_format** [one-parameter function, optional] Formatter function to apply to columns’ elements if they are floats, default None.
- **header** [bool, default True] Add the Series header (index name).
- **index** [bool, optional] Add index (row) labels, default True.
- **length** [bool, default False] Add the Series length.
- **dtype** [bool, default False] Add the Series dtype.
- **name** [bool, default False] Add the Series name if not None.
- **max_rows** [int, optional] Maximum number of rows to show before truncating. If None, show all.
- **min_rows** [int, optional] The number of rows to display in a truncated repr (when number of rows is above max_rows).
pandas: powerful Python data analysis toolkit, Release 1.3.1

Returns

str or None  String representation of Series if buf=None, otherwise None.

pandas.Series.to_timestamp

Series.to_timestamp (freq=None, how='start', copy=True)
Cast to DatetimeIndex of Timestamps, at beginning of period.

Parameters

freq  [str, default frequency of PeriodIndex] Desired frequency.

how  [{$'s$', $'e$', $'start$', $'end'$}] Convention for converting period to timestamp; start of period vs. end.

copy  [bool, default True] Whether or not to return a copy.

Returns

Series with DatetimeIndex

pandas.Series.to_xarray

Series.to_xarray()
Return an xarray object from the pandas object.

Returns

xarray.DataArray or xarray.Dataset  Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

See also:

DataFrame.to_hdf  Write DataFrame to an HDF5 file.

DataFrame.to_parquet  Write a DataFrame to the binary parquet format.

Notes

See the xarray docs

Examples

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0, 2),
...         ('parrot', 'bird', 24.0, 2),
...         ('lion', 'mammal', 80.5, 4),
...         ('monkey', 'mammal', np.nan, 4)],
...         columns=['name', 'class', 'max_speed',
...                  'num_legs'])
>>> df
          name  class max_speed  num_legs
0   falcon    bird     389.0          2
1  parrot    bird      24.0          2
2     lion  mammal     80.5          4
3   monkey  mammal     NaN          4
```
>>> df.to_xarray()
<xarray.Dataset>
Dimensions:   (index: 4)
Coordinates:
 * index      (index) int64 0 1 2 3
Data variables:
   name        (index) object 'falcon' 'parrot' 'lion' 'monkey'
   class       (index) object 'bird' 'bird' 'mammal' 'mammal'
   max_speed   (index) float64 389.0 24.0 80.5 nan
   num_legs    (index) int64 2 2 4 4

>>> df['max_speed'].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389., 24., 80.5, nan])
Coordinates:
 * index      (index) int64 0 1 2 3

>>> dates = pd.to_datetime(['2018-01-01', '2018-01-01', ...
                            '2018-01-02', '2018-01-02'])
>>> df_multiindex = pd.DataFrame({'date': dates,
                                ...
                                'animal': ['falcon', 'parrot',
                                ...
                                'falcon', 'parrot'],
                                ...
                                'speed': [350, 18, 361, 15]})
>>> df_multiindex = df_multiindex.set_index(['date', 'animal'])

>>> df_multiindex
   speed
date animal
2018-01-01 falcon 350
          parrot 18
2018-01-02 falcon 361
          parrot 15

>>> df_multiindex.to_xarray()
<xarray.Dataset>
Dimensions:   (animal: 2, date: 2)
Coordinates:
 * date       (date) datetime64[ns] 2018-01-01 2018-01-02
 * animal     (animal) object 'falcon' 'parrot'
Data variables:
   speed       (date, animal) int64 350 18 361 15

pandas.Series.tolist

Series.tolist()

Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns

list

See also:
numpy.ndarray.tolist  Return the array as an a ndim-levels deep nested list of Python scalars.

pandas.Series.transform

Series.transform(func, axis=0, *args, **kwargs)
Call func on self producing a Series with transformed values.
Produced Series will have same axis length as self.
Parameters

- func [function, str, list-like or dict-like] Function to use for transforming the data. If a function, must either work when passed a Series or when passed to Series.apply. If func is both list-like and dict-like, dict-like behavior takes precedence.
  Accepted combinations are:
  - function
  - string function name
  - list-like of functions and/or function names, e.g. [np.exp, 'sqrt']
  - dict-like of axis labels -> functions, function names or list-like of such.

- axis [{0 or 'index'}] Parameter needed for compatibility with DataFrame.

- *args Positional arguments to pass to func.

- **kwargs Keyword arguments to pass to func.

Returns

- Series A Series that must have the same length as self.

Raises

- ValueError [If the returned Series has a different length than self.]

See also:

- Series.agg Only perform aggregating type operations.
- Series.apply Invoke function on a Series.

Notes

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported.
See Mutating with User Defined Function (UDF) methods for more details.

Examples

```python
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
   A  B
0  0  1
1  1  2
2  2  3

>>> df.transform(lambda x: x + 1)
```
(continues on next page)
Even though the resulting Series must have the same length as the input Series, it is possible to provide several input functions:

```python
>>> s = pd.Series(range(3))
>>> s
0 0
1 1
2 2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
   sqrt   exp
0 0.000000 1.000000
1 1.000000 2.718282
2 1.414214 7.389056
```

You can call transform on a GroupBy object:

```python
>>> df = pd.DataFrame(
...    
...    "Date": ["2015-05-08", "2015-05-07", "2015-05-06", "2015-05-05", 
...    "Data": [5, 8, 6, 1, 50, 100, 60, 120],
...    
...)
>>> df
      Date  Data
0  2015-05-08     5
1  2015-05-07     8
2  2015-05-06     6
3  2015-05-05     1
4  2015-05-08    50
5  2015-05-07   100
6  2015-05-06    60
7  2015-05-05   120
>>> df.groupby('Date')['Data'].transform('sum')
0    55
1   108
2    66
3   121
4    55
5   108
6    66
7   121
Name: Data, dtype: int64
```

```python
>>> df = pd.DataFrame(
...    
...    "c": [1, 1, 1, 2, 2, 2, 2],
...    "type": ["m", "n", "o", "m", "m", "n", "n"]
...    
...)
>>> df
    c   type
0  1     m
1  1     n
```

(continues on next page)
>>> df['size'] = df.groupby('c')['type'].transform(len)

<table>
<thead>
<tr>
<th>c</th>
<th>type</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>m</td>
<td>3</td>
</tr>
<tr>
<td>1</td>
<td>n</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>o</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>m</td>
<td>4</td>
</tr>
<tr>
<td>4</td>
<td>m</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>n</td>
<td>4</td>
</tr>
<tr>
<td>6</td>
<td>n</td>
<td>4</td>
</tr>
</tbody>
</table>

**pandas.Series.transpose**

*Series.transpose(*args, **kwargs)*

Return the transpose, which is by definition self.

**Returns**

%(klass)s

**pandas.Series.truediv**

*Series.truediv(other, level=None, fill_value=None, axis=0)*

Return Floating division of series and other, element-wise (binary operator truediv).

Equivalent to `series / other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

**Parameters**

- `other` [Series or scalar value]

- `fill_value` [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

- `level` [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

Series The result of the operation.

**See also:**

*Series.rtruediv* Reverse of the Floating division operator, see Python documentation for more details.
Examples

```python
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.divide(b, fill_value=0)
a    1.0
b    inf
c    inf
d    0.0
e    NaN
dtype: float64
```

`pandas.Series.truncate`

Series.truncate (before=None, after=None, axis=None, copy=True)

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

**Parameters**

- **before** [date, str, int] Truncate all rows before this index value.
- **after** [date, str, int] Truncate all rows after this index value.
- **axis** [{0 or 'index', 1 or 'columns'}, optional] Axis to truncate. Truncates the index (rows) by default.
- **copy** [bool, default is True.] Return a copy of the truncated section.

**Returns**

type of caller The truncated Series or DataFrame.

See also:

- **DataFrame.loc** Select a subset of a DataFrame by label.
- **DataFrame.iloc** Select a subset of a DataFrame by position.
Notes

If the index being truncated contains only datetime values, before and after may be specified as strings instead of Timestamps.

Examples

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
...                    'B': ['f', 'g', 'h', 'i', 'j'],
...                    'C': ['k', 'l', 'm', 'n', 'o']},
...                    index=[1, 2, 3, 4, 5])
>>> df
   A  B  C
1  a  f  k
2  b  g  l
3  c  h  m
4  d  i  n
5  e  j  o
```

The columns of a DataFrame can be truncated.

```python
>>> df.truncate(before=2, after=4)
   A  B  C
2  b  g  l
3  c  h  m
4  d  i  n
```

For Series, only rows can be truncated.

```python
>>> df['A'].truncate(before=2, after=4)
2    b
3    c
4    d
Name: A, dtype: object
```

The index values in truncate can be datetimes or string dates.

```python
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
   A
2016-01-31 23:59:56 1
2016-01-31 23:59:57 1
2016-01-31 23:59:58 1
2016-01-31 23:59:59 1
2016-02-01 00:00:00 1
```
Because the index is a DatetimeIndex containing only dates, we can specify `before` and `after` as strings. They will be coerced to Timestamps before truncation.

```python
>>> df.truncate('2016-01-05', '2016-01-10').tail()
A
2016-01-09 23:59:56 1
2016-01-09 23:59:57 1
2016-01-09 23:59:58 1
2016-01-09 23:59:59 1
2016-01-10 00:00:00 1
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```python
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
A
2016-01-10 23:59:55 1
2016-01-10 23:59:56 1
2016-01-10 23:59:57 1
2016-01-10 23:59:58 1
2016-01-10 23:59:59 1
```

### pandas.Series.tshift

**Series.tshift** *(periods=1, freq=None, axis=0)*

Shift the time index, using the index’s frequency if available.

Deprecated since version 1.1.0: Use `shift` instead.

**Parameters**

- **periods** [int] Number of periods to move, can be positive or negative.
- **freq** [DateOffset, timedelta, or str, default None] Increment to use from the tseries module or time rule expressed as a string (e.g. ‘EOM’).
- **axis** [[0 or ‘index’, 1 or ‘columns’, None], default 0] Corresponds to the axis that contains the Index.

**Returns**

- **shifted** [Series/DataFrame]
Notes

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown.

`pandas.Series.tz_convert`

`Series.tz_convert(tz, axis=0, level=None, copy=True)`
Convert tz-aware axis to target time zone.

Parameters

- `tz` [str or tzinfo object]
- `axis` [the axis to convert]
- `level` [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None.
- `copy` [bool, default True] Also make a copy of the underlying data.

Returns

- `{klass}` Object with time zone converted axis.

Raises

- `TypeError` If the axis is tz-naive.

`pandas.Series.tz_localize`

`Series.tz_localize(tz, axis=0, level=None, copy=True, ambiguous='raise', nonexistent='raise')`
Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use `Series.dt.tz_localize()`.

Parameters

- `tz` [str or tzinfo]
- `axis` [the axis to localize]
- `level` [int, str, default None] If axis ia a MultiIndex, localize a specific level. Otherwise must be None.
- `copy` [bool, default True] Also make a copy of the underlying data.
- `ambiguous` ['infer', bool-ndarray, ‘NaT’, default ‘raise’] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the `ambiguous` parameter dictates how ambiguous times should be handled.
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.
nonexistent [str, default ‘raise’] A nonexistent time does not exist in a particular time-zone where clocks moved forward due to DST. Valid values are:

- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

Series or DataFrame Same type as the input.

Raises

TypeError If the TimeSeries is tz-aware and tz is not None.

Examples

Localize local times:

```python
>>> s = pd.Series([1],
...                index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00 1
dtype: int64
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```python
>>> s = pd.Series(range(7),
...                index=pd.DatetimeIndex(['2018-10-28 01:30:00',
...                                        '2018-10-28 02:00:00',
...                                        '2018-10-28 02:30:00',
...                                        '2018-10-28 02:00:00',
...                                        '2018-10-28 02:30:00',
...                                        '2018-10-28 03:00:00',
...                                        '2018-10-28 03:30:00']))
>>> s.tz_localize('CET', ambiguous='infer')
2018-10-28 01:30:00+02:00 0
2018-10-28 02:00:00+02:00 1
2018-10-28 02:30:00+02:00 2
2018-10-28 02:00:00+01:00 3
2018-10-28 02:30:00+01:00 4
2018-10-28 03:00:00+01:00 5
2018-10-28 03:30:00+01:00 6
dtype: int64
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly

```python
>>> s = pd.Series(range(3),
...                index=pd.DatetimeIndex(['2018-10-28 01:20:00',
...                                        '2018-10-28 02:36:00',
...                                        '2018-10-28 03:46:00']))
```
If the DST transition causes nonexistent times, you can shift these dates forward or backward with a timedelta object or 'shift_forward' or 'shift_backward'.

```python
>>> s = pd.Series(range(2),
...                   index=pd.DatetimeIndex(['2015-03-29 02:30:00',
...                                             '2015-03-29 03:30:00']))
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
2015-03-29 03:00:00+02:00 0
2015-03-29 03:30:00+02:00 1
dtype: int64
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
2015-03-29 01:59:59.999999999+01:00 0
2015-03-29 03:30:00+02:00 1
dtype: int64
>>> s.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
2015-03-29 03:30:00+02:00 0
2015-03-29 03:30:00+02:00 1
dtype: int64
```

### pandas.Series.unique

Series.unique()  
Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

**Returns**

- ndarray or ExtensionArray  
The unique values returned as a NumPy array. See Notes.

**See also:**

- unique  
Top-level unique method for any 1-d array-like object.

- Index.unique  
Return Index with unique values from an Index object.

**Notes**

Returns the unique values as a NumPy array. In case of an extension-array backed Series, a new ExtensionArray of that type with just the unique values is returned. This includes

- Categorical
- Period
- Datetime with Timezone
- Interval
- Sparse
• IntegerNA

See Examples section.

Examples

```python
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])

>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')

>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern') for _ in range(3)]).unique()
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]
```

An Categorical will return categories in the order of appearance and with the same dtype.

```python
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
['b', 'a', 'c']
Categories (3, object): ['a', 'b', 'c']

>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'), ordered=True)).unique()
['b', 'a', 'c']
Categories (3, object): ['a' < 'b' < 'c']
```

pandas.Series.unstack

Series.unstack(level=-1, fill_value=None)

Unstack, also known as pivot, Series with MultiIndex to produce DataFrame.

Parameters

level [int, str, or list of these, default last level] Level(s) to unstack, can pass level name.

fill_value [scalar value, default None] Value to use when replacing NaN values.

Returns

DataFrame Unstacked Series.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4],
... index=pd.MultiIndex.from_product([['one', 'two'],
... ['a', 'b']]))

>>> s
one a 1
   b 2
two a 3
   b 4
dtype: int64
```
pandas.Series.update

Series.update(other)
Modify Series in place using values from passed Series.

Uses non-NA values from passed Series to make updates. Aligns on index.

Parameters
other [Series, or object coercible into Series]

Examples

```python
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6]))
>>> s
0    4
1    5
2    6
dtype: int64
```

```python
>>> s = pd.Series(['a', 'b', 'c'])
>>> s.update(pd.Series(['d', 'e'], index=[0, 2]))
>>> s
0    d
1    b
2    e
dtype: object
```

```python
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, 5, 6, 7, 8]))
>>> s
0    4
1    5
2    6
dtype: int64
```

If other contains NaNs the corresponding values are not updated in the original Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.update(pd.Series([4, np.nan, 6]))
>>> s
0    4
1    2
```

(continues on next page)
other can also be a non-Series object type that is coercible into a Series

```python
>>> s = pd.Series([1, 2, 3])
>>> s.update([4, np.nan, 6])
>>> s
0  4
1  2
2  6
```

dtype: int64

```python
>>> s = pd.Series([1, 2, 3])
>>> s.update({1: 9})
>>> s
0  1
1  9
2  3
```
dtype: int64

dataframe.Series.value_counts

Series.value_counts(normalize=False, sort=True, ascending=False, bins=None, dropna=True)

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

Parameters

- **normalize** [bool, default False] If True then the object returned will contain the relative frequencies of the unique values.
- **sort** [bool, default True] Sort by frequencies.
- **ascending** [bool, default False] Sort in ascending order.
- **bins** [int, optional] Rather than count values, group them into half-open bins, a convenience for pd.cut, only works with numeric data.
- **dropna** [bool, default True] Don’t include counts of NaN.

Returns

Series

See also:

- **Series.count** Number of non-NA elements in a Series.
- **DataFrame.count** Number of non-NA elements in a DataFrame.
- **DataFrame.value_counts** Equivalent method on DataFrames.
Examples

```python
>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3    2
1    1
2    1
4    1
dtype: int64
```

With `normalize` set to `True`, returns the relative frequency by dividing all values by the sum of values.

```python
>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3    0.4
1    0.2
2    0.2
4    0.2
dtype: float64
```

**bins**

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.

```python
>>> s.value_counts(bins=3)
(0.996, 2.0]   2
(2.0, 3.0]   2
(3.0, 4.0]   1
dtype: int64
```

**dropna**

With `dropna` set to `False` we can also see NaN index values.

```python
>>> s.value_counts(dropna=False)
3    2
1    1
2    1
4    1
NaN  1
dtype: int64
```

**pandas.Series.var**

```python
Series.var(\axi=\text{None}, \skipna=\text{None}, \level=\text{None}, \ddof=1, \numeric_only=\text{None}, **k\text{wargs})
```

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the `ddof` argument.

**Parameters**

- **axis** [(index (0))]  
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.
ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

scalar or Series (if level specified)

Notes

To have the same behaviour as numpy.std, use ddof=0 (instead of the default ddof=1)

pandas.Series.view

Series.view (dtype=None)

Create a new view of the Series.

This function will return a new Series with a view of the same underlying values in memory, optionally reinterpreted with a new data type. The new data type must preserve the same size in bytes as to not cause index misalignment.

Parameters

dtype [data type] Data type object or one of their string representations.

Returns

Series A new Series object as a view of the same data in memory.

See also:

numpy.ndarray.view Equivalent numpy function to create a new view of the same data in memory.

Notes

Series are instantiated with dtype=float64 by default. While numpy.ndarray.view() will return a view with the same data type as the original array, Series.view() (without specified dtype) will try using float64 and may fail if the original data type size in bytes is not the same.

Examples

```python
>>> s = pd.Series([-2, -1, 0, 1, 2], dtype='int8')
>>> s
0  -2
1  -1
2   0
3   1
4   2
dtype: int8
```

The 8 bit signed integer representation of -1 is 0b1111111, but the same bytes represent 255 if read as an 8 bit unsigned integer:
>>> us = s.view('uint8')

>>> us
0   254
1   255
2     0
3     1
4     2
dtype: uint8

The views share the same underlying values:

>>> us[0] = 128

>>> s
0  -128
1     -1
2     0
3     1
4     2
dtype: int8

pandas.Series.where

Series.where(cond, other=nan, inplace=False, axis=None, level=None, errors='raise',
try_cast=<no_default>)

Replace values where the condition is False.

Parameters

cond [bool Series/DataFrame, array-like, or callable] Where cond is True, keep the
original value. Where False, replace with corresponding value from other. If cond
is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

other [scalar, Series/DataFrame, or callable] Entries where cond is False are replaced
with corresponding value from other. If other is callable, it is computed on the
Series/DataFrame and should return scalar or Series/DataFrame. The callable must
not change input Series/DataFrame (though pandas doesn’t check it).

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {‘raise’, ‘ignore’}, default ‘raise’] Note that currently this parameter won’t
affect the results and will always coerce to a suitable dtype.

• ‘raise’ : allow exceptions to be raised.
• ‘ignore’ : suppress exceptions. On error return original object.

try_cast [bool, default None] Try to cast the result back to the input type (if possible).

DeprecationWarning: try_cast will be removed in a future version

Returns

Same type as caller or None if inplace=True.

See also:
**Dataframe.mask()** Return an object of same shape as self.

**Notes**

The where method is an application of the if-then idiom. For each element in the calling DataFrame, if `cond` is `True` the element is used; otherwise the corresponding element from the DataFrame `other` is used.

The signature for `Dataframe.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

For further details and examples see the `where` documentation in `indexing`.

**Examples**

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1     1.0
2     2.0
3     3.0
4     4.0
dtype: float64
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```python
>>> s.where(s > 1, 10)
0     10
1     10
2      2
3      3
4      4
dtype: int64
>>> s.mask(s > 1, 10)
0     0
1     1
2     10
3     10
4     10
dtype: int64
```

```python
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
>>> m = df % 3 == 0
```

(continues on next page)
pandas.Series.xs

Series.xs(key, axis=0, level=None, drop_level=True)

Return cross-section from the Series/DataFrame.

This method takes a key argument to select data at a particular level of a MultiIndex.

Parameters

- **key** [label or tuple of label] Label contained in the index, or partially in a MultiIndex.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis to retrieve cross-section on.
- **level** [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.
- **drop_level** [bool, default True] If False, returns object with same levels as self.

Returns

Series or DataFrame Cross-section from the original Series or DataFrame corresponding to the selected index levels.

See also:

- **DataFrame.loc** Access a group of rows and columns by label(s) or a boolean array.
- **DataFrame.iloc** Purely integer-location based indexing for selection by position.
Notes

`xs` cannot be used to set values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of `xs` functionality, see *MultiIndex Slicers*.

Examples

```python
>>> d = {'num_legs': [4, 4, 2, 2],
... 'num_wings': [0, 0, 2, 2],
... 'class': ['mammal', 'mammal', 'mammal', 'bird'],
... 'animal': ['cat', 'dog', 'bat', 'penguin'],
... 'locomotion': ['walks', 'walks', 'flies', 'walks']})
>>> df = pd.DataFrame(data=d)
>>> df = df.set_index(['class', 'animal', 'locomotion'])
```

```
class | animal | locomotion |
-------|--------|------------
mammal | cat    | walks      |
mammal | dog    | walks      |
mammal | bat    | flies      |
bird   | penguin| walks      |
```

Get values at specified index

```python
>>> df.xs('mammal')
```

```
num_legs | num_wings |
---------|----------|
animal   | locomotion |
---------|----------|
cat      | walks     |
dog      | walks     |
bat      | flies     |
```

Get values at several indexes

```python
>>> df.xs(('mammal', 'dog'))
```

```
locomotion |
walks      |
---------|
```

Get values at specified index and level

```python
>>> df.xs('cat', level=1)
```

```
class | locomotion |
-------|------------
mammal | walks      |
```

Get values at several indexes and levels

```python
>>> df.xs(('bird', 'walks'),
... level=[0, 'locomotion'])
```

```
animal |
--------|
penguin |
```

Get values at specified column and axis
>>> df.xs('num_wings', axis=1)

<table>

Name: num_wings, dtype: int64

3.3.2 Attributes

Axes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.index</td>
<td>The index (axis labels) of the Series.</td>
</tr>
<tr>
<td>Series.array</td>
<td>The ExtensionArray of the data backing this Series or Index.</td>
</tr>
<tr>
<td>Series.values</td>
<td>Return Series as ndarray or ndarray-like depending on the dtype.</td>
</tr>
<tr>
<td>Series.dtype</td>
<td>Return the dtype object of the underlying data.</td>
</tr>
<tr>
<td>Series.shape</td>
<td>Return a tuple of the shape of the underlying data.</td>
</tr>
<tr>
<td>Series.nbytes</td>
<td>Return the number of bytes in the underlying data.</td>
</tr>
<tr>
<td>Series.ndim</td>
<td>Number of dimensions of the underlying data, by definition 1.</td>
</tr>
<tr>
<td>Series.size</td>
<td>Return the number of elements in the underlying data.</td>
</tr>
<tr>
<td>Series.T</td>
<td>Return the transpose, which is by definition self.</td>
</tr>
<tr>
<td>Series.memory_usage</td>
<td>Return the memory usage of the Series.</td>
</tr>
<tr>
<td>Series.hasnans</td>
<td>Return if I have any nans; enables various perf speedups.</td>
</tr>
<tr>
<td>Series.empty</td>
<td>Indicator whether DataFrame is empty.</td>
</tr>
<tr>
<td>Series.dtypes</td>
<td>Return the dtype object of the underlying data.</td>
</tr>
<tr>
<td>Series.name</td>
<td>Return the name of the Series.</td>
</tr>
<tr>
<td>Series.flags</td>
<td>Get the properties associated with this pandas object.</td>
</tr>
<tr>
<td>Series.set_flags</td>
<td>Return a new object with updated flags.</td>
</tr>
</tbody>
</table>

pandas.Series.empty

**property Series.empty**

Indicator whether DataFrame is empty.

True if DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

**Returns**

*bool* If DataFrame is empty, return True, if not return False.

**See also:**

*Series.dropna* Return series without null values.
*DataFrame.dropna* Return DataFrame with labels on given axis omitted where (all or any) data are missing.
Notes

If DataFrame contains only NaNs, it is still not considered empty. See the example below.

Examples

An example of an actual empty DataFrame. Notice the index is empty:

```python
>>> df_empty = pd.DataFrame({'A' : []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []
>>> df_empty.empty
True
```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```python
>>> df = pd.DataFrame({'A' : [np.nan]})
>>> df
    A
0   NaN
>>> df.empty
False
>>> df.dropna().empty
True
```

3.3.3 Conversion

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.astype(dtype[, copy, errors])</td>
<td>Cast a pandas object to a specified dtype dtype.</td>
</tr>
<tr>
<td>Series.convert_dtypes([infer_objects, ...])</td>
<td>Convert columns to best possible dtypes using dtypes supporting pd.NA.</td>
</tr>
<tr>
<td>Series.infer_objects()</td>
<td>Attempt to infer better dtypes for object columns.</td>
</tr>
<tr>
<td>Series.copy([deep])</td>
<td>Make a copy of this object’s indices and data.</td>
</tr>
<tr>
<td>Series.bool()</td>
<td>Return the bool of a single element Series or DataFrame.</td>
</tr>
<tr>
<td>Series.to_numpy([dtype, copy, na_value])</td>
<td>A NumPy ndarray representing the values in this Series or Index.</td>
</tr>
<tr>
<td>Series.to_period([freq, copy])</td>
<td>Convert Series from DatetimeIndex to PeriodIndex.</td>
</tr>
<tr>
<td>Series.to_timestamp([freq, how, copy])</td>
<td>Cast to DatetimeIndex of Timestamps, at beginning of period.</td>
</tr>
<tr>
<td>Series.to_list()</td>
<td>Return a list of the values.</td>
</tr>
<tr>
<td>Series.<strong>array</strong>(dtype)</td>
<td>Return the values as a NumPy array.</td>
</tr>
</tbody>
</table>
pandas.Series.__array__

Series.__array__(dtype=None)
Return the values as a NumPy array.

Users should not call this directly. Rather, it is invoked by `numpy.array()` and `numpy.asarray()`.

Parameters

dtype [str or numpy.dtype, optional] The dtype to use for the resulting NumPy array. By default, the dtype is inferred from the data.

Returns

numpy.ndarray The values in the series converted to a numpy.ndarray with the specified dtype.

See also:

array Create a new array from data.
Series.array Zero-copy view to the array backing the Series.
Series.to_numpy Series method for similar behavior.

Examples

```python
>>> ser = pd.Series([1, 2, 3])
>>> np.asarray(ser)
array([1, 2, 3])
```

For timezone-aware data, the timezones may be retained with `dtype='object'`

```python
>>> tzser = pd.Series(pd.date_range('2000', periods=2, tz='CET'))
>>> np.asarray(tzser, dtype='object')
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET'),
      Timestamp('2000-01-02 00:00:00+0100', tz='CET')],
      dtype=object)
```

Or the values may be localized to UTC and the tzinfo discarded with `dtype='datetime64[ns]'`

```python
>>> np.asarray(tzser, dtype='datetime64[ns]')
array(['1999-12-31T23:00:00.000000000', ...
```

3.3.4 Indexing, iteration

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.get(key[, default])</td>
<td>Get item from object for given key (ex: DataFrame column).</td>
</tr>
<tr>
<td>Series.at</td>
<td>Access a single value for a row/column label pair.</td>
</tr>
<tr>
<td>Series.iat</td>
<td>Access a single value for a row/column pair by integer position.</td>
</tr>
<tr>
<td>Series.loc</td>
<td>Access a group of rows and columns by label(s) or a boolean array.</td>
</tr>
<tr>
<td>Series.iloc</td>
<td>Purely integer-location based indexing for selection by position.</td>
</tr>
<tr>
<td>Series.<strong>iter</strong>()</td>
<td>Return an iterator of the values.</td>
</tr>
</tbody>
</table>
Table 37 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.items()</code></td>
<td>Lazily iterate over (index, value) tuples.</td>
</tr>
<tr>
<td><code>Series.iteritems()</code></td>
<td>Lazily iterate over (index, value) tuples.</td>
</tr>
<tr>
<td><code>Series.keys()</code></td>
<td>Return alias for index.</td>
</tr>
<tr>
<td><code>Series.pop(item)</code></td>
<td>Return item and drops from series.</td>
</tr>
<tr>
<td><code>Series.item()</code></td>
<td>Return the first element of the underlying data as a Python scalar.</td>
</tr>
</tbody>
</table>
| ```Series.xs(key[, axis, level, drop_level])``` | Return cross-section from the Series/DataFrame.

---

### pandas.Series.__iter__

**Series.__iter__()**

Return an iterator of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

**Returns**

iterator

For more information on `.at`, `.iat`, `.loc`, and `.iloc`, see the **indexing documentation**.

### 3.3.5 Binary operator functions

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.add(other[, level, fill_value, axis])</code></td>
<td>Return Addition of series and other, element-wise (binary operator <code>add</code>).</td>
</tr>
<tr>
<td><code>Series.sub(other[, level, fill_value, axis])</code></td>
<td>Return Subtraction of series and other, element-wise (binary operator <code>sub</code>).</td>
</tr>
<tr>
<td><code>Series.mul(other[, level, fill_value, axis])</code></td>
<td>Return Multiplication of series and other, element-wise (binary operator <code>mul</code>).</td>
</tr>
<tr>
<td><code>Series.div(other[, level, fill_value, axis])</code></td>
<td>Return Floating division of series and other, element-wise (binary operator <code>truediv</code>).</td>
</tr>
<tr>
<td><code>Series.truediv(other[, level, fill_value, axis])</code></td>
<td>Return Floating division of series and other, element-wise (binary operator <code>truediv</code>).</td>
</tr>
<tr>
<td><code>Series.floordiv(other[, level, fill_value, axis])</code></td>
<td>Return Integer division of series and other, element-wise (binary operator <code>floordiv</code>).</td>
</tr>
<tr>
<td><code>Series.mod(other[, level, fill_value, axis])</code></td>
<td>Return Modulo of series and other, element-wise (binary operator <code>mod</code>).</td>
</tr>
<tr>
<td><code>Series.pow(other[, level, fill_value, axis])</code></td>
<td>Return Exponential power of series and other, element-wise (binary operator <code>pow</code>).</td>
</tr>
<tr>
<td><code>Series.radd(other[, level, fill_value, axis])</code></td>
<td>Return Addition of series and other, element-wise (binary operator <code>radd</code>).</td>
</tr>
<tr>
<td><code>Series.rsub(other[, level, fill_value, axis])</code></td>
<td>Return Subtraction of series and other, element-wise (binary operator <code>rsub</code>).</td>
</tr>
<tr>
<td><code>Series.rmul(other[, level, fill_value, axis])</code></td>
<td>Return Multiplication of series and other, element-wise (binary operator <code>rmul</code>).</td>
</tr>
<tr>
<td><code>Series.rdiv(other[, level, fill_value, axis])</code></td>
<td>Return Floating division of series and other, element-wise (binary operator <code>rtruediv</code>).</td>
</tr>
<tr>
<td><code>Series.rtruediv(other[, level, fill_value, axis])</code></td>
<td>Return Floating division of series and other, element-wise (binary operator <code>rtruediv</code>).</td>
</tr>
</tbody>
</table>

continues on next page
Table 38 – continued from previous page

- **Series.rfloordiv(other[, level, fill_value, ...])** Return Integer division of series and other, element-wise (binary operator `rfloordiv`).
- **Series.rmod(other[, level, fill_value, axis])** Return Modulo of series and other, element-wise (binary operator `rmod`).
- **Series.rpow(other[, level, fill_value, axis])** Return Exponential power of series and other, element-wise (binary operator `rpow`).
- **Series.combine(other, func[, fill_value])** Combine the Series with a Series or scalar according to `func`.
- **Series.combine_first(other)** Update null elements with value in the same location in ‘other’.
- **Series.round([decimals])** Round each value in a Series to the given number of decimals.
- **Series.lt(other[, level, fill_value, axis])** Return Less than of series and other, element-wise (binary operator `lt`).
- **Series.gt(other[, level, fill_value, axis])** Return Greater than of series and other, element-wise (binary operator `gt`).
- **Series.le(other[, level, fill_value, axis])** Return Less than or equal to of series and other, element-wise (binary operator `le`).
- **Series.ge(other[, level, fill_value, axis])** Return Greater than or equal to of series and other, element-wise (binary operator `ge`).
- **Series.ne(other[, level, fill_value, axis])** Return Not equal to of series and other, element-wise (binary operator `ne`).
- **Series.eq(other[, level, fill_value, axis])** Return Equal to of series and other, element-wise (binary operator `eq`).
- **Series.product([axis, skipna, level, ...])** Return the product of the values over the requested axis.
- **Series.dot(other)** Compute the dot product between the Series and the columns of other.

3.3.6 Function application, GroupBy & window

- **Series.apply(func[, convert_dtype, args])** Invoke function on values of Series.
- **Series.agg([func, axis])** Aggregate using one or more operations over the specified axis.
- **Series.aggregate([func, axis])** Aggregate using one or more operations over the specified axis.
- **Series.transform(func[, axis])** Call `func` on self producing a Series with transformed values.
- **Series.map(arg[, na_action])** Map values of Series according to input correspondence.
- **Series.groupby([by, axis, level, as_index, ...])** Group Series using a mapper or by a Series of columns.
- **Series.rolling(window[, min_periods, ...])** Provide rolling window calculations.
- **Series.expanding([min_periods, center, ...])** Provide expanding transformations.
- **Series.ewm([com, span, halflife, alpha, ...])** Provide exponential weighted (EW) functions.
- **Series.pipe(func, *args, **kwargs)** Apply `func(self, *args, **kwargs)`.
3.3.7 Computations / descriptive stats

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.abs()</code></td>
<td>Return a Series/DataFrame with absolute numeric value of each element.</td>
</tr>
<tr>
<td><code>Series.all()</code></td>
<td>Return whether all elements are True, potentially over an axis.</td>
</tr>
<tr>
<td><code>Series.any()</code></td>
<td>Return whether any element is True, potentially over an axis.</td>
</tr>
<tr>
<td><code>Series.autocorr()</code></td>
<td>Compute the lag-N autocorrelation.</td>
</tr>
<tr>
<td><code>Series.between()</code></td>
<td>Return boolean Series equivalent to left &lt;= series &lt;= right.</td>
</tr>
<tr>
<td><code>Series.clip()</code></td>
<td>Trim values at input threshold(s).</td>
</tr>
<tr>
<td><code>Series.corr()</code></td>
<td>Compute correlation with other Series, excluding missing values.</td>
</tr>
<tr>
<td><code>Series.count()</code></td>
<td>Return number of non-NA/null observations in the Series.</td>
</tr>
<tr>
<td><code>Series.cov()</code></td>
<td>Compute covariance with Series, excluding missing values.</td>
</tr>
<tr>
<td><code>Series.cummax()</code></td>
<td>Return cumulative maximum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>Series.cummin()</code></td>
<td>Return cumulative minimum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>Series.cumprod()</code></td>
<td>Return cumulative product over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>Series.cumsum()</code></td>
<td>Return cumulative sum over a DataFrame or Series axis.</td>
</tr>
<tr>
<td><code>Series.describe()</code></td>
<td>Generate descriptive statistics.</td>
</tr>
<tr>
<td><code>Series.diff()</code></td>
<td>First discrete difference of element.</td>
</tr>
<tr>
<td><code>Series.factorize()</code></td>
<td>Encode the object as an enumerated type or categorical variable.</td>
</tr>
<tr>
<td><code>Series.kurt()</code></td>
<td>Return unbiased kurtosis over requested axis.</td>
</tr>
<tr>
<td><code>Series.mad()</code></td>
<td>Return the mean absolute deviation of the values over the requested axis.</td>
</tr>
<tr>
<td><code>Series.max()</code></td>
<td>Return the maximum of the values over the requested axis.</td>
</tr>
<tr>
<td><code>Series.mean()</code></td>
<td>Return the mean of the values over the requested axis.</td>
</tr>
<tr>
<td><code>Series.median()</code></td>
<td>Return the median of the values over the requested axis.</td>
</tr>
<tr>
<td><code>Series.min()</code></td>
<td>Return the minimum of the values over the requested axis.</td>
</tr>
<tr>
<td><code>Series.mode()</code></td>
<td>Return the mode(s) of the Series.</td>
</tr>
<tr>
<td><code>Series.nlargest()</code></td>
<td>Return the largest (n) elements.</td>
</tr>
<tr>
<td><code>Series.nsmallest()</code></td>
<td>Return the smallest (n) elements.</td>
</tr>
<tr>
<td><code>Series.pct_change()</code></td>
<td>Percentage change between the current and a prior element.</td>
</tr>
<tr>
<td><code>Series.prod()</code></td>
<td>Return the product of the values over the requested axis.</td>
</tr>
<tr>
<td><code>Series.quantile()</code></td>
<td>Return value at the given quantile.</td>
</tr>
<tr>
<td><code>Series.rank()</code></td>
<td>Compute numerical data ranks (1 through (n)) along axis.</td>
</tr>
<tr>
<td><code>Series.sem()</code></td>
<td>Return unbiased standard error of the mean over requested axis.</td>
</tr>
<tr>
<td><code>Series.skew()</code></td>
<td>Return unbiased skew over requested axis.</td>
</tr>
<tr>
<td><code>Series.std()</code></td>
<td>Return sample standard deviation over requested axis.</td>
</tr>
<tr>
<td><code>Series.sum()</code></td>
<td>Return the sum of the values over the requested axis.</td>
</tr>
</tbody>
</table>

<tr>
<td><code>Series.is_monotonic</code></td>
<td>Return boolean if values in the object are monotonic_increasing.</td>
</tr>
<tr>
<td><code>Series.is_monotonic_increasing</code></td>
<td>Alias for is_monotonic.</td>
</tr>
<tr>
<td><code>Series.is_monotonic_decreasing</code></td>
<td>Return boolean if values in the object are monotonic_decreasing.</td>
</tr>
<tr>
<td><code>Series.value_counts([normalize, sort, ...])</code></td>
<td>Return a Series containing counts of unique values.</td>
</tr>
</tbody>
</table>

#### 3.3.8 Reindexing / selection / label manipulation

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.align(other[, join, axis, level, ...])</code></td>
<td>Align two objects on their axes with the specified join method.</td>
</tr>
<tr>
<td><code>Series.drop([labels, axis, index, columns, ...])</code></td>
<td>Return Series with specified index labels removed.</td>
</tr>
<tr>
<td><code>Series.droplevel(level[, axis])</code></td>
<td>Return Series/DataFrame with requested index / column level(s) removed.</td>
</tr>
<tr>
<td><code>Series.drop_duplicates([keep])</code></td>
<td>Return Series with duplicate values removed.</td>
</tr>
<tr>
<td><code>Series.equals(other)</code></td>
<td>Test whether two objects contain the same elements.</td>
</tr>
<tr>
<td><code>Series.first</code>(offset)</td>
<td>Select initial periods of time series data based on a date offset.</td>
</tr>
<tr>
<td><code>Series.head(n)</code></td>
<td>Return the first n rows.</td>
</tr>
<tr>
<td><code>Series.idxmax([axis, skipna])</code></td>
<td>Return the row label of the maximum value.</td>
</tr>
<tr>
<td><code>Series.idxmin([axis, skipna])</code></td>
<td>Return the row label of the minimum value.</td>
</tr>
<tr>
<td><code>Series.isin(values)</code></td>
<td>Whether elements in Series are contained in values.</td>
</tr>
<tr>
<td><code>Series.last</code>(offset)</td>
<td>Select final periods of time series data based on a date offset.</td>
</tr>
<tr>
<td><code>Series.reindex(index)</code></td>
<td>Conform Series to new index with optional filling logic.</td>
</tr>
<tr>
<td><code>Series.reindex_like(other[, method, copy, ...])</code></td>
<td>Return an object with matching indices as other object.</td>
</tr>
<tr>
<td><code>Series.rename([index, axis, copy, inplace, ...])</code></td>
<td>Alter Series index labels or name.</td>
</tr>
<tr>
<td><code>Series.rename_axis([mapper, index, columns, ...])</code></td>
<td>Set the name of the axis for the index or columns.</td>
</tr>
<tr>
<td><code>Series.reset_index([level, drop, name, inplace])</code></td>
<td>Generate a new DataFrame or Series with the index reset.</td>
</tr>
<tr>
<td><code>Series.sample([n, frac, replace, weights, ...])</code></td>
<td>Return a random sample of items from an axis of object.</td>
</tr>
<tr>
<td><code>Series.set_axis(labels[, axis, inplace])</code></td>
<td>Assign desired index to given axis.</td>
</tr>
<tr>
<td><code>Series.take(indices[, axis, is_copy])</code></td>
<td>Return the elements in the given positional indices along an axis.</td>
</tr>
<tr>
<td><code>Series.tail(n)</code></td>
<td>Return the last n rows.</td>
</tr>
<tr>
<td><code>Series.truncate([before, after, axis, copy])</code></td>
<td>Truncate a Series or DataFrame before and after some index value.</td>
</tr>
<tr>
<td><code>Series.where(cond[, other, inplace, axis, ...])</code></td>
<td>Replace values where the condition is False.</td>
</tr>
<tr>
<td><code>Series.mask(cond[, other, inplace, axis, ...])</code></td>
<td>Replace values where the condition is True.</td>
</tr>
<tr>
<td><code>Series.add_prefix(prefix)</code></td>
<td>Prefix labels with string prefix.</td>
</tr>
<tr>
<td><code>Series.add_suffix(suffix)</code></td>
<td>Suffix labels with string suffix.</td>
</tr>
</tbody>

3.3.9 Missing data handling

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.backfill()</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code>.</td>
</tr>
<tr>
<td><code>Series.bfill()</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code>.</td>
</tr>
<tr>
<td><code>Series.dropna()</code></td>
<td>Return a new Series with missing values removed.</td>
</tr>
<tr>
<td><code>Series.ffill()</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code>.</td>
</tr>
<tr>
<td><code>Series.fillna()</code></td>
<td>Fill NA/NaN values using the specified method.</td>
</tr>
<tr>
<td><code>Series.isna()</code></td>
<td>Detect missing values.</td>
</tr>
<tr>
<td><code>Series.isnull()</code></td>
<td>Detect missing values.</td>
</tr>
<tr>
<td><code>Series.notna()</code></td>
<td>Detect existing (non-missing) values.</td>
</tr>
<tr>
<td><code>Series.notnull()</code></td>
<td>Detect existing (non-missing) values.</td>
</tr>
<tr>
<td><code>Series.pad()</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code>.</td>
</tr>
<tr>
<td><code>Series.replace()</code></td>
<td>Replace values given in <code>to_replace</code> with <code>value</code>.</td>
</tr>
</tbody>
</table>

3.3.10 Reshaping, sorting

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.argsort()</code></td>
<td>Return the integer indices that would sort the Series values.</td>
</tr>
<tr>
<td><code>Series.argmin()</code></td>
<td>Return int position of the smallest value in the Series.</td>
</tr>
<tr>
<td><code>Series.argmax()</code></td>
<td>Return int position of the largest value in the Series.</td>
</tr>
<tr>
<td><code>Series.reorder_levels()</code></td>
<td>Rearrange index levels using input order.</td>
</tr>
<tr>
<td><code>Series.sort_values()</code></td>
<td>Sort by the values.</td>
</tr>
<tr>
<td><code>Series.sort_index()</code></td>
<td>Sort Series by index labels.</td>
</tr>
<tr>
<td><code>Series.swaplevel()</code></td>
<td>Swap levels i and j in a <code>MultiIndex</code>.</td>
</tr>
<tr>
<td><code>Series.unstack()</code></td>
<td>Unstack, also known as pivot, Series with MultiIndex to produce DataFrame.</td>
</tr>
<tr>
<td><code>Series.explode()</code></td>
<td>Transform each element of a list-like to a row.</td>
</tr>
<tr>
<td><code>Series.searchsorted()</code></td>
<td>Find indices where elements should be inserted to maintain order.</td>
</tr>
<tr>
<td><code>Series.ravel()</code></td>
<td>Return the flattened underlying data as an ndarray.</td>
</tr>
<tr>
<td><code>Series.repeat()</code></td>
<td>Repeat elements of a Series.</td>
</tr>
<tr>
<td><code>Series.squeeze()</code></td>
<td>Squeeze 1 dimensional axis objects into scalars.</td>
</tr>
<tr>
<td><code>Series.view()</code></td>
<td>Create a new view of the Series.</td>
</tr>
</tbody>
</table>
### 3.3.11 Combining / comparing / joining / merging

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.append</td>
<td>Concatenate two or more Series.</td>
</tr>
<tr>
<td>Series.compare</td>
<td>Compare to another Series and show the differences.</td>
</tr>
<tr>
<td>Series.update</td>
<td>Modify Series in place using values from passed Series.</td>
</tr>
</tbody>
</table>

### 3.3.12 Time Series-related

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.asfreq</td>
<td>Convert time series to specified frequency.</td>
</tr>
<tr>
<td>Series.asof</td>
<td>Return the last row(s) without any NaNs before where.</td>
</tr>
<tr>
<td>Series.shift</td>
<td>Shift index by desired number of periods with an optional time freq.</td>
</tr>
<tr>
<td>Series.first_valid_index</td>
<td>Return index for first non-NA value or None, if no NA value is found.</td>
</tr>
<tr>
<td>Series.last_valid_index</td>
<td>Return index for last non-NA value or None, if no NA value is found.</td>
</tr>
<tr>
<td>Series.resample</td>
<td>Resample time-series data.</td>
</tr>
<tr>
<td>Series.tz_convert</td>
<td>Convert tz-aware axis to target time zone.</td>
</tr>
<tr>
<td>Series.tz_localize</td>
<td>Localize tz-naive index of a Series or DataFrame to target time zone.</td>
</tr>
<tr>
<td>Series.at_time</td>
<td>Select values at particular time of day (e.g., 9:30AM).</td>
</tr>
<tr>
<td>Series.between_time</td>
<td>Select values between particular times of the day (e.g., 9:00-9:30 AM).</td>
</tr>
<tr>
<td>Series.tshift</td>
<td>(DEPRECATED) Shift the time index, using the index’s frequency if available.</td>
</tr>
<tr>
<td>Series.slice_shift</td>
<td>(DEPRECATED) Equivalent to shift without copying data.</td>
</tr>
</tbody>
</table>

### 3.3.13 Accessors

pandas provides dtype-specific methods under various accessors. These are separate namespaces within Series that only apply to specific data types.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Accessor</th>
</tr>
</thead>
<tbody>
<tr>
<td>Datetime, Timedelta, Period</td>
<td>dt</td>
</tr>
<tr>
<td>String</td>
<td>str</td>
</tr>
<tr>
<td>Categorical</td>
<td>cat</td>
</tr>
<tr>
<td>Sparse</td>
<td>sparse</td>
</tr>
</tbody>
</table>
Datetimelike properties

Series.dt can be used to access the values of the series as datetimelike and return several properties. These can be accessed like Series.dt.<property>.

Datetime properties

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.dt.date</td>
<td>Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).</td>
</tr>
<tr>
<td>Series.dt.time</td>
<td>Returns numpy array of datetime.time.</td>
</tr>
<tr>
<td>Series.dt.timetz</td>
<td>Returns numpy array of datetime.time also containing timezone information.</td>
</tr>
<tr>
<td>Series.dt.year</td>
<td>The year of the datetime.</td>
</tr>
<tr>
<td>Series.dt.month</td>
<td>The month as January=1, December=12.</td>
</tr>
<tr>
<td>Series.dt.day</td>
<td>The day of the datetime.</td>
</tr>
<tr>
<td>Series.dt.hour</td>
<td>The hours of the datetime.</td>
</tr>
<tr>
<td>Series.dt.minute</td>
<td>The minutes of the datetime.</td>
</tr>
<tr>
<td>Series.dt.second</td>
<td>The seconds of the datetime.</td>
</tr>
<tr>
<td>Series.dt.microsecond</td>
<td>The microseconds of the datetime.</td>
</tr>
<tr>
<td>Series.dt.nanosecond</td>
<td>The nanoseconds of the datetime.</td>
</tr>
<tr>
<td>Series.dt.week</td>
<td>The week ordinal of the year.</td>
</tr>
<tr>
<td>Series.dt.dayofweek</td>
<td>The day of the week with Monday=0, Sunday=6.</td>
</tr>
<tr>
<td>Series.dt.day_of_week</td>
<td>The day of the week with Monday=0, Sunday=6.</td>
</tr>
<tr>
<td>Series.dt.weekday</td>
<td>The day of the week with Monday=0, Sunday=6.</td>
</tr>
<tr>
<td>Series.dt.dayofyear</td>
<td>The ordinal day of the year.</td>
</tr>
<tr>
<td>Series.dt.day_of_year</td>
<td>The ordinal day of the year.</td>
</tr>
<tr>
<td>Series.dt.quarter</td>
<td>The quarter of the date.</td>
</tr>
<tr>
<td>Series.dt.is_month_start</td>
<td>Indicates whether the date is the first day of the month.</td>
</tr>
<tr>
<td>Series.dt.is_month_end</td>
<td>Indicates whether the date is the last day of the month.</td>
</tr>
<tr>
<td>Series.dt.is_quarter_start</td>
<td>Indicator for whether the date is the first day of a quarter.</td>
</tr>
<tr>
<td>Series.dt.is_quarter_end</td>
<td>Indicator for whether the date is the last day of a quarter.</td>
</tr>
<tr>
<td>Series.dt.is_year_start</td>
<td>Indicate whether the date is the first day of a year.</td>
</tr>
<tr>
<td>Series.dt.is_year_end</td>
<td>Indicate whether the date is the last day of the year.</td>
</tr>
<tr>
<td>Series.dt.is_leap_year</td>
<td>Boolean indicator if the date belongs to a leap year.</td>
</tr>
<tr>
<td>Series.dt.daysinmonth</td>
<td>The number of days in the month.</td>
</tr>
<tr>
<td>Series.dt.days_in_month</td>
<td>The number of days in the month.</td>
</tr>
<tr>
<td>Series.dt.tz</td>
<td>Return timezone, if any.</td>
</tr>
<tr>
<td>Series.dt.freq</td>
<td>Return the frequency object for this PeriodArray.</td>
</tr>
</tbody>
</table>
pandas.Series.dt.date

Series.dt.date  
Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).

pandas.Series.dt.time

Series.dt.time  
Returns numpy array of datetime.time. The time part of the Timestamps.

pandas.Series.dt.timetz

Series.dt.timetz  
Returns numpy array of datetime.time also containing timezone information. The time part of the Timestamps.

pandas.Series.dt.year

Series.dt.year  
The year of the datetime.

Examples

```python
g>>> datetime_series = pd.Series(  ...
...     pd.date_range("2000-01-01", periods=3, freq="Y")  ...
... )
g>>> datetime_series
g0  2000-12-31
1  2001-12-31
2  2002-12-31
dtype: datetime64[ns]
g>>> datetime_series.dt.year
g0  2000
1  2001
2  2002
dtype: int64
```

pandas.Series.dt.month

Series.dt.month  
The month as January=1, December=12.
Examples

```python
>>> datetime_series = pd.Series(
    ...    pd.date_range("2000-01-01", periods=3, freq="M")
    ... )
>>> datetime_series
datetime_series
0 2000-01-31
1 2000-02-29
2 2000-03-31
dtype: datetime64[ns]
>>> datetime_series.dt.month
0 1
1 2
2 3
dtype: int64
```

pandas.Series.dt.day

Series.dt.day

The day of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
    ...    pd.date_range("2000-01-01", periods=3, freq="D")
    ... )
>>> datetime_series
datetime_series
0 2000-01-01
1 2000-01-02
2 2000-01-03
dtype: datetime64[ns]
>>> datetime_series.dt.day
0 1
1 2
2 3
dtype: int64
```
pandas.Series.dt.hour

Series.dt.hour
The hours of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="h")
... )
>>> datetime_series
0  2000-01-01 00:00:00
1  2000-01-01 01:00:00
2  2000-01-01 02:00:00
dtype: datetime64[ns]
>>> datetime_series.dt.hour
0  0
1  1
2  2
dtype: int64
```

pandas.Series.dt.minute

Series.dt.minute
The minutes of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="T")
... )
>>> datetime_series
0  2000-01-01 00:00:00
1  2000-01-01 00:01:00
2  2000-01-01 00:02:00
dtype: datetime64[ns]
>>> datetime_series.dt.minute
0  0
1  1
2  2
dtype: int64
```
pandas.Series.dt.second

Series.dt.second
The seconds of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="s")
... )
>>> datetime_series
0  2000-01-01 00:00:00
1  2000-01-01 00:00:01
2  2000-01-01 00:00:02
dtype: datetime64[ns]
>>> datetime_series.dt.second
0  0
1  1
2  2
dtype: int64
```

pandas.Series.dt.microsecond

Series.dt.microsecond
The microseconds of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="us")
... )
>>> datetime_series
0  2000-01-01 00:00:00.000000
1  2000-01-01 00:00:00.000001
2  2000-01-01 00:00:00.000002
dtype: datetime64[ns]
>>> datetime_series.dt.microsecond
0  0
1  1
2  2
dtype: int64
```
pandas.Series.dt.nanosecond

Series.dt.nanosecond
The nanoseconds of the datetime.

Examples

```python
>>> datetime_series = pd.Series(...
    pd.date_range("2000-01-01", periods=3, freq="ns")
...)
>>> datetime_series
time_series
0 2000-01-01 00:00:00.000000000
1 2000-01-01 00:00:00.000000001
2 2000-01-01 00:00:00.000000002
dtype: datetime64[ns]
>>> datetime_series.dt.nanosecond
0 0
1 1
2 2
dtype: int64
```

pandas.Series.dt.week

Series.dt.week
The week ordinal of the year.

Depreciated since version 1.1.0.

Series.dt.weekofyear and Series.dt.week have been deprecated. Please use Series.dt.isocalendar().week instead.

pandas.Series.dt.weekofyear

Series.dt.weekofyear
The week ordinal of the year.

Depreciated since version 1.1.0.

Series.dt.weekofyear and Series.dt.week have been deprecated. Please use Series.dt.isocalendar().week instead.

pandas.Series.dt.dayofweek

Series.dt.dayofweek
The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the dt accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:
Series.dt.dayofweek Alias.
Series.dt.weekday Alias.
Series.dt.day_name Returns the name of the day of the week.

Examples

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

pandas.Series.dt.day_of_week

Series.dt.day_of_week
The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the dt accessor) or DatetimeIndex.

Returns

Series or Index Containing integers indicating the day number.

See also:

- Series.dt.dayofweek Alias.
- Series.dt.weekday Alias.
- Series.dt.day_name Returns the name of the day of the week.

Examples

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```
**pandas.Series.dt.weekday**

Series.dt.weekday

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the dt accessor) or DatetimeIndex.

**Returns**

Series or Index Containing integers indicating the day number.

**See also:**

Series.dt.dayofweek Alias.
Series.dt.weekofweek Alias.
Series.dt.day_name Returns the name of the day of the week.

**Examples**

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

**pandas.Series.dt.dayofyear**

Series.dt.dayofyear

The ordinal day of the year.

**pandas.Series.dt.day_of_year**

Series.dt.day_of_year

The ordinal day of the year.

**pandas.Series.dt.quarter**

Series.dt.quarter

The quarter of the date.
**pandas.Series.dt.is_month_start**

Series.dt.is_month_start

Indicates whether the date is the first day of the month.

**Returns**

Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

**See also:**

* is_month_start Return a boolean indicating whether the date is the first day of the month.
* is_month_end Return a boolean indicating whether the date is the last day of the month.

**Examples**

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
def is_month_start(array):
    return array.is_month_start

def is_month_end(array):
    return array.is_month_end

>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0  2018-02-27
1  2018-02-28
2  2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0  False
1  False
2  True
dtype: bool
>>> s.dt.is_month_end
0  False
1  True
2  False
dtype: bool
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```

**pandas.Series.dt.is_month_end**

Series.dt.is_month_end

Indicates whether the date is the last day of the month.

**Returns**

Series or array For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

**See also:**

* is_month_start Return a boolean indicating whether the date is the first day of the month.
* is_month_end Return a boolean indicating whether the date is the last day of the month.
Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```python
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0 2018-02-27
1 2018-02-28
2 2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0 False
1 False
2 True
dtype: bool
>>> s.dt.is_month_end
0 False
1 True
2 False
dtype: bool
```

```python
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```

**pandas.Series.dt.is_quarter_start**

Series.dt.is_quarter_start

Indicator for whether the date is the first day of a quarter.

Returns

is_quarter_start  [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

- `quarter` Return the quarter of the date.
- `is_quarter_end` Similar property for indicating the quarter start.

Examples

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```python
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30", periods=4)})
```

```python
>>> df.assign(quarter=df.dates.dt.quarter,
... is_quarter_start=df.dates.dt.is_quarter_start)
```

<table>
<thead>
<tr>
<th>dates</th>
<th>quarter</th>
<th>is_quarter_start</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017-03-30</td>
<td>1</td>
<td>False</td>
</tr>
<tr>
<td>2017-03-31</td>
<td>1</td>
<td>False</td>
</tr>
<tr>
<td>2017-04-01</td>
<td>2</td>
<td>True</td>
</tr>
<tr>
<td>2017-04-02</td>
<td>2</td>
<td>False</td>
</tr>
</tbody>
</table>
pandas.Series.dt.is_quarter_end

Series.dt.is_quarter_end

Indicator for whether the date is the last day of a quarter.

Returns

is_quarter_end [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

quarter Return the quarter of the date.

is_quarter_start Similar property indicating the quarter start.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30", periods=4)})
>>> df.assign(quarter=df.dates.dt.quarter,
            is_quarter_end=df.dates.dt.is_quarter_end)
                   dates    quarter is_quarter_end
0  2017-03-30       1        False
1  2017-03-31       1         True
2  2017-04-01       2        False
3  2017-04-02       2        False
```
**pandas.Series.dt.is_year_start**

Series.dt.is_year_start  
Indicate whether the date is the first day of a year.  

**Returns**  
Series or DatetimeIndex  
The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.  

**See also:**  
is_year_end  
Similar property indicating the last day of the year.

**Examples**

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python  
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))  
>>> dates  
0    2017-12-30  
1    2017-12-31  
2    2018-01-01  
dtype: datetime64[ns]  

>>> dates.dt.is_year_start  
0   False  
1   False  
2   True  
dtype: bool
```

```python  
>>> idx = pd.date_range("2017-12-30", periods=3)  
>>> idx  
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],  
dtype='datetime64[ns]', freq='D')
```

```python  
>>> idx.is_year_start  
array([False, False, True])
```

**pandas.Series.dt.is_year_end**

Series.dt.is_year_end  
Indicate whether the date is the last day of the year.  

**Returns**  
Series or DatetimeIndex  
The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.  

**See also:**  
is_year_start  
Similar property indicating the start of the year.
Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
datetime_index:
0 2017-12-30
1 2017-12-31
2 2018-01-01
dtype: datetime64[ns]
```

```python
>>> dates.dt.is_year_end
0  False
1   True
2  False
dtype: bool
```

```python
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
dtype='datetime64[ns]', freq='D')
```

```python
>>> idx.is_year_end
array([False, True, False])
```

**pandas.Series.dt.is_leap_year**

`Series.dt.is_leap_year`

Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

**Returns**

Series or ndarray  Booleans indicating if dates belong to a leap year.

**Examples**

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> idx = pd.date_range("2012-01-01", "2015-01-01", freq="Y")
>>> idx
DatetimeIndex(['2012-12-31', '2013-12-31', '2014-12-31'],
dtype='datetime64[ns]', freq='A-DEC')
```

```python
>>> idx.is_leap_year
array([ True, False, False])
```

```python
>>> dates_series = pd.Series(idx)
>>> dates_series
datetime_index:
0 2012-12-31
1 2013-12-31
2 2014-12-31
dtype: datetime64[ns]
```

```python
>>> dates_series.dt.is_leap_year
array([ True, False, False])
```
0    True
1    False
2    False
dtype: bool

`pandas.Series.dt.daysinmonth`

Series.dt.daysinmonth
The number of days in the month.

`pandas.Series.dt.days_in_month`

Series.dt.days_in_month
The number of days in the month.

`pandas.Series.dt.tz`

Series.dt.tz
Return timezone, if any.

Returns
```
datetime.tzinfo, pytz.tzinfo.BaseTZInfo, dateutil.tz.tzfile, or None  Returns  None
```
when the array is tz-naive.

`pandas.Series.dt.freq`

Series.dt.freq

Datetime methods

```
Series.dt.to_period(*args, **kwargs)  Cast to PeriodArray/Index at a particular frequency.
Series.dt.to_pydatetime()  Return the data as an array of native Python datetime objects.
Series.dt.tz_localize(*args, **kwargs)  Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.
Series.dt.tz_convert(*args, **kwargs)  Convert tz-aware Datetime Array/Index from one timezone to another.
Series.dt.normalize(*args, **kwargs)  Convert times to midnight.
Series.dt.strftime(*args, **kwargs)  Convert to Index using specified date_format.
Series.dt.round(*args, **kwargs)  Perform round operation on the data to the specified freq.
Series.dt.floor(*args, **kwargs)  Perform floor operation on the data to the specified freq.
Series.dt.ceil(*args, **kwargs)  Perform ceiling operation on the data to the specified freq.
Series.dt.month_name(*args, **kwargs)  Return the month names of the DateTimeIndex with specified locale.
```

continues on next page
pandas.Series.dt.day_name(*args, **kwargs)
Return the day names of the DateTimeIndex with specified locale.

pandas.Series.dt.to_period
Series.dt.to_period(*args, **kwargs)
Cast to PeriodArray/Index at a particular frequency.
Converts DatetimeArray/Index to PeriodArray/Index.

Parameters
freq [str or Offset, optional] One of pandas’ offset strings or an Offset object. Will be inferred by default.

Returns
PeriodArray/Index

Raises
ValueError When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

See also:
PeriodIndex Immutable ndarray holding ordinal values.
DatetimeIndex.to_pydatetime Return DatetimeIndex as object.

Examples

```python
>>> df = pd.DataFrame({'y': [1, 2, 3]})
...                               index=pd.to_datetime(['2000-03-31 00:00:00',
...                               '2000-05-31 00:00:00',
...                               '2000-08-31 00:00:00'])
>>> df.index.to_period('M')
PeriodIndex(['2000-03', '2000-05', '2000-08'],
            dtype='period[M]')
```

Infer the daily frequency

```python
>>> idx = pd.date_range('2017-01-01', periods=2)
>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
            dtype='period[D]')
```

pandas.Series.dt.to_pydatetime
Series.dt.to_pydatetime()
Return the data as an array of native Python datetime objects.
Timezone information is retained if present.

Warning: Python’s datetime uses microsecond resolution, which is lower than pandas (nanosecond). The values are truncated.
**pandas**: powerful Python data analysis toolkit, Release 1.3.1

**Returns**

`numpy.ndarray` Object dtype array containing native Python datetime objects.

**See also:**

`datetime.datetime` Standard library value for a datetime.

**Examples**

```python
>>> s = pd.Series(pd.date_range('20180310', periods=2))
>>> s
0    2018-03-10
1    2018-03-11
dtype: datetime64[ns]

>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 11, 0, 0)], dtype=object)
```

pandas’ nanosecond precision is truncated to microseconds.

```python
>>> s = pd.Series(pd.date_range('20180310', periods=2, freq='ns'))
>>> s
0    2018-03-10 00:00:00.000000000
1    2018-03-10 00:00:00.000000001
dtype: datetime64[ns]

>>> s.dt.to_pydatetime()
array([datetime.datetime(2018, 3, 10, 0, 0),
       datetime.datetime(2018, 3, 10, 0, 0)], dtype=object)
```

**pandas.Series.dt.tz_localize**

`Series.dt.tz_localize(*args, **kwargs)`

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone.

This method can also be used to do the inverse – to create a time zone unaware object from an aware object. To that end, pass `tz=None`.

**Parameters**

- `tz` [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone to convert timestamps to. Passing `None` will remove the time zone information preserving local time.
- `ambiguous` ['infer', 'NaT', bool array, default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the `ambiguous` parameter dictates how ambiguous times should be handled.
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
• ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

• ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
• ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
• ‘NaT’ will return NaT where there are nonexistent times
• timedelta objects will shift nonexistent times by the timedelta
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

Same type as self Array/Index converted to the specified time zone.

Raises

TypeError If the Datetime Array/Index is tz-aware and tz is not None.

See also:

DatetimeIndex.tz_convert Convert tz-aware DatetimeIndex from one time zone to another.

Examples

```python
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')

Localize DatetimeIndex in US/Eastern time zone:

```python
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
               '2018-03-02 09:00:00-05:00',
               '2018-03-03 09:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)

With the tz=None, we can remove the time zone information while keeping the local time (not converted to UTC):

```python
>>> tz_aware.tz_localize(None)
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```python
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:30:00',
                                ...'2018-10-28 02:00:00',
                                ...'2018-10-28 02:30:00'],
                               tz='US/Eastern'))
```

(continues on next page)
In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly.

```python
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:20:00',
                                  '2018-10-28 02:36:00',
                                  '2018-10-28 03:46:00']))
>>> s.dt.tz_localize('CET', ambiguous=np.array([True, True, False]))
0    2018-10-28 01:20:00+02:00
1    2018-10-28 02:36:00+02:00
2    2018-10-28 03:46:00+01:00
dtype: datetime64[ns, CET]
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a timedelta object or 'shift_forward' or 'shift_backwards'.

```python
>>> s = pd.to_datetime(pd.Series(['2015-03-29 02:30:00',
                                  '2015-03-29 03:30:00']))
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
0    2015-03-29 03:00:00+02:00
1    2015-03-29 03:30:00+01:00
dtype: datetime64[ns, Europe/Warsaw]
```

```python
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
0    2015-03-29 01:59:59.999999999+01:00
1    2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```

```python
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
0    2015-03-29 03:30:00+02:00
1    2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]
```
Series.dt.tz_convert

Series.dt.tz_convert(*args, **kwargs)
Convert tz-aware Datetime Array/Index from one time zone to another.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A tz of None will convert to UTC and remove the timezone information.

Returns

Array or Index

Raises

TypeError If Datetime Array/Index is tz-naive.

See also:

DatetimeIndex.tz A timezone that has a variable offset from UTC.
DatetimeIndex.tz_localize Localize tz-naive DatetimeIndex to a given time zone, or remove timezone from a tz-aware DatetimeIndex.

Examples

With the tz parameter, we can change the DatetimeIndex to other time zones:

```python
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                     freq='H', periods=3, tz='Europe/Berlin')

>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
              '2014-08-01 10:00:00+02:00',
              '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')

>>> dti.tz_convert('US/Central')
DatetimeIndex(['2014-08-01 02:00:00-05:00',
              '2014-08-01 03:00:00-05:00',
              '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the tz=None, we can remove the timezone (after converting to UTC if necessary):

```python
>>> dti = pd.date_range(start='2014-08-01 09:00',
...                     freq='H', periods=3, tz='Europe/Berlin')

>>> dti
DatetimeIndex(['2014-08-01 09:00:00+02:00',
              '2014-08-01 10:00:00+02:00',
              '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')

>>> dti.tz_convert(None)
DatetimeIndex(['2014-08-01 07:00:00',
              '2014-08-01 08:00:00',
              '2014-08-01 09:00:00'],
              dtype='datetime64[ns]', freq='H')
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.Series.dt.normalize

Series.dt.normalize(*args, **kwargs)

Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the
time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the .dt accessor, and directly on Datetime
Array/Index.

Returns

DatetimeArray, DatetimeIndex or Series  The same type as the original data. Series will
have the same name and index. DatetimeIndex will have the same name.

See also:

floor  Floor the datetimes to the specified freq.
ceil  Ceil the datetimes to the specified freq.
round  Round the datetimes to the specified freq.

Examples

```python
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H',
                      ...                 periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
               '2014-08-01 11:00:00+05:30',
               '2014-08-01 12:00:00+05:30'],
               dtype='datetime64[ns, Asia/Calcutta]', freq='H')
>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30',
               '2014-08-01 00:00:00+05:30'],
               dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```

pandas.Series.dt.strftime

Series.dt.strftime(*args, **kwargs)

Convert to Index using specified date_format.

Return an Index of formatted strings specified by date_format, which supports the same string format as the
python standard library. Details of the string format can be found in python string format doc.

Parameters

date_format  [str] Date format string (e.g. “%Y-%m-%d”).

Returns

ndarray  NumPy ndarray of formatted strings.

See also:
to_datetime  Convert the given argument to datetime.

DatetimeIndex.normalize  Return DatetimeIndex with times to midnight.

DatetimeIndex.round  Round the DatetimeIndex to the specified freq.

DatetimeIndex.floor  Floor the DatetimeIndex to the specified freq.

Examples

```python
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
...                      periods=3, freq='s')
...                    
...                    
...>>> rng.strftime('%B %d, %Y, %r')
Index(["March 10, 2018, 09:00:00 AM", "March 10, 2018, 09:00:01 AM", "March 10, 2018, 09:00:02 AM"],
      dtype='object')
```

pandas.Series.dt.round

Series.dt.round(*args, **kwargs)
Perform round operation on the data to the specified freq.

Parameters

freq  [str or Offset] The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

ambiguous  ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:
- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent  ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST:
- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series  Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.
Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
 '2018-01-01 12:01:00'],
 dtype='datetime64[ns]', freq='T')
```

```python
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
 '2018-01-01 12:00:00'],
 dtype='datetime64[ns]', freq=None)
```

```python
Series

```python
>>> pd.Series(rng).dt.round("H")
0 2018-01-01 12:00:00
1 2018-01-01 12:00:00
2 2018-01-01 12:00:00
```

datetime64[ns]

pandas.Series.dt.floor

Series.dt.floor(*args, **kwargs)

Perform floor operation on the data to the specified freq.

Parameters:

- `freq` [str or Offset]: The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

- `ambiguous` ['infer', bool-ndarray, ‘NaT’, default ‘raise’]: Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

- `nonexistent` ['shift_forward', 'shift_backward', ‘NaT’, timedelta, default ‘raise’]: A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST:
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns:
**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**

ValueError if the `freq` cannot be converted.

**Examples**

**DatetimeIndex**

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'], dtype='datetime64[ns]', freq='T')
```

```python
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'], dtype='datetime64[ns]', freq=None)
```

**Series**

```python
>>> pd.Series(rng).dt.floor("H")
0    2018-01-01 11:00:00
1    2018-01-01 12:00:00
2    2018-01-01 12:00:00
dtype: datetime64[ns]
```

**pandas.Series.dt.ceil**

Series.dt.ceil(*args, **kwargs)

Perform ceil operation on the data to the specified `freq`.

**Parameters**

- `freq` [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See `frequency aliases` for a list of possible `freq` values.

- `ambiguous` ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

- `nonexistent` ['shift_forward', 'shift_backward', ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST:
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
‘NaT’ will return NaT where there are nonexistent times
• timedelta objects will shift nonexistent times by the timedelta
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

**DatetimeIndex, TimedeltaIndex, or Series** Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**

ValueError if the freq cannot be converted.

**Examples**

**DatetimeIndex**

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00', '2018-01-01 12:01:00'], dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00', '2018-01-01 13:00:00'],
               dtype='datetime64[ns]', freq=None)
```

**Series**

```python
>>> pd.Series(rng).dt.ceil("H")
0  2018-01-01 12:00:00
1  2018-01-01 12:00:00
2  2018-01-01 13:00:00
dtype: datetime64[ns]
```

**pandas.Series.dt.month_name**

Series.dt.month_name(*args, **kwargs)

Return the month names of the DateTimeIndex with specified locale.

**Parameters**

locale [str, optional] Locale determining the language in which to return the month name.

Default is English locale.

**Returns**

Index Index of month names.
Examples

```python
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31'],
dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```

**pandas.Series.dt.day**

Series.dt.day(*args, **kwargs)

Return the day names of the DateTimeIndex with specified locale.

Parameters

locale [str, optional] Locale determining the language in which to return the day name. Default is English locale.

Returns

Index Index of day names.

Examples

```python
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
dtype='datetime64[ns]', freq='D')
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

**Period properties**

- `Series.dt.qyear`
- `Series.dt.start_time`
- `Series.dt.end_time`
**pandas: powerful Python data analysis toolkit, Release 1.3.1**

**pandas.Series.dt.qyear**

Series.dt.qyear

**pandas.Series.dt.start_time**

Series.dt.start_time

**pandas.Series.dt.end_time**

Series.dt.end_time

**Timedelta properties**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.dt.days</td>
<td>Number of days for each element.</td>
</tr>
<tr>
<td>Series.dt.seconds</td>
<td>Number of seconds (&gt;= 0 and less than 1 day) for each element.</td>
</tr>
<tr>
<td>Series.dt.microseconds</td>
<td>Number of microseconds (&gt;= 0 and less than 1 second) for each element.</td>

</tr>
</tbody>
</table>

**pandas.Series.dt.days**

Series.dt.days
   Number of days for each element.

**pandas.Series.dt.seconds**

Series.dt.seconds
   Number of seconds (>= 0 and less than 1 day) for each element.

**pandas.Series.dt.microseconds**

Series.dt.microseconds
   Number of microseconds (>= 0 and less than 1 second) for each element.
**pandas.Series.dt.nanoseconds**

Series.dt.nanoseconds

Number of nanoseconds (>= 0 and less than 1 microsecond) for each element.

**pandas.Series.dt.components**

Series.dt.components

Return a DataFrame of the components of the Timedeltas.

Returns

DataFrame

**Examples**

```python
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='s'))
>>> s
day   hour   minute second  millisecond  microsecond nanosecond
0     0       0       0       0             0          0
1     0       0       0       1             0          0
2     0       0       0       2             0          0
3     0       0       0       3             0          0
4     0       0       0       4             0          0
```

**Timedelta methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.dt.to_pytimedelta()</code></td>
<td>Return an array of native <code>datetime.timedelta</code> objects.</td>
</tr>
<tr>
<td><code>Series.dt.total_seconds(*args, **kwargs)</code></td>
<td>Return total duration of each element expressed in seconds.</td>
</tr>
</tbody>
</table>

**pandas.Series.dt.to_pytimedelta**

Series.dt.to_pytimedelta()

Return an array of native `datetime.timedelta` objects.

Python’s standard `datetime` library uses a different representation timedelta’s. This method converts a Series of pandas Timedeltas to `datetime.timedelta` format with the same length as the original Series.

Returns

numpy.ndarray Array of 1D containing data with `datetime.timedelta` type.

See also:

datetime.timedelta A duration expressing the difference between two date, time, or datetime.
Examples

```python
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit="d"))
>>> s
dtype: timedelta64[ns]
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]
```

```python
>>> s.dt.to_pytimedelta()
array([datetime.timedelta(0), datetime.timedelta(days=1),
       datetime.timedelta(days=2), datetime.timedelta(days=3),
       datetime.timedelta(days=4)], dtype=object)
```

**pandas.Series.dt.total_seconds**

Series.dt.total_seconds(*args, **kwargs)

Return total duration of each element expressed in seconds.

This method is available directly on TimedeltaArray, TimedeltaIndex and on Series containing timedelta values under the .dt namespace.

**Returns**

- **seconds** [ndarray, Float64Index, Series] When the calling object is a TimedeltaArray, the return type is ndarray. When the calling object is a TimedeltaIndex, the return type is a Float64Index. When the calling object is a Series, the return type is Series of type float64 whose index is the same as the original.

**See also:**

- **datetime.timedelta.total_seconds** Standard library version of this method.
- **TimedeltaIndex.components** Return a DataFrame with components of each Timedelta.

Examples

**Series**

```python
>>> s = pd.Series(pd.to_timedelta(np.arange(5), unit='d'))
>>> s
dtype: timedelta64[ns]
0    0 days
1    1 days
2    2 days
3    3 days
4    4 days
dtype: timedelta64[ns]
```

```python
>>> s.dt.total_seconds()
0    0.0
1  86400.0
2 172800.0
3 259200.0
4 345600.0
dtype: float64
```
**TimedeltaIndex**

```python
>>> idx = pd.to_timedelta(np.arange(5), unit='d')
>>> idx
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
                dtype='timedelta64[ns]', freq=None)
```

```python
>>> idx.total_seconds()
Float64Index([0.0, 86400.0, 172800.0, 259200.0, 345600.0],
              dtype='float64')
```

**String handling**

`Series.str` can be used to access the values of the series as strings and apply several methods to it. These can be accessed like `Series.str.<function/property>`.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.str.capitalize()</code></td>

pandas: powerful Python data analysis toolkit, Release 1.3.1
pandas.Series.str.capitalize

Series.str\_capitalize()  
Convert strings in the Series/Index to be capitalized.  
Equivalent to \texttt{str.capitalize()}.  
Returns  
Series or Index of object

See also:  
**Series.str.lower** Converts all characters to lowercase.  
**Series.str.upper** Converts all characters to uppercase.  
**Series.str.title** Converts first character of each word to uppercase and remaining to lowercase.  
**Series.str.capitalize** Converts first character to uppercase and remaining to lowercase.  
**Series.str.swapcase** Converts uppercase to lowercase and lowercase to uppercase.  
**Series.str.casefold** Removes all case distinctions in the string.

Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0    lower
1  CAPITALS
2  this is a sentence
3    SwApCaSe
dtype: object

>>> s.str.lower()
0    lower
1  capitals
2  this is a sentence
3  swapcase
dtype: object

>>> s.str.upper()
0    LOWER
1  CAPITALS
2  THIS IS A SENTENCE
3  SWAPCASE
dtype: object

>>> s.str.title()
0    Lower
1    Capitals
2    This Is A Sentence
3    Swapcase
dtype: object

>>> s.str.capitalize()
0    Lower
1    Capitals
2    This is a sentence
3    Swapcase
dtype: object
```
>>> s.str.swapcase()
0    LOWER
1    capitals
2    THIS IS A SENTENCE
3    sWaFcaSe
dtype: object

pandas.Series.str.casefold

Series.str.casefold()
Convert strings in the Series/Index to be casefolded.

New in version 0.25.0.
Equivalent to str.casefold().

Returns
Series or Index of object

See also:
Series.str.lower  Converts all characters to lowercase.
Series.str.upper  Converts all characters to uppercase.
Series.str.title  Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize  Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase  Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold  Removes all case distinctions in the string.

Examples

>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])

>>> s
0   lower
1     capitals
2  this is a sentence
3     SwApCaSe
dtype: object

>>> s.str.lower()
0    lower
1    capitals
2    this is a sentence
3    swapcase
dtype: object

>>> s.str.upper()
0    LOWER
1     CAPITALS
2    THIS IS A SENTENCE
3     SWAPCASE
dtype: object

>>> s.str.title()
0    Lower
(continues on next page)
pandas.Series.str.cat

Series.str.cat(others=None, sep=None, na_rep=None, join='left')

Concatenate strings in the Series/Index with given separator.

If others is specified, this function concatenates the Series/Index and elements of others element-wise. If others is not passed, then all values in the Series/Index are concatenated into a single string with a given sep.

Parameters

others [Series, Index, DataFrame, np.ndarray or list-like] Series, Index, DataFrame, np.ndarray (one- or two-dimensional) and other list-likes of strings must have the same length as the calling Series/Index, with the exception of indexed objects (i.e. Series/Index/DataFrame) if join is not None.

If others is a list-like that contains a combination of Series, Index or np.ndarray (1-dim), then all elements will be unpacked and must satisfy the above criteria individually.

If others is None, the method returns the concatenation of all strings in the calling Series/Index.

sep [str, default ‘’] The separator between the different elements/columns. By default the empty string ‘’ is used.

na_rep [str or None, default None] Representation that is inserted for all missing values:

• If na_rep is None, and others is None, missing values in the Series/Index are omitted from the result.

• If na_rep is None, and others is not None, a row containing a missing value in any of the columns (before concatenation) will have a missing value in the result.

join [{‘left’, ‘right’, ‘outer’, ‘inner’}, default ‘left’] Determines the join-style between the calling Series/Index and any Series/Index/DataFrame in others (objects without an index need to match the length of the calling Series/Index). To disable alignment, use .values on any Series/Index/DataFrame in others.

New in version 0.23.0.

Changed in version 1.0.0: Changed default of join from None to ‘left’.

3.3. Series 1399
Returns

str, Series or Index  If others is None, str is returned, otherwise a Series/Index (same type as
caller) of objects is returned.

See also:
split  Split each string in the Series/Index.
join  Join lists contained as elements in the Series/Index.

Examples

When not passing others, all values are concatenated into a single string:

```python
>>> s = pd.Series(['a', 'b', np.nan, 'd'])
>>> s.str.cat(sep=' ')
'a b d'
```

By default, NA values in the Series are ignored. Using na_rep, they can be given a representation:

```python
>>> s.str.cat(sep=' ', na_rep='?')
'a b ? d'
```

If others is specified, corresponding values are concatenated with the separator. Result will be a Series of strings.

```python
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',')
0 a,A
1 b,B
2 NaN
3 d,D
dtype: object
```

Missing values will remain missing in the result, but can again be represented using na_rep

```python
>>> s.str.cat(['A', 'B', 'C', 'D'], sep=',', na_rep='-')
0 a,A
1 b,B
2 -,C
3 d,D
dtype: object
```

If sep is not specified, the values are concatenated without separation.

```python
>>> s.str.cat(['A', 'B', 'C', 'D'], na_rep='-')
0 aA
1 bB
2 -,C
3 dD
dtype: object
```

Series with different indexes can be aligned before concatenation. The join-keyword works as in other methods.

```python
>>> t = pd.Series(['d', 'a', 'e', 'c'], index=[3, 0, 4, 2])
>>> s.str.cat(t, join='left', na_rep='-')
0 aa
1 b-
2 -c
3 dd
```

(continues on next page)
dtype: object

```python
>>> s.str.cat(t, join='outer', na_rep='-',)
    0  aa
    1  b-
    2  -c
    3  dd
    4  -e
```
dtype: object

```python
>>> s.str.cat(t, join='inner', na_rep='-',)
    0  aa
    2  -c
    3  dd
```
dtype: object

```python
>>> s.str.cat(t, join='right', na_rep='-',)
    3  dd
    0  aa
    4  -e
    2  -c
```
dtype: object

For more examples, see [here](#).

**pandas.Series.str.center**

Series.str.center(*width, fillchar=' '*)

Pad left and right side of strings in the Series/Index.

Equivalent to str.center().

**Parameters**

- **width** [int] Minimum width of resulting string; additional characters will be filled with fillchar.
- **fillchar** [str] Additional character for filling, default is whitespace.

**Returns**

filled [Series/Index of objects.]

**pandas.Series.str.contains**

Series.str.contains(*pat, case=True, flags=0, na=None, regex=True*)

Test if pattern or regex is contained within a string of a Series or Index.

Return boolean Series or Index based on whether a given pattern or regex is contained within a string of a Series or Index.

**Parameters**

- **pat** [str] Character sequence or regular expression.
- **case** [bool, default True] If True, case sensitive.
- **flags** [int, default 0 (no flags)] Flags to pass through to the re module, e.g. re.IGNORECASE.
na [scalar, optional] Fill value for missing values. The default depends on dtype of the array. For object-dtype, numpy.nan is used. For StringDtype, pandas.NA is used.

regex [bool, default True] If True, assumes the pat is a regular expression. If False, treats the pat as a literal string.

Returns

Series or Index of boolean values A Series or Index of boolean values indicating whether the given pattern is contained within the string of each element of the Series or Index.

See also:

match Analogous, but stricter, relying on re.match instead of re.search.
Series.str.startswith Test if the start of each string element matches a pattern.
Series.str.endswith Same as startswith, but tests the end of string.

Examples

Returning a Series of booleans using only a literal pattern.

```python
def s1 = pd.Series(["Mouse", "dog", "house and parrot", "23", np.NaN])
>>> s1.str.contains("og", regex=False)
0   False
1    True
2   False
3   False
4    NaN
dtype: object
```

Returning an Index of booleans using only a literal pattern.

```python
def ind = pd.Index(["Mouse", "dog", "house and parrot", "23.0", np.NaN])
>>> ind.str.contains("23", regex=False)
Index([False, False, False, True, nan], dtype='object')
```

Specifying case sensitivity using case.

```python
def s1.str.contains("oG", case=True, regex=True)
0   False
1   False
2   False
3   False
4    NaN
dtype: object
```

Specifying na to be False instead of NaN replaces NaN values with False. If Series or Index does not contain NaN values the resultant dtype will be bool, otherwise, an object dtype.

```python
def s1.str.contains("og", na=False, regex=True)
0   False
1    True
2   False
3   False
4   False
dtype: bool
```

Returning ‘house’ or ‘dog’ when either expression occurs in a string.
>>> s1.str.contains('house|dog', regex=True)
0    False
1     True
2     True
3    False
4     NaN
dtype: object

Ignoring case sensitivity using flags with regex.

>>> import re

>>> s1.str.contains('PARROT', flags=re.IGNORECASE, regex=True)
0    False
1    False
2     True
3    False
4      NaN
dtype: object

Returning any digit using regular expression.

>>> s1.str.contains('\\d', regex=True)
0    False
1    False
2    False
3     True
4     NaN
dtype: object

Ensure pat is not a literal pattern when regex is set to True. Note in the following example one might expect only s2[1] and s2[3] to return True. However, ‘.0’ as a regex matches any character followed by a 0.

>>> s2 = pd.Series(['40', '40.0', '41', '41.0', '35'])

>>> s2.str.contains('.0', regex=True)
0     True
1     True
2    False
3     True
4    False
dtype: bool

pandas.Series.str.count

Series.str.count (pat, flags=0)
Count occurrences of pattern in each string of the Series/Index.

This function is used to count the number of times a particular regex pattern is repeated in each of the string elements of the Series.

Parameters

pat [str] Valid regular expression.
flags [int, default 0, meaning no flags] Flags for the re module. For a complete list, see here.
**kwargs For compatibility with other string methods. Not used.

Returns
Series or Index  Same type as the calling object containing the integer counts.

See also:

re  Standard library module for regular expressions.
str.count  Standard library version, without regular expression support.

Notes

Some characters need to be escaped when passing in pat. eg. '$' has a special meaning in regex and must be escaped when finding this literal character.

Examples

```python
>>> s = pd.Series(['A', 'B', 'Aaba', 'Baca', np.nan, 'CABA', 'cat'])
>>> s.str.count('a')
0    0.0
1    0.0
2    2.0
3    2.0
4    NaN
5    0.0
6    1.0
dtype: float64
```

Escape '$' to find the literal dollar sign.

```python
>>> s = pd.Series(['$', 'B', 'Aab$', '$$ca', 'C$B$', 'cat'])
>>> s.str.count('\\$')
0     1
1     0
2     1
3     2
4     2
5     0
dtype: int64
```

This is also available on Index

```python
>>> pd.Index(['A', 'A', 'Aaba', 'cat']).str.count('a')
Int64Index([0, 0, 2, 1], dtype='int64')
```

pandas.Series.str.decode

Series.str.decode (encoding, errors='strict')

Decode character string in the Series/Index using indicated encoding.

Equivalent to str.decode() in python2 and bytes.decode() in python3.

Parameters

- **encoding** [str]
- **errors** [str, optional]

Returns

Series or Index
**pandas.Series.str.encode**

Series.str.encode(encoding, errors='strict')

Encode character string in the Series/Index using indicated encoding.

Equivalent to str.encode().

**Parameters**

- **encoding** [str]
- **errors** [str, optional]

**Returns**

- **encoded** [Series/Index of objects]

**pandas.Series.str.endswith**

Series.str.endswith(pat, na=None)

Test if the end of each string element matches a pattern.

Equivalent to str.endswith().

**Parameters**

- **pat** [str] Character sequence. Regular expressions are not accepted.
- **na** [object, default NaN] Object shown if element tested is not a string. The default depends on dtype of the array. For object-dtype, numpy.nan is used. For StringDtype, pandas.NA is used.

**Returns**

- **Series or Index of bool** A Series of booleans indicating whether the given pattern matches the end of each string element.

**See also:**

- str.endswith Python standard library string method.
- Series.str.startswith Same as endswith, but tests the start of string.
- Series.str.contains Tests if string element contains a pattern.

**Examples**

```python
>>> s = pd.Series(['bat', 'bear', 'caT', np.nan])
>>> s
0    bat
1    bear
2     caT
3     NaN
dtype: object

>>> s.str.endswith('t')
0    True
1   False
2    False
3     NaN
dtype: object
```

Specifying na to be False instead of NaN.
```python
>>> s.str.endswith('t', na=False)
0    True
1    False
2    False
3    False
dtype: bool
```

**pandas.Series.str.extract**

Series.str.extract *(pat, flags=0, expand=True)*

Extract capture groups in the regex *pat* as columns in a DataFrame.

For each subject string in the Series, extract groups from the first match of regular expression *pat*.

**Parameters**

- **pat** [str] Regular expression pattern with capturing groups.
- **flags** [int, default 0 (no flags)] Flags from the *re* module, e.g. *re.IGNORECASE*, that modify regular expression matching for things like case, spaces, etc. For more details, see *re*.
- **expand** [bool, default True] If True, return DataFrame with one column per capture group. If False, return a Series/Index if there is one capture group or DataFrame if there are multiple capture groups.

**Returns**

- **DataFrame or Series or Index** A DataFrame with one row for each subject string, and one column for each group. Any capture group names in regular expression *pat* will be used for column names; otherwise capture group numbers will be used. The dtype of each result column is always object, even when no match is found. If *expand=False* and *pat* has only one capture group, then return a Series (if subject is a Series) or Index (if subject is an Index).

**See also:**

- **extractall** Returns all matches (not just the first match).

**Examples**

A pattern with two groups will return a DataFrame with two columns. Non-matches will be NaN.

```python
>>> s = pd.Series(['a1', 'b2', 'c3'])
>>> s.str.extract(r'([ab])\d)')
   0  1
0  a  1
1  b  2
2  NaN NaN
```

A pattern may contain optional groups.

```python
>>> s.str.extract(r'([ab])?\d)')
   0  1
0  a  1
1  b  2
2  NaN NaN
```

Named groups will become column names in the result.
```python
>>> s.str.extract(r'(?P<letter>[ab]) (?P<digit>\d)')
   letter digit
0     a     1
1     b     2
2   NaN   NaN
```

A pattern with one group will return a DataFrame with one column if expand=True.

```python
>>> s.str.extract(r'\[ab\](\d)', expand=True)
   0 1
0 1
1 2
2 NaN
```

A pattern with one group will return a Series if expand=False.

```python
>>> s.str.extract(r'\[ab\](\d)', expand=False)
0 1
1 2
2 NaN
dtype: object
```

### pandas.Series.str.extractall

**Series.str.extractall** *(pat, flags=0)*

Extract capture groups in the regex *pat* as columns in DataFrame.

For each subject string in the Series, extract groups from all matches of regular expression *pat*. When each subject string in the Series has exactly one match, extractall(*pat*).xs(0, level='match') is the same as extract(*pat*).

**Parameters**

- **pat** [str] Regular expression pattern with capturing groups.
- **flags** [int, default 0 (no flags)] A re module flag, for example re.IGNORECASE. These allow to modify regular expression matching for things like case, spaces, etc. Multiple flags can be combined with the bitwise OR operator, for example re.IGNORECASE | re.MULTILINE.

**Returns**

**DataFrame** A DataFrame with one row for each match, and one column for each group. Its rows have a MultiIndex with first levels that come from the subject Series. The last level is named 'match' and indexes the matches in each item of the Series. Any capture group names in regular expression *pat* will be used for column names; otherwise capture group numbers will be used.

**See also:**

- **extract** Returns first match only (not all matches).
Examples

A pattern with one group will return a DataFrame with one column. Indices with no matches will not appear in
the result.

```python
>>> s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"])
>>> s.str.extractall(r"[ab](\d)")
     match
   0   1
A   0   1
   1   2
B   0   1
```

Capture group names are used for column names of the result.

```python
>>> s.str.extractall(r"[ab](?P<digit>\d)")
     digit
   match
   A   0   1
   1   2
   B   0   1
```

A pattern with two groups will return a DataFrame with two columns.

```python
>>> s.str.extractall(r"(?P<letter>[ab])(?P<digit>\d)")
     letter  digit
   match
   A   a   1
   1   a   2
   B   b   1
```

Optional groups that do not match are NaN in the result.

```python
>>> s.str.extractall(r"(?P<letter>[ab])?(?P<digit>\d)")
     letter  digit
   match
   A   a   1
   1   a   2
   B   b   1
   C   NaN  1
```

**pandas.Series.str.find**

*Series.str.find*(sub, start=0, end=None)

Return lowest indexes in each strings in the Series/Index.

Each of returned indexes corresponds to the position where the substring is fully contained between [start:end].
Return -1 on failure. Equivalent to standard *str.find()*.

**Parameters**

- **sub** [str] Substring being searched.
- **start** [int] Left edge index.
- **end** [int] Right edge index.

**Returns**
Series or Index of int.

See also:

`rfind` Return highest indexes in each strings.

**pandas.Series.str.findall**

Series.str.findall(*pat*, *flags=0*)

Find all occurrences of pattern or regular expression in the Series/Index.

Equivalent to applying `re.findall()` to all the elements in the Series/Index.

**Parameters**

- **pat** [str] Pattern or regular expression.
- **flags** [int, default 0] Flags from `re` module, e.g. `re.IGNORECASE` (default is 0, which means no flags).

**Returns**

Series/Index of lists of strings All non-overlapping matches of pattern or regular expression in each string of this Series/Index.

See also:

`count` Count occurrences of pattern or regular expression in each string of the Series/Index.
`extractall` For each string in the Series, extract groups from all matches of regular expression and return a DataFrame with one row for each match and one column for each group.
`re.findall` The equivalent `re` function to all non-overlapping matches of pattern or regular expression in string, as a list of strings.

**Examples**

```python
>>> s = pd.Series(['Lion', 'Monkey', 'Rabbit'])
```

The search for the pattern ‘Monkey’ returns one match:

```python
>>> s.str.findall('Monkey')
0  []
1  ['Monkey']
2  []
dtype: object
```

On the other hand, the search for the pattern ‘MONKEY’ doesn’t return any match:

```python
>>> s.str.findall('MONKEY')
0  []
1  []
2  []
dtype: object
```

Flags can be added to the pattern or regular expression. For instance, to find the pattern ‘MONKEY’ ignoring the case:

```python
>>> import re
>>> s.str.findall('MONKEY', flags=re.IGNORECASE)
0  []
```

(continues on next page)
When the pattern matches more than one string in the Series, all matches are returned:

```python
>>> s.str.findall('on')
0  [on]
1  [on]
2  []
dtype: object
```

Regular expressions are supported too. For instance, the search for all the strings ending with the word ‘on’ is shown next:

```python
>>> s.str.findall('on$')
0  [on]
1  []
2  []
dtype: object
```

If the pattern is found more than once in the same string, then a list of multiple strings is returned:

```python
>>> s.str.findall('b')
0  []
1  []
2  [b, b]
dtype: object
```

### pandas.Series.str.fullmatch

**Series.str.fullmatch(pat, case=True, flags=0, na=None)**

Determine if each string entirely matches a regular expression.

**New in version 1.1.0.**

**Parameters**

- **pat** [str] Character sequence or regular expression.
- **case** [bool, default True] If True, case sensitive.
- **flags** [int, default 0 (no flags)] Regex module flags, e.g. re.IGNORECASE.
- **na** [scalar, optional] Fill value for missing values. The default depends on dtype of the array. For object-dtype, numpy.nan is used. For StringDtype, pandas.NA is used.

**Returns**

Series/Index/array of boolean values

**See also:**

- **match** Similar, but also returns True when only a prefix of the string matches the regular expression.
- **extract** Extract matched groups.
**pandas.Series.str.get**

Series.str.get(i)

Extract element from each component at specified position.

Extract element from lists, tuples, or strings in each element in the Series/Index.

**Parameters**

- **i** [int] Position of element to extract.

**Returns**

Series or Index

**Examples**

```python
>>> s = pd.Series(["String",
... (1, 2, 3),
... ["a", "b", "c"],
... 123,
... -456,
... {1: "Hello", "2": "World"}])

>>> s
0    String
1    (1, 2, 3)
2    [a, b, c]
3    123
4    -456
5     {1: 'Hello', '2': 'World'}
dtype: object

>>> s.str.get(1)
0    t
1    2
2    b
3    NaN
4    NaN
5    Hello
dtype: object

>>> s.str.get(-1)
0    g
1    3
2    c
3    NaN
4    NaN
5    None
dtype: object
```
**pandas.Series.str.index**

```python
Series.str.index(sub, start=0, end=None)
```

Return lowest indexes in each string in Series/Index.

Each of the returned indexes corresponds to the position where the substring is fully contained between [start:end]. This is the same as `str.find` except instead of returning -1, it raises a `ValueError` when the substring is not found. Equivalent to standard `str.index`.

**Parameters**

- `sub` [str] Substring being searched.
- `start` [int] Left edge index.
- `end` [int] Right edge index.

**Returns**

Series or Index of object

See also:

- `rindex` Return highest indexes in each strings.

**pandas.Series.str.join**

```python
Series.str.join(sep)
```

Join lists contained as elements in the Series/Index with passed delimiter.

If the elements of a Series are lists themselves, join the content of these lists using the delimiter passed to the function. This function is an equivalent to `str.join()`.

**Parameters**

- `sep` [str] Delimiter to use between list entries.

**Returns**

Series/Index: object The list entries concatenated by intervening occurrences of the delimiter.

**Raises**

- `AttributeError` If the supplied Series contains neither strings nor lists.

See also:

- `str.join` Standard library version of this method.
- `Series.str.split` Split strings around given separator/delimiter.

**Notes**

If any of the list items is not a string object, the result of the join will be `NaN`.
Examples

Example with a list that contains non-string elements.

```python
>>> s = pd.Series([['lion', 'elephant', 'zebra'],
...                  [1.1, 2.2, 3.3],
...                  ['cat', np.nan, 'dog'],
...                  ['cow', 4.5, 'goat'],
...                  ['duck', ['swan', 'fish'], 'guppy']])
```

```python
>>> s
0    [lion, elephant, zebra]
1   [1.1, 2.2, 3.3]
2    [cat, nan, dog]
3   [cow, 4.5, goat]
4  [duck, [swan, fish], guppy]
dtype: object
```

Join all lists using a `-`. The lists containing object(s) of types other than str will produce a NaN.

```python
>>> s.str.join('-')
0  lion-elephant-zebra
1  NaN
2  NaN
3  NaN
4  NaN
```

dtype: object

**pandas.Series.str.len**

*Series.str.len()*

Compute the length of each element in the Series/Index.

The element may be a sequence (such as a string, tuple or list) or a collection (such as a dictionary).

**Returns**

*Series or Index of int*  A Series or Index of integer values indicating the length of each element in the Series or Index.

**See also:**

str.len Python built-in function returning the length of an object.

Series.size Returns the length of the Series.

**Examples**

Returns the length (number of characters) in a string. Returns the number of entries for dictionaries, lists or tuples.

```python
>>> s = pd.Series(['dog',
...                 ',',
...                 5,
...                 {'foo' : 'bar'},
...                 [2, 3, 5, 7],
...                 ['one', 'two', 'three']])
```

```python
>>> s
0   dog
```

(continues on next page)
{'foo': 'bar'}
[2, 3, 5, 7]
(one, two, three)
dtype: object

>>> s.str.len()
0   3.0
1   0.0
2   NaN
3   1.0
4   4.0
5   3.0
dtype: float64

**pandas.Series.str.ljust**

Series.str.ljust(width, fillchar=')

Pad right side of strings in the Series/Index.

Equivalent to str.ljust().

**Parameters**

- **width** [int] Minimum width of resulting string; additional characters will be filled with
  fillchar.
- **fillchar** [str] Additional character for filling, default is whitespace.

**Returns**

filled [Series/Index of objects.]

**pandas.Series.str.lower**

Series.str.lower()

Convert strings in the Series/Index to lowercase.

Equivalent to str.lower().

**Returns**

Series or Index of object

**See also:**

- **Series.str.lower** Converts all characters to lowercase.
- **Series.str.upper** Converts all characters to uppercase.
- **Series.str.title** Converts first character of each word to uppercase and remaining to lowercase.
- **Series.str.capitalize** Converts first character to uppercase and remaining to lowercase.
- **Series.str.swapcase** Converts uppercase to lowercase and lowercase to uppercase.
- **Series.str.casefold** Removes all case distinctions in the string.
### Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0    lower
1  CAPITALS
2  this is a sentence
3      SwApCaSe
dtype: object

>>> s.str.lower()
0    lower
1   capitals
2  this is a sentence
3     swapcase
dtype: object

>>> s.str.upper()
0     LOWER
1  CAPITALS
2 THIS IS A SENTENCE
3    SWAPCASE
dtype: object

>>> s.str.title()
0      Lower
1   Capitals
2 This Is A Sentence
3     Swapcase
dtype: object

>>> s.str.capitalize()
0      Lower
1   Capitals
2  This is a sentence
3     Swapcase
dtype: object

>>> s.str.swapcase()
0    LOWER
1  capitals
2 THIS IS A SENTENCE
3      sWaPcAsE
dtype: object
```
**pandas.Series.str.lstrip**

`Series.str.lstrip(to_strip=None)`  
Remove leading characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left side. Equivalent to `str.lstrip()`.

**Parameters**

- **to_strip** [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

**Returns**

Series or Index of object

**See also:**

- `Series.str.strip` Remove leading and trailing characters in Series/Index.
- `Series.str.lstrip` Remove leading characters in Series/Index.
- `Series.str.rstrip` Remove trailing characters in Series/Index.

**Examples**

```python
>>> s = pd.Series(['1. Ant. ', '2. Bee!
', '3. Cat?	', np.nan])

>>> s
0    1. Ant.
1    2. Bee!
2    3. Cat?
3    NaN
dtype: object

>>> s.str.strip()
0    1. Ant.
1    2. Bee!
2    3. Cat?
3    NaN
dtype: object

>>> s.str.lstrip('123.(')
0    Ant.
1    Bee!
2    Cat?
3    NaN
dtype: object

>>> s.str.rstrip('!?
	')
0    1. Ant
1    2. Bee
2    3. Cat
3    NaN
dtype: object

>>> s.str.strip('123.!? 
\t')
0    Ant
(continues on next page)```
pandas.Series.str.match

Series.str.match (pat, case=True, flags=0, na=None)
Determine if each string starts with a match of a regular expression.

Parameters

- **pat** [str] Character sequence or regular expression.
- **case** [bool, default True] If True, case sensitive.
- **flags** [int, default 0 (no flags)] Regex module flags, e.g. re.IGNORECASE.
- **na** [scalar, optional] Fill value for missing values. The default depends on dtype of the array.
  For object-dtype, numpy.nan is used. For StringDtype, pandas.NA is used.

Returns

Series/Index/array of boolean values

See also:

- fullmatch Stricter matching that requires the entire string to match.
- contains Analogous, but less strict, relying on re.search instead of re.match.
- extract Extract matched groups.

pandas.Series.str.normalize

Series.str.normalize (form)
Return the Unicode normal form for the strings in the Series/Index.

For more information on the forms, see the unicodedata.normalize().

Parameters

Returns

normalized [Series/Index of objects]

pandas.Series.str.pad

Series.str.pad (width, side='left', fillchar=' ‘)
Pad strings in the Series/Index up to width.

Parameters

- **width** [int] Minimum width of resulting string; additional characters will be filled with character defined in fillchar.
- **side** [{‘left’, ‘right’, ‘both’}, default ‘left’] Side from which to fill resulting string.
- **fillchar** [str, default ‘ ‘] Additional character for filling, default is whitespace.

Returns

3.3. Series
Series or Index of object  Returns Series or Index with minimum number of char in object.

See also:

- **Series.str.rjust** Fills the left side of strings with an arbitrary character. Equivalent to `Series.str.pad(side='left')`.
- **Series.str.ljust** Fills the right side of strings with an arbitrary character. Equivalent to `Series.str.pad(side='right')`.
- **Series.str.center** Fills both sides of strings with an arbitrary character. Equivalent to `Series.str.pad(side='both')`.
- **Series.str.zfill** Pad strings in the Series/Index by prepending ‘0’ character. Equivalent to `Series.str.pad(side='left', fillchar='0')`.

Examples

```python
>>> s = pd.Series(['caribou', 'tiger'])

>>> s
0 caribou
1 tiger
dtype: object

>>> s.str.pad(width=10)
0 caribou
1 tiger
dtype: object

>>> s.str.pad(width=10, side='right', fillchar='\-')
0 caribou\-
1 tiger--
dtype: object

>>> s.str.pad(width=10, side='both', fillchar='\-')
0 -caribou--
1 --tiger---
dtype: object
```

pandas.Series.str.partition

Series.str.partition(sep='\', expand=True)

Split the string at the first occurrence of `sep`.

This method splits the string at the first occurrence of `sep`, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing the string itself, followed by two empty strings.

Parameters

- **sep**  [str, default whitespace] String to split on.
- **expand**  [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality. If False, return Series/Index.

Returns

DataFrame/MultiIndex or Series/Index of objects

See also:

- **rpartition** Split the string at the last occurrence of `sep`.
**Series.str.split**  Split strings around given separators.

**str.partition**  Standard library version.

### Examples

```python
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0    Linda van der Berg
1    George Pitt-Rivers
dtype: object

>>> s.str.partition()
     0    1    2
0    Linda  van der Berg
1    George  Pitt-Rivers

To partition by the last space instead of the first one:

```python
>>> s.str.rpartition()
     0  1    2
0    Linda    van der Berg
1    George    Pitt-Rivers
```

To partition by something different than a space:

```python
>>> s.str.partition('-')
     0  1  2
0    Linda    van der Berg
1    George     Pitt - Rivers
```

To return a Series containing tuples instead of a DataFrame:

```python
>>> s.str.partition('-', expand=False)
0 (Linda van der Berg, , )
1 (George Pitt, -, Rivers)
dtype: object
```

Also available on indices:

```python
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')

Which will create a MultiIndex:

```python
>>> idx.str.partition()
MultiIndex([('X', '', '123'),
            ('Y', '', '999')],
           )
```

Or an index with tuples with expand=False:

```python
>>> idx.str.partition(expand=False)
Index([('X', '', '123'), ('Y', '', '999')], dtype='object')
```
pandas.Series.str.repeat

Series.str.repeat(repeats)
Duplicate each string in the Series or Index.

Parameters

repeats [int or sequence of int] Same value for all (int) or different value per (sequence).

Returns

Series or Index of object  Series or Index of repeated string objects specified by input parameter repeats.

Examples

```python
>>> s = pd.Series(['a', 'b', 'c'])
>>> s
0 a
1 b
2 c
dtype: object

Single int repeats string in Series

```python
>>> s.str.repeat(repeats=2)
0  aa
1  bb
2  cc
dtype: object
```

Sequence of int repeats corresponding string in Series

```python
>>> s.str.repeat(repeats=[1, 2, 3])
0  a
1  bb
2  ccc
dtype: object
```

pandas.Series.str.replace

Series.str.replace(pat, repl, n=-1, case=None, flags=0, regex=None)
Replace each occurrence of pattern/regex in the Series/Index.

Equivalent to str.replace() or re.sub(), depending on the regex value.

Parameters

pat [str or compiled regex] String can be a character sequence or regular expression.

repl [str or callable] Replacement string or a callable. The callable is passed the regex match object and must return a replacement string to be used. See re.sub().

n [int, default -1 (all)] Number of replacements to make from start.

case [bool, default None] Determines if replace is case sensitive:
  • If True, case sensitive (the default if pat is a string)
  • Set to False for case insensitive
• Cannot be set if pat is a compiled regex.

flags [int, default 0 (no flags)] Regex module flags, e.g. re.IGNORECASE. Cannot be set if pat is a compiled regex.

regex [bool, default True] Determines if the passed-in pattern is a regular expression:

• If True, assumes the passed-in pattern is a regular expression.
• If False, treats the pattern as a literal string
• Cannot be set to False if pat is a compiled regex or repl is a callable.

New in version 0.23.0.

Returns

Series or Index of object A copy of the object with all matching occurrences of pat replaced by repl.

Raises

ValueError

• if regex is False and repl is a callable or pat is a compiled regex
• if pat is a compiled regex and case or flags is set

Notes

When pat is a compiled regex, all flags should be included in the compiled regex. Use of case, flags, or regex=False with a compiled regex will raise an error.

Examples

When pat is a string and regex is True (the default), the given pat is compiled as a regex. When repl is a string, it replaces matching regex patterns as with re.sub(). NaN value(s) in the Series are left as is:

```
>>> pd.Series(['foo', 'fuz', np.nan]).str.replace('f.', 'ba', regex=True)
0  bao
1  baz
2  NaN
dtype: object
```

When pat is a string and regex is False, every pat is replaced with repl as with str.replace():

```
>>> pd.Series(['f.o', 'fuz', np.nan]).str.replace('f.', 'ba', regex=False)
0  bao
1  fuz
2  NaN
dtype: object
```

When repl is a callable, it is called on every pat using re.sub(). The callable should expect one positional argument (a regex object) and return a string.

To get the idea:
Reverse every lowercase alphabetic word:

```python
group(0)[::-1]
```

Using regex groups (extract second group and swap case):

```python
tWO
bar
```

Using a compiled regex with flags

```python
import re
```
pandas.Series.str.rindex

Series.str \texttt{rindex}(sub, start=0, end=None)  
Return highest indexes in each string in Series/Index.  
Each of the returned indexes corresponds to the position where the substring is fully contained between [start:end]. This is the same as \texttt{str.rfind} except instead of returning -1, it raises a ValueError when the substring is not found. Equivalent to standard \texttt{str.index}.

\textbf{Parameters}

\begin{itemize}
  \item \texttt{sub} [str] Substring being searched.
  \item \texttt{start} [int] Left edge index.
  \item \texttt{end} [int] Right edge index.
\end{itemize}

\textbf{Returns}

Series or Index of object

\textbf{See also:}

\texttt{index} Return lowest indexes in each strings.

pandas.Series.str.rjust

Series.str \texttt{rjust}(width, fillchar=' ')  
Pad left side of strings in the Series/Index.  
Equivalent to \texttt{str.rjust}().

\textbf{Parameters}

\begin{itemize}
  \item \texttt{width} [int] Minimum width of resulting string; additional characters will be filled with \texttt{fillchar}.
  \item \texttt{fillchar} [str] Additional character for filling, default is whitespace.
\end{itemize}

\textbf{Returns}

filled [Series/Index of objects.]

pandas.Series.str.rpartition

Series.str \texttt{rpartition}(sep=' ', expand=True)  
Split the string at the last occurrence of \texttt{sep}.

This method splits the string at the last occurrence of \texttt{sep}, and returns 3 elements containing the part before the separator, the separator itself, and the part after the separator. If the separator is not found, return 3 elements containing two empty strings, followed by the string itself.

\textbf{Parameters}

\begin{itemize}
  \item \texttt{sep} [str, default whitespace] String to split on.
  \item \texttt{expand} [bool, default True] If True, return DataFrame/MultiIndex expanding dimensionality. If False, return Series/Index.
\end{itemize}

\textbf{Returns}

DataFrame/MultiIndex or Series/Index of objects

\textbf{See also:}

\texttt{partition} Split the string at the first occurrence of \texttt{sep}.
Series.str.split  Split strings around given separators.
str.partition  Standard library version.

Examples

```python
>>> s = pd.Series(['Linda van der Berg', 'George Pitt-Rivers'])
>>> s
0  Linda van der Berg
1  George Pitt-Rivers
dtype: object

>>> s.str.partition()
 0  1  2
0  Linda  van der Berg
1  George  Pitt-Rivers

To partition by the last space instead of the first one:

```python
>>> s.str.rpartition()
 0  1  2
0  Linda  van der Berg
1  George  Pitt-Rivers
```

To partition by something different than a space:

```python
>>> s.str.partition('-')
 0  1  2
0  Linda  van der Berg
1  George  Pitt - Rivers
```

To return a Series containing tuples instead of a DataFrame:

```python
>>> s.str.partition('-', expand=False)
0   (Linda van der Berg, , )
1   (George Pitt, -, Rivers)
dtype: object
```

Also available on indices:

```python
>>> idx = pd.Index(['X 123', 'Y 999'])
>>> idx
Index(['X 123', 'Y 999'], dtype='object')
```

Which will create a MultiIndex:

```python
>>> idx.str.partition()
MultiIndex([('X', ' ', '123'),
             ('Y', ' ', '999')],
            )
```

Or an index with tuples with expand=False:

```python
>>> idx.str.partition(expand=False)
Index([('X', ' ', '123'), ('Y', ' ', '999')], dtype='object')
```
**pandas.Series.str.rstrip**

Series.str**.rstrip**(to_strip=None)

Remove trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from right side. Equivalent to `str.rstrip()`.

**Parameters**

- **to_strip** [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

**Returns**

Series or Index of object

**See also:**

- `Series.str.strip` Remove leading and trailing characters in Series/Index.
- `Series.str.lstrip` Remove leading characters in Series/Index.
- `Series.str.rstrip` Remove trailing characters in Series/Index.

**Examples**

```python
>>> s = pd.Series(['1. Ant. ', '2. Bee!\n', '3. Cat?\t', np.nan])
>>> s
0   1. Ant.
1  2. Bee!\n
2   3. Cat?\t
3  NaN
dtype: object

>>> s.str.strip()
0   1. Ant.
1  2. Bee!

2   3. Cat
3  NaN
dtype: object

>>> s.str.lstrip('123.\n\t')
0    Ant.
1  Bee!\n
2   Cat?\t
3   NaN
dtype: object

>>> s.str.rstrip('.!\n\t')
0   1. Ant
1   2. Bee

2   3. Cat
3   NaN
dtype: object

>>> s.str.strip('123.?!\n\t')
0   Ant
```

(continues on next page)
1 Bee
2 Cat
3 NaN
dtype: object

**pandas.Series.str.slice**

Series.str.slice\( (\text{start}=\text{None}, \text{stop}=\text{None}, \text{step}=\text{None}) \)
Slice substrings from each element in the Series or Index.

**Parameters**

- **start** [int, optional] Start position for slice operation.
- **stop** [int, optional] Stop position for slice operation.
- **step** [int, optional] Step size for slice operation.

**Returns**

Series or Index of object Series or Index from sliced substring from original string object.

**See also:**

- **Series.str.slice_replace** Replace a slice with a string.
- **Series.str.get** Return element at position. Equivalent to Series.str.slice\( (\text{start}=i, \text{stop}=i+1) \) with \( i \) being the position.

**Examples**

```python
>>> s = pd.Series(['koala', 'dog', 'chameleon'])
>>> s
0    koala
1      dog
2  chameleon
dtype: object

>>> s.str.slice(start=1)
0    oala
1      og
2  hameleon
dtype: object

>>> s.str.slice(start=-1)
0     a
1    g
2   n
dtype: object

>>> s.str.slice(stop=2)
0    ko
1    do
2    ch
dtype: object
```
```python
>>> s.str.slice(step=2)
0    kaa
1     dg
2   caeen
dtype: object
```

```python
>>> s.str.slice(start=0, stop=5, step=3)
0     kl
1      d
2    cm
dtype: object
```

Equivalent behaviour to:

```python
>>> s.str[0:5:3]
0     kl
1      d
2    cm
dtype: object
```

**pandas.Series.str.slice_replace**

Series.str.slice_replace \(start=None, stop=None, repl=None\)

Replace a positional slice of a string with another value.

**Parameters**

- **start** [int, optional] Left index position to use for the slice. If not specified (None), the slice is unbounded on the left, i.e. slice from the start of the string.
- **stop** [int, optional] Right index position to use for the slice. If not specified (None), the slice is unbounded on the right, i.e. slice until the end of the string.
- **repl** [str, optional] String for replacement. If not specified (None), the sliced region is replaced with an empty string.

**Returns**

Series or Index  Same type as the original object.

**See also:**

*Series.str.slice* Just slicing without replacement.

**Examples**

```python
>>> s = pd.Series(['a', 'ab', 'abc', 'abdc', 'abcde'])
>>> s
0    a
1   ab
2   abc
3  abdc
4  abcde
dtype: object
```

Specify just start, meaning replace start until the end of the string with repl.

3.3. Series
>>> s.str.slice_replace(1, repl='X')
0  aX
1  aX
2  aX
3  aX
4  aX
dtype: object

Specify just `stop`, meaning the start of the string to `stop` is replaced with `repl`, and the rest of the string is included.

>>> s.str.slice_replace(stop=2, repl='X')
0  X
1  X
2  Xc
3  Xdc
4  Xcde
dtype: object

Specify `start` and `stop`, meaning the slice from `start` to `stop` is replaced with `repl`. Everything before or after `start` and `stop` is included as is.

>>> s.str.slice_replace(start=1, stop=3, repl='X')
0  aX
1  aX
2  aX
3  aXc
4  aXde
dtype: object

**pandas.Series.str.split**

`Series.str.split(pat=None, n=-1, expand=False)`

Split strings around given separator/delimiter.

Splits the string in the Series/Index from the beginning, at the specified delimiter string. Equivalent to `str.split()`.

**Parameters**

- `pat` [str, optional] String or regular expression to split on. If not specified, split on whitespace.
- `n` [int, default -1 (all)] Limit number of splits in output. None, 0 and -1 will be interpreted as return all splits.
- `expand` [bool, default False] Expand the split strings into separate columns.
  - If `True`, return DataFrame/MultiIndex expanding dimensionality.
  - If `False`, return Series/Index, containing lists of strings.

**Returns**

- `Series, Index, DataFrame or MultiIndex` Type matches caller unless `expand=True` (see Notes).

**See also:**

- `Series.str.split` Split strings around given separator/delimiter.
- `Series.str.rsplit` Splits string around given separator/delimiter, starting from the right.
- `Series.str.join` Join lists contained as elements in the Series/Index with passed delimiter.
**str.split**  Standard library version for split.
**str.rsplit**  Standard library version for rsplit.

**Notes**

The handling of the \( n \) keyword depends on the number of found splits:
- If found splits > \( n \), make first \( n \) splits only
- If found splits \( \leq n \), make all splits
- If for a certain row the number of found splits < \( n \), append None for padding up to \( n \) if expand=True

If using expand=True, Series and Index callers return DataFrame and MultiIndex objects, respectively.

**Examples**

```python
>>> s = pd.Series([
...     "this is a regular sentence",
...     "https://docs.python.org/3/tutorial/index.html",
...     np.nan
... ]
... )
>>> s
0 this is a regular sentence
1 https://docs.python.org/3/tutorial/index.html
2 NaN
dtype: object

In the default setting, the string is split by whitespace.

```python
>>> s.str.split()
0 [this, is, a, regular, sentence]
1 [https://docs.python.org/3/tutorial/index.html]
2 NaN
dtype: object
```

Without the \( n \) parameter, the outputs of rsplit and split are identical.

```python
>>> s.str.rsplit()
0 [this, is, a, regular, sentence]
1 [https://docs.python.org/3/tutorial/index.html]
2 NaN
dtype: object
```

The \( n \) parameter can be used to limit the number of splits on the delimiter. The outputs of split and rsplit are different.

```python
>>> s.str.split(n=2)
0 [this, is, a regular sentence]
1 [https://docs.python.org/3/tutorial/index.html]
2 NaN
dtype: object

>>> s.str.rsplit(n=2)
0 [this is a, regular, sentence]
1 [https://docs.python.org/3/tutorial/index.html]
```

(continues on next page)
The `pat` parameter can be used to split by other characters.

```python
>>> s.str.split(pat="/\")
0   [this is a regular sentence]
1   [https:, , docs.python.org, 3, tutorial, index...
2       NaN
dtype: object
```

When using `expand=True`, the split elements will expand out into separate columns. If NaN is present, it is propagated throughout the columns during the split.

```python
>>> s.str.split(expand=True)
```

For slightly more complex use cases like splitting the html document name from a url, a combination of parameter settings can be used.

```python
>>> s.str.rsplit("/\", n=1, expand=True)
```

Remember to escape special characters when explicitly using regular expressions.

```python
>>> s = pd.Series(["1+1=2"])
>>> s
0 1+1=2
dtype: object
```

```python
>>> s.str.split(r"\+|=", expand=True)
```

---

**pandas.Series.str.rsplit**

`Series.str.rsplit (pat=None, n=-1, expand=False)`

Splits the string in the Series/Index from the end, at the specified delimiter string. Equivalent to `str.rsplit()`.

**Parameters**

- `pat` [str, optional] String or regular expression to split on. If not specified, split on whitespace.
- `n` [int, default -1 (all)] Limit number of splits in output. None, 0 and -1 will be interpreted as return all splits.
- `expand` [bool, default False] Expand the split strings into separate columns.
  - If True, return DataFrame/MultiIndex expanding dimensionality.
• If False, return Series/Index, containing lists of strings.

Returns

Series, Index, DataFrame or MultiIndex  Type matches caller unless expand=True (see Notes).

See also:

Series.str.split  Split strings around given separator/delimiter.
Series.str.rsplit  Splits string around given separator/delimiter, starting from the right.
Series.str.join  Join lists contained as elements in the Series/Index with passed delimiter.
str.split  Standard library version for split.
str.rsplit  Standard library version for rsplit.

Notes

The handling of the \( n \) keyword depends on the number of found splits:

• If found splits > \( n \), make first \( n \) splits only
• If found splits \( \leq n \), make all splits
• If for a certain row the number of found splits < \( n \), append None for padding up to \( n \) if expand=True

If using expand=True, Series and Index callers return DataFrame and MultiIndex objects, respectively.

Examples

```python
>>> s = pd.Series(
...     [  
...         "this is a regular sentence",
...         "https://docs.python.org/3/tutorial/index.html",
...         np.nan
...     ]
... )
```

In the default setting, the string is split by whitespace.

```python
>>> s.str.split()
0       [this, is, a, regular, sentence]
1       [https://docs.python.org/3/tutorial/index.html]
2          NaN
```

Without the \( n \) parameter, the outputs of rsplit and split are identical.

```python
>>> s.str.rsplit()
0       [this, is, a, regular, sentence]
1       [https://docs.python.org/3/tutorial/index.html]
2          NaN
```

The \( n \) parameter can be used to limit the number of splits on the delimiter. The outputs of split and rsplit are different.
The `pat` parameter can be used to split by other characters.

When using `expand=True`, the split elements will expand out into separate columns. If NaN is present, it is propagated throughout the columns during the split.

For slightly more complex use cases like splitting the html document name from a url, a combination of parameter settings can be used.

Remember to escape special characters when explicitly using regular expressions.
pandas.Series.str.startswith

Series.str.startwith(pat, na=None)
Test if the start of each string element matches a pattern.

Equivalent to str.startswith().

Parameters
- **pat** [str] Character sequence. Regular expressions are not accepted.
- **na** [object, default NaN] Object shown if element tested is not a string. The default depends on dtype of the array. For object-dtype, numpy.nan is used. For StringDtype, pandas.NA is used.

Returns
- **Series or Index of bool** A Series of booleans indicating whether the given pattern matches the start of each string element.

See also:
- **str.startswith** Python standard library string method.
- **Series.str.endswith** Same as startswith, but tests the end of string.
- **Series.str.contains** Tests if string element contains a pattern.

Examples

```python
>>> s = pd.Series(['bat', 'Bear', 'cat', np.nan])
>>> s
0    bat
1    Bear
2     cat
3     NaN
dtype: object

>>> s.str.startswith('b')
0   True
1   False
2   False
3    NaN
dtype: object

Specifying na to be False instead of NaN.

>>> s.str.startswith('b', na=False)
0   False
1   False
2   False
3   False
dtype: bool
```
pandas.Series.str.strip

Series.str.strip(to_strip=None)

Remove leading and trailing characters.

Strip whitespaces (including newlines) or a set of specified characters from each string in the Series/Index from left and right sides. Equivalent to str.strip().

Parameters

- to_strip [str or None, default None] Specifying the set of characters to be removed. All combinations of this set of characters will be stripped. If None then whitespaces are removed.

Returns

Series or Index of object

See also:

Series.str.strip Remove leading and trailing characters in Series/Index.
Series.str.lstrip Remove leading characters in Series/Index.
Series.str.rstrip Remove trailing characters in Series/Index.

Examples

```python
>>> s = pd.Series(['1. Ant. ', '2. Bee!
', '3. Cat?	', np.nan])

>>> s
0 1. Ant. 
1 2. Bee!

2 3. Cat?
3 NaN

dtype: object

>>> s.str.strip()
0 1. Ant. 
1 2. Bee!

2 3. Cat?
3 NaN

dtype: object

>>> s.str.lstrip('123.')
0 Ant. 
1 Bee!

2 Cat?
3 NaN

dtype: object

>>> s.str.rstrip('.!? 
	')
0 1. Ant
1 2. Bee

2 3. Cat
3 NaN

dtype: object

>>> s.str.strip('123.!? 
	')
0 Ant
```

(continues on next page)
pandas.Series.str.swapcase

Series.str.swapcase()
Convert strings in the Series/Index to be swapcased.

Equivalent to str.swapcase().

Returns
Series or Index of object

See also:
Series.str.lower Converts all characters to lowercase.
Series.str.upper Converts all characters to uppercase.
Series.str.title Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold Removes all case distinctions in the string.

Examples

>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])

>>> s
0    lower
1  CAPITALS
2   this is a sentence
3   SwApCaSe
dtype: object

>>> s.str.lower()
0    lower
1  capitals
2    this is a sentence
3   swapcase
dtype: object

>>> s.str.upper()
0     LOWER
1  CAPITALS
2  THIS IS A SENTENCE
3    SWAPCASE
dtype: object

>>> s.str.title()
0    Lower
1  Capitals
2  This Is A Sentence
3    Swapcase
dtype: object
pandas.Series.str.title

Series.str.title()  
Convert strings in the Series/Index to titlecase.

Equivalent to str.title().

Returns

Series or Index of object

See also:

Series.str.lower  Converts all characters to lowercase.
Series.str.upper  Converts all characters to uppercase.
Series.str.title  Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize  Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase  Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold  Removes all case distinctions in the string.

Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
```
```python
>>> s
0     lower
1   CAPITALS
2   this is a sentence
3      SwApCaSe
dtype: object
```
```python
>>> s.str.lower()
0     lower
1   capitals
2   this is a sentence
3      swapcase
dtype: object
```
```python
>>> s.str.upper()
0     LOWER
1   CAPITALS
2   THIS IS A SENTENCE
3      sWaPcAsE
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
>>> s.str.title()
0     Lower
1   Capitals
2 This Is A Sentence
3    Swapcase
dtype: object
```

```python
>>> s.str.capitalize()
0     Lower
1   Capitals
2    This is a sentence
3    Swapcase
dtype: object
```

```python
>>> s.str.swapcase()
0    LOWER
1  capitals
2   THIS IS A SENTENCE
3    sWaPcAsE
dtype: object
```

**pandas.Series.str.translate**

Series.str.**translate**(table)
Map all characters in the string through the given mapping table.
Equivalent to standard **str.translate()**.

**Parameters**
- **table** [dict] Table is a mapping of Unicode ordinals to Unicode ordinals, strings, or None. Unmapped characters are left untouched. Characters mapped to None are deleted. **str.maketrans()** is a helper function for making translation tables.

**Returns**
Series or Index

**pandas.Series.str.upper**

Series.str.**upper**()
Convert strings in the Series/Index to uppercase.
Equivalent to **str.upper()**.

**Returns**
Series or Index of object

See also:
- **Series.str.lower** Converts all characters to lowercase.
- **Series.str.upper** Converts all characters to uppercase.
- **Series.str.title** Converts first character of each word to uppercase and remaining to lowercase.
Series.str.capitalize Converts first character to uppercase and remaining to lowercase.
Series.str.swapcase Converts uppercase to lowercase and lowercase to uppercase.
Series.str.casefold Removes all case distinctions in the string.

Examples

```python
>>> s = pd.Series(['lower', 'CAPITALS', 'this is a sentence', 'SwApCaSe'])
>>> s
0    lower
1  CAPITALS
2  this is a sentence
3     SwApCaSe
dtype: object

>>> s.str.lower()
0    lower
1   capitals
2  this is a sentence
3     swapcase
dtype: object

>>> s.str.upper()
0    LOWER
1  CAPITALS
2  THIS IS A SENTENCE
3     SWAPCASE
dtype: object

>>> s.str.title()
0      Lower
1    Capitals
2  This Is A Sentence
3   Swapcase
dtype: object

>>> s.str.capitalize()
0    Lower
1   Capitals
2  This is a sentence
3   Swapcase
dtype: object

>>> s.str.swapcase()
0    LOWER
1   capitals
2  THIS IS A SENTENCE
3   sWApCaSe
dtype: object
```
pandas.Series.str.wrap

Series.str.wrap(width, **kwargs)
Wrap strings in Series/Index at specified line width.

This method has the same keyword parameters and defaults as textwrap.TextWrapper.

Parameters

- **width** [int] Maximum line width.
- **expand_tabs** [bool, optional] If True, tab characters will be expanded to spaces (default: True).
- **replace_whitespace** [bool, optional] If True, each whitespace character (as defined by string.whitespace) remaining after tab expansion will be replaced by a single space (default: True).
- **drop_whitespace** [bool, optional] If True, whitespace that, after wrapping, happens to end up at the beginning or end of a line is dropped (default: True).
- **break_long_words** [bool, optional] If True, then words longer than width will be broken in order to ensure that no lines are longer than width. If it is false, long words will not be broken, and some lines may be longer than width (default: True).
- **break_on_hyphens** [bool, optional] If True, wrapping will occur preferably on whitespace and right after hyphens in compound words, as it is customary in English. If false, only whitespaces will be considered as potentially good places for line breaks, but you need to set break_long_words to false if you want truly inseparable words (default: True).

Returns

- Series or Index

Notes

Internally, this method uses a textwrap.TextWrapper instance with default settings. To achieve behavior matching R’s stringr library str_wrap function, use the arguments:
- **expand_tabs** = False
- **replace_whitespace** = True
- **drop_whitespace** = True
- **break_long_words** = False
- **break_on_hyphens** = False

Examples

```python
>>> s = pd.Series(['line to be wrapped', 'another line to be wrapped'])
>>> s.str.wrap(12)

0   line to be\nwrapped
1   another line\nto be\nwrapped
```

dtype: object

3.3. Series 1439
pandas.Series.str.zfill

Series.str.zfill(width)
Pad strings in the Series/Index by prepending ‘0’ characters.

Strings in the Series/Index are padded with ‘0’ characters on the left of the string to reach a total string length \textit{width}. Strings in the Series/Index with length greater or equal to \textit{width} are unchanged.

**Parameters**

- width [int] Minimum length of resulting string; strings with length less than \textit{width} be prepended with ‘0’ characters.

**Returns**

Series/Index of objects.

**See also:**

- Series.str.rjust Fills the left side of strings with an arbitrary character.
- Series.str.ljust Fills the right side of strings with an arbitrary character.
- Series.str.pad Fills the specified sides of strings with an arbitrary character.
- Series.str.center Fills both sides of strings with an arbitrary character.

**Notes**

Differs from \texttt{str.zfill()} which has special handling for ‘+’/-’ in the string.

**Examples**

```python
g = pd.Series(['-1', '1', '1000', 10, np.nan])
g
0   -1  
1    1  
2   1000  
3    10  
4    NaN
```

Note that \texttt{10} and \texttt{NaN} are not strings, therefore they are converted to \texttt{NaN}. The minus sign in ‘-1’ is treated as a regular character and the zero is added to the left of it (\texttt{str.zfill()} would have moved it to the left). \texttt{1000} remains unchanged as it is longer than \textit{width}.

```python
g.str.zfill(3)
0   0-1  
1    001  
2   1000  
3    NaN  
4    NaN  
```

pandas.Series.str.isalnum

Series.str.isalnum()  
Check whether all characters in each string are alphanumeric.  

This is equivalent to running the Python string method `str.isalnum()` for each element of the Series/Index. If a string has zero characters, False is returned for that check.  

Returns  

Series or Index of bool  Series or Index of boolean values with the same length as the original Series/Index.  

See also:  

Series.str.isalpha  Check whether all characters are alphabetic.  
Series.str.isnumeric  Check whether all characters are numeric.  
Series.str.isalnum  Check whether all characters are alphanumeric.  
Series.str.isdigit  Check whether all characters are digits.  
Series.str.isdecimal  Check whether all characters are decimal.  
Series.str.isspace  Check whether all characters are whitespace.  
Series.str.islower  Check whether all characters are lowercase.  
Series.str.isupper  Check whether all characters are uppercase.  
Series.str.istitle  Check whether all characters are titlecase.  

Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool

>>> s1.str.isalnum()
0   True
1   True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
```

(continues on next page)
More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool
```

The `s3.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
1    True
2    False
3    False
dtype: bool
```

The `s3.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
0    True
1    False
```

(continues on next page)
The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0   False
1    True
2   False
3   False
dtype: bool
```

### pandas.Series.str.isalpha

`Series.str.isalpha()` checks whether all characters in each string are alphabetic.

This is equivalent to running the Python string method `str.isalpha()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

- **Series or Index of bool**: Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- `Series.str.isalpha` Check whether all characters are alphabetic.
- `Series.str.isnumeric` Check whether all characters are numeric.
- `Series.str.isalnum` Check whether all characters are alphanumeric.
- `Series.str.isdigit` Check whether all characters are digits.
- `Series.str.isdecimal` Check whether all characters are decimal.
- `Series.str.isspace` Check whether all characters are whitespace.
- `Series.str.islower` Check whether all characters are lowercase.
- `Series.str.isupper` Check whether all characters are uppercase.
- `Series.str.istitle` Check whether all characters are titlecase.
Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```python
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```python
>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```python
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
```

```python
>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '³', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
```

(continues on next page)
The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```python
>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0    False
1    True
2    False
3    False
dtype: bool
```
Series.\texttt{str.isdigit()}  
Check whether all characters in each string are digits.  

This is equivalent to running the Python string method \texttt{str.isdigit()} for each element of the Series/Index.  
If a string has zero characters, \texttt{False} is returned for that check.  

Returns  

\paragraph{Series or Index of bool} Series or Index of boolean values with the same length as the original Series/Index.  

See also:  
\item \texttt{Series.str.isalpha} Check whether all characters are alphabetic.  
\item \texttt{Series.str.isnumeric} Check whether all characters are numeric.  
\item \texttt{Series.str.isalnum} Check whether all characters are alphanumeric.  
\item \texttt{Series.str.isdigit} Check whether all characters are digits.  
\item \texttt{Series.str.isdecimal} Check whether all characters are decimal.  
\item \texttt{Series.str.isspace} Check whether all characters are whitespace.  
\item \texttt{Series.str.islower} Check whether all characters are lowercase.  
\item \texttt{Series.str.isupper} Check whether all characters are uppercase.  
\item \texttt{Series.str.istitle} Check whether all characters are titlecase.  

Examples  

Checks for Alphabetic and Numeric Characters

\begin{verbatim}
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0   True
1  False
2  False
3  False
dtype: bool

>>> s1.str.isnumeric()
0  False
1  False
2   True
3  False
dtype: bool

>>> s1.str.isalnum()
0   True
1   True
2   True
3  False
dtype: bool
\end{verbatim}

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

\begin{verbatim}
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()

>>> s5.str.islower()
0    True
1    False
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.1

The `s5.str.isupper` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.isupper()
0   False
1   False
2    True
3   False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0   False
1    True
2   False
3   False
dtype: bool
```

**pandas.Series.str.isspace**

`Series.str.isspace()` checks whether all characters in each string are whitespace.

This is equivalent to running the Python string method `str.isspace()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

- **Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- `Series.str.isalpha` Check whether all characters are alphabetic.
- `Series.str.isnumeric` Check whether all characters are numeric.
- `Series.str.isalnum` Check whether all characters are alphanumeric.
- `Series.str.isdigit` Check whether all characters are digits.
- `Series.str.isdecimal` Check whether all characters are decimal.
- `Series.str.isspace` Check whether all characters are whitespace.
- `Series.str.islower` Check whether all characters are lowercase.
- `Series.str.isupper` Check whether all characters are uppercase.
- `Series.str.istitle` Check whether all characters are titlecase.
Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool

>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
```
The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

### Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '
	\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

### Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```python
>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0    False
1    True
2    False
3    False
dtype: bool
```
pandas.Series.str.islower

Series.str.islower()
Check whether all characters in each string are lowercase.

This is equivalent to running the Python string method `str.islower()` for each element of the Series/Index. If a string has zero characters, False is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.

Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool

>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
0  False
1  False
2  False
(continues on next page)
```
More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0   True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0   True
1   True
2   False
3   False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0   True
1   True
2   True
3   False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\r\n', ''])
```

```python
>>> s4.str.isspace()
0   True
1   True
2   False
dtype: bool
```

Checks for Character Case

```python

```

```python
>>> s5.str.islower()
0   True
1   False
```

(continues on next page)
The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```
>>> s5.str.istitle()
0   False
1    True
2   False
3   False
dtype: bool
```

### pandas.Series.str.isupper

`pandas.Series.str.isupper()` checks if all characters in each string are uppercase.

- **Check** whether all characters in each string are uppercase.
- **This** is equivalent to running the Python string method `str.isupper()` for each element of the Series/Index.
- If a string has zero characters, `False` is returned for that check.

#### Returns

- **Series or Index of bool** Series or Index of boolean values with the same length as the original Series/Index.

#### See also:

- `Series.str.isalpha` Check whether all characters are alphabetic.
- `Series.str.isnumeric` Check whether all characters are numeric.
- `Series.str.isalnum` Check whether all characters are alphanumeric.
- `Series.str.isdigit` Check whether all characters are digits.
- `Series.str.isdecimal` Check whether all characters are decimal.
- `Series.str.isspace` Check whether all characters are whitespace.
- `Series.str.islower` Check whether all characters are lowercase.
- `Series.str.isupper` Check whether all characters are uppercase.
- `Series.str.istitle` Check whether all characters are titlecase.
Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])

>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool

>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])

>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
1   False
2   False
3   False
```

(continues on next page)
The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\n', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```python
>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0    False
1    True
2    False
3    False
dtype: bool
```
pandas.Series.str.istitle

Series.str.istitle()

Check whether all characters in each string are titlecase.

This is equivalent to running the Python string method `str.istitle()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

**Returns**

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

**See also:**

- `Series.str.isalpha` Check whether all characters are alphabetic.
- `Series.str.isnumeric` Check whether all characters are numeric.
- `Series.str.isalnum` Check whether all characters are alphanumeric.
- `Series.str.isdigit` Check whether all characters are digits.
- `Series.str.isdecimal` Check whether all characters are decimal.
- `Series.str.isspace` Check whether all characters are whitespace.
- `Series.str.islower` Check whether all characters are lowercase.
- `Series.str.isupper` Check whether all characters are uppercase.
- `Series.str.istitle` Check whether all characters are titlecase.

**Examples**

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```python
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool
```

```python
>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool
```

```python
>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
```

```python
>>> s2.str.isalnum()
(continues on next page)```
More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
1    True
2    False
3    False
dtype: bool
```

The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\r\n ', ''])

>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

Checks for Character Case

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])

>>> s5.str.islower()
0    True
1    False
dtype: bool
```

(continues on next page)
The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0    False
1     True
2    False
3    False
dtype: bool
```

**pandas.Series.str.isnumeric**

`Series.str.isnumeric()`  
Check whether all characters in each string are numeric.

This is equivalent to running the Python string method `str.isnumeric()` for each element of the `Series/Index`. If a string has zero characters, `False` is returned for that check.

**Returns**

Series or Index of bool  
Series or Index of boolean values with the same length as the original `Series/Index`.

**See also:**

- `Series.str.isalpha`  
  Check whether all characters are alphabetic.
- `Series.str.isnumeric`  
  Check whether all characters are numeric.
- `Series.str.isalnum`  
  Check whether all characters are alphanumeric.
- `Series.str.isdigit`  
  Check whether all characters are digits.
- `Series.str.isdecimal`  
  Check whether all characters are decimal.
- `Series.str.isspace`  
  Check whether all characters are whitespace.
- `Series.str.islower`  
  Check whether all characters are lowercase.
- `Series.str.isupper`  
  Check whether all characters are uppercase.
- `Series.str.istitle`  
  Check whether all characters are titlecase.
Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])
```

```python
>>> s1.str.isalpha()
0   True
1   False
2   False
3   False
dtype: bool
```

```python
>>> s1.str.isnumeric()
0   False
1   False
2   True
3   False
dtype: bool
```

```python
>>> s1.str.isalnum()
0   True
1   True
2   True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
```

```python
>>> s2.str.isalnum()
0   False
1   False
2   False
dtype: bool
```

More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '³', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0   True
1   False
2   False
3   False
dtype: bool
```

The `s.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0   True
```

(continues on next page)
The `s.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

**Checks for Whitespace**

```python
>>> s4 = pd.Series([' ', '	\n', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

**Checks for Character Case**

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
0    True
1    False
2    False
3    False
dtype: bool
```

```python
>>> s5.str.isupper()
0    False
1    False
2    True
3    False
dtype: bool
```

The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0    False
1    True
2    False
3    False
dtype: bool
```
pandas.Series.str.isdecimal

Series.str.isdecimal()
Check whether all characters in each string are decimal.

This is equivalent to running the Python string method `str.isdecimal()` for each element of the Series/Index. If a string has zero characters, `False` is returned for that check.

Returns

Series or Index of bool Series or Index of boolean values with the same length as the original Series/Index.

See also:

Series.str.isalpha Check whether all characters are alphabetic.
Series.str.isnumeric Check whether all characters are numeric.
Series.str.isalnum Check whether all characters are alphanumeric.
Series.str.isdigit Check whether all characters are digits.
Series.str.isdecimal Check whether all characters are decimal.
Series.str.isspace Check whether all characters are whitespace.
Series.str.islower Check whether all characters are lowercase.
Series.str.isupper Check whether all characters are uppercase.
Series.str.istitle Check whether all characters are titlecase.

Examples

Checks for Alphabetic and Numeric Characters

```python
>>> s1 = pd.Series(['one', 'one1', '1', ''])
>>> s1.str.isalpha()
0    True
1   False
2   False
3   False
dtype: bool

>>> s1.str.isnumeric()
0   False
1   False
2    True
3   False
dtype: bool

>>> s1.str.isalnum()
0    True
1    True
2    True
3   False
dtype: bool
```

Note that checks against characters mixed with any additional punctuation or whitespace will evaluate to false for an alphanumeric check.

```python
>>> s2 = pd.Series(['A B', '1.5', '3,000'])
>>> s2.str.isalnum()
```

(continues on next page)
More Detailed Checks for Numeric Characters

There are several different but overlapping sets of numeric characters that can be checked for.

```python
>>> s3 = pd.Series(['23', '3', '', ''])
```

The `s3.str.isdecimal` method checks for characters used to form numbers in base 10.

```python
>>> s3.str.isdecimal()
0    True
1    False
2    False
3    False
dtype: bool
```

The `s3.str.isdigit` method is the same as `s3.str.isdecimal` but also includes special digits, like superscripted and subscripted digits in unicode.

```python
>>> s3.str.isdigit()
0    True
1    True
2    False
3    False
dtype: bool
```

The `s3.str.isnumeric` method is the same as `s3.str.isdigit` but also includes other characters that can represent quantities such as unicode fractions.

```python
>>> s3.str.isnumeric()
0    True
1    True
2    True
3    False
dtype: bool
```

Checks for Whitespace

```python
>>> s4 = pd.Series([' ', '	\r\n ', ''])
>>> s4.str.isspace()
0    True
1    True
2    False
dtype: bool
```

```python
>>> s5 = pd.Series(['leopard', 'Golden Eagle', 'SNAKE', ''])
>>> s5.str.islower()
0    True
1    False
```

(continues on next page)
The `s5.str.istitle` method checks for whether all words are in title case (whether only the first letter of each word is capitalized). Words are assumed to be as any sequence of non-numeric characters separated by whitespace characters.

```python
>>> s5.str.istitle()
0   False
1    True
2   False
3   False
dtype: bool
```

### pandas.Series.str.get_dummies

`Series.str.get_dummies(sep=|)`

Return DataFrame of dummy/indicator variables for Series.

Each string in Series is split by `sep` and returned as a DataFrame of dummy/indicator variables.

**Parameters**

- `sep` [str, default “|”] String to split on.

**Returns**

- `DataFrame` Dummy variables corresponding to values of the Series.

**See also:**

- `get_dummies` Convert categorical variable into dummy/indicator variables.

**Examples**

```python
>>> pd.Series(['a|b', 'a', 'a|c']).str.get_dummies()
d   a  b  c
0 1   1  0
1 1   0  0
2 1   0  1

>>> pd.Series(['a|b', np.nan, 'a|c']).str.get_dummies()
d   a  b  c
0 1   1  0
1 0   0  0
2 1   0  1
```
Categorical accessor

Categorical-dtype specific methods and attributes are available under the `Series.cat` accessor.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.cat.categories</code></td>
<td>The categories of this categorical.</td>
</tr>
<tr>
<td><code>Series.cat.ordered</code></td>
<td>Whether the categories have an ordered relationship.</td>
</tr>
<tr>
<td><code>Series.cat.codes</code></td>
<td>Return Series of codes as well as the index.</td>
</tr>
</tbody>
</table>

**pandas.Series.cat.categories**

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to `categories` is an inplace operation!

**Raises**

ValueError If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

**See also:**

- `rename_categories` Rename categories.
- `reorder_categories` Reorder categories.
- `add_categories` Add new categories.
- `remove_categories` Remove the specified categories.
- `remove_unused_categories` Remove categories which are not used.
- `set_categories` Set the categories to the specified ones.

**pandas.Series.cat.ordered**

Whether the categories have an ordered relationship.

**pandas.Series.cat.codes**

Return Series of codes as well as the index.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Series.cat.rename_categories</code></td>
<td>Rename categories.</td>
</tr>
<tr>
<td><code>Series.cat.reorder_categories</code></td>
<td>Reorder categories as specified in <code>new_categories</code>.</td>
</tr>
<tr>
<td><code>Series.cat.add_categories</code></td>
<td>Add new categories.</td>
</tr>
<tr>
<td><code>Series.cat.remove_categories</code></td>
<td>Remove the specified categories.</td>
</tr>
<tr>
<td><code>Series.cat.remove_unused_categories</code></td>
<td>Remove categories which are not used.</td>
</tr>
</tbody>
</table>

continues on next page
Series.cat.set_categories(*args, **kwargs) Set the categories to the specified new_categories.

Series.cat.as_ordered(*args, **kwargs) Set the Categorical to be ordered.

Series.cat.as_unordered(*args, **kwargs) Set the Categorical to be unordered.

### pandas.Series.cat.rename_categories

Series.cat.rename_categories(*args, **kwargs)

Rename categories.

**Parameters**

- **new_categories** [list-like, dict-like or callable] New categories which will replace old categories.
  
  - list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
  
  - dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.

  - callable: a callable that is called on all items in the old categories and whose return values comprise the new categories.

- **inplace** [bool, default False] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

  Deprecated since version 1.3.0.

**Returns**

- **cat** [Categorical or None] Categorical with removed categories or None if inplace=True.

**Raises**

- **ValueError** If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories.

**See also:**

- reorder_categories Reorder categories.
- add_categories Add new categories.
- remove_categories Remove the specified categories.
- remove_unused_categories Remove categories which are not used.
- set_categories Set the categories to the specified ones.

### Examples

```python
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like new_categories, extra keys are ignored and categories not in the dictionary are passed through

```python
>>> c.rename_categories({'a': 'A', 'c': 'C'})
['A', 'A', 'b']
Categories (2, object): ['A', 'b']
```

You may also provide a callable to create the new categories
```python
>>> c.rename_categories(lambda x: x.upper())
['A', 'A', 'B']
Categories (2, object): ['A', 'B']
```

**pandas.Series.cat.reorder_categories**

Series.cat.reorder_categories(*args, **kwargs)
Reorder categories as specified in new_categories.

new_categories need to include all old categories and no new category items.

Parameters

- **new_categories** [Index-like] The categories in new order.
- **ordered** [bool, optional] Whether or not the categorical is treated as a ordered categorical.
  If not given, do not change the ordered information.
- **inplace** [bool, default False] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

Returns

- **cat** [Categorical or None] Categorical with removed categories or None if inplace=True.

Raises

- **ValueError** If the new categories do not contain all old category items or any new ones

See also:

- rename_categories Rename categories.
- add_categories Add new categories.
- remove_categories Remove the specified categories.
- remove_unused_categories Remove categories which are not used.
- set_categories Set the categories to the specified ones.

**pandas.Series.cat.add_categories**

Series.cat.add_categories(*args, **kwargs)
Add new categories.

new_categories will be included at the last/highest place in the categories and will be unused directly after this call.

Parameters

- **new_categories** [category or list-like of category] The new categories to be included.
- **inplace** [bool, default False] Whether or not to add the categories inplace or return a copy of this categorical with added categories.

Returns

- **cat** [Categorical or None] Categorical with new categories added or None if inplace=True.

Raises
ValueError  If the new categories include old categories or do not validate as categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

pandas.Series.cat.remove_categories

Series.cat.remove_categories(*args, **kwargs)
Remove the specified categories.

removals must be included in the old categories. Values which were in the removed categories will be set to NaN

Parameters

removals [category or list of categories] The categories which should be removed.

inplace [bool, default False] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

Deprecated since version 1.3.0.

Returns

cat [Categorical or None] Categorical with removed categories or None if inplace=True.

Raises

ValueError  If the removals are not contained in the categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

pandas.Series.cat.remove_unused_categories

Series.cat.remove_unused_categories(*args, **kwargs)
Remove categories which are not used.

Parameters

inplace [bool, default False] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.

Deprecated since version 1.2.0.

Returns

cat [Categorical or None] Categorical with unused categories dropped or None if inplace=True.

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
set_categories Set the categories to the specified ones.

pandas.Series.cat.set_categories

Series.cat.set_categories(*args, **kwargs)
Set the categories to the specified new_categories.

new_categories can include new categories (which will result in unused categories) or remove old categories (which results in values set to NaN). If rename==True, the categories will simple be renamed (less or more items than in old categories will result in values set to NaN or in unused categories respectively).

This method can be used to perform more than one action of adding, removing, and reordering simultaneously and is therefore faster than performing the individual steps via the more specialised methods.

On the other hand this methods does not do checks (e.g., whether the old categories are included in the new categories on a reorder), which can result in surprising changes, for example when using special string dtypes, which does not considers a S1 string equal to a single char python string.

Parameters

- **new_categories** [Index-like] The categories in new order.
- **ordered** [bool, default False] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.
- **rename** [bool, default False] Whether or not the new_categories should be considered as a rename of the old categories or as reordered categories.
- **inplace** [bool, default False] Whether or not to reorder the categories in-place or return a copy of this categorical with reordered categories.

Returns

Categorical with reordered categories or None if inplace.

Raises

- **ValueError** If new_categories does not validate as categories

See also:
- rename_categories Rename categories.
- reorder_categories Reorder categories.
- add_categories Add new categories.
- remove_categories Remove the specified categories.
- remove_unused_categories Remove categories which are not used.
**pandas.Series.cat.as_ordered**

```
Series.cat.as_ordered(*args, **kwargs)
Set the Categorical to be ordered.

Parameters

    inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a
copy of this categorical with ordered set to True.

Returns

    Categorical or None Ordered Categorical or None if inplace=True.
```

**pandas.Series.cat.as_unordered**

```
Series.cat.as_unordered(*args, **kwargs)
Set the Categorical to be unordered.

Parameters

    inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a
copy of this categorical with ordered set to False.

Returns

    Categorical or None Unordered Categorical or None if inplace=True.
```

**Sparse accessor**

Sparse-dtype specific methods and attributes are provided under the `Series.sparse` accessor.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.sparse.npoints</td>
<td>The number of non-fill_value points.</td>
</tr>
<tr>
<td>Series.sparse.density</td>
<td>The percent of non-fill_value points, as decimal.</td>
</tr>
<tr>
<td>Series.sparse.fill_value</td>
<td>Elements in data that are fill_value are not stored.</td>
</tr>
<tr>
<td>Series.sparse.sp_values</td>
<td>An ndarray containing the non-fill_value values.</td>
</tr>
</tbody>
</table>

**pandas.Series.sparse.npoints**

```
Series.sparse.npoints
The number of non-fill_value points.
```

3.3. Series
Examples

```python
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.npoints
3
```

**pandas.Series.sparse.density**

Series.sparse.density
The percent of non-fill_value points, as decimal.

Examples

```python
>>> s = SparseArray([0, 0, 1, 1, 1], fill_value=0)
>>> s.density
0.6
```

**pandas.Series.sparse.fill_value**

Series.sparse.fill_value
Elements in data that are fill_value are not stored.
For memory savings, this should be the most common value in the array.

**pandas.Series.sparse.sp_values**

Series.sparse.sp_values
An ndarray containing the non-fill_value values.

Examples

```python
>>> s = SparseArray([0, 0, 1, 0, 2], fill_value=0)
>>> s.sp_values
array([1, 2])
```

| **Series.sparse.from_coo** *(A[, dense_index])* | Create a Series with sparse values from a scipy.sparse.coo_matrix. |
| **Series.sparse.to_coo** *(row_levels, …)* | Create a scipy.sparse.coo_matrix from a Series with MultiIndex. |
pandas.Series.sparse.from_coo

classmethod Series.sparse.from_coo(A, dense_index=False)
Create a Series with sparse values from a scipy.sparse.coo_matrix.

Parameters

- A [scipy.sparse.coo_matrix]
- dense_index [bool, default False] If False (default), the SparseSeries index consists of only the coords of the non-null entries of the original coo_matrix. If True, the SparseSeries index consists of the full sorted (row, col) coordinates of the coo_matrix.

Returns

- s [Series] A Series with sparse values.

Examples

```python
>>> from scipy import sparse

>>> A = sparse.coo_matrix([[3.0, 1.0, 2.0], [0, 2, 3]], shape=(3, 4))

>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>

>>> A.todense()
matrix([[0., 0., 1., 2.],
        [3., 0., 0., 0.],
        [0., 0., 0., 0.]])

>>> ss = pd.Series.sparse.from_coo(A)
>>> ss
0 2 1.0
3 2.0
1 0 3.0
dtype: Sparse[float64, nan]
```

pandas.Series.sparse.to_coo

Series.sparse.to_coo(row_levels=(0), column_levels=(1), sort_labels=False)
Create a scipy.sparse.coo_matrix from a Series with MultiIndex.

Use row_levels and column_levels to determine the row and column coordinates respectively. row_levels and column_levels are the names (labels) or numbers of the levels. {row_levels, column_levels} must be a partition of the MultiIndex level names (or numbers).

Parameters

- row_levels [tuple/list]
- column_levels [tuple/list]
- sort_labels [bool, default False] Sort the row and column labels before forming the sparse matrix.
**Returns**

- `y` [scipy.sparse.coo_matrix]
- `rows` [list (row labels)]
- `columns` [list (column labels)]

**Examples**

```python
code_snippet1
>>> s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
>>> s.index = pd.MultiIndex.from_tuples(
...   [(1, 2, "a", 0),
...    (1, 2, "a", 1),
...    (1, 1, "b", 0),
...    (1, 1, "b", 1),
...    (2, 1, "b", 0),
...    (2, 1, "b", 1)],
...   names=["A", "B", "C", "D"],
...)
>>> s
A  B  C  D
1  2  a  0  3.0
    1  NaN
1  b  0  1.0
    1  3.0
2  1  b  0  NaN
    1  NaN
dtype: float64
```

```python
code_snippet2
>>> ss = s.astype("Sparse")
>>> ss
A  B  C  D
1  2  a  0  3.0
    1  NaN
1  b  0  1.0
    1  3.0
2  1  b  0  NaN
    1  NaN
dtype: Sparse[float64, nan]
```

```python
code_snippet3
>>> A, rows, columns = ss.sparse.to_coo(
...   row_levels=["A", "B"], column_levels=["C", "D"], sort_labels=True
...)
>>> A
<3x4 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>
>>> A.todense()
matrix([[0., 0., 1., 3.],
 [3., 0., 0., 0.],
 [0., 0., 0., 0.],
[0., 0., 0., 0.]], dtype=float64)
```

```python
code_snippet4
>>> rows
[(1, 1), (1, 2), (2, 1)]
```
```
Flags

Flags refer to attributes of the pandas object. Properties of the dataset (like the date it was recorded, the URL it was accessed from, etc.) should be stored in `Series.attrs`.

```python
>>> columns
[('a', 0), ('a', 1), ('b', 0), ('b', 1)]
```

### Flags

```python
Flags(obj, *, allows_duplicate_labels)
```

Flags that apply to pandas objects.

**pandas.Flags**

```python
class pandas.Flags(obj, *, allows_duplicate_labels)
```

Flags that apply to pandas objects.

- **New in version 1.2.0.**

**Parameters**

- `obj` [Series or DataFrame] The object these flags are associated with.
- `allows_duplicate_labels` [bool, default True] Whether to allow duplicate labels in this object. By default, duplicate labels are permitted. Setting this to `False` will cause an `errors.DuplicateLabelError` to be raised when `index` (or columns for DataFrame) is not unique, or any subsequent operation on introduces duplicates. See `Disallowing Duplicate Labels` for more.

**Warning:** This is an experimental feature. Currently, many methods fail to propagate the `allows_duplicate_labels` value. In future versions it is expected that every method taking or returning one or more DataFrame or Series objects will propagate `allows_duplicate_labels`.

#### Notes

Attributes can be set in two ways

```python
>>> df = pd.DataFrame()
>>> df.flags
<Flags(allows_duplicate_labels=True)>
>>> df.flags.allows_duplicate_labels = False
>>> df.flags
<Flags(allows_duplicate_labels=False)>
```

```python
>>> df.flags['allows_duplicate_labels'] = True
>>> df.flags
<Flags(allows_duplicate_labels=True)>
```
Attributes

**allows_duplicate_labels**
Whether this object allows duplicate labels.

**pandas.Flags.allows_duplicate_labels**

**property** Flags.allows_duplicate_labels
Whether this object allows duplicate labels.

Setting `allows_duplicate_labels=False` ensures that the index (and columns of a DataFrame) are unique. Most methods that accept and return a Series or DataFrame will propagate the value of `allows_duplicate_labels`.

See `Duplicate Labels` for more.

See also:

* **DataFrame.attrs** Set global metadata on this object.
* **DataFrame.set_flags** Set global flags on this object.

Examples

```python
>>> df = pd.DataFrame({"A": [1, 2]}, index=['a', 'a'])
```

```
>>> df.allows_duplicate_labels
True
```

```
>>> df.allows_duplicate_labels = False
Traceback (most recent call last):
 ...:
pandas.errors.DuplicateLabelError: Index has duplicates.
positions
label
a   [0, 1]
```

Metadata

**Series.attrs** is a dictionary for storing global metadata for this Series.

**Warning:** Series.attrs is considered experimental and may change without warning.

**Series.attrs**
Dictionary of global attributes of this dataset.
3.3.14 Plotting

Series.plot is both a callable method and a namespace attribute for specific plotting methods of the form Series.plot.<kind>.

```
Series.plot(kind, ax, figsize, . . . .
```

Series.plot.area(x, y) Draw a stacked area plot.
Series.plot.bar(x, y) Vertical bar plot.
Series.plot.barh(x, y) Make a horizontal bar plot.
Series.plot.box(by) Make a box plot of the DataFrame columns.
Series.plot.density(by_method, ind) Generate Kernel Density Estimate plot using Gaussian kernels.
Series.plot.hist(by, bins) Draw one histogram of the DataFrame’s columns.
Series.plot.kde(by_method, ind) Generate Kernel Density Estimate plot using Gaussian kernels.
Series.plot.line(x, y) Plot Series or DataFrame as lines.
Series.plot.pie(**kwargs) Generate a pie plot.

**pandas.Series.plot.area**

Series.plot.area(x=None, y=None, **kwargs)

An area plot displays quantitative data visually. This function wraps the matplotlib area function.

**Parameters**

x [label or position, optional] Coordinates for the X axis. By default uses the index.
y [label or position, optional] Column to plot. By default uses all columns.

stacked [bool, default True] Area plots are stacked by default. Set to False to create a unstacked plot.

**kwargs** Additional keyword arguments are documented in DataFrame.plot().

**Returns**

matplotlib.axes.Axes or numpy.ndarray Area plot, or array of area plots if subplots is True.

See also:

DataFrame.plot Make plots of DataFrame using matplotlib / pylab.

**Examples**

Draw an area plot based on basic business metrics:

```python
>>> df = pd.DataFrame({
...   'sales': [3, 2, 3, 9, 10, 6],
...   'signups': [5, 5, 6, 12, 14, 13],
...   'visits': [20, 42, 28, 62, 81, 50],
... }, index=pd.date_range(start='2018/01/01', end='2018/07/01',
... freq='M'))
>>> ax = df.plot.area()
```
Area plots are stacked by default. To produce an unstacked plot, pass `stacked=False`:

```python
>>> ax = df.plot.area(stacked=False)
```

Draw an area plot for a single column:

```python
>>> ax = df.plot.area(y='sales')
```

Draw with a different `x`:

```python
>>> df = pd.DataFrame(
...     {'sales': [3, 2, 3],
...      'visits': [20, 42, 28],
...      'day': [1, 2, 3],
...     })
>>> ax = df.plot.area(x='day')
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.Series.plot.bar

Series.plot.bar(x=None, y=None, **kwargs)

Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- **color** [str, array-like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:
  - A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
  - A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance [‘green’, ‘yellow’] each column’s bar will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.
  - A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {‘a’: ‘green’, ‘b’: ‘red’} will color bars for column a in green and bars for column b in red.

New in version 1.1.0.

- **kwargs** Additional keyword arguments are documented in DataFrame.plot().

Returns

- matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

- DataFrame.plot.barh Horizontal bar plot.
- DataFrame.plot Make plots of a DataFrame.
- matplotlib.pyplot.bar Make a bar plot with matplotlib.

Examples

Basic plot.

```python
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.
3.3. Series
Plot stacked bar charts for the DataFrame

```python
>>> ax = df.plot.bar(stacked=True)
```

Instead of nesting, the figure can be split by column with `subplots=True`. In this case, a `numpy.ndarray` of `matplotlib.axes.Axes` are returned.

```python
>>> axes = df.plot.bar(rot=0, subplots=True)
>>> axes[1].legend(loc=2)
```

If you don’t like the default colours, you can specify how you’d like each column to be colored.

```python
>>> axes = df.plot.bar(
...     rot=0, subplots=True, color={"speed": "red", "lifespan": "green"}
... )
>>> axes[1].legend(loc=2)
```
3.3. Series
Plot a single column.

```python
>>> ax = df.plot.bar(y='speed', rot=0)
```

![Horizontal bar plot example](image)

Plot only selected categories for the DataFrame.

```python
>>> ax = df.plot.bar(x='lifespan', rot=0)
```

### pandas.Series.plot.barh

**Series.plot.barh**

```python
Series.plot.barh(x=None, y=None, **kwargs)
```

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

**Parameters**

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
color [str, array-like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:

- A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
- A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green','yellow'] each column’s bar will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.
- A dict of the form {column name [color], so that each column will be} colored accordingly. For example, if your columns are called a and b, then passing {‘a’: ‘green’, ‘b’: ‘red’} will color bars for column a in green and bars for column b in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

DataFrame.plot.bar  Vertical bar plot.
DataFrame.plot Make plots of DataFrame using matplotlib.
matplotlib.axes.Axes.bar Plot a vertical bar plot using matplotlib.

Examples

Basic example

```python
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')
```

Plot a whole DataFrame to a horizontal bar plot

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant', ...
'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
```

Plot stacked barh charts for the DataFrame

```python
>>> ax = df.plot.barh(stacked=True)
```

We can specify colors for each column

```python
>>> ax = df.plot.barh(color={"speed": "red", "lifespan": "green"})
```

Plot a column of the DataFrame to a horizontal bar plot
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...           'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                     'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(y='speed')
pandas.Series.plot.box

Series.plot.box(by=None, **kwargs)

Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to 1.5*IQR (IQR = Q3 - Q1) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia’s entry for boxplot.

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

Parameters

by [str or sequence] Column in the DataFrame to group by.

**kwargs Additional keywords are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

DataFrame.boxplot Another method to draw a box plot.
Series.plot.box Draw a box plot from a Series object.
matplotlib.pyplot.boxplot Draw a box plot in matplotlib.

Examples

Draw a box plot from a DataFrame with four columns of randomly generated data.

```python
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```

pandas.Series.plot.density

Series.plot.density(bw_method=None, ind=None, **kwargs)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If None (default), 'scott' is used. See scipy.stats.gaussian_kde for more information.

ind [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.

**kwargs Additional keyword arguments are documented in pandas.%{this-datatype}s.plot().
pandas: powerful Python data analysis toolkit, Release 1.3.1

Chapter 3. API reference
Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

scipy.stats.gaussian_kde  Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

![Graph of a Gaussian KDE estimate](image)

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:
3.3. Series
For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame({
    'x': [1, 2, 2.5, 3, 3.5, 4, 5],
    'y': [4, 4, 4.5, 5, 5.5, 6, 6],
})
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5])
```
**pandas.Series.plot.hist**

Series.plot.hist(by=None, bins=10, **kwargs)

Draw one histogram of the DataFrame’s columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one matplotlib.axes.Axes. This is useful when the DataFrame’s Series are in a similar scale.

**Parameters**

- **by** [str or sequence, optional] Column in the DataFrame to group by.
- **bins** [int, default 10] Number of histogram bins to be used.
- **kwargs** Additional keyword arguments are documented in DataFrame.plot().

**Returns**

- **class:matplotlib.AxesSubplot** Return a histogram plot.

See also:

- **DataFrame.hist** Draw histograms per DataFrame’s Series.
- **Series.hist** Draw a histogram with Series’ data.

**Examples**

When we draw a dice 6000 times, we expect to get each value around 1000 times. But when we draw two dices and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```python
>>> df = pd.DataFrame(
...     np.random.randint(1, 7, 6000),
...     columns = ['one'])
>>> df['two'] = df['one'] + np.random.randint(1, 7, 6000)
>>> ax = df.plot.hist(bins=12, alpha=0.5)
```

**pandas.Series.plot.kde**

Series.plot.kde(bw_method=None, ind=None, **kwargs)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

**Parameters**

- **bw_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See scipy.stats.gaussian_kde for more information.
- **ind** [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.
- **kwargs** Additional keyword arguments are documented in pandas.%{this-datatype}s.plot().

**Returns**
matplotlib.axes.Axes or numpy.ndarray of them

See also:

scipy.stats.gaussian_kde  Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:
For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame(
...     {'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
...     })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5])
```
**Series.plot.line**

Series.plot.**line**(x=None, y=None, **kwargs)

Plot Series or DataFrame as lines.

This function is useful to plot lines using DataFrame’s values as coordinates.

**Parameters**

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- **color** [str, array-like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:
  - A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
  - A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance [‘green’, ‘yellow’] each column’s line will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.
  - A dict of the form {column name: [color]}, so that each column will be colored accordingly. For example, if your columns are called *a* and *b*, then passing {‘a’: ‘green’, ‘b’: ‘red’} will color lines for column *a* in green and lines for column *b* in red.

New in version 1.1.0.

**kwargs** Additional keyword arguments are documented in **Dataframe.plot()**.

**Returns**

**matplotlib.axes.Axes** or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

**See also:**

- **matplotlib.pyplot.plot** Plot y versus x as lines and/or markers.

**Examples**

```python
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()
```

The following example shows the populations for some animals over the years.

```python
>>> df = pd.DataFrame({
...     'pig': [20, 18, 489, 675, 1776],
...     'horse': [4, 25, 281, 600, 1900]
>>> lines = df.plot.line()
```

An example with subplots, so an array of axes is returned.
Let’s repeat the same example, but specifying colors for each column (in this case, for each animal).

```python
>>> axes = df.plot.line(subplots=True)
>>> type(axes)
<class 'numpy.ndarray'>
```

The following example shows the relationship between both populations.

```python
>>> lines = df.plot.line(x='pig', y='horse')
```
**pandas.Series.plot.pie**

Series.plot.pie(**kwargs)
Generate a pie plot.

A pie plot is a proportional representation of the numerical data in a column. This function wraps matplotlib.pyplot.pie() for the specified column. If no column reference is passed and subplots=True a pie plot is drawn for each numerical column independently.

**Parameters**

- y [int or label, optional] Label or position of the column to plot. If not provided, subplots=True argument must be passed.
- **kwargs Keyword arguments to pass on to DataFrame.plot().

**Returns**

- `matplotlib.axes.Axes or np.ndarray of them` A NumPy array is returned when subplots is True.

**See also:**

Series.plot.pie Generate a pie plot for a Series.
DataFrame.plot Make plots of a DataFrame.

**Examples**

In the example below we have a DataFrame with the information about planet’s mass and radius. We pass the ‘mass’ column to the pie function to get a pie plot.

```python
>>> df = pd.DataFrame({'mass': [0.330, 4.87 , 5.97],
...                   'radius': [2439.7, 6051.8, 6378.1]},
...                   index=['Mercury', 'Venus', 'Earth'])
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
```

```python
>>> plot = df.plot.pie(subplots=True, figsize=(11, 6))
```

**Series.hist**([by, ax, grid, xlabelsize, ...]) Draw histogram of the input series using matplotlib.

### 3.3.15 Serialization / IO / conversion

- **Series.to_pickle**(path[, compression, ...]) Pickle (serialize) object to file.
- **Series.to_csv**([path_or_buf, sep, na_rep, ...]) Write object to a comma-separated values (csv) file.
- **Series.to_dict**(into) Convert Series to {label -> value} dict or dict-like object.
- **Series.to_excel**(excel_writer[, sheet_name, ...]) Write object to an Excel sheet.
- **Series.to_frame**(name) Convert Series to DataFrame.
- **Series.to_xarray**() Return an xarray object from the pandas object.
- **Series.to_hdf**(path_or_buf, key[, mode, ...]) Write the contained data to an HDF5 file using HDFStore.
- **Series.to_sql**(name, con[, schema, ...]) Write records stored in a DataFrame to a SQL database.
- **Series.to_json**([path_or_buf, orient, ...]) Convert the object to a JSON string.
- **Series.to_string**([buf, na_rep, ...]) Render a string representation of the Series.

3.4 DataFrame

3.4.1 Constructor

| DataFrame([data, index, columns, dtype, copy]) | Two-dimensional, size-mutable, potentially heterogeneous tabular data. |

pandas.DataFrame

class pandas.DataFrame(data=None, index=None, columns=None, dtype=None, copy=None)

Two-dimensional, size-mutable, potentially heterogeneous tabular data.

Data structure also contains labeled axes (rows and columns). Arithmetic operations align on both row and column labels. Can be thought of as a dict-like container for Series objects. The primary pandas data structure.

Parameters

- **data** [ndarray (structured or homogeneous), Iterable, dict, or DataFrame] Dict can contain Series, arrays, constants, dataclass or list-like objects. If data is a dict, column order follows insertion-order.
  
  Changed in version 0.25.0: If data is a list of dicts, column order follows insertion-order.

- **index** [Index or array-like] Index to use for resulting frame. Will default to RangeIndex if no indexing information part of input data and no index provided.

- **columns** [Index or array-like] Column labels to use for resulting frame when data does not have them, defaulting to RangeIndex(0, 1, 2, ..., n). If data contains column labels, will perform column selection instead.

- **dtype** [dtype, default None] Data type to force. Only a single dtype is allowed. If None, infer.

- **copy** [bool or None, default None] Copy data from inputs. For dict data, the default of None behaves like copy=True. For DataFrame or 2d ndarray input, the default of None behaves like copy=False.
  
  Changed in version 1.3.0.

See also:

- DataFrame.from_records Constructor from tuples, also record arrays.
- DataFrame.from_dict From dicts of Series, arrays, or dicts.
- read_csv Read a comma-separated values (csv) file into DataFrame.
- read_table Read general delimited file into DataFrame.
- read_clipboard Read text from clipboard into DataFrame.
Examples

Constructing DataFrame from a dictionary.

```
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df
col1  col2
0    1    3
1    2    4
```

Notice that the inferred dtype is int64.

```
>>> df.dtypes
col1 int64
col2 int64
dtype: object
```

To enforce a single dtype:

```
>>> df = pd.DataFrame(data=d, dtype=np.int8)
>>> df.dtypes
col1 int8
col2 int8
dtype: object
```

Constructing DataFrame from numpy ndarray:

```
>>> df2 = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]),
                    columns=['a', 'b', 'c'])
>>> df2
 a  b  c
0 1 2 3
1 4 5 6
2 7 8 9
```

Constructing DataFrame from a numpy ndarray that has labeled columns:

```
>>> data = np.array([(1, 2, 3), (4, 5, 6), (7, 8, 9)],
                  dtype=[('a', 'i4'), ('b', 'i4'), ('c', 'i4')])
>>> df3 = pd.DataFrame(data, columns=['c', 'a'])
>>> df3
 c  a
0 3 1
1 6 4
2 9 7
```

Constructing DataFrame from dataclass:

```
>>> from dataclasses import make_dataclass
>>> Point = make_dataclass("Point", [('x', int), ('y', int)])
>>> pd.DataFrame([Point(0, 0), Point(0, 3), Point(2, 3)])
 x  y
0 0 0
1 0 3
2 2 3
```

### pandas.DataFrame.at

**property** `DataFrame.at`

Access a single value for a row/column label pair.

Similar to `loc`, in that both provide label-based lookups. Use `at` if you only need to get or set a single value in a DataFrame or Series.

**Raises**

- **KeyError** If ‘label’ does not exist in DataFrame.

**See also:**

- `DataFrame.iat` Access a single value for a row/column pair by integer position.
- `DataFrame.loc` Access a group of rows and columns by label(s).
- `Series.at` Access a single value using a label.
Examples

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
                     index=[4, 5, 6], columns=['A', 'B', 'C'])
>>> df
   A  B  C
4  0  2  3
5  0  4  1
6 10 20 30
```

Get value at specified row/column pair

```python
>>> df.at[4, 'B']
2
```

Set value at specified row/column pair

```python
>>> df.at[4, 'B'] = 10
>>> df.at[4, 'B']
10
```

Get value within a Series

```python
>>> df.loc[5].at['B']
4
```

**pandas.DataFrame.attrs**

**property DataFrame.attrs**

Dictionary of global attributes of this dataset.

**Warning:** attrs is experimental and may change without warning.

See also:

*DataFrame.flags* Global flags applying to this object.

**pandas.DataFrame.axes**

**property DataFrame.axes**

Return a list representing the axes of the DataFrame.

It has the row axis labels and column axis labels as the only members. They are returned in that order.
Examples

```python
>>> df = pd.DataFrame({"col1": [1, 2], "col2": [3, 4]})
>>> df.axes

[RangeIndex(start=0, stop=2, step=1), Index(['col1', 'col2'],
dtype='object')]
```

**pandas.DataFrame.columns**

*DataFrame.columns: Index*

The column labels of the DataFrame.

**pandas.DataFrame.dtypes**

*property DataFrame.dtypes*

Return the dtypes in the DataFrame.

This returns a Series with the data type of each column. The result's index is the original DataFrame's columns. Columns with mixed types are stored with the object dtype. See the User Guide for more.

**Returns**

* pandas.Series The data type of each column.

Examples

```python
>>> df = pd.DataFrame({'float': [1.0],
...                    'int': [1],
...                    'datetime': [pd.Timestamp('20180310')],
...                    'string': ['foo']})

>>> df.dtypes
float       float64
int         int64
datetime    datetime64[ns]
string      object
dtype: object
```

**pandas.DataFrame.empty**

*property DataFrame.empty*

Indicator whether DataFrame is empty.

True if DataFrame is entirely empty (no items), meaning any of the axes are of length 0.

**Returns**

* bool If DataFrame is empty, return True, if not return False.

See also:

* Series.dropna Return series without null values.
* DataFrame.dropna Return DataFrame with labels on given axis omitted where (all or any) data are missing.
Notes

If DataFrame contains only NaNs, it is still not considered empty. See the example below.

Examples

An example of an actual empty DataFrame. Notice the index is empty:

```python
>>> df_empty = pd.DataFrame({'A' : []})
>>> df_empty
Empty DataFrame
Columns: [A]
Index: []
>>> df_empty.empty
True
```

If we only have NaNs in our DataFrame, it is not considered empty! We will need to drop the NaNs to make the DataFrame empty:

```python
>>> df = pd.DataFrame({'A' : [np.nan]})
>>> df
   A
0  NaN
>>> df.empty
False
>>> df.dropna().empty
True
```

**pandas.DataFrame.flags**

**property** `DataFrame.flags`

Get the properties associated with this pandas object.

The available flags are

- `Flags.allows_duplicate_labels`

**See also:**

- `Flags` Flags that apply to pandas objects.
- `DataFrame.attrs` Global metadata applying to this dataset.

**Notes**

“Flags” differ from “metadata”. Flags reflect properties of the pandas object (the Series or DataFrame). Metadata refer to properties of the dataset, and should be stored in `DataFrame.attrs`.

Examples

```python
>>> df = pd.DataFrame({"A": [1, 2]})
>>> df.flags
<Flags(allow_duplicates_labels=True)>

Flags can be get or set using:

```python
>>> df.flags.allows_duplicate_labels
True
>>> df.flags.allows_duplicate_labels = False
```

Or by slicing with a key:

```python
>>> df.flags["allows_duplicate_labels"]
False
>>> df.flags["allows_duplicate_labels"] = True
```

**pandas.DataFrame.iat**

**property** `DataFrame.iat`

Access a single value for a row/column pair by integer position.

Similar to `iloc`, in that both provide integer-based lookups. Use `iat` if you only need to get or set a single value in a DataFrame or Series.

**Raises**

`IndexError` When integer position is out of bounds.

**See also:**

- `DataFrame.at` Access a single value for a row/column label pair.
- `DataFrame.loc` Access a group of rows and columns by label(s).
- `DataFrame.iloc` Access a group of rows and columns by integer position(s).

**Examples**

```python
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
... columns=['A', 'B', 'C'])
```

Get value at specified row/column pair:

```python
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair:
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10

Get value within a series

```python
>>> df.loc[0].iat[1]
2
```

**pandas.DataFrame.iloc**

**property** DataFrame.iloc

Purely integer-location based indexing for selection by position.

.iloc[] is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. [4, 3, 0].
- A slice object with ints, e.g. 1:7.
- A boolean array.
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don’t have a reference to the calling object, but would like to base your selection on some value.

.iloc will raise IndexError if a requested indexer is out-of-bounds, except slice indexers which allow out-of-bounds indexing (this conforms with python/numpy slice semantics).

See more at Selection by Position.

See also:

**DataFrame.iat** Fast integer location scalar accessor.

**DataFrame.loc** Purely label-location based indexer for selection by label.

**Series.iloc** Purely integer-location based indexing for selection by position.

**Examples**

```python
>>> mydict = [{'a': 1, 'b': 2, 'c': 3, 'd': 4},
... {'a': 100, 'b': 200, 'c': 300, 'd': 400},
... {'a': 1000, 'b': 2000, 'c': 3000, 'd': 4000}]
```

```python
>>> df = pd.DataFrame(mydict)
```

```python
>>> df
   a  b  c  d
0  1  2  3  4
1 100 200 300 400
2 1000 2000 3000 4000
```

**Indexing just the rows**

With a scalar integer.
>>> type(df.iloc[0])
<class 'pandas.core.series.Series'>
>>> df.iloc[0]
a 1
b 2
c 3
d 4
Name: 0, dtype: int64
With a list of integers.

>>> df.iloc[[0]]
   a  b  c  d
0  1  2  3  4
>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>

>>> df.iloc[[0, 1]]
   a   b   c   d
0  1  100  2  1000
1  1  200  3  3000
2  1  300  4  4000
With a slice object.

>>> df.iloc[:3]
   a   b   c   d
0   1   2   3   4
1  100  200  300  400
2 1000 2000 3000 4000
With a boolean mask the same length as the index.

>>> df.iloc[[True, False, True]]
   a   b   c   d
0   1   2   3   4
2 1000 2000 3000 4000
With a callable, useful in method chains. The x passed to the lambda is the DataFrame being sliced. This selects the rows whose index label even.

>>> df.iloc[lambda x: x.index % 2 == 0]
   a   b   c   d
0   1   2   3   4
2 1000 2000 3000 4000

Indexing both axes
You can mix the indexer types for the index and columns. Use : to select the entire axis.

With scalar integers.

>>> df.iloc[0, 1]
2
With lists of integers.
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
>>> df.iloc[[0, 2], [1, 3]]
  b  d
0  2  4
2 2000 4000

With slice objects.

```python
>>> df.iloc[1:3, 0:3]
  a  b  c
1 100 200 300
2 1000 2000 3000

With a boolean array whose length matches the columns.

```python
>>> df.iloc[:, [True, False, True, False]]
  a  c
0  1  3
1 100 300
2 1000 3000

With a callable function that expects the Series or DataFrame.

```python
>>> df.iloc[:, lambda df: [0, 2]]
  a  c
0  1  3
1 100 300
2 1000 3000

```

pandas.DataFrame.index

DataFrame.index: Index

The index (row labels) of the DataFrame.

pandas.DataFrame.loc

property DataFrame.loc

Access a group of rows and columns by label(s) or a boolean array.

.loc[] is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a label of the index, and never as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a':'f'.

**Warning:** Note that contrary to usual python slices, both the start and the stop are included.

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- An alignable boolean Series. The index of the key will be aligned before masking.
• An alignable Index. The Index of the returned selection will be the input.
• A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above)

See more at Selection by Label.

Raises

- KeyError If any items are not found.
- IndexError If an indexed key is passed and its index is unalignable to the frame index.

See also:

- DataFrame.at Access a single value for a row/column label pair.
- DataFrame.iloc Access group of rows and columns by integer position(s).
- DataFrame.xs Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.
- Series.loc Access group of values using labels.

Examples

Getting values

```python
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                    index=['cobra', 'viper', 'sidewinder'],
...                    columns=['max_speed', 'shield'])
>>> df
           max_speed  shield
    cobra       1       2
    viper       4       5
    sidewinder  7       8
```

Single label. Note this returns the row as a Series.

```python
>>> df.loc['viper']
max_speed  4  
shield     5  
Name: viper, dtype: int64
```

List of labels. Note using [[]] returns a DataFrame.

```python
>>> df.loc[['viper', 'sidewinder']]
              max_speed  shield
    viper       4       5
    sidewinder  7       8
```

Single label for row and column

```python
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.
Booleans list with the same length as the row axis

```
>>> df.loc[[False, False, True]]
   max_speed  shield
sidewinder    7     8
```

Alignable boolean Series:

```
>>> df.loc[pd.Series([False, True, False],
                    index=['viper', 'sidewinder', 'cobra'])]
   max_speed  shield
sidewinder    7     8
```

Index (same behavior as `df.reindex`)

```
>>> df.loc[pd.Index(['cobra', 'viper'], name='foo')]
   max_speed  shield
foo
cobra     1     2
viper     4     5
```

Conditional that returns a boolean Series

```
>>> df.loc[df['shield'] > 6]
   max_speed  shield
sidewinder    7     8
```

Conditional that returns a boolean Series with column labels specified

```
>>> df.loc[df['shield'] > 6, ['max_speed']]
   max_speed
sidewinder    7
```

Callable that returns a boolean Series

```
>>> df.loc[lambda df: df['shield'] == 8]
   max_speed  shield
sidewinder    7     8
```

Setting values

Set value for all items matching the list of labels

```
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
   max_speed  shield
   cobra     1     2
   viper     4     50
   sidewinder 7     50
```

Set value for an entire row
```python
>>> df.loc['cobra'] = 10
>>> df
   max_speed  shield
cobra      10      10
viper       4      50
sidewinder   7      50

Set value for an entire column

>>> df.loc[:, 'max_speed'] = 30
>>> df
   max_speed  shield
cobra      30      10
viper      30      50
sidewinder 30      50

Set value for rows matching callable condition

>>> df.loc[df['shield'] > 35] = 0
>>> df
   max_speed  shield
cobra      30      10
viper       0       0
sidewinder   0       0

Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```python
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                   index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
   max_speed  shield
7          1      2
8          4      5
9          7      8

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```python
>>> df.loc[7:9]
   max_speed  shield
7          1      2
8          4      5
9          7      8

Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```python
>>> tuples = [
...     ('cobra', 'mark i'), ('cobra', 'mark ii'),
...     ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
...     ('viper', 'mark ii'), ('viper', 'mark iii')
... ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
...            [1, 4], [7, 1], [16, 36]]
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.1

(continued from previous page)

```python
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)

>>> df
   max_speed  shield
  cobra       mark i  12      2
             mark ii  0      4
  sidewinder mark i  10     20
             mark ii  1      4
  viper      mark ii  7      1
             mark iii  16     36

Single label. Note this returns a DataFrame with a single index.

```
pandas.DataFrame.ndim

**property** DataFrame.ndim

Return an int representing the number of axes / array dimensions.

Return 1 if Series. Otherwise return 2 if DataFrame.

See also:

ndarray.ndim Number of array dimensions.

Examples

```python
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.ndim
1

>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.ndim
2
```

pandas.DataFrame.shape

**property** DataFrame.shape

Return a tuple representing the dimensionality of the DataFrame.

See also:

ndarray.shape Tuple of array dimensions.

Examples

```python
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.shape
(2, 2)

>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4],
...                    'col3': [5, 6]})
>>> df.shape
(2, 3)
```
**pandas.DataFrame.size**

**property** DataFrame.size
Return an int representing the number of elements in this object.

Return the number of rows if Series. Otherwise return the number of rows times number of columns if DataFrame.

See also:

ndarray.size Number of elements in the array.

**Examples**

```python
>>> s = pd.Series({'a': 1, 'b': 2, 'c': 3})
>>> s.size
3

>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df.size
4
```

**pandas.DataFrame.style**

**property** DataFrame.style
Returns a Styler object.

Contains methods for building a styled HTML representation of the DataFrame.

See also:

io.formats.style.Styler Helps style a DataFrame or Series according to the data with HTML and CSS.

**pandas.DataFrame.values**

**property** DataFrame.values
Return a Numpy representation of the DataFrame.

**Warning:** We recommend using DataFrame.to_numpy() instead.

Only the values in the DataFrame will be returned, the axes labels will be removed.

**Returns**

numpy.ndarray The values of the DataFrame.

See also:

DataFrame.to_numpy Recommended alternative to this method.

DataFrame.index Retrieve the index labels.

DataFrame.columns Retrieving the column names.
Notes

The dtype will be a lower-common-denominator dtype (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen. Use this with care if you are not dealing with the blocks.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. If dtypes are int32 and uint8, dtype will be upcast to int32. By numpy.find_common_type() convention, mixing int64 and uint64 will result in a float64 dtype.

Examples

A DataFrame where all columns are the same type (e.g., int64) results in an array of the same type.

```python
>>> df = pd.DataFrame({'age': [ 3, 29],
...                    'height': [94, 170],
...                    'weight': [31, 115]})
>>> df
    age  height  weight
0     3       94      31
1    29      170     115
>>> df.dtypes
age   int64
height int64
weight int64
dtype: object
>>> df.values
array([[ 3, 94, 31],
       [29, 170, 115]])
```

A DataFrame with mixed type columns (e.g., str/object, int64, float32) results in an ndarray of the broadest type that accommodates these mixed types (e.g., object).

```python
>>> df2 = pd.DataFrame([('parrot', 24.0, 'second'),
                     ('lion', 80.5, 1),
                     ('monkey', np.nan, None)],
                     columns=('name', 'max_speed', 'rank'))
>>> df2.dtypes
name   object
max_speed  float64
rank     object
dtype: object
>>> df2.values
array([['parrot', 24.0, 'second'],
       ['lion', 80.5, 1],
       ['monkey', nan, None]], dtype=object)
```
# Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>abs()</code></td>
<td>Return a Series/DataFrame with absolute numeric value of each element.</td>

<tr>
<td><code>bool()</code></td>
<td>Return the bool of a single element Series or DataFrame.</td>
</tr>
<tr>
<td><code>boxplot([column, by, ax, fontsize, rot, ...])</code></td>
<td>Make a box plot from DataFrame columns.</td>
</tr>
<tr>
<td><code>clip([lower, upper, axis, inplace])</code></td>
<td>Trim values at input threshold(s).</td>
</tr>
<tr>
<td><code>combine([other, func[, fill_value, overwrite]])</code></td>
<td>Perform column-wise combine with another DataFrame.</td>
</tr>
<tr>
<td><code>combine_first([other])</code></td>
<td>Update null elements with value in the same location in <code>other</code>.</td>
</tr>
<tr>
<td><code>compare([other[, align_axis, keep_shape, ...]])</code></td>
<td>Compare to another DataFrame and show the differences.</td>
</tr>
<tr>
<td><code>convert_dtypes([infer_objects, ...])</code></td>
<td>Convert columns to best possible dtypes using dtypes supporting pd.NA.</td>
</tr>
<tr>
<td><code>copy([deep])</code></td>
<td>Make a copy of this object’s indices and data.</td>
</tr>
<tr>
<td><code>corr([method, min_periods])</code></td>
<td>Compute pairwise correlation of columns, excluding NA/null values.</td>
</tr>
<tr>
<td><code>corrwith([other[, axis, drop, method]])</code></td>
<td>Compute pairwise correlation.</td>
</tr>
</tbody>
</table>

*continues on next page*
Table 65 – continued from previous page

- count([axis, level, numeric_only]) \n  Count non-NA cells for each column or row.
- cov([min_periods, ddof]) \n  Compute pairwise covariance of columns, excluding NA/null values.
- cummax([axis, skipna]) \n  Return cumulative maximum over a DataFrame or Series axis.
- cummin([axis, skipna]) \n  Return cumulative minimum over a DataFrame or Series axis.
- cumprod([axis, skipna]) \n  Return cumulative product over a DataFrame or Series axis.
- cumsum([axis, skipna]) \n  Return cumulative sum over a DataFrame or Series axis.
- describe([percentiles, include, exclude, ...]) \n  Generate descriptive statistics.
- diff([periods, axis]) \n  First discrete difference of element.
- div(other[, axis, level, fill_value]) \n  Get 'Floating division of dataframe and other, element-wise (binary operator truediv).
- divide(other[, axis, level, fill_value]) \n  Get Floating division of dataframe and other, element-wise (binary operator truediv).
- dot(other) \n  Compute the matrix multiplication between the DataFrame and other.
- drop([labels, axis, index, columns, level, ...]) \n  Drop specified labels from rows or columns.
- drop_duplicates([subset, keep, inplace, ...]) \n  Return DataFrame with duplicate rows removed.
- droplevel([level[, axis]]) \n  Return Series/DataFrame with requested index / column level(s) removed.
- dropna([axis, how, thresh, subset, inplace]) \n  Remove missing values.
- duplicated([subset, keep]) \n  Return boolean Series denoting duplicate rows.
- eq(other[, axis, level]) \n  Get Equal to of dataframe and other, element-wise (binary operator eq).
- equals(other) \n  Test whether two objects contain the same elements.
- eval(expr[, inplace]) \n  Evaluate a string describing operations on DataFrame columns.
- ewm([com, span, halflife, alpha, ...]) \n  Provide exponential weighted (EW) functions.
- expanding([min_periods, center, axis, method]) \n  Provide expanding transformations.
- explode(column[, ignore_index]) \n  Transform each element of a list-like to a row, replicating index values.
- ffill([axis, inplace, limit, downcast]) \n  Synonym for DataFrame.fillna() with method='ffill'.
- fillna([value, method, axis, inplace, ...]) \n  Fill NA/NaN values using the specified method.
- filter([items, like, regex, axis]) \n  Subset the dataframe rows or columns according to the specified index labels.
- first(offset) \n  Select initial periods of time series data based on a date offset.
- first_valid_index() \n  Return index for first non-NA value or None, if no NA value is found.
- floordiv(other[, axis, level, fill_value]) \n  Get Integer division of dataframe and other, element-wise (binary operator floordiv).
- from_dict(data[, orient, dtype, columns]) \n  Construct DataFrame from dict of array-like or dicts.
- from_records(data[, index, exclude, ...]) \n  Convert structured or record ndarray to DataFrame.
- ge(other[, axis, level]) \n  Get Greater than or equal to of dataframe and other, element-wise (binary operator ge).
- get(key[, default]) \n  Get item from object for given key (ex: DataFrame column).

pandas.DataFrame.abs

DataFrame.abs()
Return a Series/DataFrame with absolute numeric value of each element.
This function only applies to elements that are all numeric.

Returns

abs  Series/DataFrame containing the absolute value of each element.

See also:

numpy.absolute  Calculate the absolute value element-wise.

Notes

For complex inputs, 1.2 + 1j, the absolute value is $\sqrt{a^2 + b^2}$.

Examples

Absolute numeric values in a Series.

```python
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0   1.10
1   2.00
2   3.33
3   4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```python
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0   1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```python
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0   1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using argsort (from StackOverflow).
```python
>>> df = pd.DataFrame(
...     {'a': [4, 5, 6, 7],
...      'b': [10, 20, 30, 40],
...      'c': [100, 50, -30, -50]}
... )
>>> df
   a  b  c
0  4 10 100
1  5 20  50
2  6 30 -30
3  7 40 -50
>>> df.loc[(df.c - 43).abs().argsort()]
   a  b  c
0  4 10 100
1  5 20  50
2  6 30 -30
3  7 40 -50
```

### pandas.DataFrame.add

DataFrame.add(other, axis='columns', level=None, fill_value=None)

Get Addition of dataframe and other, element-wise (binary operator add).

Equivalent to dataframe + other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, radd.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [0 or 'index', 1 or 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

- **DataFrame** Result of the arithmetic operation.

**See also:**

- **DataFrame.add** Add DataFrames.
- **DataFrame.sub** Subtract DataFrames.
- **DataFrame.mul** Multiply DataFrames.
- **DataFrame.div** Divide DataFrames (float division).
- **DataFrame.truediv** Divide DataFrames (float division).
- **DataFrame.floordiv** Divide DataFrames (integer division).
**Dataframe.mod** Calculate modulo (remainder after division).

**Dataframe.pow** Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

**Examples**

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
                    'degrees': [360, 180, 360],
                    index=['circle', 'triangle', 'rectangle'])
```

```
>>> df
   angles  degrees
circle    0       360
triangle   3       180
rectangle  4       360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle    1       361
triangle   4       181
rectangle  5       361
```

```python
>>> df.add(1)
   angles  degrees
circle    1       361
triangle   4       181
rectangle  5       361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle   0.0     36.0
triangle 0.3     18.0
rectangle 0.4     36.0
```

```python
>>> df.rdiv(10)
   angles  degrees
circle   inf     0.027778
triangle 3.333333 0.055556
rectangle 2.500000 0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
   angles  degrees
circle   -1      358
triangle     2     178
rectangle    3      358
```
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])
```

```python
>>> df * other
  angles  degrees
circle 0  NaN
triangle 3  NaN
rectangle 16 NaN
```

```python
>>> df.mul(other, fill_value=0)
  angles  degrees
circle 0  0.0
triangle 3  0.0
rectangle 16  0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               index=['A', 'A', 'A', 'B', 'B', 'B']})
```

```python
>>> df_multindex
  angles  degrees
A circle 0  360
triangle 3  180
rectangle 4  360
B square 4  360
pentagon 5  540
hexagon 6  720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
  angles  degrees
A circle NaN  1.0
triangle 1.0  1.0
rectangle 1.0  1.0
```

(continues on next page)
**pandas.DataFrame.add_prefix**

DataFrame.add_prefix(prefix)

Prefix labels with string prefix.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

**Parameters**

prefix  [str] The string to add before each label.

**Returns**

Series or DataFrame  New Series or DataFrame with updated labels.

**See also:**

Series.add_suffix  Suffix row labels with string suffix.

DataFrame.add_suffix  Suffix column labels with string suffix.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0   1
1   2
2   3
3   4
dtype: int64

>>> s.add_prefix('item_')
item_0 1
item_1 2
item_2 3
item_3 4
dtype: int64

>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6

>>> df.add_prefix('col_')
col_A  col_B
0   1   3
1   2   4
```

(continues on next page)
pandas.DataFrame.add_suffix

DataFrame.add_suffix(suffix)

Suffix labels with string suffix.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

Parameters

suffix [str] The string to add after each label.

Returns

Series or DataFrame  New Series or DataFrame with updated labels.

See also:

Series.add_prefix Prefix row labels with string prefix.

DataFrame.add_prefix Prefix column labels with string prefix.

Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0 1
1 2
2 3
3 4
dtype: int64

>>> s.add_suffix('_item')
0_item 1
1_item 2
2_item 3
3_item 4
dtype: int64

>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A  B
0  1  3
1  2  4
2  3  5
3  4  6

>>> df.add_suffix('_col')
   A_col  B_col
0      1      3
1      2      4
2      3      5
3      4      6
```
pandas.DataFrame.agg

DataFrame.agg(func=None, axis=0, *args, **kwargs)
Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:
• function
• string function name
• list of functions and/or function names, e.g. [np.sum, 'mean']
• dict of axis labels -> functions, function names or list of such.

axis [(0 or ‘index’, 1 or ‘columns’), default 0] If 0 or ‘index’: apply function to each column. If 1 or ‘columns’: apply function to each row.

*args Positional arguments to pass to func.

**kwargs Keyword arguments to pass to func.

Returns

scalar, Series or DataFrame The return can be:
• scalar : when Series.agg is called with single function
• Series : when DataFrame.agg is called with a single function
• DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from numpy aggregation functions (mean, median, prod, sum, std, var), where the default is to compute the aggregation of the flattened array, e.g., numpy.mean(arr_2d) as opposed to numpy.mean(arr_2d, axis=0).

agg is an alias for aggregate. Use the alias.

See also:

DataFrame.apply Perform any type of operations.

DataFrame.transform Perform transformation type operations.

core.groupby.GroupBy Perform operations over groups.

core.resample.Resampler Perform operations over resampled bins.

core.window.Rolling Perform operations over rolling window.

core.window.Expanding Perform operations over expanding window.

core.window.ExponentialMovingWindow Perform operation over exponential weighted window.
Notes

`agg` is an alias for `aggregate`. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
def df = pd.DataFrame([[1, 2, 3],
... [4, 5, 6],
... [7, 8, 9],
... [np.nan, np.nan, np.nan]],
... columns=['A', 'B', 'C'])
```

Aggregate these functions over the rows.

```python
>>> df.agg(['sum', 'min'])
A   B   C
-- -- --
sum 12.0 15.0 18.0
min 1.0  2.0  3.0
```

Different aggregations per column.

```python
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
   A  B
-- --
sum 12.0 NaN
min 1.0  2.0
max NaN  8.0
```

Aggregate different functions over the columns and rename the index of the resulting DataFrame.

```python
>>> df.agg(x=('A', max), y=('B', 'min'), z=('C', np.mean))
   A   B   C
-- -- --
x  7.0 NaN NaN
y NaN  2.0 NaN
z NaN NaN  6.0
```

Aggregate over the columns.

```python
>>> df.agg("mean", axis="columns")
   0  1  2
-- -- --
0  2.0 5.0 8.0
1  NaN  NaN NaN
dtype: float64
```
pandas.DataFrame.aggregate

DataFrame.aggregate (func=None, axis=0, *args, **kwargs)
Aggregate using one or more operations over the specified axis.

Parameters

- func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.
  Accepted combinations are:
  * function
  * string function name
  * list of functions and/or function names, e.g. [np.sum, 'mean']
  * dict of axis labels -> functions, function names or list of such.
- axis [[0 or ‘index’, 1 or ‘columns’], default 0] If 0 or ‘index’: apply function to each column. If 1 or ‘columns’: apply function to each row.
- *args Positional arguments to pass to func.
- **kwargs Keyword arguments to pass to func.

Returns

scalar, Series or DataFrame The return can be:
  * scalar : when Series.agg is called with single function
  * Series : when DataFrame.agg is called with a single function
  * DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

The aggregation operations are always performed over an axis, either the index (default) or the column axis. This behavior is different from numpy aggregation functions (mean, median, prod, sum, std, var), where the default is to compute the aggregation of the flattened array, e.g., numpy.mean(arr_2d) as opposed to numpy.mean(arr_2d, axis=0).

tag is an alias for aggregate. Use the alias.

See also:

DataFrame.apply Perform any type of operations.
DataFrame.transform Perform transformation type operations.
core.groupby.GroupBy Perform operations over groups.
core.resample.Resampler Perform operations over resampled bins.
core.window.Rolling Perform operations over rolling window.
core.window.Expanding Perform operations over expanding window.
core.window.ExponentialMovingWindow Perform operation over exponential weighted window.
Notes

agg is an alias for aggregate. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> df = pd.DataFrame([[1, 2, 3],
...                     [4, 5, 6],
...                     [7, 8, 9],
...                     [np.nan, np.nan, np.nan]],
...                     columns=['A', 'B', 'C'])

Aggregate these functions over the rows.

```python
>>> df.agg(['sum', 'min'])
          A     B     C
    sum  12.0  15.0  18.0
   min   1.0   2.0   3.0
```

Different aggregations per column.

```python
>>> df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
          A     B
    sum  12.0  NaN
   min   1.0   2.0
  max  NaN   8.0
```

Aggregate different functions over the columns and rename the index of the resulting DataFrame.

```python
>>> df.agg(x=('A', max), y=('B', 'min'), z=('C', np.mean))
          A   B    C
    x   7.0 NaN  NaN
    y  NaN  2.0  NaN
    z  NaN  NaN  6.0
```

Aggregate over the columns.

```python
>>> df.agg("mean", axis="columns")
    0   2.0
   1   5.0
   2   8.0
   3     NaN
dtype: float64
```
**pandas DataFrame.align**

Dataframe.align(other, join='outer', axis=None, level=None, copy=True, fill_value=None, method=None, limit=None, fill_axis=0, broadcast_axis=None)

Align two objects on their axes with the specified join method.

Join method is specified for each axis Index.

**Parameters**

- **other** [DataFrame or Series]
- **join** [{‘outer’, ‘inner’, ‘left’, ‘right’}, default ‘outer’]
- **axis** [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None).
- **level** [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **copy** [bool, default True] Always returns new objects. If copy=False and no reindexing is required then original objects are returned.
- **fill_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.
- **method** [{‘backfill’, ‘bfill’, ‘pad’, ‘ffill’, None}, default None] Method to use for filling holes in reindexed Series:
  - pad / ffill: propagate last valid observation forward to next valid.
  - backfill / bfill: use NEXT valid observation to fill gap.
- **limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.
- **fill_axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Filling axis, method and limit.
- **broadcast_axis** [{0 or ‘index’, 1 or ‘columns’}, default None] Broadcast values along this axis, if aligning two objects of different dimensions.

**Returns**

(left, right) [(DataFrame, type of other)] Aligned objects.

**pandas DataFrame.all**

Dataframe.all(axis=0, bool_only=None, skipna=True, level=None, **kwargs)

Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

**Parameters**

- **axis** [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Indicate which axis or axes should be reduced.
  - 0 / ‘index’: reduce the index, return a Series whose index is the original column labels.
• 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
• None : reduce all axes, return a scalar.

**bool_only** [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

**skipna** [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

**level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

**kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

**Series or DataFrame** If level is specified, then, DataFrame is returned; otherwise, Series is returned.

See also:

**Series.all** Return True if all elements are True.

**DataFrame.any** Return True if one (or more) elements are True.

Examples

**Series**

```python
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([], dtype="float64").all()
True
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

**DataFrames**

Create a dataframe from a dictionary.

```python
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})
>>> df
  col1  col2
0  True  True
1  True  False
```

Default behaviour checks if column-wise values all return True.

```python
>>> df.all()
  col1  True
  col2  False
dtype: bool
```
Specify `axis='columns'` to check if row-wise values all return True.

```python
>>> df.all(axis='columns')
0   True
1   False
dtype: bool
```

Or `axis=None` for whether every value is True.

```python
>>> df.all(axis=None)
False
```

```{admonition} pandas.DataFrame.any

DataFrame.any (axis=0, bool_only=None, skipna=True, level=None, **kwargs)

Return whether any element is True, potentially over an axis.

Returns False unless there is at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

**Parameters**

- `axis` [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Indicate which axis or axes should be reduced.
  - 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
  - 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
  - None : reduce all axes, return a scalar.
- `bool_only` [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.
- `skipna` [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.
- `level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- `**kwargs` [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

Series or DataFrame If level is specified, then DataFrame is returned; otherwise, Series is returned.

**See also:**

- `numpy.any` Numpy version of this method.
- `Series.any` Return whether any element is True.
- `Series.all` Return whether all elements are True.
- `DataFrame.any` Return whether any element is True over requested axis.
- `DataFrame.all` Return whether all elements are True over requested axis.
Examples

Series

For Series input, the output is a scalar indicating whether any element is True.

```python
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([], dtype="float64").any()
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True
```

DataFrame

Whether each column contains at least one True element (the default).

```python
>>> df = pd.DataFrame({"A": [1, 2], "B": [0, 2], "C": [0, 0]})
>>> df
   A  B  C
0  1  0  0
1  2  2  0

>>> df.any()
A    True
B    True
C   False
dtype: bool

Aggregating over the columns.

```python
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 2]})
>>> df
   A  B
0  True 1
1  False 2

>>> df.any(axis='columns')
0   True
1   True
dtype: bool
```

```python
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})
   A  B
0  True 1
1  False 0

>>> df.any(axis='columns')
0   True
1   False
dtype: bool
```

Aggregating over the entire DataFrame with `axis=None`.
any for an empty DataFrame is an empty Series.

```python
>>> pd.DataFrame([]).any()
Series([], dtype: bool)
```

### pandas.DataFrame.append

DataFrame. **append** (other, ignore_index=False, verify_integrity=False, sort=False)

Append rows of other to the end of caller, returning a new object.

Columns in other that are not in the caller are added as new columns.

**Parameters**

- **other** [DataFrame or Series/dict-like object, or list of these] The data to append.
- **ignore_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.
- **verify_integrity** [bool, default False] If True, raise ValueError on creating index with duplicates.
- **sort** [bool, default False] Sort columns if the columns of self and other are not aligned.

**Returns**

- **DataFrame** A new DataFrame consisting of the rows of caller and the rows of other.

**See also:**

- **concat** General function to concatenate DataFrame or Series objects.

**Notes**

If a list of dict/series is passed and the keys are all contained in the DataFrame’s index, the order of the columns in the resulting DataFrame will be unchanged.

Iteratively appending rows to a DataFrame can be more computationally intensive than a single concatenate. A better solution is to append those rows to a list and then concatenate the list with the original DataFrame all at once.

**Examples**

```python
>>> df = pd.DataFrame([[1, 2], [3, 4]], columns=list('AB'), index=['x', 'y'])
>>> df
  A  B
x 1  2
y 3  4
>>> df2 = pd.DataFrame([[5, 6], [7, 8]], columns=list('AB'), index=['x', 'y'])
>>> df.append(df2)
```

(continues on next page)
With `ignore_index` set to True:

```
>>> df.append(df2, ignore_index=True)
   A  B
 0  1  2
 1  3  4
 2  5  6
 3  7  8
```

The following, while not recommended methods for generating DataFrames, show two ways to generate a DataFrame from multiple data sources.

Less efficient:

```
>>> df = pd.DataFrame(columns=['A'])
>>> for i in range(5):
...     df = df.append({'A': i}, ignore_index=True)
...     df
   A
 0  0
 1  1
 2  2
 3  3
 4  4
```

More efficient:

```
>>> pd.concat([pd.DataFrame([i], columns=['A']) for i in range(5)],
            ignore_index=True)
   A
 0  0
 1  1
 2  2
 3  3
 4  4
```

**pandas.DataFrame.apply**

`DataFrame.apply(func, axis=0, raw=False, result_type=None, args=(), **kwargs)`

Apply a function along an axis of the DataFrame.

Objects passed to the function are Series objects whose index is either the DataFrame’s index (axis=0) or the DataFrame’s columns (axis=1). By default (result_type=None), the final return type is inferred from the return type of the applied function. Otherwise, it depends on the result_type argument.

Parameters:

- `func` [function] Function to apply to each column or row.
- `axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis along which the function is applied:
• 0 or ‘index’: apply function to each column.
• 1 or ‘columns’: apply function to each row.

**raw** [bool, default False] Determines if row or column is passed as a Series or ndarray object:
• False: passes each row or column as a Series to the function.
• True: the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

**result_type** [{‘expand’, ‘reduce’, ‘broadcast’, None}, default None] These only act when axis=1 (columns):
• ‘expand’ : list-like results will be turned into columns.
• ‘reduce’ : returns a Series if possible rather than expanding list-like results. This is the opposite of ‘expand’.
• ‘broadcast’ : results will be broadcast to the original shape of the DataFrame, the original index and columns will be retained.

The default behaviour (None) depends on the return value of the applied function: list-like results will be returned as a Series of those. However if the apply function returns a Series these are expanded to columns.

**args** [tuple] Positional arguments to pass to *func* in addition to the array/series.

**kwargs** Additional keyword arguments to pass as keywords arguments to *func*.

**Returns**

Series or DataFrame Result of applying *func* along the given axis of the DataFrame.

**See also:**
*DataFrame.applymap* For elementwise operations.
*DataFrame.aggregate* Only perform aggregating type operations.
*DataFrame.transform* Only perform transforming type operations.

**Notes**

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

**Examples**

```python
>>> df = pd.DataFrame([[4, 9]] * 3, columns=['A', 'B'])
>>> df
   A  B
0  4  9
1  4  9
2  4  9

Using a numpy universal function (in this case the same as np.sqrt(df)):
>>> df.apply(np.sqrt)
   A  B
0  2.0  3.0
1  2.0  3.0
2  2.0  3.0

Using a reducing function on either axis

>>> df.apply(np.sum, axis=0)
   A  12
   B  27
dtype: int64

>>> df.apply(np.sum, axis=1)
   0  13
   1  13
   2  13
dtype: int64

Returning a list-like will result in a Series

>>> df.apply(lambda x: [1, 2], axis=1)
   0   [1, 2]
   1   [1, 2]
   2   [1, 2]
dtype: object

Passing result_type='expand' will expand list-like results to columns of a Dataframe

>>> df.apply(lambda x: [1, 2], axis=1, result_type='expand')
   A  0  1  2
   B  0  1  2
   1  1  2
   2  1  2

Returning a Series inside the function is similar to passing result_type='expand'. The resulting column names will be the Series index.

>>> df.apply(lambda x: pd.Series([1, 2], index=['foo', 'bar']), axis=1)
   foo  bar
   0  1  2
   1  1  2
   2  1  2

Passing result_type='broadcast' will ensure the same shape result, whether list-like or scalar is returned by the function, and broadcast it along the axis. The resulting column names will be the originals.

>>> df.apply(lambda x: [1, 2], axis=1, result_type='broadcast')
   A  B
   0  1  2
   1  1  2
   2  1  2
**pandas.DataFrame.applymap**

Data Frame .applymap (func, na_action=None, **kwargs)

Apply a function to a Dataframe elementwise.

This method applies a function that accepts and returns a scalar to every element of a DataFrame.

**Parameters**

- **func** [callable] Python function, returns a single value from a single value.
- **na_action** [{None, ‘ignore’}, default None] If ‘ignore’, propagate NaN values, without passing them to func.
  
  New in version 1.2.
- **kwargs** Additional keyword arguments to pass as keywords arguments to func.
  
  New in version 1.3.0.

**Returns**

Data Frame Transformed DataFrame.

**See also:**

Data Frame .apply Apply a function along input axis of DataFrame.

**Examples**

```python
>>> df = pd.DataFrame([[1, 2.12], [3.356, 4.567]])
>>> df
   0   1
0  1.000  2.120
1  3.356  4.567
```

```python
>>> df.applymap(lambda x: len(str(x)))
   0   1
0   3   4
1   5   5
```

Like Series.map, NA values can be ignored:

```python
>>> df_copy = df.copy()
>>> df_copy.iloc[0, 0] = pd.NA
>>> df_copy.applymap(lambda x: len(str(x)), na_action='ignore')
   0   1
0  <NA>  4
1   5   5
```

Note that a vectorized version of func often exists, which will be much faster. You could square each number elementwise.

```python
>>> df.applymap(lambda x: x**2)
   0   1
0  1.000000  4.494400
1 11.262736 20.857489
```

But it’s better to avoid applymap in that case.
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
>>> df ** 2
0    1.000000  4.494400
1   11.262736  20.857489
```

**pandas.DataFrame.asfreq**

DataFrame.asfreq(freq=None, method=None, how=None, normalize=False, fill_value=None)

Convert time series to specified frequency.

Returns the original data conformed to a new index with the specified frequency.

If the index of this DataFrame is a PeriodIndex, the new index is the result of transforming the original index with PeriodIndex.asfreq (so the original index will map one-to-one to the new index).

Otherwise, the new index will be equivalent to `pd.date_range(start, end, freq=freq)` where `start` and `end` are, respectively, the first and last entries in the original index (see pandas.date_range()). The values corresponding to any timesteps in the new index which were not present in the original index will be null (NaN), unless a method for filling such unknowns is provided (see the method parameter below).

The resample() method is more appropriate if an operation on each group of timesteps (such as an aggregate) is necessary to represent the data at the new frequency.

**Parameters**

- `freq` [DateOffset or str] Frequency DateOffset or string.
- `method` ['backfill'/'bfill', 'pad'/'ffill'], default None] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):
  - 'pad' / 'ffill': propagate last valid observation forward to next valid
  - 'backfill' / 'bfill': use NEXT valid observation to fill.
- `how` ['start', 'end'], default end] For PeriodIndex only (see PeriodIndex.asfreq).
- `normalize` [bool, default False] Whether to reset output index to midnight.
- `fill_value` [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

**Returns**

DataFrame DataFrame object reindexed to the specified frequency.

**See also:**

- reindex Conform DataFrame to new index with optional filling logic.
Notes

To learn more about the frequency strings, please see this link.

Examples

Start by creating a series with 4 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s': series})
>>> df
             s
2000-01-01 00:00:00  0.0
2000-01-01 00:01:00  NaN
2000-01-01 00:02:00  2.0
2000-01-01 00:03:00  3.0
```

Upsample the series into 30 second bins.

```python
>>> df.asfreq(freq='30S')
             s
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  NaN
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  NaN
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  NaN
2000-01-01 00:03:00  3.0
```

Upsample again, providing a fill value.

```python
>>> df.asfreq(freq='30S', fill_value=9.0)
             s
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  9.0
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  9.0
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  9.0
2000-01-01 00:03:00  3.0
```

Upsample again, providing a method.

```python
>>> df.asfreq(freq='30S', method='bfill')
             s
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  NaN
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  2.0
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  3.0
2000-01-01 00:03:00  3.0
```
pandas.DataFrame.asof

DataFrame.asof(where, subset=None)

Return the last row(s) without any NaNs before where.

The last row (for each element in where, if list) without any NaN is taken. In case of a DataFrame, the last row without NaN considering only the subset of columns (if not None)

If there is no good value, NaN is returned for a Series or a Series of NaN values for a DataFrame

Parameters

where [date or array-like of dates] Date(s) before which the last row(s) are returned.

subset [str or array-like of str, default None] For DataFrame, if not None, only use these columns to check for NaNs.

Returns

scalar, Series, or DataFrame The return can be:

• scalar : when self is a Series and where is a scalar

• Series: when self is a Series and where is an array-like, or when self is a DataFrame and where is a scalar

• DataFrame : when self is a DataFrame and where is an array-like

Return scalar, Series, or DataFrame.

See also:

merge_asof Perform an asof merge. Similar to left join.

Notes

Dates are assumed to be sorted. Raises if this is not the case.

Examples

A Series and a scalar where.

```python
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10    1.0
20    2.0
30   NaN
40    4.0
dtype: float64

>>> s.asof(20)
2.0
```

For a sequence where, a Series is returned. The first value is NaN, because the first element of where is before the first index value.
>>> s.asof([5, 20])
5  NaN
20  2.0
dtype: float64

Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

>>> s.asof(30)
2.0

Take all columns into consideration

```python
>>> df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
                     'b': [None, None, None, None, 500],
                     index=pd.DatetimeIndex(['2018-02-27 09:01:00',
                                              '2018-02-27 09:02:00',
                                              '2018-02-27 09:03:00',
                                              '2018-02-27 09:04:00',
                                              '2018-02-27 09:05:00'])})
```

```python
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
                             '2018-02-27 09:04:30']))
```

```
a  b
2018-02-27 09:03:30 NaN NaN
2018-02-27 09:04:30 NaN NaN
```

Take a single column into consideration

```python
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
                             '2018-02-27 09:04:30']),
                             subset=['a'])
```

```
a  b
2018-02-27 09:03:30 30.0 NaN
2018-02-27 09:04:30 40.0 NaN
```

**pandas.DataFrame.assign**

DataFrame.assign(**kwargs)

Assign new columns to a DataFrame.

Returns a new object with all original columns in addition to new ones. Existing columns that are re-assigned will be overwritten.

**Parameters**

- **kwargs** [dict of {str: callable or Series}] The column names are keywords. If the values are callable, they are computed on the DataFrame and assigned to the new columns. The callable must not change input DataFrame (though pandas doesn’t check it). If the values are not callable, (e.g. a Series, scalar, or array), they are simply assigned.

**Returns**

- **DataFrame** A new DataFrame with the new columns in addition to all the existing columns.
Notes

Assigning multiple columns within the same `assign` is possible. Later items in `**kwargs` may refer to newly created or modified columns in `df`; items are computed and assigned into `df` in order.

Examples

```python
>>> df = pd.DataFrame({'temp_c': [17.0, 25.0],
...                   index=['Portland', 'Berkeley'])
>>> df
   temp_c
Portland   17.0
Berkeley   25.0
```

Where the value is a callable, evaluated on `df`:

```python
>>> df.assign(temp_f=lambda x: x.temp_c * 9 / 5 + 32)
   temp_c   temp_f
Portland  17.0      62.6
Berkeley  25.0      77.0
```

Alternatively, the same behavior can be achieved by directly referencing an existing Series or sequence:

```python
>>> df.assign(temp_f=df['temp_c'] * 9 / 5 + 32)
   temp_c   temp_f
Portland  17.0      62.6
Berkeley  25.0      77.0
```

You can create multiple columns within the same assign where one of the columns depends on another one defined within the same assign:

```python
>>> df.assign(temp_f=lambda x: x['temp_c'] * 9 / 5 + 32,
...            temp_k=lambda x: (x['temp_f'] + 459.67) * 5 / 9)
   temp_c   temp_f   temp_k
Portland  17.0      62.6      290.15
Berkeley  25.0      77.0      298.15
```

**pandas.DataFrame.astype**

DataFrame `astype(dtype, copy=True, errors='raise')`

Cast a pandas object to a specified `dtype` `dtype`.

**Parameters**

- `dtype` [data type, or dict of column name -> data type] Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use `{col: dtype, ...}`, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame’s columns to column-specific types.
- `copy` [bool, default True] Return a copy when `copy=True` (be very careful setting `copy=False` as changes to values then may propagate to other pandas objects).
- `errors` [[‘raise’, ‘ignore’], default ‘raise’] Control raising of exceptions on invalid data for provided dtype.
  - `raise`: allow exceptions to be raised
• ignore: suppress exceptions. On error return original object.

Returns
casted [same type as caller]

See also:

to_datetime Convert argument to datetime.
to_timedelta Convert argument to timedelta.
to_numeric Convert argument to a numeric type.
numpy.ndarray.astype Cast a numpy array to a specified type.

Notes

Deprecated since version 1.3.0: Using astype to convert from timezone-naive dtype to timezone-aware dtype is deprecated and will raise in a future version. Use Series.dt.tz_localize() instead.

Examples

Create a DataFrame:

```python
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df.dtypes
coll  int64
coll2  int64
dtype: object
```

Cast all columns to int32:

```python
>>> df.astype('int32').dtypes
coll  int32
coll2  int32
dtype: object
```

Cast col1 to int32 using a dictionary:

```python
>>> df.astype({'col1': 'int32'}).dtypes
coll  int32
coll2  int64
dtype: object
```

Create a series:

```python
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0  1
1  2
dtype: int32
>>> ser.astype('int64')
0  1
1  2
dtype: int64
```
Convert to categorical type:

```python
>>> ser.astype('category')
0 1
1 2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```python
>>> from pandas.api.types import CategoricalDtype
>>> cat_dtype = CategoricalDtype(...
...    categories=[2, 1], ordered=True)
>>> ser.astype(cat_dtype)
0 1
1 2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```python
>>> s1 = pd.Series([1, 2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1
# note that s1[0] has changed too
0 10
1 2
dtype: int64
```

Create a series of dates:

```python
>>> ser_date = pd.Series(pd.date_range('20200101', periods=3))
>>> ser_date
0 2020-01-01
1 2020-01-02
2 2020-01-03
dtype: datetime64[ns]
```

**pandas.DataFrame.at_time**

DataFrame.at_time(*time*, asof=False, axis=None) Select values at particular time of day (e.g., 9:30AM).

**Parameters**

- **time** [datetime.time or str]
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0]

**Returns**

Series or DataFrame

**Raises**

TypeError If the index is not a DatetimeIndex

**See also:**

between_time Select values between particular times of the day.
**first** Select initial periods of time series based on a date offset.

**last** Select final periods of time series based on a date offset.

**DatetimeIndex.indexer_at_time** Get just the index locations for values at particular time of the day.

### Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
   A
2018-04-09 00:00:00  1
2018-04-09 12:00:00  2
2018-04-10 00:00:00  3
2018-04-10 12:00:00  4

>>> ts.at_time('12:00')
   A
2018-04-09 12:00:00  2
2018-04-10 12:00:00  4
```

**pandas.DataFrame.backfill**

DataFrame.**backfill** *(axis=None, inplace=False, limit=None, downcast=None)*

Synonym for DataFrame.fillna() with method='bfill'.

**Returns**

- **Series/DataFrame or None** Object with missing values filled or None if inplace=True.

**pandas.DataFrame.between_time**

DataFrame.**between_time** *(start_time, end_time, include_start=True, include_end=True, axis=None)*

Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting start_time to be later than end_time, you can get the times that are not between the two times.

**Parameters**

- **start_time** [datetime.time or str] Initial time as a time filter limit.
- **end_time** [datetime.time or str] End time as a time filter limit.
- **include_start** [bool, default True] Whether the start time needs to be included in the result.
- **include_end** [bool, default True] Whether the end time needs to be included in the result.
- **axis** [(0 or ‘index’, 1 or ‘columns’), default 0] Determine range time on index or columns value.
Returns

Series or DataFrame  Data from the original object filtered to the specified dates range.

Raises

TypeError  If the index is not a DatetimeIndex

See also:

at_time  Select values at a particular time of the day.
first  Select initial periods of time series based on a date offset.
last  Select final periods of time series based on a date offset.

DatetimeIndex.indexer_between_time  Get just the index locations for values between particular times of the day.

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
   A
2018-04-09 00:00:00  1
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3
2018-04-12 01:00:00  4
```

```python
>>> ts.between_time('0:15', '0:45')
   A
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3
```

You get the times that are not between two times by setting start_time later than end_time:

```python
>>> ts.between_time('0:45', '0:15')
   A
2018-04-09 00:00:00  1
2018-04-12 01:00:00  4
```

pandas.DataFrame.bfill

DataFrame.bfill (axis=None, inplace=False, limit=None, downcast=None)

Synonym for DataFrame.fillna() with method='bfill'.

Returns

Series/DataFrame or None  Object with missing values filled or None if inplace=True.
pandas.DataFrame.bool

DataFrame.bool()
Return the bool of a single element Series or DataFrame.
This must be a boolean scalar value, either True or False. It will raise a ValueError if the Series or
DataFrame does not have exactly 1 element, or that element is not boolean (integer values 0 and 1 will
also raise an exception).

Returns

bool The value in the Series or DataFrame.

See also:

Series.astype Change the data type of a Series, including to boolean.
DataFrame.astype Change the data type of a DataFrame, including to boolean.
numpy.bool_ NumPy boolean data type, used by pandas for boolean values.

Examples

The method will only work for single element objects with a boolean value:

```python
>>> pd.Series([True]).bool()
True
>>> pd.Series([False]).bool()
False
```

pandas.DataFrame.boxplot

DataFrame.boxplot (column=None, by=None, ax=None, fontsize=None, rot=0, grid=True, figsize=None, layout=None, return_type=None, backend=None, **kwargs)
Make a box plot from DataFrame columns.
Make a box-and-whisker plot from DataFrame columns, optionally grouped by some other columns. A
box plot is a method for graphically depicting groups of numerical data through their quartiles. The box
extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend
from the edges of box to show the range of the data. By default, they extend no more than 1.5 * IQR (IQR
= Q3 - Q1) from the edges of the box, ending at the farthest data point within that interval. Outliers are
plotted as separate dots.
For further details see Wikipedia’s entry for boxplot.

Parameters

column [str or list of str, optional] Column name or list of names, or vector. Can be
any valid input to pandas.DataFrame.groupby().

by [str or array-like, optional] Column in the DataFrame to pandas.DataFrame.
    groupby(). One box-plot will be done per value of columns in by.
**Boxplot**

```python
DataFrame.boxplot(
    ax=None,
    fontsize=None,
    rot=None,
    grid=None,
    figsize=None,
    layout=None,
    return_type=None,
    backend=None,
    **kwargs)
```

**Parameters**

* `ax` [object of class matplotlib.axes.Axes, optional] The matplotlib axes to be used by boxplot.
* `fontsize` [float or str] Tick label font size in points or as a string (e.g., "large").
* `rot` [int or float, default 0] The rotation angle of labels (in degrees) with respect to the screen coordinate system.
* `grid` [bool, default True] Setting this to True will show the grid.
* `figsize` [A tuple (width, height) in inches] The size of the figure to create in matplotlib.
* `layout` [tuple (rows, columns), optional] For example, (3, 5) will display the subplots using 3 columns and 5 rows, starting from the top-left.
* `return_type` ['axes', 'dict', 'both'] or None, default 'axes'] The kind of object to return. The default is `axes`.
  * 'axes' returns the matplotlib axes the boxplot is drawn on.
  * 'dict' returns a dictionary whose values are the matplotlib Lines of the boxplot.
  * 'both' returns a namedtuple with the axes and dict.
  * when grouping with `by`, a Series mapping columns to `return_type` is returned.

  If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned.
* `backend` [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, 'matplotlib'. Alternatively, to specify the plotting backend for the whole session, set `pd.options.plotting.backend`.

  New in version 1.0.0.
* `**kwargs` All other plotting keyword arguments to be passed to `matplotlib.pyplot.boxplot()`.

**Returns**

result See Notes.

**See also:**

- `Series.plot.hist` Make a histogram.
- `matplotlib.pyplot.boxplot` Matplotlib equivalent plot.

**Notes**

The return type depends on the `return_type` parameter:

* 'axes' : object of class matplotlib.axes.Axes
* 'dict' : dict of matplotlib.lines.Line2D objects
* 'both' : a namedtuple with structure (ax, lines)

For data grouped with `by`, return a Series of the above or a numpy array:

* `Series`
* `array` (for `return_type` = `None`)
Use \texttt{return\_type='dict'} when you want to tweak the appearance of the lines after plotting. In this case a dict containing the Lines making up the boxes, caps, fliers, medians, and whiskers is returned.

**Examples**

Boxplots can be created for every column in the dataframe by \texttt{df.boxplot()} or indicating the columns to be used:

\begin{verbatim}
>>> np.random.seed(1234)
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                    columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
\end{verbatim}

Boxplots of variables distributions grouped by the values of a third variable can be created using the option \texttt{by}. For instance:

\begin{verbatim}
>>> df = pd.DataFrame(np.random.randn(10, 2),
...                    columns=['Col1', 'Col2'])
...                      'B', 'B', 'B', 'B', 'B'])
>>> boxplot = df.boxplot(by='X')
\end{verbatim}

A list of strings (i.e. ['X', 'Y']) can be passed to boxplot in order to group the data by combination of the variables in the x-axis:
```python
>>> df = pd.DataFrame(np.random.randn(10, 3),
...                   columns=['Col1', 'Col2', 'Col3'])
...                      'B', 'B', 'B', 'B', 'B'])
>>> df['Y'] = pd.Series(['A', 'B', 'A', 'B', 'A',
...                      'B', 'A', 'B', 'A', 'B'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])

The layout of boxplot can be adjusted giving a tuple to layout:
```n
def boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                          layout=(2, 1))
```

Additional formatting can be done to the boxplot, like suppressing the grid (grid=False), rotating the labels in the x-axis (i.e. rot=45) or changing the fontsize (i.e. fontsize=15):

```python
>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)

The parameter return_type can be used to select the type of element returned by boxplot. When return_type='axes' is selected, the matplotlib axes on which the boxplot is drawn are returned:
```n
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
>>> type(boxplot)
<class 'matplotlib.axes._subplots.AxesSubplot'>
```
When grouping with `by`, a Series mapping columns to `return_type` is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                       return_type='axes')
>>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                       return_type=None)
>>> type(boxplot)
<class 'numpy.ndarray'>
```

---

**pandas.DataFrame.clip**

`DataFrame.clip(lower=None, upper=None, axis=None, inplace=False, *args, **kwargs)`

Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

**Parameters**

- `lower` [float or array-like, default None] Minimum threshold value. All values below this threshold will be set to it. A missing threshold (e.g NA) will not clip the value.
- `upper` [float or array-like, default None] Maximum threshold value. All values above this threshold will be set to it. A missing threshold (e.g NA) will not clip the value.
- `axis` [int or str axis name, optional] Align object with lower and upper along the given axis.
- `inplace` [bool, default False] Whether to perform the operation in place on the data.
- `*args, **kwargs` Additional keywords have no effect but might be accepted for compatibility with numpy.

**Returns**

- Series or DataFrame or None Same type as calling object with the values outside the clip boundaries replaced or None if `inplace=True`.

**See also:**

- `Series.clip` Trim values at input threshold in series.
- `DataFrame.clip` Trim values at input threshold in dataframe.
- `numpy.clip` Clip (limit) the values in an array.
Examples

```python
>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
  col_0  col_1
0     9    -2
1    -3    -7
2     0     6
3    -1     8
4     5    -5

Clips per column using lower and upper thresholds:

```python
>>> df.clip(-4, 6)
  col_0  col_1
0     6    -2
1    -3    -4
2     0     6
3    -1     6
4     5    -4
```

Clips using specific lower and upper thresholds per column element:

```python
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0    2.0
1    -4.0
2    -1.0
3     6.0
4     3.0
dtype: float64
```  
```python
>>> df.clip(t, t + 4, axis=0)
  col_0  col_1
0     6     2
1    -3    -4
2     0     3
3     6     8
4     5     3
```

Clips using specific lower threshold per column element, with missing values:

```python
>>> t = pd.Series([2, -4, np.NaN, 6, 3])
>>> t
0     2.0
1    -4.0
2      NaN
3     6.0
4     3.0
dtype: float64
```  
```python
>>> df.clip(t, axis=0)
  col_0  col_1
0     9     2
1    -3    -4
2     0     6
(continues on next page)
pandas.DataFrame.combine

DataFrame.combine(other, func, fill_value=None, overwrite=True)

Perform column-wise combine with another DataFrame.

Combines a DataFrame with other DataFrame using func to element-wise combine columns. The row and column indexes of the resulting DataFrame will be the union of the two.

Parameters

- **other** [DataFrame] The DataFrame to merge column-wise.
- **func** [function] Function that takes two series as inputs and return a Series or a scalar. Used to merge the two dataframes column by columns.
- **fill_value** [scalar value, default None] The value to fill NaNs with prior to passing any column to the merge func.
- **overwrite** [bool, default True] If True, columns in self that do not exist in other will be overwritten with NaNs.

Returns

DataFrame Combination of the provided DataFrames.

See also:

DataFrame.combine_first Combine two DataFrame objects and default to non-null values in frame calling the method.

Examples

Combine using a simple function that chooses the smaller column.

```python
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> take_smaller = lambda s1, s2: s1 if s1.sum() < s2.sum() else s2
>>> df1.combine(df2, take_smaller)
  A  B
0 0 3
1 0 3
```

Example using a true element-wise combine function.

```python
>>> df1 = pd.DataFrame({'A': [5, 0], 'B': [2, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, np.minimum)
  A  B
0 1 2
1 0 3
```

Using fill_value fills Nones prior to passing the column to the merge function.
>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [3, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
   A   B
0  0  -5.0
1  0   4.0

However, if the same element in both dataframes is None, that None is preserved

>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [None, 4]})
>>> df2 = pd.DataFrame({'A': [1, 1], 'B': [None, 3]})
>>> df1.combine(df2, take_smaller, fill_value=-5)
   A   B
0  0   -5.0
1  0     3.0

Example that demonstrates the use of overwrite and behavior when the axis differ between the dataframes.

>>> df1 = pd.DataFrame({'A': [0, 0], 'B': [4, 4]})
>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [-10, 1], }, index=[1, 2])
>>> df1.combine(df2, take_smaller)
   A  B  C
0  NaN NaN NaN
1  0.0  3.0 -10.0
2  NaN  3.0   1.0

>>> df1.combine(df2, take_smaller, overwrite=False)
   A  B  C
0  0.0 NaN NaN
1  0.0  3.0 -10.0
2  NaN  3.0   1.0

Demonstrating the preference of the passed in dataframe.

>>> df2 = pd.DataFrame({'B': [3, 3], 'C': [1, 1], }, index=[1, 2])
>>> df2.combine(df1, take_smaller)
   A  B  C
0  NaN NaN NaN
1  0.0  3.0 NaN
2  NaN  3.0 NaN

>>> df2.combine(df1, take_smaller, overwrite=False)
   A  B  C
0  NaN NaN NaN
1  0.0  3.0   1.0
2  NaN  3.0   1.0
DataFrame.combine_first

DataFrame.combine_first(other)
Update null elements with value in the same location in other.

Combine two DataFrame objects by filling null values in one DataFrame with non-null values from other DataFrame. The row and column indexes of the resulting DataFrame will be the union of the two.

Parameters
- other [DataFrame] Provided DataFrame to use to fill null values.

Returns
- DataFrame The result of combining the provided DataFrame with the other object.

See also:
DataFrame.combine Perform series-wise operation on two DataFrames using a given function.

Examples

```python
>>> df1 = pd.DataFrame({"A": [None, 0], "B": [None, 4]})
>>> df2 = pd.DataFrame({"A": [1, 1], "B": [3, 3]})
>>> df1.combine_first(df2)
     A  B
0 1.0 3.0
1 0.0 4.0
```

Null values still persist if the location of that null value does not exist in other

```python
>>> df1 = pd.DataFrame({"A": [None, 0], "B": [4, None]})
>>> df2 = pd.DataFrame({"B": [3, 3], "C": [1, 1]}, index=[1, 2])
>>> df1.combine_first(df2)
     A  B   C
0  NaN 4.0  NaN
1  0.0 3.0  1.0
2  NaN 3.0  1.0
```

DataFrame.compare

DataFrame.compare(other, align_axis=1, keep_shape=False, keep_equal=False)
Compare to another DataFrame and show the differences.

New in version 1.1.0.

Parameters
- other [DataFrame] Object to compare with.
- align_axis [0 or ‘index’, 1 or ‘columns’], default 1] Determine which axis to align the comparison on.
  - 0, or ‘index’ [Resulting differences are stacked vertically] with rows drawn alternately from self and other.
  - 1, or ‘columns’ [Resulting differences are aligned horizontally] with columns drawn alternately from self and other.
**keep_shape** [bool, default False] If true, all rows and columns are kept. Otherwise, only the ones with different values are kept.

**keep_equal** [bool, default False] If true, the result keeps values that are equal. Otherwise, equal values are shown as NaNs.

Returns

**DataFrame** DataFrame that shows the differences stacked side by side.

The resulting index will be a MultiIndex with ‘self’ and ‘other’ stacked alternately at the inner level.

Raises

**ValueError** When the two DataFrames don’t have identical labels or shape.

See also:

*Series.compare* Compare with another Series and show differences.

*DataFrame.equals* Test whether two objects contain the same elements.

Notes

Matching NaNs will not appear as a difference.

Can only compare identically-labeled (i.e. same shape, identical row and column labels) DataFrames

Examples

```python
>>> df = pd.DataFrame(
...    {
...        "col1": ["a", "a", "b", "b", "a"],
...        "col2": [1.0, 2.0, 3.0, np.nan, 5.0],
...        "col3": [1.0, 2.0, 3.0, 4.0, 5.0]
...    },
...    columns=["col1", "col2", "col3"],
...)
...)
```

```
       col1  col2  col3
0      a     1.0   1.0
1      a     2.0   2.0
2      b     3.0   3.0
3      b    NaN   4.0
4      a     5.0   5.0
```

```python
>>> df2 = df.copy()
>>> df2.loc[0, 'col1'] = 'c'
>>> df2.loc[2, 'col3'] = 4.0
>>> df2
```

```
       col1  col2  col3
0      c     1.0   1.0
1      a     2.0   2.0
2      b     3.0   4.0
3      b    NaN   4.0
4      a     5.0   5.0
```

Align the differences on columns
>>> df.compare(df2)
coll col3
self other self other
0  a  c  NaN  NaN
2  NaN  NaN  3.0  4.0

Stack the differences on rows

>>> df.compare(df2, align_axis=0)
coll col3
self a NaN
t other c NaN
2 self NaN 3.0
t other NaN 4.0

Keep the equal values

>>> df.compare(df2, keep_equal=True)
coll col3
self other self other
0  a  c  1.0  1.0
2  b  b  3.0  4.0

Keep all original rows and columns

>>> df.compare(df2, keep_shape=True)
coll col2 col3
self other self other self other
0  a  c  NaN NaN NaN NaN
1 NaN NaN NaN NaN NaN NaN
2 NaN NaN NaN NaN 3.0  4.0
3 NaN NaN NaN NaN NaN NaN
4 NaN NaN NaN NaN NaN NaN

Keep all original rows and columns and also all original values

>>> df.compare(df2, keep_shape=True, keep_equal=True)
coll col2 col3
self other self other self other
0  a  c  1.0  1.0  1.0  1.0
1  a  a  2.0  2.0  2.0  2.0
2  b  b  3.0  3.0  3.0  4.0
3  b  b  NaN NaN  4.0  4.0
4  a  a  5.0  5.0  5.0  5.0

pandas.DataFrame.convert_dtypes

DataFrame.convert_dtypes(infer_objects=True, convert_string=True, convert_integer=True, convert_boolean=True, convert_floating=True)

Convert columns to best possible dtypes using dtypes supporting pd.NA.

New in version 1.0.0.

Parameters

infer_objects [bool, default True] Whether object dtypes should be converted to the best possible types.
convert_string [bool, default True] Whether object dtypes should be converted to StringDtype().

convert_integer [bool, default True] Whether, if possible, conversion can be done to integer extension types.

convert_boolean [bool, defaults True] Whether object dtypes should be converted to BooleanDtypes().

convert_floating [bool, defaults True] Whether, if possible, conversion can be done to floating extension types. If convert_integer is also True, preference will be given to integer dtypes if the floats can be faithfully casted to integers.

New in version 1.2.0.

Returns

Series or DataFrame Copy of input object with new dtype.

See also:

infer_objects Infer dtypes of objects.
to_datetime Convert argument to datetime.
to_timedelta Convert argument to timedelta.
to_numeric Convert argument to a numeric type.

Notes

By default, convert_dtypes will attempt to convert a Series (or each Series in a DataFrame) to dtypes that support pd.NA. By using the options convert_string, convert_integer, convert_boolean and convert_boolean, it is possible to turn off individual conversions to StringDtype, the integer extension types, BooleanDtype or floating extension types, respectively.

For object-dtyped columns, if infer_objects is True, use the inference rules as during normal Series/DataFrame construction. Then, if possible, convert to StringDtype, BooleanDtype or an appropriate integer or floating extension type, otherwise leave as object.

If the dtype is integer, convert to an appropriate integer extension type.

If the dtype is numeric, and consists of all integers, convert to an appropriate integer extension type. Otherwise, convert to an appropriate floating extension type.

Changed in version 1.2: Starting with pandas 1.2, this method also converts float columns to the nullable floating extension type.

In the future, as new dtypes are added that support pd.NA, the results of this method will change to support those new dtypes.
Examples

```python
>>> df = pd.DataFrame(
...     {  
...         "a": pd.Series([1, 2, 3], dtype=np.dtype("int32")),  
...         "b": pd.Series(["x", "y", "z"], dtype=np.dtype("O")),  
...         "c": pd.Series([True, False, np.nan], dtype=np.dtype("O")),  
...         "d": pd.Series(["h", "i", np.nan], dtype=np.dtype("O")),  
...         "e": pd.Series([10, np.nan, 20], dtype=np.dtype("float")),  
...         "f": pd.Series([np.nan, 100.5, 200], dtype=np.dtype("float")),  
...     }
... )

Start with a DataFrame with default dtypes.

```python
>>> df
  a  b  c  d  e  f
0 1  x  True  h  10.0  NaN
1 2  y  False  i  <NA>  100.5
2 3  z  <NA>  <NA>  20.0  200.0
``` 

```python
>>> df.dtypes
a   int32
b   object
c   object
d   object
e   float64
f   float64
dtype: object
```

Convert the DataFrame to use best possible dtypes.

```python
>>> dfn = df.convert_dtypes()
```

```python
>>> dfn
  a  b  c  d  e  f
0 1  x  True  h  10 <NA>
1 2  y  False  i  <NA>  100.5
2 3  z  <NA>  <NA>  20  200.0
``` 

```python
>>> dfn.dtypes
a   Int32
b   string
c   boolean
d   string
e   Int64
f   Float64
dtype: object
```

Start with a Series of strings and missing data represented by np.nan.

```python
>>> s = pd.Series(["a", "b", np.nan])
```

```python
>>> s
0  a
1  b
2  NaN
dtype: object
```
Obtain a Series with dtype StringDtype.

```python
>>> s.convert_dtypes()
0   a
1   b
2  <NA>
dtype: string
```

pandas.DataFrame.copy

DataFrame.copy (deep=True)
Make a copy of this object’s indices and data.

When deep=True (default), a new object will be created with a copy of the calling object’s data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When deep=False, a new object will be created without copying the calling object’s data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

Parameters

- **deep** [bool, default True] Make a deep copy, including a copy of the data and the indices. With deep=False neither the indices nor the data are copied.

Returns

- **copy** [Series or DataFrame] Object type matches caller.

Notes

When deep=True, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to copy.deepcopy in the Standard Library, which recursively copies object data (see examples below).

While Index objects are copied when deep=True, the underlying numpy array is not copied for performance reasons. Since Index is immutable, the underlying data can be safely shared and a copy is not needed.

Examples

```python
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> s
a    1
b    2
dtype: int64

>>> s_copy = s.copy()
>>> s_copy
a    1
b    2
dtype: int64
```

Shallow copy versus default (deep) copy:
Shallow copy shares data and index with original.

```python
>>> s is shallow
False
>>> s.values is shallow.values and s.index is shallow.index
True
```

Deep copy has own copy of data and index.

```python
>>> s is deep
False
>>> s.values is deep.values or s.index is deep.index
False
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```python
>>> s[0] = 3
>>> shallow[1] = 4
>>> s
a  3
b  4
dtype: int64
>>> shallow
a  3
b  4
dtype: int64
>>> deep
a  1
b  2
dtype: int64
```

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```python
>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
>>> s
0  [10, 2]
1  [3, 4]
dtype: object
>>> deep
0  [10, 2]
1  [3, 4]
dtype: object
```
DataFrame.corr

Compute pairwise correlation of columns, excluding NA/null values.

Parameters

- **method** [{‘pearson’, ‘kendall’, ‘spearman’} or callable] Method of correlation:
  - pearson : standard correlation coefficient
  - kendall : Kendall Tau correlation coefficient
  - spearman : Spearman rank correlation
  - callable: callable with input two 1d ndarrays and returning a float. Note that the returned matrix from corr will have 1 along the diagonals and will be symmetric regardless of the callable’s behavior.

- **min_periods** [int, optional] Minimum number of observations required per pair of columns to have a valid result.

Returns

- **DataFrame** Correlation matrix.

See also:

- **DataFrame.corrwith** Compute pairwise correlation with another DataFrame or Series.
- **Series.corr** Compute the correlation between two Series.

Examples

```python
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v
... >>> df = pd.DataFrame([(0.2, 0.3), (0.0, 0.6), (0.6, 0.0), (0.2, 0.1)],
...     columns=['dogs', 'cats'])
... >>> df.corr(method=histogram_intersection)
dogs   cats
dogs  1.0  0.3
cats  0.3  1.0
```

DataFrame.corrwith

Compute pairwise correlation with another DataFrame or Series.

Pairwise correlation is computed between rows or columns of DataFrame with rows or columns of Series or DataFrame. DataFrames are first aligned along both axes before computing the correlations.

Parameters

- **other** [DataFrame, Series] Object with which to compute correlations.
- **axis** [0 or ‘index’, 1 or ‘columns’], default 0] The axis to use. 0 or ‘index’ to compute column-wise, 1 or ‘columns’ for row-wise.
- **drop** [bool, default False] Drop missing indices from result.
method [{‘pearson’, ‘kendall’, ‘spearman’} or callable] Method of correlation:

• pearson : standard correlation coefficient
• kendall : Kendall Tau correlation coefficient
• spearman : Spearman rank correlation
• callable: callable with input two 1d ndarrays and returning a float.

Returns

Series Pairwise correlations.

See also:

DataFrame.corr Compute pairwise correlation of columns.

pandas.DataFrame.count

DataFrame.count (axis=0, level=None, numeric_only=False)
Count non-NA cells for each column or row.

The values None, NaN, NaT, and optionally numpy.inf (depending on pandas.options.mode.use_inf_as_na) are considered NA.

Parameters

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] If 0 or ‘index’ counts are generated for each column. If 1 or ‘columns’ counts are generated for each row.

level [int or str, optional] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a DataFrame. A str specifies the level name.

numeric_only [bool, default False] Include only float, int or boolean data.

Returns

Series or DataFrame For each column/row the number of non-NA/null entries. If level is specified returns a DataFrame.

See also:

Series.count Number of non-NA elements in a Series.

DataFrame.value_counts Count unique combinations of columns.

DataFrame.shape Number of DataFrame rows and columns (including NA elements).

DataFrame.isna Boolean same-sized DataFrame showing places of NA elements.

Examples

Constructing DataFrame from a dictionary:

```python
>>> df = pd.DataFrame({"Person":
...                     ["John", "Myla", "Lewis", "John", "Myla"],
...                     "Age": [24., np.nan, 21., 33, 26],
...                     "Single": [False, True, True, True, False])
>>> df
     Person  Age  Single
0    John   24.0   False
1   Myla    NaN    True
2  Lewis   21.0    True
3    John   33.0    True
4   Myla   26.0   False
```
Notice the uncounted NA values:

```python
>>> df.count()
Person      5
Age         4
Single      5
dtype: int64
```

Counts for each row:

```python
>>> df.count(axis='columns')
0 3
1 2
2 3
3 3
4 3
dtype: int64
```

**pandas.DataFrame.cov**

DataFrame.cov (*min_periods=None, ddof=1*)

Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the covariance matrix of the columns of the DataFrame.

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as NaN.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

**Parameters**

- **min_periods** [int, optional] Minimum number of observations required per pair of columns to have a valid result.
- **ddof** [int, default 1] Delta degrees of freedom. The divisor used in calculations is $N - ddof$, where $N$ represents the number of elements.

New in version 1.1.0.

**Returns**

DataFrame The covariance matrix of the series of the DataFrame.

**See also:**

- **Series.cov** Compute covariance with another Series.
- **core.window.ExponentialMovingWindow.cov** Exponential weighted sample covariance.
core.window.Expanding.cov  Expanding sample covariance.

core.window.Rolling.cov  Rolling sample covariance.

Notes

Returns the covariance matrix of the DataFrame’s time series. The covariance is normalized by N-ddof.

For DataFrames that have Series that are missing data (assuming that data is missing at random) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.

Examples

```python
>>> df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
                    columns=['dogs', 'cats'])
>>> df.cov()
dogs  cats
dogs  0.666667 -1.000000
cats -1.000000  1.666667

>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(1000, 5),
                    columns=['a', 'b', 'c', 'd', 'e'])
>>> df.cov()
a         b         c         d         e
a  0.998438  -0.020161  0.059277  -0.008943  0.014144
b -0.020161  1.059352  -0.008543  -0.024738  0.009826
c  0.059277  -0.008543  1.010670  -0.001486  -0.000271
d -0.008943  -0.024738  -0.001486  0.921297  -0.013692
e  0.014144  0.009826  -0.000271  -0.013692  0.977795
```

Minimum number of periods

This method also supports an optional min_periods keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```python
>>> np.random.seed(42)
>>> df = pd.DataFrame(np.random.randn(20, 3),
                    columns=['a', 'b', 'c'])
>>> df.loc[df.index[:5], 'a'] = np.nan
>>> df.loc[df.index[5:10], 'b'] = np.nan
>>> df.cov(min_periods=12)
a         b         c
a  0.316741  NaN   -0.150812
b  NaN   1.248003  0.191417
c -0.150812  0.191417  0.895202
```
pandas.DataFrame.cummax

DataFrame.cummax (axis=None, skipna=True, *args, **kwargs)
Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

Parameters
axis [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.
skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
*args, **kwargs Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns
Series or DataFrame Return cumulative maximum of Series or DataFrame.

See also:
core.window.Expanding.max Similar functionality but ignores NaN values.
DataFrame.max Return the maximum over DataFrame axis.
DataFrame.cummax Return cumulative maximum over DataFrame axis.
DataFrame.cummin Return cumulative minimum over DataFrame axis.
DataFrame.cumsum Return cumulative sum over DataFrame axis.
DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples
Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2     5.0
3   -1.0
4     0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cummax()
0    2.0
1    NaN
2     5.0
3     5.0
4     5.0
```

dtype: float64

To include NA values in the operation, use skipna=False
```python
>>> s.cummax(skipna=False)
0   2.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64
```

**DataFrame**

```python
>>> df = pd.DataFrame([[2.0, 1.0],
                      [3.0, np.nan],
                      [1.0, 0.0]],
                      columns=list('AB'))

>>> df
   A  B
0  2.0  1.0
1  3.0   NaN
2  1.0  0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cummax()
   A   B
0  2.0  2.0
1  3.0   NaN
2  1.0  1.0
```

To iterate over columns and find the maximum in each row, use `axis=1`

```python
>>> df.cummax(axis=1)
   A   B
0  2.0  2.0
1  3.0   NaN
2  1.0  1.0
```

**pandas.DataFrame.cummin**

`DataFrame.cummin(axis=None, skipna=True, *args, **kwargs)`

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

**Parameters**

- `axis` ([0 or ‘index’, 1 or ‘columns’], default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.
- `skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- `*args, **kwargs` Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

Series or DataFrame Return cumulative minimum of Series or DataFrame.
See also:

**core.window.Expanding.min** Similar functionality but ignores NaN values.

**DataFrame.min** Return the minimum over DataFrame axis.

**DataFrame.cummax** Return cumulative maximum over DataFrame axis.

**DataFrame.cummin** Return cumulative minimum over DataFrame axis.

**DataFrame.cumsum** Return cumulative sum over DataFrame axis.

**DataFrame.cumprod** Return cumulative product over DataFrame axis.

### Examples

#### Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cummin()
0    2.0
1    NaN
2    2.0
3   -1.0
4   -1.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cummin(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

#### DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A  B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```
By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```python
>>> df.cummin()
   A   B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```python
>>> df.cummin(axis=1)
   A   B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

**pandas.DataFrame.cumprod**

`DataFrame.cumprod(axis=None, skipna=True, *args, **kwargs)`

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

**Parameters**

- `axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.
- `skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- `*args, **kwargs` Additional keywords have no effect but might be accepted for compatibility with NumPy.

**Returns**

- `Series` or `DataFrame` Return cumulative product of Series or DataFrame.

See also:

- `core.window.Expanding.prod` Similar functionality but ignores NaN values.
- `DataFrame.prod` Return the product over DataFrame axis.
- `DataFrame.cummax` Return cumulative maximum over DataFrame axis.
- `DataFrame.cummin` Return cumulative minimum over DataFrame axis.
- `DataFrame.cumsum` Return cumulative sum over DataFrame axis.
- `DataFrame.cumprod` Return cumulative product over DataFrame axis.
Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4     0.0
dtype: float64
```

By default, NA values are ignored.

```python
>>> s.cumprod()
0    2.0
1    NaN
2   10.0
3  -10.0
4    -0.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```python
>>> s.cumprod(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```python
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                    columns=list('AB'))
>>> df
   A   B
0  2.0  1.0
1  3.0   NaN
2  1.0   0.0
```

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'

```python
>>> df.cumprod()
   A   B
0  2.0  1.0
1  6.0   NaN
2  6.0   0.0
```

To iterate over columns and find the product in each row, use `axis=1`

```python
>>> df.cumprod(axis=1)
   A   B
0  2.0  1.0
1  6.0   NaN
2  6.0   0.0
```
pandas.DataFrame.cumsum

DataFrame.cumsum(axis=None, skipna=True, *args, **kwargs)

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

Parameters

- **axis** [{0 or 'index', 1 or 'columns'}, default 0] The index or the name of the axis. 0 is equivalent to None or 'index'.
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- ***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

- **Series or DataFrame** Return cumulative sum of Series or DataFrame.

See also:

core.window.Expanding.sum Similar functionality but ignores NaN values.

DataFrame.sum Return the sum over DataFrame axis.

DataFrame.cummax Return cumulative maximum over DataFrame axis.

DataFrame.cummin Return cumulative minimum over DataFrame axis.

DataFrame.cumsum Return cumulative sum over DataFrame axis.

DataFrame.cumprod Return cumulative product over DataFrame axis.

Examples

Series

```python
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.
>>> s.cumsum()
0   2.0
1   NaN
2   7.0
3   6.0
4   6.0
dtype: float64

To include NA values in the operation, use `skipna=False`

>>> s.cumsum(skipna=False)
0   2.0
1   NaN
2   NaN
3   NaN
4   NaN
dtype: float64

DataFrame

>>> df = pd.DataFrame([[2.0, 1.0],
                      ... [3.0, np.nan],
                      ... [1.0, 0.0]],
                      ... columns=list('AB'))

>>> df
   A  B
0  2.0 1.0
1  3.0 NaN
2  1.0 0.0

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

>>> df.cumsum()
   A  B
0  2.0 1.0
1  5.0 NaN
2  6.0 1.0

To iterate over columns and find the sum in each row, use `axis=1`

>>> df.cumsum(axis=1)
   A  B
0  2.0 3.0
1  3.0 NaN
2  1.0 1.0
pandas.DataFrame.describe

DataFrame.describe(percentiles=None, include=None, exclude=None, datetime_is_numeric=False)

Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset’s distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

percentiles [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

include ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for Series. Here are the options:
• ‘all’ : All columns of the input will be included in the output.
• A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit numpy.number. To limit it instead to object columns submit the numpy.object data type. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To select pandas categorical columns, use 'category'
• None (default) : The result will include all numeric columns.

exclude [list-like of dtypes or None (default), optional] A black list of data types to omit from the result. Ignored for Series. Here are the options:
• A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit numpy.number. To exclude object columns submit the data type numpy.object. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To exclude pandas categorical columns, use 'category'
• None (default) : The result will exclude nothing.

datetime_is_numeric [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

New in version 1.1.0.

Returns

Series or DataFrame Summary statistics of the Series or Dataframe provided.

See also:

DataFrame.count Count number of non-NA/null observations.
DataFrame.max Maximum of the values in the object.
DataFrame.min Minimum of the values in the object.
DataFrame.mean Mean of the values.
DataFrame.std Standard deviation of the observations.
**DataFrame.select_dtypes** Subset of a DataFrame including/excluding columns based on their dtype.

**Notes**

For numeric data, the result’s index will include `count`, `mean`, `std`, `min`, `max` as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result’s index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value’s frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a DataFrame, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a DataFrame are analyzed for the output. The parameters are ignored when analyzing a Series.

**Examples**

Describing a numeric Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count    3.0
mean     2.0
std      1.0
min      1.0
25%      1.5
50%      2.0
75%      2.5
max      3.0
dtype: float64
```

Describing a categorical Series.

```python
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count      4.0
unique     3.0
top         a
freq       2.0
dtype: object
```

Describing a timestamp Series.

```python
>>> s = pd.Series([
...     np.datetime64("2000-01-01"),
...     np.datetime64("2010-01-01"),
...     np.datetime64("2010-01-01")
...  ])
```
Describing a DataFrame. By default only numeric fields are returned.

```python
>>> s.describe(datetime_is_numeric=True)
count   3
mean    2006-09-01 08:00:00
min     2000-01-01 00:00:00
25%     2004-12-31 12:00:00
50%     2010-01-01 00:00:00
75%     2010-01-01 00:00:00
max     2010-01-01 00:00:00
dtype: object
```

Describing all columns of a DataFrame regardless of data type.

```python
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d','e','f']),
...                    'numeric': [1, 2, 3],
...                    'object': ['a', 'b', 'c']})
>>> df.describe(include='all')
categorical         numeric          object
                         count   3.0           3
                         unique   3       NaN         3
                          top     f     NaN        NaN
                         freq   1       NaN         1
                          mean    NaN      2.0       NaN
                         std     NaN      1.0       NaN
                         min     NaN       1.0       NaN
                         25%    NaN      1.5       NaN
                         50%    NaN      2.0       NaN
                         75%    NaN      2.5       NaN
                          max    NaN      3.0       NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```python
>>> df.numeric.describe()
count   3.0
mean    2.0
std     1.0
min     1.0
25%     1.5
50%     2.0
75%     2.5
max     3.0
Name: numeric, dtype: float64
```
Including only numeric columns in a DataFrame description.

```python
>>> df.describe(include=[np.number])
    numeric
     count 3.0
      mean 2.0
       std 1.0
       min 1.0
      25% 1.5
     50% 2.0
     75% 2.5
      max 3.0
```

Including only string columns in a DataFrame description.

```python
>>> df.describe(include=[object])
     object
       count 3
      unique 3
        top  a
       freq 1
```

Including only categorical columns from a DataFrame description.

```python
>>> df.describe(include=['category'])
    categorical
     count 3
    unique 3
categorical top d
     freq 1
```

Excluding numeric columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.number])
    categorical object
     count 3 3
    unique 3 3
categorical top f a
     freq 1 1
```

Excluding object columns from a DataFrame description.

```python
>>> df.describe(exclude=[object])
    categorical numeric
     count 3 3.0
    unique 3 NaN
     top  f NaN
categorical freq 1 NaN
     mean NaN 2.0
    std  NaN 1.0
    min NaN 1.0
   25% NaN 1.5
   50% NaN 2.0
  75% NaN 2.5
     max NaN 3.0
```
DataFrame.diff

**DataFrame.diff**(periods=1, axis=0)

First discrete difference of element.

Calculates the difference of a DataFrame element compared with another element in the DataFrame (default is element in previous row).

**Parameters**

- **periods** [int, default 1] Periods to shift for calculating difference, accepts negative values.
- **axis** [[0 or ‘index’, 1 or ‘columns’], default 0] Take difference over rows (0) or columns (1).

**Returns**

- Dataframe First differences of the Series.

**See also:**

- **DataFrame.pct_change** Percent change over given number of periods.
- **DataFrame.shift** Shift index by desired number of periods with an optional time freq.
- **Series.diff** First discrete difference of object.

**Notes**

For boolean dtypes, this uses `operator.xor()` rather than `operator.sub()`. The result is calculated according to current dtype in DataFrame, however dtype of the result is always float64.

**Examples**

Difference with previous row

```python
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
...                    'b': [1, 1, 2, 3, 5, 8],
...                    'c': [1, 4, 9, 16, 25, 36]})

>>> df
   a  b  c
0  1  1  1
1  2  1  4
2  3  2  9
3  4  3 16
4  5  5 25
5  6  8 36

>>> df.diff()
   a  b  c
0  NaN NaN NaN
1  1.0  0.0  3.0
2  1.0  1.0  5.0
3  1.0  1.0  7.0
4  1.0  2.0  9.0
5  1.0  3.0 11.0
```
Difference with previous column

```python
>>> df.diff(axis=1)
     a  b  c
0   NaN 0  0
1   NaN -1  3
2   NaN -1  7
3   NaN -1 13
4   NaN  0 20
5   NaN  2 28
```

Difference with 3rd previous row

```python
>>> df.diff(periods=3)
     a  b  c
0   NaN NaN NaN
1   NaN NaN NaN
2   NaN NaN NaN
3   3.0 2.0 15.0
4   3.0 4.0 21.0
5   3.0 6.0 27.0
```

Difference with following row

```python
>>> df.diff(periods=-1)
     a  b  c
0  -1.0 0.0 -3.0
1  -1.0 -1.0 -5.0
2  -1.0 -1.0 -7.0
3  -1.0 -2.0 -9.0
4  -1.0 -3.0 -11.0
5   NaN NaN NaN
```

Overflow in input dtype

```python
>>> df = pd.DataFrame({'a': [1, 0]}, dtype=np.uint8)
>>> df.diff()
     a
0   NaN
1  255.0
```

### pandas.DataFrame.div

DataFrame.div (other, axis='columns', level=None, fill_value=None)  
Get Floating division of dataframe and other, element-wise (binary operator truediv).

Equivalent to dataframe / other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rtruediv.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

- **axis** [[0 or 'index', 1 or 'columns']] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360]},
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle    0       360
triangle   3       180
rectangle  4       360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle    1       361
triangle   4       181
rectangle  5       361
```

```python
>>> df.add(1)
   angles  degrees
circle    1       361
triangle   4       181
rectangle  5       361
```
Divide by constant with reverse version.

```python
>>> df.div(10)
angles   degrees
circle  0.0       36.0
triangle 0.3       18.0
rectangle 0.4      36.0
```

```python
>>> df.rdiv(10)
angles   degrees
circle   inf       0.027778
triangle 3.333333  0.055556
rectangle 2.500000 0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
angles   degrees
circle  -1       358
triangle  2       178
rectangle  3      358
```

```python
>>> df.sub([1, 2], axis='columns')
angles   degrees
circle  -1       358
triangle  2       178
rectangle  3      358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
angles   degrees
circle  -1       359
triangle  2       179
rectangle  3      359
```

Multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({'angles': [0, 3, 4]},
                      index=['circle', 'triangle', 'rectangle'])

>>> df * other
angles   degrees
circle  0       NaN
triangle  9       NaN
rectangle 16      NaN
```

```python
>>> df.mul(other, fill_value=0)
angles   degrees
circle  0       0.0
triangle  9       0.0
rectangle 16      0.0
```
Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                             'degrees': [360, 180, 360, 360, 540, 720]},
...                             index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                             ['circle', 'triangle', 'rectangle',
...                             'square', 'pentagon', 'hexagon']])
```

```plaintext
df_multindex
angles   degrees
A circle    0    360
triangle    3    180
rectangle   4    360
B square    4    360
pentagon    5    540
hexagon    6    720
```

```python
>>> df_multindex.div(df_multindex, level=1, fill_value=0)
```

```plaintext
df_multindex.div(df_multindex, level=1, fill_value=0)
angles   degrees
A circle    NaN    1.0
triangle    1.0    1.0
rectangle   1.0    1.0
B square    0.0    0.0
pentagon    0.0    0.0
hexagon    0.0    0.0
```

**pandas.DataFrame.divide**

```python
DataFrame.divide(other, axis='columns', level=None, fill_value=None)
```

Get Floating division of dataframe and other, element-wise (binary operator truediv).

Equivalent to `dataframe / other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `rtruediv`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `.-`, `/`, `//`, `%`, `**`.

**Parameters**

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- `fill_value` [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

- `DataFrame` Result of the arithmetic operation.

**See also:**

- `DataFrame.add` Add DataFrames.
- `DataFrame.sub` Subtract DataFrames.
**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

**Examples**

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
     angles  degrees
circle     0      360
triangle    3      180
rectangle   4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
     angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

```python
>>> df.add(1)
     angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
     angles  degrees
circle    0      36.0
triangle   0.3     18.0
rectangle  0.4     36.0
```

```python
>>> df.rdiv(10)
      angles  degrees
circle       inf   0.027778
triangle  3.333333   0.055556
rectangle  2.500000   0.027778
```

Subtract a list and Series by axis with operator version.
>>> df = [1, 2]
    angles  degrees
  circle   -1     358
   triangle    2     178
   rectangle    3     358

>>> df.sub([1, 2], axis='columns')
    angles  degrees
  circle   -1     358
   triangle    2     178
   rectangle    3     358

>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
    angles  degrees
  circle   -1     359
   triangle    2     179
   rectangle    3     359

Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])

>>> df * other
    angles  degrees
  circle    0    NaN
   triangle   9    NaN
   rectangle 16    NaN

>>> df.mul(other, fill_value=0)
    angles  degrees
  circle    0     0.0
   triangle   9     0.0
   rectangle 16     0.0

Divide by a MultiIndex by level.

>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               index=['A', 'A', 'A', 'B', 'B', 'B'],
                               columns=['circle', 'triangle', 'rectangle',
                                        'square', 'pentagon', 'hexagon'])

>>> df_multindex
    angles  degrees
  A circle    0     360
   triangle    3     180
   rectangle    4     360
  B square    4     360
   pentagon    5     540
   hexagon    6     720
pandas: powerful Python data analysis toolkit, Release 1.3.1

```
>>> df.div(df_multindex, level=1, fill_value=0)
     angles  degrees
   A  circle    NaN      1.0
       triangle  1.0      1.0
       rectangle 1.0      1.0
   B   square  0.0      0.0
       pentagon 0.0      0.0
       hexagon 0.0      0.0
```

### pandas.DataFrame.dot

*DataFrame.dot(other)*

Compute the matrix multiplication between the DataFrame and other.

This method computes the matrix product between the DataFrame and the values of an other Series, DataFrame or a numpy array.

It can also be called using `self @ other` in Python >= 3.5.

**Parameters**

- **other** [Series, DataFrame or array-like] The other object to compute the matrix product with.

**Returns**

- **Series or DataFrame** If other is a Series, return the matrix product between self and other as a Series. If other is a DataFrame or a numpy.array, return the matrix product of self and other in a DataFrame of a np.array.

**See also:**

- **Series.dot** Similar method for Series.

**Notes**

The dimensions of DataFrame and other must be compatible in order to compute the matrix multiplication. In addition, the column names of DataFrame and the index of other must contain the same values, as they will be aligned prior to the multiplication.

The dot method for Series computes the inner product, instead of the matrix product here.

**Examples**

Here we multiply a DataFrame with a Series.

```
>>> df = pd.DataFrame([[0, 1, -2, -1], [1, 1, 1, 1]])
>>> s = pd.Series([1, 1, 2, 1])
>>> df.dot(s)
0   -4
1    5
```

```
Here we multiply a DataFrame with another DataFrame.
```
>>> other = pd.DataFrame([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(other)
    0  1
0  0  1  4
1  1  2  2

Note that the dot method give the same result as @

>>> df @ other
    0  1
0  0  1  4
1  1  2  2

The dot method works also if other is an np.array.

>>> arr = np.array([[0, 1], [1, 2], [-1, -1], [2, 0]])
>>> df.dot(arr)
    0  1
0  0  1  4
1  1  2  2

Note how shuffling of the objects does not change the result.

>>> s2 = s.reindex([1, 0, 2, 3])
>>> df.dot(s2)
    0  1
dtype: int64

pandas.DataFrame.drop

DataFrame.drop(labels=None, axis=0, index=None, columns=None, level=None, inplace=False, errors='raise')

Drop specified labels from rows or columns.

Remove rows or columns by specifying label names and corresponding axis, or by specifying directly
index or column names. When using a multi-index, labels on different levels can be removed by specifying
the level. See the user guide <advanced.shown_levels> for more information about the now unused levels.

Parameters

- labels [single label or list-like] Index or column labels to drop.
- axis [[0 or ‘index’, 1 or ‘columns’], default 0] Whether to drop labels from the index
  (0 or ‘index’) or columns (1 or ‘columns’).
- index [single label or list-like] Alternative to specifying axis (labels, axis=0 is
equivalent to index=labels).
- columns [single label or list-like] Alternative to specifying axis (labels, axis=1
  is equivalent to columns=labels).
- level [int or level name, optional] For MultiIndex, level from which the labels will be
  removed.
- inplace [bool, default False] If False, return a copy. Otherwise, do operation inplace
  and return None.
**errors**  [(‘ignore’, ‘raise’), default ‘raise’] If ‘ignore’, suppress error and only existing labels are dropped.

**Returns**

DataFrame or None  DataFrame without the removed index or column labels or None if inplace=True.

**Raises**

**KeyError**  If any of the labels is not found in the selected axis.

**See also:**

*DataFrame.loc*  Label-location based indexer for selection by label.

*DataFrame.dropna*  Return DataFrame with labels on given axis omitted where (all or any) data are missing.

*DataFrame.drop_duplicates*  Return DataFrame with duplicate rows removed, optionally only considering certain columns.

*Series.drop*  Return Series with specified index labels removed.

**Examples**

```python
>>> df = pd.DataFrame(np.arange(12).reshape(3, 4),
                   columns=['A', 'B', 'C', 'D'])
>>> df
   A  B  C  D
0  0  1  2  3
1  4  5  6  7
2  8  9 10 11
```

Drop columns

```python
>>> df.drop(['B', 'C'], axis=1)
   A  D
0  0  3
1  4  7
2  8 11
```

```python
>>> df.drop(columns=['B', 'C'])
   A  D
0  0  3
1  4  7
2  8 11
```

Drop a row by index

```python
>>> df.drop([0, 1])
   A  B  C  D
2  8  9 10 11
```

Drop columns and/or rows of MultiIndex DataFrame

```python
>>> midx = pd.MultiIndex(levels=[['lama', 'cow', 'falcon'], ['speed', 'weight', 'length']])
>>> midx
```

(continues on next page)
codes=[[0, 0, 0, 1, 1, 1, 2, 2, 2],
[0, 1, 2, 0, 1, 2, 0, 1, 2]])

>>> df = pd.DataFrame(index=midx, columns=['big', 'small'],
                    data=[[45, 30], [200, 100], [1.5, 1], [30, 20],
                    [250, 150], [1.5, 0.8], [320, 250],
                    [1, 0.8], [0.3, 0.2]])

>>> df
                  big   small
lama   speed  45.0  30.0
        weight 200.0 100.0
        length  1.5   1.0
cow    speed  30.0  20.0
        weight 250.0 150.0
        length  1.5   0.8
falcon speed 320.0 250.0
        weight  1.0   0.8
        length  0.3   0.2

>>> df.drop(index='cow', columns='small')
                  big
lama   speed  45.0
        weight 200.0
        length  1.5
falcon speed 320.0
        weight  1.0
        length  0.3

>>> df.drop(index='length', level=1)
                  big   small
lama   speed  45.0  30.0
        weight 200.0 100.0
cow    speed  30.0  20.0
        weight 250.0 150.0
falcon speed 320.0 250.0
        weight  1.0   0.8

**pandas.DataFrame.drop_duplicates**

DataFrame.drop_duplicates (subset=None, keep='first', inplace=False, ignore_index=False)
Return DataFrame with duplicate rows removed.

Considering certain columns is optional. Indexes, including time indexes are ignored.

**Parameters**

- **subset** [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns.
- **keep** ['first', 'last', False], default ‘first’ Determines which duplicates (if any) to keep. - first : Drop duplicates except for the first occurrence. - last : Drop duplicates except for the last occurrence. - False : Drop all duplicates.
- **inplace** [bool, default False] Whether to drop duplicates in place or to return a copy.
- **ignore_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.
New in version 1.0.0.

Returns

DataFrame or None  DataFrame with duplicates removed or None if inplace=True.

See also:

DataFrame.value_counts  Count unique combinations of columns.

Examples

Consider dataset containing ramen rating.

```python
>>> df = pd.DataFrame(
...     {  
...         'brand': ['Yum Yum', 'Yum Yum', 'Indomie', 'Indomie', 'Indomie'],  
...         'style': ['cup', 'cup', 'cup', 'pack', 'pack'],  
...         'rating': [4, 4, 3.5, 15, 5]  
...     })

>>> df
     brand style rating
0    Yum Yum     cup    4.0
1    Yum Yum     cup    4.0
2   Indomie     cup    3.5
3   Indomie     pack   15.0
4   Indomie     pack    5.0
```

By default, it removes duplicate rows based on all columns.

```python
>>> df.drop_duplicates()
     brand style rating
0    Yum Yum     cup    4.0
2   Indomie     cup    3.5
3   Indomie     pack   15.0
4   Indomie     pack    5.0
```

To remove duplicates on specific column(s), use subset.

```python
>>> df.drop_duplicates(subset=['brand'])
     brand style rating
0    Yum Yum     cup    4.0
2   Indomie     cup    3.5
```

To remove duplicates and keep last occurrences, use keep.

```python
>>> df.drop_duplicates(subset=['brand', 'style'], keep='last')
     brand style rating
1    Yum Yum     cup    4.0
2   Indomie     cup    3.5
4   Indomie     pack    5.0
```
DataFrame.droplevel

DataFrame.droplevel (level, axis=0)
Return Series/DataFrame with requested index / column level(s) removed.

Parameters

- **level** [int, str, or list-like] If a string is given, must be the name of a level If list-like, elements must be names or positional indexes of levels.
- **axis** [{0 or 'index', 1 or 'columns'}, default 0] Axis along which the level(s) is removed:
  - 0 or 'index': remove level(s) in column.
  - 1 or 'columns': remove level(s) in row.

Returns

Series/DataFrame  Series/DataFrame with requested index / column level(s) removed.

Examples

```python
>>> df = pd.DataFrame([  
...     [1, 2, 3, 4],  
...     [5, 6, 7, 8],  
...     [9, 10, 11, 12]  
... ]).set_index([0, 1]).rename_axis(['a', 'b'])

>>> df.columns = pd.MultiIndex.from_tuples([  
...     ('c', 'e'), ('d', 'f')  
... ], names=['level_1', 'level_2'])

>>> df
     level_1  c  d
    level_2  e  f
   a  b
  1  2  3  4
  5  6  7  8
  9 10 11 12

>>> df.droplevel('a')
     level_1  c  d
    level_2  e  f
   b
  2  3  4
  6  7  8
 10 11 12

>>> df.droplevel('level_2', axis=1)
     level_1  c  d
    a  b
  1  2  3  4
  5  6  7  8
  9 10 11 12
```
pandas.DataFrame.dropna

DataFrame.dropna (axis=0, how='any', thresh=None, subset=None, inplace=False)
Remove missing values.

See the User Guide for more on which values are considered missing, and how to work with missing data.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] Determine if rows or columns which contain missing values are removed.

• 0, or 'index': Drop rows which contain missing values.
• 1, or 'columns': Drop columns which contain missing value.

Changed in version 1.0.0: Pass tuple or list to drop on multiple axes. Only a single axis is allowed.

how [{'any', 'all'}, default 'any'] Determine if row or column is removed from DataFrame, when we have at least one NA or all NA.

• 'any': If any NA values are present, drop that row or column.
• 'all': If all values are NA, drop that row or column.

thresh [int, optional] Require that many non-NA values.

subset [array-like, optional] Labels along other axis to consider, e.g. if you are dropping rows these would be a list of columns to include.

inplace [bool, default False] If True, do operation inplace and return None.

Returns

DataFrame or None DataFrame with NA entries dropped from it or None if inplace=True.

See also:

DataFrame.isna Indicate missing values.
DataFrame.notna Indicate existing (non-missing) values.
DataFrame.fillna Replace missing values.
Series.dropna Drop missing values.
Index.dropna Drop missing indices.

Examples

```python
>>> df = pd.DataFrame({"name": ['Alfred', 'Batman', 'Catwoman'],
... "toy": [np.nan, 'Batmobile', 'Bullwhip'],
... "born": [pd.NaT, pd.Timestamp("1940-04-25"),
... pd.NaT]})
```
```
>>> df
  name   toy      born
0  Alfred   NaN      NaT
1  Batman  Batmobile 1940-04-25
2  Catwoman  Bullwhip      NaT
```

Drop the rows where at least one element is missing.
```python
>>> df.dropna()
   name    toy    born
0  Alfred     NaN    NaT
1  Batman  Batmobile 1940-04-25
2  Catwoman    Bullwhip    NaT
```

Drop the columns where at least one element is missing.

```python
>>> df.dropna(axis='columns')
   name
0  Alfred
1  Batman
2  Catwoman
```

Drop the rows where all elements are missing.

```python
>>> df.dropna(how='all')
   name    toy    born
0  Alfred    NaN    NaT
1  Batman  Batmobile 1940-04-25
2  Catwoman    Bullwhip    NaT
```

Keep only the rows with at least 2 non-NA values.

```python
>>> df.dropna(thresh=2)
   name    toy    born
1  Batman  Batmobile 1940-04-25
2  Catwoman    Bullwhip    NaT
```

Define in which columns to look for missing values.

```python
>>> df.dropna(subset=['name', 'toy'])
   name    toy    born
0  Alfred     NaN    NaT
1  Batman  Batmobile 1940-04-25
2  Catwoman    Bullwhip    NaT
```

Keep the DataFrame with valid entries in the same variable.

```python
>>> df.dropna(inplace=True)
>>> df
   name    toy    born
0  Alfred     NaN    NaT
1  Batman  Batmobile 1940-04-25
2  Catwoman    Bullwhip    NaT
```

### pandas.DataFrame.duplicated

DataFrame.duplicated(subset=None, keep='first')

Return boolean Series denoting duplicate rows.

Considering certain columns is optional.

**Parameters**

- **subset** [column label or sequence of labels, optional] Only consider certain columns for identifying duplicates, by default use all of the columns.

- **keep** [['first', 'last', False], default 'first'] Determines which duplicates (if any) to mark.
  - first: Mark duplicates as True except for the first occurrence.
last: Mark duplicates as True except for the last occurrence.

False: Mark all duplicates as True.

Returns

Series Boolean series for each duplicated rows.

See also:

Index.duplicated Equivalent method on index.

Series.duplicated Equivalent method on Series.

Series.drop_duplicates Remove duplicate values from Series.

DataFrame.drop_duplicates Remove duplicate values from DataFrame.

Examples

Consider dataset containing ramen rating.

```python
>>> df = pd.DataFrame({
...   'brand': ['Yum Yum', 'Yum Yum', 'Indomie', 'Indomie', 'Indomie'],
...   'style': ['cup', 'cup', 'cup', 'pack', 'pack'],
...   'rating': [4, 4, 3.5, 15, 5]
... })
```

```python
>>> df
     brand style rating
0    Yum Yum  cup    4.0
1    Yum Yum  cup    4.0
2   Indomie  cup    3.5
3   Indomie  pack   15.0
4   Indomie  pack    5.0
```

By default, for each set of duplicated values, the first occurrence is set on False and all others on True.

```python
>>> df.duplicated()
0     False
1      True
2     False
3     False
4     False
dtype: bool
```

By using ‘last’, the last occurrence of each set of duplicated values is set on False and all others on True.

```python
>>> df.duplicated(keep='last')
0      True
1     False
2     False
3     False
4     False
dtype: bool
```

By setting keep on False, all duplicates are True.
>>> df.duplicated(keep=False)
0    True
1    True
2     False
3     False
4     False
dtype: bool

To find duplicates on specific column(s), use subset.

>>> df.duplicated(subset=['brand'])
0    False
1     True
2    False
3     True
4     True
dtype: bool

pandas.DataFrame.eq

DataFrame.eq(other, axis='columns', level=None)

Get Equal to of dataframe and other, element-wise (binary operator eq).

Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.

Equivalent to ==, !=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’).

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.
DataFrame.ne Compare DataFrames for inequality elementwise.
DataFrame.le Compare DataFrames for less than inequality or equality elementwise.
DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.
DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.
DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.
Notes

Mismatched indices will be unioned together. \( NaN \) values are considered different (i.e. \( NaN \neq NaN \)).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                     'revenue': [100, 250, 300]},
...                     index=['A', 'B', 'C'])

>>> df
   cost  revenue
A    250      100
B    150      250
C    100      300

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
   cost  revenue
A   False     True
B   False    False
C    True    False

```python
>>> df.eq(100)
   cost  revenue
A   False     True
B   False    False
C    True    False

When \( other \) is a \textit{Series}, the columns of a DataFrame are aligned with the index of \( other \) and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
   cost  revenue
A   True     True
B   True    False
C  False     True

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
   cost  revenue
A   True    False
B   True     True
C   True     True
D   True     True

When comparing to an arbitrary sequence, the number of columns must match the number elements in \( other \):

```python
>>> df == [250, 100]
   cost  revenue
A    True     True
B   False    False
C  False    False

Use the method to control the axis:
Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150],
...                       index=['A', 'B', 'C', 'D'])

>>> other
revenue
A  300
B  250
C  100
D  150
```

```python
>>> df.gt(other)
cost revenue
A  False False
B  False False
C  False True
D  False False
```

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225],
...                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                      ['A', 'B', 'C', 'A', 'B', 'C']])

>>> df_multindex
   cost  revenue
Q1 A   250     100
     B   150     250
     C    100     300
Q2 A   150     200
     B   300     175
     C   220     225
```

```python
>>> df.le(df_multindex, level=1)
cost  revenue
Q1 A   True    True
     B   True    True
     C   True    True
Q2 A  False    True
     B   True    False
     C   True    False
```
**pandas.DataFrame.equals**

**DataFrame.equals (other)**

Test whether two objects contain the same elements.

This function allows two Series or DataFrames to be compared against each other to see if they have the same shape and elements. NaNs in the same location are considered equal.

The row/column index do not need to have the same type, as long as the values are considered equal. Corresponding columns must be of the same dtype.

**Parameters**

- **other** [Series or DataFrame] The other Series or DataFrame to be compared with the first.

**Returns**

bool True if all elements are the same in both objects, False otherwise.

**See also:**

*Series.eq* Compare two Series objects of the same length and return a Series where each element is True if the element in each Series is equal, False otherwise.

*DataFrame.eq* Compare two DataFrame objects of the same shape and return a DataFrame where each element is True if the respective element in each DataFrame is equal, False otherwise.

*testing.assert_series_equal* Raises an AssertionError if left and right are not equal. Provides an easy interface to ignore inequality in dtypes, indexes and precision among others.

*testing.assert_frame_equal* Like assert_series_equal, but targets DataFrames.

*numpy.array_equal* Return True if two arrays have the same shape and elements, False otherwise.

**Examples**

```python
>>> df = pd.DataFrame({1: [10], 2: [20]})
>>> df
   1  2
0  10 20

DataFrames df and exactly_equal have the same types and values for their elements and column labels, which will return True.

```python
>>> exactly_equal = pd.DataFrame({1: [10], 2: [20]})
>>> exactly_equal
   1  2
0 10 20
>>> df.equals(exactly_equal)
True
```

DataFrames df and different_column_type have the same element types and values, but have different types for the column labels, which will still return True.

```python
>>> different_column_type = pd.DataFrame({1.0: [10], 2.0: [20]})
>>> different_column_type
   1.0  2.0
0    10   20
```

(continues on next page)
DataFrames df and different_data_type have different types for the same values for their elements, and will return False even though their column labels are the same values and types.

```
>>> different_data_type = pd.DataFrame({1: [10.0], 2: [20.0]})
>>> different_data_type
   1  2
0 10.0 20.0
>>> df.equals(different_data_type)
False
```

**pandas.DataFrame.eval**

**DataFrame.eval** *(expr, inplace=False, **kwargs)*

Evaluate a string describing operations on DataFrame columns.

Operates on columns only, not specific rows or elements. This allows eval to run arbitrary code, which can make you vulnerable to code injection if you pass user input to this function.

**Parameters**

- **expr** *(str)* The expression string to evaluate.
- **inplace** *(bool, default False)* If the expression contains an assignment, whether to perform the operation inplace and mutate the existing DataFrame. Otherwise, a new DataFrame is returned.
- **kwargs**

  See the documentation for **eval()** for complete details on the keyword arguments accepted by **query()**.

**Returns**

- **ndarray, scalar, pandas object, or None** The result of the evaluation or None if inplace=True.

**See also:**

- **DataFrame.query** Evaluates a boolean expression to query the columns of a frame.
- **DataFrame.assign** Can evaluate an expression or function to create new values for a column.
- **eval** Evaluate a Python expression as a string using various backends.

**Notes**

For more details see the API documentation for **eval()**. For detailed examples see enhancing performance with eval.
Examples

```python
>>> df = pd.DataFrame({'A': range(1, 6), 'B': range(10, 0, -2)})
>>> df
   A  B
0  1 10
1  2  8
2  3  6
3  4  4
4  5  2
>>> df.eval('A + B')
   0  1  2  3  4
0  11
1  10
2  9
3  8
4  7
dtype: int64
Assignment is allowed though by default the original DataFrame is not modified.

>>> df.eval('C = A + B')
   A  B  C
0  1 10 11
1  2  8 10
2  3  6  9
3  4  4  8
4  5  2  7
>>> df
   A  B
0  1 10
1  2  8
2  3  6
3  4  4
4  5  2
Use inplace=True to modify the original DataFrame.

>>> df.eval('C = A + B', inplace=True)
>>> df
   A  B  C
0  1 10 11
1  2  8 10
2  3  6  9
3  4  4  8
4  5  2  7
Multiple columns can be assigned to using multi-line expressions:

```python
>>> df.eval('...
...   
...   C = A + B
...   D = A - B
...   
...   )
   A  B  C  D
0  1 10 11  -9
1  2  8  10  -6
```
pandas.DataFrame.ewm

DataFrame.ewm (com=None, span=None, halflife=None, alpha=None, min_periods=0, adjust=True, ignore_na=False, axis=0, times=None)

Provide exponential weighted (EW) functions.

Available EW functions: mean(), var(), std(), corr(), cov().

Exactly one parameter: com, span, halflife, or alpha must be provided.

Parameters

com [float, optional] Specify decay in terms of center of mass, \( \alpha = 1/(1 + com) \), for \( com \geq 0 \).

span [float, optional] Specify decay in terms of span, \( \alpha = 2/(span+1) \), for \( span \geq 1 \).

halflife [float, str, timedelta, optional] Specify decay in terms of half-life, \( \alpha = 1 - \exp(-\ln(2)/halflife) \), for \( halflife > 0 \).

If times is specified, the time unit (str or timedelta) over which an observation decays to half its value. Only applicable to mean() and halflife value will not apply to the other functions.

New in version 1.1.0.

alpha [float, optional] Specify smoothing factor \( \alpha \) directly, \( 0 < \alpha \leq 1 \).

min_periods [int, default 0] Minimum number of observations in window required to have a value (otherwise result is NA).

adjust [bool, default True] Divide by decaying adjustment factor in beginning periods to account for imbalance in relative weightings (viewing EWMA as a moving average).

• When adjust=True (default), the EW function is calculated using weights \( w_t = (1 - \alpha)^t \). For example, the EW moving average of the series \([x_0, x_1, ..., x_t]\) would be:

\[
y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + ... + (1 - \alpha)^tx_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + ... + (1 - \alpha)^t}
\]

• When adjust=False, the exponentially weighted function is calculated recursively:

\[
y_0 = x_0 \\
y_t = (1 - \alpha)y_{t-1} + \alpha x_t,
\]

ignore_na [bool, default False] Ignore missing values when calculating weights; specify True to reproduce pre-0.15.0 behavior.

• When ignore_na=False (default), weights are based on absolute positions. For example, the weights of \( x_0 \) and \( x_2 \) used in calculating the final weighted average of \([x_0, None, x_2]\) are \((1 - \alpha)^2\) and 1 if adjust=True, and \((1 - \alpha)^2\) and \(\alpha\) if adjust=False.
• When `ignore_na=True` (reproducing pre-0.15.0 behavior), weights are based on relative positions. For example, the weights of $x_0$ and $x_2$ used in calculating the final weighted average of [$x_0$, None, $x_2$] are $1 - \alpha$ and 1 if `adjust=True`, and $1 - \alpha$ and $\alpha$ if `adjust=False`.

`axis` [[0, 1], default 0] The axis to use. The value 0 identifies the rows, and 1 identifies the columns.

`times` [str, np.ndarray, Series, default None] New in version 1.1.0.

Times corresponding to the observations. Must be monotonically increasing and `datetime64[ns]` dtype.

If str, the name of the column in the DataFrame representing the times.

If 1-D array like, a sequence with the same shape as the observations.

Only applicable to `mean()`.

Returns

**DataFrame** A Window sub-classed for the particular operation.

See also:

**rolling** Provides rolling window calculations.

**expanding** Provides expanding transformations.

Notes

More details can be found at: [Exponentially weighted windows](#).

Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0

>>> df.ewm(com=0.5).mean()
   B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213

Specifying `times` with a timedelta `halflife` when computing mean.

```python
>>> times = ['2020-01-01', '2020-01-03', '2020-01-10', '2020-01-15', '2020-01-17']
>>> df.ewm(halflife='4 days', times=pd.DatetimeIndex(times)).mean()
   B
0  0.000000
1  0.750000
2  1.615385
3  1.615385
4  3.670213
```
pandas.DataFrame.expanding

DataFrame.expanding(min_periods=1, center=None, axis=0, method='single')

Provide expanding transformations.

Parameters

- **min_periods** [int, default 1] Minimum number of observations in window required to have a value (otherwise result is NA).
- **center** [bool, default False] Set the labels at the center of the window.
- **axis** [int or str, default 0]
- **method** [str {'single', 'table'}, default 'single'] Execute the rolling operation per single column or row ('single') or over the entire object ('table').

This argument is only implemented when specifying engine='numba' in the method call.

New in version 1.3.0.

Returns

a Window sub-classed for the particular operation

See also:

- **rolling** Provides rolling window calculations.
- **ewm** Provides exponential weighted functions.

Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting center=True.

Examples

```python
>>> df = pd.DataFrame({"B": [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
>>> df.expanding(2).sum()
   B
0  NaN
1  1.0
2  3.0
3  3.0
4  7.0
```

**pandas.DataFrame=explode**

```python
DataFrame.explode(column, ignore_index=False)
```
Transform each element of a list-like to a row, replicating index values.

New in version 0.25.0.

**Parameters**

- `column` [str or tuple or list thereof] Column(s) to explode. For multiple columns, specify a non-empty list with each element be str or tuple, and all specified columns their list-like data on same row of the frame must have matching length.

  New in version 1.3.0: Multi-column explode

- `ignore_index` [bool, default False] If True, the resulting index will be labeled 0, 1, . . . , n - 1.

  New in version 1.1.0.

**Returns**

- `DataFrame` Exploded lists to rows of the subset columns; index will be duplicated for these rows.

**Raises**

- `ValueError`:  
  - If columns of the frame are not unique.
  - If specified columns to explode is empty list.
  - If specified columns to explode have not matching count of elements rowwise in the frame.

**See also:**

- `DataFrame.unstack` Pivot a level of the (necessarily hierarchical) index labels.
- `DataFrame.melt` Unpivot a DataFrame from wide format to long format.
- `Series.explode` Explode a DataFrame from list-like columns to long format.
Notes

This routine will explode list-likes including lists, tuples, sets, Series, and np.ndarray. The result dtype of the subset rows will be object. Scalars will be returned unchanged, and empty list-likes will result in a np.nan for that row. In addition, the ordering of rows in the output will be non-deterministic when exploding sets.

Examples

```python
>>> df = pd.DataFrame({'A': [[0, 1, 2], 'foo', [], [3, 4]],
                    'B': [1, 1, 1, 1],
                    'C': [['a', 'b', 'c'], np.nan, [], ['d', 'e']])
>>> df
     A      B      C
0  [0, 1, 2]   1  [a, b, c]
1        foo   1  NaN
2          []   1  []
3  [3, 4]   1  [d, e]

Single-column explode.

```python
>>> df.explode('A')
     A  B  C
0    0  1  a
0    1  1  b
0    2  1  c
1  foo  1  NaN
2  NaN  1  NaN
3    3  1  d
3    4  1  e
```

Multi-column explode.

```python
>>> df.explode(list('AC'))
     A  B  C
0    0  1  a
0    1  1  b
0    2  1  c
1  foo  1  NaN
2  NaN  1  NaN
3    3  1  d
3    4  1  e
```

pandas.DataFrame.ffill

DataFrame.ffill (axis=None, inplace=False, limit=None, downcast=None)  
Synonym for DataFrame.fillna() with method='ffill'.

Returns

Series/DataFrame or None Object with missing values filled or None if inplace=True.
pandas.DataFrame.fillna

DataFrame.fillna(value=None, method=None, axis=None, inplace=False, limit=None, downcast=None)

Fill NA/NaN values using the specified method.

Parameters

  value [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

  axis [{0 or ‘index’, 1 or ‘columns’}] Axis along which to fill missing values.

  inplace [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

  limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

  downcast [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns

  DataFrame or None Object with missing values filled or None if inplace=True.

See also:

  interpolate Fill NaN values using interpolation.

  reindex Conform object to new index.

  asfreq Convert TimeSeries to specified frequency.

Examples

```python
>>> df = pd.DataFrame([[np.nan, 2, np.nan, 0],
...                     [3, 4, np.nan, 1],
...                     [np.nan, np.nan, np.nan, 5],
...                     [np.nan, 3, np.nan, 4]],
...                    columns=list("ABCD"))
>>> df
   A    B    C    D
0  NaN  2.0  NaN  0.0
1  3.0  4.0  NaN  1.0
2  NaN  NaN  NaN  5.0
3  NaN  3.0  NaN  4.0

Replace all NaN elements with 0s.
```
We can also propagate non-null values forward or backward.

```
>>> df.fillna(method="ffill")
   A  B  C  D
0  NaN 2.0 NaN 0
1  3.0 4.0 NaN 1
2  3.0 4.0 NaN 5
3  3.0 3.0 NaN 4
```

Replace all NaN elements in column ‘A’, ‘B’, ‘C’, and ‘D’, with 0, 1, 2, and 3 respectively.

```
>>> values = {"A": 0, "B": 1, "C": 2, "D": 3}
>>> df.fillna(value=values)
   A  B  C  D
0  0.0 2.0 2.0 0
1  3.0 4.0 2.0 1
2  0.0 1.0 2.0 5
3  0.0 3.0 2.0 4
```

Only replace the first NaN element.

```
>>> df.fillna(value=values, limit=1)
   A  B  C  D
0  0.0 2.0 2.0 0
1  3.0 4.0 NaN 1
2  NaN 1.0 NaN 5
3  NaN 3.0 NaN 4
```

When filling using a DataFrame, replacement happens along the same column names and same indices

```
>>> df2 = pd.DataFrame(np.zeros((4, 4)), columns=list("ABCE"))
>>> df.fillna(df2)
   A  B  C  D
0  0.0 2.0 0.0 0
1  3.0 4.0 0.0 1
2  0.0 0.0 0.0 5
3  0.0 3.0 0.0 4
```

**pandas.DataFrame.filter**

Dataframe.filter(**items=**None, **like=**None, **regex=**None, **axis=**None)

Subset the dataframe rows or columns according to the specified index labels.

Note that this routine does not filter a dataframe on its contents. The filter is applied to the labels of the index.

**Parameters**

- **items** ([list-like]) Keep labels from axis which are in items.
like  [str] Keep labels from axis for which “like in label == True”.

regex  [str (regular expression)] Keep labels from axis for which re.search(regex, label) == True.

axis  [[0 or ‘index’, 1 or ‘columns’, None], default None] The axis to filter on, expressed either as an index (int) or axis name (str). By default this is the info axis, ‘index’ for Series, ‘columns’ for DataFrame.

Returns

same type as input object

See also:

DataFrame.loc Access a group of rows and columns by label(s) or a boolean array.

Notes

The items, like, and regex parameters are enforced to be mutually exclusive.

axis defaults to the info axis that is used when indexing with [].

Examples

```python
>>> df = pd.DataFrame(np.array([[1, 2, 3], [4, 5, 6]]),
                      index=['mouse', 'rabbit'],
                      columns=['one', 'two', 'three'])
>>> df
   one  two  three
mouse  1  2    3
rabbit  4  5    6

>>> # select columns by name
>>> df.filter(items=['one', 'three'])
   one  three
mouse  1    3
rabbit  4    6

>>> # select columns by regular expression
>>> df.filter(regex='e$', axis=1)
   one  three
mouse  1    3
rabbit  4    6

>>> # select rows containing 'bbi'
>>> df.filter(like='bbi', axis=0)
   one  two  three
rabbit  4  5    6
```
pandas.DataFrame.first

DataFrame.first(offset)
Select initial periods of time series data based on a date offset.
When having a DataFrame with dates as index, this function can select the first few rows based on a date offset.

Parameters
offset [str, DateOffset or dateutil.relativedelta] The offset length of the data that will be selected. For instance, ‘1M’ will display all the rows having their index within the first month.

Returns
Series or DataFrame A subset of the caller.

Raises
TypeError If the index is not a DatetimeIndex

See also:
last Select final periods of time series based on a date offset.
at_time Select values at a particular time of the day.
between_time Select values between particular times of the day.

Examples

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
   A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4

Get the rows for the first 3 days:
```
```python
>>> ts.first('3D')
   A
2018-04-09  1
2018-04-11  2
```

Notice the data for 3 first calendar days were returned, not the first 3 days observed in the dataset, and therefore data for 2018-04-13 was not returned.
pandas.DataFrame.first_valid_index

DataFrame.first_valid_index()
Return index for first non-NA value or None, if no NA value is found.

Returns
scalar [type of index]

Notes
If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

pandas.DataFrame.floordiv

DataFrame.floordiv(other, axis='columns', level=None, fill_value=None)
Get Integer division of dataframe and other, element-wise (binary operator floordiv).
Equivalent to dataframe // other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rfloordiv.
Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters
other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis [(0 or ‘index’, 1 or ‘columns’) Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns
DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                     'degrees': [360, 180, 360],
...                     index=['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle    0      360
triangle   3      180
rectangle  4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

```python
>>> df.add(1)
   angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle    0.0    36.0
triangle   0.3    18.0
rectangle  0.4    36.0
```

```python
>>> df.rdiv(10)
   angles  degrees
circle    inf    0.027778
triangle   3.333333  0.055556
rectangle  2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
   angles  degrees
circle    -1      358
triangle    2      178
rectangle    3      358
```

```python
>>> df.sub([1, 2], axis='columns')
   angles  degrees
circle    -1      358
triangle    2      178
rectangle    3      358
```
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
    index=['circle', 'triangle', 'rectangle'])
>>> df + other
    angles  degrees
  circle    0  NaN
  triangle  9  NaN
  rectangle 16  NaN
```

```python
>>> df.mul(other, fill_value=0)
    angles  degrees
  circle    0  0.0
  triangle  9  0.0
  rectangle 16  0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6],
    'degrees': [360, 180, 360, 540, 720],
    'index': ['A', 'A', 'A', 'B', 'B'],
    'multiindex': ['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon'])
>>> df_multindex
      angles  degrees
   A circle   0  360
   triangle  3  180
   rectangle 4  360
   B square  4  360
   pentagon  5  540
   hexagon  6  720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
      angles  degrees
   A circle  NaN   1.0
   triangle  1.0   1.0
   rectangle 1.0   1.0
   B square   0.0   0.0
   pentagon   0.0   0.0
   hexagon   0.0   0.0
```
pandas.DataFrame.from_dict

**classmethod** `DataFrame.from_dict` *(data, orient='columns', dtype=None, columns=None)*  
Construct DataFrame from dict of array-like or dicts.

Creates DataFrame object from dictionary by columns or by index allowing dtype specification.

**Parameters**

- `data` [dict] Of the form {field : array-like} or {field : dict}.
- `orient` [{'columns', ‘index’}, default ‘columns’] The “orientation” of the data. If the keys of the passed dict should be the columns of the resulting DataFrame, pass ‘columns’ (default). Otherwise if the keys should be rows, pass ‘index’.
- `dtype` [dtype, default None] Data type to force, otherwise infer.
- `columns` [list, default None] Column labels to use when orient='index'. Raises a ValueError if used with orient='columns'.

**Returns**

DataFrame

See also:

- `DataFrame.from_records` DataFrame from structured ndarray, sequence of tuples or dicts, or DataFrame.
- `DataFrame` DataFrame object creation using constructor.

**Examples**

By default the keys of the dict become the DataFrame columns:

```python
>>> data = {'col_1': [3, 2, 1, 0], 'col_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data)
   col_1 col_2
0     3    a
1     2    b
2     1    c
3     0    d
```

Specify `orient='index'` to create the DataFrame using dictionary keys as rows:

```python
>>> data = {'row_1': [3, 2, 1, 0], 'row_2': ['a', 'b', 'c', 'd']}
>>> pd.DataFrame.from_dict(data, orient='index')
   0  1  2  3
row_1 3  2  1  0
row_2  a  b  c  d
```

When using the ‘index’ orientation, the column names can be specified manually:

```python
>>> pd.DataFrame.from_dict(data, orient='index',
columns=[A, B, C, D])
   A  B  C  D
row_1 3  2  1  0
row_2  a  b  c  d
```
Convert structured or record ndarray to DataFrame.

**Parameters**

- **data** [structured ndarray, sequence of tuples or dicts, or DataFrame] Structured input data.
- **index** [str, list of fields, array-like] Field of array to use as the index, alternately a specific set of input labels to use.
- **exclude** [sequence, default None] Columns or fields to exclude.
- **columns** [sequence, default None] Column names to use. If the passed data do not have names associated with them, this argument provides names for the columns. Otherwise this argument indicates the order of the columns in the result (any names not found in the data will become all-NA columns).
- **coerce_float** [bool, default False] Attempt to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets.
- **nrows** [int, default None] Number of rows to read if data is an iterator.

**Returns**

DataFrame

**See also:**

- **DataFrame.from_dict** DataFrame from dict of array-like or dicts.
- **DataFrame** DataFrame object creation using constructor.

**Examples**

Data can be provided as a structured ndarray:

```python
>>> data = np.array([(3, 'a'), (2, 'b'), (1, 'c'), (0, 'd')],
...                  dtype=[('col_1', 'i4'), ('col_2', 'U1')])
>>> pd.DataFrame.from_records(data)
col_1  col_2
0 3 a
1 2 b
2 1 c
3 0 d
```

Data can be provided as a list of dicts:

```python
>>> data = [{'col_1': 3, 'col_2': 'a'},
...          {'col_1': 2, 'col_2': 'b'},
...          {'col_1': 1, 'col_2': 'c'},
...          {'col_1': 0, 'col_2': 'd'}]
>>> pd.DataFrame.from_records(data)
col_1  col_2
0 3 a
```

(continues on next page)
Data can be provided as a list of tuples with corresponding columns:

```
>>> data = [(3, 'a'), (2, 'b'), (1, 'c'), (0, 'd')]
>>> pd.DataFrame.from_records(data, columns=['col_1', 'col_2'])
```

```
   col_1 col_2
0      3   a
1      2   b
2      1   c
3      0   d
```

**pandas.DataFrame.ge**

`DataFrame.ge(other, axis='columns', level=None)`

Get Greater than or equal to of dataframe and other, element-wise (binary operator `ge`).

Among flexible wrappers (`eq, ne, le, lt, ge, gt`) to comparison operators.

Equivalent to `==, /=, <=, <, >=, >` with support to choose axis (rows or columns) and level for comparison.

**Parameters**

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

**Returns**

`DataFrame of bool` Result of the comparison.

**See also:**

- `DataFrame.eq` Compare DataFrames for equality elementwise.
- `DataFrame.ne` Compare DataFrames for inequality elementwise.
- `DataFrame.le` Compare DataFrames for less than inequality or equality elementwise.
- `DataFrame.lt` Compare DataFrames for strictly less than inequality elementwise.
- `DataFrame.ge` Compare DataFrames for greater than inequality or equality elementwise.
- `DataFrame.gt` Compare DataFrames for strictly greater than inequality elementwise.
Notes

Mismatched indices will be unioned together. $NaN$ values are considered different (i.e. $NaN$ != $NaN$).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                     'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
   cost  revenue
A  False   True
B  False  False
C  True  False
```

```python
>>> df.eq(100)
   cost  revenue
A  False   True
B  False  False
C  True  False
```

When other is a `Series`, the columns of a DataFrame are aligned with the index of other and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
   cost  revenue
A   True   True
B   True  False
C  False   True

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
   cost  revenue
A   True  False
B   True   True
C  False  False
D   True   True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in other:

```python
>>> df == [250, 100]
   cost  revenue
A   True   True
B  False  False
C  False  False
```

Use the method to control the axis:
```python
>>> df.eq([250, 250, 100], axis='index')
   cost  revenue
A   True   False
B   False   True
C   True   False

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                       index=['A', 'B', 'C', 'D'])
>>> other
   revenue
A   300
B   250
C   100
D   150
```python
>>> df.gt(other)
   cost  revenue
A  False  False
B  False  False
C  False   True
D  False  False

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
                               'revenue': [100, 250, 300, 200, 175, 225],
                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'], ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
     cost  revenue
   Q1 A  250   100
    B  150   250
    C  100   300
   Q2 A  150   200
    B  300   175
    C  220   225
```python
>>> df.le(df_multindex, level=1)
   cost  revenue
Q1 A  True   True
    B  True   True
    C  True   True
Q2 A  False   True
    B  True  False
    C  True  False
```
**pandas.DataFrame.get**

```python
DataFrame.get(key, default=None)
```

Get item from object for given key (ex: DataFrame column). Returns default value if not found.

**Parameters**

- `key` [object]

**Returns**

- `value` [same type as items contained in object]

**pandas.DataFrame.groupby**

```python
DataFrame.groupby(by=None, axis=0, level=None, as_index=True, sort=True, group_keys=True, squeeze=<no_default>, observed=False, dropna=True)
```

Group DataFrame using a mapper or by a Series of columns.

A groupby operation involves some combination of splitting the object, applying a function, and combining the results. This can be used to group large amounts of data and compute operations on these groups.

**Parameters**

- `by` [mapping, function, label, or list of labels] Used to determine the groups for the groupby. If `by` is a function, it’s called on each value of the object’s index. If a dict or Series is passed, the Series or dict VALUES will be used to determine the groups (the Series’ values are first aligned; see `.align()` method). If an ndarray is passed, the values are used as-is to determine the groups. A label or list of labels may be passed to group by the columns in `self`. Notice that a tuple is interpreted as a (single) key.

- `axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] Split along rows (0) or columns (1).

- `level` [int, level name, or sequence of such, default None] If the axis is a MultiIndex (hierarchical), group by a particular level or levels.

- `as_index` [bool, default True] For aggregated output, return object with group labels as the index. Only relevant for DataFrame input. `as_index=False` is effectively “SQL-style” grouped output.

- `sort` [bool, default True] Sort group keys. Get better performance by turning this off. Note this does not influence the order of observations within each group. Groupby preserves the order of rows within each group.

- `group_keys` [bool, default True] When calling apply, add group keys to index to identify pieces.

- `squeeze` [bool, default False] Reduce the dimensionality of the return type if possible, otherwise return a consistent type. Deprecated since version 1.1.0.

- `observed` [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.
**dropna** [bool, default True] If True, and if group keys contain NA values, NA values together with row/column will be dropped. If False, NA values will also be treated as the key in groups

New in version 1.1.0.

**Returns**

`DataFrameGroupBy` Returns a groupby object that contains information about the groups.

**See also:**

`resample` Convenience method for frequency conversion and resampling of time series.

**Notes**

See the user guide for more.

**Examples**

```python
>>> df = pd.DataFrame({'Animal': ['Falcon', 'Falcon', 'Parrot', 'Parrot'],
...                    'Max Speed': [380., 370., 24., 26.]})
>>> df
        Animal  Max Speed
0       Falcon      380.0
1       Falcon      370.0
2      Parrot        24.0
3      Parrot        26.0
>>> df.groupby(['Animal']).mean()
        Max Speed
Animal
Falcon   375.0
Parrot   25.0
```

**Hierarchical Indexes**

We can groupby different levels of a hierarchical index using the `level` parameter:

```python
>>> arrays = [['Falcon', 'Falcon', 'Parrot', 'Parrot'],
...            ['Captive', 'Wild', 'Captive', 'Wild']]
>>> index = pd.MultiIndex.from_arrays(arrays, names=('Animal', 'Type'))
>>> df = pd.DataFrame({'Max Speed': [390., 350., 30., 20.]},
...                   index=index)
>>> df
        Animal  Type     Max Speed
0       Falcon Captive   390.0
1       Falcon   Wild    350.0
2      Parrot Captive   30.0
3      Parrot   Wild     20.0
>>> df.groupby(level=0).mean()
        Max Speed
Animal
Falcon   370.0
Parrot   25.0
```

(continues on next page)
>>> df.groupby(level="Type").mean()
    Max Speed
    Type
      Captive   210.0
      Wild     185.0

We can also choose to include NA in group keys or not by setting dropna parameter, the default setting is True:

>>> l = [[1, 2, 3], [1, None, 4], [2, 1, 3], [1, 2, 2]]
>>> df = pd.DataFrame(l, columns=['a', 'b', 'c'])

>>> df.groupby(by=['b']).sum()
    a  c
    b
      1.0  2  3
      2.0  2  5

>>> df.groupby(by=['b'], dropna=False).sum()
    a  c
    b
      1.0  2  3
      2.0  2  5
      NaN  1  4

>>> l = [['a', 12, 12], [None, 12.3, 33.], ['b', 12.3, 123], ['a', 1, 1]]
>>> df = pd.DataFrame(l, columns=['a', 'b', 'c'])

>>> df.groupby(by='a').sum()
    b  c
    a
      13.0  13.0
      12.3  123.0

>>> df.groupby(by='a', dropna=False).sum()
    b  c
    a
      13.0  13.0
      12.3  123.0
      NaN  12.3  33.0

pandas.DataFrame.gt

DataFrame.gt (other, axis='columns', level=None)
    Get Greater than of dataframe and other, element-wise (binary operator gt).
    Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.
    Equivalent to ==, !=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

    other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis [[0 or ‘index’, 1 or ‘columns’], default ‘columns’] Whether to compare by the
index (0 or ‘index’) or columns (1 or ‘columns’).

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.
DataFrame.ne Compare DataFrames for inequality elementwise.
DataFrame.le Compare DataFrames for less than inequality or equality elementwise.
DataFrame.lt Compare DataFrames for strictly less than inequality elementwise.
DataFrame.ge Compare DataFrames for greater than inequality or equality elementwise.
DataFrame.gt Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. NaN values are considered different (i.e. NaN != NaN).

Examples

>>> df = pd.DataFrame({'cost': [250, 150, 100],
... 'revenue': [100, 250, 300]},
... index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300

Comparison with a scalar, using either the operator or method:

>>> df == 100
   cost  revenue
A  False   True
B  False  False
C   True  False

>>> df.eq(100)
   cost  revenue
A  False   True
B  False  False
C   True  False

When other is a Series, the columns of a DataFrame are aligned with the index of other and broadcast:

>>> df != pd.Series([100, 250], index=["cost", "revenue"])
   cost  revenue
A   True   True
(continues on next page)
Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
    cost  revenue
A    True    False
B    True     True
C    True     True
D    True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```python
>>> df == [250, 100]
    cost  revenue
A    True    True
B   False    False
C   False    False
```

Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
    cost  revenue
A    True    False
B   False     True
C    True    False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150],
...                        index=['A', 'B', 'C', 'D'])
>>> df.gt(other)
    cost  revenue
A  False    False
B  False    False
C  False    True
D  False    False
```

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
...                               'revenue': [100, 250, 300, 200, 175, 225],
...                               index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
...                                      ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
     cost  revenue
Q1 A  250    100
...```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.1

(pandas: powerful Python data analysis toolkit, Release 1.3.1)

(continued from previous page)

B 150 250
C 100 300
Q2 A 150 200
   B 300 175
   C 220 225

>>> df.le(df_multindex, level=1)
   cost  revenue
Q1 A    True  True
   B    True  True
   C    True  True
Q2 A   False  True
   B    True False
   C    True False

pandas.DataFrame.head

DataFrame.head(n=5)
Return the first n rows.

This function returns the first n rows for the object based on position. It is useful for quickly testing if your object has the right type of data in it.

For negative values of n, this function returns all rows except the last n rows, equivalent to df[:n].

Parameters

n [int, default 5] Number of rows to select.

Returns

same type as caller The first n rows of the caller object.

See also:

DataFrame.tail Returns the last n rows.

Examples

>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion',
...  'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0  alligator
1     bee
2  falcon
3    lion
4  monkey
5    parrot
6   shark
7   whale
8   zebra

Viewing the first 5 lines
Viewing the first \( n \) lines (three in this case)

```
>>> df.head(3)
    animal
0    alligator
1      bee
2   falcon
```

For negative values of \( n \)

```
>>> df.head(-3)
    animal
0    alligator
1      bee
2   falcon
3      lion
4    monkey
5   parrot
```

**pandas.DataFrame.hist**

Dataframe.hist(\( column=None, by=None, grid=True, xlabelsize=None, xrot=None, ylabelsize=None, yrot=None, ax=None, sharex=False, sharey=False, figsize=None, layout=None, bins=10, backend=None, legend=False, **kwargs)\)

Make a histogram of the DataFrame’s columns.

A histogram is a representation of the distribution of data. This function calls matplotlib.pyplot.hist(), on each series in the DataFrame, resulting in one histogram per column.

Parameters

- **data** [DataFrame] The pandas object holding the data.
- **column** [str or sequence, optional] If passed, will be used to limit data to a subset of columns.
- **by** [object, optional] If passed, then used to form histograms for separate groups.
- **grid** [bool, default True] Whether to show axis grid lines.
- **xlabelsize** [int, default None] If specified changes the x-axis label size.
- **xrot** [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.
- **ylabelsize** [int, default None] If specified changes the y-axis label size.
- **yrot** [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.
- **ax** [Matplotlib axes object, default None] The axes to plot the histogram on.
sharex [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.

sharey [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.

figsize [tuple, optional] The size in inches of the figure to create. Uses the value in matplotlib.rcParams by default.

layout [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.

bins [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

backend [str, default None] Backend to use instead of the backend specified in the option plotting.backend. For instance, ‘matplotlib’. Alternatively, to specify the plotting.backend for the whole session, set pd.options.plotting.backend.

New in version 1.0.0.

legend [bool, default False] Whether to show the legend.

New in version 1.1.0.

**kwargs All other plotting keyword arguments to be passed to matplotlib.pyplot.hist().

Returns

matplotlib.AxesSubplot or numpy.ndarray of them

See also:

matplotlib.pyplot.hist Plot a histogram using matplotlib.

Examples

This example draws a histogram based on the length and width of some animals, displayed in three bins

```python
>>> df = pd.DataFrame({
...     'length': [1.5, 0.5, 1.2, 0.9, 3],
...     'width': [0.7, 0.2, 0.15, 0.2, 1.1]
... }, index=['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```
DataFrame.idxmax

DataFrame.idxmax (axis=0, skipna=True)
Return index of first occurrence of maximum over requested axis.
NA/null values are excluded.

Parameters

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to use. 0 or 'index' for row-wise, 1 or 'columns' for column-wise.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

Series Indexes of maxima along the specified axis.

Raises

ValueError
- If the row/column is empty

See also:

Series.idxmax Return index of the maximum element.

Notes

This method is the DataFrame version of ndarray.argmax.

Examples

Consider a dataset containing food consumption in Argentina.

```python
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
...                     'co2_emissions': [37.2, 19.66, 1712]},
...                     index=['Pork', 'Wheat Products', 'Beef'])
```

By default, it returns the index for the maximum value in each column.

```python
>>> df.idxmax()
consumption    Wheat Products
co2_emissions    Beef
dtype: object
```

To return the index for the maximum value in each row, use axis="columns".
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
>>> df.idxmax(axis="columns")
Pork       co2_emissions
Wheat Products consumption
Beef       co2_emissions
dtype: object
```

**pandas.DataFrame.idxmin**

DataFrame. **idxmin**(*axis=0, skipna=True*)

Return index of first occurrence of minimum over requested axis. NA/null values are excluded.

**Parameters**

- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**Returns**

- **Series** Indexes of minima along the specified axis.

**Raises**

- **ValueError**
  - If the row/column is empty

**See also:**

- **Series.idxmin** Return index of the minimum element.

**Notes**

This method is the DataFrame version of *ndarray.argmin*.

**Examples**

Consider a dataset containing food consumption in Argentina.

```python
>>> df = pd.DataFrame({
    'consumption': [10.51, 103.11, 55.48],
    'co2_emissions': [37.2, 19.66, 1712],
    'index': ['Pork', 'Wheat Products', 'Beef']
})
```

```python
>>> df
consumption  co2_emissions
Pork         10.51       37.20
Wheat Products 103.11      19.66
Beef          55.48      1712.00
```

By default, it returns the index for the minimum value in each column.
```python
>>> df.idxmin()
consumption    Pork
co2_emissions  Wheat Products
dtype: object
```

To return the index for the minimum value in each row, use `axis="columns"`.

```python
>>> df.idxmin(axis="columns")
Pork          consumption
Wheat Products co2_emissions
Beef          consumption
dtype: object
```

### pandas.DataFrame.infer_objects

DataFrame.infer_objects()  
Attempt to infer better dtypes for object columns.

Attempts soft conversion of object-dtyped columns, leaving non-object and unconvertible columns unchanged. The inference rules are the same as during normal Series/DataFrame construction.

**Returns**

- **converted** [same type as input object]

**See also:**

- `to_datetime` Convert argument to datetime.
- `to_timedelta` Convert argument to timedelta.
- `to_numeric` Convert argument to numeric type.
- `convert_dtypes` Convert argument to best possible dtype.

**Examples**

```python
>>> df = pd.DataFrame({"A": ["a", 1, 2, 3]})
>>> df = df.iloc[1:]
>>> df
     A
0   1
1   2
2   3

>>> df.dtypes
A    object
dtype: object

>>> df.infer_objects().dtypes
A    int64
dtype: object
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.DataFrame.info

DataFrame.info(\texttt{verbose=None, \quad \texttt{buf=None, \quad max_cols=None, \quad memory_usage=None,}}
\texttt{\quad \quad \quad \quad \quad show_counts=None, \quad null_counts=None})

Print a concise summary of a DataFrame.

This method prints information about a DataFrame including the index dtype and columns, non-null values and memory usage.

Parameters

data [DataFrame] DataFrame to print information about.

verbose [bool, optional] Whether to print the full summary. By default, the setting in \texttt{pandas.options.display.max_info_columns} is followed.

buf [writable buffer, defaults to \texttt{sys.stdout}] Where to send the output. By default, the output is printed to \texttt{sys.stdout}. Pass a writable buffer if you need to further process the output.

max_cols [int, optional] When to switch from the verbose to the truncated output. If the DataFrame has more than \texttt{max_cols} columns, the truncated output is used. By default, the setting in \texttt{pandas.options.display.max_info_columns} is used.

memory_usage [bool, str, optional] Specifies whether total memory usage of the DataFrame elements (including the index) should be displayed. By default, this follows the \texttt{pandas.options.display.memory_usage} setting.

True always show memory usage. False never shows memory usage. A value of ‘deep’ is equivalent to “True with deep introspection”. Memory usage is shown in human-readable units (base-2 representation). Without deep introspection a memory estimation is made based in column dtype and number of rows assuming values consume the same memory amount for corresponding dtypes. With deep memory introspection, a real memory usage calculation is performed at the cost of computational resources.

show_counts [bool, optional] Whether to show the non-null counts. By default, this is shown only if the DataFrame is smaller than \texttt{pandas.options.display.max_info_rows} and \texttt{pandas.options.display.max_info_columns}. A value of True always shows the counts, and False never shows the counts.

null_counts [bool, optional] Deprecated since version 1.2.0: Use show_counts instead.

Returns

None This method prints a summary of a DataFrame and returns None.

See also:

\texttt{DataFrame.describe} Generate descriptive statistics of DataFrame columns.

\texttt{DataFrame.memory_usage} Memory usage of DataFrame columns.
Examples

```python
>>> int_values = [1, 2, 3, 4, 5]
>>> text_values = ['alpha', 'beta', 'gamma', 'delta', 'epsilon']
>>> float_values = [0.0, 0.25, 0.5, 0.75, 1.0]
>>> df = pd.DataFrame({'int_col': int_values, 'text_col': text_values, ...
                        'float_col': float_values})
>>> df
   int_col text_col  float_col
0      1     alpha    0.00
1      2      beta    0.25
2      3    gamma    0.50
3      4    delta    0.75
4      5  epsilon    1.00
```

Prints information of all columns:

```python
>>> df.info(quiet=False)
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5 entries, 0 to 4
Columns: 3 entries, int_col to float_col
dtypes: float64(1), int64(1), object(1)
memory usage: 248.0+ bytes
```

Pipe output of DataFrame.info to buffer instead of sys.stdout, get buffer content and writes to a text file:

```python
>>> import io
>>> buffer = io.StringIO()
>>> df.info(buf=buffer)
>>> s = buffer.getvalue()
>>> with open("df_info.txt", "w", encoding="utf-8") as f:
...     f.write(s)
260
```

The `memory_usage` parameter allows deep introspection mode, specially useful for big DataFrames and fine-tune memory optimization:

```python
>>> random_strings_array = np.random.choice(['a', 'b', 'c'], 10 ** 6)
>>> df = pd.DataFrame({...
...    'column_1': np.random.choice(['a', 'b', 'c'], 10 ** 6),
...    'column_2': np.random.choice(['a', 'b', 'c'], 10 ** 6),
...    'column_3': np.random.choice(['a', 'b', 'c'], 10 ** 6)
...})
(continues on next page)```
... })
>>> df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
# Column  Non-Null Count  Dtype
--- ------ -------------- ----- 
0 column_1  1000000 non-null  object
1 column_2  1000000 non-null  object
2 column_3  1000000 non-null  object
dtypes: object(3)
memory usage: 22.9+ MB

>>> df.info(memory_usage='deep')
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 3 columns):
# Column  Non-Null Count  Dtype
--- ------ -------------- ----- 
0 column_1  1000000 non-null  object
1 column_2  1000000 non-null  object
2 column_3  1000000 non-null  object
dtypes: object(3)
memory usage: 165.9 MB

pandas.DataFrame.insert

DataFrame.insert (loc, column, value, allow_duplicates=False)
Insert column into DataFrame at specified location.

Raises a ValueError if column is already contained in the DataFrame, unless allow_duplicates is set to True.

Parameters

loc [int] Insertion index. Must verify 0 <= loc <= len(columns).

column [str, number, or hashable object] Label of the inserted column.

value [int, Series, or array-like]

allow_duplicates [bool, optional]

See also:

Index.insert Insert new item by index.
Examples

```python
>>> df = pd.DataFrame({'col1': [1, 2], 'col2': [3, 4]})
>>> df
   col1  col2
0    1    3
1    2    4
>>> df.insert(1, "newcol", [99, 99])
>>> df
   col1  newcol  col2
0    1       99    3
1    2       99    4
>>> df.insert(0, "col1", [100, 100], allow_duplicates=True)
>>> df
   col1  col1  newcol  col2
0  100     1      99    3
1  100     2      99    4
```

Notice that pandas uses index alignment in case of value from type Series:

```python
>>> df.insert(0, "col0", pd.Series([5, 6], index=[1, 2]))
>>> df
   col0  col1  col1  newcol  col2
0  NaN    100     1      99    3
1  5.0    100     2      99    4
```

**pandas.DataFrame.interpolate**

DataFrame.interpolate(method='linear', axis=0, limit=None, inplace=False, limit_direction=None, limit_area=None, downcast=None, **kwargs)

Fill NaN values using an interpolation method.

Please note that only method='linear' is supported for DataFrame/Series with a MultiIndex.

**Parameters**

- **method** [str, default 'linear'] Interpolation technique to use. One of:
  - ‘linear’: Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
  - ‘time’: Works on daily and higher resolution data to interpolate given length of interval.
  - ‘index’, ‘values’: use the actual numerical values of the index.
  - ‘pad’: Fill in NaNs using existing values.
  - ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘spline’, ‘barycentric’, ‘polynomial’: Passed to scipy.interpolate.interp1d. These methods use the numerical values of the index. Both 'polynomial' and 'spline' require that you also specify an order (int), e.g. df.interpolate(method='polynomial', order=5).
  - ‘from_derivatives’: Refers to scipy.interpolate.BPoly.from_derivatives which replaces 'piecewise_polynomial' interpolation method in scipy 0.18.
axis  [[[0 or 'index', 1 or 'columns', None]], default None] Axis to interpolate along.

limit  [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

inplace  [bool, default False] Update the data in place if possible.

limit_direction  [[[‘forward’, ‘backward’, ‘both’]], Optional] Consecutive NaNs will be filled in this direction.

If limit is specified:

- If ‘method’ is ‘pad’ or ‘ffill’, ‘limit_direction’ must be ‘forward’.
- If ‘method’ is ‘backfill’ or ‘bfill’, ‘limit_direction’ must be ‘backwards’.

If ‘limit’ is not specified:

- If ‘method’ is ‘backfill’ or ‘bfill’, the default is ‘backward’
- else the default is ‘forward’

Changed in version 1.1.0: raises ValueError if limit_direction is ‘forward’ or ‘both’ and method is ‘backfill’ or ‘bfill’. raises ValueError if limit_direction is ‘backward’ or ‘both’ and method is ‘pad’ or ‘ffill’.

limit_area  [[[None, ‘inside’, ‘outside’]], default None] If limit is specified, consecutive NaNs will be filled with this restriction.

- None: No fill restriction.
- ‘inside’: Only fill NaNs surrounded by valid values (interpolate).
- ‘outside’: Only fill NaNs outside valid values (extrapolate).

downcast  [optional, ‘infer’ or None, defaults to None] Downcast dtypes if possible.

``**kwargs``  [optional] Keyword arguments to pass on to the interpolating function.

Returns

Series or DataFrame or None  Returns the same object type as the caller, interpolated at some or all NaN values or None if inplace=True.

See also:

fillna  Fill missing values using different methods.

scipy.interpolate.Akima1DInterpolator  Piecewise cubic polynomials (Akima interpolator).

scipy.interpolate.BPoly.from_derivatives  Piecewise polynomial in the Bernstein basis.

scipy.interpolate.interp1d  Interpolate a 1-D function.

scipy.interpolate.KroghInterpolator  Interpolate polynomial (Krogh interpolator).

scipy.interpolate.PchipInterpolator  PCHIP 1-d monotonic cubic interpolation.

scipy.interpolate.CubicSpline  Cubic spline data interpolator.
Notes

The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the SciPy documentation and SciPy tutorial.

Examples

Filling in NaN in a Series via linear interpolation.

```python
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2  NaN
3    3.0
dtype: float64

>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.

```python
>>> s = pd.Series([np.nan, "single_one", np.nan, ...
...     "fill_two_more", np.nan, np.nan, np.nan, ...
...     4.71, np.nan])
>>> s
0      NaN
1      single_one
2        NaN
3  fill_two_more
4        NaN
5        NaN
6        NaN
7    4.71
8      NaN
dtype: object

>>> s.interpolate(method='pad', limit=2)
0      NaN
1      single_one
2      single_one
3  fill_two_more
4  fill_two_more
5  fill_two_more
6        NaN
7    4.71
8    4.71
dtype: object
```

Filling in NaN in a Series via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an order (int).
>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
    0    0.000000
    1    2.000000
    2   4.666667
    3    8.000000
dtype: float64

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use
for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it
to use for interpolation.

>>> df = pd.DataFrame([0.0, np.nan, -1.0, 1.0),
...                   (np.nan, 2.0, np.nan, np.nan),
...                   (2.0, 3.0, np.nan, 9.0),
...                   (np.nan, 4.0, -4.0, 16.0)],
...                   columns=list('abcd'))
>>> df
   a    b    c    d
0  0.0  NaN  -1.0  1.0
1  NaN   2.0  NaN   NaN
2  2.0   3.0  NaN   9.0
3  NaN   4.0  -4.0  16.0

Using polynomial interpolation.

>>> df['d'].interpolate(method='polynomial', order=2)
   0  1.0
   1  4.0
   2  9.0
   3 16.0
Name: d, dtype: float64

pandas.DataFrame.isin

DataFrame.isin(values)
Whether each element in the DataFrame is contained in values.

Parameters

values [iterable, Series, DataFrame or dict] The result will only be true at a location if
all the labels match. If values is a Series, that’s the index. If values is a dict, the
keys must be the column names, which must match. If values is a DataFrame, then
both the index and column labels must match.

Returns

DataFrame Dataframe of booleans showing whether each element in the DataFrame
is contained in values.
See also:

**DataFrame.eq** Equality test for DataFrame.

**Series.isin** Equivalent method on Series.

**Series.str.contains** Test if pattern or regex is contained within a string of a Series or Index.

### Examples

```python
>>> df = pd.DataFrame({'num_legs': [2, 4], 'num_wings': [2, 0]},
...                    index=['falcon', 'dog'])
>>> df
   num_legs  num_wings
falcon     2          2
dog        4          0

When `values` is a list check whether every value in the DataFrame is present in the list (which animals have 0 or 2 legs or wings)

```python
>>> df.isin([0, 2])
   num_legs  num_wings
falcon    True       True
dog      False       True
```

When `values` is a dict, we can pass values to check for each column separately:

```python
>>> df.isin({'num_wings': [0, 3]})
   num_legs  num_wings
falcon    False      False
dog      False       True
```

When `values` is a Series or DataFrame the index and column must match. Note that ‘falcon’ does not match based on the number of legs in df2.

```python
>>> other = pd.DataFrame({'num_legs': [8, 2], 'num_wings': [0, 2]},
...                       index=['spider', 'falcon'])
>>> df.isin(other)
   num_legs  num_wings
falcon    True       True
dog       False      False
```

### pandas.DataFrame.isna

**DataFrame.isna()**

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy.Nan, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).

**Returns**

- **DataFrame** Mask of bool values for each element in DataFrame that indicates whether an element is an NA value.
See also:

**DataFrame.isnull** Alias of isna.

**DataFrame.notna** Boolean inverse of isna.

**DataFrame.dropna** Omit axes labels with missing values.

**isna** Top-level isna.

## Examples

Show which entries in a DataFrame are NA.

```python
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
... born=[pd.NaT, pd.Timestamp('1939-05-27'),
... pd.Timestamp('1940-04-25')],
... name=['Alfred', 'Batman', ''],
... toy=[None, 'Batmobile', 'Joker'])
```

```bash
age  born  name  toy
0  5.0   NaT   Alfred None
1  6.0  1939-05-27  Batman Batmobile
2  NaN  1940-04-25   Joker
```

```python
>>> df.isna()
    age  born  name  toy
0  False  True  False  True
1  False  False  False  False
2  True  False  False  False
```

Show which entries in a Series are NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
```

```bash
0  5.0
1  6.0
2  NaN
dtype: float64
```

```python
>>> ser.isna()
0  False
1  False
2  True
dtype: bool
```

## pandas.DataFrame.isnull

**DataFrame.isnull()**

Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as None or numpy. NaN, gets mapped to True values. Everything else gets mapped to False values. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True).
Returns

**DataFrame** Mask of bool values for each element in DataFrame that indicates whether an element is an NA value.

See also:

*DataFrame.isnull* Alias of isna.

*DataFrame.notna* Boolean inverse of isna.

*DataFrame.dropna* Omit axes labels with missing values.

*isna* Top-level isna.

Examples

Show which entries in a DataFrame are NA.

```python
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
                           pd.Timestamp('1940-04-25')],
                      name=['Alfred', 'Batman', ''],
                      toy=[None, 'Batmobile', 'Joker']))

>>> df
   age  born        name  toy
0   5.0  NaT       Alfred  None
1   6.0 1939-05-27  Batman  Batmobile
2  NaN  1940-04-25    Joker

>>> df.isna()
   age  born  name  toy
0  False  True False  True
1  False  False False  False
2  True  False False  False

Show which entries in a Series are NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
```

```python
>>> ser
0    5.0
1    6.0
2   NaN
dtype: float64
```

```python
>>> ser.isna()
0  False
1  False
2  True
dtype: bool
```
pandas.DataFrame.items

DataFrame.items()  
Iterate over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

Yields

  label [object] The column names for the DataFrame being iterated over.
  content [Series] The column entries belonging to each label, as a Series.

See also:

 DataFrame.iterrows  Iterate over DataFrame rows as (index, Series) pairs.
  DataFrame.itertuples  Iterate over DataFrame rows as namedtuples of the values.

Examples

```python
>>> df = pd.DataFrame({'species': ['bear', 'bear', 'marsupial'],
...    'population': [1864, 22000, 80000]},
...    index=['panda', 'polar', 'koala'])
>>> df
   species  population
panda    bear    1864
polar    bear    22000
koala    marsupial    80000

>>> for label, content in df.items():
...    print(f'label: {label}')
...    print(f'content: {content}', sep='n')
...                                
label: species
content:
panda    bear
polar    bear
koala    marsupial
Name: species, dtype: object

label: population
content:
panda    1864
polar    22000
koala    80000
Name: population, dtype: int64
```

pandas.DataFrame.iteritems

DataFrame.iteritems()  
Iterate over (column name, Series) pairs.

Iterates over the DataFrame columns, returning a tuple with the column name and the content as a Series.

Yields

  label [object] The column names for the DataFrame being iterated over.
  content [Series] The column entries belonging to each label, as a Series.
See also:

**DataFrame.iterrows** Iterate over DataFrame rows as (index, Series) pairs.

**DataFrame.itertuples** Iterate over DataFrame rows as namedtuples of the values.

Examples

```python
>>> df = pd.DataFrame({'species': ['bear', 'bear', 'marsupial'],
...                    'population': [1864, 22000, 80000],
...                    'index': ['panda', 'polar', 'koala']})
>>> df
      species  population
panda     bear        1864
polar     bear       22000
koala   marsupial    80000
>>> for label, content in df.items():
...     print(f'label: {label}')
...     print(f'content: {content}', sep='
')
... 
label: species
content: panda
      bear
polar
      bear
koala
      marsupial
Name: species, dtype: object
label: population
content: panda
      1864
polar
      22000
koala
      80000
Name: population, dtype: int64
```

**pandas.DataFrame.iterrows**

DataFrame.iterrows()

<table>
<thead>
<tr>
<th>Yields</th>
</tr>
</thead>
<tbody>
<tr>
<td>index [label or tuple of label] The index of the row. A tuple for a MultiIndex.</td>
</tr>
<tr>
<td>data [Series] The data of the row as a Series.</td>
</tr>
</tbody>
</table>

See also:

**DataFrame.itertuples** Iterate over DataFrame rows as namedtuples of the values.

**DataFrame.items** Iterate over (column name, Series) pairs.
**Notes**

1. Because `iterrows` returns a Series for each row, it does **not** preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```python
>>> df = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])
>>> row = next(df.iterrows())[1]
>>> row
int    1.0
float  1.5
Name: 0, dtype: float64
>>> print(row['int'].dtype)
float64
>>> print(df['int'].dtype)
int64
```

To preserve dtypes while iterating over the rows, it is better to use `itertuples()` which returns namedtuples of the values and which is generally faster than `iterrows`.

2. You should **never modify** something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect.

**pandas.DataFrame.itertuples**

The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. On python versions < 3.7 regular tuples are returned for DataFrames with a large number of columns (>254).

```python
>>> df.itertuples()
```

**DataFrame.iterrows** Iterate over DataFrame rows as namedtuples.

**Parameters**

- `index` [bool, default True] If True, return the index as the first element of the tuple.
- `name` [str or None, default “Pandas”] The name of the returned namedtuples or None to return regular tuples.

**Returns**

- `iterator` An object to iterate over namedtuples for each row in the DataFrame with the first field possibly being the index and following fields being the column values.

See also:

- `DataFrame.iterrows` Iterate over DataFrame rows as (index, Series) pairs.
- `DataFrame.items` Iterate over (column name, Series) pairs.
Examples

```python
>>> df = pd.DataFrame({'num_legs': [4, 2], 'num_wings': [0, 2]},
                   index=['dog', 'hawk'])
>>> df
num_legs  num_wings
dog       4          0
hawk      2          2
>>> for row in df.itertuples():
    print(row)
    ...
Pandas(Index='dog', num_legs=4, num_wings=0)
Pandas(Index='hawk', num_legs=2, num_wings=2)
```

By setting the `index` parameter to `False` we can remove the index as the first element of the tuple:

```python
>>> for row in df.itertuples(index=False):
    print(row)
    ...
Pandas(num_legs=4, num_wings=0)
Pandas(num_legs=2, num_wings=2)
```

With the `name` parameter set we set a custom name for the yielded namedtuples:

```python
>>> for row in df.itertuples(name='Animal'):
    print(row)
    ...
Animal(Index='dog', num_legs=4, num_wings=0)
Animal(Index='hawk', num_legs=2, num_wings=2)
```

**pandas.DataFrame.join**

DataFrame.join(other, on=None, how='left', lsuffix='', rsuffix='', sort=False)

Join columns of another DataFrame.

Join columns with `other` DataFrame either on index or on a key column. Efficiently join multiple DataFrame objects by index at once by passing a list.

**Parameters**

- **other** [DataFrame, Series, or list of DataFrame] Index should be similar to one of the columns in this one. If a Series is passed, its name attribute must be set, and that will be used as the column name in the resulting joined DataFrame.
- **on** [str, list of str, or array-like, optional] Column or index level name(s) in the caller to join on the index in `other`, otherwise joins index-on-index. If multiple values given, the `other` DataFrame must have a MultiIndex. Can pass an array as the join key if it is not already contained in the calling DataFrame. Like an Excel VLOOKUP operation.
- **how** [{‘left’, ‘right’, ‘outer’, ‘inner’}, default ‘left’] How to handle the operation of the two objects.
  - left: use calling frame’s index (or column if on is specified)
  - right: use `other`’s index.
• outer: form union of calling frame’s index (or column if on is specified) with other’s index, and sort it lexicographically.

• inner: form intersection of calling frame’s index (or column if on is specified) with other’s index, preserving the order of the calling’s one.

lsuffix [str, default ‘’] Suffix to use from left frame’s overlapping columns.
rsuffix [str, default ‘’] Suffix to use from right frame’s overlapping columns.
sort [bool, default False] Order result DataFrame lexicographically by the join key. If False, the order of the join key depends on the join type (how keyword).

Returns
DataFrame A dataframe containing columns from both the caller and other.

See also:
DataFrame.merge For column(s)-on-column(s) operations.

Notes
Parameters on, lsuffix, and rsuffix are not supported when passing a list of DataFrame objects.
Support for specifying index levels as the on parameter was added in version 0.23.0.

Examples

```python
>>> df = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3', 'K4', 'K5'],
                      'A': ['A0', 'A1', 'A2', 'A3', 'A4', 'A5']})
```

```python
>>> df
key  A
0 K0  A0
1 K1  A1
2 K2  A2
3 K3  A3
4 K4  A4
5 K5  A5
```

```python
>>> other = pd.DataFrame({'key': ['K0', 'K1', 'K2'],
                        'B': ['B0', 'B1', 'B2']})
```

```python
>>> other
key  B
0 K0  B0
1 K1  B1
2 K2  B2
```

Join DataFrames using their indexes.

```python
>>> df.join(other, lsuffix='_caller', rsuffix='_other')
key_caller  A  key_other  B
0  K0  A0    K0  B0
1  K1  A1    K1  B1
2  K2  A2    K2  B2
```

(continues on next page)
If we want to join using the key columns, we need to set key to be the index in both `df` and `other`. The joined DataFrame will have key as its index.

```python
>>> df.set_index('key').join(other.set_index('key'))
   A  B
key
K0  A0 B0
K1  A1 B1
K2  A2 B2
K3  A3 NaN
K4  A4 NaN
K5  A5 NaN
```

Another option to join using the key columns is to use the `on` parameter. `DataFrame.join` always uses `other`’s index but we can use any column in `df`. This method preserves the original DataFrame’s index in the result.

```python
>>> df.join(other.set_index('key'), on='key')
   key  A  B
  0   K0 A0 B0
  1   K1 A1 B1
  2   K2 A2 B2
  3   K3 A3 NaN
  4   K4 A4 NaN
  5   K5 A5 NaN
```

**pandas.DataFrame.keys**

DataFrames have a `.keys` method which returns the info axis:

```python
>>> df.keys()
Index
```

This is index for Series, columns for DataFrame.

**pandas.DataFrame.kurt**

DataFrames also have a `.kurt` method which returns the unbiased kurtosis:

```python
>>> df.kurt()
```

Kurtosis obtained using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

**Parameters**

- `axis` ([index (0), columns (1)]) Axis for the function to be applied on.
- `skipna` [bool, default True] Exclude NA/null values when computing the result.
- `level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
**numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

### pandas.DataFrame.kurtosis

DataFrame.kurtosis(\text{axis=\text{None}, skipna=\text{None}, level=\text{None}, numeric_only=\text{None}, **\text{kwargs}})

Return unbiased kurtosis over requested axis.

Kurtosis obtained using Fisher’s definition of kurtosis (kurtosis of normal == 0.0). Normalized by N-1.

**Parameters**

axis [[index (0), columns (1)]] Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

### pandas.DataFrame.last

DataFrame.last(\text{\text{offset}})

Select final periods of time series data based on a date offset.

For a DataFrame with a sorted DatetimeIndex, this function selects the last few rows based on a date offset.

**Parameters**

offset [str, DateOffset, dateutil.relativedelta] The offset length of the data that will be selected. For instance, ‘3D’ will display all the rows having their index within the last 3 days.

**Returns**

Series or DataFrame A subset of the caller.

**Raises**

TypeError If the index is not a DatetimeIndex

See also:

*first* Select initial periods of time series based on a date offset.
**at_time** Select values at a particular time of the day.

**between_time** Select values between particular times of the day.

**Examples**

```python
def df_last_valid_index(df):
    return df.last_valid_index()
```

```python
>>> i = pd.date_range('2018-04-09', periods=4, freq='2D')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
    A
2018-04-09  1
2018-04-11  2
2018-04-13  3
2018-04-15  4
```

Get the rows for the last 3 days:

```python
>>> ts.last('3D')
    A
2018-04-13  3
2018-04-15  4
```

Notice the data for 3 last calendar days were returned, not the last 3 observed days in the dataset, and therefore data for 2018-04-11 was not returned.

**pandas.DataFrame.last_valid_index**

**DataFrame.last_valid_index()**

Return index for last non-NA value or None, if no NA value is found.

**Returns**

Scalar [type of index]

**Notes**

If all elements are non-NA/null, returns None. Also returns None for empty Series/DataFrame.

**pandas.DataFrame.le**

**DataFrame.le(other, axis='columns', level=None)**

Get Less than or equal to of dataframe and other, element-wise (binary operator le).

Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.

Equivalent to \( ==, /=, \leq, <, \geq, > \) with support to choose axis (rows or columns) and level for comparison.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

- **axis** [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').
level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

**DataFrame.eq** Compare DataFrames for equality elementwise.

**DataFrame.ne** Compare DataFrames for inequality elementwise.

**DataFrame.le** Compare DataFrames for less than inequality or equality elementwise.

**DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.

**DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.

**DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. NaN values are considered different (i.e. NaN != NaN).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
... 'revenue': [100, 250, 300]},
... index=['A', 'B', 'C'])
>>> df
   cost  revenue
A    250      100
B    150      250
C    100      300
Comparison with a scalar, using either the operator or method:
```
```python
>>> df == 100
   cost  revenue
A    False   True
B    False  False
C     True   False
>>> df.eq(100)
   cost  revenue
A    False   True
B    False  False
C     True   False
```

When other is a **Series**, the columns of a DataFrame are aligned with the index of other and broadcast:

```python
>>> df != pd.Series([100, 250], index=['cost', 'revenue'])
   cost  revenue
A    True   True
B    True  False
C   False   True
```
Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'D']), axis='index')
  cost  revenue
A    True    False
B    True     True
C    True     True
D    True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in `other`:

```python
>>> df == [250, 100]
  cost  revenue
A    True    True
B    False    False
C    False    False
```

Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
  cost  revenue
A    True    False
B    False     True
C    True    False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                      index=['A', 'B', 'C', 'D'])

>>> df.gt(other)
  cost  revenue
A   False    False
B   False    False
C   False     True
D   False    False
```

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
                              'revenue': [100, 250, 300, 200, 175, 225]},
                             index=[['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
                             ['A', 'B', 'C', 'A', 'B', 'C']])

>>> df_multindex
  cost  revenue
Q1 A   250    100
    B   150    250
    C   100    300
Q2 A   150    200
    B   300    175
    C   220    225
```
pandas.DataFrame.lookup

DataFrame.lookup(row_labels, col_labels)

Label-based “fancy indexing” function for DataFrame. Given equal-length arrays of row and column labels, return an array of the values corresponding to each (row, col) pair.

Deprecated since version 1.2.0: DataFrame.lookup is deprecated, use DataFrame.melt and DataFrame.loc instead. For further details see Looking up values by index/column labels.

Parameters

row_labels [sequence] The row labels to use for lookup.

col_labels [sequence] The column labels to use for lookup.

Returns
	numpy.ndarray The found values.

pandas.DataFrame.lt

DataFrame.lt(other, axis='columns', level=None)

Get Less than of dataframe and other, element-wise (binary operator lt).

Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.

Equivalent to ==, /=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [[0 or ‘index’, 1 or ‘columns’], default ‘columns’] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’).

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

DataFrame of bool Result of the comparison.

See also:

DataFrame.eq Compare DataFrames for equality elementwise.

DataFrame.ne Compare DataFrames for inequality elementwise.

DataFrame.le Compare DataFrames for less than inequality or equality elementwise.
**DataFrame.lt** Compare DataFrames for strictly less than inequality elementwise.

**DataFrame.ge** Compare DataFrames for greater than inequality or equality elementwise.

**DataFrame.gt** Compare DataFrames for strictly greater than inequality elementwise.

**Notes**

Mismatched indices will be unioned together. NaN values are considered different (i.e. `NaN != NaN`).

**Examples**

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
                       'revenue': [100, 250, 300]},
                       index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
   cost  revenue
A  False    True
B  False   False
C   True    False
```

```python
>>> df.eq(100)
   cost  revenue
A  False    True
B  False   False
C   True    False
```

When *other* is a *Series*, the columns of a DataFrame are aligned with the index of *other* and broadcast:

```python
>>> df != pd.Series([100, 250], index=['A', 'B', 'C'])
   cost  revenue
A   True    False
B   True     True
C   False    True
```

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=['A', 'B', 'C'], axis='index')
   cost  revenue
A   True    False
B   True     True
C   True    False
D   True     True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in *other*.
Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
   cost  revenue
A   True    False
B   False    True
C   True    False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({'revenue': [300, 250, 100, 150]},
                        index=['A', 'B', 'C', 'D'])
>>> other
 revenue
 A  300
 B  250
 C  100
 D  150
```

```python
>>> df.gt(other)
   cost  revenue
A   False   False
B   False   False
C   True    False
D   False   False
```

Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
                                'revenue': [100, 250, 300, 200, 175, 225],
                                'index': [['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
                                          ['A', 'B', 'C', 'A', 'B', 'C']])
>>> df_multindex
    cost  revenue
 Q1   250    100
   B   150    250
   C   100    300
 Q2   150    200
   B   300    175
   C   220    225
```

```python
>>> df.le(df_multindex, level=1)
   cost  revenue
 Q1   True    True
   B   True    True
   C   True    True
 Q2   False    True
   B   True    False
   C   True    False
```
pandas.DataFrame.mad

DataFrame.mad (axis=None, skipna=None, level=None)
Return the mean absolute deviation of the values over the requested axis.

Parameters
axis [{index (0), columns (1)}] Axis for the function to be applied on.
skipna [bool, default None] Exclude NA/null values when computing the result.
level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

Returns
Series or DataFrame (if level specified)

pandas.DataFrame.mask

DataFrame.mask (cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=<no_default>)
Replace values where the condition is True.

Parameters
cond [bool Series/DataFrame, array-like, or callable] Where cond is False, keep the original value. Where True, replace with corresponding value from other. If cond is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn’t check it).
other [scalar, Series/DataFrame, or callable] Entries where cond is True are replaced with corresponding value from other. If other is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn’t check it).
inplace [bool, default False] Whether to perform the operation in place on the data.
axis [int, default None] Alignment axis if needed.
level [int, default None] Alignment level if needed.
errors [str, {'raise', 'ignore'}, default ‘raise’] Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.
  • ‘raise’ : allow exceptions to be raised.
  • ‘ignore’ : suppress exceptions. On error return original object.
try_cast [bool, default None] Try to cast the result back to the input type (if possible).

Deprecated since version 1.3.0: Manually cast back if necessary.

Returns
Same type as caller or None if inplace=True.

See also:

DataFrame.where() Return an object of same shape as self.
Notes

The mask method is an application of the if-then idiom. For each element in the calling DataFrame, if `cond` is `False` the element is used; otherwise the corresponding element from the DataFrame `other` is used.

The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2).

For further details and examples see the mask documentation in indexing.

Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1      1
2      2
3      3
4      4
dtype: float64
>>> s.mask(s > 0)
0     0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```python
>>> s.where(s > 1, 10)
0    10
1    10
2      2
3      3
4      4
dtype: int64
>>> s.mask(s > 1, 10)
0     0
1     1
2    10
3    10
4    10
dtype: int64
```

```python
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
```

```python
>>> m = df % 3 == 0
>>> df.where(m, -df)
A     B
0    -1
1      1
2    10
3    10
4    10
```
```
1 -2 3
2 -4 -5
3 6 -7
4 -8 9

```python
>>> df.where(m, -df) == np.where(m, df, -df)
   A  B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True

>>> df.where(m, -df) == df.mask(~m, -df)
   A  B
0  True  True
1  True  True
2  True  True
3  True  True
4  True  True
```

**pandas.DataFrame.max**

DataFrame.max(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return the maximum of the values over the requested axis.

If you want the index of the maximum, use idxmax. This is the equivalent of the numpy.ndarray method argmax.

**Parameters**

- **axis** ([index (0), columns (1)]) Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- ****kwargs Additional keyword arguments to be passed to the function.

**Returns**

Series or DataFrame (if level specified)

See also:

- **Series.sum** Return the sum.
- **Series.min** Return the minimum.
- **Series.max** Return the maximum.
- **Series.idxmin** Return the index of the minimum.
- **Series.idxmax** Return the index of the maximum.
- **DataFrame.sum** Return the sum over the requested axis.
- **DataFrame.min** Return the minimum over the requested axis.
**DataFrame.max**  Return the maximum over the requested axis.

**DataFrame.idxmin**  Return the index of the minimum over the requested axis.

**DataFrame.idxmax**  Return the index of the maximum over the requested axis.

**Examples**

```python
>>> idx = pd.MultiIndex.from_arrays(
... ['warm', 'warm', 'cold', 'cold'],
... ['dog', 'falcon', 'fish', 'spider'],
... names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
  warm  dog  4
  falcon  2
  cold  fish  0
  spider  8
Name: legs, dtype: int64

>>> s.max()
8
```

**pandas.DataFrame.mean**

DataFrame.mean *(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)*  
Return the mean of the values over the requested axis.

**Parameters**

- **axis**  [[index (0), columns (1)]] Axis for the function to be applied on.

- **skipna**  [bool, default True] Exclude NA/null values when computing the result.

- **level**  [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

- **numeric_only**  [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

- **kwargs**  Additional keyword arguments to be passed to the function.

**Returns**

Series or DataFrame (if level specified)
**pandas.DataFrame.median**

**DataFrame.median** *(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)*

Return the median of the values over the requested axis.

**Parameters**

- **axis** [{index (0), columns (1)}] Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs** Additional keyword arguments to be passed to the function.

**Returns**

Series or DataFrame (if level specified)

**pandas.DataFrame.melt**

**DataFrame.melt** *(id_vars=None, value_vars=None, var_name=None, value_name='value', col_level=None, ignore_index=True)*

Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (*id_vars*), while all other columns, considered measured variables (*value_vars*), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’.

**Parameters**

- **id_vars** [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.
- **value_vars** [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as *id_vars*.
- **var_name** [scalar] Name to use for the ‘variable’ column. If None it uses frame.columns.name or ‘variable’.
- **value_name** [scalar, default ‘value’] Name to use for the ‘value’ column.
- **col_level** [int or str, optional] If columns are a MultiIndex then use this level to melt.
- **ignore_index** [bool, default True] If True, original index is ignored. If False, the original index is retained. Index labels will be repeated as necessary.

New in version 1.1.0.

**Returns**

DataFrame Unpivoted DataFrame.

**See also:**

- melt Identical method.
- pivot_table Create a spreadsheet-style pivot table as a DataFrame.
- DataFrame.pivot Return reshaped DataFrame organized by given index / column values.
**DataFrame.explode** Explode a DataFrame from list-like columns to long format.

### Examples

```python
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
                    'B': {0: 1, 1: 3, 2: 5},
                    'C': {0: 2, 1: 4, 2: 6}})
```

```
A  B  C
0  a  1  2
1  b  3  4
2  c  5  6
```

```python
>>> df.melt(id_vars=['A'], value_vars=['B'])
```

```
A     variable  value
0    a          B  1
1    b          B  3
2    c          B  5
```

```python
>>> df.melt(id_vars=['A'], value_vars=['B', 'C'])
```

```
A     variable  value
0    a          B  1
1    b          B  3
2    c          B  5
3    a          C  2
4    b          C  4
5    c          C  6
```

The names of `variable` and `value` columns can be customized:

```python
>>> df.melt(id_vars=['A'], value_vars=['B', 'C'],
          var_name='myVarname', value_name='myValname')
```

```
A    myVarname  myValname
0    a          B  1
1    b          B  3
2    c          B  5
3    a          C  2
4    b          C  4
5    c          C  6
```

Original index values can be kept around:

```python
>>> df.melt(id_vars=['A'], value_vars=['B', 'C'], ignore_index=False)
```

```
A    variable  value
0    a          B  1
1    b          B  3
2    c          B  5
0    a          C  2
1    b          C  4
2    c          C  6
```

If you have multi-index columns:

```python
>>> df.columns = [list('ABC'), list('DEF')]
```

```
A  B  C
D  E  F
0  a  1  2
```
>>> df.melt(col_level=0, id_vars=['A'], value_vars=['B'])
   A  variable  value
0  a        B     1
1  b        B     3
2  c        B     5

>>> df.melt(id_vars=['A', 'D'], value_vars=['B', 'E'])
   (A, D)  variable_0  variable_1  value
0  a       B       E     1
1  b       B       E     3
2  c       B       E     5

pandas.DataFrame.memory_usage

DataFrame.memory_usage(index=True, deep=False)
Return the memory usage of each column in bytes.

The memory usage can optionally include the contribution of the index and elements of object dtype.

This value is displayed in DataFrame.info by default. This can be suppressed by setting pandas.options.display.memory_usage to False.

Parameters

- **index** [bool, default True] Specifies whether to include the memory usage of the DataFrame’s index in returned Series. If index=True, the memory usage of the index is the first item in the output.

- **deep** [bool, default False] If True, introspect the data deeply by interrogating object dtypes for system-level memory consumption, and include it in the returned values.

Returns

- **Series** A Series whose index is the original column names and whose values is the memory usage of each column in bytes.

See also:

- numpy.ndarray.nbytes Total bytes consumed by the elements of an ndarray.
- Series.memory_usage Bytes consumed by a Series.
- Categorical Memory-efficient array for string values with many repeated values.
- DataFrame.info Concise summary of a DataFrame.
Examples

```python
>>> dtypes = ['int64', 'float64', 'complex128', 'object', 'bool']
>>> data = dict([(t, np.ones(shape=5000, dtype=t).astype(t))
...     for t in dtypes])
>>> df = pd.DataFrame(data)
>>> df.head()
          int64  float64  complex128  object  bool
    0    1.00 1.00+0.0j    1.0+0.0j    1.00     True
    1    1.00 1.00+0.0j    1.0+0.0j    1.00     True
    2    1.00 1.00+0.0j    1.0+0.0j    1.00     True
    3    1.00 1.00+0.0j    1.0+0.0j    1.00     True
    4    1.00 1.00+0.0j    1.0+0.0j    1.00     True
```

```python
>>> df.memory_usage()
   Index 128
   int64 40000
   float64 40000
   complex128 80000
   object 40000
   bool 5000
   dtype: int64
```

```python
>>> df.memory_usage(index=False)
   int64 40000
   float64 40000
   complex128 80000
   object 40000
   bool 5000
   dtype: int64
```

The memory footprint of `object` dtype columns is ignored by default:

```python
>>> df.memory_usage(deep=True)
   Index 128
   int64 40000
   float64 40000
   complex128 80000
   object 180000
   bool 5000
   dtype: int64
```

Use a Categorical for efficient storage of an object-dtype column with many repeated values.

```python
>>> df['object'].astype('category').memory_usage(deep=True)
5244
```
**pandas.DataFrame.merge**

DataFrame.merge(right, how='inner', on=None, left_on=None, right_on=None, left_index=False, right_index=False, sort=False, suffixes=('_x', '_y'), copy=True, indicator=False, validate=None)

Merge DataFrame or named Series objects with a database-style join.

A named Series object is treated as a DataFrame with a single named column.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes **will be ignored**. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on. When performing a cross merge, no column specifications to merge on are allowed.

**Parameters**

- **right** [DataFrame or named Series] Object to merge with.
- **how** [{'left’, ‘right’, ‘outer’, ‘inner’, ‘cross’}, default ‘inner’] Type of merge to be performed.
  - left: use only keys from left frame, similar to a SQL left outer join; preserve key order.
  - right: use only keys from right frame, similar to a SQL right outer join; preserve key order.
  - outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
  - inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.
  - cross: creates the cartesian product from both frames, preserves the order of the left keys.

  New in version 1.2.0.

- **on** [label or list] Column or index level names to join on. These must be found in both DataFrames. If on is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

- **left_on** [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

- **right_on** [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

- **left_index** [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

- **right_index** [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as left_index.

- **sort** [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword).

- **suffixes** [list-like, default is (“_x”, “_y”)] A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in left and right respectively. Pass a value of None instead of a string to indicate that the
column name from \textit{left} or \textit{right} should be left as-is, with no suffix. At least one of the values must not be None.

\textbf{copy} [bool, default True] If False, avoid copy if possible.

\textbf{indicator} [bool or str, default False] If True, adds a column to the output DataFrame called “\_merge” with information on the source of each row. The column can be given a different name by providing a string argument. The column will have a Categorical type with the value of “left\_only” for observations whose merge key only appears in the left DataFrame, “right\_only” for observations whose merge key only appears in the right DataFrame, and “both” if the observation’s merge key is found in both DataFrames.

\textbf{validate} [str, optional] If specified, checks if merge is of specified type.

- “one\_to\_one” or “1:1”: check if merge keys are unique in both left and right datasets.
- “one\_to\_many” or “1:m”: check if merge keys are unique in left dataset.
- “many\_to\_one” or “m:1”: check if merge keys are unique in right dataset.
- “many\_to\_many” or “m:m”: allowed, but does not result in checks.

\textbf{Returns}

\texttt{DataFrame} A DataFrame of the two merged objects.

\textbf{See also:}

\texttt{merge\_ordered} Merge with optional filling/interpolation.

\texttt{merge\_asof} Merge on nearest keys.

\texttt{DataFrame.join} Similar method using indices.

\textbf{Notes}

Support for specifying index levels as the \texttt{on}, \texttt{left\_on}, and \texttt{right\_on} parameters was added in version 0.23.0

Support for merging named Series objects was added in version 0.24.0

\textbf{Examples}

```python
>>> df1 = pd.DataFrame({'lkey': ['foo', 'bar', 'baz', 'foo'],
... 'value': [1, 2, 3, 5])
>>> df2 = pd.DataFrame({'rkey': ['foo', 'bar', 'baz', 'foo'],
... 'value': [5, 6, 7, 8])
>>> df1
lkey value
0   foo   1
1   bar   2
2   baz   3
3   foo   5
>>> df2
rkey value
0   foo   5
1   bar   6
2   baz   7
3   foo   8
```
Merge df1 and df2 on the lkey and rkey columns. The value columns have the default suffixes, _x and _y, appended.

```python
>>> df1.merge(df2, left_on='lkey', right_on='rkey')
lkey  value_x  rkey  value_y
 0  foo     1  foo     5
 1  foo     1  foo     8
 2  foo     5  foo     5
 3  foo     5  foo     8
 4  bar     2  bar     6
 5  baz     3  baz     7
```

Merge DataFrames df1 and df2 with specified left and right suffixes appended to any overlapping columns.

```python
>>> df1.merge(df2, left_on='lkey', right_on='rkey',
            suffixes=('value_left', 'value_right'))
lkey  value_left  rkey  value_right
 0  foo          1  foo          5
 1  foo          1  foo          8
 2  foo          5  foo          5
 3  foo          5  foo          8
 4  bar          2  bar          6
 5  baz          3  baz          7
```

Merge DataFrames df1 and df2, but raise an exception if the DataFrames have any overlapping columns.

```python
>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=(False, False))
Traceback (most recent call last):
  ... ValueError: columns overlap but no suffix specified:
    Index(['value'], dtype='object')
```

```python
df1 = pd.DataFrame({'a': ['foo', 'bar'], 'b': [1, 2]})
df2 = pd.DataFrame({'a': ['foo', 'baz'], 'c': [3, 4]})
>>> df1
  a  b
0  foo  1
1  bar  2
>>> df2
  a  c
0  foo  3
1  baz  4
```

```python
>>> df1.merge(df2, how='inner', on='a')
  a  b  c
0  foo  1  3
```

```python
>>> df1.merge(df2, how='left', on='a')
  a  b  c
0  foo  1  3.0
1  bar  2  NaN
```

```python
df1 = pd.DataFrame({'left': ['foo', 'bar']})
df2 = pd.DataFrame({'right': [7, 8]})
```

(continues on next page)
pandas.DataFrame.min

DataFrame.min(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)
Return the minimum of the values over the requested axis.
If you want the index of the minimum, use idxmin. This is the equivalent of the numpy.ndarray method argmin.

Parameters
axis [[index (0), columns (1)]] Axis for the function to be applied on.
skipna [bool, default True] Exclude NA/null values when computing the result.
level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**kwargs Additional keyword arguments to be passed to the function.

Returns
Series or DataFrame (if level specified)

See also:
Series.sum Return the sum.
Series.min Return the minimum.
Series.max Return the maximum.
Series.idxmin Return the index of the minimum.
Series.idxmax Return the index of the maximum.
DataFrame.sum Return the sum over the requested axis.
DataFrame.min Return the minimum over the requested axis.
DataFrame.max Return the maximum over the requested axis.
DataFrame.idxmin Return the index of the minimum over the requested axis.
**DataFrame.idxmax**  Return the index of the maximum over the requested axis.

**Examples**

```python
>>> idx = pd.MultiIndex.from_arrays([
... ['warm', 'warm', 'cold', 'cold'],
... ['dog', 'falcon', 'fish', 'spider']],
... names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded animal
  warm  dog  4
      falcon  2
  cold  fish  0
      spider  8
Name: legs, dtype: int64

>>> s.min()
0
```

**pandas.DataFrame.mod**

DataFrame.mod (other, axis='columns', level=None, fill_value=None)  Get Modulo of dataframe and other, element-wise (binary operator mod).

Equivalent to dataframe % other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rmod.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** {{0 or 'index', 1 or 'columns'}} Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame  Result of the arithmetic operation.

**See also:**

- **DataFrame.add** Add DataFrames.
- **DataFrame.sub** Subtract DataFrames.
- **DataFrame.mul** Multiply DataFrames.
- **DataFrame.div** Divide DataFrames (float division).
**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

### Notes

Mismatched indices will be unioned together.

### Examples

```python
def df = pd.DataFrame({'angles': [0, 3, 4],
                      'degrees': [360, 180, 360],
                      index=['circle', 'triangle', 'rectangle'])
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0</td>
</tr>
<tr>
<td>triangle</td>
<td>3</td>
</tr>
<tr>
<td>rectangle</td>
<td>4</td>
</tr>
</tbody>
</table>

Add a scalar with operator version which return the same results.

```python
def + 1
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
</tbody>
</table>

```python
def.add(1)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
</tbody>
</table>

Divide by constant with reverse version.

```python
def.div(10)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0</td>
</tr>
<tr>
<td>triangle</td>
<td>0.3</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.4</td>
</tr>
</tbody>
</table>

```python
def.rdiv(10)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>inf</td>
</tr>
<tr>
<td>triangle</td>
<td>0.333333</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.25</td>
</tr>
</tbody>
</table>

Subtract a list and Series by axis with operator version.

```python
def - [1, 2]
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td></td>
</tr>
<tr>
<td>triangle</td>
<td></td>
</tr>
<tr>
<td>rectangle</td>
<td></td>
</tr>
</tbody>
</table>
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])
>>> other
   angles
circle  0
triangle 3
rectangle 4
```

```python
>>> df * other
   angles   degrees
circle   0.0      NaN
triangle  9.0      NaN
rectangle 16.0      NaN
```

```python
>>> df.mul(other, fill_value=0)
   angles   degrees
circle   0.0      0.0
triangle  9.0      0.0
rectangle 16.0     0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               index=['A', 'A', 'A', 'B', 'B', 'B'],
                               ['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon'])
>>> df_multindex
   angles   degrees
A circle  0.0      360
triangle  3.0      180
rectangle 4.0      360
B square  4.0      360
pentagon  5.0      540
hexagon  6.0      720
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

```
>>> df.div(df_multindex, level=1, fill_value=0)

          angles  degrees
   A circle  NaN       1.0
      triangle  1.0       1.0
   rectangle  1.0       1.0
   B square  0.0        0.0
     pentagon  0.0        0.0
    hexagon  0.0        0.0
```

**pandas.DataFrame.mode**

`DataFrame.mode(axis=0, numeric_only=False, dropna=True)`

Get the mode(s) of each element along the selected axis.

The mode of a set of values is the value that appears most often. It can be multiple values.

**Parameters**

- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to iterate over while searching for the mode:
  - 0 or ‘index’: get mode of each column
  - 1 or ‘columns’: get mode of each row.
- **numeric_only** [bool, default False] If True, only apply to numeric columns.
- **dropna** [bool, default True] Don’t consider counts of NaN/NaT.

**Returns**

- **DataFrame** The modes of each column or row.

**See also:**

- **Series.mode** Return the highest frequency value in a Series.
- **Series.value_counts** Return the counts of values in a Series.

**Examples**

```
>>> df = pd.DataFrame([('bird', 2, 2),
...                    ('mammal', 4, np.nan),
...                    ('arthropod', 8, 0),
...                    ('bird', 2, np.nan)],
...                   index=('falcon', 'horse', 'spider', 'ostrich'),
...                   columns=('species', 'legs', 'wings'))
```

```
>>> df

species   legs   wings
falcon     bird   2.0
horse      mammal 4.0  NaN
spider     arthropod 8.0 0.0
ostrich    bird   2.0  NaN
```

By default, missing values are not considered, and the mode of wings are both 0 and 2. Because the resulting DataFrame has two rows, the second row of `species` and `legs` contains NaN.
>>> df.mode()
   species  legs  wings
0   bird    2.0   0.0
1   NaN    NaN   2.0

Setting `dropna=False` NaN values are considered and they can be the mode (like for wings).

>>> df.mode(dropna=False)
   species  legs  wings
0   bird    2.0   NaN

Setting `numeric_only=True`, only the mode of numeric columns is computed, and columns of other types are ignored.

>>> df.mode(numeric_only=True)
      legs  wings
0  2.000  0.000
1  NaN   2.000

To compute the mode over columns and not rows, use the `axis` parameter:

>>> df.mode(axis='columns', numeric_only=True)
          0  1
  falcon  2.0 NaN
  horse   4.0 NaN
  spider  0.0  8.0
 ostrich  2.0 NaN

`pandas.DataFrame.mul`

`DataFrame.mul` *(other, axis='columns', level=None, fill_value=None)*

Get Multiplication of dataframe and other, element-wise (binary operator `mul`).
Equivalent to `dataframe * other`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `rmul`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `−`, `∗`, `÷`, `%`, `**`.

Parameters

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- `fill_value` [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

- `DataFrame` Result of the arithmetic operation.

See also:
**DataFrame.add** Add DataFrames.

**DataFrame.sub** Subtract DataFrames.

**DataFrame.mul** Multiply DataFrames.

**DataFrame.div** Divide DataFrames (float division).

**DataFrame.truediv** Divide DataFrames (float division).

**DataFrame.floordiv** Divide DataFrames (integer division).

**DataFrame.mod** Calculate modulo (remainder after division).

**DataFrame.pow** Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.

**Examples**

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])

>>> df
angles  degrees
circle       0  360
triangle     3  180
rectangle    4  360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
angles  degrees
circle    1  361
triangle   4  181
rectangle  5  361
```  

```python
>>> df.add(1)
angles  degrees
circle    1  361
triangle   4  181
rectangle  5  361
```  

Divide by constant with reverse version.

```python
>>> df.div(10)
angles  degrees
circle   0.0  36.0
triangle 0.3  18.0
rectangle 0.4  36.0
```  

```python
>>> df.rdiv(10)
angles  degrees
circle  inf  0.027778
triangle 3.333333  0.055556
rectangle 2.500000  0.027778
```
Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
   angles  degrees
   circle     -1     358
   triangle     2     178
   rectangle    3     358

>>> df.sub([1, 2], axis='columns')
   angles  degrees
   circle     -1     358
   triangle     2     178
   rectangle    3     358

>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
          axis='index')
   angles  degrees
   circle     -1     359
   triangle     2     179
   rectangle    3     359
```

Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                      index=['circle', 'triangle', 'rectangle'])
```

```python
>>> df * other
   angles  degrees
   circle     0      NaN
   triangle    9      NaN
   rectangle   16      NaN

>>> df.mul(other, fill_value=0)
   angles  degrees
   circle     0       0.0
   triangle    9       0.0
   rectangle   16       0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               'index': ['circle', 'triangle', 'rectangle',
                                         'square', 'pentagon', 'hexagon']})
```

```python
>>> df_multindex
   angles  degrees
   A circle     0     360
   triangle     3     180
   rectangle    4     360
   B square     4     360
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.1

pentagon 5 540
hexagon 6 720

```python
>>> df.div(df_multindex, level=1, fill_value=0)
angles  degrees
A circle   NaN   1.0
triangle  1.0   1.0
rectangle 1.0   1.0
B square  0.0   0.0
pentagon 0.0   0.0
hexagon  0.0   0.0
```

**pandas.DataFrame.multiply**

Dataframe.multiply(other, axis='columns', level=None, fill_value=None)

Get Multiplication of dataframe and other, element-wise (binary operator mul).

Equivalent to dataframes * other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rmul.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame Result of the arithmetic operation.

See also:

- DataFrame.add Add DataFrames.
- DataFrame.sub Subtract DataFrames.
- DataFrame.mul Multiply DataFrames.
- DataFrame.div Divide DataFrames (float division).
- DataFrame.truediv Divide DataFrames (float division).
- DataFrame.floordiv Divide DataFrames (integer division).
- DataFrame.mod Calculate modulo (remainder after division).
- DataFrame.pow Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle     0     360
triangle    3     180
rectangle   4     360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle     1     361
triangle    4     181
rectangle   5     361
```

```python
def.add(1)
   angles  degrees
circle     1     361
triangle    4     181
rectangle   5     361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle  0.0     36.0
triangle 0.3     18.0
rectangle 0.4     36.0
```

```python
def.rdiv(10)
   angles  degrees
circle  inf     0.027778
triangle 3.333333 0.055556
rectangle 2.500000 0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
   angles  degrees
circle   -1     358
triangle    2     178
rectangle   3     358
```

```python
def.sub([1, 2], axis='columns')
   angles  degrees
circle   -1     358
triangle    2     178
rectangle   3     358
```
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                       index=['circle', 'triangle', 'rectangle'])
>>> other
angles    
circle    0
triangle   3
rectangle  4

>>> df + other
angles     degrees
circle  0          NaN
triangle  9          NaN
rectangle 16         NaN

>>> df.mul(other, fill_value=0)
angles     degrees
circle    0          0.0
triangle  9          0.0
rectangle 16         0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720]},
                              index=['A', 'A', 'A', 'B', 'B', 'B'],
                              [ 'circle', 'triangle', 'rectangle',
                                'square', 'pentagon', 'hexagon'])
>>> df_multindex
angles     degrees
A circle    0          360
triangle    3          180
rectangle   4          360
B square    4          360
pentagon    5          540
hexagon     6          720

>>> df.div(df_multindex, level=1, fill_value=0)
angles     degrees
A circle   NaN          1.0
triangle   1.0          1.0
rectangle  1.0          1.0
B square   0.0          0.0
pentagon   0.0          0.0
hexagon    0.0          0.0
```
pandas.DataFrame.ne

DataFrame.ne(other, axis='columns', level=None)

Get Not equal to of dataframe and other, element-wise (binary operator ne).
Among flexible wrappers (eq, ne, le, lt, ge, gt) to comparison operators.
Equivalent to ==, /=, <=, <, >=, > with support to choose axis (rows or columns) and level for comparison.

Parameters

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` [{0 or 'index', 1 or 'columns'}, default 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns').
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

Returns

- `DataFrame of bool` Result of the comparison.

See also:

- `DataFrame.eq` Compare DataFrames for equality elementwise.
- `DataFrame.ne` Compare DataFrames for inequality elementwise.
- `DataFrame.le` Compare DataFrames for less than inequality or equality elementwise.
- `DataFrame.lt` Compare DataFrames for strictly less than inequality elementwise.
- `DataFrame.ge` Compare DataFrames for greater than inequality or equality elementwise.
- `DataFrame.gt` Compare DataFrames for strictly greater than inequality elementwise.

Notes

Mismatched indices will be unioned together. `NaN` values are considered different (i.e. `NaN != NaN`).

Examples

```python
>>> df = pd.DataFrame({'cost': [250, 150, 100],
...                     'revenue': [100, 250, 300]},
...                    index=['A', 'B', 'C'])
>>> df
   cost  revenue
A   250     100
B   150     250
C   100     300

Comparison with a scalar, using either the operator or method:

```python
>>> df == 100
   cost  revenue
A  False     True
```
When other is a Series, the columns of a DataFrame are aligned with the index of other and broadcast:

```python
>>> df != pd.Series([100, 250], index=["cost", "revenue"])
cost  revenue
A   True  True
B   True  False
C  False  True
```

Use the method to control the broadcast axis:

```python
>>> df.ne(pd.Series([100, 300], index=["A", "D"], index='index'))
cost  revenue
A   True  False
B   True  True
C  True  True
D  True  True
```

When comparing to an arbitrary sequence, the number of columns must match the number elements in other:

```python
>>> df == [250, 100]
cost  revenue
A   True  True
B  False  False
C  False  False
```

Use the method to control the axis:

```python
>>> df.eq([250, 250, 100], axis='index')
cost  revenue
A   True  False
B  False  True
C  True  False
```

Compare to a DataFrame of different shape.

```python
>>> other = pd.DataFrame({"revenue": [300, 250, 100, 150], ...
index=["A", "B", "C", "D"]})
>>> other
revenue
A  300
B  250
C  100
D  150
```

```python
>>> df.gt(other)
cost  revenue
```

(continues on next page)
Compare to a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'cost': [250, 150, 100, 150, 300, 220],
... 'revenue': [100, 250, 300, 200, 175, 225],
... index=['Q1', 'Q1', 'Q1', 'Q2', 'Q2', 'Q2'],
... ['A', 'B', 'C', 'A', 'B', 'C']})
```

```python
>>> df_multindex
          cost  revenue
    Q1       A    250    100
         B    150    250
         C    100    300
    Q2       A    150    200
         B    300    175
         C    220    225
```

```python
>>> df.le(df_multindex, level=1)
          cost  revenue
    Q1       A  True  True
         B  True  True
         C  True  True
    Q2       A  False  True
         B  True  False
         C  True  False
```

### pandas.DataFrame.nlargest

DataFrame.nlargest(n, columns, keep='first')

Return the first n rows ordered by columns in descending order.

Return the first n rows with the largest values in columns, in descending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to `df.sort_values(columns, ascending=False).head(n)`, but more performant.

**Parameters**

- **n** [int] Number of rows to return.
- **columns** [label or list of labels] Column label(s) to order by.
- **keep** [{'first', 'last', 'all'}, default 'first'] Where there are duplicate values:
  - first : prioritize the first occurrence(s)
  - last : prioritize the last occurrence(s)
  - all  [do not drop any duplicates, even it means] selecting more than n items.

**Returns**

- **DataFrame** The first n rows ordered by the given columns in descending order.

**See also:**
**DataFrame.nsmallest** Return the first \( n \) rows ordered by columns in ascending order.

**DataFrame.sort_values** Sort DataFrame by the values.

**DataFrame.head** Return the first \( n \) rows without re-ordering.

**Notes**

This function cannot be used with all column types. For example, when specifying columns with *object* or *category* dtypes, *TypeError* is raised.

**Examples**

```python
>>> df = pd.DataFrame({'population': [59000000, 65000000, 434000,
... 434000, 434000, 337000, 11300,
... 11300, 11300],
... 'GDP': [1937894, 2583560, 12011, 4520, 12128,
... 17036, 182, 38, 311],
... 'alpha-2': ['IT', 'FR', 'MT', 'MV', 'BN',
... 'IS', 'NR', 'TV', 'AI']},
... index=['Italy', 'France', 'Malta',
... 'Maldives', 'Brunei', 'Iceland',
... 'Nauru', 'Tuvalu', 'Anguilla'])
```

<table>
<thead>
<tr>
<th>Country</th>
<th>Population</th>
<th>GDP</th>
<th>Alpha-2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Italy</td>
<td>59000000</td>
<td>1937894</td>
<td>IT</td>
</tr>
<tr>
<td>France</td>
<td>65000000</td>
<td>2583560</td>
<td>FR</td>
</tr>
<tr>
<td>Malta</td>
<td>434000</td>
<td>12011</td>
<td>MT</td>
</tr>
<tr>
<td>Maldives</td>
<td>434000</td>
<td>4520</td>
<td>MV</td>
</tr>
<tr>
<td>Brunei</td>
<td>434000</td>
<td>12128</td>
<td>BN</td>
</tr>
<tr>
<td>Iceland</td>
<td>337000</td>
<td>17036</td>
<td>IS</td>
</tr>
<tr>
<td>Nauru</td>
<td>11300</td>
<td>182</td>
<td>NR</td>
</tr>
<tr>
<td>Tuvalu</td>
<td>11300</td>
<td>38</td>
<td>TV</td>
</tr>
<tr>
<td>Anguilla</td>
<td>11300</td>
<td>311</td>
<td>AI</td>
</tr>
</tbody>
</table>

In the following example, we will use *nlargest* to select the three rows having the largest values in column “population”.

```python
>>> df.nlargest(3, 'population')
```

<table>
<thead>
<tr>
<th>Country</th>
<th>Population</th>
<th>GDP</th>
<th>Alpha-2</th>
</tr>
</thead>
<tbody>
<tr>
<td>France</td>
<td>65000000</td>
<td>2583560</td>
<td>FR</td>
</tr>
<tr>
<td>Italy</td>
<td>59000000</td>
<td>1937894</td>
<td>IT</td>
</tr>
<tr>
<td>Malta</td>
<td>434000</td>
<td>12011</td>
<td>MT</td>
</tr>
</tbody>
</table>

When using *keep='last'* , ties are resolved in reverse order:

```python
>>> df.nlargest(3, 'population', keep='last')
```

<table>
<thead>
<tr>
<th>Country</th>
<th>Population</th>
<th>GDP</th>
<th>Alpha-2</th>
</tr>
</thead>
<tbody>
<tr>
<td>France</td>
<td>65000000</td>
<td>2583560</td>
<td>FR</td>
</tr>
<tr>
<td>Italy</td>
<td>59000000</td>
<td>1937894</td>
<td>IT</td>
</tr>
<tr>
<td>Brunei</td>
<td>434000</td>
<td>12128</td>
<td>BN</td>
</tr>
</tbody>
</table>

When using *keep='all'* , all duplicate items are maintained:
To order by the largest values in column “population” and then “GDP”, we can specify multiple columns like in the next example.

```python
>>> df.nlargest(3, ['population', 'GDP'])
```

<table>
<thead>
<tr>
<th>population</th>
<th>GDP</th>
<th>alpha-2</th>
</tr>
</thead>
<tbody>
<tr>
<td>France</td>
<td>65000000</td>
<td>2583560</td>
</tr>
<tr>
<td>Italy</td>
<td>59000000</td>
<td>1937894</td>
</tr>
<tr>
<td>Brunei</td>
<td>434000</td>
<td>12128</td>
</tr>
</tbody>
</table>

**pandas.DataFrame.notna**

DataFrame.notna()  
Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or numpy.inf are not considered NA values (unless you set pandas.options.mode.use_inf_as_na = True). NA values, such as None or numpy.NaN, get mapped to False values.

Returns

DataFrame Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

See also:

DataFrame.notnull Alias of notna.

DataFrame.isna Boolean inverse of notna.

DataFrame.dropna Omit axes labels with missing values.

notna Top-level notna.

**Examples**

Show which entries in a DataFrame are not NA.

```python
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
... born=[pd.NaT, pd.Timestamp('1939-05-27'),
... pd.Timestamp('1940-04-25')],
... name=['Alfred', 'Batman', ''],
... toy=[None, 'Batmobile', 'Joker']))

>>> df
   age  born   name    toy
0   5.0  NaT   Alfred  None
1  6.0  1939-05-27  Batman  Batmobile
2  NaN  1940-04-25  Joker
```
Show which entries in a Series are not NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0  5.0
1  6.0
2  NaN
dtype: float64
```

```python
>>> ser.notna()
0  True
1  True
2  False
dtype: bool
```

### pandas.DataFrame.notnull

**DataFrame.notnull()**  
Detect existing (non-missing) values.

Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to True. Characters such as empty strings '' or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to False values.

**Returns**  
DataFrame  Mask of bool values for each element in DataFrame that indicates whether an element is not an NA value.

**See also:**

- `DataFrame.isna` Boolean inverse of `notna`.  
- `DataFrame.dropna` Omit axes labels with missing values.  
- `notna` Top-level `notna`.

**Examples**

Show which entries in a DataFrame are not NA.

```python
>>> df = pd.DataFrame(dict(age=[5, 6, np.NaN],
...                    born=[pd.NaT, pd.Timestamp('1939-05-27'),
...                       pd.Timestamp('1940-04-25')],
...                    name=['Alfred', 'Batman', ''],
...                    toy=[None, 'Batmobile', 'Joker']))
>>> df
```

(continues on next page)
Show which entries in a Series are not NA.

```python
>>> ser = pd.Series([5, 6, np.NaN])
>>> ser
0  5.0
1  6.0
2   NaN
dtype: float64
```

```python
>>> ser.notna()
0  True
1  True
2  False
dtype: bool
```

### pandas.DataFrame.nsmallest

DataFrame.nsmallest \((n, \text{columns}, \text{keep}='\text{first}')\)

Return the first \(n\) rows ordered by \text{columns} in ascending order.

Return the first \(n\) rows with the smallest values in \text{columns}, in ascending order. The columns that are not specified are returned as well, but not used for ordering.

This method is equivalent to \text{df.sort_values(columns, ascending=True).head(n)}, but more performant.

**Parameters**

- \(n\) [int] Number of items to retrieve.
- \text{columns} [list or str] Column name or names to order by.
- \text{keep} [{‘first’, ‘last’, ‘all’}, default ‘first’] Where there are duplicate values:
  - \text{first}: take the first occurrence.
  - \text{last}: take the last occurrence.
  - \text{all}: do not drop any duplicates, even it means selecting more than \(n\) items.

**Returns**

DataFrame

**See also:**

\text{DataFrame.nlargest} Return the first \(n\) rows ordered by \text{columns} in descending order.
**DataFrame.sort_values** Sort DataFrame by the values.

**DataFrame.head** Return the first \( n \) rows without re-ordering.

**Examples**

```python
>>> df = pd.DataFrame({'population': [59000000, 65000000, 434000,
... 434000, 434000, 337000, 337000,
... 11300, 11300],
... 'GDP': [1937894, 2583560, 12011, 4520, 12128,
... 17036, 182, 38, 311],
... 'alpha-2': ['IT', 'FR', 'MT', 'MV', 'BN',
... 'IS', 'NR', 'TV', 'AI'],
... index=['Italy', 'France', 'Malta',
... 'Maldives', 'Brunei', 'Iceland',
... 'Nauru', 'Tuvalu', 'Anguilla'])
```

```plaintext
In the following example, we will use \( \text{nsmallest} \) to select the three rows having the smallest values in column “population”.

```python
>>> df.nsmallest(3, 'population')
```

```plaintext
<table>
<thead>
<tr>
<th>population</th>
<th>GDP</th>
<th>alpha-2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tuvalu</td>
<td>11300</td>
<td>38 TV</td>
</tr>
<tr>
<td>Anguilla</td>
<td>11300</td>
<td>311 AI</td>
</tr>
<tr>
<td>Iceland</td>
<td>337000</td>
<td>17036 IS</td>
</tr>
</tbody>
</table>
```

When using \( \text{keep}='\text{last}' \), ties are resolved in reverse order:

```python
>>> df.nsmallest(3, 'population', keep='last')
```

```plaintext
<table>
<thead>
<tr>
<th>population</th>
<th>GDP</th>
<th>alpha-2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anguilla</td>
<td>11300</td>
<td>311 AI</td>
</tr>
<tr>
<td>Tuvalu</td>
<td>11300</td>
<td>38 TV</td>
</tr>
<tr>
<td>Nauru</td>
<td>337000</td>
<td>182 NR</td>
</tr>
</tbody>
</table>
```

When using \( \text{keep}='\text{all}' \), all duplicate items are maintained:

```python
>>> df.nsmallest(3, 'population', keep='all')
```

```plaintext
<table>
<thead>
<tr>
<th>population</th>
<th>GDP</th>
<th>alpha-2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tuvalu</td>
<td>11300</td>
<td>38 TV</td>
</tr>
<tr>
<td>Anguilla</td>
<td>11300</td>
<td>311 AI</td>
</tr>
<tr>
<td>Iceland</td>
<td>337000</td>
<td>17036 IS</td>
</tr>
<tr>
<td>Nauru</td>
<td>337000</td>
<td>182 NR</td>
</tr>
</tbody>
</table>
```

To order by the smallest values in column “population” and then “GDP”, we can specify multiple columns like in the next example.
```python
>>> df.nsmallest(3, ['population', 'GDP'])
   population  GDP  alpha-2
Tuvalu   11300   38  TV
Anguilla 11300   311  AI
Nauru   337000  182  NR
```

**pandas.DataFrame.nunique**

Dataframe.nunique(axis=0, dropna=True)

Count number of distinct elements in specified axis.

Return Series with number of distinct elements. Can ignore NaN values.

**Parameters**

- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.
- **dropna** [bool, default True] Don’t include NaN in the counts.

**Returns**

Series

See also:

- **Series.nunique** Method unique for Series.
- **DataFrame.count** Count non-NA cells for each column or row.

**Examples**

```python
>>> df = pd.DataFrame({'A': [4, 5, 6], 'B': [4, 1, 1]})
>>> df.nunique()
A 3
B 2
```

```python
>>> df.nunique(axis=1)
0 1
1 2
2 2
```

**pandas.DataFrame.pad**

Dataframe.pad(axis=None, inplace=False, limit=None, downcast=None)

Synonym for DataFrame.fillna() with method='ffill'.

**Returns**

Series/DataFrame or None Object with missing values filled or None if inplace=True.
**DataFrame.pct_change**

**DataFrame.pct_change**(periods=1, fill_method='pad', limit=None, freq=None, **kwargs)

Percentage change between the current and a prior element.

Computes the percentage change from the immediately previous row by default. This is useful in comparing the percentage of change in a time series of elements.

**Parameters**

- **periods** [int, default 1] Periods to shift for forming percent change.
- **fill_method** [str, default ‘pad’] How to handle NAs before computing percent changes.
- **limit** [int, default None] The number of consecutive NAs to fill before stopping.
- **freq** [DateOffset, timedelta, or str, optional] Increment to use from time series API (e.g. ‘M’ or BDay()).
- ****kwargs Additional keyword arguments are passed into DataFrame.shift or Series.shift.

**Returns**

- **chg** [Series or DataFrame] The same type as the calling object.

See also:

- **Series.diff** Compute the difference of two elements in a Series.
- **DataFrame.diff** Compute the difference of two elements in a DataFrame.
- **Series.shift** Shift the index by some number of periods.
- **DataFrame.shift** Shift the index by some number of periods.

**Examples**

**Series**

```python
>>> s = pd.Series([90, 91, 85])
>>> s
0  90
1  91
2  85
dtype: int64
```

```python
>>> s.pct_change()
0   NaN
1  0.011111
2 -0.065934
dtype: float64
```

```python
>>> s.pct_change(periods=2)
0   NaN
1   NaN
2 -0.055556
dtype: float64
```

See the percentage change in a Series where filling NAs with last valid observation forward to next valid.
```python
>>> s = pd.Series([90, 91, None, 85])
>>> s
0    90.0
1    91.0
2     NaN
3    85.0
dtype: float64

>>> s.pct_change(fill_method='ffill')
0      NaN
1  0.011111
2    0.000000
3 -0.065934
dtype: float64

```

**DataFrame**

Percentage change in French franc, Deutsche Mark, and Italian lira from 1980-01-01 to 1980-03-01.

```python
>>> df = pd.DataFrame({'FR': [4.0405, 4.0963, 4.3149],
...                    'GR': [1.7246, 1.7482, 1.8519],
...                    'IT': [804.74, 810.01, 860.13]},
...                   index=['1980-01-01', '1980-02-01', '1980-03-01'])

```  

```python
>>> df
   FR    GR    IT
1980-01-01  4.0405  1.7246  804.74
1980-02-01  4.0963  1.7482  810.01
1980-03-01  4.3149  1.8519  860.13

```  

```python
>>> df.pct_change()
   FR    GR    IT
1980-01-01 NaN  NaN  NaN
1980-02-01 0.013810 0.013684 0.006549
1980-03-01 0.053365 0.059318 0.061876

```

Percentage of change in GOOG and APPL stock volume. Shows computing the percentage change between columns.

```python
>>> df = pd.DataFrame({'2016': [1769950, 30586265],
...                    '2015': [1500923, 40912316],
...                    '2014': [1371819, 41403351]},
...                   index=['GOOG', 'APPL'])

```  

```python
>>> df
   2016  2015  2014
GOOG  1769950  1500923  1371819
APPL  30586265  40912316  41403351

```  

```python
>>> df.pct_change(axis='columns', periods=-1)
   2016  2015  2014
GOOG    0.179241  0.094112  NaN
APPL   -0.252395  -0.011860  NaN

```

3.4. DataFrame
pandas.DataFrame.pipe

DataFrame.pipe(func, *args, **kwargs)
Apply func(self, *args, **kwargs).

Parameters
  func [function] Function to apply to the Series/DataFrame. args, and kwargs are passed into func. Alternatively a (callable, data_keyword) tuple where data_keyword is a string indicating the keyword of callable that expects the Series/DataFrame.
  args [iterable, optional] Positional arguments passed into func.
  kwargs [mapping, optional] A dictionary of keyword arguments passed into func.

Returns
  object [the return type of func.]

See also:
DataFrame.apply Apply a function along input axis of DataFrame.
DataFrame.applymap Apply a function elementwise on a whole DataFrame.
Series.map Apply a mapping correspondence on a Series.

Notes

Use .pipe when chaining together functions that expect Series, DataFrames or GroupBy objects. Instead of writing

```python
>>> func(g(h(df), arg1=a), arg2=b, arg3=c)
```

You can write

```python
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe(func, arg2=b, arg3=c)
... )
```

If you have a function that takes the data as (say) the second argument, pass a tuple indicating which keyword expects the data. For example, suppose f takes its data as arg2:

```python
>>> (df.pipe(h)
...   .pipe(g, arg1=a)
...   .pipe((func, 'arg2'), arg1=a, arg3=c)
... )
```
pandas.DataFrame.pivot

DataFrame.pivot(index=None, columns=None, values=None)
Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified index / columns to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the User Guide for more on reshaping.

Parameters

index [str or object or a list of str, optional] Column to use to make new frame’s index.
If None, uses existing index.
Changed in version 1.1.0: Also accept list of index names.

columns [str or object or a list of str] Column to use to make new frame’s columns.
Changed in version 1.1.0: Also accept list of columns names.

values [str, object or a list of the previous, optional] Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.

Returns

DataFrame Returns reshaped DataFrame.

Raises

ValueError: When there are any index, columns combinations with multiple values.
DataFrame.pivot_table when you need to aggregate.

See also:

DataFrame.pivot_table Generalization of pivot that can handle duplicate values for one index/column pair.
DataFrame.unstack Pivot based on the index values instead of a column.
wide_to_long Wide panel to long format. Less flexible but more user-friendly than melt.

Notes

For finer-tuned control, see hierarchical indexing documentation along with the related stack/unstack methods.

Examples

```python
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two', ...
...                     'two'],
...                     'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
...                     'baz': [1, 2, 3, 4, 5, 6],
...                     'zoo': ['x', 'y', 'z', 'q', 'w', 't']})
>>> df
  foo  bar  baz  zoo
0  one   A   1   x
1  one   B   2   y
2  one   C   3   z
```

(continues on next page)
3  two  A  4  q
4  two  B  5  w
5  two  C  6  t

>>> df.pivot(index='foo', columns='bar', values='baz')
bar     A  B  C
foo
one     1  2  3
two     4  5  6

>>> df.pivot(index='foo', columns='bar')['baz']
bar     A  B  C
foo
one     1  2  3
two     4  5  6

>>> df.pivot(index='foo', columns='bar', values=['baz', 'zoo'])
    baz  zoo
bar     A  B  C  A  B  C
foo
one     1  2  3   x  y  z
two     4  5  6   q  w  t

You could also assign a list of column names or a list of index names.

>>> df = pd.DataFrame({
...     "lev1": [1, 1, 1, 2, 2, 2],
...     "lev2": [1, 1, 2, 1, 1, 2],
...     "lev3": [1, 2, 1, 2, 1, 2],
...     "lev4": [1, 2, 3, 4, 5, 6],
...     "values": [0, 1, 2, 3, 4, 5]})

>>> df
     lev1  lev2  lev3  lev4  values
0  1.00  1.00  1.00  1.00   1.00
1  1.00  1.00  1.00  1.00   1.00
2  1.00  1.00  1.00  1.00   1.00
3  1.00  1.00  1.00  1.00   1.00
4  1.00  1.00  1.00  1.00   1.00
5  1.00  1.00  1.00  1.00   1.00

>>> df.pivot(index="lev1", columns="lev2", lev3, values="values")
lev2  lev3
lev1
1  0.0  1.0  2.0  NaN
2  4.0  3.0  NaN  5.0

>>> df.pivot(index="lev1", lev2, columns="lev3", values="values")
lev3  lev1  lev2
1  0.0  1.0  1.0
2  2.0  NaN
2  4.0  3.0
2  NaN  5.0

A ValueError is raised if there are any duplicates.
>>> df = pd.DataFrame({"foo": ['one', 'one', 'two', 'two'],
...                     "bar": ['A', 'A', 'B', 'C'],
...                     "baz": [1, 2, 3, 4]})
>>> df
  foo bar baz
0 one A 1
1 one A 2
2 two B 3
3 two C 4

Notice that the first two rows are the same for our `index` and `columns` arguments.

>>> df.pivot(index='foo', columns='bar', values='baz')
Traceback (most recent call last):
  ...
ValueError: Index contains duplicate entries, cannot reshape

**pandas.DataFrame.pivot_table**

DataFrame.pivot_table(values=None, index=None, columns=None, aggfunc='mean', fill_value=None, margins=False, dropna=True, margins_name='All', observed=False, sort=True)

Create a spreadsheet-style pivot table as a DataFrame.

The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

**Parameters**

- **values**  [column to aggregate, optional]
- **index**  [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.
- **columns**  [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.
- **aggfunc**  [function, list of functions, dict, default numpy.mean] If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions.
- **fill_value**  [scalar, default None] Value to replace missing values with (in the resulting pivot table, after aggregation).
- **margins**  [bool, default False] Add all row / columns (e.g. for subtotal / grand totals).
- **dropna**  [bool, default True] Do not include columns whose entries are all NaN.
- **margins_name**  [str, default ‘All’] Name of the row / column that will contain the totals when margins is True.
- **observed**  [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.
Changed in version 0.25.0.

**sort** [bool, default True] Specifies if the result should be sorted.

New in version 1.3.0.

**Returns**

**DataFrame** An Excel style pivot table.

**See also:**

*DataFrame.pivot* Pivot without aggregation that can handle non-numeric data.

*DataFrame.melt* Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

*wide_to_long* Wide panel to long format. Less flexible but more user-friendly than melt.

**Examples**

```python
>>> df = pd.DataFrame({
    "A": ["foo", "foo", "foo", "foo", "foo", "bar", "bar", "bar", "bar"],
    "B": ["one", "one", "one", "two", "two", "one", "two", "two"],
    "C": ["small", "large", "large", "small", "small", "large", "small", "small"],
    "D": [1, 2, 2, 3, 3, 4, 5, 6, 7],
    "E": [2, 4, 5, 5, 6, 6, 8, 9, 9]
})
>>> df
   A    B    C    D    E
0  foo  one  small  1.0  2.0
1  foo  one  large  2.0  4.0
2  foo  one  large  2.0  5.0
3  foo  two  small  3.0  5.0
4  foo  two  small  3.0  6.0
5  bar  one  large  4.0  6.0
6  bar  one  large  5.0  8.0
7  bar  two  small  6.0  9.0
8  bar  two  large  7.0  9.0
```

This first example aggregates values by taking the sum.

```python
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
                        columns=['C'], aggfunc=np.sum)
>>> table
     C
 A     B
bar  one  4.0  5.0
     two  7.0  6.0
foo  one  4.0  1.0
     two  NaN  6.0
```

We can also fill missing values using the *fill_value* parameter.

```python
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
                        columns=['C'], aggfunc=np.sum, fill_value=0)
>>> table
     C
 A     B
bar  one  4.0  0.0
     two  7.0  0.0
foo  one  4.0  1.0
     two  NaN  6.0
```

(continues on next page)
The next example aggregates by taking the mean across multiple columns.

```python
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                        aggfunc={'D': np.mean,
...                                'E': np.mean})
```

```plaintext
<table>
<thead>
<tr>
<th></th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td>5.500</td>
<td>7.500</td>
</tr>
<tr>
<td></td>
<td>5.500</td>
<td>8.500</td>
</tr>
<tr>
<td>foo</td>
<td>2.000</td>
<td>4.500</td>
</tr>
<tr>
<td></td>
<td>2.333</td>
<td>4.333</td>
</tr>
</tbody>
</table>
```

We can also calculate multiple types of aggregations for any given value column.

```python
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                        aggfunc={'D': np.mean,
...                                'E': [min, max, np.mean]})
```

```plaintext
<table>
<thead>
<tr>
<th></th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>mean</td>
<td>max</td>
</tr>
<tr>
<td>bar</td>
<td>5.500</td>
<td>9.0</td>
</tr>
<tr>
<td></td>
<td>5.500</td>
<td>9.0</td>
</tr>
<tr>
<td>foo</td>
<td>2.000</td>
<td>5.0</td>
</tr>
<tr>
<td></td>
<td>2.333</td>
<td>6.0</td>
</tr>
</tbody>
</table>
```

`pandas.DataFrame.plot`

`DataFrame.plot(*args, **kwargs)`

Make plots of Series or DataFrame.

Uses the backend specified by the option `plotting.backend`. By default, matplotlib is used.

**Parameters**

- `data` [Series or DataFrame] The object for which the method is called.
- `x` [label or position, default None] Only used if data is a DataFrame.
- `y` [label, position or list of label, positions, default None] Allows plotting of one column versus another. Only used if data is a DataFrame.
- `kind` [str] The kind of plot to produce:
  - ‘line’: line plot (default)
  - ‘bar’: vertical bar plot
  - ‘barh’: horizontal bar plot
  - ‘hist’: histogram
• ‘box’ : boxplot
• ‘kde’ : Kernel Density Estimation plot
• ‘density’ : same as ‘kde’
• ‘area’ : area plot
• ‘pie’ : pie plot
• ‘scatter’ : scatter plot (DataFrame only)
• ‘hexbin’ : hexbin plot (DataFrame only)

ax  [matplotlib axes object, default None] An axes of the current figure.

subplots  [bool, default False] Make separate subplots for each column.

sharex  [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in; Be aware, that passing in both an ax and sharex=True will alter all x axis labels for all axis in a figure.

sharey  [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.

layout  [tuple, optional] (rows, columns) for the layout of subplots.

figsize  [a tuple (width, height) in inches] Size of a figure object.

use_index  [bool, default True] Use index as ticks for x axis.

title  [str or list] Title to use for the plot. If a string is passed, print the string at the top of the figure. If a list is passed and subplots is True, print each item in the list above the corresponding subplot.

grid  [bool, default None (matlab style default)] Axis grid lines.

legend  [bool or {'reverse'}] Place legend on axis subplots.

style  [list or dict] The matplotlib line style per column.

logx  [bool or ‘sym’, default False] Use log scaling or symlog scaling on x axis. .. versionchanged:: 0.25.0

logy  [bool or ‘sym’ default False] Use log scaling or symlog scaling on y axis. .. versionchanged:: 0.25.0

loglog  [bool or ‘sym’, default False] Use log scaling or symlog scaling on both x and y axes. .. versionchanged:: 0.25.0

xticks  [sequence] Values to use for the xticks.

yticks  [sequence] Values to use for the yticks.

xlim  [2-tuple/list] Set the x limits of the current axes.

ylim  [2-tuple/list] Set the y limits of the current axes.

xlabel  [label, optional] Name to use for the xlabel on x-axis. Default uses index name as xlabel, or the x-column name for planar plots.

New in version 1.1.0.

Changed in version 1.2.0: Now applicable to planar plots (scatter, hexbin).
ylabel [label, optional] Name to use for the ylabel on y-axis. Default will show no ylabel, or the y-column name for planar plots.

New in version 1.1.0.

Changed in version 1.2.0: Now applicable to planar plots (scatter, hexbin).

rot [int, default None] Rotation for ticks (xticks for vertical, yticks for horizontal plots).

fontsize [int, default None] Font size for xticks and yticks.

colormap [str or matplotlib colormap object, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

colorbar [bool, optional] If True, plot colorbar (only relevant for ‘scatter’ and ‘hexbin’ plots).

position [float] Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center).

table [bool, Series or DataFrame, default False] If True, draw a table using the data in the DataFrame and the data will be transposed to meet matplotlib’s default layout. If a Series or DataFrame is passed, use passed data to draw a table.

xerr [DataFrame, Series, array-like, dict and str] Equivalent to yerr.

stacked [bool, default False in line and bar plots, and True in area plot] If True, create stacked plot.

sort_columns [bool, default False] Sort column names to determine plot ordering.

secondary_y [bool or sequence, default False] Whether to plot on the secondary y-axis if a list/tuple, which columns to plot on secondary y-axis.

mark_right [bool, default True] When using a secondary_y axis, automatically mark the column labels with “(right)” in the legend.

include_bool [bool, default is False] If True, boolean values can be plotted.

backend [str, default None] Backend to use instead of the backend specified in the option \texttt{plotting.backend}. For instance, ‘matplotlib’. Alternatively, to specify the \texttt{plotting.backend} for the whole session, set \texttt{pd.options.plotting.backend}.

New in version 1.0.0.

**kwargs Options to pass to matplotlib plotting method.

Returns

\texttt{matplotlib.axes.Axes} or \texttt{numpy.ndarray} of them If the backend is not the default matplotlib one, the return value will be the object returned by the backend.
Notes

- See matplotlib documentation online for more on this subject
- If kind = ‘bar’ or ‘barh’, you can specify relative alignments for bar plot layout by position keyword. From 0 (left/bottom-end) to 1 (right/top-end). Default is 0.5 (center)

pandas.DataFrame.pop

DataFrame.pop(item)
Return item and drop from frame. Raise KeyError if not found.

Parameters

- item [label] Label of column to be popped.

Returns

- Series

Examples

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
                     ('parrot', 'bird', 24.0),
                     ('lion', 'mammal', 80.5),
                     ('monkey', 'mammal', np.nan)],
                    columns=('name', 'class', 'max_speed'))
>>> df
   name     class  max_speed
0  falcon    bird      389.0
1  parrot    bird       24.0
2     lion  mammal      80.5
3  monkey  mammal        NaN

>>> df.pop('class')
0  bird
1  bird
2  mammal
3  mammal
Name: class, dtype: object

>>> df
   name  max_speed
0  falcon      389.0
1  parrot       24.0
2     lion      80.5
3  monkey        NaN
```
DataFrame.pow

`DataFrame.pow(other, axis='columns', level=None, fill_value=None)`

Get Exponential power of dataframe and other, element-wise (binary operator pow).

Equivalent to `dataframe ** other`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, `rpow`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

- **DataFrame** Result of the arithmetic operation.

**See also:**

- `DataFrame.add` Add DataFrames.
- `DataFrame.sub` Subtract DataFrames.
- `DataFrame.mul` Multiply DataFrames.
- `DataFrame.div` Divide DataFrames (float division).
- `DataFrame.truediv` Divide DataFrames (float division).
- `DataFrame.floordiv` Divide DataFrames (integer division).
- `DataFrame.mod` Calculate modulo (remainder after division).
- `DataFrame.pow` Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
          angles    degrees
circle   0          360
triangle 3          180
rectangle 4          360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
          angles    degrees
circle   1          361
triangle 4          181
rectangle 5          361
```

```python
>>> df.add(1)
          angles    degrees
circle   1          361
triangle 4          181
rectangle 5          361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
          angles    degrees
circle   0.0        36.0
triangle 0.3        18.0
rectangle 0.4       36.0
```

```python
>>> df.rdiv(10)
          angles    degrees
circle   inf        0.027778
triangle 3.333333   0.055556
rectangle 2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
          angles    degrees
circle   -1        358
triangle  2         178
rectangle 3        358
```

```python
>>> df.sub([1, 2], axis='columns')
          angles    degrees
circle   -1        358
triangle  2         178
rectangle 3        358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
          angles    degrees
```

(continues on next page)
Multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({'angles': [0, 3, 4]},
                     index=['circle', 'triangle', 'rectangle'])
other
```

```
angles
circle 0
triangle 3
rectangle 4
```

```python
df * other
```

```
angles    degrees
circle    0.0 NaN
triangle  9.0 0.0
rectangle 16.0 0.0
```

```python
df.mul(other, fill_value=0)
```

```
angles    degrees
circle  0.0 0.0
triangle 9.0 0.0
rectangle 16.0 0.0
```

Divide by a MultiIndex by level.

```python
df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                             'degrees': [360, 180, 360, 360, 540, 720],
                             index=['A', 'A', 'A', 'B', 'B', 'B'],
                             ['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon'])
```

```python
df_multindex
```

```
angles    degrees
A circle  0.0 360
triangle  3.0 180
rectangle 4.0 360
B square  4.0 360
pentagon  5.0 540
hexagon  6.0 720
```

```python
df.div(df_multindex, level=1, fill_value=0)
```

```
angles    degrees
A circle  NaN 1.0
triangle  1.0 1.0
rectangle 1.0 1.0
B square  0.0 0.0
pentagon  0.0 0.0
hexagon  0.0 0.0
```
pandas.DataFrame.prod

DataFrame.prod(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)

Return the product of the values over the requested axis.

Parameters

axis ([index (0), columns (1)]]) Axis for the function to be applied on.

skipna [bool, default True] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

**kwargs Additional keyword arguments to be passed to the function.

Returns

Series or DataFrame (if level specified)

See also:

Series.sum Return the sum.

Series.min Return the minimum.

Series.max Return the maximum.

Series.idxmin Return the index of the minimum.

Series.idxmax Return the index of the maximum.

DataFrame.sum Return the sum over the requested axis.

DataFrame.min Return the minimum over the requested axis.

DataFrame.max Return the maximum over the requested axis.

DataFrame.idxmin Return the index of the minimum over the requested axis.

DataFrame.idxmax Return the index of the maximum over the requested axis.

Examples

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([], dtype="float64").prod()
1.0
```

This can be controlled with the min_count parameter

```python
>>> pd.Series([], dtype="float64").prod(min_count=1)
nan
```
Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0

>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

**pandas.DataFrame.product**

`DataFrame.product` *(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)*

Return the product of the values over the requested axis.

**Parameters**

- `axis` ([index (0), columns (1)]) Axis for the function to be applied on.
- `skipna` [bool, default True] Exclude NA/null values when computing the result.
- `level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- `numeric_only` [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- `min_count` [int, default 0] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.
- `**kwargs` Additional keyword arguments to be passed to the function.

**Returns**

Series or DataFrame (if level specified)

**See also:**

- `Series.sum` Return the sum.
- `Series.min` Return the minimum.
- `Series.max` Return the maximum.
- `Series.idxmin` Return the index of the minimum.
- `Series.idxmax` Return the index of the maximum.
- `DataFrame.sum` Return the sum over the requested axis.
- `DataFrame.min` Return the minimum over the requested axis.
- `DataFrame.max` Return the maximum over the requested axis.
- `DataFrame.idxmin` Return the index of the minimum over the requested axis.
- `DataFrame.idxmax` Return the index of the maximum over the requested axis.
Examples

By default, the product of an empty or all-NA Series is 1

```python
>>> pd.Series([], dtype="float64").prod()
1.0
```

This can be controlled with the `min_count` parameter

```python
>>> pd.Series([], dtype="float64").prod(min_count=1)
nan
```

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

```python
>>> pd.Series([np.nan]).prod()
1.0

>>> pd.Series([np.nan]).prod(min_count=1)
nan
```

`pandas.DataFrame.quantile`

DataFrame.quantile(q=0.5, axis=0, numeric_only=True, interpolation='linear')

Return values at the given quantile over requested axis.

Parameters

- **q** [float or array-like, default 0.5 (50% quantile)] Value between 0 <= q <= 1, the quantile(s) to compute.
- **axis** [[0, 1, ‘index’, ‘columns’], default 0] Equals 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.
- **numeric_only** [bool, default True] If False, the quantile of datetime and timedelta data will be computed as well.
- **interpolation** [[‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’]] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points $i$ and $j$:
  - linear: $i + (j - i) \times \text{fraction}$, where fraction is the fractional part of the index surrounded by $i$ and $j$.
  - lower: $i$.
  - higher: $j$.
  - nearest: $i$ or $j$ whichever is nearest.
  - midpoint: $(i + j) / 2$.

Returns

Series or DataFrame

If q is an array, a DataFrame will be returned where the index is q, the columns are the columns of self, and the values are the quantiles.

If q is a float, a Series will be returned where the index is the columns of self and the values are the quantiles.
See also:

```
core.window.Rolling.quantile` Rolling quantile.
```
numpy.percentile` Numpy function to compute the percentile.
```

Examples

```python
>>> df = pd.DataFrame(np.array([[1, 1], [2, 10], [3, 100], [4, 100]]),
                    columns=['a', 'b'])
>>> df.quantile(.1)
a  1.3
b  3.7
Name: 0.1, dtype: float64
>>> df.quantile([.1, .5])
a  b
0.1 1.3 3.7
0.5 2.5 55.0
```

Specifying `numeric_only=False` will also compute the quantile of datetime and timedelta data.

```python
>>> df = pd.DataFrame({'A': [1, 2],
                    'B': [pd.Timestamp('2010'),
                          pd.Timestamp('2011')],
                    'C': [pd.Timedelta('1 days'),
                          pd.Timedelta('2 days')]})
>>> df.quantile(0.5, numeric_only=False)
A  1.5
B  2010-07-02 12:00:00
C  1 days 12:00:00
Name: 0.5, dtype: object
```

`pandas.DataFrame.query`

`DataFrame.query` `expr`, `inplace=False`, `**kwargs`

Query the columns of a DataFrame with a boolean expression.

**Parameters**

- **expr** [str] The query string to evaluate.

You can refer to variables in the environment by prefixing them with an `@` character like `@a + b`.

You can refer to column names that are not valid Python variable names by surrounding them in backticks. Thus, column names containing spaces or punctuations (besides underscores) or starting with digits must be surrounded by backticks. (For example, a column named “Area (cm^2)” would be referenced as `Area (cm^2)`). Column names which are Python keywords (like “list”, “for”, “import”, etc) cannot be used.

For example, if one of your columns is called `a a` and you want to sum it with `b`, your query should be `a a` + `b`.

New in version 0.25.0: Backtick quoting introduced.
New in version 1.0.0: Expanding functionality of backtick quoting for more than only spaces.

**inplace** [bool] Whether the query should modify the data in place or return a modified copy.

**kwargs** See the documentation for `eval()` for complete details on the keyword arguments accepted by `DataFrame.query()`.

**Returns**

**DataFrame or None** DataFrame resulting from the provided query expression or None if inplace=True.

**See also:**

`eval` Evaluate a string describing operations on DataFrame columns.

`DataFrame.eval` Evaluate a string describing operations on DataFrame columns.

**Notes**

The result of the evaluation of this expression is first passed to `DataFrame.loc` and if that fails because of a multidimensional key (e.g., a DataFrame) then the result will be passed to `DataFrame.__getitem__()`.

This method uses the top-level `eval()` function to evaluate the passed query.

The `query()` method uses a slightly modified Python syntax by default. For example, the & and | (bitwise) operators have the precedence of their boolean cousins, and and or. This is syntactically valid Python, however the semantics are different.

You can change the semantics of the expression by passing the keyword argument parser='python'. This enforces the same semantics as evaluation in Python space. Likewise, you can pass engine='python' to evaluate an expression using Python itself as a backend. This is not recommended as it is inefficient compared to using numexpr as the engine.

The `DataFrame.index` and `DataFrame.columns` attributes of the `DataFrame` instance are placed in the query namespace by default, which allows you to treat both the index and columns of the frame as a column in the frame. The identifier index is used for the frame index; you can also use the name of the index to identify it in a query. Please note that Python keywords may not be used as identifiers.

For further details and examples see the query documentation in `indexing`.

**Backtick quoted variables**

Backtick quoted variables are parsed as literal Python code and are converted internally to a Python valid identifier. This can lead to the following problems.

During parsing a number of disallowed characters inside the backtick quoted string are replaced by strings that are allowed as a Python identifier. These characters include all operators in Python, the space character, the question mark, the exclamation mark, the dollar sign, and the euro sign. For other characters that fall outside the ASCII range (U+0001..U+007F) and those that are not further specified in PEP 3131, the query parser will raise an error. This excludes whitespace different than the space character, but also the hashtag (as it is used for comments) and the backtick itself (backtick can also not be escaped).

In a special case, quotes that make a pair around a backtick can confuse the parser. For example, `it's` > `that's` will raise an error, as it forms a quoted string (`'s > `that'`) with a backtick inside.
See also the Python documentation about lexical analysis (https://docs.python.org/3/reference/lexical_analysis.html) in combination with the source code in pandas.core.computation.parsing.

**Examples**

```python
>>> df = pd.DataFrame({'A': range(1, 6),
...                    'B': range(10, 0, -2),
...                    'C C': range(10, 5, -1)})
```

```text
A  B  C  C
0  1  10 10
1  2  8  9
2  3  6  8
3  4  4  7
4  5  2  6
```

```python
>>> df.query('A > B')
```

```text
A  B  C  C
4  5  2  6
```

The previous expression is equivalent to

```python
>>> df[df.A > df.B]
```

```text
A  B  C  C
4  5  2  6
```

For columns with spaces in their name, you can use backtick quoting.

```python
>>> df.query('B == `C C``')
```

```text
A  B  C  C
0  1  10 10
```

The previous expression is equivalent to

```python
>>> df[df.B == df['C C']]  
```

```text
A  B  C  C
0  1  10 10
```

**pandas.DataFrame.radd**

`DataFrame.radd(other, axis='columns', level=None, fill_value=None)`

Get Addition of dataframe and other, element-wise (binary operator radd).

Equivalent to `other + dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `add`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns
DataFrame Result of the arithmetic operation.

See also:
DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes
Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                   'degrees': [360, 180, 360],
...                   index=['circle', 'triangle', 'rectangle'])

>>> df
    angles  degrees
circle     0      360
triangle    3      180
rectangle   4      360

Add a scalar with operator version which return the same results.

>>> df + 1
    angles  degrees
circle     1      361
triangle    4      181
rectangle   5      361

>>> df.add(1)
    angles  degrees
circle     1      361
triangle    4      181
rectangle   5      361

Divide by constant with reverse version.
```
```python
>>> df.div(10)
    angles  degrees
   circle   0.0    36.0
   triangle  0.3    18.0
   rectangle 0.4    36.0

>>> df.rdiv(10)
    angles  degrees
      circle    inf    0.027778
      triangle 3.333333  0.055556
      rectangle 2.500000  0.027778

Subtract a list and Series by axis with operator version.

>>> df - [1, 2]
    angles  degrees
     circle   -1    358
     triangle    2    178
     rectangle    3    358

>>> df.sub([1, 2], axis='columns')
    angles  degrees
     circle   -1    358
     triangle    2    178
     rectangle    3    358

>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
         axis='index')
    angles  degrees
     circle   -1    359
     triangle    2    179
     rectangle    3    359

Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4],
                         'index': ['circle', 'triangle', 'rectangle']})
>>> df * other
    angles  degrees
     circle    0  NaN
     triangle   9  NaN
     rectangle 16  NaN

>>> df.mul(other, fill_value=0)
    angles  degrees
     circle    0  0.0
     triangle   9  0.0
     rectangle 16  0.0

Divide by a MultiIndex by level.
```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                  'degrees': [360, 180, 360, 360, 540, 720]},
...                  index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                  ['circle', 'triangle', 'rectangle',
...                  'square', 'pentagon', 'hexagon']])
```
```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>circle</td>
</tr>
<tr>
<td></td>
<td>triangle</td>
</tr>
<tr>
<td></td>
<td>rectangle</td>
</tr>
<tr>
<td>B</td>
<td>square</td>
</tr>
<tr>
<td></td>
<td>pentagon</td>
</tr>
<tr>
<td></td>
<td>hexagon</td>
</tr>
</tbody>
</table>
```

```python
>>> df_multindex
```
```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>circle</td>
</tr>
<tr>
<td></td>
<td>triangle</td>
</tr>
<tr>
<td></td>
<td>rectangle</td>
</tr>
<tr>
<td>B</td>
<td>square</td>
</tr>
<tr>
<td></td>
<td>pentagon</td>
</tr>
<tr>
<td></td>
<td>hexagon</td>
</tr>
</tbody>
</table>
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
```
```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>circle</td>
</tr>
<tr>

<td>rectangle</td>
</tr>
<tr>
<td>B</td>
<td>square</td>
</tr>
<tr>
<td></td>
<td>pentagon</td>
</tr>
<tr>
<td></td>
<td>hexagon</td>
</tr>
</tbody>
</table>
```

pandas.DataFrame.rank

DataFrame.rank(**axis=0, method='average', numeric_only=None, na_option='keep', ascending=True, pct=False**)

Compute numerical data ranks (1 through n) along axis.

By default, equal values are assigned a rank that is the average of the ranks of those values.

**Parameters**

- **axis** ([0 or ‘index’, 1 or ‘columns’], default 0) Index to direct ranking.
- **method** [{'average', 'min', 'max', 'first', 'dense'}, default ‘average’] How to rank the group of records that have the same value (i.e. ties):
  - average: average rank of the group
  - min: lowest rank in the group
  - max: highest rank in the group
  - first: ranks assigned in order they appear in the array
  - dense: like ‘min’, but rank always increases by 1 between groups.
- **numeric_only** [bool, optional] For DataFrame objects, rank only numeric columns if set to True.
- **na_option** [{'keep', ‘top’, ‘bottom’}, default ‘keep’] How to rank NaN values:
  - keep: assign NaN rank to NaN values
  - top: assign lowest rank to NaN values
  - bottom: assign highest rank to NaN values
- **ascending** [bool, default True] Whether or not the elements should be ranked in ascending order.
pct  [bool, default False] Whether or not to display the returned rankings in percentile form.

Returns

same type as caller  Return a Series or DataFrame with data ranks as values.

See also:

- `core.groupby.GroupBy.rank`  Rank of values within each group.

Examples

```python
>>> df = pd.DataFrame(data={'Animal': ['cat', 'penguin', 'dog', 'spider', 'snake'],
                      'Number_legs': [4, 2, 4, 8, np.nan]})
>>> df
Animal  Number_legs
0      cat          4.0
1  penguin        2.0
2      dog          4.0
3   spider         8.0
4   snake        NaN
```

The following example shows how the method behaves with the above parameters:

- **default_rank**: this is the default behaviour obtained without using any parameter.
- **max_rank**: setting `method = 'max'` the records that have the same values are ranked using the highest rank (e.g.: since ‘cat’ and ‘dog’ are both in the 2nd and 3rd position, rank 3 is assigned.)
- **NA_bottom**: choosing `na_option = 'bottom'`, if there are records with NaN values they are placed at the bottom of the ranking.
- **pct_rank**: when setting `pct = True`, the ranking is expressed as percentile rank.

```python
>>> df['default_rank'] = df['Number_legs'].rank()
>>> df['max_rank'] = df['Number_legs'].rank(method='max')
>>> df['NA_bottom'] = df['Number_legs'].rank(na_option='bottom')
>>> df['pct_rank'] = df['Number_legs'].rank(pct=True)
>>> df
Animal  Number_legs  default_rank  max_rank  NA_bottom  pct_rank
0      cat          4.0          2.5       3.0      2.5  0.625
1  penguin        2.0          1.0       1.0      1.0  0.250
2      dog          4.0          2.5       3.0      2.5  0.625
3   spider         8.0          4.0       4.0      4.0  1.000
4   snake        NaN          NaN       NaN      NaN  NaN
```
pandas.DataFrame.rdiv

`DataFrame.rdiv(other, axis='columns', level=None, fill_value=None)`

Get floating division of dataframe and other, element-wise (binary operator `rtruediv`).

Equivalent to `other / dataframe`, but with support to substitute a `fill_value` for missing data in one of the inputs. With reverse version, `truediv`.

Among flexible wrappers (`add, sub, mul, div, mod, pow`) to arithmetic operators: `+`, `-`, `*`, `/`, `//`, `%`, `**`.

**Parameters**

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` `{0 or 'index', 1 or 'columns'}` Whether to compare by the index (0 or `index`) or columns (1 or `columns`). For Series input, axis to match Series index on.
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- `fill_value` [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

- `DataFrame` Result of the arithmetic operation.

**See also:**

- `DataFrame.add` Add DataFrames.
- `DataFrame.sub` Subtract DataFrames.
- `DataFrame.mul` Multiply DataFrames.
- `DataFrame.div` Divide DataFrames (float division).
- `DataFrame.truediv` Divide DataFrames (float division).
- `DataFrame.floordiv` Divide DataFrames (integer division).
- `DataFrame.mod` Calculate modulo (remainder after division).
- `DataFrame.pow` Calculate exponential power.

**Notes**

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0</td>
</tr>
<tr>
<td>triangle</td>
<td>3</td>
</tr>
<tr>
<td>rectangle</td>
<td>4</td>
</tr>
</tbody>
</table>

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
</tbody>
</table>

```python
>>> df.add(1)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
</tbody>
</table>

Divide by constant with reverse version.

```python
>>> df.div(10)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0</td>
</tr>
<tr>
<td>triangle</td>
<td>0.3</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.4</td>
</tr>
</tbody>
</table>

```python
>>> df.rdiv(10)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>inf</td>
</tr>
<tr>
<td>triangle</td>
<td>3.333333</td>
</tr>
<tr>
<td>rectangle</td>
<td>2.5</td>
</tr>
</tbody>
</table>

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>

```python
>>> df.sub([1, 2], axis='columns')
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
```

(continues on next page)
Multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({'angles': [0, 3, 4]},
                     index=['circle', 'triangle', 'rectangle'])
other
```

```plaintext
angles
circle 0
triangle 3
rectangle 4
```

```python
df * other
```

```plaintext
angles degrees
circle 0 NaN
triangle 9 NaN
rectangle 16 NaN
```

```python
df.mul(other, fill_value=0)
```

```plaintext
angles degrees
circle 0 0.0
triangle 9 0.0
rectangle 16 0.0
```

Divide by a MultiIndex by level.

```python
df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                            'degrees': [360, 180, 360, 360, 540, 720],
                            index=['A', 'A', 'A', 'B', 'B', 'B'],
                            ['circle', 'triangle', 'rectangle',
                             'square', 'pentagon', 'hexagon'])
```

```python
df_multindex
```

```plaintext
angles degrees
A circle 0 360
triangle 3 180
rectangle 4 360
B square 4 360
pentagon 5 540
hexagon 6 720
```

```python
df.div(df_multindex, level=1, fill_value=0)
```

```plaintext
angles degrees
A circle NaN 1.0
triangle 1.0 1.0
rectangle 1.0 1.0
B square 0.0 0.0
pentagon 0.0 0.0
hexagon 0.0 0.0
```
**DataFrame.reindex**

DataFrame.reindex(*labels=None, index=None, columns=None, axis=None, method=None, copy=True, level=None, fill_value=\text{nan}, limit=None, tolerance=None*)

Conform Series/DataFrame to new index with optional filling logic. Places NA/NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

**Parameters**

- **keywords for axes** [array-like, optional] New labels / index to conform to, should be specified using keywords. Preferably an Index object to avoid duplicating data.
- **method** [{None, ‘backfill’/’bfill’, ‘pad’/’ffill’, ‘nearest’}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.
  - None (default): don’t fill gaps
  - pad / ffill: Propagate last valid observation forward to next valid.
  - backfill / bfill: Use next valid observation to fill gap.
  - nearest: Use nearest valid observations to fill gap.
- **copy** [bool, default True] Return a new object, even if the passed indexes are the same.
- **level** [int or name] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.
- **limit** [int, default None] Maximum number of consecutive elements to forward or backward fill.
- **tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations most satisfy the equation abs(index[indexer] - target) <= tolerance.

  Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

**Returns**

Series/DataFrame with changed index.

See also:

- **DataFrame.set_index** Set row labels.
- **DataFrame.reset_index** Remove row labels or move them to new columns.
- **DataFrame.reindex_like** Change to same indices as other DataFrame.
Examples

DataFrame.reindex supports two calling conventions

• (index=index_labels, columns=column_labels, ...)
• (labels, axis={'index', 'columns'}, ...)

We highly recommend using keyword arguments to clarify your intent.

Create a dataframe with some fictional data.

```python
>>> index = ['Firefox', 'Chrome', 'Safari', 'IE10', 'Konqueror']

>>> df = pd.DataFrame({
                      'http_status': [200, 200, 404, 404, 301],
                      'response_time': [0.04, 0.02, 0.07, 0.08, 1.0],
                      ... },
                      index=index)

>>> df
http_status    response_time
Firefox         200.0        0.04
Chrome          200.0        0.02
Safari          404.0        0.07
IE10            404.0        0.08
Konqueror       301.0        1.00

Create a new index and reindex the dataframe. By default values in the new index that do not have corresponding records in the dataframe are assigned NaN.

```python
>>> new_index = ['Safari', 'Iceweasel', 'Comodo Dragon', 'IE10',
                'Chrome']

>>> df.reindex(new_index)
http_status    response_time
Safari          404.0        0.07
Iceweasel       NaN          NaN
Comodo Dragon   NaN          NaN
IE10            404.0        0.08
Chrome          200.0        0.02

We can fill in the missing values by passing a value to the keyword fill_value. Because the index is not monotonically increasing or decreasing, we cannot use arguments to the keyword method to fill the NaN values.

```python
>>> df.reindex(new_index, fill_value=0)
http_status    response_time
Safari          404.0        0.07
Iceweasel       0            0.00
Comodo Dragon   0            0.00
IE10            404.0        0.08
Chrome          200.0        0.02

>>> df.reindex(new_index, fill_value='missing')
http_status    response_time
Safari          404.0        0.07
Iceweasel       missing      missing
Comodo Dragon   missing      missing
IE10            404.0        0.08
Chrome          200.0        0.02

We can also reindex the columns.
Or we can use “axis-style” keyword arguments

To further illustrate the filling functionality in `reindex`, we will create a dataframe with a monotonically increasing index (for example, a sequence of dates).

Suppose we decide to expand the dataframe to cover a wider date range.

The index entries that did not have a value in the original data frame (for example, ‘2009-12-29’) are by default filled with NaN. If desired, we can fill in the missing values using one of several options.

For example, to back-propagate the last valid value to fill the NaN values, pass `bfill` as an argument to the `method` keyword.
Please note that the NaN value present in the original dataframe (at index value 2010-01-03) will not be filled by any of the value propagation schemes. This is because filling while reindexing does not look at dataframe values, but only compares the original and desired indexes. If you do want to fill in the NaN values present in the original dataframe, use the `fillna()` method.

See the user guide for more.

**pandas.DataFrame.reindex_like**

DataFrame.reindex_like(other, method=None, copy=True, limit=None, tolerance=None)

Return an object with matching indices as other object.

Conform the object to the same index on all axes. Optional filling logic, placing NaN in locations having no value in the previous index. A new object is produced unless the new index is equivalent to the current one and copy=False.

**Parameters**

- **other** [Object of the same data type] Its row and column indices are used to define the new indices of this object.
- **method** [{None, ‘backfill’/‘bfill’, ‘pad’/‘ffill’, ‘nearest’}] Method to use for filling holes in reindexed DataFrame. Please note: this is only applicable to DataFrames/Series with a monotonically increasing/decreasing index.
  - None (default): don’t fill gaps
  - pad / ffill: propagate last valid observation forward to next valid
  - backfill / bfill: use next valid observation to fill gap
  - nearest: use nearest valid observations to fill gap.
- **copy** [bool, default True] Return a new object, even if the passed indexes are the same.
- **limit** [int, default None] Maximum number of consecutive labels to fill for inexact matches.
- **tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation $\text{abs}([\text{index}][\text{indexer}] - \text{target}) \leq \text{tolerance}$. Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

**Returns**

(continued from previous page)
Series or DataFrame  Same type as caller, but with changed indices on each axis.

See also:

DataFrame.set_index  Set row labels.
DataFrame.reset_index  Remove row labels or move them to new columns.
DataFrame.reindex  Change to new indices or expand indices.

Notes

Same as calling .reindex(index=other.index, columns=other.columns,...).

Examples

```python
>>> df1 = pd.DataFrame([[24.3, 75.7, 'high'],
...                     [31.0, 87.8, 'high'],
...                     [22.0, 71.6, 'medium'],
...                     [35.0, 95.0, 'medium']],
...                    columns=['temp_celsius', 'temp_fahrenheit', 'windspeed'],
...                    index=pd.date_range(start='2014-02-12',
...                                         end='2014-02-15', freq='D'))

>>> df1
   temp_celsius  temp_fahrenheit  windspeed
2014-02-12     24.3             75.7     high
2014-02-13     31.0             87.8     high
2014-02-14     22.0             71.6     medium
2014-02-15     35.0             95.0     medium

>>> df2 = pd.DataFrame([[28, 'low'],
...                     [30, 'low'],
...                     [35.1, 'medium']],
...                    columns=['temp_celsius', 'windspeed'],
...                    index=pd.DatetimeIndex(['2014-02-12', '2014-02-13', '2014-02-15']))

>>> df2
   temp_celsius  windspeed
2014-02-12     28.0       low
2014-02-13     30.0       low
2014-02-15     35.1       medium

```
pandas.DataFrame.rename

DataFrame.rename(mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False, level=None, errors='ignore')

Alter axes labels.
Function / dict values must be unique (1-to-1). Labels not contained in a dict / Series will be left as-is.
Extra labels listed don’t throw an error.
See the user guide for more.

Parameters

mapper [dict-like or function] Dict-like or function transformations to apply to that
axis’ values. Use either mapper and axis to specify the axis to target with
mapper, or index and columns.

index [dict-like or function] Alternative to specifying axis (mapper, axis=0 is
equivalent to index=mapper).

columns [dict-like or function] Alternative to specifying axis (mapper, axis=1 is
equivalent to columns=mapper).

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis to target with mapper. Can be
either the axis name (‘index’, ‘columns’) or number (0, 1). The default is ‘index’.

copy [bool, default True] Also copy underlying data.

inplace [bool, default False] Whether to return a new DataFrame. If True then value of
copy is ignored.

level [int or level name, default None] In case of a MultiIndex, only rename labels in
the specified level.

ersors [{‘ignore’, ‘raise’}, default ‘ignore’] If ‘raise’, raise a KeyError when a dict-
like mapper, index, or columns contains labels that are not present in the Index
being transformed. If ‘ignore’, existing keys will be renamed and extra keys will
be ignored.

Returns

DataFrame or None DataFrame with the renamed axis labels or None if
inplace=True.

Raises

KeyError If any of the labels is not found in the selected axis and “errors=’raise’”.

See also:

DataFrame.rename_axis Set the name of the axis.
Examples

DataFrame.rename supports two calling conventions

- (index=index_mapper, columns=columns_mapper, ...)
- (mapper, axis={'index', 'columns'}, ...)

We highly recommend using keyword arguments to clarify your intent.

Rename columns using a mapping:

```python
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})
>>> df.rename(columns={"A": "a", "B": "c"})
a  c
0 1 4
1 2 5
2 3 6
```

Rename index using a mapping:

```python
>>> df.rename(index={0: "x", 1: "y", 2: "z"})
A  B
x 1 4
y 2 5
z 3 6
```

Cast index labels to a different type:

```python
>>> df.index
RangeIndex(start=0, stop=3, step=1)
>>> df.rename(index=str).index
Index(["0", "1", "2"], dtype='object')
```

```python
>>> df.rename(columns={"A": "a", "B": "b", "C": "c"}, errors="raise")
Traceback (most recent call last):
  File "<ipython-input-7-7506572b892c", line 1, in <cell魔术方法>
    df.rename(columns={"A": "a", "B": "b", "C": "c"}, errors="raise")
KeyError: ['C'] not found in axis
```

Using axis-style parameters:

```python
>>> df.rename(str.lower, axis='columns')
a  b
0 1 4
1 2 5
2 3 6
```

```python
>>> df.rename({1: 2, 2: 4}, axis='index')
A  B
0 1 4
2 2 5
4 3 6
```
pandas.DataFrame.rename_axis

DataFrame.rename_axis(mapper=None, index=None, columns=None, axis=None, copy=True, inplace=False)

Set the name of the axis for the index or columns.

Parameters

mapper [scalar, list-like, optional] Value to set the axis name attribute.

index, columns [scalar, list-like, dict-like or function, optional] A scalar, list-like, dict-like or functions transformations to apply to that axis’ values. Note that the columns parameter is not allowed if the object is a Series. This parameter only apply for DataFrame type objects.

Use either mapper and axis to specify the axis to target with mapper, or index and/or columns.

axis [{0 or 'index', 1 or 'columns'}, default 0] The axis to rename.

copy [bool, default True] Also copy underlying data.

inplace [bool, default False] Modifies the object directly, instead of creating a new Series or DataFrame.

Returns

Series, DataFrame, or None The same type as the caller or None if inplace=True.

See also:

Series.rename Alter Series index labels or name.

DataFrame.rename Alter DataFrame index labels or name.

Index.rename Set new names on index.

Notes

DataFrame.rename_axis supports two calling conventions

• (index=index_mapper, columns=columns_mapper, ...)
• (mapper, axis=('index', 'columns'), ...)

The first calling convention will only modify the names of the index and/or the names of the Index object that is the columns. In this case, the parameter copy is ignored.

The second calling convention will modify the names of the corresponding index if mapper is a list or a scalar. However, if mapper is dict-like or a function, it will use the deprecated behavior of modifying the axis labels.

We highly recommend using keyword arguments to clarify your intent.
Examples

Series

```python
>>> s = pd.Series(['dog', 'cat', 'monkey'])
>>> s
0   dog
1   cat
2  monkey
dtype: object
>>> s.rename_axis('animal')
animal
0   dog
1   cat
2  monkey
dtype: object
```

DataFrame

```python
>>> df = pd.DataFrame({
    'num_legs': [4, 4, 2],
    'num_arms': [0, 0, 2],
},
columns=['dog', 'cat', 'monkey'])
>>> df
   num_legs  num_arms
dog        4      0
cat        4      0
monkey     2      2
```  

```python
>>> df = df.rename_axis('animal')
>>> df
   num_legs  num_arms
animal
  dog        4      0
cat        4      0
monkey     2      2
```  

```python
>>> df = df.rename_axis('limbs', axis='columns')
>>> df
   limbs  num_legs  num_arms
animal
  dog        4      0
cat        4      0
monkey     2      2
```  

MultiIndex

```python
>>> df.index = pd.MultiIndex.from_product([['mammal'], ['dog', 'cat', 'monkey']], names=['type', 'name'])
>>> df
   limbs  num_legs  num_arms
animal
  dog        4      0
cat        4      0
monkey     2      2
```  

```python
>>> df.rename_axis(index={'type': 'class'})
   limbs  num_legs  num_arms
class
  name
```  

(continues on next page)
mammal  dog  4  0
   cat      4  0
   monkey   2  2

>>> df.rename_axis(columns=str.upper)
LIMBS  num_legs  num_arms
  type  name
mammal  dog  4  0
      cat  4  0
     monkey  2  2

pandas.DataFrame.reorder_levels

DataFrame.reorder_levels(order, axis=0)
Rearrange index levels using input order. May not drop or duplicate levels.

Parameters

- **order** [list of int or list of str] List representing new level order. Reference level by number (position) or by key (label).
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Where to reorder levels.

Returns

DataFrame

pandas.DataFrame.replace

DataFrame.replace(to_replace=None, value=None, inplace=False, limit=None, regex=False, method='pad')
Replace values given in to_replace with value.

Values of the DataFrame are replaced with other values dynamically.
This differs from updating with .loc or .iloc, which require you to specify a location to update with some value.

Parameters

- **to_replace** [str, regex, list, dict, Series, int, float, or None] How to find the values that will be replaced.
  - numeric, str or regex:
    - numeric: numeric values equal to to_replace will be replaced with value
    - str: string exactly matching to_replace will be replaced with value
    - regex: regexs matching to_replace will be replaced with value
  - list of str, regex, or numeric:
    - First, if to_replace and value are both lists, they must be the same length.
- Second, if regex=True then all of the strings in both lists will be interpreted as regexes otherwise they will match directly. This doesn’t matter much for value since there are only a few possible substitution regexes you can use.

- str, regex and numeric rules apply as above.
  - dict:
    - Dicts can be used to specify different replacement values for different existing values. For example, {'a': 'b', 'y': 'z'} replaces the value ‘a’ with ‘b’ and ‘y’ with ‘z’.
    - For a DataFrame a dict can specify that different values should be replaced in different columns. For example, {'a': 1, 'b': 'z'} looks for the value 1 in column ‘a’ and the value ‘z’ in column ‘b’ and replaces these values with whatever is specified in value. The value parameter should not be None in this case. You can treat this as a special case of passing two lists except that you are specifying the column to search in.
    - For a DataFrame nested dictionaries, e.g., {'a': {'b': np.nan}}, are read as follows: look in column ‘a’ for the value ‘b’ and replace it with NaN. The value parameter should be None to use a nested dict in this way. You can nest regular expressions as well. Note that column names (the top-level dictionary keys in a nested dictionary) cannot be regular expressions.
  - None:
    - This means that the regex argument must be a string, compiled regular expression, or list, dict, ndarry or Series of such elements. If value is also None then this must be a nested dictionary or Series.

See the examples section for examples of each of these.

value [scalar, dict, list, str, regex, default None] Value to replace any values matching to_replace with. For a DataFrame a dict of values can be used to specify which value to use for each column (columns not in the dict will not be filled). Regular expressions, strings and lists or dicts of such objects are also allowed.

inplace [bool, default False] If True, performs operation inplace and returns None.

limit [int, default None] Maximum size gap to forward or backward fill.

regex [bool or same types as to_replace, default False] Whether to interpret to_replace and/or value as regular expressions. If this is True then to_replace must be a string. Alternatively, this could be a regular expression or a list, dict, or array of regular expressions in which case to_replace must be None.

method [{‘pad’, ‘ffill’, ‘bfill’, None}] The method to use when for replacement, when to_replace is a scalar, list or tuple and value is None.

Changed in version 0.23.0: Added to DataFrame.

Returns

DataFrame Object after replacement.

Raises

AssertionError
• If `regex` is not a `bool` and `to_replace` is not `None`. `TypeError`
  • If `to_replace` is not a scalar, array-like, `dict`, or `None`
  • If `to_replace` is a `dict` and `value` is not a `list`, `dict`, `ndarray`, or `Series`
  • If `to_replace` is `None` and `regex` is not compilable into a regular expression or is a list, `dict`, `ndarray`, or `Series`.
  • When replacing multiple `bool` or `datetime64` objects and the arguments to `to_replace` does not match the type of the value being replaced `ValueError`
  • If a `list` or an `ndarray` is passed to `to_replace` and `value` but they are not the same length.

See also:

`DataFrame.fillna` Fill NA values.

`DataFrame.where` Replace values based on boolean condition.

`Series.str.replace` Simple string replacement.

Notes

• Regex substitution is performed under the hood with `re.sub`. The rules for substitution for `re.sub` are the same.

• Regular expressions will only substitute on strings, meaning you cannot provide, for example, a regular expression matching floating point numbers and expect the columns in your frame that have a numeric dtype to be matched. However, if those floating point numbers are strings, then you can do this.

• This method has a lot of options. You are encouraged to experiment and play with this method to gain intuition about how it works.

• When `dict` is used as the `to_replace` value, it is like key(s) in the dict are the `to_replace` part and value(s) in the dict are the value parameter.

Examples

Scalar ``to_replace` and `value`

```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.replace(0, 5)
0   5
1   1
2   2
3   3
4   4
dtype: int64
```
```
>>> df = pd.DataFrame({'A': [0, 1, 2, 3, 4],
...                   'B': [5, 6, 7, 8, 9],
...                   'C': ['a', 'b', 'c', 'd', 'e']})

>>> df.replace(0, 5)
    A  B  C
0  5  5  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e

List-like `to_replace`

>>> df.replace([0, 1, 2, 3], 4)
   A  B  C
0  4  5  a
1  4  6  b
2  4  7  c
3  4  8  d
4  4  9  e

>>> df.replace([0, 1, 2, 3], [4, 3, 2, 1])
   A  B  C
0  4  5  a
1  3  6  b
2  2  7  c
3  1  8  d
4  4  9  e

>>> s.replace([1, 2], method='bfill')
0  0
1  3
2  3
3  3
4  4
dtype: int64

dictionary `to_replace`

>>> df.replace({0: 10, 1: 100})
   A  B  C
0 10  5  a
1 100 6  b
2  2  7  c
3  3  8  d
4  4  9  e

>>> df.replace({'A': 0, 'B': 5}, 100)
   A  B  C
0 100 100  a
1  1  6  b
2  2  7  c
3  3  8  d
4  4  9  e
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
>>> df.replace({'A': {0: 100, 4: 400}})
     A  B  C
0  100  5  a
1    1  6  b
2    2  7  c
3    3  8  d
4  400  9  e
```

Regular expression `to_replace`

```python
>>> df = pd.DataFrame({'A': ['bat', 'foo', 'bait'], 'B': ['abc', 'bar', 'xyz']})
>>> df.replace(to_replace=r'^ba.$', value='new', regex=True)
     A  B
0  new  abc
1   foo  new
2  bait  xyz
```

```python
>>> df.replace(regex=r'^ba.$', value='new')
     A  B
0  new  abc
1   foo  new
2  bait  xyz
```

```python
>>> df.replace(regex={r'^ba.$': 'new', 'foo': 'xyz'})
     A  B
0  new  abc
1  xyz  new
2  bait  xyz
```

```python
>>> df.replace(regex=[r'^ba.$', 'foo'], value='new')
     A  B
0  new  abc
1   new  new
2  bait  xyz
```

Compare the behavior of `s.replace({'a': None})` and `s.replace('a', None)` to understand the peculiarities of the `to_replace` parameter:

```python
>>> s = pd.Series([10, 'a', 'a', 'b', 'a'])
>>> s.replace({'a': None})
0  10
1  None
2  None
```

When one uses a dict as the `to_replace` value, it is like the value(s) in the dict are equal to the `value` parameter. `s.replace({'a': None})` is equivalent to `s.replace(to_replace={'a': None}, value=None, method=None):

```python
>>> s.replace({'a': None})
0  10
1  None
2  None
```

(continues on next page)
When `value=None` and `to_replace` is a scalar, list or tuple, `replace` uses the method parameter (default 'pad') to do the replacement. So this is why the 'a' values are being replaced by 10 in rows 1 and 2 and 'b' in row 4 in this case. The command `s.replace('a', None)` is actually equivalent to `s.replace(to_replace='a', value=None, method='pad')`:

```python
>>> s.replace('a', None)
0    10
1    10
2    10
3    b
4    b
dtype: object
```

### pandas.DataFrame.resample

DataFrame.resample(rule, axis=0, closed=None, label=None, convention='start', kind=None, loffset=None, base=None, on=None, level=None, origin='start_day', offset=None)

Resample time-series data.

Convenience method for frequency conversion and resampling of time series. The object must have a datetime-like index (DatetimeIndex, PeriodIndex, or TimedeltaIndex), or the caller must pass the label of a datetime-like series/index to the `on`/`level` keyword parameter.

**Parameters**

- **rule** [DateOffset, Timedelta or str] The offset string or object representing target conversion.
- **axis** [{0 or 'index', 1 or 'columns'}, default 0] Which axis to use for up- or down-sampling. For Series this will default to 0, i.e. along the rows. Must be DatetimeIndex, TimedeltaIndex or PeriodIndex.
- **label** [{‘right’, ‘left’}, default None] Which bin edge label to label bucket with. The default is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.
- **convention** [{‘start’, ‘end’, ‘s’, ‘e’}, default ‘start’] For PeriodIndex only, controls whether to use the start or end of `rule`.
- **kind** [{‘timestamp’, ‘period’}, optional, default None] Pass ‘timestamp’ to convert the resulting index to a DatetimeIndex or ‘period’ to convert it to a PeriodIndex. By default the input representation is retained.
- **loffset** [timedelta, default None] Adjust the resampled time labels. Deprecated since version 1.1.0: You should add the loffset to the `df.index` after the resample. See below.
**base** [int, default 0] For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0.

Deprecated since version 1.1.0: The new arguments that you should use are ‘offset’ or ‘origin’.

**on** [str, optional] For a DataFrame, column to use instead of index for resampling. Column must be datetime-like.

**level** [str or int, optional] For a MultiIndex, level (name or number) to use for resampling. level must be datetime-like.

**origin** [{‘epoch’, ‘start’, ‘start_day’, ‘end’, ‘end_day’}, Timestamp] or str, default ‘start_day’ The timestamp on which to adjust the grouping. The timezone of origin must match the timezone of the index. If a timestamp is not used, these values are also supported:

- ‘epoch’: origin is 1970-01-01
- ‘start’: origin is the first value of the timeseries
- ‘start_day’: origin is the first day at midnight of the timeseries

New in version 1.1.0.

- ‘end’: origin is the last value of the timeseries
- ‘end_day’: origin is the ceiling midnight of the last day

New in version 1.3.0.

**offset** [Timedelta or str, default is None] An offset timedelta added to the origin.

New in version 1.1.0.

**Returns**

pandas.core.Resampler Resampler object.

See also:

* Series.resample Resample a Series.
* DataFrame.resample Resample a DataFrame.
* groupby Group DataFrame by mapping, function, label, or list of labels.
* asfreq Reindex a DataFrame with the given frequency without grouping.

**Notes**

See the user guide for more.

To learn more about the offset strings, please see this link.
## Examples

Start by creating a series with 9 one minute timestamps.

```python
>>> index = pd.date_range('1/1/2000', periods=9, freq='T')
>>> series = pd.Series(range(9), index=index)
>>> series
0 2000-01-01 00:00:00 0
1 2000-01-01 00:01:00 1
2 2000-01-01 00:02:00 2
3 2000-01-01 00:03:00 3
4 2000-01-01 00:04:00 4
5 2000-01-01 00:05:00 5
6 2000-01-01 00:06:00 6
7 2000-01-01 00:07:00 7
8 2000-01-01 00:08:00 8
Freq: T, dtype: int64
```

Downsample the series into 3 minute bins and sum the values of the timestamps falling into a bin.

```python
>>> series.resample('3T').sum()
2000-01-01 00:00:00 3
2000-01-01 00:03:00 12
2000-01-01 00:06:00 21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but label each bin using the right edge instead of the left. Please note that the value in the bucket used as the label is not included in the bucket, which it labels. For example, in the original series the bucket 2000–01–01 00:03:00 contains the value 3, but the summed value in the resampled bucket with the label 2000–01–01 00:03:00 does not include 3 (if it did, the summed value would be 6, not 3). To include this value close the right side of the bin interval as illustrated in the example below this one.

```python
>>> series.resample('3T', label='right').sum()
2000-01-01 00:03:00 3
2000-01-01 00:06:00 12
2000-01-01 00:09:00 21
Freq: 3T, dtype: int64
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```python
>>> series.resample('3T', label='right', closed='right').sum()
2000-01-01 00:00:00 0
2000-01-01 00:03:00 6
2000-01-01 00:06:00 15
2000-01-01 00:09:00 15
Freq: 3T, dtype: int64
```

Upsample the series into 30 second bins.

```python
>>> series.resample('30S').asfreq()[0:5] # Select first 5 rows
2000-01-01 00:00:00 0.0
2000-01-01 00:00:30 NaN
2000-01-01 00:01:00 1.0
2000-01-01 00:01:30 NaN
2000-01-01 00:02:00 2.0
Freq: 30S, dtype: float64
```

3.4. DataFrame 1755
Upsample the series into 30 second bins and fill the NaN values using the pad method.

```python
>>> series.resample('30S').pad()[0:5]
2000-01-01 00:00:00 0
2000-01-01 00:00:30 0
2000-01-01 00:01:00 1
2000-01-01 00:01:30 1
2000-01-01 00:02:00 2
Freq: 30S, dtype: int64
```

Upsample the series into 30 second bins and fill the NaN values using the bfill method.

```python
>>> series.resample('30S').bfill()[0:5]
2000-01-01 00:00:00 0
2000-01-01 00:00:30 1
2000-01-01 00:01:00 1
2000-01-01 00:01:30 2
2000-01-01 00:02:00 2
Freq: 30S, dtype: int64
```

Pass a custom function via apply

```python
>>> def custom_resampler(arraylike):
...     return np.sum(arraylike) + 5
...
>>> series.resample('3T').apply(custom_resampler)
2000-01-01 00:00:00 8
2000-01-01 00:03:00 17
2000-01-01 00:06:00 26
Freq: 3T, dtype: int64
```

For a Series with a PeriodIndex, the keyword `convention` can be used to control whether to use the start or end of rule.

Resample a year by quarter using ‘start’ convention. Values are assigned to the first quarter of the period.

```python
>>> s = pd.Series([1, 2], index=pd.period_range('2012-01-01',
...                freq='A',
...                periods=2))
>>> s
2012 1
2013 2
Freq: A-DEC, dtype: int64
```

```python
>>> s.resample('Q', convention='start').asfreq()
2012Q1 1.0
2012Q2 NaN
2012Q3 NaN
2012Q4 NaN
2013Q1 2.0
2013Q2 NaN
2013Q3 NaN
2013Q4 NaN
Freq: Q-DEC, dtype: float64
```

Resample quarters by month using ‘end’ convention. Values are assigned to the last month of the period.

```python
>>> q = pd.Series([1, 2, 3, 4], index=pd.period_range('2018-01-01',
...                freq='Q',
...                periods=4))
```
..., periods=4))

```python
q
2018Q1 1
2018Q2 2
2018Q3 3
2018Q4 4
Freq: Q-DEC, dtype: int64
```

```python
q.resample('M', convention='end').asfreq()
2018-03 1.0
2018-04 NaN
2018-05 NaN
2018-06 2.0
2018-07 NaN
2018-08 NaN
2018-09 3.0
2018-10 NaN
2018-11 NaN
2018-12 4.0
Freq: M, dtype: float64
```

For DataFrame objects, the keyword `on` can be used to specify the column instead of the index for resampling.

```python
>>> d = {'price': [10, 11, 9, 13, 14, 18, 17, 19],
       'volume': [50, 60, 40, 100, 50, 100, 40, 50]}
>>> df = pd.DataFrame(d)
>>> df['week_starting'] = pd.date_range('01/01/2018',
                                            periods=8,
                                            freq='W')
>>> df
            price  volume  week_starting
0     10      50  2018-01-07
1     11      60  2018-01-14
2      9      40  2018-01-21
3     13     100  2018-01-28
4     14      50  2018-02-04
5     18     100  2018-02-11
6     17      40  2018-02-18
7     19      50  2018-02-25
```  

```python
>>> df.resample('M', on='week_starting').mean()
      price  volume
week_starting
2018-01-31 10.75  62.5
2018-02-28 17.00  60.0
```

For a DataFrame with MultiIndex, the keyword `level` can be used to specify on which level the resampling needs to take place.

```python
>>> days = pd.date_range('1/1/2000', periods=4, freq='D')
>>> d2 = {'price': [10, 11, 9, 13, 14, 18, 17, 19],
       'volume': [50, 60, 40, 100, 50, 100, 40, 50]}
>>> df2 = pd.DataFrame(
                      ... d2,
                      ... index=pd.MultiIndex.from_product(
                      ... [days, ['morning', 'afternoon']])
                      ...
                      )
```
If you want to adjust the start of the bins based on a fixed timestamp:

```python
>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
>>> ts

2000-10-01 23:30:00     0
2000-10-01 23:37:00     3
2000-10-01 23:44:00     6
2000-10-01 23:51:00     9
2000-10-01 23:58:00    12
2000-10-02 00:05:00    15
2000-10-02 00:12:00    18
2000-10-02 00:19:00    21
2000-10-02 00:26:00    24
Freq: 7T, dtype: int64
```

```python
>>> ts.resample('17min').sum()

2000-10-01 23:14:00     0
2000-10-01 23:31:00     9
2000-10-01 23:48:00    21
2000-10-02 00:05:00    54
2000-10-02 00:22:00    24
Freq: 17T, dtype: int64
```

```python
>>> ts.resample('17min', origin='epoch').sum()

2000-10-01 23:18:00     0
2000-10-01 23:35:00    18
2000-10-01 23:52:00    27
2000-10-02 00:09:00    39
2000-10-02 00:26:00    24
Freq: 17T, dtype: int64
```

```python
>>> ts.resample('17min', origin='2000-01-01').sum()

2000-10-01 23:24:00     3
2000-10-01 23:41:00    15
2000-10-01 23:58:00    45
```

If you want to adjust the start of the bins based on a fixed timestamp:
If you want to adjust the start of the bins with an offset Timedelta, the two following lines are equivalent:

```python
>>> ts.resample('17min', origin='start').sum()
2000-10-01 23:30:00  9
2000-10-01 23:47:00  21
2000-10-02 00:04:00  54
2000-10-02 00:21:00  24
Freq: 17T, dtype: int64
```

```python
>>> ts.resample('17min', offset='23h30min').sum()
2000-10-01 23:30:00  9
2000-10-01 23:47:00  21
2000-10-02 00:04:00  54
2000-10-02 00:21:00  24
Freq: 17T, dtype: int64
```

If you want to take the largest Timestamp as the end of the bins:

```python
>>> ts.resample('17min', origin='end').sum()
2000-10-01 23:35:00  0
2000-10-01 23:52:00  18
2000-10-02 00:09:00  27
2000-10-02 00:26:00  63
Freq: 17T, dtype: int64
```

In contrast with the `start_day`, you can use `end_day` to take the ceiling midnight of the largest Timestamp as the end of the bins and drop the bins not containing data:

```python
>>> ts.resample('17min', origin='end_day').sum()
2000-10-01 23:38:00  3
2000-10-01 23:55:00  15
2000-10-02 00:12:00  45
2000-10-02 00:29:00  45
Freq: 17T, dtype: int64
```

To replace the use of the deprecated `base` argument, you can now use `offset`, in this example it is equivalent to have `base=2`:

```python
>>> ts.resample('17min', offset='2min').sum()
2000-10-01 23:16:00   0
2000-10-01 23:33:00   9
2000-10-01 23:50:00  36
2000-10-02 00:07:00  39
2000-10-02 00:24:00  24
Freq: 17T, dtype: int64
```

To replace the use of the deprecated `loffset` argument:

```python
>>> from pandas.tseries.frequencies import to_offset
>>> loffset = '19min'
>>> ts_out = ts.resample('17min').sum()
>>> ts_out.index = ts_out.index + to_offset(loffset)
>>> ts_out
```
pandas.DataFrame.reset_index

DataFrame.reset_index (level=None, drop=False, inplace=False, col_level=0, col_fill="")
Reset the index, or a level of it.

Parameters

- **level** [int, str, tuple, or list, default None] Only remove the given levels from the index. Removes all levels by default.
- **drop** [bool, default False] Do not try to insert index into dataframe columns. This resets the index to the default integer index.
- **inplace** [bool, default False] Modify the DataFrame in place (do not create a new object).
- **col_level** [int or str, default 0] If the columns have multiple levels, determines which level the labels are inserted into. By default it is inserted into the first level.
- **col_fill** [object, default ‘’] If the columns have multiple levels, determines how the other levels are named. If None then the index name is repeated.

Returns

Dataframe or None  DataFrame with the new index or None if inplace=True.

See also:

- **DataFrame.set_index**  Opposite of reset_index.
- **DataFrame.reindex**  Change to new indices or expand indices.
- **DataFrame.reindex_like**  Change to same indices as other DataFrame.

Examples

```python
>>> df = pd.DataFrame([('bird', 389.0),
... ('bird', 24.0),
... ('mammal', 80.5),
... ('mammal', np.nan),
...], index=['falcon', 'parrot', 'lion', 'monkey'],
... columns=('class', 'max_speed'))
>>> df
   class  max_speed
falcon  bird     389.0
parrot  bird      24.0
```

When we reset the index, the old index is added as a column, and a new sequential index is used:

```python
>>> df.reset_index()
   index     class   max_speed
0      falcon  bird       389.0
1       parrot  bird        24.0
2        lion  mammal       80.5
3      monkey  mammal        NaN
```

We can use the `drop` parameter to avoid the old index being added as a column:

```python
>>> df.reset_index(drop=True)
     class   max_speed
0      bird       389.0
1      bird        24.0
2  mammal       80.5
3  mammal        NaN
```

You can also use `reset_index` with `MultiIndex`.

```python
>>> index = pd.MultiIndex.from_tuples([("bird", "falcon"),
                                      (...,
                                      ("mammal", "lion"),
                                      (...,
                                      ("mammal", "monkey")),
                                      (...,
                                      names=["class", "name"])
>>> columns = pd.MultiIndex.from_tuples([("speed", "max"),
                                      (...,
                                      ("species", "type"))
>>> df = pd.DataFrame([(389.0, 'fly'),
                      (...,
                      ( 24.0, 'fly'),
                      (...,
                      ( 80.5, 'run'),
                      (...,
                      (np.nan, 'jump'))],
                      index=index,
                      columns=columns)
>>> df
    speed     species
     max  type
   class name
    bird  falcon       389.0  fly
    parrot  24.0  fly
    mammal lion       80.5  run
    monkey mammal        NaN  jump
```

If the index has multiple levels, we can reset a subset of them:

```python
>>> df.reset_index(level='class')
   class     speed     species
      max  type
    name
   falcon  bird       389.0  fly
   parrot  bird        24.0  fly
    lion  mammal       80.5  run
   monkey mammal        NaN  jump
```

If we are not dropping the index, by default, it is placed in the top level. We can place it in another level:
When the index is inserted under another level, we can specify under which one with the parameter `col_fill`:

```python
>>> df.reset_index(level='class', col_level=1, col_fill='species')
```

<table>
<thead>
<tr>
<th>species</th>
<th>speed</th>
<th>type</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td>max</td>
<td>type</td>
</tr>
<tr>
<td>name</td>
<td></td>
<td></td>
</tr>
<tr>
<td>falcon</td>
<td>bird</td>
<td>389.0</td>
</tr>
<tr>
<td>parrot</td>
<td>bird</td>
<td>24.0</td>
</tr>
<tr>
<td>lion</td>
<td>mammal</td>
<td>80.5</td>
</tr>
<tr>
<td>monkey</td>
<td>mammal</td>
<td>NaN</td>
</tr>
</tbody>
</table>

If we specify a nonexistent level for `col_fill`, it is created:

```python
>>> df.reset_index(level='class', col_level=1, col_fill='genus')
```

<table>
<thead>
<tr>
<th>genus</th>
<th>speed</th>
<th>species</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td>max</td>
<td>type</td>
</tr>
<tr>
<td>name</td>
<td></td>
<td></td>
</tr>
<tr>
<td>falcon</td>
<td>bird</td>
<td>389.0</td>
</tr>
<tr>
<td>parrot</td>
<td>bird</td>
<td>24.0</td>
</tr>
<tr>
<td>lion</td>
<td>mammal</td>
<td>80.5</td>
</tr>
<tr>
<td>monkey</td>
<td>mammal</td>
<td>NaN</td>
</tr>
</tbody>
</table>

### pandas.DataFrame.rfloordiv

DataFrame method `rfloordiv(other, axis='columns', level=None, fill_value=None)`

Get integer division of dataframe and other, element-wise (binary operator `rfloordiv`).

Equivalent to `other // dataframe`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, `floordiv`.

Among flexible wrappers (`add`, `sub`, `mul`, `div`, `mod`, `pow`) to arithmetic operators: `+`, `*`, `/`, `//`, `%`, `**`. Parameters

- `other` [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- `axis` [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- `level` [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- `fill_value` [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.
Returns

**DataFrame** Result of the arithmetic operation.

See also:

- **DataFrame.add** Add DataFrames.
- **DataFrame.sub** Subtract DataFrames.
- **DataFrame.mul** Multiply DataFrames.
- **DataFrame.div** Divide DataFrames (float division).
- **DataFrame.truediv** Divide DataFrames (float division).
- **DataFrame.floordiv** Divide DataFrames (integer division).
- **DataFrame.mod** Calculate modulo (remainder after division).
- **DataFrame.pow** Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle     0      360
triangle    3      180
rectangle   4      360

Add a scalar with operator version which return the same results.
```

```python
>>> df + 1
   angles  degrees
circle     1      361
triangle    4      181
rectangle   5      361
```

```python
>>> df.add(1)
   angles  degrees
circle     1      361
triangle    4      181
rectangle   5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle   0.0      36.0
triangle 0.3      18.0
rectangle 0.4     36.0
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
angles  degrees
   circle   -1  358
   triangle    2  178
   rectangle    3  358
```

```python
>>> df.sub([1, 2], axis='columns')
angles  degrees
   circle   -1  358
   triangle    2  178
   rectangle    3  358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
angles  degrees
   circle   -1  359
   triangle    2  179
   rectangle    3  359
```

Multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({'angles': [0, 3, 4]}, index=['circle', 'triangle', 'rectangle'])
```

```python
>>> df * other
angles  degrees
   circle     0  NaN
   triangle    9  NaN
   rectangle   16  NaN
```

```python
>>> df.mul(other, fill_value=0)
angles  degrees
   circle     0   0.0
   triangle    9   0.0
   rectangle   16   0.0
```

Divide by a MultiIndex by level.

```python
df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                   'degrees': [360, 180, 360, 360, 540, 720]},
                   index=['circle', 'triangle', 'rectangle',
                          'square', 'pentagon', 'hexagon'])
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.1

>>> df_multindex
   angles  degrees
A  circle     0     360
     triangle  3     180
     rectangle  4     360
B     square  4     360
     pentagon  5     540
     hexagon  6     720

>>> df.div(df_multindex, level=1, fill_value=0)
   angles  degrees
A  circle   NaN     1.0
     triangle    1.0     1.0
     rectangle   1.0     1.0
B     square    0.0     0.0
     pentagon    0.0     0.0
     hexagon    0.0     0.0

pandas.DataFrame.rmod

DataFrame.rmod(other, axis='columns', level=None, fill_value=None)

Get Modulo of dataframe and other, element-wise (binary operator rmod).
Equivalent to other % dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, mod.
Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters
other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns
DataFrame Result of the arithmetic operation.

See also:
DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv  Divide DataFrames (integer division).
DataFrame.mod  Calculate modulo (remainder after division).
DataFrame.pow  Calculate exponential power.

Notes
Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4], 'degrees': [360, 180, 360]}, index=['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle     0      360
triangle   3      180
rectangle  4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

```python
>>> df.add(1)
   angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle   0.0    36.0
triangle 0.3    18.0
rectangle 0.4   36.0
```

```python
>>> df.rdiv(10)
   angles  degrees
circle  inf     0.027778
triangle 3.333333 0.055556
rectangle 2.500000 0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
   angles  degrees
circle   -1     358
triangle   2      178
rectangle  3     358
```
>>> df.sub([1, 2], axis='columns')

    angles  degrees
  circle    -1       358
   triangle     2       178
  rectangle     3       358

>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')

    angles  degrees
  circle    -1       359
   triangle     2       179
  rectangle     3       359

Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4], 'degrees': [360, 180, 360]}, index=['circle', 'triangle', 'rectangle'])

>>> df * other

    angles  degrees
  circle    0       NaN
   triangle    9       NaN
  rectangle   16       NaN

>>> df.mul(other, fill_value=0)

    angles  degrees
  circle    0       0.0
   triangle    9       0.0
  rectangle   16       0.0

Divide by a MultiIndex by level.

>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 5, 6], 'degrees': [360, 180, 360, 360, 540, 720]}, index=['A', 'A', 'A', 'B', 'B', 'B'], ['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon'])

>>> df_multindex

    angles  degrees
  A circle    0       360
   triangle    3       180
  rectangle    4       360
  B square    4       360
     pentagon    5       540
    hexagon    6       720

>>> df.div(df_multindex, level=1, fill_value=0)

    angles  degrees
  A circle  NaN       1.0
   triangle  1.0       1.0
  rectangle  1.0       1.0

pandas.DataFrame.rmul

DataFrame.rmul(other, axis='columns', level=None, fill_value=None)

Get Multiplication of dataframe and other, element-wise (binary operator rmul).

Equivalent to other * dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, mul.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, //, %, **.

Parameters

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

- DataFrame.add Add DataFrames.
- DataFrame.sub Subtract DataFrames.
- DataFrame.mul Multiply DataFrames.
- DataFrame.div Divide DataFrames (float division).
- DataFrame.truediv Divide DataFrames (float division).
- DataFrame.floordiv Divide DataFrames (integer division).
- DataFrame.mod Calculate modulo (remainder after division).
- DataFrame.pow Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
             angles  degrees
      circle      0      360
      triangle     3      180
     rectangle     4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
             angles  degrees
      circle      1      361
      triangle     4      181
     rectangle     5      361
```

```python
>>> df.add(1)
             angles  degrees
      circle      1      361
      triangle     4      181
     rectangle     5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
             angles  degrees
      circle    0.0      36.0
      triangle  0.3      18.0
     rectangle  0.4      36.0
```

```python
>>> df.rdiv(10)
             angles  degrees
      circle     inf      0.027778
      triangle  3.333333      0.055556
     rectangle  2.500000      0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
             angles  degrees
      circle     -1      358
      triangle      2      178
     rectangle      3      358
```

```python
>>> df.sub([1, 2], axis='columns')
             angles  degrees
      circle     -1      358
      triangle      2      178
     rectangle      3      358
```
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])
>>> other
   angles
circle   0
triangle  3
rectangle 4
```

```python
>>> df + other
   angles  degrees
  circle   0   NaN
  triangle  9   NaN
  rectangle 16   NaN
```

```python
>>> df.mul(other, fill_value=0)
   angles  degrees
  circle   0   0.0
  triangle  9   0.0
  rectangle 16   0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               index=['A', 'A', 'A', 'B', 'B', 'B'],
                               ['circle', 'triangle', 'rectangle',
                                'square', 'pentagon', 'hexagon'])
>>> df_multindex
   angles  degrees
  A circle   0   360
  triangle  3   180
  rectangle 4   360
  B square  4   360
  pentagon  5   540
  hexagon  6   720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
   angles  degrees
  A circle   NaN    1.0
  triangle  1.0    1.0
  rectangle 1.0    1.0
  B square   0.0    0.0
  pentagon  0.0    0.0
  hexagon  0.0    0.0
```
**DataFrame.rolling**

DataFrame.rolling(window, min_periods=None, center=False, win_type=None, on=None, axis=0, closed=None, method='single')

Provide rolling window calculations.

**Parameters**

- **window** [int, offset, or BaseIndexer subclass] Size of the moving window. This is the number of observations used for calculating the statistic. Each window will be a fixed size.
  
  If its an offset then this will be the time period of each window. Each window will be a variable sized based on the observations included in the time-period. This is only valid for datetimelike indexes.
  
  If a BaseIndexer subclass is passed, calculates the window boundaries based on the defined get_window_bounds method. Additional rolling keyword arguments, namely min_periods, center, and closed will be passed to get_window_bounds.

- **min_periods** [int, default None] Minimum number of observations in window required to have a value (otherwise result is NA). For a window that is specified by an offset, min_periods will default to 1. Otherwise, min_periods will default to the size of the window.

- **center** [bool, default False] Set the labels at the center of the window.

- **win_type** [str, default None] Provide a window type. If None, all points are evenly weighted. See the notes below for further information.

- **on** [str, optional] For a DataFrame, a datetime-like column or Index level on which to calculate the rolling window, rather than the DataFrame’s index. Provided integer column is ignored and excluded from result since an integer index is not used to calculate the rolling window.

- **axis** [int or str, default 0]

- **closed** [str, default None] Make the interval closed on the ‘right’, ‘left’, ‘both’ or ‘neither’ endpoints. Defaults to ‘right’.
  
  Changed in version 1.2.0: The closed parameter with fixed windows is now supported.

- **method** [str {'single', 'table'}, default 'single'] Execute the rolling operation per single column or row (‘single’) or over the entire object (‘table’).
  
  This argument is only implemented when specifying engine='numba' in the method call.
  
  New in version 1.3.0.

**Returns**

a Window or Rolling sub-classed for the particular operation

**See also:**

- **expanding** Provides expanding transformations.
- **ewm** Provides exponential weighted functions.
Notes

By default, the result is set to the right edge of the window. This can be changed to the center of the window by setting `center=True`.

To learn more about the offsets & frequency strings, please see this link.

If `win_type=None`, all points are evenly weighted; otherwise, `win_type` can accept a string of any `scipy.signal` window function.

Certain Scipy window types require additional parameters to be passed in the aggregation function. The additional parameters must match the keywords specified in the Scipy window type method signature. Please see the third example below on how to add the additional parameters.

Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})

>>> df
   B
0  0.0
1  1.0
2  2.0
3 NaN
4  4.0

Rolling sum with a window length of 2, using the 'triang' window type.

```python
>>> df.rolling(2, win_type='triang').sum()
   B
0  NaN
1  0.5
2  1.5
3  NaN
4  NaN
``` 

Rolling sum with a window length of 2, using the 'gaussian' window type (note how we need to specify `std`).

```python
>>> df.rolling(2, win_type='gaussian').sum(std=3)
   B
0  NaN
1  0.986207
2  2.958621
3  NaN
4  NaN
``` 

Rolling sum with a window length of 2, `min_periods` defaults to the window length.

```python
>>> df.rolling(2).sum()
   B
0  NaN
1  1.0
2  3.0
3  NaN
4  NaN
``` 

Same as above, but explicitly set the `min_periods`
```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
                    index = [pd.Timestamp('20130101 09:00:00'),
                             pd.Timestamp('20130101 09:00:02'),
                             pd.Timestamp('20130101 09:00:03'),
                             pd.Timestamp('20130101 09:00:05'),
                             pd.Timestamp('20130101 09:00:06')])
>>> df
   B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

Contrasting to an integer rolling window, this will roll a variable length window corresponding to the time period. The default for min_periods is 1.

```python
>>> df.rolling('2s').sum()
   B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```
pandas.DataFrame.round

DataFrame.round (decimals=0, *args, **kwargs)
Round a DataFrame to a variable number of decimal places.

Parameters

decimals [int, dict, Series] Number of decimal places to round each column to. If an int is given, round each column to the same number of places. Otherwise dict and Series round to variable numbers of places. Column names should be in the keys if decimals is a dict-like, or in the index if decimals is a Series. Any columns not included in decimals will be left as is. Elements of decimals which are not columns of the input will be ignored.

*args Additional keywords have no effect but might be accepted for compatibility with numpy.

**kwargs Additional keywords have no effect but might be accepted for compatibility with numpy.

Returns

DataFrame A DataFrame with the affected columns rounded to the specified number of decimal places.

See also:

numpy.around Round a numpy array to the given number of decimals.

Series.round Round a Series to the given number of decimals.

Examples

```python
>>> df = pd.DataFrame([(0.21, 0.32), (0.01, 0.67), (0.66, 0.03), (0.21, 0.18)],
...                       columns=['dogs', 'cats'])
>>> df
      dogs   cats
0  0.210  0.320
1  0.010  0.670
2  0.660  0.030
3  0.210  0.180
```

By providing an integer each column is rounded to the same number of decimal places

```python
>>> df.round(1)
      dogs   cats
0  0.200  0.300
1  0.000  0.700
2  0.700  0.000
3  0.200  0.200
```

With a dict, the number of places for specific columns can be specified with the column names as key and the number of decimal places as value

```python
>>> df.round({'dogs': 1, 'cats': 0})
      dogs   cats
0  0.200  0.000
1  0.000  1.000
```
Using a Series, the number of places for specific columns can be specified with the column names as index and the number of decimal places as value

```
>>> decimals = pd.Series([0, 1], index=['cats', 'dogs'])
>>> df.round(decimals)
   dogs  cats
0  0.2  0.0
1  0.0  1.0
2  0.7  0.0
3  0.2  0.0
```

**pandas.DataFrame.rpow**

DataFrame\_.rpow\((other, axis='columns', level=None, fill_value=None)\)

Get Exponential power of dataframe and other, element-wise (binary operator rpow).

Equivalent to other ** dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, pow.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
- **fill_value** [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame Result of the arithmetic operation.

**See also:**

- **Dataframe.add** Add DataFrames.
- **Dataframe.sub** Subtract DataFrames.
- **Dataframe.mul** Multiply DataFrames.
- **Dataframe.div** Divide DataFrames (float division).
- **Dataframe.truediv** Divide DataFrames (float division).
- **Dataframe.floordiv** Divide DataFrames (integer division).
- **Dataframe.mod** Calculate modulo (remainder after division).
- **Dataframe.pow** Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle     0       360
triangle   3       180
rectangle  4       360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle     1       361
triangle   4       181
rectangle  5       361
```

```python
>>> df.add(1)
   angles  degrees
circle     1       361
triangle   4       181
rectangle  5       361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
   angles  degrees
circle   0.0     36.0
triangle 0.3     18.0
rectangle 0.4    36.0
```

```python
>>> df.rdiv(10)
   angles  degrees
circle     inf   0.027778
triangle  3.333333  0.055556
rectangle 2.500000  0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
   angles  degrees
circle   -1      358
triangle    2     178
rectangle   3      358
```

```python
>>> df.sub([1, 2], axis='columns')
   angles  degrees
circle   -1      358
triangle    2     178
rectangle   3      358
```
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
    index=['circle', 'triangle', 'rectangle'])

>>> other
angles
circle    0
triangle   3
rectangle  4

>>> df + other
angles  degrees
circle    0   NaN
triangle   3   NaN
rectangle 16   NaN

>>> df.mul(other, fill_value=0)
angles  degrees
circle   0   0.0
triangle  9   0.0
rectangle 16  0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
    'degrees': [360, 180, 360, 360, 540, 720],
    index=['A', 'A', 'B', 'B', 'B', 'B'],
    ['circle', 'triangle', 'rectangle',
     'square', 'pentagon', 'hexagon'])

>>> df_multindex
angles  degrees
A circle    0   360
triangle    3   180
rectangle   4   360
B square    4   360
pentagon    5   540
hexagon     6   720

>>> df.div(df_multindex, level=1, fill_value=0)
angles  degrees
A circle   NaN    1.0
triangle   1.0    1.0
rectangle  1.0    1.0
B square   0.0    0.0
pentagon   0.0    0.0
hexagon    0.0    0.0
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.DataFrame.rsub

DataFrame.rsub(other, axis='columns', level=None, fill_value=None)
Get Subtraction of dataframe and other, element-wise (binary operator rsub).
Equivalent to other - dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, sub.
Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
axis [{0 or 'index', 1 or 'columns'}] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.
level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360],
...                    index=['circle', 'triangle', 'rectangle'])
>>> df
     angles  degrees
circle      0      360
triangle     3      180
rectangle    4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
     angles  degrees
circle     1      361
triangle    4      181
rectangle   5      361
```

```python
>>> df.add(1)
     angles  degrees
circle     1      361
triangle    4      181
rectangle   5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
     angles  degrees
circle   0.0     36.0
triangle 0.3     18.0
rectangle 0.4     36.0
```

```python
>>> df.rdiv(10)
     angles  degrees
circle  inf    0.027778
triangle 3.333333 0.055556
rectangle 2.500000 0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
     angles  degrees
circle    -1      358
triangle     2      178
rectangle    3      358
```

```python
>>> df.sub([1, 2], axis='columns')
     angles  degrees
circle    -1      358
triangle     2      178
rectangle    3      358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
     angles  degrees
```

(continues on next page)
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])

>>> df * other
angles  degrees
circle   0.0    NaN
triangle  9.0    NaN
rectangle 16.0    NaN

>>> df.mul(other, fill_value=0)
angles  degrees
circle   0.0
triangle  9.0
rectangle 16.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               index=['A', 'A', 'A', 'B', 'B', 'B'],
                               ['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon']
                               
>>> df_multindex
angles  degrees
A circle   0    360
triangle   3    180
rectangle  4    360
B square   4    360
pentagon   5    540
hexagon    6    720

>>> df.div(df_multindex, level=1, fill_value=0)
angles  degrees
A circle   NaN    1.0
triangle   1.0    1.0
rectangle  1.0    1.0
B square   0.0    0.0
pentagon   0.0    0.0
hexagon    0.0    0.0
```
DataFrame.rtruediv

Get Floating division of dataframe and other, element-wise (binary operator rtruediv).

Equivalent to other / dataframe, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, truediv.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis {[0 or ‘index’, 1 or ‘columns’]} Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

Notes

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                    'degrees': [360, 180, 360]},
...                   index=['circle', 'triangle', 'rectangle'])
```

```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0</td>
</tr>
<tr>
<td>triangle</td>
<td>3</td>
</tr>
<tr>
<td>rectangle</td>
<td>4</td>
</tr>
</tbody>
</table>
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
```

```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
</tbody>
</table>
```

```python
>>> df.add(1)
```

```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>1</td>
</tr>
<tr>
<td>triangle</td>
<td>4</td>
</tr>
<tr>
<td>rectangle</td>
<td>5</td>
</tr>
</tbody>
</table>
```

Divide by constant with reverse version.

```python
>>> df.div(10)
```

```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0</td>
</tr>
<tr>
<td>triangle</td>
<td>0.3</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.4</td>
</tr>
</tbody>
</table>
```

```python
>>> df.rdiv(10)
```

```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>inf</td>
</tr>
<tr>
<td>triangle</td>
<td>3.333333</td>
</tr>
<tr>
<td>rectangle</td>
<td>2.5</td>
</tr>
</tbody>
</table>
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
```

```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>
```

```python
>>> df.sub([1, 2], axis='columns')
```

```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']), axis='index')
```

```
<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>-1</td>
</tr>
<tr>
<td>triangle</td>
<td>2</td>
</tr>
<tr>
<td>rectangle</td>
<td>3</td>
</tr>
</tbody>
</table>
```

(continues on next page)
Multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({'angles': [0, 3, 4]},
                     index=['circle', 'triangle', 'rectangle'])

other
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0</td>
</tr>
<tr>
<td>triangle</td>
<td>3</td>
</tr>
<tr>
<td>rectangle</td>
<td>4</td>
</tr>
</tbody>
</table>

```python
df * other
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>NaN</td>
</tr>
<tr>
<td>triangle</td>
<td>9</td>
</tr>
<tr>
<td>rectangle</td>
<td>16</td>
</tr>
</tbody>
</table>

```python
df.mul(other, fill_value=0)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>circle</td>
<td>0.0</td>
</tr>
<tr>
<td>triangle</td>
<td>0.0</td>
</tr>
<tr>
<td>rectangle</td>
<td>0.0</td>
</tr>
</tbody>
</table>

Divide by a MultiIndex by level.

```python
df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                             'degrees': [360, 180, 360, 360, 540, 720],
                             index=['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon'])

df_multindex
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>A circle</td>
<td>0</td>
</tr>
<tr>
<td>triangle</td>
<td>3</td>
</tr>
<tr>
<td>rectangle</td>
<td>4</td>
</tr>
<tr>
<td>B square</td>
<td>4</td>
</tr>
<tr>
<td>pentagon</td>
<td>5</td>
</tr>
<tr>
<td>hexagon</td>
<td>6</td>
</tr>
</tbody>
</table>

```python
df.div(df_multindex, level=1, fill_value=0)
```

<table>
<thead>
<tr>
<th>angles</th>
<th>degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>A circle</td>
<td>NaN</td>
</tr>
<tr>
<td>triangle</td>
<td>1.0</td>
</tr>
<tr>
<td>rectangle</td>
<td>1.0</td>
</tr>
<tr>
<td>B square</td>
<td>0.0</td>
</tr>
<tr>
<td>pentagon</td>
<td>0.0</td>
</tr>
<tr>
<td>hexagon</td>
<td>0.0</td>
</tr>
</tbody>
</table>
pandas.DataFrame.sample

DataFrame.sample(n=None, frac=None, replace=False, weights=None, random_state=None, axis=None, ignore_index=False)

Return a random sample of items from an axis of an object.

You can use `random_state` for reproducibility.

**Parameters**

- **n** [int, optional] Number of items from axis to return. Cannot be used with `frac`. Default = 1 if `frac = None`.
- **frac** [float, optional] Fraction of axis items to return. Cannot be used with `n`.
- **replace** [bool, default False] Allow or disallow sampling of the same row more than once.
- **weights** [str or ndarray-like, optional] Default ‘None’ results in equal probability weighting. If passed a Series, will align with target object on index. Index values in weights not found in sampled object will be ignored and index values in sampled object not in weights will be assigned weights of zero. If called on a DataFrame, will accept the name of a column when `axis = 0`. Unless weights are a Series, weights must be same length as axis being sampled. If weights do not sum to 1, they will be normalized to sum to 1. Missing values in the weights column will be treated as zero. Infinite values not allowed.
- **random_state** [int, array-like, BitGenerator, np.random.RandomState, optional] If int, array-like, or BitGenerator (NumPy>=1.17), seed for random number generator. If `np.random.RandomState`, use as numpy RandomState object.
  
  Changed in version 1.1.0: array-like and BitGenerator (for NumPy>=1.17) object now passed to `np.random.RandomState()` as seed
- **axis** [[0 or ‘index’, 1 or ‘columns’, None], default None] Axis to sample. Accepts axis number or name. Default is stat axis for given data type (0 for Series and DataFrames).
- **ignore_index** [bool, default False] If True, the resulting index will be labeled 0, 1, …, `n - 1`.

**Returns**

Series or DataFrame A new object of same type as caller containing `n` items randomly sampled from the caller object.

See also:

DataFrameGroupBy.sample Generates random samples from each group of a DataFrame object.

SeriesGroupBy.sample Generates random samples from each group of a Series object.

numpy.random.choice Generates a random sample from a given 1-D numpy array.
Notes

If \( \text{frac} > 1 \), \textit{replacement} should be set to \textit{True}.

Examples

```python
>>> df = pd.DataFrame({'num_legs': [2, 4, 8, 0],
...'num_wings': [2, 0, 0, 0],
...'num_specimen_seen': [10, 2, 1, 8]},
...index=['falcon', 'dog', 'spider', 'fish'])
```

Extract 3 random elements from the Series \textit{df['num_legs']}: Note that we use \textit{random_state} to ensure the reproducibility of the examples.

```python
>>> df['num_legs'].sample(n=3, random_state=1)
fish 0
spider 8
falcon 2
Name: num_legs, dtype: int64
```

A random 50\% sample of the DataFrame with replacement:

```python
>>> df.sample(frac=0.5, replace=True, random_state=1)
```

An upsample sample of the DataFrame with replacement: Note that \textit{replace} parameter has to be \textit{True} for \textit{frac} parameter > 1.

```python
>>> df.sample(frac=2, replace=True, random_state=1)
```

Using a DataFrame column as weights. Rows with larger value in the \textit{num_specimen_seen} column are more likely to be sampled.
pandas.DataFrame.select_dtypes

DataFrame.select_dtypes(include=None, exclude=None)
Return a subset of the DataFrame’s columns based on the column dtypes.

Parameters
include, exclude [scalar or list-like] A selection of dtypes or strings to be included/excluded. At least one of these parameters must be supplied.

Returns
DataFrame The subset of the frame including the dtypes in include and excluding the dtypes in exclude.

Raises
ValueError
• If both of include and exclude are empty
• If include and exclude have overlapping elements
• If any kind of string dtype is passed in.

See also:
DataFrame.dtypes Return Series with the data type of each column.

Notes
• To select all numeric types, use np.number or 'number'
• To select strings you must use the object dtype, but note that this will return all object dtype columns
• See the numpy dtype hierarchy
• To select datetimes, use np.datetime64, 'datetime' or 'datetime64'
• To select timedeltas, use np.timedelta64, 'timedelta' or 'timedelta64'
• To select Pandas categorical dtypes, use 'category'
• To select Pandas datetimetz dtypes, use 'datetimetz' (new in 0.20.0) or 'datetime64[ns, tz]'

Examples

```python
>>> df = pd.DataFrame({'a': [1, 2] * 3,
...                    'b': [True, False] * 3,
...                    'c': [1.0, 2.0] * 3})
>>> df
     a    b     c
0  1.0  True  1.0
1  2.0   False  2.0
2  1.0  True  1.0
3  2.0   False  2.0
4  1.0  True  1.0
5  2.0   False  2.0
```
>>> df.select_dtypes(include='bool')
   b
0  True
1  False
2  True
3  False
4  True
5  False

>>> df.select_dtypes(include=['float64'])
   c
0  1.0
1  2.0
2  1.0
3  2.0
4  1.0
5  2.0

>>> df.select_dtypes(exclude=['int64'])
   b  c
0  True  1.0
1  False  2.0
2  True  1.0
3  False  2.0
4  True  1.0
5  False  2.0

pandas.DataFrame.sem

DataFrame.sem(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)
Return unbiased standard error of the mean over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

Parameters

axis [[index (0), columns (1)]]

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.

numeric_only [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

Returns

Series or DataFrame (if level specified)
Notes

To have the same behaviour as `numpy.std`, use `ddof=0` (instead of the default `ddof=1`)

**pandas.DataFrame.set_axis**

DataFrame.set_axis(labels, axis=0, inplace=False)

Assign desired index to given axis.

Indexes for column or row labels can be changed by assigning a list-like or Index.

**Parameters**

labels [list-like, Index] The values for the new index.

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to update. The value 0 identifies the rows, and 1 identifies the columns.

inplace [bool, default False] Whether to return a new DataFrame instance.

**Returns**

renamed [DataFrame or None] An object of type DataFrame or None if inplace=True.

See also:

**DataFrame.rename_axis** Alter the name of the index or columns.

**Examples**

```python
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})

Change the row labels.

```python
>>> df.set_axis(['a', 'b', 'c'], axis='index')

<table>
<thead>
<tr>
<th></th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1</td>
</tr>
<tr>
<td>b</td>
<td>2</td>
</tr>
<tr>
<td>c</td>
<td>3</td>
</tr>
</tbody>
</table>

Change the column labels.

```python
>>> df.set_axis(['I', 'II'], axis='columns')

<table>
<thead>
<tr>
<th>I</th>
<th>II</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>

Now, update the labels inplace.

```python
>>> df.set_axis(['i', 'ii'], axis='columns', inplace=True)

<table>
<thead>
<tr>
<th>i</th>
<th>ii</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>
pandas.DataFrame.set_flags

DataFrame.set_flags(*, copy=False, allows_duplicate_labels=None)
Return a new object with updated flags.

Parameters

allows_duplicate_labels [bool, optional] Whether the returned object allows duplicate labels.

Returns

Series or DataFrame The same type as the caller.

See also:

DataFrame.attrs Global metadata applying to this dataset.
DataFrame.flags Global flags applying to this object.

Notes

This method returns a new object that’s a view on the same data as the input. Mutating the input or the output values will be reflected in the other.

This method is intended to be used in method chains.

“Flags” differ from “metadata”. Flags reflect properties of the pandas object (the Series or DataFrame). Metadata refer to properties of the dataset, and should be stored in DataFrame.attrs.

Examples

```python
>>> df = pd.DataFrame({"A": [1, 2]})
>>> df.flags.allows_duplicate_labels
True
>>> df2 = df.set_flags(allows_duplicate_labels=False)
>>> df2.flags.allows_duplicate_labels
False
```

pandas.DataFrame.set_index

DataFrame.set_index(keys, drop=True, append=False, inplace=False, verify_integrity=False)
Set the DataFrame index using existing columns.

Set the DataFrame index (row labels) using one or more existing columns or arrays (of the correct length). The index can replace the existing index or expand on it.

Parameters

keys [label or array-like or list of labels/arrays] This parameter can be either a single column key, a single array of the same length as the calling DataFrame, or a list containing an arbitrary combination of column keys and arrays. Here, “array” encompasses Series, Index, np.ndarray, and instances of Iterator.

drop [bool, default True] Delete columns to be used as the new index.

append [bool, default False] Whether to append columns to existing index.

3.4. DataFrame 1789
inplace  [bool, default False] If True, modifies the DataFrame in place (do not create a new object).

verify_integrity  [bool, default False] Check the new index for duplicates. Otherwise defer the check until necessary. Setting to False will improve the performance of this method.

Returns

DataFrame or None  Changed row labels or None if inplace=True.

See also:

DataFrame.reset_index  Opposite of set_index.

DataFrame.reindex  Change to new indices or expand indices.

DataFrame.reindex_like  Change to same indices as other DataFrame.

Examples

```python
>>> df = pd.DataFrame({'month': [1, 4, 7, 10],
... 'year': [2012, 2014, 2013, 2014],
... 'sale': [55, 40, 84, 31]})
>>> df
   month  year  sale
0      1  2012   55
1      4  2014   40
2      7  2013   84
3     10  2014   31

Set the index to become the ‘month’ column:

```python
>>> df.set_index('month')
   year  sale
month
1  2012   55
4  2014   40
7  2013   84
10 2014   31

Create a MultiIndex using columns ‘year’ and ‘month’:

```python
>>> df.set_index(['year', 'month'])
   sale
year  month
2012 1  55
2014 4  40
2013 7  84
2014 10 31

Create a MultiIndex using an Index and a column:

```python
>>> df.set_index([pd.Index([1, 2, 3, 4]), 'year'])
   month  sale
year
1  2012  55
2  2014  40

(continues on next page)
Create a MultiIndex using two Series:

```
>>> s = pd.Series([1, 2, 3, 4])
>>> df.set_index([s, s**2])
```

```
Month Year Sale
1 1 1 2012 55
2 4 4 2014 40
3 9 7 2013 84
4 16 10 2014 31
```

### pandas.DataFrame.shift

DataFrame.shift(periods=1, freq=None, axis=0, fill_value=<no_default>)

Shift index by desired number of periods with an optional time freq.

When freq is not passed, shift the index without realigning the data. If freq is passed (in this case, the index must be date or datetime, or it will raise a NotImplementedError), the index will be increased using the periods and the freq. freq can be inferred when specified as “infer” as long as either freq or inferred_freq attribute is set in the index.

**Parameters**

- **periods** [int] Number of periods to shift. Can be positive or negative.
- **freq** [DateOffset, tseries.offsets, timedelta, or str, optional] Offset to use from the tseries module or time rule (e.g. ‘EOM’). If freq is specified then the index values are shifted but the data is not realigned. That is, use freq if you would like to extend the index when shifting and preserve the original data. If freq is specified as “infer” then it will be inferred from the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown.
- **axis** [{0 or ‘index’, 1 or ‘columns’, None}, default None] Shift direction.
- **fill_value** [object, optional] The scalar value to use for newly introduced missing values. the default depends on the dtype of self. For numeric data, np.nan is used. For datetime, timedelta, or period data, etc. NaT is used. For extension dtypes, self.dtype.na_value is used.

**Returns**

DataFrame Copy of input object, shifted.

See also:

- **Index.shift** Shift values of Index.
- **DatetimeIndex.shift** Shift values of DatetimeIndex.
- **PeriodIndex.shift** Shift values of PeriodIndex.
- **tshift** Shift the time index, using the index’s frequency if available.
## Examples

```python
>>> df = pd.DataFrame({"Col1": [10, 20, 15, 30, 45],
... "Col2": [13, 23, 18, 33, 48],
... "Col3": [17, 27, 22, 37, 52]},
... index=pd.date_range("2020-01-01", "2020-01-05"))
>>> df
          Col1  Col2  Col3
2020-01-01  10    13   17
2020-01-02  20    23   27
2020-01-03  15    18   22
2020-01-04  30    33   37
2020-01-05  45    48   52

>>> df.shift(periods=3)
          Col1  Col2  Col3
2020-01-01    NaN   NaN   NaN
2020-01-02    NaN   NaN   NaN
2020-01-03    NaN   NaN   NaN
2020-01-04   10.0   13.0  17.0
2020-01-05   20.0   23.0  27.0

>>> df.shift(periods=1, axis="columns")
          Col1  Col2  Col3
2020-01-01    NaN    10   13
2020-01-02    NaN    20   23
2020-01-03    NaN    15   18
2020-01-04    NaN    30   33
2020-01-05    NaN    45   48

>>> df.shift(periods=3, fill_value=0)
          Col1  Col2  Col3
2020-01-01     0      0    0
2020-01-02     0      0    0
2020-01-03     0      0    0
2020-01-04   10.0   13.0  17.0
2020-01-05   20.0   23.0  27.0

>>> df.shift(periods=3, freq="D")
          Col1  Col2  Col3
2020-01-04   10    13    17
2020-01-05   20    23    27
2020-01-06   15    18    22
2020-01-07   30    33    37
2020-01-08   45    48    52

>>> df.shift(periods=3, freq="infer")
          Col1  Col2  Col3
2020-01-04   10    13    17
2020-01-05   20    23    27
2020-01-06   15    18    22
2020-01-07   30    33    37
2020-01-08   45    48    52
```
**pandas.DataFrame.skew**

DataFrame.skew(axis=None, skipna=None, level=None, numeric_only=None, **kwargs)

Return unbiased skew over requested axis.

Normalized by N-1.

**Parameters**

- **axis** [{index (0), columns (1)}] Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **kwargs** Additional keyword arguments to be passed to the function.

**Returns**

Series or DataFrame (if level specified)

**pandas.DataFrame.slice_shift**

DataFrame.slice_shift(periods=1, axis=0)

Equivalent to shift without copying data. The shifted data will not include the dropped periods and the shifted axis will be smaller than the original.

Deprecated since version 1.2.0: slice_shift is deprecated, use DataFrame/Series.shift instead.

**Parameters**

- **periods** [int] Number of periods to move, can be positive or negative.

**Returns**

shifted [same type as caller]

**Notes**

While the slice_shift is faster than shift, you may pay for it later during alignment.

**pandas.DataFrame.sort_index**

DataFrame.sort_index(axis=0, level=None, ascending=True, inplace=False, kind='quicksort', na_position='last', sort_remaining=True, ignore_index=False, key=None)

Sort object by labels (along an axis).

Returns a new DataFrame sorted by label if inplace argument is False, otherwise updates the original DataFrame and returns None.

**Parameters**

- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis along which to sort. The value 0 identifies the rows, and 1 identifies the columns.
level [int or level name or list of ints or list of level names] If not None, sort on values in specified index level(s).

ascending [bool or list-like of bools, default True] Sort ascending vs. descending. When the index is a MultiIndex the sort direction can be controlled for each level individually.

inplace [bool, default False] If True, perform operation in-place.

kind [{‘quicksort’, ‘mergesort’, ‘heapsort’, ‘stable’}, default ‘quicksort’] Choice of sorting algorithm. See also numpy.sort() for more information. mergesort and stable are the only stable algorithms. For DataFrames, this option is only applied when sorting on a single column or label.

na_position [{‘first’, ‘last’}, default ‘last’] Puts NaNs at the beginning if first; last puts NaNs at the end. Not implemented for MultiIndex.

sort_remaining [bool, default True] If True and sorting by level and index is multi-level, sort by other levels too (in order) after sorting by specified level.

ignore_index [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

New in version 1.0.0.

key [callable, optional] If not None, apply the key function to the index values before sorting. This is similar to the key argument in the builtin sorted() function, with the notable difference that this key function should be vectorized. It should expect an Index and return an Index of the same shape. For MultiIndex inputs, the key is applied per level.

New in version 1.1.0.

Returns

DataFrame or None The original DataFrame sorted by the labels or None if inplace=True.

See also:

Series.sort_index Sort Series by the index.

DataFrame.sort_values Sort DataFrame by the value.

Series.sort_values Sort Series by the value.

Examples

```python
>>> df = pd.DataFrame([1, 2, 3, 4, 5], index=[100, 29, 234, 1, 150],
                     columns=['A'])
>>> df.sort_index()
   A
  1  4
 29  2
100 1
150 5
234 3
```

By default, it sorts in ascending order, to sort in descending order, use ascending=False
A key function can be specified which is applied to the index before sorting. For a `MultiIndex` this is applied to each level separately.

```python
>>> df = pd.DataFrame({"a": [1, 2, 3, 4]}, index=['A', 'b', 'C', 'd'])
>>> df.sort_index(key=lambda x: x.str.lower())
     a
A  1
b  2
C  3
d  4
```

`pandas.DataFrame.sort_values`

DataFrame.sort_values(by, axis=0, ascending=True, inplace=False, kind='quicksort', na_position='last', ignore_index=False, key=None)

Sort by the values along either axis.

Parameters

- **by** [str or list of str] Name or list of names to sort by.
  - if `axis` is 0 or `index` then `by` may contain index levels and/or column labels.
  - if `axis` is 1 or `columns` then `by` may contain column levels and/or index labels.

- **axis** [0 or 'index', 1 or 'columns'], default 0] Axis to be sorted.

- **ascending** [bool or list of bool, default True] Sort ascending vs. descending. Specify list for multiple sort orders. If this is a list of bools, must match the length of the `by`.

- **inplace** [bool, default False] If True, perform operation in-place.

- **kind** [{'quicksort', 'mergesort', 'heapsort', 'stable'}, default 'quicksort'] Choice of sorting algorithm. See also `numpy.sort()` for more information. `mergesort` and `stable` are the only stable algorithms. For DataFrames, this option is only applied when sorting on a single column or label.

- **na_position** [{'first', 'last'}, default 'last'] Puts NaNs at the beginning if `first`; `last` puts NaNs at the end.

- **ignore_index** [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.
  - New in version 1.0.0.

- **key** [callable, optional] Apply the key function to the values before sorting. This is similar to the `key` argument in the builtin `sorted()` function, with the notable difference that this `key` function should be vectorized. It should expect a Series and return a Series with the same shape as the input. It will be applied to each column in `by` independently.
pandas: powerful Python data analysis toolkit, Release 1.3.1

New in version 1.1.0.

Returns

DataFrame or None  DataFrame with sorted values or None if inplace=True.

See also:

DataFrame.sort_index  Sort a DataFrame by the index.
Series.sort_values  Similar method for a Series.

Examples

```python
>>> df = pd.DataFrame(
...   {'col1': ['A', 'A', 'B', np.nan, 'D', 'C'],
...    'col2': [2, 1, 9, 8, 7, 4],
...    'col3': [0, 1, 9, 4, 2, 3],
...    'col4': ['a', 'B', 'c', 'D', 'e', 'F']
...  })
>>> df
   col1 col2  col3  col4
0     A    2     0    a
1     A    1     1    B
2     B    9     9    c
3  NaN    8     4    D
4     D    7     2    e
5     C    4     3    F
```

Sort by col1

```python
>>> df.sort_values(by=['col1'])
   col1  col2  col3  col4
0     A    2     0    a
1     A    1     1    B
2     B    9     9    c
5     C    4     3    F
3  NaN    8     4    D
```

Sort by multiple columns

```python
>>> df.sort_values(by=['col1', 'col2'])
   col1  col2  col3  col4
1     A    1     1    B
0     A    2     0    a
2     B    9     9    c
5     C    4     3    F
4     D    7     2    e
3  NaN    8     4    D
```

Sort Descending

```python
>>> df.sort_values(by='col1', ascending=False)
   col1  col2  col3  col4
4     D    7     2    e
5     C    4     3    F
2     B    9     9    c
```

(continues on next page)
Putting NAs first

```python
>>> df.sort_values(by='col1', ascending=False, na_position='first')
col1  col2  col3  col4
3    NaN  8    4    D
4    D    7    2    e
5    C    4    3    F
2    B    9    9    c
0    A    2    0    a
1    A    1    1    B
```

Sorting with a key function

```python
>>> df.sort_values(by='col4', key=lambda col: col.str.lower())
col1  col2  col3  col4
0    A    2    0    a
1    A    1    1    B
2    B    9    9    c
3    NaN  8    4    D
4    D    7    2    e
5    C    4    3    F
```

Natural sort with the key argument, using the `natsort <https://github.com/SethMMorton/natsort>`_ package.

```python
>>> df = pd.DataFrame({
...     "time": ['0hr', '128hr', '72hr', '48hr', '96hr'],
...     "value": [10, 20, 30, 40, 50]
... })
>>> df.sort_values(by="time",
...     key=lambda x: np.argsort(index_natsorted(df["time"])))
time  value
0    0hr   10
1   128hr  20
2    72hr  30
3    48hr  40
4    96hr  50
```

3.4. DataFrame
pandas.DataFrame.sparse

DataFrame.sparse()
DataFrame accessor for sparse data.
New in version 0.25.0.

pandas.DataFrame.squeeze

DataFrame.squeeze(axis=None)
Squeeze 1 dimensional axis objects into scalars.
Series or DataFrames with a single element are squeezed to a scalar. DataFrames with a single column or a single row are squeezed to a Series. Otherwise the object is unchanged.
This method is most useful when you don’t know if your object is a Series or DataFrame, but you do know it has just a single column. In that case you can safely call squeeze to ensure you have a Series.

Parameters
axis {{0 or ‘index’, 1 or ‘columns’, None}, default None} A specific axis to squeeze.
By default, all length-1 axes are squeezed.

Returns
DataFrame, Series, or scalar The projection after squeezing axis or all the axes.

See also:
Series.iloc Integer-location based indexing for selecting scalars.
DataFrame.iloc Integer-location based indexing for selecting Series.
Series.to_frame Inverse of DataFrame.squeeze for a single-column DataFrame.

Examples

```python
>>> primes = pd.Series([2, 3, 5, 7])
```

Slicing might produce a Series with a single value:

```python
>>> even_primes = primes[primes % 2 == 0]
```

```
0   2
dtype: int64
```

```python
>>> even_primes.squeeze()
```

```
2
```

Squeezing objects with more than one value in every axis does nothing:

```python
>>> odd_primes = primes[primes % 2 == 1]
```

```
1   3
2   5
3   7
dtype: int64
```
Squeezing is even more effective when used with DataFrames.

```python
gf = pd.DataFrame([[1, 2], [3, 4]], columns=['a', 'b'])
gf
   a  b
0  1  2
1  3  4
```

Slicing a single column will produce a DataFrame with the columns having only one value:

```python
df_a = gf[['a']]
df_a
    a
0  1
1  3
```

So the columns can be squeezed down, resulting in a Series:

```python
df_a.squeeze('columns')
0  1
1  3
Name: a, dtype: int64
```

Slicing a single row from a single column will produce a single scalar DataFrame:

```python
df_0a = gf.loc[gf.index < 1, ['a']]
df_0a
    a
0  1
```

Squeezing the rows produces a single scalar Series:

```python
df_0a.squeeze('rows')
a  1
Name: 0, dtype: int64
```

Squeezing all axes will project directly into a scalar:

```python
df_0a.squeeze()
1
```
**pandas.DataFrame.stack**

`DataFrame.stack(level=-1, dropna=True)`

Stack the prescribed level(s) from columns to index.

Return a reshaped DataFrame or Series having a multi-level index with one or more new inner-most levels compared to the current DataFrame. The new inner-most levels are created by pivoting the columns of the current dataframe:

- if the columns have a single level, the output is a Series;
- if the columns have multiple levels, the new index level(s) is (are) taken from the prescribed level(s) and the output is a DataFrame.

**Parameters**

- `level` [int, str, list, default -1] Level(s) to stack from the column axis onto the index axis, defined as one index or label, or a list of indices or labels.
- `dropna` [bool, default True] Whether to drop rows in the resulting Frame/Series with missing values. Stacking a column level onto the index axis can create combinations of index and column values that are missing from the original dataframe. See Examples section.

**Returns**

`DataFrame or Series` Stacked dataframe or series.

**See also:**

- `DataFrame.unstack` Unstack prescribed level(s) from index axis onto column axis.
- `DataFrame.pivot` Reshape dataframe from long format to wide format.
- `DataFrame.pivot_table` Create a spreadsheet-style pivot table as a DataFrame.

**Notes**

The function is named by analogy with a collection of books being reorganized from being side by side on a horizontal position (the columns of the dataframe) to being stacked vertically on top of each other (in the index of the dataframe).

**Examples**

**Single level columns**

```python
generate_code_table

>>> df_single_level_cols = pd.DataFrame([[0, 1], [2, 3]],
... index=['cat', 'dog'],
... columns=['weight', 'height'])
```

Stacking a dataframe with a single level column axis returns a Series:

```python
generate_code_table

>>> df_single_level_cols
   weight  height
  cat   0     1
  dog   2     3
```

```python
generate_code_table

>>> df_single_level_cols.stack()
```

(continues on next page)
Multi level columns: simple case

```python
>>> multicoll = pd.MultiIndex.from_tuples([('weight', 'kg'),
                                          ('weight', 'pounds')])
>>> df_multi_level_cols1 = pd.DataFrame([[1, 2], [2, 4]],
                                        index=['cat', 'dog'],
                                        columns=multicol1)
```

Stacking a dataframe with a multi-level column axis:

```python
>>> df_multi_level_cols1
    weight
cat    kg  1
      pounds  2
dog    kg  2
      pounds  4
```

```
>>> df_multi_level_cols1.stack()
    weight
cat    kg  1
      pounds  2
dog    kg  2
      pounds  4
```

Missing values

```python
>>> multicoll2 = pd.MultiIndex.from_tuples([('weight', 'kg'),
                                           ('height', 'm')])
>>> df_multi_level_cols2 = pd.DataFrame([[1.0, 2.0], [3.0, 4.0]],
                                       index=['cat', 'dog'],
                                       columns=multicol2)
```

It is common to have missing values when stacking a dataframe with multi-level columns, as the stacked dataframe typically has more values than the original dataframe. Missing values are filled with NaNs:

```python
>>> df_multi_level_cols2
    weight
cat    kg   1.0
      m   2.0
dog    kg   3.0
      m   4.0
```

```
>>> df_multi_level_cols2.stack()
    weight
cat    kg   NaN
      m   1.0
    height
cat    kg   NaN
      m   1.0
dog    kg   NaN
      m   3.0
```

Prescribing the level(s) to be stacked

The first parameter controls which level or levels are stacked:

```python
>>> df_multi_level_cols2.stack(0)
```
Dropping missing values

```python
>>> df_multi_level_cols3 = pd.DataFrame([[None, 1.0], [2.0, 3.0]],
... index=['cat', 'dog'],
... columns=multicol2)
```

Note that rows where all values are missing are dropped by default but this behaviour can be controlled via the dropna keyword parameter:

```python
>>> df_multi_level_cols3
weight height
kg m
cat NaN 1.0
dog 2.0 3.0

>>> df_multi_level_cols3.stack(dropna=False)
height weight
kg NaN NaN
cat NaN NaN
m 1.0 NaN

>>> df_multi_level_cols3.stack(dropna=True)
height weight
kg NaN NaN
cat m 1.0 NaN
dog kg NaN 2.0
m 3.0 NaN
```

**pandas.DataFrame.std**

DataFrame.std(axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)

Return sample standard deviation over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

**Parameters**

- **axis** : [index (0), columns (1)]
- **skipna** : [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **level** : [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **ddof** : [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
**numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

Series or DataFrame (if level specified)

**Notes**

To have the same behaviour as `numpy.std`, use `ddof=0` (instead of the default `ddof=1`)

**pandas.DataFrame.sub**

DataFrame.sub(other, axis='columns', level=None, fill_value=None)

Get Subtraction of dataframe and other, element-wise (binary operator sub).

Equivalent to `dataframe - other`, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, `rsub`.

Among flexible wrappers (`add, sub, mul, div, mod, pow`) to arithmetic operators: `+, -, *, /, //, %, **`

**Parameters**

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [[0 or 'index', 1 or 'columns']] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

**Returns**

DataFrame Result of the arithmetic operation.

**See also:**

*DataFrame.add* Add DataFrames.
*DataFrame.sub* Subtract DataFrames.
*DataFrame.mul* Multiply DataFrames.
*DataFrame.div* Divide DataFrames (float division).
*DataFrame.truediv* Divide DataFrames (float division).
*DataFrame.floordiv* Divide DataFrames (integer division).
*DataFrame.mod* Calculate modulo (remainder after division).
*DataFrame.pow* Calculate exponential power.
Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4], 'degrees': [360, 180, 360], index=['circle', 'triangle', 'rectangle'])
>>> df
    angles  degrees
  circle     0      360
  triangle   3      180
  rectangle  4      360

Add a scalar with operator version which return the same results.

```python
>>> df + 1
    angles  degrees
  circle     1      361
  triangle   4      181
  rectangle  5      361
```

```python
>>> df.add(1)
    angles  degrees
  circle     1      361
  triangle   4      181
  rectangle  5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
    angles  degrees
  circle   0.0      36.0
  triangle 0.3      18.0
  rectangle 0.4      36.0
```

```python
>>> df.rdiv(10)
    angles  degrees
  circle  inf      0.027778
  triangle 3.333333 0.055556
  rectangle 2.500000 0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
    angles  degrees
  circle   -1      358
  triangle   2      178
  rectangle   3      358
```

```python
>>> df.sub([1, 2], axis='columns')
    angles  degrees
  circle   -1      358
  triangle   2      178
  rectangle   3      358
```
Multiply a DataFrame of different shape with operator version.

```python
>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])
>>> other
angles
circle 0
triangle 3
rectangle 4

>>> df * other
angles degrees
circle 0 NaN
triangle 9 NaN
rectangle 16 NaN

>>> df.mul(other, fill_value=0)
angles degrees
circle 0 0.0
triangle 9 0.0
rectangle 16 0.0
```

Divide by a MultiIndex by level.

```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                               'degrees': [360, 180, 360, 360, 540, 720],
                               index=['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon'])
>>> df_multindex
angles degrees
circle 0 360
triangle 3 180
rectangle 4 360
square 4 360
pentagon 5 540
hexagon 6 720

>>> df.div(df_multindex, level=1, fill_value=0)
angles degrees
A circle NaN 1.0
triangle 1.0 1.0
rectangle 1.0 1.0
B square 0.0 0.0
pentagon 0.0 0.0
hexagon 0.0 0.0
```
pandas.DataFrame.subtract

DataFramesubtract(other, axis='columns', level=None, fill_value=None)

Get Subtraction of dataframe and other, element-wise (binary operator sub).

Equivalent to dataframe - other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rsub.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

Parameters

other [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.

axis [0 or 'index', 1 or 'columns'] Whether to compare by the index (0 or 'index') or columns (1 or 'columns'). For Series input, axis to match Series index on.

level [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.

fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

DataFrame.add Add DataFrames.
DataFrame.sub Subtract DataFrames.
DataFrame.mul Multiply DataFrames.
DataFrame.div Divide DataFrames (float division).
DataFrame.truediv Divide DataFrames (float division).
DataFrame.floordiv Divide DataFrames (integer division).
DataFrame.mod Calculate modulo (remainder after division).
DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.
Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...                   'degrees': [360, 180, 360],
...                   index=['circle', 'triangle', 'rectangle'])
>>> df
            angles  degrees
    circle     0      360
    triangle   3      180
    rectangle  4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
            angles  degrees
    circle      1      361
    triangle    4      181
    rectangle   5      361
```

```python
>>> df.add(1)
            angles  degrees
    circle      1      361
    triangle    4      181
    rectangle   5      361
```

Divide by constant with reverse version.

```python
>>> df.div(10)
            angles  degrees
    circle 0.0      36.0
    triangle 0.3      18.0
    rectangle 0.4      36.0
```

```python
>>> df.rdiv(10)
            angles  degrees
    circle inf      0.027778
    triangle 3.333333      0.055556
    rectangle 2.500000      0.027778
```

Subtract a list and Series by axis with operator version.

```python
>>> df - [1, 2]
            angles  degrees
    circle   -1      358
    triangle    2      178
    rectangle   3      358
```

```python
>>> df.sub([1, 2], axis='columns')
            angles  degrees
    circle   -1      358
    triangle    2      178
    rectangle   3      358
```

```python
>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
...         axis='index')
```

(continues on next page)
Multiply a DataFrame of different shape with operator version.

```python
other = pd.DataFrame({'angles': [0, 3, 4],
                      'degrees': [360, 180, 360, 360, 540, 720]},
                     index=['circle', 'triangle', 'rectangle',
                            'square', 'pentagon', 'hexagon'])
```

```python
>>> other
    angles  degrees
 circle   0       360
triangle  3       180
rectangle 4       360
```

```python
>>> df.mul(other, fill_value=0)
    angles  degrees
 circle    0.0        0.0
triangle   0.0        0.0
rectangle  0.0        0.0
```

Divide by a MultiIndex by level.

```python
df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
                             'degrees': [360, 180, 360, 360, 540, 720]},
                             index=['circle', 'triangle', 'rectangle',
                                    'square', 'pentagon', 'hexagon'])
```

```python
>>> df_multindex
    angles  degrees
 A circle    0       360
 triangle    3       180
 rectangle   4       360
 B square    4       360
 pentagon    5       540
 hexagon     6       720
```

```python
>>> df.div(df_multindex, level=1, fill_value=0)
    angles  degrees
 A circle   NaN        1.0
 triangle   1.0        1.0
 rectangle  1.0        1.0
 B square   0.0        0.0
 pentagon   0.0        0.0
 hexagon    0.0        0.0
```
**DataFrame.sum**

DataFrame.sum(axis=None, skipna=None, level=None, numeric_only=None, min_count=0, **kwargs)

Return the sum of the values over the requested axis.

This is equivalent to the method `numpy.sum`.

**Parameters**

- **axis** [(index (0), columns (1))] Axis for the function to be applied on.
- **skipna** [bool, default True] Exclude NA/null values when computing the result.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.
- **min_count** [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.
- **kwargs** Additional keyword arguments to be passed to the function.

**Returns**

- Series or DataFrame (if level specified)

See also:

- `Series.sum` Return the sum.
- `Series.min` Return the minimum.
- `Series.max` Return the maximum.
- `Series.idxmin` Return the index of the minimum.
- `Series.idxmax` Return the index of the maximum.
- `DataFrame.sum` Return the sum over the requested axis.
- `DataFrame.min` Return the minimum over the requested axis.
- `DataFrame.max` Return the maximum over the requested axis.
- `DataFrame.idxmin` Return the index of the minimum over the requested axis.
- `DataFrame.idxmax` Return the index of the maximum over the requested axis.

**Examples**

```python
>>> idx = pd.MultiIndex.from_arrays([
...     ['warm', 'warm', 'cold', 'cold'],
...     ['dog', 'falcon', 'fish', 'spider']],
...     names=['blooded', 'animal'])
>>> s = pd.Series([4, 2, 0, 8], name='legs', index=idx)
>>> s
blooded  animal
  warm  dog  4
```

(continues on next page)
falcon  2
cold  fish  0
spider  8
Name: legs, dtype: int64

>>> s.sum()
14

By default, the sum of an empty or all-NA Series is 0.

>>> pd.Series([], dtype="float64").sum()  # min_count=0 is the default
0.0

This can be controlled with the `min_count` parameter. For example, if you’d like the sum of an empty series to be NaN, pass `min_count=1`.

>>> pd.Series([], dtype="float64").sum(min_count=1)
nan

Thanks to the `skipna` parameter, `min_count` handles all-NA and empty series identically.

>>> pd.Series([np.nan]).sum()
0.0

>>> pd.Series([np.nan]).sum(min_count=1)
nan

**pandas.DataFrame.swapaxes**

DataFrame.swapaxes(axis1, axis2, copy=True)
Interchange axes and swap values axes appropriately.

Returns
y [same as input]

**pandas.DataFrame.swaplevel**

DataFrame.swaplevel(i=-2, j=-1, axis=0)
Swap levels i and j in a MultiIndex.
Default is to swap the two innermost levels of the index.

Parameters
i, j [int or str] Levels of the indices to be swapped. Can pass level name as string.
axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to swap levels on. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.

Returns
DataFrame DataFrame with levels swapped in MultiIndex.
Examples

```python
>>> df = pd.DataFrame(
...    {"Grade": ["A", "B", "A", "C"],
...     index=[
...         ["Final exam", "Final exam", "Coursework", "Coursework"],
...         ["History", "Geography", "History", "Geography"],
...         ["January", "February", "March", "April"],
...     ]
...    ),
...)

>>> df

Grade
Final exam History January A
Geography February B
Coursework History March A
Geography April C

In the following example, we will swap the levels of the indices. Here, we will swap the levels column-wise, but levels can be swapped row-wise in a similar manner. Note that column-wise is the default behaviour. By not supplying any arguments for i and j, we swap the last and second to last indices.

```python
>>> df.swaplevel()

Grade
Final exam January History A
February Geography B
Coursework March History A
April Geography C
```

By supplying one argument, we can choose which index to swap the last index with. We can for example swap the first index with the last one as follows.

```python
>>> df.swaplevel(0)

Grade
January History Final exam A
February Geography Final exam B
March History Coursework A
April Geography Coursework C
```

We can also define explicitly which indices we want to swap by supplying values for both i and j. Here, we for example swap the first and second indices.

```python
>>> df.swaplevel(0, 1)

Grade
History Final exam January A
Geography Final exam February B
Coursework March A
Geography Coursework April C
```
pandas.DataFrame.tail

DataFrame.tail(n=5)
Return the last n rows.

This function returns last n rows from the object based on position. It is useful for quickly verifying data, for example, after sorting or appending rows.

For negative values of n, this function returns all rows except the first n rows, equivalent to df[n:].

Parameters

n [int, default 5] Number of rows to select.

Returns

type of caller The last n rows of the caller object.

See also:

DataFrame.head The first n rows of the caller object.

Examples

>>> df = pd.DataFrame({'animal': ['alligator', 'bee', 'falcon', 'lion', ...
                                'monkey', 'parrot', 'shark', 'whale', 'zebra']})
>>> df
   animal
0  alligator
1     bee
2  falcon
3     lion
4  monkey
5    parrot
6   shark
7   whale
8   zebra

Viewing the last 5 lines

>>> df.tail()
   animal
4  monkey
5    parrot
6   shark
7   whale
8   zebra

Viewing the last n lines (three in this case)

>>> df.tail(3)
   animal
6   shark
7   whale
8   zebra

For negative values of n
pandas.DataFrame.take

DataFrame.take(indices, axis=0, is_copy=None, **kwargs)

Return the elements in the given positional indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

Parameters

- indices [array-like] An array of ints indicating which positions to take.
- axis [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements. 0 means that we are selecting rows, 1 means that we are selecting columns.
- is_copy [bool] Before pandas 1.0, is_copy=False can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, take always returns a copy, and the keyword is therefore deprecated.

Deprecated since version 1.0.0.

**kwargs For compatibility with numpy.take(). Has no effect on the output.

Returns

taken [same type as caller] An array-like containing the elements taken from the object.

See also:

DataFrame.loc Select a subset of a DataFrame by labels.
DataFrame.iloc Select a subset of a DataFrame by positions.
numpy.take Take elements from an array along an axis.

Examples

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                    ('parrot', 'bird', 24.0),
...                    ('lion', 'mammal', 80.5),
...                    ('monkey', 'mammal', np.nan)],
...                   columns=['name', 'class', 'max_speed'],
...                   index=[0, 2, 3, 1])
>>> df
  name    class  max_speed
0  falcon   bird     389.0
1  parrot   bird      24.0
2   lion  mammal      80.5
3 monkey  mammal       NaN
```
Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That’s because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```python
>>> df.take([0, 3])
   name  class   max_speed
0  falcon  bird       389.0
1  monkey  mammal       NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).

```python
>>> df.take([1, 2], axis=1)
     class   max_speed
0     bird       389.0
1     bird       24.0
2  mammal       80.5
3  mammal       NaN
```

We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```python
>>> df.take([-1, -2])
   name  class   max_speed
1  monkey  mammal       NaN
3    lion  mammal       80.5
```

**pandas.DataFrame.to_dict**

DataFrame.to_dict (orient='dict', into=<class 'dict'>) Convert the DataFrame to a dictionary.

The type of the key-value pairs can be customized with the parameters (see below).

**Parameters**

- **orient** [str {'dict', 'list', 'series', 'split', 'records', 'index'}] Determines the type of the values of the dictionary.
  - 'dict' (default) : dict like {column -> {index -> value}}
  - 'list' : dict like {column -> [values]}
  - 'series' : dict like {column -> Series(values)}
  - 'split' : dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
  - 'records' : list like [{column -> value}, . . . , {column -> value}]
  - 'index' : dict like {index -> {column -> value}}

Abbreviations are allowed. s indicates series and sp indicates split.

- **into** [class, default dict] The collections.abc.Mapping subclass used for all Mappings in the return value. Can be the actual class or an empty instance of the mapping type you want. If you want a collections.defaultdict, you must pass it initialized.

**Returns**
dict, list or collections.abc.Mapping  Return a collections.abc.Mapping object representing the DataFrame. The resulting transformation depends on the `orient` parameter.

See also:

**DataFrame.from_dict**  Create a DataFrame from a dictionary.

**DataFrame.to_json**  Convert a DataFrame to JSON format.

Examples

```python
>>> df = pd.DataFrame({'col1': [1, 2],
... 'col2': [0.5, 0.75]},
... index=['row1', 'row2'])
>>> df
col1  col2
row1   1  0.50
row2   2  0.75

You can specify the return orientation.

```python
>>> df = pd.DataFrame({'col1': [1, 2],
... 'col2': [0.5, 0.75]},
... index=['row1', 'row2'])
>>> df
col1  col2
row1   1  0.50
row2   2  0.75

```python
>>> df = pd.DataFrame({'col1': [1, 2],
... 'col2': [0.5, 0.75]},
... index=['row1', 'row2'])
>>> df
col1  col2
row1   1  0.50
row2   2  0.75

You can also specify the mapping type.

```python
>>> from collections import OrderedDict, defaultdict

```python

If you want a `defaultdict`, you need to initialize it:

```python
>>> dd = defaultdict(list)
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.DataFrame.to_gbq

DataFrame.to_gbq(destination_table, project_id=None, chunksize=None, reauth=False, if_exists='fail', auth_local_webserver=False, table_schema=None, location=None, progress_bar=True, credentials=None)

Write a DataFrame to a Google BigQuery table.

This function requires the pandas-gbq package.

See the How to authenticate with Google BigQuery guide for authentication instructions.

Parameters

destination_table [str] Name of table to be written, in the form datasettablename.

project_id [str, optional] Google BigQuery Account project ID. Optional when available from the environment.

chunksize [int, optional] Number of rows to be inserted in each chunk from the dataframe. Set to None to load the whole dataframe at once.

reauth [bool, default False] Force Google BigQuery to re-authenticate the user. This is useful if multiple accounts are used.

if_exists [str, default ‘fail’] Behavior when the destination table exists. Value can be one of:

'fail' If table exists raise pandas_gbq.gbq.TableCreationError.
'replace' If table exists, drop it, recreate it, and insert data.
'append' If table exists, insert data. Create if does not exist.

auth_local_webserver [bool, default False] Use the local webserver flow instead of the console flow when getting user credentials.

New in version 0.2.0 of pandas-gbq.

table_schema [list of dicts, optional] List of BigQuery table fields to which according DataFrame columns conform to, e.g. [{‘name’: ‘col1’, ‘type’: ‘STRING’},...]. If schema is not provided, it will be generated according to dtypes of DataFrame columns. See BigQuery API documentation on available names of a field.

New in version 0.3.1 of pandas-gbq.

location [str, optional] Location where the load job should run. See the BigQuery locations documentation for a list of available locations. The location must match that of the target dataset.

New in version 0.5.0 of pandas-gbq.

progress_bar [bool, default True] Use the library tqdm to show the progress bar for the upload, chunk by chunk.

New in version 0.5.0 of pandas-gbq.

credentials [google.auth.credentials.Credentials, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine google.auth.compute_engine.Credentials or Service Account google.oauth2.service_account.Credentials directly.
New in version 0.8.0 of pandas-gbq.

See also:

- pandas_gbq.to_gbq: This function in the pandas-gbq library.
- read_gbq: Read a DataFrame from Google BigQuery.

### pandas.DataFrame.to_hdf

DataFrame.to_hdf(path_or_buf, key, mode='a', complevel=None, complib=None, append=False, format=None, index=True, min_itemsize=None, nan_rep=None, dropna=None, data_columns=None, errors='strict', encoding='UTF-8')

Write the contained data to an HDF5 file using HDFStore.

Hierarchical Data Format (HDF) is self-describing, allowing an application to interpret the structure and contents of a file with no outside information. One HDF file can hold a mix of related objects which can be accessed as a group or as individual objects.

In order to add another DataFrame or Series to an existing HDF file please use append mode and a different key.

**Warning:** One can store a subclass of DataFrame or Series to HDF5, but the type of the subclass is lost upon storing.

For more information see the user guide.

**Parameters**

- **path_or_buf** [str or pandas.HDFStore] File path or HDFStore object.
- **key** [str] Identifier for the group in the store.
- **mode** [‘a’, ‘w’, ‘r+’], default ‘a’ Mode to open file:
  - ‘w’: write, a new file is created (an existing file with the same name would be deleted).
  - ‘a’: append, an existing file is opened for reading and writing, and if the file does not exist it is created.
  - ‘r+’: similar to ‘a’, but the file must already exist.
- **complevel** [0-9], optional] Specifies a compression level for data. A value of 0 disables compression.
- **append** [bool, default False] For Table formats, append the input data to the existing.
- **format** ['fixed', 'table', None], default ‘fixed’] Possible values:
• `table`: Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.

• If None, pd.get_option(‘io.hdf.default_format’) is checked, followed by fallback to “fixed”

**errors** [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

**encoding** [str, default “UTF-8”]

**min_itemsize** [dict or int, optional] Map column names to minimum string sizes for columns.

**nan_rep** [Any, optional] How to represent null values as str. Not allowed with append=True.

**data_columns** [list of columns or True, optional] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See Query via data columns. Applicable only to format=’table’.

See also:

read_hdf Read from HDF file.

DataFrame.to_parquet Write a DataFrame to the binary parquet format.

DataFrame.to_sql Write to a SQL table.

DataFrame.to_feather Write out feather-format for DataFrames.

DataFrame.to_csv Write out to a csv file.

Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]},
...                     index=['a', 'b', 'c'])
>>> df.to_hdf('data.h5', key='df', mode='w')
```

We can add another object to the same file:

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.to_hdf('data.h5', key='s')
```

Reading from HDF file:

```python
>>> pd.read_hdf('data.h5', 'df')
A   B
a 1  4
b 2  5
c 3  6
```

```python
>>> pd.read_hdf('data.h5', 's')
0 1
1 2
2 3
3 4
dtype: int64
```
Deleting file with data:

```python
>>> import os
>>> os.remove('data.h5')
```

**pandas.DataFrame.to_json**

DataFrame.to_json(path_or_buf=None, orient=None, date_format=None, double_precision=10, force_ascii=True, date_unit='ms', default_handler=None, lines=False, compression='infer', index=True, indent=None, storage_options=None)

Convert the object to a JSON string.

Note NaN’s and None will be converted to null and datetime objects will be converted to UNIX timestamps.

**Parameters**

- **path_or_buf** [str or file handle, optional] File path or object. If not specified, the result is returned as a string.
- **orient** [str] Indication of expected JSON string format.
  - Series:
    - default is ‘index’
    - allowed values are: {'split', 'records', 'index', 'table'}.
  - DataFrame:
    - default is ‘columns’
    - allowed values are: {'split', 'records', 'index', 'columns', 'values', 'table'}.
  - The format of the JSON string:
    - ‘split’: dict like {'index' -> [index], 'columns' -> [columns], 'data' -> [values]}
    - ‘records’: list like [{column -> value}, . . . , {column -> value}]
    - ‘index’: dict like {index -> {column -> value}}
    - ‘columns’: dict like {column -> {index -> value}}
    - ‘values’: just the values array
    - ‘table’: dict like {'schema': {schema}, 'data': {data}}

Describing the data, where data component is like orient='records'.

- **date_format** [{None, ‘epoch’, ‘iso’}] Type of date conversion. ‘epoch’ = epoch milliseconds, ‘iso’ = ISO8601. The default depends on the orient. For orient='table', the default is ‘iso’. For all other orient, the default is ‘epoch’.
- **double_precision** [int, default 10] The number of decimal places to use when encoding floating point values.
- **force_ascii** [bool, default True] Force encoded string to be ASCII.
**date_unit** [str, default ‘ms’ (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’, ‘ns’ for second, millisecond, microsecond, and nanosecond respectively.

**default_handler** [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

**lines** [bool, default False] If ‘orient’ is ‘records’ write out line-delimited json format. Will throw ValueError if incorrect ‘orient’ since others are not list-like.

**compression** [{‘infer’, ‘gzip’, ‘bz2’, ‘zip’, ‘xz’, None}] A string representing the compression to use in the output file, only used when the first argument is a filename. By default, the compression is inferred from the filename.

**index** [bool, default True] Whether to include the index values in the JSON string. Not including the index (index=False) is only supported when orient is ‘split’ or ‘table’.

**indent** [int, optional] Length of whitespace used to indent each record. New in version 1.0.0.

**storage_options** [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details. New in version 1.2.0.

**Returns**

None or str If path_or_buf is None, returns the resulting json format as a string. Otherwise returns None.

**See also:**

read_json Convert a JSON string to pandas object.

**Notes**

The behavior of indent=0 varies from the stdlib, which does not indent the output but does insert newlines. Currently, indent=0 and the default indent=None are equivalent in pandas, though this may change in a future release.

orient='table' contains a ‘pandas_version’ field under ‘schema’. This stores the version of pandas used in the latest revision of the schema.
Examples

```python
>>> import json

>>> df = pd.DataFrame(
...     [["a", "b"], ["c", "d"],
...     index=["row 1", "row 2"],
...     columns=["col 1", "col 2"],
...     )

>>> result = df.to_json(orient="split")
>>> parsed = json.loads(result)
>>>
>>> json.dumps(parsed, indent=4)
{
    "columns": [
        "col 1",
        "col 2"
    ],
    "index": [
        "row 1",
        "row 2"
    ],
    "data": [
        ["a",
         "b"],
        ["c",
         "d"
    ]
}
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```python
>>> result = df.to_json(orient="records")
>>> parsed = json.loads(result)
>>>
>>> json.dumps(parsed, indent=4)
[{
    "col 1": "a",
    "col 2": "b"
},
{
    "col 1": "c",
    "col 2": "d"
}
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```python
>>> result = df.to_json(orient="index")
>>> parsed = json.loads(result)
>>>
>>> json.dumps(parsed, indent=4)
{
    "row 1": {
... (continues on next page)
Encoding/decoding a Dataframe using 'columns' formatted JSON:

```python
>>> result = df.to_json(orient="columns")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
  "col 1": {
    "row 1": "a",
    "row 2": "c"
  },
  "col 2": {
    "row 1": "b",
    "row 2": "d"
  }
}
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```python
>>> result = df.to_json(orient="values")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[ [ "a", "b" ],
  [ "c", "d" ]
]
```

Encoding with Table Schema:

```python
>>> result = df.to_json(orient="table")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{ "schema": {
  "fields": [
  { "name": "index", "type": "string" },
  { "name": "col 1", "type": "string" }
  ],
  "type": "array" }]
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

{  
  "name": "col 2",
  "type": "string"
},
"primaryKey": [
  "index"
],
"pandas_version": "0.20.0"
},
"data": [
  {
    "index": "row 1",
    "col 1": "a",
    "col 2": "b"
  },
  {
    "index": "row 2",
    "col 1": "c",
    "col 2": "d"
  }
]
}

pandas.DataFrame.to_markdown

**DataFrame.to_markdown** *(buf=None, mode='wt', index=True, storage_options=None, **kwargs)*

Print DataFrame in Markdown-friendly format.

New in version 1.0.0.

**Parameters**

*buf* [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

*mode* [str, optional] Mode in which file is opened, “wt” by default.

*index* [bool, optional, default True] Add index (row) labels.

New in version 1.1.0.

*storage_options* [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

New in version 1.2.0.

**kwargs** These parameters will be passed to tabulate.

**Returns**

*str* DataFrame in Markdown-friendly format.
**Notes**

Requires the `tabulate` package.

**Examples**

```python
>>> s = pd.Series(["elk", "pig", "dog", "quetzal"], name="animal")
>>> print(s.to_markdown())
<table>
<thead>
<tr>
<th></th>
<th>animal</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>elk</td>
</tr>
<tr>
<td>1</td>
<td>pig</td>
</tr>
<tr>
<td>2</td>
<td>dog</td>
</tr>
<tr>
<td>3</td>
<td>quetzal</td>
</tr>
</tbody>
</table>
```

Output markdown with a tabulate option.

```python
>>> print(s.to_markdown(tablefmt="grid"))
+----+----------+
|    | animal   |
|----+----------+
| 0  | elk      |
|----+----------+
| 1  | pig      |
|----+----------+
| 2  | dog      |
|----+----------+
| 3  | quetzal  |
```

**pandas.DataFrame.to_numpy**

`DataFrame.to_numpy(dtype=None, copy=False, na_value=<no_default>)`  
Convert the DataFrame to a NumPy array.

By default, the dtype of the returned array will be the common NumPy dtype of all types in the DataFrame. For example, if the dtypes are `float16` and `float32`, the results dtype will be `float32`. This may require copying data and coercing values, which may be expensive.

**Parameters**

- `dtype` [str or numpy.dtype, optional] The dtype to pass to `numpy.asarray()`.
- `copy` [bool, default False] Whether to ensure that the returned value is not a view on another array. Note that `copy=False` does not ensure that `to_numpy()` is no-copy. Rather, `copy=True` ensure that a copy is made, even if not strictly necessary.
- `na_value` [Any, optional] The value to use for missing values. The default value depends on `dtype` and the dtypes of the DataFrame columns.

New in version 1.1.0.

**Returns**

- `numpy.ndarray`

**See also**

numpy.ndarray
**Series.to_numpy** Similar method for Series.

**Examples**

```python
code=
>>> pd.DataFrame({'A': [1, 2], 'B': [3, 4]}).to_numpy()
array([[1, 3],
       [2, 4]])
```

With heterogeneous data, the lowest common type will have to be used.

```python
code=
>>> df = pd.DataFrame({'A': [1, 2], 'B': [3.0, 4.5]})
>>> df.to_numpy()
array([[1., 3.],
       [2., 4.5]])
```

For a mix of numeric and non-numeric types, the output array will have object dtype.

```python
code=
>>> df['C'] = pd.date_range('2000', periods=2)
>>> df.to_numpy()
array([[1, 3.0, Timestamp('2000-01-01 00:00:00')],
       [2, 4.5, Timestamp('2000-01-02 00:00:00')]], dtype=object)
```

**pandas.DataFrame.to_period**

DataFrame.to_period(freq=None, axis=0, copy=True)
Convert DataFrame from DatetimeIndex to PeriodIndex.
Convert DataFrame from DatetimeIndex to PeriodIndex with desired frequency (inferred from index if not passed).

- **Parameters**
  - `freq` [str, default] Frequency of the PeriodIndex.
  - `axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to convert (the index by default).
  - `copy` [bool, default True] If False then underlying input data is not copied.

- **Returns**
  - DataFrame with PeriodIndex

**pandas.DataFrame.to_records**

DataFrame.to_records(index=True, column_dtypes=None, index_dtypes=None)
Convert DataFrame to a NumPy record array.
Index will be included as the first field of the record array if requested.

- **Parameters**
  - `index` [bool, default True] Include index in resulting record array, stored in ‘index’ field or using the index label, if set.
**column_dtypes** [str, type, dict, default None] If a string or type, the data type to store all columns. If a dictionary, a mapping of column names and indices (zero-indexed) to specific data types.

**index_dtypes** [str, type, dict, default None] If a string or type, the data type to store all index levels. If a dictionary, a mapping of index level names and indices (zero-indexed) to specific data types.

This mapping is applied only if `index=True`.

**Returns**

numpy.recarray NumPy ndarray with the DataFrame labels as fields and each row of the DataFrame as entries.

See also:

*DataFrame.from_records* Convert structured or record ndarray to DataFrame.

numpy.recarray An ndarray that allows field access using attributes, analogous to typed columns in a spreadsheet.

**Examples**

```python
>>> df = pd.DataFrame({'A': [1, 2], 'B': [0.5, 0.75]},
                     index=['a', 'b'])
>>> df
   A  B
a  1  0.50
b  2  0.75
>>> df.to_records()  # default is that the index does not have a label
rec.array([(b'a', 1), (b'b', 2)],
          dtype=[(b'A', '<i8'), (b'B', '<f8')])
```

If the DataFrame index has no label then the recarray field name is set to ‘index’. If the index has a label then this is used as the field name:

```python
>>> df.index = df.index.rename("I")
>>> df.to_records()  # the recarray field name is set to 'I'
rec.array([(b'a', 1), (b'b', 2)],
          dtype=[(b'I', '<i8'), (b'A', '<i8'), (b'B', '<f8')])
```

The index can be excluded from the record array:

```python
>>> df.to_records(index=False)  # excludes the index
rec.array([(1, 0.5), (2, 0.75)],
          dtype=[(b'A', '<i8'), (b'B', '<f8')])
```

Data types can be specified for the columns:

```python
>>> df.to_records(column_dtypes={"A": "int32"})
rec.array([(b'a', 1), (b'b', 2)],
          dtype=[(b'I', '<i8'), (b'A', '<i8'), (b'B', '<f8')])
```

As well as for the index:
```python
>>> df.to_records(index_dtypes="<S2")
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
          dtype=[('I', 'S2'), ('A', '<i8'), ('B', '<f8')])

>>> index_dtypes = f"<S{df.index.str.len().max()}/"
>>> df.to_records(index_dtypes=index_dtypes)
rec.array([(b'a', 1, 0.5 ), (b'b', 2, 0.75)],
          dtype=[('I', 'S1'), ('A', '<i8'), ('B', '<f8')])
```

**pandas.DataFrame.to_string**

DataFrame.to_string(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN', formatters=None, float_format=None, sparsify=None, index_names=True, justify=None, max_rows=None, min_rows=None, max_cols=None, show_dimensions=False, decimal='.', line_width=None, max_colwidth=None, encoding=None)

Render a DataFrame to a console-friendly tabular output.

**Parameters**

- **buf** [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.
- **columns** [sequence, optional, default None] The subset of columns to write. Writes all columns by default.
- **col_space** [int, list or dict of int, optional] The minimum width of each column.
- **header** [bool or sequence, optional] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.
- **index** [bool, optional, default True] Whether to print index (row) labels.
- **na_rep** [str, optional, default ‘NaN’] String representation of NaN to use.
- **formatters** [list, tuple or dict of one-param. functions, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List/tuple must be of length equal to the number of columns.
- **float_format** [one-parameter function, optional, default None] Formatter function to apply to columns’ elements if they are floats. This function must return a unicode string and will be applied only to the non-NaN elements, with NaN being handled by `na_rep`.

Changed in version 1.2.0.
- **sparsify** [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.
- **index_names** [bool, optional, default True] Prints the names of the indexes.
- **justify** [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by set_option), ‘right’ out of the box. Valid values are
  - left
  - right
  - center
• justify
• justify-all
• start
• end
• inherit
• match-parent
• initial
• unset.

max_rows  [int, optional] Maximum number of rows to display in the console.

min_rows  [int, optional] The number of rows to display in the console in a truncated
    repr (when number of rows is above max_rows).

max_cols  [int, optional] Maximum number of columns to display in the console.

show_dimensions  [bool, default False] Display DataFrame dimensions (number of
    rows by number of columns).

decimal  [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

line_width  [int, optional] Width to wrap a line in characters.

max_colwidth  [int, optional] Max width to truncate each column in characters. By
    default, no limit.

    New in version 1.0.0.

ingcoding  [str, default “utf-8”] Set character encoding.

    New in version 1.0.

Returns

str or None  If buf is None, returns the result as a string. Otherwise returns None.

See also:

to_html  Convert DataFrame to HTML.

Examples

```python
>>> d = {‘col1’: [1, 2, 3], ‘col2’: [4, 5, 6]}
>>> df = pd.DataFrame(d)
>>> print(df.to_string())
coll  col2
0    1    4
1    2    5
2    3    6
```
pandas.DataFrame.to_timestamp

DataFrame.to_timestamp (freq=None, how='start', axis=0, copy=True)  
Cast to DatetimeIndex of timestamps, at beginning of period.

Parameters

freq [str, default frequency of PeriodIndex] Desired frequency.

how [[‘s’, ‘e’, ‘start’, ‘end’]] Convention for converting period to timestamp; start of period vs. end.

axis [[0 or ‘index’, 1 or ‘columns’], default 0] The axis to convert (the index by default).

copy [bool, default True] If False then underlying input data is not copied.

Returns

DataFrame with DatetimeIndex

pandas.DataFrame.to_xarray

DataFrame.to_xarray ()
Return an xarray object from the pandas object.

Returns

xarray.DataArray or xarray.Dataset Data in the pandas structure converted to Dataset if the object is a DataFrame, or a DataArray if the object is a Series.

See also:

DataFrame.to_hdf Write DataFrame to an HDF5 file.
DataFrame.to_parquet Write a DataFrame to the binary parquet format.

Notes

See the xarray docs

Examples

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0, 2),
...                    ('parrot', 'bird', 24.0, 2),
...                    ('lion', 'mammal', 80.5, 4),
...                    ('monkey', 'mammal', np.nan, 4)],
...                   columns=['name', 'class', 'max_speed', 'num_legs'])
>>> df
     name   class  max_speed  num_legs
0  falcon   bird     389.0          2
1  parrot   bird      24.0          2
2   lion  mammal      80.5          4
3 monkey  mammal    nan          4
```
>>> df.to_xarray()
<xarray.Dataset>
Dimensions:  (index: 4)
Coordinates:
* index   (index) int64 0 1 2 3
Data variables:
    name   (index) object 'falcon' 'parrot' 'lion' 'monkey'
    class  (index) object 'bird' 'bird' 'mammal' 'mammal'
    max_speed  (index) float64 389.0 24.0 80.5 nan
    num_legs (index) int64 2 2 4 4

>>> df['max_speed'].to_xarray()
<xarray.DataArray 'max_speed' (index: 4)>
array([389., 24., 80.5, nan])
Coordinates:
* index   (index) int64 0 1 2 3

>>> dates = pd.to_datetime(['2018-01-01', '2018-01-01',
                          '2018-01-02', '2018-01-02'])
>>> df_multiindex = pd.DataFrame({'date': dates,
                                ...   'animal': ['falcon', 'parrot',
                                ...              'falcon', 'parrot'],
                                ...   'speed': [350, 18, 361, 15]})
>>> df_multiindex = df_multiindex.set_index(['date', 'animal'])

>>> df_multiindex
                  speed
    date  animal
2018-01-01  falcon       350
          parrot       18
2018-01-02  falcon       361
          parrot       15

>>> df_multiindex.to_xarray()
<xarray.Dataset>
Dimensions:  (animal: 2, date: 2)
Coordinates:
* date   (date) datetime64[ns] 2018-01-01 2018-01-02
* animal (animal) object 'falcon' 'parrot'
Data variables:
    speed  (date, animal) int64 350 18 361 15

**pandas.DataFrame.transform**

DataFrame.transform(func, axis=0, *args, **kwargs)

Call func on self producing a DataFrame with transformed values.

Produced DataFrame will have same axis length as self.

**Parameters**

- func [function, str, list-like or dict-like] Function to use for transforming the data.
  If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.
  If func is both list-like and dict-like, dict-like behavior takes precedence.
Accepted combinations are:

- function
- string function name
- list-like of functions and/or function names, e.g. `[np.exp, 'sqrt']`
- dict-like of axis labels -> functions, function names or list-like of such.

**axis** [[0 or 'index', 1 or 'columns'], default 0] If 0 or 'index': apply function to each column. If 1 or 'columns': apply function to each row.

**args** Positional arguments to pass to `func`.

**kwargs** Keyword arguments to pass to `func`.

**Returns**

- **DataFrame** A DataFrame that must have the same length as self.

**Raises**

- **ValueError** [If the returned DataFrame has a different length than self.]

**See also:**

- **DataFrame.agg** Only perform aggregating type operations.
- **DataFrame.apply** Invoke function on a DataFrame.

**Notes**

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

**Examples**

```python
>>> df = pd.DataFrame({'A': range(3), 'B': range(1, 4)})
>>> df
   A  B
0  0  1
1  1  2
2  2  3
>>> df.transform(lambda x: x + 1)
   A  B
0  1  2
1  2  3
2  3  4
```

Even though the resulting DataFrame must have the same length as the input DataFrame, it is possible to provide several input functions:

```python
>>> s = pd.Series(range(3))
>>> s
0  0
1  1
2  2
dtype: int64
>>> s.transform([np.sqrt, np.exp])
```

(continues on next page)
You can call transform on a GroupBy object:

```python
>>> df = pd.DataFrame({
...     "Date": [
...     "Data": [5, 8, 6, 1, 50, 100, 60, 120],
... })

>>> df
Date  Data
0  2015-05-08  5
1  2015-05-07  8
2  2015-05-06  6
3  2015-05-05  1
4  2015-05-08  50
5  2015-05-07  100
6  2015-05-06  60
7  2015-05-05  120

>>> df.groupby('Date')['Data'].transform('sum')
0   55
1  108
2   66
3  121
4   55
5  108
6   66
7  121
Name: Data, dtype: int64
```

```python
>>> df = pd.DataFrame({
...     "c": [1, 1, 1, 2, 2, 2, 2],
...     "type": ["m", "n", "o", "m", "m", "n", "n"]
... })

>>> df
     c  type
0     1   m
1     1   n
2     1   o
3     2   m
4     2   m
5     2   n
6     2   n

>>> df['size'] = df.groupby('c')['type'].transform(len)

>>> df
     c  type  size
0     1   m    3
1     1   n    3
2     1   o    3
3     2   m    4
4     2   m    4
5     2   n    4
6     2   n    4
```
**pandas.DataFrame.transpose**

```python
DataFrame.transpose(*args, copy=False)
```

Transpose index and columns.

Reflect the DataFrame over its main diagonal by writing rows as columns and vice-versa. The property $T$ is an accessor to the method `transpose()`.

**Parameters**

- `*args` [tuple, optional] Accepted for compatibility with NumPy.
- `copy` [bool, default False] Whether to copy the data after transposing, even for DataFrames with a single dtype.

Note that a copy is always required for mixed dtype DataFrames, or for DataFrames with any extension types.

**Returns**

`DataFrame` The transposed DataFrame.

**See also:**

- `numpy.transpose` Permute the dimensions of a given array.

**Notes**

Transposing a DataFrame with mixed dtypes will result in a homogeneous DataFrame with the `object` dtype. In such a case, a copy of the data is always made.

**Examples**

**Square DataFrame with homogeneous dtype**

```python
>>> d1 = {'col1': [1, 2], 'col2': [3, 4]}
>>> df1 = pd.DataFrame(data=d1)
>>> df1
   col1 col2
0    1    3
1    2    4
```

```python
>>> df1_transposed = df1.T  # or df1.transpose()
>>> df1_transposed
     0
col1  1
col2  3
```

When the dtype is homogeneous in the original DataFrame, we get a transposed DataFrame with the same dtype:

```python
>>> df1.dtypes
col1    int64
col2    int64
dtype: object
```

```python
>>> df1_transposed.dtypes
0    int64
```

(continues on next page)
Non-square DataFrame with mixed dtypes

```python
>>> d2 = {'name': ['Alice', 'Bob'],
...       'score': [9.5, 8],
...       'employed': [False, True],
...       'kids': [0, 0]}
>>> df2 = pd.DataFrame(data=d2)
>>> df2
   name  score employed  kids
0  Alice   9.5      False   0
1    Bob    8.0       True   0
```

```python
>>> df2_transposed = df2.T  # or df2.transpose()
>>> df2_transposed
   0  1
name Alice  Bob
score   9.5  8.0
employed  False  True
kids  0  0
```

When the DataFrame has mixed dtypes, we get a transposed DataFrame with the `object` dtype:

```python
>>> df2.dtypes
name    object
score  float64
employed  bool
kids   int64
dtype: object
```

```python
>>> df2_transposed.dtypes
0    object
1    object
dtype: object
```

**pandas.DataFrame.truediv**

DataFrame.

**truediv**(other, axis='columns', level=None, fill_value=None)

Get Floating division of dataframe and other, element-wise (binary operator truediv).

Equivalent to dataframe / other, but with support to substitute a fill_value for missing data in one of the inputs. With reverse version, rtruediv.

Among flexible wrappers (add, sub, mul, div, mod, pow) to arithmetic operators: +, -, *, /, //, %, **.

**Parameters**

- **other** [scalar, sequence, Series, or DataFrame] Any single or multiple element data structure, or list-like object.
- **axis** [{0 or ‘index’, 1 or ‘columns’}] Whether to compare by the index (0 or ‘index’) or columns (1 or ‘columns’). For Series input, axis to match Series index on.
- **level** [int or label] Broadcast across a level, matching Index values on the passed MultiIndex level.
fill_value [float or None, default None] Fill existing missing (NaN) values, and any new element needed for successful DataFrame alignment, with this value before computation. If data in both corresponding DataFrame locations is missing the result will be missing.

Returns

DataFrame Result of the arithmetic operation.

See also:

- DataFrame.add Add DataFrames.
- DataFrame.sub Subtract DataFrames.
- DataFrame.mul Multiply DataFrames.
- DataFrame.div Divide DataFrames (float division).
- DataFrame.truediv Divide DataFrames (float division).
- DataFrame.floordiv Divide DataFrames (integer division).
- DataFrame.mod Calculate modulo (remainder after division).
- DataFrame.pow Calculate exponential power.

Notes

Mismatched indices will be unioned together.

Examples

```python
>>> df = pd.DataFrame({'angles': [0, 3, 4],
...    'degrees': [360, 180, 360],
...    index=['circle', 'triangle', 'rectangle'])
>>> df
   angles  degrees
circle    0      360
triangle   3      180
rectangle  4      360
```

Add a scalar with operator version which return the same results.

```python
>>> df + 1
   angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

```python
>>> df.add(1)
   angles  degrees
circle    1      361
triangle   4      181
rectangle  5      361
```

Divide by constant with reverse version.
>>> df.div(10)
   angles  degrees
   circle   0.0  36.0
   triangle 0.3  18.0
   rectangle 0.4  36.0

>>> df.rdiv(10)
   angles  degrees
   circle   inf  0.027778
   triangle 3.333333  0.055556
   rectangle 2.500000  0.027778

Subtract a list and Series by axis with operator version.

>>> df - [1, 2]
   angles  degrees
   circle  -1  358
   triangle  2  178
   rectangle  3  358

>>> df.sub([1, 2], axis='columns')
   angles  degrees
   circle  -1  358
   triangle  2  178
   rectangle  3  358

>>> df.sub(pd.Series([1, 1, 1], index=['circle', 'triangle', 'rectangle']),
           axis='index')
   angles  degrees
   circle  -1  359
   triangle  2  179
   rectangle  3  359

Multiply a DataFrame of different shape with operator version.

>>> other = pd.DataFrame({'angles': [0, 3, 4]},
                        index=['circle', 'triangle', 'rectangle'])

>>> df * other
   angles  degrees
   circle  0  NaN
   triangle  9  NaN
   rectangle 16  NaN

>>> df.mul(other, fill_value=0)
   angles  degrees
   circle  0  0.0
   triangle  9  0.0
   rectangle 16  0.0

Divide by a MultiIndex by level.
```python
>>> df_multindex = pd.DataFrame({'angles': [0, 3, 4, 4, 5, 6],
...                           'degrees': [360, 180, 360, 360, 540, 720],
...                           index=[['A', 'A', 'A', 'B', 'B', 'B'],
...                     ['circle', 'triangle', 'rectangle', 'square', 'pentagon', 'hexagon']])
```

<table>

</tbody>
</table>

**pandas.DataFrame.truncate**

DataFrame **truncate** *(before=None, after=None, axis=None, copy=True)*

Truncate a Series or DataFrame before and after some index value.

This is a useful shorthand for boolean indexing based on index values above or below certain thresholds.

**Parameters**

- **before** [date, str, int] Truncate all rows before this index value.
- **after** [date, str, int] Truncate all rows after this index value.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, optional] Axis to truncate. Truncates the index (rows) by default.
- **copy** [bool, default is True] Return a copy of the truncated section.

**Returns**

- **type of caller** The truncated Series or DataFrame.

**See also:**

- **DataFrame.loc** Select a subset of a DataFrame by label.
- **DataFrame.iloc** Select a subset of a DataFrame by position.
Notes

If the index being truncated contains only datetime values, *before* and *after* may be specified as strings instead of Timestamps.

Examples

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c', 'd', 'e'],
...                   'B': ['f', 'g', 'h', 'i', 'j'],
...                   'C': ['k', 'l', 'm', 'n', 'o'],
...                   index=[1, 2, 3, 4, 5])
>>> df
   A  B  C
1  a  f  k
2  b  g  l
3  c  h  m
4  d  i  n
5  e  j  o

>>> df.truncate(before=2, after=4)
   A  B  C
2  b  g  l
3  c  h  m
4  d  i  n
```

The columns of a DataFrame can be truncated.

```python
>>> df.truncate(before="A", after="B", axis="columns")
   A  B
1  a  f
2  b  g
3  c  h
4  d  i
5  e  j
```

For Series, only rows can be truncated.

```python
>>> df['A'].truncate(before=2, after=4)
2  b
3  c
4  d
Name: A, dtype: object
```

The index values in *truncate* can be datetimes or string dates.

```python
>>> dates = pd.date_range('2016-01-01', '2016-02-01', freq='s')
>>> df = pd.DataFrame(index=dates, data={'A': 1})
>>> df.tail()
       A
2016-01-31 23:59:56 1
2016-01-31 23:59:57 1
2016-01-31 23:59:58 1
2016-01-31 23:59:59 1
2016-02-01 00:00:00 1
```
Because the index is a DatetimeIndex containing only dates, we can specify `before` and `after` as strings. They will be coerced to Timestamps before truncation.

```python
>>> df.truncate('2016-01-05', '2016-01-10').tail()
```

```
A
2016-01-09 23:59:56 1
2016-01-09 23:59:57 1
2016-01-09 23:59:58 1
2016-01-09 23:59:59 1
2016-01-10 00:00:00 1
```

Note that `truncate` assumes a 0 value for any unspecified time component (midnight). This differs from partial string slicing, which returns any partially matching dates.

```python
>>> df.loc['2016-01-05':'2016-01-10', :].tail()
```

```
A
2016-01-10 23:59:55 1
2016-01-10 23:59:56 1
2016-01-10 23:59:57 1
2016-01-10 23:59:58 1
2016-01-10 23:59:59 1
```

### `pandas.DataFrame.tshift`

DataFrames have a method `tshift` to shift the time index, using the index's frequency if available. This method is deprecated since version 1.1.0. Use the `shift` method instead.

#### Parameters

- `periods` : int
  Number of periods to move, can be positive or negative.

- `freq` : DateOffset, timedelta, or str, default None
  Increment to use from the tseries module or time rule expressed as a string (e.g. 'EOM').

- `axis` : 0 or 'index', 1 or 'columns', None, default 0
  Corresponds to the axis that contains the Index.

#### Returns

- `shifted` : Series/DataFrame
Notes

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown.

pandas.DataFrame.tz_convert

DataFrame.tz_convert (tz, axis=0, level=None, copy=True)
Convert tz-aware axis to target time zone.

Parameters

- tz [str or tzinfo object]
- axis [the axis to convert]
- level [int, str, default None] If axis is a MultiIndex, convert a specific level. Otherwise must be None.
- copy [bool, default True] Also make a copy of the underlying data.

Returns

{klass} Object with time zone converted axis.

Raises

TypeError If the axis is tz-naive.

pandas.DataFrame.tz_localize

DataFrame.tz_localize (tz, axis=0, level=None, copy=True, ambiguous='raise', nonexistent='raise')
Localize tz-naive index of a Series or DataFrame to target time zone.

This operation localizes the Index. To localize the values in a timezone-naive Series, use Series.dt.tz_localize().

Parameters

- tz [str or tzinfo]
- axis [the axis to localize]
- level [int, str, default None] If axis is a MultiIndex, localize a specific level. Otherwise must be None.
- copy [bool, default True] Also make a copy of the underlying data.
- ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the ambiguous parameter dictates how ambiguous times should be handled.
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent [str, default ‘raise’] A nonexistent time does not exist in a particular time-zone where clocks moved forward due to DST. Valid values are:

• ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
• ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
• ‘NaT’ will return NaT where there are nonexistent times
• timedelta objects will shift nonexistent times by the timedelta
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

Series or DataFrame Same type as the input.

Raises

TypeError If the TimeSeries is tz-aware and tz is not None.

Examples

Localize local times:

```
>>> s = pd.Series([1],
...                 index=pd.DatetimeIndex(['2018-09-15 01:30:00']))
>>> s.tz_localize('CET')
2018-09-15 01:30:00+02:00 1
dtype: int64
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```
>>> s = pd.Series(range(7),
...                index=pd.DatetimeIndex(['2018-10-28 01:30:00',
...                                        '2018-10-28 02:00:00',
...                                        '2018-10-28 02:30:00',
...                                        '2018-10-28 02:00:00',
...                                        '2018-10-28 02:30:00',
...                                        '2018-10-28 03:00:00',
...                                        '2018-10-28 03:30:00']))
```

```
>>> s.tz_localize('CET', ambiguous='infer')
2018-10-28 01:30:00+02:00 0
2018-10-28 02:00:00+02:00 1
2018-10-28 02:30:00+02:00 2
2018-10-28 02:00:00+01:00 3
2018-10-28 02:30:00+01:00 4
2018-10-28 03:00:00+01:00 5
2018-10-28 03:30:00+01:00 6
dtype: int64
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
>>> s = pd.Series(range(3),
...               index=pd.DatetimeIndex(['2018-10-28 01:20:00',
...                                       '2018-10-28 02:36:00',
...                                       '2018-10-28 03:46:00']))
>>> s.tz_localize('CET', ambiguous=np.array([True, True, False]))
2018-10-28 01:20:00+02:00 0
2018-10-28 02:36:00+02:00 1
2018-10-28 03:46:00+01:00 2
dtype: int64
```

If the DST transition causes nonexistent times, you can shift these dates forward or backward with a timedelta object or 'shift_forward' or 'shift_backward'.

```python
>>> s = pd.Series(range(2),
...               index=pd.DatetimeIndex(['2015-03-29 02:30:00',
...                                       '2015-03-29 03:30:00']))
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
2015-03-29 03:00:00+02:00 0
2015-03-29 03:30:00+02:00 1
dtype: int64
>>> s.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
2015-03-29 01:59:59.999999999+01:00 0
2015-03-29 03:30:00+02:00 1
dtype: int64
>>> s.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
2015-03-29 03:30:00+02:00 0
2015-03-29 03:30:00+02:00 1
dtype: int64
```

**pandas.DataFrame.unstack**

DataFrame.unstack(level=-1, fill_value=None)

Pivot a level of the (necessarily hierarchical) index labels.

Returns a DataFrame having a new level of column labels whose inner-most level consists of the pivoted index labels.

If the index is not a MultiIndex, the output will be a Series (the analogue of stack when the columns are not a MultiIndex).

**Parameters**

- **level** [int, str, or list of these, default -1 (last level)] Level(s) of index to unstack, can pass level name.
- **fill_value** [int, str or dict] Replace NaN with this value if the unstack produces missing values.

**Returns**

Series or DataFrame

See also:

- **DataFrame.pivot** Pivot a table based on column values.
- **DataFrame.stack** Pivot a level of the column labels (inverse operation from unstack).
Examples

```python
>>> index = pd.MultiIndex.from_tuples([('one', 'a'), ('one', 'b'),
... ('two', 'a'), ('two', 'b')])
>>> s = pd.Series(np.arange(1.0, 5.0), index=index)
>>> s
one a 1.0
   b 2.0
two a 3.0
   b 4.0
dtype: float64

>>> s.unstack(level=-1)
   a  b
one 1.0 2.0
two 3.0 4.0

>>> s.unstack(level=0)
   one two
   a 1.0 3.0
   b 2.0 4.0

>>> df = s.unstack(level=0)
>>> df.unstack()
   one a 1.0
   b 2.0
two a 3.0
   b 4.0
dtype: float64
```

pandas.DataFrame.update

```
DataFrame.update(other, join='left', overwrite=True, filter_func=None, errors='ignore')
```
Modify in place using non-NA values from another DataFrame.

Aligns on indices. There is no return value.

**Parameters**

- `other` [DataFrame, or object coercible into a DataFrame] Should have at least one matching index/column label with the original DataFrame. If a Series is passed, its name attribute must be set, and that will be used as the column name to align with the original DataFrame.

- `join` [‘left’, default ‘left’] Only left join is implemented, keeping the index and columns of the original object.

- `overwrite` [bool, default True] How to handle non-NA values for overlapping keys:
  - True: overwrite original DataFrame’s values with values from `other`.
  - False: only update values that are NA in the original DataFrame.

- `filter_func` [callable(1d-array) -> bool 1d-array, optional] Can choose to replace values other than NA. Return True for values that should be updated.

- `errors` [‘raise’, ‘ignore’], default ‘ignore’] If ‘raise’, will raise a ValueError if the DataFrame and `other` both contain non-NA data in the same place.
Returns

None  [method directly changes calling object]

Raises

ValueError

• When errors=’raise’ and there’s overlapping non-NA data.
• When errors is not either ‘ignore’ or ‘raise’

NotImplementedError

• If join != ‘left’

See also:

dict.update  Similar method for dictionaries.
DataFrame.merge  For column(s)-on-column(s) operations.

Examples

```python
>>> df = pd.DataFrame({'A': [1, 2, 3],
...                     'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, 5, 6],
...                        'C': [7, 8, 9]})
>>> df.update(new_df)
>>> df
  A  B
0  1  4
1  2  5
2  3  6
```

The DataFrame’s length does not increase as a result of the update, only values at matching index/column labels are updated.

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                     'B': ['x', 'y', 'z']})
>>> new_df = pd.DataFrame({'B': ['d', 'e', 'f', 'g', 'h', 'i']})
>>> df.update(new_df)
>>> df
  A  B
0 a  d
1 b  e
2 c  f
```

For Series, its name attribute must be set.

```python
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                     'B': ['x', 'y', 'z']})
>>> new_column = pd.Series(['d', 'e'], name='B', index=[0, 2])
>>> df.update(new_column)
>>> df
  A  B
0 a  d
1 b  y
2 c  e
```

(continues on next page)
>>> df = pd.DataFrame({'A': ['a', 'b', 'c'],
...                   'B': ['x', 'y', 'z']})
>>> new_df = pd.DataFrame({'B': ['d', 'e']}, index=[1, 2])
>>> df.update(new_df)
>>> df
   A B
0 a x
1 b d
2 c e

If other contains NaNs the corresponding values are not updated in the original dataframe.

>>> df = pd.DataFrame({'A': [1, 2, 3],
...                    'B': [400, 500, 600]})
>>> new_df = pd.DataFrame({'B': [4, np.nan, 6]})
>>> df.update(new_df)
>>> df
   A  B
0  1  4.0
1  2  500.0
2  3   6.0

pandas.DataFrame.value_counts

DataFrame.value_counts(subset=None, normalize=False, sort=True, ascending=False, dropna=True)

Return a Series containing counts of unique rows in the DataFrame.

New in version 1.1.0.

Parameters

- **subset** [list-like, optional] Columns to use when counting unique combinations.
- **normalize** [bool, default False] Return proportions rather than frequencies.
- **sort** [bool, default True] Sort by frequencies.
- **ascending** [bool, default False] Sort in ascending order.
- **dropna** [bool, default True] Don’t include counts of rows that contain NA values.

New in version 1.3.0.

Returns

Series

See also:

- Series.value_counts Equivalent method on Series.
Notes

The returned Series will have a MultiIndex with one level per input column. By default, rows that contain any NA values are omitted from the result. By default, the resulting Series will be in descending order so that the first element is the most frequently-occurring row.

Examples

```python
>>> df = pd.DataFrame({'num_legs': [2, 4, 4, 6],
...                    'num_wings': [2, 0, 0, 0]},
...                    index=['falcon', 'dog', 'cat', 'ant'])
```

```python
>>> df
   num_legs  num_wings
falcon     2            2
dog        4            0
cat        4            0
ant        6            0
```

```python
>>> df.value_counts()
   num_legs  num_wings
      4            0   2
      2            2   1
      6            0   1
dtype: int64
```

```python
>>> df.value_counts(sort=False)
   num_legs  num_wings
      2            0   1
      4            0   2
      6            0   1
dtype: int64
```

```python
>>> df.value_counts(ascending=True)
   num_legs  num_wings
      2            0   1
      6            0   1
      4            0   2
dtype: int64
```

```python
>>> df.value_counts(normalize=True)
   num_legs  num_wings
      4            0   0.50
      2            0   0.25
      6            0   0.25
dtype: float64
```

With dropna set to False we can also count rows with NA values.

```python
>>> df = pd.DataFrame({'first_name': ['John', 'Anne', 'John', 'Beth'],
...                    'middle_name': ['Smith', pd.NA, pd.NA, 'Louise']})
```

```python
>>> df
  first_name  middle_name
    0       John      Smith
    1       Anne       <NA>
```
df.value_counts()

<table>
<thead>
<tr>
<th>first_name</th>
<th>middle_name</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>Beth</td>
<td>Louise</td>
<td>1</td>
</tr>
<tr>
<td>John</td>
<td>Smith</td>
<td>1</td>
</tr>
</tbody>
</table>

dtype: int64

>>> df.value_counts(dropna=False)

<table>
<thead>
<tr>
<th>first_name</th>
<th>middle_name</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anne</td>
<td>NaN</td>
<td>1</td>
</tr>
<tr>
<td>Beth</td>
<td>Louise</td>
<td>1</td>
</tr>
<tr>
<td>John</td>
<td>Smith</td>
<td>1</td>
</tr>
<tr>
<td>NaN</td>
<td>NaN</td>
<td>1</td>
</tr>
</tbody>
</table>

dtype: int64

**pandas.DataFrame.var**

DataFrame.var (axis=None, skipna=None, level=None, ddof=1, numeric_only=None, **kwargs)

Return unbiased variance over requested axis.

Normalized by N-1 by default. This can be changed using the ddof argument

**Parameters**

- **axis** [{index (0), columns (1)}]
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.
- **level** [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.
- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- **numeric_only** [bool, default None] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data. Not implemented for Series.

**Returns**

Series or DataFrame (if level specified)

**Notes**

To have the same behaviour as numpy.std, use ddof=0 (instead of the default ddof=1)
pandas.DataFrame.where

pandas.DataFrame.where (cond, other=nan, inplace=False, axis=None, level=None, errors='raise', try_cast=<no_default>)
Replace values where the condition is False.

Parameters

cond [bool Series/DataFrame, array-like, or callable] Where cond is True, keep the original value. Where False, replace with corresponding value from other. If cond is callable, it is computed on the Series/DataFrame and should return boolean Series/DataFrame or array. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

other [scalar, Series/DataFrame, or callable] Entries where cond is False are replaced with corresponding value from other. If other is callable, it is computed on the Series/DataFrame and should return scalar or Series/DataFrame. The callable must not change input Series/DataFrame (though pandas doesn’t check it).

inplace [bool, default False] Whether to perform the operation in place on the data.

axis [int, default None] Alignment axis if needed.

level [int, default None] Alignment level if needed.

errors [str, {'raise', 'ignore'}, default 'raise'] Note that currently this parameter won’t affect the results and will always coerce to a suitable dtype.

• ‘raise’ : allow exceptions to be raised.
• ‘ignore’ : suppress exceptions. On error return original object.

try_cast [bool, default None] Try to cast the result back to the input type (if possible).

Deprecated since version 1.3.0: Manually cast back if necessary.

Returns

Same type as caller or None if inplace=True.

See also:

DataFrame.mask() Return an object of same shape as self.

Notes

The where method is an application of the if-then idiom. For each element in the calling DataFrame, if cond is True the element is used; otherwise the corresponding element from the DataFrame other is used.

The signature for DataFrame.where() differs from numpy.where(). Roughly df1.where(m, df2) is equivalent to np.where(m, df1, df2).

For further details and examples see the where documentation in indexing.
Examples

```python
>>> s = pd.Series(range(5))
>>> s.where(s > 0)
0    NaN
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
>>> s.mask(s > 0)
0    0.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

```python
>>> s.where(s > 1, 10)
0   10
1   10
2    2
3    3
4    4
dtype: int64
```

```python
>>> df = pd.DataFrame(np.arange(10).reshape(-1, 2), columns=['A', 'B'])
>>> df
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
4  8  9
```

```python
>>> m = df % 3 == 0
```

```python
>>> df.where(m, -df)
   A  B
0   0 -1
1  -2   3
2  -4  -5
3   6  -7
4  -8   9
```

```python
>>> df.where(m, -df) == np.where(m, df, -df)
   A  B
0  True True
1  True True
2  True True
3  True True
4  True True
```

(continues on next page)
pandas.DataFrame.xs

DataFrame.xs (key, axis=0, level=None, drop_level=True)
Return cross-section from the Series/DataFrame.

This method takes a key argument to select data at a particular level of a MultiIndex.

Parameters

- **key** [label or tuple of label] Label contained in the index, or partially in a MultiIndex.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Axis to retrieve cross-section on.
- **level** [object, defaults to first n levels (n=1 or len(key))] In case of a key partially contained in a MultiIndex, indicate which levels are used. Levels can be referred by label or position.
- **drop_level** [bool, default True] If False, returns object with same levels as self.

Returns

Series or DataFrame Cross-section from the original Series or DataFrame corresponding to the selected index levels.

See also:

- **DataFrame.loc** Access a group of rows and columns by label(s) or a boolean array.
- **DataFrame.iloc** Purely integer-location based indexing for selection by position.

Notes

xs can not be used to set values.

MultiIndex Slicers is a generic way to get/set values on any level or levels. It is a superset of xs functionality, see MultiIndex Slicers.

Examples

```python
>>> d = {'num_legs': [4, 4, 2, 2],
...      'num_wings': [0, 0, 2, 2],
...      'class': ['mammal', 'mammal', 'mammal', 'bird'],
...      'animal': ['cat', 'dog', 'bat', 'penguin'],
...      'locomotion': ['walks', 'walks', 'flies', 'walks']}
>>> df = pd.DataFrame(data=d)
>>> df = df.set_index(['class', 'animal', 'locomotion'])
>>> df
   num_legs  num_wings
0     True     True
1     True     True
2     True     True
3     True     True
4     True     True
```
class animal locomotion
mammal cat  walks  4  0
dog   walks  4  0
    bat  flies  2  2
bird   penguin walks  2  2

Get values at specified index

```python
>>> df.xs('mammal')
animal locomotion  num_legs  num_wings
cat   walks       4         0
dog   walks       4         0
bat   flies       2         2
```

Get values at several indexes

```python
>>> df.xs(('mammal', 'dog'))
locomotion  num_legs  num_wings
walks       4         0
```

Get values at specified index and level

```python
>>> df.xs('cat', level=1)
class locomotion  num_legs  num_wings
mammal walks     4         0
```

Get values at several indexes and levels

```python
>>> df.xs(('bird', 'walks'),
...       level=[0, 'locomotion'])
animal  num_legs  num_wings
penguin  2         2
```

Get values at specified column and axis

```python
>>> df.xs('num_wings', axis=1)
class animal locomotion
mammal cat  walks  0
dog   walks  0
    bat  flies  2
bird   penguin walks  2
Name: num_wings, dtype: int64
```
### 3.4.2 Attributes and underlying data

#### Axes

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.index</code></td>
<td>The index (row labels) of the DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.columns</code></td>
<td>The column labels of the DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.dtypes</code></td>
<td>Return the dtypes in the DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.info</code></td>
<td>Print a concise summary of a DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.select_dtypes</code></td>
<td>Return a subset of the DataFrame’s columns based on the column dtypes.</td>
</tr>
<tr>
<td><code>DataFrame.values</code></td>
<td>Return a Numpy representation of the DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.axes</code></td>
<td>Return a list representing the axes of the DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.ndim</code></td>
<td>Return an int representing the number of axes / array dimensions.</td>
</tr>
<tr>
<td><code>DataFrame.size</code></td>
<td>Return an int representing the number of elements in this object.</td>
</tr>
<tr>
<td><code>DataFrame.shape</code></td>
<td>Return a tuple representing the dimensionality of the DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.memory_usage</code></td>
<td>Return the memory usage of each column in bytes.</td>
</tr>
<tr>
<td><code>DataFrame.empty</code></td>
<td>Indicator whether DataFrame is empty.</td>
</tr>
<tr>
<td><code>DataFrame.set_flags</code></td>
<td>Return a new object with updated flags.</td>
</tr>
</tbody>
</table>

### 3.4.3 Conversion

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.astype</code></td>
<td>Cast a pandas object to a specified dtype <code>dtype</code>.</td>
</tr>
<tr>
<td><code>DataFrame.convert_dtypes</code></td>
<td>Convert columns to best possible dtypes using dtypes supporting pd.NA.</td>
</tr>
<tr>
<td><code>DataFrame.infer_objects</code></td>
<td>Attempt to infer better dtypes for object columns.</td>
</tr>
<tr>
<td><code>DataFrame.copy</code></td>
<td>Make a copy of this object’s indices and data.</td>
</tr>
<tr>
<td><code>DataFrame.bool</code></td>
<td>Return the bool of a single element Series or DataFrame.</td>
</tr>
</tbody>
</table>

### 3.4.4 Indexing, iteration

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.head</code></td>
<td>Return the first $n$ rows.</td>
</tr>
<tr>
<td><code>DataFrame.at</code></td>
<td>Access a single value for a row/column label pair.</td>
</tr>
<tr>
<td><code>DataFrame.iat</code></td>
<td>Access a single value for a row/column pair by integer position.</td>
</tr>
<tr>
<td><code>DataFrame.loc</code></td>
<td>Access a group of rows and columns by label(s) or a boolean array.</td>
</tr>
<tr>
<td><code>DataFrame.iloc</code></td>
<td>Purely integer-location based indexing for selection by position.</td>
</tr>
<tr>
<td><code>DataFrame.insert</code></td>
<td>Insert column into DataFrame at specified location.</td>
</tr>
<tr>
<td><code>DataFrame.__iter__</code></td>
<td>Iterate over info axis.</td>
</tr>
<tr>
<td><code>DataFrame.items</code></td>
<td>Iterate over (column name, Series) pairs.</td>
</tr>
<tr>
<td><code>DataFrame.iteritems</code></td>
<td>Iterate over (column name, Series) pairs.</td>
</tr>
</tbody>
</table>

continues on next page
DataFrame.keys() Get the ‘info axis’ (see Indexing for more).
DataFrame.iterrows() Iterate over DataFrame rows as (index, Series) pairs.
DataFrame.itertuples((index, name)) Iterate over DataFrame rows as namedtuples.
DataFrame.lookup(row_labels, col_labels) (DEPRECATED) Label-based “fancy indexing” function for DataFrame.
DataFrame.pop(item) Return item and drop from frame.
DataFrame.tail([n]) Return the last n rows.
DataFrame.xs(key[, axis, level, drop_level]) Return cross-section from the Series/DataFrame.
DataFrame.get(key[, default]) Get item from object for given key (ex: DataFrame column).
DataFrame.isin(values) Whether each element in the DataFrame is contained in values.
DataFrame.where(cond[, other, inplace, ...]) Replace values where the condition is False.
DataFrame.mask(cond[, other, inplace, axis, ...]) Replace values where the condition is True.
DataFrame.query(expr[, inplace]) Query the columns of a DataFrame with a boolean expression.

DataFrame.__iter__

DataFrame.__iter__() Iterate over info axis.

Returns

iterator Info axis as iterator.

For more information on .at, .iat, .loc, and .iloc, see the indexing documentation.

3.4.5 Binary operator functions

DataFrame.add(other[, axis, level, fill_value]) Get Addition of dataframe and other, element-wise (binary operator add).
DataFrame.sub(other[, axis, level, fill_value]) Get Subtraction of dataframe and other, element-wise (binary operator sub).
DataFrame.mul(other[, axis, level, fill_value]) Get Multiplication of dataframe and other, element-wise (binary operator mul).
DataFrame.div(other[, axis, level, fill_value]) Get Floating division of dataframe and other, element-wise (binary operator truediv).
DataFrame.truediv(other[, axis, level, ...]) Get Floating division of dataframe and other, element-wise (binary operator truediv).
DataFrame.floordiv(other[, axis, level, ...]) Get Integer division of dataframe and other, element-wise (binary operator floordiv).
DataFrame.mod(other[, axis, level, fill_value]) Get Modulo of dataframe and other, element-wise (binary operator mod).
DataFrame.pow(other[, axis, level, fill_value]) Get Exponential power of dataframe and other, element-wise (binary operator pow).
DataFrame.dot(other) Compute the matrix multiplication between the DataFrame and other.
DataFrame.radd(other[, axis, level, fill_value]) Get Addition of dataframe and other, element-wise (binary operator radd).

Table 70 – continued from previous page

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.rsub(other[, axis, level, fill_value])</code></td>
<td>Get Subtraction of dataframe and other, element-wise (binary operator rsub).</td>
</tr>
<tr>
<td><code>DataFrame.rmul(other[, axis, level, fill_value])</code></td>
<td>Get Multiplication of dataframe and other, element-wise (binary operator rmul).</td>
</tr>
<tr>
<td><code>DataFrame.rdiv(other[, axis, level, fill_value])</code></td>
<td>Get Floating division of dataframe and other, element-wise (binary operator rtruediv).</td>
</tr>
<tr>
<td><code>DataFrame.rtruediv(other[, axis, level, ...])</code></td>
<td>Get Floating division of dataframe and other, element-wise (binary operator rtruediv).</td>
</tr>
<tr>
<td><code>DataFrame.rfloordiv(other[, axis, level, ...])</code></td>
<td>Get Integer division of dataframe and other, element-wise (binary operator rfloordiv).</td>
</tr>
<tr>
<td><code>DataFrame.rmod(other[, axis, level, fill_value])</code></td>
<td>Get Modulo of dataframe and other, element-wise (binary operator rmod).</td>
</tr>
<tr>
<td><code>DataFrame.rpow(other[, axis, level, fill_value])</code></td>
<td>Get Exponential power of dataframe and other, element-wise (binary operator rpow).</td>
</tr>
<tr>
<td><code>DataFrame.lt(other[, axis, level])</code></td>
<td>Get Less than of dataframe and other, element-wise (binary operator lt).</td>
</tr>
<tr>
<td><code>DataFrame.gt(other[, axis, level])</code></td>
<td>Get Greater than of dataframe and other, element-wise (binary operator gt).</td>
</tr>
<tr>
<td><code>DataFrame.le(other[, axis, level])</code></td>
<td>Get Less than or equal to of dataframe and other, element-wise (binary operator le).</td>
</tr>
<tr>
<td><code>DataFrame.ge(other[, axis, level])</code></td>
<td>Get Greater than or equal to of dataframe and other, element-wise (binary operator ge).</td>
</tr>
<tr>
<td><code>DataFrame.ne(other[, axis, level])</code></td>
<td>Get Not equal to of dataframe and other, element-wise (binary operator ne).</td>
</tr>
<tr>
<td><code>DataFrame.eq(other[, axis, level])</code></td>
<td>Get Equal to of dataframe and other, element-wise (binary operator eq).</td>
</tr>
<tr>
<td><code>DataFrame.combine(other, func[, fill_value, ...])</code></td>
<td>Perform column-wise combine with another DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.combine_first(other)</code></td>
<td>Update null elements with value in the same location in other.</td>
</tr>
</tbody>
</table>

3.4.6 Function application, GroupBy & window

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.apply(func[, axis, raw, ...])</code></td>
<td>Apply a function along an axis of the DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.applymap(func[, na_action])</code></td>
<td>Apply a function to a Dataframe elementwise.</td>
</tr>
<tr>
<td><code>DataFrame.pipe(func, *args, **kwargs)</code></td>
<td>Apply func(self, *args, **kwargs).</td>
</tr>
<tr>
<td><code>DataFrame.agg([func, axis])</code></td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td><code>DataFrame.aggregate([func, axis])</code></td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td><code>DataFrame.transform(func[, axis])</code></td>
<td>Call func on self producing a DataFrame with transformed values.</td>
</tr>
<tr>
<td><code>DataFrame.groupby([by, axis, level, ...])</code></td>
<td>Group DataFrame using a mapper or by a Series of columns.</td>
</tr>
<tr>
<td><code>DataFrame.rolling(window[, min_periods, ...])</code></td>
<td>Provide rolling window calculations.</td>
</tr>
<tr>
<td><code>DataFrame.expanding([min_periods, center, ...])</code></td>
<td>Provide expanding transformations.</td>
</tr>
<tr>
<td><code>DataFrame.ewm([com, span, halflife, alpha, ...])</code></td>
<td>Provide exponential weighted (EW) functions.</td>
</tr>
</tbody>
</table>
3.4.7 Computations / descriptive stats

- `DataFrame.abs`(): Return a Series/DataFrame with absolute numeric value of each element.
- `DataFrame.all`([axis, bool_only, skipna, level]): Return whether all elements are True, potentially over an axis.
- `DataFrame.any`([axis, bool_only, skipna, level]): Return whether any element is True, potentially over an axis.
- `DataFrame.clip`([lower, upper, axis, inplace]): Trim values at input threshold(s).
- `DataFrame.corr`([method, min_periods]): Compute pairwise correlation of columns, excluding NA/null values.
- `DataFrame.corrwith`([other, axis, drop, method]): Compute pairwise correlation.
- `DataFrame.count`([axis, level, numeric_only]): Count non-NA cells for each column or row.
- `DataFrame.cov`([min_periods, ddof]): Compute pairwise covariance of columns, excluding NA/null values.
- `DataFrame.cummax`([axis, skipna]): Return cumulative maximum over a DataFrame or Series axis.
- `DataFrame.cummin`([axis, skipna]): Return cumulative minimum over a DataFrame or Series axis.
- `DataFrame.cumprod`([axis, skipna]): Return cumulative product over a DataFrame or Series axis.
- `DataFrame.cumsum`([axis, skipna]): Return cumulative sum over a DataFrame or Series axis.
- `DataFrame.describe`([percentiles, include, ...]): Generate descriptive statistics.
- `DataFrame.diff`([periods, axis]): First discrete difference of element.
- `DataFrame.eval`([expr[, inplace]]): Evaluate a string describing operations on DataFrame columns.
- `DataFrame.kurt`([axis, skipna, level, ...]): Return unbiased kurtosis over requested axis.
- `DataFrame.kurtosis`([axis, skipna, level, ...]): Return unbiased kurtosis over requested axis.
- `DataFrame.mad`([axis, skipna, level]): Return the mean absolute deviation of the values over the requested axis.
- `DataFrame.max`([axis, skipna, level, ...]): Return the maximum of the values over the requested axis.
- `DataFrame.mean`([axis, skipna, level, ...]): Return the mean of the values over the requested axis.
- `DataFrame.median`([axis, skipna, level, ...]): Return the median of the values over the requested axis.
- `DataFrame.min`([axis, skipna, level, ...]): Return the minimum of the values over the requested axis.
- `DataFrame.mode`([axis, numeric_only, dropna]): Get the mode(s) of each element along the selected axis.
- `DataFrame.pct_change`([periods, fill_method, ...]): Percentage change between the current and a prior element.
- `DataFrame.prod`([axis, skipna, level, ...]): Return the product of the values over the requested axis.
- `DataFrame.product`([axis, skipna, level, ...]): Return the product of the values over the requested axis.
- `DataFrame.quantile`([q, axis, numeric_only, ...]): Return values at the given quantile over requested axis.
- `DataFrame.rank`([axis, method, numeric_only, ...]): Compute numerical data ranks (1 through n) along axis.
- `DataFrame.round`([decimals]): Round a DataFrame to a variable number of decimal places.
- `DataFrame.sem`([axis, skipna, level, ddof, ...]): Return unbiased standard error of the mean over requested axis.
- `DataFrame.skew`([axis, skipna, level, ...]): Return unbiased skew over requested axis.
- `DataFrame.sum`([axis, skipna, level, ...]): Return the sum of the values over the requested axis.

Table 72 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.std([axis, skipna, level, ddof, ...])</code></td>
<td>Return sample standard deviation over requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.var([axis, skipna, level, ddof, ...])</code></td>
<td>Return unbiased variance over requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.nunique([axis, dropna])</code></td>
<td>Count number of distinct elements in specified axis.</td>
</tr>
<tr>
<td><code>DataFrame.value_counts([subset, normalize, ...])</code></td>
<td>Return a Series containing counts of unique rows in the DataFrame.</td>
</tr>
</tbody>
</table>

### 3.4.8 Reindexing / selection / label manipulation

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.add_prefix(prefix)</code></td>
<td>Prefix labels with string prefix.</td>
</tr>
<tr>
<td><code>DataFrame.add_suffix(suffix)</code></td>
<td>Suffix labels with string suffix.</td>
</tr>
<tr>
<td><code>DataFrame.align(other[, join, axis, level, ...])</code></td>
<td>Align two objects on their axes with the specified join method.</td>
</tr>
<tr>
<td><code>DataFrame.at_time(time[, asof, axis])</code></td>
<td>Select values at particular time of day (e.g., 9:30AM).</td>
</tr>
<tr>
<td><code>DataFrame.between_time(start_time, end_time)</code></td>
<td>Select values between particular times of the day (e.g., 9:00-9:30 AM).</td>
</tr>
<tr>
<td><code>DataFrame.drop([labels, axis, index, ...])</code></td>
<td>Drop specified labels from rows or columns.</td>
</tr>
<tr>
<td><code>DataFrame.drop_duplicates([subset, keep, ...])</code></td>
<td>Return DataFrame with duplicate rows removed.</td>
</tr>
<tr>
<td><code>DataFrame.duplicated([subset, keep])</code></td>
<td>Return boolean Series denoting duplicate rows.</td>
</tr>
<tr>
<td><code>DataFrame.equals(other)</code></td>
<td>Test whether two objects contain the same elements.</td>
</tr>
<tr>
<td><code>DataFrame.filter([items, like, regex, axis])</code></td>
<td>Subset the dataframe rows or columns according to the specified index labels.</td>
</tr>
<tr>
<td><code>DataFrame.first(offset)</code></td>
<td>Select initial periods of time series data based on a date offset.</td>
</tr>
<tr>
<td><code>DataFrame.head([n])</code></td>
<td>Return the first n rows.</td>
</tr>
<tr>
<td><code>DataFrame.idxmax([axis, skipna])</code></td>
<td>Return index of first occurrence of maximum over requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.idxmin([axis, skipna])</code></td>
<td>Return index of first occurrence of minimum over requested axis.</td>
</tr>
<tr>
<td><code>DataFrame.last(offset)</code></td>
<td>Select final periods of time series data based on a date offset.</td>
</tr>
<tr>
<td><code>DataFrame.reindex([labels, index, columns, ...])</code></td>
<td>Conform Series/DataFrame to new index with optional filling logic.</td>
</tr>
<tr>
<td><code>DataFrame.reindex_like(other[, method, ...])</code></td>
<td>Return an object with matching indices as other object.</td>
</tr>
<tr>
<td><code>DataFrame.rename([mapper, index, columns, ...])</code></td>
<td>Alter axes labels.</td>
</tr>
<tr>
<td><code>DataFrame.rename_axis([mapper, index, ...])</code></td>
<td>Set the name of the axis for the index or columns.</td>
</tr>
<tr>
<td><code>DataFrame.reset_index([level, drop, ...])</code></td>
<td>Reset the index, or a level of it.</td>
</tr>
<tr>
<td><code>DataFrame.sample([n, frac, replace, ...])</code></td>
<td>Return a random sample of items from an axis of object.</td>
</tr>
<tr>
<td><code>DataFrame.set_index(keys[, axis, inplace])</code></td>
<td>Assign desired index to given axis.</td>
</tr>
<tr>
<td><code>DataFrame.set_index(keys[, axis, inplace])</code></td>
<td>Set the DataFrame index using existing columns.</td>
</tr>
<tr>
<td><code>DataFrame.tail([n])</code></td>
<td>Return the last n rows.</td>
</tr>
<tr>
<td><code>DataFrame.take([indices[, axis, is_copy]])</code></td>
<td>Return the elements in the given positional indices along an axis.</td>
</tr>
<tr>
<td><code>DataFrame.truncate([before, after, axis, copy])</code></td>
<td>Truncate a Series or DataFrame before and after some index value.</td>
</tr>
</tbody>
</table>
### 3.4.9 Missing data handling

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.backfill()</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code>.</td>
</tr>
<tr>
<td><code>DataFrame.bfill()</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code>.</td>
</tr>
<tr>
<td><code>DataFrame.dropna()</code></td>
<td>Remove missing values.</td>
</tr>
<tr>
<td><code>DataFrame.ffill()</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code>.</td>
</tr>
<tr>
<td><code>DataFrame.interpolate()</code></td>
<td>Fill NaN values using an interpolation method.</td>
</tr>
<tr>
<td><code>DataFrame.isna()</code></td>
<td>Detect missing values.</td>
</tr>
<tr>
<td><code>DataFrame.isnull()</code></td>
<td>Detect missing values.</td>
</tr>
<tr>
<td><code>DataFrame.notna()</code></td>
<td>Detect existing (non-missing) values.</td>
</tr>
<tr>
<td><code>DataFrame.notnull()</code></td>
<td>Detect existing (non-missing) values.</td>
</tr>
<tr>
<td><code>DataFrame.pad()</code></td>
<td>Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code>.</td>
</tr>
<tr>
<td><code>DataFrame.replace()</code></td>
<td>Replace values given in <code>to_replace</code> with <code>value</code>.</td>
</tr>
</tbody>
</table>

### 3.4.10 Reshaping, sorting, transposing

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.droplevel()</code></td>
<td>Return Series/DataFrame with requested index / column level(s) removed.</td>
</tr>
<tr>
<td><code>DataFrame.pivot()</code></td>
<td>Return reshaped DataFrame organized by given index / column values.</td>
</tr>
<tr>
<td><code>DataFrame.pivot_table()</code></td>
<td>Create a spreadsheet-style pivot table as a DataFrame.</td>
</tr>
<tr>
<td><code>DataFrame.reorder_levels()</code></td>
<td>Rearrange index levels using input order.</td>
</tr>
<tr>
<td><code>DataFrame.sort_values()</code></td>
<td>Sort by the values along either axis.</td>
</tr>
<tr>
<td><code>DataFrame.sort_index()</code></td>
<td>Sort object by labels (along an axis).</td>
</tr>
<tr>
<td><code>DataFrame.nlargest()</code></td>
<td>Return the first n rows ordered by <code>columns</code> in descending order.</td>
</tr>
<tr>
<td><code>DataFrame.nsmallest()</code></td>
<td>Return the first n rows ordered by <code>columns</code> in ascending order.</td>
</tr>
<tr>
<td><code>DataFrame.swaplevel()</code></td>
<td>Swap levels i and j in a <code>MultiIndex</code>.</td>
</tr>
<tr>
<td><code>DataFrame.stack()</code></td>
<td>Stack the prescribed level(s) from columns to index.</td>
</tr>
<tr>
<td><code>DataFrame.unstack()</code></td>
<td>Pivot a level of the (necessarily hierarchical) index labels.</td>
</tr>
<tr>
<td><code>DataFrame.swapaxes()</code></td>
<td>Interchange axes and swap values axes appropriately.</td>
</tr>
<tr>
<td><code>DataFrame.melt()</code></td>
<td>Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.</td>
</tr>
<tr>
<td><code>DataFrameexplode()</code></td>
<td>Transform each element of a list-like to a row, replicating index values.</td>
</tr>
<tr>
<td><code>DataFrame.squeeze()</code></td>
<td>Squeeze 1 dimensional axis objects into scalars.</td>
</tr>
<tr>
<td><code>DataFrame.to_xarray()</code></td>
<td>Return an xarray object from the pandas object.</td>
</tr>
<tr>
<td><code>DataFrame.T</code></td>
<td>Transpose index and columns.</td>
</tr>
</tbody>
</table>
3.4.11 Combining / comparing / joining / merging

**DataFrame.append**(other[, ignore_index, ...])  
Append rows of other to the end of caller, returning a new object.

**DataFrame.assign**(**kwargs)  
Assign new columns to a DataFrame.

**DataFrame.compare**(other[, align_axis, ...])  
Compare to another DataFrame and show the differences.

**DataFrame.join**(other[, on, how, lsuffix, ...])  
Join columns of another DataFrame.

**DataFrame.merge**(right[, how, on, left_on, ...])  
Merge DataFrame or named Series objects with a database-style join.

**DataFrame.update**(other[, join, overwrite, ...])  
Modify in place using non-NA values from another DataFrame.

3.4.12 Time Series-related

**DataFrame.asfreq**(freq[, method, how, ...])  
Convert time series to specified frequency.

**DataFrame.asof**(where[, subset])  
Return the last row(s) without any NaNs before where.

**DataFrame.shift**([[periods, freq, axis, ...]])  
Shift index by desired number of periods with an optional time freq.

**DataFrame.slice_shift**(periods, axis)  
(DEPRECATED) Equivalent to shift without copying data.

**DataFrame.tshift**(periods, freq, axis)  
(DEPRECATED) Shift the time index, using the index’s frequency if available.

**DataFrame.first_valid_index**()  
Return index for first non-NA value or None, if no NA value is found.

**DataFrame.last_valid_index**()  
Return index for last non-NA value or None, if no NA value is found.

**DataFrame.resample**(rule[, axis, closed, ...])  
Resample time-series data.

**DataFrame.to_period**(freq, axis, copy)  
Convert DataFrame from DatetimeIndex to PeriodIndex.

**DataFrame.to_timestamp**(freq, how, axis, copy)  
Cast to DatetimeIndex of timestamps, at beginning of period.

**DataFrame.tz_convert**(tz[, axis, level, copy])  
Convert tz-aware axis to target time zone.

**DataFrame.tz_localize**(tz[, axis, level, ...])  
Localize tz-naive index of a Series or DataFrame to target time zone.
3.4.13 Flags

Flags refer to attributes of the pandas object. Properties of the dataset (like the date it was recorded, the URL it was accessed from, etc.) should be stored in `DataFrame.attrs`.

<table>
<thead>
<tr>
<th>Flags</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Flags(obj, *, allows_duplicate_labels)</code></td>
<td>Flags that apply to pandas objects.</td>
</tr>
</tbody>
</table>

3.4.14 Metadata

`DataFrame.attrs` is a dictionary for storing global metadata for this DataFrame.

**Warning**: `DataFrame.attrs` is considered experimental and may change without warning.

<table>
<thead>
<tr>
<th>DataFrame.attrs</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DataFrame.attrs</code></td>
<td>Dictionary of global attributes of this dataset.</td>
</tr>
</tbody>
</table>

3.4.15 Plotting

`DataFrame.plot` is both a callable method and a namespace attribute for specific plotting methods of the form `DataFrame.plot.<kind>`.

<table>
<thead>
<tr>
<th><code>DataFrame.plot([x, y, kind, ax, ....])</code></th>
<th>DataFrame plotting accessor and method</th>
</tr>
</thead>
<tbody>
<tr>

<td>Create a scatter plot with varying marker point size and color.</td>
</tr>
</tbody>
</table>

3.4. DataFrame
**pandas.DataFrame.plot.area**

DataFrame.plot.area(x=None, y=None, **kwargs)

Draw a stacked area plot.

An area plot displays quantitative data visually. This function wraps the matplotlib area function.

**Parameters**

- **x** [label or position, optional] Coordinates for the X axis. By default uses the index.
- **y** [label or position, optional] Column to plot. By default uses all columns.
- **stacked** [bool, default True] Area plots are stacked by default. Set to False to create a unstacked plot.
- **kwargs** Additional keyword arguments are documented in `DataFrame.plot()`.

**Returns**

- `matplotlib.axes.Axes` or `numpy.ndarray` Area plot, or array of area plots if subplots is True.

**See also:**

- `DataFrame.plot` Make plots of DataFrame using matplotlib / pylab.

## Examples

Draw an area plot based on basic business metrics:

```python
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3, 9, 10, 6],
...     'signups': [5, 5, 6, 12, 14, 13],
...     'visits': [20, 42, 28, 62, 81, 50],
... }, index=pd.date_range(start='2018/01/01', end='2018/07/01', freq='M'))
>>> ax = df.plot.area()
```

Area plots are stacked by default. To produce an unstacked plot, pass `stacked=False`:

```python
>>> ax = df.plot.area(stacked=False)
```

Draw an area plot for a single column:

```python
>>> ax = df.plot.area(y='sales')
```

Draw with a different x:

```python
>>> df = pd.DataFrame({
...     'sales': [3, 2, 3],
...     'visits': [20, 42, 28],
...     'day': [1, 2, 3],
... })
>>> ax = df.plot.area(x='day')
```
3.4. DataFrame
3.4. DataFrame
pandas.DataFrame.plot.bar

DataFrame.plot.bar(x=None, y=None, **kwargs)

Vertical bar plot.

A bar plot is a plot that presents categorical data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

Parameters

- **x** [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- **y** [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
- **color** [str, array-like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:
  - A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.
  - A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column’s bar will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.
  - A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {'a': 'green', 'b': 'red'} will color bars for column a in green and bars for column b in red.

New in version 1.1.0.

- **kwargs** Additional keyword arguments are documented in DataFrame.plot().

Returns

- matplotlib.axes.Axes or np.ndarray of them An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

- DataFrame.plot.barh Horizontal bar plot.
- DataFrame.plot Make plots of a DataFrame.
- matplotlib.pyplot.bar Make a bar plot with matplotlib.
- matplotlib.pyplot.barb Make a bar plot with matplotlib.

Examples

Basic plot.

```python
>>> df = pd.DataFrame({'lab':['A', 'B', 'C'], 'val':[10, 30, 20]})
>>> ax = df.plot.bar(x='lab', y='val', rot=0)
```

Plot a whole dataframe to a bar plot. Each column is assigned a distinct color, and each row is nested in a group along the horizontal axis.
A bar chart showing the values of three groups (A, B, C) with the following values:

- A: 10
- B: 30
- C: 20

The y-axis represents the values ranging from 0 to 30.
```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
... 'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
... 'lifespan': lifespan}, index=index)
>>> ax = df.plot.bar(rot=0)
```

Plot stacked bar charts for the DataFrame

```python
>>> ax = df.plot.bar(stacked=True)
```

Instead of nesting, the figure can be split by column with `subplots=True`. In this case, a `numpy.ndarray` of `matplotlib.axes.Axes` are returned.

```python
>>> axes = df.plot.bar(rot=0, subplots=True)
>>> axes[1].legend(loc=2)
```

If you don’t like the default colours, you can specify how you’d like each column to be colored.

```python
>>> axes = df.plot.bar(
...     rot=0, subplots=True, color="speed": "red", "lifespan": "green"
... )
>>> axes[1].legend(loc=2)
```
pandas: powerful Python data analysis toolkit, Release 1.3.1
Plot a single column.

```python
>>> ax = df.plot.bar(y='speed', rot=0)
```

![Graph showing speed comparison across different animal species]

Plot only selected categories for the DataFrame.

```python
>>> ax = df.plot.bar(x='lifespan', rot=0)
```

---

### pandas.DataFrame.plot.barh

**DataFrame.plot.barh** *(x=None, y=None, **kwargs)*

Make a horizontal bar plot.

A horizontal bar plot is a plot that presents quantitative data with rectangular bars with lengths proportional to the values that they represent. A bar plot shows comparisons among discrete categories. One axis of the plot shows the specific categories being compared, and the other axis represents a measured value.

**Parameters**

- `x` [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.

- `y` [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
**color**  [str, array-like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:

- A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.

- A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column’s bar will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.

- A dict of the form {column name: color}, so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {"a": 'green', "b": 'red'} will color bars for column a in green and bars for column b in red.

New in version 1.1.0.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.axes.Axes or np.ndarray of them  An ndarray is returned with one matplotlib.axes.Axes per column when subplots=True.

See also:

- **DataFrame.plot.bar**  Vertical bar plot.
- **DataFrame.plot**  Make plots of DataFrame using matplotlib.
- **matplotlib.axes.Axes.bar**  Plot a vertical bar plot using matplotlib.

Examples

Basic example

```python
>>> df = pd.DataFrame({'lab': ['A', 'B', 'C'], 'val': [10, 30, 20]})
>>> ax = df.plot.barh(x='lab', y='val')
```

Plot a whole DataFrame to a horizontal bar plot

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant', 'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed, 'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh()
```

Plot stacked barh charts for the DataFrame

```python
>>> ax = df.plot.barh(stacked=True)
```

We can specify colors for each column

```python
>>> ax = df.plot.barh(color={"speed": "red", "lifespan": "green"})
```

Plot a column of the DataFrame to a horizontal bar plot
3.4. DataFrame
```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...          'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                   'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(y='speed')
```

Plot DataFrame versus the desired column

```python
>>> speed = [0.1, 17.5, 40, 48, 52, 69, 88]
>>> lifespan = [2, 8, 70, 1.5, 25, 12, 28]
>>> index = ['snail', 'pig', 'elephant',
...          'rabbit', 'giraffe', 'coyote', 'horse']
>>> df = pd.DataFrame({'speed': speed,
...                    'lifespan': lifespan}, index=index)
>>> ax = df.plot.barh(x='lifespan')
```
3.4. DataFrame
**pandas.DataFrame.plot.box**

`DataFrame.plot.box(by=None, **kwargs)`

Make a box plot of the DataFrame columns.

A box plot is a method for graphically depicting groups of numerical data through their quartiles. The box extends from the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of box to show the range of the data. The position of the whiskers is set by default to 1.5*IQR (IQR = Q3 - Q1) from the edges of the box. Outlier points are those past the end of the whiskers.

For further details see Wikipedia’s entry for boxplot.

A consideration when using this chart is that the box and the whiskers can overlap, which is very common when plotting small sets of data.

**Parameters**

- `by` [str or sequence] Column in the DataFrame to group by.
- `**kwargs` Additional keywords are documented in `DataFrame.plot()`.

**Returns**

`matplotlib.axes.Axes` or `numpy.ndarray` of them

See also:

- `DataFrame.boxplot` Another method to draw a box plot.
- `Series.plot.box` Draw a box plot from a Series object.
- `matplotlib.pyplot.boxplot` Draw a box plot in matplotlib.

**Examples**

Draw a box plot from a DataFrame with four columns of randomly generated data.

```python
>>> data = np.random.randn(25, 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'))
>>> ax = df.plot.box()
```

**pandas.DataFrame.plot.density**

`DataFrame.plot.density(bw_method=None, ind=None, **kwargs)`

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

**Parameters**

- `bw_method` [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See `scipy.stats.gaussian_kde` for more information.
- `ind` [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If `ind` is a NumPy array, the KDE is evaluated at the points passed. If `ind` is an integer, `ind` number of equally spaced points are used.
- `**kwargs` Additional keyword arguments are documented in `pandas.%{this-datatype}s.plot()`.
3.4. DataFrame
Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

scipy.stats.gaussian_kde Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:
For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)
```

```python
>>> ax = df.plot.kde(bw_method=3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```
pandas.DataFrame.plot.hexbin

DataFrame.plot.hexbin(x, y, C=None, reduce_C_function=None, gridsize=None, **kwargs)

Generate a hexagonal binning plot.

Generate a hexagonal binning plot of x versus y. If C is None (the default), this is a histogram of the number of occurrences of the observations at (x[i], y[i]).

If C is specified, specifies values at given coordinates (x[i], y[i]). These values are accumulated for each hexagonal bin and then reduced according to reduce_C_function, having as default the NumPy’s mean function (numpy.mean()). (If C is specified, it must also be a 1-D sequence of the same length as x and y, or a column label.)

Parameters

x [int or str] The column label or position for x points.
y [int or str] The column label or position for y points.
C [int or str, optional] The column label or position for the value of (x, y) point.
reduce_C_function [callable, default np.mean] Function of one argument that reduces all the values in a bin to a single number (e.g. np.mean, np.max, np.sum, np.std).
gridsize [int or tuple of (int, int), default 100] The number of hexagons in the x-direction.
The corresponding number of hexagons in the y-direction is chosen in a way that the hexagons are approximately regular. Alternatively, gridsize can be a tuple with two elements specifying the number of hexagons in the x-direction and the y-direction.
**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

matplotlib.AxesSubplot The matplotlib Axes on which the hexbin is plotted.

See also:
DataFrame.plot Make plots of a DataFrame.
matplotlib.pyplot.hexbin Hexagonal binning plot using matplotlib, the matplotlib function that is used under the hood.

Examples

The following examples are generated with random data from a normal distribution.

```python
>>> n = 10000
>>> df = pd.DataFrame({'x': np.random.randn(n),
... 'y': np.random.randn(n)})
>>> ax = df.plot.hexbin(x='x', y='y', gridsize=20)
```

The next example uses C and np.sum as reduce_C_function. Note that ‘observations’ values ranges from 1 to 5 but the result plot shows values up to more than 25. This is because of the reduce_C_function.

```python
>>> n = 500
>>> df = pd.DataFrame({
... 'coord_x': np.random.uniform(-3, 3, size=n),
... 'coord_y': np.random.uniform(30, 50, size=n),
... 'observations': np.random.randint(1,5, size=n)
... })
>>> ax = df.plot.hexbin(x='coord_x',
... y='coord_y',
```

(continues on next page)
... C='observations',
... reduce_C_function=np.sum,
... gridsize=10,
... cmap="viridis")

pandas.DataFrame.plot.hist

DataFrame.plot.hist(by=None, bins=10, **kwargs)

Draw one histogram of the DataFrame's columns.

A histogram is a representation of the distribution of data. This function groups the values of all given Series in the DataFrame into bins and draws all bins in one matplotlib.axes.Axes. This is useful when the DataFrame's Series are in a similar scale.

Parameters

by [str or sequence, optional] Column in the DataFrame to group by.

bins [int, default 10] Number of histogram bins to be used.

**kwargs Additional keyword arguments are documented in DataFrame.plot().

Returns

class:matplotlib.AxesSubplot Return a histogram plot.
See also:

*DataFrame.hist* Draw histograms per DataFrame's Series.
*Series.hist* Draw a histogram with Series' data.

**Examples**

When we draw a dice 6000 times, we expect to get each value around 1000 times. But when we draw two dices and sum the result, the distribution is going to be quite different. A histogram illustrates those distributions.

```python
>>> df = pd.DataFrame(
...     np.random.randint(1, 7, 6000),
...     columns=['one'])
>>> df['two'] = df['one'] + np.random.randint(1, 7, 6000)
>>> ax = df.plot.hist(bins=12, alpha=0.5)
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.DataFrame.plot.kde

DataFrame.plot.kde(bw_method=None, ind=None, **kwargs)

Generate Kernel Density Estimate plot using Gaussian kernels.

In statistics, kernel density estimation (KDE) is a non-parametric way to estimate the probability density function (PDF) of a random variable. This function uses Gaussian kernels and includes automatic bandwidth determination.

Parameters

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If None (default), ‘scott’ is used. See scipy.stats.gaussian_kde for more information.

ind [NumPy array or int, optional] Evaluation points for the estimated PDF. If None (default), 1000 equally spaced points are used. If ind is a NumPy array, the KDE is evaluated at the points passed. If ind is an integer, ind number of equally spaced points are used.

**kwargs Additional keyword arguments are documented in pandas.%(this-datatype)s.plot().

Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

scipy.stats.gaussian_kde Representation of a kernel-density estimate using Gaussian kernels. This is the function used internally to estimate the PDF.

Examples

Given a Series of points randomly sampled from an unknown distribution, estimate its PDF using KDE with automatic bandwidth determination and plot the results, evaluating them at 1000 equally spaced points (default):

```python
>>> s = pd.Series([1, 2, 2.5, 3, 3.5, 4, 5])
>>> ax = s.plot.kde()
```

A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = s.plot.kde(bw_method=0.3)
```

```python
>>> ax = s.plot.kde(bw_method=3)
```

Finally, the ind parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = s.plot.kde(ind=[1, 2, 3, 4, 5])
```

For DataFrame, it works in the same way:

```python
>>> df = pd.DataFrame({
...     'x': [1, 2, 2.5, 3, 3.5, 4, 5],
...     'y': [4, 4, 4.5, 5, 5.5, 6, 6],
... })
>>> ax = df.plot.kde()
```
3.4. DataFrame

![Graph showing density distribution for variables x and y.](image-url)
A scalar bandwidth can be specified. Using a small bandwidth value can lead to over-fitting, while using a large bandwidth value may result in under-fitting:

```python
>>> ax = df.plot.kde(bw_method=0.3)
```

Finally, the `ind` parameter determines the evaluation points for the plot of the estimated PDF:

```python
>>> ax = df.plot.kde(ind=[1, 2, 3, 4, 5, 6])
```

### pandas.DataFrame.plot.line

DataFrame.plot.line(x=None, y=None, **kwargs)

Plot Series or DataFrame as lines.

This function is useful to plot lines using DataFrame’s values as coordinates.

**Parameters**

- `x` [label or position, optional] Allows plotting of one column versus another. If not specified, the index of the DataFrame is used.
- `y` [label or position, optional] Allows plotting of one column versus another. If not specified, all numerical columns are used.
**color**  [str, array-like, or dict, optional] The color for each of the DataFrame’s columns. Possible values are:

- A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.

- A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each column recursively. For instance ['green', 'yellow'] each column’s line will be filled in green or yellow, alternatively. If there is only a single column to be plotted, then only the first color from the color list will be used.

- A dict of the form {column name} [color], so that each column will be colored accordingly. For example, if your columns are called a and b, then passing {'a': 'green', 'b': 'red'} will color lines for column a in green and lines for column b in red.

*New in version 1.1.0.*

**kwargs**  Additional keyword arguments are documented in `DataFrame.plot()`.

Returns

- `matplotlib.axes.Axes` or `np.ndarray of them` An ndarray is returned with one `matplotlib.axes.Axes` per column when `subplots=True`.

See also:

- `matplotlib.pyplot.plot`  Plot y versus x as lines and/or markers.

### Examples

```python
>>> s = pd.Series([1, 3, 2])
>>> s.plot.line()

The following example shows the populations for some animals over the years.

```python
>>> df = pd.DataFrame(
...     ...
...     'pig': [20, 18, 489, 675, 1776],
...     ...
...     'horse': [4, 25, 281, 600, 1900]
...     ...
>>> lines = df.plot.line()

An example with subplots, so an array of axes is returned.

```python
>>> axes = df.plot.line(subplots=True)
>>> type(axes)
<class 'numpy.ndarray'>

Let’s repeat the same example, but specifying colors for each column (in this case, for each animal).

```python
>>> axes = df.plot.line(
...     ...
...     subplots=True, color={'pig': 'pink', 'horse': '#742802'}
...     ...
... )

The following example shows the relationship between both populations.

```python
>>> lines = df.plot.line(x='pig', y='horse')
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.DataFrame.plot.pie

Dataframe.plot.pie(**kwargs)
Generate a pie plot.

A pie plot is a proportional representation of the numerical data in a column. This function wraps matplotlib.pyplot.pie() for the specified column. If no column reference is passed and subplots=True a pie plot is drawn for each numerical column independently.

Parameters

- **y** [int or label, optional] Label or position of the column to plot. If not provided, subplots=True argument must be passed.

- **kwargs** Keyword arguments to pass on to DataFrame.plot().

Returns

- matplotlib.axes.Axes or np.ndarray of them A NumPy array is returned when subplots is True.

See also:

- Series.plot.pie Generate a pie plot for a Series.
- DataFrame.plot Make plots of a DataFrame.

Examples

In the example below we have a DataFrame with the information about planet’s mass and radius. We pass the ‘mass’ column to the pie function to get a pie plot.

```python
>>> df = pd.DataFrame({'mass': [0.330, 4.87 , 5.97],
... 'radius': [2439.7, 6051.8, 6378.1]},
... index=[ 'Mercury', 'Venus', 'Earth'])
>>> plot = df.plot.pie(y='mass', figsize=(5, 5))
```

```python
>>> plot = df.plot.pie(subplots=True, figsize=(11, 6))
```

pandas.DataFrame.plot.scatter

Dataframe.plot.scatter(x, y, s=None, c=None, **kwargs)
Create a scatter plot with varying marker point size and color.

The coordinates of each point are defined by two dataframe columns and filled circles are used to represent each point. This kind of plot is useful to see complex correlations between two variables. Points could be for instance natural 2D coordinates like longitude and latitude in a map or, in general, any pair of metrics that can be plotted against each other.

Parameters

- **x** [int or str] The column name or column position to be used as horizontal coordinates for each point.

- **y** [int or str] The column name or column position to be used as vertical coordinates for each point.

- **s** [str, scalar or array-like, optional] The size of each point. Possible values are:
  - A string with the name of the column to be used for marker’s size.
  - A single scalar so all points have the same size.
• A sequence of scalars, which will be used for each point’s size recursively. For instance, when passing [2,14] all points size will be either 2 or 14, alternatively.

Changed in version 1.1.0.

c  [str, int or array-like, optional] The color of each point. Possible values are:

• A single color string referred to by name, RGB or RGBA code, for instance ‘red’ or ‘#a98d19’.

• A sequence of color strings referred to by name, RGB or RGBA code, which will be used for each point’s color recursively. For instance [‘green’, ‘yellow’] all points will be filled in green or yellow, alternatively.

• A column name or position whose values will be used to color the marker points according to a colormap.

**kwargs  Keyword arguments to pass on to DataFrame.plot().

Returns

matplotlib.axes.Axes or numpy.ndarray of them

See also:

matplotlib.pyplot.scatter  Scatter plot using multiple input data formats.

Examples

Let’s see how to draw a scatter plot using coordinates from the values in a DataFrame’s columns.

```python
>>> df = pd.DataFrame([[5.1, 3.5, 0], [4.9, 3.0, 0], [7.0, 3.2, 1],
... [6.4, 3.2, 1], [5.9, 3.0, 2]],
... columns=['length', 'width', 'species'])
>>> ax1 = df.plot.scatter(x='length',
... y='width',
... c='DarkBlue')
```

And now with the color determined by a column as well.

```python
>>> ax2 = df.plot.scatter(x='length',
... y='width',
... c='species',
... colormap='viridis')
```

Dataframe.boxplot([column, by, ax, ...])  Make a box plot from DataFrame columns.

Dataframe.hist([column, by, grid, ...])  Make a histogram of the DataFrame’s columns.

3.4.16 Sparse accessor

Sparse-dtype specific methods and attributes are provided under the DataFrame.sparse accessor.

DataFrame.sparse.density  Ratio of non-sparse points to total (dense) data points.
### pandas.DataFrame.sparse.density

**DataFrame.sparse.density**

Ratio of non-sparse points to total (dense) data points.

- `DataFrame.sparse.from_spmatrix(data[, ...)]

Create a new DataFrame from a scipy sparse matrix.

- `DataFrame.sparse.to_coo()

Return the contents of the frame as a sparse SciPy COO matrix.

- `DataFrame.sparse.to_dense()

Convert a DataFrame with sparse values to dense.

### pandas.DataFrame.sparse.from_spmatrix

**classmethod DataFrame.sparse.from_spmatrix(data, index=None, columns=None)**

Create a new DataFrame from a scipy sparse matrix.

New in version 0.25.0.

**Parameters**

- `data` [scipy.sparse.spmatrix] Must be convertible to csc format.
- `index, columns` [Index, optional] Row and column labels to use for the resulting DataFrame. Defaults to a RangeIndex.

**Returns**

- `DataFrame` Each column of the DataFrame is stored as a `arrays.SparseArray`.

**Examples**

```python
>>> import scipy.sparse

>>> mat = scipy.sparse.eye(3)

>>> pd.DataFrame.sparse.from_spmatrix(mat)
            0  1  2
     0  1.0  0.0  0.0
     1  0.0  1.0  0.0
     2  0.0  0.0  1.0
```

### pandas.DataFrame.sparse.to_coo

**DataFrame.sparse.to_coo()**

Return the contents of the frame as a sparse SciPy COO matrix.

New in version 0.25.0.

**Returns**

- `coo_matrix` [scipy.sparse.spmatrix] If the caller is heterogeneous and contains booleans or objects, the result will be of dtype=object. See Notes.
Notes

The dtype will be the lowest-common-denominator type (implicit upcasting); that is to say if the dtypes (even of numeric types) are mixed, the one that accommodates all will be chosen.

e.g. If the dtypes are float16 and float32, dtype will be upcast to float32. By numpy.find_common_type convention, mixing int64 and and uint64 will result in a float64 dtype.

pandas.DataFrame.sparse.to_dense

DataFrame.sparse.to_dense()
Convert a DataFrame with sparse values to dense.

New in version 0.25.0.

Returns

DataFrame A DataFrame with the same values stored as dense arrays.

Examples

>>> df = pd.DataFrame({'A': pd.arrays.SparseArray([0, 1, 0])})
>>> df.sparse.to_dense()

A
0 0
1 1
2 0

3.4.17 Serialization / IO / conversion

DataFrame.from_dict(data[, orient, dtype, ...]) Construct DataFrame from dict of array-like or dicts.

DataFrame.from_records(data[, index, ...]) Convert structured or record ndarray to DataFrame.

DataFrame.to_parquet([path, engine, ...]) Write a DataFrame to the binary parquet format.

DataFrame.to_pickle(path[, compression, ...]) Pickle (serialize) object to file.

DataFrame.to_csv([path_or_buf, sep, na_rep, ...]) Write object to a comma-separated values (csv) file.

DataFrame.to_hdf(path_or_buf, key[, mode, ...]) Write the contained data to an HDF5 file using HDFS-tore.

DataFrame.to_sql(name, con[, schema, ...]) Write records stored in a DataFrame to a SQL database.

DataFrame.to_dict([orient, into]) Convert the DataFrame to a dictionary.

DataFrame.to_json([path_or_buf, orient, ...]) Convert the object to a JSON string.

DataFrame.to_excel(excel_writer[, ...]) Write object to an Excel sheet.

DataFrame.to_html([buf, columns, col_space, ...]) Render a DataFrame as an HTML table.

DataFrame.to_feather(path, **kwargs) Write a DataFrame to the binary Feather format.

DataFrame.to_latex([buf, columns, ...]) Render object to a LaTeX tabular, longtable, or nested table/tabular.

DataFrame.to_stata(path[, convert_dates, ...]) Export DataFrame object to Stata dta format.

DataFrame.to_gbq(destination_table[, ...]) Write a DataFrame to a Google BigQuery table.

DataFrame.to_records([index, column_dtypes, ...]) Convert DataFrame to a NumPy record array.

3.5 pandas arrays

For most data types, pandas uses NumPy arrays as the concrete objects contained with a `Index`, `Series`, or `DataFrame`.

For some data types, pandas extends NumPy's type system. String aliases for these types can be found at `dtypes`.

<table>
<thead>
<tr>
<th>Kind of Data</th>
<th>pandas Data Type</th>
<th>Scalar</th>
<th>Array</th>
</tr>
</thead>
<tbody>
<tr>
<td>TZ-aware datetime</td>
<td>DatetimeTZDtype</td>
<td>Timestamp</td>
<td>Datetime data</td>
</tr>
<tr>
<td>Timedelta</td>
<td>(none)</td>

<td>Text data</td>
</tr>
<tr>
<td>Boolean (with NA)</td>
<td>BooleanDtype</td>
<td>bool</td>
<td>Boolean data with missing values</td>
</tr>
</tbody>
</table>

pandas and third-party libraries can extend NumPy’s type system (see `Extension types`). The top-level `array()` method can be used to create a new array, which may be stored in a `Series`, `Index`, or as a column in a `DataFrame`.

```
array(data[, dtype, copy])                               Create an array.
```

3.5.1 pandas.array

```
pandas.array (data, dtype=None, copy=True)
Create an array.
```

**Parameters**

- `data` [Sequence of objects] The scalars inside `data` should be instances of the scalar type for `dtype`. It's expected that `data` represents a 1-dimensional array of data.

  When `data` is an Index or Series, the underlying array will be extracted from `data`.

- `dtype` [str, np.dtype, or ExtensionDtype, optional] The dtype to use for the array. This may be a NumPy dtype or an extension type registered with pandas using `pandas_api.extensions.register_extension_dtype()`.

  If not specified, there are two possibilities:

  1. When `data` is a `Series`, `Index`, or `ExtensionArray`, the `dtype` will be taken from the data.

  2. Otherwise, pandas will attempt to infer the `dtype` from the data.
Note that when `data` is a NumPy array, `data.dtype` is not used for inferring the array type. This is because NumPy cannot represent all the types of data that can be held in extension arrays.

Currently, pandas will infer an extension dtype for sequences of

<table>
<thead>
<tr>
<th>Scalar Type</th>
<th>Array Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>pandas.Interval</td>
<td>pandas.arrays.IntervalArray</td>
</tr>
<tr>
<td>pandas.Period</td>
<td>pandas.arrays.PeriodArray</td>
</tr>
<tr>
<td>datetime</td>
<td>pandas.arrays.DateTimeArray</td>
</tr>
<tr>
<td>timedelta</td>
<td>pandas.arrays.TimedeltaArray</td>
</tr>
<tr>
<td>int</td>
<td>pandas.arrays.IntegerArray</td>
</tr>
<tr>
<td>float</td>
<td>pandas.arrays.FloatingArray</td>
</tr>
<tr>
<td>str</td>
<td>pandas.arrays.StringArray</td>
</tr>
<tr>
<td>bool</td>
<td>pandas.arrays.BooleanArray</td>
</tr>
</tbody>
</table>

The ExtensionArray created when the scalar type is `str` is determined by `pd.options.mode.string_storage` if the dtype is not explicitly given.

For all other cases, NumPy’s usual inference rules will be used.

Changed in version 1.0.0: Pandas infers nullable-integer dtype for integer data, string dtype for string data, and nullable-boolean dtype for boolean data.

Changed in version 1.2.0: Pandas now also infers nullable-floating dtype for float-like input data

- `copy` [bool, default True] Whether to copy the data, even if not necessary. Depending on the type of `data`, creating the new array may require copying data, even if `copy=False`.

**Returns**

- `ExtensionArray` The newly created array.

**Raises**

- `ValueError` When `data` is not 1-dimensional.

**See also:**

- `numpy.array` Construct a NumPy array.
- `Series` Construct a pandas Series.
- `Index` Construct a pandas Index.
- `arrays.PandasArray` ExtensionArray wrapping a NumPy array.
- `Series.array` Extract the array stored within a Series.
Notes

Omitting the *dtype* argument means pandas will attempt to infer the best array type from the values in the
data. As new array types are added by pandas and 3rd party libraries, the “best” array type may change. We
recommend specifying *dtype* to ensure that

1. the correct array type for the data is returned
2. the returned array type doesn’t change as new extension types are added by pandas and third-party libraries

Additionally, if the underlying memory representation of the returned array matters, we recommend specifying
the *dtype* as a concrete object rather than a string alias or allowing it to be inferred. For example, a future
version of pandas or a 3rd-party library may include a dedicated ExtensionArray for string data. In this event,
the following would no longer return a *arrays.PandasArray* backed by a NumPy array.

```python
>>> pd.array(['a', 'b'], dtype=str)
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

This would instead return the new ExtensionArray dedicated for string data. If you really need the new array to
be backed by a NumPy array, specify that in the *dtype*.

```python
>>> pd.array(['a', 'b'], dtype=np.dtype("<U1"))
<PandasArray>
['a', 'b']
Length: 2, dtype: str32
```

Finally, Pandas has arrays that mostly overlap with NumPy

- *arrays.DatetimeArray*
- *arrays.TimedeltaArray*

When data with a *datetime64[ns]* or *timedelta64[ns]* *dtype* is passed, pandas will always return a
DatetimeArray or TimedeltaArray rather than a PandasArray. This is for symmetry with the case
of timezone-aware data, which NumPy does not natively support.

```python
>>> pd.array(['2015', '2016'], dtype='datetime64[ns]')
<DatetimeArray>
['2015-01-01 00:00:00', '2016-01-01 00:00:00']
Length: 2, dtype: datetime64[ns]
```

```python
>>> pd.array(["1H", "2H"], dtype='timedelta64[ns]')
<TimedeltaArray>
['0 days 01:00:00', '0 days 02:00:00']
Length: 2, dtype: timedelta64[ns]
```

Examples

If a *dtype* is not specified, pandas will infer the best *dtype* from the values. See the description of *dtype* for the
types pandas infers for.

```python
>>> pd.array([1, 2])
<IntegerArray>
[1, 2]
Length: 2, dtype: Int64
```

```python
>>> pd.array([1, 2, np.nan])
<IntegerArray>
(continues on next page)
```
You can use the string alias for `dtype`

```python
>>> pd.array(['a', 'b', 'a'], dtype='category')
['a', 'b', 'a']
Categories (2, object): ['a', 'b']
```

Or specify the actual `dtype`

```python
>>> pd.array(['a', 'b', 'a'],
           dtype=pd.CategoricalDtype(['a', 'b', 'c'], ordered=True))
['a', 'b', 'a']
Categories (3, object): ['a' < 'b' < 'c']
```

If pandas does not infer a dedicated extension type a `arrays.PandasArray` is returned.

```python
>>> pd.array([1 + 1j, 3 + 2j])
<PandasArray>
[(1+1j), (3+2j)]
Length: 2, dtype: complex128
```

As mentioned in the “Notes” section, new extension types may be added in the future (by pandas or 3rd party libraries), causing the return value to no longer be a `arrays.PandasArray`. Specify the `dtype` as a NumPy `dtype` if you need to ensure there’s no future change in behavior.

```python
>>> pd.array([1, 2], dtype=np.dtype("int32"))
<PandasArray>
[1, 2]
Length: 2, dtype: int32
```

`data` must be 1-dimensional. A `ValueError` is raised when the input has the wrong dimensionality.
>>> pd.array(1)
Traceback (most recent call last):
...
ValueError: Cannot pass scalar '1' to 'pandas.array'.

3.5.2 Datetime data

NumPy cannot natively represent timezone-aware datetimes. pandas supports this with the arrays. 
DatetimeArray extension array, which can hold timezone-naive or timezone-aware values.

Timestamp, a subclass of datetime.datetime, is pandas’ scalar type for timezone-naive or timezone-aware 
datetime data.

<table>
<thead>
<tr>
<th>Timestamp([ts_input, freq, tz, unit, year, ...])</th>
<th>Pandas replacement for python datetime.datetime object.</th>
</tr>
</thead>
</table>

pandas.Timestamp

class pandas.Timestamp(ts_input=<object object>, freq=None, tz=None, unit=None, year=None, 
month=None, day=None, hour=None, minute=None, second=None, microsecond=None, nanosecond=None, tzinfo=None, *, fold=None)

Pandas replacement for python datetime.datetime object.

Timestamp is the pandas equivalent of python’s Datetime and is interchangeable with it in most cases. It’s the 
type used for the entries that make up a DatetimeIndex, and other timeseries oriented data structures in pandas.

Parameters

ts_input [datetime-like, str, int, float] Value to be converted to Timestamp.

freq [str, DateOffset] Offset which Timestamp will have.

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will 
have.

unit [str] Unit used for conversion if ts_input is of type int or float. The valid values are 

year, month, day [int]

hour, minute, second, microsecond [int, optional, default 0]

nanosecond [int, optional, default 0]

tzinfo [datetime.tzinfo, optional, default None]

fold [{0, 1}, default None, keyword-only] Due to daylight saving time, one wall clock time 
can occur twice when shifting from summer to winter time; fold describes whether the 
datetime-like corresponds to the first (0) or the second time (1) the wall clock hits the 
ambiguous time.

New in version 1.1.0.
Notes

There are essentially three calling conventions for the constructor. The primary form accepts four parameters. They can be passed by position or keyword.

The other two forms mimic the parameters from `datetime.datetime`. They can be passed by either position or keyword, but not both mixed together.

Examples

Using the primary calling convention:

This converts a datetime-like string

```python
>>> pd.Timestamp('2017-01-01T12')
Timestamp('2017-01-01 12:00:00')
```

This converts a float representing a Unix epoch in units of seconds

```python
>>> pd.Timestamp(1513393355.5, unit='s')
Timestamp('2017-12-16 03:02:35.500000')
```

This converts an int representing a Unix-epoch in units of seconds and for a particular timezone

```python
>>> pd.Timestamp(1513393355, unit='s', tz='US/Pacific')
Timestamp('2017-12-15 19:02:35-0800', tz='US/Pacific')
```

Using the other two forms that mimic the API for `datetime.datetime`:

```python
>>> pd.Timestamp(2017, 1, 1, 12)
Timestamp('2017-01-01 12:00:00')
```

```python
>>> pd.Timestamp(year=2017, month=1, day=1, hour=12)
Timestamp('2017-01-01 12:00:00')
```

**pandas.Timestamp.asm8**

Timestamp.asm8

Return numpy datetime64 format in nanoseconds.

**Examples**

```python
>>> ts = pd.Timestamp(2020, 3, 14, 15)
>>> ts.asm8
numpy.datetime64('2020-03-14T15:00:00.000000000')
```

**pandas.Timestamp.day_of_week**

Timestamp.day_of_week

Return day of the week.

**Examples**

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.day_of_week
5
```

**pandas.Timestamp.day_of_year**

Timestamp.day_of_year

Return the day of the year.

**Examples**

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.day_of_year
74
```
pandas.Timestamp.dayofweek

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.day_of_week
5
```

pandas.Timestamp.dayofyear

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.day_of_year
74
```

pandas.Timestamp.days_in_month

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.days_in_month
31
```

pandas.Timestamp.daysinmonth

```
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.days_in_month
31
```
## pandas.Timestamp.freqstr

**property** pandas.Timestamp.freqstr

Return the total number of days in the month.

### Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.days_in_month
31
```

## pandas.Timestamp.is_leap_year

**Timestamp.is_leap_year**

Return True if year is a leap year.

### Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_leap_year
True
```

## pandas.Timestamp.is_month_end

**Timestamp.is_month_end**

Return True if date is last day of month.

### Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_month_end
False
>>> ts = pd.Timestamp(2020, 12, 31)
>>> ts.is_month_end
True
```

## pandas.Timestamp.is_month_start

**Timestamp.is_month_start**

Return True if date is first day of month.
Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_month_start
False

>>> ts = pd.Timestamp(2020, 1, 1)
>>> ts.is_month_start
True
```

**pandas.Timestamp.is_quarter_end**

Timestamp.is_quarter_end
Return True if date is last day of the quarter.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_quarter_end
False

>>> ts = pd.Timestamp(2020, 3, 31)
>>> ts.is_quarter_end
True
```

**pandas.Timestamp.is_quarter_start**

Timestamp.is_quarter_start
Return True if date is first day of the quarter.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_quarter_start
False

>>> ts = pd.Timestamp(2020, 4, 1)
>>> ts.is_quarter_start
True
```
pandas.Timestamp.is_year_end

Timestamp.is_year_end
Return True if date is last day of the year.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_year_end
False

>>> ts = pd.Timestamp(2020, 12, 31)
>>> ts.is_year_end
True
```

pandas.Timestamp.is_year_start

Timestamp.is_year_start
Return True if date is first day of the year.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.is_year_start
False

>>> ts = pd.Timestamp(2020, 1, 1)
>>> ts.is_year_start
True
```

pandas.Timestamp.quarter

Timestamp.quarter
Return the quarter of the year.

Examples

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.quarter
1
```
pandas.Timestamp.tz

**property** Timestamp.tz

Alias for tzinfo.

**Examples**

```python
>>> ts = pd.Timestamp(1584226800, unit='s', tz='Europe/Stockholm')
>>> ts.tz
<DstTzInfo 'Europe/Stockholm' CET+1:00:00 STD>
```

pandas.Timestamp.week

Timestamp.week

Return the week number of the year.

**Examples**

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.week
11
```

pandas.Timestamp.weekofyear

Timestamp.weekofyear

Return the week number of the year.

**Examples**

```python
>>> ts = pd.Timestamp(2020, 3, 14)
>>> ts.week
11
```
## Methods

**pandas.Timestamp.astimezone**

`Timestamp.astimezone(tz)`

Convert tz-aware Timestamp to another time zone.

**Parameters**

- `tz` [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding UTC time.

**Returns**

- `converted` [Timestamp]

**Raises**

- `TypeError` If Timestamp is tz-naive.

**Examples**

Create a timestamp object with UTC timezone:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651', tz='UTC')
>>> ts
Timestamp('2020-03-14 15:32:52.192548651+0000', tz='UTC')
```

Change to Tokyo timezone:

```python
>>> ts.tz_convert(tz='Asia/Tokyo')
Timestamp('2020-03-15 00:32:52.192548651+0900', tz='Asia/Tokyo')
```

Can also use `astimezone`:

```python
>>> ts.astimezone(tz='Asia/Tokyo')
Timestamp('2020-03-15 00:32:52.192548651+0900', tz='Asia/Tokyo')
```

Analogous for `pd.NaT`:

```python
>>> pd.NaT.tz_convert(tz='Asia/Tokyo')
NaT
```
**pandas.Timestamp.ceil**

`Timestamp.ceil(freq, ambiguous='raise', nonexistent='raise')`

Return a new Timestamp ceiled to this resolution.

**Parameters**

- `freq` [str] Frequency string indicating the ceiling resolution.
- `ambiguous` [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:
  - bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
  - ‘NaT’ will return NaT for an ambiguous time.
  - ‘raise’ will raise an AmbiguousTimeError for an ambiguous time.
- `nonexistent` [{'raise', 'shift_forward', 'shift_backward', 'NaT', timedelta}, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time.
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time.
  - ‘NaT’ will return NaT where there are nonexistent times.
  - timedelta objects will shift nonexistent times by the timedelta.
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

**Raises**

ValueError if the freq cannot be converted.

**Examples**

Create a timestamp object:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
```

A timestamp can be ceiled using multiple frequency units:

```python
>>> ts.ceil(freq='H')  # hour
Timestamp('2020-03-14 16:00:00')
```

```python
>>> ts.ceil(freq='T')  # minute
Timestamp('2020-03-14 15:33:00')
```

```python
>>> ts.ceil(freq='S')  # seconds
Timestamp('2020-03-14 15:32:53')
```

```python
>>> ts.ceil(freq='U')  # microseconds
Timestamp('2020-03-14 15:32:52.192549')
```

`freq` can also be a multiple of a single unit, like ‘5T’ (i.e. 5 minutes):
or a combination of multiple units, like ‘1H30T’ (i.e. 1 hour and 30 minutes):

```python
>>> ts.ceil(freq='1H30T')
Timestamp('2020-03-14 16:30:00')
```

Analogous for pd.NaT:

```python
>>> pd.NaT.ceil()
NaT
```

### pandas.Timestamp.combine

**classmethod** *Timestamp.combine*(date, time)
Combine date, time into datetime with same date and time fields.

**Examples**

```python
>>> from datetime import date, time
>>> pd.Timestamp.combine(date(2020, 3, 14), time(15, 30, 15))
Timestamp('2020-03-14 15:30:15')
```

### pandas.Timestamp.ctime

*Timestamp.ctime()*
Return ctime() style string.

### pandas.Timestamp.date

*Timestamp.date()*
Return date object with same year, month and day.

### pandas.Timestamp.day_name

*Timestamp.day_name()*
Return the day name of the Timestamp with specified locale.

**Parameters**

- **locale** [str, default None (English locale)] Locale determining the language in which to return the day name.

**Returns**

- **str**
Examples

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.day_name()
'Saturday'
```

Analogous for `pd.NaT`:

```python
>>> pd.NaT.day_name()
nan
```

**pandas.Timestamp.dst**

`Timestamp.dst()`

Return `self.tzinfo.dst(self)`.

**pandas.Timestamp.floor**

`Timestamp.floor(freq, ambiguous='raise', nonexistent='raise')`

Return a new Timestamp floored to this resolution.

**Parameters**

- **freq** [str] Frequency string indicating the flooring resolution.
- **ambiguous** [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:
  - bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
  - ‘NaT’ will return NaT for an ambiguous time.
  - ‘raise’ will raise an AmbiguousTimeError for an ambiguous time.
- **nonexistent** [{‘raise’, ‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta}, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time.
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time.
  - ‘NaT’ will return NaT where there are nonexistent times.
  - timedelta objects will shift nonexistent times by the timedelta.
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

**Raises**

ValueError if the freq cannot be converted.
Examples

Create a timestamp object:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
```

A timestamp can be floored using multiple frequency units:

```python
>>> ts.floor(freq='H') # hour
Timestamp('2020-03-14 15:00:00')

>>> ts.floor(freq='T') # minute
Timestamp('2020-03-14 15:32:00')

>>> ts.floor(freq='S') # seconds
Timestamp('2020-03-14 15:32:52')

>>> ts.floor(freq='N') # nanoseconds
Timestamp('2020-03-14 15:32:52.192548651')
```

dfreq can also be a multiple of a single unit, like ‘5T’ (i.e. 5 minutes):

```python
>>> ts.floor(freq='5T')
Timestamp('2020-03-14 15:30:00')
```

or a combination of multiple units, like ‘1H30T’ (i.e. 1 hour and 30 minutes):

```python
>>> ts.floor(freq='1H30T')
Timestamp('2020-03-14 15:00:00')
```

Analogous for pd.NaT:

```python
>>> pd.NaT.floor()
NaT
```

**pandas.Timestamp.fromisocalendar**

Timestamp. fromisocalendar ()
int, int, int -> Construct a date from the ISO year, week number and weekday.
This is the inverse of the date.isocalendar() function

**pandas.Timestamp.fromisoformat**

Timestamp. fromisoformat ()
string -> datetime from datetime.isoformat() output
pandas.Timestamp.fromordinal

**classmethod** `Timestamp.fromordinal(ordinal, freq=None, tz=None)`
Passed an ordinal, translate and convert to a ts. Note: by definition there cannot be any tz info on the ordinal itself.

**Parameters**

- **ordinal** [int] Date corresponding to a proleptic Gregorian ordinal.
- **freq** [str, DateOffset] Offset to apply to the Timestamp.
- **tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for the Timestamp.

**Examples**

```python
>>> pd.Timestamp.fromordinal(737425)
Timestamp('2020-01-01 00:00:00')
```

pandas.Timestamp.fromtimestamp

**classmethod** `Timestamp.fromtimestamp(ts)`
Transform timestamp[, tz] to tz’s local time from POSIX timestamp.

**Examples**

```python
>>> pd.Timestamp.utcfromtimestamp(1584199972)
Timestamp('2020-03-14 15:32:52')
```

Note that the output may change depending on your local time.

pandas.Timestamp.isocalendar

**Timestamp.isocalendar()**
Return a 3-tuple containing ISO year, week number, and weekday.

pandas.Timestamp.isoformat

**Timestamp.isoformat()**
[sep] -> string in ISO 8601 format, YYYY-MM-DDT[HH[:MM[:SS[.mmm[uuu]][+HH:MM]]]]. sep is used to separate the year from the time, and defaults to ‘T’. The optional argument timespec specifies the number of additional terms of the time to include. Valid options are ‘auto’, ‘hours’, ‘minutes’, ‘seconds’, ‘milliseconds’ and ‘microseconds’.
pandas.Timestamp.isoweekday

Timestamp.isoweekday()
Return the day of the week represented by the date. Monday == 1 ... Sunday == 7

pandas.Timestamp.month_name

Timestamp.month_name()
Return the month name of the Timestamp with specified locale.

Parameters
locale [str, default None (English locale)] Locale determining the language in which to return the month name.

Returns
str

Examples

```python
ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
ts.month_name()
'March'
```

Analogous for pd.NaT:

```python
pd.NaT.month_name()
nan
```

pandas.Timestamp.normalize

Timestamp.normalize()
Normalize Timestamp to midnight, preserving tz information.

Examples

```python
ts = pd.Timestamp(2020, 3, 14, 15, 30)
ts.normalize()
Timestamp('2020-03-14 00:00:00')
```

pandas.Timestamp.now

classmethod Timestamp.now(tz=None)
Return new Timestamp object representing current time local to tz.

Parameters
tz [str or timezone object, default None] Timezone to localize to.
Examples

```python
>>> pd.Timestamp.now()
Timestamp('2020-11-16 22:06:16.378782')
```

Analogous for `pd.NaT`:

```python
>>> pd.NaT.now()
NaT
```

**pandas.Timestamp.replace**

`pandas.Timestamp.replace`

- `year=None, month=None, day=None, hour=None, minute=None, second=None, microsecond=None, nanosecond=None, tzinfo=<class 'object'>, fold=None`

  Implements datetime.replace, handles nanoseconds.

- **Parameters**
  - `year` [int, optional]
  - `month` [int, optional]
  - `day` [int, optional]
  - `hour` [int, optional]
  - `minute` [int, optional]
  - `second` [int, optional]
  - `microsecond` [int, optional]
  - `nanosecond` [int, optional]
  - `tzinfo` [tz-convertible, optional]
  - `fold` [int, optional]

- **Returns**
  - `Timestamp` with fields replaced

**Examples**

Create a timestamp object:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651', tz='UTC')
>>> ts
Timestamp('2020-03-14 15:32:52.192548651+0000', tz='UTC')
```

Replace year and the hour:

```python
>>> ts.replace(year=1999, hour=10)
Timestamp('1999-03-14 10:32:52.192548651+0000', tz='UTC')
```

Replace timezone (not a conversion):
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
>>> import pytz

>>> ts.replace(tzinfo=pytz.timezone('US/Pacific'))
Timestamp('2020-03-14 15:32:52.192548651-0700', tz='US/Pacific')

Analogous for pd.NaT:

>>> pd.NaT.replace(tzinfo=pytz.timezone('US/Pacific'))
NaT
```

**pandas.Timestamp.round**

`Timestamp.round(freq, ambiguous='raise', nonexistent='raise')`

Round the Timestamp to the specified resolution.

**Parameters**

- `freq` [str] Frequency string indicating the rounding resolution.
- `ambiguous` [bool or {'raise', 'NaT'}, default 'raise'] The behavior is as follows:
  - bool contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
  - ‘NaT’ will return NaT for an ambiguous time.
  - ‘raise’ will raise an AmbiguousTimeError for an ambiguous time.
- `nonexistent` [{‘raise’, ‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta}, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time.
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time.
  - ‘NaT’ will return NaT where there are nonexistent times.
  - timedelta objects will shift nonexistent times by the timedelta.
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

**Returns**

A new Timestamp rounded to the given resolution of `freq`

**Raises**

ValueError if the freq cannot be converted
Examples

Create a timestamp object:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
```

A timestamp can be rounded using multiple frequency units:

```python
>>> ts.round(freq='H') # hour
Timestamp('2020-03-14 16:00:00')
```

```python
>>> ts.round(freq='T') # minute
Timestamp('2020-03-14 15:33:00')
```

```python
>>> ts.round(freq='S') # seconds
Timestamp('2020-03-14 15:32:52')
```

```python
>>> ts.round(freq='L') # milliseconds
Timestamp('2020-03-14 15:32:52.193000')
```

freq can also be a multiple of a single unit, like ‘5T’ (i.e. 5 minutes):

```python
>>> ts.round(freq='5T')
Timestamp('2020-03-14 15:35:00')
```

or a combination of multiple units, like ‘1H30T’ (i.e. 1 hour and 30 minutes):

```python
>>> ts.round(freq='1H30T')
Timestamp('2020-03-14 15:00:00')
```

Analogous for pd.NaT:

```python
>>> pd.NaT.round()
NaT
```

**pandas.Timestamp.strftime**

`Timestamp.strftime(format)`

Return a string representing the given POSIX timestamp controlled by an explicit format string.

**Parameters**

- **format** [str] Format string to convert Timestamp to string. See strftime documentation for more information on the format string: https://docs.python.org/3/library/datetime.html#strftime-and-strptime-behavior.
Examples

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.strftime('%Y-%m-%d %X')
'2020-03-14 15:32:52'
```

**pandas.Timestamp.strptime**

*classmethod* `Timestamp.strptime(string, format)`

Function is not implemented. Use `pd.to_datetime()`.

**pandas.Timestamp.time**

`Timestamp.time()`

Return time object with same time but with tzinfo=None.

**pandas.Timestamp.timestamp**

`Timestamp.timestamp()`

Return POSIX timestamp as float.

Examples

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548')
>>> ts.timestamp()
1584199972.192548
```

**pandas.Timestamp.timetuple**

`Timestamp.timetuple()`

Return time tuple, compatible with `time.localtime()`.

**pandas.Timestamp.timetz**

`Timestamp.timetz()`

Return time object with same time and tzinfo.
pandas.Timestamp.to_datetime64

Timestamp.to_datetime64()
Return a numpy.datetime64 object with ‘ns’ precision.

pandas.Timestamp.to_julian_date

Timestamp.to_julian_date()
Convert TimeStamp to a Julian Date. 0 Julian date is noon January 1, 4713 BC.

Examples

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52')
>>> ts.to_julian_date()
2458923.147824074
```

pandas.Timestamp.to_numpy

Timestamp.to_numpy()
Convert the Timestamp to a NumPy datetime64.
New in version 0.25.0.
This is an alias method for Timestamp.to_datetime64(). The dtype and copy parameters are available here only for compatibility. Their values will not affect the return value.

Returns

numpy.datetime64

See also:

datetimeIndex.to_numpy  Similar method for DatetimeIndex.

Examples

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.to_numpy()
numpy.datetime64('2020-03-14T15:32:52.192548651')
```

Analogous for pd.NaT:

```python
>>> pd.NaT.to_numpy()
numpy.datetime64('NaT')
```
**pandas.Timestamp.to_period**

Timestamp.to_period()  
Return an period of which this timestamp is an observation.

**Examples**

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts.to_period(freq='Y') # Year end frequency  
numpy.datetime64('2020-03-14T15:32:52.192548651')

>>> ts.to_period(freq='M') # Month end frequency  
Period('2020-03', 'M')

>>> ts.to_period(freq='W') # Weekly frequency  
Period('2020-03-09/2020-03-15', 'W-SUN')

>>> ts.to_period(freq='Q') # Quarter end frequency  
Period('2020Q1', 'Q-DEC')
```

**pandas.Timestamp.to_pydatetime**

Timestamp.to_pydatetime()  
Convert a Timestamp object to a native Python datetime object.  
If warn=True, issue a warning if nanoseconds is nonzero.

**Examples**

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548')
>>> ts.to_pydatetime()  
datetime.datetime(2020, 3, 14, 15, 32, 52, 192548)

Analogous for pd.NaT:

>>> pd.NaT.to_pydatetime()  
NaT
```

**pandas.Timestamp.today**

classmethod Timestamp.today(cls, tz=None)  
Return the current time in the local timezone. This differs from datetime.today() in that it can be localized to a passed timezone.

**Parameters**

- **tz** [str or timezone object, default None] Timezone to localize to.
Examples

```python
>>> pd.Timestamp.today()
Timestamp('2020-11-16 22:37:39.969883')
```

Analogous for `pd.NaT`:

```python
>>> pd.NaT.today()
NaT
```

**pandas.Timestamp.toordinal**

`Timestamp.toordinal()`

Return proleptic Gregorian ordinal. January 1 of year 1 is day 1.

**pandas.Timestamp.tz_convert**

`Timestamp.tz_convert(tz)`

Convert tz-aware `Timestamp` to another time zone.

Parameters

- `tz` [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which `Timestamp` will be converted to. None will remove timezone holding UTC time.

Returns

- `converted` [Timestamp]

Raises

- `TypeError` If `Timestamp` is tz-naive.

Examples

Create a timestamp object with UTC timezone:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651', tz='UTC')
```

```python
>>> ts
Timestamp('2020-03-14 15:32:52.192548651+0000', tz='UTC')
```

Change to Tokyo timezone:

```python
>>> ts.tz_convert(tz='Asia/Tokyo')
```

```python
Timestamp('2020-03-15 00:32:52.192548651+0900', tz='Asia/Tokyo')
```

Can also use `astimezone`:

```python
>>> ts.astimezone(tz='Asia/Tokyo')
```

```python
Timestamp('2020-03-15 00:32:52.192548651+0900', tz='Asia/Tokyo')
```

Analogous for `pd.NaT`:

```python
>>> pd.NaT.tz_convert(tz='Asia/Tokyo')
NaT
```
pandas.Timestamp.tz_localize

`pandas.Timestamp.tz_localize(tz, ambiguous='raise', nonexistent='raise')`

Convert naive Timestamp to local time zone, or remove timezone from tz-aware Timestamp.

**Parameters**

- **tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time which Timestamp will be converted to. None will remove timezone holding local time.
- **ambiguous** [bool, ‘NaT’, default ‘raise’] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the `ambiguous` parameter dictates how ambiguous times should be handled.
  - `bool` contains flags to determine if time is dst or not (note that this flag is only applicable for ambiguous fall dst dates).
  - ‘NaT’ will return NaT for an ambiguous time.
  - ‘raise’ will raise an AmbiguousTimeError for an ambiguous time.
- **nonexistent** [‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time.
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time.
  - ‘NaT’ will return NaT where there are nonexistent times.
  - timedelta objects will shift nonexistent times by the timedelta.
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

**Returns**

- **localized** [Timestamp]

**Raises**

- **TypeError** If the Timestamp is tz-aware and tz is not None.

**Examples**

Create a naive timestamp object:

```python
>>> ts = pd.Timestamp('2020-03-14T15:32:52.192548651')
>>> ts
Timestamp('2020-03-14 15:32:52.192548651')
```

Add ‘Europe/Stockholm’ as timezone:
>>> ts.tz_localize(tz='Europe/Stockholm')
Timestamp('2020-03-14 15:32:52.192548651+0100', tz='Europe/Stockholm')

Analogous for pd.NaT:

>>> pd.NaT.tz_localize()
NaT

**pandas.Timestamp.tzname**

Timestamp.tzname()
Return self.tzinfo.tzname(self).

**pandas.Timestamp.utcnow**

classmethod Timestamp.utcnow()
Return a new Timestamp representing UTC day and time.

Examples

```python
>>> pd.Timestamp.utcnow()
Timestamp('2020-11-16 22:50:18.092888+0000', tz='UTC')
```

**pandas.Timestamp.utcoffset**

Timestamp.utcoffset()
Return self.tzinfo.utcoffset(self).

Examples

```python
>>> pd.Timestamp.utcoffset()
Timestamp('2020-11-16 22:50:18.092888+0000', tz='UTC')
```
pandas.Timestamp.utctimetuple

```
pandas.Timestamp.utctimetuple()
```

Return UTC time tuple, compatible with time.localtime().

pandas.Timestamp.weekday

```
pandas.Timestamp.weekday()
```

Return the day of the week represented by the date. Monday == 0 ... Sunday == 6

**Properties**

- `Timestamp.asm8` Return numpy datetime64 format in nanoseconds.
- `Timestamp.day`
- `Timestamp.day_of_week` Return day of the week.
- `Timestamp.dayOfYear` Return the day of the year.
- `Timestamp.day_of_year` Return the day of the year.
- `Timestamp.days_in_month` Return the number of days in the month.
- `Timestamp.daysInMonth` Return the number of days in the month.
- `Timestamp.fold`
- `Timestamp.hour`
- `Timestamp.is_leap_year` Return True if year is a leap year.
- `Timestamp.is_month_end` Return True if date is last day of month.
- `Timestamp.is_month_start` Return True if date is first day of month.
- `Timestamp.is_quarter_end` Return True if date is last day of the quarter.
- `Timestamp.is_quarter_start` Return True if date is first day of the quarter.
- `Timestamp.is_year_end` Return True if date is last day of the year.
- `Timestamp.is_year_start` Return True if date is first day of the year.
- `Timestamp.max`
- `Timestamp.microsecond`
- `Timestamp.min`
- `Timestamp.minute`
- `Timestamp.month`
- `Timestamp.nanosecond`
- `Timestamp.quarter` Return the quarter of the year.
- `Timestamp.resolution`
- `Timestamp.second`

</tbody>
</table>
```
pandas.Timestamp.freq

Timestamp.freq

A collection of timestamps may be stored in a `arrays.DatetimeArray`. For timezone-aware data, the `.dtype` of a `DatetimeArray` is a `DatetimeTZDtype`. For timezone-naive data, `np.dtype("datetime64[ns]")` is used.

If the data are tz-aware, then every value in the array must have the same timezone.

```
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.DatetimeTZDtype

class pandas.DatetimeTZDtype(unit='ns', tz=None)
   An ExtensionDtype for timezone-aware datetime data.
   This is not an actual numpy dtype, but a duck type.
   Parameters
   unit [str, default “ns”] The precision of the datetime data. Currently limited to "ns".
   tz [str, int, or datetime.tzinfo] The timezone.
   Raises
   pytz.UnknownTimeZoneError When the requested timezone cannot be found.

Examples

```python
>>> pd.DatetimeTZDtype(tz='UTC')
datetime64[ns, UTC]
```

```python
>>> pd.DatetimeTZDtype(tz='dateutil/US/Central')
datetime64[ns, tzfile('/usr/share/zoneinfo/US/Central')]
```

Attributes

<table>
<thead>
<tr>
<th>unit</th>
<th>The precision of the datetime data.</th>
</tr>
</thead>
<tbody>
<tr>
<td>tz</td>
<td>The timezone.</td>
</tr>
</tbody>
</table>

pandas.DatetimeTZDtype.unit

property DatetimeTZDtype.unit
   The precision of the datetime data.

pandas.DatetimeTZDtype.tz

property DatetimeTZDtype.tz
   The timezone.

Methods

None
3.5.3 Timedelta data

NumPy can natively represent timedeltas. pandas provides `Timedelta` for symmetry with `Timestamp`.

```python
timedelta([value, unit])
```

Represents a duration, the difference between two dates or times.

### pandas.Timedelta

**class** `pandas.Timedelta` *(value=<object object>, unit=None, **kwargs)*

Represents a duration, the difference between two dates or times.

Timedelta is the pandas equivalent of python's `datetime.timedelta` and is interchangeable with it in most cases.

**Parameters**

- **value** [Timedelta, timedelta, np.timedelta64, str, or int]
- **unit** [str, default ‘ns’] Denote the unit of the input, if input is an integer.

Possible values:

- ‘days’ or ‘day’
- ‘hours’, ‘hour’, ‘hr’, or ‘h’
- ‘minutes’, ‘minute’, ‘min’, or ‘m’
- ‘seconds’, ‘second’, or ‘sec’
- ‘milliseconds’, ‘millisecond’, ‘millis’, or ‘milli’
- ‘microseconds’, ‘microsecond’, ‘micros’, or ‘micro’

**kwargs** Available kwargs: {days, seconds, microseconds, milliseconds, minutes, hours, weeks}. Values for construction in compat with `datetime.timedelta`. Numpy ints and floats will be coerced to python ints and floats.

**Notes**

The `.value` attribute is always in ns.

If the precision is higher than nanoseconds, the precision of the duration is truncated to nanoseconds.

**Attributes**

- **asm8** Return a numpy timedelta64 array scalar view.
- **components** Return a components namedtuplike.
- **days** Number of days.
- **delta** Return the timedelta in nanoseconds (ns), for internal compatibility.

continues on next page
Table 96 – continued from previous page

<table>
<thead>
<tr>
<th><strong>microseconds</strong></th>
<th>Number of microseconds (&gt;= 0 and less than 1 second).</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>nanoseconds</strong></td>
<td>Return the number of nanoseconds (n), where 0 &lt;= n &lt; 1 microsecond.</td>
</tr>
<tr>
<td><strong>resolution_string</strong></td>
<td>Return a string representing the lowest timedelta resolution.</td>
</tr>
<tr>
<td><strong>seconds</strong></td>
<td>Number of seconds (&gt;= 0 and less than 1 day).</td>
</tr>
</tbody>
</table>

**pandas.Timedelta.asm8**

Timedelta.asm8

Return a numpy timedelta64 array scalar view.

Provides access to the array scalar view (i.e. a combination of the value and the units) associated with the numpy.timedelta64().view(), including a 64-bit integer representation of the timedelta in nanoseconds (Python int compatible).

**Returns**

**numpy timedelta64 array scalar view** Array scalar view of the timedelta in nanoseconds.

**Examples**

```python
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.asm8
numpy.timedelta64(86520000003042,'ns')

>>> td = pd.Timedelta('2 min 3 s')
>>> td.asm8
numpy.timedelta64(123000000000,'ns')

>>> td = pd.Timedelta('3 ms 5 us')
>>> td.asm8
numpy.timedelta64(3005000,'ns')

>>> td = pd.Timedelta(42, unit='ns')
>>> td.asm8
numpy.timedelta64(42,'ns')
```

**pandas.Timedelta.components**

Timedelta.components

Return a components namedtuple-like.
pandas.Timedelta.days

Timedelta.days
Number of days.

pandas.Timedelta.delta

Timedelta.delta
Return the timedelta in nanoseconds (ns), for internal compatibility.

Returns
int Timedelta in nanoseconds.

Examples

```python
>>> td = pd.Timedelta('1 days 42 ns')
>>> td.delta
8640000000042

>>> td = pd.Timedelta('3 s')
>>> td.delta
3000000000

>>> td = pd.Timedelta('3 ms 5 us')
>>> td.delta
3005000

>>> td = pd.Timedelta(42, unit='ns')
>>> td.delta
42
```

pandas.Timedelta.microseconds

Timedelta.microseconds
Number of microseconds (>= 0 and less than 1 second).

pandas.Timedelta.nanoseconds

Timedelta.nanoseconds
Return the number of nanoseconds (n), where 0 <= n < 1 microsecond.

Returns
int Number of nanoseconds.

See also:

Timedelta.components Return all attributes with assigned values (i.e. days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds).
Examples

Using string input

```python
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.nanoseconds
42
```

Using integer input

```python
>>> td = pd.Timedelta(42, unit='ns')
>>> td.nanoseconds
42
```

**pandas.Timedelta.resolution_string**

Timedelta. resolution_string

Return a string representing the lowest timedelta resolution.

Each timedelta has a defined resolution that represents the lowest OR most granular level of precision. Each level of resolution is represented by a short string as defined below:

Resolution: Return value
- Days: ‘D’
- Hours: ‘H’
- Minutes: ‘T’
- Seconds: ‘S’
- Milliseconds: ‘L’
- Microseconds: ‘U’
- Nanoseconds: ‘N’

Returns

str Timedelta resolution.

Examples

```python
>>> td = pd.Timedelta('1 days 2 min 3 us 42 ns')
>>> td.resolution_string
'N'
```

```python
>>> td = pd.Timedelta('1 days 2 min 3 us')
>>> td.resolution_string
'U'
```

```python
>>> td = pd.Timedelta('2 min 3 s')
>>> td.resolution_string
'S'
```
```python
>>> td = pd.Timedelta(36, unit='us')
>>> td.resolution_string
'U'
```

**pandas.Timedelta.seconds**

Timedelta.seconds

Number of seconds (>= 0 and less than 1 day).

<table>
<thead>
<tr>
<th>freq</th>
<th>is_populated</th>
<th>value</th>
</tr>
</thead>
</table>

**Methods**

- `ceil(freq)`
  Return a new Timedelta ceiled to this resolution.

- `floor(freq)`
  Return a new Timedelta floored to this resolution.

- `isoformat`

- `round(freq)`
  Round the Timedelta to the specified resolution.

- `to_numpy`
  Convert the Timedelta to a NumPy timedelta64.

- `to_pytimedelta`
  Convert a pandas Timedelta object into a python timedelta object.

- `to_timedelta64`
  Return a numpy.timedelta64 object with 'ns' precision.

- `total_seconds`
  Total seconds in the duration.

- `view`
  Array view compatibility.

**pandas.Timedelta.ceil**

Timedelta.ceil(freq)

Return a new Timedelta ceiled to this resolution.

**Parameters**

- `freq` [str] Frequency string indicating the ceiling resolution.

**pandas.Timedelta.floor**

Timedelta.floor(freq)

Return a new Timedelta floored to this resolution.

**Parameters**

- `freq` [str] Frequency string indicating the flooring resolution.
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.Timedelta.isoformat

Timedelta.

isoformat()

Returns

str

See also:

Timestamp.isoformat  Function is used to convert the given Timestamp object into the ISO format.

Notes

The longest component is days, whose value may be larger than 365. Every component is always included, even if its value is 0. Pandas uses nanosecond precision, so up to 9 decimal places may be included in the seconds component. Trailing 0’s are removed from the seconds component after the decimal. We do not 0 pad components, so it’s $T5H$, not $T05H$.

Examples

```python
>>> td = pd.Timedelta(days=6, minutes=50, seconds=3,
              milliseconds=10, microseconds=10, nanoseconds=12)

>>> td.isoformat()
'P6DT0H50M3.010010012S'

>>> pd.Timedelta(hours=1, seconds=10).isoformat()
'P0DT1H0M10S'

>>> pd.Timedelta(days=500.5).isoformat()
'P500DT12H0M0S'
```

pandas.Timedelta.round

Timedelta.

round(freq)

Round the Timedelta to the specified resolution.

Parameters

- freq  [str] Frequency string indicating the rounding resolution.

Returns

- a new Timedelta rounded to the given resolution of freq

Raises

- ValueError if the freq cannot be converted
pandas.Timedelta.to_numpy

Timedelta.to_numpy()
Convert the Timedelta to a NumPy timedelta64.
New in version 0.25.0.
This is an alias method for Timedelta.to_timedelta64(). The dtype and copy parameters are available here only for compatibility. Their values will not affect the return value.

Returns
numpy.timedelta64
See also:
Series.to_numpy Similar method for Series.

pandas.Timedelta.to_pytimedelta

Timedelta.to_pytimedelta()
Convert a pandas Timedelta object into a python timedelta object.
Timedelta objects are internally saved as numpy datetime64[ns] dtype. Use to_pytimedelta() to convert to object dtype.

Returns
datetime.timedelta or numpy.array of datetime.timedelta
See also:
to_timedelta Convert argument to Timedelta type.

Notes
Any nanosecond resolution will be lost.

pandas.Timedelta.to_timedelta64

Timedelta.to_timedelta64()
Return a numpy.timedelta64 object with ‘ns’ precision.

pandas.Timedelta.total_seconds

Timedelta.total_seconds()
Total seconds in the duration.
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.Timedelta.view

Timedelta.view()
Array view compatibility.

</table>

A collection of timedeltas may be stored in a TimedeltaArray.

```
arrays.TimedeltaArray(values[, dtype, freq, ...])
```

pandas.arrays.TimedeltaArray

```
class pandas.arrays.TimedeltaArray(values, dtype=dtype('<m8[ns]'), freq=<no_default>, copy=False)
```

Pandas ExtensionArray for timedelta data.

**Warning:** TimedeltaArray is currently experimental, and its API may change without warning. In particular, TimedeltaArray.dtype is expected to change to be an instance of an ExtensionDtype subclass.

**Parameters**

- `values` [array-like] The timedelta data.
- `dtype` [numpy.dtype] Currently, only `numpy.dtype("timedelta64[ns]")` is accepted.
- `freq` [Offset, optional]
copy  [bool, default False] Whether to copy the underlying array of data.

Attributes

Methods

3.5.4 Timespan data

pandas represents spans of times as Period objects.

3.5.5 Period

pandas.Period

class pandas.Period(value=None, freq=None, ordinal=None, year=None, month=1, quarter=None, day=None, hour=None, minute=None, second=None)

Represents a period of time.

Parameters

value  [Period or str, default None] The time period represented (e.g., ‘4Q2005’).
freq  [str, default None] One of pandas period strings or corresponding objects.
ordinal  [int, default None] The period offset from the proleptic Gregorian epoch.
year  [int, default None] Year value of the period.
month  [int, default 1] Month value of the period.
quarter  [int, default None] Quarter value of the period.
day  [int, default 1] Day value of the period.
hour  [int, default 0] Hour value of the period.
minute  [int, default 0] Minute value of the period.
second  [int, default 0] Second value of the period.
### Attributes

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>day</code></td>
<td>Get day of the month that a Period falls on.</td>
</tr>
<tr>
<td><code>day_of_week</code></td>
<td>Day of the week the period lies in, with Monday=0 and Sunday=6.</td>
</tr>
<tr>
<td><code>day_of_year</code></td>

<td>Day of the week the period lies in, with Monday=0 and Sunday=6.</td>
</tr>
</tbody>
</table>

```python
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.day
11
```
pandas.Period.day_of_week

Period.day_of_week
Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

Returns

int Day of the week.

See also:

Period.day_of_week Day of the week the period lies in.
Period.weekday Alias of Period.day_of_week.
Period.day Day of the month.
Period.dayofyear Day of the year.

Examples

```python
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.day_of_week
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```python
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.day_of_week
6
>>> per.start_time.day_of_week
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```python
>>> per = pd.Period('2018-01', 'M')
>>> per.day_of_week
2
>>> per.end_time.day_of_week
2
```

pandas.Period.day_of_year

Period.day_of_year
Return the day of the year.

This attribute returns the day of the year on which the particular date occurs. The return value ranges between 1 to 365 for regular years and 1 to 366 for leap years.

Returns

int The day of year.

See also:
**Period.day**  Return the day of the month.

**Period.day_of_week**  Return the day of week.

**PeriodIndex.day_of_year**  Return the day of year of all indexes.

**Examples**

```python
good
>>> period = pd.Period("2015-10-23", freq='H')
>>> period.day_of_year
296
>>> period = pd.Period("2012-12-31", freq='D')
>>> period.day_of_year
366
>>> period = pd.Period("2013-01-01", freq='D')
>>> period.day_of_year
1
```

**pandas.Period.dayofweek**

**Period.dayofweek**

Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

**Returns**

*int*  Day of the week.

**See also:**

**Period.day_of_week**  Day of the week the period lies in.

**Period.weekday**  Alias of Period.day_of_week.

**Period.day**  Day of the month.

**Period.dayofyear**  Day of the year.

**Examples**

```python
good
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.day_of_week
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```python
good
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.day_of_week
6
>>> per.start_time.day_of_week
6
```

For periods with a frequency higher than days, the last day of the period is returned.
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
>>> per = pd.Period('2018-01', 'M')
>>> per.day_of_week
2
>>> per.end_time.day_of_week
2
```

**pandas.Period.dayofyear**

Period.dayofyear

Return the day of the year.

This attribute returns the day of the year on which the particular date occurs. The return value ranges between 1 to 365 for regular years and 1 to 366 for leap years.

**Returns**

int The day of year.

**See also:**

Period.day Return the day of the month.

Period.day_of_week Return the day of week.

PeriodIndex.day_of_year Return the day of year of all indexes.

**Examples**

```python
>>> period = pd.Period("2015-10-23", freq='H')
>>> period.day_of_year
296
>>> period = pd.Period("2012-12-31", freq='D')
>>> period.day_of_year
366
>>> period = pd.Period("2013-01-01", freq='D')
>>> period.day_of_year
1
```

**pandas.Period.days_in_month**

Period.days_in_month

Get the total number of days in the month that this period falls on.

**Returns**

int

**See also:**

Period.daysinmonth Gets the number of days in the month.

DatetimeIndex.daysinmonth Gets the number of days in the month.

calendar.monthrange Returns a tuple containing weekday (0-6 ~ Mon-Sun) and number of days (28-31).
Examples

```python
>>> p = pd.Period('2018-2-17')
>>> p.days_in_month
28

>>> pd.Period('2018-03-01').days_in_month
31

Handles the leap year case as well:

```python
>>> p = pd.Period('2016-2-17')
>>> p.days_in_month
29
```

pandas.Period.daysinmonth

**Period.daysinmonth**
Get the total number of days of the month that the Period falls in.

**Returns**

`int`

**See also:**

*Period.days_in_month* Return the days of the month.

*Period.dayofyear* Return the day of the year.

Examples

```python
>>> p = pd.Period("2018-03-11", freq='H')
>>> p.daysinmonth
31
```

pandas.Period.hour

**Period.hour**
Get the hour of the day component of the Period.

**Returns**

`int` The hour as an integer, between 0 and 23.

**See also:**

*Period.second* Get the second component of the Period.

*Period.minute* Get the minute component of the Period.
Examples

```python
>>> p.hour
13
```

Period longer than a day

```python
>>> p = pd.Period("2018-03-11", freq="M")
>>> p.hour
0
```

**pandas.Period.minute**

Period.minute
Get minute of the hour component of the Period.

Returns
- int: The minute as an integer, between 0 and 59.

See also:

- **Period.hour**: Get the hour component of the Period.
- **Period.second**: Get the second component of the Period.

Examples

```python
>>> p.minute
3
```

**pandas.Period.qyear**

Period.qyear
Fiscal year the Period lies in according to its starting-quarter.

The *year* and the *qyear* of the period will be the same if the fiscal and calendar years are the same. When they are not, the fiscal year can be different from the calendar year of the period.

Returns
- int: The fiscal year of the period.

See also:

- **Period.year**: Return the calendar year of the period.
Examples

If the natural and fiscal year are the same, qyear and year will be the same.

```python
>>> per = pd.Period('2018Q1', freq='Q')
>>> per.qyear
2018
>>> per.year
2018
```

If the fiscal year starts in April (Q-MAR), the first quarter of 2018 will start in April 2017. year will then be 2018, but qyear will be the fiscal year, 2018.

```python
>>> per = pd.Period('2018Q1', freq='Q-MAR')
>>> per.start_time
Timestamp('2017-04-01 00:00:00')
>>> per.qyear
2018
>>> per.year
2017
```

pandas.Period.second

**Period.second**
Get the second component of the Period.

**Returns**

- `int` The second of the Period (ranges from 0 to 59).

**See also:**

- **Period.hour** Get the hour component of the Period.
- **Period.minute** Get the minute component of the Period.

**Examples**

```python
>>> p.second
12
```

pandas.Period.start_time

**Period.start_time**
Get the Timestamp for the start of the period.

**Returns**

- `Timestamp`

**See also:**

- **Period.end_time** Return the end Timestamp.
- **Period.dayofyear** Return the day of year.
**Period.daysinmonth**  Return the days in that month.

**Period.dayofweek**  Return the day of the week.

**Examples**

```python
>>> period = pd.Period('2012-1-1', freq='D')
>>> period
Period('2012-01-01', 'D')
```

```python
>>> period.start_time
Timestamp('2012-01-01 00:00:00')
```

```python
>>> period.end_time
Timestamp('2012-01-01 23:59:59.999999999')
```

**pandas.Period.week**

**Period.week**  Get the week of the year on the given Period.

**Returns**

int

**See also:**

**Period.dayofweek**  Get the day component of the Period.

**Period.weekday**  Get the day component of the Period.

**Examples**

```python
>>> p = pd.Period("2018-03-11", "H")
>>> p.week
10
```

```python
>>> p = pd.Period("2018-02-01", "D")
>>> p.week
5
```

```python
>>> p = pd.Period("2018-01-06", "D")
>>> p.week
1
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.Period.weekday

Period.weekday
Day of the week the period lies in, with Monday=0 and Sunday=6.

If the period frequency is lower than daily (e.g. hourly), and the period spans over multiple days, the day at the start of the period is used.

If the frequency is higher than daily (e.g. monthly), the last day of the period is used.

Returns

int Day of the week.

See also:

Period.dayofweek Day of the week the period lies in.

Period.weekday Alias of Period.dayofweek.

Period.day Day of the month.

Period.dayofyear Day of the year.

Examples

```python
>>> per = pd.Period('2017-12-31 22:00', 'H')
>>> per.dayofweek
6
```

For periods that span over multiple days, the day at the beginning of the period is returned.

```python
>>> per = pd.Period('2017-12-31 22:00', '4H')
>>> per.dayofweek
6
>>> per.start_time.dayofweek
6
```

For periods with a frequency higher than days, the last day of the period is returned.

```python
>>> per = pd.Period('2018-01', 'M')
>>> per.dayofweek
2
>>> per.end_time.dayofweek
2
```

<table>

</table>

**pandas.Period.asfreq**

Period.asfreq()
Convert Period to desired frequency, at the start or end of the interval.

Parameters

freq [str] The desired frequency.

how [{‘E’, ‘S’, ‘end’, ‘start’}, default ‘end’] Start or end of the timespan.

Returns

resampled [Period]

**pandas.Period.strftime**

Period.strftime()
Returns the string representation of the Period, depending on the selected fmt. fmt must be a string containing one or several directives. The method recognizes the same directives as the time.strftime() function of the standard Python distribution, as well as the specific additional directives %f, %F, %q. (formatting & docs originally from scikits.timeries).
<table>
<thead>
<tr>
<th>Directive</th>
<th>Meaning</th>
<th>Notes</th>

<td></td>
</tr>
<tr>
<td>%S</td>
<td>Second as a decimal number [00,61].</td>
<td>(4)</td>
</tr>
<tr>
<td>%U</td>
<td>Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0.</td>
<td>(5)</td>
</tr>
<tr>
<td>%W</td>
<td>Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday are considered to be in week 0.</td>
<td>(5)</td>
</tr>
<tr>
<td>%x</td>
<td>Locale’s appropriate date representation.</td>
<td></td>
</tr>
<tr>
<td>%X</td>
<td>Locale’s appropriate time representation.</td>
<td></td>
</tr>
<tr>
<td>%y</td>
<td>Year without century as a decimal number [00,99].</td>
<td></td>
</tr>
<tr>
<td>%Y</td>
<td>Year with century as a decimal number.</td>
<td></td>
</tr>
<tr>
<td>%Z</td>
<td>Time zone name (no characters if no time zone exists).</td>
<td></td>
</tr>
<tr>
<td>%%</td>
<td>A literal ‘%’ character.</td>
<td></td>
</tr>
</tbody>
</table>

Notes

1. The %f directive is the same as %y if the frequency is not quarterly. Otherwise, it corresponds to the ‘fiscal’ year, as defined by the qyear attribute.
2. The %F directive is the same as %Y if the frequency is not quarterly. Otherwise, it corresponds to the ‘fiscal’ year, as defined by the qyear attribute.
3. The %p directive only affects the output hour field if the %I directive is used to parse the hour.
4. The range really is 0 to 61; this accounts for leap seconds and the (very rare) double leap seconds.
5. The %U and %W directives are only used in calculations when the day of the week and the year are specified.
Examples

```python
>>> a = Period(freq='Q-JUL', year=2006, quarter=1)
>>> a.strftime('%Y-Q%q')
'2006-Q1'
>>> # Output the last month in the quarter of this date
>>> a.strftime('%b-%Y')
'Oct-2005'
>>> a = Period(freq='D', year=2001, month=1, day=1)
>>> a.strftime('%d-%b-%Y')
'01-Jan-2006'
>>> a.strftime('%b. %d, %Y was a %A')
'Jan. 01, 2001 was a Monday'
```

`pandas.Period.to_timestamp`

`Period.to_timestamp()`

Return the Timestamp representation of the Period.

Uses the target frequency specified at the part of the period specified by `how`, which is either `Start` or `Finish`.

**Parameters**

- `freq` [str or DateOffset] Target frequency. Default is ‘D’ if self.freq is week or longer and ‘S’ otherwise.

**Returns**

- **Timestamp**

**Properties**

- `Period.day` Get day of the month that a Period falls on.
- `Period.dayofweek` Day of the week the period lies in, with Monday=0 and Sunday=6.
- `Period.day_of_week` Day of the week the period lies in, with Monday=0 and Sunday=6.
- `Period.dayofyear` Return the day of the year.
- `Period.day_of_year` Return the day of the year.
- `Period.days_in_month` Get the total number of days in the month that this period falls on.
- `Period.daysinmonth` Get the total number of days of the month that the Period falls in.
- `Period.end_time` continues on next page

**pandas.Period.now**

Period.now()

A collection of timedeltas may be stored in a arrays.PeriodArray. Every period in a PeriodArray must have the same freq.

arrays.PeriodArray(values[, dtype, freq, copy]) Pandas ExtensionArray for storing Period data.
pandas.arrays.PeriodArray

class pandas.arrays.PeriodArray (values, dtype=None, freq=None, copy=False)
Pandas ExtensionArray for storing Period data.

Users should use period_array() to create new instances. Alternatively, array() can be used to create new instances from a sequence of Period scalars.

Parameters
values [Union[PeriodArray, Series[period], ndarray[int], PeriodIndex]] The data to store. These should be arrays that can be directly converted to ordinals without inference or copy (PeriodArray, ndarray[int64]), or a box around such an array (Series[period], PeriodIndex).
dtype [PeriodDtype, optional] A PeriodDtype instance from which to extract a freq. If both freq and dtype are specified, then the frequencies must match.
freq [str or DateOffset] The freq to use for the array. Mostly applicable when values is an ndarray of integers, when freq is required. When values is a PeriodArray (or box around), it's checked that values.freq matches freq.
copy [bool, default False] Whether to copy the ordinals before storing.

See also:
Period Represents a period of time.
PeriodIndex Immutable Index for period data.
period_range Create a fixed-frequency PeriodArray.
array Construct a pandas array.

Notes

There are two components to a PeriodArray
• ordinals : integer ndarray
• freq : pd.tseries.offsets.Offset

The values are physically stored as a 1-D ndarray of integers. These are called “ordinals” and represent some kind of offset from a base.

The freq indicates the span covered by each element of the array. All elements in the PeriodArray have the same freq.

Attributes

| None |

Methods

| None |

PeriodDtype([freq]) An ExtensionDtype for Period data.
**pandas.PeriodDtype**

*class* pandas.PeriodDtype(*freq=None*)

An ExtensionDtype for Period data.

This is not an actual numpy dtype, but a duck type.

**Parameters**

*freq* [str or DateOffset] The frequency of this PeriodDtype.

**Examples**

```python
>>> pd.PeriodDtype(freq='D')
period[D]
```

```python
>>> pd.PeriodDtype(freq=pd.offsets.MonthEnd())
period[M]
```

**Attributes**

<table>
<thead>
<tr>
<th>freq</th>

</tr>
</thead>
</table>

**pandas.PeriodDtype.freq**

**property** PeriodDtype.freq

The frequency object of this PeriodDtype.

**Methods**

None

### 3.5.6 Interval data

Arbitrary intervals can be represented as *Interval* objects.

<table>
<thead>
<tr>
<th>Interval</th>
<th>Immutable object implementing an Interval, a bounded slice-like interval.</th>
</tr>
</thead>
</table>
pandas.Interval

class pandas.Interval
   Immutable object implementing an Interval, a bounded slice-like interval.

   Parameters
       left  [orderable scalar] Left bound for the interval.
       right [orderable scalar] Right bound for the interval.
       closed [[‘right’, ‘left’, ‘both’, ‘neither’], default ‘right’] Whether the interval is closed on
              the left-side, right-side, both or neither. See the Notes for more detailed explanation.

   See also:
       IntervalIndex An Index of Interval objects that are all closed on the same side.
       cut       Convert continuous data into discrete bins (Categorical of Interval objects).
       qcut     Convert continuous data into bins (Categorical of Interval objects) based on quantiles.
       Period   Represents a period of time.

   Notes
   The parameters left and right must be from the same type, you must be able to compare them and they must
   satisfy left <= right.
   A closed interval (in mathematics denoted by square brackets) contains its endpoints, i.e. the closed interval
   [0, 5] is characterized by the conditions 0 <= x <= 5. This is what closed='both' stands for. An
   open interval (in mathematics denoted by parentheses) does not contain its endpoints, i.e. the open interval (0,
   5) is characterized by the conditions 0 < x < 5. This is what closed='neither' stands for. Intervals
   can also be half-open or half-closed, i.e. [0, 5) is described by 0 <= x < 5(closed='left') and (0,
   5] is described by 0 < x <= 5(closed='right').

   Examples
   It is possible to build Intervals of different types, like numeric ones:

   >>> iv = pd.Interval(left=0, right=5)
   >>> iv
   Interval(0, 5, closed='right')

   You can check if an element belongs to it

   >>> 2.5 in iv
   True

   You can test the bounds (closed='right', so 0 < x <= 5):

   >>> 0 in iv
   False
   >>> 5 in iv
   True
   >>> 0.0001 in iv
   True

   Calculate its length

   >>> iv.length
   5
You can operate with `+` and `*` over an `Interval` and the operation is applied to each of its bounds, so the result depends on the type of the bound elements:

```python
>>> shifted_iv = iv + 3
>>> shifted_iv
Interval(3, 8, closed='right')
>>> extended_iv = iv * 10.0
>>> extended_iv
Interval(0.0, 50.0, closed='right')
```

To create a time interval you can use `Timestamps` as the bounds:

```python
>>> year_2017 = pd.Interval(pd.Timestamp('2017-01-01 00:00:00'),
... pd.Timestamp('2018-01-01 00:00:00'),
... closed='left')
>>> pd.Timestamp('2017-01-01 00:00') in year_2017
True
>>> year_2017.length
Timedelta('365 days 00:00:00')
```

### Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>closed</code></td>
<td>Whether the interval is closed on the left-side, right-side, both or neither.</td>
</tr>

<tr>
<td><code>right</code></td>
<td>Right bound for the interval.</td>
</tr>
</tbody>
</table>

**pandas.Interval.closed**

`Interval.closed`

Whether the interval is closed on the left-side, right-side, both or neither.

**pandas.Interval.closed_left**

`Interval.closed_left`

Check if the interval is closed on the left side.

For the meaning of `closed` and `open` see `Interval`.

**Returns**

`bool` True if the Interval is closed on the left-side.
pandas.Interval.closed_right

Interval.closed_right
Check if the interval is closed on the right side.
For the meaning of closed and open see Interval.

Returns

bool True if the Interval is closed on the left-side.

pandas.Interval.is_empty

Interval.is_empty
Indicates if an interval is empty, meaning it contains no points.
New in version 0.25.0.

Returns

bool or ndarray A boolean indicating if a scalar Interval is empty, or a boolean
ndarray positionally indicating if an Interval in an IntervalArray or
IntervalIndex is empty.

Examples

An Interval that contains points is not empty:

```python
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```python
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:

```python
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An IntervalArray or IntervalIndex returns a boolean ndarray positionally indicating if an
Interval is empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'),
         pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:
>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>> pd.IntervalIndex(ivs).is_empty
array([ True, False])

pandas.Interval.left

Interval.left
Left bound for the interval.

pandas.Interval.length

Interval.length
Return the length of the Interval.

pandas.Interval.mid

Interval.mid
Return the midpoint of the Interval.

pandas.Interval.open_left

Interval.open_left
Check if the interval is open on the left side.
For the meaning of closed and open see Interval.

Returns

   bool  True if the Interval is closed on the left-side.

pandas.Interval.open_right

Interval.open_right
Check if the interval is open on the right side.
For the meaning of closed and open see Interval.

Returns

   bool  True if the Interval is closed on the left-side.
pandas.Interval.right

Interval.right
Right bound for the interval.

Methods

overlaps
Check whether two Interval objects overlap.

pandas.Interval.overlaps

Interval.overlaps()
Check whether two Interval objects overlap.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

Parameters

other [Interval] Interval to check against for an overlap.

Returns

bool True if the two intervals overlap.

See also:
IntervalArray.overlaps The corresponding method for IntervalArray.
IntervalIndex.overlaps The corresponding method for IntervalIndex.

Examples

```python
>>> i1 = pd.Interval(0, 2)
>>> i2 = pd.Interval(1, 3)
>>> i1.overlaps(i2)
True
>>> i3 = pd.Interval(4, 5)
>>> i1.overlaps(i3)
False
```

Intervals that share closed endpoints overlap:

```python
>>> i4 = pd.Interval(0, 1, closed='both')
>>> i5 = pd.Interval(1, 2, closed='both')
>>> i4.overlaps(i5)
True
```

Intervals that only have an open endpoint in common do not overlap:

```python
>>> i6 = pd.Interval(1, 2, closed='neither')
>>> i4.overlaps(i6)
False
```
## Properties

<table>

</tbody>
</table>

A collection of intervals may be stored in an `arrays.IntervalArray`.

```python
arrays.IntervalArray(data[, closed, dtype, ...])
```

Pandas array for interval data that are closed on the same side.

## Pandas.arrays.IntervalArray

**class** `pandas.arrays.IntervalArray(data, closed=None, dtype=None, copy=False, verify_integrity=True)`

Pandas array for interval data that are closed on the same side.

New in version 0.24.0.

**Parameters**

- `data` [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalArray.
- `closed` [‘left’, ‘right’, ‘both’, ‘neither’], default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.
- `dtype` [dtype or None, default None] If None, dtype will be inferred.
- `copy` [bool, default False] Copy the input data.
- `verify_integrity` [bool, default True] Verify that the IntervalArray is valid.

**See also:**

- `Index` The base pandas Index type.
- `Interval` A bounded slice-like interval; the elements of an IntervalArray.
- `interval_range` Function to create a fixed frequency IntervalIndex.
- `cut` Bin values into discrete Intervals.
- `qcut` Bin values into equal-sized Intervals based on rank or sample quantiles.
Notes

See the user guide for more.

Examples

A new IntervalArray can be constructed directly from an array-like of Interval objects:

```python
>>> pd.arrays.IntervalArray([pd.Interval(0, 1), pd.Interval(1, 5)])
<IntervalArray>
[(0, 1], (1, 5]]
Length: 2, dtype: interval[int64, right]
```

It may also be constructed using one of the constructor methods: `IntervalArray.from_arrays()`, `IntervalArray.from_breaks()`, and `IntervalArray.from_tuples()`.

Attributes

<table>
<thead>
<tr>
<th>attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>left</code></td>
<td>Return the left endpoints of each Interval in the IntervalArray as an Index.</td>
</tr>
<tr>
<td><code>right</code></td>
<td>Return the right endpoints of each Interval in the IntervalArray as an Index.</td>
</tr>
<tr>
<td><code>closed</code></td>
<td>Whether the intervals are closed on the left-side, right-side, both or neither.</td>
</tr>
<tr>
<td><code>mid</code></td>
<td>Return the midpoint of each Interval in the IntervalArray as an Index.</td>
</tr>
<tr>
<td><code>length</code></td>
<td>Return an Index with entries denoting the length of each Interval in the IntervalArray.</td>
</tr>
<tr>
<td><code>is_empty</code></td>
<td>Indicates if an interval is empty, meaning it contains no points.</td>
</tr>
<tr>
<td><code>is_non_overlapping_monotonic</code></td>
<td>Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.</td>
</tr>
</tbody>
</table>

`pandas.arrays.IntervalArray.left`

```python
property IntervalArray.left
```

Return the left endpoints of each Interval in the IntervalArray as an Index.
pandas.arrays.IntervalArray.right

**property** IntervalArray.right

Return the right endpoints of each Interval in the IntervalArray as an Index.

pandas.arrays.IntervalArray.closed

**property** IntervalArray.closed

Whether the intervals are closed on the left-side, right-side, both or neither.

pandas.arrays.IntervalArray.mid

**property** IntervalArray.mid

Return the midpoint of each Interval in the IntervalArray as an Index.

pandas.arrays.IntervalArray.length

**property** IntervalArray.length

Return an Index with entries denoting the length of each Interval in the IntervalArray.

pandas.arrays.IntervalArray.is_empty

IntervalArray.is_empty

Indicates if an interval is empty, meaning it contains no points.

New in version 0.25.0.

**Returns**

bool or ndarray  A boolean indicating if a scalar Interval is empty, or a boolean ndarray positionally indicating if an Interval in an IntervalArray or IntervalIndex is empty.

**Examples**

An Interval that contains points is not empty:

```python
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```python
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:
An `IntervalArray` or `IntervalIndex` returns a boolean ndarray positionally indicating if an Interval is empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'),
        pd.Interval(0, 0, closed='neither'),
        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([ True, False])
```

### pandas.arrays.IntervalArray.is_non_overlapping_monotonic

**property** `IntervalArray.is_non_overlapping_monotonic`

Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.

### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>from_arrays</code></td>
<td>Construct from two arrays defining the left and right bounds.</td>
</tr>
<tr>
<td><code>from_tuples</code></td>
<td>Construct an IntervalArray from an array-like of tuples.</td>
</tr>
<tr>
<td><code>from_breaks</code></td>
<td>Construct an IntervalArray from an array of splits.</td>
</tr>
<tr>
<td><code>contains</code></td>
<td>Check elementwise if the Intervals contain the value.</td>
</tr>
<tr>
<td><code>overlaps</code></td>
<td>Check elementwise if an Interval overlaps the values in the IntervalArray.</td>
</tr>
<tr>
<td><code>set_closed</code></td>
<td>Return an IntervalArray identical to the current one, but closed on the specified side.</td>
</tr>
<tr>
<td><code>to_tuples</code></td>
<td>Return an ndarray of tuples of the form (left, right).</td>
</tr>
</tbody>
</table>

#### pandas.arrays.IntervalArray.from_arrays

**classmethod** `IntervalArray.from_arrays` (left, right[, closed, copy, dtype])

Construct from two arrays defining the left and right bounds.

**Parameters**

- `left` [array-like (1-dimensional)] Left bounds for each interval.
- `right` [array-like (1-dimensional)] Right bounds for each interval.
- `closed` [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.
- `copy` [bool, default False] Copy the data.
dtype  [dtype, optional] If None, dtype will be inferred.

Returns

IntervalArray

 Raises

ValueError  When a value is missing in only one of left or right. When a value in left is greater than the corresponding value in right.

See also:

interval_range  Function to create a fixed frequency IntervalIndex.

IntervalArray.from_breaks  Construct an IntervalArray from an array of splits.

IntervalArray.from_tuples  Construct an IntervalArray from an array-like of tuples.

Notes

Each element of left must be less than or equal to the right element at the same position. If an element is missing, it must be missing in both left and right. A TypeError is raised when using an unsupported type for left or right. At the moment, ‘category’, ‘object’, and ‘string’ subtypes are not supported.

```python
>>> pd.arrays.IntervalArray.from_arrays([0, 1, 2], [1, 2, 3])
<IntervalArray>
[(0, 1], (1, 2], (2, 3])
Length: 3, dtype: interval[int64, right]
```

pandas.arrays.IntervalArray.from_tuples

classmethod IntervalArray.from_tuples(data, closed='right', copy=False, dtype=None)

Construct an IntervalArray from an array-like of tuples.

Parameters

data  [array-like (1-dimensional)] Array of tuples.

closed  [‘left’, ‘right’, ‘both’, ‘neither’], default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.

copy  [bool, default False] By-default copy the data, this is compat only and ignored.

dtype  [dtype or None, default None] If None, dtype will be inferred.

Returns

IntervalArray

See also:

interval_range  Function to create a fixed frequency IntervalIndex.

IntervalArray.from_arrays  Construct an IntervalArray from a left and right array.

IntervalArray.from_breaks  Construct an IntervalArray from an array of splits.
Examples

```python
>>> pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 2)])
<IntervalArray>
[(0, 1], (1, 2])
Length: 2, dtype: interval[int64, right]
```

```python
def pandas.arrays.IntervalArray.from_breaks(breaks, closed='right', copy=False, dtype=None):
    Construct an IntervalArray from an array of splits.

    Parameters
    ----------
    breaks : array-like (1-dimensional)
        Left and right bounds for each interval.
    closed : {'left', 'right', 'both', 'neither'}, default 'right'
        Whether the intervals are closed on the left-side, right-side, both or neither.
    copy : bool, default False
        Copy the data.
    dtype : dtype or None, default None
        If None, dtype will be inferred.

    Returns
    -------
    IntervalArray

    See also:
    --------
    interval_range Function to create a fixed frequency IntervalIndex.
    IntervalArray.from_arrays Construct from a left and right array.
    IntervalArray.from_tuples Construct from a sequence of tuples.
```

```python
>>> pd.arrays.IntervalArray.from_breaks([0, 1, 2, 3])
<IntervalArray>
[(0, 1], (1, 2], (2, 3])
Length: 3, dtype: interval[int64, right]
```

```python
def pandas.arrays.IntervalArray.contains(other)
    Check elementwise if the Intervals contain the value.

    Return a boolean mask whether the value is contained in the Intervals of the IntervalArray.

    New in version 0.25.0.

    Parameters
    ----------
    other : scalar
        The value to check whether it is contained in the Intervals.

    Returns
    -------
```
boolean array

See also:

**Interval.contains** Check whether Interval object contains value.

**IntervalArray.overlaps** Check if an Interval overlaps the values in the IntervalArray.

### Examples

```python
test_intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
test_intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]
Length: 3, dtype: interval[int64, right]
```

```python
test_intervals.contains(0.5)
array([ True, False, False])
```

**pandas.arrays.IntervalArray.overlaps**

`IntervalArray.overlaps(other)`

Check elementwise if an Interval overlaps the values in the IntervalArray.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

**Parameters**

- `other` [IntervalArray] Interval to check against for an overlap.

**Returns**

- `ndarray` Boolean array positionally indicating where an overlap occurs.

See also:

**Interval.overlaps** Check whether two Interval objects overlap.

### Examples

```python
test_intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
test_intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]
Length: 3, dtype: interval[int64, right]
```

```python
test_intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True, True, False])
```

Intervals that share closed endpoints overlap:

```python
test_intervals.overlaps(pd.Interval(1, 3, closed='left'))
array([ True, True, True])
```
Intervals that only have an open endpoint in common do not overlap:

```python
>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False, True, False])
```

**pandas.arrays.IntervalArray.set_closed**

IntervalArray.set_closed(closed)

Return an IntervalArray identical to the current one, but closed on the specified side.

**Parameters**

closed [{'left', 'right', 'both', 'neither'}] Whether the intervals are closed on the left-side, right-side, both or neither.

**Returns**

new_index [IntervalArray]

**Examples**

```python
>>> index = pd.arrays.IntervalArray.from_breaks(range(4))
>>> index
<IntervalArray>
[(0, 1], (1, 2], (2, 3)]
Length: 3, dtype: interval[int64, right]
>>> index.set_closed('both')
<IntervalArray>
[[0, 1], [1, 2], [2, 3]]
Length: 3, dtype: interval[int64, both]
```

**pandas.arrays.IntervalArray.to_tuples**

IntervalArray.to_tuples(na_tuple=True)

Return an ndarray of tuples of the form (left, right).

**Parameters**

na_tuple [bool, default True] Returns NA as a tuple if True, (nan, nan), or just as the NA value itself if False, nan.

**Returns**

tuples: ndarray

**IntervalDtype([subtype, closed])] An ExtensionDtype for Interval data.**
pandas.IntervalDtype

class pandas.IntervalDtype (subtype=None, closed=None)
An ExtensionDtype for Interval data.

This is not an actual numpy dtype, but a duck type.

Parameters

Examples

```python
>>> pd.IntervalDtype(subtype='int64', closed='both')
interval[int64, both]
```

Attributes

subtype The dtype of the Interval bounds.

pandas.IntervalDtypesubtype

property IntervalDtype.subtype
The dtype of the Interval bounds.

Methods

3.5.7 Nullable integer

numpy.ndarray cannot natively represent integer-data with missing values. pandas provides this through arrays.IntegerArray.

arrays.IntegerArray(values, mask[, copy]) Array of integer (optional missing) values.

pandas.arrays.IntegerArray

class pandas.arrays.IntegerArray (values, mask, copy=False)
Array of integer (optional missing) values.

Changed in version 1.0.0: Now uses pandas.NA as the missing value rather than numpy.nan.

Warning: IntegerArray is currently experimental, and its API or internal implementation may change without warning.

We represent an IntegerArray with 2 numpy arrays:
• data: contains a numpy integer array of the appropriate dtype
• mask: a boolean array holding a mask on the data, True is missing

To construct an IntegerArray from generic array-like input, use `pandas.array()` with one of the integer dtypes (see examples).

See Nullable integer data type for more.

**Parameters**

- `values` ([numpy.ndarray]) A 1-d integer-dtype array.
- `mask` ([numpy.ndarray]) A 1-d boolean-dtype array indicating missing values.
- `copy` ([bool, default False]) Whether to copy the `values` and `mask`.

**Returns**

- `IntegerArray`

**Examples**

Create an IntegerArray with `pandas.array()`.

```python
>>> int_array = pd.array([1, None, 3], dtype=pd.Int32Dtype())
>>> int_array
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: Int32
```

String aliases for the dtypes are also available. They are capitalized.

```python
>>> pd.array([1, None, 3], dtype='Int32')
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: Int32

>>> pd.array([1, None, 3], dtype='UInt16')
<IntegerArray>
[1, <NA>, 3]
Length: 3, dtype: UInt16
```

**Attributes**

- `None`

**Methods**

- `None`

pandas.UInt64Dtype

class pandas.UInt64Dtype
   An ExtensionDtype for uint64 integer data.
   Changed in version 1.0.0: Now uses pandas.NA as its missing value, rather than numpy.nan.
3.5.8 Categorical data

pandas defines a custom data type for representing data that can take only a limited, fixed set of values. The dtype of a Categorical can be described by a pandas.api.types.CategoricalDtype.

**CategoricalDtype**

Typetr for categorical data with the categories and orderedness.

```
CategoricalDtype(categories, ordered)
```

<table>
<thead>
<tr>
<th>pandas.CategoricalDtype</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>class</strong> pandas.CategoricalDtype(<strong>categories</strong>=None, <strong>ordered</strong>=False)</td>
</tr>
<tr>
<td>Type for categorical data with the categories and orderedness.</td>
</tr>
<tr>
<td><strong>Parameters</strong></td>
</tr>
<tr>
<td><strong>categories</strong> [sequence, optional] Must be unique, and must not contain any nulls. The categories are stored in an Index, and if an index is provided the dtype of that index will be used.</td>
</tr>
<tr>
<td><strong>ordered</strong> [bool or None, default False] Whether or not this categorical is treated as a ordered categorical. None can be used to maintain the ordered value of existing categoricals when used in operations that combine categoricals, e.g. astype, and will resolve to False if there is no existing ordered to maintain.</td>
</tr>
</tbody>
</table>

See also:

**Categorical** Represent a categorical variable in classic R / S-plus fashion.

Notes

This class is useful for specifying the type of a Categorical independent of the values. See CategoricalDtype for more.

Examples

```python
>>> t = pd.CategoricalDtype(categories=['b', 'a'], ordered=True)
>>> pd.Series(['a', 'b', 'a', 'c'], dtype=t)
0    a
1    b
2    a
3   NaN
dtype: category
Categories (2, object): ['b' < 'a']
```
An empty CategoricalDtype with a specific dtype can be created by providing an empty index. As follows,

```python
>>> pd.CategoricalDtype(pd.DatetimeIndex([])).categories.dtype
dtype('<M8[ns]')
```

### Attributes

- **categories**
  - An Index containing the unique categories allowed.

- **ordered**
  - Whether the categories have an ordered relationship.

```python
pandas.CategoricalDtype.categories
```

**property** `CategoricalDtype.categories`

An Index containing the unique categories allowed.

```python
pandas.CategoricalDtype.ordered
```

**property** `CategoricalDtype.ordered`

Whether the categories have an ordered relationship.

### Methods

<table>
<thead>
<tr>
<th>Method Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Categorical data can be stored in a `pandas.Categorical`

```python
Categorical(values[, categories, ordered, ...])
```

Represent a categorical variable in classic R / S-plus fashion.

```python
pandas.Categorical
```

**class** `pandas.Categorical`(values, categories=None, ordered=None, dtype=None, fastpath=False, copy=True)

Represent a categorical variable in classic R / S-plus fashion.

Categoricals can only take on only a limited, and usually fixed, number of possible values (categories). In contrast to statistical categorical variables, a Categorical might have an order, but numerical operations (additions, divisions, ...) are not possible.

All values of the Categorical are either in categories or np.nan. Assigning values outside of categories will raise a ValueError. Order is defined by the order of the categories, not lexical order of the values.

**Parameters**

- **values** [list-like] The values of the categorical. If categories are given, values not in cate-
categories will be replaced with NaN.

categories [Index-like (unique), optional] The unique categories for this categorical. If not
given, the categories are assumed to be the unique values of values (sorted, if possible,
otherwise in the order in which they appear).

ordered [bool, default False] Whether or not this categorical is treated as a ordered categor-
cical. If True, the resulting categorical will be ordered. An ordered categorical respects,
when sorted, the order of its categories attribute (which in turn is the categories argu-
ment, if provided).

dtype [CategoricalDtype] An instance of CategoricalDtype to use for this categorical.

Raises

ValueError If the categories do not validate.

TypeError If an explicit ordered=True is given but no categories and the values are not
sortable.

See also:

CategoricalDtype Type for categorical data.
CategoricalIndex An Index with an underlying Categorical.

Notes

See the user guide for more.

Examples

```python
g   pd.Categorical([1, 2, 3, 1, 2, 3])
[1, 2, 3, 1, 2, 3]
Categories (3, int64): [1, 2, 3]

>>> pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'])
['a', 'b', 'c', 'a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']

Missing values are not included as a category.

```python
>>> c = pd.Categorical([1, 2, 3, 1, 2, 3, np.nan])
>>> c
[1, 2, 3, 1, 2, 3, NaN]
Categories (3, int64): [1, 2, 3]

However, their presence is indicated in the codes attribute by code -1.

```python
>>> c.codes
array([ 0, 1, 2, 0, 1, 2, -1], dtype=int8)

Ordered Categoricals can be sorted according to the custom order of the categories and can have a min and max
value.

```python
>>> c = pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'], ordered=True,
... categories=['c', 'b', 'a'])
>>> c
['a', 'b', 'c', 'a', 'b', 'c']
(continues on next page)

</tbody>
</table>

**pandas.Categorical.categories**

*property Categorical.categories*

The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).

The assigned value has to be a list-like object. All items must be unique and the number of items in the new categories must be the same as the number of items in the old categories.

Assigning to `categories` is a inplace operation!

*Raises*

- **ValueError** If the new categories do not validate as categories or if the number of new categories is unequal the number of old categories

*See also:*

- `rename_categories` Rename categories.
- `reorder_categories` Reorder categories.
- `add_categories` Add new categories.
- `remove_categories` Remove the specified categories.
- `remove_unused_categories` Remove categories which are not used.
- `set_categories` Set the categories to the specified ones.

**pandas.Categorical.codes**

*property Categorical.codes*

The category codes of this categorical.

Codes are an array of integers which are the positions of the actual values in the categories array.

There is no setter, use the other categorical methods and the normal item setter to change values in the categorical.

*Returns*

### pandas.Categorical.ordered

**property**  
`Categorical.ordered`  
Whether the categories have an ordered relationship.

### pandas.Categorical.dtype

**property**  
`Categorical.dtype`  
The `CategoricalDtype` for this instance.

### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>from_codes(codes[, categories, ordered, dtype])</code></td>
<td>Make a Categorical type from codes and categories or dtype.</td>
</tr>
<tr>
<td><code>__array__([dtype])</code></td>
<td>The numpy array interface.</td>
</tr>
</tbody>
</table>

### pandas.Categorical.from_codes

**classmethod**  
`Categorical.from_codes(codes[, categories, ordered, dtype])`  
Make a Categorical type from codes and categories or dtype.

This constructor is useful if you already have codes and categories/dtype and so do not need the (computation intensive) factorization step, which is usually done on the constructor.

If your data does not follow this convention, please use the normal constructor.

**Parameters**

- `codes` [array-like of int] An integer array, where each integer points to a category in categories or dtype.categories, or else is -1 for NaN.
- `categories` [index-like, optional] The categories for the categorical. Items need to be unique. If the categories are not given here, then they must be provided in `dtype`.  
- `ordered` [bool, optional] Whether or not this categorical is treated as an ordered categorical. If not given here or in `dtype`, the resulting categorical will be unordered.
- `dtype` [CategoricalDtype or “category”, optional] If `CategoricalDtype`, cannot be used together with `categories` or `ordered`.

**Returns**

- `Categorical`
Examples

```python
>>> dtype = pd.CategoricalDtype(['a', 'b'], ordered=True)
>>> pd.Categorical.from_codes(codes=[0, 1, 0, 1], dtype=dtype)
['a', 'b', 'a', 'b']
Categories (2, object): ['a' < 'b']
```

**pandas.Categorical.__array__**

Categorical.__array__(dtype=None)
The numpy array interface.

Returns

- **numpy.array** A numpy array of either the specified dtype or, if dtype=None (default), the same dtype as categorical.categories.dtype.

The alternative Categorical.from_codes() constructor can be used when you have the categories and integer codes already:

```python
Categorical.from_codes(codes[, categories, ...])
```

Make a Categorical type from codes and categories or dtype.

The dtype information is available on the Categorical

<table>
<thead>
<tr>
<th>Categorical.dtype</th>
<th>The CategoricalDtype for this instance.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Categorical.categories</td>
<td>The categories of this categorical.</td>
</tr>
<tr>
<td>Categorical.ordered</td>
<td>Whether the categories have an ordered relationship.</td>
</tr>
<tr>
<td>Categorical.codes</td>
<td>The category codes of this categorical.</td>
</tr>
</tbody>
</table>

np.asarray(categorical) works by implementing the array interface. Be aware, that this converts the Categorical back to a NumPy array, so categories and order information is not preserved!

Categorical.__array__((dtype)) The numpy array interface.

A Categorical can be stored in a Series or DataFrame. To create a Series of dtype category, use cat = s.astype(dtype) or Series(..., dtype=dtype) where dtype is either

- the string 'category'
- an instance of CategoricalDtype.

If the Series is of dtype CategoricalDtype, Series.cat can be used to change the categorical data. See Categorical accessor for more.
3.5.9 Sparse data

Data where a single value is repeated many times (e.g. 0 or NaN) may be stored efficiently as a `arrays.SparseArray`.

`arrays.SparseArray(data, sparse_index=None, index=None, fill_value=None, kind='integer', dtype=None, copy=False)`

An ExtensionArray for storing sparse data.

Parameters

- `data` [array-like] A dense array of values to store in the SparseArray. This may contain `fill_value`.
- `sparse_index` [SparseIndex, optional]
- `index` [Index]
- `fill_value` [scalar, optional] Elements in `data` that are `fill_value` are not stored in the SparseArray. For memory savings, this should be the most common value in `data`. By default, `fill_value` depends on the dtype of `data`:

<table>
<thead>
<tr>
<th>dtype</th>
<th>na_value</th>
</tr>
</thead>
<tbody>
<tr>
<td>float</td>
<td>np.nan</td>
</tr>
<tr>
<td>int</td>
<td>0</td>
</tr>
<tr>
<td>bool</td>
<td>False</td>
</tr>
<tr>
<td>datetime64</td>
<td>pd.NaT</td>
</tr>
<tr>
<td>timedelta64</td>
<td>pd.NaT</td>
</tr>
</tbody>
</table>

The fill value is potentially specified in three ways. In order of precedence, these are

1. The `fill_value` argument
2. `dtype.fill_value` if `fill_value` is None and `dtype` is a SparseDtype
3. `data.dtype.fill_value` if `fill_value` is None and `dtype` is not a SparseDtype and `data` is a SparseArray.

`kind` [‘integer’, ‘block’], default ‘integer’] The type of storage for sparse locations.

- ‘block’: Stores a `block` and `block_length` for each contiguous `span` of sparse values. This is best when sparse data tends to be clumped together, with large regions of fill-value values between sparse values.
- ‘integer’: uses an integer to store the location of each sparse value.

`dtype` [np.dtype or SparseDtype, optional] The dtype to use for the SparseArray. For numpy dtypes, this determines the dtype of self.sp_values. For SparseDtype, this determines self.sp_values and self.fill_value.

`copy` [bool, default False] Whether to explicitly copy the incoming `data` array.
Examples

```python
>>> from pandas.arrays import SparseArray
>>> arr = SparseArray([0, 0, 1, 2])
>>> arr
[0, 0, 1, 2]
Fill: 0
IntIndex
Indices: array([2, 3], dtype=int32)
```

Attributes

- None

Methods

- None

`SparseDtype(dtype, fill_value)`

Dtype for data stored in `SparseArray`.

**pandas.SparseDtype**

```python
class pandas.SparseDtype(dtype=<class 'numpy.float64'>, fill_value=None)
```

Dtype for data stored in `SparseArray`.

This dtype implements the pandas ExtensionDtype interface.

**Parameters**

- **dtype** [str, ExtensionDtype, numpy.dtype, type, default numpy.float64] The dtype of the underlying array storing the non-fill value values.

- **fill_value** [scalar, optional] The scalar value not stored in the SparseArray. By default, this depends on `dtype`.

<table>
<thead>
<tr>
<th>dtype</th>
<th>na_value</th>
</tr>
</thead>
<tbody>
<tr>
<td>float</td>
<td>np.nan</td>
</tr>
<tr>
<td>int</td>
<td>0</td>
</tr>
<tr>
<td>bool</td>
<td>False</td>
</tr>
<tr>
<td>datetime64</td>
<td>pd.NaT</td>
</tr>
<tr>
<td>timedelta64</td>
<td>pd.NaT</td>
</tr>
</tbody>
</table>

The default value may be overridden by specifying a `fill_value`. 
The `Series.sparse` accessor may be used to access sparse-specific attributes and methods if the `Series` contains sparse values. See `Sparse accessor` for more.

### 3.5.10 Text data

When working with text data, where each valid element is a string or missing, we recommend using `StringDtype` (with the alias "string").

#### pandas.arrays.StringArray

**class** `pandas.arrays.StringArray(values[, copy])`

Extension array for string data.

New in version 1.0.0.

**Warning:** StringArray is considered experimental. The implementation and parts of the API may change without warning.

**Parameters**

- **values** [array-like] The array of data.

  **Warning:** Currently, this expects an object-dtype ndarray where the elements are Python strings or `pandas.NA`. This may change without warning in the future. Use `pandas.array()` with `dtype="string"` for a stable way of creating a `StringArray` from any sequence.

- **copy** [bool, default False] Whether to copy the array of data.

**See also:**

- `array` The recommended function for creating a StringArray.
- `Series.str` The string methods are available on Series backed by a StringArray.
Notes

StringArray returns a BooleanArray for comparison methods.

Examples

```python
>>> pd.array(['This is', 'some text', None, 'data.'], dtype="string")
<StringArray>
['This is', 'some text', <NA>, 'data.']
Length: 4, dtype: string

Unlike arrays instantiated with dtype="object", StringArray will convert the values to strings.

```python
>>> pd.array([1, 1], dtype="object")
<PandasArray>
[1, 1]
Length: 2, dtype: object

```python
>>> pd.array([1, 1], dtype="string")
<StringArray>
[1, 1]
Length: 2, dtype: string

```python
However, instantiating StringArrays directly with non-strings will raise an error.

For comparison methods, StringArray returns a pandas.BooleanArray:

```python
>>> pd.array(["a", None, "c"], dtype="string") == "a"
<BooleanArray>
[True, <NA>, False]
Length: 3, dtype: boolean
```

Attributes

None

Methods

None

pandas.arrays.ArrowStringArray

class pandas.arrays.ArrowStringArray(values)

Extension array for string data in a pyarrow.ChunkedArray.

New in version 1.2.0.

Warning: ArrowStringArray is considered experimental. The implementation and parts of the API may change without warning.

Parameters
values  [pyarrow.Array or pyarrow.ChunkedArray] The array of data.

See also:
array  The recommended function for creating a ArrowStringArray.
Series.str  The string methods are available on Series backed by a ArrowStringArray.

Notes
ArrowStringArray returns a BooleanArray for comparison methods.

Examples

```python
>>> pd.array(['This is', 'some text', None, 'data.'], dtype="string[pyarrow]"
<ArrowStringArray>
['This is', 'some text', <NA>, 'data.']
Length: 4, dtype: string
```

Attributes

None

Methods

None

StringDtype(

```python
StringDtype(storage)
Extension dtype for string data.
```

pandas.StringDtype

class pandas.StringDtype (storage=None)

Extension dtype for string data.

New in version 1.0.0.

Warning:  StringDtype is considered experimental. The implementation and parts of the API may change without warning.
In particular, StringDtype.na_value may change to no longer be numpy.nan.

Parameters

storage  [{"python", "pyarrow"}, optional] If not given, the value of pd.options.mode.string_storage.
Examples

```python
>>> pd.StringDtype()
string[python]
```

```python
>>> pd.StringDtype(storage="pyarrow")
string[pyarrow]
```

Attributes

None

Methods

None

The `Series.str` accessor is available for `Series` backed by a `arrays.StringArray`. See String handling for more.

3.5.11 Boolean data with missing values

The boolean dtype (with the alias "boolean") provides support for storing boolean data (True, False values) with missing values, which is not possible with a bool `numpy.ndarray`.

```python
arrays.BooleanArray(values, mask[, copy])
```

Array of boolean (True/False) data with missing values.

**pandas.arrays.BooleanArray**

```python
class pandas.arrays.BooleanArray(values, mask, copy=False)
```

Array of boolean (True/False) data with missing values.

This is a pandas Extension array for boolean data, under the hood represented by 2 numpy arrays: a boolean array with the data and a boolean array with the mask (True indicating missing).

BooleanArray implements Kleene logic (sometimes called three-value logic) for logical operations. See Kleene logical operations for more.

To construct an BooleanArray from generic array-like input, use `pandas.array()` specifying `dtype="boolean"` (see examples below).

New in version 1.0.0.

**Warning:** BooleanArray is considered experimental. The implementation and parts of the API may change without warning.

**Parameters**

- `values` [numpy.ndarray] A 1-d boolean-dtype array with the data.
mask [numpy.ndarray] A 1-d boolean-dtype array indicating missing values (True indicates missing).

copy [bool, default False] Whether to copy the values and mask arrays.

Returns

BooleanArray

Examples

Create an BooleanArray with pandas.array():

```python
>>> pd.array([True, False, None], dtype="boolean")
<BooleanArray>
[True, False, <NA>]
Length: 3, dtype: boolean
```

Attributes

None

Methods

None

BooleanDtype

pandas.BooleanDtype

class pandas.BooleanDtype

Extension dtype for boolean data.

New in version 1.0.0.

Warning: BooleanDtype is considered experimental. The implementation and parts of the API may change without warning.

Examples

```python
>>> pd.BooleanDtype()
BooleanDtype
```
### Attributes

## 3.6 Index objects

### 3.6.1 Index

Many of these methods or variants thereof are available on the objects that contain an index (Series/DataFrame) and those should most likely be used before calling these methods directly.

```
Index([data, dtype, copy, name, tupleize_cols])  # Immutable sequence used for indexing and alignment.
```

### pandas.Index

```
class pandas.Index(data=None, dtype=None, copy=False, name=None, tupleize_cols=True, **kwargs)
```

Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects.

#### Parameters

- **data** [array-like (1-dimensional)]
- **dtype** [NumPy dtype (default: object)] If dtype is None, we find the dtype that best fits the data. If an actual dtype is provided, we coerce to that dtype if it’s safe. Otherwise, an error will be raised.
- **copy** [bool] Make a copy of input ndarray.
- **name** [object] Name to be stored in the index.
- **tupleize_cols** [bool (default: True)] When True, attempt to create a MultiIndex if possible.

#### See also:

- `RangeIndex` Index implementing a monotonic integer range.
- `CategoricalIndex` Index of `Categoricals`.
- `MultiIndex` A multi-level, or hierarchical Index.
- `IntervalIndex` An Index of `Intervals`.
- `DatetimeIndex` Index of datetime64 data.
- `TimedeltaIndex` Index of timedelta64 data.
- `PeriodIndex` Index of Period data.
- `Int64Index` A special case of `Index` with purely integer labels.
- `UInt64Index` A special case of `Index` with purely unsigned integer labels.
- `Float64Index` A special case of `Index` with purely float labels.
Notes

An Index instance can only contain hashable objects

Examples

```python
>>> pd.Index([1, 2, 3])
Int64Index([1, 2, 3], dtype='int64')
```

```python
>>> pd.Index(list('abc'))
Index(['a', 'b', 'c'], dtype='object')
```

Attributes

- `T`: Return the transpose, which is by definition self.
- `array`: The ExtensionArray of the data backing this Series or Index.
- `asi8`: Integer representation of the values.
- `dtype`: Return the dtypes of the underlying data.
- `has_duplicates`: Check if the Index has duplicate values.
- `hasnans`: Return if I have any nans; enables various perf speedups.
- `inferred_type`: Return a string of the type inferred from the values.
- `is_all_dates`: Whether or not the index values only consist of dates.
- `is_monotonic`: Alias for is_monotonic_increasing.
- `is_monotonic_decreasing`: Return if the index is monotonic decreasing (only equal or decreasing) values.
- `is_monotonic_increasing`: Return if the index is monotonic increasing (only equal or increasing) values.
- `is_unique`: Return if the index has unique values.
- `name`: Return Index or MultiIndex name.
- `nbytes`: Return the number of bytes in the underlying data.
- `ndim`: Number of dimensions of the underlying data, by definition 1.
- `nlevels`: Number of levels.
- `shape`: Return a tuple of the shape of the underlying data.
- `size`: Return the number of elements in the underlying data.
- `values`: Return an array representing the data in the Index.
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.Index.T

**property** Index.T
Return the transpose, which is by definition self.

pandas.Index.array

Index.array
The ExtensionArray of the data backing this Series or Index.

**Returns**

**ExtensionArray** An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around numpy.ndarray.

.array differs .values which may require converting the data to a different form.

See also:

*Index.to_numpy* Similar method that always returns a NumPy array.

*Series.to_numpy* Similar method that always returns a NumPy array.

Notes

This table lays out the different array types for each extension dtype within pandas.

<table>
<thead>
<tr>
<th>dtype</th>
<th>array type</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>Categorical</td>
</tr>
<tr>
<td>period</td>
<td>PeriodArray</td>
</tr>
<tr>
<td>interval</td>
<td>IntervalArray</td>
</tr>
<tr>
<td>IntegerNA</td>
<td>IntegerArray</td>
</tr>
<tr>
<td>string</td>
<td>StringArray</td>
</tr>
<tr>
<td>boolean</td>
<td>BooleanArray</td>
</tr>
<tr>
<td>datetime64[ns, tz]</td>
<td>DatetimeArray</td>
</tr>
</tbody>
</table>

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes .array will be a arrays.NumpyExtensionArray wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use Series.to_numpy() instead.
Examples

For regular NumPy types like int, and float, a PandasArray is returned.

```python
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

For extension types, like Categorical, the actual ExtensionArray is returned

```python
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
['a', 'b', 'a']
Categories (2, object): ['a', 'b']
```

pandas.Index asi8

**property** `Index.asi8`

Integer representation of the values.

**Returns**

- **ndarray** An ndarray with int64 dtype.

pandas.Index dtype

**Index.dtype**

Return the dtype object of the underlying data.

pandas.Index has duplicates

**property** `Index.has_duplicates`

Check if the Index has duplicate values.

**Returns**

- **bool** Whether or not the Index has duplicate values.

Examples

```python
>>> idx = pd.Index([1, 5, 7, 7])
>>> idx.has_duplicates
True
```

```python
>>> idx = pd.Index([1, 5, 7])
>>> idx.has_duplicates
False
```

```python
>>> idx = pd.Index(['Watermelon', 'Orange', 'Apple', ...
... 'Watermelon']).astype('category')
>>> idx.has_duplicates
True
```
```python
>>> idx = pd.Index(['Orange', 'Apple', ... , 'Watermelon']).astype('category')
>>> idx.has_duplicates
False
```

**pandas.Index.hasnans**

`Index.hasnans`
Return if I have any nans; enables various perf speedups.

**pandas.Index.inferred_type**

`Index.inferred_type`
Return a string of the type inferred from the values.

**pandas.Index.is_all_dates**

`Index.is_all_dates`
Whether or not the index values only consist of dates.

**pandas.Index.is_monotonic**

`property Index.is_monotonic`
Alias for is_monotonic_increasing.

**pandas.Index.is_monotonic_decreasing**

`property Index.is_monotonic_decreasing`
Return if the index is monotonic decreasing (only equal or decreasing) values.

**Examples**

```python
>>> Index([3, 2, 1]).is_monotonic_decreasing
True
>>> Index([3, 2, 2]).is_monotonic_decreasing
True
>>> Index([3, 1, 2]).is_monotonic_decreasing
False
```
**pandas.Index.is_monotonic_increasing**

**property**  
`Index.is_monotonic_increasing`  
Return if the index is monotonic increasing (only equal or increasing) values.

**Examples**

```python
>>> Index([1, 2, 3]).is_monotonic_increasing
True
>>> Index([1, 2, 2]).is_monotonic_increasing
True
>>> Index([1, 3, 2]).is_monotonic_increasing
False
```

**pandas.Index.is_unique**

`Index.is_unique`  
Return if the index has unique values.

**pandas.Index.name**

**property**  
`Index.name`  
Return Index or MultiIndex name.

**pandas.Index.nbytes**

**property**  
`Index.nbytes`  
Return the number of bytes in the underlying data.

**pandas.Index.ndim**

**property**  
`Index.ndim`  
Number of dimensions of the underlying data, by definition 1.

**pandas.Index.nlevels**

**property**  
`Index.nlevels`  
Number of levels.
pandas.Index.shape

**property** `Index.shape`

Return a tuple of the shape of the underlying data.

pandas.Index.size

**property** `Index.size`

Return the number of elements in the underlying data.

pandas.Index.values

**property** `Index.values`

Return an array representing the data in the Index.

**Warning:** We recommend using `Index.array` or `Index.to_numpy()`, depending on whether you need a reference to the underlying data or a NumPy array.

**Returns**

array: `numpy.ndarray` or `ExtensionArray`

**See also:**

`Index.array` Reference to the underlying data.

`Index.to_numpy` A NumPy array representing the underlying data.

<table>
<thead>
<tr>
<th>empty</th>
<th>names</th>
</tr>
</thead>
</table>

**Methods**

- `all(*args, **kwargs)` Return whether all elements are Truthy.
- `any(*args, **kwargs)` Return whether any element is Truthy.
- `append(other)` Append a collection of Index options together.
- `argmax([axis, skipna])` Return int position of the largest value in the Series.
- `argmin([axis, skipna])` Return int position of the smallest value in the Series.
- `argsort(*args, **kwargs)` Return the integer indices that would sort the index.
- `asof(label)` Return the label from the indices, or, if not present, the previous one.
- `asof_locs(where, mask)` Return the locations (indices) of labels in the index.
- `astype(dtype[, copy])` Create an Index with values cast to dtypes.
- `copy([name, deep, dtype, names])` Make a copy of this object.
- `delete(loc)` Make new Index with passed location(-s) deleted.
- `difference(other[, sort])` Return a new Index with elements of index not in other.

<td><strong>to_flat_index</strong>()</td>
<td>Identity method.</td>
</tr>
<tr>
<td><strong>to_frame</strong>(index, name)</td>
<td>Create a DataFrame with a column containing the Index.</td>
</tr>
<tr>
<td><strong>to_list</strong>()</td>
<td>Return a list of the values.</td>
</tr>
<tr>
<td><strong>to_native_types</strong>(slicer)</td>
<td>(DEPRECATED) Format specified values of self and return them.</td>
</tr>
<tr>
<td><strong>to_numpy</strong>(dtype, copy, na_value)</td>
<td>A NumPy ndarray representing the values in this Series or Index.</td>
</tr>
<tr>
<td><strong>to_series</strong>(index, name)</td>
<td>Create a Series with both index and values equal to the index keys.</td>
</tr>
<tr>
<td><strong>tolist</strong>()</td>
<td>Return a list of the values.</td>
</tr>
<tr>
<td><strong>transpose</strong>(args, **kwargs)</td>
<td>Return the transpose, which is by definition self.</td>
</tr>
<tr>
<td><strong>union</strong>(other[, sort])</td>
<td>Form the union of two Index objects.</td>
</tr>
<tr>
<td><strong>unique</strong>(level)</td>
<td>Return unique values in the index.</td>
</tr>
<tr>
<td><strong>value_counts</strong>(normalize, sort, ascending, ...)</td>
<td>Return a Series containing counts of unique values.</td>
</tr>
<tr>
<td><strong>where</strong>(cond[, other])</td>
<td>Replace values where the condition is False.</td>
</tr>
</tbody>
</table>
pandas.Index.all

Index.all (*args, **kwargs)
Return whether all elements are Truthy.

Parameters

*args Required for compatibility with numpy.
**kwargs Required for compatibility with numpy.

Returns

all [bool or array-like (if axis is specified)] A single element array-like may be converted to bool.

See also:

Index.any Return whether any element in an Index is True.
Series.any Return whether any element in a Series is True.
Series.all Return whether all elements in a Series are True.

Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

Examples

all

True, because nonzero integers are considered True.

```python
>>> pd.Index([1, 2, 3]).all()
True
```

False, because 0 is considered False.

```python
>>> pd.Index([0, 1, 2]).all()
False
```

any

True, because 1 is considered True.

```python
>>> pd.Index([0, 1, 2]).any()
True
```

False, because 0 is considered False.

```python
>>> pd.Index([0, 0, 1]).any()
False
```
pandas.Index.any

Index.any(*args, **kwargs)
Return whether any element is Truthy.

Parameters

*args    Required for compatibility with numpy.
**kwargs Required for compatibility with numpy.

Returns

any    [bool or array-like (if axis is specified)] A single element array-like may be converted to bool.

See also:

Index.all   Return whether all elements are True.
Series.all  Return whether all elements are True.

Notes

Not a Number (NaN), positive infinity and negative infinity evaluate to True because these are not equal to zero.

Examples

```python
>>> index = pd.Index([0, 1, 2])
>>> index.any()
True

>>> index = pd.Index([0, 0, 0])
>>> index.any()
False
```

pandas.Index.append

Index.append(other)
Append a collection of Index options together.

Parameters

other    [Index or list/tuple of indices]

Returns

Index
pandas.Index.argmax

Index.argmax (axis=None, skipna=True, *args, **kwargs)
Return int position of the largest value in the Series.
If the maximum is achieved in multiple locations, the first row position is returned.

Parameters

axis [{None}] Dummy argument for consistency with Series.
skipna [bool, default True] Exclude NA/null values when showing the result.
*args, **kwargs Additional arguments and keywords for compatibility with NumPy.

Returns

int Row position of the maximum value.

See also:

Series.argmax Return position of the maximum value.
Series.argmin Return position of the minimum value.
numpy.ndarray.argmax Equivalent method for numpy arrays.
Series.idxmax Return index label of the maximum values.
Series.idxmin Return index label of the minimum values.

Examples

Consider dataset containing cereal calories

```python
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,
... 'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
```

```python
>>> s
Corn Flakes    100.0
Almond Delight 110.0
Cinnamon Toast Crunch 120.0
Cocoa Puff    110.0
dtype: float64
```

```python
>>> s.argmax()
2
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.
pandas/Index.argmin

Index.argmin (axis=None, skipna=True, *args, **kwargs)

Return int position of the smallest value in the Series.
If the minimum is achieved in multiple locations, the first row position is returned.

Parameters

axis [{None}] Dummy argument for consistency with Series.
skipna [bool, default True] Exclude NA/null values when showing the result.
*args, **kwargs Additional arguments and keywords for compatibility with NumPy.

Returns

int Row position of the minimum value.

See also:

Series.argmin Return position of the minimum value.
Series.argmax Return position of the maximum value.
numpy.ndarray.argmin Equivalent method for numpy arrays.
Series.idxmax Return index label of the maximum values.
Series.idxmin Return index label of the minimum values.

Examples

Consider dataset containing cereal calories

```python
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,
                 'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
>>> s
Corn Flakes    100.0
Almond Delight 110.0
Cinnamon Toast Crunch 120.0
Cocoa Puff     110.0
dtype: float64

>>> s.argmax()
2
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.
pandas.Index.argsort

Index.argsort(*args, **kwargs)

Return the integer indices that would sort the index.

Parameters

*args Passed to numpy.ndarray.argsort.

**kwargs Passed to numpy.ndarray.argsort.

Returns

np.ndarray[np.intp] Integer indices that would sort the index if used as an indexer.

See also:

numpy.argsort Similar method for NumPy arrays.

Index.sort_values Return sorted copy of Index.

Examples

```python
>>> idx = pd.Index(['b', 'a', 'd', 'c'])
>>> idx
Index(['b', 'a', 'd', 'c'], dtype='object')
```

```python
>>> order = idx.argsort()
>>> order
array([1, 0, 3, 2])
```

```python
>>> idx[order]
Index(['a', 'b', 'c', 'd'], dtype='object')
```

pandas.Index.asof

Index.asof(label)

Return the label from the index, or, if not present, the previous one.

Assuming that the index is sorted, return the passed index label if it is in the index, or return the previous index label if the passed one is not in the index.

Parameters

label [object] The label up to which the method returns the latest index label.

Returns

object The passed label if it is in the index. The previous label if the passed label is not in the sorted index or NaN if there is no such label.

See also:

Series.asof Return the latest value in a Series up to the passed index.

merge_asof Perform an asof merge (similar to left join but it matches on nearest key rather than equal key).

Index.get_loc An asof is a thin wrapper around get_loc with method='pad'.
Examples

`Index.asof` returns the latest index label up to the passed label.

```python
gs = pd.Index(['2013-12-31', '2014-01-02', '2014-01-03'])
gs.asof('2014-01-01')

'2013-12-31'
```

If the label is in the index, the method returns the passed label.

```python
gs.asof('2014-01-02')

'2014-01-02'
```

If all of the labels in the index are later than the passed label, NaN is returned.

```python
gs.asof('1999-01-02')

nan
```

If the index is not sorted, an error is raised.

```python
idx_not_sorted = pd.Index(['2013-12-31', '2015-01-02',
... '2014-01-03'])
idx_not_sorted.asof('2013-12-31')

Traceback (most recent call last):
  ValueError: index must be monotonic increasing or decreasing
```

`pandas.Index.asof_locs`

`Index.asof_locs(where, mask)`

Return the locations (indices) of labels in the index.

As in the `asof` function, if the label (a particular entry in `where`) is not in the index, the latest index label up to the passed label is chosen and its index returned.

If all of the labels in the index are later than a label in `where`, -1 is returned.

`mask` is used to ignore NA values in the index during calculation.

**Parameters**

- `where` [Index] An Index consisting of an array of timestamps.
- `mask` [np.ndarray[bool]] Array of booleans denoting where values in the original data are not NA.

**Returns**

- `np.ndarray[np.intp]` An array of locations (indices) of the labels from the Index which correspond to the return values of the `asof` function for every element in `where`. 
pandas.Index.astype

Index.astype(dtype, copy=True)

Create an Index with values cast to dtypes.

The class of a new Index is determined by dtype. When conversion is impossible, a TypeError exception is raised.

**Parameters**

- **dtype** [numpy dtype or pandas type] Note that any signed integer dtype is treated as 'int64', and any unsigned integer dtype is treated as 'uint64', regardless of the size.
- **copy** [bool, default True] By default, astype always returns a newly allocated object. If copy is set to False and internal requirements on dtype are satisfied, the original data is used to create a new Index or the original Index is returned.

**Returns**

- **Index** Index with values cast to specified dtype.

pandas.Index.copy

Index.copy(name=None, deep=False, dtype=None, names=None)

Make a copy of this object.

Name and dtype sets those attributes on the new object.

**Parameters**

- **name** [Label, optional] Set name for new object.
- **deep** [bool, default False]
- **dtype** [numpy dtype or pandas type, optional] Set dtype for new object.

Deprecated since version 1.2.0: use astype method instead.

- **names** [list-like, optional] Kept for compatibility with MultiIndex. Should not be used.

**Returns**

- **Index** Index refer to new object which is a copy of this object.

**Notes**

In most cases, there should be no functional difference from using deep, but if deep is passed it will attempt to deepcopy.
pandas.Index.delete

Index.delete(loc)
Make new Index with passed location(-s) deleted.

Parameters

loc [int or list of int] Location of item(-s) which will be deleted. Use a list of locations to delete more than one value at the same time.

Returns

Index Will be same type as self, except for RangeIndex.

See also:

numpy.delete Delete any rows and column from NumPy array (ndarray).

Examples

```python
>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx.delete(1)
Index(['a', 'c'], dtype='object')
```

```python
>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx.delete([0, 2])
Index(['b'], dtype='object')
```

pandas.Index.difference

Index.difference(other, sort=None)
Return a new Index with elements of index not in other.
This is the set difference of two Index objects.

Parameters

other [Index or array-like]

sort [False or None, default None] Whether to sort the resulting index. By default, the values are attempted to be sorted, but any TypeError from incomparable elements is caught by pandas.
  • None : Attempt to sort the result, but catch any TypeErrors from comparing incomparable elements.
  • False : Do not sort the result.

Returns

difference [Index]
Examples

```python
>>> idx1 = pd.Index([2, 1, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.difference(idx2)
Int64Index([1, 2], dtype='int64')
>>> idx1.difference(idx2, sort=False)
Int64Index([2, 1], dtype='int64')
```

**pandas.Index.drop**

Index.drop(labels, errors='raise')

Make new Index with passed list of labels deleted.

**Parameters**

- **labels** [array-like]
- **errors** [{'ignore', 'raise'}, default 'raise'] If ‘ignore’, suppress error and existing labels are dropped.

**Returns**

- **dropped** [Index] Will be same type as self, except for RangeIndex.

**Raises**

- **KeyError** If not all of the labels are found in the selected axis

**pandas.Index.drop_duplicates**

Index.drop_duplicates(keep='first')

Return Index with duplicate values removed.

**Parameters**

- **keep** ['first', 'last', False], default 'first']
  - 'first': Drop duplicates except for the first occurrence.
  - 'last': Drop duplicates except for the last occurrence.
  - False: Drop all duplicates.

**Returns**

- **deduplicated** [Index]

See also:

- Series.drop_duplicates Equivalent method on Series.
- DataFrame.drop_duplicates Equivalent method on DataFrame.
- Index.duplicated Related method on Index, indicating duplicate Index values.
Examples

Generate an pandas.Index with duplicate values.

```python
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama', 'hippo'])
```

The `keep` parameter controls which duplicate values are removed. The value ‘first’ keeps the first occurrence for each set of duplicated entries. The default value of `keep` is ‘first’.

```python
>>> idx.drop_duplicates(keep='first')
Index(['lama', 'cow', 'beetle', 'hippo'], dtype='object')
```

The value ‘last’ keeps the last occurrence for each set of duplicated entries.

```python
>>> idx.drop_duplicates(keep='last')
Index(['cow', 'beetle', 'lama', 'hippo'], dtype='object')
```

The value `False` discards all sets of duplicated entries.

```python
>>> idx.drop_duplicates(keep=False)
Index(['cow', 'beetle', 'hippo'], dtype='object')
```

pandas.Index.droplevel

`Index.droplevel(level=0)`

Return index with requested level(s) removed.

If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

Parameters

- `level` [int, str, or list-like, default 0] If a string is given, must be the name of a level If list-like, elements must be names or indexes of levels.

Returns

- Index or MultiIndex

Examples

```python
>>> mi = pd.MultiIndex.from_arrays(
... [[1, 2], [3, 4], [5, 6]], names=['x', 'y', 'z'])
>>> mi
MultiIndex([[1, 3, 5],
            [2, 4, 6]],
           names=['x', 'y', 'z'])
```

```python
>>> mi.droplevel()  # If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.
MultiIndex([[3, 5],
            [4, 6]],
           names=['y', 'z'])
```

```python
>>> mi.droplevel(2)  # and levels at the same time.
MultiIndex([[1, 3],
            [2, 4]],
           names=['x', 'y'])
```
```python
>>> mi.droplevel('z')
MultiIndex([(1, 3),
            (2, 4)],
           names=['x', 'y'])

>>> mi.droplevel(['x', 'y'])
Int64Index([5, 6], dtype='int64', name='z')
```

### pandas.Index.dropna

**Index.dropna** *(how='any')*

Return Index without NA/NaN values.

**Parameters**

- **how**  
  [{‘any’, ‘all’}, default ‘any’] If the Index is a MultiIndex, drop the value when any or all levels are NaN.

**Returns**

- **Index**

### pandas.Index.duplicated

**Index.duplicated** *(keep='first')*

Indicate duplicate index values.

Duplicated values are indicated as True values in the resulting array. Either all duplicates, all except the first, or all except the last occurrence of duplicates can be indicated.

**Parameters**

- **keep**  
  [{‘first’, ‘last’, False}, default ‘first’] The value or values in a set of duplicates to mark as missing.
    
  - ‘first’: Mark duplicates as True except for the first occurrence.
  - ‘last’: Mark duplicates as True except for the last occurrence.
  - False: Mark all duplicates as True.

**Returns**

- np.ndarray[bool]

See also:

- **Series.duplicated** Equivalent method on pandas.Series.
- **DataFrame.duplicated** Equivalent method on pandas.DataFrame.
- **Index.drop_duplicates** Remove duplicate values from Index.
Examples

By default, for each set of duplicated values, the first occurrence is set to False and all others to True:

```python
>>> idx = pd.Index(['lama', 'cow', 'lama', 'beetle', 'lama'])
>>> idx.duplicated()
array([False, False, True, False, True])
```

which is equivalent to

```python
>>> idx.duplicated(keep='first')
array([False, False, True, False, True])
```

By using ‘last’, the last occurrence of each set of duplicated values is set on False and all others on True:

```python
>>> idx.duplicated(keep='last')
array([ True, False, True, False, False])
```

By setting keep on False, all duplicates are True:

```python
>>> idx.duplicated(keep=False)
array([ True, False, True, False, True])
```

pandas.Index.equals

Index.equals(other)

Determine if two Index object are equal.

The things that are being compared are:

- The elements inside the Index object.
- The order of the elements inside the Index object.

Parameters

other [Any] The other object to compare against.

Returns

bool True if “other” is an Index and it has the same elements and order as the calling index; False otherwise.

Examples

```python
>>> idx1 = pd.Index([1, 2, 3])
>>> idx1
Int64Index([1, 2, 3], dtype='int64')
>>> idx1.equals(pd.Index([1, 2, 3]))
True
```

The elements inside are compared

```python
>>> idx2 = pd.Index(['1', '2', '3'])
>>> idx2
Index(['1', '2', '3'], dtype='object')
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

>>> idx1.equals(idx2)
False

The order is compared

>>> ascending_idx = pd.Index([1, 2, 3])
>>> ascending_idx
Int64Index([1, 2, 3], dtype='int64')

>>> descending_idx = pd.Index([3, 2, 1])
>>> descending_idx
Int64Index([3, 2, 1], dtype='int64')

>>> ascending_idx.equals(descending_idx)
False

The dtype is not compared

>>> int64_idx = pd.Int64Index([1, 2, 3])
>>> int64_idx
Int64Index([1, 2, 3], dtype='int64')

>>> uint64_idx = pd.UInt64Index([1, 2, 3])
>>> uint64_idx
UInt64Index([1, 2, 3], dtype='uint64')

>>> int64_idx.equals(uint64_idx)
True

pandas.Index.factorize

Index.factorize(sort=False, na_sentinel=-1)
Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. factorize is available as both a top-level function pandas.factorize(), and as a method Series.factorize() and Index.factorize().

Parameters

sort [bool, default False] Sort uniques and shuffle codes to maintain the relationship.
na_sentinel [int or None, default -1] Value to mark “not found”. If None, will not drop the NaN from the uniques of the values.

Changed in version 1.1.2.

Returns

codes [ndarray] An integer ndarray that’s an indexer into uniques. uniques.take(codes) will have the same values as values.
uniques [ndarray, Index, or Categorical] The unique valid values. When values is Categorical, uniques is a Categorical. When values is some other pandas object, an Index is returned. Otherwise, a 1-D ndarray is returned.

Note: Even if there’s a missing value in values, uniques will not contain an entry for it.

See also:
**cut** Discretize continuous-valued array.

**unique** Find the unique value in an array.

**Examples**

These examples all show `factorize` as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> codes
array([0, 0, 1, 2, 0]...)
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the `uniques` will be sorted, and `codes` will be shuffled so that the relationship is maintained.

```python
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> codes
array([1, 1, 0, 2, 1]...)
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in `codes` with `na_sentinel` (−1 by default). Note that missing values are never included in `uniques`.

```python
>>> codes, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> codes
array([ 0, -1, 1, 2, 0]...)
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we’ve only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of `uniques` will differ. For Categoricals, a `Categorical` is returned.

```python
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1]...)
>>> uniques
['a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```python
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1]...)
>>> uniques
Index(['a', 'c'], dtype='object')
```

If NaN is in the values, and we want to include NaN in the unique values, it can be achieved by setting `na_sentinel=None`.
>>> values = np.array([1, 2, 1, np.nan])
>>> codes, uniques = pd.factorize(values)  # default: na_sentinel=-1
>>> codes
array([ 0, 1, 0, -1])
>>> uniques
array([1., 2.])

>>> codes, uniques = pd.factorize(values, na_sentinel=None)
>>> codes
array([0, 1, 0, 2])
>>> uniques
array([ 1., 2., nan])

pandas.Index.fillna

Index.fillna(value=None, downcast=None)
Fill NA/NaN values with the specified value.

Parameters
value [scalar] Scalar value to use to fill holes (e.g. 0). This value cannot be a list-likes.
downcast [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns
Index

See also:
Dataframe.fillna Fill NaN values of a DataFrame.
Series.fillna Fill NaN Values of a Series.

pandas.Index.format

Index.format(name=False, formatter=None, na_rep='NaN')
Render a string representation of the Index.

pandas.Index.get_indexer

Index.get_indexer(target, method=None, limit=None, tolerance=None)
Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

Parameters
target [Index]
method [{None, ‘pad’/’ffill’, ‘backfill’/’bfill’, ‘nearest’}, optional]
  • default: exact matches only.
  • pad / ffill: find the PREVIOUS index value if no exact match.
• backfill / bfill: use NEXT index value if no exact match
• nearest: use the NEAREST index value if no exact match. Tied distances are
  broken by preferring the larger index value.

**limit** [int, optional] Maximum number of consecutive labels in target to match for
  inexact matches.

**tolerance** [optional] Maximum distance between original and new labels for inexact
  matches. The values of the index at the matching locations must satisfy the equa-
  tion \( \text{abs}(\text{index[indexer]} - \text{target}) \leq \text{tolerance} \).

Tolerance may be a scalar value, which applies the same tolerance to all values, or
list-like, which applies variable tolerance per element. List-like includes list, tuple,
array, Series, and must be the same size as the index and its dtype must exactly
match the index’s type.

**Returns**

**indexer** [np.ndarray[np.intp]] Integers from 0 to n - 1 indicating that the index at these
  positions matches the corresponding target values. Missing values in the target are
  marked by -1.

**Examples**

```python
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([1, 2, -1])
```

Notice that the return value is an array of locations in `index` and `x` is marked by -1, as it is not in `index`.

**pandas.Index.get_indexer_for**

Index.get_indexer_for(target, **kwargs)

Guaranteed return of an indexer even when non-unique.

This dispatches to get_indexer or get_indexer_non_unique as appropriate.

**Returns**

**np.ndarray[np.intp]** List of indices.

**pandas.Index.get_indexer_non_unique**

Index.get_indexer_non_unique(target)

Compute indexer and mask for new index given the current index. The indexer should be then used as an
input to ndarray.take to align the current data to the new index.

**Parameters**

**target** [Index]

**Returns**

**indexer** [np.ndarray[np.intp]] Integers from 0 to n - 1 indicating that the index at these
  positions matches the corresponding target values. Missing values in the target are
  marked by -1.
missing [np.ndarray[np.intp]] An indexer into the target of the values not found. These correspond to the -1 in the indexer array.

pandas.Index.get_level_values

Index.get_level_values(level)
Return an Index of values for requested level.

This is primarily useful to get an individual level of values from a MultiIndex, but is provided on Index as well for compatibility.

Parameters

level [int or str] It is either the integer position or the name of the level.

Returns

Index Calling object, as there is only one level in the Index.

See also:

MultiIndex.get_level_values Get values for a level of a MultiIndex.

Notes

For Index, level should be 0, since there are no multiple levels.

Examples

```python
>>> idx = pd.Index(list('abc'))
>>> idx
Index(['a', 'b', 'c'], dtype='object')
Get level values by supplying level as integer:
```
```python
>>> idx.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object')
```

pandas.Index.get_loc

Index.get_loc(key, method=None, tolerance=None)
Get integer location, slice or boolean mask for requested label.

Parameters

key [label]

method [{None, ‘pad’/’ffill’, ‘backfill’/’bfill’, ‘nearest’}, optional]
* default: exact matches only.
* pad / ffill: find the PREVIOUS index value if no exact match.
* backfill / bfill: use NEXT index value if no exact match
* nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
tolerance [int or float, optional] Maximum distance from index value for inexact matches. The value of the index at the matching location must satisfy the equation \( \text{abs} \left( \text{index}[\text{loc}] - \text{key} \right) \leq \text{tolerance} \).

Returns

loc [int if unique index, slice if monotonic index, else mask]

Examples

```python
>>> unique_index = pd.Index(list('abc'))
>>> unique_index.get_loc('b')
1
```

```python
>>> monotonic_index = pd.Index(list('abbc'))
>>> monotonic_index.get_loc('b')
slice(1, 3, None)
```

```python
>>> non_monotonic_index = pd.Index(list('abcb'))
>>> non_monotonic_index.get_loc('b')
array([False, True, False, True])
```

pandas.Index.get_slice_bound

Index.get_slice_bound(label, side, kind=None)
Calculate slice bound that corresponds to given label.

Returns leftmost (one-past-the-rightmost if side=='right') position of given label.

Parameters

- label [object]
- side [{'left', 'right'}]
- kind [{'loc', 'getitem'} or None]

Returns

int Index of label.

pandas.Index.get_value

Index.get_value(series, key)
Fast lookup of value from 1-dimensional ndarray.

Only use this if you know what you’re doing.

Returns

scalar or Series
pandas.Index.groupby

Index.groupby(values)
Group the index labels by a given array of values.

Parameters
values [array] Values used to determine the groups.

Returns
dict {group name -> group labels}

pandas.Index.holds_integer

Index.holds_integer()
Whether the type is an integer type.

pandas.Index.identical

Index.identical(other)
Similar to equals, but checks that object attributes and types are also equal.

Returns
bool If two Index objects have equal elements and same type True, otherwise False.

pandas.Index.insert

Index.insert(loc, item)
Make new Index inserting new item at location.
Follows Python list.append semantics for negative values.

Parameters
loc [int]
item [object]

Returns
new_index [Index]

pandas.Index.intersection

Index.intersection(other, sort=False)
Form the intersection of two Index objects.
This returns a new Index with elements common to the index and other.

Parameters
other [Index or array-like]
sort [False or None, default False] Whether to sort the resulting index.
• False : do not sort the result.
• None: sort the result, except when self and other are equal or when the values cannot be compared.

Returns

intersection [Index]

Examples

```python
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.intersection(idx2)
Int64Index([3, 4], dtype='int64')
```

pandas.Index.is_

Index.is_(other)
More flexible, faster check like is but that works through views.

Note: this is not the same as Index.identical(), which checks that metadata is also the same.

Parameters

other [object] Other object to compare against.

Returns

bool True if both have same underlying data, False otherwise.

See also:

Index.identical Works like Index.is_ but also checks metadata.

pandas.Index.is_boolean

Index.is_boolean()
Check if the Index only consists of booleans.

Returns

bool Whether or not the Index only consists of booleans.

See also:

is_integer Check if the Index only consists of integers.

is_floating Check if the Index is a floating type.

is_numeric Check if the Index only consists of numeric data.

is_object Check if the Index is of the object dtype.

is_categorical Check if the Index holds categorical data.

is_interval Check if the Index holds Interval objects.

is_mixed Check if the Index holds data with mixed data types.
Examples

```python
>>> idx = pd.Index([True, False, True])
>>> idx.is_boolean()
True

>>> idx = pd.Index(["True", "False", "True"])
>>> idx.is_boolean()
False

>>> idx = pd.Index([True, False, "True"])
>>> idx.is_boolean()
False
```

`pandas.Index.is_categorical`

Index.is_categorical()

Check if the Index holds categorical data.

**Returns**

*bool*  True if the Index is categorical.

**See also:**

*CategoricalIndex*  Index for categorical data.

*is_boolean*  Check if the Index only consists of boolean.

*is_integer*  Check if the Index only consists of integers.

*is_floating*  Check if the Index is a floating type.

*is_numeric*  Check if the Index only consists of numeric data.

*is_object*  Check if the Index is of the object dtype.

*is_interval*  Check if the Index holds Interval objects.

*is_mixed*  Check if the Index holds data with mixed data types.

Examples

```python
>>> idx = pd.Index(["Watermelon", "Orange", "Apple", ...
...                   "Watermelon"]).astype("category")
>>> idx.is_categorical()
True

>>> idx = pd.Index([1, 3, 5, 7])
>>> idx.is_categorical()
False

>>> s = pd.Series(["Peter", "Victor", "Elisabeth", "Mar"])
>>> s
0    Peter
1    Victor
(continues on next page)"
pandas: powerful Python data analysis toolkit, Release 1.3.1

(continued from previous page)

>>> s.index.is_categorical()
False

pandas.Index.is_floating

Index.is_floating()
Check if the Index is a floating type.
The Index may consist of only floats, NaNs, or a mix of floats, integers, or NaNs.

Returns

bool Whether or not the Index only consists of only consists of floats, NaNs, or a mix of floats, integers, or NaNs.

See also:

is_boolean Check if the Index only consists of booleans.
is_integer Check if the Index only consists of integers.
is_numeric Check if the Index only consists of numeric data.
is_object Check if the Index is of the object dtype.
is_categorical Check if the Index holds categorical data.
is_interval Check if the Index holds Interval objects.
is_mixed Check if the Index holds data with mixed data types.

Examples

>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_floating()
True

>>> idx = pd.Index([1.0, 2.0, np.nan, 4.0])
>>> idx.is_floating()
True

>>> idx = pd.Index([1, 2, 3, 4, np.nan])
>>> idx.is_floating()
True

>>> idx = pd.Index([1, 2, 3, 4])
>>> idx.is_floating()
False
pandas.Index.is_integer

Index.is_integer()
Check if the Index only consists of integers.

Returns
   bool Whether or not the Index only consists of integers.

See also:

   is_boolean Check if the Index only consists of booleans.
   is_floating Check if the Index is a floating type.
   is_numeric Check if the Index only consists of numeric data.
   is_object Check if the Index is of the object dtype.
   is_categorical Check if the Index holds categorical data.
   is_interval Check if the Index holds Interval objects.
   is_mixed Check if the Index holds data with mixed data types.

Examples

>>> idx = pd.Index([1, 2, 3, 4])
>>> idx.is_integer()
True

>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_integer()
False

>>> idx = pd.Index(["Apple", "Mango", "Watermelon"])
>>> idx.is_integer()
False

pandas.Index.is_interval

Index.is_interval()
Check if the Index holds Interval objects.

Returns
   bool Whether or not the Index holds Interval objects.

See also:

   IntervalIndex Index for Interval objects.
   is_boolean Check if the Index only consists of booleans.
   is_integer Check if the Index only consists of integers.
   is_floating Check if the Index is a floating type.
   is_numeric Check if the Index only consists of numeric data.
**is_object** Check if the Index is of the object dtype.

**is_categorical** Check if the Index holds categorical data.

**is_mixed** Check if the Index holds data with mixed data types.

### Examples

```python
guideline = pd.Index([pd.Interval(left=0, right=5),
                      pd.Interval(left=5, right=10)])
guideline.is_interval()  # True
```

```python
guideline = pd.Index([1, 3, 5, 7])
guideline.is_interval()  # False
```

### pandas.Index.is_mixed

**Index.is_mixed()**

Check if the Index holds data with mixed data types.

**Returns**

- **bool** Whether or not the Index holds data with mixed data types.

**See also:**

- **is_boolean** Check if the Index only consists of booleans.
- **is_integer** Check if the Index only consists of integers.
- **is_floating** Check if the Index is a floating type.
- **is_numeric** Check if the Index only consists of numeric data.
- **is_object** Check if the Index is of the object dtype.
- **is_categorical** Check if the Index holds categorical data.
- **is_interval** Check if the Index holds Interval objects.

### Examples

```python
guideline = pd.Index(['a', np.nan, 'b'])
guideline.is_mixed()  # True
```

```python
guideline = pd.Index([1.0, 2.0, 3.0, 5.0])
guideline.is_mixed()  # False
```
pandas.Index.is_numeric

Index.is_numeric()
    Check if the Index only consists of numeric data.

    Returns
        bool  Whether or not the Index only consists of numeric data.

See also:

    is_boolean  Check if the Index only consists of booleans.
    is_integer  Check if the Index only consists of integers.
    is_floating  Check if the Index is a floating type.
    is_object  Check if the Index is of the object dtype.
    is_categorical  Check if the Index holds categorical data.
    is_interval  Check if the Index holds Interval objects.
    is_mixed  Check if the Index holds data with mixed data types.

Examples

    >>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
    >>> idx.is_numeric()
    True

    >>> idx = pd.Index([1, 2, 3, 4.0])
    >>> idx.is_numeric()
    True

    >>> idx = pd.Index([1, 2, 3, 4])
    >>> idx.is_numeric()
    True

    >>> idx = pd.Index([1, 2, 3, 4.0, np.nan])
    >>> idx.is_numeric()
    True

    >>> idx = pd.Index([1, 2, 3, 4.0, np.nan, "Apple"])
    >>> idx.is_numeric()
    False
pandas.Index.is_object

Index.is_object()
Check if the Index is of the object dtype.

Returns

bool Whether or not the Index is of the object dtype.

See also:

is_boolean Check if the Index only consists of booleans.
is_integer Check if the Index only consists of integers.
is_floating Check if the Index is a floating type.
is_numeric Check if the Index only consists of numeric data.
is_categorical Check if the Index holds categorical data.
is_interval Check if the Index holds Interval objects.
is_mixed Check if the Index holds data with mixed data types.

Examples

>>> idx = pd.Index(
"Apple", "Mango", "Watermelon"
)  
>>> idx.is_object()
True

>>> idx = pd.Index(
"Apple", "Mango", 2.0
)  
>>> idx.is_object()
True

>>> idx = pd.Index(
"Watermelon", "Orange", "Apple",
"Watermelon").astype("category")
>>> idx.is_object()
False

>>> idx = pd.Index([1.0, 2.0, 3.0, 4.0])
>>> idx.is_object()
False

pandas.Index.is_type_compatible

Index.is_type_compatible(kind)
Whether the index type is compatible with the provided type.
**pandas.Index.isin**

Index.isin(values, level=None)

Return a boolean array where the index values are in values.

Compute boolean array of whether each index value is found in the passed set of values. The length of the returned boolean array matches the length of the index.

**Parameters**

- values [set or list-like] Sought values.
- level [str or int, optional] Name or position of the index level to use (if the index is a MultiIndex).

**Returns**

np.ndarray[bool] NumPy array of boolean values.

**See also:**

Series.isin Same for Series.

DataFrame.isin Same method for DataFrames.

**Notes**

In the case of MultiIndex you must either specify values as a list-like object containing tuples that are the same length as the number of levels, or specify level. Otherwise it will raise a ValueError.

If level is specified:

- if it is the name of one and only one index level, use that level;
- otherwise it should be a number indicating level position.

**Examples**

```python
>>> idx = pd.Index([1, 2, 3])
>>> idx
Int64Index([1, 2, 3], dtype='int64')
Check whether each index value in a list of values.

>>> idx.isin([1, 4])
array([ True, False, False])
```

```python
>>> midx = pd.MultiIndex.from_arrays([[1, 2, 3],
...                                    ['red', 'blue', 'green']],
...                                    names=('number', 'color'))
>>> midx
MultiIndex([[1, 'red'],
            (2, 'blue'),
            (3, 'green')],
           names=['number', 'color'])
Check whether the strings in the ‘color’ level of the MultiIndex are in a list of colors.
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
>>> midx.isin(['red', 'orange', 'yellow'], level='color')
array([True, False, False])
```

To check across the levels of a MultiIndex, pass a list of tuples:

```python
>>> midx.isin([(1, 'red'), (3, 'red')])
array([True, False, False])
```

For a DatetimeIndex, string values in `values` are converted to Timestamps.

```python
>>> dates = ['2000-03-11', '2000-03-12', '2000-03-13']
>>> dti = pd.to_datetime(dates)
>>> dti
DatetimeIndex(['2000-03-11', '2000-03-12', '2000-03-13'],
dtype='datetime64[ns]', freq=None)
```

```python
>>> dti.isin(['2000-03-11'])
array([True, False, False])
```

### pandas.Index.isna

`Index.isna()`  
Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as `None`, `numpy.NaN` or `pd.NaT`, get mapped to `True` values. Everything else get mapped to `False` values. Characters such as empty strings `''` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`).

**Returns**  
`numpy.ndarray[bool]` A boolean array of whether my values are NA.

**See also:**

- `Index.notna` Boolean inverse of isna.
- `Index.dropna` Omit entries with missing values.
- `isna` Top-level isna.
- `Series.isna` Detect missing values in Series object.

**Examples**

Show which entries in a pandas.Index are NA. The result is an array.

```python
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.isna()
array([False, False, True])
```

Empty strings are not considered NA values. None is considered an NA value.
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.isna()
array([False, False, False, True])

For datetimes, \textit{NaT} (Not a Time) is considered as an NA value.

>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
... pd.Timestamp(''),
... None,
... pd.NaT])
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
              dtype='datetime64[ns]', freq=None)
>>> idx.isna()
array([False, True, True, True])

\texttt{pandas.Index.isnull}

\texttt{Index.isnull()} \\
Detect missing values.

Return a boolean same-sized object indicating if the values are NA. NA values, such as \texttt{None}, \texttt{numpy.NaN} or \texttt{pd.NaT}, get mapped to \texttt{True} values. Everything else get mapped to \texttt{False} values. Characters such as empty strings '' or \texttt{numpy.inf} are not considered NA values (unless you set \texttt{pandas.options.mode.use_inf_as_na = True}).

Returns

\texttt{numpy.ndarray[bool]} A boolean array of whether my values are NA.

See also:

\texttt{Index.notna} Boolean inverse of isna.

\texttt{Index.dropna} Omit entries with missing values.

\texttt{isna} Top-level isna.

\texttt{Series.isna} Detect missing values in Series object.

\textbf{Examples}

Show which entries in a pandas.Index are NA. The result is an array.

>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.isna()
array([False, False, True])

Empty strings are not considered NA values. None is considered an NA value. 

>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.isna()
array([False, False, False, True])

3.6. Index objects
For datetimes, `NaT` (Not a Time) is considered as an NA value.

```python
>>> idx = pd.DatetimeIndex([pd.Timestamp('1940-04-25'),
...                          pd.Timestamp(''),
...                          None, pd.NaT])
>>> idx
DatetimeIndex(['1940-04-25', 'NaT', 'NaT', 'NaT'],
               dtype='datetime64[ns]', freq=None)
>>> idx.isna()
array([False,  True,  True,  True])
```

**pandas.Index.item**

`Index.item()`

Return the first element of the underlying data as a Python scalar.

Returns

- **scalar** The first element of `%(klass)s`.

Raises

- **ValueError** If the data is not length-1.

**pandas.Index.join**

`Index.join(other, how='left', level=None, return_indexers=False, sort=False)`

Compute join_index and indexers to conform data structures to the new index.

Parameters

- **other** [Index]
- **how** [{'left', 'right', 'inner', 'outer'}]
- **level** [int or level name, default None]
- **return_indexers** [bool, default False]
- **sort** [bool, default False] Sort the join keys lexicographically in the result Index. If False, the order of the join keys depends on the join type (how keyword).

Returns

- **join_index, (left_indexer, right_indexer)**

**pandas.Index.map**

`Index.map(mapper, na_action=None)`

Map values using input correspondence (a dict, Series, or function).

Parameters

- **mapper** [function, dict, or Series] Mapping correspondence.
- **na_action** [[None, 'ignore']] If ‘ignore’, propagate NA values, without passing them to the mapping correspondence.

Returns
applied [Union[Index, MultiIndex], inferred] The output of the mapping function applied to the index. If the function returns a tuple with more than one element a MultiIndex will be returned.

pandas.Index.max

Index.max (axis=None, skipna=True, *args, **kwargs)
Return the maximum value of the Index.

Parameters
- axis [int, optional] For compatibility with NumPy. Only 0 or None are allowed.
- skipna [bool, default True] Exclude NA/null values when showing the result.
- *args, **kwargs Additional arguments and keywords for compatibility with NumPy.

Returns
- scalar Maximum value.

See also:
- Index.min Return the minimum value in an Index.
- Series.max Return the maximum value in a Series.
- DataFrame.max Return the maximum values in a DataFrame.

Examples

```python
>>> idx = pd.Index([3, 2, 1])
>>> idx.max()
3

>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.max()
'c'
```

For a MultiIndex, the maximum is determined lexicographically.

```python
>>> idx = pd.MultiIndex.from_product([('a', 'b'), (2, 1)])
>>> idx.max()
('b', 2)
```

pandas.Index.memory_usage

Index.memory_usage (deep=False)
Memory usage of the values.

Parameters
- deep [bool, default False] Introspect the data deeply, interrogate object dtypes for system-level memory consumption.

Returns
- bytes used
See also:

numpy.ndarray.nbytes Total bytes consumed by the elements of the array.

Notes

Memory usage does not include memory consumed by elements that are not components of the array if deep=False or if used on PyPy

pandas.Index.min

Index.min(axis=None, skipna=True, *args, **kwargs)

Return the minimum value of the Index.

Parameters

axis [{None}] Dummy argument for consistency with Series.

skipna [bool, default True] Exclude NA/null values when showing the result.

*args, **kwargs Additional arguments and keywords for compatibility with NumPy.

Returns

scalar Minimum value.

See also:

Index.max Return the maximum value of the object.

Series.min Return the minimum value in a Series.

DataFrame.min Return the minimum values in a DataFrame.

Examples

```python
>>> idx = pd.Index([3, 2, 1])
>>> idx.min()
1

>>> idx = pd.Index(['c', 'b', 'a'])
>>> idx.min()
'a'

For a MultiIndex, the minimum is determined lexicographically.

>>> idx = pd.MultiIndex.from_product([['a', 'b'], (2, 1)])
>>> idx.min()
('a', 1)
```
**pandas.Index.notna**

`Index.notna()`  
Detect existing (non-missing) values.  
Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to `True`. Characters such as empty strings `' '` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to `False` values.  

Returns  
`numpy.ndarray[bool]` Boolean array to indicate which entries are not NA.  

See also:  
`Index.notnull` Alias of `notna`.  
`Index.isna` Inverse of `notna`.  
`notna` Top-level `notna`.  

**Examples**  
Show which entries in an Index are not NA. The result is an array.  

```python  
>>> idx = pd.Index([5.2, 6.0, np.NaN])  
>>> idx  
Float64Index([5.2, 6.0, nan], dtype='float64')  
>>> idx.notna()  
array([True, True, False])  
```

Empty strings are not considered NA values. None is considered a NA value.  

```python  
>>> idx = pd.Index(['black', '', 'red', None])  
>>> idx  
Index(['black', '', 'red', None], dtype='object')  
>>> idx.notna()  
array([True, True, True, False])  
```

**pandas.Index.notnull**

`Index.notnull()`  
Detect existing (non-missing) values.  
Return a boolean same-sized object indicating if the values are not NA. Non-missing values get mapped to `True`. Characters such as empty strings `' '` or `numpy.inf` are not considered NA values (unless you set `pandas.options.mode.use_inf_as_na = True`). NA values, such as `None` or `numpy.NaN`, get mapped to `False` values.  

Returns  
`numpy.ndarray[bool]` Boolean array to indicate which entries are not NA.  

See also:  
`Index.notnull` Alias of `notna`.  

3.6. Index objects 2049
**Index.isna** Inverse of notna.

**notna** Top-level notna.

## Examples

Show which entries in an Index are not NA. The result is an array.

```python
>>> idx = pd.Index([5.2, 6.0, np.NaN])
>>> idx
Float64Index([5.2, 6.0, nan], dtype='float64')
>>> idx.notna()
array([ True, True, False])
```

Empty strings are not considered NA values. None is considered a NA value.

```python
>>> idx = pd.Index(['black', '', 'red', None])
>>> idx
Index(['black', '', 'red', None], dtype='object')
>>> idx.notna()
array([ True, True, True, False])
```

### pandas.Index.nunique

**Index.nunique** *(dropna=True)*

Return number of unique elements in the object.

Excludes NA values by default.

**Parameters**

- **dropna** [bool, default True] Don’t include NaN in the count.

**Returns**

int

**See also:**

*DataFrame.nunique* Method nunique for DataFrame.

*Series.count* Count non-NA/null observations in the Series.

## Examples

```python
>>> s = pd.Series([1, 3, 5, 7, 7])
>>> s
0    1
1    3
2    5
3    7
4    7
dtype: int64

>>> s.nunique()
4
```
pandas.Index.putmask

Index.putmask(mask, value)
Return a new Index of the values set with the mask.

Returns
Index

See also:

numpy.ndarray.putmask Changes elements of an array based on conditional and input values.

pandas.Index.ravel

Index.ravel(order='C')
Return an ndarray of the flattened values of the underlying data.

Returns
numpy.ndarray Flattened array.

See also:

numpy.ndarray.ravel Return a flattened array.

pandas.Index.reindex

Index.reindex(target, method=None, level=None, limit=None, tolerance=None)
Create index with target’s values.

Parameters
target [an iterable]

Returns
new_index [pd.Index] Resulting index.
indexer [np.ndarray[np.intp] or None] Indices of output values in original index.

pandas.Index.rename

Index.rename(name, inplace=False)
Alter Index or MultiIndex name.

Able to set new names without level. Defaults to returning new index. Length of names must match number of levels in MultiIndex.

Parameters
name [label or list of labels] Name(s) to set.
inplace [bool, default False] Modifies the object directly, instead of creating a new Index or MultiIndex.

Returns
Index or None The same type as the caller or None if inplace=True.
See also:

*Index.set_names* Able to set new names partially and by level.

**Examples**

```python
>>> idx = pd.Index(['A', 'C', 'A', 'B'], name='score')
>>> idx.rename('grade')
Index(['A', 'C', 'A', 'B'], dtype='object', name='grade')

>>> idx = pd.MultiIndex.from_product([['python', 'cobra'], [2018, 2019]], names=['kind', 'year'])
>>> idx
MultiIndex([('python', 2018), ('python', 2019), ('cobra', 2018), ('cobra', 2019)], names=['kind', 'year'])

>>> idx.rename([['species', 'year']])
MultiIndex([('python', 2018), ('python', 2019), ('cobra', 2018), ('cobra', 2019)], names=['species', 'year'])

>>> idx.rename('species')
Traceback (most recent call last):
  TypeError: Must pass list-like as 'names'.
```

**pandas.Index.repeat**

*Index.repeat*(repeats, axis=None)

Repeat elements of a Index.

Returns a new Index where each element of the current Index is repeated consecutively a given number of times.

**Parameters**

- **repeats** [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty Index.

- **axis** [None] Must be None. Has no effect but is accepted for compatibility with numpy.

**Returns**

- **repeated_index** [Index] Newly created Index with repeated elements.

**See also:**

*Series.repeat* Equivalent function for Series.

*numpy.repeat* Similar method for numpy.ndarray.
Examples

```python
>>> idx = pd.Index(['a', 'b', 'c'])
>>> idx
Index(['a', 'b', 'c'], dtype='object')
>>> idx.repeat(2)
Index(['a', 'a', 'b', 'b', 'c', 'c'], dtype='object')
>>> idx.repeat([1, 2, 3])
Index(['a', 'b', 'b', 'c', 'c', 'c'], dtype='object')
```

**pandas.Index.searchsorted**

`Index.searchsorted(value, side='left', sorter=None)`

Find indices where elements should be inserted to maintain order.

Find the indices into a sorted Index `self` such that, if the corresponding elements in `value` were inserted before the indices, the order of `self` would be preserved.

**Note:** The Index must be monotonically sorted, otherwise wrong locations will likely be returned. Pandas does not check this for you.

**Parameters**

- `value` [array-like] Values to insert into `self`.
- `side` [‘left’, ‘right’], optional] If ‘left’, the index of the first suitable location found is given. If ‘right’, return the last such index. If there is no suitable index, return either 0 or N (where N is the length of `self`).
- `sorter` [1-D array-like, optional] Optional array of integer indices that sort `self` into ascending order. They are typically the result of `np.argsort`.

**Returns**

- `int or array of int` A scalar or array of insertion points with the same shape as `value`.

**See also:**

- `sort_values` Sort by the values along either axis.
- `numpy.searchsorted` Similar method from NumPy.

**Notes**

Binary search is used to find the required insertion points.
Examples

```python
>>> ser = pd.Series([1, 2, 3])
>>> ser
0   1
1   2
2   3
dtype: int64

>>> ser.searchsorted(4)
3

>>> ser.searchsorted([0, 4])
array([0, 3])

>>> ser.searchsorted([1, 3], side='left')
array([0, 2])

>>> ser.searchsorted([1, 3], side='right')
array([1, 3])

>>> ser
0  2000-03-11
1  2000-03-12
2  2000-03-13
dtype: datetime64[ns]

>>> ser.searchsorted('3/14/2000')
3

>>> ser = pd.Categorical(
...    ['apple', 'bread', 'bread', 'cheese', 'milk'], ordered=True
...
>>> ser
['apple', 'bread', 'bread', 'cheese', 'milk']
Categories (4, object): ['apple' < 'bread' < 'cheese' < 'milk']

>>> ser.searchsorted('bread')
1

>>> ser.searchsorted(['bread'], side='right')
array([3])
```

If the values are not monotonically sorted, wrong locations may be returned:

```python
>>> ser = pd.Series([2, 1, 3])
>>> ser
0   2
1   1
2   3
dtype: int64
```
>>> ser.searchsorted(1)
0  # wrong result, correct would be 1

pandas.Index.set_names

Index.set_names(names, level=None, inplace=False)

Set Index or MultiIndex name.

Able to set new names partially and by level.

Parameters

- names  [label or list of label or dict-like for MultiIndex] Name(s) to set.
  Changed in version 1.3.0.
- level  [int, label or list of int or label, optional] If the index is a MultiIndex and names is not dict-like, level(s) to set (None for all levels). Otherwise level must be None.
  Changed in version 1.3.0.
- inplace  [bool, default False] Modifies the object directly, instead of creating a new Index or MultiIndex.

Returns

- Index or None  The same type as the caller or None if inplace=True.

See also:

Index.rename  Able to set new names without level.

Examples

```python
>>> idx = pd.Index([1, 2, 3, 4])
>>> idx
Int64Index([1, 2, 3, 4], dtype='int64')
>>> idx.set_names('quarter')
Int64Index([1, 2, 3, 4], dtype='int64', name='quarter')

>>> idx = pd.MultiIndex.from_product([['python', 'cobra'], [2018, 2019]])
>>> idx
MultiIndex([( 'python', 2018),
             ( 'python', 2019),
             ( 'cobra', 2018),
             ( 'cobra', 2019)],
            names=('kind', 'year'))
>>> idx.set_names(['kind', 'year'], inplace=True)
>>> idx
MultiIndex([( 'python', 2018),
             ( 'python', 2019),
             ( 'cobra', 2018),
             ( 'cobra', 2019)],
            names=('kind', 'year'))
```

(continues on next page)
When renaming levels with a dict, levels cannot be passed.

```python
>>> idx.set_names({"kind": 'snake'})
MultiIndex([('python', 2018),
            ('python', 2019),
            ('cobra', 2018),
            ('cobra', 2019)],
           names=['snake', 'year'])
```

**pandas.Index.set_value**

`Index.set_value(arr, key, value)`
Fast lookup of value from 1-dimensional ndarray.
DeprecatedRoute since version 1.0.

**Notes**

Only use this if you know what you’re doing.

**pandas.Index.shift**

`Index.shift(periods=1, freq=None)`
Shift index by desired number of time frequency increments.

This method is for shifting the values of datetime-like indexes by a specified time increment a given number of times.

**Parameters**

- **periods** [int, default 1] Number of periods (or increments) to shift by, can be positive or negative.
- **freq** [pandas.DateOffset, pandas.Timedelta or str, optional] Frequency increment to shift by. If None, the index is shifted by its own `freq` attribute. Offset aliases are valid strings, e.g., ‘D’, ‘W’, ‘M’ etc.

**Returns**

- `pandas.Index` Shifted index.

**See also:**

- `Series.shift` Shift values of Series.
Notes

This method is only implemented for datetime-like index classes, i.e., DatetimeIndex, PeriodIndex and TimedeltaIndex.

Examples

Put the first 5 month starts of 2011 into an index.

```python
>>> month_starts = pd.date_range('1/1/2011', periods=5, freq='MS')
>>> month_starts
DatetimeIndex(['2011-01-01', '2011-02-01', '2011-03-01', '2011-04-01',
               '2011-05-01'],
          dtype='datetime64[ns]', freq='MS')
```

Shift the index by 10 days.

```python
>>> month_starts.shift(10, freq='D')
               '2011-05-11'],
          dtype='datetime64[ns]', freq=None)
```

The default value of `freq` is the `freq` attribute of the index, which is ‘MS’ (month start) in this example.

```python
>>> month_starts.shift(10)
DatetimeIndex(['2011-11-01', '2011-12-01', '2012-01-01', '2012-02-01',
               '2012-03-01'],
          dtype='datetime64[ns]', freq='MS')
```

pandas.Index.slice_indexer

Index.**slice_indexer**(start=None, end=None, step=None, kind=None)

Compute the slice indexer for input labels and step.

Index needs to be ordered and unique.

**Parameters**

- **start** [label, default None] If None, defaults to the beginning.
- **end** [label, default None] If None, defaults to the end.
- **step** [int, default None]
- **kind** [str, default None]

**Returns**

- **indexer** [slice]

**Raises**

- **KeyError** [If key does not exist, or key is not unique and index is] not ordered.
Notes

This function assumes that the data is sorted, so use at your own peril

Examples

This is a method on all index types. For example you can do:

```python
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_indexer(start='b', end='c')
slice(1, 3, None)
```

```python
>>> idx = pd.MultiIndex.from_arrays([list('abcd'), list('efgh')])
>>> idx.slice_indexer(start='b', end=('c', 'g'))
slice(1, 3, None)
```

pandas.Index.slice_locs

Index.slice_locs(start=None, end=None, step=None, kind=None)
compute slice locations for input labels.

Parameters

- `start` [label, default None] If None, defaults to the beginning.
- `end` [label, default None] If None, defaults to the end.
- `step` [int, defaults None] If None, defaults to 1.
- `kind` [{‘loc’, ‘getitem’} or None]

Returns

- `start, end` [int]

See also:

Index.get_loc Get location for a single label.

Notes

This method only works if the index is monotonic or unique.

Examples

```python
>>> idx = pd.Index(list('abcd'))
>>> idx.slice_locs(start='b', end='c')
(1, 3)
```
**pandas.Index.sort**

Index.sort(*args, **kwargs)
Use sort_values instead.

**pandas.Index.sort_values**

Index.sort_values(return_indexer=False, ascending=True, na_position='last', key=None)
Return a sorted copy of the index.
Return a sorted copy of the index, and optionally return the indices that sorted the index itself.

**Parameters**

- **return_indexer** [bool, default False] Should the indices that would sort the index be returned.
- **ascending** [bool, default True] Should the index values be sorted in an ascending order.
- **na_position** [{‘first’ or ‘last’}, default ‘last’] Argument ‘first’ puts NaNs at the beginning, ‘last’ puts NaNs at the end.
  New in version 1.2.0.
- **key** [callable, optional] If not None, apply the key function to the index values before sorting. This is similar to the key argument in the builtin sorted() function, with the notable difference that this key function should be vectorized. It should expect an Index and return an Index of the same shape.
  New in version 1.1.0.

**Returns**

- **sorted_index** [pandas.Index] Sorted copy of the index.
- **indexer** [numpy.ndarray, optional] The indices that the index itself was sorted by.

See also:

**Series.sort_values** Sort values of a Series.
**DataFrame.sort_values** Sort values in a DataFrame.

**Examples**

```python
>>> idx = pd.Index([10, 100, 1, 1000])
>>> idx
Int64Index([10, 100, 1, 1000], dtype='int64')
```
Sort values in ascending order (default behavior).

```python
>>> idx.sort_values()
Int64Index([1, 10, 100, 1000], dtype='int64')
```
Sort values in descending order, and also get the indices idx was sorted by.

```python
>>> idx.sort_values(ascending=False, return_indexer=True)
(Int64Index([1000, 100, 10, 1], dtype='int64'), array([3, 1, 0, 2]))
```
pandas.Index.sortlevel

`Index.sortlevel(level=None, ascending=True, sort_remaining=None)`

For internal compatibility with the Index API.

Sort the Index. This is for compat with MultiIndex

**Parameters**

- `ascending` [bool, default True] False to sort in descending order
- `level`, `sort_remaining` are compat parameters

**Returns**

Index

pandas.Index.str

`Index.str()`

Vectorized string functions for Series and Index.

NA as stay NA unless handled otherwise by a particular method. Patterned after Python’s string methods, with some inspiration from R’s stringr package.

**Examples**

```python
>>> s = pd.Series(["A_Str_Series"])
>>> s
0   A_Str_Series
dtype: object

>>> s.str.split("_")
0   [A, Str, Series]
dtype: object

>>> s.str.replace("_", "")
0   AStrSeries
dtype: object
```

pandas.Index.symmetric_difference

`Index.symmetric_difference(other, result_name=None, sort=None)`

Compute the symmetric difference of two Index objects.

**Parameters**

- `other` [Index or array-like]
- `result_name` [str]
- `sort` [False or None, default None] Whether to sort the resulting index. By default, the values are attempted to be sorted, but any TypeError from incomparable elements is caught by pandas.
- None: Attempt to sort the result, but catch any TypeErrors from comparing incomparable elements.
- False: Do not sort the result.

**Returns**

**symmetric_difference** [Index]

**Notes**

symmetric_difference contains elements that appear in either idx1 or idx2 but not both. Equivalent to the Index created by idx1.difference(idx2) | idx2.difference(idx1) with duplicates dropped.

**Examples**

```python
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([2, 3, 4, 5])
>>> idx1.symmetric_difference(idx2)
Int64Index([1, 5], dtype='int64')
```

**pandas.Index.take**

*Index*.take(indices, axis=0, allow_fill=True, fill_value=None, **kwargs)*

Return a new Index of the values selected by the indices.

For internal compatibility with numpy arrays.

**Parameters**

- **indices** [array-like] Indices to be taken.
- **axis** [int, optional] The axis over which to select values, always 0.
- **allow_fill** [bool, default True]
- **fill_value** [scalar, default None] If allow_fill=True and fill_value is not None, indices specified by -1 are regarded as NA. If Index doesn’t hold NA, raise ValueError.

**Returns**

**Index** An index formed of elements at the given indices. Will be the same type as self, except for RangeIndex.

**See also:**

- **numpy.ndarray.take** Return an array formed from the elements of a at the given indices.
pandas.Index.to_flat_index

Index.to_flat_index()
Identity method.
This is implemented for compatibility with subclass implementations when chaining.

Returns
pd.Index Caller.

See also:
MultiIndex.to_flat_index Subclass implementation.

pandas.Index.to_frame

Index.to_frame(index=True, name=None)
Create a DataFrame with a column containing the Index.

Parameters
index [bool, default True] Set the index of the returned DataFrame as the original Index.
name [object, default None] The passed name should substitute for the index name (if it has one).

Returns
DataFrame DataFrame containing the original Index data.

See also:
Index.to_series Convert an Index to a Series.
Series.to_frame Convert Series to DataFrame.

Examples

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
   animal
      0  Ant
      1  Bear
      2  Cow
```

By default, the original Index is reused. To enforce a new Index:

```python
>>> idx.to_frame(index=False)
   animal
      0  Ant
      1  Bear
      2  Cow
```

To override the name of the resulting column, specify name:
>>> idx.to_frame(index=False, name='zoo')
   zoo
0  Ant
1  Bear
2  Cow

pandas.Index.to_list

Index.to_list()
Return a list of the values.
These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns
list

See also:

numpy.ndarray.tolist Return the array as an a.ndim-levels deep nested list of Python scalars.

pandas.Index.to_native_types

Index.to_native_types(slicer=None, **kwargs)
Format specified values of self and return them.
Deprecation since version 1.2.0.

Parameters

slicer [int, array-like] An indexer into self that specifies which values are used in the formatting process.

kwargs [dict] Options for specifying how the values should be formatted. These options include the following:
1) na_rep [str] The value that serves as a placeholder for NULL values
2) quoting [bool or None] Whether or not there are quoted values in self
3) date_format [str] The format used to represent date-like values.

Returns

numpy.ndarray Formatted values.

pandas.Index.to_numpy

Index.to_numpy(dtype=None, copy=False, na_value=<no_default>, **kwargs)
A NumPy ndarray representing the values in this Series or Index.

Parameters

dtype [str or numpy.dtype, optional] The dtype to pass to numpy.asarray().
copy [bool, default False] Whether to ensure that the returned value is not a view on another array. Note that copy=False does not ensure that to_numpy() is no-copy. Rather, copy=True ensure that a copy is made, even if not strictly necessary.

na_value [Any, optional] The value to use for missing values. The default value depends on dtype and the type of the array.

New in version 1.0.0.

**kwargs Additional keywords passed through to the to_numpy method of the underlying array (for extension arrays).

New in version 1.0.0.

Returns

numpy.ndarray

See also:

Series.array Get the actual data stored within.
Index.array Get the actual data stored within.
DataFrame.to_numpy Similar method for DataFrame.

Notes

The returned array will be the same up to equality (values equal in self will be equal in the returned array; likewise for values that are not equal). When self contains an ExtensionArray, the dtype may be different. For example, for a category-dtype Series, to_numpy() will return a NumPy array and the categorical dtype will be lost.

For NumPy dtypes, this will be a reference to the actual data stored in this Series or Index (assuming copy=False). Modifying the result in place will modify the data stored in the Series or Index (not that we recommend doing that).

For extension types, to_numpy() may require copying data and coercing the result to a NumPy type (possibly object), which may be expensive. When you need a no-copy reference to the underlying data, Series.array should be used instead.

This table lays out the different dtypes and default return types of to_numpy() for various dtypes within pandas.

<table>
<thead>
<tr>
<th>dtype</th>
<th>array type</th>
</tr>
</thead>
<tbody>
<tr>
<td>category[T]</td>
<td>ndarray[T] (same dtype as input)</td>
</tr>
<tr>
<td>period</td>
<td>ndarray[object] (Periods)</td>
</tr>
<tr>
<td>interval</td>
<td>ndarray[object] (Intervals)</td>
</tr>
<tr>
<td>IntegerNA</td>
<td>ndarray[object]</td>
</tr>
<tr>
<td>datetime64[ns]</td>
<td>datetime64[ns]</td>
</tr>
<tr>
<td>datetime64[ns, tz]</td>
<td>ndarray[object] (Timestamps)</td>
</tr>
</tbody>
</table>
Examples

```python
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.to_numpy()
array(['a', 'b', 'a'], dtype=object)
```

Specify the `dtype` to control how datetime-aware data is represented. Use `dtype=object` to return an ndarray of pandas `Timestamp` objects, each with the correct tz.

```python
>>> ser = pd.Series(pd.date_range('2000', periods=2, tz="CET"))
>>> ser.to_numpy(dtype=object)
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET'),
     Timestamp('2000-01-02 00:00:00+0100', tz='CET'),
     dtype=object])
```

Or `dtype='datetime64[ns]'` to return an ndarray of native `datetime64` values. The values are converted to UTC and the timezone info is dropped.

```python
>>> ser.to_numpy(dtype="datetime64[ns]"")
... array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00...',
     dtype='datetime64[ns]'
)
```

### pandas.Index.to_series

`Index.to_series(index=None, name=None)`

Create a Series with both index and values equal to the index keys.

Useful with map for returning an indexer based on an index.

**Parameters**

- **index** [Index, optional] Index of resulting Series. If None, defaults to original index.
- **name** [str, optional] Name of resulting Series. If None, defaults to name of original index.

**Returns**

- **Series** The dtype will be based on the type of the Index values.

**See also:**

- `Index.to_frame`: Convert an Index to a DataFrame.
- `Series.to_frame`: Convert Series to DataFrame.

**Examples**

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
```

By default, the original Index and original name is reused.

```python
>>> idx.to_series()
animal
Ant   Ant
```

(continues on next page)
To enforce a new Index, specify new labels to `index`:

```python
>>> idx.to_series(index=[0, 1, 2])
0  Ant
1  Bear
2  Cow
Name: animal, dtype: object
```

To override the name of the resulting column, specify `name`:

```python
>>> idx.to_series(name='zoo')
aminal
   Ant
  Ant
Bear  Bear
Cow   Cow
Name: zoo, dtype: object
```

### pandas.Index.tolist

Index.tolist()  
Return a list of the values.

These are each a scalar type, which is a Python scalar (for str, int, float) or a pandas scalar (for Timestamp/Timedelta/Interval/Period)

Returns  
list

See also:

numpy.ndarray.tolist Return the array as an a.ndim-levels deep nested list of Python scalars.

### pandas.Index.transpose

Index.transpose(*args, **kwargs)  
Return the transpose, which is by definition self.

Returns  
%(klass)s
pandas.Index.union

Index.union(other, sort=None)
Form the union of two Index objects.

If the Index objects are incompatible, both Index objects will be cast to dtype('object') first.

Changed in version 0.25.0.

Parameters

other [Index or array-like]

sort [bool or None, default None] Whether to sort the resulting Index.

• None : Sort the result, except when
  1. self and other are equal.
  2. self or other has length 0.
  3. Some values in self or other cannot be compared. A RuntimeWarning is issued in this case.

• False : do not sort the result.

Returns

union [Index]

Examples

Union matching dtypes

```python
>>> idx1 = pd.Index([1, 2, 3, 4])
>>> idx2 = pd.Index([3, 4, 5, 6])
>>> idx1.union(idx2)
Int64Index([1, 2, 3, 4, 5, 6], dtype='int64')
```

Union mismatched dtypes

```python
>>> idx1 = pd.Index(['a', 'b', 'c', 'd'])
>>> idx2 = pd.Index([1, 2, 3, 4])
>>> idx1.union(idx2)
Index(['a', 'b', 'c', 'd', 1, 2, 3, 4], dtype='object')
```

MultiIndex case

```python
>>> idx1 = pd.MultiIndex.from_arrays(
...     [[1, 1, 2, 2], ['Red', 'Blue', 'Red', 'Blue']],
... )
>>> idx1
MultiIndex([(1, 'Red'),
            (1, 'Blue'),
            (2, 'Red'),
            (2, 'Blue')],
           )
>>> idx2 = pd.MultiIndex.from_arrays(
...     [[3, 3, 2, 2], ['Red', 'Green', 'Red', 'Green']],
... )
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
>>> idx2
MultiIndex([(3, 'Red'),
            (3, 'Green'),
            (2, 'Red'),
            (2, 'Green')],
           )

>>> idx1.union(idx2)
MultiIndex([(1, 'Blue'),
            (1, 'Red'),
            (2, 'Blue'),
            (2, 'Green'),
            (2, 'Red'),
            (3, 'Green'),
            (3, 'Red')],
           )

>>> idx1.union(idx2, sort=False)
MultiIndex([(1, 'Red'),
            (1, 'Blue'),
            (2, 'Red'),
            (2, 'Blue'),
            (2, 'Green'),
            (3, 'Red'),
            (3, 'Green'),
            (2, 'Green')],
           )
```

**pandas.Index.unique**

Index.unique(level=None)

Return unique values in the index.

Unique values are returned in order of appearance, this does NOT sort.

**Parameters**

- **level** [int or hashable, optional] Only return values from specified level (for MultiIndex). If int, gets the level by integer position, else by level name.

**Returns**

- **Index**

**See also:**

- **unique** Numpy array of unique values in that column.
- **Series.unique** Return unique values of Series object.
pandas.Index.value_counts

Index.value_counts(normalize=False, sort=True, ascending=False, bins=None, dropna=True)

Return a Series containing counts of unique values.

The resulting object will be in descending order so that the first element is the most frequently-occurring element. Excludes NA values by default.

Parameters

- normalize [bool, default False] If True then the object returned will contain the relative frequencies of the unique values.
- sort [bool, default True] Sort by frequencies.
- ascending [bool, default False] Sort in ascending order.
- bins [int, optional] Rather than count values, group them into half-open bins, a convenience for pd.cut, only works with numeric data.
- dropna [bool, default True] Don’t include counts of NaN.

Returns

Series

See also:

Series.count Number of non-NA elements in a Series.
DataFrame.count Number of non-NA elements in a DataFrame.
DataFrame.value_counts Equivalent method on DataFrames.

Examples

```python
>>> index = pd.Index([3, 1, 2, 3, 4, np.nan])
>>> index.value_counts()
3.0  2
1.0  1
2.0  1
4.0  1
dtype: int64
```

With normalize set to True, returns the relative frequency by dividing all values by the sum of values.

```python
>>> s = pd.Series([3, 1, 2, 3, 4, np.nan])
>>> s.value_counts(normalize=True)
3.0  0.4
1.0  0.2
2.0  0.2
4.0  0.2
dtype: float64
```

bins

Bins can be useful for going from a continuous variable to a categorical variable; instead of counting unique apparitions of values, divide the index in the specified number of half-open bins.
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
>>> s.value_counts(bins=3)
(0.996, 2.0]  2
(2.0, 3.0]  2
(3.0, 4.0]  1
dtype: int64
```

`dropna`

With `dropna` set to `False` we can also see NaN index values.

```python
>>> s.value_counts(dropna=False)
3.0  2
1.0  1
2.0  1
4.0  1
NaN  1
dtype: int64
```

**pandas.Index.where**

`Index.where` *(cond, other=None)*

Replace values where the condition is False.

The replacement is taken from other.

**Parameters**

- **cond** [bool array-like with the same length as self] Condition to select the values on.
- **other** [scalar, or array-like, default None] Replacement if the condition is False.

**Returns**

- **pandas.Index** A copy of self with values replaced from other where the condition is False.

**See also:**

- **Series.where** Same method for Series.
- **DataFrame.where** Same method for DataFrame.

**Examples**

```python
>>> idx = pd.Index(['car', 'bike', 'train', 'tractor'])
>>> idx
Index(['car', 'bike', 'train', 'tractor'], dtype='object')
>>> idx.where(idx.isin(['car', 'train']), 'other')
Index(['car', 'other', 'train', 'other'], dtype='object')
```
## Properties

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Index.values</code></td>
<td>Return an array representing the data in the Index.</td>
</tr>
<tr>
<td><code>Index.is_monotonic</code></td>
<td>Alias for <code>is_monotonic_increasing</code>.</td>
</tr>
<tr>
<td><code>Index.is_monotonic_increasing</code></td>
<td>Return if the index is monotonic increasing (only equal or increasing) values.</td>
</tr>
<tr>
<td><code>Index.is_monotonic_decreasing</code></td>
<td>Return if the index is monotonic decreasing (only equal or decreasing) values.</td>
</tr>
<tr>
<td><code>Index.is_unique</code></td>
<td>Return if the index has unique values.</td>
</tr>
<tr>
<td><code>Index.has_duplicates</code></td>
<td>Check if the Index has duplicate values.</td>
</tr>
<tr>
<td><code>Index.hasnans</code></td>
<td>Return if I have any nans; enables various perf speedups.</td>
</tr>
<tr>
<td><code>Index.dtype</code></td>
<td>Return the dtype object of the underlying data.</td>
</tr>
<tr>
<td><code>Index.inferred_type</code></td>
<td>Return a string of the type inferred from the values.</td>
</tr>
<tr>
<td><code>Index.is_all_dates</code></td>
<td>Whether or not the index values only consist of dates.</td>
</tr>
<tr>
<td><code>Index.shape</code></td>
<td>Return a tuple of the shape of the underlying data.</td>
</tr>
<tr>
<td><code>Index.name</code></td>
<td>Return Index or MultiIndex name.</td>
</tr>
<tr>
<td><code>Index.names</code></td>
<td></td>
</tr>
<tr>
<td><code>Index.nbytes</code></td>
<td>Return the number of bytes in the underlying data.</td>
</tr>
<tr>
<td><code>Index.ndim</code></td>
<td>Number of dimensions of the underlying data, by definition 1.</td>
</tr>
<tr>
<td><code>Index.size</code></td>
<td>Return the number of elements in the underlying data.</td>
</tr>
<tr>
<td><code>Index.empty</code></td>
<td></td>
</tr>
<tr>
<td><code>Index.T</code></td>
<td>Return the transpose, which is by definition self.</td>
</tr>
<tr>
<td><code>Index.memory_usage</code></td>
<td>Memory usage of the values.</td>
</tr>

<tr>
<td><code>Index.get_loc(key[, method, tolerance])</code></td>
<td>Get integer location, slice or boolean mask for requested label.</td>
</tr>
<tr>
<td><code>Index.get_slice_bound(label, side[, kind])</code></td>
<td>Calculate slice bound that corresponds to given label.</td>
</tr>
<tr>
<td><code>Index.get_value(series, key)</code></td>
<td>Fast lookup of value from 1-dimensional ndarray.</td>
</tr>
<tr>
<td><code>Index.isin(values[, level])</code></td>
<td>Return a boolean array where the index values are in values.</td>
</tr>
<tr>
<td><code>Index.slice_indexer([start, end, step, kind])</code></td>
<td>Compute the slice indexer for input labels and step.</td>
</tr>
<tr>
<td><code>Index.slice_locs([start, end, step, kind])</code></td>
<td>Compute slice locations for input labels.</td>
</tr>
</tbody>
</table>

### 3.6.2 Numeric Index

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>RangeIndex([start, stop, step, dtype, copy, ...])</code></td>
<td>Immutable Index implementing a monotonic integer range.</td>
</tr>
<tr>
<td><code>Int64Index([data, dtype, copy, name])</code></td>
<td>Immutable sequence used for indexing and alignment.</td>
</tr>
<tr>
<td><code>UInt64Index([data, dtype, copy, name])</code></td>
<td>Immutable sequence used for indexing and alignment.</td>
</tr>
<tr>
<td><code>Float64Index([data, dtype, copy, name])</code></td>
<td>Immutable sequence used for indexing and alignment.</td>
</tr>
</tbody>
</table>

**pandas.RangeIndex**

```python
class pandas.RangeIndex(start=None, stop=None, step=None, dtype=None, copy=False, name=None)
```

Immutable Index implementing a monotonic integer range.

RangeIndex is a memory-saving special case of Int64Index limited to representing monotonic ranges. Using RangeIndex may in some instances improve computing speed.

This is the default index type used by DataFrame and Series when no explicit index is provided by the user.

**Parameters**

- `start` [int (default: 0), range, or other RangeIndex instance] If int and “stop” is not given, interpreted as “stop” instead.
- `stop` [int (default: 0)]
- `step` [int (default: 1)]
- `dtype` [np.int64] Unused, accepted for homogeneity with other index types.
- `copy` [bool, default False] Unused, accepted for homogeneity with other index types.
- `name` [object, optional] Name to be stored in the index.

**See also:**
**Index**  The base pandas Index type.

**Int64Index**  Index of int64 data.

### Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>start</code></td>
<td>The value of the <code>start</code> parameter (0 if this was not supplied).</td>
</tr>
<tr>
<td><code>stop</code></td>
<td>The value of the <code>stop</code> parameter.</td>
</tr>
<tr>
<td><code>step</code></td>
<td>The value of the <code>step</code> parameter (1 if this was not supplied).</td>
</tr>
</tbody>
</table>

**pandas.RangeIndex.start**

**property**  `RangeIndex.start`

The value of the `start` parameter (0 if this was not supplied).

**pandas.RangeIndex.stop**

**property**  `RangeIndex.stop`

The value of the `stop` parameter.

**pandas.RangeIndex.step**

**property**  `RangeIndex.step`

The value of the `step` parameter (1 if this was not supplied).

### Methods

**from_range**(data[, name, dtype])  
Create RangeIndex from a range object.

**pandas.RangeIndex.from_range**

**classmethod**  `RangeIndex.from_range`(data, name=None, dtype=None)

Create RangeIndex from a range object.

**Returns**

`RangeIndex`
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.Int64Index
class pandas.Int64Index (data=None, dtype=None, copy=False, name=None)
Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects. Int64Index is a special case of Index with purely integer labels.

Parameters

- data [array-like (1-dimensional)]
- dtype [NumPy dtype (default: int64)]
- copy [bool] Make a copy of input ndarray.
- name [object] Name to be stored in the index.

See also:

Index The base pandas Index type.

Notes

An Index instance can only contain hashable objects.

Attributes

None

Methods

None

pandas.UInt64Index
class pandas.UInt64Index (data=None, dtype=None, copy=False, name=None)
Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects. UInt64Index is a special case of Index with purely unsigned integer labels.

Parameters

- data [array-like (1-dimensional)]
- dtype [NumPy dtype (default: uint64)]
- copy [bool] Make a copy of input ndarray.
- name [object] Name to be stored in the index.

See also:

Index The base pandas Index type.
Notes

An Index instance can only contain hashable objects.

Attributes

None

Methods

None

pandas.Float64Index

class pandas.Float64Index (data=None, dtype=None, copy=False, name=None)

Immutable sequence used for indexing and alignment. The basic object storing axis labels for all pandas objects. Float64Index is a special case of Index with purely float labels.

Parameters

data [array-like (1-dimensional)]
dtype [NumPy dtype (default: float64)]
copy [bool] Make a copy of input ndarray.
name [object] Name to be stored in the index.

See also:

Index The base pandas Index type.

Notes

An Index instance can only contain hashable objects.

</tbody>
</table>

### 3.6.3 CategoricalIndex

CategoricalIndex is an index based on an underlying Categorical. It can only take on a limited, and usually fixed, number of possible values (categories). It can have an order, but numerical operations (additions, divisions, ...) are not possible.

**Class**

```python
class pandas.CategoricalIndex(data=None, categories=None, ordered=None, dtype=None, copy=False, name=None)
```

This class is used to create an index based on a Categorical. It follows the same rules as Categorical, but is specifically for index purposes.

**Parameters**

- `data` [array-like (1-dimensional)] The values of the categorical. If `categories` are given, values not in `categories` will be replaced with NaN.
- `categories` [index-like, optional] The categories for the categorical. Items need to be unique.
  - If the categories are not given here (and also not in `dtype`), they will be inferred from the `data`.
- `ordered` [bool, optional] Whether or not this categorical is treated as an ordered categorical.
  - If not given here or in `dtype`, the resulting categorical will be unordered.
- `dtype` [CategoricalDtype or “category”, optional] If CategoricalDtype cannot be used together with categories or ordered.
- `copy` [bool, default False] Make a copy of input ndarray.
- `name` [object, optional] Name to be stored in the index.

**Raises**

- `ValueError` If the categories do not validate.
- `TypeError` If an explicit `ordered=True` is given but no `categories` and the `values` are not sortable.

**See also:**

- `Index` The base pandas Index type.
- `Categorical` A categorical array.
- `CategoricalDtype` Type for categorical data.
Notes

See the user guide for more.

Examples

```python
>>> pd.CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'])
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], categories=['a', 'b', 'c'], ordered=False, dtype='category')
```

CategoricalIndex can also be instantiated from a Categorical:

```python
>>> c = pd.Categorical(['a', 'b', 'c', 'a', 'b', 'c'])
>>> pd.CategoricalIndex(c)
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], categories=['a', 'b', 'c'], ordered=False, dtype='category')
```

Ordered CategoricalIndex can have a min and max value.

```python
>>> ci = pd.CategoricalIndex(...
... ["a", "b", "c", "a", "b", "c"], ordered=True, categories=['c', 'b', 'a']
... )
>>> ci
CategoricalIndex(['a', 'b', 'c', 'a', 'b', 'c'], categories=['c', 'b', 'a'], ordered=True, dtype='category')
>>> ci.min()
'c'
```

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>codes</td>
<td>The category codes of this categorical.</td>
</tr>
<tr>
<td>categories</td>
<td>The categories of this categorical.</td>
</tr>
<tr>
<td>ordered</td>
<td>Whether the categories have an ordered relationship.</td>
</tr>
</tbody>
</table>

```python
pandas.CategoricalIndex.codes

property CategoricalIndex.codes
The category codes of this categorical.

Codes are an array of integers which are the positions of the actual values in the categories array.

There is no setter, use the other categorical methods and the normal item setter to change values in the categorical.

Returns

ndarray[int] A non-writable view of the codes array.
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.CategoricalIndex.categories

property CategoricalIndex.categories
The categories of this categorical.

Setting assigns new values to each category (effectively a rename of each individual category).
The assigned value has to be a list-like object. All items must be unique and the number of items in the
new categories must be the same as the number of items in the old categories.
Assigning to categories is an in-place operation!

Raises

ValueError If the new categories do not validate as categories or if the number of new
categories is unequal the number of old categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.
set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.ordered

property CategoricalIndex.ordered
Whether the categories have an ordered relationship.

Methods

rename_categories(*args, **kwargs) Rename categories.
reorder_categories(*args, **kwargs) Reorder categories as specified in new_categories.
add_categories(*args, **kwargs) Add new categories.
remove_categories(*args, **kwargs) Remove the specified categories.
remove_unused_categories(*args, **kwargs) Remove categories which are not used.
set_categories(*args, **kwargs) Set the categories to the specified new_categories.
as_ordered(*args, **kwargs) Set the Categorical to be ordered.
as_unordered(*args, **kwargs) Set the Categorical to be unordered.
map(mapper) Map values using input correspondence (a dict, Series, or function).
pandas.CategoricalIndex.rename_categories

CategoricalIndex.rename_categories(*args, **kwargs)

Rename categories.

Parameters

new_categories [list-like, dict-like or callable] New categories which will replace old categories.

- list-like: all items must be unique and the number of items in the new categories must match the existing number of categories.
- dict-like: specifies a mapping from old categories to new. Categories not contained in the mapping are passed through and extra categories in the mapping are ignored.
- callable: a callable that is called on all items in the old categories and whose return values comprise the new categories.

inplace [bool, default False] Whether or not to rename the categories inplace or return a copy of this categorical with renamed categories.

Deprecated since version 1.3.0.

Returns

cat [Categorical or None] Categorical with removed categories or None if inplace=True.

Raises

ValueError If new categories are list-like and do not have the same number of items than the current categories or do not validate as categories

See also:

generate_index CategoricalIndex Categorical

Examples

```python
>>> c = pd.Categorical(['a', 'a', 'b'])
>>> c.rename_categories([0, 1])
[0, 0, 1]
Categories (2, int64): [0, 1]
```

For dict-like new_categories, extra keys are ignored and categories not in the dictionary are passed through

```python
>>> c.rename_categories({'a': 'A', 'c': 'C'})
['A', 'A', 'b']
Categories (2, object): ['A', 'b']
```
You may also provide a callable to create the new categories

```python
>>> c.rename_categories(lambda x: x.upper())
['A', 'A', 'B']
Categories (2, object): ['A', 'B']
```

**pandas.CategoricalIndex.reorder_categories**

CategoricalIndex.reorder_categories(*args, **kwargs)

Reorder categories as specified in new_categories.

new_categories need to include all old categories and no new category items.

**Parameters**

- **new_categories** [Index-like] The categories in new order.
- **ordered** [bool, optional] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.
- **inplace** [bool, default False] Whether or not to reorder the categories inplace or return a copy of this categorical with reordered categories.

Deprecatable since version 1.3.0.

**Returns**

- **cat** [Categorical or None] Categorical with removed categories or None if inplace=True.

**Raises**

- **ValueError** If the new categories do not contain all old category items or any new ones

**See also:**

- rename_categories Rename categories.
- add_categories Add new categories.
- remove_categories Remove the specified categories.
- remove_unused_categories Remove categories which are not used.
- set_categories Set the categories to the specified ones.

**pandas.CategoricalIndex.add_categories**

CategoricalIndex.add_categories(*args, **kwargs)

Add new categories.

new_categories will be included at the last/highest place in the categories and will be unused directly after this call.

**Parameters**

- **new_categories** [category or list-like of category] The new categories to be included.
- **inplace** [bool, default False] Whether or not to add the categories inplace or return a copy of this categorical with added categories.

Deprecatable since version 1.3.0.
Returns

`cat` [Categorical or None] Categorical with new categories added or None if `inplace=True`.

Raises

`ValueError` If the new categories include old categories or do not validate as categories

See also:

- `rename_categories` Rename categories.
- `reorder_categories` Reorder categories.
- `remove_categories` Remove the specified categories.
- `remove_unused_categories` Remove categories which are not used.
- `set_categories` Set the categories to the specified ones.

---

`pandas.CategoricalIndex.remove_categories`

`CategoricalIndex.remove_categories(*args, **kwargs)`

Remove the specified categories.

`removals` must be included in the old categories. Values which were in the removed categories will be set to NaN

Parameters

- `removals` [category or list of categories] The categories which should be removed.
- `inplace` [bool, default False] Whether or not to remove the categories inplace or return a copy of this categorical with removed categories.

**Deprecated since version 1.3.0.**

Returns

`cat` [Categorical or None] Categorical with removed categories or None if `inplace=True`.

Raises

`ValueError` If the removals are not contained in the categories

See also:

- `rename_categories` Rename categories.
- `reorder_categories` Reorder categories.
- `add_categories` Add new categories.
- `remove_unused_categories` Remove categories which are not used.
- `set_categories` Set the categories to the specified ones.
pandas.CategoricalIndex.remove_unused_categories

CategoricalIndex.remove_unused_categories(*args, **kwargs)
Remove categories which are not used.

Parameters

- inplace [bool, default False] Whether or not to drop unused categories inplace or return a copy of this categorical with unused categories dropped.
  
  Deprecated since version 1.2.0.

Returns

- cat [Categorical or None] Categorical with unused categories dropped or None if inplace=True.

See also:

- rename_categories Rename categories.
- reorder_categories Reorder categories.
- add_categories Add new categories.
- remove_categories Remove the specified categories.
- set_categories Set the categories to the specified ones.

pandas.CategoricalIndex.set_categories

CategoricalIndex.set_categories(*args, **kwargs)
Set the categories to the specified new_categories.

- new_categories [Index-like] The categories in new order.

- ordered [bool, default False] Whether or not the categorical is treated as a ordered categorical. If not given, do not change the ordered information.

- rename [bool, default False] Whether or not the new_categories should be considered as a rename of the old categories or as reordered categories.

- inplace [bool, default False] Whether or not to reorder the categories in-place or return a copy of this categorical with reordered categories.
  
  Deprecated since version 1.3.0.

Returns

- Categorical with reordered categories or None if inplace.
Raises

ValueError  If new_categories does not validate as categories

See also:

rename_categories Rename categories.
reorder_categories Reorder categories.
add_categories Add new categories.
remove_categories Remove the specified categories.
remove_unused_categories Remove categories which are not used.

pandas.CategoricalIndex.as_ordered

CategoricalIndex.as_ordered(*args, **kwargs)
Set the Categorical to be ordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to True.

Returns

Categorical or None  Ordered Categorical or None if inplace=True.

pandas.CategoricalIndex.as_unordered

CategoricalIndex.as_unordered(*args, **kwargs)
Set the Categorical to be unordered.

Parameters

inplace [bool, default False] Whether or not to set the ordered attribute in-place or return a copy of this categorical with ordered set to False.

Returns

Categorical or None  Unordered Categorical or None if inplace=True.

pandas.CategoricalIndex.map

CategoricalIndex.map(mapper)
Map values using input correspondence (a dict, Series, or function).
Maps the values (their categories, not the codes) of the index to new categories. If the mapping correspondence is one-to-one the result is a CategoricalIndex which has the same order property as the original, otherwise an Index is returned.

If a dict or Series is used any unmapped category is mapped to NaN. Note that if this happens an Index will be returned.

Parameters

mapper [function, dict, or Series] Mapping correspondence.
Returs

pandas.CategoricalIndex or pandas.Index  Mapped index.

See also:

Index.map  Apply a mapping correspondence on an Index.
Series.map  Apply a mapping correspondence on a Series.
Series.apply  Apply more complex functions on a Series.

Examples

```python
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'])
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'],
                   ordered=False, dtype='category')
>>> idx.map(lambda x: x.upper())
CategoricalIndex(['A', 'B', 'C'], categories=['A', 'B', 'C'],
                   ordered=False, dtype='category')
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'third'})
CategoricalIndex(['first', 'second', 'third'], categories=['first',
                                                             'second', 'third'],
                                                             ordered=False, dtype='category')
```

If the mapping is one-to-one the ordering of the categories is preserved:

```python
>>> idx = pd.CategoricalIndex(['a', 'b', 'c'], ordered=True)
>>> idx
CategoricalIndex(['a', 'b', 'c'], categories=['a', 'b', 'c'],
                   ordered=True, dtype='category')
>>> idx.map({'a': 3, 'b': 2, 'c': 1})
CategoricalIndex([3, 2, 1], categories=[3, 2, 1], ordered=True,
                   dtype='category')
```

If the mapping is not one-to-one an Index is returned:

```python
>>> idx.map({'a': 'first', 'b': 'second', 'c': 'first'})
Index(['first', 'second', 'first'], dtype='object')
```

If a dict is used, all unmapped categories are mapped to NaN and the result is an Index:

```python
>>> idx.map({'a': 'first', 'b': 'second'})
Index(['first', 'second', nan], dtype='object')
```

<td>Map values using input correspondence (a dict, Series, or function).</td>
</tr>
<tr>
<td><code>CategoricalIndex.equals(other)</code></td>
<td>Determine if two CategoricalIndex objects contain the same elements.</td>
</tr>
</tbody>
</table>

**pandas.CategoricalIndex.equals**

`CategoricalIndex.equals(other)`

Determine if two CategoricalIndex objects contain the same elements.

**Returns**

`bool` If two CategoricalIndex objects have equal elements True, otherwise False.

**3.6.4 IntervalIndex**

`IntervalIndex(data[, closed, dtype, copy, ...])` Immutable index of intervals that are closed on the same side.

**pandas.IntervalIndex**

`class pandas.IntervalIndex(data, closed=None, dtype=None, copy=False, name=None, verify_integrity=True)`

Immutable index of intervals that are closed on the same side.

New in version 0.20.0.

**Parameters**

- `data` [array-like (1-dimensional)] Array-like containing Interval objects from which to build the IntervalIndex.
- `closed` [‘left’, ‘right’, ‘both’, ‘neither’], default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.
- `dtype` [dtype or None, default None] If None, dtype will be inferred.
**copy**  [bool, default False] Copy the input data.

**name**  [object, optional] Name to be stored in the index.

**verify_integrity**  [bool, default True] Verify that the IntervalIndex is valid.

**See also:**

**Index**  The base pandas Index type.

**Interval**  A bounded slice-like interval; the elements of an IntervalIndex.

**interval_range**  Function to create a fixed frequency IntervalIndex.

**cut**  Bin values into discrete Intervals.

**qcut**  Bin values into equal-sized Intervals based on rank or sample quantiles.

**Notes**

See the user guide for more.

**Examples**

A new IntervalIndex is typically constructed using `interval_range()`:

```python
gpd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]],
dtype='interval[int64, right]')
```

It may also be constructed using one of the constructor methods: `IntervalIndex.from_arrays()`, `IntervalIndex.from_breaks()`, and `IntervalIndex.from_tuples()`.

See further examples in the doc strings of `interval_range` and the mentioned constructor methods.

**Attributes**

<table>

<td>Return an array representing the data in the Index.</td>
</tr>
</tbody>
</table>
pandas.IntervalIndex.closed

IntervalIndex.closed: str
Whether the intervals are closed on the left-side, right-side, both or neither.

pandas.IntervalIndex.is_empty

property IntervalIndex.is_empty
Indicates if an interval is empty, meaning it contains no points.
New in version 0.25.0.

Returns

bool or ndarray A boolean indicating if a scalar Interval is empty, or a boolean ndarray positionally indicating if an Interval in an IntervalArray or IntervalIndex is empty.

Examples

An Interval that contains points is not empty:

```python
>>> pd.Interval(0, 1, closed='right').is_empty
False
```

An Interval that does not contain any points is empty:

```python
>>> pd.Interval(0, 0, closed='right').is_empty
True
>>> pd.Interval(0, 0, closed='left').is_empty
True
>>> pd.Interval(0, 0, closed='neither').is_empty
True
```

An Interval that contains a single point is not empty:

```python
>>> pd.Interval(0, 0, closed='both').is_empty
False
```

An IntervalArray or IntervalIndex returns a boolean ndarray positionally indicating if an Interval is empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'),
        ...        pd.Interval(1, 2, closed='neither')]
>>> pd.arrays.IntervalArray(ivs).is_empty
array([ True, False])
```

Missing values are not considered empty:

```python
>>> ivs = [pd.Interval(0, 0, closed='neither'), np.nan]
>>> pd.IntervalIndex(ivs).is_empty
array([[ True, False]])
```
pandas.IntervalIndex.is_non_overlapping_monotonic

IntervalIndex.is_non_overlapping_monotonic: bool
Return True if the IntervalArray is non-overlapping (no Intervals share points) and is either monotonic increasing or monotonic decreasing, else False.

pandas.IntervalIndex.is_overlapping

property IntervalIndex.is_overlapping
Return True if the IntervalIndex has overlapping intervals, else False.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

Returns

bool Boolean indicating if the IntervalIndex has overlapping intervals.

See also:

Interval.overlaps Check whether two Interval objects overlap.
IntervalIndex.overlaps Check an IntervalIndex elementwise for overlaps.

Examples

```python
>>> index = pd.IntervalIndex.from_tuples([(0, 2), (1, 3), (4, 5)])
>>> index
IntervalIndex([(0, 2], (1, 3], (4, 5]],
   dtype='interval[int64, right]')
>>> index.is_overlapping
True
```

Intervals that share closed endpoints overlap:

```python
>>> index = pd.interval_range(0, 3, closed='both')
>>> index
IntervalIndex([[[0, 1], [1, 2], [2, 3]],
   dtype='interval[int64, both]')
>>> index.is_overlapping
True
```

Intervals that only have an open endpoint in common do not overlap:

```python
>>> index = pd.interval_range(0, 3, closed='left')
>>> index
IntervalIndex([[[0, 1), [1, 2), [2, 3)),
   dtype='interval[int64, left]')
>>> index.is_overlapping
False
```
**pandas.IntervalIndex.values**

**property IntervalIndex.values**
Return an array representing the data in the Index.

Warning: We recommend using `Index.array` or `Index.to_numpy()`, depending on whether you need a reference to the underlying data or a NumPy array.

Returns
array: numpy.ndarray or ExtensionArray

See also:
Index.array Reference to the underlying data.
Index.to_numpy A NumPy array representing the underlying data.

<table>
<thead>
<tr>
<th>left</th>
<th>right</th>
<th>mid</th>
<th>length</th>
</tr>
</thead>
</table>

**Methods**

```
from_arrays(left, right[, closed, name, ...]) Construct from two arrays defining the left and right bounds.
from_tuples(data[, closed, name, copy, dtype]) Construct an IntervalIndex from an array-like of tuples.
from_breaks(breaks[, closed, name, copy, dtype]) Construct an IntervalIndex from an array of splits.
contains(*args, **kwargs) Check elementwise if the Intervals contain the value.
overlaps(*args, **kwargs) Check elementwise if an Interval overlaps the values in the IntervalArray.
set_closed(*args, **kwargs) Return an IntervalArray identical to the current one, but closed on the specified side.
to_tuples(*args, **kwargs) Return an ndarray of tuples of the form (left, right).
```

**pandas.IntervalIndex.from_arrays**

```
classmethod IntervalIndex.from_arrays (left, right, closed='right', name=None, copy=False, dtype=None)
Construct from two arrays defining the left and right bounds.
```

Parameters
left [array-like (1-dimensional)] Left bounds for each interval.
right [array-like (1-dimensional)] Right bounds for each interval.
closed [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are
closed on the left-side, right-side, both or neither.

**copy** [bool, default False] Copy the data.

**dtype** [dtype, optional] If None, dtype will be inferred.

### Returns

**IntervalIndex**

### Raises

**ValueError** When a value is missing in only one of `left` or `right`. When a value in `left` is greater than the corresponding value in `right`.

### See also:

- `interval_range` Function to create a fixed frequency IntervalIndex.
- `IntervalIndex.from_breaks` Construct an IntervalIndex from an array of splits.
- `IntervalIndex.from_tuples` Construct an IntervalIndex from an array-like of tuples.

### Notes

Each element of `left` must be less than or equal to the `right` element at the same position. If an element is missing, it must be missing in both `left` and `right`. A TypeError is raised when using an unsupported type for `left` or `right`. At the moment, ‘category’, ‘object’, and ‘string’ subtypes are not supported.

### Examples

```python
>>> pd.IntervalIndex.from_arrays([0, 1, 2], [1, 2, 3])
IntervalIndex([(0, 1], (1, 2], (2, 3)
   dtype='interval[int64, right]')
```

### pandas.IntervalIndex.from_tuples

#### classmethod IntervalIndex.from_tuples(data, closed='right', name=None, copy=False, dtype=None)

Construct an IntervalIndex from an array-like of tuples.

**Parameters**

- **data** [array-like (1-dimensional)] Array of tuples.
- **closed** [{'left', 'right', 'both', 'neither'}, default 'right'] Whether the intervals are closed on the left-side, right-side, both or neither.
- **copy** [bool, default False] By-default copy the data, this is compat only and ignored.
- **dtype** [dtype or None, default None] If None, dtype will be inferred.

### Returns

**IntervalIndex**

### See also:

- `interval_range` Function to create a fixed frequency IntervalIndex.
IntervalIndex.from_arrays Construct an IntervalIndex from a left and right array.

IntervalIndex.from_breaks Construct an IntervalIndex from an array of splits.

Examples

```python
>>> pd.IntervalIndex.from_tuples([(0, 1), (1, 2)])
IntervalIndex([(0, 1], (1, 2]),
dtype='interval[int64, right]')
```

pandas.IntervalIndex.from_breaks
classmethod IntervalIndex.from_breaks (breaks, closed='right', name=None, copy=False, dtype=None)

Construct an IntervalIndex from an array of splits.

Parameters

- breaks [array-like (1-dimensional)] Left and right bounds for each interval.
- closed [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.
- copy [bool, default False] Copy the data.
- dtype [dtype or None, default None] If None, dtype will be inferred.

Returns

IntervalIndex

See also:

- interval_range Function to create a fixed frequency IntervalIndex.
- IntervalIndex.from_arrays Construct from a left and right array.
- IntervalIndex.from_tuples Construct from a sequence of tuples.

Examples

```python
>>> pd.IntervalIndex.from_breaks([0, 1, 2, 3])
IntervalIndex([(0, 1], (1, 2], (2, 3]],
dtype='interval[int64, right]')
```

pandas.IntervalIndex.contains

IntervalIndex.contains (*args, **kwargs)

Check elementwise if the Intervals contain the value.

Return a boolean mask whether the value is contained in the Intervals of the IntervalArray.

New in version 0.25.0.

Parameters

- other [scalar] The value to check whether it is contained in the Intervals.
Returns

boolean array

See also:

*Interval.contains* Check whether Interval object contains value.

*IntervalArray.overlaps* Check if an Interval overlaps the values in the IntervalArray.

Examples

```python
>>> intervals = pd.arrays.IntervalArray.from_tuples([(0, 1), (1, 3), (2, 4)])
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]]
Length: 3, dtype: interval[int64, right]

>>> intervals.contains(0.5)
array([ True, False, False])
```

**pandas.IntervalIndex.overlaps**

*IntervalIndex.overlaps* (*args, **kwargs*)
Check elementwise if an Interval overlaps the values in the IntervalArray.

Two intervals overlap if they share a common point, including closed endpoints. Intervals that only have an open endpoint in common do not overlap.

Parameters

other [IntervalArray] Interval to check against for an overlap.

Returns

ndarray Boolean array positionally indicating where an overlap occurs.

See also:

*Interval.overlaps* Check whether two Interval objects overlap.

Examples

```python
>>> data = [(0, 1), (1, 3), (2, 4)]
>>> intervals = pd.arrays.IntervalArray.from_tuples(data)
>>> intervals
<IntervalArray>
[(0, 1], (1, 3], (2, 4]]
Length: 3, dtype: interval[int64, right]

>>> intervals.overlaps(pd.Interval(0.5, 1.5))
array([ True,  True, False])
```

Intervals that share closed endpoints overlap:
Intervals that only have an open endpoint in common do not overlap:

```python
>>> intervals.overlaps(pd.Interval(1, 2, closed='right'))
array([False, True, False])
```

**pandas.IntervalIndex.set_closed**

IntervalIndex.set_closed(*args, **kwargs)
Return an IntervalArray identical to the current one, but closed on the specified side.

**Parameters**

closed [{‘left’, ‘right’, ‘both’, ‘neither’}] Whether the intervals are closed on the left-side, right-side, both or neither.

**Returns**

new_index [IntervalArray]

**Examples**

```python
>>> index = pd.arrays.IntervalArray.from_breaks(range(4))
>>> index
<IntervalArray>
[(0, 1], (1, 2], (2, 3)]
Length: 3, dtype: interval[int64, right]
>>> index.set_closed('both')
<IntervalArray>
[[0, 1], [1, 2], [2, 3]]
Length: 3, dtype: interval[int64, both]
```

**pandas.IntervalIndex.to_tuples**

IntervalIndex.to_tuples(*args, **kwargs)
Return an ndarray of tuples of the form (left, right).

**Parameters**
	na_tuple [bool, default True] Returns NA as a tuple if True, (nan, nan), or just as the NA value itself if False, nan.

**Returns**

tuples: ndarray

### pandas.IntervalIndex.left

`IntervalIndex.left`
pandas.IntervalIndex.right

IntervalIndex.right

pandas.IntervalIndex.mid

IntervalIndex.mid

pandas.IntervalIndex.length

property IntervalIndex.length

pandas.IntervalIndex.get_loc

IntervalIndex.get_loc(key, method=None, tolerance=None)

Get integer location, slice or boolean mask for requested label.

Parameters

key [label]

method [{None}, optional]

  • default: matches where the label is within an interval only.

Returns

int if unique index, slice if monotonic index, else mask

Examples

```python
>>> i1, i2 = pd.Interval(0, 1), pd.Interval(1, 2)
>>> index = pd.IntervalIndex([i1, i2])
>>> index.get_loc(1)
0
```

You can also supply a point inside an interval.

```python
>>> index.get_loc(1.5)
1
```

If a label is in several intervals, you get the locations of all the relevant intervals.

```python
>>> i3 = pd.Interval(0, 2)
>>> overlapping_index = pd.IntervalIndex([i1, i2, i3])
>>> overlapping_index.get_loc(0.5)
array([ True, False,  True])
```

Only exact matches will be returned if an interval is provided.

```python
>>> index.get_loc(pd.Interval(0, 1))
0
```
pandas.IntervalIndex.get_indexer

IntervalIndex.get_indexer(target, method=None, limit=None, tolerance=None)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

Parameters

- **target** [Index]
- **method** [{None, ‘pad’/’ffill’, ‘backfill’/’bfill’, ‘nearest’}, optional]
  - default: exact matches only.
  - pad / ffill: find the PREVIOUS index value if no exact match.
  - backfill / bfill: use NEXT index value if no exact match
  - nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
- **limit** [int, optional] Maximum number of consecutive labels in target to match for inexact matches.
- **tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation abs(index[indexer] - target) <= tolerance.

  Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

Returns

- **indexer** [np.ndarray[np.intp]] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

Examples

```python
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1, 2, -1])
```

Notice that the return value is an array of locations in index and x is marked by -1, as it is not in index.

### 3.6.5 MultiIndex

MultiIndex([levels, codes, sortorder, ...])

A multi-level, or hierarchical, index object for pandas objects.
class pandas.MultiIndex(levels=None, codes=None, sortorder=None, names=None, dtype=None, copy=False, name=None, verify_integrity=True)
A multi-level, or hierarchical, index object for pandas objects.

Parameters

- **levels** [sequence of arrays] The unique labels for each level.
- **codes** [sequence of arrays] Integers for each level designating which label at each location.
- **sortorder** [optional int] Level of sortedness (must be lexicographically sorted by that level).
- **names** [optional sequence of objects] Names for each of the index levels. (name is accepted for compat).
- **copy** [bool, default False] Copy the meta-data.
- **verify_integrity** [bool, default True] Check that the levels/codes are consistent and valid.

See also:

- `MultiIndex.from_arrays` Convert list of arrays to MultiIndex.
- `MultiIndex.from_product` Create a MultiIndex from the cartesian product of iterables.
- `MultiIndex.from_tuples` Convert list of tuples to a MultiIndex.
- `MultiIndex.from_frame` Make a MultiIndex from a DataFrame.

**Index** The base pandas Index type.

**Notes**

See the user guide for more.

**Examples**

A new MultiIndex is typically constructed using one of the helper methods `MultiIndex.from_arrays()`, `MultiIndex.from_product()` and `MultiIndex.from_tuples()`. For example (using `from_arrays`):

```python
>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex([(1, 'red'),
   (1, 'blue'),
   (2, 'red'),
   (2, 'blue')],
   names=['number', 'color'])
```

See further examples for how to construct a MultiIndex in the doc strings of the mentioned helper methods.
Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>names</code></td>
<td>Names of levels in MultiIndex.</td>
</tr>
<tr>
<td><code>nlevels</code></td>
<td>Integer number of levels in this MultiIndex.</td>
</tr>
<tr>
<td><code>levshape</code></td>
<td>A tuple with the length of each level.</td>
</tr>
</tbody>
</table>

**pandas.MultiIndex.names**

**property** `MultiIndex.names`

Names of levels in MultiIndex.

**Examples**

```python
>>> mi = pd.MultiIndex.from_arrays(
... [[1, 2], [3, 4], [5, 6]], names=['x', 'y', 'z'])
>>> mi
MultiIndex([(1, 3, 5),
            (2, 4, 6)],
           names=['x', 'y', 'z'])
>>> mi.names
FrozenList(['x', 'y', 'z'])
```

**pandas.MultiIndex.nlevels**

**property** `MultiIndex.nlevels`

Integer number of levels in this MultiIndex.

**Examples**

```python
>>> mi = pd.MultiIndex.from_arrays([['a'], ['b'], ['c']])
>>> mi
MultiIndex([['a', 'b', 'c']],
           )
>>> mi.nlevels
3
```

**pandas.MultiIndex.levshape**

**property** `MultiIndex.levshape`

A tuple with the length of each level.
Examples

```python
>>> mi = pd.MultiIndex.from_arrays([['a'], ['b'], ['c']])
>>> mi
MultiIndex([('a', 'b', 'c')],
          )
>>> mi.levshape
(1, 1, 1)
```

pandas.MultiIndex.from_arrays

```python
classmethod MultiIndex.from_arrays(arrays, sortorder=None, names=<no_default>)
```

Convert arrays to MultiIndex.

Parameters

- **arrays** [list / sequence of array-likes] Each array-like gives one level’s value for each data point. len(arrays) is the number of levels.
- **sortorder** [int or None] Level of sortedness (must be lexicographically sorted by that level).
- **names** [list / sequence of str, optional] Names for the levels in the index.

Returns

MultiIndex

See also:
MultiIndex.from_tuples  Convert list of tuples to MultiIndex.

MultiIndex.from_product  Make a MultiIndex from cartesian product of iterables.

MultiIndex.from_frame  Make a MultiIndex from a DataFrame.

Examples

```python
>>> arrays = [[1, 1, 2, 2], ['red', 'blue', 'red', 'blue']]
>>> pd.MultiIndex.from_arrays(arrays, names=('number', 'color'))
MultiIndex([(1, 'red'),
           (1, 'blue'),
           (2, 'red'),
           (2, 'blue')],
          names=['number', 'color'])
```

pandas.MultiIndex.from_tuples

classmethod MultiIndex.from_tuples(tuples=None, sortorder=None, names=None)
Convert list of tuples to MultiIndex.

Parameters
- **tuples** [list / sequence of tuple-likes] Each tuple is the index of one row/column.
- **sortorder** [int or None] Level of sortedness (must be lexicographically sorted by that level).
- **names** [list / sequence of str, optional] Names for the levels in the index.

Returns
- MultiIndex

See also:

MultiIndex.from_arrays  Convert list of arrays to MultiIndex.

MultiIndex.from_product  Make a MultiIndex from cartesian product of iterables.

MultiIndex.from_frame  Make a MultiIndex from a DataFrame.

Examples

```python
>>> tuples = [(1, 'red'), (1, 'blue'),
            (2, 'red'), (2, 'blue')]
>>> pd.MultiIndex.from_tuples(tuples, names=('number', 'color'))
MultiIndex([(1, 'red'),
           (1, 'blue'),
           (2, 'red'),
           (2, 'blue')],
          names=['number', 'color'])
```
pandas.MultiIndex.from_product

classmethod MultiIndex.from_product(iterables=iterables, sortorder=None, names=names)

Make a MultiIndex from the cartesian product of multiple iterables.

Parameters

iterables [list / sequence of iterables] Each iterable has unique labels for each level of
the index.

sortorder [int or None] Level of sortedness (must be lexicographically sorted by that
level).

names [list / sequence of str, optional] Names for the levels in the index.

Changed in version 1.0.0: If not explicitly provided, names will be inferred from
the elements of iterables if an element has a name attribute

Returns

MultiIndex

See also:

MultiIndex.from_arrays Convert list of arrays to MultiIndex.

MultiIndex.from_tuples Convert list of tuples to MultiIndex.

MultiIndex.from_frame Make a MultiIndex from a DataFrame.

Examples

```python
>>> numbers = [0, 1, 2]
>>> colors = ['green', 'purple']
>>> pd.MultiIndex.from_product([[numbers, colors],
...                           names=['number', 'color'])
MultiIndex([(0, 'green'),
(0, 'purple'),
(1, 'green'),
(1, 'purple'),
(2, 'green'),
(2, 'purple')],
names=['number', 'color'])
```

pandas.MultiIndex.from_frame

classmethod MultiIndex.from_frame(df, sortorder=None, names=None)

Make a MultiIndex from a DataFrame.

Parameters

df [DataFrame] DataFrame to be converted to MultiIndex.

sortorder [int, optional] Level of sortedness (must be lexicographically sorted by that
level).

names [list-like, optional] If no names are provided, use the column names, or tuple of
column names if the columns is a MultiIndex. If a sequence, overwrite names with
the given sequence.
pandas: powerful Python data analysis toolkit, Release 1.3.1

Returns

MultiIndex  The MultiIndex representation of the given DataFrame.

See also:

MultiIndex.from_arrays  Convert list of arrays to MultiIndex.
MultiIndex.from_tuples  Convert list of tuples to MultiIndex.
MultiIndex.from_product  Make a MultiIndex from cartesian product of iterables.

Examples

```python
def = pd.DataFrame([['HI', 'Temp'], ['HI', 'Precip'], ...
                     ['NJ', 'Temp'], ['NJ', 'Precip']], ...
                     columns=['a', 'b'])
def
a  b
0  HI  Temp
1  HI  Precip
2  NJ  Temp
3  NJ  Precip
```

```python
def.MultiIndex.from_frame(df)
MultiIndex([('HI', 'Temp'),
            ('HI', 'Precip'),
            ('NJ', 'Temp'),
            ('NJ', 'Precip')],
           names=['a', 'b'])
```

Using explicit names, instead of the column names

```python
def.MultiIndex.from_frame(df, names=['state', 'observation'])
MultiIndex([('HI', 'Temp'),
            ('HI', 'Precip'),
            ('NJ', 'Temp'),
            ('NJ', 'Precip')],
           names=['state', 'observation'])
```

pandas.MultiIndex.set_levels

MultiIndex.set_levels(levels, level=None, inplace=None, verify_integrity=True)
Set new levels on MultiIndex. Defaults to returning new index.

Parameters

levels  [sequence or list of sequence] New level(s) to apply.
level  [int, level name, or sequence of int/level names (default None)] Level(s) to set (None for all levels).
inplace  [bool] If True, mutates in place.
    Deprecated since version 1.2.0.
verify_integrity  [bool, default True] If True, checks that levels and codes are compatible.
Returns

new index (of same type and class...etc) or None  The same type as the caller or
None if inplace=True.

Examples

```python
>>> idx = pd.MultiIndex.from_tuples(
...     [(1, "one"),
...      (1, "two"),
...      (2, "one"),
...      (2, "two"),
...      (3, "one"),
...      (3, "two")
...],
...     names=["foo", "bar"]
...)
>>> idx
MultiIndex([(1, 'one'),
    (1, 'two'),
    (2, 'one'),
    (2, 'two'),
    (3, 'one'),
    (3, 'two')],
   names=['foo', 'bar'])

>>> idx.set_levels([['a', 'b', 'c'], [1, 2]])
MultiIndex([['a', 'b', 'c'],
    ['a', 1],
    ['a', 2],
    ['b', 1],
    ['b', 2],
    ['c', 1],
    ['c', 2]],
   names=['foo', 'bar'])

>>> idx.set_levels([['a', 'b', 'c'], level=0])
MultiIndex([['a', 'b', 'c'],
    ['a', 'one'],
    ['a', 'two'],
    ['b', 'one'],
    ['b', 'two'],
    ['c', 'one'],
    ['c', 'two']],
   names=['foo', 'bar'])

>>> idx.set_levels([['a', 'b'], level='bar])
MultiIndex([(1, 'a'),
    (1, 'b'),
    (2, 'a'),
    (2, 'b'),
    (3, 'a'),
    (3, 'b')],
   names=['foo', 'bar'])
```

If any of the levels passed to `set_levels()` exceeds the existing length, all of the values from that argument will be stored in the MultiIndex levels, though the values will be truncated in the MultiIndex output.
```python
>>> idx.set_levels([['a', 'b', 'c'], [1, 2, 3, 4]], level=[0, 1])
MultiIndex([('a', 1),
    ('a', 2),
    ('b', 1),
    ('b', 2),
    ('c', 1),
    ('c', 2)],
    names=['foo', 'bar'])
>>> idx.set_levels([['a', 'b', 'c'], [1, 2, 3, 4]], level=[0, 1]).levels
FrozenList([['a', 'b', 'c'], [1, 2, 3, 4]])
```

**pandas.MultiIndex.set_codes**

MultiIndex.set_codes (codes, level=None, inplace=None, verify_integrity=True)

Set new codes on MultiIndex. Defaults to returning new index.

**Parameters**

- **codes** [sequence or list of sequence] New codes to apply.
- **level** [int, level name, or sequence of int/level names (default None)] Level(s) to set (None for all levels).
- **inplace** [bool] If True, mutates in place.
  
  Deprecated since version 1.2.0.
- **verify_integrity** [bool, default True] If True, checks that levels and codes are compatible.

**Returns**

- **new index (of same type and class...etc) or None** The same type as the caller or None if inplace=True.

**Examples**

```python
>>> idx = pd.MultiIndex.from_tuples(...
    [(1, "one"), (1, "two"), (2, "one"), (2, "two")], names=['foo', 'bar'])
...)
>>> idx
MultiIndex([(1, 'one'),
    (1, 'two'),
    (2, 'one'),
    (2, 'two')],
    names=['foo', 'bar'])
```

```python
>>> idx.set_codes([[1, 0, 1, 0], [0, 0, 1, 1]])
MultiIndex([(1, 'one'),
    (1, 'one'),
    (2, 'two'),
    (1, 'two')],
    names=['foo', 'bar'])
>>> idx.set_codes([1, 0, 1, 0], level=0)
MultiIndex([(1, 'one'),
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.1

(continued from previous page)

```python
>>> idx.set_codes([0, 0, 1, 1], level='bar')
MultiIndex([(1, 'one'),
            (1, 'two'),
            (2, 'one'),
            (2, 'two')],
           names=['foo', 'bar'])
>>> idx.set_codes([[1, 0, 1, 0], [0, 0, 1, 1]], level=[0, 1])
MultiIndex([(2, 'one'),
            (1, 'two')],
           names=['foo', 'bar'])
```

pandas.MultiIndex.to_frame

```python
pandas.MultiIndex.to_frame
```  

MultiIndex .to_frame(index=True, name=None)  
Create a DataFrame with the levels of the MultiIndex as columns.  
Column ordering is determined by the DataFrame constructor with data as a dict.  

Parameters

- **index** [bool, default True] Set the index of the returned DataFrame as the original MultiIndex.  
- **name** [list / sequence of str, optional] The passed names should substitute index level names.  

Returns  
DataFrame [a DataFrame containing the original MultiIndex data.]  

See also:  

DataFrame Two-dimensional, size-mutable, potentially heterogeneous tabular data.  

Examples

```python
>>> mi = pd.MultiIndex.from_arrays([['a', 'b'], ['c', 'd']])
>>> mi
MultiIndex([('a', 'c'), ('b', 'd')],
           )
>>> df = mi.to_frame()
>>> df
   0 1
a c a c
b d b d
```
```python
>>> df = mi.to_frame(index=False)
>>> df
   0  1
0  a  c
1  b  d

>>> df = mi.to_frame(name=['x', 'y'])
>>> df
   x  y
0  a  c
1  b  d
```

### pandas.MultiIndex.to_flat_index

**MultiIndex.to_flat_index()**

Convert a MultiIndex to an Index of Tuples containing the level values.

**Returns**

- **pd.Index** Index with the MultiIndex data represented in Tuples.

**See also:**

- **MultiIndex.from_tuples** Convert flat index back to MultiIndex.

**Notes**

This method will simply return the caller if called by anything other than a MultiIndex.

**Examples**

```python
>>> index = pd.MultiIndex.from_product(...
...     [['foo', 'bar'], ['baz', 'qux']],
...     names=['a', 'b'])
>>> index.to_flat_index()
Index([('foo', 'baz'), ('foo', 'qux'),
     ('bar', 'baz'), ('bar', 'qux')],
dtype='object')
```

### pandas.MultiIndex.sortlevel

**MultiIndex.sortlevel(level=0, ascending=True, sort_remaining=True)**

Sort MultiIndex at the requested level.

The result will respect the original ordering of the associated factor at that level.

**Parameters**

- **level** [list-like, int or str, default 0] If a string is given, must be a name of the level. If list-like must be names or ints of levels.

- **ascending** [bool, default True] False to sort in descending order. Can also be a list to specify a directed ordering.
sort_remaining  [sort by the remaining levels after level]

Returns

sorted_index  [pd.MultiIndex] Resulting index.

indexer  [np.ndarray] Indices of output values in original index.

Examples

```python
def main()
    mi = MultiIndex.from_arrays([[0, 0], [2, 1]])
    print(mi)
    print(mi.sortlevel())
    print(mi.sortlevel(sort_remaining=False))
    print(mi.sortlevel(1))
    print(mi.sortlevel(1, ascending=False))

if __name__ == '__main__':
    main()
```

pandas.MultiIndex.droplevel

MultiIndex.droplevel(level=0)

Return index with requested level(s) removed.

If resulting index has only 1 level left, the result will be of Index type, not MultiIndex.

Parameters

level  [int, str, or list-like, default 0] If a string is given, must be the name of a level
If list-like, elements must be names or indexes of levels.

Returns

Index or MultiIndex
Examples

```python
>>> mi = pd.MultiIndex.from_arrays(
... [[1, 2], [3, 4], [5, 6]], names=['x', 'y', 'z'])
>>> mi
MultiIndex([(1, 3, 5),
             (2, 4, 6)],
           names=['x', 'y', 'z'])

>>> mi.droplevel()  
MultiIndex([(3, 5),            
             (4, 6)],
           names=['y', 'z'])

>>> mi.droplevel(2)  
MultiIndex([(1, 3),            
             (2, 4)],
           names=['x', 'y'])

>>> mi.droplevel('z')
MultiIndex([(1, 3),            
             (2, 4)],
           names=['x', 'y'])

>>> mi.droplevel(['x', 'y'])
Int64Index([5, 6], dtype='int64', name='z')
```

`pandas.MultiIndex.swaplevel`

`MultiIndex.swaplevel(i=-2, j=-1)`

Swap level i with level j. Calling this method does not change the ordering of the values.

**Parameters**

- `i` [int, str, default -2] First level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.

- `j` [int, str, default -1] Second level of index to be swapped. Can pass level name as string. Type of parameters can be mixed.

**Returns**

- `MultiIndex` A new MultiIndex.

**See also:**

- `Series.swaplevel` Swap levels i and j in a MultiIndex.
- `Dataframe.swaplevel` Swap levels i and j in a MultiIndex on a particular axis.
Examples

```python
>>> mi = pd.MultiIndex(levels=[['a', 'b'], ['bb', 'aa']],
  ...            codes=[[0, 0, 1, 1], [0, 1, 0, 1]])
>>> mi
MultiIndex([('a', 'bb'),
             ('a', 'aa'),
             ('b', 'bb'),
             ('b', 'aa')],
            )
```

```python
>>> mi.swaplevel(0, 1)
MultiIndex([('bb', 'a'),
             ('aa', 'a'),
             ('bb', 'b'),
             ('aa', 'b')],
            )
```

```python
pandas.MultiIndex.reorder_levels
```

```
MultiIndex.reorder_levels(order)
```

Rearrange levels using input order. May not drop or duplicate levels.

**Parameters**

order [list of int or list of str] List representing new level order. Reference level by number (position) or by key (label).

**Returns**

MultiIndex

**Examples**

```python
>>> mi = pd.MultiIndex.from_arrays([[1, 2], [3, 4]], names=['x', 'y'])
>>> mi
MultiIndex([(1, 3),
            (2, 4)],
           names=['x', 'y'])
```

```python
>>> mi.reorder_levels(order=[1, 0])
MultiIndex([(3, 1),
            (4, 2)],
           names=['y', 'x'])
```

```python
>>> mi.reorder_levels(order=['y', 'x'])
MultiIndex([(3, 1),
            (4, 2)],
           names=['y', 'x'])
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.MultiIndex.remove_unused_levels

MultiIndex\texttt{.remove unused levels()}  
Create new MultiIndex from current that removes unused levels.

Unused level(s) means levels that are not expressed in the labels. The resulting MultiIndex will have the same outward appearance, meaning the same .values and ordering. It will also be .equals() to the original.

Returns

MultiIndex

Examples

```python
>>> mi = pd.MultiIndex.from_product([range(2), list('ab')])
>>> mi
MultiIndex([(0, 'a'),
(0, 'b'),
(1, 'a'),
(1, 'b')],
)  
```

```python
>>> mi[2:]
MultiIndex([(1, 'a'),
(1, 'b')],
)
```

The 0 from the first level is not represented and can be removed

```python
>>> mi2 = mi[2:].remove_unused_levels()
>>> mi2.levels
FrozenList([[1], ['a', 'b']])
```

pandas.MultiIndex.get_locs

MultiIndex\texttt{.get locs(seq)}  
Get location for a sequence of labels.

Parameters

\texttt{seq}  
[label, slice, list, mask or a sequence of such] You should use one of the above for each level. If a level should not be used, set it to slice(None).

Returns

\texttt{numpy.ndarray}  
NumPy array of integers suitable for passing to iloc.

See also:

\texttt{MultiIndex.get loc}  
Get location for a label or a tuple of labels.

\texttt{MultiIndex.slice locs}  
Get slice location given start label(s) and end label(s).
Examples

```python
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')])
```

```python
>>> mi.get_locs('b')
array([1, 2], dtype=int64)
```

```python
>>> mi.get_locs([slice(None), ['e', 'f']])
array([1, 2], dtype=int64)
```

```python
>>> mi.get_locs([[True, False, True], slice('e', 'f')])
array([2], dtype=int64)
```

**IndexSlice**

Create an object to more easily perform multi-index slicing.

**pandas.IndexSlice**

```
pandas.IndexSlice = <pandas.core.indexing._IndexSlice object>
```

Create an object to more easily perform multi-index slicing.

See also:

**MultiIndex.remove_unused_levels** New MultiIndex with no unused levels.

Notes

See Defined Levels for further info on slicing a MultiIndex.

Examples

```python
>>> midx = pd.MultiIndex.from_product([['A0','A1'], ['B0','B1','B2','B3']])
>>> columns = ['foo', 'bar']
>>> dfmi = pd.DataFrame(np.arange(16).reshape((len(midx), len(columns))),
... index=midx, columns=columns)
```

Using the default slice command:

```python
>>> dfmi.loc[(slice(None), slice('B0', 'B1')), :]
   foo  bar
A0  B0  0  1
    B1  2  3
A1  B0  8  9
    B1 10 11
```

Using the IndexSlice class for a more intuitive command:

```python
>>> idx = pd.IndexSlice
>>> dfmi.loc[idx[:, 'B0':'B1'], :]
   foo  bar
A0  B0  0  1
    B1  2  3
```

(continues on next page)
MultiIndex constructors

**MultiIndex.from_arrays**(*arrays[, sortorder, ...]*)  
Convert arrays to MultiIndex.

**MultiIndex.from_tuples**(*tuples[, sortorder, ...]*)  
Convert list of tuples to MultiIndex.

**MultiIndex.from_product**(*iterables[, ...]*)  
Make a MultiIndex from the cartesian product of multiple iterables.

**MultiIndex.from_frame**(*df[, sortorder, names]*)  
Make a MultiIndex from a DataFrame.

MultiIndex properties

**MultiIndex.names**  
Names of levels in MultiIndex.

**MultiIndex.levels**

**MultiIndex.codes**

**MultiIndex.nlevels**  
Integer number of levels in this MultiIndex.

**MultiIndex.levshape**  
A tuple with the length of each level.

**MultiIndex.dtypes**  
Return the dtypes as a Series for the underlying MultiIndex.

```
pandas.MultiIndex.levels

MultiIndex.levels

pandas.MultiIndex.codes

property MultiIndex.codes

pandas.MultiIndex.dtypes

MultiIndex.dtypes
    Return the dtypes as a Series for the underlying MultiIndex
```
MultIndex components

- `MultiIndex.set_levels(levels[, level, ...])` Set new levels on MultiIndex.
- `MultiIndex.set_codes(codes[, level, ...])` Set new codes on MultiIndex.
- `MultiIndex.to_flat_index()` Convert a MultiIndex to an Index of Tuples containing the level values.
- `MultiIndex.to_frame([index, name])` Create a DataFrame with the levels of the MultiIndex as columns.
- `MultiIndex.sortlevel([level, ascending, ...])` Sort MultiIndex at the requested level.
- `MultiIndex.droplevel([level])` Return index with requested level(s) removed.
- `MultiIndex.swaplevel([i, j])` Swap level i with level j.
- `MultiIndex.reorder_levels(order)` Rearrange levels using input order.
- `MultiIndex.remove_unused_levels()` Create new MultiIndex from current that removes unused levels.

MultIndex selecting

- `MultiIndex.get_loc(key[, method])` Get location for a label or a tuple of labels.
- `MultiIndex.get_locs(seq)` Get location for a sequence of labels.
- `MultiIndex.get_loc_level(key[, level, ...])` Get location and sliced index for requested label(s)/level(s).
- `MultiIndex.get_indexer(target[, method, ...])` Compute indexer and mask for new index given the current index.
- `MultiIndex.get_level_values(level)` Return vector of label values for requested level.

pandas.MultiIndex.get_loc

MultIndex.get_loc(key, method=None)
Get location for a label or a tuple of labels.

The location is returned as an integer/slice or boolean mask.

Parameters

- key [label or tuple of labels (one for each level)]
- method [None]

Returns

- loc [int, slice object or boolean mask] If the key is past the lexsort depth, the return may be a boolean mask array, otherwise it is always a slice or int.

See also:

- Index.get_loc The get_loc method for (single-level) index.
- MultiIndex.slice_locs Get slice location given start label(s) and end label(s).
- MultiIndex.get_locs Get location for a label/slice/list/mask or a sequence of such.
Notes

The key cannot be a slice, list of same-level labels, a boolean mask, or a sequence of such. If you want to use those, use MultiIndex.get_locs() instead.

Examples

```python
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')])

>>> mi.get_loc('b')
slice(1, 3, None)

>>> mi.get_loc(('b', 'e'))
1
```

pandas.MultiIndex.get_loc_level

MultiIndex.get_loc_level(key, level=0, drop_level=True)

Get location and sliced index for requested label(s)/level(s).

Parameters

- **key** [label or sequence of labels]
- **level** [int/level name or list thereof, optional]
- **drop_level** [bool, default True] If False, the resulting index will not drop any level.

Returns

- **loc** [A 2-tuple where the elements are:] Element 0: int, slice object or boolean array Element 1: The resulting sliced multiindex/index. If the key contains all levels, this will be None.

See also:

MultiIndex.get_loc Get location for a label or a tuple of labels.
MultiIndex.get_locs Get location for a label/slice/list/mask or a sequence of such.

Examples

```python
>>> mi = pd.MultiIndex.from_arrays([list('abb'), list('def')],
...               names=['A', 'B'])

>>> mi.get_loc_level('b')
(slice(1, 3, None), Index(['e', 'f'], dtype='object', name='B'))

>>> mi.get_loc_level('e', level='B')
(array([False, True, False]), Index(['b'], dtype='object', name='A'))

>>> mi.get_loc_level(['b', 'e'])
(1, None)
```
pandas.MultiIndex.get_indexer

MultiIndex.get_indexer(target, method=None, limit=None, tolerance=None)

Compute indexer and mask for new index given the current index. The indexer should be then used as an input to ndarray.take to align the current data to the new index.

Parameters

- **target** [Index]
- **method** [{None, 'pad'/ffill', 'backfill'/bfill', 'nearest'}, optional]
  - default: exact matches only.
  - pad / ffill: find the PREVIOUS index value if no exact match.
  - backfill / bfill: use NEXT index value if no exact match
  - nearest: use the NEAREST index value if no exact match. Tied distances are broken by preferring the larger index value.
- **limit** [int, optional] Maximum number of consecutive labels in target to match for inexact matches.
- **tolerance** [optional] Maximum distance between original and new labels for inexact matches. The values of the index at the matching locations must satisfy the equation \( \text{abs}(\text{index}[\text{indexer}] - \text{target}) \leq \text{tolerance} \).
  
  Tolerance may be a scalar value, which applies the same tolerance to all values, or list-like, which applies variable tolerance per element. List-like includes list, tuple, array, Series, and must be the same size as the index and its dtype must exactly match the index’s type.

Returns

- **indexer** [np.ndarray[np.intp]] Integers from 0 to n - 1 indicating that the index at these positions matches the corresponding target values. Missing values in the target are marked by -1.

Examples

```python
>>> index = pd.Index(['c', 'a', 'b'])
>>> index.get_indexer(['a', 'b', 'x'])
array([ 1, 2, -1])
```

Notice that the return value is an array of locations in index and x is marked by -1, as it is not in index.

pandas.MultiIndex.get_level_values

MultiIndex.get_level_values(level)

Return vector of label values for requested level.

Length of returned vector is equal to the length of the index.

Parameters

- **level** [int or str] level is either the integer position of the level in the MultiIndex, or the name of the level.

Returns
values [Index] Values is a level of this MultiIndex converted to a single Index (or subclass thereof).

Examples

Create a MultiIndex:

```python
>>> mi = pd.MultiIndex.from_arrays((list('abc'), list('def')))
>>> mi.names = ['level_1', 'level_2']
```

Get level values by supplying level as either integer or name:

```python
>>> mi.get_level_values(0)
Index(['a', 'b', 'c'], dtype='object', name='level_1')
>>> mi.get_level_values('level_2')
Index(['d', 'e', 'f'], dtype='object', name='level_2')
```

3.6.6 DatetimeIndex

Datetimex

\[
\text{pandas.DatetimeIndex(data=None, freq=<no_default>, tz=None, normalize=False, closed=None, ambiguous='infer', dayfirst=False, yearfirst=False, dtype=None, copy=False, name=None)}
\]

Immutable ndarray-like of datetime64 data.

Parameters

data [array-like (1-dimensional), optional] Optional datetime-like data to construct index with.

tz [pytz.timezone or dateutil.tz.tzfile or datetime.tzinfo or str] Set the Timezone of the data.

normalize [bool, default False] Normalize start/end dates to midnight before generating date range.

closed [[‘left’, ‘right’], optional] Set whether to include \textit{start} and \textit{end} that are on the boundary. The default includes boundary points on either end.

ambiguous [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the \textit{ambiguous} parameter dictates how ambiguous times should be handled.

- ‘infer’ will attempt to infer fall dst-transition hours based on order
• bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
• ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

**dayfirst** [bool, default False] If True, parse dates in data with the day first order.

**yearfirst** [bool, default False] If True parse dates in data with the year first order.

**dtype** [numpy.dtype or DatetimeTZDtype or str, default None] Note that the only NumPy dtype allowed is ‘datetime64[ns]’.

**copy** [bool, default False] Make a copy of input ndarray.

**name** [label, default None] Name to be stored in the index.

See also:

**Index** The base pandas Index type.

**TimedeltaIndex** Index of timedelta64 data.

**PeriodIndex** Index of Period data.

**to_datetime** Convert argument to datetime.

**date_range** Create a fixed-frequency DatetimeIndex.

Notes

To learn more about the frequency strings, please see this link.

#### pandas.DatetimeIndex.year

- **property** `DatetimeIndex.year`  
  The year of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(  
...     pd.date_range("2000-01-01", periods=3, freq="Y")  
... )
>>> datetime_series
0  2000-12-31
1  2001-12-31
2  2002-12-31
dtype: datetime64[ns]
>>> datetime_series.dt.year
0  2000
1  2001
2  2002
```

#### pandas.DatetimeIndex.month

- **property** `DatetimeIndex.month`  
  The month as January=1, December=12.
Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="M")
... )
>>> datetime_series
0 2000-01-31
1 2000-02-29
2 2000-03-31
dtype: datetime64[ns]
>>> datetime_series.dt.month
0 1
1 2
2 3
dtype: int64
```

**pandas.DatetimeIndex.day**

property DatetimeIndex.day

The day of the datetime.

Examples

```python
>>> datetime_series = pd.Series(
...     pd.date_range("2000-01-01", periods=3, freq="D")
... )
>>> datetime_series
0 2000-01-01
1 2000-01-02
2 2000-01-03
dtype: datetime64[ns]
>>> datetime_series.dt.day
0 1
1 2
2 3
dtype: int64
```
pandas.DatetimeIndex.hour

**property** DatetimeIndex.hour
The hours of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(  
...    pd.date_range("2000-01-01", periods=3, freq="h")
... )
>>> datetime_series
0 2000-01-01 00:00:00
1 2000-01-01 01:00:00
2 2000-01-01 02:00:00
dtype: datetime64[ns]
```
```python
>>> datetime_series.dt.hour
0 0
1 1
2 2
```

pandas.DatetimeIndex.minute

**property** DatetimeIndex.minute
The minutes of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(  
...    pd.date_range("2000-01-01", periods=3, freq="T")
... )
>>> datetime_series
0 2000-01-01 00:00:00
1 2000-01-01 00:01:00
2 2000-01-01 00:02:00
```
```python
>>> datetime_series.dt.minute
0 0
1 1
2 2
```

dtype: int64
pandas.DatetimeIndex.second

**property** DatetimeIndex.second

The seconds of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(
    ...    pd.date_range("2000-01-01", periods=3, freq="s")
    ... )
>>> datetime_series
0 2000-01-01 00:00:00
1 2000-01-01 00:00:01
2 2000-01-01 00:00:02
dtype: datetime64[ns]
```

```python
>>> datetime_series.dt.second
0 0
1 1
2 2
dtype: int64
```

pandas.DatetimeIndex.microsecond

**property** DatetimeIndex.microsecond

The microseconds of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(
    ...    pd.date_range("2000-01-01", periods=3, freq="us")
    ... )
>>> datetime_series
0 2000-01-01 00:00:00.000000
1 2000-01-01 00:00:00.000001
2 2000-01-01 00:00:00.000002
dtype: datetime64[ns]
```

```python
>>> datetime_series.dt.microsecond
0 0
1 1
2 2
dtype: int64
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.DatetimeIndex.nanosecond

**property** `DatetimeIndex.nanosecond`

The nanoseconds of the datetime.

**Examples**

```python
>>> datetime_series = pd.Series(
    ...      pd.date_range("2000-01-01", periods=3, freq="ns")
    ...  )
>>> datetime_series
0 2000-01-01 00:00:00.000000000
1 2000-01-01 00:00:00.000000001
2 2000-01-01 00:00:00.000000002
dtype: datetime64[ns]
```

```python
>>> datetime_series.dt.nanosecond
0 0
1 1
2 2
dtype: int64
```

pandas.DatetimeIndex.date

**property** `DatetimeIndex.date`

Returns numpy array of python datetime.date objects (namely, the date part of Timestamps without timezone information).

pandas.DatetimeIndex.time

**property** `DatetimeIndex.time`

Returns numpy array of datetime.time. The time part of the Timestamps.

pandas.DatetimeIndex.timetz

**property** `DatetimeIndex.timetz`

Returns numpy array of datetime.time also containing timezone information. The time part of the Timestamps.

pandas.DatetimeIndex.dayofyear

**property** `DatetimeIndex.dayofyear`

The ordinal day of the year.
**pandas.DatetimeIndex.day_of_year**

**property DatetimeIndex.day_of_year**
The ordinal day of the year.

**pandas.DatetimeIndex.weekofyear**

**property DatetimeIndex.weekofyear**
The week ordinal of the year.

Depreciated since version 1.1.0.

weekofyear and week have been deprecated. Please use DatetimeIndex.isocalendar().week instead.

**pandas.DatetimeIndex.week**

**property DatetimeIndex.week**
The week ordinal of the year.

Depreciated since version 1.1.0.

weekofyear and week have been deprecated. Please use DatetimeIndex.isocalendar().week instead.

**pandas.DatetimeIndex.dayofweek**

**property DatetimeIndex.dayofweek**
The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the dt accessor) or DatetimeIndex.

**Returns**

**Series or Index** Containing integers indicating the day number.

**See also:**

*Series.dt.dayofweek* Alias.

*Series.dt.weekday* Alias.

*Series.dt.day_name* Returns the name of the day of the week.

**Examples**

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
  2016-12-31    5
  2017-01-01    6
  2017-01-02    0
  2017-01-03    1
  2017-01-04    2
  2017-01-05    3
  2017-01-06    4
```

(continues on next page)
pandas.DatetimeIndex.day_of_week

**property** DatetimeIndex.day_of_week

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the dt accessor) or DatetimeIndex.

**Returns**

Series or Index Containing integers indicating the day number.

See also:

Series.dt.dayofweek Alias.
Series.dt.weekday Alias.
Series.dt.day_name Returns the name of the day of the week.

**Examples**

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31    5
2017-01-01    6
2017-01-02    0
2017-01-03    1
2017-01-04    2
2017-01-05    3
2017-01-06    4
2017-01-07    5
2017-01-08    6
Freq: D, dtype: int64
```

pandas.DatetimeIndex.weekday

**property** DatetimeIndex.weekday

The day of the week with Monday=0, Sunday=6.

Return the day of the week. It is assumed the week starts on Monday, which is denoted by 0 and ends on Sunday which is denoted by 6. This method is available on both Series with datetime values (using the dt accessor) or DatetimeIndex.

**Returns**

Series or Index Containing integers indicating the day number.

See also:
**Series.dt.dayofweek** Alias.

**Series.dt.weekday** Alias.

**Series.dt.day_name** Returns the name of the day of the week.

### Examples

```python
>>> s = pd.date_range('2016-12-31', '2017-01-08', freq='D').to_series()
>>> s.dt.dayofweek
2016-12-31  5
2017-01-01  6
2017-01-02  0
2017-01-03  1
2017-01-04  2
2017-01-05  3
2017-01-06  4
2017-01-07  5
2017-01-08  6
Freq: D, dtype: int64
```

**pandas.DatetimeIndex.quarter**

**property** DatetimeIndex.quarter

The quarter of the date.

**pandas.DatetimeIndex.tz**

**property** DatetimeIndex.tz

Return timezone, if any.

**Returns**

- `datetime.tzinfo`, `pytz.tzinfo.BaseTZInfo`, `dateutil.tz.tzfile`, or **None** Returns None when the array is tz-naive.

**pandas.DatetimeIndex.freq**

**property** DatetimeIndex.freq

Return the frequency object if it is set, otherwise None.

**pandas.DatetimeIndex.freqstr**

**property** DatetimeIndex.freqstr

Return the frequency object as a string if its set, otherwise None.
**pandas.DatetimeIndex.is_month_start**

**property** `DatetimeIndex.is_month_start`

Indicates whether the date is the first day of the month.

**Returns**

- **Series or array**  
  For Series, returns a Series with boolean values. For DatetimeIndex, returns a boolean array.

**See also:**

- `is_month_start` Return a boolean indicating whether the date is the first day of the month.
- `is_month_end` Return a boolean indicating whether the date is the last day of the month.

**Examples**

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```python
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0 2018-02-27
1 2018-02-28
2 2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0 False
1 False
2 True
dtype: bool
```

```python
>>> s.dt.is_month_end
0 False
1 True
2 False
dtype: bool
```

```python
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])

>>> idx.is_month_end
array([False, True, False])
```
is_month_end Return a boolean indicating whether the date is the last day of the month.

Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> s = pd.Series(pd.date_range("2018-02-27", periods=3))
>>> s
0 2018-02-27
1 2018-02-28
2 2018-03-01
dtype: datetime64[ns]
>>> s.dt.is_month_start
0 False
1 False
2 True
dtype: bool
>>> s.dt.is_month_end
0 False
1 True
2 False
dtype: bool
```

```python
>>> idx = pd.date_range("2018-02-27", periods=3)
>>> idx.is_month_start
array([False, False, True])
>>> idx.is_month_end
array([False, True, False])
```

pandas.DatetimeIndex.is_quarter_start

property DatetimeIndex.is_quarter_start

Indicator for whether the date is the first day of a quarter.

Returns

is_quarter_start [Series or DatetimeIndex] The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

See also:

quarter Return the quarter of the date.

is_quarter_end Similar property for indicating the quarter start.
Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> df = pd.DataFrame({'dates': pd.date_range("2017-03-30", periods=4))
>>> df.assign(quarter=df.dates.dt.quarter,
... is_quarter_start=df.dates.dt.is_quarter_start)
   dates    quarter  is_quarter_start
0 2017-03-30     1         False
1 2017-03-31     1         False
2 2017-04-01     2         True
3 2017-04-02     2         False
```

```python
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
dtype='datetime64[ns]', freq='D')
```
>>> idx = pd.date_range('2017-03-30', periods=4)
>>> idx
DatetimeIndex(['2017-03-30', '2017-03-31', '2017-04-01', '2017-04-02'],
dtype='datetime64[ns]', freq='D')

>>> idx.is_quarter_end
array([False,  True, False, False])

**pandas.DatetimeIndex.is_year_start**

**property** `DatetimeIndex.is_year_start`

Indicate whether the date is the first day of a year.

**Returns**

- **Series or DatetimeIndex** The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

- `is_year_end` Similar property indicating the last day of the year.

**Examples**

This method is available on Series with datetime values under the `.dt` accessor, and directly on DatetimeIndex.

```python
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0  2017-12-30
1  2017-12-31
2  2018-01-01
dtype: datetime64[ns]

>>> dates.dt.is_year_start
0  False
1  False
2  True
dtype: bool
```

```python
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
dtype='datetime64[ns]', freq='D')

>>> idx.is_year_start
array([False, False,  True])
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.DatetimeIndex.is_year_end

**property** DatetimeIndex.is_year_end

Indicate whether the date is the last day of the year.

**Returns**

Series or DatetimeIndex The same type as the original data with boolean values. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

*is_year_start* Similar property indicating the start of the year.

**Examples**

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
>>> dates = pd.Series(pd.date_range("2017-12-30", periods=3))
>>> dates
0   2017-12-30
1   2017-12-31
2   2018-01-01
dtype: datetime64[ns]

>>> dates.dt.is_year_end
0   False
1   True
2   False
dtype: bool
```

```python
>>> idx = pd.date_range("2017-12-30", periods=3)
>>> idx
DatetimeIndex(['2017-12-30', '2017-12-31', '2018-01-01'],
               dtype='datetime64[ns]', freq='D')

>>> idx.is_year_end
array([False, True, False])
```

pandas.DatetimeIndex.is_leap_year

**property** DatetimeIndex.is_leap_year

Boolean indicator if the date belongs to a leap year.

A leap year is a year, which has 366 days (instead of 365) including 29th of February as an intercalary day. Leap years are years which are multiples of four with the exception of years divisible by 100 but not by 400.

**Returns**

Series or ndarray Booleans indicating if dates belong to a leap year.
Examples

This method is available on Series with datetime values under the .dt accessor, and directly on DatetimeIndex.

```python
generate the code here as is
```
Table 170 – continued from previous page

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>to_series([keep_tz, index, name])</code></td>
<td>Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.</td>
</tr>
<tr>
<td><code>to_frame([index, name])</code></td>
<td>Create a DataFrame with a column containing the Index.</td>
</tr>
<tr>
<td><code>month_name(*args, **kwargs)</code></td>
<td>Return the month names of the DateTimeIndex with specified locale.</td>
</tr>
<tr>
<td><code>day_name(*args, **kwargs)</code></td>
<td>Return the day names of the DateTimeIndex with specified locale.</td>
</tr>
<tr>
<td><code>mean(*args, **kwargs)</code></td>
<td>Return the mean value of the Array.</td>
</tr>
</tbody>
</table>

**pandas.DatetimeIndex.normalize**

`DatetimeIndex.normalize(*args, **kwargs)`

Convert times to midnight.

The time component of the date-time is converted to midnight i.e. 00:00:00. This is useful in cases, when the time does not matter. Length is unaltered. The timezones are unaffected.

This method is available on Series with datetime values under the `.dt` accessor, and directly on Datetime Array/Index.

**Returns**

`DatetimeArray, DatetimeIndex or Series` The same type as the original data. Series will have the same name and index. DatetimeIndex will have the same name.

**See also:**

- `floor` Floor the datetimes to the specified freq.
- `ceil` Ceil the datetimes to the specified freq.
- `round` Round the datetimes to the specified freq.

**Examples**

```python
>>> idx = pd.date_range(start='2014-08-01 10:00', freq='H', periods=3, tz='Asia/Calcutta')
>>> idx
DatetimeIndex(['2014-08-01 10:00:00+05:30',
              '2014-08-01 11:00:00+05:30',
              '2014-08-01 12:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq='H')

>>> idx.normalize()
DatetimeIndex(['2014-08-01 00:00:00+05:30',
              '2014-08-01 00:00:00+05:30',
              '2014-08-01 00:00:00+05:30'],
              dtype='datetime64[ns, Asia/Calcutta]', freq=None)
```
pandas.DatetimeIndex.strftime

DatetimeIndex.strftime(*args, **kwargs)
Convert to Index using specified date_format.

Return an Index of formatted strings specified by date_format, which supports the same string format as the python standard library. Details of the string format can be found in python string format doc.

Parameters

date_format [str] Date format string (e.g. "%Y-%m-%d").

Returns

donarray NumPy ndarray of formatted strings.

See also:
to_datetime Convert the given argument to datetime.
DatetimeIndex.normalize Return DatetimeIndex with times to midnight.
DatetimeIndex.round Round the DatetimeIndex to the specified freq.
DatetimeIndex.floor Floor the DatetimeIndex to the specified freq.

Examples

```python
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
             periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
    'March 10, 2018, 09:00:02 AM'],
dtype='object')
```

pandas.DatetimeIndex.snap

DatetimeIndex.snap(freq='S')
Snap time stamps to nearest occurring frequency.

Returns

DatetimeIndex

pandas.DatetimeIndex.tz_convert

DatetimeIndex.tz_convert(tz)
Convert tz-aware Datetime Array/Index from one time zone to another.

Parameters

tz [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone for time. Corresponding timestamps would be converted to this time zone of the Datetime Array/Index. A tz of None will convert to UTC and remove the timezone information.

Returns

Array or Index
Raises

```
TypeError If Datetime Array/Index is tz-naive.
```

See also:

```
DatetimeIndex.tz A timezone that has a variable offset from UTC.
```

```
DatetimeIndex.tz_localize Localize tz-naive DatetimeIndex to a given time zone, or remove timezone from a tz-aware DatetimeIndex.
```

Examples

With the `tz` parameter, we can change the DatetimeIndex to other time zones:

```python
>>> dti = pd.date_range(start='2014-08-01 09:00',
                      freq='H', periods=3, tz='Europe/Berlin')
```

```python
>>> dti
DateTimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```python
>>> dti.tz_convert('US/Central')
DateTimeIndex(['2014-08-01 02:00:00-05:00',
               '2014-08-01 03:00:00-05:00',
               '2014-08-01 04:00:00-05:00'],
              dtype='datetime64[ns, US/Central]', freq='H')
```

With the `tz=None`, we can remove the timezone (after converting to UTC if necessary):

```python
>>> dti = pd.date_range(start='2014-08-01 09:00',
                      freq='H', periods=3, tz='Europe/Berlin')
```

```python
>>> dti
DateTimeIndex(['2014-08-01 09:00:00+02:00',
               '2014-08-01 10:00:00+02:00',
               '2014-08-01 11:00:00+02:00'],
              dtype='datetime64[ns, Europe/Berlin]', freq='H')
```

```python
>>> dti.tz_convert(None)
DateTimeIndex(['2014-08-01 07:00:00',
               '2014-08-01 08:00:00',
               '2014-08-01 09:00:00'],
              dtype='datetime64[ns]', freq='H')
```
pandas.DatetimeIndex.tz_localize

**Datet imeIndex.tz_localize(tz, ambiguous='raise', nonexistent='raise')**

Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.

This method takes a time zone (tz) naive Datetime Array/Index object and makes this time zone aware. It does not move the time to another time zone.

This method can also be used to do the inverse – to create a time zone unaware object from an aware object. To that end, pass tz=None.

**Parameters**

- **tz** [str, pytz.timezone, dateutil.tz.tzfile or None] Time zone to convert timestamps to. Passing None will remove the time zone information preserving local time.

- **ambiguous** [‘infer’, ‘NaT’, bool array, default ‘raise’] When clocks moved backward due to DST, ambiguous times may arise. For example in Central European Time (UTC+01), when going from 03:00 DST to 02:00 non-DST, 02:30:00 local time occurs both at 00:30:00 UTC and at 01:30:00 UTC. In such a situation, the ambiguous parameter dictates how ambiguous times should be handled.
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False signifies a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

- **nonexistent** [‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaN where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

**Returns**

- **Same type as self** Array/Index converted to the specified time zone.

**Raises**

- **TypeError** If the Datetime Array/Index is tz-aware and tz is not None.

**See also:**

- **Datet imeIndex.tz_convert** Convert tz-aware DatetimeIndex from one time zone to another.
Examples

```python
>>> tz_naive = pd.date_range('2018-03-01 09:00', periods=3)
>>> tz_naive
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq='D')

Localize DatetimeIndex in US/Eastern time zone:

```python
>>> tz_aware = tz_naive.tz_localize(tz='US/Eastern')
>>> tz_aware
DatetimeIndex(['2018-03-01 09:00:00-05:00',
               '2018-03-02 09:00:00-05:00',
               '2018-03-03 09:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)
```

With the tz=None, we can remove the time zone information while keeping the local time (not converted to UTC):

```python
>>> tz_aware.tz_localize(None)
DatetimeIndex(['2018-03-01 09:00:00', '2018-03-02 09:00:00',
               '2018-03-03 09:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Be careful with DST changes. When there is sequential data, pandas can infer the DST time:

```python
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:30:00',
                                 '2018-10-28 02:00:00',
                                 '2018-10-28 02:30:00',
                                 '2018-10-28 02:00:00',
                                 '2018-10-28 02:30:00',
                                 '2018-10-28 03:00:00',
                                 '2018-10-28 03:30:00']))
```python
```
0 2018-10-28 01:30:00+02:00
1 2018-10-28 02:00:00+02:00
2 2018-10-28 02:30:00+02:00
3 2018-10-28 02:00:00+01:00
4 2018-10-28 02:30:00+01:00
5 2018-10-28 03:00:00+01:00
6 2018-10-28 03:30:00+01:00
dtype: datetime64[ns, CET]
```

In some cases, inferring the DST is impossible. In such cases, you can pass an ndarray to the ambiguous parameter to set the DST explicitly:

```python
>>> s = pd.to_datetime(pd.Series(['2018-10-28 01:20:00',
                                 '2018-10-28 02:36:00',
                                 '2018-10-28 03:46:00']))
```python
```
0 2018-10-28 01:20:00+02:00
1 2018-10-28 02:36:00+02:00
2 2018-10-28 03:46:00+01:00
dtype: datetime64[ns, CET]
```

If the DST transition causes nonexistent times, you can shift these dates forward or backwards with a timedelta object or `shift_forward` or `shift_backwards`. 
pandas: powerful Python data analysis toolkit, Release 1.3.1

>>> s = pd.to_datetime(pd.Series(['2015-03-29 02:30:00',
                                 '2015-03-29 03:30:00']))
>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_forward')
0 2015-03-29 03:00:00+02:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]

>>> s.dt.tz_localize('Europe/Warsaw', nonexistent='shift_backward')
0 2015-03-29 01:59:59.999999999+01:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]

>>> s.dt.tz_localize('Europe/Warsaw', nonexistent=pd.Timedelta('1H'))
0 2015-03-29 03:30:00+02:00
1 2015-03-29 03:30:00+02:00
dtype: datetime64[ns, Europe/Warsaw]

pandas.DatetimeIndex.round

DatetimeIndex.round(*args, **kwargs)
Perform round operation on the data to the specified freq.

Parameters

freq [str or Offset] The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:
- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent ['shift_forward', ‘shift_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

3.6. Index objects
Raises

ValueError if the freq cannot be converted.

Examples

DatetimeIndex

```python
def round(rng)
DatetiemIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00', '2018-01-01 12:01:00'], dtype='datetime64[ns]', freq='T')
```

Series

```python
def round(pd.Series(rng).dt.round("H")
```

pandas.DatetimeIndex.floor

```
pandas.DatetimeIndex.floor(*args, **kwargs)
```

Perform floor operation on the data to the specified freq.

Parameters

- **freq** [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.
- **ambiguous** ['infer', bool-ndarray, 'NaT', default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.
- **nonexistent** ['shift_forward', 'shift_backward', ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
• ‘NaT’ will return NaT where there are nonexistent times
• timedelta objects will shift nonexistent times by the timedelta
• ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series  Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'], dtype='datetime64[ns]', freq='T')
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'], dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.floor("H")
0 2018-01-01 11:00:00
1 2018-01-01 12:00:00
2 2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.DatetimeIndex.ceil

DatetimeIndex.ceil(*args, **kwargs)

Perform ceil operation on the data to the specified freq.

Parameters

freq [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

ambiguous ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:

• ‘infer’ will attempt to infer fall dst-transition hours based on order
• bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
• ‘NaT’ will return NaT where there are ambiguous times
• ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.
nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.

- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.

Examples

DatetimeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
               dtype='datetime64[ns]', freq='T')
>>> rng.ceil('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 13:00:00'],
               dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.ceil("H")
0 2018-01-01 12:00:00
1 2018-01-01 12:00:00
2 2018-01-01 13:00:00
dtype: datetime64[ns]
```

pandas.DatetimeIndex.to_period

DatetimeIndex.to_period(*args, **kwargs)
Cast to PeriodArray/Index at a particular frequency.
Converts DatetimeArray/Index to PeriodArray/Index.

Parameters

- freq [str or Offset, optional] One of pandas’ offset strings or an Offset object. Will be inferred by default.

Returns
PeriodArray/Index

Raises

**ValueError** When converting a DatetimeArray/Index with non-regular values, so that a frequency cannot be inferred.

See also:

**PeriodIndex** Immutable ndarray holding ordinal values.

**DatetimeIndex.to_pydatetime** Return DatetimeIndex as object.

Examples

```
>>> df = pd.DataFrame({"y": [1, 2, 3]},
...                   index=pd.to_datetime(["2000-03-31 00:00:00",
...                                             "2000-05-31 00:00:00",
...                                             "2000-08-31 00:00:00"]))
>>> df.index.to_period("M")
PeriodIndex(['2000-03', '2000-05', '2000-08'],
           dtype='period[M]')
```

Infer the daily frequency

```
>>> idx = pd.date_range("2017-01-01", periods=2)
>>> idx.to_period()
PeriodIndex(['2017-01-01', '2017-01-02'],
            dtype='period[D]')
```

**pandas.DatetimeIndex.to_perioddelta**

**DatetimeIndex.to_perioddelta** *(freq)*

Calculate TimedeltaArray of difference between index values and index converted to PeriodArray at specified freq. Used for vectorized offsets.

Parameters

- **freq** [Period frequency]

Returns

TimedeltaArray/Index

**pandas.DatetimeIndex.to_pydatetime**

**DatetimeIndex.to_pydatetime** (*args, **kwargs*)

Return Datetime Array/Index as object ndarray of datetime.datetime objects.

Returns

- **datetimes** [ndarray[object]]
pandas.DatetimeIndex.to_series

DatetimeIndex.to_series(keep_tz=<no_default>, index=None, name=None)
Create a Series with both index and values equal to the index keys useful with map for returning an indexer based on an index.

Parameters

- keep_tz [optional, defaults True] Return the data keeping the timezone.
  If keep_tz is True:
    - If the timezone is not set, the resulting Series will have a datetime64[ns] dtype.
    - Otherwise the Series will have an datetime64[ns, tz] dtype; the tz will be preserved.
  If keep_tz is False:
    - Series will have a datetime64[ns] dtype. TZ aware objects will have the tz removed.

Changed in version 1.0.0: The default value is now True. In a future version, this keyword will be removed entirely. Stop passing the argument to obtain the future behavior and silence the warning.

- index [Index, optional] Index of resulting Series. If None, defaults to original index.
- name [str, optional] Name of resulting Series. If None, defaults to name of original index.

Returns

Series

pandas.DatetimeIndex.to_frame

DatetimeIndex.to_frame(index=True, name=None)
Create a DataFrame with a column containing the Index.

Parameters

- index [bool, default True] Set the index of the returned DataFrame as the original Index.
- name [object, default None] The passed name should substitute for the index name (if it has one).

Returns

DataFrame DataFrame containing the original Index data.

See also:

- Index.to_series Convert an Index to a Series.
- Series.to_frame Convert Series to DataFrame.
Examples

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
   animal
    Ant  Ant
    Bear Bear
    Cow  Cow
```

By default, the original Index is reused. To enforce a new Index:

```python
>>> idx.to_frame(index=False)
   animal
    0  Ant
    1  Bear
    2  Cow
```

To override the name of the resulting column, specify `name`:

```python
>>> idx.to_frame(index=False, name='zoo')
   zoo
    0  Ant
    1  Bear
    2  Cow
```

pandas.DatetimeIndex.month_name

DatetimeIndex.month_name(*args, **kwargs)

Return the month names of the DateTimeIndex with specified locale.

Parameters

- `locale` [str, optional] Locale determining the language in which to return the month name. Default is English locale.

Returns

- `Index` Index of month names.

Examples

```python
>>> idx = pd.date_range(start='2018-01', freq='M', periods=3)
>>> idx
DateRange(['2018-01-31', '2018-02-28', '2018-03-31'],
          dtype='datetime64[ns]', freq='M')
>>> idx.month_name()
Index(['January', 'February', 'March'], dtype='object')
```
pandas.DatetimeIndex.day_name

DatetimeIndex.day_name(*args, **kwargs)
Return the day names of the DateTimeIndex with specified locale.

Parameters
locale [str, optional] Locale determining the language in which to return the day name.
Default is English locale.

Returns
Index Index of day names.

Examples

```python
>>> idx = pd.date_range(start='2018-01-01', freq='D', periods=3)
>>> idx
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03'],
dtype='datetime64[ns]', freq='D')
```

```python
>>> idx.day_name()
Index(['Monday', 'Tuesday', 'Wednesday'], dtype='object')
```

pandas.DatetimeIndex.mean

DatetimeIndex.mean(*args, **kwargs)
Return the mean value of the Array.
New in version 0.25.0.

Parameters
skipna [bool, default True] Whether to ignore any NaT elements.
axis [int, optional, default 0]

Returns
scalar Timestamp or Timedelta.

See also:
numpy.ndarray.mean Returns the average of array elements along a given axis.
Series.mean Return the mean value in a Series.

Notes

mean is only defined for Datetime and Timedelta dtypes, not for Period.
**Time/date components**

</tr>
</tbody>
</table>
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.DatetimeIndex.indexer_at_time

DatetimeIndex.indexer_at_time(\textit{time}, asof=False)
Return index locations of values at particular time of day (e.g. 9:30AM).

Parameters

\textit{time} [datetime.time or str] Time passed in either as object (datetime.time) or as string in appropriate format ("%H:%M", "%H%M", "%I:%M%p", "%I%M%p", "%H:%M:%S", "%H%M%S", "%I:%M:%S%p", "%I%M%S%p").

Returns

np.ndarray[np.intp]

See also:

\textit{indexer_between_time} Get index locations of values between particular times of day.
\textit{DataFrame.at_time} Select values at particular time of day.

pandas.DatetimeIndex.indexer_between_time

DatetimeIndex.indexer_between_time(\textit{start_time}, \textit{end_time}, include_start=True, include_end=True)
Return index locations of values between particular times of day (e.g., 9:00-9:30AM).

Parameters

\textit{start_time}, \textit{end_time} [datetime.time, str] Time passed either as object (datetime.time) or as string in appropriate format ("%H:%M", "%H%M", "%I:%M%p", "%I%M%p", "%H:%M:%S", "%H%M%S", "%I:%M:%S%p", "%I%M%S%p").

\textit{include_start} [bool, default True]
\textit{include_end} [bool, default True]

Returns

np.ndarray[np.intp]

See also:

\textit{indexer_at_time} Get index locations of values at particular time of day.
\textit{DataFrame.between_time} Select values between particular times of day.

Time-specific operations

\begin{itemize}
\item \texttt{DatetimeIndex.normalize(*args, **kwargs)} Convert times to midnight.
\item \texttt{DatetimeIndex.strftime(*args, **kwargs)} Convert to Index using specified date_format.
\item \texttt{DatetimeIndex.snap([freq])} Snap time stamps to nearest occurring frequency.
\item \texttt{DatetimeIndex.tz_convert(tz)} Convert tz-aware Datetime Array/Index from one time zone to another.
\item \texttt{DatetimeIndex.tz_localize([tz], ambiguous, ...)} Localize tz-naive Datetime Array/Index to tz-aware Datetime Array/Index.
\item \texttt{DatetimeIndex.round(*args, **kwargs)} Perform round operation on the data to the specified freq.
\item \texttt{DatetimeIndex.floor(*args, **kwargs)} Perform floor operation on the data to the specified freq.
\item \texttt{DatetimeIndex.ceil(*args, **kwargs)} Perform ceil operation on the data to the specified freq.
\end{itemize}

### 3.6.7 TimedeltaIndex

**pandas.TimedeltaIndex**

```python
class pandas.TimedeltaIndex(data=None, unit=None, freq=<no_default>, closed=None, dtype=dtypes('<m8[ns]'), copy=False, name=None)
```

Immutable ndarray of timedelta64 data, represented internally as int64, and which can be boxed to timedelta objects.

**Parameters**

- `data` [array-like (1-dimensional), optional] Optional timedelta-like data to construct index with.
- `unit` [unit of the arg (D,h,m,s,ms,us,ns) denote the unit, optional] Which is an integer/float number.
- `freq` [str or pandas offset object, optional] One of pandas date offset strings or corresponding objects. The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation.
- `copy` [bool] Make a copy of input ndarray.
- `name` [object] Name to be stored in the index.
See also:

- **Index** The base pandas Index type.
- **Timedelta** Represents a duration between two dates or times.
- **DatetimeIndex** Index of datetime64 data.
- **PeriodIndex** Index of Period data.
- **timedelta_range** Create a fixed-frequency TimedeltaIndex.

Notes

To learn more about the frequency strings, please see this link.

Attributes

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>days</strong></td>
<td>Number of days for each element.</td>
</tr>
<tr>
<td><strong>seconds</strong></td>
<td>Number of seconds (&gt;= 0 and less than 1 day) for each element.</td>
</tr>
<tr>
<td><strong>microseconds</strong></td>
<td>Number of microseconds (&gt;= 0 and less than 1 second) for each element.</td>
</tr>
<tr>
<td><strong>nanoseconds</strong></td>
<td>Number of nanoseconds (&gt;= 0 and less than 1 microsecond) for each element.</td>

<tr>
<td><strong>components</strong></td>
<td>Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.</td>
</tr>
<tr>
<td><strong>inferred_freq</strong></td>
<td>Tries to return a string representing a frequency guess, generated by infer_freq.</td>
</tr>
</tbody>
</table>

**pandas.TimedeltaIndex.days**

- **property** TimedeltaIndex.days
  - Number of days for each element.

**pandas.TimedeltaIndex.seconds**

- **property** TimedeltaIndex.seconds
  - Number of seconds (>= 0 and less than 1 day) for each element.

**pandas.TimedeltaIndex.microseconds**

- **property** TimedeltaIndex.microseconds
  - Number of microseconds (>= 0 and less than 1 second) for each element.
pandas.TimedeltaIndex.nanoseconds

**property TimedeltaIndex.nanoseconds**
Number of nanoseconds (>= 0 and less than 1 microsecond) for each element.

pandas.TimedeltaIndex.components

**property TimedeltaIndex.components**
Return a dataframe of the components (days, hours, minutes, seconds, milliseconds, microseconds, nanoseconds) of the Timedeltas.

Returns

DataFrame

pandas.TimedeltaIndex.inferred_freq

**TimedeltaIndex.inferred_freq**
Tries to return a string representing a frequency guess, generated by infer_freq. Returns None if it can’t autodetect the frequency.

Methods

<table>
<thead>
<tr>
<th>to_pytimedelta(*args, **kwargs)</th>
<th>Return Timedelta Array/Index as object ndarray of datetime.timedelta objects.</th>
</tr>
</thead>
<tbody>
<tr>
<td>to_series(index, name))</td>
<td>Create a Series with both index and values equal to the index keys.</td>
</tr>
<tr>
<td>round(*args, **kwargs)</td>
<td>Perform round operation on the data to the specified freq.</td>
</tr>
<tr>
<td>floor(*args, **kwargs)</td>
<td>Perform floor operation on the data to the specified freq.</td>
</tr>
<tr>
<td>ceil(*args, **kwargs)</td>
<td>Perform ceil operation on the data to the specified freq.</td>
</tr>
<tr>
<td>to_frame(index, name)</td>
<td>Create a DataFrame with a column containing the Index.</td>
</tr>
<tr>
<td>mean(*args, **kwargs)</td>
<td>Return the mean value of the Array.</td>
</tr>
</tbody>
</table>

pandas.TimedeltaIndex.to_pytimedelta

**TimedeltaIndex.to_pytimedelta(*args, **kwargs)**
Return Timedelta Array/Index as object ndarray of datetime.timedelta objects.

Returns

timedeltas [ndarray[object]]
pandas.TimedeltaIndex.to_series

TimedeltaIndex.to_series(index=None, name=None)
Create a Series with both index and values equal to the index keys.
Useful with map for returning an indexer based on an index.

Parameters

- **index** [Index, optional] Index of resulting Series. If None, defaults to original index.
- **name** [str, optional] Name of resulting Series. If None, defaults to name of original index.

Returns

Series The dtype will be based on the type of the Index values.

See also:

- **Index.to_frame** Convert an Index to a DataFrame.
- **Series.to_frame** Convert Series to DataFrame.

Examples

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
```
By default, the original Index and original name is reused.

```python
>>> idx.to_series()
animal
     Ant
    Bear
    Cow
Name: animal, dtype: object
```
To enforce a new Index, specify new labels to **index**:

```python
>>> idx.to_series(index=[0, 1, 2])
     0
    Ant
     1
    Bear
     2
    Cow
Name: animal, dtype: object
```
To override the name of the resulting column, specify **name**:

```python
>>> idx.to_series(name='zoo')
animal
     Ant
    Bear
    Cow
Name: zoo, dtype: object
```
pandas.TimedeltaIndex.round

TimedeltaIndex.round(*args, **kwargs)
Perform round operation on the data to the specified freq.

Parameters

freq [str or Offset] The frequency level to round the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

ambiguous ['infer', bool-ndarray, 'NaT', default 'raise'] Only relevant for DatetimeIndex:
- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent ['shift_forward', 'shift_backward', 'NaT', timedelta, default 'raise'] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

Returns

DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.

Examples

DatetimeIndex

>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
               '2018-01-01 12:01:00'],
               dtype='datetime64[ns]', freq='T')
>>> rng.round('H')
DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
               '2018-01-01 12:00:00'],
               dtype='datetime64[ns]', freq=None)
Series

```python
>>> pd.Series(rng).dt.round("H")
0 2018-01-01 12:00:00
1 2018-01-01 12:00:00
2 2018-01-01 12:00:00
dtype: datetime64[ns]
```

**pandas.TimedeltaIndex.floor**

TimedeltaIndex.floor(*args, **kwargs)

Perform floor operation on the data to the specified `freq`.

**Parameters**

- `freq` [str or Offset] The frequency level to floor the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible `freq` values.
- `ambiguous` ['infer', bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
  - ‘infer’ will attempt to infer fall dst-transition hours based on order
  - bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
  - ‘NaT’ will return NaT where there are ambiguous times
  - ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.
- `nonexistent` ['shift_forward', ‘shift_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
  - ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
  - ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
  - ‘NaT’ will return NaT where there are nonexistent times
  - timedelta objects will shift nonexistent times by the timedelta
  - ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.

**Returns**

- DatetimeIndex, TimedeltaIndex, or Series Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

**Raises**

- ValueError if the `freq` cannot be converted.
Examples

Datet imeIndex

```python
>>> rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
>>> rng
DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
             '2018-01-01 12:01:00'],
       dtype='datetime64[ns]', freq='T')
```

```python
>>> rng.floor('H')
DatetimeIndex(['2018-01-01 11:00:00', '2018-01-01 12:00:00',
              '2018-01-01 12:00:00'],
       dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.floor("H")
0 2018-01-01 11:00:00
1 2018-01-01 12:00:00
2 2018-01-01 12:00:00
dtype: datetime64[ns]
```

pandas.TimedeltaIndex.ceil

TimedeltaIndex.ceil(*args, **kwargs)
Perform ceil operation on the data to the specified freq.

Parameters

freq [str or Offset] The frequency level to ceil the index to. Must be a fixed frequency like ‘S’ (second) not ‘ME’ (month end). See frequency aliases for a list of possible freq values.

ambiguous [‘infer’, bool-ndarray, ‘NaT’, default ‘raise’] Only relevant for DatetimeIndex:
- ‘infer’ will attempt to infer fall dst-transition hours based on order
- bool-ndarray where True signifies a DST time, False designates a non-DST time (note that this flag is only applicable for ambiguous times)
- ‘NaT’ will return NaT where there are ambiguous times
- ‘raise’ will raise an AmbiguousTimeError if there are ambiguous times.

nonexistent [‘shift_forward’, ‘shift_backward’, ‘NaT’, timedelta, default ‘raise’] A nonexistent time does not exist in a particular timezone where clocks moved forward due to DST.
- ‘shift_forward’ will shift the nonexistent time forward to the closest existing time
- ‘shift_backward’ will shift the nonexistent time backward to the closest existing time
- ‘NaT’ will return NaT where there are nonexistent times
- timedelta objects will shift nonexistent times by the timedelta
- ‘raise’ will raise an NonExistentTimeError if there are nonexistent times.
Returns

(DateTimeIndex, TimedeltaIndex, or Series) Index of the same type for a DatetimeIndex or TimedeltaIndex, or a Series with the same index for a Series.

Raises

ValueError if the freq cannot be converted.

Examples

DatetimeIndex

```python
def main():
    rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
    print(rng)
    print(rng.ceil('H'))
```

```python
In [1]: rng = pd.date_range('1/1/2018 11:59:00', periods=3, freq='min')
In [2]: rng
Out[2]: DatetimeIndex(['2018-01-01 11:59:00', '2018-01-01 12:00:00',
                     '2018-01-01 12:01:00'], dtype='datetime64[ns]', freq='T')
In [3]: rng.ceil('H')
Out[3]: DatetimeIndex(['2018-01-01 12:00:00', '2018-01-01 12:00:00',
                     '2018-01-01 13:00:00'], dtype='datetime64[ns]', freq=None)
```

Series

```python
>>> pd.Series(rng).dt.ceil("H")
0   2018-01-01 12:00:00
1   2018-01-01 12:00:00
2   2018-01-01 13:00:00
dtype: datetime64[ns]
```

pandas.TimedeltaIndex.to_frame

```
TimedeltaIndex.to_frame(index=True, name=None)
Create a DataFrame with a column containing the Index.

Parameters

index [bool, default True] Set the index of the returned DataFrame as the original Index.

name [object, default None] The passed name should substitute for the index name (if it has one).

Returns

DataFrame DataFrame containing the original Index data.

See also:

Index.to_series Convert an Index to a Series.
Series.to_frame Convert Series to DataFrame.
```
Examples

```python
>>> idx = pd.Index(['Ant', 'Bear', 'Cow'], name='animal')
>>> idx.to_frame()
animal
   animal
      Ant
      Bear
      Cow

By default, the original Index is reused. To enforce a new Index:

```python
>>> idx.to_frame(index=False)
   animal
   0 Ant
   1 Bear
   2 Cow
```

To override the name of the resulting column, specify `name`:

```python
>>> idx.to_frame(index=False, name='zoo')
   zoo
   0 Ant
   1 Bear
   2 Cow
```

**pandas.TimedeltaIndex.mean**

TimedeltaIndex.mean(*args, **kwargs)

Return the mean value of the Array.

New in version 0.25.0.

**Parameters**

- `skipna` [bool, default True] Whether to ignore any NaT elements.
- `axis` [int, optional, default 0]

**Returns**

- `scalar` Timestamp or Timedelta.

**See also:**

- `numpy.ndarray.mean` Returns the average of array elements along a given axis.
- `Series.mean` Return the mean value in a Series.
Notes

mean is only defined for Datetime and Timedelta dtypes, not for Period.

Components

<table>
<thead>
<tr>
<th>TimedeltaIndex.days</th>
<th>Number of days for each element.</th>
</tr>
</thead>
<tbody>
<tr>
<td>TimedeltaIndex.seconds</td>

</tbody>
</table>

Conversion

| TimedeltaIndex.to_pytimedelta(*args, **kwargs) | Return Timedelta Array/Index as object ndarray of datetime.timedelta objects. |
| TimedeltaIndex.to_series([index, name]) | Create a Series with both index and values equal to the index keys. |
| TimedeltaIndex.round(*args, **kwargs) | Perform round operation on the data to the specified freq. |
| TimedeltaIndex.floor(*args, **kwargs) | Perform floor operation on the data to the specified freq. |
| TimedeltaIndex.ceil(*args, **kwargs) | Perform ceil operation on the data to the specified freq. |
| TimedeltaIndex.to_frame([index, name]) | Create a DataFrame with a column containing the Index. |

Methods

| TimedeltaIndex.mean(*args, **kwargs) | Return the mean value of the Array. |

3.6.8 PeriodIndex

| PeriodIndex([data, ordinal, freq, dtype, ...]) | Immutable ndarray holding ordinal values indicating regular periods in time. |
pandas.PeriodIndex

```python
class pandas.PeriodIndex(data=None, ordinal=None, freq=None, dtype=None, copy=False, name=None, **fields):
```
Immutable ndarray holding ordinal values indicating regular periods in time.

Index keys are boxed to Period objects which carry the metadata (eg, frequency information).

**Parameters**

- `data` [array-like (1d int np.ndarray or PeriodArray), optional] Optional period-like data to construct index with.
- `copy` [bool] Make a copy of input ndarray.
- `freq` [str or period object, optional] One of pandas period strings or corresponding objects.
- `year` [int, array, or Series, default None]
- `month` [int, array, or Series, default None]
- `quarter` [int, array, or Series, default None]
- `day` [int, array, or Series, default None]
- `hour` [int, array, or Series, default None]
- `minute` [int, array, or Series, default None]
- `second` [int, array, or Series, default None]
- `dtype` [str or PeriodDtype, default None]

**See also:**

- `Index` The base pandas Index type.
- `Period` Represents a period of time.
- `DatetimeIndex` Index with datetime64 data.
- `TimedeltaIndex` Index of timedelta64 data.
- `period_range` Create a fixed-frequency PeriodIndex.

**Examples**

```python
>>> idx = pd.PeriodIndex(year=[2000, 2002], quarter=[1, 3])
>>> idx
PeriodIndex(['2000Q1', '2002Q3'], dtype='period[Q-DEC]')
```

**Attributes**

- `day` The days of the period.
- `dayofweek` The day of the week with Monday=0, Sunday=6.
- `day_of_week` The day of the week with Monday=0, Sunday=6.
- `dayofyear` The ordinal day of the year.
- `day_of_year` The ordinal day of the year.
- `days_in_month` The number of days in the month.
- `daysinmonth` The number of days in the month.
- `freq` Return the frequency object if it is set, otherwise None.

**pandas.PeriodIndex.day**

*property* PeriodIndex.day

The days of the period.

**pandas.PeriodIndex.dayofweek**

*property* PeriodIndex.dayofweek

The day of the week with Monday=0, Sunday=6.

**pandas.PeriodIndex.day_of_week**

*property* PeriodIndex.day_of_week

The day of the week with Monday=0, Sunday=6.

**pandas.PeriodIndex.dayofyear**

*property* PeriodIndex.dayofyear

The ordinal day of the year.

**pandas.PeriodIndex.day_of_year**

*property* PeriodIndex.day_of_year

The ordinal day of the year.
pandas.PeriodIndex.days_in_month

property PeriodIndex.days_in_month
The number of days in the month.

pandas.PeriodIndex.daysinmonth

property PeriodIndex.daysinmonth
The number of days in the month.

pandas.PeriodIndex.freq

property PeriodIndex.freq
Return the frequency object if it is set, otherwise None.

pandas.PeriodIndex.freqstr

property PeriodIndex.freqstr
Return the frequency object as a string if its set, otherwise None.

pandas.PeriodIndex.hour

property PeriodIndex.hour
The hour of the period.

pandas.PeriodIndex.is_leap_year

property PeriodIndex.is_leap_year
Logical indicating if the date belongs to a leap year.

pandas.PeriodIndex.minute

property PeriodIndex.minute
The minute of the period.

pandas.PeriodIndex.month

property PeriodIndex.month
The month as January=1, December=12.
pandas.PeriodIndex.quarter

property PeriodIndex.quarter
The quarter of the date.

pandas.PeriodIndex.second

property PeriodIndex.second
The second of the period.

pandas.PeriodIndex.week

property PeriodIndex.week
The week ordinal of the year.

pandas.PeriodIndex.weekday

property PeriodIndex.weekday
The day of the week with Monday=0, Sunday=6.

pandas.PeriodIndex.weekofyear

property PeriodIndex.weekofyear
The week ordinal of the year.

pandas.PeriodIndex.year

property PeriodIndex.year
The year of the period.

Methods

asfreq(freq, how)
Convert the PeriodArray to the specified frequency freq.

strftime(*args, **kwargs)
Convert to Index using specified date_format.

to_timestamp(freq, how)
Cast to DatetimeArray/Index.
pandas.PeriodIndex.asfreq

PeriodIndex.asfreq(freq=None, how='E')
Convert the PeriodArray to the specified frequency freq.

Equivalent to applying pandas.Period.asfreq() with the given arguments to each Period in this PeriodArray.

Parameters
- **freq** [str] A frequency.
- **how** [str {'E', 'S'}, default 'E'] Whether the elements should be aligned to the end or start within a period.
  - ‘E’, ‘END’, or ‘FINISH’ for end,
  - ‘S’, ‘START’, or ‘BEGIN’ for start.
January 31st (‘END’) vs. January 1st (‘START’) for example.

Returns
- PeriodArray The transformed PeriodArray with the new frequency.

See also:
- **pandas.arrays.PeriodArray.asfreq** Convert each Period in a PeriodArray to the given frequency.
- **Period.asfreq** Convert a Period object to the given frequency.

Examples

```python
>>> pidx = pd.period_range('2010-01-01', '2015-01-01', freq='A')
>>> pidx

>>> pidx.asfreq('M')
PeriodIndex(['2010-12', '2011-12', '2012-12', '2013-12', '2014-12', '2015-12'], dtype='period[M]')

>>> pidx.asfreq('M', how='S')
```

pandas.PeriodIndex.strftime

PeriodIndex.strftime(*args, **kwargs)
Convert to Index using specified date_format. Return an Index of formatted strings specified by date_format, which supports the same string format as the python standard library. Details of the string format can be found in python string format doc.

Parameters
- **date_format** [str] Date format string (e.g. “%Y-%m-%d”).
pandas: powerful Python data analysis toolkit, Release 1.3.1

Returns

\texttt{ndarray} NumPy ndarray of formatted strings.

See also:

\texttt{to_datetime} Convert the given argument to \texttt{datetime}.
\texttt{DatetimeIndex.normalize} Return \texttt{DatetimeIndex} with times to midnight.
\texttt{DatetimeIndex.round} Round the \texttt{DatetimeIndex} to the specified \texttt{freq}.
\texttt{DatetimeIndex.floor} Floor the \texttt{DatetimeIndex} to the specified \texttt{freq}.

Examples

```python
>>> rng = pd.date_range(pd.Timestamp("2018-03-10 09:00"),
                      periods=3, freq='s')
>>> rng.strftime('%B %d, %Y, %r')
Index(['March 10, 2018, 09:00:00 AM', 'March 10, 2018, 09:00:01 AM',
      'March 10, 2018, 09:00:02 AM'],
dtype='object')
```

\texttt{pandas.PeriodIndex.to_timestamp}

\texttt{PeriodIndex.to_timestamp} (\texttt{freq=\textit{None}, how=\textquoteleft\textit{start}\textquoteright})
Cast to \texttt{DatetimeArray/Index}.

Parameters

- \texttt{freq} [str or \texttt{DateOffset}, optional] Target frequency. The default is ‘D’ for week or longer, ‘S’ otherwise.
- \texttt{how} [\{‘s’, ‘e’, ‘start’, ‘end’\}] Whether to use the start or end of the time period being converted.

Returns

\texttt{DatetimeArray/Index}

### 3.7 Date offsets

#### 3.7.1 DateOffset

- **DateOffset** Standard kind of date increment used for a date range.
**pandas.tseries.offsets.DateOffset**

*class pandas.tseries.offsets.DateOffset*

Standard kind of date increment used for a date range.

Works exactly like relativedelta in terms of the keyword args you pass in, use of the keyword n is discouraged—you would be better off specifying n in the keywords you use, but regardless it is there for you. n is needed for DateOffset subclasses.

DateOffsets work as follows. Each offset specify a set of dates that conform to the DateOffset. For example, Bday defines this set to be the set of dates that are weekdays (M-F). To test if a date is in the set of a DateOffset dateOffset we can use the is_on_offset method: dateOffset.is_on_offset(date).

If a date is not on a valid date, the rollback and rollforward methods can be used to roll the date to the nearest valid date before/after the date.

DateOffsets can be created to move dates forward a given number of valid dates. For example, Bday(2) can be added to a date to move it two business days forward. If the date does not start on a valid date, first it is moved to a valid date. Thus pseudo code is:

```python
def __add__(date):
    date = rollback(date) # does nothing if date is valid return + <n number of periods>
```

When a date offset is created for a negative number of periods, the date is first rolled forward. The pseudo code is:

```python
def __add__(date):
    date = rollforward(date) # does nothing is date is valid return date + <n number of periods>
```

Zero presents a problem. Should it roll forward or back? We arbitrarily have it rollforward:

```
date + BDay(0) == BDay.rollover(date)
```

Since 0 is a bit weird, we suggest avoiding its use.

**Parameters**

- **n** [int, default 1] The number of time periods the offset represents.
- **normalize** [bool, default False] Whether to round the result of a DateOffset addition down to the previous midnight.
- **kwds** Temporal parameter that add to or replace the offset value.

**Parameters**

Parameters that **add** to the offset (like Timedelta):

- years
- months
- weeks
- days
- hours
- minutes
- seconds
- microseconds
- nanoseconds

Parameters that **replace** the offset value:

- year
- month
- day
- weekday
pandas: powerful Python data analysis toolkit, Release 1.3.1

- hour
- minute
- second
- microsecond
- nanosecond.

See also:

dateutil.relativedelta.relativedelta The relativedelta type is designed to be applied to an existing datetime and can replace specific components of that datetime, or represents an interval of time.

Examples

```python
>>> from pandas.tseries.offsets import DateOffset
>>> ts = pd.Timestamp('2017-01-01 09:10:11')
>>> ts + DateOffset(months=3)
Timestamp('2017-04-01 09:10:11')
```

```python
>>> ts = pd.Timestamp('2017-01-01 09:10:11')
>>> ts + DateOffset(months=2)
Timestamp('2017-03-01 09:10:11')
```

Attributes

| base | Returns a copy of the calling offset object with n=1 and all other attributes equal. |

pandas.tseries.offsets.DateOffset.base

DateOffset.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.
Methods

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

pandas.tseries.offsets.DateOffset.__call__

DateOffset.__call__(*args, **kwargs)
Call self as a function.

pandas.tseries.offsets.DateOffset.rollback

DateOffset.rollback()
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.DateOffset.rollforward

DateOffset.rollforward()
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

3.7. Date offsets
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.tseries.offsets.BusinessHour

class pandas.tseries.offsets.BusinessHour
DateOffset subclass representing possibly n business hours.

Parameters
- `n` [int, default 1] The number of months represented.
- `normalize` [bool, default False] Normalize start/end dates to midnight before generating date range.
- `weekmask` [str, Default ‘Mon Tue Wed Thu Fri’] Weekmask of valid business days, passed to numpy.busdaycalendar.
- `start` [str, default “09:00”] Start time of your custom business hour in 24h format.
- `end` [str, default: “17:00”] End time of your custom business hour in 24h format.

3.7.4 CustomBusinessDay

<table>
<thead>
<tr>
<th>CustomBusinessDay</th>
<th>DateOffset subclass representing custom business days excluding holidays.</th>
</tr>
</thead>
</table>

pandas.tseries.offsets.CustomBusinessDay

class pandas.tseries.offsets.CustomBusinessDay

DateOffset subclass representing custom business days excluding holidays.

Parameters

- n [int, default 1]
- normalize [bool, default False] Normalize start/end dates to midnight before generating date range.
- weekmask [str, Default ‘Mon Tue Wed Thu Fri’] Weekmask of valid business days, passed to numpy.busdaycalendar.
- holidays [list] List/array of dates to exclude from the set of valid business days, passed to numpy.busdaycalendar.
- calendar [pd.HolidayCalendar or np.busdaycalendar]
- offset [timedelta, default timedelta(0)]
**Attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base</td>

**pandas.tseries.offsets.CustomBusinessDay.__call__**

CustomBusinessDay.__call__(*args, **kwargs)

Call self as a function.
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.tseries.offsets.CustomBusinessDay.rollback

CustomBusinessDay.rollback()
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.CustomBusinessDay.rollforward

CustomBusinessDay.rollforward()
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.CustomBusinessHour

class pandas.tseries.offsets.CustomBusinessHour

DateOffset subclass representing possibly n custom business days.

Parameters

- **n** [int, default 1] The number of months represented.

- **normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.

- **weekmask** [str, Default ‘Mon Tue Wed Thu Fri’] Weekmask of valid business days, passed to numpy.busdaycalendar.

- **start** [str, default “09:00”] Start time of your custom business hour in 24h format.

- **end** [str, default: “17:00”] End time of your custom business hour in 24h format.

<tr>
<th>BusinessMonthBegin</th>
<th>DateOffset of one month at the first business day.</th>
</tr>
</thead>
</table>

pandas.tseries.offsets.BusinessMonthBegin

```python
class pandas.tseries.offsets.BusinessMonthBegin
    DateOffset of one month at the first business day.
```

3.7. Date offsets
Examples

```python
>>> from pandas.tseries.offset import BMonthBegin
>>> ts=pd.Timestamp('2020-05-24 05:01:15')
>>> ts + BMonthBegin()
Timestamp('2020-06-01 05:01:15')
>>> ts + BMonthBegin(2)
Timestamp('2020-07-01 05:01:15')
>>> ts + BMonthBegin(-3)
Timestamp('2020-03-02 05:01:15')
```

Attributes

```
base
```

Returns a copy of the calling offset object with n=1 and all other attributes equal.

```
pandas.tseries.offsets.BusinessMonthBegin.base
```

BusinessMonthBegin.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.

```
freqstr
kwds
n
name
nanos
normalize
rule_code
```

Methods

```
__call__(*args, **kwargs) Call self as a function.
rollback
Roll provided date backward to next offset only if not on offset.
rollforward
Roll provided date forward to next offset only if not on offset.
```
pandas.tseries.offsets.BusinessMonthBegin.__call__

BusinessMonthBegin.__call__(*args, **kwargs)
Call self as a function.

pandas.tseries.offsets.BusinessMonthBegin.rollback

BusinessMonthBegin.rollback()
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.BusinessMonthBegin.rollforward

BusinessMonthBegin.rollforward()
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

**Methods**

- **`__call__`**(*args, **kwargs*)
  
  Call self as a function.

- **`rollback`**
  
  Roll provided date backward to next offset only if not on offset.

- **`rollforward`**
  
  Roll provided date forward to next offset only if not on offset.
pandas.tseries.offsets.SemiMonthEnd.__call__

SemiMonthEnd.__call__(*args, **kwargs)
Call self as a function.

pandas.tseries.offsets.SemiMonthEnd.rollback

SemiMonthEnd.rollback()
Roll provided date backward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

pandas.tseries.offsets.SemiMonthEnd.rollforward

SemiMonthEnd.rollforward()
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

3.7.13 SemiMonthBegin

Two DateOffset’s per month repeating on the first day of the month and day_of_month.

Parameters

- `n` [int]
- `normalize` [bool, default False]
- `day_of_month` [int, {2, 3, ..., 27}, default 15]

Attributes

- `base` Returns a copy of the calling offset object with n=1 and all other attributes equal.

3.7.15 WeekOfMonth

WeekOfMonth

| WeekOfMonth | Describes monthly dates like “the Tuesday of the 2nd week of each month”. |

pandas.tseries.offsets.WeekOfMonth

class pandas.tseries.offsets.WeekOfMonth

| WeekOfMonth | Describes monthly dates like “the Tuesday of the 2nd week of each month”. |

Parameters

- **n** [int]

- **week** [int {0, 1, 2, 3, ...}, default 0] A specific integer for the week of the month. e.g. 0 is 1st week of month, 1 is the 2nd week, etc.

- **weekday** [int {0, 1, ..., 6}, default 0] A specific integer for the day of the week.

  - 0 is Monday
1 is Tuesday
2 is Wednesday
3 is Thursday
4 is Friday
5 is Saturday
6 is Sunday.

Attributes

| base | Returns a copy of the calling offset object with n=1 and all other attributes equal. |

pandas.tseries.offsets.WeekOfMonth.base

WeekOfMonth.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.

3.7.17 BQuarterEnd

| BQuarterEnd | DateOffset increments between the last business day of each Quarter. |
pandas.tseries.offsets.BQuarterEnd

```python
class pandas.tseries.offsets.BQuarterEnd
    DateOffset increments between the last business day of each Quarter.
    startingMonth = 1 corresponds to dates like 1/31/2007, 4/30/2007, ... startingMonth = 2 corresponds to dates like 2/28/2007, 5/31/2007, ... startingMonth = 3 corresponds to dates like 3/30/2007, 6/29/2007, ...
```

Examples

```python
>>> from pandas.tseries.offset import BQuarterEnd
>>> ts = pd.Timestamp('2020-05-24 05:01:15')
>>> ts + BQuarterEnd()
Timestamp('2020-06-30 05:01:15')
>>> ts + BQuarterEnd(2)
Timestamp('2020-09-30 05:01:15')
>>> ts + BQuarterEnd(1, startingMonth=2)
Timestamp('2020-05-29 05:01:15')
```

Attributes

```python
base
```

Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.BQuarterEnd.base

BQuarterEnd.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.
Methods

3.7.18 BQuarterBegin

BQuarterBegin

DateOffset increments between the first business day of each Quarter.

pandas.tseries.offsets.BQuarterBegin

class pandas.tseries.offsets.BQuarterBegin

DateOffset increments between the first business day of each Quarter.

startingMonth = 1 corresponds to dates like 1/01/2007, 4/01/2007, … startingMonth = 2 corresponds to dates like 2/01/2007, 5/01/2007, … startingMonth = 3 corresponds to dates like 3/01/2007, 6/01/2007, …

Examples:

```python
>>> from pandas.tseries.offset import BQuarterBegin
>>> ts = pd.Timestamp('2020-05-24 05:01:15')
>>> ts + BQuarterBegin()
Timestamp('2020-06-01 05:01:15')
>>> ts + BQuarterBegin(2)
Timestamp('2020-09-01 05:01:15')
>>> ts + BQuarterBegin(startingMonth=2)
Timestamp('2020-08-03 05:01:15')
>>> ts + BQuarterBegin(-1)
Timestamp('2020-03-02 05:01:15')
```
## Attributes

| base | Returns a copy of the calling offset object with n=1 and all other attributes equal. |

### pandas.tseries.offsets.BQuarterBegin.base

**BQuarterBegin.base**

Returns a copy of the calling offset object with n=1 and all other attributes equal.

3.7.25 FY5253

<table>
<thead>
<tr>
<th>FY5253</th>
<th>Describes 52-53 week fiscal year.</th>
</tr>
</thead>
</table>

pandas.tseries.offsets.FY5253

```
class pandas.tseries.offsets.FY5253
    Describes 52-53 week fiscal year. This is also known as a 4-4-5 calendar.

    It is used by companies that desire that their fiscal year always end on the same day of the week.

    It is a method of managing accounting periods. It is a common calendar structure for some industries, such as retail, manufacturing and parking industry.

    For more information see: https://en.wikipedia.org/wiki/4-4-5_calendar

    The year may either:
    • end on the last X day of the Y month.
    • end on the last X day closest to the last day of the Y month.

    X is a specific day of the week. Y is a certain month of the year

    Parameters

    n [int]

    weekday [int {0, 1, . . . , 6}, default 0] A specific integer for the day of the week.
```

• 0 is Monday
• 1 is Tuesday
• 2 is Wednesday
• 3 is Thursday
• 4 is Friday
• 5 is Saturday
• 6 is Sunday.

startingMonth  [int {1, 2, … 12}, default 1] The month in which the fiscal year ends.

variation  [str, default “nearest”] Method of employing 4-4-5 calendar.

There are two options:

• “nearest” means year end is weekday closest to last day of month in year.
• “last” means year end is final weekday of the final month in fiscal year.

### 3.7.26 FY5253Quarter

<table>
<thead>
<tr>
<th>FY5253Quarter</th>
<th>DateOffset increments between business quarter dates for 52-53 week fiscal year (also known as a 4-4-5 calendar).</th>
</tr>
</thead>
</table>

```python
pandas.tseries.offsets.FY5253Quarter
class pandas.tseries.offsets.FY5253Quarter
    DateOffset increments between business quarter dates for 52-53 week fiscal year (also known as a 4-4-5 calendar).

    It is used by companies that desire that their fiscal year always end on the same day of the week.

    It is a method of managing accounting periods. It is a common calendar structure for some industries, such as retail, manufacturing and parking industry.

    For more information see: https://en.wikipedia.org/wiki/4-4-5_calendar
```
The year may either:
  • end on the last X day of the Y month.
  • end on the last X day closest to the last day of the Y month.

X is a specific day of the week. Y is a certain month of the year

startingMonth = 1 corresponds to dates like 1/31/2007, 4/30/2007, ... startingMonth = 2 corresponds to dates like 2/28/2007, 5/31/2007, ... startingMonth = 3 corresponds to dates like 3/30/2007, 6/29/2007, ...

Parameters

n [int] 

weekday [int {0, 1, . . . , 6}, default 0] A specific integer for the day of the week.
  • 0 is Monday
  • 1 is Tuesday
  • 2 is Wednesday
  • 3 is Thursday
  • 4 is Friday
  • 5 is Saturday
  • 6 is Sunday.

startingMonth [int {1, 2, . . . , 12}, default 1] The month in which fiscal years end.

qtr_with_extra_week [int {1, 2, 3, 4}, default 1] The quarter number that has the leap or 14 week when needed.

variation [str, default “nearest”] Method of employing 4-4-5 calendar.

There are two options:
  • “nearest” means year end is weekday closest to last day of month in year.
  • “last” means year end is final weekday of the final month in fiscal year.

Attributes

base

Returns a copy of the calling offset object with n=1 and all other attributes equal.

pandas.tseries.offsets.FY5253Quarter.base

FY5253Quarter.base

Returns a copy of the calling offset object with n=1 and all other attributes equal.

3.7.27 Easter

<table>
<thead>
<tr>
<th>Easter</th>
<th>DateOffset for the Easter holiday using logic defined in dateutil.</th>
</tr>
</thead>
</table>

pandas.tseries.offsets.Easter

class pandas.tseries.offsets.Easter
    DateOffset for the Easter holiday using logic defined in dateutil.
    
    Right now uses the revised method which is valid in years 1583-4099.
Attributes

| base | Returns a copy of the calling offset object with n=1 and all other attributes equal. |

```
pandas.tseries.offsets.Easter.base
```

Easter.base
Returns a copy of the calling offset object with n=1 and all other attributes equal.

<table>
<thead>
<tr>
<th>freqstr</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>kwds</td>
<td></td>

<tr>
<td>nanos</td>
<td></td>
</tr>
<tr>
<td>normalize</td>
<td></td>
</tr>
<tr>
<td>rule_code</td>
<td></td>
</tr>
</tbody>
</table>

Methods

```
__call__(*args, **kwargs)*
Call self as a function.
```

```
rollback
Roll provided date backward to next offset only if not on offset.
```

```
rollforward
Roll provided date forward to next offset only if not on offset.
```

```
pandas.tseries.offsets.Easter.__call__
```

Easter.__call__(*args, **kwargs)
Call self as a function.

```
pandas.tseries.offsets.Easter.rollback
```

Easter.rollback()
Roll provided date backward to next offset only if not on offset.

Returns

| TimeStamp | Rolled timestamp if not on offset, otherwise unchanged timestamp. |
Easter.rollforward

Easter.rollforward()
Roll provided date forward to next offset only if not on offset.

Returns

TimeStamp Rolled timestamp if not on offset, otherwise unchanged timestamp.

3.8 Frequencies

<table>
<thead>
<tr>
<th>to_offset</th>
<th>Return DateOffset object from string or tuple representation or datetime.timedelta object.</th>
</tr>
</thead>
</table>

2356 Chapter 3. API reference
3.8.1 pandas.tseries.frequencies.to_offset

pandas.tseries.frequencies.to_offset()

Return DateOffset object from string or tuple representation or datetime.timedelta object.

Parameters

freq [str, tuple, datetime.timedelta, DateOffset or None]

Returns

DateOffset or None

Raises

ValueError If freq is an invalid frequency

See also:

DateOffset Standard kind of date increment used for a date range.

Examples

```python
>>> to_offset("5min")
<5 * Minutes>
```
```python
>>> to_offset("1D1H")
<25 * Hours>
```
```python
>>> to_offset("2W")
<2 * Weeks: weekday=6>
```
```python
>>> to_offset("2B")
<2 * BusinessDays>
```
```python
>>> to_offset(pd.Timedelta(days=1))
<Day>
```
```python
>>> to_offset(Hour())
<Hour>
```

3.9 Window

Rolling objects are returned by .rolling calls: pandas.DataFrame.rolling(), pandas.Series.rolling(), etc. Expanding objects are returned by .expanding calls: pandas.DataFrame.expanding(), pandas.Series.expanding(), etc. ExponentialMovingWindow objects are returned by .ewm calls: pandas.DataFrame.ewm(), pandas.Series.ewm(), etc.
3.9.1 Rolling window functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Rolling.count()</code></td>
<td>Calculate the rolling count of non NaN observations.</td>
</tr>
<tr>
<td><code>Rolling.sum(*args[, engine, engine_kwvars])</code></td>
<td>Calculate the rolling sum.</td>
</tr>
<tr>
<td><code>Rolling.mean(*args[, engine, engine_kwvars])</code></td>
<td>Calculate the rolling mean.</td>
</tr>
<tr>
<td><code>Rolling.median([engine, engine_kwvars])</code></td>
<td>Calculate the rolling median.</td>
</tr>
<tr>
<td><code>Rolling.var([ddof])</code></td>
<td>Calculate the rolling variance.</td>
</tr>
<tr>
<td><code>Rolling.std([ddof])</code></td>
<td>Calculate the rolling standard deviation.</td>
</tr>
<tr>
<td><code>Rolling.min(*args[, engine, engine_kwvars])</code></td>
<td>Calculate the rolling minimum.</td>
</tr>
<tr>
<td><code>Rolling.max(*args[, engine, engine_kwvars])</code></td>
<td>Calculate the rolling maximum.</td>
</tr>
<tr>
<td><code>Rolling.corr([other, pairwise, ddof])</code></td>
<td>Calculate the rolling correlation.</td>
</tr>
<tr>
<td><code>Rolling.cov([other, pairwise, ddof])</code></td>
<td>Calculate the rolling sample covariance.</td>
</tr>
<tr>
<td><code>Rolling.skew(**kwargs)</code></td>
<td>Calculate the rolling unbiased skewness.</td>
</tr>
<tr>
<td><code>Rolling.kurt(**kwargs)</code></td>
<td>Calculate the rolling Fisher’s definition of kurtosis without bias.</td>
</tr>
<tr>
<td><code>Rolling.apply(func[, raw, engine, ...])</code></td>
<td>Calculate the rolling custom aggregation function.</td>
</tr>
<tr>
<td><code>Rolling.aggregate(func, *args, **kwargs)</code></td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td><code>Rolling.quantile(quantile[, interpolation])</code></td>
<td>Calculate the rolling quantile.</td>
</tr>
<tr>
<td><code>Rolling.sem([ddof])</code></td>
<td>Calculate the rolling standard error of mean.</td>
</tr>
</tbody>
</table>

**pandas.core.window.rolling.Rolling.count**

`Rolling.count()`
Calculate the rolling count of non NaN observations.

**Returns**

- **Series or DataFrame**  
  Return type is the same as the original object.

**See also:**

- `pandas.Series.rolling` Calling rolling with Series data.
- `pandas.DataFrame.rolling` Calling rolling with DataFrames.
- `pandas.Series.count` Aggregating count for Series.
- `pandas.DataFrame.count` Aggregating count for DataFrame.

**Examples**

```python
>>> s = pd.Series([2, 3, np.nan, 10])
>>> s.rolling(2).count()
0    1.0
1    2.0
2    1.0
3    1.0
dtype: float64
>>> s.rolling(3).count()
0    1.0
1    2.0
2    2.0
3    2.0
dtype: float64
>>> s.rolling(4).count()
0    1.0
```

(continues on next page)
pandas.core.window.rolling.Rolling.sum

Rolling.\texttt{sum}(\*\texttt{args}, \texttt{engine}=None, \texttt{engine\_kwars}=None, **\texttt{kwars})

Calculate the rolling sum.

\textbf{Parameters}

*\texttt{args} For NumPy compatibility and will not have an effect on the result.

\texttt{engine} [str, default None]

- 'cython': Runs the operation through C-extensions from cython.
- 'numba': Runs the operation through JIT compiled code from numba.
- None: Defaults to 'cython' or globally setting compute.use_numba

\textbf{engine\_kwars} [dict, default None]

- For 'cython' engine, there are no accepted engine\_kwars
- For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine\_kwars for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}

\textbf{Returns}

Series or DataFrame Return type is the same as the original object.

\textbf{See also:}

pandas.Series.rolling Calling rolling with Series data.
pandas.DataFrame.rolling Calling rolling with DataFrames.
pandas.Series.sum Aggregating sum for Series.
pandas.DataFrame.sum Aggregating sum for DataFrame.

\textbf{Notes}

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.
Examples

```python
>>> s = pd.Series([1, 2, 3, 4, 5])
>>> s
0    1
1    2
2    3
3    4
4    5
dtype: int64

>>> s.rolling(3).sum()
0   NaN
1   NaN
2    6.0
3    9.0
4   12.0
dtype: float64

>>> s.rolling(3, center=True).sum()
0   NaN
1    6.0
2    9.0
3   12.0
4   NaN
dtype: float64

For DataFrame, each sum is computed column-wise.

```
pandas: powerful Python data analysis toolkit, Release 1.3.1

**pandas.core.window.rolling.Rolling.mean**

Rolling.mean(*args, engine=None, engine_kwars=None, **kwargs)

Calculate the rolling mean.

**Parameters**

*args For NumPy compatibility and will not have an effect on the result.

engine [str, default None]
- 'cython': Runs the operation through C-extensions from cython.
- 'numba': Runs the operation through JIT compiled code from numba.
- None: Defaults to 'cython' or globally setting `compute.use_numba`

New in version 1.3.0.

engine_kwargs [dict, default None]
- For 'cython' engine, there are no accepted engine_kwargs
- For 'numba' engine, the engine can accept nopython, nogil and parallel
dictionary keys. The values must either be True or False. The default
engine_kwargs for the 'numba' engine is {'nopython': True,
'nogil': False, 'parallel': False}

New in version 1.3.0.

**kwargs For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame Return type is the same as the original object.

See also:

- **pandas.Series.rolling** Calling rolling with Series data.
- **pandas.DataFrame.rolling** Calling rolling with DataFrames.
- **pandas.Series.mean** Aggregating mean for Series.
- **pandas.DataFrame.mean** Aggregating mean for DataFrame.

**Notes**

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

**Examples**

The below examples will show rolling mean calculations with window sizes of two and three, respectively.

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).mean()
0   NaN
1    1.5
2    2.5
3    3.5
dtype: float64
```
```python
>>> s.rolling(3).mean()
0   NaN
1   NaN
2   2.0
3   3.0
dtype: float64
```

**pandas.core.window.rolling.Rolling.median**

Rolling median \( (\text{engine=}'None', \text{engine_kwargs=}'None', \text{**kwargs}) \)

Calculate the rolling median.

**Parameters**

- **engine** [str, default None]
  - 'cython': Runs the operation through C-extensions from cython.
  - 'numba': Runs the operation through JIT compiled code from numba.
  - None: Defaults to 'cython' or globally setting compute.use_numba

  New in version 1.3.0.

- **engine_kwargs** [dict, default None]
  - For 'cython' engine, there are no accepted engine_kwargs
  - For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}

  New in version 1.3.0.

- **kwargs** For NumPy compatibility and will not have an effect on the result.

**Returns**

- Series or DataFrame Return type is the same as the original object.

**See also:**

- pandas.Series.rolling Calling rolling with Series data.
- pandas.DataFrame.rolling Calling rolling with DataFrames.
- pandas.Series.median Aggregating median for Series.
- pandas.DataFrame.median Aggregating median for DataFrame.

**Notes**

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.
Examples

Compute the rolling median of a series with a window size of 3.

```python
>>> s = pd.Series([0, 1, 2, 3, 4])
>>> s.rolling(3).median()
0   NaN
1   NaN
2   1.0
3   2.0
4   3.0
dtype: float64
```

```
pandas.core.window.rolling.Rolling.var
```

Rolling.var (ddof=1, *args, **kwargs)
Calculate the rolling variance.

Parameters

- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- *args For NumPy compatibility and will not have an effect on the result.
- **kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:
- `numpy.var` Equivalent method for NumPy array.
- `pandas.Series.rolling` Calling rolling with Series data.
- `pandas.DataFrame.rolling` Calling rolling with DataFrames.
- `pandas.Series.var` Aggregating var for Series.
- `pandas.DataFrame.var` Aggregating var for DataFrame.

Notes

The default ddof of 1 used in Series.var() is different than the default ddof of 0 in numpy.var().

A minimum of one period is required for the rolling calculation.

The implementation is susceptible to floating point imprecision as shown in the example below.

Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).var()
0   NaN
1   NaN
2   3.333333e-01
3   1.000000e+00
4   1.000000e+00
5   1.333333e+00
```
pandas.core.window.rolling.Rolling.std

Rolling.std(ddof=1, *args, **kwargs)

Calculate the rolling standard deviation.

Parameters

- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.

- **args** For NumPy compatibility and will not have an effect on the result.

- **kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

- **Series or DataFrame** Return type is the same as the original object.

See also:

- `numpy.std` Equivalent method for NumPy array.
- `pandas.Series.rolling` Calling rolling with Series data.
- `pandas.DataFrame.rolling` Calling rolling with DataFrames.
- `pandas.Series.std` Aggregating std for Series.
- `pandas.DataFrame.std` Aggregating std for DataFrame.

Notes

The default `ddof` of 1 used in `Series.std()` is different than the default `ddof` of 0 in `numpy.std()`.

A minimum of one period is required for the rolling calculation.

The implementation is susceptible to floating point imprecision as shown in the example below.

Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
>>> s.rolling(3).std()
0    NaN
1    NaN
2    5.773503e-01
3    1.000000e+00
4    1.000000e+00
5    1.154701e+00
6    2.580957e-08
dtype: float64
```
pandas.core.window.rolling.Rolling.min

Rolling.min(*args, engine=None, engine_kwars=None, **kwargs)
Calculate the rolling minimum.

**Parameters**

*args  For NumPy compatibility and will not have an effect on the result.

engine  [str, default None]
- 'cython': Runs the operation through C-extensions from cython.
- 'numba': Runs the operation through JIT compiled code from numba.
- None: Defaults to 'cython' or globally setting compute.use_numba
  New in version 1.3.0.

engine_kwars  [dict, default None]
- For 'cython' engine, there are no accepted engine_kwars
- For 'numba' engine, the engine can accept nopython, nogil and parallel
dictionary keys. The values must either be True or False. The default
engine_kwars for the 'numba' engine is {'nopython': True,
'nogil': False, 'parallel': False}
  New in version 1.3.0.

**kwargs  For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame  Return type is the same as the original object.

See also:

pandas.Series.rolling  Calling rolling with Series data.
pandas.DataFrame.rolling  Calling rolling with DataFrames.
pandas.Series.min  Aggregating min for Series.
pandas.DataFrame.min  Aggregating min for DataFrame.

**Notes**

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

**Examples**

Performing a rolling minimum with a window size of 3.

```python
>>> s = pd.Series([4, 3, 5, 2, 6])
>>> s.rolling(3).min()
0   NaN
1   NaN
2   3.0
3   2.0
4   2.0
dtype: float64
```
**pandas.core.window.rolling.Rolling.max**

Rolling.max(*args, engine=None, engine_kwargs=None, **kwargs)

Calculate the rolling maximum.

**Parameters**

*args For NumPy compatibility and will not have an effect on the result.

**engine** [str, default None]

- 'cython': Runs the operation through C-extensions from cython.
- 'numba': Runs the operation through JIT compiled code from numba.
- None: Defaults to 'cython' or globally setting `compute.use_numba`

New in version 1.3.0.

**engine_kwargs** [dict, default None]

- For 'cython' engine, there are no accepted `engine_kwargs`
- For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be True or False. The default `engine_kwargs` for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}`

New in version 1.3.0.

**kwargs For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame Return type is the same as the original object.

See also:

- `pandas.Series.rolling` Calling rolling with Series data.
- `pandas.DataFrame.rolling` Calling rolling with DataFrames.
- `pandas.Series.max` Aggregating max for Series.
- `pandas.DataFrame.max` Aggregating max for DataFrame.

**Notes**

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

**pandas.core.window.rolling.Rolling.corr**

Rolling.corr(other=None, pairwise=None, ddof=1, **kwargs)

Calculate the rolling correlation.

**Parameters**

other [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.
ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is $N - ddof$, where $N$ represents the number of elements.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

cov Similar method to calculate covariance.

numpy.corrcoef NumPy Pearson’s correlation calculation.

dataframe.rolling Calling rolling with Series data.

pandas.DataFrame.rolling Calling rolling with DataFrames.

pandas.Series.rolling Aggregating corr for Series.

pandas.DataFrame.corr Aggregating corr for DataFrame.

Notes

This function uses Pearson’s definition of correlation (https://en.wikipedia.org/wiki/Pearson_correlation_coefficient).

When other is not specified, the output will be self correlation (e.g. all 1’s), except for DataFrame inputs with pairwise set to True.

Function will return NaN for correlations of equal valued sequences; this is the result of a 0/0 division error.

When pairwise is set to False, only matching columns between self and other will be used.

When pairwise is set to True, the output will be a MultiIndex DataFrame with the original index on the first level, and the other DataFrame columns on the second level.

In the case of missing elements, only complete pairwise observations will be used.

Examples

The below example shows a rolling calculation with a window size of four matching the equivalent function call using numpy.corrcoef().

```python
>>> v1 = [3, 3, 3, 5, 8]
>>> v2 = [3, 4, 4, 4, 8]
>>> # numpy returns a 2x2 array, the correlation coefficient
>>> # is the number at entry [0][1]
>>> print(f"{np.corrcoef(v1[:-1], v2[:-1])[0,1]:.6f}")
0.333333
>>> print(f"{np.corrcoef(v1[1:], v2[1:])[0,1]:.6f}")
0.916949
>>> s1 = pd.Series(v1)
>>> s2 = pd.Series(v2)
>>> s1.rolling(4).corr(s2)
0    NaN
1    NaN
2    NaN
3    0.333333
4    0.916949
dtype: float64
```

The below example shows a similar rolling calculation on a DataFrame using the pairwise option.
```python
>>> print(np.corrcoef(matrix[:-1,0], matrix[:-1,1]).round(7))
[[1. 0.6263001]
 [0.6263001 1. ]]
>>> print(np.corrcoef(matrix[1:,0], matrix[1:,1]).round(7))
[[1. 0.5553681]
 [0.5553681 1. ]]
>>> df = pd.DataFrame(matrix, columns=['X','Y'])
>>> df
   X   Y
0 51.0 35.0
1 49.0 30.0
2 47.0 32.0
3 46.0 31.0
4 50.0 36.0
>>> df.rolling(4).corr(pairwise=True)
   X    Y
0   NaN NaN
1   NaN NaN
2   NaN NaN
3   1.000000 0.626300
     0.626300 1.000000
4   1.000000 0.555368
     0.555368 1.000000
```

**pandas.core.window.rolling.Rolling.cov**

Calculates the rolling sample covariance.

**Parameters**

- `other` [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.
- `pairwise` [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.
- `ddof` [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- `**kwargs` For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame Return type is the same as the original object.

See also:

- `pandas.Series.rolling` Calling rolling with Series data.
- `pandas.DataFrame.rolling` Calling rolling with DataFrames.
- `pandas.Series.cov` Aggregating cov for Series.
- `pandas.DataFrame.cov` Aggregating cov for DataFrame.
**pandas.core.window.rolling.Rolling.skew**

Rolling.skew(**kwargs)

Calculate the rolling unbiased skewness.

**Parameters**

**kwargs: For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame: Return type is the same as the original object.

See also:

scipy.stats.skew Third moment of a probability density.
pandas.Series.rolling Calling rolling with Series data.
pandas.DataFrame.rolling Calling rolling with DataFrames.
pandas.Series.skew Aggregating skew for Series.
pandas.DataFrame.skew Aggregating skew for DataFrame.

**Notes**

A minimum of three periods is required for the rolling calculation.

**pandas.core.window.rolling.Rolling.kurt**

Rolling.kurt(**kwargs)

Calculate the rolling Fisher’s definition of kurtosis without bias.

**Parameters**

**kwargs: For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame: Return type is the same as the original object.

See also:

pandas.Series.rolling Calling rolling with Series data.
pandas.DataFrame.rolling Calling rolling with DataFrames.
pandas.Series.kurt Aggregating kurt for Series.
pandas.DataFrame.kurt Aggregating kurt for DataFrame.

**Notes**

A minimum of four periods is required for the calculation.
Examples

The example below will show a rolling calculation with a window size of four matching the equivalent function call using `scipy.stats`.

```python
>>> arr = [1, 2, 3, 4, 999]
>>> import scipy.stats
>>> print(f"(scipy.stats.kurtosis(arr[:-1], bias=False):.6f)")
-1.200000
>>> print(f"(scipy.stats.kurtosis(arr[1:], bias=False):.6f)")
3.999946
>>> s = pd.Series(arr)
>>> s.rolling(4).kurt()
0    NaN
1    NaN
2    NaN
3   -1.20000
4    3.999946
dtype: float64
```

**pandas.core.window.rolling.Rolling.apply**

Rolling.apply(func, raw=False, engine=None, engine_kwags=None, args=None, kwags=None)

Calculate the rolling custom aggregation function.

**Parameters**

- **func** [function] Must produce a single value from an ndarray input if `raw=True` or a single value from a Series if `raw=False`. Can also accept a Numba JIT function with `engine='numba'` specified.
  
  Changed in version 1.0.0.

- **raw** [bool, default None]
  
  - `False`: passes each row or column as a Series to the function.
  
  - `True`: the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

- **engine** [str, default None]
  
  - `'cython'`: Runs rolling apply through C-extensions from cython.
  
  - `'numba'`: Runs rolling apply through JIT compiled code from numba. Only available when `raw` is set to `True`.

  New in version 1.0.0.

- **engine_kwargs** [dict, default None]
  
  - For `cython' engine, there are no accepted `engine_kwargs`
  
  - For `numba' engine, the engine can accept `nopython`, `nogil` and `parallel` dictionary keys. The values must either be `True` or `False`. The default `engine_kwags` for the `numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}` and will be applied to both the `func` and the apply rolling aggregation.

  New in version 1.0.0.
args  [tuple, default None] Positional arguments to be passed into func.

kwargs  [dict, default None] Keyword arguments to be passed into func.

Returns

Series or DataFrame  Return type is the same as the original object.

See also:

pandas.Series.rolling  Calling rolling with Series data.
pandas.DataFrame.rolling  Calling rolling with DataFrames.
pandas.Series.apply  Aggregating apply for Series.
pandas.DataFrame.apply  Aggregating apply for DataFrame.

pandas.core.window.rolling.Rolling.aggregate

Rolling.aggregate(func, *args, **kwargs)
Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must
either work when passed a Series/Dataframe or when passed to Series/Dataframe.apply.

Accepted combinations are:

• function
• string function name
• list of functions and/or function names, e.g. [np.sum, 'mean']
• dict of axis labels -> functions, function names or list of such.

*args  Positional arguments to pass to func.

**kwargs  Keyword arguments to pass to func.

Returns

scalar, Series or DataFrame  The return can be:

• scalar : when Series.agg is called with single function
• Series : when DataFrame.agg is called with a single function
• DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

pandas.Series.rolling  Calling object with Series data.
pandas.DataFrame.rolling  Calling object with DataFrame data.
Notes

`agg` is an alias for `aggregate`. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See *Mutating with User Defined Function (UDF) methods* for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6], "C": [7, 8, 9]})
>>> df
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9

>>> df.rolling(2).sum()
   A  B  C
0 NaN NaN NaN
1  3.0  9.0 15.0
2  5.0 11.0 17.0

>>> df.rolling(2).agg({"A": "sum", "B": "min"})
   A  B
0 NaN NaN
1  3.0  4.0
2  5.0  5.0
```

*pandas.core.window.rolling.Rolling.quantile*

Rolling. `quantile` *(quantile, interpolation='linear', **kwargs)*

Calculate the rolling quantile.

**Parameters**

- `quantile` [float] Quantile to compute. 0 <= quantile <= 1.
- `interpolation` [\{‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’\}] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points `i` and `j`:
  - linear: `i + (j - i) * fraction`, where `fraction` is the fractional part of the index surrounded by `i` and `j`.
  - lower: `i`.
  - higher: `j`.
  - nearest: `i` or `j` whichever is nearest.
  - midpoint: `(i + j) / 2`.
- `**kwargs` For NumPy compatibility and will not have an effect on the result.

**Returns**

- `Series` or `DataFrame` Return type is the same as the original object.
See also:

- `pandas.Series.rolling` Calling rolling with Series data.
- `pandas.DataFrame.rolling` Calling rolling with DataFrames.
- `pandas.Series.quantile` Aggregating quantile for Series.
- `pandas.DataFrame.quantile` Aggregating quantile for DataFrame.

### Examples

```python
>>> s = pd.Series([1, 2, 3, 4])
>>> s.rolling(2).quantile(.4, interpolation='lower')
0   NaN
1   1.0
2   2.0
3   3.0
dtype: float64
```

```python
>>> s.rolling(2).quantile(.4, interpolation='midpoint')
0   NaN
1   1.5
2   2.5
3   3.5
dtype: float64
```

### `pandas.core.window.rolling.Rolling.sem`

The `sem` method calculates the rolling standard error of mean.

**Parameters**

- `ddof` [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is N – ddof, where N represents the number of elements.
- `*args` For NumPy compatibility and will not have an effect on the result.
- `**kwargs` For NumPy compatibility and will not have an effect on the result.

**Returns**

- `Series` or `DataFrame` Return type is the same as the original object.

See also:

- `pandas.Series.rolling` Calling rolling with Series data.
- `pandas.DataFrame.rolling` Calling rolling with DataFrames.
- `pandas.Series.sem` Aggregating sem for Series.
- `pandas.DataFrame.sem` Aggregating sem for DataFrame.
Notes

A minimum of one period is required for the calculation.

Examples

```python
>>> s = pd.Series([0, 1, 2, 3])
>>> s.rolling(2, min_periods=1).sem()
0   NaN
1   0.707107
2   0.707107
3   0.707107
dtype: float64
```

3.9.2 Weighted window functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Window.mean(*args, **kwargs)</td>
<td>Calculate the rolling weighted window mean.</td>
</tr>
<tr>

<tr>
<td>Window.var([ddof])</td>
<td>Calculate the rolling weighted window variance.</td>
</tr>
<tr>
<td>Window.std([ddof])</td>
<td>Calculate the rolling weighted window standard deviation.</td>
</tr>
</tbody>
</table>

**pandas.core.window.rolling.Window.mean**

`Window.mean(*args, **kwargs)`

Calculate the rolling weighted window mean.

**Parameters**

**kwargs Keyword arguments to configure the SciPy weighted window type.**

**Returns**

Series or DataFrame Return type is the same as the original object.

**See also:**

- `pandas.Series.rolling` Calling rolling with Series data.
- `pandas.DataFrame.rolling` Calling rolling with DataFrames.
- `pandas.Series.mean` Aggregating mean for Series.
- `pandas.DataFrame.mean` Aggregating mean for DataFrame.

**pandas.core.window.rolling.Window.sum**

`Window.sum(*args, **kwargs)`

Calculate the rolling weighted window sum.

**Parameters**

**kwargs Keyword arguments to configure the SciPy weighted window type.**

**Returns**

Series or DataFrame Return type is the same as the original object.

**See also:**

- `pandas.Series.rolling` Calling rolling with Series data.
- `pandas.DataFrame.rolling` Calling rolling with DataFrames.
- `pandas.Series.mean` Aggregating mean for Series.
- `pandas.DataFrame.mean` Aggregating mean for DataFrame.
**pandas.Series.rolling** Calling rolling with Series data.
**pandas.DataFrame.rolling** Calling rolling with DataFrames.
**pandas.Series.sum** Aggregating sum for Series.
**pandas.DataFrame.sum** Aggregating sum for DataFrame.

```python
pandas.core.window.rolling.Window.var(ddof=1, *args, **kwargs)
```
Calculate the rolling weighted window variance.

- **New in version 1.0.0.**
- **Parameters**
  - **kwargs** Keyword arguments to configure the `SciPy` weighted window type.
- **Returns**
  - **Series or DataFrame** Return type is the same as the original object.

See also:
- **pandas.Series.rolling** Calling rolling with Series data.
- **pandas.DataFrame.rolling** Calling rolling with DataFrames.
- **pandas.Series.var** Aggregating var for Series.

### pandas.core.window.expanding.Expanding.count

`Expanding.count()`

 Calculate the expanding count of non NaN observations.

**Returns**

- **Series or DataFrame**  
  Return type is the same as the original object.

**See also:**

- `pandas.Series.expanding`  
  Calling expanding with Series data.
- `pandas.DataFrame.expanding`  
  Calling expanding with DataFrames.
- `pandas.Series.count`  
  Aggregating count for Series.
- `pandas.DataFrame.count`  
  Aggregating count for DataFrame.

### pandas.core.window.expanding.Expanding.sum

`Expanding.sum(*args, engine=None, engine_kwars=None, **kwargs)`

Calculate the expanding sum.

**Parameters**

- **args**  
  For NumPy compatibility and will not have an effect on the result.
- **engine**  
  [str, default None]
  - 'cython' : Runs the operation through C-extensions from cython.
  - 'numba' : Runs the operation through JIT compiled code from numba.
  - None : Defaults to 'cython' or globally setting `compute.use_numba`

  New in version 1.3.0.

- **engine_kwars**  
  [dict, default None]
  - For 'cython' engine, there are no accepted engine_kwars
  - For 'numba' engine, the engine can accept `nopython, nogil` and `parallel` dictionary keys.  
    The values must either be True or False. The default `engine_kwars` for the 'numba' engine is `{ 'nopython': True, 'nogil': False, 'parallel': False }`

  New in version 1.3.0.

- **kwargs**  
  For NumPy compatibility and will not have an effect on the result.

**Returns**

- **Series or DataFrame**  
  Return type is the same as the original object.
See also:

- `pandas.Series.expanding` Calling expanding with Series data.
- `pandas.DataFrame.expanding` Calling expanding with DataFrames.
- `pandas.Series.cumsum` Aggregating sum for Series.
- `pandas.DataFrame.cumsum` Aggregating sum for DataFrame.

Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

`pandas.core.window.expanding.Expanding.mean`

Expanding.mean(*args, engine=None, engine_kwargs=None, **kwargs)

Calculate the expanding mean.

Parameters

*args For NumPy compatibility and will not have an effect on the result.

engine [str, default None]

- 'cython': Runs the operation through C-extensions from cython.
- 'numba': Runs the operation through JIT compiled code from numba.
- None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.3.0.

engine_kwargs [dict, default None]

- For 'cython' engine, there are no accepted engine_kwargs
- For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}

New in version 1.3.0.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

- `pandas.Series.expanding` Calling expanding with Series data.
- `pandas.DataFrame.expanding` Calling expanding with DataFrames.
- `pandas.Series.cumsum` Aggregating sum for Series.
- `pandas.DataFrame.cumsum` Aggregating sum for DataFrame.
Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.median

Expanding.median(engine=None, engine_kwargs=None, **kwargs)
Calculate the expanding median.

Parameters

engine [str, default None]
- 'cython': Runs the operation through C-extensions from cython.
- 'numba': Runs the operation through JIT compiled code from numba.
- None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.3.0.

engine_kwargs [dict, default None]
- For 'cython' engine, there are no accepted engine_kwargs.
- For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}

New in version 1.3.0.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.median Aggregating median for Series.
pandas.DataFrame.median Aggregating median for DataFrame.

Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.core.window.expanding.Expanding.var

Expanding.var(ddof=1, *args, **kwargs)
Calculate the expanding variance.

Parameters

- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.

- **args** For NumPy compatibility and will not have an effect on the result.

- **kwargs** For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame  Return type is the same as the original object.

See also:

- numpy.var  Equivalent method for NumPy array.
- pandas.Series.expanding  Calling expanding with Series data.
- pandas.DataFrame.expanding  Calling expanding with DataFrames.
- pandas.Series.var  Aggregating var for Series.
- pandas.DataFrame.var  Aggregating var for DataFrame.

Notes

The default ddof of 1 used in Series.var() is different than the default ddof of 0 in numpy.var().

A minimum of one period is required for the rolling calculation.

Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])

>>> s.expanding(3).var()
0    NaN
1    NaN
2    0.333333
3    0.916667
4    0.800000
5    0.700000
6    0.619048
dtype: float64
```

pandas.core.window.expanding.Expanding.std

Expanding.std(ddof=1, *args, **kwargs)
Calculate the expanding standard deviation.

Parameters

- **ddof** [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.

- **args** For NumPy compatibility and will not have an effect on the result.

- **kwargs** For NumPy compatibility and will not have an effect on the result.
Returns

Series or DataFrame  Return type is the same as the original object.

See also:

numpy.std  Equivalent method for NumPy array.
pandas.Series.expanding  Calling expanding with Series data.
pandas.DataFrame.expanding  Calling expanding with DataFrames.
pandas.Series.std  Aggregating std for Series.
pandas.DataFrame.std  Aggregating std for DataFrame.

Notes

The default ddof of 1 used in Series.std() is different than the default ddof of 0 in numpy.std().
A minimum of one period is required for the rolling calculation.

Examples

```python
>>> s = pd.Series([5, 5, 6, 7, 5, 5, 5])
```

```python
>>> s.expanding(3).std()
0     NaN
1     NaN
2  0.577350
3  0.957427
4  0.894427
5  0.836660
6  0.786796
dtype: float64
```

pandas.core.window.expanding.Expanding.min

Expanding.min(*args, engine=None, engine_kwars=None, **kwargs)
Calculate the expanding minimum.

Parameters

*args  For NumPy compatibility and will not have an effect on the result.

engine  [str, default None]

  * 'cython': Runs the operation through C-extensions from cython.
  * 'numba': Runs the operation through JIT compiled code from numba.
  * None: Defaults to 'cython' or globally setting compute.use_numba

  New in version 1.3.0.

engine_kwars  [dict, default None]

  * For 'cython' engine, there are no accepted engine_kwars
  * For 'numba' engine, the engine can accept nopython, nogil and parallel
dictionary keys. The values must either be True or False. The de-
default engine_kwars for the 'numba' engine is {'nopython': True,
  'nogil': False, 'parallel': False}
**kwargs For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame Return type is the same as the original object.

See also:

pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.min Aggregating min for Series.
pandas.DataFrame.min Aggregating min for DataFrame.

Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.max

Expanding.max(*args, engine=None, engine_kwars=None, **kwargs)

Calculate the expanding maximum.

Parameters

*args For NumPy compatibility and will not have an effect on the result.

engine [str, default None]

- 'cython': Runs the operation through C-extensions from cython.
- 'numba': Runs the operation through JIT compiled code from numba.
- None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.3.0.

engine_kwars [dict, default None]

- For 'cython' engine, there are no accepted engine_kwars

- For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwars for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False}

New in version 1.3.0.

**kwargs For NumPy compatibility and will not have an effect on the result.

**Returns**

Series or DataFrame Return type is the same as the original object.

See also:

pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.max Aggregating max for Series.
pandas.DataFrame.max Aggregating max for DataFrame.
Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations for the Numba engine.

pandas.core.window.expanding.Expanding.corr

Expanding.corr(other=None, pairwise=None, ddof=1, **kwargs)

Calculate the expanding correlation.

Parameters

other [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

cov Similar method to calculate covariance.
numpy.corrcoef NumPy Pearson’s correlation calculation.
pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.corr Aggregating corr for Series.
pandas.DataFrame.corr Aggregating corr for DataFrame.

Notes

This function uses Pearson’s definition of correlation (https://en.wikipedia.org/wiki/Pearson_correlation_coefficient).

When other is not specified, the output will be self correlation (e.g. all 1’s), except for DataFrame inputs with pairwise set to True.

Function will return NaN for correlations of equal valued sequences; this is the result of a 0/0 division error.

When pairwise is set to False, only matching columns between self and other will be used.

When pairwise is set to True, the output will be a MultiIndex DataFrame with the original index on the first level, and the other DataFrame columns on the second level.

In the case of missing elements, only complete pairwise observations will be used.
pandas.core.window.expanding.Expanding.cov

Expanding.cov(other=None, pairwise=None, ddof=1, **kwargs)
Calculate the expanding sample covariance.

Parameters

other [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.

pairwise [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndexed DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.

ddof [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.cov Aggregating cov for Series.
pandas.DataFrame.cov Aggregating cov for DataFrame.

pandas.core.window.expanding.Expanding.skew

Expanding.skew(**kwargs)
Calculate the expanding unbiased skewness.

Parameters

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

scipy.stats.skew Third moment of a probability density.
pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.skew Aggregating skew for Series.
pandas.DataFrame.skew Aggregating skew for DataFrame.
Notes

A minimum of three periods is required for the rolling calculation.

*pandas.core.window.expanding.Expanding.kurt*

```
Expanding.kurt (**kwargs)
Calculate the expanding Fisher's definition of kurtosis without bias.

Parameters

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.kurt Aggregating kurt for Series.
pandas.DataFrame.kurt Aggregating kurt for DataFrame.
```

Notes

A minimum of four periods is required for the calculation.

Examples

The example below will show a rolling calculation with a window size of four matching the equivalent function call using scipy.stats.

```python
>>> arr = [1, 2, 3, 4, 999]
>>> import scipy.stats
>>> print(f"scipy.stats.kurtosis(arr[:-1], bias=False):.6f")
-1.200000
>>> print(f"scipy.stats.kurtosis(arr, bias=False):.6f")
4.999874
>>> s = pd.Series(arr)
>>> s.expanding(4).kurt()
0    NaN
e1   NaN
2    NaN
3 -1.200000
4    4.999874
dtype: float64
```
Expanding.apply (func, raw=False, engine=None, engine_kwargs=None, args=None, kwags=None)

Calculate the expanding custom aggregation function.

Parameters

func [function] Must produce a single value from an ndarray input if raw=True or a single value from a Series if raw=False. Can also accept a Numba JIT function with engine='numba' specified.

Changed in version 1.0.0.

raw [bool, default None]

• False: passes each row or column as a Series to the function.
• True: the passed function will receive ndarray objects instead. If you are just applying a NumPy reduction function this will achieve much better performance.

engine [str, default None]

• 'cython': Runs rolling apply through C-extensions from cython.
• 'numba': Runs rolling apply through JIT compiled code from numba. Only available when raw is set to True.
• None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.0.0.

engine_kwargs [dict, default None]

• For 'cython' engine, there are no accepted engine_kwargs
• For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwargs for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False} and will be applied to both the func and the apply rolling aggregation.

New in version 1.0.0.

args [tuple, default None] Positional arguments to be passed into func.

kwags [dict, default None] Keyword arguments to be passed into func.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.apply Aggregating apply for Series.
pandas.DataFrame.apply Aggregating apply for DataFrame.
pandas.core.window.expanding.Expanding.aggregate

Expanding.aggregate(func, *args, **kwargs)

Aggregate using one or more operations over the specified axis.

Parameters

- **func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series/Dataframe or when passed to Series/Dataframe.apply.

  Accepted combinations are:
  - function
  - string function name
  - list of functions and/or function names, e.g. [np.sum, 'mean']
  - dict of axis labels -> functions, function names or list of such.

- *args Positional arguments to pass to func.

- **kwargs Keyword arguments to pass to func.

Returns

- scalar, Series or DataFrame The return can be:
  - scalar : when Series.agg is called with single function
  - Series : when DataFrame.agg is called with a single function
  - DataFrame : when DataFrame.agg is called with several functions

  Return scalar, Series or DataFrame.

See also:

- pandas.DataFrame.aggregate Similar DataFrame method.
- pandas.Series.aggregate Similar Series method.

Notes

agg is an alias for aggregate. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6], "C": [7, 8, 9]})
>>> df
   A  B  C
0  1  4  7
1  2  5  8
2  3  6  9
```

```python
>>> df.ewm(alpha=0.5).mean()
   A         B         C
0 1.000000 4.000000 7.000000
```

pandas.core.window.expanding.Expanding.quantile

Expanding.quantile(quantile, interpolation='linear', **kwargs)

Calculate the expanding quantile.

Parameters

quantile [float] Quantile to compute. 0 <= quantile <= 1.

interpolation [{'linear', 'lower', 'higher', 'midpoint', 'nearest'}] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points i and j:

- linear: \(i + (j - i) \times \text{fraction}\), where \text{fraction} is the fractional part of the index surrounded by i and j.
- lower: i.
- higher: j.
- nearest: i or j whichever is nearest.
- midpoint: \((i + j) / 2\).

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:
pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.quantile Aggregating quantile for Series.
pandas.DataFrame.quantile Aggregating quantile for DataFrame.

pandas.core.window.expanding.Expanding.sem

Expanding.sem(ddof=1, *args, **kwargs)

Calculate the expanding standard error of mean.

Parameters

ddf [int, default 1] Delta Degrees of Freedom. The divisor used in calculations is \(N - ddf\), where \(N\) represents the number of elements.

*args For NumPy compatibility and will not have an effect on the result.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:
pandas.Series.expanding Calling expanding with Series data.
pandas.DataFrame.expanding Calling expanding with DataFrames.
pandas.Series.sem Aggregating sem for Series.
**pandas.DataFrame.sem**  Aggregating sem for DataFrame.

**Notes**

A minimum of one period is required for the calculation.

**Examples**

```python
>>> s = pd.Series([0, 1, 2, 3])

>>> s.expanding().sem()
0    NaN
1  0.707107
2  0.707107
3  0.745356
dtype: float64
```

### 3.9.4 Exponentially-weighted window functions

- **ExponentialMovingWindow.mean(***args**, ...)**: Calculate the ewm (exponential weighted moment) mean.
- **ExponentialMovingWindow.std((bias))**: Calculate the ewm (exponential weighted moment) standard deviation.
- **ExponentialMovingWindow.var((bias))**: Calculate the ewm (exponential weighted moment) variance.
- **ExponentialMovingWindow.corr((other, pairwise))**: Calculate the ewm (exponential weighted moment) sample correlation.
- **ExponentialMovingWindow.cov((other, ...))**: Calculate the ewm (exponential weighted moment) sample covariance.

#### pandas.core.window.ewm.ExponentialMovingWindow.mean

**ExponentialMovingWindow.mean(***args**, **engine=None, engine_kwargs=None, **kwargs)**

Calculate the ewm (exponential weighted moment) mean.

**Parameters**

- ***args**  For NumPy compatibility and will not have an effect on the result.
- **engine**  [str, default None]
  - 'cython': Runs the operation through C-extensions from cython.
  - 'numba': Runs the operation through JIT compiled code from numba.
  - None: Defaults to 'cython' or globally setting `compute.use_numba`
    - New in version 1.3.0.
- **engine_kwargs**  [dict, default None]
  - For 'cython' engine, there are no accepted engine_kwargs
• For 'numba' engine, the engine can accept nopython, nogil and parallel
dictionary keys. The values must either be True or False. The de-
default engine_kwargs for the 'numba' engine is {'nopython': True,
'nogil': False, 'parallel': False}

New in version 1.3.0.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

pandas.Series.ewm Calling ewm with Series data.
pandas.DataFrame.ewm Calling ewm with DataFrames.
pandas.Series.mean Aggregating mean for Series.
pandas.DataFrame.mean Aggregating mean for DataFrame.

Notes

See Numba engine and Numba (JIT compilation) for extended documentation and performance considerations
for the Numba engine.

pandas.core.window.ewm.ExponentialMovingWindow.std

ExponentialMovingWindow.std(bias=False, *args, **kwargs)
Calculate the ewm (exponential weighted moment) standard deviation.

Parameters

bias [bool, default False] Use a standard estimation bias correction.

*args For NumPy compatibility and will not have an effect on the result.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

pandas.Series.ewm Calling ewm with Series data.
pandas.DataFrame.ewm Calling ewm with DataFrames.
pandas.Series.std Aggregating std for Series.
pandas.DataFrame.std Aggregating std for DataFrame.

pandas.core.window.ewm.ExponentialMovingWindow.var

ExponentialMovingWindow.var(bias=False, *args, **kwargs)
Calculate the ewm (exponential weighted moment) variance.

Parameters

bias [bool, default False] Use a standard estimation bias correction.

*args For NumPy compatibility and will not have an effect on the result.

**kwargs For NumPy compatibility and will not have an effect on the result.

Returns

Series or DataFrame Return type is the same as the original object.

See also:

pandas.Series.ewm Calling ewm with Series data.
pandas.DataFrame.ewm Calling ewm with DataFrames.
pandas.Series.var Aggregating var for Series.
pandas.DataFrame.var Aggregating var for DataFrame.
Series or DataFrame  Return type is the same as the original object.

See also:
- pandas.Series.ewm  Calling ewm with Series data.
- pandas.DataFrame.ewm  Calling ewm with DataFrames.
- pandas.Series.var  Aggregating var for Series.
- pandas.DataFrame.var  Aggregating var for DataFrame.

pandas.core.window.ewm.ExponentialMovingWindow.corr

ExponentialMovingWindow.corr (other=None, pairwise=None, **kwargs)
Calculate the ewm (exponential weighted moment) sample correlation.

Parameters
- other  [Series or DataFrame, optional] If not supplied then will default to self and produce pairwise output.
- pairwise  [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.
- **kwargs  For NumPy compatibility and will not have an effect on the result.

Returns
Series or DataFrame  Return type is the same as the original object.

See also:
- pandas.Series.ewm  Calling ewm with Series data.
- pandas.DataFrame.ewm  Calling ewm with DataFrames.
- pandas.Series.corr  Aggregating corr for Series.
- pandas.DataFrame.corr  Aggregating corr for DataFrame.

pandas.core.window.ewm.ExponentialMovingWindow.cov

ExponentialMovingWindow.cov (other=None, pairwise=None, bias=False, **kwargs)
Calculate the ewm (exponential weighted moment) sample covariance.

Parameters
- other  [Series or DataFrame , optional] If not supplied then will default to self and produce pairwise output.
- pairwise  [bool, default None] If False then only matching columns between self and other will be used and the output will be a DataFrame. If True then all pairwise combinations will be calculated and the output will be a MultiIndex DataFrame in the case of DataFrame inputs. In the case of missing elements, only complete pairwise observations will be used.
- bias  [bool, default False] Use a standard estimation bias correction.
- **kwargs  For NumPy compatibility and will not have an effect on the result.

Returns
Series or DataFrame  Return type is the same as the original object.

See also:
- pandas.Series.ewm  Calling ewm with Series data.
**3.9.5 Window indexer**

Base class for defining custom window boundaries.

```
api.indexers.BaseIndexer([index_array, ...])  # Base class for window bounds calculations.
api.indexers.FixedForwardWindowIndexer([...])  # Creates window boundaries for fixed-length windows that include the current row.
api.indexers.VariableOffsetWindowIndexer([...])  # Calculate window boundaries based on a non-fixed offset such as a BusinessDay
```

**pandas.api.indexers.BaseIndexer**

class pandas.api.indexers.BaseIndexer (index_array=None, window_size=0, **kwargs)

Base class for window bounds calculations.

**Methods**

```
get_window_bounds([num_values, min_periods,...])  # Computes the bounds of a window.
```

**pandas.api.indexers.BaseIndexer.get_window_bounds**

BaseIndexer.get_window_bounds (num_values=0, min_periods=None, center=None, closed=None)

Computes the bounds of a window.

**Parameters**

- num_values [int, default 0] number of values that will be aggregated over
- window_size [int, default 0] the number of rows in a window
- min_periods [int, default None] min_periods passed from the top level rolling API
- center [bool, default None] center passed from the top level rolling API
- closed [str, default None] closed passed from the top level rolling API
- win_type [str, default None] win_type passed from the top level rolling API

**Returns**

A tuple of ndarray[int64], indicating the boundaries of each window
pandas.api.indexers.FixedForwardWindowIndexer

```python
class pandas.api.indexers.FixedForwardWindowIndexer(index_array=None, window_size=0, **kwargs)

Creates window boundaries for fixed-length windows that include the current row.
```

### Examples

```python
>>> df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})
>>> df
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0

>>> indexer = pd.api.indexers.FixedForwardWindowIndexer(window_size=2)
>>> df.rolling(window=indexer, min_periods=1).sum()
   B
0  1.0
1  3.0
2  2.0
3  4.0
4  4.0
```

### Methods

- **get_window_bounds**
  ```python
  pandas.api.indexers.FixedForwardWindowIndexer.get_window_bounds(num_values=0, min_periods=None, center=None, closed=None)
  
  Computes the bounds of a window.
  ```

- **Parameters**
  - `num_values` [int, default 0] number of values that will be aggregated over
  - `window_size` [int, default 0] the number of rows in a window
  - `min_periods` [int, default None] min_periods passed from the top level rolling API
  - `center` [bool, default None] center passed from the top level rolling API
  - `closed` [str, default None] closed passed from the top level rolling API

- **Returns**
  A tuple of ndarray[int64]s, indicating the boundaries of each window
pandas.api.indexers.VariableOffsetWindowIndexer

**class pandas.api.indexers.VariableOffsetWindowIndexer**

(index_array=None, window_size=0, index=None, offset=None, **kwargs)

Calculate window boundaries based on a non-fixed offset such as a BusinessDay

**Methods**

```
get_window_bounds([num_values, min_periods, ...])
```

Computes the bounds of a window.

**pandas.api.indexers.VariableOffsetWindowIndexer.get_window_bounds**

VariableOffsetWindowIndexer.get_window_bounds(num_values=0, min_periods=None, center=None, closed=None)

Computes the bounds of a window.

**Parameters**

- **num_values** [int, default 0] number of values that will be aggregated over
- **window_size** [int, default 0] the number of rows in a window
- **min_periods** [int, default None] min_periods passed from the top level rolling API
- **center** [bool, default None] center passed from the top level rolling API
- **closed** [str, default None] closed passed from the top level rolling API
- **win_type** [str, default None] win_type passed from the top level rolling API

**Returns**

A tuple of ndarray[int64]s, indicating the boundaries of each window

---

### 3.10 GroupBy

GroupBy objects are returned by groupby calls: `pandas.DataFrame.groupby()`, `pandas.Series.groupby()`, etc.

#### 3.10.1 Indexing, iteration

<table>
<thead>
<tr>
<th>GroupBy.<strong>iter</strong>()</th>
<th>Groupby iterator.</th>
</tr>
</thead>
<tbody>
<tr>
<td>GroupBy.groups</td>
<td>Dict {group name -&gt; group labels}.</td>
</tr>
<tr>
<td>GroupBy.indices</td>
<td>Dict {group name -&gt; group indices}.</td>
</tr>
<tr>
<td>GroupBy.get_group(name[, obj])</td>
<td>Construct DataFrame from group with provided name.</td>
</tr>
</tbody>
</table>
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.core.groupby.GroupBy.

__iter__

GroupBy.

__iter__()
    Groupby iterator.

Returns
    Generator yielding sequence of (name, subsetted object)
    for each group

pandas.core.groupby.GroupBy.groups

property GroupBy.

groups
    Dict {group name -> group labels}.

pandas.core.groupby.GroupBy.indices

property GroupBy.

indices
    Dict {group name -> group indices}.

pandas.core.groupby.GroupBy.get_group

GroupBy.

get_group (name, obj=None)
    Construct DataFrame from group with provided name.

Parameters
    name [object] The name of the group to get as a DataFrame.
    obj [DataFrame, default None] The DataFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used.

Returns
    group [same type as obj]

Grouper(*args, **kwargs)
    A Grouper allows the user to specify a groupby instruction for an object.

pandas.Grouper

class pandas.

Grouper (*args, **kwargs)
    A Grouper allows the user to specify a groupby instruction for an object.

This specification will select a column via the key parameter, or if the level and/or axis parameters are given, a level of the index of the target object.

If axis and/or level are passed as keywords to both Grouper and groupby, the values passed to Grouper take precedence.

Parameters
    key [str, defaults to None] Groupby key, which selects the grouping column of the target.
    level [name/number, defaults to None] The level for the target index.
    freq [str / frequency object, defaults to None] This will groupby the specified frequency if the target selection (via key or level) is a datetime-like object. For full specification of
available frequencies, please see here.

**axis** [str, int, defaults to 0] Number/name of the axis.

**sort** [bool, default to False] Whether to sort the resulting labels.

**closed** [‘left’ or ‘right’] Closed end of interval. Only when *freq* parameter is passed.

**label** [‘left’ or ‘right’] Interval boundary to use for labeling. Only when *freq* parameter is passed.

**convention** [‘start’, ‘end’, ‘e’, ‘s’] If grouper is PeriodIndex and *freq* parameter is passed.

**base** [int, default 0] Only when *freq* parameter is passed. For frequencies that evenly subdivide 1 day, the “origin” of the aggregated intervals. For example, for ‘5min’ frequency, base could range from 0 through 4. Defaults to 0.

   Deprecated since version 1.1.0: The new arguments that you should use are ‘offset’ or ‘origin’.

**loffset** [str, DateOffset, timedelta object] Only when *freq* parameter is passed.

   Deprecated since version 1.1.0: loffset is only working for .resample(...) and not for Grouper (GH28302). However, loffset is also deprecated for .resample(...) See: DataFrame.resample

**origin** [‘epoch’, ‘start’, ‘start_day’, ‘end’, ‘end_day’], Timestamp] or str, default ‘start_day’ The timestamp on which to adjust the grouping. The timezone of origin must match the timezone of the index. If a timestamp is not used, these values are also supported:

   • ‘epoch’: *origin* is 1970-01-01
   • ‘start’: *origin* is the first value of the timeseries
   • ‘start_day’: *origin* is the first day at midnight of the timeseries

   New in version 1.1.0.

   • ‘end’: *origin* is the last value of the timeseries
   • ‘end_day’: *origin* is the ceiling midnight of the last day

   New in version 1.3.0.

**offset** [Timedelta or str, default is None] An offset timedelta added to the origin.

   New in version 1.1.0.

**dropna** [bool, default True] If True, and if group keys contain NA values, NA values together with row/column will be dropped. If False, NA values will also be treated as the key in groups.

   New in version 1.2.0.

**Returns**

A specification for a groupby instruction
Examples

Syntactic sugar for df.groupby('A')

```python
>>> df = pd.DataFrame(
...     {  
...         "Animal": ["Falcon", "Parrot", "Falcon", "Falcon", "Parrot"],  
...         "Speed": [100, 5, 200, 300, 15],  
...     }  
... )

>>> df
Animal  Speed
0   Falcon  100
1     Parrot   5
2   Falcon  200
3   Falcon  300
4     Parrot   15

>>> df.groupby(pd.Grouper(key="Animal")).mean()
    Animal
Speed  
Falcon  200.0
Parrot  10.0
```

Specify a resample operation on the column ‘Publish date’

```python
>>> df = pd.DataFrame(
...     {  
...         "ID": [0, 1, 2, 3],  
...         "Price": [10, 20, 30, 40]  
...     }  
... )

>>> df
   Publish date  ID  Price
0 2000-01-02   0    10
1 2000-01-02   1    20
2 2000-01-09   2    30
3 2000-01-16   3    40

>>> df.groupby(pd.Grouper(key="Publish date", freq="1W")).mean()
    Publish date
ID  Price
2000-01-02  0.5   15.0
2000-01-09  2.0   30.0
2000-01-16  3.0   40.0
```

If you want to adjust the start of the bins based on a fixed timestamp:

```python
>>> start, end = '2000-10-01 23:30:00', '2000-10-02 00:30:00'
>>> rng = pd.date_range(start, end, freq='7min')
>>> ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
>>> ts
2000-10-01 23:30:00   0
2000-10-01 23:37:00   3
```
2000-10-01 23:44:00   6
2000-10-01 23:51:00   9
2000-10-01 23:58:00  12
2000-10-02 00:05:00  15
2000-10-02 00:12:00  18
2000-10-02 00:19:00  21
2000-10-02 00:26:00  24
Freq: 7T, dtype: int64

```python
>>> ts.groupby(pd.Grouper(freq='17min')).sum()
2000-10-01 23:14:00   0
2000-10-01 23:31:00   9
2000-10-01 23:48:00  21
2000-10-02 00:05:00  54
2000-10-02 00:22:00  24
Freq: 17T, dtype: int64
```  

```python
>>> ts.groupby(pd.Grouper(freq='17min', origin='epoch')).sum()
2000-10-01 23:18:00   0
2000-10-01 23:35:00  18
2000-10-01 23:52:00  27
2000-10-02 00:09:00  39
2000-10-02 00:26:00  24
Freq: 17T, dtype: int64
```  

```python
>>> ts.groupby(pd.Grouper(freq='17min', origin='2000-01-01')).sum()
2000-10-01 23:24:00   3
2000-10-01 23:41:00  15
2000-10-01 23:58:00  45
2000-10-02 00:15:00  45
Freq: 17T, dtype: int64
```  

If you want to adjust the start of the bins with an *offset* Timedelta, the two following lines are equivalent:

```python
>>> ts.groupby(pd.Grouper(freq='17min', origin='start')).sum()
2000-10-01 23:30:00   9
2000-10-01 23:47:00  21
2000-10-02 00:04:00  54
2000-10-02 00:21:00  24
Freq: 17T, dtype: int64
```  

```python
>>> ts.groupby(pd.Grouper(freq='17min', offset='23h30min')).sum()
2000-10-01 23:30:00   9
2000-10-01 23:47:00  21
2000-10-02 00:04:00  54
2000-10-02 00:21:00  24
Freq: 17T, dtype: int64
```  

To replace the use of the deprecated *base* argument, you can now use *offset*, in this example it is equivalent to have *base=2*:

```python
>>> ts.groupby(pd.Grouper(freq='17min', offset='2min')).sum()
2000-10-01 23:16:00   0
2000-10-01 23:33:00   9
2000-10-01 23:50:00  36
```
3.10.2 Function application

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GroupBy.apply</td>
<td>Apply function <code>func</code> group-wise and combine the results together.</td>
</tr>
<tr>
<td>GroupBy.agg</td>
<td></td>
</tr>
<tr>
<td>SeriesGroupBy.aggregate</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>DataFrameGroupBy.aggregate</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>SeriesGroupBy.transform</td>
<td>Call function producing a like-indexed Series on each group and return a Series having the same indexes as the original object filled with the transformed values</td>
</tr>
<tr>
<td>DataFrameGroupBy.transform</td>
<td>Call function producing a like-indexed DataFrame on each group and return a DataFrame having the same indexes as the original object filled with the transformed values</td>
</tr>
<tr>
<td>GroupBy.pipe</td>
<td>Apply a function <code>func</code> with arguments to this GroupBy object and return the function’s result.</td>
</tr>
</tbody>
</table>

**pandas.core.groupby.GroupBy.apply**

`GroupBy.apply(func, *args, **kwargs)`

Apply function `func` group-wise and combine the results together.

The function passed to `apply` must take a dataframe as its first argument and return a DataFrame, Series or scalar. `apply` will then take care of combining the results back together into a single dataframe or series. `apply` is therefore a highly flexible grouping method.

While `apply` is a very flexible method, its downside is that using it can be quite a bit slower than using more specific methods like `agg` or `transform`. Pandas offers a wide range of method that will be much faster than using `apply` for their specific purposes, so try to use them before reaching for `apply`.

**Parameters**

- `func` [callable] A callable that takes a dataframe as its first argument, and returns a dataframe, a series or a scalar. In addition the callable may take positional and keyword arguments.
- `args, kwargs` [tuple and dict] Optional positional and keyword arguments to pass to `func`.

**Returns**

- `applied` [Series or DataFrame]
See also:

- **pipe** Apply function to the full GroupBy object instead of to each group.
- **aggregate** Apply aggregate function to the GroupBy object.
- **transform** Apply function column-by-column to the GroupBy object.
- **Series.apply** Apply a function to a Series.
- **DataFrame.apply** Apply a function to each row or column of a DataFrame.

Notes

In the current implementation `apply` calls `func` twice on the first group to decide whether it can take a fast or slow code path. This can lead to unexpected behavior if `func` has side-effects, as they will take effect twice for the first group.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`, see the examples below.

Examples

```python
def df = pd.DataFrame({'A': 'a a b'.split(),
                      'B': [1,2,3],
                      'C': [4,6,5]})
g = df.groupby('A')
```

Notice that `g` has two groups, `a` and `b`. Calling `apply` in various ways, we can get different grouping results:

Example 1: below the function passed to `apply` takes a DataFrame as its argument and returns a DataFrame. `apply` combines the result for each group together into a new DataFrame:

```python
g[['B', 'C']].apply(lambda x: x / x.sum())
```

<table>
<thead>
<tr>
<th></th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.333333</td>
<td>0.4</td>
</tr>
<tr>
<td>1</td>
<td>0.666667</td>
<td>0.6</td>
</tr>
<tr>
<td>2</td>
<td>1.000000</td>
<td>1.0</td>
</tr>
</tbody>
</table>

Example 2: The function passed to `apply` takes a DataFrame as its argument and returns a Series. `apply` combines the result for each group together into a new DataFrame.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`.

```python
g[['B', 'C']].apply(lambda x: x.astype(float).max() - x.min())
```

<table>
<thead>
<tr>
<th></th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>a</td>
<td>2.0</td>
</tr>
<tr>
<td>b</td>
<td>0.0</td>
<td>0.0</td>
</tr>
</tbody>
</table>

Example 3: The function passed to `apply` takes a DataFrame as its argument and returns a scalar. `apply` combines the result for each group together into a Series, including setting the index as appropriate:

```python
g.apply(lambda x: x.C.max() - x.B.min())
```

<table>
<thead>
<tr>
<th></th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>5</td>
</tr>
<tr>
<td>b</td>
<td>2</td>
</tr>
</tbody>
</table>

dtype: int64
`pandas.core.groupby.GroupBy.agg`

GroupBy.\texttt{agg}(\texttt{func}, \*\texttt{args}, \**\texttt{kwargs})

`pandas.core.groupby.SeriesGroupBy.aggregate`

SeriesGroupBy.\texttt{aggregate}(\texttt{func=None}, \*\texttt{args}, \texttt{engine=None}, \texttt{engine_kwargs=None}, \**\texttt{kwargs})

Aggregate using one or more operations over the specified axis.

\textbf{Parameters}

- **func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to \texttt{Series.apply}.

  Accepted combinations are:

  - function
  - string function name
  - list of functions and/or function names, e.g. \texttt{[np.sum, 'mean']}.
  - dict of axis labels -> functions, function names or list of such.

  Can also accept a Numba JIT function with \texttt{engine='numba'} specified. Only passing a single function is supported with this engine.

  If the \texttt{'numba'} engine is chosen, the function must be a user defined function with \texttt{values} and \texttt{index} as the first and second arguments respectively in the function signature. Each group’s index will be passed to the user defined function and optionally available for use.

  Changed in version 1.1.0.

- **args** Positional arguments to pass to func.

- **engine** [str, default None]
  - \texttt{'cython'}: Runs the function through C-extensions from cython.
  - \texttt{'numba'}: Runs the function through JIT compiled code from numba.
  - None: Defaults to \texttt{'cython'} or globally setting \texttt{compute.use_numba}

  New in version 1.1.0.

- **engine\_kw\_args** [dict, default None]
  - For \texttt{'cython'} engine, there are no accepted \texttt{engine\_kw\_args}
  - For \texttt{'numba'} engine, the engine can accept \texttt{nopython}, \texttt{nogil} and \texttt{parallel} dictionary keys. The values must either be \texttt{True} or \texttt{False}. The default \texttt{engine\_kw\_args} for the \texttt{'numba'} engine is \texttt{\{'nopython': True, 'nogil': False, 'parallel': False\}} and will be applied to the function.

  New in version 1.1.0.

- **kwargs** Keyword arguments to be passed into func.

\textbf{Returns}

Series

\textbf{See also:}

- \texttt{Series.groupby.apply} Apply function \texttt{func} group-wise and combine the results together.
**Series.groupby.transform** Aggregate using one or more operations over the specified axis.

**Series.aggregate** Transforms the Series on each group based on the given function.

**Notes**

When using `engine='numba'`, there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See [Mutating with User Defined Function (UDF) methods](#) for more details.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`, see the examples below.

**Examples**

```python
>>> s = pd.Series([1, 2, 3, 4])
```

```python
>>> s
0 1
1 2
2 3
3 4
dtype: int64
```

```python
>>> s.groupby([1, 1, 2, 2]).min()
1 1
2 3
dtype: int64
```

```python
>>> s.groupby([1, 1, 2, 2]).agg('min')
1 1
2 3
dtype: int64
```

```python
>>> s.groupby([1, 1, 2, 2]).agg(['min', 'max'])
min max
1 1 2
2 3 4
```

The output column names can be controlled by passing the desired column names and aggregations as keyword arguments.

```python
>>> s.groupby([1, 1, 2, 2]).agg(
...     minimum='min',
...     maximum='max',
... )
minimum maximum
1 1 2
2 3 4
```

Changed in version 1.3.0: The resulting dtype will reflect the return value of the aggregating function.
>>> s.groupby([1, 1, 2, 2]).agg(lambda x: x.astype(float).min())
   1  1.0
   2  3.0
dtype: float64

pandas.core.groupby.DataFrameGroupBy.aggregate

DataFrameGroupBy.aggregate(func=None, *args, engine=None, engine_kwars=None, **kwargs)

Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. [np.sum, 'mean']
- dict of axis labels -> functions, function names or list of such.

Can also accept a Numba JIT function with engine='numba' specified. Only passing a single function is supported with this engine.

If the 'numba' engine is chosen, the function must be a user defined function with values and index as the first and second arguments respectively in the function signature. Each group’s index will be passed to the user defined function and optionally available for use.

Changed in version 1.1.0.

*args Positional arguments to pass to func.

engine [str, default None]

- 'cython': Runs the function through C-extensions from cython.
- 'numba': Runs the function through JIT compiled code from numba.
- None: Defaults to 'cython' or globally setting compute.use_numba

New in version 1.1.0.

engine_kwars [dict, default None]

- For 'cython' engine, there are no accepted engine_kwars
- For 'numba' engine, the engine can accept nopython, nogil and parallel dictionary keys. The values must either be True or False. The default engine_kwars for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False} and will be applied to the function

New in version 1.1.0.

**kwargs Keyword arguments to be passed into func.

Returns

DataFrame
See also:

`DataFrame.groupby.apply` Apply function `func` group-wise and combine the results together.
`DataFrame.groupby.transform` Aggregate using one or more operations over the specified axis.
`DataFrame.aggregate` Transforms the Series on each group based on the given function.

**Notes**

When using `engine='numba'`, there will be no “fall back” behavior internally. The group data and group index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See `Mutating with User Defined Function (UDF) methods` for more details.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`, see the examples below.

**Examples**

```python
>>> df = pd.DataFrame(
...     {
...         "A": [1, 1, 2, 2],
...         "B": [1, 2, 3, 4],
...         "C": [0.362838, 0.227877, 1.267767, -0.562860],
...     }
... )
```

```python
>>> df
   A  B         C
0  1  1   0.362838
1  1  2   0.227877
2  2  3   1.267767
3  2  4  -0.562860
```

The aggregation is for each column.

```python
>>> df.groupby('A').agg('min')
   B    C
A
1  1  0.227877
2  3  -0.562860
```

Multiple aggregations

```python
>>> df.groupby('A').agg(['min', 'max'])
   B      C
min max    min max
A
1  1  2  0.227877  0.362838
2  3  4 -0.562860  1.267767
```

Select a column for aggregation

3.10. GroupBy
Different aggregations per column

```python
>>> df.groupby('A').agg(['min', 'max'])
                   min  max
    A
      1   1   2
      2   3   4
```

To control the output names with different aggregations per column, pandas supports “named aggregation”

```python
>>> df.groupby('A').agg({'B': ['min', 'max'], 'C': 'sum'})
          B  C
     min  max  sum
    A
      1  1.0  2.0  0.590715
      2  3.0  4.0  0.704907
```

- The keywords are the output column names
- The values are tuples whose first element is the column to select and the second element is the aggregation to apply to that column. Pandas provides the `pandas.NamedAgg` namedtuple with the fields 'column', 'aggfunc' to make it clearer what the arguments are. As usual, the aggregation can be a callable or a string alias.

See Named aggregation for more.

Changed in version 1.3.0: The resulting dtypes will reflect the return value of the aggregating function.

```python
>>> df.groupby('A')[['B']].agg(lambda x: x.astype(float).min())
      B
    A
      1  1.0
      2  3.0
```

**pandas.core.groupby.SeriesGroupBy.transform**

SeriesGroupBy.transform(func, *args, engine=None, engine_kwargs=None, **kwargs)

Call function producing a like-indexed Series on each group and return a Series having the same indexes as the original object filled with the transformed values

**Parameters**

- `f` [function] Function to apply to each group.

  Can also accept a Numba JIT function with `engine='numba'` specified.

  If the 'numba' engine is chosen, the function must be a user defined function with `values` and `index` as the first and second arguments respectively in the function signature. Each group’s index will be passed to the user defined function and optionally available for use.

  Changed in version 1.1.0.
*args  Positional arguments to pass to func.

engine  [str, default None]
- 'cython': Runs the function through C-extensions from cython.
- 'numba': Runs the function through JIT compiled code from numba.
- None: Defaults to 'cython' or the global setting compute.use_numba

New in version 1.1.0.

eengine_kwargs  [dict, default None]
- For 'cython' engine, there are no accepted engine_kwargs
- For 'numba' engine, the engine can accept nopython, nogil and parallel
dictionary keys. The values must either be True or False. The default engine_kwargs
for the 'numba' engine is {'nopython': True, 'nogil': False, 'parallel': False} and will be applied to the func-
tion

New in version 1.1.0.

**kwargs  Keyword arguments to be passed into func.

Returns

Series

See also:

Series.groupby.apply  Apply function func group-wise and combine the results together.
Series.groupby.aggregate  Aggregate using one or more operations over the specified axis.
Series.transform  Call func on self producing a Series with transformed values.

Notes

Each group is endowed the attribute ‘name’ in case you need to know which group you are working on.

The current implementation imposes three requirements on f:
- f must return a value that either has the same shape as the input subframe or can be broadcast to the shape
of the input subframe. For example, if f returns a scalar it will be broadcast to have the same shape as the
input subframe.
- if this is a DataFrame, f must support application column-by-column in the subframe. If f also supports
application to the entire subframe, then a fast path is used starting from the second chunk.
- f must not mutate groups. Mutation is not supported and may produce unexpected results. See Mutating
with User Defined Function (UDF) methods for more details.

When using engine='numba', there will be no “fall back” behavior internally. The group data and group
index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts
will be tried.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed func, see the examples
below.
Examples

```python
>>> df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
... 'foo', 'bar'],
... 'B' : ['one', 'one', 'two', 'three',
... 'two', 'two'],
... 'C' : [1, 5, 5, 2, 5, 5],
... 'D' : [2.0, 5., 8., 1., 2., 9.])

>>> grouped = df.groupby('A')
>>> grouped.transform(lambda x: (x - x.mean()) / x.std())

<table>
<thead>
<tr>
<th></th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-1.154701</td>
<td>-0.577350</td>
</tr>
<tr>
<td>1</td>
<td>0.577350</td>
<td>0.000000</td>
</tr>
<tr>
<td>2</td>
<td>0.577350</td>
<td>1.154701</td>
</tr>
<tr>
<td>3</td>
<td>-1.154701</td>
<td>-1.000000</td>
</tr>
<tr>
<td>4</td>
<td>0.577350</td>
<td>-0.577350</td>
</tr>
<tr>
<td>5</td>
<td>0.577350</td>
<td>1.000000</td>
</tr>
</tbody>
</table>
```

Broadcast result of the transformation

```python
>>> grouped.transform(lambda x: x.max() - x.min())

<table>
<thead>
<tr>
<th></th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4.0</td>
<td>6.0</td>
</tr>
<tr>
<td>1</td>
<td>3.0</td>
<td>8.0</td>
</tr>
<tr>
<td>2</td>
<td>4.0</td>
<td>6.0</td>
</tr>
<tr>
<td>3</td>
<td>3.0</td>
<td>8.0</td>
</tr>
<tr>
<td>4</td>
<td>4.0</td>
<td>6.0</td>
</tr>
<tr>
<td>5</td>
<td>3.0</td>
<td>8.0</td>
</tr>
</tbody>
</table>
```

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`, for example:

```python
>>> grouped[['C', 'D']].transform(lambda x: x.astype(int).max())

<table>
<thead>
<tr>
<th></th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>5</td>
<td>8</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>9</td>
</tr>
<tr>
<td>2</td>
<td>5</td>
<td>8</td>
</tr>
<tr>
<td>3</td>
<td>5</td>
<td>9</td>
</tr>
<tr>
<td>4</td>
<td>5</td>
<td>8</td>
</tr>
<tr>
<td>5</td>
<td>5</td>
<td>9</td>
</tr>
</tbody>
</table>
```

**pandas.core.groupby.DataFrameGroupBy.transform**

Call function producing a like-indexed DataFrame on each group and return a DataFrame having the same indexes as the original object filled with the transformed values.

**Parameters**

- `f` [function] Function to apply to each group.

  Can also accept a Numba JIT function with `engine='numba'` specified.

  If the 'numba' engine is chosen, the function must be a user defined function with
  values and index as the first and second arguments respectively in the function
  signature. Each group’s index will be passed to the user defined function and optionally
  available for use.

  Changed in version 1.1.0.
*args  Positional arguments to pass to func.

groupby  [str, default None]

- 'cython': Runs the function through C-extensions from cython.
- 'numba': Runs the function through JIT compiled code from numba.
- None: Defaults to 'cython' or the global setting `compute.use_numba`

New in version 1.1.0.

groupby_kwarg  [dict, default None]

- For 'cython' engine, there are no accepted `groupby_kwarg`
- For 'numba' engine, the engine can accept `nopython`, `nogil` and `parallel`
dictionary keys. The values must either be True or False. The default `groupby_kwarg`
for the 'numba' engine is `{'nopython': True, 'nogil': False, 'parallel': False}` and will be applied to the func-
tion

New in version 1.1.0.

**kwargs  Keyword arguments to be passed into func.

Returns

DataFrame

See also:

- `DataFrame.groupby.apply` Apply function `func` group-wise and combine the results together.
- `DataFrame.groupby.aggregate` Aggregate using one or more operations over the specified axis.
- `DataFrame.transform` Call `func` on self producing a DataFrame with transformed values.

Notes

Each group is endowed the attribute ‘name’ in case you need to know which group you are working on.

The current implementation imposes three requirements on `f`:

- `f` must return a value that either has the same shape as the input subframe or can be broadcast to the shape
  of the input subframe. For example, if `f` returns a scalar it will be broadcast to have the same shape as the
  input subframe.
- if this is a DataFrame, `f` must support application column-by-column in the subframe. If `f` also supports
  application to the entire subframe, then a fast path is used starting from the second chunk.
- `f` must not mutate groups. Mutation is not supported and may produce unexpected results. See Mutating
  with User Defined Function (UDF) methods for more details.

When using `engine='numba'`, there will be no “fall back” behavior internally. The group data and group
index will be passed as numpy arrays to the JITed user defined function, and no alternative execution attempts
will be tried.

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed `func`, see the examples
below.
Examples

```python
>>> df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar',
... 'foo', 'bar'],
... 'B': ['one', 'one', 'two', 'three',
... 'two', 'two'],
... 'C': [1, 5, 5, 2, 5, 5],
... 'D': [2.0, 5., 8., 1., 2., 9.]})
>>> grouped = df.groupby('A')
>>> grouped.transform(lambda x: (x - x.mean()) / x.std())
            C        D
0 -1.154701 -0.577350
1  0.577350  0.000000
2  0.577350  1.154701
3 -1.154701 -1.000000
4  0.577350 -0.577350
5  0.577350  1.000000
```

Broadcast result of the transformation

```python
>>> grouped.transform(lambda x: x.max() - x.min())
            C        D
0          4        6.0
1          3        8.0
2          4        6.0
3          3        8.0
4          4        6.0
5          3        8.0
```

Changed in version 1.3.0: The resulting dtype will reflect the return value of the passed func, for example:

```python
>>> grouped[['C', 'D']].transform(lambda x: x.astype(int).max())
            C        D
0          5        8
1          5        9
2          5        8
3          5        9
4          5        8
5          5        9
```

**pandas.core.groupby.GroupBy.pipe**

GroupBy.pipe (func, *args, **kwargs)

Apply a function `func` with arguments to this GroupBy object and return the function’s result.

Use .pipe when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing

```python
>>> h(g(f(df.groupby('group'))), arg1=a, arg2=b, arg3=c)
```

You can write

```python
>>> (df.groupby('group')
... .pipe(f)
... .pipe(g, arg1=a)
... .pipe(h, arg2=b, arg3=c))
```
which is much more readable.

**Parameters**

- **func** [callable or tuple of (callable, str)] Function to apply to this GroupBy object or, alternatively, a (callable, data_keyword) tuple where data_keyword is a string indicating the keyword of callable that expects the GroupBy object.

- **args** [iterable, optional] Positional arguments passed into func.

- **kwargs** [dict, optional] A dictionary of keyword arguments passed into func.

**Returns**

- **object** [the return type of func.]

**See also:**

- `Series.pipe` Apply a function with arguments to a series.
- `DataFrame.pipe` Apply a function with arguments to a dataframe.
- `apply` Apply function to each group instead of to the full GroupBy object.

**Notes**

See more [here](#).

**Examples**

```python
>>> df = pd.DataFrame({'A': 'a b a b'.split(), 'B': [1, 2, 3, 4]})
>>> df
   A  B
0  a  1
1  b  2
2  a  3
3  b  4
```

To get the difference between each groups maximum and minimum value in one pass, you can do

```python
>>> df.groupby('A').pipe(lambda x: x.max() - x.min())
   B
A
 a  2
 b  2
```

---

**pandas.core.groupby.GroupBy.all**

`GroupBy.all(skipna=True)`

Return True if all values in the group are truthful, else False.

**Parameters**

- `skipna` [bool, default True] Flag to ignore nan values during truth testing.

**Returns**

Series or DataFrame Dataframe or Series of boolean values, where a value is True if all elements are True within its respective group, False otherwise.

**See also:**

- `Series.groupby` Apply a function groupby to a Series.
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.
pandas.core.groupby.GroupBy.any

GroupBy.\texttt{any} \texttt{(skipna=True)}
Return True if any value in the group is truthful, else False.

Parameters

\texttt{skipna} [bool, default True] Flag to ignore nan values during truth testing.

Returns

\texttt{Series or DataFrame} DataFrame or Series of boolean values, where a value is True if any element is True within its respective group, False otherwise.

See also:

\texttt{Series.groupby} Apply a function groupby to a Series.
\texttt{DataFrame.groupby} Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.bfill

GroupBy.\texttt{bfill} \texttt{(limit=None)}
Backward fill the values.

Parameters

\texttt{limit} [int, optional] Limit of how many values to fill.

Returns

\texttt{Series or DataFrame} Object with missing values filled.

See also:

\texttt{Series.backfill} Backward fill the missing values in the dataset.
\texttt{DataFrame.backfill} Backward fill the missing values in the dataset.
\texttt{Series.fillna} Fill NaN values of a Series.
\texttt{DataFrame.fillna} Fill NaN values of a DataFrame.

pandas.core.groupby.GroupBy.backfill

GroupBy.\texttt{backfill} \texttt{(limit=None)}
Backward fill the values.

Parameters

\texttt{limit} [int, optional] Limit of how many values to fill.

Returns

\texttt{Series or DataFrame} Object with missing values filled.

See also:

\texttt{Series.backfill} Backward fill the missing values in the dataset.
\texttt{DataFrame.backfill} Backward fill the missing values in the dataset.
\texttt{Series.fillna} Fill NaN values of a Series.
\texttt{DataFrame.fillna} Fill NaN values of a DataFrame.
pandas.core.groupby.GroupBy.count

GroupBy.count()
Compute count of group, excluding missing values.

Returns
Series or DataFrame Count of values within each group.

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.cumcount

GroupBy.cumcount(ascending=True)
Number each item in each group from 0 to the length of that group - 1.

Essentially this is equivalent to

```python
self.apply(lambda x: pd.Series(np.arange(len(x)), x.index))
```

Parameters

ascending [bool, default True] If False, number in reverse, from length of group - 1 to 0.

Returns

Series Sequence number of each element within each group.

See also:
ngroup Number the groups themselves.

Examples

```python
>>> df = pd.DataFrame([['a'], ['a'], ['a'], ['b'], ['b'], ['a']],
                   columns=['A'])
>>> df
   A
0 a
1 a
2 a
3 b
4 b
5 a
>>> df.groupby('A').cumcount()
0 0
1 1
2 2
3 0
4 1
5 3
dtype: int64
>>> df.groupby('A').cumcount(ascending=False)
0 3
1 2
2 1
3 1
```

(continues on next page)
pandas.core.groupby.GroupBy.cummax

GroupBy.cummax(axis=0, **kwargs)
Cumulative max for each group.
Returns
Series or DataFrame
See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.cummin

GroupBy.cummin(axis=0, **kwargs)
Cumulative min for each group.
Returns
Series or DataFrame
See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.cumprod

GroupBy.cumprod(axis=0, *args, **kwargs)
Cumulative product for each group.
Returns
Series or DataFrame
See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.GroupBy.cumsum

GroupBy.cumsum(axis=0, *args, **kwargs)
Cumulative sum for each group.
Returns
Series or DataFrame
See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.
pandas.core.groupby.GroupBy.ffill

GroupBy.ffill(limit=None)
Forward fill the values.

Parameters

- limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.pad Returns Series with minimum number of char in object.
DataFrame.pad Object with missing values filled or None if inplace=True.
Series.fillna Fill NaN values of a Series.
DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.GroupBy.first

GroupBy.first(numeric_only=False, min_count=-1)
Compute first of group values.

Parameters

- numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
- min_count [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed first of values within each group.

pandas.core.groupby.GroupBy.head

GroupBy.head(n=5)
Return first n rows of each group.

Similar to .apply(lambda x: x.head(n)), but it returns a subset of rows from the original DataFrame with original index and order preserved (as_index flag is ignored).

Does not work for negative values of n.

Returns

Series or DataFrame

See also:

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.
Examples

```python
>>> df = pd.DataFrame([[1, 2], [1, 4], [5, 6]],
...                    columns=['A', 'B'])
>>> df.groupby('A').head(1)
   A  B
0 1  2
2 5  6
>>> df.groupby('A').head(-1)
Empty DataFrame
Columns: [A, B]
Index: []
```

**pandas.core.groupby.GroupBy.last**

GroupBy . last  

`numeric_only=False, min_count=-1`  
Compute last of group values.

**Parameters**

- `numeric_only` [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
- `min_count` [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

**Returns**

Series or DataFrame  
Computed last of values within each group.

**pandas.core.groupby.GroupBy.max**

GroupBy . max  

`numeric_only=False, min_count=-1`  
Compute max of group values.

**Parameters**

- `numeric_only` [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
- `min_count` [int, default -1] The required number of valid values to perform the operation. If fewer than `min_count` non-NA values are present the result will be NA.

**Returns**

Series or DataFrame  
Computed max of values within each group.

**pandas.core.groupby.GroupBy.mean**

GroupBy . mean  

`numeric_only=<no_default>`  
Compute mean of groups, excluding missing values.

**Parameters**

- `numeric_only` [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

**Returns**

pandas.Series or pandas.DataFrame
See also:

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

Examples

```python
df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
                  'B': [np.nan, 2, 3, 4, 5],
                  'C': [1, 2, 1, 1, 2]}, columns=['A', 'B', 'C'])
```

Group by one column and return the mean of the remaining columns in each group.

```python
>>> df.groupby('A').mean()
   B     C
A  3.0  1.333333
  4.0  1.500000
```

Group by two columns and return the mean of the remaining column.

```python
>>> df.groupby(['A', 'B']).mean()
   C
A B
1.0  2.0  2.0
    4.0  1.0
2.0  3.0  1.0
    5.0  2.0
```

Group by one column and return the mean of only particular column in the group.

```python
>>> df.groupby('A')[['B']].mean()
   A
Name: B, dtype: float64
```

pandas.core.groupby.GroupBy.median

GroupBy.median(numeric_only=<no_default>)

Compute median of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

Returns

Series or DataFrame Median of values within each group.

See also:

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.
pandas.core.groupby.GroupBy.min

GroupBy.min(numeric_only=False, min_count=-1)
Compute min of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed min of values within each group.

pandas.core.groupby.GroupBy.ngroup

GroupBy.ngroup(ascending=True)
Number each group from 0 to the number of groups - 1.
This is the enumerative complement of cumcount. Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the groupby object, not the order they are first observed.

Parameters

ascending [bool, default True] If False, number in reverse, from number of group - 1 to 0.

Returns

Series Unique numbers for each group.

See also:

cumcount Number the rows in each group.

Examples

```python
>>> df = pd.DataFrame({"A": list("aaabba")})
>>> df
   A
0  a
1  a
2  a
3  b
4  b
5  a
>>> df.groupby('A').ngroup()
0 0
1 0
2 0
3 1
4 1
5 0
dtype: int64
>>> df.groupby('A').ngroup(ascending=False)
0 1
1 1
2 1
3 0
(continues on next page)```
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
4  0
dtype: int64
>>> df.groupby(["A", [1,1,2,3,2,1]]).ngroup()
0  0
1  0
2  1
3  3
4  2
5  0
dtype: int64
```

### pandas.core.groupby.GroupBy.nth

**GroupBy.** `nth(n, dropna=None)`

Take the nth row from each group if n is an int, or a subset of rows if n is a list of ints.

If dropna, will take the nth non-null row, dropna is either ‘all’ or ‘any’; this is equivalent to calling dropna(how=dropna) before the groupby.

**Parameters**

- **n** [int or list of ints] A single nth value for the row or a list of nth values.
- **dropna** [‘any’, ‘all’, None], default None] Apply the specified dropna operation before counting which row is the nth row.

**Returns**

- **Series** or **DataFrame** N-th value within each group.

**See also:**
- **Series.groupby** Apply a function groupby to a Series.
- **DataFrame.groupby** Apply a function groupby to each row or column of a DataFrame.

**Examples**

```python
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
...                     'B': [np.nan, 2, 3, 4, 5]}, columns=['A', 'B'])
>>> g = df.groupby('A')
>>> g.nth(0)
   B
A
1 NaN
2  3.0
>>> g.nth(1)
   B
A
1   2.0
2   5.0
>>> g.nth(-1)
   B
A
1  4.0
2  5.0
>>> g.nth([0, 1])
```

(continues on next page)
Specifying `dropna` allows count ignoring NaN

```python
>>> g.nth(0, dropna='any')
   B
A
1  2.0
2  3.0
```

NaNs denote group exhausted when using dropna

```python
>>> g.nth(3, dropna='any')
   B
A
1  NaN
2  NaN
```

Specifying `as_index=False` in `groupby` keeps the original index.

```python
>>> df.groupby('A', as_index=False).nth(1)
   A   B
1  1  2.0
4  2  5.0
```

### pandas.core.groupby.GroupBy.ohlc

**GroupBy.ohlc()**

Compute open, high, low and close values of a group, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

**Returns**

DataFrame  Open, high, low and close values within each group.

**See also:**

- `Series.groupby`  Apply a function groupby to a Series.
- `DataFrame.groupby`  Apply a function groupby to each row or column of a DataFrame.

### pandas.core.groupby.GroupBy.pad

**GroupBy.pad(**`limit=None`**)

Forward fill the values.

**Parameters**

- `limit`  [int, optional]  Limit of how many values to fill.

**Returns**

Series or DataFrame  Object with missing values filled.

**See also:**
Series.pad Returns Series with minimum number of char in object.
DataFrame.pad Object with missing values filled or None if inplace=True.
Series.fillna Fill NaN values of a Series.
DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.GroupBy.prod

GroupBy.prod(numeric_only=<no_default>, min_count=0)
Compute prod of group values.

Parameters
numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns
Series or DataFrame Computed prod of values within each group.

pandas.core.groupby.GroupBy.rank

GroupBy.rank(method='average', ascending=True, na_option='keep', pct=False, axis=0)
Provide the rank of values within each group.

Parameters
method [{'average', 'min', 'max', 'first', 'dense'}, default 'average']
  • average: average rank of group.
  • min: lowest rank in group.
  • max: highest rank in group.
  • first: ranks assigned in order they appear in the array.
  • dense: like ‘min’, but rank always increases by 1 between groups.
ascending [bool, default True] False for ranks by high (1) to low (N).
na_option [{'keep', 'top', 'bottom'}, default ‘keep’]
  • keep: leave NA values where they are.
  • top: smallest rank if ascending.
  • bottom: smallest rank if descending.
pct [bool, default False] Compute percentage rank of data within each group.
axis [int, default 0] The axis of the object over which to compute the rank.

Returns
DataFrame with ranking of values within each group

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.
**pandas.core.groupby.GroupBy.pct_change**

GroupBy.pct_change(periods=1, fill_method='pad', limit=None, freq=None, axis=0)

Calculate pct_change of each value to previous entry in group.

**Returns**

- Series or DataFrame  Percentage changes within each group.

**See also:**

- Series.groupby  Apply a function groupby to a Series.
- DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.GroupBy.size**

GroupBy.size()

Compute group sizes.

**Returns**

- DataFrame or Series  Number of rows in each group as a Series if as_index is True or a DataFrame if as_index is False.

**See also:**

- Series.groupby  Apply a function groupby to a Series.
- DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.GroupBy.sem**

GroupBy.sem(ddof=1)

Compute standard error of the mean of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

**Parameters**

- ddof  [int, default 1] Degrees of freedom.

**Returns**

- Series or DataFrame  Standard error of the mean of values within each group.

**See also:**

- Series.groupby  Apply a function groupby to a Series.
- DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.GroupBy.std**

GroupBy.std(ddof=1)

Compute standard deviation of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

**Parameters**

- ddof  [int, default 1] Degrees of freedom.

**Returns**

- Series or DataFrame  Standard deviation of values within each group.

**See also:**

- Series.groupby  Apply a function groupby to a Series.
**Dataframe.groupby**  Apply a function groupby to each row or column of a DataFrame.

### pandas.core.groupby.GroupBy.sum

GroupBy.sum(numeric_only=<no_default>, min_count=0)

Compute sum of group values.

**Parameters**
- **numeric_only** [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
- **min_count** [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

**Returns**
- **Series or DataFrame** Computed sum of values within each group.

### pandas.core.groupby.GroupBy.var

GroupBy.var(ddof=1)

Compute variance of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

**Parameters**
- **ddof** [int, default 1] Degrees of freedom.

**Returns**
- **Series or DataFrame** Variance of values within each group.

See also:
- **Series.groupby** Apply a function groupby to a Series.
- **DataFrame.groupby** Apply a function groupby to each row or column of a DataFrame.

### pandas.core.groupby.GroupBy.tail

GroupBy.tail(n=5)

Return last n rows of each group.

Similar to .apply(lambda x: x.tail(n)), but it returns a subset of rows from the original DataFrame with original index and order preserved (as_index flag is ignored).

Does not work for negative values of n.

**Returns**
- **Series or DataFrame**

See also:
- **Series.groupby** Apply a function groupby to a Series.
- **DataFrame.groupby** Apply a function groupby to each row or column of a DataFrame.
Examples

```python
>>> df = pd.DataFrame([['a', 1], ['a', 2], ['b', 1], ['b', 2]],
                    columns=['A', 'B'])
>>> df.groupby('A').tail(1)
     A  B
1  a  2
3  b  2
>>> df.groupby('A').tail(-1)
Empty DataFrame
Columns: [A, B]
Index: []
```

The following methods are available in both SeriesGroupBy and DataFrameGroupBy objects, but may differ slightly, usually in that the DataFrameGroupBy version usually permits the specification of an axis argument, and often an argument indicating whether to restrict application to columns of a specific data type.

- `DataFrameGroupBy.all([skipna])`: Return True if all values in the group are truthful, else False.
- `DataFrameGroupBy.any([skipna])`: Return True if any value in the group is truthful, else False.
- `DataFrameGroupBy.backfill([limit])`: Backward fill the values.
- `DataFrameGroupBy.bfill([limit])`: Backward fill the values.
- `DataFrameGroupBy.corr()`: Compute pairwise correlation of columns, excluding NA/null values.
- `DataFrameGroupBy.count()`: Compute count of group, excluding missing values.
- `DataFrameGroupBy.cov()`: Compute pairwise covariance of columns, excluding NA/null values.
- `DataFrameGroupBy.cumcount([ascending])`: Number each item in each group from 0 to the length of that group - 1.
- `DataFrameGroupBy.cummax([axis])`: Cumulative max for each group.
- `DataFrameGroupBy.cummin([axis])`: Cumulative min for each group.
- `DataFrameGroupBy.cumprod([axis])`: Cumulative product for each group.
- `DataFrameGroupBy.cumsum([axis])`: Cumulative sum for each group.
- `DataFrameGroupBy.describe(**kwargs)`: Generate descriptive statistics.
- `DataFrameGroupBy.diff()`: First discrete difference of element.
- `DataFrameGroupBy.ffill([limit])`: Forward fill the values.
- `DataFrameGroupBy.fillna()`: Fill NA/NaN values using the specified method.
- `DataFrameGroupBy.filter(func[, dropna])`: Return a copy of a DataFrame excluding filtered elements.
- `DataFrameGroupBy.hist()`: Make a histogram of the DataFrame’s columns.
- `DataFrameGroupBy.idxmax([axis, skipna])`: Return index of first occurrence of maximum over requested axis.
- `DataFrameGroupBy.idxmin([axis, skipna])`: Return index of first occurrence of minimum over requested axis.
- `DataFrameGroupBy.mad()`: Return the mean absolute deviation of the values over the requested axis.
- `DataFrameGroupBy.nunique([dropna])`: Return DataFrame with counts of unique elements in each position.
- `DataFrameGroupBy.pad([limit])`: Forward fill the values.
- `DataFrameGroupBy.pct_change([periods, ...])`: Calculate pct_change of each value to previous entry in group.

**pandas.core.groupby.DataFrameGroupBy.all**

DataFrameGroupBy.all(**skipna=True**)

Return True if all values in the group are truthful, else False.

**Parameters**

- **skipna** [bool, default True] Flag to ignore nan values during truth testing.

**Returns**

Series or DataFrame  DataFrame or Series of boolean values, where a value is True if all elements are True within its respective group, False otherwise.

**See also:**

- Series.groupby  Apply a function groupby to a Series.
- DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.

**pandas.core.groupby.DataFrameGroupBy.any**

DataFrameGroupBy.any(**skipna=True**)

Return True if any value in the group is truthful, else False.

**Parameters**

- **skipna** [bool, default True] Flag to ignore nan values during truth testing.

**Returns**

Series or DataFrame  DataFrame or Series of boolean values, where a value is True if any element is True within its respective group, False otherwise.

**See also:**

- Series.groupby  Apply a function groupby to a Series.
- DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.
pandas.core.groupby.DataFrameGroupBy.backfill

DataFrameGroupBy.backfill(limit=None)
Backward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.backfill Backward fill the missing values in the dataset.
DataFrame.backfill Backward fill the missing values in the dataset.
Series.fillna Fill NaN values of a Series.
DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.bfill

DataFrameGroupBy.bfill(limit=None)
Backward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.backfill Backward fill the missing values in the dataset.
DataFrame.backfill Backward fill the missing values in the dataset.
Series.fillna Fill NaN values of a Series.
DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.corr

property DataFrameGroupBy.corr
Compute pairwise correlation of columns, excluding NA/null values.

Parameters

method [{‘pearson’, ‘kendall’, ‘spearman’} or callable] Method of correlation:
  * pearson : standard correlation coefficient
  * kendall : Kendall Tau correlation coefficient
  * spearman : Spearman rank correlation
  * callable: callable with input two 1d ndarrays and returning a float. Note that the returned matrix from corr will have 1 along the diagonals and will be symmetric regardless of the callable’s behavior.

min_periods [int, optional] Minimum number of observations required per pair of columns to have a valid result.

Returns

DataFrame Correlation matrix.
See also:

**DataFrame.corrwith**  Compute pairwise correlation with another DataFrame or Series.

**Series.corr**  Compute the correlation between two Series.

**Examples**

```python
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v

>>> df = pd.DataFrame([(.2, .3), (.0, .6), (.6, .0), (.2, .1)],
...                    columns=['dogs', 'cats'])

>>> df.corr(method=histogram_intersection)
   dogs   cats
dogs  1.0  0.3
cats  0.3  1.0
```

**pandas.core.groupby.DataFrameGroupBy.count**

DataFrameGroupBy.count()  
Compute count of group, excluding missing values.

**Returns**

- **DataFrame**  Count of values within each group.

**pandas.core.groupby.DataFrameGroupBy.cov**

**property**  DataFrameGroupBy.cov  
Compute pairwise covariance of columns, excluding NA/null values.

Compute the pairwise covariance among the series of a DataFrame. The returned data frame is the covariance matrix of the columns of the DataFrame.

Both NA and null values are automatically excluded from the calculation. (See the note below about bias from missing values.) A threshold can be set for the minimum number of observations for each value created. Comparisons with observations below this threshold will be returned as NaN.

This method is generally used for the analysis of time series data to understand the relationship between different measures across time.

**Parameters**

- **min_periods**  [int, optional] Minimum number of observations required per pair of columns to have a valid result.

- **ddof**  [int, default 1] Delta degrees of freedom. The divisor used in calculations is \( N - ddof \), where \( N \) represents the number of elements.

**Returns**

- **DataFrame**  The covariance matrix of the series of the DataFrame.

See also:

**Series.cov**  Compute covariance with another Series.

**core.window.ExponentialMovingWindow.cov**  Exponential weighted sample covariance.

**core.window.Expanding.cov**  Expanding sample covariance.
core.window.Rolling.cov Rolling sample covariance.

Notes

Returns the covariance matrix of the DataFrame’s time series. The covariance is normalized by N-ddof.

For DataFrames that have Series that are missing data (assuming that data is missing at random) the returned covariance matrix will be an unbiased estimate of the variance and covariance between the member Series.

However, for many applications this estimate may not be acceptable because the estimate covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimate correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.

Examples

```python
def df = pd.DataFrame([(1, 2), (0, 3), (2, 0), (1, 1)],
                     columns=['dogs', 'cats'])
def.cov()
   dogs   cats
dogs  0.666667 -1.000000
cats -1.000000  1.666667
```

```python
np.random.seed(42)
df = pd.DataFrame(np.random.randn(1000, 5),
                  columns=['a', 'b', 'c', 'd', 'e'])
df.cov()
   a     b     c     d     e
a  0.998438 -0.020161 0.059277 -0.008943 0.014144
b -0.020161 1.059352 -0.008543 -0.024738 0.009826
c  0.059277 -0.008543 1.010670 -0.001486 -0.000271
d -0.008943 -0.024738 -0.001486 0.921297 -0.013692
e  0.014144  0.009826 -0.000271 -0.013692 0.977795
```

Minimum number of periods

This method also supports an optional min_periods keyword that specifies the required minimum number of non-NA observations for each column pair in order to have a valid result:

```python
np.random.seed(42)
df = pd.DataFrame(np.random.randn(20, 3),
                  columns=['a', 'b', 'c'])
df.loc[df.index[:5], 'a'] = np.nan
df.loc[df.index[5:10], 'b'] = np.nan
df.cov(min_periods=12)
   a     b     c
a  0.316741 NaN -0.150812
b  NaN  1.248003 0.191417
c -0.150812 0.191417 0.895202
```
pandas.core.groupby.DataFrameGroupBy.cumcount

DataFrameGroupBy.cumcount (ascending=True)

Number each item in each group from 0 to the length of that group - 1.

Essentially this is equivalent to

```python
self.apply(lambda x: pd.Series(np.arange(len(x)), x.index))
```

Parameters

- **ascending** [bool, default True] If False, number in reverse, from length of group - 1 to 0.

Returns

- **Series** Sequence number of each element within each group.

See also:

- `ngroup` Number the groups themselves.

Examples

```python
>>> df = pd.DataFrame([['a'], ['a'], ['a'], ['b'], ['b'], ['a']],
                     columns=['A'])
>>> df
   A
0 a
1 a
2 a
3 b
4 b
5 a
>>> df.groupby('A').cumcount()
0 0
1 1
2 2
3 0
4 1
5 3
dtype: int64
>>> df.groupby('A').cumcount(ascending=False)
0 3
1 2
2 1
3 1
4 0
5 0
dtype: int64
```
pandas.core.groupby.DataFrameGroupBy.cummax

DataFrameGroupBy.cummax(axis=0, **kwargs)
Cumulative max for each group.

Returns
Series or DataFrame

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.cummin

DataFrameGroupBy.cummin(axis=0, **kwargs)
Cumulative min for each group.

Returns
Series or DataFrame

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.cumprod

DataFrameGroupBy.cumprod(axis=0, *args, **kwargs)
Cumulative product for each group.

Returns
Series or DataFrame

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.cumsum

DataFrameGroupBy.cumsum(axis=0, *args, **kwargs)
Cumulative sum for each group.

Returns
Series or DataFrame

See also:
Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.
pandas.core.groupby.DataFrameGroupBy.describe

DataFrameGroupBy.describe(**kwargs)
Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset’s distribution, excluding NaN values.

Analyzes both numeric and object series, as well as DataFrame column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

percentiles [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

include ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for Series. Here are the options:

• ‘all’ : All columns of the input will be included in the output.
• A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit numpy.number. To limit it instead to object columns submit the numpy.object data type. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To select pandas categorical columns, use 'category'
• None (default) : The result will include all numeric columns.

exclude [list-like of dtypes or None (default), optional] A black list of data types to omit from the result. Ignored for Series. Here are the options:

• A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit numpy.number. To exclude object columns submit the data type numpy.object. Strings can also be used in the style of select_dtypes (e.g. df.describe(include=['O'])). To exclude pandas categorical columns, use 'category'
• None (default) : The result will exclude nothing.

datetime_is_numeric [bool, default False] Whether to treat datetime dtypes as numeric. This affects statistics calculated for the column. For DataFrame input, this also controls whether datetime columns are included by default.

New in version 1.1.0.

Returns

Series or DataFrame Summary statistics of the Series or DataFrame provided.

See also:

DataFrame.count Count number of non-NA/null observations.
DataFrame.max Maximum of the values in the object.
DataFrame.min Minimum of the values in the object.
DataFrame.mean Mean of the values.
DataFrame.std Standard deviation of the observations.
DataFrame.select_dtypes Subset of a DataFrame including/excluding columns based on their dtype.
Notes

For numeric data, the result’s index will include `count`, `mean`, `std`, `min`, `max` as well as lower, 50 and upper percentiles. By default the lower percentile is 25 and the upper percentile is 75. The 50 percentile is the same as the median.

For object data (e.g. strings or timestamps), the result’s index will include `count`, `unique`, `top`, and `freq`. The `top` is the most common value. The `freq` is the most common value’s frequency. Timestamps also include the `first` and `last` items.

If multiple object values have the highest count, then the `count` and `top` results will be arbitrarily chosen from among those with the highest count.

For mixed data types provided via a DataFrame, the default is to return only an analysis of numeric columns. If the dataframe consists only of object and categorical data without any numeric columns, the default is to return an analysis of both the object and categorical columns. If `include='all'` is provided as an option, the result will include a union of attributes of each type.

The `include` and `exclude` parameters can be used to limit which columns in a DataFrame are analyzed for the output. The parameters are ignored when analyzing a Series.

Examples

Describing a numeric Series.

```python
>>> s = pd.Series([1, 2, 3])
>>> s.describe()
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
dtype: float64
```

Describing a categorical Series.

```python
>>> s = pd.Series(['a', 'a', 'b', 'c'])
>>> s.describe()
count 4
unique 3
top a
dtype: object
```

Describing a timestamp Series.

```python
>>> s = pd.Series([...
... np.datetime64("2000-01-01"),
... np.datetime64("2010-01-01"),
... np.datetime64("2010-01-01")
... ])
>>> s.describe(datetime_is_numeric=True)
count 3
mean 2006-09-01 08:00:00
```

(continues on next page)
Describing a DataFrame. By default only numeric fields are returned.

```python
>>> df = pd.DataFrame({'categorical': pd.Categorical(['d','e','f']),
...                    'numeric': [1, 2, 3],
...                    'object': ['a', 'b', 'c']
...                 })
>>> df.describe()
numeric
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
```

Describing all columns of a DataFrame regardless of data type.

```python
>>> df.describe(include='all')
categorical numeric object
count 3 3.0 3
unique 3 NaN 3
top f NaN a
freq 1 NaN 1
mean NaN 2.0 NaN
std NaN 1.0 NaN
min NaN 1.0 NaN
25% NaN 1.5 NaN
50% NaN 2.0 NaN
75% NaN 2.5 NaN
max NaN 3.0 NaN
```

Describing a column from a DataFrame by accessing it as an attribute.

```python
>>> df.numeric.describe()
count 3.0
mean 2.0
std 1.0
min 1.0
25% 1.5
50% 2.0
75% 2.5
max 3.0
Name: numeric, dtype: float64
```

Including only numeric columns in a DataFrame description.

```python
>>> df.describe(include=[np.number])
numeric
```

...
Including only string columns in a DataFrame description.

```python
>>> df.describe(include=[object])
    object
count      3
unique     3
top        a
freq       1
```

Including only categorical columns from a DataFrame description.

```python
>>> df.describe(include=['category'])
    categorical
count      3
unique     3
top        d
freq       1
```

Excluding numeric columns from a DataFrame description.

```python
>>> df.describe(exclude=[np.number])
    categorical  object
count      3      3
unique     3      3
top        f      a
freq       1      1
```

Excluding object columns from a DataFrame description.

```python
>>> df.describe(exclude=[object])
    categorical  numeric
count      3      3.0
unique     3      NaN
top        f      NaN
freq       1      NaN
mean       NaN     2.0
std        NaN     1.0
min        NaN     1.0
25%        NaN     1.5
50%        NaN     2.0
75%        NaN     2.5
max        NaN     3.0
```
property DataFrameGroupBy.diff

First discrete difference of element.

Calculates the difference of a Dataframe element compared with another element in the Dataframe (default is element in previous row).

Parameters

- **periods** [int, default 1] Periods to shift for calculating difference, accepts negative values.
- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] Take difference over rows (0) or columns (1).

Returns

- **DataFrame** First differences of the Series.

See also:

- **DataFrame.pct_change** Percent change over given number of periods.
- **DataFrame.shift** Shift index by desired number of periods with an optional time freq.
- **Series.diff** First discrete difference of object.

Notes

For boolean dtypes, this uses `operator.xor()` rather than `operator.sub()`. The result is calculated according to current dtype in Dataframe, however dtype of the result is always float64.

Examples

Difference with previous row

```python
>>> df = pd.DataFrame({'a': [1, 2, 3, 4, 5, 6],
                      'b': [1, 1, 2, 3, 5, 8],
                      'c': [1, 4, 9, 16, 25, 36]})
>>> df
df
   a  b  c
0  1  1  1
1  2  1  4
2  3  2  9
3  4  3 16
4  5  5 25
5  6  8 36
```

```python
>>> df.diff()
df.diff()
   a  b  c
0  NaN NaN NaN
1  1.0 0.0 3.0
2  1.0 1.0 5.0
3  1.0 1.0 7.0
4  1.0 2.0 9.0
5  1.0 3.0 11.0
```

Difference with previous column

```python
>>> df.diff(axis=1)
df.diff(axis=1)
   a  b  c
0  NaN 0  0
1  1.0 1.0 2.0
2  1.0 1.0 2.0
3  1.0 1.0 2.0
4  1.0 1.0 2.0
5  1.0 1.0 2.0
```
Difference with 3rd previous row

```python
>>> df.diff(periods=3)
   a    b    c
0  NaN  NaN  NaN
1  NaN  NaN  NaN
2  NaN  NaN  NaN
3  3.0  2.0  15.0
4  3.0  4.0  21.0
5  3.0  6.0  27.0
```

Difference with following row

```python
>>> df.diff(periods=-1)
   a    b    c
0 -1.0  0.0  -3.0
1 -1.0 -1.0  -5.0
2 -1.0 -1.0  -7.0
3 -1.0 -2.0  -9.0
4 -1.0 -3.0 -11.0
5  NaN  NaN  NaN
```

Overflow in input dtype

```python
>>> df = pd.DataFrame({'a': [1, 0]}, dtype=np.uint8)
>>> df.diff()
   a
0  NaN
1  255.0
```

### pandas.core.groupby.DataFrameGroupBy.ffill

DataFrameGroupBy.ffill(limit=None)
Forward fill the values.

**Parameters**

- **limit**  [int, optional] Limit of how many values to fill.

**Returns**

Series or DataFrame  Object with missing values filled.

**See also:**

Series.pad  Returns Series with minimum number of char in object.
DataFrame.pad  Object with missing values filled or None if inplace=True.
Series.fillna  Fill NaN values of a Series.
DataFrame.fillna  Fill NaN values of a Series.
property DataFrameGroupBy.fillna

Fill NA/NaN values using the specified method.

Parameters

- **value** [scalar, dict, Series, or DataFrame] Value to use to fill holes (e.g. 0), alternately a dict/Series/DataFrame of values specifying which value to use for each index (for a Series) or column (for a DataFrame). Values not in the dict/Series/DataFrame will not be filled. This value cannot be a list.

- **method** ['backfill', 'bfill', 'pad', 'ffill', None], default None Method to use for filling holes in reindexed Series pad / ffill: propagate last valid observation forward to next valid backfill / bfill: use next valid observation to fill gap.

- **axis** [0 or 'index', 1 or 'columns'] Axis along which to fill missing values.

- **inplace** [bool, default False] If True, fill in-place. Note: this will modify any other views on this object (e.g., a no-copy slice for a column in a DataFrame).

- **limit** [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

- **downcast** [dict, default is None] A dict of item->dtype of what to downcast if possible, or the string ‘infer’ which will try to downcast to an appropriate equal type (e.g. float64 to int64 if possible).

Returns

DataFrame or None Object with missing values filled or None if inplace=True.

See also:

- **interpolate** Fill NaN values using interpolation.
- **reindex** Conform object to new index.
- **asfreq** Convert TimeSeries to specified frequency.

Examples

```python
>>> df = pd.DataFrame([np.nan, 2, np.nan, 0],
...                     [3, 4, np.nan, 1],
...                     [np.nan, np.nan, np.nan, 5],
...                     [np.nan, 3, np.nan, 4]],
...                     columns=list("ABCD"))
>>> df
     A     B     C     D
0  NaN  2.0  NaN   0.0
1   3.0  4.0  NaN   1.0
2  NaN  NaN  NaN   5.0
3  NaN  3.0  NaN   4.0
Replace all NaN elements with 0s.

>>> df.fillna(0)
     A     B     C     D
0  0.0  2.0  0.0  0.0
(continues on next page)```
We can also propagate non-null values forward or backward.

```python
>>> df.fillna(method="ffill")
   A   B   C   D
0  NaN 2.0  NaN 0.0
1  3.0 4.0  NaN 1.0
2  3.0 4.0  NaN 5.0
3  3.0 3.0  NaN 4.0
```

Replace all NaN elements in column ‘A’, ‘B’, ‘C’, and ‘D’, with 0, 1, 2, and 3 respectively.

```python
>>> values = {"A": 0, "B": 1, "C": 2, "D": 3}
>>> df.fillna(value=values)
   A   B   C   D
0  0.0 2.0  2.0 0.0
1  3.0 4.0  2.0 1.0
2  0.0 1.0  2.0 5.0
3  0.0 3.0  2.0 4.0
```

Only replace the first NaN element.

```python
>>> df.fillna(value=values, limit=1)
   A   B   C   D
0  0.0 2.0  2.0 0.0
1  3.0 4.0  NaN 1.0
2  NaN 1.0  NaN 5.0
3  NaN 3.0  NaN 4.0
```

When filling using a DataFrame, replacement happens along the same column names and same indices

```python
>>> df2 = pd.DataFrame(np.zeros((4, 4)), columns=list("ABCE"))
>>> df.fillna(df2)
   A   B   C   D
0  0.0 2.0  0.0 0.0
1  3.0 4.0  0.0 1.0
2  NaN 1.0  NaN 5.0
3  NaN 3.0  NaN 4.0
```

---

**pandas.core.groupby.DataFrameGroupBy.filter**

```
DataFrameGroupBy.filter(func, dropna=True, *args, **kwargs)
```

Return a copy of a DataFrame excluding filtered elements.

Elements from groups are filtered if they do not satisfy the boolean criterion specified by func.

**Parameters**

- `func` [function] Function to apply to each subframe. Should return True or False.
- `dropna` [Drop groups that do not pass the filter. True by default:] If False, groups that evaluate False are filled with NaNs.

**Returns**
filtered [DataFrame]

Notes

Each subframe is endowed the attribute ‘name’ in case you need to know which group you are working on.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

Examples

```python
>>> df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
...                        'foo', 'bar'],
...                    'B' : [1, 2, 3, 4, 5, 6],
...                    'C' : [2.0, 5., 8., 1., 2., 9.])
>>> grouped = df.groupby('A')
>>> grouped.filter(lambda x: x['B'].mean() > 3.)
   A  B  C
0  1  bar  2.0
2  3  bar  1.0
4  5  bar  9.0
```

pandas.core.groupby.DataFrameGroupBy.hist

property DataFrameGroupBy.hist

Make a histogram of the DataFrame’s columns.

A histogram is a representation of the distribution of data. This function calls matplotlib.pyplot.hist(), on each series in the DataFrame, resulting in one histogram per column.

Parameters

data [DataFrame] The pandas object holding the data.

column [str or sequence, optional] If passed, will be used to limit data to a subset of columns.

by [object, optional] If passed, then used to form histograms for separate groups.

grid [bool, default True] Whether to show axis grid lines.

xlabelsize [int, default None] If specified changes the x-axis label size.

xrot [float, default None] Rotation of x axis labels. For example, a value of 90 displays the x labels rotated 90 degrees clockwise.

ylabelsize [int, default None] If specified changes the y-axis label size.

yrot [float, default None] Rotation of y axis labels. For example, a value of 90 displays the y labels rotated 90 degrees clockwise.

ax [Matplotlib axes object, default None] The axes to plot the histogram on.

sharex [bool, default True if ax is None else False] In case subplots=True, share x axis and set some x axis labels to invisible; defaults to True if ax is None otherwise False if an ax is passed in. Note that passing in both an ax and sharex=True will alter all x axis labels for all subplots in a figure.

sharey [bool, default False] In case subplots=True, share y axis and set some y axis labels to invisible.
**figsize** [tuple, optional] The size in inches of the figure to create. Uses the value in *matplotlib.rcParams* by default.

**layout** [tuple, optional] Tuple of (rows, columns) for the layout of the histograms.

**bins** [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

**backend** [str, default None] Backend to use instead of the backend specified in the option *plotting.backend*. For instance, ‘matplotlib’. Alternatively, to specify the *plotting.backend* for the whole session, set *pd.options.plotting.backend*.

New in version 1.0.0.

**legend** [bool, default False] Whether to show the legend.

New in version 1.1.0.

**kwargs** All other plotting keyword arguments to be passed to *matplotlib.pyplot.hist*.

Returns

*matplotlib.AxesSubplot* or *numpy.ndarray* of them

See also:

*matplotlib.pyplot.hist* Plot a histogram using *matplotlib*.

**Examples**

This example draws a histogram based on the length and width of some animals, displayed in three bins

```python
>>> df = pd.DataFrame({
...     'length': [1.5, 0.5, 1.2, 0.9, 3],
...     'width': [0.7, 0.2, 0.15, 0.2, 1.1]
... }, index=['pig', 'rabbit', 'duck', 'chicken', 'horse'])
>>> hist = df.hist(bins=3)
```

**pandas.core.groupby.DataFrameGroupBy.idxmax**

*DataFrameGroupBy.idxmax*(axis=0, skipna=True)  
Return index of first occurrence of maximum over requested axis.

NA/null values are excluded.

**Parameters**

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

**Returns**

Series Indexes of maxima along the specified axis.

Raises
ValueError

- If the row/column is empty

See also:

Series.idxmax Return index of the maximum element.

Notes

This method is the DataFrame version of ndarray.argmax.

Examples

Consider a dataset containing food consumption in Argentina.

```python
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48],
... 'co2_emissions': [37.2, 19.66, 1712]},
... index=['Pork', 'Wheat Products', 'Beef'])

>>> df
consumption  co2_emissions
Pork          10.51          37.20
Wheat Products 103.11         19.66
Beef           55.48       1712.00

By default, it returns the index for the maximum value in each column.

>>> df.idxmax()
consumption Wheat Products
co2_emissions Beef
dtype: object

To return the index for the maximum value in each row, use axis="columns".

>>> df.idxmax(axis="columns")
Pork co2_emissions
Wheat Products consumption
Beef co2_emissions
dtype: object
```

pandas.core.groupby.DataFrameGroupBy.idxmin

DataFrameGroupBy.idxmin(axis=0, skipna=True)

Return index of first occurrence of minimum over requested axis.

NA/null values are excluded.

Parameters

- **axis** [{0 or ‘index’, 1 or ‘columns’}, default 0] The axis to use. 0 or ‘index’ for row-wise, 1 or ‘columns’ for column-wise.
- **skipna** [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

Returns

Series Indexes of minima along the specified axis.
pandas: powerful Python data analysis toolkit, Release 1.3.1

Raises

ValueError

• If the row/column is empty

See also:

Series.idxmin Return index of the minimum element.

Notes

This method is the DataFrame version of ndarray.argmin.

Examples

Consider a dataset containing food consumption in Argentina.

```python
>>> df = pd.DataFrame({'consumption': [10.51, 103.11, 55.48], 'co2_emissions': [37.2, 19.66, 1712]}, index=['Pork', 'Wheat Products', 'Beef'])

>>> df
     consumption  co2_emissions
Pork         10.51         37.20
Wheat Products 103.11         19.66
Beef          55.48        1712.00
```

By default, it returns the index for the minimum value in each column.

```python
>>> df.idxmin()
consumption    Pork
co2_emissions  Wheat Products
```

type: object

To return the index for the minimum value in each row, use `axis="columns"`.

```python
>>> df.idxmin(axis="columns")
Pork  consumption
Wheat Products  co2_emissions
Beef       consumption
```

type: object

pandas.core.groupby.DataFrameGroupBy.mad

property DataFrameGroupBy.mad

Return the mean absolute deviation of the values over the requested axis.

Parameters

axis [[index (0), columns (1)]] Axis for the function to be applied on.

skipna [bool, default None] Exclude NA/null values when computing the result.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a Series.

Returns
Series or DataFrame (if level specified)

pandas.core.groupby.DataFrameGroupBy.nunique

DataFrameGroupBy.nunique(dropna=True)
Return DataFrame with counts of unique elements in each position.

Parameters

dropna [bool, default True] Don’t include NaN in the counts.

Returns

nunique: DataFrame

Examples

```python
>>> df = pd.DataFrame({'id': ['spam', 'egg', 'egg', 'spam', ...
...   'ham', 'ham'],
...   'value1': [1, 5, 5, 2, 5, 5],
...   'value2': list('abbaxy'))

>>> df
   id  value1  value2
0   spam     1     a
1    egg     5     b
2    egg     5     b
3   spam     2     a
4    ham     5     x
5    ham     5     y

>>> df.groupby('id').nunique()

   value1  value2
id
egg     1     1
ham     1     2
spam    2     1

Check for rows with the same id but conflicting values:

>>> df.groupby('id').filter(lambda g: (g.nunique() > 1).any())

   id  value1  value2
0   spam     1     a
3   spam     2     a
4    ham     5     x
5    ham     5     y
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.core.groupby.DataFrameGroupBy.pad

DataFrameGroupBy.pad(limit=None)
Forward fill the values.

Parameters

limit [int, optional] Limit of how many values to fill.

Returns

Series or DataFrame Object with missing values filled.

See also:

Series.pad Returns Series with minimum number of char in object.
DataFrame.pad Object with missing values filled or None if inplace=True.
Series.fillna Fill NaN values of a Series.
DataFrame.fillna Fill NaN values of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.pct_change

DataFrameGroupBy.pct_change(periods=1, fill_method='pad', limit=None, freq=None, axis=0)
Calculate pct_change of each value to previous entry in group.

Returns

Series or DataFrame Percentage changes within each group.

See also:

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.plot

property DataFrameGroupBy.plot
Class implementing the .plot attribute for groupby objects.

pandas.core.groupby.DataFrameGroupBy.quantile

DataFrameGroupBy.quantile(q=0.5, interpolation='linear')
Return group values at the given quantile, a la numpy.percentile.

Parameters

q [float or array-like, default 0.5 (50% quantile)] Value(s) between 0 and 1 providing the
quantile(s) to compute.

interpolation [{‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’}] Method to use when the
desired quantile falls between two points.

Returns

Series or DataFrame Return type determined by caller of GroupBy object.

See also:

Series.quantile Similar method for Series.
DataFrame.quantile Similar method for DataFrame.
numpy.percentile NumPy method to compute qth percentile.
Examples

```python
def = pd.DataFrame(
    ... [['a', 1], ['a', 2], ['a', 3],
    ... ['b', 1], ['b', 3], ['b', 5]
    ... ], columns=['key', 'val'])
def.groupby('key').quantile()
```

<table>
<thead>
<tr>
<th>key</th>
<th>val</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>2.0</td>
</tr>
<tr>
<td>b</td>
<td>3.0</td>
</tr>
</tbody>
</table>

**pandas.core.groupby.DataFrameGroupBy.rank**

DataFrameGroupBy.rank (method='average', ascending=True, na_option='keep', pct=False, axis=0)

Provide the rank of values within each group.

**Parameters**

  - average: average rank of group.
  - min: lowest rank in group.
  - max: highest rank in group.
  - first: ranks assigned in order they appear in the array.
  - dense: like ‘min’, but rank always increases by 1 between groups.

- `ascending` [bool, default True] False for ranks by high (1) to low (N).

- `na_option` [{‘keep’, ‘top’, ‘bottom’}, default ‘keep’]
  - keep: leave NA values where they are.
  - top: smallest rank if ascending.
  - bottom: smallest rank if descending.

- `pct` [bool, default False] Compute percentage rank of data within each group.

- `axis` [int, default 0] The axis of the object over which to compute the rank.

**Returns**

DataFrame with ranking of values within each group

**See also:**

- `Series.groupby` Apply a function groupby to a Series.
- `DataFrame.groupby` Apply a function groupby to each row or column of a DataFrame.
pandas: powerful Python data analysis toolkit, Release 1.3.1

**pandas.core.groupby.DataFrameGroupBy.resample**

DataFrameGroupBy.resample(*rule*, **kwargs)

Provide resampling when using a TimeGrouper.

Given a grouper, the function resamples it according to a string “string” -> “frequency”.

See the frequency aliases documentation for more details.

**Parameters**

- **rule** [str or DateOffset] The offset string or object representing target grouper conversion.
- **args**, **kwargs** Possible arguments are how, fill_method, limit, kind, and on, and other arguments of TimeGrouper.

**Returns**

Grouper Return a new grouper with our resampler appended.

See also:

- **Grouper** Specify a frequency to resample with when grouping by a key.
- **DatetimeIndex.resample** Frequency conversion and resampling of time series.

**Examples**

```python
>>> idx = pd.date_range('1/1/2000', periods=4, freq='T')
>>> df = pd.DataFrame(data=4 * [range(2)],
...                   index=idx,
...                   columns=['a', 'b'])
>>> df.iloc[2, 0] = 5
>>> df
   a    b
2000-01-01 00:00:00 0 1
2000-01-01 00:01:00 0 1
2000-01-01 00:02:00 5 1
2000-01-01 00:03:00 0 1

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 2000-01-01 00:00:00</td>
<td>0 2</td>
</tr>
<tr>
<td>2000-01-01 00:01:00</td>
<td>0 1</td>
</tr>
<tr>
<td>2000-01-01 00:02:00</td>
<td>0 1</td>
</tr>
<tr>
<td>5 2000-01-01 00:03:00</td>
<td>5 1</td>
</tr>
</tbody>
</table>

Downsample the DataFrame into 3 minute bins and sum the values of the timestamps falling into a bin.

```python
>>> df.groupby('a').resample('3T').sum()
   a    b
      a
0 2000-01-01 00:00:00 0 2
   2000-01-01 00:03:00 0 1
   5 2000-01-01 00:00:00 5 1
```

Upsample the series into 30 second bins.

```python
>>> df.groupby('a').resample('30S').sum()
   a    b
      a
0 2000-01-01 00:00:00 0 1
   2000-01-01 00:00:30 0 0
   2000-01-01 00:01:00 0 1
   2000-01-01 00:01:30 0 0
   2000-01-01 00:02:00 0 0
   2000-01-01 00:02:30 0 0
   2000-01-01 00:03:00 0 1
   5 2000-01-01 00:02:00 5 1
```
Resample by month. Values are assigned to the month of the period.

```python
>>> df.groupby('a').resample('M').sum()
df
a  b
0  2000-01-31 0 3
5  2000-01-31 5 1
```

Downsample the series into 3 minute bins as above, but close the right side of the bin interval.

```python
>>> df.groupby('a').resample('3T', closed='right').sum()
da  b
0  1999-12-31 23:57:00 0 1
  2000-01-01 00:00:00 0 2
5  2000-01-01 00:00:00 5 1
```

Downsample the series into 3 minute bins and close the right side of the bin interval, but label each bin using the right edge instead of the left.

```python
>>> df.groupby('a').resample('3T', closed='right', label='right').sum()
da  b
0  2000-01-01 00:00:00 0 1
  2000-01-01 00:03:00 0 2
5  2000-01-01 00:03:00 5 1
```

### pandas.core.groupby.DataFrameGroupBy.sample

DataFrameGroupBy. `sample` (n=None, frac=None, replace=False, weights=None, random_state=None)

Return a random sample of items from each group.

You can use `random_state` for reproducibility.

New in version 1.1.0.

**Parameters**

- `n` [int, optional] Number of items to return for each group. Cannot be used with `frac` and must be no larger than the smallest group unless `replace` is True. Default is one if `frac` is None.

- `frac` [float, optional] Fraction of items to return. Cannot be used with `n`.

- `replace` [bool, default False] Allow or disallow sampling of the same row more than once.

- `weights` [list-like, optional] Default None results in equal probability weighting. If passed a list-like then values must have the same length as the underlying DataFrame or Series object and will be used as sampling probabilities after normalization within each group. Values must be non-negative with at least one positive element within each group.

- `random_state` [int, array-like, BitGenerator, np.random.RandomState, optional] If int, array-like, or BitGenerator (NumPy>=1.17), seed for random number generator If np.random.RandomState, use as numpy RandomState object.

**Returns**

- Series or DataFrame A new object of same type as caller containing items randomly sampled within each group from the caller object.

**See also:**

3.10. GroupBy
**DataFrame.sample** Generate random samples from a DataFrame object.

**numpy.random.choice** Generate a random sample from a given 1-D numpy array.

### Examples

```python
code snippet
>>> df = pd.DataFrame(
    ...   {
    ...     "a": ["red"] * 2 + ["blue"] * 2 + ["black"] * 2,
    ...     "b": range(6)
    ...   }
    ...)
>>> df
       a  b
0  red  0
1  red  1
2  blue  2
3  blue  3
4  black  4
5  black  5

Select one row at random for each distinct value in column a. The `random_state` argument can be used to guarantee reproducibility:

```python
code snippet
>>> df.groupby("a").sample(n=1, random_state=1)
       a  b
0  red  0
2  blue  2
1  red  1
```

Set `frac` to sample fixed proportions rather than counts:

```python
code snippet
>>> df.groupby("a")["b"].sample(frac=0.5, random_state=2)
    0  0
   2  2
   5  5
Name: b, dtype: int64
```

Control sample probabilities within groups by setting weights:

```python
code snippet
>>> df.groupby("a").sample(
    ...   n=1,
    ...   weights=[1, 1, 1, 0, 0, 1],
    ...   random_state=1,
    ...)
       a  b
0  red  0
2  blue  2
5  black  5
```
pandas.core.groupby.DataFrameGroupBy.shift

DataFrameGroupBy.shift (periods=1, freq=None, axis=0, fill_value=None)
Shift each group by periods observations.
If freq is passed, the index will be increased using the periods and the freq.
Parameters
  periods [int, default 1] Number of periods to shift.
  freq [str, optional] Frequency string.
  axis [axis to shift, default 0] Shift direction.
  fill_value [optional] The scalar value to use for newly introduced missing values.
Returns
  Series or DataFrame Object shifted within each group.
See also:
  Index.shift Shift values of Index.
  tshift Shift the time index, using the index’s frequency if available.

pandas.core.groupby.DataFrameGroupBy.size

DataFrameGroupBy.size()
Compute group sizes.
Returns
  DataFrame or Series Number of rows in each group as a Series if as_index is True or a
  DataFrame if as_index is False.
See also:
  Series.groupby Apply a function groupby to a Series.
  DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.groupby.DataFrameGroupBy.skew

property DataFrameGroupBy.skew
Return unbiased skew over requested axis.
Normalized by N-1.
Parameters
  axis [{index (0), columns (1)] Axis for the function to be applied on.
  skipna [bool, default True] Exclude NA/null values when computing the result.
  level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along
  a particular level, collapsing into a Series.
  numeric_only [bool, default None] Include only float, int, boolean columns. If None, will
  attempt to use everything, then use only numeric data. Not implemented for Series.
  **kwargs Additional keyword arguments to be passed to the function.
Returns
  Series or DataFrame (if level specified)
property DataFrameGroupBy.take

Return the elements in the given positional indices along an axis.

This means that we are not indexing according to actual values in the index attribute of the object. We are indexing according to the actual position of the element in the object.

Parameters

- **indices** [array-like] An array of ints indicating which positions to take.
- **axis** [{0 or 'index', 1 or 'columns', None}, default 0] The axis on which to select elements.
  - 0 means that we are selecting rows, 1 means that we are selecting columns.
- **is_copy** [bool] Before pandas 1.0, is_copy=False can be specified to ensure that the return value is an actual copy. Starting with pandas 1.0, take always returns a copy, and the keyword is therefore deprecated.
  - Deprecated since version 1.0.0.
- **kwargs** For compatibility with numpy.take(). Has no effect on the output.

Returns

- **taken** [same type as caller] An array-like containing the elements taken from the object.

See also:

- **DataFrame.loc** Select a subset of a DataFrame by labels.
- **DataFrame.iloc** Select a subset of a DataFrame by positions.
- **numpy.take** Take elements from an array along an axis.

Examples

```python
>>> df = pd.DataFrame([('falcon', 'bird', 389.0),
...                     ('parrot', 'bird', 24.0),
...                     ('lion', 'mammal', 80.5),
...                     ('monkey', 'mammal', np.nan)],
...                     columns=['name', 'class', 'max_speed'],
...                     index=[0, 2, 3, 1])
```

```python
df
```
```
name  class     max_speed
0     falcon  bird         389.0
2     parrot  bird          24.0
3     lion    mammal       80.5
1     monkey  mammal        NaN
```

Take elements at positions 0 and 3 along the axis 0 (default).

Note how the actual indices selected (0 and 1) do not correspond to our selected indices 0 and 3. That’s because we are selecting the 0th and 3rd rows, not rows whose indices equal 0 and 3.

```python
>>> df.take([0, 3])
```
```
name  class     max_speed
0     falcon  bird         389.0
1     monkey  mammal        NaN
```

Take elements at indices 1 and 2 along the axis 1 (column selection).
We may take elements using negative integers for positive indices, starting from the end of the object, just like with Python lists.

```python
>>> df.take([-1, -2])
name   class  max_speed
1  monkey  mammal       NaN
3    lion  mammal       80.5
```

### pandas.core.groupby.DataFrameGroupBy.tshift

**property** DataFrameGroupBy.tshift

Shift the time index, using the index’s frequency if available.

Deprecated since version 1.1.0: Use shift instead.

**Parameters**

- **periods** [int] Number of periods to move, can be positive or negative.
- **freq** [DateOffset, timedelta, or str, default None] Increment to use from the tseries module or time rule expressed as a string (e.g. ‘EOM’).
- **axis** [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Corresponds to the axis that contains the Index.

**Returns**

shifted [Series/DataFrame]

**Notes**

If freq is not specified then tries to use the freq or inferred_freq attributes of the index. If neither of those attributes exist, a ValueError is thrown.

The following methods are available only for SeriesGroupBy objects.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SeriesGroupBy.hist</td>
<td>Draw histogram of the input series using matplotlib.</td>
</tr>
<tr>
<td>SeriesGroupBy.nlargest</td>
<td>Return the largest ( n ) elements.</td>
</tr>
<tr>
<td>SeriesGroupBy.nsmallest</td>
<td>Return the smallest ( n ) elements.</td>
</tr>
<tr>
<td>SeriesGroupBy.unique</td>
<td>Return number of unique elements in the group.</td>
</tr>
<tr>
<td>SeriesGroupBy.unique</td>
<td>Return unique values of Series object.</td>
</tr>
<tr>
<td>SeriesGroupBy.value_counts</td>
<td>Alias for is_monotonic.</td>
</tr>
<tr>
<td>SeriesGroupBy.is_monotonic_increasing</td>
<td>Return boolean if values in the object are monotonic_increasing.</td>
</tr>
<tr>
<td>SeriesGroupBy.is_monotonic_decreasing</td>
<td>Return boolean if values in the object are monotonic_decreasing.</td>
</tr>
</tbody>
</table>
pandas.core.groupby.SeriesGroupBy.hist

**property SeriesGroupBy.hist**

Draw histogram of the input series using matplotlib.

**Parameters**

- `by` [object, optional] If passed, then used to form histograms for separate groups.
- `ax` [matplotlib axis object] If not passed, uses gca().
- `grid` [bool, default True] Whether to show axis grid lines.
- `xlabelsize` [int, default None] If specified changes the x-axis label size.
- `xrot` [float, default None] Rotation of x axis labels.
- `ylabelsize` [int, default None] If specified changes the y-axis label size.
- `yrot` [float, default None] Rotation of y axis labels.
- `figsize` [tuple, default None] Figure size in inches by default.
- `bins` [int or sequence, default 10] Number of histogram bins to be used. If an integer is given, bins + 1 bin edges are calculated and returned. If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.
- `backend` [str, default None] Backend to use instead of the backend specified in the option `plotting.backend`. For instance, ‘matplotlib’. Alternatively, to specify the `plotting.backend` for the whole session, set `pd.options.plotting.backend`.

New in version 1.0.0.

- `legend` [bool, default False] Whether to show the legend.

New in version 1.1.0.

- `**kwargs` To be passed to the actual plotting function.

**Returns**

- `matplotlib.AxesSubplot` A histogram plot.

**See also:**

- `matplotlib.axes.Axes.hist` Plot a histogram using matplotlib.

pandas.core.groupby.SeriesGroupBy.nlargest

**property SeriesGroupBy.nlargest**

Return the largest \( n \) elements.

**Parameters**

- `n` [int, default 5] Return this many descending sorted values.
- `keep` [{'first', 'last', 'all'}, default 'first'] When there are duplicate values that cannot all fit in a Series of \( n \) elements:
  - 'first' [return the first \( n \) occurrences in order] of appearance.
  - 'last' [return the last \( n \) occurrences in reverse order] of appearance.
  - 'all' [keep all occurrences. This can result in a Series of] size larger than \( n \).

**Returns**
Series  The \( n \) largest values in the Series, sorted in decreasing order.

See also:
Series.nsmallest  Get the \( n \) smallest elements.
Series.sort_values  Sort Series by values.
Series.head  Return the first \( n \) rows.

Notes
Faster than `.sort_values(ascending=False).head(n)` for small \( n \) relative to the size of the Series object.

Examples

```python
>>> countries_population = {"Italy": 59000000, "France": 65000000,
...   "Malta": 434000, "Maldives": 434000,
...   "Brunei": 434000, "Iceland": 337000,
...   "Nauru": 11300, "Tuvalu": 11300,
...   "Anguilla": 11300, "Montserrat": 5200}
>>> s = pd.Series(countries_population)
>>> s
Italy     59000000
France    65000000
Malta     434000
Maldives  434000
Brunei    434000
Iceland   337000
Nauru     11300
Tuvalu    11300
Anguilla  11300
Montserrat 5200
dtype: int64
```

The \( n \) largest elements where \( n=5 \) by default.

```python
>>> s.nlargest()
France     65000000
Italy      59000000
Malta      434000
Maldives   434000
Brunei     434000
dtype: int64
```

The \( n \) largest elements where \( n=3 \). Default `keep` value is ‘first’ so Malta will be kept.

```python
>>> s.nlargest(3)
France     65000000
Italy      59000000
Malta      434000
```

The \( n \) largest elements where \( n=3 \) and keeping the last duplicates. Brunei will be kept since it is the last with value 434000 based on the index order.
The $n$ largest elements where $n=3$ with all duplicates kept. Note that the returned Series has five elements due to the three duplicates.

```python
>>> s.nlargest(3, keep='all')
France    65000000
Italy     59000000
Malta     4340000
Maldives  4340000
Brunei    4340000
dtype: int64
```

The `pandas.core.groupby.SeriesGroupBy.nsmallest` property

**SeriesGroupBy.nsmallest**

Return the smallest $n$ elements.

**Parameters**

- **n** [int, default 5] Return this many ascending sorted values.
- **keep** [‘first’, ‘last’, ‘all’], default ‘first’ When there are duplicate values that cannot all fit in a Series of $n$ elements:
  - **first** [return the first $n$ occurrences in order] of appearance.
  - **last** [return the last $n$ occurrences in reverse] order of appearance.
  - **all** [keep all occurrences. This can result in a Series of] size larger than $n$.

**Returns**

**Series** The $n$ smallest values in the Series, sorted in increasing order.

**See also:**

- **Series.nlargest** Get the $n$ largest elements.
- **Series.sort_values** Sort Series by values.
- **Series.head** Return the first $n$ rows.

**Notes**

Faster than `.sort_values().head(n)` for small $n$ relative to the size of the `Series` object.
Examples

```python
>>> countries_population = {"Italy": 59000000, "France": 65000000,
... "Brunei": 434000, "Malta": 434000,
... "Maldives": 434000, "Iceland": 337000,
... "Nauru": 11300, "Tuvalu": 11300,
... "Anguilla": 11300, "Montserrat": 5200}

>>> s = pd.Series(countries_population)
>>> s
Italy     59000000
France    65000000
Brunei    434000
Malta     434000
Maldives  434000
Iceland   337000
Nauru     11300
Tuvalu    11300
Anguilla  11300
Montserrat 5200
dtype: int64

The $n$ smallest elements where $n=5$ by default.

```python
>>> s.nsmallest ()
Montserrat     5200
Nauru          11300
Tuvalu         11300
Anguilla       11300
Iceland        337000
dtype: int64
```

The $n$ smallest elements where $n=3$. Default keep value is ‘first’ so Nauru and Tuvalu will be kept.

```python
>>> s.nsmallest (3)
Montserrat     5200
Nauru          11300
Tuvalu         11300
dtype: int64
```

The $n$ smallest elements where $n=3$ and keeping the last duplicates. Anguilla and Tuvalu will be kept since they are the last with value 11300 based on the index order.

```python
>>> s.nsmallest (3, keep='last')
Montserrat     5200
Anguilla       11300
Tuvalu         11300
dtype: int64
```

The $n$ smallest elements where $n=3$ with all duplicates kept. Note that the returned Series has four elements due to the three duplicates.

```python
>>> s.nsmallest (3, keep='all')
Montserrat     5200
Nauru          11300
Tuvalu         11300
Anguilla       11300
dtype: int64
```
pandas.core.groupby.SeriesGroupBy.nunique

`SeriesGroupBy.nunique(dropna=True)`

Return number of unique elements in the group.

**Returns**

*Series*  Number of unique values within each group.

pandas.core.groupby.SeriesGroupBy.unique

**property**  `SeriesGroupBy.unique`

Return unique values of Series object.

Uniques are returned in order of appearance. Hash table-based unique, therefore does NOT sort.

**Returns**

*ndarray or ExtensionArray*  The unique values returned as a NumPy array. See Notes.

See also:

unique Top-level unique method for any 1-d array-like object.

Index.unique Return Index with unique values from an Index object.

Notes

Returns the unique values as a NumPy array. In case of an extension-array backed Series, a new ExtensionArray of that type with just the unique values is returned. This includes

- Categorical
- Period
- Datetime with Timezone
- Interval
- Sparse
- IntegerNA

See Examples section.

Examples

```python
>>> pd.Series([2, 1, 3, 3], name='A').unique()
array([2, 1, 3])
```

```python
>>> pd.Series([pd.Timestamp('2016-01-01') for _ in range(3)]).unique()
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```python
>>> pd.Series([pd.Timestamp('2016-01-01', tz='US/Eastern')
... for _ in range(3)]).unique()
< DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]
```

An Categorical will return categories in the order of appearance and with the same dtype.

```python
>>> pd.Series(pd.Categorical(list('baabc'))).unique()
['b', 'a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.1

```python
>>> pd.Series(pd.Categorical(list('baabc'), categories=list('abc'),
    ...          ordered=True)).unique()
['b', 'a', 'c']
Categories (3, object): ['a' < 'b' < 'c']
```

**pandas.core.groupby.SeriesGroupBy.value_counts**

SeriesGroupBy.value_counts(normalize=False, sort=True, ascending=False, bins=None, dropna=True)

**pandas.core.groupby.SeriesGroupBy.is_monotonic_increasing**

property SeriesGroupBy.is_monotonic_increasing

Alias for is_monotonic.

**pandas.core.groupby.SeriesGroupBy.is_monotonic_decreasing**

property SeriesGroupBy.is_monotonic_decreasing

Return boolean if values in the object are monotonic_decreasing.

Returns

bool

The following methods are available only for DataFrameGroupBy objects.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataFrameGroupBy.corrwith</td>
<td>Compute pairwise correlation.</td>
</tr>
<tr>
<td>DataFrameGroupBy.boxplot([...])</td>
<td>Make box plots from DataFrameGroupBy data.</td>
</tr>
</tbody>
</table>

**pandas.core.groupby.DataFrameGroupBy.corrwith**

property DataFrameGroupBy.corrwith

Compute pairwise correlation.

Pairwise correlation is computed between rows or columns of DataFrame with rows or columns of Series or DataFrame. DataFrames are first aligned along both axes before computing the correlations.

Parameters

- other [DataFrame, Series] Object with which to compute correlations.
- axis [0 or ‘index’, 1 or ‘columns’], default 0 The axis to use. 0 or ‘index’ to compute column-wise, 1 or ‘columns’ for row-wise.
- drop [bool, default False] Drop missing indices from result.
- method [‘pearson’, ‘kendall’, ‘spearman’] or callable] Method of correlation:
  - pearson : standard correlation coefficient
  - kendall : Kendall Tau correlation coefficient
  - spearman : Spearman rank correlation
  - callable: callable with input two 1d ndarrays and returning a float.
Returns

Series  Pairwise correlations.

See also:

DataFrame.corr  Compute pairwise correlation of columns.

pandas.core.groupby.DataFrameGroupBy.boxplot

df.boxplot(subplots=True, column=None, fontsize=None, rot=0, grid=True, ax=None, figsize=None, layout=None, sharex=False, sharey=True, backend=None, **kwargs)

Make box plots from DataFrameGroupBy data.

Parameters

grouped  [Grouped DataFrame]

subplots  [bool]
  • False - no subplots will be used
  • True - create a subplot for each group.

column  [column name or list of names, or vector] Can be any valid input to groupby.

fontsize  [int or str]

rot  [label rotation angle]

grid  [Setting this to True will show the grid]

ax  [Matplotlib axis object, default None]

figsize  [A tuple (width, height) in inches]

layout  [tuple (optional)] The layout of the plot: (rows, columns).

sharex  [bool, default False] Whether x-axes will be shared among subplots.

sharey  [bool, default True] Whether y-axes will be shared among subplots.

backend  [str, default None] Backend to use instead of the backend specified in the op-
tion plotting.backend. For instance, ‘matplotlib’. Alternatively, to specify the plotting.backend for the whole session, set pd.options.plotting.

backend.

New in version 1.0.0.

**kwargs  All other plotting keyword arguments to be passed to matplotlib’s boxplot func-
tion.

Returns

dict of key/value = group key/DataFrame.boxplot return value

or DataFrame.boxplot return value in case subplots=figures=False
Examples

You can create boxplots for grouped data and show them as separate subplots:

```python
>>> import itertools
>>> tuples = [(t for t in itertools.product(range(1000), range(4))]
>>> index = pd.MultiIndex.from_tuples(tuples, names=['lvl0', 'lvl1'])
>>> data = np.random.randn(len(index), 4)
>>> df = pd.DataFrame(data, columns=list('ABCD'), index=index)
>>> grouped = df.groupby(level='lvl1')
>>> grouped.boxplot(rot=45, fontsize=12, figsize=(8,10))
```

The `subplots=False` option shows the boxplots in a single figure.

```python
>>> grouped.boxplot(subplots=False, rot=45, fontsize=12)
```

3.11 Resampling

Resampler objects are returned by resample calls: `pandas.DataFrame.resample()`, `pandas.Series.resample()`.

3.11.1 Indexing, iteration

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Resampler.__iter__()</code></td>
<td>Groupby iterator.</td>
</tr>
<tr>
<td><code>Resampler.groups</code></td>
<td>Dict {group name -&gt; group labels}.</td>
</tr>
<tr>
<td><code>Resampler.indices</code></td>
<td>Dict {group name -&gt; group indices}.</td>
</tr>
<tr>
<td><code>Resampler.get_group(name[, obj])</code></td>
<td>Construct DataFrame from group with provided name.</td>
</tr>
</tbody>
</table>

```python
pandas.core.resample.Resampler.__iter__

Resampler.__iter__()
Groupby iterator.

Returns
Generator yielding sequence of (name, subsetted object)
for each group
```
Chapter 3. API reference
pandas.core.resample.Resampler.groups

**property** Resampler.groups
   Dict {group name -> group labels}.

pandas.core.resample.Resampler.indices

**property** Resampler.indices
   Dict {group name -> group indices}.

pandas.core.resample.Resampler.get_group

Resampler.get_group(name, obj=None)
   Construct DataFrame from group with provided name.

   **Parameters**
   name [object] The name of the group to get as a DataFrame.
   obj [DataFrame, default None] The DataFrame to take the DataFrame out of. If it is None, the object groupby was called on will be used.

   **Returns**
   group [same type as obj]

3.11.2 Function application

<table>
<thead>
<tr>
<th>Resampler.apply(func, *args, **kwargs)</th>
<th>Aggregate using one or more operations over the specified axis.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resampler.aggregate(func, *args, **kwargs)</td>
<td>Aggregate using one or more operations over the specified axis.</td>
</tr>
<tr>
<td>Resampler.transform(arg, *args, **kwargs)</td>
<td>Call function producing a like-indexed Series on each group and return a Series with the transformed values.</td>
</tr>
<tr>
<td>Resampler.pipe(func, *args, **kwargs)</td>
<td>Apply a function func with arguments to this Resampler object and return the function’s result.</td>
</tr>
</tbody>
</table>

pandas.core.resample.Resampler.apply

Resampler.apply(func, *args, **kwargs)
   Aggregate using one or more operations over the specified axis.

   **Parameters**
   func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.

   Accepted combinations are:
   - function
   - string function name
   - list of functions and/or function names, e.g. [np.sum, 'mean']
   - dict of axis labels -> functions, function names or list of such.
*args  Positional arguments to pass to func.

**kwargs  Keyword arguments to pass to func.

Returns

scalar, Series or DataFrame  The return can be:

• scalar : when Series.agg is called with single function
• Series : when DataFrame.agg is called with a single function
• DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

DataFrame.groupby.aggregate  Aggregate using callable, string, dict, or list of string/callables.

DataFrame.resample.transform  Transforms the Series on each group based on the given function.

DataFrame.aggregate  Aggregate using one or more operations over the specified axis.

Notes

agg is an alias for aggregate. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```python
>>> s = pd.Series([1,2,3,4,5],
                  index=pd.date_range('20130101', periods=5,freq='s'))
  2013-01-01 00:00:00    1
  2013-01-01 00:00:01    2
  2013-01-01 00:00:02    3
  2013-01-01 00:00:03    4
  2013-01-01 00:00:04    5
Freq: S, dtype: int64

>>> r = s.resample('2s')
```

```
DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left,
                        label=left, convention=start]
```

```python
>>> r.agg(np.sum)
  2013-01-01 00:00:00    3
  2013-01-01 00:00:02    7
  2013-01-01 00:00:04    5
Freq: 2S, dtype: int64
```

```python
>>> r.agg(['sum','mean','max'])
  sum  mean  max
2013-01-01 00:00:00   3    1.5  2
2013-01-01 00:00:02   7    3.5  4
2013-01-01 00:00:04   5    5.0  5
```

3.11. Resampling
>>> r.agg({'result': lambda x: x.mean() / x.std(),
           'total': np.sum})

pandas.core.resample.Resampler.aggregate

Resampler.aggregate(func, *args, **kwargs)

Aggregate using one or more operations over the specified axis.

Parameters

- **func** [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a DataFrame or when passed to DataFrame.apply.
  Accepted combinations are:
  - function
  - string function name
  - list of functions and/or function names, e.g. [np.sum, 'mean']
  - dict of axis labels -> functions, function names or list of such.

- *args Positional arguments to pass to func.

- **kwargs Keyword arguments to pass to func.

Returns

- scalar, Series or DataFrame The return can be:
  - scalar : when Series.agg is called with single function
  - Series : when DataFrame.agg is called with a single function
  - DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

- DataFrame.groupby.aggregate Aggregate using callable, string, dict, or list of string/callables.
- DataFrame.resample.transform Transforms the Series on each group based on the given function.
- DataFrame.aggregate Aggregate using one or more operations over the specified axis.

Notes

agg is an alias for aggregate. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See Mutating with User Defined Function (UDF) methods for more details.

A passed user-defined-function will be passed a Series for evaluation.
Examples

```python
>>> s = pd.Series([1,2,3,4,5],
    index=pd.date_range('20130101', periods=5,freq='s'))
2013-01-01 00:00:00 1
2013-01-01 00:00:01 2
2013-01-01 00:00:02 3
2013-01-01 00:00:03 4
2013-01-01 00:00:04 5
Freq: S, dtype: int64
```

```python
>>> r = s.resample('2s')
DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left,
    label=left, convention=start]
```

```python
>>> r.agg(np.sum)
2013-01-01 00:00:00 3
2013-01-01 00:00:02 7
2013-01-01 00:00:04 5
Freq: 2S, dtype: int64
```

```python
>>> r.agg(['sum','mean','max'])
  sum  mean  max
2013-01-01 00:00:00  3  1.5  2
2013-01-01 00:00:02  7  3.5  4
2013-01-01 00:00:04  5  5.0  5
```

```python
>>> r.agg({'result' : lambda x: x.mean() / x.std(),
    'total' : np.sum})
  total  result
2013-01-01 00:00:00  3  2.121320
2013-01-01 00:00:02  7  4.949747
2013-01-01 00:00:04  5 NaN
```

```
pandas.core.resample.Resampler.transform
```

Resampler.transform(arg, *args, **kwargs)

Call function producing a like-indexed Series on each group and return a Series with the transformed values.

- **Parameters**
  - arg  [function] To apply to each group. Should return a Series with the same index.

- **Returns**
  - transformed  [Series]
Examples

```python
>>> resampled.transform(lambda x: (x - x.mean()) / x.std())
```

pandas.core.resample.Resampler.pipe

Resampler.pipe(func, *args, **kwargs)

Apply a function `func` with arguments to this Resampler object and return the function’s result.

Use `.pipe` when you want to improve readability by chaining together functions that expect Series, DataFrames, GroupBy or Resampler objects. Instead of writing

```python
>>> h(g(f(df.groupby('group')), arg1=a), arg2=b, arg3=c)
```

You can write

```python
>>> (df.groupby('group')
... .pipe(f)
... .pipe(g, arg1=a)
... .pipe(h, arg2=b, arg3=c))
```

which is much more readable.

**Parameters**

- **func** [callable or tuple of (callable, str)] Function to apply to this Resampler object or, alternatively, a `(callable, data_keyword)` tuple where `data_keyword` is a string indicating the keyword of `callable` that expects the Resampler object.

- **args** [iterable, optional] Positional arguments passed into `func`.

- **kwargs** [dict, optional] A dictionary of keyword arguments passed into `func`.

**Returns**

- **object** [the return type of `func`]

See also:

- `Series.pipe` Apply a function with arguments to a series.
- `DataFrame.pipe` Apply a function with arguments to a dataframe.
- `apply` Apply function to each group instead of to the full Resampler object.

**Notes**

See more here

**Examples**

```python
>>> df = pd.DataFrame({'A': [1, 2, 3, 4]},
...                   index=pd.date_range('2012-08-02', periods=4))
```

```python
>>> df
   A
2012-08-02  1
2012-08-03  2
2012-08-04  3
2012-08-05  4
```
To get the difference between each 2-day period’s maximum and minimum value in one pass, you can do

```python
>>> df.resample('2D').pipe(lambda x: x.max() - x.min())
A
2012-08-02  1
2012-08-04  1
```

### 3.11.3 Upsampling

<table>

</tbody>
</table>

#### pandas.core.resample.Resampler.fffill

`Resampler.fffill(limit=None)`

Forward fill the values.

**Parameters**

- `limit` [int, optional] Limit of how many values to fill.

**Returns**

An upsampled Series.

**See also:**

- `Series.fillna` Fill NA/NaN values using the specified method.
- `DataFrame.fillna` Fill NA/NaN values using the specified method.

#### pandas.core.resample.Resampler.backfill

`Resampler.backfill(limit=None)`

Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

**Parameters**

- `limit` [int, optional] Limit of how many values to fill.

**Returns**

- `Series, DataFrame` An upsampled Series or DataFrame with backward filled NaN values.

**See also:**

[1]: #1234
**bfill**
Alias of backfill.

**fillna**
Fill NaN values using the specified method, which can be ‘backfill’.

**nearest**
Fill NaN values with nearest neighbor starting from center.

**pad**
Forward fill NaN values.

**Series.fillna**
Fill NaN values in the Series using the specified method, which can be ‘backfill’.

**DataFrame.fillna**
Fill NaN values in the DataFrame using the specified method, which can be ‘backfill’.

**References**

[1]

**Examples**

Resampling a Series:

```python
>>> s = pd.Series([1, 2, 3],
                 index=pd.date_range('20180101', periods=3, freq='h'))
```

```bash
>>> s
2018-01-01 00:00:00 1
2018-01-01 01:00:00 2
2018-01-01 02:00:00 3
Freq: H, dtype: int64
```

```bash
>>> s.resample('30min').backfill()
2018-01-01 00:00:00 1
2018-01-01 00:30:00 2
2018-01-01 01:00:00 2
2018-01-01 01:30:00 3
2018-01-01 02:00:00 3
Freq: 30T, dtype: int64
```

```bash
>>> s.resample('15min').backfill(limit=2)
2018-01-01 00:00:00 1.0
2018-01-01 00:15:00 NaN
2018-01-01 00:30:00 2.0
2018-01-01 00:45:00 2.0
2018-01-01 01:00:00 2.0
2018-01-01 01:15:00 NaN
2018-01-01 01:30:00 3.0
2018-01-01 01:45:00 3.0
2018-01-01 02:00:00 3.0
Freq: 15T, dtype: float64
```

Resampling a DataFrame that has missing values:

```python
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
                    index=pd.date_range('20180101', periods=3, freq='h'))
```

```bash
>>> df
   a  b
2018-01-01 00:00:00 2.0 1
2018-01-01 01:00:00 NaN 3
2018-01-01 02:00:00 6.0 5
```
>>> df.resample('30min').backfill()
     a    b
2018-01-01 00:00:00  2.0  1
2018-01-01 00:30:00  NaN  3
2018-01-01 01:00:00  NaN  3
2018-01-01 01:30:00  6.0  5
2018-01-01 02:00:00  6.0  5

>>> df.resample('15min').backfill(limit=2)
     a    b
2018-01-01 00:00:00  2.0  1.0
2018-01-01 00:15:00  NaN  NaN
2018-01-01 00:30:00  NaN  3.0
2018-01-01 00:45:00  NaN  3.0
2018-01-01 01:00:00  NaN  3.0
2018-01-01 01:15:00  NaN  NaN
2018-01-01 01:30:00  6.0  5.0
2018-01-01 01:45:00  6.0  5.0
2018-01-01 02:00:00  6.0  5.0

```
%(pandas.core.resample.Resampler.bfill)s
```

**Resampler.bfill**

Backward fill the new missing values in the resampled data.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The backward fill will replace NaN values that appeared in the resampled data with the next value in the original sequence. Missing values that existed in the original data will not be modified.

**Parameters**

- `limit` [int, optional] Limit of how many values to fill.

**Returns**

- `Series, DataFrame` An upsampled Series or DataFrame with backward filled NaN values.

**See also:**

- `bfill` Alias of backfill.
- `fillna` Fill NaN values using the specified method, which can be ‘backfill’.
- `nearest` Fill NaN values with nearest neighbor starting from center.
- `pad` Forward fill NaN values.
- `Series.fillna` Fill NaN values in the Series using the specified method, which can be ‘backfill’.
- `DataFrame.fillna` Fill NaN values in the DataFrame using the specified method, which can be ‘backfill’.

Examples

Resampling a Series:

```python
>>> s = pd.Series([1, 2, 3],
                 index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64
```

```python
>>> s.resample('30min').backfill()
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```python
>>> s.resample('15min').backfill(limit=2)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    NaN
2018-01-01 00:30:00    2.0
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
2018-01-01 01:15:00    NaN
2018-01-01 01:30:00    3.0
2018-01-01 01:45:00    3.0
2018-01-01 02:00:00    3.0
Freq: 15T, dtype: float64
```

Resampling a DataFrame that has missing values:

```python
>>> df = pd.DataFrame({'a': [2, np.nan, 6], 'b': [1, 3, 5]},
                    index=pd.date_range('20180101', periods=3,
                                        freq='h'))
>>> df
       a   b
2018-01-01 00:00:00  2.0  1
2018-01-01 01:00:00  NaN  3
2018-01-01 02:00:00  6.0  5
```

```python
>>> df.resample('30min').backfill()
       a   b
2018-01-01 00:00:00  2.0  1
2018-01-01 00:30:00  NaN  3
2018-01-01 01:00:00  NaN  3
2018-01-01 01:30:00  6.0  5
2018-01-01 02:00:00  6.0  5
```

```python
>>> df.resample('15min').backfill(limit=2)
       a   b
2018-01-01 00:00:00  2.0  1.0
2018-01-01 00:15:00  NaN  NaN
2018-01-01 00:30:00  NaN  3.0
(continues on next page)```
pandas.core.resample.Resampler.pad

Resampler.pad(limit=\text{None})
Forward fill the values.

Parameters

\begin{itemize}
\item limit \text{[int, optional]} Limit of how many values to fill.
\end{itemize}

Returns

An upsampled Series.

See also:

Series.fillna Fill NA/NaN values using the specified method.
DataFrame.fillna Fill NA/NaN values using the specified method.

pandas.core.resample.Resampler.nearest

Resampler.nearest(limit=\text{None})
Resample by using the nearest value.

When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency). The nearest method will replace NaN values that appeared in the resampled data with the value from the nearest member of the sequence, based on the index value. Missing values that existed in the original data will not be modified. If limit is given, fill only this many values in each direction for each of the original values.

Parameters

\begin{itemize}
\item limit \text{[int, optional]} Limit of how many values to fill.
\end{itemize}

Returns

Series or DataFrame An upsampled Series or DataFrame with NaN values filled with their nearest value.

See also:

backfill Backward fill the new missing values in the resampled data.
pad Forward fill NaN values.
Examples

```python
>>> s = pd.Series([1, 2],
...                index=pd.date_range('20180101',
...                                      periods=2,
...                                      freq='1h'))
```

```
>>> s
2018-01-01 00:00:00 1
2018-01-01 01:00:00 2
Freq: H, dtype: int64
```

```
>>> s.resample('15min').nearest()
2018-01-01 00:00:00 1
2018-01-01 00:15:00 1
2018-01-01 00:30:00 2
2018-01-01 00:45:00 2
2018-01-01 01:00:00 2
Freq: 15T, dtype: int64
```

Limit the number of upsampled values imputed by the nearest:

```
>>> s.resample('15min').nearest(limit=1)
2018-01-01 00:00:00 1.0
2018-01-01 00:15:00 1.0
2018-01-01 00:30:00 NaN
2018-01-01 00:45:00 2.0
2018-01-01 01:00:00 2.0
Freq: 15T, dtype: float64
```

### pandas.core.resample.Resampler.fillna

Resampler.fillna(method, limit=None)

Fill missing values introduced by upsampling.

In statistics, imputation is the process of replacing missing data with substituted values [1]. When resampling data, missing values may appear (e.g., when the resampling frequency is higher than the original frequency).

Missing values that existed in the original data will not be modified.

**Parameters**

- **method** ([{'pad’, ‘backfill’, ‘ffill’, ‘bfill’, ‘nearest’}] Method to use for filling holes in resampled data
  - ‘pad’ or ‘ffill’: use previous valid observation to fill gap (forward fill).
  - ‘backfill’ or ‘bfill’: use next valid observation to fill gap.
  - ‘nearest’: use nearest valid observation to fill gap.

- **limit** [int, optional] Limit of how many consecutive missing values to fill.

**Returns**

- **Series or DataFrame** An upsampled Series or DataFrame with missing values filled.

**See also:**

- **backfill** Backward fill NaN values in the resampled data.
- **pad** Forward fill NaN values in the resampled data.
- **nearest** Fill NaN values in the resampled data with nearest neighbor starting from center.
interpolate  Fill NaN values using interpolation.

Series.fillna  Fill NaN values in the Series using the specified method, which can be ‘bfill’ and ‘ffill’.

DataFrame.fillna  Fill NaN values in the DataFrame using the specified method, which can be ‘bfill’ and ‘ffill’.

References

[1]

Examples

Resampling a Series:

```python
>>> s = pd.Series([1, 2, 3],
                 index=pd.date_range('20180101', periods=3, freq='h'))
>>> s
2018-01-01 00:00:00    1
2018-01-01 01:00:00    2
2018-01-01 02:00:00    3
Freq: H, dtype: int64
```

Without filling the missing values you get:

```python
>>> s.resample("30min").asfreq()
2018-01-01 00:00:00    1.0
2018-01-01 00:30:00    NaN
2018-01-01 01:00:00    2.0
2018-01-01 01:30:00    NaN
2018-01-01 02:00:00    3.0
Freq: 30T, dtype: float64
```

```python
>>> s.resample('30min').fillna("backfill")
2018-01-01 00:00:00    1
2018-01-01 00:30:00    2.0
2018-01-01 01:00:00    2
2018-01-01 01:30:00    3
2018-01-01 02:00:00    3
Freq: 30T, dtype: int64
```

```python
>>> s.resample('15min').fillna("backfill", limit=2)
2018-01-01 00:00:00    1.0
2018-01-01 00:15:00    NaN
2018-01-01 00:30:00    2.0
2018-01-01 00:45:00    2.0
2018-01-01 01:00:00    2.0
2018-01-01 01:15:00    NaN
2018-01-01 01:30:00    3.0
2018-01-01 01:45:00    3.0
2018-01-01 02:00:00    3.0
Freq: 15T, dtype: float64
```

```python
>>> s.resample('30min').fillna("pad")
2018-01-01 00:00:00    1
2018-01-01 00:30:00    1
```

(continues on next page)
2018-01-01 01:00:00 2
2018-01-01 01:30:00 2
2018-01-01 02:00:00 3
Freq: 30T, dtype: int64

>>> s.resample('30min').fillna("nearest")
2018-01-01 00:00:00 1
2018-01-01 00:30:00 2
2018-01-01 01:00:00 2
2018-01-01 01:30:00 3
2018-01-01 02:00:00 3
Freq: 30T, dtype: int64

Missing values present before the upsampling are not affected.

>>> sm = pd.Series([1, None, 3],
                   index=pd.date_range('20180101', periods=3, freq='h'))

>>> sm
2018-01-01 00:00:00 1.0

2018-01-01 02:00:00 6.0 5
```

**pandas.core.resample.Resampler.asfreq**

Resampler.asfreq(fill_value=None)

Return the values at the new freq, essentially a reindex.

Parameters

- fill_value [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

Returns

- DataFrame or Series Values at the specified freq.

See also:

- Series.asfreq Convert TimeSeries to specified frequency.
- DataFrame.asfreq Convert TimeSeries to specified frequency.

**pandas.core.resample.Resampler.interpolate**

Resampler.interpolate(method='linear', axis=0, limit=None, inplace=False, limit_direction='forward', limit_area=None, downcast=None, **kwargs)

Interpolate values according to different methods.

Fill NaN values using an interpolation method.

Please note that only method='linear' is supported for DataFrame/Series with a MultiIndex.

Parameters

- method [str, default ‘linear’] Interpolation technique to use. One of:
  - ‘linear’: Ignore the index and treat the values as equally spaced. This is the only method supported on MultiIndexes.
  - ‘time’: Works on daily and higher resolution data to interpolate given length of interval.
  - ‘index’, ‘values’: use the actual numerical values of the index.
  - ‘pad’: Fill in NaNs using existing values.
  - ‘nearest’, ‘zero’, ‘slinear’, ‘quadratic’, ‘cubic’, ‘spline’, ‘barycentric’, ‘polynomial’: Passed to scipy.interpolate.interp1d. These methods use the numerical values of the index. Both ‘polynomial’ and ‘spline’ require that you also specify an order (int), e.g. df.interpolate(method='polynomial', order=5).
• ‘from_derivatives’: Refers to scipy.interpolate.BPoly.from_derivatives which replaces ‘piecewise_polynomial’ interpolation method in scipy 0.18.

axis [[{0 or ‘index’, 1 or ‘columns’, None}], default None] Axis to interpolate along.

limit [int, optional] Maximum number of consecutive NaNs to fill. Must be greater than 0.

inplace [bool, default False] Update the data in place if possible.

limit_direction [{‘forward’, ‘backward’, ‘both’}], Optional] Consecutive NaNs will be filled in this direction.

If limit is specified:
• If ‘method’ is ‘pad’ or ‘ffill’, ‘limit_direction’ must be ‘forward’.
• If ‘method’ is ‘backfill’ or ‘bfill’, ‘limit_direction’ must be ‘backwards’.

If ‘limit’ is not specified:
• If ‘method’ is ‘backfill’ or ‘bfill’, the default is ‘backward’
• else the default is ‘forward’

Changed in version 1.1.0: raises ValueError if limit_direction is ‘forward’ or ‘both’ and method is ‘backfill’ or ‘bfill’. raises ValueError if limit_direction is ‘backward’ or ‘both’ and method is ‘pad’ or ‘ffill’.

limit_area [{‘None’, ‘inside’, ‘outside’}], default None] If limit is specified, consecutive NaNs will be filled with this restriction.

• None: No fill restriction.
• ‘inside’: Only fill NaNs surrounded by valid values (interpolate).
• ‘outside’: Only fill NaNs outside valid values (extrapolate).

downcast [optional, ‘infer’ or None, defaults to None] Downcast dtypes if possible.

`**kwargs` [optional] Keyword arguments to pass on to the interpolating function.

Returns

Series or DataFrame or None Returns the same object type as the caller, interpolated at some or all NaN values or None if inplace=True.

See also:

fillna Fill missing values using different methods.

scipy.interpolate.Akima1DInterpolator Piecewise cubic polynomials (Akima interpolator).

scipy.interpolate.BPoly.from_derivatives Piecewise polynomial in the Bernstein basis.

scipy.interpolate.interp1d Interpolate a 1-D function.

scipy.interpolate.KroghInterpolator Interpolate polynomial (Krogh interpolator).

scipy.interpolate.PchipInterpolator PCHIP 1-d monotonic cubic interpolation.

scipy.interpolate.CubicSpline Cubic spline data interpolator.
Notes

The ‘krogh’, ‘piecewise_polynomial’, ‘spline’, ‘pchip’ and ‘akima’ methods are wrappers around the respective SciPy implementations of similar names. These use the actual numerical values of the index. For more information on their behavior, see the SciPy documentation and SciPy tutorial.

Examples

Filling in NaN in a Series via linear interpolation.

```python
>>> s = pd.Series([0, 1, np.nan, 3])
>>> s
0    0.0
1    1.0
2    NaN
3    3.0
dtype: float64

>>> s.interpolate()
0    0.0
1    1.0
2    2.0
3    3.0
dtype: float64
```

Filling in NaN in a Series by padding, but filling at most two consecutive NaN at a time.

```python
>>> s = pd.Series([np.nan, "single_one", np.nan,
... "fill_two_more", np.nan, np.nan, np.nan,
... 4.71, np.nan])

>>> s
0    NaN
1    single_one
2    NaN
3    fill_two_more
4    NaN
5    NaN
6    NaN
7    4.71
8    NaN
dtype: object

>>> s.interpolate(method='pad', limit=2)
0    NaN
1    single_one
2    single_one
3    fill_two_more
4    fill_two_more
5    fill_two_more
6    NaN
7    4.71
8    4.71
dtype: object
```

Filling in NaN in a Series via polynomial interpolation or splines: Both ‘polynomial’ and ‘spline’ methods require that you also specify an order (int).
>>> s = pd.Series([0, 2, np.nan, 8])
>>> s.interpolate(method='polynomial', order=2)
0    0.000000
1    2.000000
2    4.666667
3    8.000000
dtype: float64

Fill the DataFrame forward (that is, going down) along each column using linear interpolation.

Note how the last entry in column ‘a’ is interpolated differently, because there is no entry after it to use for interpolation. Note how the first entry in column ‘b’ remains NaN, because there is no entry before it to use for interpolation.

>>> df = pd.DataFrame([(0.0, np.nan, -1.0, 1.0),
... (np.nan, 2.0, np.nan, np.nan),
... (2.0, 3.0, np.nan, 9.0),
... (np.nan, 4.0, -4.0, 16.0)],
... columns=list('abcd'))

Using polynomial interpolation.

>>> df['d'].interpolate(method='polynomial', order=2)
0    1.0
1    4.0
2    9.0
3   16.0
Name: d, dtype: float64

3.11.4 Computations / descriptive stats

| Resampler.count()                  | Compute count of group, excluding missing values. |
| Resampler.nunique([_method])       | Return number of unique elements in the group.    |
| Resampler.first([_method, min_count]) | Compute first of group values.                 |
| Resampler.last([_method, min_count]) | Compute last of group values.                |
| Resampler.max([_method, min_count]) | Compute max of group values.                  |
| Resampler.mean([_method])          | Compute mean of groups, excluding missing values.|
| Resampler.median([_method])        | Compute median of groups, excluding missing values.|
| Resampler.min([_method, min_count]) | Compute min of group values.                 |
| Resampler.ohlc([_method])          | Compute open, high, low and close values of a group, excluding missing values. |

**pandas.core.resample.Resampler.count**

Resampler.count ()
Compute count of group, excluding missing values.

Returns:
- **Series or DataFrame**  Count of values within each group.

See also:
- `Series.groupby`  Apply a function groupby to a Series.
- `DataFrame.groupby`  Apply a function groupby to each row or column of a DataFrame.

**pandas.core.resample.Resampler.nunique**

Resampler.nunique (_method='nunique')
Return number of unique elements in the group.

Returns:
- **Series**  Number of unique values within each group.

**pandas.core.resample.Resampler.first**

Resampler.first (_method='first', min_count=0, *args, **kwargs)
Compute first of group values.

Parameters:
- **numeric_only**  [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
- **min_count**  [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns:
- **Series or DataFrame**  Computed first of values within each group.
pandas.core.resample.Resampler.last

Resampler.last(_method='last', min_count=0, *args, **kwargs)
Compute last of group values.

Parameters

- numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
- min_count [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame  Computed last of values within each group.

pandas.core.resample.Resampler.max

Resampler.max(_method='max', min_count=0, *args, **kwargs)
Compute max of group values.

Parameters

- numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.
- min_count [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame  Computed max of values within each group.

pandas.core.resample.Resampler.mean

Resampler.mean(_method='mean', *args, **kwargs)
Compute mean of groups, excluding missing values.

Parameters

- numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

Returns

pandas.Series or pandas.DataFrame

See also:

Series.groupby  Apply a function groupby to a Series.
DataFrame.groupby  Apply a function groupby to each row or column of a DataFrame.
Examples

```python
>>> df = pd.DataFrame({'A': [1, 1, 2, 1, 2],
...                    'B': [np.nan, 2, 3, 4, 5],
...                    'C': [1, 2, 1, 1, 2]}, columns=['A', 'B', 'C'])
```

Groupby one column and return the mean of the remaining columns in each group.

```python
>>> df.groupby('A').mean()
```

<table>
<thead>
<tr>
<th></th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3.0</td>
<td>1.333333</td>
</tr>
<tr>
<td>2</td>
<td>4.0</td>
<td>1.500000</td>
</tr>
</tbody>
</table>

Groupby two columns and return the mean of the remaining column.

```python
>>> df.groupby(['A', 'B']).mean()
```

<table>
<thead>
<tr>
<th></th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2.0</td>
<td>2.0</td>
</tr>
<tr>
<td></td>
<td>4.0</td>
<td>1.0</td>
</tr>
<tr>
<td>2</td>
<td>3.0</td>
<td>1.0</td>
</tr>
<tr>
<td></td>
<td>5.0</td>
<td>2.0</td>
</tr>
</tbody>
</table>

Groupby one column and return the mean of only particular column in the group.

```python
>>> df.groupby('A')['B'].mean()
```

<table>
<thead>
<tr>
<th></th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3.0</td>
</tr>
<tr>
<td>2</td>
<td>4.0</td>
</tr>
</tbody>
</table>

Name: B, dtype: float64

**pandas.core.resample.Resampler.median**

```python
Resampler.median(_method='median', *args, **kwargs)
```

Compute median of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

- **numeric_only** [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

Returns

- **Series or DataFrame** Median of values within each group.

See also:

- **Series.groupby** Apply a function groupby to a Series.
- **DataFrame.groupby** Apply a function groupby to each row or column of a DataFrame.
pandas.core.resample.Resampler.min

Resampler.min(_method='min', min_count=0, *args, **kwargs)
Compute min of group values.

Parameters

numeric_only [bool, default False] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default -1] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed min of values within each group.

pandas.core.resample.Resampler.ohlc

Resampler.ohlc(_method='ohlc', *args, **kwargs)
Compute open, high, low and close values of a group, excluding missing values.

For multiple groupings, the result index will be a MultiIndex

Returns

DataFrame Open, high, low and close values within each group.

See also:

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.resample.Resampler.prod

Resampler.prod(_method='prod', min_count=0, *args, **kwargs)
Compute prod of group values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed prod of values within each group.

pandas.core.resample.Resampler.size

Resampler.size()
Compute group sizes.

Returns

DataFrame or Series Number of rows in each group as a Series if as_index is True or a DataFrame if as_index is False.

See also:

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.
pandas.core.resample.Resampler.sem

Resampler.sem(_method='sem', *args, **kwargs)
Compute standard error of the mean of groups, excluding missing values.

For multiple groupings, the result index will be a MultiIndex.

Parameters

ddf [int, default 1] Degrees of freedom.

Returns

Series or DataFrame Standard error of the mean of values within each group.

See also:

Series.groupby Apply a function groupby to a Series.
DataFrame.groupby Apply a function groupby to each row or column of a DataFrame.

pandas.core.resample.Resampler.std

Resampler.std(ddof=1, *args, **kwargs)
Compute standard deviation of groups, excluding missing values.

Parameters

ddf [int, default 1] Degrees of freedom.

Returns

DataFrame or Series Standard deviation of values within each group.

pandas.core.resample.Resampler.sum

Resampler.sum(_method='sum', min_count=0, *args, **kwargs)
Compute sum of group values.

Parameters

numeric_only [bool, default True] Include only float, int, boolean columns. If None, will attempt to use everything, then use only numeric data.

min_count [int, default 0] The required number of valid values to perform the operation. If fewer than min_count non-NA values are present the result will be NA.

Returns

Series or DataFrame Computed sum of values within each group.

pandas.core.resample.Resampler.var

Resampler.var(ddof=1, *args, **kwargs)
Compute variance of groups, excluding missing values.

Parameters

ddf [int, default 1] Degrees of freedom.

Returns

DataFrame or Series Variance of values within each group.
pandas.core.resample.Resampler.quantile

Resampler.quantile(q=0.5, **kwargs)
Return value at the given quantile.

Parameters

- q [float or array-like, default 0.5 (50% quantile)]

Returns

DataFrame or Series Quantile of values within each group.

See also:

- Series.quantile Return a series, where the index is q and the values are the quantiles.
- DataFrame.quantile Return a DataFrame, where the columns are the columns of self, and the values are the quantiles.
- DataFrameGroupBy.quantile Return a DataFrame, where the columns are groupby columns, and the values are its quantiles.

3.12 Style

Styler objects are returned by pandas.DataFrame.style.

3.12.1 Styler constructor

<table>
<thead>
<tr>
<th>Styler(data[, precision, table_styles, ...])</th>
<th>Helps style a DataFrame or Series according to the data with HTML and CSS.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Styler.from_custom_template(searchpath[, ...])</td>
<td>Factory function for creating a subclass of Styler.</td>
</tr>
</tbody>
</table>

class pandas.io.formats.style.Styler

| pandas.io.formats.style.Styler(data, precision=None, table_styles=None, uuid=None, caption=None, table_attributes=None, cell_ids=True, na_rep=None, uuid_len=5, decimal='.', thousands=None, escape=None) | Helps style a DataFrame or Series according to the data with HTML and CSS. |

Parameters

- data [Series or DataFrame] Data to be styled - either a Series or DataFrame.
- precision [int] Precision to round floats to, defaults to pd.options.display.precision.
- table_styles [list-like, default None] List of {selector: (attr, value)} dicts; see Notes.
- uuid [str, default None] A unique identifier to avoid CSS collisions; generated automatically.
- caption [str, tuple, default None] String caption to attach to the table. Tuple only used for LaTeX dual captions.
- table_attributes [str, default None] Items that show up in the opening <table> tag in addition to automatic (by default) id.
- cell_ids [bool, default True] If True, each cell will have an id attribute in their HTML tag. The id takes the form T_<uuid>_row<num_row>_col<num_col> where
<uuid> is the unique identifier, <num_row> is the row number and <num_col> is the column number.

**na_rep** [str, optional] Representation for missing values. If na_rep is None, no special formatting is applied.

New in version 1.0.0.

**uuid_len** [int, default 5] If uuid is not specified, the length of the uuid to randomly generate expressed in hex characters, in range [0, 32].

New in version 1.2.0.

**decimal** [str, default “.”] Character used as decimal separator for floats, complex and integers

New in version 1.3.0.

**thousands** [str, optional, default None] Character used as thousands separator for floats, complex and integers

New in version 1.3.0.

**escape** [str, optional] Use ‘html’ to replace the characters &, <, >, ' and " in cell display string with HTML-safe sequences. Use ‘latex’ to replace the characters &, %, $, #, _, {, }, ~, ^, and \ in the cell display string with LaTeX-safe sequences.

New in version 1.3.0.

See also:

**DataFrame.style** Return a Styler object containing methods for building a styled HTML representation for the DataFrame.

Notes

Most styling will be done by passing style functions into Styler.apply or Styler.applymap. Style functions should return values with strings containing CSS 'attr: value' that will be applied to the indicated cells.

If using in the Jupyter notebook, Styler has defined a _repr_html_ to automatically render itself. Otherwise call Styler.render to get the generated HTML.

CSS classes are attached to the generated HTML

- Index and Column names include index_name and level<k> where k is its level in a MultiIndex
- Index label cells include
  - row_heading
  - row<n> where n is the numeric position of the row
  - level<k> where k is the level in a MultiIndex
- Column label cells include *col_heading *col<n> where n is the numeric position of the column
  * level<k> where k is the level in a MultiIndex
- Blank cells include blank
- Data cells include data
Attributes

<table>
<thead>
<tr>
<th>env</th>
<th>(Jinja2 jinja2.Environment)</th>
</tr>
</thead>
<tbody>
<tr>
<td>template</td>
<td>(Jinja2 Template)</td>
</tr>
<tr>
<td>loader</td>
<td>(Jinja2 Loader)</td>
</tr>
</tbody>
</table>

Methods

- **apply**(func[, axis, subset])
  Apply a CSS-styling function column-wise, row-wise, or table-wise.

- **applymap**(func, subset)
  Apply a CSS-styling function elementwise.

- **background_gradient**(cmap, low, high, axis, ...
  Color the background in a gradient style.

- **bar**(subset, axis, color, width, align, ...) Draw bar chart in the cell backgrounds.

- **clear**()
  Reset the Styler, removing any previously applied styles.

- **export**()
  Export the styles applied to the current Styler.

- **format**(formatter, subset, na_rep, ...) Format the text display value of cells.

- **from_custom_template**(searchpath[, ...]) Factory function for creating a subclass of Styler.

- **hide_columns**(subset)
  Hide the column headers or specific keys in the columns from rendering.

- **hide_index**(subset)
  Hide the entire index, or specific keys in the index from rendering.

- **highlight_between**(subset, color, axis, ...
  Highlight a defined range with a style.

- **highlight_max**(subset, color, axis, props)
  Highlight the maximum with a style.

- **highlight_min**(subset, color, axis, props)
  Highlight the minimum with a style.

- **highlight_null**(null_color, subset, props)
  Highlight missing values with a style.

- **highlight_quantile**(subset, color, axis, ...
  Highlight values defined by a quantile with a style.

- **pipe**(func, *args, **kwargs)
  Apply func(self, *args, **kwargs), and return the result.

- **render**(sparse_index, sparse_columns)
  Render the Styler including all applied styles to HTML.

- **set_caption**(caption)
  Set the text added to a <caption> HTML element.

- **set_na_rep**(na_rep)
  (DEPRECATED) Set the missing data representation on a Styler.

- **set_precision**(precision)
  (DEPRECATED) Set the precision used to display values.

- **set_properties**(subset)
  Set defined CSS-properties to each <td> HTML element within the given subset.

- **set_sticky**(axis, pixel_size, levels)
  Add CSS to permanently display the index or column headers in a scrolling frame.

- **set_table_attributes**(attributes)
  Set the table attributes added to the <table> HTML element.

- **set_table_styles**(table_styles[, axis, overwrite])
  Set the table styles included within the <style> HTML element.

- **set_td_classes**(classes)
  Set the DataFrame of strings added to the class attribute of <td> HTML elements.

- **set_tooltips**(ttips[, props, css_class])
  Set the DataFrame of strings on Styler generating :hover tooltips.

**pandas.io.formats.style.Styler.apply**

Styler.apply (func, axis=0, subset=None, **kwargs)

Apply a CSS-styling function column-wise, row-wise, or table-wise.

Updates the HTML representation with the result.

Parameters

- **func** [function] func should take a Series if axis in [0,1] and return an object of same length, also with identical index if the object is a Series. func should take a DataFrame if axis is None and return either an ndarray with the same shape or a DataFrame with identical columns and index.

  Changed in version 1.3.0.

- **axis** [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.

- **subset** [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.iloc[, <subset>] where the columns are prioritised, to limit data to before applying the function.

  **kwargs [dict] Pass along to func.

Returns

- **self** [Styler]

See also:

- *Styler.applymap* Apply a CSS-styling function elementwise.
Notes

The elements of the output of `func` should be CSS styles as strings, in the format ‘attribute: value; attribute2: value2; …’ or, if nothing is to be applied to that element, an empty string or `None`.

This is similar to `DataFrame.apply`, except that `axis=None` applies the function to the entire DataFrame at once, rather than column-wise or row-wise.

Examples

```python
>>> def highlight_max(x, color):
...     return np.where(x == np.nanmax(x.to_numpy()), f"color: {color};", "None")
...     return np.where(x == np.nanmax(x.to_numpy()), f"color: {color};", None)

>>> df = pd.DataFrame(np.random.randn(5, 2), columns=['A', 'B'])
>>> df.style.apply(highlight_max, color='red')
>>> df.style.apply(highlight_max, color='blue', axis=1)
>>> df.style.apply(highlight_max, color='green', axis=None)

Using subset to restrict application to a single column or multiple columns

```python
>>> df.style.apply(highlight_max, color='red', subset="A")
>>> df.style.apply(highlight_max, color='red', subset=['A', 'B'])
```  

Using a 2d input to subset to select rows in addition to columns

```python
>>> df.style.apply(highlight_max, color='red', subset=(\[0,1,2\], slice(None)))
>>> df.style.apply(highlight_max, color='red', subset=(slice(0,5,2), "A")
```  

pandas.io.formats.style.Styler.applymap

**Styler.applymap** *(func, subset=None, **kwargs)*

Apply a CSS-styling function elementwise.

Updates the HTML representation with the result.

**Parameters**

- `func` [function] `func` should take a scalar and return a scalar.
- `subset` [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.
- **kwargs** [dict] Pass along to `func`.

**Returns**

- `self` [Styler]

See also:

- **Styler.apply** Apply a CSS-styling function column-wise, row-wise, or table-wise.
Notes

The elements of the output of `func` should be CSS styles as strings, in the format `attribute: value; attribute2: value2; ...` or, if nothing is to be applied to that element, an empty string or `None`.

Examples

```python
>>> def color_negative(v, color):
...     return f"color: {color};" if v < 0 else None
>>> df = pd.DataFrame(np.random.randn(5, 2), columns=['A', 'B'])
>>> df.style.applymap(color_negative, color='red')
```

Using `subset` to restrict application to a single column or multiple columns

```python
>>> df.style.applymap(color_negative, color='red', subset="A")
>>> df.style.applymap(color_negative, color='red', subset=['A', 'B'])
```

Using a 2d input to `subset` to select rows in addition to columns

```python
>>> df.style.applymap(color_negative, color='red', subset=(slice(0,5,2), "A"))
```

### pandas.io.formats.style.Styler.background_gradient

`Styler.background_gradient(cmap='PuBu', low=0, high=0, axis=0, subset=None, text_color_threshold=0.408, vmin=None, vmax=None, gmap=None)`

Color the background in a gradient style.

The background color is determined according to the data in each column, row or frame, or by a given gradient map. Requires matplotlib.

**Parameters**

- `cmap` [str or colormap] Matplotlib colormap.
- `low` [float] Compress the color range at the low end. This is a multiple of the data range to extend below the minimum; good values usually in [0, 1], defaults to 0.
- `high` [float] Compress the color range at the high end. This is a multiple of the data range to extend above the maximum; good values usually in [0, 1], defaults to 0.
- `axis` [[0 or 'index', 1 or 'columns', None], default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.
- `subset` [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.
- `text_color_threshold` [float or int] Luminance threshold for determining text color in [0, 1]. Facilitates text visibility across varying background colors. All text is dark if 0, and light if 1, defaults to 0.408.
vmin [float, optional] Minimum data value that corresponds to colormap minimum value. If not specified the minimum value of the data (or gmap) will be used.

   New in version 1.0.0.

vmax [float, optional] Maximum data value that corresponds to colormap maximum value. If not specified the maximum value of the data (or gmap) will be used.

   New in version 1.0.0.

gmap [array-like, optional] Gradient map for determining the background colors. If not supplied will use the underlying data from rows, columns or frame. If given as an ndarray or list-like must be an identical shape to the underlying data considering axis and subset. If given as DataFrame or Series must have same index and column labels considering axis and subset. If supplied, vmin and vmax should be given relative to this gradient map.

   New in version 1.3.0.

Returns

self [Styler]

See also:

Styler.text_gradient Color the text in a gradient style.

Notes

When using low and high the range of the gradient, given by the data if gmap is not given or by gmap, is extended at the low end effectively by map.min - low * map.range and at the high end by map.max + high * map.range before the colors are normalized and determined.

If combining with vmin and vmax the map.min, map.max and map.range are replaced by values according to the values derived from vmin and vmax.

This method will preselect numeric columns and ignore non-numeric columns unless a gmap is supplied in which case no preselection occurs.

Examples

```python
>>> df = pd.DataFrame(columns=["City", "Temp (c)", "Rain (mm)", "Wind (m/s)"],
...                     data=[["Stockholm", 21.6, 5.0, 3.2],
...                         ["Oslo", 22.4, 13.3, 3.1],
...                         ["Copenhagen", 24.5, 0.0, 6.7]])
```

Shading the values column-wise, with axis=0, preselecting numeric columns

```python
>>> df.style.background_gradient(axis=0)
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (c)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stockholm</td>
<td>21.60000</td>
<td>5.00000</td>
<td>3.20000</td>
</tr>
<tr>
<td>Oslo</td>
<td>22.40000</td>
<td>13.30000</td>
<td>3.10000</td>
</tr>
<tr>
<td>Copenhagen</td>
<td>24.50000</td>
<td>0.00000</td>
<td>6.70000</td>
</tr>
</tbody>
</table>
Shading all values collectively using `axis=None`

```python
>>> df.style.background_gradient(axis=None)
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (°C)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>21.600000</td>
<td>5.000000</td>
<td>3.200000</td>
</tr>
<tr>
<td>1</td>
<td>22.400000</td>
<td>13.300000</td>
<td>3.100000</td>
</tr>
<tr>
<td>2</td>
<td>24.500000</td>
<td>0.000000</td>
<td>6.700000</td>
</tr>
</tbody>
</table>

Compress the color map from the both low and high ends

```python
>>> df.style.background_gradient(axis=None, low=0.75, high=1.0)
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (°C)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>21.600000</td>
<td>5.000000</td>
<td>3.200000</td>
</tr>
<tr>
<td>1</td>
<td>22.400000</td>
<td>13.300000</td>
<td>3.100000</td>
</tr>
<tr>
<td>2</td>
<td>24.500000</td>
<td>0.000000</td>
<td>6.700000</td>
</tr>
</tbody>
</table>

Manually setting `vmin` and `vmax` gradient thresholds

```python
>>> df.style.background_gradient(axis=None, vmin=6.7, vmax=21.6)
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (°C)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>21.600000</td>
<td>5.000000</td>
<td>3.200000</td>
</tr>
<tr>
<td>1</td>
<td>22.400000</td>
<td>13.300000</td>
<td>3.100000</td>
</tr>
<tr>
<td>2</td>
<td>24.500000</td>
<td>0.000000</td>
<td>6.700000</td>
</tr>
</tbody>
</table>

Setting a `gmap` and applying to all columns with another `cmap`

```python
>>> df.style.background_gradient(axis=0, gmap=df['Temp (°C)'], cmap='YlOrRd')
```

Setting the gradient map for a dataframe (i.e. `axis=None`), we need to explicitly state `subset` to match the `gmap` shape

```python
>>> gmap = np.array([[1,2,3], [2,3,4], [3,4,5]])
>>> df.style.background_gradient(axis=None, gmap=gmap, ...
... cmap='YlOrRd', subset=['Temp (°C)', 'Rain (mm)', 'Wind (m/s)'])
... )
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

```
<table>
<thead>
<tr>
<th>City</th>
<th>Temp (°C)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>21.600000</td>
<td>5.000000</td>
<td>3.200000</td>
</tr>
<tr>
<td>1</td>
<td>22.400000</td>
<td>13.300000</td>
<td>3.100000</td>
</tr>
<tr>
<td>2</td>
<td>24.500000</td>
<td>0.000000</td>
<td>6.700000</td>
</tr>
</tbody>
</table>
```

**pandas.io.formats.style.Styler.bar**

Styler.bar(subset=None, axis=0, color='#d65f5f', width=100, align='left', vmin=None, vmax=None)

Draw bar chart in the cell backgrounds.

**Parameters**

- `subset` [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.

- `axis` [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.

- `color` [str or 2-tuple/list] If a str is passed, the color is the same for both negative and positive numbers. If 2-tuple/list is used, the first element is the color_negative and the second is the color_positive (eg: ['#d65f5f', '#5fba7d']).

- `width` [float, default 100] A number between 0 or 100. The largest value will cover width percent of the cell’s width.

- `align` [{‘left’, ‘zero’, ‘mid’}, default ‘left’] How to align the bars with the cells.
  - ‘left’: the min value starts at the left of the cell.
  - ‘zero’: a value of zero is located at the center of the cell.
  - ‘mid’: the center of the cell is at (max-min)/2, or if values are all negative (positive) the zero is aligned at the right (left) of the cell.

- `vmin` [float, optional] Minimum bar value, defining the left hand limit of the bar drawing range, lower values are clipped to vmin. When None (default): the minimum value of the data will be used.

- `vmax` [float, optional] Maximum bar value, defining the right hand limit of the bar drawing range, higher values are clipped to vmax. When None (default): the maximum value of the data will be used.

**Returns**

- `self` [Styler]
pandas.io.formats.style.Styler.clear

Styler.clear()

Reset the Styler, removing any previously applied styles.

Returns None.

pandas.io.formats.style.Styler.export

Styler.export()

Export the styles applied to the current Styler.

Can be applied to a second Styler with Styler.use.

Returns

styles [list]

See also:

Styler.use Set the styles on the current Styler.

pandas.io.formats.style.Styler.format

Styler.format(formatter=None, subset=None, na_rep=None, precision=None, decimal='.', thousands=None, escape=None)

Format the text display value of cells.

Parameters

formatter [str, callable, dict or None] Object to define how values are displayed. See notes.

subset [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.

na_rep [str, optional] Representation for missing values. If na_rep is None, no special formatting is applied.

New in version 1.0.0.

precision [int, optional] Floating point precision to use for display purposes, if not determined by the specified formatter.

New in version 1.3.0.

decimal [str, default “.”] Character used as decimal separator for floats, complex and integers

New in version 1.3.0.

thousands [str, optional, default None] Character used as thousands separator for floats, complex and integers

New in version 1.3.0.
**escape** [str, optional] Use ‘html’ to replace the characters &lt;, &gt;, ‚, and " in cell display string with HTML-safe sequences. Use ‘latex’ to replace the characters \%, $, #, _, ( ), ~, ^, and \ in the cell display string with LaTeX-safe sequences. Escaping is done before `formatter`.
New in version 1.3.0.

**Returns**

self [Styler]

**Notes**

This method assigns a formatting function, `formatter`, to each cell in the DataFrame. If `formatter` is None, then the default formatter is used. If a callable then that function should take a data value as input and return a displayable representation, such as a string. If `formatter` is given as a string this is assumed to be a valid Python format specification and is wrapped to a callable as `string.format(x)`. If a dict is given, keys should correspond to column names, and values should be string or callable, as above.

The default formatter currently expresses floats and complex numbers with the pandas display precision unless using the `precision` argument here. The default formatter does not adjust the representation of missing values unless the `na_rep` argument is used.

The `subset` argument defines which region to apply the formatting function to. If the `formatter` argument is given in dict form but does not include all columns within the subset then these columns will have the default formatter applied. Any columns in the formatter dict excluded from the subset will raise a `KeyError`.

When using a `formatter` string the dtypes must be compatible, otherwise a `ValueError` will be raised.

**Examples**

Using `na_rep` and `precision` with the default formatter

```python
>>> df = pd.DataFrame([[np.nan, 1.0, 'A'], [2.0, np.nan, 3.0]])
3 1
>>> df.style.format(na_rep='MISS', precision=3)
0 1 2
MISS 1.000 A
1 2.000 MISS 3.000
```

Using a `formatter` specification on consistent column dtypes

```python
>>> df.style.format('{:.2f}', na_rep='MISS', subset=[0, 1])
0 1 2
MISS 1.00 A
1 2.00 MISS 3.000000
```

Using the default `formatter` for unspecified columns

```python
>>> df.style.format({0: '{:.2f}', 1: '£ {:.1f}'}, na_rep='MISS', precision=1)
0 1 2
MISS £ 1.0 A
1 2.00 MISS 3.0
```

Multiple `na_rep` or `precision` specifications under the default `formatter`.  

---

Pandas: powerful Python data analysis toolkit, Release 1.3.1
Using a callable formatter function.

```python
>>> func = lambda s: 'STRING' if isinstance(s, str) else 'FLOAT'
```  
```python
>>> df.style.format({0: '{:.1f}', 2: func}, precision=4, na_rep='MISS')
```  
3.12. Style 2495
pandas: powerful Python data analysis toolkit, Release 1.3.1

New in version 1.3.0.
Returns
MyStyler [subclass of Styler] Has the correct env,``template_html``,
template_html_table and template_html_style class attributes
set.
pandas.io.formats.style.Styler.hide_columns
Styler.hide_columns(subset=None)
Hide the column headers or specific keys in the columns from rendering.
This method has dual functionality:
• if subset is None then the entire column headers row will be hidden whilst the data-values remain
visible.
• if a subset is given then those specific columns, including the data-values will be hidden, whilst
the column headers row remains visible.
Changed in version 1.3.0.
Parameters
subset [label, array-like, IndexSlice, optional] A valid 1d input or single key along the
columns axis within DataFrame.loc[:, <subset>], to limit data to before applying
the function.
Returns
self [Styler]
See also:
Styler.hide_index Hide the entire index, or specific keys in the index.
Examples
Simple application hiding specific columns:
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=["a", "b", "c"])
>>> df.style.hide_columns(["a", "b"])
c
0
3
1
6

Hide column headers and retain the data values:
>>>
>>>
>>>
x

y

2496

midx = pd.MultiIndex.from_product([["x", "y"], ["a", "b", "c"]])
df = pd.DataFrame(np.random.randn(6,6), index=midx, columns=midx)
df.style.format("{:.1f}").hide_columns()

Chapter 3. API reference


Hide specific columns but retain the column headers:

```python
>>> df.style.format("{:.1f}").hide_columns(subset=(slice(None), ["a", "c"]))
    x  y
   a 0.0 0.6
   b 1.0 -0.0
   c-0.8 -0.4
  y a 1.0 -1.2
   b 1.2 0.3
   c 0.5 2.2
```

Hide specific columns and the column headers:

```python
>>> df.style.format("{:.1f}").hide_columns(subset=(slice(None), ["a", "c"]))
... .hide_columns()
    x  y
   a 0.0 0.6
   b 1.0 -0.0
   c-0.8 -0.4
  y a 1.0 -1.2
   b 1.2 0.3
   c 0.5 2.2
```

**pandas.io.formats.style.Styler.hide_index**

`Styler.hide_index(subset=\text{None})`  
Hide the entire index, or specific keys in the index from rendering.

This method has dual functionality:

- if `subset` is `\text{None}` then the entire index will be hidden whilst displaying all data-rows.
- if a `subset` is given then those specific rows will be hidden whilst the index itself remains visible.

Changed in version 1.3.0.

**Parameters**

`subset` [\text{label, array-like, IndexSlice, optional}] A valid 1d input or single key along the index axis within `\text{DataFrame.loc[subset, :]}`, to limit data to \text{before} applying the function.

**Returns**

`self` [Styler]

**See also:**

`Styler.hide_columns`  
Hide the entire column headers row, or specific columns.
Examples

Simple application hiding specific rows:

```python
>>> df = pd.DataFrame([[1,2], [3,4], [5,6]], index=["a", "b", "c")
>>> df.style.hide_index(['a', 'b'])
  0 1
 c 5 6
```

Hide the index and retain the data values:

```python
>>> midx = pd.MultiIndex.from_product(["x", "y", ["a", "b", "c"]])
>>> df = pd.DataFrame(np.random.randn(6,6), index=midx, columns=midx)
>>> df.style.format("{:.1f}").hide_index()
```

Hide specific rows but retain the index:

```python
>>> df.style.format("{:.1f}").hide_index(subset=(slice(None), ["a", "c")])
```

Hide specific rows and the index:

```python
>>> df.style.format("{:.1f}").hide_index(subset=(slice(None), ["a", "c")])
... .hide_index()
```

`pandas.io.formats.style.Styler.highlight_between`

Styler.highlight_between(subset=None, color='yellow', axis=0, left=None, right=None, inclusive='both', props=None)

Highlight a defined range with a style.

New in version 1.3.0.

Parameters

- subset [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>]`, or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.

- color [str, default ‘yellow’] Background color to use for highlighting.
axis [[0 or 'index', 1 or 'columns', None], default 0] If left or right given as sequence, axis along which to apply those boundaries. See examples.

left [scalar or datetime-like, or sequence or array-like, default None] Left bound for defining the range.

right [scalar or datetime-like, or sequence or array-like, default None] Right bound for defining the range.

inclusive [{‘both’, ‘neither’, ‘left’, ‘right’}] Identify whether bounds are closed or open.

props [str, default None] CSS properties to use for highlighting. If props is given, color is not used.

Returns

self [Styler]

See also:

Styler.highlight_null Highlight missing values with a style.

Styler.highlight_max Highlight the maximum with a style.

Styler.highlight_min Highlight the minimum with a style.

Styler.highlight_quantile Highlight values defined by a quantile with a style.

Notes

If left is None only the right bound is applied. If right is None only the left bound is applied. If both are None all values are highlighted.

axis is only needed if left or right are provided as a sequence or an array-like object for aligning the shapes. If left and right are both scalars then all axis inputs will give the same result.

This function only works with compatible dtypes. For example a datetime-like region can only use equivalent datetime-like left and right arguments. Use subset to control regions which have multiple dtypes.

Examples

Basic usage

```python
>>> df = pd.DataFrame({
...     'One': [1.2, 1.6, 1.5],
...     'Two': [2.9, 2.1, 2.5],
...     'Three': [3.1, 3.2, 3.8],
... })
>>> df.style.highlight_between(left=2.1, right=2.9)
```

<table>
<thead>
<tr>
<th>One</th>
<th>Two</th>
<th>Three</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0</td>
<td>1.2</td>
<td>2.9</td>
</tr>
<tr>
<td>1.0</td>
<td>1.6</td>
<td>2.1</td>
</tr>
<tr>
<td>2.0</td>
<td>1.5</td>
<td>2.5</td>
</tr>
</tbody>
</table>
Using a range input sequence along an axis, in this case setting a left and right for each column individually

```python
>>> df.style.highlight_between(left=[1.4, 2.4, 3.4], right=[1.6, 2.6, 3.6], axis=1, color="#fffd75")
```

<table>
<thead>
<tr>
<th></th>
<th>One</th>
<th>Two</th>
<th>Three</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1.2</td>
<td>2.9</td>
<td>3.1</td>
</tr>
<tr>
<td>1</td>
<td>1.6</td>
<td>2.1</td>
<td>3.2</td>
</tr>
<tr>
<td>2</td>
<td>1.5</td>
<td>2.5</td>
<td>3.8</td>
</tr>
</tbody>
</table>

Using axis=None and providing the left argument as an array that matches the input DataFrame, with a constant right

```python
>>> df.style.highlight_between(left=[[2,2,3],[2,2,3],[3,3,3]], right=3.5, axis=None, color="#fffd75")
```

<table>
<thead>

<td>3.8</td>
</tr>
</tbody>
</table>

**pandas.io.formats.style.Styler.highlight_max**

Styler.highlight_max (subset=None, color='yellow', axis=0, props=None)
Highlight the maximum with a style.

**Parameters**

- **subset** [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.
- **color** [str, default 'yellow'] Background color to use for highlighting.
- **axis** [[0 or 'index', 1 or 'columns', None], default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.
props [str, default None] CSS properties to use for highlighting. If props is given, color is not used.

New in version 1.3.0.

Returns

self [Styler]

See also:

Styler.highlight_null Highlight missing values with a style.
Styler.highlight_min Highlight the minimum with a style.
Styler.highlight_between Highlight a defined range with a style.
Styler.highlight_quantile Highlight values defined by a quantile with a style.

pandas.io.formats.style.Styler.highlight_min

Styler.highlight_min (subset=None, color='yellow', axis=0, props=None)

Highlight the minimum with a style.

Parameters

subset [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.

color [str, default 'yellow'] Background color to use for highlighting.

axis [{0 or 'index', 1 or 'columns', None}, default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.

props [str, default None] CSS properties to use for highlighting. If props is given, color is not used.

New in version 1.3.0.

Returns

self [Styler]

See also:

Styler.highlight_null Highlight missing values with a style.
Styler.highlight_max Highlight the maximum with a style.
Styler.highlight_between Highlight a defined range with a style.
Styler.highlight_quantile Highlight values defined by a quantile with a style.
pandas.io.formats.style.Styler.highlight_null

Styler.highlight_null(null_color='red', subset=None, props=None)
Highlight missing values with a style.

Parameters

null_color [str, default ‘red’]

subset [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.

New in version 1.1.0.

props [str, default None] CSS properties to use for highlighting. If props is given, color is not used.

New in version 1.3.0.

Returns

self [Styler]

See also:

Styler.highlight_max Highlight the maximum with a style.
Styler.highlight_min Highlight the minimum with a style.
Styler.highlight_between Highlight a defined range with a style.
Styler.highlight_quantile Highlight values defined by a quantile with a style.

pandas.io.formats.style.Styler.highlight_quantile

Styler.highlight_quantile(subset=None, color='yellow', axis=0, q_left=0.0, q_right=1.0, interpolation='linear', inclusive='both', props=None)
Highlight values defined by a quantile with a style.

New in version 1.3.0.

Parameters

subset [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.

color [str, default ‘yellow’] Background color to use for highlighting

axis [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Axis along which to determine and highlight quantiles. If None quantiles are measured over the entire DataFrame. See examples.

q_left [float, default 0.0] Left bound, in [0, q_right), for the target quantile range.

q_right [float, default 1.0] Right bound, in (q_left, 1], for the target quantile range.

inclusive ([‘both’, ‘neither’, ‘left’, ‘right’]) Identify whether quantile bounds are closed or open.

props [str, default None] CSS properties to use for highlighting. If props is given, color is not used.

Returns

self [Styler]

See also:

Styler.highlight_null Highlight missing values with a style.
Styler.highlight_max Highlight the maximum with a style.
Styler.highlight_min Highlight the minimum with a style.
Styler.highlight_between Highlight a defined range with a style.

Notes

This function does not work with str dtypes.

Examples

Using axis=None and apply a quantile to all collective data

```python
>>> df = pd.DataFrame(np.arange(10).reshape(2,5) + 1)
>>> df.style.highlight_quantile(axis=None, q_left=0.8, color="#fffd75")
```

```
   0  1  2  3  4
0  0  1  2  3  4  5
1  6  7  8  9  10
```

Or highlight quantiles row-wise or column-wise, in this case by row-wise

```python
>>> df.style.highlight_quantile(axis=1, q_left=0.8, color="#fffd75")
```

```
   0  1  2  3  4
0  0  1  2  3  4  5
1  6  7  8  9  10
```

Use props instead of default background coloring

```python
>>> df.style.highlight_quantile(axis=None, q_left=0.2, q_right=0.8,
...   props='font-weight:bold;color:#e83e8c')
```

```
   0  1  2  3  4
0  0  1  2  3  4  5
1  6  7  8  9  10
```
Styler.pipe(func, *args, **kwargs)

Apply func(self, *args, **kwargs), and return the result.

**Parameters**

- **func** [function] Function to apply to the Styler. Alternatively, a (callable, keyword) tuple where keyword is a string indicating the keyword of callable that expects the Styler.
- **args** [optional] Arguments passed to func.
- **kwargs** [optional] A dictionary of keyword arguments passed into func.

**Returns**

object : The value returned by func.

**See also:**

*DataFrame.pipe* Analogous method for DataFrame.

*Styler.apply* Apply a CSS-styling function column-wise, row-wise, or table-wise.

**Notes**

Like DataFrame.pipe(), this method can simplify the application of several user-defined functions to a styler. Instead of writing:

```python
f(g(df.style.set_precision(3), arg1=a), arg2=b, arg3=c)
```

users can write:

```python
(df.style.set_precision(3)
 .pipe(g, arg1=a)
 .pipe(f, arg2=b, arg3=c))
```

In particular, this allows users to define functions that take a styler object, along with other parameters, and return the styler after making styling changes (such as calling Styler.apply() or Styler.set_properties()). Using .pipe, these user-defined style “transformations” can be interleaved with calls to the built-in Styler interface.

**Examples**

```python
def format_conversion(styler):
    ...   return (styler.set_properties(**{'text-align': 'right'}))
    ...         .format({'conversion': '{:.1%}'}))
```

The user-defined format_conversion function above can be called within a sequence of other style modifications:

```python
def = pd.DataFrame({'trial': list(range(5)),
...                     'conversion': [0.75, 0.85, np.nan, 0.7, 0.72]})
(df.style
 ...   .highlight_min(subset=['conversion'], color='yellow')
```

(continues on next page)
... .pipe(format_conversion)
... .set_caption("Results with minimum conversion highlighted.")

pandas.io.formats.style.Styler.render

Styler.render(sparse_index=None, sparse_columns=None, **kwargs)
Render the Styler including all applied styles to HTML.

Parameters

sparse_index [bool, optional] Whether to sparsify the display of a hierarchical index.
Setting to False will display each explicit level element in a hierarchical key for each row. Defaults to pandas.options.styler.sparse.index value.

sparse_columns [bool, optional] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. Defaults to pandas.options.styler.sparse.columns value.

**kwargs Any additional keyword arguments are passed through to self.template.render. This is useful when you need to provide additional variables for a custom template.

Returns

rendered [str] The rendered HTML.

Notes

Styler objects have defined the _repr_html_ method which automatically calls self.render() when it’s the last item in a Notebook cell. When calling Styler.render() directly, wrap the result in IPython.display.HTML to view the rendered HTML in the notebook.

Pandas uses the following keys in render. Arguments passed in **kwargs take precedence, so think carefully if you want to override them:

- head
- cellstyle
- body
- uuid
- table_styles
- caption
- table_attributes
pandas: powerful Python data analysis toolkit, Release 1.3.1

**pandas.io.formats.style.Styler.set_caption**

Styler.set_caption(caption)

Set the text added to a <caption> HTML element.

**Parameters**

caption [str, tuple] For HTML output either the string input is used or the first element of the tuple. For LaTeX the string input provides a caption and the additional tuple input allows for full captions and short captions, in that order.

**Returns**

self [Styler]

**pandas.io.formats.style.Styler.set_na_rep**

Styler.set_na_rep(na_rep)

Set the missing data representation on a Styler.

New in version 1.0.0.

Deprecated since version 1.3.0.

**Parameters**

na_rep [str]

**Returns**

self [Styler]

**Notes**

This method is deprecated. See Styler.format()

**pandas.io.formats.style.Styler.set_precision**

Styler.set_precision(precision)

Set the precision used to display values.

Deprecated since version 1.3.0.

**Parameters**

precision [int]

**Returns**

self [Styler]
Notes

This method is deprecated see `Styler.format`.

**pandas.io.formats.style.Styler.set_properties**

`Styler.set_properties(subset=None, **kwargs)`

Set defined CSS-properties to each `<td>` HTML element within the given subset.

**Parameters**

- `subset` [label, array-like, IndexSlice, optional] A valid 2d input to `DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to `DataFrame.loc[:, <subset>]` where the columns are prioritised, to limit data to before applying the function.

- `**kwargs` [dict] A dictionary of property, value pairs to be set for each cell.

**Returns**

- `self` [Styler]

Notes

This is a convenience method which wraps the `Styler.applymap()` calling a function returning the CSS-properties independently of the data.

**Examples**

```python
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_properties(color="white", align="right")
>>> df.style.set_properties(**{"background-color": "yellow"})
```

**pandas.io.formats.style.Styler.set_sticky**

`Styler.set_sticky(axis=0, pixel_size=None, levels=None)`

Add CSS to permanently display the index or column headers in a scrolling frame.

**Parameters**

- `axis` [0 or ‘index’, 1 or ‘columns’, None], default 0] Whether to make the index or column headers sticky.

- `pixel_size` [int, optional] Required to configure the width of index cells or the height of column header cells when sticking a MultiIndex (or with a named Index). Defaults to 75 and 25 respectively.

- `levels` [list of int] If `axis` is a MultiIndex the specific levels to stick. If `None` will stick all levels.

**Returns**

- `self` [Styler]
Notes

This method uses the CSS ‘position: sticky;’ property to display. It is designed to work with visible axes, therefore both:

- `styler.set_sticky(axis="index").hide_index()`
- `styler.set_sticky(axis="columns").hide_columns()`

may produce strange behaviour due to CSS controls with missing elements.

**pandas.io.formats.style.Styler.set_table_attributes**

**Styler.set_table_attributes**(attributes)

Set the table attributes added to the `<table>` HTML element.

These are items in addition to automatic (by default) `id` attribute.

**Parameters**

attributes [str]

**Returns**

self [Styler]

**See also:**

*Styler.set_table_styles* Set the table styles included within the `<style>` HTML element.

*Styler.set_td_classes* Set the DataFrame of strings added to the `class` attribute of `<td>` HTML elements.

**Examples**

```python
>>> df = pd.DataFrame(np.random.randn(10, 4))
>>> df.style.set_table_attributes('class="pure-table"')
# ... <table class="pure-table"> ...
```

**pandas.io.formats.style.Styler.set_table_styles**

**Styler.set_table_styles**(table_styles, axis=0, overwrite=True)

Set the table styles included within the `<style>` HTML element.

This function can be used to style the entire table, columns, rows or specific HTML selectors.

**Parameters**

  **table_styles** [list or dict] If supplying a list, each individual table_style should be a dictionary with selector and props keys. selector should be a CSS selector that the style will be applied to (automatically prefixed by the table’s UUID) and props should be a list of tuples with (attribute, value). If supplying a dict, the dict keys should correspond to column names or index values, depending upon the specified `axis` argument. These will be mapped to row or col CSS selectors. MultiIndex values as dict keys should be in their respective tuple form. The dict values should be a list as specified in the form with CSS selectors and props that will be applied to the specified row or column.
Changed in version 1.2.0.

**axis** [[0 or ‘index’, 1 or ‘columns’, None], default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'). Only used if `table_styles` is dict.

New in version 1.2.0.

**overwrite** [bool, default True] Styles are replaced if True, or extended if False. CSS rules are preserved so most recent styles set will dominate if selectors intersect.

New in version 1.2.0.

**Returns**

self [Styler]

**See also:**

*Styler.set_td_classes* Set the DataFrame of strings added to the class attribute of `<td>` HTML elements.

*Styler.set_table_attributes* Set the table attributes added to the `<table>` HTML element.

**Examples**

```py
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                   columns=['A', 'B', 'C', 'D'])
>>> df.style.set_table_styles(
...     [{'selector': 'tr:hover',
...       'props': [('background-color', 'yellow')]}])
```

Or with CSS strings

```py
>>> df.style.set_table_styles(
...     [{'selector': 'tr:hover',
...       'props': 'background-color: yellow; font-size: 1em;'}])
```

Adding column styling by name

```py
>>> df.style.set_table_styles(
...     {'A': [{'selector': '',
...            'props': [('color', 'red')]}],
...      'B': [{'selector': 'td',
...             'props': 'color: blue;}])}, overwrite=False)
```

Adding row styling

```py
>>> df.style.set_table_styles(
...     {0: [{'selector': 'td:hover',
...          'props': [('font-size', '25px')]})}, axis=1, overwrite=False)
```
Styler.set_td_classes(classes)

Set the DataFrame of strings added to the class attribute of <td> HTML elements.

Parameters

classes [DataFrame] DataFrame containing strings that will be translated to CSS classes, mapped by identical column and index key values that must exist on the underlying Styler data. None, NaN values, and empty strings will be ignored and not affect the rendered HTML.

Returns

self [Styler]

See also:

Styler.set_table_styles Set the table styles included within the <style> HTML element.
Styler.set_table_attributes Set the table attributes added to the <table> HTML element.

Notes

Can be used in combination with Styler.set_table_styles to define an internal CSS solution without reference to external CSS files.

Examples

```python
>>> df = pd.DataFrame(data=[[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
>>> classes = pd.DataFrame(["min-val red", '', "blue"],
...                        ["red", None, "blue max-val"],
...                        index=df.index, columns=df.columns)
>>> df.style.set_td_classes(classes)
```

Using MultiIndex columns and a classes DataFrame as a subset of the underlying,

```python
>>> df = pd.DataFrame([[1,2],[3,4]], index=['a', 'b'],
...                    columns=["level0", "level0b"])
>>> classes = pd.DataFrame(["min-val"], index=['a'],
...                         columns=["level0","levella"])
>>> df.style.set_td_classes(classes)
```

Form of the output with new additional css classes,

```python
>>> df = pd.DataFrame(([1,])
>>> css = pd.DataFrame(["other-class"])
>>> s = Styler(df, uuid="__", cell_ids=False).set_td_classes(css)
>>> s.hide_index().render()
'<style type="text/css"></style>'
'<table id="T__">'
'  <thead>'
'    <th class="col_heading level0 col0" >0</th>'
'  </thead>'
'  <tbody>
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.io.formats.style.Styler.set_tooltips

Styler.set_tooltips (ttips, props=None, css_class=None)

Set the DataFrame of strings on Styler generating :hover tooltips. These string based tooltips are only applicable to <td> HTML elements, and cannot be used for column or index headers.

New in version 1.3.0.

Parameters

- **ttips** [DataFrame] DataFrame containing strings that will be translated to tooltips, mapped by identical column and index values that must exist on the underlying Styler data. None, NaN values, and empty strings will be ignored and not affect the rendered HTML.

- **props** [list-like or str, optional] List of (attr, value) tuples or a valid CSS string. If None adopts the internal default values described in notes.

- **css_class** [str, optional] Name of the tooltip class used in CSS, should conform to HTML standards. Only useful if integrating tooltips with external CSS. If None uses the internal default value ‘pd-t’.

Returns

- **self** [Styler]

Notes

Tooltips are created by adding <span class="pd-t"></span> to each data cell and then manipulating the table level CSS to attach pseudo hover and pseudo after selectors to produce the required the results.

The default properties for the tooltip CSS class are:

- visibility: hidden
- position: absolute
- z-index: 1
- background-color: black
- color: white
- transform: translate(-20px, -20px)

The property ‘visibility: hidden;’ is a key prerequisite to the hover functionality, and should always be included in any manual properties specification, using the **props** argument.

Tooltips are not designed to be efficient, and can add large amounts of additional HTML for larger tables, since they also require that **cell_ids** is forced to **True**.
### Examples

**Basic application**

```python
>>> df = pd.DataFrame(data=[[0, 1], [2, 3]])
>>> ttips = pd.DataFrame(...
    data=[["Min", ""], [np.nan, "Max"], columns=df.columns, index=df.
    index(...)
>>> s = df.style.set_tooltips(ttips).render()
```

**Optionally controlling the tooltip visual display**

```python
>>> df.style.set_tooltips(ttips, css_class='tt-add', props=[
    ('visibility', 'hidden'),
    ('position', 'absolute'),
    ('z-index', 1)])
>>> df.style.set_tooltips(ttips, css_class='tt-add',
    props='visibility:hidden; position:absolute; z-index:1;')
```

---

**pandas.io.formats.style.Styler.set_uuid**

Styler.set_uuid(uuid)

Set the uuid applied to id attributes of HTML elements.

**Parameters**

- **uuid** [str]

**Returns**

- **self** [Styler]

**Notes**

Almost all HTML elements within the table, and including the <table> element are assigned id attributes. The format is T_uuid_<extra> where <extra> is typically a more specific identifier, such as row1_col2.

---

**pandas.io.formats.style.Styler.text_gradient**

Styler.text_gradient(cmap='PuBu', low=0, high=0, axis=0, subset=None, vmin=None, vmax=None, gmap=None)

Color the text in a gradient style.

The text color is determined according to the data in each column, row or frame, or by a given gradient map. Requires matplotlib.

**Parameters**

- **cmap** [str or colormap] Matplotlib colormap.

- **low** [float] Compress the color range at the low end. This is a multiple of the data range to extend below the minimum; good values usually in [0, 1], defaults to 0.

- **high** [float] Compress the color range at the high end. This is a multiple of the data range to extend above the maximum; good values usually in [0, 1], defaults to 0.
axis [(0 or 'index', 1 or 'columns', None), default 0] Apply to each column (axis=0 or 'index'), to each row (axis=1 or 'columns'), or to the entire DataFrame at once with axis=None.

subset [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.

text_color_threshold [float or int] This argument is ignored (only used in background_gradient). Luminance threshold for determining text color in [0, 1]. Facilitates text visibility across varying background colors. All text is dark if 0, and light if 1, defaults to 0.408.

vmin [float, optional] Minimum data value that corresponds to colormap minimum value. If not specified the minimum value of the data (or gmap) will be used.

New in version 1.0.0.

vmax [float, optional] Maximum data value that corresponds to colormap maximum value. If not specified the maximum value of the data (or gmap) will be used.

New in version 1.0.0.

gmap [array-like, optional] Gradient map for determining the text colors. If not supplied will use the underlying data from rows, columns or frame. If given as an ndarray or list-like must be an identical shape to the underlying data considering axis and subset. If given as DataFrame or Series must have same index and column labels considering axis and subset. If supplied, vmin and vmax should be given relative to this gradient map.

New in version 1.3.0.

Returns

self [Styler]

See also:

Styler.background_gradient Color the background in a gradient style.

Notes

When using low and high the range of the gradient, given by the data if gmap is not given or by gmap, is extended at the low end effectively by map.min - low * map.range and at the high end by map.max + high * map.range before the colors are normalized and determined.

If combining with vmin and vmax the map.min, map.max and map.range are replaced by values according to the values derived from vmin and vmax.

This method will preselect numeric columns and ignore non-numeric columns unless a gmap is supplied in which case no preselection occurs.
Examples

```python
>>> df = pd.DataFrame(columns=['City', 'Temp (°C)', 'Rain (mm)', 'Wind (m/s)'],
                    data=[['Stockholm', 21.6, 5.0, 3.2],
                          ['Oslo', 22.4, 13.3, 3.1],
                          ['Copenhagen', 24.5, 0.0, 6.7]])

Shading the values column-wise, with `axis=0`, preselecting numeric columns

```python
>>> df.style.text_gradient(axis=0)
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (°C)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Stockholm</td>
<td>21.600000</td>
<td>5.000000</td>
</tr>
<tr>
<td>1</td>
<td>Oslo</td>
<td>22.400000</td>
<td>13.300000</td>
</tr>
<tr>
<td>2</td>
<td>Copenhagen</td>
<td>24.500000</td>
<td>0.000000</td>
</tr>
</tbody>
</table>

Shading all values collectively using `axis=None`

```python
>>> df.style.text_gradient(axis=None)
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (°C)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Stockholm</td>
<td>21.600000</td>
<td>5.000000</td>
</tr>
<tr>
<td>1</td>
<td>Oslo</td>
<td>22.400000</td>
<td>13.300000</td>
</tr>
<tr>
<td>2</td>
<td>Copenhagen</td>
<td>24.500000</td>
<td>0.000000</td>
</tr>
</tbody>
</table>

Compress the color map from the both low and high ends

```python
>>> df.style.text_gradient(axis=None, low=0.75, high=1.0)
```

<table>
<thead>
<tr>
<th>City</th>
<th>Temp (°C)</th>
<th>Rain (mm)</th>
<th>Wind (m/s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Stockholm</td>
<td>21.600000</td>
<td>5.000000</td>
</tr>
<tr>
<td>1</td>
<td>Oslo</td>
<td>22.400000</td>
<td>13.300000</td>
</tr>
<tr>
<td>2</td>
<td>Copenhagen</td>
<td>24.500000</td>
<td>0.000000</td>
</tr>
</tbody>
</table>

Manually setting `vmin` and `vmax` gradient thresholds

```python
>>> df.style.text_gradient(axis=None, vmin=6.7, vmax=21.6)
```

Setting a `gmap` and applying to all columns with another `cmap`

```python
>>> df.style.text_gradient(axis=0, gmap=df['Temp (°C)'], cmap='YlOrRd')
```

Setting the gradient map for a dataframe (i.e. `axis=None`), we need to explicitly state `subset` to match the `gmap` shape

**pandas.io.formats.style.Styler.use**

Styler.use(styles)

Set the styles on the current Styler.

Possibly uses styles from Styler.export.

Parameters

- styles [list] List of style functions.

Returns

- self [Styler]

See also:

- Styler.export Export the styles to applied to the current Styler.

3.12. Style 2515
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas.io.formats.style.Styler.where

Styler.where(cond, value, other=None, subset=None, **kwargs)

Apply CSS-styles based on a conditional function elementwise.

Deprecated since version 1.3.0.

Updates the HTML representation with a style which is selected in accordance with the return value of a function.

Parameters

- **cond** [callable] cond should take a scalar, and optional keyword arguments, and return a boolean.
- **value** [str] Applied when cond returns true.
- **other** [str] Applied when cond returns false.
- **subset** [label, array-like, IndexSlice, optional] A valid 2d input to DataFrame.loc[<subset>], or, in the case of a 1d input or single key, to DataFrame.loc[:, <subset>] where the columns are prioritised, to limit data to before applying the function.
- **kwargs** [dict] Pass along to cond.

Returns

self [Styler]

See also:

- **Styler.applymap** Apply a CSS-styling function elementwise.
- **Styler.apply** Apply a CSS-styling function column-wise, row-wise, or table-wise.

Notes

This method is deprecated.

This method is a convenience wrapper for Styler.applymap(), which we recommend using instead.

The example:

```python
>>> df = pd.DataFrame([[1, 2], [3, 4]])
>>> def cond(v, limit=4):
...     return v > 1 and v != limit
>>> df.style.where(cond, value='color:green;', other='color:red;')
```

should be refactored to:

```python
>>> def style_func(v, value, other, limit=4):
...     cond = v > 1 and v != limit
...     return value if cond else other
>>> df.style.applymap(style_func, value='color:green;', other='color:red;')
```

<tr>
<td><code>table(ax, data[, rowLabels, colLabels])</code></td>
<td>Helper function to convert DataFrame and Series to matplotlib.table.</td>
</tr>
</tbody>
</table>

3.13.1 pandas.plotting.andrews_curves

`pandas.plotting.andrews_curves(frame, class_column, ax=None, samples=200, color=None, colormap=None, **kwargs)` Generate a matplotlib plot of Andrews curves, for visualising clusters of multivariate data.

Andrews curves have the functional form:

\[ f(t) = x_1/sqrt(2) + x_2 \sin(t) + x_3 \cos(t) + x_4 \sin(2t) + x_5 \cos(2t) + \ldots \]

Where \( x \) coefficients correspond to the values of each dimension and \( t \) is linearly spaced between -\( \pi \) and +\( \pi \). Each row of frame then corresponds to a single curve.

**Parameters**

- `frame` [DataFrame] Data to be plotted, preferably normalized to (0.0, 1.0).
- `class_column` [Name of the column containing class names]
- `ax` [matplotlib axes object, default None]
- `samples` [Number of points to plot in each curve]
color  [list or tuple, optional] Colors to use for the different classes.

colormap  [str or matplotlib colormap object, default None] Colormap to select colors from.
  If string, load colormap with that name from matplotlib.

**kwargs  Options to pass to matplotlib plotting method.

Returns

class: matplotlib.axis.Axes

Examples

```python
>>> df = pd.read_csv(
...     'https://raw.githubusercontent.com/pandas-dev/
...     pandas/master/pandas/tests/io/data/csv/iris.csv'
... )
>>> pd.plotting.andrews_curves(df, 'Name')
```
3.13.2 pandas.plotting.autocorrelation_plot

def pandas.plotting.autocorrelation_plot(series, ax=None, **kwargs):
    Autocorrelation plot for time series.

    Parameters
    ----------
    series : Time series
    ax : Matplotlib axis object, optional
    **kwargs : Options to pass to matplotlib plotting method.

    Returns
    -------
    class: matplotlib.axis.Axes

Examples

The horizontal lines in the plot correspond to 95% and 99% confidence bands.
The dashed line is 99% confidence band.

```python
>>> spacing = np.linspace(-9 * np.pi, 9 * np.pi, num=1000)
>>> s = pd.Series(0.7 * np.random.rand(1000) + 0.3 * np.sin(spacing))
>>> pd.plotting.autocorrelation_plot(s)
```
pandas.plotting.bootstrap_plot

```
pandas.plotting.bootstrap_plot (series, fig=None, size=50, samples=500, **kwds)
Bootstrap plot on mean, median and mid-range statistics.
```

The bootstrap plot is used to estimate the uncertainty of a statistic by relaying on random sampling with re-placement [1]. This function will generate bootstrapping plots for mean, median and mid-range statistics for the
given number of samples of the given size.

**Parameters**

- `series` [pandas.Series] Series from where to get the samplings for the bootstrapping.
- `fig` [matplotlib.figure.Figure, default None] If given, it will use the `fig` reference for plotting instead of creating a new one with default parameters.
- `size` [int, default 50] Number of data points to consider during each sampling. It must be less than or equal to the length of the `series`.
- `samples` [int, default 500] Number of times the bootstrap procedure is performed.
- `**kwds` Options to pass to matplotlib plotting method.

**Returns**

- `matplotlib.figure.Figure` Matplotlib figure.

**See also:**

- `DataFrame.plot` Basic plotting for DataFrame objects.
- `Series.plot` Basic plotting for Series objects.

**Examples**

This example draws a basic bootstrap plot for a Series.

```
>>> s = pd.Series(np.random.uniform(size=100))
>>> pd.plotting.bootstrap_plot(s)
```

3.13.4 pandas.plotting.boxplot

```
pandas.plotting.boxplot (data, column=None, by=None, ax=None, fontsize=None, rot=0, grid=True, figsize=None, layout=None, return_type=None, **kwargs)
Make a box plot from DataFrame columns.
```

Make a box-and-whisker plot from DataFrame columns, optionally grouped by some other columns. A box plot
is a method for graphically depicting groups of numerical data through their quartiles. The box extends from
the Q1 to Q3 quartile values of the data, with a line at the median (Q2). The whiskers extend from the edges of
the box to show the range of the data. By default, they extend no more than 1.5 * IQR (IQR = Q3 - Q1) from the
edges of the box, ending at the farthest data point within that interval. Outliers are plotted as separate dots.
For further details see Wikipedia’s entry for boxplot.

**Parameters**

- `column` [str or list of str, optional] Column name or list of names, or vector. Can be any valid input to pandas.DataFrame.groupby().
- `by` [str or array-like, optional] Column in the DataFrame to pandas.DataFrame.
groupby(). One box-plot will be done per value of columns in `by`.
- `ax` [object of class matplotlib.axes.Axes, optional] The matplotlib axes to be used by boxplot.
The `boxplot()` function in pandas is used to create box plots, which are graphical representations of the distribution of data. The function accepts several parameters:

- **fontsize**: [float or str] Tick label font size in points or as a string (e.g., `large`).
- **rot**: [int or float, default 0] The rotation angle of labels (in degrees) with respect to the screen coordinate system.
- **grid**: [bool, default True] Setting this to True will show the grid.
- **figsize**: [A tuple (width, height) in inches] The size of the figure to create in matplotlib.
- **layout**: [tuple (rows, columns), optional] For example, (3, 5) will display the subplots using 3 columns and 5 rows, starting from the top-left.
- **return_type**: [{‘axes’, ‘dict’, ‘both’} or None, default ‘axes’] The kind of object to return. The default is `axes`.
  - ‘axes’ returns the matplotlib axes the boxplot is drawn on.
  - ‘dict’ returns a dictionary whose values are the matplotlib Lines of the boxplot.
  - ‘both’ returns a namedtuple with the axes and dict.
  - when grouping with `by`, a Series mapping columns to `return_type` is returned.

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned.

**kwargs: All other plotting keyword arguments to be passed to `matplotlib.pyplot.boxplot()`.

**Returns**
- **result**: See Notes.

**See also:**
- `Series.plot.hist` Make a histogram.
- `matplotlib.pyplot.boxplot` Matplotlib equivalent plot.

**Notes**

The return type depends on the `return_type` parameter:
- ‘axes’ : object of class matplotlib.axes.Axes
- ‘dict’ : dict of matplotlib.lines.Line2D objects
- ‘both’ : a namedtuple with the axes and dict.

For data grouped with `by`, return a Series of the above or a numpy array:
- `Series`
- `array` (for `return_type = None`)

Use `return_type='dict'` when you want to tweak the appearance of the lines after plotting. In this case a dict containing the Lines making up the boxes, caps, fliers, medians, and whiskers is returned.

**Examples**

Boxplots can be created for every column in the dataframe by `df.boxplot()` or indicating the columns to be used:

```python
>>> np.random.seed(1234)
>>> df = pd.DataFrame(np.random.randn(10, 4),
...                   columns=['Col1', 'Col2', 'Col3', 'Col4'])
>>> boxplot = df.boxplot(column=['Col1', 'Col2', 'Col3'])
```
3.13. Plotting
Boxplots of variables distributions grouped by the values of a third variable can be created using the option by. For instance:

```python
def = pd.DataFrame(np.random.randn(10, 2),
                   columns=['Col1', 'Col2'])
                     'B', 'B', 'B', 'B', 'B'])
boxplot = df.boxplot(by='X')
```

A list of strings (i.e. ['X', 'Y']) can be passed to boxplot in order to group the data by combination of the variables in the x-axis:

```python
def = pd.DataFrame(np.random.randn(10, 3),
                   columns=['Col1', 'Col2', 'Col3'])
                     'B', 'B', 'B', 'B', 'B'])
def['Y'] = pd.Series(['A', 'B', 'A', 'B', 'A',
                     'B', 'A', 'B', 'A', 'B'])
boxplot = df.boxplot(column=['Col1', 'Col2'], by=['X', 'Y'])
```

The layout of boxplot can be adjusted giving a tuple to layout:

```python
boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                     layout=(2, 1))
```

Additional formatting can be done to the boxplot, like suppressing the grid (grid=False), rotating the labels
in the x-axis (i.e. rot=45) or changing the fontsize (i.e. fontsize=15):

```python
>>> boxplot = df.boxplot(grid=False, rot=45, fontsize=15)
```

The parameter `return_type` can be used to select the type of element returned by `boxplot`. When `return_type='axes'` is selected, the matplotlib axes on which the boxplot is drawn are returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], return_type='axes')
>>> type(boxplot)
<class 'matplotlib.axes._subplots.AxesSubplot'>
```

When grouping with `by`, a Series mapping columns to `return_type` is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                       return_type='axes')
>>> type(boxplot)
<class 'pandas.core.series.Series'>
```

If `return_type` is `None`, a NumPy array of axes with the same shape as `layout` is returned:

```python
>>> boxplot = df.boxplot(column=['Col1', 'Col2'], by='X',
                       ... return_type=None)
>>> type(boxplot)
<class 'numpy.ndarray'>
```
3.13.5 pandas.plotting.deregister_matplotlib_converters

```
pandas.plotting.deregister_matplotlib_converters()
```

Remove pandas formatters and converters.

Removes the custom converters added by `register()`. This attempts to set the state of the registry back to the state before pandas registered its own units. Converters for pandas’ own types like `Timestamp` and `Period` are removed completely. Converters for types pandas overwrites, like `datetime.datetime`, are restored to their original value.

**See also:**

`register_matplotlib_converters` Register pandas formatters and converters with matplotlib.

3.13.6 pandas.plotting.lag_plot

```
pandas.plotting.lag_plot(series, lag=1, ax=None, **kwds)
```

Lag plot for time series.

**Parameters**

- `series` [Time series]
- `lag` [lag of the scatter plot, default 1]
- `ax` [Matplotlib axis object, optional]
- `**kwds` Matplotlib scatter method keyword arguments.

**Returns**

`class:matplotlib.axis.Axes`

**Examples**

Lag plots are most commonly used to look for patterns in time series data.

Given the following time series

```
>>> np.random.seed(5)
>>> x = np.cumsum(np.random.normal(loc=1, scale=5, size=50))
>>> s = pd.Series(x)
>>> s.plot()
```

A lag plot with `lag=1` returns

```
>>> pd.plotting.lag_plot(s, lag=1)
```
**class_column**  [str] Column name containing class names.

**cols**  [list, optional] A list of column names to use.

**ax**  [matplotlib.axis, optional] Matplotlib axis object.

**color**  [list or tuple, optional] Colors to use for the different classes.

**use_columns**  [bool, optional] If true, columns will be used as xticks.

**xticks**  [list or tuple, optional] A list of values to use for xticks.

**colormap**  [str or matplotlib colormap, default None] Colormap to use for line colors.

**axvlines**  [bool, optional] If true, vertical lines will be added at each xtick.

**axvlines_kwds**  [keywords, optional] Options to be passed to axvline method for vertical lines.

**sort_labels**  [bool, default False] Sort class_column labels, useful when assigning colors.

**kwargs**  Options to pass to matplotlib plotting method.

---

**Examples**

```python
def = pd.read_csv(  
...   'https://raw.github.com/pandas-dev/'  
...   'pandas/master/pandas/tests/io/data/csv/iris.csv'  
... )
def.plotting.parallel_coordinates(  
...   df, 'Name', color=('#556270', '#4ECDC4', '#C7F464')  
... )
```

---

### 3.13.8 pandas.plotting.plot_params

**pandas.plotting.plot_params = {\'xaxis.compat\': False}**

Stores pandas plotting options.

Allows for parameter aliasing so you can just use parameter names that are the same as the plot function parameters, but is stored in a canonical format that makes it easy to breakdown into groups later.

### 3.13.9 pandas.plotting.radviz

**pandas.plotting.radviz(frame, class_column, ax=None, color=None, colormap=None, **kwds)**

Plot a multidimensional dataset in 2D.

Each Series in the DataFrame is represented as a evenly distributed slice on a circle. Each data point is rendered in the circle according to the value on each Series. Highly correlated Series in the DataFrame are placed closer on the unit circle.

RadViz allow to project a N-dimensional data set into a 2D space where the influence of each dimension can be interpreted as a balance between the influence of all dimensions.

More info available at the original article describing RadViz.
frame [DataFrame] Object holding the data.

class_column [str] Column name containing the name of the data point category.

ax [matplotlib.axes.Axes, optional] A plot instance to which to add the information.

color [list[str] or tuple[str], optional] Assign a color to each category. Example: ['blue', 'green'].

colormap [str or matplotlib.colors.Colormap, default None] Colormap to select colors from. If string, load colormap with that name from matplotlib.

**kwds Options to pass to matplotlib scatter plotting method.

Returns

class:matplotlib.axes.Axes

See also:

plotting.andrews_curves Plot clustering visualization.

Examples

```python
>>> df = pd.DataFrame(
...     {
...         'SepalLength': [6.5, 7.7, 5.1, 5.8, 7.6, 5.0, 5.4, 4.6, 6.7, 4.6],
...         'SepalWidth': [3.0, 3.8, 3.8, 2.7, 3.0, 2.3, 3.0, 3.2, 3.3, 3.6],
...         'PetalLength': [5.5, 6.7, 1.9, 5.1, 6.6, 3.3, 4.5, 1.4, 5.7, 1.0],
...         'PetalWidth': [1.8, 2.2, 0.4, 1.9, 2.1, 1.0, 1.5, 0.2, 2.1, 0.2],
...         'Category': ['virginica', 'virginica', 'setosa', 'virginica', 'virginica', 'versicolor', 'versicolor', 'setosa', 'virginica', 'setosa']
...     }
... )

>>> pd.plotting.radviz(df, 'Category')
```

3.13.10 pandas.plotting.register_matplotlib_converters

pandas.plotting.register_matplotlib_converters()

Register pandas formatters and converters with matplotlib.

This function modifies the global matplotlib.units.registry dictionary. pandas adds custom converters for

- pd.Timestamp
- pd.Period
- np.datetime64
- datetime.datetime
- datetime.date
- datetime.time
See also:

deregister_matplotlib_converters Remove pandas formatters and converters.

3.13.11 pandas.plotting.scatter_matrix

pandas.plotting.scatter_matrix(frame, alpha=0.5, figsize=None, ax=None, grid=False, diagonal='hist', marker='.', density_kwds=None, hist_kwds=None, range_padding=0.05, **kwargs)

Draw a matrix of scatter plots.

Parameters

- **frame** [DataFrame]
- **alpha** [float, optional] Amount of transparency applied.
- **figsize** [(float, float), optional] A tuple (width, height) in inches.
- **ax** [Matplotlib axis object, optional]
- **grid** [bool, optional] Setting this to True will show the grid.
- **diagonal** [{'hist', 'kde'}] Pick between ‘kde’ and ‘hist’ for either Kernel Density Estimation or Histogram plot in the diagonal.
- **marker** [str, optional] Matplotlib marker type, default ‘.’.
- **density_kwds** [keywords] Keyword arguments to be passed to kernel density estimate plot.
- **hist_kwds** [keywords] Keyword arguments to be passed to hist function.
- **range_padding** [float, default 0.05] Relative extension of axis range in x and y with respect to (x_max - x_min) or (y_max - y_min).
- ****kwargs** Keyword arguments to be passed to scatter function.

Returns

- **numpy.ndarray** A matrix of scatter plots.

Examples

```python
>>> df = pd.DataFrame(np.random.randn(1000, 4), columns=['A','B','C','D'])
>>> pd.plotting.scatter_matrix(df, alpha=0.2)
```

3.13.12 pandas.plotting.table

pandas.plotting.table(ax, data, rowLabels=None, colLabels=None, **kwargs)

Helper function to convert DataFrame and Series to matplotlib.table.

Parameters

- **ax** [Matplotlib axes object]
- **data** [DataFrame or Series] Data for table contents.
- ****kwargs** Keyword arguments to be passed to matplotlib.table.table. If rowLabels or colLabels is not specified, data index or column name will be used.

Returns

- **matplotlib table object**
3.14 General utility functions

3.14.1 Working with options

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>describe_option()</code></td>
<td>Prints the description for one or more registered options.</td>
</tr>
<tr>
<td><code>reset_option()</code></td>
<td>Reset one or more options to their default value.</td>
</tr>
<tr>
<td><code>get_option()</code></td>
<td>Retrieves the value of the specified option.</td>
</tr>
<tr>
<td><code>set_option()</code></td>
<td>Sets the value of the specified option.</td>
</tr>
<tr>
<td><code>option_context()</code></td>
<td>Context manager to temporarily set options in the with statement context.</td>
</tr>
</tbody>
</table>

**pandas.describe_option**

```python
pandas.describe_option(pat, _print_desc=False) = <pandas._config.config.CallableDynamicDoc object>
```

Prints the description for one or more registered options.

Call with not arguments to get a listing for all registered options.

Available options:
- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]
- io.excel.ods.[reader, writer]
- io.excel.xls.[reader, writer]
- io.excel.xlsb.[reader]
- io.excel.xlsm.[reader, writer]
- io.excel.xlsx.[reader, writer]
- io.hdf.[default_format, dropna_table]
- io.parquet.[engine]
- io.sql.[engine]
- mode.[chained_assignment, data_manager, sim_interactive, string_storage, use_inf_as_na, use_inf_as_null]
- plotting.[backend]
- plotting.matplotlib.[register_converters]
- styler.render.[max_elements]
- styler.sparse.[columns, index]

**Parameters**
- `pat` [str] Regex pattern. All matching keys will have their description displayed.
- `_print_desc` [bool, default True] If True (default) the description(s) will be printed to stdout. Otherwise, the description(s) will be returned as a unicode string (for testing).

**Returns**
None by default, the description(s) as a unicode string if _print_desc
is False

Notes

The available options with its descriptions:

**compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True
Valid values: False,True [default: True] [currently: True]

**compute.use_numba** [bool] Use the numba engine option for select operations if it is installed, the default is False
Valid values: False,True [default: False] [currently: False]

**compute.use_numexpr** [bool] Use the numexpr library to accelerate computation if it is installed, the default is True
Valid values: False,True [default: True] [currently: True]

**display.chop_threshold** [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]

**display.colheader_justify** ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]

**display.column_space** No description available. [default: 12] [currently: 12]

**display.date_dayfirst** [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]

**display.date_yearfirst** [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]

**display.encoding** [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]

**display.expand_frame_repr** [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple "pages" if its width exceeds display.width. [default: True] [currently: True]

**display.float_format** [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]

**display.html.border** [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]

**display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]

**display.html.use_mathjax** [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]

**display.large_repr** ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]

**display.latex.escape** [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: False] [currently: False]

**display.latex.longtable** [bool] This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: True] [currently: True]

**display.latex.multiprint** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]

**display.latex.multicolumn_format** [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False,True [default: True] [currently: True]

**display.latex.multitrag** [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]

**display.latex.repr** [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]
**display.max_categories** [int] This sets the maximum number of categories pandas should output when printing out a *Categorical* or a *Series* of dtype “category”. [default: 8] [currently: 8]

**display.max_columns** [int] If max_cols is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

**display.max_colwidth** [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]

**display.max_info_columns** [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]

**display.max_info_rows** [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

**display.max_rows** [int] If max_rows is exceeded, switch to truncate view. Depending on *large_repr*, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and *large_repr* equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]

**display.max_seq_items** [int or None] When pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

**display.memory_usage** [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,’deep’ [default: True] [currently: True]

**display.min_rows** [int] The numbers of rows to show in a truncated view (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows. [default: 10] [currently: 10]

**display.multi_sparse** [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]

**display.notebook_repr_html** [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

**display.pprint_nest_depth** [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

**display.precision** [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to precision in numpy. set_printoptions(). [default: 6] [currently: 6]

**display.show_dimensions** [boolean or ‘truncate’) Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

**display.unicode.ambiguous_as_wide** [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

**display.unicode.east_asian_width** [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

**display.width** [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]
io.hdf.default_format [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]
io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]
mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]
mode.data_manager [string] Internal data manager type; can be “block” or “array”. Defaults to “block”, unless overridden by the ‘PANDAS_DATA_MANAGER’ environment variable (needs to be set before pandas is imported). [default: block] [currently: block]
mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]
mode.string_storage [string] The default storage for StringDtype. [default: python] [currently: python]
mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]
mode.use_inf_as_null [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)
plotting.backend [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]
plotting.matplotlib.register_converters [bool or ‘auto’] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]
styler.render.max_elements [int] The maximum number of data-cell (<td>) elements that will be rendered before trimming will occur over columns, rows or both if needed. [default: 262144] [currently: 262144]
stylersparse.columns [bool] Whether to sparsefy the display of hierarchical columns. Setting to False will display each explicit level element in a hierarchical key for each column. [default: True] [currently: True]
stylersparse.index [bool] Whether to sparsefy the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. [default: True] [currently: True]
pandas: powerful Python data analysis toolkit, Release 1.3.1

#### pandas.reset_option

```python
pandas.reset_option(pat) = <pandas._config.config.CallableDynamicDoc object>
```

Reset one or more options to their default value.

Pass “all” as argument to reset all options.

**Available options:**

- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]
- io.excel.ods.[reader, writer]
- io.excel.xls.[reader, writer]
- io.excel.xlsb.[reader]
- io.excel.xlsm.[reader, writer]
- io.excel.xlsx.[reader, writer]
- io.hdf.[default_format, dropna_table]
- io.parquet.[engine]
- io.sql.[engine]
- mode.[chained_assignment, data_manager, sim_interactive, string_storage, use_inf_as_na, use_inf_as_null]
- plotting.[backend]
- plotting.matplotlib.[register_converters]
- styler.render.[max_elements]
- styler.sparse.[columns, index]

**Parameters**

- **pat** [str/regex] If specified only options matching prefix* will be reset. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.

**Returns**

- **None**

**Notes**

The available options with its descriptions:

- **compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True
  
  Valid values: False, True [default: True] [currently: True]

- **compute.use_numba** [bool] Use the numba engine option for select operations if it is installed, the default is False
  
  Valid values: False, True [default: False] [currently: False]

- **compute.use_numexpr** [bool] Use the numexpr library to accelerate computation if it is installed, the default is True
  
  Valid values: False, True [default: True] [currently: True]

---

3.14. General utility functions 2543
display.chop_threshold [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
display.colheader_justify ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]
display.column_space No description available. [default: 12] [currently: 12]
display.date_dayfirst [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]
display.date_yearfirst [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]
display.encoding [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]
display.expand_frame_repr [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width. [default: True] [currently: True]
display.float_format [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]
display.html.border [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]
display.html.table_schema [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]
display.html.use_mathjax [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]
display.large_repr ['truncate'/'info'] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]
display.latex.escape [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False, True [default: True] [currently: True]
display.latex.longtable :bool This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False, True [default: False] [currently: False]
display.latex.multiprint [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False, True [default: True] [currently: True]
display.latex.multiprint_format [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False, True [default: True] [currently: True]
display.latex.multirow [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False, True [default: False] [currently: False]
display.latex.repr [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]
display.max_categories [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype category. [default: 8] [currently: 8]
display.max_columns [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited. In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]
display.max_colwidth [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]
display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]
**display.max_info_rows** [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

**display.max_rows** [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]

**display.max_seq_items** [int or None] When pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

**display.memory_usage** [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,’deep’ [default: True] [currently: True]

**display.min_rows** [int] The numbers of rows to show in a truncated view (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows. [default: 10] [currently: 10]

**display.multi_sparse** [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]

**display.notebook_repr_html** [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

**display.pprint_nest_depth** [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

**display.precision** [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to precision in numpy.set_printoptions(). [default: 6] [currently: 6]

**display.show_dimensions** [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

**display.unicode.ambiguous_as_wide** [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

**display.unicode.east_asian_width** [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

**display.width** [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

io.hdf.default_format [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]

io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment, The default is warn [default: warn] [currently: warn]

mode.data_manager [string] Internal data manager type; can be “block” or “array”. Defaults to “block”, unless overridden by the ‘PANDAS_DATA_MANAGER’ environment variable (needs to be set before pandas is imported). [default: block] [currently: block]

mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

mode.string_storage [string] The default storage for StringDtype. [default: python] [currently: python]

mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

mode.use_inf_as_null [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)

plotting.backend [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

plotting.matplotlib.register_converters [bool or ‘auto’] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

styler.render.max_elements [int] The maximum number of data-cell (<td>) elements that will be rendered before trimming will occur over columns, rows or both if needed. [default: 262144] [currently: 262144]

styler.sparse.columns [bool] Whether to sparsify the display of hierarchical columns. Setting to False will display each explicit level element in a hierarchical key for each column. [default: True] [currently: True]

styler.sparse.index [bool] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. [default: True] [currently: True]

**pandas.get_option**

pandas.get_option(pat) = <pandas._config.config.CallableDynamicDoc object>

Retrieves the value of the specified option.

Available options:

- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
• display.[width]
• io.excel.ods.[reader, writer]
• io.excel.xls.[reader, writer]
• io.excel.xlsb.[reader]
• io.excel.xlsm.[reader, writer]
• io.excel.xlsx.[reader, writer]
• io.hdf.[default_format, dropna_table]
• io.parquet.[engine]
• io.sql.[engine]
• mode.[chained_assignment, data_manager, sim_interactive, string_storage, use_inf_as_na, use_inf_as_null]
• plotting.[backend]
• plotting.matplotlib.[register_converters]
• styler.render.[max_elements]
• styler.sparse.[columns, index]

Parameters

    pat [str] Regexp which should match a single option. Note: partial matches are supported
    for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your
    code may break in future versions if new options with similar names are introduced.

Returns

    result [the value of the option]

Raises

    OptionError [if no such option exists]

Notes

The available options with its descriptions:

compute.use_bottleneck [bool] Use the bottleneck library to accelerate if it is installed, the default is True
    Valid values: False,True [default: True] [currently: True]
compute.use_numba [bool] Use the numba engine option for select operations if it is installed, the default is
    False Valid values: False,True [default: False] [currently: False]
compute.use_numexpr [bool] Use the numexpr library to accelerate computation if it is installed, the default
    is True Valid values: False,True [default: True] [currently: True]
display.chop_threshold [float or None] if set to a float value, all float values smaller then the given threshold
    will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]
display.colheader_justify ['left'/'right'] Controls the justification of column headers. used by DataFrameFor-
    matter. [default: right] [currently: right]
display.column_space No description available. [default: 12] [currently: 12]
display.date_dayfirst [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default:
    False] [currently: False]
display.date_yearfirst [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default:
    False] [currently: False]
display.encoding [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be
    used for strings returned by to_string, these are generally strings meant to be displayed on the console.
    [default: utf-8] [currently: utf-8]
display.expand_frame_repr [boolean] Whether to print out the full DataFrame repr for wide DataFrames
    across multiple lines, max_columns is still respected, but the output will wrap-around across multiple
    “pages” if its width exceeds display.width. [default: True] [currently: True]
display.float_format [callable] The callable should accept a floating point number and return a string with
the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]

display.html.border [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]

display.html.table_schema [boolean] Whether to publish a Table Schema representation for frontends that support it. (default: False) [default: False] [currently: False]

display.html.use_mathjax [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. (default: True) [default: True] [currently: True]

display.large_repr ['truncate'/’info’) For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]

display.latex.escape [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: False] [currently: True]

display.latex.longtable :bool This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False,True [default: False] [currently: False]

display.latex.multicolumn [bool] This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False, True [default: True] [currently: True]

display.latex.multicolumn_format [bool] This specifies if the to_latex method of a Dataframe uses multi-columns to pretty-print MultiIndex columns. Valid values: False, True [default: l] [currently: l]

display.latex.multirow [bool] This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False,True [default: False] [currently: False]

display.latex.repr [boolean] Whether to produce a latex DataFrame representation for jupyter environments that support it. (default: False) [default: False] [currently: False]

display.max_categories [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dttype “category”. [default: 8] [currently: 8]

display.max_columns [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

display.max_colwidth [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “…” placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]

display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]

display.max_info_rows [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

display.max_rows [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]

display.max_seq_items [int or None] When pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True,False,’deep’ [default: True] [currently: True]

display.min_rows [int] The numbers of rows to show in a truncated view (when max_rows is exceeded). Ig-
nored when \textit{max\_rows} is set to None or 0. When set to None, follows the value of \textit{max\_rows}. [default: 10] [currently: 10]

\textbf{display.multi\_sparse} [boolean] “sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]

\textbf{display.notebook\_repr\_html} [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

\textbf{display.pprint\_nest\_depth} [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

\textbf{display.precision} [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to \texttt{precision} in numpy. \texttt{set\_printoptions}(). [default: 6] [currently: 6]

\textbf{display.show\_dimensions} [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]

\textbf{display.unicode.ambiguous\_as\_wide} [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance [default: False] [currently: False]

\textbf{display.unicode.east\_asian\_width} [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance [default: False] [currently: False]

\textbf{display.width} [int] Width of the display in characters. In case python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

\textbf{io.hdf.default\_format} [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]

\textbf{io.hdf.dropna\_table} [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

\textbf{mode.chained\_assignment} [string] Raise an exception, warn, or no action if trying to use chained assignment. The default is warn [default: warn] [currently: warn]

\textbf{mode.data\_manager} [string] Internal data manager type; can be “block” or “array”. Defaults to “block”, unless overridden by the ‘PANDAS\_DATA\_MANAGER’ environment variable (needs to be set before

3.14. General utility functions 2549
pandas: powerful Python data analysis toolkit, Release 1.3.1

pandas is imported). [default: block] [currently: block]

**mode.sim_interactive** [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

**mode.string_storage** [string] The default storage for StringDtype. [default: python] [currently: python]

**mode.use_inf_as_na** [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

**mode.use_inf_as_null** [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)

**plotting.backend** [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

**plotting.matplotlib.register_converters** [bool or ‘auto’.] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring any converters that pandas overwrote. [default: auto] [currently: auto]

**styler.render.max_elements** [int] The maximum number of data-cell (<td>) elements that will be rendered before trimming will occur over columns, rows or both if needed. [default: 262144] [currently: 262144]

**styler.sparse.columns** [bool] Whether to sparsify the display of hierarchical columns. Setting to False will display each explicit level element in a hierarchical key for each column. [default: True] [currently: True]

**styler.sparse.index** [bool] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. [default: True] [currently: True]

### pandas.set_option

```python
pandas.set_option(pat, value) = <pandas._config.config.CallableDynamicDoc object>
```

Sets the value of the specified option.

Available options:

- compute.[use_bottleneck, use_numba, use_numexpr]
- display.[chop_threshold, colheader_justify, column_space, date_dayfirst, date_yearfirst, encoding, expand_frame_repr, float_format]
- display.html.[border, table_schema, use_mathjax]
- display.[large_repr]
- display.latex.[escape, longtable, multicolumn, multicolumn_format, multirow, repr]
- display.[max_categories, max_columns, max_colwidth, max_info_columns, max_info_rows, max_rows, max_seq_items, memory_usage, min_rows, multi_sparse, notebook_repr_html, pprint_nest_depth, precision, show_dimensions]
- display.unicode.[ambiguous_as_wide, east_asian_width]
- display.[width]
- io.excel.ods.[reader, writer]
- io.excel.xls.[reader, writer]
- io.excel.xlsb.[reader]
- io.excel.xlsm.[reader, writer]
- io.excel.xlsx.[reader, writer]
- io.hdf.[default_format, dropna_table]
- io.parquet.[engine]
- io.sql.[engine]
- mode.[chained_assignment, data_manager, sim_interactive, string_storage, use_inf_as_na, use_inf_as_null]
- plotting.[backend]
- plotting.matplotlib.register_converters]
- styler.render.[max_elements]
- styler.sparse.[columns, index]
Parameters

- **pat** [str] Regexp which should match a single option. Note: partial matches are supported for convenience, but unless you use the full option name (e.g. x.y.z.option_name), your code may break in future versions if new options with similar names are introduced.

- **value** [object] New value of option.

Returns

- None

Raises

- OptionError if no such option exists

Notes

The available options with its descriptions:

- **compute.use_bottleneck** [bool] Use the bottleneck library to accelerate if it is installed, the default is True
  Valid values: False,True [default: True] [currently: True]

- **compute.use_numba** [bool] Use the numba engine option for select operations if it is installed, the default is False
  Valid values: False,True [default: False] [currently: False]

- **compute.use_numexpr** [bool] Use the numexpr library to accelerate computation if it is installed, the default is True
  Valid values: False,True [default: True] [currently: True]

- **display.chop_threshold** [float or None] if set to a float value, all float values smaller then the given threshold will be displayed as exactly 0 by repr and friends. [default: None] [currently: None]

- **display.colheader_justify** ['left'/'right'] Controls the justification of column headers. used by DataFrameFormatter. [default: right] [currently: right]

- **display.column_space** No description available. [default: 12] [currently: 12]

- **display.date_dayfirst** [boolean] When True, prints and parses dates with the day first, eg 20/01/2005 [default: False] [currently: False]

- **display.date_yearfirst** [boolean] When True, prints and parses dates with the year first, eg 2005/01/20 [default: False] [currently: False]

- **display.encoding** [str/unicode] Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by to_string, these are generally strings meant to be displayed on the console. [default: utf-8] [currently: utf-8]

- **display.expand_frame_repr** [boolean] Whether to print out the full DataFrame repr for wide DataFrames across multiple lines, max_columns is still respected, but the output will wrap-around across multiple “pages” if its width exceeds display.width. [default: True] [currently: True]

- **display.float_format** [callable] The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See formats.format.EngFormatter for an example. [default: None] [currently: None]

- **display.html.border** [int] A border=value attribute is inserted in the <table> tag for the DataFrame HTML repr. [default: 1] [currently: 1]

- **display.html.table_schema** [boolean] Whether to publish a Table Schema representation for frontends that support it. [default: False] [currently: False]

- **display.html.use_mathjax** [boolean] When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol. [default: True] [currently: True]

- **display.large_repr** ['truncate’/’info’] For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default from 0.13), or switch to the view from df.info() (the behaviour in earlier versions of pandas). [default: truncate] [currently: truncate]

- **display.latex.escape** [bool] This specifies if the to_latex method of a Dataframe uses escapes special characters. Valid values: False,True [default: True] [currently: True]
display.latex.longtable :bool This specifies if the to_latex method of a Dataframe uses the longtable format. Valid values: False, True [default: False] [currently: False]

display.latex.multicolumn :bool This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False, True [default: True] [currently: True]

display.latex.multicolumn_format :bool This specifies if the to_latex method of a Dataframe uses multicolumns to pretty-print MultiIndex columns. Valid values: False, True [default: 1] [currently: 1]

display.latex.multirow :bool This specifies if the to_latex method of a Dataframe uses multirows to pretty-print MultiIndex rows. Valid values: False, True [default: False] [currently: False]

display.latex.repr [boolean] Whether to produce a latex DataFrame representation for Jupyter environments that support it. (default: False) [default: False] [currently: False]

display.max_categories [int] This sets the maximum number of categories pandas should output when printing out a Categorical or a Series of dtype “category”. [default: 8] [currently: 8]

display.max_columns [int] If max_cols is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the width of the terminal and print a truncated object which fits the screen width. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 0] [currently: 0]

display.max_colwidth [int or None] The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a ‘...’ placeholder is embedded in the output. A ‘None’ value means unlimited. [default: 50] [currently: 50]

display.max_info_columns [int] max_info_columns is used in DataFrame.info method to decide if per column information will be printed. [default: 100] [currently: 100]

display.max_info_rows [int or None] df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified. [default: 1690785] [currently: 1690785]

display.max_rows [int] If max_rows is exceeded, switch to truncate view. Depending on large_repr, objects are either centrally truncated or printed as a summary view. ‘None’ value means unlimited.

In case python/IPython is running in a terminal and large_repr equals ‘truncate’ this can be set to 0 and pandas will auto-detect the height of the terminal and print a truncated object which fits the screen height. The IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection. [default: 60] [currently: 60]

display.max_seq_items [int or None] When pretty-printing a long sequence, no more then max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “…” to the resulting string.

If set to None, the number of items to be printed is unlimited. [default: 100] [currently: 100]

display.memory_usage [bool, string or None] This specifies if the memory usage of a DataFrame should be displayed when df.info() is called. Valid values True, False, ‘deep’ [default: True] [currently: True]

display.min_rows [int] The numbers of rows to show in a truncated view (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows. [default: 10] [currently: 10]

display.multi_sparse [boolean] ‘sparsify’ MultiIndex display (don’t display repeated elements in outer levels within groups) [default: True] [currently: True]

display.notebook_repr_html [boolean] When True, IPython notebook will use html representation for pandas objects (if it is available). [default: True] [currently: True]

display.pprint_nest_depth [int] Controls the number of nested levels to process when pretty-printing [default: 3] [currently: 3]

display.precision [int] Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to precision in numpy. set_printoptions(). [default: 6] [currently: 6]

display.show_dimensions [boolean or ‘truncate’] Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns) [default: truncate] [currently: truncate]
display.unicode.ambiguous_as_wide [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.unicode.east_asian_width [boolean] Whether to use the Unicode East Asian Width to calculate the display text width. Enabling this may affect to the performance (default: False) [default: False] [currently: False]

display.width [int] Width of the display in characters. In case python/ IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width. [default: 80] [currently: 80]

io.hdf.default_format [format] default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’ [default: None] [currently: None]

io.hdf.dropna_table [boolean] drop ALL nan rows when appending to a table [default: False] [currently: False]

mode.chained_assignment [string] Raise an exception, warn, or no action if trying to use chained assignment. The default is warn [default: warn] [currently: warn]

mode.data_manager [string] Internal data manager type; can be “block” or “array”. Defaults to “block”, unless overridden by the ‘PANDAS_DATA_MANAGER’ environment variable (needs to be set before pandas is imported). [default: block] [currently: block]

mode.sim_interactive [boolean] Whether to simulate interactive mode for purposes of testing [default: False] [currently: False]

mode.string_storage [string] The default storage for StringDtype. [default: python] [currently: python]

mode.use_inf_as_na [boolean] True means treat None, NaN, INF, -INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way). [default: False] [currently: False]

mode.use_inf_as_null [boolean] use_inf_as_null had been deprecated and will be removed in a future version. Use use_inf_as_na instead. [default: False] [currently: False] (Deprecated, use mode.use_inf_as_na instead.)

plotting.backend [str] The plotting backend to use. The default value is “matplotlib”, the backend provided with pandas. Other backends can be specified by providing the name of the module that implements the backend. [default: matplotlib] [currently: matplotlib]

plotting.matplotlib.register_converters [bool or ‘auto’.] Whether to register converters with matplotlib’s units registry for dates, times, datetimes, and Periods. Toggling to False will remove the converters, restoring
any converters that pandas overwrote. [default: auto] [currently: auto]

**styler.render.max_elements** [int] The maximum number of data-cell (<td>) elements that will be rendered before trimming will occur over columns, rows or both if needed. [default: 262144] [currently: 262144]

**styler.sparse.columns** [bool] Whether to sparsify the display of hierarchical columns. Setting to False will display each explicit level element in a hierarchical key for each column. [default: True] [currently: True]

**styler.sparse.index** [bool] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. [default: True] [currently: True]

---

**pandas.option_context**

*class* pandas.option_context(*args*)

Context manager to temporarily set options in the with statement context.

You need to invoke as option_context(pat, val, [(pat, val), ...]).

**Examples**

```python
>>> with option_context('display.max_rows', 10, 'display.max_columns', 5):
...  ...
```

**Methods**

```python
__call__(func)                         # Call self as a function.
```

**pandas.option_context.__call__**

```python
option_context.__call__(func)         # Call self as a function.
```

---

### 3.14.2 Testing functions

- `testing.assert_frame_equal(left, right[, ...])` Check that left and right DataFrame are equal.
- `testing.assert_series_equal(left, right[, ...])` Check that left and right Series are equal.
- `testing.assert_index_equal(left, right[, ...])` Check that left and right Index are equal.
- `testing.assert_extension_array_equal(left, right)` Check that left and right ExtensionArrays are equal.
pandas.testing.assert_frame_equal

`pandas.testing.assert_frame_equal(left, right, check_dtype=True, check_index_type='equiv', check_column_type='equiv', check_frame_type=True, check_less_precise=<no_default>, check_names=True, by_blocks=False, check_exact=False, check_datetimelike_compat=False, check_categorical=True, check_like=False, check_freq=True, check_flags=True, rtol=1e-05, atol=1e-08, obj='DataFrame')`

Check that left and right DataFrame are equal.

This function is intended to compare two DataFrames and output any differences. It is mostly intended for use in unit tests. Additional parameters allow varying the strictness of the equality checks performed.

**Parameters**

- `left` [DataFrame] First DataFrame to compare.
- `right` [DataFrame] Second DataFrame to compare.
- `check_dtype` [bool, default True] Whether to check the DataFrame dtype is identical.
- `check_index_type` [bool or {'equiv'}, default 'equiv'] Whether to check the Index class, dtype and inferred_type are identical.
- `check_column_type` [bool or {'equiv'}, default 'equiv'] Whether to check the columns class, dtype and inferred_type are identical. Is passed as the `exact` argument of `assert_index_equal()`.
- `check_frame_type` [bool, default True] Whether to check the DataFrame class is identical.
- `check_less_precise` [bool or int, default False] Specify comparison precision. Only used when `check_exact` is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

When comparing two numbers, if the first number has magnitude less than 1e-5, we compare the two numbers directly and check whether they are equivalent within the specified precision. Otherwise, we compare the ratio of the second number to the first number and check whether it is equivalent to 1 within the specified precision.

Deprecated since version 1.1.0: Use `rtol` and `atol` instead to define relative/absolute tolerance, respectively. Similar to `math.isclose()`.

- `check_names` [bool, default True] Whether to check that the `names` attribute for both the `index` and `column` attributes of the DataFrame is identical.
- `by_blocks` [bool, default False] Specify how to compare internal data. If False, compare by columns. If True, compare by blocks.
- `check_exact` [bool, default False] Whether to compare number exactly.
- `check_datetimelike_compat` [bool, default False] Compare datetime-like which is comparable ignoring dtype.
- `check_categorical` [bool, default True] Whether to compare internal Categorical exactly.
- `check_like` [bool, default False] If True, ignore the order of index & columns. Note: index labels must match their respective rows (same as in columns) - same labels must be with the same data.
- `check_freq` [bool, default True] Whether to check the `freq` attribute on a DatetimeIndex or TimedeltaIndex.
New in version 1.1.0.

**check_flags** [bool, default True] Whether to check the *flags* attribute.

**rtol** [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.

**atol** [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.

**obj** [str, default ‘DataFrame’] Specify object name being compared, internally used to show appropriate assertion message.

See also:

- `assert_series_equal` Equivalent method for asserting Series equality.
- `DataFrame.equals` Check DataFrame equality.

### Examples

This example shows comparing two DataFrames that are equal but with columns of differing dtypes.

```python
>>> from pandas._testing import assert_frame_equal
>>> df1 = pd.DataFrame({'a': [1, 2], 'b': [3, 4]})
>>> df2 = pd.DataFrame({'a': [1, 2], 'b': [3.0, 4.0]})
```

df1 equals itself.

```python
>>> assert_frame_equal(df1, df1)
```

df1 differs from df2 as column ‘b’ is of a different type.

```python
>>> assert_frame_equal(df1, df2)
Traceback (most recent call last):
  ...  
AssertionError: Attributes of DataFrame.iloc[:, 1] (column name="b") are different
```

Attribute “dtype” are different [left]: int64 [right]: float64

Ignore differing dtypes in columns with check_dtype.

```python
>>> assert_frame_equal(df1, df2, check_dtype=False)
```

### pandas.testing.assert_series_equal

**pandas.testing.assert_series_equal**(left, right, **check_dtype=True, check_index_type='equiv', check_series_type=True, check_less_precise=<no_default>, check_names=True, check_exact=False, check_datetimelike_compat=False, check_categorical=True, check_category_order=True, check_freq=True, check_flags=True, rtol=1e-05, atol=1e-08, obj='Series', *, check_index=True)

Check that left and right Series are equal.

**Parameters**

- **left** [Series]
- **right** [Series]
check_dtype [bool, default True] Whether to check the Series dtype is identical.

check_index_type [bool or {'equiv'}, default 'equiv'] Whether to check the Index class, dtype and inferred_type are identical.

check_series_type [bool, default True] Whether to check the Series class is identical.

check_less_precise [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.

When comparing two numbers, if the first number has magnitude less than 1e-5, we compare the two numbers directly and check whether they are equivalent within the specified precision. Otherwise, we compare the ratio of the second number to the first number and check whether it is equivalent to 1 within the specified precision.

Deprecated since version 1.1.0: Use rtol and atol instead to define relative/absolute tolerance, respectively. Similar to math.isclose().

check_names [bool, default True] Whether to check the Series and Index names attribute.

check_exact [bool, default False] Whether to compare number exactly.

check_datetimelike_compat [bool, default False] Compare datetime-like which is comparable ignoring dtype.

check_categorical [bool, default True] Whether to compare internal Categorical exactly.

check_category_order [bool, default True] Whether to compare category order of internal Categoricals.

New in version 1.0.2.

check_freq [bool, default True] Whether to check the freq attribute on a DatetimeIndex or TimedeltaIndex.

New in version 1.1.0.

check_flags [bool, default True] Whether to check the flags attribute.

New in version 1.2.0.

rtol [float, default 1e-5] Relative tolerance. Only used when check_exact is False.

New in version 1.1.0.

atol [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.

New in version 1.1.0.

obj [str, default ‘Series’] Specify object name being compared, internally used to show appropriate assertion message.

check_index [bool, default True] Whether to check index equivalence. If False, then compare only values.

New in version 1.3.0.
Examples

```python
>>> from pandas.testing import assert_series_equal
>>> a = pd.Series([1, 2, 3, 4])
>>> b = pd.Series([1, 2, 3, 4])
>>> assert_series_equal(a, b)
```

```
pandas.testing.assert_index_equal
```

pandas.testing.assert_index_equal

```python
pandas.testing.assert_index_equal(left, right, exact='equiv', check_names=True,
check_less_precise=None, check_exact=True,
check_categorical=True, check_order=True,
rtol=1e-05, atol=1e-08, obj='Index')
```

Check that left and right Index are equal.

Parameters

- **left** [Index]
- **right** [Index]
- **exact** [bool or ‘equiv’, default ‘equiv’] Whether to check the Index class, dtype and inferred_type are identical. If ‘equiv’, then RangeIndex can be substituted for Int64Index as well.
- **check_names** [bool, default True] Whether to check the names attribute.
- **check_less_precise** [bool or int, default False] Specify comparison precision. Only used when check_exact is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.
  
  Deprecated since version 1.1.0: Use rtol and atol instead to define relative/absolute tolerance, respectively. Similar to `math.isclose()`.
- **check_exact** [bool, default True] Whether to compare number exactly.
- **check_categorical** [bool, default True] Whether to compare internal Categorical exactly.
- **check_order** [bool, default True] Whether to compare the order of index entries as well as their values. If True, both indexes must contain the same elements, in the same order. If False, both indexes must contain the same elements, but in any order.
  
  New in version 1.2.0.
- **rtol** [float, default 1e-5] Relative tolerance. Only used when check_exact is False.
  
  New in version 1.1.0.
- **atol** [float, default 1e-8] Absolute tolerance. Only used when check_exact is False.
  
  New in version 1.1.0.
- **obj** [str, default ‘Index’] Specify object name being compared, internally used to show appropriate assertion message.
Examples

```python
>>> from pandas.testing import assert_index_equal
>>> a = pd.Index([1, 2, 3])
>>> b = pd.Index([1, 2, 3])
>>> assert_index_equal(a, b)
```

**pandas.testing.assert_extension_array_equal**

`pandas.testing.assert_extension_array_equal(left, right, check_dtype=True, index_values=None, check_less_precise=<no_default>, check_exact=False, rtol=1e-05, atol=1e-08)`

Check that left and right ExtensionArrays are equal.

**Parameters**

- `left, right` [ExtensionArray] The two arrays to compare.
- `check_dtype` [bool, default True] Whether to check if the ExtensionArray dtypes are identical.
- `index_values` [numpy.ndarray, default None] Optional index (shared by both left and right), used in output.
- `check_less_precise` [bool or int, default False] Specify comparison precision. Only used when `check_exact` is False. 5 digits (False) or 3 digits (True) after decimal points are compared. If int, then specify the digits to compare.
  
  Deprecated since version 1.1.0: Use `rtol` and `atol` instead to define relative/absolute tolerance, respectively. Similar to `math.isclose()`.
- `check_exact` [bool, default False] Whether to compare number exactly.
- `rtol` [float, default 1e-5] Relative tolerance. Only used when `check_exact` is False.
  
  New in version 1.1.0.
- `atol` [float, default 1e-8] Absolute tolerance. Only used when `check_exact` is False.
  
  New in version 1.1.0.

**Notes**

Missing values are checked separately from valid values. A mask of missing values is computed for each and checked to match. The remaining all-valid values are cast to object dtype and checked.

**Examples**

```python
>>> from pandas.testing import assert_extension_array_equal
>>> a = pd.Series([1, 2, 3, 4])
>>> b, c = a.array, a.array
>>> assert_extension_array_equal(b, c)
```
### 3.14.3 Exceptions and warnings

<table>
<thead>
<tr>
<th>Exception Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>errors.AccessorRegistrationWarning</code></td>
<td>Warning for attribute conflicts in accessor registration.</td>
</tr>
<tr>
<td><code>errors.DtypeWarning</code></td>
<td>Warning raised when reading different dtypes in a column from a file.</td>

</tr>
<tr>
<td><code>errors.UnsupportedFunctionCall</code></td>
<td>Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g.</td>
</tr>
</tbody>
</table>

**pandas.errors.AccessorRegistrationWarning**

**pandas.errors.DtypeWarning**

---

## pandas.errorsAccessExceptionWarning

**exception** pandas.errors.AccessorRegistrationWarning

Warning for attribute conflicts in accessor registration.

**pandas.errors.DtypeWarning**

**exception** pandas.errors.DtypeWarning

Warning raised when reading different dtypes in a column from a file.

Raised for a dtype incompatibility. This can happen whenever `read_csv` or `read_table` encounter non-uniform dtypes in a column(s) of a given CSV file.

See also:

- **read_csv** Read CSV (comma-separated) file into a DataFrame.
- **read_table** Read general delimited file into a DataFrame.
Notes

This warning is issued when dealing with larger files because the dtype checking happens per chunk read. Despite the warning, the CSV file is read with mixed types in a single column which will be an object type. See the examples below to better understand this issue.

Examples

This example creates and reads a large CSV file with a column that contains \textit{int} and \textit{str}.

\begin{verbatim}
>>> df = pd.DataFrame({'a': (['1'] * 100000 + ['X'] * 100000 + ...
                          ['1'] * 100000),
                     'b': ['b'] * 300000})
>>> df.to_csv('test.csv', index=False)
>>> df2 = pd.read_csv('test.csv')
... # DtypeWarning: Columns (0) have mixed types

Important to notice that \texttt{df2} will contain both \textit{str} and \textit{int} for the same input, ‘1’.

\begin{verbatim}
>>> df2.iloc[262140, 0]
'1'
>>> type(df2.iloc[262140, 0])
<class 'str'>
>>> df2.iloc[262150, 0]
1
>>> type(df2.iloc[262150, 0])
<class 'int'>
\end{verbatim}

One way to solve this issue is using the \texttt{dtype} parameter in the \texttt{read_csv} and \texttt{read_table} functions to explicit the conversion:

\begin{verbatim}
>>> df2 = pd.read_csv('test.csv', sep=',', dtype={'a': str})
\end{verbatim}

No warning was issued.

\begin{verbatim}
>>> import os
>>> os.remove('test.csv')
\end{verbatim}

\textbf{pandas.errors.DuplicateLabelError}

\textbf{exception pandas.errors.DuplicateLabelError}

Error raised when an operation would introduce duplicate labels.

New in version 1.2.0.
Examples

```python
>>> s = pd.Series([0, 1, 2], index=['a', 'b', 'c']).set_flags(...
    allows_duplicate_labels=False
...)
>>> s.reindex(['a', 'a', 'b'])
Traceback (most recent call last):
...
DuplicateLabelError: Index has duplicates.
    positions
      label
      a       [0, 1]
```

pandas.errors.EmptyDataError

**exception pandas.errors.EmptyDataError**  
Exception that is thrown in `pd.read_csv` (by both the C and Python engines) when empty data or header is encountered.

pandas.errors.InvalidIndexError

**exception pandas.errors.InvalidIndexError**  
Exception raised when attempting to use an invalid index key.

New in version 1.1.0.

pandas.errors.MergeError

**exception pandas.errors.MergeError**  
Error raised when problems arise during merging due to problems with input data. Subclass of `ValueError`.

pandas.errors.NullFrequencyError

**exception pandas.errors.NullFrequencyError**  
Error raised when a null `freq` attribute is used in an operation that needs a non-null frequency, particularly `DatetimeIndex.shift`, `TimedeltaIndex.shift`, `PeriodIndex.shift`.

pandas.errors.NumbaUtilError

**exception pandas.errors.NumbaUtilError**  
Error raised for unsupported Numba engine routines.
pandas.errors.OutOfBoundsDatetime

exception pandas.errors.OutOfBoundsDatetime

pandas.errors.OutOfBoundsTimedelta

exception pandas.errors.OutOfBoundsTimedelta

Raised when encountering a timedelta value that cannot be represented as a timedelta64[ns].

pandas.errors.ParserError

exception pandas.errors.ParserError

Exception that is raised by an error encountered in parsing file contents.

This is a generic error raised for errors encountered when functions like read_csv or read_html are parsing contents of a file.

See also:

read_csv Read CSV (comma-separated) file into a DataFrame.
read_html Read HTML table into a DataFrame.

pandas.errors.ParserWarning

exception pandas.errors.ParserWarning

Warning raised when reading a file that doesn’t use the default ‘c’ parser.

Raised by pd.read_csv and pd.read_table when it is necessary to change parsers, generally from the default ‘c’ parser to ‘python’.

It happens due to a lack of support or functionality for parsing a particular attribute of a CSV file with the requested engine.

Currently, ‘c’ unsupported options include the following parameters:
1. sep other than a single character (e.g. regex separators)
2. skipfooter higher than 0
3. sep=None with delim_whitespace=False

The warning can be avoided by adding engine=’python’ as a parameter in pd.read_csv and pd.read_table methods.

See also:

pd.read_csv Read CSV (comma-separated) file into DataFrame.
pd.read_table Read general delimited file into DataFrame.

Examples

Using a sep in pd.read_csv other than a single character:

```python
generate-latex
```
Adding `engine='python'` to `pd.read_csv` removes the Warning:

```python
>>> df = pd.read_csv(io.StringIO(csv), sep='[;]', engine='python')
```

### pandas.errors.PerformanceWarning

**Exception** `pandas.errors.PerformanceWarning`

Warning raised when there is a possible performance impact.

### pandas.errors.UnsortedIndexError

**Exception** `pandas.errors.UnsortedIndexError`

Error raised when attempting to get a slice of a MultiIndex, and the index has not been lexsorted. Subclass of `KeyError`.

### pandas.errors.UnsupportedFunctionCall

**Exception** `pandas.errors.UnsupportedFunctionCall`

Exception raised when attempting to call a numpy function on a pandas object, but that function is not supported by the object e.g. `np.cumsum(groupby_object)`.

#### 3.14.4 Data types related functionality

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>api.types.union_categoricals(to_union[, ...])</code></td>
<td>Combine list-like of Categorical-like, unioning categories.</td>
</tr>
<tr>
<td><code>api.types.infer_dtype</code></td>
<td>Efficiently infer the type of a passed val, or list-like array of values.</td>
</tr>
<tr>
<td><code>api.types.pandas_dtype(dtype)</code></td>
<td>Convert input into a pandas only dtype object or a numpy dtype object.</td>
</tr>
</tbody>
</table>

**pandas.api.types.union_categoricals**

Combine list-like of Categorical-like, unioning categories.

All categories must have the same dtype.

**Parameters**

- `to_union` [list-like] Categorical, CategoricalIndex, or Series with dtype='category'.
- `sort_categories` [bool, default False] If true, resulting categories will be lexsorted, otherwise they will be ordered as they appear in the data.
- `ignore_order` [bool, default False] If true, the ordered attribute of the Categoricals will be ignored. Results in an unordered categorical.

**Returns**

- `Categorical`

**Raises**

- `TypeError`
• all inputs do not have the same dtype
• all inputs do not have the same ordered property
• all inputs are ordered and their categories are not identical
• sort_categories=True and Categoricals are ordered

ValueError Empty list of categoricals passed

Notes

To learn more about categories, see link

Examples

```python
>>> from pandas.api.types import union_categoricals

If you want to combine categoricals that do not necessarily have the same categories, `union_categoricals` will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```python
>>> a = pd.Categorical(["b", "c"], ordered=True)
>>> b = pd.Categorical(["a", "b"], ordered=True)
>>> union_categoricals([a, b])
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

By default, the resulting categories will be ordered as they appear in the categories of the data. If you want the categories to be lexsorted, use `sort_categories=True` argument.

```python
>>> union_categoricals([a, b], sort_categories=True)
['b', 'c', 'a', 'b']
Categories (3, object): ['a', 'b', 'c']
```

`union_categoricals` also works with the case of combining two categoricals of the same categories and order information (e.g. what you could also append for).

```python
>>> a = pd.Categorical(["a", "b"], ordered=True)
>>> b = pd.Categorical(["a", "b", "a"], ordered=True)
>>> union_categoricals([a, b])
['a', 'b', 'a', 'b', 'a']
Categories (2, object): ['a' < 'b']
```

Raises `TypeError` because the categories are ordered and not identical.

```python
>>> a = pd.Categorical(["a", "b"], ordered=True)
>>> b = pd.Categorical(["a", "b", "c"], ordered=True)
>>> union_categoricals([a, b])
Traceback (most recent call last):
  ...
TypeError: to union ordered Categoricals, all categories must be the same
```

New in version 0.20.0

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.
>>> a = pd.Categorical(["a", "b", "c"], ordered=True)
>>> b = pd.Categorical(["c", "b", "a"], ordered=True)
>>> union_categoricals([a, b], ignore_order=True)
['a', 'b', 'c', 'c', 'b', 'a']
Categories (3, object): ['a', 'b', 'c']

union_categoricals also works with a CategoricalIndex, or Series containing categorical data, but note that the resulting array will always be a plain Categorical

>>> a = pd.Series(["b", "c"], dtype='category')
>>> b = pd.Series(["a", "b"], dtype='category')
>>> union_categoricals([a, b])
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']

pandas.api.types.infer_dtype

pandas.api.types.infer_dtype()
Efficiently infer the type of a passed val, or list-like array of values. Return a string describing the type.

Parameters

value [scalar, list, ndarray, or pandas type]

skipna [bool, default True] Ignore NaN values when inferring the type.

Returns

str Describing the common type of the input data.

Results can include:

- string
- bytes
- floating
- integer
- mixed-integer
- mixed-integer-float
- decimal
- complex
- categorical
- boolean
- datetime64
- datetime
- date
- timedelta64
- timedelta
- time
- period
• mixed
• unknown-array

Raises

TypeError If ndarray-like but cannot infer the dtype

Notes

• ‘mixed’ is the catchall for anything that is not otherwise specialized
• ‘mixed-integer-float’ are floats and integers
• ‘mixed-integer’ are integers mixed with non-integers
• ‘unknown-array’ is the catchall for something that is an array (has a dtype attribute), but has a dtype unknown to pandas (e.g. external extension array)

Examples

```python
>>> infer_dtype(['foo', 'bar'])
'string'

>>> infer_dtype(['a', np.nan, 'b'], skipna=True)
'string'

>>> infer_dtype(['a', np.nan, 'b'], skipna=False)
'mixed'

>>> infer_dtype([b'foo', b'bar'])
'bytes'

>>> infer_dtype([1, 2, 3])
'integer'

>>> infer_dtype([1, 2, 3.5])
'mixed-integer-float'

>>> infer_dtype([1.0, 2.0, 3.5])
'floating'

>>> infer_dtype(['a', 1])
'mixed-integer'

>>> infer_dtype([Decimal(1), Decimal(2.0)])
'decimal'

>>> infer_dtype([True, False])
'boolean'

>>> infer_dtype([True, False, np.nan])
'boolean'
```
>>> infer_dtypes([pd.Timestamp('20130101')])
'datetime'

>>> infer_dtypes([datetime.date(2013, 1, 1)])
'date'

>>> infer_dtypes([np.datetime64('2013-01-01')])
'datetime64'

>>> infer_dtypes([datetime.timedelta(0, 1, 1)])
'timedelta'

>>> infer_dtypes(pd.Series(list('aabc')).astype('category'))
'categorical'

pandas.api.types.pandas_dtype

pandas api.types.pandas_dtype(dtype)
Convert input into a pandas only dtype object or a numpy dtype object.

Parameters

dtype [object to be converted]

Returns

np.dtype or a pandas dtype

Raises

TypeError if not a dtype

Dtype introspection

api.types.is_bool_dtype(arr_or_dtype) Check whether the provided array or dtype is of a boolean dtype.

api.types.is_categorical_dtype(arr_or_dtype) Check whether the provided array or dtype is of the Categorical dtype.

api.types.is_complex_dtype(arr_or_dtype) Check whether the provided array or dtype is of a complex dtype.

api.types.is_datetime64_any_dtype(arr_or_dtype) Check whether the provided array or dtype is of the datetime64 dtype.

api.types.is_datetime64_dtype(arr_or_dtype) Check whether an array-like or dtype is of the datetime64 dtype.

api.types.is_datetime64_ns_dtype(arr_or_dtype) Check whether the provided array or dtype is of the datetime64[ns] dtype.

api.types.is_datetime64tz_dtype(arr_or_dtype) Check whether an array-like or dtype is of a DatetimeTZDtype dtype.

api.types.is_extension_type(arr) (DEPRECATED) Check whether an array-like is of a pandas extension class instance.

api.types.is_extension_array_dtype(arr_or_dtype) if an object is a pandas extension array type.

api.types.is_float_dtype(arr_or_dtype) Check whether the provided array or dtype is of a float dtype.

continues on next page
### pandas.api.types.is_bool_dtype

`pandas.api.types.is_bool_dtype(arr_or_dtype)`

Check whether the provided array or dtype is of a boolean dtype.

**Parameters**

- `arr_or_dtype` [array-like] The array or dtype to check.

**Returns**

- boolean Whether or not the array or dtype is of a boolean dtype.

**Notes**

An ExtensionArray is considered boolean when the `_is_boolean` attribute is set to True.

**Examples**

```python
>>> is_bool_dtype(str)
False
>>> is_bool_dtype(int)
False
>>> is_bool_dtype(bool)
True
>>> is_bool_dtype(np.bool_)
True
```
pandas.api.types.is_categorical_dtype

pandas.api.types.is_categorical_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the Categorical dtype.

Parameters

- arr_or_dtype [array-like] The array-like or dtype to check.

Returns

- boolean Whether or not the array-like or dtype is of the Categorical dtype.

Examples

```python
>>> is_categorical_dtype(object)
False
>>> is_categorical_dtype(CategoricalDtype())
True
>>> is_categorical_dtype([1, 2, 3])
False
>>> is_categorical_dtype(pd.Categorical([1, 2, 3]))
True
>>> is_categorical_dtype(pd.CategoricalIndex([1, 2, 3]))
True
```

pandas.api.types.is_complex_dtype

pandas.api.types.is_complex_dtype(arr_or_dtype)
Check whether the provided array or dtype is of a complex dtype.

Parameters

- arr_or_dtype [array-like] The array or dtype to check.

Returns

- boolean Whether or not the array or dtype is of a complex dtype.
### Examples

```python
>>> is_complex_dtype(str)
False
>>> is_complex_dtype(int)
False
>>> is_complex_dtype(np.complex_)
True
>>> is_complex_dtype(np.array(['a', 'b']))
False
>>> is_complex_dtype(pd.Series([1, 2]))
False
>>> is_complex_dtype(np.array([1 + 1j, 5]))
True
```

### pandas.api.types.is_datetime64_any_dtype

**Pandas**

#### pandas.api.types.is_datetime64_any_dtype(arr_or_dtype)

Check whether the provided array or dtype is of the datetime64 dtype.

**Parameters**

- **arr_or_dtype** [array-like] The array or dtype to check.

**Returns**

- **bool** Whether or not the array or dtype is of the datetime64 dtype.

#### Examples

```python
>>> is_datetime64_any_dtype(str)
False
>>> is_datetime64_any_dtype(int)
False
>>> is_datetime64_any_dtype(np.datetime64)  # can be tz-naive
True
>>> is_datetime64_any_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_any_dtype(np.array(['a', 'b']))
False
>>> is_datetime64_any_dtype(np.array([1, 2]))
False
>>> is_datetime64_any_dtype(np.array([], dtype="datetime64[ns]"))
True
>>> is_datetime64_any_dtype(pd.DatetimeIndex([1, 2, 3], dtype="datetime64[ns]"))
True
```
pandas.api.types.is_datetime64_dtype

pandas.api.types.is_datetime64_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the datetime64 dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the datetime64 dtype.

Examples

>>> is_datetime64_dtype(object)
False
>>> is_datetime64_dtype(np.datetime64)
True
>>> is_datetime64_dtype(np.array([], dtype=int))
False
>>> is_datetime64_dtype(np.array([], dtype=np.datetime64))
True
>>> is_datetime64_dtype([1, 2, 3])
False

pandas.api.types.is_datetime64_ns_dtype

pandas.api.types.is_datetime64_ns_dtype(arr_or_dtype)
Check whether the provided array or dtype is of the datetime64[ns] dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

bool Whether or not the array or dtype is of the datetime64[ns] dtype.

Examples

>>> is_datetime64_ns_dtype(str)
False
>>> is_datetime64_ns_dtype(int)
False
>>> is_datetime64_ns_dtype(np.datetime64)  # no unit
False
>>> is_datetime64_ns_dtype(DatetimeTZDtype("ns", "US/Eastern"))
True
>>> is_datetime64_ns_dtype(np.array(["a", "b"]))
False
>>> is_datetime64_ns_dtype(np.array([1, 2]))
False
>>> is_datetime64_ns_dtype(np.array([], dtype="datetime64"))  # no unit
False
>>> is_datetime64_ns_dtype(np.array([], dtype="datetime64[ps]"))  # wrong unit
False
(continues on next page)
pandas: powerful Python data analysis toolkit, Release 1.3.1

False
>>> is_datetime64_ns_dtype(pd.DatetimeIndex([1, 2, 3], dtype="datetime64[ns]"))
True

pandas.api.types.is_datetime64tz_dtype

pandas.api.types.is_datetime64tz_dtype(arr_or_dtype)
Check whether an array-like or dtype is of a DatetimeTZDtype dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of a DatetimeTZDtype dtype.

Examples

>>> is_datetime64tz_dtype(object)
False
>>> is_datetime64tz_dtype([1, 2, 3])
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3])) # tz-naive
False
>>> is_datetime64tz_dtype(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True

>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_datetime64tz_dtype(dtype)
True
>>> is_datetime64tz_dtype(s)
True

pandas.api.types.is_extension_type

pandas.api.types.is_extension_type(arr)
Check whether an array-like is of a pandas extension class instance.

Deprecated since version 1.0.0: Use is_extension_array_dtype instead.

Extension classes include categoricals, pandas sparse objects (i.e. classes represented within the pandas library and not ones external to it like scipy sparse matrices), and datetime-like arrays.

Parameters

arr [array-like] The array-like to check.

Returns

boolean Whether or not the array-like is of a pandas extension class instance.
Examples

```python
>>> is_extension_type([1, 2, 3])
False
>>> is_extension_type(np.array([1, 2, 3]))
False
>>> cat = pd.Categorical([1, 2, 3])
>>> is_extension_type(cat)
True
>>> is_extension_type(pd.Series(cat))
True
>>> is_extension_type(pd.arrays.SparseArray([1, 2, 3]))
True
>>> from scipy.sparse import bsr_matrix
>>> is_extension_type(bsr_matrix([1, 2, 3]))
False
>>> is_extension_type(pd.DatetimeIndex([1, 2, 3]))
False
>>> is_extension_type(pd.DatetimeIndex([1, 2, 3], tz="US/Eastern"))
True
>>> dtype = DatetimeTZDtype("ns", tz="US/Eastern")
>>> s = pd.Series([], dtype=dtype)
>>> is_extension_type(s)
True
```

pandas.api.types.is_extension_array_dtype

pandas.api.types.is_extension_array_dtype(arr_or_dtype)
Check if an object is a pandas extension array type.

See the Use Guide for more.

Parameters

arr_or_dtype [object] For array-like input, the .dtype attribute will be extracted.

Returns

bool Whether the arr_or_dtype is an extension array type.

Notes

This checks whether an object implements the pandas extension array interface. In pandas, this includes:
- Categorical
- Sparse
- Interval
- Period
- DatetimeArray
- TimedeltaArray

Third-party libraries may implement arrays or types satisfying this interface as well.
Examples

```python
>>> from pandas.api.types import is_extension_array_dtype
>>> arr = pd.Categorical(['a', 'b'])
>>> is_extension_array_dtype(arr)
True
>>> is_extension_array_dtype(arr.dtype)
True

>>> arr = np.array(['a', 'b'])
>>> is_extension_array_dtype(arr.dtype)
False
```

**pandas.api.types.is_float_dtype**

Check whether the provided array or dtype is of a float dtype.

This function is internal and should not be exposed in the public API.

**Parameters**

- `arr_or_dtype` [array-like] The array or dtype to check.

**Returns**

- `boolean` Whether or not the array or dtype is of a float dtype.

**Examples**

```python
>>> is_float_dtype(str)
False
>>> is_float_dtype(int)
False
>>> is_float_dtype(float)
True
>>> is_float_dtype(np.array(['a', 'b']))
False
>>> is_float_dtype(pd.Series([1, 2]))
False
>>> is_float_dtype(pd.Index([1, 2.]))
True
```

**pandas.api.types.is_int64_dtype**

Check whether the provided array or dtype is of the int64 dtype.

**Parameters**

- `arr_or_dtype` [array-like] The array or dtype to check.

**Returns**

- `boolean` Whether or not the array or dtype is of the int64 dtype.
Notes

Depending on system architecture, the return value of `is_int64_dtype(int)` will be True if the OS uses 64-bit integers and False if the OS uses 32-bit integers.

Examples

```python
>>> is_int64_dtype(str)
False
>>> is_int64_dtype(np.int32)
False
>>> is_int64_dtype(np.int64)
True
>>> is_int64_dtype('int8')
False
>>> is_int64_dtype('Int8')
False
>>> is_int64_dtype(pd.Int64Dtype)
True
>>> is_int64_dtype(float)
False
>>> is_int64_dtype(np.uint64)  # unsigned
False
>>> is_int64_dtype(np.array(['a', 'b']))
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.int64))
True
>>> is_int64_dtype(pd.Index([1, 2.]))  # float
False
>>> is_int64_dtype(np.array([1, 2], dtype=np.uint32))  # unsigned
False
```

pandas.api.types.is_integer_dtype

pandas.api.types.is_integer_dtype(arr_or_dtype)

Check whether the provided array or dtype is of an integer dtype.

Unlike in `in_any_int_dtype`, timedelta64 instances will return False.

The nullable Integer dtypes (e.g. pandas.Int64Dtype) are also considered as integer by this function.

Parameters

- **arr_or_dtype** [array-like] The array or dtype to check.

Returns

- **boolean** Whether or not the array or dtype is of an integer dtype and not an instance of timedelta64.
Examples

>>> is_integer_dtype(str)
False
>>> is_integer_dtype(int)
True
>>> is_integer_dtype(float)
False
>>> is_integer_dtype(np.uint64)
True
>>> is_integer_dtype('int8')
True
>>> is_integer_dtype('Int8')
True
>>> is_integer_dtype(pd.Int8Dtype)
True
>>> is_integer_dtype(np.datetime64)
False
>>> is_integer_dtype(np.timedelta64)
False
>>> is_integer_dtype(np.array(['a', 'b']))
False
>>> is_integer_dtype(pd.Series([1, 2]))
True
>>> is_integer_dtype(np.array([], dtype=np.timedelta64))
False
>>> is_integer_dtype(pd.Index([1, 2.])) # float
False

pandas.api.types.is_interval_dtype

pandas.api.types.is_interval_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the Interval dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the Interval dtype.

Examples

>>> is_interval_dtype(object)
False
>>> is_interval_dtype(IntervalDtype())
True
>>> is_interval_dtype([1, 2, 3])
False
>>> interval = pd.Interval(1, 2, closed="right")
>>> is_interval_dtype(interval)
False
>>> is_interval_dtype(pd.IntervalIndex([interval]))
True
pandas.api.types.is_numeric_dtype

pandas.api.types.is_numeric_dtype(arr_or_dtype)
Check whether the provided array or dtype is of a numeric dtype.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of a numeric dtype.

Examples

>>> is_numeric_dtype(str)
False
>>> is_numeric_dtype(int)
True
>>> is_numeric_dtype(float)
True
>>> is_numeric_dtype(np.uint64)
True
>>> is_numeric_dtype(np.datetime64)
False
>>> is_numeric_dtype(np.timedelta64)
False
>>> is_numeric_dtype(np.array([\'a\', \'b\']))
False
>>> is_numeric_dtype(pd.Series([1, 2]))
True
>>> is_numeric_dtype(pd.Index([1, 2.]))
True
>>> is_numeric_dtype(np.array([], dtype=np.timedelta64))
False

pandas.api.types.is_object_dtype

pandas.api.types.is_object_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the object dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the object dtype.
### Examples

```python
>>> is_object_dtype(object)
True
>>> is_object_dtype(int)
False
>>> is_object_dtype(np.array([], dtype=object))
True
>>> is_object_dtype(np.array([], dtype=int))
False
>>> is_object_dtype([1, 2, 3])
False
```

```python
pandas.api.types.is_period_dtype

pandas.api.types.is_period_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the Period dtype.

Parameters
``arr_or_dtype``  [array-like] The array-like or dtype to check.

Returns
``boolean``  Whether or not the array-like or dtype is of the Period dtype.

### Examples

```python
>>> is_period_dtype(object)
False
>>> is_period_dtype(PeriodDtype(freq="D"))
True
>>> is_period_dtype([1, 2, 3])
False
>>> is_period_dtype(pd.Period("2017-01-01"))
False
>>> is_period_dtype(pd.PeriodIndex([], freq="A"))
True
```

### pandas.api.types.is_signed_integer_dtype

```python
pandas.api.types.is_signed_integer_dtype(arr_or_dtype)
Check whether the provided array or dtype is of a signed integer dtype.

Unlike in in_any_int_dtype, timedelta64 instances will return False.
The nullable Integer dtypes (e.g. pandas.Int64Dtype) are also considered as integer by this function.

Parameters
``arr_or_dtype``  [array-like] The array or dtype to check.

Returns
``boolean``  Whether or not the array or dtype is of a signed integer dtype and not an instance of timedelta64.
```
Examples

```python
>>> is_signed_integer_dtype(str)
False
>>> is_signed_integer_dtype(int)
True
>>> is_signed_integer_dtype(float)
False
>>> is_signed_integer_dtype(np.uint64)  # unsigned
False
>>> is_signed_integer_dtype('int8')
True
>>> is_signed_integer_dtype('Int8')
True
>>> is_signed_integer_dtype(pd.Int8Dtype)
True
>>> is_signed_integer_dtype(np.datetime64)
False
>>> is_signed_integer_dtype(np.timedelta64)
False
>>> is_signed_integer_dtype(np.array(['a', 'b']))
False
>>> is_signed_integer_dtype(pd.Series([1, 2]))
True
>>> is_signed_integer_dtype(np.array([], dtype=np.timedelta64))
False
>>> is_signed_integer_dtype(pd.Index([1, 2.]))  # float
False
>>> is_signed_integer_dtype(np.array([1, 2.], dtype=np.uint32))  # unsigned
False
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

>>> is_string_dtype(pd.Series([1, 2]))
False

pandas.api.types.is_timedelta64_dtype

pandas.api.types.is_timedelta64_dtype(arr_or_dtype)
Check whether an array-like or dtype is of the timedelta64 dtype.

Parameters

arr_or_dtype [array-like] The array-like or dtype to check.

Returns

boolean Whether or not the array-like or dtype is of the timedelta64 dtype.

Examples

>>> is_timedelta64_dtype(object)
False
>>> is_timedelta64_dtype(np.timedelta64)
True
>>> is_timedelta64_dtype([1, 2, 3])
False
>>> is_timedelta64_dtype(pd.Series([], dtype="timedelta64[ns]"))
True
>>> is_timedelta64_dtype('0 days')
False

pandas.api.types.is_timedelta64_ns_dtype

pandas.api.types.is_timedelta64_ns_dtype(arr_or_dtype)
Check whether the provided array or dtype is of the timedelta64[ns] dtype.
This is a very specific dtype, so generic ones like np.timedelta64 will return False if passed into this function.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of the timedelta64[ns] dtype.

Examples

>>> is_timedelta64_ns_dtype(np.dtype('m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.dtype('m8[ps]'))  # Wrong frequency
False
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype='m8[ns]'))
True
>>> is_timedelta64_ns_dtype(np.array([1, 2], dtype=np.timedelta64))
False

3.14. General utility functions
pandas.api.types.is_unsigned_integer_dtype

pandas.api.types.is_unsigned_integer_dtype(arr_or_dtype)

Check whether the provided array or dtype is of an unsigned integer dtype.

The nullable Integer dtypes (e.g. pandas.UInt64Dtype) are also considered as integer by this function.

Parameters

arr_or_dtype [array-like] The array or dtype to check.

Returns

boolean Whether or not the array or dtype is of an unsigned integer dtype.

Examples

```python
>>> is_unsigned_integer_dtype(str)
False
>>> is_unsigned_integer_dtype(int)  # signed
False
>>> is_unsigned_integer_dtype(float)
False
>>> is_unsigned_integer_dtype(np.uint64)
True
>>> is_unsigned_integer_dtype('uint8')
True
>>> is_unsigned_integer_dtype('UInt8')
True
>>> is_unsigned_integer_dtype(pd.UInt8Dtype)
True
>>> is_unsigned_integer_dtype(np.array([a, b]))
False
```

pandas.api.types.is_sparse

pandas.api.types.is_sparse(arr)

Check whether an array-like is a 1-D pandas sparse array.

Check that the one-dimensional array-like is a pandas sparse array. Returns True if it is a pandas sparse array, not another type of sparse array.

Parameters

arr [array-like] Array-like to check.

Returns

bool Whether or not the array-like is a pandas sparse array.

```python
>>> is_sparse(str)
False
>>> is_sparse(int)  # signed
False
>>> is_sparse(float)
False
>>> is_sparse(np.uint64)
True
>>> is_sparse('uint8')
True
>>> is_sparse('UInt8')
True
>>> is_sparse(pd.UInt8Dtype)
True
>>> is_sparse(np.array([a, b]))
False
```
Examples

Returns True if the parameter is a 1-D pandas sparse array.

```python
>>> is_sparse(pd.arrays.SparseArray([0, 0, 1, 0]))
True
>>> is_sparse(pd.Series(pd.arrays.SparseArray([0, 0, 1, 0])))
True
```

Returns False if the parameter is not sparse.

```python
>>> is_sparse(np.array([0, 0, 1, 0]))
False
>>> is_sparse(pd.Series([0, 1, 0, 0]))
False
```

Returns False if the parameter is not a pandas sparse array.

```python
>>> from scipy.sparse import bsr_matrix
>>> is_sparse(bsr_matrix([0, 1, 0, 0]))
False
```

Returns False if the parameter has more than one dimension.

Iterable introspection

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>api.types.is_dict_like(obj)</code></td>
<td>Check if the object is dict-like.</td>
</tr>
<tr>
<td><code>api.types.is_file_like(obj)</code></td>
<td>Check if the object is a file-like object.</td>
</tr>
<tr>
<td><code>api.types.is_list_like</code></td>
<td>Check if the object is list-like.</td>
</tr>
<tr>
<td><code>api.types.is_named_tuple(obj)</code></td>
<td>Check if the object is a named tuple.</td>
</tr>
<tr>
<td><code>api.types.is_iterator</code></td>
<td>Check if the object is an iterator.</td>
</tr>
</tbody>
</table>

pandas.api.types.is_dict_like

pandas.api.types.is_dict_like(obj)
Check if the object is dict-like.

Parameters

- **obj** [The object to check]

Returns

- **is_dict_like** [bool] Whether obj has dict-like properties.
Examples

```python
>>> is_dict_like({1: 2})
True
>>> is_dict_like([1, 2, 3])
False
>>> is_dict_like(dict)
False
>>> is_dict_like(dict())
True
```

**pandas.api.types.is_file_like**

The function `pandas.api.types.is_file_like(obj)` checks if the object is a file-like object.

For objects to be considered file-like, they must be an iterator AND have either a `read` and/or `write` method as an attribute.

Note: file-like objects must be iterable, but iterable objects need not be file-like.

**Parameters**

- `obj` [The object to check]

**Returns**

- `is_file_like` [bool] Whether `obj` has file-like properties.

Examples

```python
>>> import io
>>> buffer = io.StringIO("data")
>>> is_file_like(buffer)
True
>>> is_file_like([1, 2, 3])
False
```

**pandas.api.types.is_list_like**

The function `pandas.api.types.is_list_like()` checks if the object is list-like.

Objects that are considered list-like are for example Python lists, tuples, sets, NumPy arrays, and Pandas Series.

Strings and datetime objects, however, are not considered list-like.

**Parameters**

- `obj` [object] Object to check.
- `allow_sets` [bool, default True] If this parameter is False, sets will not be considered list-like.

**Returns**

- `bool` Whether `obj` has list-like properties.
Examples

```python
>>> is_list_like([1, 2, 3])
True
>>> is_list_like((1, 2, 3))
True
>>> is_list_like(datetime(2017, 1, 1))
False
>>> is_list_like("foo")
False
>>> is_list_like(1)
False
>>> is_list_like(np.array([2]))
True
>>> is_list_like(np.array(2))
False
```

**pandas.api.types.is_named_tuple**

**pandas.api.types.is_named_tuple**(obj)

Check if the object is a named tuple.

**Parameters**

- **obj** [The object to check]

**Returns**

- **is_named_tuple** [bool] Whether obj is a named tuple.

**Examples**

```python
>>> from collections import namedtuple
>>> Point = namedtuple("Point", ["x", "y"])
>>> p = Point(1, 2)

>>> is_named_tuple(p)
True
>>> is_named_tuple((1, 2))
False
```

**pandas.api.types.is_iterator**

**pandas.api.types.is_iterator**()

Check if the object is an iterator.

This is intended for generators, not list-like objects.

**Parameters**

- **obj** [The object to check]

**Returns**

- **is_iter** [bool] Whether obj is an iterator.
Examples

```python
>>> is_iterator((x for x in []))
True
>>> is_iterator([1, 2, 3])
False
>>> is_iterator(datetime(2017, 1, 1))
False
>>> is_iterator("foo")
False
>>> is_iterator(1)
False
```

Scalar introspection

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>api.types.is_bool</code></td>
<td>Return True if given object is boolean.</td>
</tr>
<tr>
<td><code>api.types.is_categorical(arr)</code></td>
<td>Check whether an array-like is a Categorical instance.</td>
</tr>
<tr>
<td><code>api.types.is_complex</code></td>
<td>Return True if given object is complex.</td>
</tr>
<tr>
<td><code>api.types.is_float</code></td>
<td>Return True if given object is float.</td>

</tr>
<tr>
<td><code>api.types.is_re_compilable(obj)</code></td>
<td>Check if the object can be compiled into a regex pattern instance.</td>
</tr>
<tr>
<td><code>api.types.is_scalar</code></td>
<td>Return True if given object is scalar.</td>
</tr>
</tbody>
</table>

**pandas.api.types.is_bool**

`pandas.api.types.is_bool()`

Return True if given object is boolean.

Returns

```
bool
```

**pandas.api.types.is_categorical**

`pandas.api.types.is_categorical(arr)`

Check whether an array-like is a Categorical instance.

Parameters

- `arr` [array-like] The array-like to check.

Returns

```
boolean Whether or not the array-like is of a Categorical instance.
```
pandas: powerful Python data analysis toolkit, Release 1.3.1

Examples

```python
>>> is_categorical([1, 2, 3])
False
Categoricals, Series Categoricals, and CategoricalIndex will return True.

>>> cat = pd.Categorical([1, 2, 3])
>>> is_categorical(cat)
True
>>> is_categorical(pd.Series(cat))
True
>>> is_categorical(pd.CategoricalIndex([1, 2, 3]))
True
```

pandas.api.types.is_complex

pandas.api.types.is_complex()  
Return True if given object is complex.  
Returns  
   bool

pandas.api.types.is_float

pandas.api.types.is_float()  
Return True if given object is float.  
Returns  
   bool

pandas.api.types.is_hashable

pandas.api.types.is_hashable(obj)  
Return True if hash(obj) will succeed, False otherwise.  
Some types will pass a test against collections.abc.Hashable but fail when they are actually hashed with hash().  
Distinguish between these and other types by trying the call to hash() and seeing if they raise TypeError.  
Returns  
   bool

Examples

```python
>>> import collections
>>> a = (1,)
>>> isinstance(a, collections.abc.Hashable)
True
>>> is_hashable(a)
False
```
pandas.api.types.is_integer

pandas.api.types.is_integer()  
Return True if given object is integer.  
Returns  
    bool

pandas.api.types.is_interval

pandas.api.types.is_interval()

pandas.api.types.is_number

pandas.api.types.is_number(obj)  
Check if the object is a number.  
Returns True when the object is a number, and False if is not.  
Parameters  
    obj [any type] The object to check if is a number.  
Returns  
    is_number [bool] Whether obj is a number or not.  
See also:  
    api.types.is_integer Checks a subgroup of numbers.

Examples

```python
>>> from pandas.api.types import is_number
>>> is_number(1)
True
>>> is_number(7.15)
True
Booleans are valid because they are int subclass.
```

```python
>>> is_number(False)
True
```
pandas.api.types.is_re

pandas.api.types.is_re(obj)
Check if the object is a regex pattern instance.
Parameters

obj [The object to check]

Returns

is_regex [bool] Whether obj is a regex pattern.

Examples

```python
>>> is_re(re.compile(".*"))
True
>>> is_re("foo")
False
```

pandas.api.types.is_re_compilable

pandas.api.types.is_re_compilable(obj)
Check if the object can be compiled into a regex pattern instance.
Parameters

obj [The object to check]

Returns

is_regex_compilable [bool] Whether obj can be compiled as a regex pattern.

Examples

```python
>>> is_re_compilable(".*")
True
>>> is_re_compilable(1)
False
```

pandas.api.types.is_scalar

pandas.api.types.is_scalar()
Return True if given object is scalar.
Parameters

val [object] This includes:
- numpy array scalar (e.g. np.int64)
- Python builtin numerics
- Python builtin byte arrays and strings
- None
- datetime.datetime

3.14. General utility functions 2589
Returns

bool  Return True if given object is scalar.

Examples

```python
>>> dt = datetime.datetime(2018, 10, 3)
>>> pd.api.types.is_scalar(dt)
True

>>> pd.api.types.is_scalar([2, 3])
False

>>> pd.api.types.is_scalar({0: 1, 2: 3})
False

>>> pd.api.types.is_scalar((0, 2))
False
```

pandas supports PEP 3141 numbers:

```python
>>> from fractions import Fraction
>>> pd.api.types.is_scalar(Fraction(3, 5))
True
```

### 3.14.5 Bug report function

`show_versions([as_json])`  
Provide useful information, important for bug reports.

#### pandas.show_versions

`pandas.show_versions(as_json=False)`  
Provide useful information, important for bug reports.

It comprises info about hosting operation system, pandas version, and versions of other installed relative packages.

Parameters

- **as_json** [str or bool, default False]
  - If False, outputs info in a human readable form to the console.
• If str, it will be considered as a path to a file. Info will be written to that file in JSON format.
• If True, outputs info in JSON format to the console.

3.15 Extensions

These are primarily intended for library authors looking to extend pandas objects.

api.extensions.register_extension_dtype(cls)
Register an ExtensionType with pandas as class decorator.

api.extensions.register_dataframe_accessor(name)
Register a custom accessor on DataFrame objects.

api.extensions.register_series_accessor(name)
Register a custom accessor on Series objects.

api.extensions.register_index_accessor(name)
Register a custom accessor on Index objects.

api.extensions.ExtensionDtype()
A custom data type, to be paired with an ExtensionArray.

3.15.1 pandas.api.extensions.register_extension_dtype

pandas.api.extensions.register_extension_dtype(cls)
Register an ExtensionType with pandas as class decorator.

This enables operations like .astype(name) for the name of the ExtensionDtype.

Returns
callable A class decorator.

Examples

```python
>>> from pandas.api.extensions import register_extension_dtype
>>> from pandas.api.extensions import ExtensionDtype
>>> @register_extension_dtype
... class MyExtensionDtype(ExtensionDtype):
...     name = "myextension"
```

3.15.2 pandas.api.extensions.register_dataframe_accessor

pandas.api.extensions.register_dataframe_accessor(name)
Register a custom accessor on DataFrame objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

Returns
callable A class decorator.

See also:

register_dataframe_accessor Register a custom accessor on DataFrame objects.
register_series_accessor Register a custom accessor on Series objects.
register_index_accessor Register a custom accessor on Index objects.
Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```python
def __init__(self, pandas_object):  # noqa: E999
    ...
```

For consistency with pandas methods, you should raise an `AttributeError` if the data passed to your accessor has an incorrect dtype.

```python
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```python
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:

```python
In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10),
...:                     "latitude": np.linspace(0, 20)})
In [2]: ds.geo.center
Out[2]: (5.0, 10.0)
In [3]: ds.geo.plot()  # plots data on a map
3.15.3 pandas.api.extensions.register_series_accessor

pandas.api.extensions.register_series_accessor(name)
Register a custom accessor on Series objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this name conflicts with a preexisting attribute.

Returns
callable A class decorator.

See also:

register_dataframe_accessor Register a custom accessor on DataFrame objects.
register_series_accessor Register a custom accessor on Series objects.
register_index_accessor Register a custom accessor on Index objects.

Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the signature must be

```python
def __init__(self, pandas_object):  # noqa: E999
    ...  
```

For consistency with pandas methods, you should raise an AttributeError if the data passed to your accessor has an incorrect dtype.

```python
>>> pd.Series(['a', 'b']).dt
Traceback (most recent call last):
...  
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```python
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Back in an interactive IPython session:
3.15.4 pandas.api.extensions.register_index_accessor

pandas.api.extensions.register_index_accessor(name)

Register a custom accessor on Index objects.

Parameters

name [str] Name under which the accessor should be registered. A warning is issued if this
name conflicts with a preexisting attribute.

Returns
callable A class decorator.

See also:
register_dataframe_accessor Register a custom accessor on DataFrame objects.
register_series_accessor Register a custom accessor on Series objects.
register_index_accessor Register a custom accessor on Index objects.

Notes

When accessed, your accessor will be initialized with the pandas object the user is interacting with. So the
signature must be

```python
def __init__(self, pandas_object):  # noqa: E999
    ...  
```

For consistency with pandas methods, you should raise an AttributeError if the data passed to your ac-
cessor has an incorrect dtype.

```python
>>> pd.Series(["a", "b"]).dt
Traceback (most recent call last):
  ...  
AttributeError: Can only use .dt accessor with datetimelike values
```

Examples

In your library code:

```python
import pandas as pd

@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._obj = pandas_obj

    @property
def center(self):
        # return the geographic center point of this DataFrame
        ...  
```
Back in an interactive IPython session:

```
In [1]: ds = pd.DataFrame({"longitude": np.linspace(0, 10),
...:                     "latitude": np.linspace(0, 20)})
In [2]: ds.geo.center
Out[2]: (5.0, 10.0)
In [3]: ds.geo.plot()  # plots data on a map
```

### 3.15.5 pandas.api.extensions.ExtensionDtype

class pandas.api.extensions.ExtensionDtype
A custom data type, to be paired with an ExtensionArray.

See also:

- `extensions.register_extension_dtype` Register an ExtensionType with pandas as class decorator.
- `extensions.ExtensionArray` Abstract base class for custom 1-D array types.

**Notes**

The interface includes the following abstract methods that must be implemented by subclasses:

- `type`
- `name`
- `construct_array_type`

The following attributes and methods influence the behavior of the dtype in pandas operations:

- `is_numeric`
- `is_boolean`
- `get_common_dtype`

The `na_value` class attribute can be used to set the default NA value for this type. `numpy.nan` is used by default.

ExtensionDtypes are required to be hashable. The base class provides a default implementation, which relies on the `_metadata` class attribute. `_metadata` should be a tuple containing the strings that define your data type. For example, with `PeriodDtype` that’s the `freq` attribute.

**If you have a parametrized dtype you should set the ``_metadata`` class property.**

Ideally, the attributes in `_metadata` will match the parameters to your `ExtensionDtype.__init__` (if any). If any of the attributes in `_metadata` don’t implement the standard `__eq__` or `__hash__`, the default implementations here will not work.

For interaction with Apache Arrow (pyarrow), a `__from_arrow__` method can be implemented: this method receives a pyarrow Array or ChunkedArray as only argument and is expected to return the appropriate pandas ExtensionArray for this dtype and the passed values:
class ExtensionDtype:

def __from_arrow__(
    self, array: Union[pyarrow.Array, pyarrow.ChunkedArray]
) -> ExtensionArray:
    ...

This class does not inherit from `abc.ABCMeta` for performance reasons. Methods and properties required by the interface raise `pandas.errors(AbstractMethodError and no register method is provided for registering virtual subclasses.

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>kind</td>
<td>A character code (one of <code>biufcmMOSUV</code>), default <code>O</code></td>
</tr>
<tr>
<td>na_value</td>
<td>Default NA value to use for this type.</td>
</tr>
<tr>
<td>name</td>
<td>A string identifying the data type.</td>
</tr>
<tr>
<td>names</td>
<td>Ordered list of field names, or None if there are no fields.</td>
</tr>
<tr>
<td>type</td>
<td>The scalar type for the array, e.g.</td>
</tr>
</tbody>
</table>

**pandas.api.extensions.ExtensionDtype.kind**

**property** ExtensionDtype.kind

A character code (one of `biufcmMOSUV`), default `O`

This should match the NumPy dtype used when the array is converted to an ndarray, which is probably `O` for object if the extension type cannot be represented as a built-in NumPy type.

See also:

* numpy.dtype.kind

**pandas.api.extensions.ExtensionDtype.na_value**

**property** ExtensionDtype.na_value

Default NA value to use for this type.

This is used in e.g. ExtensionArray.take. This should be the user-facing “boxed” version of the NA value, not the physical NA value for storage. e.g. for JSONArray, this is an empty dictionary.

**pandas.api.extensions.ExtensionDtype.name**

**property** ExtensionDtype.name

A string identifying the data type.

Will be used for display in, e.g. Series.dtype
pandas.api.extensions.ExtensionDtype.names

property ExtensionDtype.names
   Ordered list of field names, or None if there are no fields.

   This is for compatibility with NumPy arrays, and may be removed in the future.

pandas.api.extensions.ExtensionDtype.type

property ExtensionDtype.type
   The scalar type for the array, e.g. int

   It’s expected ExtensionArray[item] returns an instance of ExtensionDtype.type for scalar item, assuming that value is valid (not NA). NA values do not need to be instances of type.

Methods

construct_array_type() Return the array type associated with this dtype.

construct_from_string(string) Construct this type from a string.

is_dtype(dtype) Check if we match ‘dtype’.

pandas.api.extensions.ExtensionDtype.construct_array_type

classmethod ExtensionDtype.construct_array_type()
   Return the array type associated with this dtype.

   Returns
   type

pandas.api.extensions.ExtensionDtype.construct_from_string

classmethod ExtensionDtype.construct_from_string(string)
   Construct this type from a string.

   This is useful mainly for data types that accept parameters. For example, a period dtype accepts a frequency parameter that can be set as period[H] (where H means hourly frequency).

   By default, in the abstract class, just the name of the type is expected. But subclasses can overwrite this method to accept parameters.

   Parameters
   string [str] The name of the type, for example category.

   Returns
   ExtensionDtype Instance of the dtype.

   Raises
   TypeError If a class cannot be constructed from this ‘string’.

3.15. Extensions
Examples

For extension dtypes with arguments the following may be an adequate implementation.

```python
>>> @classmethod
... def construct_from_string(cls, string):
...     pattern = re.compile(r"my_type\[(?P<arg_name>.+)\]"$
...     match = pattern.match(string)
...     if match:
...         return cls(**match.groupdict())
...     else:
...         raise TypeError(
...             f"Cannot construct a '{cls.__name__}' from '{string}'"
...         )
```

**pandas.api.extensions.ExtensionDtype.is_dtype**

**classmethod** `ExtensionDtype.is_dtype(dtype)`

Check if we match `dtype`.

**Parameters**

- `dtype` [object] The object to check.

**Returns**

- bool

**Notes**

The default implementation is True if

1. `cls.construct_from_string(dtype)` is an instance of `cls`.
2. `dtype` is an object and is an instance of `cls`
3. `dtype` has a `dtype` attribute, and any of the above conditions is true for `dtype.dtype`.

**api.extensions.ExtensionArray()**  Abstract base class for custom 1-D array types.

**arrays.PandasArray(values[, copy])**  A pandas ExtensionArray for NumPy data.

### 3.15.6 **pandas.api.extensions.ExtensionArray**

**class** `pandas.api.extensions.ExtensionArray`

Abstract base class for custom 1-D array types.

pandas will recognize instances of this class as proper arrays with a custom type and will not attempt to coerce them to objects. They may be stored directly inside a `DataFrame` or `Series`. 
Notes

The interface includes the following abstract methods that must be implemented by subclasses:

- `_from_sequence`
- `_from_factorized`
- `__getitem__`
- `__len__`
- `__eq__`
- `dtype`
- `nbytes`
- `isna`
- `take`
- `copy`
- `_concat_same_type`

A default repr displaying the type, (truncated) data, length, and dtype is provided. It can be customized or replaced by by overriding:

- `__repr__`: A default repr for the ExtensionArray.
- `_formatter`: Print scalars inside a Series or DataFrame.

Some methods require casting the ExtensionArray to an ndarray of Python objects with `self.astype(object)`, which may be expensive. When performance is a concern, we highly recommend overriding the following methods:

- `fillna`
- `dropna`
- `unique`
- `factorize / _values_for_factorize`
- `argsort / _values_for_argsort`
- `searchsorted`

The remaining methods implemented on this class should be performant, as they only compose abstract methods. Still, a more efficient implementation may be available, and these methods can be overridden.

One can implement methods to handle array reductions.

- `reduce`

One can implement methods to handle parsing from strings that will be used in methods such as `pandas.io.parsers.read_csv`.

- `_from_sequence_of_strings`

This class does not inherit from `abc.ABCMeta` for performance reasons. Methods and properties required by the interface raise `pandas.errors(AbstractMethodError and no register method is provided for registering virtual subclasses.

ExtensionArrays are limited to 1 dimension.

They may be backed by none, one, or many NumPy arrays. For example, `pandas.Categorical` is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 address may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists. Pandas makes no assumptions on how the data are stored, just that it can be converted to a NumPy array. The ExtensionArray interface does not impose any rules on how this data is stored. However, currently, the backing data cannot be stored in attributes called `.values` or `.values` to ensure full compatibility with pandas internals. But other names as `.data`, `.data`, `.items`, ... can be freely used.

If implementing NumPy’s `__array_ufunc__` interface, pandas expects that

1. You defer by returning `NotImplemented` when any Series are present in `inputs`. Pandas will extract the arrays and call the ufunc again.
2. You define a `_HANDLED_TYPES` tuple as an attribute on the class. Pandas inspect this to determine whether the ufunc is valid for the types present.

See NumPy universal functions for more.
By default, ExtensionArrays are not hashable. Immutable subclasses may override this behavior.

**Attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dtype</code></td>
<td>An instance of ‘ExtensionDtype’.</td>
</tr>
<tr>
<td><code>nbytes</code></td>
<td>The number of bytes needed to store this object in memory.</td>
</tr>
<tr>
<td><code>ndim</code></td>
<td>Extension Arrays are only allowed to be 1-dimensional.</td>
</tr>
<tr>
<td><code>shape</code></td>
<td>Return a tuple of the array dimensions.</td>
</tr>
</tbody>
</table>

**pandas.api.extensions.ExtensionArray.dtype**

**property** `ExtensionArray.dtype`  
An instance of ‘ExtensionDtype’.

**pandas.api.extensions.ExtensionArray.nbytes**

**property** `ExtensionArray.nbytes`  
The number of bytes needed to store this object in memory.

**pandas.api.extensions.ExtensionArray.ndim**

**property** `ExtensionArray.ndim`  
Extension Arrays are only allowed to be 1-dimensional.

**pandas.api.extensions.ExtensionArray.shape**

**property** `ExtensionArray.shape`  
Return a tuple of the array dimensions.

**Methods**

- `argsort([ascending, kind, na_position])`  
  Return the indices that would sort this array.

- `astype(dtype[, copy])`  
  Cast to a NumPy array with ‘dtype’.

- `copy()`  
  Return a copy of the array.

- `dropna()`  
  Return ExtensionArray without NA values.

- `factorize([na_sentinel])`  
  Encode the extension array as an enumerated type.

- `fillna([value, method, limit])`  
  Fill NA/NaN values using the specified method.

- `equals(other)`  
  Return if another array is equivalent to this array.

- `isin(values)`  
  Pointwise comparison for set containment in the given values.

- `isna()`  
  A 1-D array indicating if each value is missing.

- `ravel([order])`  
  Return a flattened view on this array.

- `repeat(repeats[, axis])`  
  Repeat elements of a ExtensionArray.

<tr>
<td><code>_values_for_factorize()</code></td>
<td>Return an array and missing value suitable for factorization.</td>
</tr>
</tbody>
</table>

### pandas.api.extensions.ExtensionArray.argsort

ExtensionArray.<code>.argsort</code>(ascending=True, kind='quicksort', na_position='last', *args, **kwargs)

Return the indices that would sort this array.

**Parameters**

- **ascending** [bool, default True] Whether the indices should result in an ascending or descending sort.
- **args, **kwargs**: Passed through to numpy.argsort().

**Returns**

np.ndarray[np.intp] Array of indices that sort self. If NaN values are contained, NaN values are placed at the end.

**See also:**

numpy.argsort Sorting implementation used internally.

### pandas.api.extensions.ExtensionArray.astype

ExtensionArray.<code>.astype</code>(dtype, copy=True)

Cast to a NumPy array with ‘dtype’.

**Parameters**

- **dtype** [str or dtype] Typecode or data-type to which the array is cast.
- **copy** [bool, default True] Whether to copy the data, even if not necessary. If False, a copy is made only if the old dtype does not match the new dtype.

**Returns**

...
array  [ndarray] NumPy ndarray with ‘dtype’ for its dtype.

pandas.api.extensions.ExtensionArray.copy

ExtensionArray.copy()
Return a copy of the array.

Returns

ExtensionArray

pandas.api.extensions.ExtensionArray.dropna

ExtensionArray.dropna()
Return ExtensionArray without NA values.

Returns

valid  [ExtensionArray]

pandas.api.extensions.ExtensionArray.factorize

ExtensionArray.factorize(na_sentinel=-1)
Encode the extension array as an enumerated type.

Parameters

na_sentinel  [int, default -1] Value to use in the codes array to indicate missing values.

Returns

codes  [ndarray] An integer NumPy array that’s an indexer into the original ExtensionArray.

uniques  [ExtensionArray] An ExtensionArray containing the unique values of self.

Note: uniques will not contain an entry for the NA value of the ExtensionArray if there are any missing values present in self.

See also:

factorize  Top-level factorize method that dispatches here.

Notes

pandas.factorize() offers a sort keyword as well.
pandas.api.extensions.ExtensionArray.fillna

ExtensionArray.fillna(value=None, method=None, limit=None)
Fill NA/NaN values using the specified method.

Parameters

value [scalar, array-like] If a scalar value is passed it is used to fill all missing values. Alternatively, an array-like ‘value’ can be given. It’s expected that the array-like have the same length as ‘self’.

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled.

Returns

ExtensionArray With NA/NaN filled.

pandas.api.extensions.ExtensionArray.equals

ExtensionArray.equals(other)
Return if another array is equivalent to this array.

Equivalent means that both arrays have the same shape and dtype, and all values compare equal. Missing values in the same location are considered equal (in contrast with normal equality).

Parameters

other [ExtensionArray] Array to compare to this Array.

Returns

boolean Whether the arrays are equivalent.

pandas.api.extensions.ExtensionArray.isin

ExtensionArray.isin(values)
Pointwise comparison for set containment in the given values.
Roughly equivalent to np.array([x in values for x in self])

Parameters

values [Sequence]

Returns

np.ndarray[bool]
pandas.api.extensions.ExtensionArray.isna

ExtensionArray.isna()
A 1-D array indicating if each value is missing.

Returns

na_values [Union[np.ndarray, ExtensionArray]] In most cases, this should return a NumPy ndarray. For exceptional cases like SparseArray, where returning an ndarray would be expensive, an ExtensionArray may be returned.

Notes

If returning an ExtensionArray, then

• na_values._is_boolean should be True
• na_values should implement ExtensionArray._reduce()
• na_values.any and na_values.all should be implemented

pandas.api.extensions.ExtensionArray.ravel

ExtensionArray.ravel(order='C')
Return a flattened view on this array.

Parameters

Returns

ExtensionArray

Notes

• Because ExtensionArrays are 1D-only, this is a no-op.
• The “order” argument is ignored, is for compatibility with NumPy.

pandas.api.extensions.ExtensionArray.repeat

ExtensionArray.repeat(repeats, axis=None)
Repeat elements of a ExtensionArray.

Returns a new ExtensionArray where each element of the current ExtensionArray is repeated consecutively a given number of times.

Parameters

repeats [int or array of ints] The number of repetitions for each element. This should be a non-negative integer. Repeating 0 times will return an empty ExtensionArray.

axis [None] Must be None. Has no effect but is accepted for compatibility with numpy.

Returns

repeated_array [ExtensionArray] Newly created ExtensionArray with repeated elements.
See also:

**Series.repeat**  Equivalent function for Series.

**Index.repeat**  Equivalent function for Index.

**numpy.repeat**  Similar method for `numpy.ndarray`.

**ExtensionArray.take**  Take arbitrary positions.

### Examples

```python
cat = pd.Categorical(['a', 'b', 'c'])
cat
['a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']
cat.repeat(2)
['a', 'a', 'b', 'b', 'c', 'c']
Categories (3, object): ['a', 'b', 'c']
cat.repeat([1, 2, 3])
['a', 'b', 'b', 'c', 'c', 'c']
Categories (3, object): ['a', 'b', 'c']
```

### pandas.api.extensions.ExtensionArray.searchsorted

ExtensionArray.searchsorted(`value`, `side='left'`, `sorter=None`)  
Find indices where elements should be inserted to maintain order.

Find the indices into a sorted array `self` (a) such that, if the corresponding elements in `value` were inserted before the indices, the order of `self` would be preserved.

Assuming that `self` is sorted:

<table>
<thead>
<tr>
<th><strong>side</strong></th>
<th><strong>returned index / satisfies</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>left</td>
<td><code>self[i-1] &lt; value &lt;= self[i]</code></td>
</tr>
<tr>
<td>right</td>
<td><code>self[i-1] &lt;= value &lt; self[i]</code></td>
</tr>
</tbody>
</table>

**Parameters**

- `value`  [array-like] Values to insert into `self`.
- `side`  [{'left', 'right'}, optional] If ‘left’, the index of the first suitable location found is given. If ‘right’, return the last such index. If there is no suitable index, return either 0 or N (where N is the length of `self`).
- `sorter`  [1-D array-like, optional] Optional array of integer indices that sort array `a` into ascending order. They are typically the result of argsort.

**Returns**

- `array of ints`  Array of insertion points with the same shape as `value`.

**See also:**

**numpy.searchsorted**  Similar method from NumPy.
pandas.api.extensions.ExtensionArray.shift

ExtensionArray.shift(periods=1, fill_value=None)
Shift values by desired number.

Newly introduced missing values are filled with self.dtype.na_value.

Parameters

periods [int, default 1] The number of periods to shift. Negative values are allowed for shifting backwards.

fill_value [object, optional] The scalar value to use for newly introduced missing values. The default is self.dtype.na_value.

Returns

ExtensionArray Shifted.

Notes

If self is empty or periods is 0, a copy of self is returned.

If periods > len(self), then an array of size len(self) is returned, with all values filled with self.dtype.na_value.

pandas.api.extensions.ExtensionArray.take

ExtensionArray.take(indices, *, allow_fill=False, fill_value=None)
Take elements from an array.

Parameters

indices [sequence of int] Indices to be taken.

allow_fill [bool, default False] How to handle negative values in indices.

• False: negative values in indices indicate positional indices from the right (the default). This is similar to numpy.take().

• True: negative values in indices indicate missing values. These values are set to fill_value. Any other other negative values raise a ValueError.

fill_value [any, optional] Fill value to use for NA-indices when allow_fill is True. This may be None, in which case the default NA value for the type, self.dtype.na_value, is used.

For many ExtensionArrays, there will be two representations of fill_value: a user-facing “boxed” scalar, and a low-level physical NA value. fill_value should be the user-facing version, and the implementation should handle translating that to the physical version for processing the take if necessary.

Returns

ExtensionArray

 Raises

IndexError When the indices are out of bounds for the array.

ValueError When indices contains negative values other than -1 and allow_fill is True.
See also:

**numpy.take** Take elements from an array along an axis.

**api.extensions.take** Take elements from an array.

**Notes**

ExtensionArray.take is called by `Series.__getitem__, .loc, iloc,` when *indices* is a sequence of values. Additionally, it’s called by `Series.reindex()`, or any other method that causes realignment, with a *fill_value*.

**Examples**

Here’s an example implementation, which relies on casting the extension array to object dtype. This uses the helper method `pandas.api.extensions.take()`.

```python
def take(self, indices, allow_fill=False, fill_value=None):
    from pandas.core.algorithms import take

    # If the ExtensionArray is backed by an ndarray, then
    # just pass that here instead of coercing to object.
    data = self.astype(object)

    if allow_fill and fill_value is None:
        fill_value = self.dtype.na_value

    # fill value should always be translated from the scalar
    # type for the array, to the physical storage type for
    # the data, before passing to take.

    result = take(data, indices, fill_value=fill_value,
                  allow_fill=allow_fill)

    return self._from_sequence(result, dtype=self.dtype)
```

**pandas.api.extensions.ExtensionArray.unique**

ExtensionArray.unique()

Compute the ExtensionArray of unique values.

**Returns**

uniques [ExtensionArray]

**pandas.api.extensions.ExtensionArray.view**

ExtensionArray.view(*dtype=None*)

Return a view on the array.

**Parameters**

* dtype [str, np.dtype, or ExtensionDtype, optional] Default None.

**Returns**

ExtensionArray or np.ndarray A view on the ExtensionArray’s data.
pandas.api.extensions.ExtensionArray._concat_same_type

classmethod ExtensionArray._concat_same_type(to_concat)
Concenate multiple array of this dtype.

Parameters

- to_concat [sequence of this type]

Returns

- ExtensionArray

pandas.api.extensions.ExtensionArray._formatter

ExtensionArray._formatter(boxed=False)
Formatting function for scalar values.

This is used in the default ‘__repr__’. The returned formatting function receives instances of your scalar type.

Parameters

- boxed [bool, default False] An indicated for whether or not your array is being printed within a Series, DataFrame, or Index (True), or just by itself (False). This may be useful if you want scalar values to appear differently within a Series versus on its own (e.g. quoted or not).

Returns

- Callable[[Any], str] A callable that gets instances of the scalar type and returns a string. By default, repr() is used when boxed=False and str() is used when boxed=True.

pandas.api.extensions.ExtensionArray._from_factorized

classmethod ExtensionArray._from_factorized(values, original)
Reconstruct an ExtensionArray after factorization.

Parameters

- values [ndarray] An integer ndarray with the factorized values.
- original [ExtensionArray] The original ExtensionArray that factorize was called on.

See also:

- factorize Top-level factorize method that dispatches here.
- ExtensionArray.factorize Encode the extension array as an enumerated type.
pandas.api.extensions.ExtensionArray._from_sequence

**classmethod** ExtensionArray._from_sequence (scalars, *, dtype=None, copy=False)

Construct a new ExtensionArray from a sequence of scalars.

**Parameters**
- **scalars** [Sequence] Each element will be an instance of the scalar type for this array, `cls.dtype.type` or be converted into this type in this method.
- **dtype** [dtype, optional] Construct for this particular dtype. This should be a Dtype compatible with the ExtensionArray.
- **copy** [bool, default False] If True, copy the underlying data.

**Returns**
- ExtensionArray

pandas.api.extensions.ExtensionArray._from_sequence_of_strings

**classmethod** ExtensionArray._from_sequence_of_strings (strings, *, dtype=None, copy=False)

Construct a new ExtensionArray from a sequence of strings.

**Parameters**
- **strings** [Sequence] Each element will be an instance of the scalar type for this array, `cls.dtype.type`.
- **dtype** [dtype, optional] Construct for this particular dtype. This should be a Dtype compatible with the ExtensionArray.
- **copy** [bool, default False] If True, copy the underlying data.

**Returns**
- ExtensionArray

pandas.api.extensions.ExtensionArray._reduce

ExtensionArray._reduce (name, *, skipna=True, **kwargs)

Return a scalar result of performing the reduction operation.

**Parameters**
- **name** [str] Name of the function, supported values are: { any, all, min, max, sum, mean, median, prod, std, var, sem, kurt, skew }.
- **skipna** [bool, default True] If True, skip NaN values.
- ****kwargs Additional keyword arguments passed to the reduction function. Currently, `ddof` is the only supported kwarg.

**Returns**
- scalar

**Raises**
- TypeError [subclass does not define reductions]
pandas.api.extensions.ExtensionArray._values_for_argsort

ExtensionArray._values_for_argsort()
Return values for sorting.

Returns

ndarray The transformed values should maintain the ordering between values within
the array.

See also:

ExtensionArray.argsort Return the indices that would sort this array.

pandas.api.extensions.ExtensionArray._values_for_factorize

ExtensionArray._values_for_factorize()
Return an array and missing value suitable for factorization.

Returns

values [ndarray] An array suitable for factorization. This should maintain order and
be a supported dtype (Float64, Int64, UInt64, String, Object). By default, the
extension array is cast to object dtype.

na_value [object] The value in values to consider missing. This will be treated as NA
in the factorization routines, so it will be coded as na_sentinel and not included in
uniques. By default, np.nan is used.

Notes

The values returned by this method are also used in pandas.util.hash_pandas_object().

3.15.7 pandas.arrays.PandasArray

class pandas.arrays.PandasArray (values, copy=False)
A pandas ExtensionArray for NumPy data.

This is mostly for internal compatibility, and is not especially useful on its own.

Parameters

values [ndarray] The NumPy ndarray to wrap. Must be 1-dimensional.

copy [bool, default False] Whether to copy values.

Attributes

None

Methods

Additionally, we have some utility methods for ensuring your object behaves correctly.

```python
api.indexers.check_array_indexer(array, indexer)
```

Check if `indexer` is a valid array indexer for `array`.

3.15.8 pandas.api.indexers.check_array_indexer

```python
pandas.api.indexers.check_array_indexer(arr, mask)
```

Check if `indexer` is a valid array indexer for `array`.

For a boolean mask, `array` and `indexer` are checked to have the same length. The dtype is validated, and if it is an integer or boolean ExtensionArray, it is checked if there are missing values present, and it is converted to the appropriate numpy array. Other dtypes will raise an error.

Non-array indexers (integer, slice, Ellipsis, tuples, ..) are passed through as is.

New in version 1.0.0.

**Parameters**

- `array` [array-like] The array that is being indexed (only used for the length).
- `indexer` [array-like or list-like] The array-like that’s used to index. List-like input that is not yet a numpy array or an ExtensionArray is converted to one. Other input types are passed through as is.

**Returns**

- `numpy.ndarray` The validated indexer as a numpy array that can be used to index.

**Raises**

- `IndexError` When the lengths don’t match.
- `ValueError` When `indexer` cannot be converted to a numpy ndarray to index (e.g. presence of missing values).

**See also:**

- `api.types.is_bool_dtype` Check if `key` is of boolean dtype.

**Examples**

When checking a boolean mask, a boolean ndarray is returned when the arguments are all valid.

```python
>>> mask = pd.array([True, False])
>>> arr = pd.array([1, 2])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([ True, False])
```

An `IndexError` is raised when the lengths don’t match.
>>> mask = pd.array([True, False, True])
>>> pd.api.indexers.check_array_indexer(arr, mask)
Traceback (most recent call last):
  ...
IndexError: Boolean index has wrong length: 3 instead of 2.

NA values in a boolean array are treated as False.

>>> mask = pd.array([True, pd.NA])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([ True, False])

A numpy boolean mask will get passed through (if the length is correct):

>>> mask = np.array([True, False])
>>> pd.api.indexers.check_array_indexer(arr, mask)
array([ True, False])

Similarly for integer indexers, an integer ndarray is returned when it is a valid indexer, otherwise an error is (for integer indexers, a matching length is not required):

>>> indexer = pd.array([0, 2], dtype="Int64")
>>> arr = pd.array([1, 2, 3])
>>> pd.api.indexers.check_array_indexer(arr, indexer)
array([0, 2])

>>> indexer = pd.array([0, pd.NA], dtype="Int64")
>>> pd.api.indexers.check_array_indexer(arr, indexer)
Traceback (most recent call last):
  ...
ValueError: Cannot index with an integer indexer containing NA values

For non-integer/boolean dtypes, an appropriate error is raised:

>>> indexer = np.array([0., 2.], dtype="float64")
>>> pd.api.indexers.check_array_indexer(arr, indexer)
Traceback (most recent call last):
  ...
IndexError: arrays used as indices must be of integer or boolean type

The sentinel pandas.api.extensions.no_default is used as the default value in some methods. Use an is comparison to check if the user provides a non-default value.
4.1 Contributing to pandas

4.1.1 Where to start?

All contributions, bug reports, bug fixes, documentation improvements, enhancements, and ideas are welcome.

If you are brand new to pandas or open-source development, we recommend going through the GitHub “issues” tab to find issues that interest you. There are a number of issues listed under Docs and good first issue where you could start out. Once you’ve found an interesting issue, you can return here to get your development environment setup.

When you start working on an issue, it’s a good idea to assign the issue to yourself, so nobody else duplicates the work on it. GitHub restricts assigning issues to maintainers of the project only. In most projects, and until recently in pandas, contributors added a comment letting others know they are working on an issue. While this is ok, you need to check each issue individually, and it’s not possible to find the unassigned ones.

For this reason, we implemented a workaround consisting of adding a comment with the exact text take. When you do it, a GitHub action will automatically assign you the issue (this will take seconds, and may require refreshing the page to see it). By doing this, it’s possible to filter the list of issues and find only the unassigned ones.

So, a good way to find an issue to start contributing to pandas is to check the list of unassigned good first issues and assign yourself one you like by writing a comment with the exact text take.

If for whatever reason you are not able to continue working with the issue, please try to unassign it, so other people know it’s available again. You can check the list of assigned issues, since people may not be working in them anymore. If you want to work on one that is assigned, feel free to kindly ask the current assignee if you can take it (please allow at least a week of inactivity before considering work in the issue discontinued).

Feel free to ask questions on the mailing list or on Gitter.

4.1.2 Bug reports and enhancement requests

Bug reports are an important part of making pandas more stable. Having a complete bug report will allow others to reproduce the bug and provide insight into fixing. See this stackoverflow article and this blogpost for tips on writing a good bug report.

Trying the bug-producing code out on the master branch is often a worthwhile exercise to confirm the bug still exists. It is also worth searching existing bug reports and pull requests to see if the issue has already been reported and/or fixed.

Bug reports must:

1. Include a short, self-contained Python snippet reproducing the problem. You can format the code nicely by using GitHub Flavored Markdown:

```python
>>> from pandas import DataFrame
>>> df = DataFrame(...) 
... 
```

2. Include the full version string of pandas and its dependencies. You can use the built-in function:

```python
>>> import pandas as pd
>>> pd.show_versions()
```

3. Explain why the current behavior is wrong/not desired and what you expect instead.

The issue will then show up to the pandas community and be open to comments/ideas from others.
4.1.3 Working with the code

Now that you have an issue you want to fix, enhancement to add, or documentation to improve, you need to learn how to work with GitHub and the pandas code base.

Version control, Git, and GitHub

To the new user, working with Git is one of the more daunting aspects of contributing to pandas. It can very quickly become overwhelming, but sticking to the guidelines below will help keep the process straightforward and mostly trouble free. As always, if you are having difficulties please feel free to ask for help.

The code is hosted on GitHub. To contribute you will need to sign up for a free GitHub account. We use Git for version control to allow many people to work together on the project.

Some great resources for learning Git:

- the GitHub help pages.
- the NumPy documentation.
- Matthew Brett’s Pydagogue.

Getting started with Git

GitHub has instructions for installing git, setting up your SSH key, and configuring git. All these steps need to be completed before you can work seamlessly between your local repository and GitHub.

Forking

You will need your own fork to work on the code. Go to the pandas project page and hit the Fork button. You will want to clone your fork to your machine:

```bash
  git clone https://github.com/your-user-name/pandas.git pandas-yourname
  cd pandas-yourname
  git remote add upstream https://github.com/pandas-dev/pandas.git
```

This creates the directory pandas-yourname and connects your repository to the upstream (main project) pandas repository.

Note that performing a shallow clone (with --depth=N, for some N greater or equal to 1) might break some tests and features as `pd.show_versions()` as the version number cannot be computed anymore.

Creating a branch

You want your master branch to reflect only production-ready code, so create a feature branch for making your changes. For example:

```bash
  git branch shiny-new-feature
  git checkout shiny-new-feature
```

The above can be simplified to:

```bash
  git checkout -b shiny-new-feature
```
This changes your working directory to the shiny-new-feature branch. Keep any changes in this branch specific to one bug or feature so it is clear what the branch brings to pandas. You can have many shiny-new-features and switch in between them using the git checkout command.

When creating this branch, make sure your master branch is up to date with the latest upstream master version. To update your local master branch, you can do:

```
$ git checkout master
$ git pull upstream master --ff-only
```

When you want to update the feature branch with changes in master after you created the branch, check the section on updating a PR.

### 4.1.4 Contributing your changes to pandas

#### Committing your code

Keep style fixes to a separate commit to make your pull request more readable.

Once you’ve made changes, you can see them by typing:

```
$ git status
```

If you have created a new file, it is not being tracked by git. Add it by typing:

```
$ git add path/to/file-to-be-added.py
```

Doing ‘git status’ again should give something like:

```
# On branch shiny-new-feature
#
#   modified:  /relative/path/to/file-you-added.py
#
```

Finally, commit your changes to your local repository with an explanatory message. pandas uses a convention for commit message prefixes and layout. Here are some common prefixes along with general guidelines for when to use them:

- **ENH**: Enhancement, new functionality
- **BUG**: Bug fix
- **DOC**: Additions/updates to documentation
- **TST**: Additions/updates to tests
- **BLD**: Updates to the build process/scripts
- **PERF**: Performance improvement
- **TYP**: Type annotations
- **CLN**: Code cleanup

The following defines how a commit message should be structured. Please reference the relevant GitHub issues in your commit message using GH1234 or #1234. Either style is fine, but the former is generally preferred:

- a subject line with < 80 chars.
- One blank line.
• Optionally, a commit message body.

Now you can commit your changes in your local repository:

```bash
git commit -m
```

### Pushing your changes

When you want your changes to appear publicly on your GitHub page, push your forked feature branch’s commits:

```bash
git push origin shiny-new-feature
```

Here `origin` is the default name given to your remote repository on GitHub. You can see the remote repositories:

```bash
git remote -v
```

If you added the upstream repository as described above you will see something like:

```
origin  git@github.com:yourname/pandas.git (fetch)
origin  git@github.com:yourname/pandas.git (push)
upstream git://github.com/pandas-dev/pandas.git (fetch)
upstream git://github.com/pandas-dev/pandas.git (push)
```

Now your code is on GitHub, but it is not yet a part of the pandas project. For that to happen, a pull request needs to be submitted on GitHub.

### Review your code

When you’re ready to ask for a code review, file a pull request. Before you do, once again make sure that you have followed all the guidelines outlined in this document regarding code style, tests, performance tests, and documentation. You should also double check your branch changes against the branch it was based on:

1. Navigate to your repository on GitHub – https://github.com/your-user-name/pandas
2. Click on **Branches**
3. Click on the **Compare** button for your feature branch
4. Select the **base** and **compare** branches, if necessary. This will be **master** and **shiny-new-feature**, respectively.

### Finally, make the pull request

If everything looks good, you are ready to make a pull request. A pull request is how code from a local repository becomes available to the GitHub community and can be looked at and eventually merged into the master version. This pull request and its associated changes will eventually be committed to the master branch and available in the next release. To submit a pull request:

1. Navigate to your repository on GitHub
2. Click on the **Pull Request** button
3. You can then click on **Commits** and **Files Changed** to make sure everything looks okay one last time
4. Write a description of your changes in the **Preview Discussion** tab
5. Click **Send Pull Request**.

This request then goes to the repository maintainers, and they will review the code.
Updating your pull request

Based on the review you get on your pull request, you will probably need to make some changes to the code. In that case, you can make them in your branch, add a new commit to that branch, push it to GitHub, and the pull request will be automatically updated. Pushing them to GitHub again is done by:

```bash
git push origin shiny-new-feature
```

This will automatically update your pull request with the latest code and restart the *Continuous Integration* tests.

Another reason you might need to update your pull request is to solve conflicts with changes that have been merged into the master branch since you opened your pull request.

To do this, you need to “merge upstream master” in your branch:

```bash
git checkout shiny-new-feature
git fetch upstream
git merge upstream/master
```

If there are no conflicts (or they could be fixed automatically), a file with a default commit message will open, and you can simply save and quit this file.

If there are merge conflicts, you need to solve those conflicts. See for example at [https://help.github.com/articles/resolving-a-merge-conflict-using-the-command-line/](https://help.github.com/articles/resolving-a-merge-conflict-using-the-command-line/) for an explanation on how to do this. Once the conflicts are merged and the files where the conflicts were solved are added, you can run `git commit` to save those fixes.

If you have uncommitted changes at the moment you want to update the branch with master, you will need to `stash` them prior to updating (see the `stash` docs). This will effectively store your changes and they can be reapplied after updating.

After the feature branch has been update locally, you can now update your pull request by pushing to the branch on GitHub:

```bash
git push origin shiny-new-feature
```

Autofixing formatting errors

We use several styling checks (e.g. `black`, `flake8`, `isort`) which are run after you make a pull request. If there is a scenario where any of these checks fail then you can comment:

```bash
@github-actions pre-commit
```

on that pull request. This will trigger a workflow which will autofix formatting errors.

Delete your merged branch (optional)

Once your feature branch is accepted into upstream, you’ll probably want to get rid of the branch. First, merge upstream master into your branch so `git` knows it is safe to delete your branch:

```bash
git fetch upstream
git checkout master
git merge upstream/master
```

Then you can do:
4.1.5 Tips for a successful pull request

If you have made it to the Review your code phase, one of the core contributors may take a look. Please note however that a handful of people are responsible for reviewing all of the contributions, which can often lead to bottlenecks.

To improve the chances of your pull request being reviewed, you should:

- Reference an open issue for non-trivial changes to clarify the PR’s purpose
- Ensure you have appropriate tests. These should be the first part of any PR
- Keep your pull requests as simple as possible. Larger PRs take longer to review
- Ensure that CI is in a green state. Reviewers may not even look otherwise
- Keep Updating your pull request, either by request or every few days

4.2 Creating a development environment

To test out code changes, you’ll need to build pandas from source, which requires a C/C++ compiler and Python environment. If you’re making documentation changes, you can skip to contributing to the documentation but if you skip creating the development environment you won’t be able to build the documentation locally before pushing your changes.

<table>

<tr>
<td>Creating a Python environment</td>
</tr>
<tr>
<td>Creating a Python environment (pip)</td>
</tr>
</tbody>
</table>

4.2.1 Creating an environment using Docker

Instead of manually setting up a development environment, you can use Docker to automatically create the environment with just several commands. pandas provides a DockerFile in the root directory to build a Docker image with a full pandas development environment.

Docker Commands

Pass your GitHub username in the DockerFile to use your own fork:
Even easier, you can integrate Docker with the following IDEs:

**Visual Studio Code**

You can use the DockerFile to launch a remote session with Visual Studio Code, a popular free IDE, using the .devcontainer.json file. See [https://code.visualstudio.com/docs/remote/containers](https://code.visualstudio.com/docs/remote/containers) for details.

**PyCharm (Professional)**

Enable Docker support and use the Services tool window to build and manage images as well as run and interact with containers. See [https://www.jetbrains.com/help/pycharm/docker.html](https://www.jetbrains.com/help/pycharm/docker.html) for details.

Note that you might need to rebuild the C extensions if/when you merge with upstream/master using:

```
python setup.py build_ext -j 4
```

### 4.2.2 Creating an environment without Docker

#### Installing a C compiler

pandas uses C extensions (mostly written using Cython) to speed up certain operations. To install pandas from source, you need to compile these C extensions, which means you need a C compiler. This process depends on which platform you’re using.

If you have setup your environment using conda, the packages `c-compiler` and `cxx-compiler` will install a fitting compiler for your platform that is compatible with the remaining conda packages. On Windows and macOS, you will also need to install the SDKs as they have to be distributed separately. These packages will automatically be installed by using the `pandas environment.yml` file.

**Windows**

You will need **Build Tools for Visual Studio 2017**.

**Warning:** You DO NOT need to install Visual Studio 2019. You only need “Build Tools for Visual Studio 2019” found by scrolling down to “All downloads” -> “Tools for Visual Studio 2019”. In the installer, select the “C++ build tools” workload.

You can install the necessary components on the commandline using `vs_buildtools.exe`:

```
vs_buildtools.exe --quiet --wait --norestart --nocache ^
--installPath C:\BuildTools ^
--add "Microsoft.VisualStudio.Workload.VCTools;includeRecommended" ^
--add Microsoft.VisualStudio.Component.VC.v141 ^
--add Microsoft.VisualStudio.Component.VC.v141.x86.x64 ^
```

To setup the right paths on the commandline, call "C:\BuildTools\VC\Auxiliary\Build\vcvars64.bat" -vcvars_ver=14.16 10.0.17763.0.

**macOS**
To use the conda-based compilers, you will need to install the Developer Tools using xcode-select --install. Otherwise information about compiler installation can be found here: https://devguide.python.org/setup/#macos

**Linux**

For Linux-based conda installations, you won’t have to install any additional components outside of the conda environment. The instructions below are only needed if your setup isn’t based on conda environments.

Some Linux distributions will come with a pre-installed C compiler. To find out which compilers (and versions) are installed on your system:

```
# for Debian/Ubuntu:
dpkg --list | grep compiler
# for Red Hat/RHEL/CentOS/Fedora:
yum list installed | grep -i --color compiler
```

GCC (GNU Compiler Collection) is a widely used compiler, which supports C and a number of other languages. If GCC is listed as an installed compiler nothing more is required. If no C compiler is installed (or you wish to install a newer version) you can install a compiler (GCC in the example code below) with:

```
# for recent Debian/Ubuntu:
sudo apt install build-essential
# for Red Hat/RHEL/CentOS/Fedora
yum groupinstall "Development Tools"
```

For other Linux distributions, consult your favorite search engine for compiler installation instructions.

Let us know if you have any difficulties by opening an issue or reaching out on Gitter.

**Creating a Python environment**

Now create an isolated pandas development environment:

- Install either Anaconda, miniconda, or miniforge
- Make sure your conda is up to date (conda update conda)
- Make sure that you have cloned the repository
- cd to the pandas source directory

We’ll now kick off a three-step process:

1. Install the build dependencies
2. Build and install pandas
3. Install the optional dependencies

```
# Create and activate the build environment
conda env create -f environment.yml
conda activate pandas-dev

# or with older versions of Anaconda:
source activate pandas-dev

# Build and install pandas
python setup.py build_ext -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517
```
At this point you should be able to import pandas from your locally built version:

```
$ python  # start an interpreter
>>> import pandas
>>> print(pandas.__version__)
0.22.0.dev0+29.g4ad6d4d74
```

This will create the new environment, and not touch any of your existing environments, nor any existing Python installation.

To view your environments:

```
conda info -e
```

To return to your root environment:

```
conda deactivate
```

See the full conda docs here.

**Creating a Python environment (pip)**

If you aren’t using conda for your development environment, follow these instructions. You’ll need to have at least the minimum Python version that pandas supports. If your Python version is 3.8.0 (or later), you might need to update your setuptools to version 42.0.0 (or later) in your development environment before installing the build dependencies:

```
pip install --upgrade setuptools
```

**Unix/macOS with virtualenv**

```
# Create a virtual environment
# Use an ENV_DIR of your choice. We'll use ~/virtualenvs/pandas-dev
# Any parent directories should already exist
python3 -m venv ~/virtualenvs/pandas-dev

# Activate the virtualenv
. ~/virtualenvs/pandas-dev/bin/activate

# Install the build dependencies
python -m pip install -r requirements-dev.txt

# Build and install pandas
python setup.py build_ext -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517
```

**Unix/macOS with pyenv**

Consult the docs for setting up pyenv here.

```
# Create a virtual environment
# Use an ENV_DIR of your choice. We'll use ~/Users/<yourname>/.pyenv/versions/pandas-
   \→dev
pyenv virtualenv <version> <name-to-give-it>

# For instance:
pyenv virtualenv 3.7.6 pandas-dev
```

(continues on next page)
# Activate the virtualenv
pyenv activate pandas-dev

$ Now install the build dependencies in the cloned pandas repo
python -m pip install -r requirements-dev.txt

$ Build and install pandas
python setup.py build_ext -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517

**Windows**

Below is a brief overview on how to set-up a virtual environment with Powershell under Windows. For details please refer to the [official virtualenv user guide](https://virtualenv.pypa.io/en/stable/user-guide/). Use an ENV_DIR of your choice. We’ll use `\virtualenv\pandas-dev` where ‘~’ is the folder pointed to by either `$env:USERPROFILE` (Powershell) or `%USERPROFILE%` (cmd.exe) environment variable. Any parent directories should already exist.

# Create a virtual environment
python -m venv $env:USERPROFILE\virtualenvs\pandas-dev

# Activate the virtualenv. Use activate.bat for cmd.exe
~\virtualenvs\pandas-dev\Scripts\Activate.ps1

# Install the build dependencies
python -m pip install -r requirements-dev.txt

# Build and install pandas
python setup.py build_ext -j 4
python -m pip install -e . --no-build-isolation --no-use-pep517

## 4.3 Contributing to the documentation

Contributing to the documentation benefits everyone who uses pandas. We encourage you to help us improve the documentation, and you don’t have to be an expert on pandas to do so! In fact, there are sections of the docs that are worse off after being written by experts. If something in the docs doesn’t make sense to you, updating the relevant section after you figure it out is a great way to ensure it will help the next person.

**Documentation:**

- About the pandas documentation
- Updating a pandas docstring
- How to build the pandas documentation
  - Requirements
  - Building the documentation
  - Building master branch documentation
- Previewing changes
4.3.1 About the pandas documentation

The documentation is written in reStructuredText, which is almost like writing in plain English, and built using Sphinx. The Sphinx Documentation has an excellent introduction to reST. Review the Sphinx docs to perform more complex changes to the documentation as well.

Some other important things to know about the docs:

- The pandas documentation consists of two parts: the docstrings in the code itself and the docs in this folder doc/.

  The docstrings provide a clear explanation of the usage of the individual functions, while the documentation in this folder consists of tutorial-like overviews per topic together with some other information (what’s new, installation, etc).

- The docstrings follow a pandas convention, based on the Numpy Docstring Standard. Follow the pandas docstring guide for detailed instructions on how to write a correct docstring.

pandas docstring guide

About docstrings and standards

A Python docstring is a string used to document a Python module, class, function or method, so programmers can understand what it does without having to read the details of the implementation.

Also, it is a common practice to generate online (html) documentation automatically from docstrings. Sphinx serves this purpose.

The next example gives an idea of what a docstring looks like:

```python
def add(num1, num2):
    
    """
    Add up two integer numbers.

    This function simply wraps the `+` operator, and does not do anything interesting, except for illustrating what the docstring of a very simple function looks like.

    Parameters
    ----------
    num1 : int
        First number to add.
    num2 : int
        Second number to add.

    Returns
    -------
    int
        The sum of `num1` and `num2`.

    See Also
    --------
    subtract : Subtract one integer from another.

    Examples
    --------
    >>> add(2, 2)
    4
    ```

(continues on next page)
Some standards regarding docstrings exist, which make them easier to read, and allow them be easily exported to other formats such as html or pdf.

The first conventions every Python docstring should follow are defined in PEP-257.

As PEP-257 is quite broad, other more specific standards also exist. In the case of pandas, the NumPy docstring convention is followed. These conventions are explained in this document:

- numpydoc docstring guide (which is based in the original Guide to NumPy/SciPy documentation)

numpydoc is a Sphinx extension to support the NumPy docstring convention.

The standard uses reStructuredText (reST). reStructuredText is a markup language that allows encoding styles in plain text files. Documentation about reStructuredText can be found in:

- Sphinx reStructuredText primer
- Quick reStructuredText reference
- Full reStructuredText specification

pandas has some helpers for sharing docstrings between related classes, see Sharing docstrings.

The rest of this document will summarize all the above guidelines, and will provide additional conventions specific to the pandas project.

Writing a docstring

General rules

Docstrings must be defined with three double-quotes. No blank lines should be left before or after the docstring. The text starts in the next line after the opening quotes. The closing quotes have their own line (meaning that they are not at the end of the last sentence).

On rare occasions reST styles like bold text or italics will be used in docstrings, but it is common to have inline code, which is presented between backticks. The following are considered inline code:

- The name of a parameter
- Python code, a module, function, built-in, type, literal... (e.g. os, list, numpy.abs, datetime, date, True)
- A pandas class (in the form :class:`pandas.Series`)
- A pandas method (in the form :meth:`pandas.Series.sum`)
- A pandas function (in the form :func:`pandas.to_datetime`)

Note: To display only the last component of the linked class, method or function, prefix it with ~. For example, :class:`~pandas.Series` will link to pandas.Series but only display the last part, Series as the link text. See Sphinx cross-referencing syntax for details.
Good:

```python
def add_values(arr):
    
    Add the values in `arr`.
    This is equivalent to Python `sum` of :meth:`pandas.Series.sum`.
    Some sections are omitted here for simplicity.
    
    return sum(arr)
```

Bad:

```python
def func():
    
    """Some function.
    With several mistakes in the docstring.
    It has a blank like after the signature `func()`:
    The text 'Some function' should go in the line after the opening quotes of the docstring, not in the same line.
    There is a blank line between the docstring and the first line of code `foo = 1`.
    The closing quotes should be in the next line, not in this one.""

    foo = 1
    bar = 2
    return foo + bar
```

Section 1: short summary

The short summary is a single sentence that expresses what the function does in a concise way.

The short summary must start with a capital letter, end with a dot, and fit in a single line. It needs to express what the object does without providing details. For functions and methods, the short summary must start with an infinitive verb.

Good:

```python
def asstype(dtype):
    
    """Cast Series type.
    This section will provide further details.
    ""
    pass
```

Bad:

```python
def asstype(dtype):
    
    """Casts Series type.
```

(continues on next page)
Verb in third-person of the present simple, should be infinitive.

```
pass
```

```python
def astype(dtype):
    """
    Method to cast Series type.
    Does not start with verb.
    """
    pass
```

```python
def astype(dtype):
    """
    Cast Series type
    Missing dot at the end.
    """
    pass
```

```python
def astype(dtype):
    """
    Cast Series type from its current type to the new type defined in the parameter dtype.
    Summary is too verbose and doesn't fit in a single line.
    """
    pass
```

Section 2: extended summary

The extended summary provides details on what the function does. It should not go into the details of the parameters, or discuss implementation notes, which go in other sections.

A blank line is left between the short summary and the extended summary. Every paragraph in the extended summary ends with a dot.

The extended summary should provide details on why the function is useful and their use cases, if it is not too generic.

```python
def unstack():
    """
    Pivot a row index to columns.
    When using a MultiIndex, a level can be pivoted so each value in the index becomes a column. This is especially useful when a subindex is repeated for the main index, and data is easier to visualize as a pivot table.
    The index level will be automatically removed from the index when added as columns.
    """
    pass
```
Section 3: parameters

The details of the parameters will be added in this section. This section has the title “Parameters”, followed by a line with a hyphen under each letter of the word “Parameters”. A blank line is left before the section title, but not after, and not between the line with the word “Parameters” and the one with the hyphens.

After the title, each parameter in the signature must be documented, including *args and **kwargs, but not self.

The parameters are defined by their name, followed by a space, a colon, another space, and the type (or types). Note that the space between the name and the colon is important. Types are not defined for *args and **kwargs, but must be defined for all other parameters. After the parameter definition, it is required to have a line with the parameter description, which is indented, and can have multiple lines. The description must start with a capital letter, and finish with a dot.

For keyword arguments with a default value, the default will be listed after a comma at the end of the type. The exact form of the type in this case will be “int, default 0”. In some cases it may be useful to explain what the default argument means, which can be added after a comma “int, default -1, meaning all cpus”.

In cases where the default value is None, meaning that the value will not be used. Instead of "str, default None", it is preferred to write "str, optional". When None is a value being used, we will keep the form “str, default None”. For example, in df.to_csv(compression=None), None is not a value being used, but means that compression is optional, and no compression is being used if not provided. In this case we will use "str, optional". Only in cases like func(value=None) and None is being used in the same way as 0 or foo would be used, then we will specify "str, int or None, default None".

Good:

class Series:
    def plot(self, kind, color='blue', **kwargs):
        ""
        Generate a plot.

        Render the data in the Series as a matplotlib plot of the
        specified kind.

        Parameters
        ----------
        kind : str
            Kind of matplotlib plot.
        color : str, default 'blue'
            Color name or rgb code.
        **kwargs
            These parameters will be passed to the matplotlib plotting
            function.
        ""
        pass

Bad:

class Series:
    def plot(self, kind, **kwargs):
        ""
        Generate a plot.

        Render the data in the Series as a matplotlib plot of the
        specified kind.
Note the blank line between the parameters title and the first parameter. Also, note that after the name of the parameter `'kind'` and before the colon, a space is missing.

Also, note that the parameter descriptions do not start with a capital letter, and do not finish with a dot.

Finally, the `**kwargs` parameter is missing.

Parameters
-----------

kind: str
    kind of matplotlib plot

""

Parameter types

When specifying the parameter types, Python built-in data types can be used directly (the Python type is preferred to the more verbose string, integer, boolean, etc):

- int
- float
- str
- bool

For complex types, define the subtypes. For dict and tuple, as more than one type is present, we use the brackets to help read the type (curly brackets for dict and normal brackets for tuple):

- list of int
- dict of {str : int}
- tuple of (str, int, int)
- tuple of (str,)
- set of str

In case where there are just a set of values allowed, list them in curly brackets and separated by commas (followed by a space). If the values are ordinal and they have an order, list them in this order. Otherwise, list the default value first, if there is one:

- {0, 10, 25}
- {'simple', 'advanced'}
- {'low', 'medium', 'high'}
- {'cat', 'dog', 'bird'}

If the type is defined in a Python module, the module must be specified:

- datetime.date
- datetime.datetime
- decimal.Decimal

4.3. Contributing to the documentation
If the type is in a package, the module must be also specified:

- `numpy.ndarray`
- `scipy.sparse.coo_matrix`

If the type is a pandas type, also specify pandas except for `Series` and `DataFrame`:

- `Series`
- `DataFrame`
- `pandas.Index`
- `pandas.Categorical`
- `pandas.arrays.SparseArray`

If the exact type is not relevant, but must be compatible with a NumPy array, `array-like` can be specified. If any type that can be iterated is accepted, `iterable` can be used:

- `array-like`
- `iterable`

If more than one type is accepted, separate them by commas, except the last two types, that need to be separated by the word ‘or’:

- `int` or `float`
- `float`, `decimal.Decimal` or `None`
- `str` or list of `str`

If `None` is one of the accepted values, it always needs to be the last in the list.

For `axis`, the convention is to use something like:

- `axis : {0 or ‘index’, 1 or ‘columns’, None}, default None`

### Section 4: returns or yields

If the method returns a value, it will be documented in this section. Also if the method yields its output.

The title of the section will be defined in the same way as the “Parameters”. With the names “Returns” or “Yields” followed by a line with as many hyphens as the letters in the preceding word.

The documentation of the return is also similar to the parameters. But in this case, no name will be provided, unless the method returns or yields more than one value (a tuple of values).

The types for “Returns” and “Yields” are the same as the ones for the “Parameters”. Also, the description must finish with a dot.

For example, with a single value:

```python
def sample():
    
    """
    Generate and return a random number.
    
    The value is sampled from a continuous uniform distribution between 0 and 1.
    """

    Returns
    ------
```

(continues on next page)
With more than one value:

```python
import string

def random_letters():
    """
    Generate and return a sequence of random letters.
    The length of the returned string is also random, and is also returned.
    """
    length = np.random.randint(1, 10)
    letters = ''.join(np.random.choice(string.ascii_lowercase) for i in range(length))
    return length, letters
```

If the method yields its value:

```python
def sample_values():
    """
    Generate an infinite sequence of random numbers.
    The values are sampled from a continuous uniform distribution between 0 and 1.
    """
    while True:
        yield np.random.random()
```

### Section 5: see also

This section is used to let users know about pandas functionality related to the one being documented. In rare cases, if no related methods or functions can be found at all, this section can be skipped.

An obvious example would be the `head()` and `tail()` methods. As `tail()` does the equivalent as `head()` but at the end of the `Series` or `DataFrame` instead of at the beginning, it is good to let the users know about it.

To give an intuition on what can be considered related, here there are some examples:
- `loc` and `iloc`, as they do the same, but in one case providing indices and in the other positions
- `max` and `min`, as they do the opposite
- `iterrows`, `itertuples` and `items`, as it is easy that a user looking for the method to iterate over columns ends up in the method to iterate over rows, and vice-versa
- `fillna` and `dropna`, as both methods are used to handle missing values
- `read_csv` and `to_csv`, as they are complementary
- `merge` and `join`, as one is a generalization of the other
- `astype` and `pandas.to_datetime`, as users may be reading the documentation of `astype` to know how to cast as a date, and the way to do it is with `pandas.to_datetime`
- `where` is related to `numpy.where`, as its functionality is based on it

When deciding what is related, you should mainly use your common sense and think about what can be useful for the users reading the documentation, especially the less experienced ones.

When relating to other libraries (mainly `numpy`), use the name of the module first (not an alias like `np`). If the function is in a module which is not the main one, like `scipy.sparse`, list the full module (e.g. `scipy.sparse.coo_matrix`).

This section has a header, “See Also” (note the capital S and A), followed by the line with hyphens and preceded by a blank line.

After the header, we will add a line for each related method or function, followed by a space, a colon, another space, and a short description that illustrates what this method or function does, why is it relevant in this context, and what the key differences are between the documented function and the one being referenced. The description must also end with a dot.

Note that in “Returns” and “Yields”, the description is located on the line after the type. In this section, however, it is located on the same line, with a colon in between. If the description does not fit on the same line, it can continue onto other lines which must be further indented.

For example:

```python
class Series:
    def head(self):
        """
        Return the first 5 elements of the Series.
        
        This function is mainly useful to preview the values of the Series without displaying the whole of it.
        """
        Returns
        ------
        Series
        Subset of the original series with the 5 first values.

        See Also
        -------
        Series.tail : Return the last 5 elements of the Series.
        Series.iloc : Return a slice of the elements in the Series, which can also be used to return the first or last n.
        """
        return self.iloc[:5]
```
**Section 6: notes**

This is an optional section used for notes about the implementation of the algorithm, or to document technical aspects of the function behavior.

Feel free to skip it, unless you are familiar with the implementation of the algorithm, or you discover some counter-intuitive behavior while writing the examples for the function.

This section follows the same format as the extended summary section.

**Section 7: examples**

This is one of the most important sections of a docstring, despite being placed in the last position, as often people understand concepts better by example than through accurate explanations.

Examples in docstrings, besides illustrating the usage of the function or method, must be valid Python code, that returns the given output in a deterministic way, and that can be copied and run by users.

Examples are presented as a session in the Python terminal. `>>>` is used to present code. `...` is used for code continuing from the previous line. Output is presented immediately after the last line of code generating the output (no blank lines in between). Comments describing the examples can be added with blank lines before and after them.

The way to present examples is as follows:

1. Import required libraries (except numpy and pandas)
2. Create the data required for the example
3. Show a very basic example that gives an idea of the most common use case
4. Add examples with explanations that illustrate how the parameters can be used for extended functionality

A simple example could be:

```python
class Series:
    def head(self, n=5):
        ""
        Return the first elements of the Series.

        This function is mainly useful to preview the values of the Series without displaying all of it.

        Parameters
        ----------
        n : int
            Number of values to return.

        Return
        ------
        pandas.Series
            Subset of the original series with the n first values.

        See Also
        --------
        tail : Return the last n elements of the Series.

        Examples
```

(continues on next page)
The examples should be as concise as possible. In cases where the complexity of the function requires long examples, it is recommended to use blocks with headers in bold. Use double star ** to make a text bold, like in **this example**.

**Conventions for the examples**

Code in examples is assumed to always start with these two lines which are not shown:

```python
import numpy as np
import pandas as pd
```

Any other module used in the examples must be explicitly imported, one per line (as recommended in PEP 8 imports) and avoiding aliases. Avoid excessive imports, but if needed, imports from the standard library go first, followed by third-party libraries (like matplotlib).

When illustrating examples with a single Series use the name `s`, and if illustrating with a single DataFrame use the name `df`. For indices, `idx` is the preferred name. If a set of homogeneous `Series` or DataFrame is used, name them `s1, s2, s3...` or `df1, df2, df3`. If the data is not homogeneous, and more than one structure is needed, name them with something meaningful, for example `df_main` and `df_to_join`.

Data used in the example should be as compact as possible. The number of rows is recommended to be around 4, but make it a number that makes sense for the specific example. For example in the `head` method, it requires to be higher than 5, to show the example with the default values. If doing the `mean`, we could use something like `[1, 2, 3]`, so it is easy to see that the value returned is the mean.

For more complex examples (grouping for example), avoid using data without interpretation, like a matrix of random numbers with columns `A, B, C, D...` And instead use a meaningful example, which makes it easier to understand the concept. Unless required by the example, use names of animals, to keep examples consistent. And numerical properties of them.

When calling the method, keywords arguments `head(n=3)` are preferred to positional arguments `head(3).

Good:
class Series:

    def mean(self):
        """
        Compute the mean of the input.

        Examples
        --------
        >>> s = pd.Series([1, 2, 3])
        >>> s.mean()
        2
        """
        pass

    def fillna(self, value):
        """
        Replace missing values by `value`.

        Examples
        --------
        >>> s = pd.Series([1, np.nan, 3])
        >>> s.fillna(0)
        [1, 0, 3]
        """
        pass

    def groupby_mean(self):
        """
        Group by index and return mean.

        Examples
        --------
        >>> s = pd.Series([380., 370., 24., 26],
        ... name='max_speed',
        ... index=['falcon', 'falcon', 'parrot', 'parrot'])
        >>> s.groupby_mean()
        index
        falcon    375.0
        parrot    25.0
        Name: max_speed, dtype: float64
        """
        pass

    def contains(self, pattern, case_sensitive=True, na=numpy.nan):
        """
        Return whether each value contains `pattern`.

        In this case, we are illustrating how to use sections, even if the example is simple enough and does not require them.

        Examples
        --------
        >>> s = pd.Series(['Antelope', 'Lion', 'Zebra', np.nan])
        >>> s.contains(pattern='a')
        0    False
        1    False
        """

(continues on next page)
**Case sensitivity**

With `'case_sensitive'` set to `'False'` we can match `'a'` with both `'a'` and `'A'`:

```python
>>> s.contains(pattern='a', case_sensitive=False)
0    True
1    False
2    True
3    NaN
dtype: bool
```

**Missing values**

We can fill missing values in the output using the `'na'` parameter:

```python
>>> s.contains(pattern='a', na=False)
0    False
1    False
2    True
3    False
dtype: bool
```

```python
""
pass
```

Bad:

```python
def method(foo=None, bar=None):
    ""
    A sample DataFrame method.
    Do not import NumPy and pandas.
    Try to use meaningful data, when it makes the example easier to understand.
    Try to avoid positional arguments like in `df.method(1)` . They can be all right if previously defined with a meaningful name, like in `present_value(interest_rate)` , but avoid them otherwise.
    When presenting the behavior with different parameters, do not place all the calls one next to the other. Instead, add a short sentence explaining what the example shows.
    Examples
    ""
    >>> import numpy as np
    >>> import pandas as pd
    >>> df = pd.DataFrame(np.random.randn(3, 3), columns=('a', 'b', 'c'))
    >>> df.method(1)
    21
    >>> df.method(bar=14)
```

(continues on next page)
Tips for getting your examples pass the doctests

Getting the examples pass the doctests in the validation script can sometimes be tricky. Here are some attention points:

– Import all needed libraries (except for pandas and NumPy, those are already imported as `import pandas as pd` and `import numpy as np`) and define all variables you use in the example.

– Try to avoid using random data. However random data might be OK in some cases, like if the function you are documenting deals with probability distributions, or if the amount of data needed to make the function result meaningful is too much, such that creating it manually is very cumbersome. In those cases, always use a fixed random seed to make the generated examples predictable. Example:

```python
>>> np.random.seed(42)
>>> df = pd.DataFrame({'normal': np.random.normal(100, 5, 20)})
```

– If you have a code snippet that wraps multiple lines, you need to use `...` on the continued lines:

```python
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], index=['a', 'b', 'c'],
...                     columns=['A', 'B'])
```

– If you want to show a case where an exception is raised, you can do:

```python
>>> pd.to_datetime(['712-01-01'])
Traceback (most recent call last):
  OutOfBoundsDatetime: Out of bounds nanosecond timestamp: 712-01-01 00:00:00
```

It is essential to include the “Traceback (most recent call last):”, but for the actual error only the error name is sufficient.

– If there is a small part of the result that can vary (e.g. a hash in an object representation), you can use `...` to represent this part.

If you want to show that `s.plot()` returns a matplotlib AxesSubplot object, this will fail the doctest

```python
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at 0x7efd0c0b0690>
```

However, you can do (notice the comment that needs to be added)

```python
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at ...>
Plots in examples

There are some methods in pandas returning plots. To render the plots generated by the examples in the documentation, the .. plot:: directive exists.

To use it, place the next code after the “Examples” header as shown below. The plot will be generated automatically when building the documentation.

```python
class Series:
    def plot(self):
        """
        Generate a plot with the `Series` data.
        
        Examples
        --------
        .. plot::
            :context: close-figs
            >>> s = pd.Series([1, 2, 3])
            >>> s.plot()
        """
        pass
```

Sharing docstrings

pandas has a system for sharing docstrings, with slight variations, between classes. This helps us keep docstrings consistent, while keeping things clear for the user reading. It comes at the cost of some complexity when writing.

Each shared docstring will have a base template with variables, like {klass}. The variables filled in later on using the doc decorator. Finally, docstrings can also be appended to with the doc decorator.

In this example, we’ll create a parent docstring normally (this is like pandas.core.generic.NDFrame). Then we’ll have two children (like pandas.core.series.Series and pandas.core.frame.DataFrame). We’ll substitute the class names in this docstring.

```python
class Parent:
    @doc(klass="Parent")
    def my_function(self):
        """Apply my function to {klass}.""
        ...

class ChildA(Parent):
    @doc(Parent.my_function, klass="ChildA")
    def my_function(self):
        ...

class ChildB(Parent):
    @doc(Parent.my_function, klass="ChildB")
    def my_function(self):
        ...
```

The resulting docstrings are
Notice:

1. We “append” the parent docstring to the children docstrings, which are initially empty.

Our files will often contain a module-level _shared_doc_kwargs with some common substitution values (things like klass, axes, etc).

You can substitute and append in one shot with something like

```python
@doc(template, **_shared_doc_kwargs)
def my_function(self):
    ...
```

where template may come from a module-level _shared_docs dictionary mapping function names to docstrings. Wherever possible, we prefer using doc, since the docstring-writing processes is slightly closer to normal.

See pandas.core.generic.NDFrame.fillna for an example template, and pandas.core.series.Series.fillna and pandas.core.generic.frame.fillna for the filled versions.

- The tutorials make heavy use of the IPython directive sphinx extension. This directive lets you put code in the documentation which will be run during the doc build. For example:

```ipython:: python
    x = 2
    x**3
```

will be rendered as:

```
In [1]: x = 2
In [2]: x**3
Out[2]: 8
```

Almost all code examples in the docs are run (and the output saved) during the doc build. This approach means that code examples will always be up to date, but it does make the doc building a bit more complex.

- Our API documentation files in doc/source/reference house the auto-generated documentation from the docstrings. For classes, there are a few subtleties around controlling which methods and attributes have pages auto-generated.

We have two autosummary templates for classes.

1. _templates/autosummary/class.rst. Use this when you want to automatically generate a page for every public method and attribute on the class. The Attributes and Methods sections will be automatically added to the class’ rendered documentation by numpydoc. See DataFrame for an example.

2. _templates/autosummary/class_without_autosummary. Use this when you want to pick a subset of methods / attributes to auto-generate pages for. When using this template, you should include an Attributes and Methods section in the class docstring. See CategoricalIndex for an example.
Every method should be included in a toctree in one of the documentation files in doc/source/reference, else Sphinx will emit a warning.

**Note:** The .rst files are used to automatically generate Markdown and HTML versions of the docs. For this reason, please do not edit CONTRIBUTING.md directly, but instead make any changes to doc/source/development/contributing.rst. Then, to generate CONTRIBUTING.md, use pandoc with the following command:

```
pandoc doc/source/development/contributing.rst -t markdown_github > CONTRIBUTING.md
```

The utility script scripts/validate_docstrings.py can be used to get a csv summary of the API documentation. And also validate common errors in the docstring of a specific class, function or method. The summary also compares the list of methods documented in the files in doc/source/reference (which is used to generate the API Reference page) and the actual public methods. This will identify methods documented in doc/source/reference that are not actually class methods, and existing methods that are not documented in doc/source/reference.

### 4.3.2 Updating a pandas docstring

When improving a single function or method’s docstring, it is not necessarily needed to build the full documentation (see next section). However, there is a script that checks a docstring (for example for the `DataFrame.mean` method):

```
python scripts/validate_docstrings.py pandas.DataFrame.mean
```

This script will indicate some formatting errors if present, and will also run and test the examples included in the docstring. Check the [pandas docstring guide](https://pandas.pydata.org/pandas-docs/stable/guides/textformatting.html) for a detailed guide on how to format the docstring.

The examples in the docstring (‘doctests’) must be valid Python code, that in a deterministic way returns the presented output, and that can be copied and run by users. This can be checked with the script above, and is also tested on Travis. A failing doctest will be a blocker for merging a PR. Check the examples section in the docstring guide for some tips and tricks to get the doctests passing.

When doing a PR with a docstring update, it is good to post the output of the validation script in a comment on github.

### 4.3.3 How to build the pandas documentation

**Requirements**

First, you need to have a development environment to be able to build pandas (see the docs on *creating a development environment*).

**Building the documentation**

So how do you build the docs? Navigate to your local `doc/` directory in the console and run:

```
python make.py html
```

Then you can find the HTML output in the folder `doc/build/html/`.

The first time you build the docs, it will take quite a while because it has to run all the code examples and build all the generated docstring pages. In subsequent evocations, sphinx will try to only build the pages that have been modified.

If you want to do a full clean build, do:
You can tell `make.py` to compile only a single section of the docs, greatly reducing the turn-around time for checking your changes.

```
# omit autosummary and API section
python make.py clean
python make.py --no-api

# compile the docs with only a single section, relative to the "source" folder.
# For example, compiling only this guide (doc/source/development/contributing.rst)
python make.py clean
python make.py --single development/contributing.rst

# compile the reference docs for a single function
python make.py clean
python make.py --single pandas.DataFrame.join

# compile whatsnw and API section (to resolve links in the whatsnw)
python make.py clean
python make.py --whatsnew
```

For comparison, a full documentation build may take 15 minutes, but a single section may take 15 seconds. Subsequent builds, which only process portions you have changed, will be faster.

The build will automatically use the number of cores available on your machine to speed up the documentation build. You can override this:

```
python make.py html --num-jobs 4
```

Open the following file in a web browser to see the full documentation you just built:

```
doc/build/html/index.html
```

And you’ll have the satisfaction of seeing your new and improved documentation!

---

### Building master branch documentation

When pull requests are merged into the pandas master branch, the main parts of the documentation are also built by Travis-CI. These docs are then hosted [here](#), see also the [Continuous Integration](#) section.

---

#### 4.3.4 Previewing changes

Once, the pull request is submitted, GitHub Actions will automatically build the documentation. To view the built site:

1. Wait for the CI / Web and docs check to complete.
2. Click Details next to it.
3. From the Artifacts drop-down, click docs or website to download the site as a ZIP file.
4.4 Contributing to the code base

Table of Contents:

• Code standards
• Pre-commit
• Optional dependencies
  – C (cpplint)
  – Python (PEP8 / black)
  – Import formatting
  – Backwards compatibility
• Type hints
  – Style guidelines
  – pandas-specific types
  – Validating type hints
• Testing with continuous integration
• Test-driven development/code writing
  – Writing tests
  – Transitioning to pytest
  – Using pytest
  – Using hypothesis
  – Testing warnings
• Running the test suite
• Running the performance test suite
• Documenting your code

4.4.1 Code standards

Writing good code is not just about what you write. It is also about how you write it. During Continuous Integration testing, several tools will be run to check your code for stylistic errors. Generating any warnings will cause the test to fail. Thus, good style is a requirement for submitting code to pandas.

There is a tool in pandas to help contributors verify their changes before contributing them to the project:

./ci/code_checks.sh

The script verifies the linting of code files, it looks for common mistake patterns (like missing spaces around sphinx directives that make the documentation not being rendered properly) and it also validates the doctests. It is possible to run the checks independently by using the parameters lint, patterns and doctests (e.g. ./ci/code_checks.sh lint).

In addition, because a lot of people use our library, it is important that we do not make sudden changes to the code
that could have the potential to break a lot of user code as a result, that is, we need it to be as backwards compatible as possible to avoid mass breakages.

In addition to ./ci/code_checks.sh, some extra checks are run by pre-commit - see here for how to run them.

Additional standards are outlined on the pandas code style guide.

### 4.4.2 Pre-commit

You can run many of these styling checks manually as we have described above. However, we encourage you to use pre-commit hooks instead to automatically run black, flake8, isort when you make a git commit. This can be done by installing pre-commit:

```
pip install pre-commit
```

and then running:

```
pre-commit install
```

from the root of the pandas repository. Now all of the styling checks will be run each time you commit changes without your needing to run each one manually. In addition, using pre-commit will also allow you to more easily remain up-to-date with our code checks as they change.

Note that if needed, you can skip these checks with `git commit --no-verify`.

If you don’t want to use pre-commit as part of your workflow, you can still use it to run its checks with:

```
pre-commit run --files <files you have modified>
```

without needing to have done pre-commit install beforehand.

If you want to run checks on all recently committed files on upstream/master you can use:

```
pre-commit run --from-ref=upstream/master --to-ref=HEAD --all-files
```

without needing to have done pre-commit install beforehand.

---

**Note:** If you have conflicting installations of virtualenv, then you may get an error - see here.

Also, due to a bug in virtualenv, you may run into issues if you’re using conda. To solve this, you can downgrade virtualenv to version 20.0.33.

---

### 4.4.3 Optional dependencies

Optional dependencies (e.g. matplotlib) should be imported with the private helper pandas.compat._optional.import_optional_dependency. This ensures a consistent error message when the dependency is not met.

All methods using an optional dependency should include a test asserting that an ImportError is raised when the optional dependency is not found. This test should be skipped if the library is present.

All optional dependencies should be documented in Optional dependencies and the minimum required version should be set in the pandas.compat._optional.VERSIONS dict.

---

4.4. Contributing to the code base
C (cpplint)

pandas uses the Google standard. Google provides an open source style checker called cpplint, but we use a fork of it that can be found here. Here are some of the more common cpplint issues:

- we restrict line-length to 80 characters to promote readability
- every header file must include a header guard to avoid name collisions if re-included

Continuous Integration will run the cpplint tool and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```
cpplint --extensions=c,h --headers=h --filter=-readability/casting,-runtime/int,-build/include_subdir modified-c-file
```

You can also run this command on an entire directory if necessary:

```
cpplint --extensions=c,h --headers=h --filter=-readability/casting,-runtime/int,-build/include_subdir --recursive modified-c-directory
```

To make your commits compliant with this standard, you can install the ClangFormat tool, which can be downloaded here. To configure, in your home directory, run the following command:

```
clang-format style=google -dump-config > .clang-format
```

Then modify the file to ensure that any indentation width parameters are at least four. Once configured, you can run the tool as follows:

```
clang-format modified-c-file
```

This will output what your file will look like if the changes are made, and to apply them, run the following command:

```
clang-format -i modified-c-file
```

To run the tool on an entire directory, you can run the following analogous commands:

```
clang-format modified-c-directory/*.c modified-c-directory/*.h
clang-format -i modified-c-directory/*.c modified-c-directory/*.h
```

Do note that this tool is best-effort, meaning that it will try to correct as many errors as possible, but it may not correct all of them. Thus, it is recommended that you run cpplint to double check and make any other style fixes manually.

Python (PEP8 / black)

pandas follows the PEP8 standard and uses Black and Flake8 to ensure a consistent code format throughout the project. We encourage you to use pre-commit.

Continuous Integration will run those tools and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```
black pandas
git diff upstream/master -u -- "*.py" | flake8 --diff
```

to auto-format your code. Additionally, many editors have plugins that will apply black as you edit files.

You should use a black version 21.5b2 as previous versions are not compatible with the pandas codebase.

One caveat about git diff upstream/master -u -- "*.py" | flake8 --diff: this command will catch any stylistic errors in your changes specifically, but be beware it may not catch all of them. For example, if
you delete the only usage of an imported function, it is stylistically incorrect to import an unused function. However, style-checking the diff will not catch this because the actual import is not part of the diff. Thus, for completeness, you should run this command, though it may take longer:

```bash
git diff upstream/master --name-only -- "*.py" | xargs -r flake8
```

Note that on OSX, the `-r` flag is not available, so you have to omit it and run this slightly modified command:

```bash
git diff upstream/master --name-only -- "*.py" | xargs flake8
```

Windows does not support the `xargs` command (unless installed for example via the MinGW toolchain), but one can imitate the behaviour as follows:

```bash
for /f %i in ('git diff upstream/master --name-only -- "*.py"') do flake8 %i
```

This will get all the files being changed by the PR (and ending with `.py`), and run `flake8` on them, one after the other.

Note that these commands can be run analogously with `black`.

### Import formatting

pandas uses `isort` to standardise import formatting across the codebase.

A guide to import layout as per pep8 can be found [here](#).

A summary of our current import sections (in order):

- Future
- Python Standard Library
- Third Party
  - `pandas._libs, pandas.compat, pandas.util._*, pandas.errors` (largely not dependent on `pandas.core`)
  - `pandas.core.dtypes` (largely not dependent on the rest of `pandas.core`)
  - Rest of `pandas.core.*`
- Non-core `pandas.io, pandas.plotting, pandas.tseries`
- Local application/library specific imports

Imports are alphabetically sorted within these sections.

As part of Continuous Integration checks we run:

```bash
isort --check-only pandas
```

to check that imports are correctly formatted as per the `setup.cfg`.

If you see output like the below in Continuous Integration checks:

```bash
Check import format using isort
ERROR: /home/travis/build/pandas-dev/pandas/pandas/io/pytables.py Imports are incorrectly sorted
Check import format using isort DONE
The command "ci/code_checks.sh" exited with 1
```

You should run:

### 4.4. Contributing to the code base
to automatically format imports correctly. This will modify your local copy of the files. Alternatively, you can run a command similar to what was suggested for black and flake8 right above:

```
git diff upstream/master --name-only -- "*.py" | xargs -r isort
```

Where similar caveats apply if you are on OSX or Windows.
You can then verify the changes look ok, then git commit and push.

**Backwards compatibility**

Please try to maintain backward compatibility. pandas has lots of users with lots of existing code, so don’t break it if at all possible. If you think breakage is required, clearly state why as part of the pull request. Also, be careful when changing method signatures and add deprecation warnings where needed. Also, add the deprecated sphinx directive to the deprecated functions or methods.

If a function with the same arguments as the one being deprecated exist, you can use the pandas.util._decorators.deprecate:

```
from pandas.util._decorators import deprecate
deprecate('old_func', 'new_func', '1.1.0')
```

Otherwise, you need to do it manually:

```
import warnings

def old_func():
    """Summary of the function.""
    .. deprecated:: 1.1.0
        Use new_func instead.
    """
    warnings.warn('Use new_func instead.', FutureWarning, stacklevel=2)
    new_func()

def new_func():
    pass
```

You’ll also need to

1. Write a new test that asserts a warning is issued when calling with the deprecated argument
2. Update all of pandas existing tests and code to use the new argument

See Testing warnings for more.
4.4.4 Type hints

pandas strongly encourages the use of PEP 484 style type hints. New development should contain type hints and pull requests to annotate existing code are accepted as well!

Style guidelines

Types imports should follow the from typing import ... convention. So rather than

```python
import typing
primes: typing.List[int] = []
```

You should write

```python
from typing import List, Optional, Union
primes: List[int] = []
```

Optional should be used where applicable, so instead of

```python
maybe_primes: List[Union[int, None]] = []
```

You should write

```python
maybe_primes: List[Optional[int]] = []
```

In some cases in the code base classes may define class variables that shadow builtins. This causes an issue as described in Mypy 1775. The defensive solution here is to create an unambiguous alias of the builtin and use that without your annotation. For example, if you come across a definition like

```python
class SomeClass1:
    str = None
```

The appropriate way to annotate this would be as follows

```python
str_type = str
class SomeClass2:
    str: str_type = None
```

In some cases you may be tempted to use cast from the typing module when you know better than the analyzer. This occurs particularly when using custom inference functions. For example

```python
from typing import cast
from pandas.core.dtypes.common import is_number
def cannot_infer_bad(obj: Union[str, int, float]):
    if is_number(obj):
        ...
    else:  # Reasonably only str objects would reach this but...
        obj = cast(str, obj)  # Mypy complains without this!
        return obj.upper()
```
The limitation here is that while a human can reasonably understand that `is_number` would catch the `int` and `float` types mypy cannot make that same inference just yet (see mypy #5206. While the above works, the use of `cast` is strongly discouraged. Where applicable a refactor of the code to appease static analysis is preferable.

```python
def cannot_infer_good(obj: Union[str, int, float]):
    if isinstance(obj, str):
        return obj.upper()
    else:
        ...
```

With custom types and inference this is not always possible so exceptions are made, but every effort should be exhausted to avoid `cast` before going down such paths.

**pandas-specific types**

Commonly used types specific to pandas will appear in `pandas._typing` and you should use these where applicable. This module is private for now but ultimately this should be exposed to third party libraries who want to implement type checking against pandas.

For example, quite a few functions in pandas accept a `dtype` argument. This can be expressed as a string like "object", a `numpy.dtype` like `np.int64` or even a `pandas.ExtensionDtype` like `pd.CategoricalDtype`. Rather than burden the user with having to constantly annotate all of those options, this can simply be imported and reused from the `pandas._typing` module.

```python
from pandas._typing import Dtype

def as_type(dtype: Dtype) -> ...:
    ...
```

This module will ultimately house types for repeatedly used concepts like “path-like”, “array-like”, “numeric”, etc… and can also hold aliases for commonly appearing parameters like `axis`. Development of this module is active so be sure to refer to the source for the most up to date list of available types.

**Validating type hints**

pandas uses `mypy` to statically analyze the code base and type hints. After making any change you can ensure your type hints are correct by running

```
mypy pandas
```

### 4.4.5 Testing with continuous integration

The pandas test suite will run automatically on GitHub Actions and Azure Pipelines continuous integration services, once your pull request is submitted. However, if you wish to run the test suite on a branch prior to submitting the pull request, then the continuous integration services need to be hooked to your GitHub repository. Instructions are here for GitHub Actions and Azure Pipelines.

A pull-request will be considered for merging when you have an all ‘green’ build. If any tests are failing, then you will get a red ‘X’, where you can click through to see the individual failed tests. This is an example of a green build.
4.4.6 Test-driven development/code writing

pandas is serious about testing and strongly encourages contributors to embrace test-driven development (TDD). This
development process “relies on the repetition of a very short development cycle: first the developer writes an (initially
failing) automated test case that defines a desired improvement or new function, then produces the minimum amount
of code to pass that test.” So, before actually writing any code, you should write your tests. Often the test can be taken
from the original GitHub issue. However, it is always worth considering additional use cases and writing corresponding
tests.

Adding tests is one of the most common requests after code is pushed to pandas. Therefore, it is worth getting in the
habit of writing tests ahead of time so this is never an issue.

Like many packages, pandas uses pytest and the convenient extensions in numpy.testing.

Note: The earliest supported pytest version is 5.0.1.

Writing tests

All tests should go into the tests subdirectory of the specific package. This folder contains many current examples of
tests, and we suggest looking to these for inspiration. If your test requires working with files or network connectivity,
there is more information on the testing page of the wiki.

The pandas._testing module has many special assert functions that make it easier to make statements about
whether Series or DataFrame objects are equivalent. The easiest way to verify that your code is correct is to explicitly
construct the result you expect, then compare the actual result to the expected correct result:

```python
def test_pivot(self):
    data = {
        'index': ['A', 'B', 'C', 'C', 'B', 'A'],
        'columns': ['One', 'One', 'One', 'Two', 'Two', 'Two'],
        'values': [1., 2., 3., 3., 2., 1.]
    }

    frame = DataFrame(data)
    pivoted = frame.pivot(index='index', columns='columns', values='values')
```

(continues on next page)
expected = DataFrame({'One': {'A': 1., 'B': 2., 'C': 3.},
                      'Two': {'A': 1., 'B': 2., 'C': 3.}})
assert_frame_equal(pivoted, expected)

Please remember to add the Github Issue Number as a comment to a new test. E.g. “# brief comment, see GH#28907”

**Transitioning to pytest**

pandas existing test structure is *mostly* class-based, meaning that you will typically find tests wrapped in a class.

```python
class TestReallyCoolFeature:
  pass
```

Going forward, we are moving to a more *functional* style using the pytest framework, which offers a richer testing framework that will facilitate testing and developing. Thus, instead of writing test classes, we will write test functions like this:

```python
def test_really_cool_feature():
  pass
```

**Using pytest**

Here is an example of a self-contained set of tests that illustrate multiple features that we like to use.

- functional style: tests are like `test_*` and *only* take arguments that are either fixtures or parameters
- `pytest.mark` can be used to set metadata on test functions, e.g. `skip` or `xfail`.
- using `parametrize`: allow testing of multiple cases
- to set a mark on a parameter, `pytest.param(..., marks=...)` syntax should be used
- `fixture`, code for object construction, on a per-test basis
- using bare `assert` for scalars and truth-testing
- `tm.assert_series_equal` (and its counter part `tm.assert_frame_equal`), for pandas object comparisons.
- the typical pattern of constructing an *expected* and comparing versus the *result*

We would name this file `test_cool_feature.py` and put in an appropriate place in the `pandas/tests/` structure.

```python
import pytest
import numpy as np
import pandas as pd

@pytest.mark.parametrize('dtype', ['int8', 'int16', 'int32', 'int64'])
def test_dtypes(dtype):
  assert str(np.dtype(dtype)) == dtype
```

(continues on next page)
@pytest.mark.parametrize('dtype', ['float32', pytest.param('int16', marks=pytest.mark.skip), pytest.param('int32', marks=pytest.mark.xfail(reason='to show how it works'))])

def test_mark(dtype):
    assert str(np.dtype(dtype)) == 'float32'

@ pytest.fixture

def series():
    return pd.Series([1, 2, 3])

@ pytest.fixture(params=['int8', 'int16', 'int32', 'int64'])

def dtype(request):
    return request.param

def test_series(series, dtype):
    result = series.astype(dtype)
    assert result.dtype == dtype
    expected = pd.Series([1, 2, 3], dtype=dtype)
    tm.assert_series_equal(result, expected)

A test run of this yields

```
((pandas) bash-3.2$ pytest test_cool_feature.py -v
================================== test session starts ======================
platform darwin -- Python 3.6.2, pytest-3.6.0, py-1.4.31, pluggy-0.4.0
collected 11 items

tester.py::test_series[int16] PASSED
tester.py::test_series[int32] PASSED
tester.py::test_series[int64] PASSED

4.4. Contributing to the code base
```
Using hypothesis

Hypothesis is a library for property-based testing. Instead of explicitly parametrizing a test, you can describe all valid inputs and let Hypothesis try to find a failing input. Even better, no matter how many random examples it tries, Hypothesis always reports a single minimal counterexample to your assertions - often an example that you would never have thought to test.

See Getting Started with Hypothesis for more of an introduction, then refer to the Hypothesis documentation for details.

```python
import json
from hypothesis import given, strategies as st
goingiven(value=any_json_value)
def test_json_roundtrip(value):
    result = json.loads(json.dumps(value))
    assert value == result
```

This test shows off several useful features of Hypothesis, as well as demonstrating a good use-case: checking properties that should hold over a large or complicated domain of inputs.

To keep the pandas test suite running quickly, parametrized tests are preferred if the inputs or logic are simple, with Hypothesis tests reserved for cases with complex logic or where there are too many combinations of options or subtle interactions to test (or think of!) all of them.

Testing warnings

By default, one of pandas CI workers will fail if any unhandled warnings are emitted.

If your change involves checking that a warning is actually emitted, use `tm.assert_produces_warning(ExpectedWarning).

```python
import pandas._testing as tm
df = pd.DataFrame()
with tm.assert_produces_warning(FutureWarning):
    df.some_operation()
```

We prefer this to the `pytest.warns` context manager because ours checks that the warning’s stacklevel is set correctly. The stacklevel is what ensure the user’s file name and line number is printed in the warning, rather than something internal to pandas. It represents the number of function calls from user code (e.g. `df.some_operation()`) to the function that actually emits the warning. Our linter will fail the build if you use `pytest.warns` in a test.

If you have a test that would emit a warning, but you aren’t actually testing the warning itself (say because it’s going to be removed in the future, or because we’re matching a 3rd-party library’s behavior), then use `pytest.mark.filterwarnings` to ignore the error.

```python
@pytest.mark.filterwarnings("ignore:msg:category")
def test_thing(self):
    ...
```
If the test generates a warning of class category whose message starts with msg, the warning will be ignored and the test will pass.

If you need finer-grained control, you can use Python’s usual warnings module to control whether a warning is ignored / raised at different places within a single test.

```python
with warnings.catch_warnings():
    warnings.simplefilter("ignore", FutureWarning)
    # Or use warnings.filterwarnings(...)```

Alternatively, consider breaking up the unit test.

### 4.4.7 Running the test suite

The tests can then be run directly inside your Git clone (without having to install pandas) by typing:

```bash
pytest pandas
```

The tests suite is exhaustive and takes around 20 minutes to run. Often it is worth running only a subset of tests first around your changes before running the entire suite.

The easiest way to do this is with:

```bash
pytest pandas/path/to/test.py -k regex_matching_test_name
```

Or with one of the following constructs:

```bash
pytest pandas/tests/[test-module].py
pytest pandas/tests/[test-module].py::[TestClass]
pytest pandas/tests/[test-module].py::[TestClass]::[test_method]
```

Using pytest-xdist, one can speed up local testing on multicore machines. To use this feature, you will need to install pytest-xdist via:

```bash
pip install pytest-xdist
```

Two scripts are provided to assist with this. These scripts distribute testing across 4 threads.

On Unix variants, one can type:

```bash
test_fast.sh
```

On Windows, one can type:

```bash
test_fast.bat
```

This can significantly reduce the time it takes to locally run tests before submitting a pull request.

For more, see the pytest documentation.

Furthermore one can run

```python
pd.test()
```

with an imported pandas to run tests similarly.
4.4.8 Running the performance test suite

Performance matters and it is worth considering whether your code has introduced performance regressions. pandas is in the process of migrating to asv benchmarks to enable easy monitoring of the performance of critical pandas operations. These benchmarks are all found in the pandas/asv_bench directory, and the test results can be found here.

To use all features of asv, you will need either conda or virtualenv. For more details please check the asv installation webpage.

To install asv:

```
pip install git+https://github.com/spacetelescope/asv
```

If you need to run a benchmark, change your directory to asv_bench/ and run:

```
asv continuous -f 1.1 upstream/master HEAD
```

You can replace HEAD with the name of the branch you are working on, and report benchmarks that changed by more than 10%. The command uses conda by default for creating the benchmark environments. If you want to use virtualenv instead, write:

```
asv continuous -f 1.1 -E virtualenv upstream/master HEAD
```

The -E virtualenv option should be added to all asv commands that run benchmarks. The default value is defined in asv.conf.json.

Running the full benchmark suite can be an all-day process, depending on your hardware and its resource utilization. However, usually it is sufficient to paste only a subset of the results into the pull request to show that the committed changes do not cause unexpected performance regressions. You can run specific benchmarks using the -b flag, which takes a regular expression. For example, this will only run benchmarks from a pandas/asv_bench/benchmarks/groupby.py file:

```
asv continuous -f 1.1 upstream/master HEAD -b ^groupby
```

If you want to only run a specific group of benchmarks from a file, you can do it using . as a separator. For example:

```
asv continuous -f 1.1 upstream/master HEAD -b groupby.GroupByMethods
```

will only run the GroupByMethods benchmark defined in groupby.py.

You can also run the benchmark suite using the version of pandas already installed in your current Python environment. This can be useful if you do not have virtualenv or conda, or are using the setup.py develop approach discussed above; for the in-place build you need to set PYTHONPATH, e.g. PYTHONPATH=":PWD/.." asv [remaining arguments]. You can run benchmarks using an existing Python environment by:

```
asv run -e -E existing
```

or, to use a specific Python interpreter:

```
asv run -e -E existing:python3.6
```

This will display stderr from the benchmarks, and use your local python that comes from your $PATH. Information on how to write a benchmark and how to use asv can be found in the asv documentation.
4.4.9 Documenting your code

Changes should be reflected in the release notes located in `doc/source/whatsnew/vx.y.z.rst`. This file contains an ongoing change log for each release. Add an entry to this file to document your fix, enhancement or (unavoidable) breaking change. Make sure to include the GitHub issue number when adding your entry (using `issue:`1234` where 1234 is the issue/pull request number).

If your code is an enhancement, it is most likely necessary to add usage examples to the existing documentation. This can be done following the section regarding `documentation`. Further, to let users know when this feature was added, the `versionadded` directive is used. The sphinx syntax for that is:

```
.. versionadded:: 1.1.0
```

This will put the text *New in version 1.1.0* wherever you put the sphinx directive. This should also be put in the docstring when adding a new function or method (example) or a new keyword argument (example).

4.5 pandas code style guide

**Table of contents:**

- **Patterns**
- **Testing**
  - Failing tests
  - Do not use `pytest.xfail`
  - Using `pytest.mark.xfail`
- **Miscellaneous**
  - Reading from a url

pandas follows the PEP8 standard and uses Black and Flake8 to ensure a consistent code format throughout the project. We encourage you to use `pre-commit` to automatically run `black`, `flake`, `isort`, and related code checks when you make a git commit.

4.5.1 Patterns

We use a `flake8` plugin, pandas-dev-flaker, to check our codebase for unwanted patterns. See its README for the up-to-date list of rules we enforce.

4.5.2 Testing

**Failing tests**

See https://docs.pytest.org/en/latest/skipping.html for background.
**Do not use `pytest.xfail`**

Do not use this method. It has the same behavior as `pytest.skip`, namely it immediately stops the test and does not check if the test will fail. If this is the behavior you desire, use `pytest.skip` instead.

**Using `pytest.mark.xfail`**

Use this method if a test is known to fail but the manner in which it fails is not meant to be captured. It is common to use this method for a test that exhibits buggy behavior or a non-implemented feature. If the failing test has flaky behavior, use the argument `strict=False`. This will make it so pytest does not fail if the test happens to pass.

Prefer the decorator `@pytest.mark.xfail` and the argument `pytest.param` over usage within a test so that the test is appropriately marked during the collection phase of pytest. For xfailing a test that involves multiple parameters, a fixture, or a combination of these, it is only possible to xfail during the testing phase. To do so, use the `request` fixture:

```python
import pytest

def test_xfail(request):
    mark = pytest.mark.xfail(raises=TypeError, reason="Indicate why here")
    request.node.add_marker(mark)
```

xfail is not to be used for tests involving failure due to invalid user arguments. For these tests, we need to verify the correct exception type and error message is being raised, using `pytest.raises` instead.

### 4.5.3 Miscellaneous

**Reading from a url**

**Good:**

```python
from pandas.io.common import urlopen

with urlopen("http://www.google.com") as url:
    raw_text = url.read()
```

### 4.6 pandas maintenance

This guide is for pandas’ maintainers. It may also be interesting to contributors looking to understand the pandas development process and what steps are necessary to become a maintainer.

The main contributing guide is available at *Contributing to pandas*.  

---

2656 Chapter 4. Development
4.6.1 Roles

pandas uses two levels of permissions: triage and core team members.

Triage members can label and close issues and pull requests.

Core team members can label and close issues and pull request, and can merge pull requests.

GitHub publishes the full list of permissions.

4.6.2 Tasks

pandas is largely a volunteer project, so these tasks shouldn’t be read as “expectations” of triage and maintainers. Rather, they’re general descriptions of what it means to be a maintainer.

- Triage newly filed issues (see Issue triage)
- Review newly opened pull requests
- Respond to updates on existing issues and pull requests
- Drive discussion and decisions on stalled issues and pull requests
- Provide experience / wisdom on API design questions to ensure consistency and maintainability
- Project organization (run / attend developer meetings, represent pandas)

https://matthewrocklin.com/blog/2019/05/18/maintainer may be interesting background reading.

4.6.3 Issue triage

Here’s a typical workflow for triaging a newly opened issue.

1. **Thank the reporter for opening an issue**

   The issue tracker is many people’s first interaction with the pandas project itself, beyond just using the library. As such, we want it to be a welcoming, pleasant experience.

2. **Is the necessary information provided?**

   Ideally reporters would fill out the issue template, but many don’t. If crucial information (like the version of pandas they used), is missing feel free to ask for that and label the issue with “Needs info”. The report should follow the guidelines in *Bug reports and enhancement requests*. You may want to link to that if they didn’t follow the template.

   Make sure that the title accurately reflects the issue. Edit it yourself if it’s not clear.

3. **Is this a duplicate issue?**

   We have many open issues. If a new issue is clearly a duplicate, label the new issue as “Duplicate” assign the milestone “No Action”, and close the issue with a link to the original issue. Make sure to still thank the reporter, and encourage them to chime in on the original issue, and perhaps try to fix it.

   If the new issue provides relevant information, such as a better or slightly different example, add it to the original issue as a comment or an edit to the original post.

4. **Is the issue minimal and reproducible?**

   For bug reports, we ask that the reporter provide a minimal reproducible example. See https://matthewrocklin.com/blog/work/2018/02/28/minimal-bug-reports for a good explanation. If the example is not reproducible, or if it’s *clearly* not minimal, feel free to ask the reporter if they can provide and example or simplify the provided
one. Do acknowledge that writing minimal reproducible examples is hard work. If the reporter is struggling, you can try to write one yourself and we’ll edit the original post to include it.

If a reproducible example can’t be provided, add the “Needs info” label.

If a reproducible example is provided, but you see a simplification, edit the original post with your simpler reproducible example.

5. **Is this a clearly defined feature request?**

Generally, pandas prefers to discuss and design new features in issues, before a pull request is made. Encourage the submitter to include a proposed API for the new feature. Having them write a full docstring is a good way to pin down specifics.

We’ll need a discussion from several pandas maintainers before deciding whether the proposal is in scope for pandas.

6. **Is this a usage question?**

We prefer that usage questions are asked on StackOverflow with the pandas tag. [https://stackoverflow.com/questions/tagged/pandas](https://stackoverflow.com/questions/tagged/pandas)

If it’s easy to answer, feel free to link to the relevant documentation section, let them know that in the future this kind of question should be on StackOverflow, and close the issue.

7. **What labels and milestones should I add?**

Apply the relevant labels. This is a bit of an art, and comes with experience. Look at similar issues to get a feel for how things are labeled.

If the issue is clearly defined and the fix seems relatively straightforward, label the issue as “Good first issue”. Typically, new issues will be assigned the “Contributions welcome” milestone, unless it’s know that this issue should be addressed in a specific release (say because it’s a large regression).

### 4.6.4 Closing issues

Be delicate here: many people interpret closing an issue as us saying that the conversation is over. It’s typically best to give the reporter some time to respond or self-close their issue if it’s determined that the behavior is not a bug, or the feature is out of scope. Sometimes reporters just go away though, and we’ll close the issue after the conversation has died.

### 4.6.5 Reviewing pull requests

Anybody can review a pull request: regular contributors, triagers, or core-team members. But only core-team members can merge pull requests when they’re ready.

Here are some things to check when reviewing a pull request.

- Tests should be in a sensible location: in the same file as closely related tests.
- New public APIs should be included somewhere in `doc/source/reference/`.
- New / changed API should use the `versionadded` or `versionchanged` directives in the docstring.
- User-facing changes should have a `whatsnew` in the appropriate file.
- Regression tests should reference the original GitHub issue number like `# GH-1234`.
- The pull request should be labeled and assigned the appropriate milestone (the next patch release for regression fixes and small bug fixes, the next minor milestone otherwise)
• Changes should comply with our Version policy.

4.6.6 Backporting

In the case you want to apply changes to a stable branch from a newer branch then you can comment:

`@meeseeksdev backport version-branch`

This will trigger a workflow which will backport a given change to a branch (e.g. @meeseeksdev backport 1.2.x)

4.6.7 Cleaning up old issues

Every open issue in pandas has a cost. Open issues make finding duplicates harder, and can make it harder to know what needs to be done in pandas. That said, closing issues isn’t a goal on its own. Our goal is to make pandas the best it can be, and that’s best done by ensuring that the quality of our open issues is high.

Occasionally, bugs are fixed but the issue isn’t linked to in the Pull Request. In these cases, comment that “This has been fixed, but could use a test.” and label the issue as “Good First Issue” and “Needs Test”.

If an older issue doesn’t follow our issue template, edit the original post to include a minimal example, the actual output, and the expected output. Uniformity in issue reports is valuable.

If an older issue lacks a reproducible example, label it as “Needs Info” and ask them to provide one (or write one yourself if possible). If one isn’t provide reasonably soon, close it according to the policies in Closing issues.

4.6.8 Cleaning up old pull requests

Occasionally, contributors are unable to finish off a pull request. If some time has passed (two weeks, say) since the last review requesting changes, gently ask if they’re still interested in working on this. If another two weeks or so passes with no response, thank them for their work and close the pull request. Comment on the original issue that “There’s a stalled PR at #1234 that may be helpful.”, and perhaps label the issue as “Good first issue” if the PR was relatively close to being accepted.

Additionally, core-team members can push to contributors branches. This can be helpful for pushing an important PR across the line, or for fixing a small merge conflict.

4.6.9 Becoming a pandas maintainer

The full process is outlined in our governance documents. In summary, we’re happy to give triage permissions to anyone who shows interest by being helpful on the issue tracker.

The current list of core-team members is at https://github.com/pandas-dev/pandas-governance/blob/master/people.md
4.6.10 Merging pull requests

Only core team members can merge pull requests. We have a few guidelines.

1. You should typically not self-merge your own pull requests. Exceptions include things like small changes to fix CI (e.g. pinning a package version).

2. You should not merge pull requests that have an active discussion, or pull requests that has any -1 votes from a core maintainer. pandas operates by consensus.

3. For larger changes, it’s good to have a +1 from at least two core team members.

In addition to the items listed in Closing issues, you should verify that the pull request is assigned the correct milestone. Pull requests merged with a patch-release milestone will typically be backported by our bot. Verify that the bot noticed the merge (it will leave a comment within a minute typically). If a manual backport is needed please do that, and remove the “Needs backport” label once you’ve done it manually. If you forget to assign a milestone before tagging, you can request the bot to backport it with:

@Meeseeksdev backport <branch>

4.7 Internals

This section will provide a look into some of pandas internals. It’s primarily intended for developers of pandas itself.

4.7.1 Indexing

In pandas there are a few objects implemented which can serve as valid containers for the axis labels:

- **Index**: the generic “ordered set” object, an ndarray of object dtype assuming nothing about its contents. The labels must be hashable (and likely immutable) and unique. Populates a dict of label to location in Cython to do O(1) lookups.

- **Int64Index**: a version of Index highly optimized for 64-bit integer data, such as time stamps

- **Float64Index**: a version of Index highly optimized for 64-bit float data

- **MultiIndex**: the standard hierarchical index object

- **DatetimeIndex**: An Index object with Timestamp boxed elements (impl are the int64 values)

- **TimedeltaIndex**: An Index object with Timedelta boxed elements (impl are the int64 values)

- **PeriodIndex**: An Index object with Period elements

There are functions that make the creation of a regular index easy:

- **date_range**: fixed frequency date range generated from a time rule or DateOffset. An ndarray of Python datetime objects

- **period_range**: fixed frequency date range generated from a time rule or DateOffset. An ndarray of Period objects, representing timespans

The motivation for having an Index class in the first place was to enable different implementations of indexing. This means that it’s possible for you, the user, to implement a custom Index subclass that may be better suited to a particular application than the ones provided in pandas.

From an internal implementation point of view, the relevant methods that an Index must define are one or more of the following (depending on how incompatible the new object internals are with the Index functions):
- **get_loc**: returns an “indexer” (an integer, or in some cases a slice object) for a label
- **slice_locs**: returns the “range” to slice between two labels
- **get_indexer**: Computes the indexing vector for reindexing / data alignment purposes. See the source / docstrings for more on this
- **get_indexer_non_unique**: Computes the indexing vector for reindexing / data alignment purposes when the index is non-unique. See the source / docstrings for more on this
- **reindex**: Does any pre-conversion of the input index then calls **get_indexer**
- **union, intersection**: computes the union or intersection of two Index objects
- **insert**: Inserts a new label into an Index, yielding a new object
- **delete**: Delete a label, yielding a new object
- **drop**: Deletes a set of labels
- **take**: Analogous to ndarray.take

### MultiIndex

Internally, the MultiIndex consists of a few things: the **levels**, the integer **codes** (until version 0.24 named **labels**), and the level **names**:

```python
In [1]: index = pd.MultiIndex.from_product(  ...
...:    [range(3), ['one', 'two']], names=['first', 'second']
...:    )
...:
In [2]: index
Out[2]:
MultiIndex([(0, 'one'),
           (0, 'two'),
           (1, 'one'),
           (1, 'two'),
           (2, 'one'),
           (2, 'two')],
           names=['first', 'second'])
```

```python
In [3]: index.levels
Out[3]: FrozenList([[0, 1, 2], ['one', 'two']])
```

```python
In [4]: index.codes
Out[4]: FrozenList([[0, 0, 1, 1, 2, 2], [0, 1, 0, 1, 0, 1]])
```

```python
In [5]: index.names
Out[5]: FrozenList(['first', 'second'])
```

You can probably guess that the codes determine which unique element is identified with that location at each layer of the index. It’s important to note that sortedness is determined **solely** from the integer codes and does not check (or care) whether the levels themselves are sorted. Fortunately, the constructors **from_tuples** and **from_arrays** ensure that this is true, but if you compute the levels and codes yourself, please be careful.
Values

pandas extends NumPy’s type system with custom types, like `Categorical` or datetimes with a timezone, so we have multiple notions of “values”. For 1-D containers (Index classes and Series) we have the following convention:

- `cls._values` refers to the “best possible” array. This could be an `ndarray` or `ExtensionArray`.

So, for example, `Series[category]._values` is a `Categorical`.

### 4.7.2 Subclassing pandas data structures

This section has been moved to *Subclassing pandas data structures*.

### 4.8 Test organization

Ideally, there should be one, and only one, obvious place for a test to reside. Until we reach that ideal, these are some rules of thumb for where a test should be located.

1. Does your test depend only on code in `pd._libs.tslibs`? This test likely belongs in one of:
   - tests.tslibs
   
   **Note:** No file in `tests.tslibs` should import from any pandas modules outside of `pd._libs.tslibs`

   - tests.scalar
   - tests.tseries.offsets

2. Does your test depend only on code in `pd._libs`? This test likely belongs in one of:
   - tests.libs
   - tests.groupby.test_libgroupby

3. Is your test for an arithmetic or comparison method? This test likely belongs in one of:
   - tests.arithmetic
   
   **Note:** These are intended for tests that can be shared to test the behavior of DataFrame/Series/Index/ExtensionArray using the `box_with_array` fixture.

   - tests.frame.test_arithmetic
   - tests.series.test_arithmetic

4. Is your test for a reduction method (min, max, sum, prod, …)? This test likely belongs in one of:
   - tests.reductions
   
   **Note:** These are intended for tests that can be shared to test the behavior of DataFrame/Series/Index/ExtensionArray.

   - tests.frame.test_reductions
• tests.series.test_reductions
• tests.test_nanops

5. Is your test for an indexing method? This is the most difficult case for deciding where a test belongs, because there are many of these tests, and many of them test more than one method (e.g. both Series.__getitem__ and Series.loc.__getitem__)

A) Is the test specifically testing an Index method (e.g. Index.get_loc, Index.get_indexer)? This test likely belongs in one of:
  • tests.indexes.test_indexing
  • tests.indexes.fooindex.test_indexing

Within that files there should be a method-specific test class e.g. TestGetLoc.

In most cases, neither Series nor DataFrame objects should be needed in these tests.

B) Is the test for a Series or DataFrame indexing method other than __getitem__ or __setitem__, e.g. xs, where, take, mask, lookup, or insert? This test likely belongs in one of:
  • tests.frame.indexing.test_methodname
  • tests.series.indexing.test_methodname

C) Is the test for any of loc, iloc, at, or iat? This test likely belongs in one of:
  • tests.indexing.test_loc
  • tests.indexing.test_iloc
  • tests.indexing.test_at
  • tests.indexing.test_iat

Within the appropriate file, test classes correspond to either types of indexers (e.g. TestLocBooleanMask) or major use cases (e.g. TestLocSetitemWithExpansion).

See the note in section D) about tests that test multiple indexing methods.

D) Is the test for Series.__getitem__, Series.__setitem__, DataFrame.__getitem__, or DataFrame.__setitem__? This test likely belongs in one of:
  • tests.series.test_getitem
  • tests.series.test_setitem
  • tests.frame.test_getitem
  • tests.frame.test_setitem

If many cases such a test may test multiple similar methods, e.g.

```python
import pandas as pd
import pandas._testing as tm

def test_getitem_listlike_of_ints():
    ser = pd.Series(range(5))

    result = ser[[3, 4]]
    expected = pd.Series([2, 3])
    tm.assert_series_equal(result, expected)

    result = ser.loc[[3, 4]]
    tm.assert_series_equal(result, expected)
```
In cases like this, the test location should be based on the underlying method being tested. Or in the case of a test for a bugfix, the location of the actual bug. So in this example, we know that `Series.__getitem__` calls `Series.loc.__getitem__`, so this is really a test for `loc.__getitem__`. So this test belongs in `tests.indexing.test_loc`.

6. Is your test for a DataFrame or Series method?
   
   A) Is the method a plotting method? This test likely belongs in one of:
      
      • tests.plotting
   
   B) Is the method an IO method? This test likely belongs in one of:
      
      • tests.io
   
   C) Otherwise This test likely belongs in one of:
      
      • tests.series.methods.test_mymethod
      • tests.frame.methods.test_mymethod

   **Note:** If a test can be shared between DataFrame/Series using the `frame_or_series` fixture, by convention it goes in the `tests.frame` file.

7. Is your test for an Index method, not depending on Series/DataFrame? This test likely belongs in one of:
   
   • tests.indexes

8) Is your test for one of the pandas-provided ExtensionArrays (`Categorical`, `DatetimeArray`, `TimedeltaArray`, `PeriodArray`, `IntervalArray`, `PandasArray`, `FloatArray`, `BoolArray`, `StringArray`)? This test likely belongs in one of:
   
   • tests.arrays

9) Is your test for all ExtensionArray subclasses (the “EA Interface”)? This test likely belongs in one of:
   
   • tests.extension

### 4.9 Debugging C extensions

Pandas uses select C extensions for high performance IO operations. In case you need to debug segfaults or general issues with those extensions, the following steps may be helpful.

First, be sure to compile the extensions with the appropriate flags to generate debug symbols and remove optimizations. This can be achieved as follows:

```
python setup.py build_ext --inplace -j4 --with-debugging-symbols
```
4.9.1 Using a debugger

Assuming you are on a Unix-like operating system, you can use either lldb or gdb to debug. The choice between either is largely dependent on your compilation toolchain - typically you would use lldb if using clang and gdb if using gcc. For macOS users, please note that gcc is on modern systems an alias for clang, so if using Xcode you usually opt for lldb. Regardless of which debugger you choose, please refer to your operating systems instructions on how to install.

After installing a debugger you can create a script that hits the extension module you are looking to debug. For demonstration purposes, let’s assume you have a script called debug_testing.py with the following contents:

```python
import pandas as pd
pd.DataFrame([[1, 2]]).to_json()
```

Place the debug_testing.py script in the project root and launch a Python process under your debugger. If using lldb:

```
lldb python
```

If using gdb:

```
gdb python
```

Before executing our script, let’s set a breakpoint in our JSON serializer in its entry function called objToJSON. The lldb syntax would look as follows:

```
breakpoint set --name objToJSON
```

Similarly for gdb:

```
b break objToJSON
```

**Note:** You may get a warning that this breakpoint cannot be resolved in lldb. gdb may give a similar warning and prompt you to make the breakpoint on a future library load, which you should say yes to. This should only happen on the very first invocation as the module you wish to debug has not yet been loaded into memory.

Now go ahead and execute your script:

```
r run <the_script>.py
```

Code execution will halt at the breakpoint defined or at the occurrence of any segfault. LLDB’s GDB to LLDB command map provides a listing of debugger command that you can execute using either debugger.

Another option to execute the entire test suite under lldb would be to run the following:

```
lldb -- python -m pytest
```

Or for gdb:

```
gdb --args python -m pytest
```

Once the process launches, simply type `run` and the test suite will begin, stopping at any segmentation fault that may occur.
4.9.2 Checking memory leaks with valgrind

You can use Valgrind to check for and log memory leaks in extensions. For instance, to check for a memory leak in a test from the suite you can run:

```
PYTHONMALLOC=malloc valgrind --leak-check=yes --track-origins=yes --log-file=valgrind-log.txt python -m pytest <path_to_a_test>
```

Note that code execution under valgrind will take much longer than usual. While you can run valgrind against extensions compiled with any optimization level, it is suggested to have optimizations turned off from compiled extensions to reduce the amount of false positives. The `--with-debugging-symbols` flag passed during package setup will do this for you automatically.

**Note:** For best results, you should run use a Python installation configured with Valgrind support (`--with-valgrind`)

4.10 Extending pandas

While pandas provides a rich set of methods, containers, and data types, your needs may not be fully satisfied. pandas offers a few options for extending pandas.

4.10.1 Registering custom accessors

Libraries can use the decorators `pandas.api.extensions.register_dataframe_accessor()`, `pandas.api.extensions.register_series_accessor()`, and `pandas.api.extensions.register_index_accessor()`, to add additional “namespaces” to pandas objects. All of these follow a similar convention: you decorate a class, providing the name of attribute to add. The class’s `__init__` method gets the object being decorated. For example:

```python
@pd.api.extensions.register_dataframe_accessor("geo")
class GeoAccessor:
    def __init__(self, pandas_obj):
        self._validate(pandas_obj)
        self._obj = pandas_obj

    @staticmethod
    def _validate(obj):
        # verify there is a column latitude and a column longitude
        if "latitude" not in obj.columns or "longitude" not in obj.columns:
            raise AttributeError("Must have 'latitude' and 'longitude'.")

    @property
    def center(self):
        # return the geographic center point of this DataFrame
        lat = self._obj.latitude
        lon = self._obj.longitude
        return (float(lon.mean()), float(lat.mean()))

    def plot(self):
        # plot this array's data on a map, e.g., using Cartopy
        pass
```

Now users can access your methods using the `geo` namespace:
This can be a convenient way to extend pandas objects without subclassing them. If you write a custom accessor, make a pull request adding it to our ecosystem page.

We highly recommend validating the data in your accessor’s `__init__`. In our GeoAccessor, we validate that the data contains the expected columns, raising an `AttributeError` when the validation fails. For a `Series` accessor, you should validate the `dtype` if the accessor applies only to certain dtypes.

### 4.10.2 Extension types

**Warning:** The `pandas.api.extensions.ExtensionDtype` and `pandas.api.extensions.ExtensionArray` APIs are new and experimental. They may change between versions without warning.

pandas defines an interface for implementing data types and arrays that extend NumPy’s type system. pandas itself uses the extension system for some types that aren’t built into NumPy (categorical, period, interval, datetime with timezone).

Libraries can define a custom array and data type. When pandas encounters these objects, they will be handled properly (i.e. not converted to an ndarray of objects). Many methods like `pandas.isna()` will dispatch to the extension type’s implementation.

If you’re building a library that implements the interface, please publicize it on ecosystem.extensions.

The interface consists of two classes.

**ExtensionDtype**

A `pandas.api.extensions.ExtensionDtype` is similar to a `numpy.dtype` object. It describes the data type. Implementors are responsible for a few unique items like the name.

One particularly important item is the `type` property. This should be the class that is the scalar type for your data. For example, if you were writing an extension array for IP Address data, this might be `ipaddress.IPv4Address`.

See the extension dtype source for interface definition.

`pandas.api.extension.ExtensionDtype` can be registered to pandas to allow creation via a string dtype name. This allows one to instantiate `Series` and `.astype()` with a registered string name, for example 'category' is a registered string accessor for the `CategoricalDtype`.

See the extension dtype dtypes for more on how to register dtypes.
**ExtensionArray**

This class provides all the array-like functionality. ExtensionArrays are limited to 1 dimension. An ExtensionArray is linked to an ExtensionDtype via the `dtype` attribute.

pandas makes no restrictions on how an extension array is created via its `__new__` or `__init__`, and puts no restrictions on how you store your data. We do require that your array be convertible to a NumPy array, even if this is relatively expensive (as it is for `Categorical`).

They may be backed by none, one, or many NumPy arrays. For example, `pandas.Categorical` is an extension array backed by two arrays, one for codes and one for categories. An array of IPv6 addresses may be backed by a NumPy structured array with two fields, one for the lower 64 bits and one for the upper 64 bits. Or they may be backed by some other storage type, like Python lists.

See the [extension array source](#) for the interface definition. The docstrings and comments contain guidance for properly implementing the interface.

**ExtensionArray operator support**

By default, there are no operators defined for the class `ExtensionArray`. There are two approaches for providing operator support for your ExtensionArray:

1. Define each of the operators on your `ExtensionArray` subclass.
2. Use an operator implementation from pandas that depends on operators that are already defined on the underlying elements (scalars) of the ExtensionArray.

**Note:** Regardless of the approach, you may want to set `__array_priority__` if you want your implementation to be called when involved in binary operations with NumPy arrays.

For the first approach, you define selected operators, e.g., `__add__`, `__le__`, etc. that you want your `ExtensionArray` subclass to support.

The second approach assumes that the underlying elements (i.e., scalar type) of the `ExtensionArray` have the individual operators already defined. In other words, if your `ExtensionArray` named `MyExtensionArray` is implemented so that each element is an instance of the class `MyExtensionElement`, then if the operators are defined for `MyExtensionElement`, the second approach will automatically define the operators for `MyExtensionArray`.

A mixin class, `ExtensionScalarOpsMixin` supports this second approach. If developing an `ExtensionArray` subclass, for example `MyExtensionArray`, can simply include `ExtensionScalarOpsMixin` as a parent class of `MyExtensionArray`, and then call the methods `__add_arithmetic_ops()` and/or `__add_comparison_ops()` to hook the operators into your `MyExtensionArray` class, as follows:

```python
from pandas.api.extensions import ExtensionArray, ExtensionScalarOpsMixin

class MyExtensionArray(ExtensionArray, ExtensionScalarOpsMixin):
    pass

MyExtensionArray.__add_arithmetic_ops()
MyExtensionArray.__add_comparison_ops()
```
Note: Since pandas automatically calls the underlying operator on each element one-by-one, this might not be as performant as implementing your own version of the associated operators directly on the ExtensionArray.

For arithmetic operations, this implementation will try to reconstruct a new ExtensionArray with the result of the element-wise operation. Whether or not that succeeds depends on whether the operation returns a result that’s valid for the ExtensionArray. If an ExtensionArray cannot be reconstructed, an ndarray containing the scalars returned instead.

For ease of implementation and consistency with operations between pandas and NumPy ndarrays, we recommend not handling Series and Indexes in your binary ops. Instead, you should detect these cases and return NotImplemented. When pandas encounters an operation like op(Series, ExtensionArray), pandas will

1. unbox the array from the Series(Series.array)
2. call result = op(values, ExtensionArray)
3. re-box the result in a Series

NumPy universal functions

Series implements __array_ufunc__. As part of the implementation, pandas unboxes the ExtensionArray from the Series, applies the ufunc, and re-boxes it if necessary.

If applicable, we highly recommend that you implement __array_ufunc__ in your extension array to avoid coercion to an ndarray. See the NumPy documentation for an example.

As part of your implementation, we require that you defer to pandas when a pandas container (Series, DataFrame, Index) is detected in inputs. If any of those is present, you should return NotImplemented. pandas will take care of unboxing the array from the container and re-calling the ufunc with the unwrapped input.

Testing extension arrays

We provide a test suite for ensuring that your extension arrays satisfy the expected behavior. To use the test suite, you must provide several pytest fixtures and inherit from the base test class. The required fixtures are found in https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/conftest.py.

To use a test, subclass it:

```python
from pandas.tests.extension import base

class TestConstructors(base.BaseConstructorsTests):
    pass
```

See https://github.com/pandas-dev/pandas/blob/master/pandas/tests/extension/base/__init__.py for a list of all the tests available.
Compatiblity with Apache Arrow

An ExtensionArray can support conversion to / from pyarrow arrays (and thus support for example serialization to the Parquet file format) by implementing two methods: ExtensionArray.__arrow_array__ and ExtensionDtype.__from_arrow__.

The ExtensionArray.__arrow_array__ ensures that pyarrow knows how to convert the specific extension array into a pyarrow.Array (also when included as a column in a pandas DataFrame):

```python
class MyExtensionArray(ExtensionArray):
    ...
    def __arrow_array__(self, type=None):
        # convert the underlying array values to a pyarrow Array
        import pyarrow
        return pyarrow.array(..., type=type)
```

The ExtensionDtype.__from_arrow__ method then controls the conversion back from pyarrow to a pandas ExtensionArray. This method receives a pyarrow Array or ChunkedArray as only argument and is expected to return the appropriate pandas ExtensionArray for this dtype and the passed values:

```python
class ExtensionDtype:
    ...
    def __from_arrow__(self, array: pyarrow.Array/ChunkedArray) -> ExtensionArray:
        ...
```

See more in the Arrow documentation.

Those methods have been implemented for the nullable integer and string extension dtypes included in pandas, and ensure roundtrip to pyarrow and the Parquet file format.

4.10.3 Subclassing pandas data structures

**Warning:** There are some easier alternatives before considering subclassing pandas data structures.

1. Extensible method chains with `pipe`
2. Use `composition`. See here.
3. Extending by `registering an accessor`
4. Extending by `extension type`

This section describes how to subclass pandas data structures to meet more specific needs. There are two points that need attention:

1. Override constructor properties.
2. Define original properties

**Note:** You can find a nice example in geopandas project.
Override constructor properties

Each data structure has several constructor properties for returning a new data structure as the result of an operation. By overriding these properties, you can retain subclasses through pandas data manipulations.

There are 3 possible constructor properties to be defined on a subclass:

- DataFrame/Series._constructor: Used when a manipulation result has the same dimension as the original.
- DataFrame._constructor_sliced: Used when a DataFrame (sub-)class manipulation result should be a Series (sub-)class.
- Series._constructor_expanddim: Used when a Series (sub-)class manipulation result should be a DataFrame (sub-)class, e.g. Series.to_frame().

Below example shows how to define SubclassedSeries and SubclassedDataFrame overriding constructor properties.

class SubclassedSeries(pd.Series):
    @property
    def _constructor(self):
        return SubclassedSeries

    @property
    def _constructor_expanddim(self):
        return SubclassedDataFrame

class SubclassedDataFrame(pd.DataFrame):
    @property
    def _constructor(self):
        return SubclassedDataFrame

    @property
    def _constructor_sliced(self):
        return SubclassedSeries

>>> s = SubclassedSeries([1, 2, 3])
>>> type(s)
<class '__main__.SubclassedSeries'>

>>> to_framed = s.to_frame()
>>> type(to_framed)
<class '__main__.SubclassedDataFrame'>

>>> df = SubclassedDataFrame(["A": [1, 2, 3], "B": [4, 5, 6], "C": [7, 8, 9]])
>>> df
  A  B  C
0 1  4  7
1 2  5  8
2 3  6  9

>>> type(df)
<class '__main__.SubclassedDataFrame'>

>>> sliced1 = df["A", "B"]
>>> sliced1
A  B
0 1 4
1 2 5
2 3 6

(continues on next page)
Define original properties

To let original data structures have additional properties, you should let pandas know what properties are added. pandas maps unknown properties to data names overriding __getattr___. Defining original properties can be done in one of 2 ways:

1. Define _internal_names and _internal_names_set for temporary properties which WILL NOT be passed to manipulation results.

2. Define _metadata for normal properties which will be passed to manipulation results.

Below is an example to define two original properties, “internal_cache” as a temporary property and “added_property” as a normal property

```python
class SubclassedDataFrame2(pd.DataFrame):
    # temporary properties
    _internal_names = pd.DataFrame._internal_names + ["internal_cache"]
    _internal_names_set = set(_internal_names)

    # normal properties
    _metadata = ["added_property"]

    @property
def __constructor__(self):
        return SubclassedDataFrame2
```

```python
>>> df = SubclassedDataFrame2({"A": [1, 2, 3], "B": [4, 5, 6], "C": [7, 8, 9]})
>>> df
  A  B  C
0 1  4  7
1 2  5  8
2 3  6  9

>>> df.internal_cache = "cached"
>>> df.added_property = "property"

>>> df.internal_cache
"cached"
```
```python
cached
>>> df.added_property
property

# properties defined in _internal_names is reset after manipulation
>>> df["A", "B"][].internal_cache
AttributeError: 'SubclassedDataFrame2' object has no attribute 'internal_cache'

# properties defined in _metadata are retained
>>> df["A", "B"][].added_property
property
```

### 4.10.4 Plotting backends

Starting in 0.25 pandas can be extended with third-party plotting backends. The main idea is letting users select a plotting backend different than the provided one based on Matplotlib. For example:

```python
>>> pd.set_option("plotting.backend", "backend.module")
>>> pd.Series([1, 2, 3]).plot()
```

This would be more or less equivalent to:

```python
>>> import backend.module
>>> backend.module.plot(pd.Series([1, 2, 3]))
```

The backend module can then use other visualization tools (Bokeh, Altair,...) to generate the plots.

Libraries implementing the plotting backend should use entry points to make their backend discoverable to pandas. The key is "pandas_plotting_backends". For example, pandas registers the default “matplotlib” backend as follows.

```python
# in setup.py
setup(  # noqa: F821
  ...,  
  entry_points={
    "pandas_plotting_backends": [
      "matplotlib = pandas:plotting._matplotlib",
    ],
  },
)
```

More information on how to implement a third-party plotting backend can be found at https://github.com/pandas-dev/pandas/blob/master/pandas/plotting/__init__.py#L1.
4.11 Developer

This section will focus on downstream applications of pandas.

4.11.1 Storing pandas DataFrame objects in Apache Parquet format

The Apache Parquet format provides key-value metadata at the file and column level, stored in the footer of the Parquet file:

```
5: optional list<KeyValue> key_value_metadata
```

where `KeyValue` is

```
struct KeyValue {
  1: required string key
  2: optional string value
}
```

So that a `pandas.DataFrame` can be faithfully reconstructed, we store a `pandas` metadata key in the `FileMetaData` with the value stored as:

```
{'index_columns': [<descr0>, <descr1>, ...],
 'column_indexes': [<ci0>, <ci1>, ..., <ciN>],
 'columns': [<c0>, <c1>, ...],
 'pandas_version': $VERSION,
 'creator': {
   'library': $LIBRARY,
   'version': $LIBRARY_VERSION
 }}
```

The “descriptor” values `<descr0>` in the 'index_columns' field are strings (referring to a column) or dictionaries with values as described below.

The `<c0>/<ci0>` and so forth are dictionaries containing the metadata for each column, including the index columns. This has JSON form:

```
{'name': column_name,
 'field_name': parquet_column_name,
 'pandas_type': pandas_type,
 'numpy_type': numpy_type,
 'metadata': metadata}
```

See below for the detailed specification for these.

Index metadata descriptors

`RangeIndex` can be stored as metadata only, not requiring serialization. The descriptor format for these as is follows:

```
index = pd.RangeIndex(0, 10, 2)
{
    "kind": "range",
    "name": index.name,
    "start": index.start,
    "stop": index.stop,
}
```

(continues on next page)
Other index types must be serialized as data columns along with the other DataFrame columns. The metadata for these is a string indicating the name of the field in the data columns, for example '__index_level_0__'.

If an index has a non-None name attribute, and there is no other column with a name matching that value, then the index.name value can be used as the descriptor. Otherwise (for unnamed indexes and ones with names colliding with other column names) a disambiguating name with pattern matching __index_level__\d+ should be used.

In cases of named indexes as data columns, name attribute is always stored in the column descriptors as above.

**Column metadata**

`pandas_type` is the logical type of the column, and is one of:

- Boolean: 'bool'
- Integers: 'int8', 'int16', 'int32', 'int64', 'uint8', 'uint16', 'uint32', 'uint64'
- Floats: 'float16', 'float32', 'float64'
- Date and Time Types: 'datetime', 'datetimetz', 'timedelta'
- String: 'unicode', 'bytes'
- Categorical: 'categorical'
- Other Python objects: 'object'

The `numpy_type` is the physical storage type of the column, which is the result of `str(dtype)` for the underlying NumPy array that holds the data. So for datetimetz this is `datetime64[ns]` and for categorical, it may be any of the supported integer categorical types.

The `metadata` field is `None` except for:

- datetimetz: `{timezone': zone, 'unit': 'ns'}, e.g. `{timezone', 'America/New_York', 'unit': 'ns'}. The 'unit' is optional, and if omitted it is assumed to be nanoseconds.
- categorical: `{num_categories': K, 'ordered': is_ordered, 'type': $TYPE}
  - Here 'type' is optional, and can be a nested pandas type specification here (but not categorical)
- unicode: {'encoding': encoding}
  - The encoding is optional, and if not present is UTF-8
- object: {'encoding': encoding}. Objects can be serialized and stored in BYTE_ARRAY Parquet columns. The encoding can be one of:
  - 'pickle'
  - 'bson'
  - 'json'
- timedelta: {'unit': 'ns'}. The 'unit' is optional, and if omitted it is assumed to be nanoseconds.

For types other than these, the 'metadata' key can be omitted. Implementations can assume `None` if the key is not present.

As an example of fully-formed metadata:
4.12 Policies

4.12.1 Version policy

Changed in version 1.0.0.

pandas uses a loose variant of semantic versioning (SemVer) to govern deprecations, API compatibility, and version numbering.

A pandas release number is made up of MAJOR.MINOR.PATCH.
API breaking changes should only occur in major releases. These changes will be documented, with clear guidance on what is changing, why it’s changing, and how to migrate existing code to the new behavior.

Whenever possible, a deprecation path will be provided rather than an outright breaking change.

pandas will introduce deprecations in minor releases. These deprecations will preserve the existing behavior while emitting a warning that provide guidance on:

- How to achieve similar behavior if an alternative is available
- The pandas version in which the deprecation will be enforced.

We will not introduce new deprecations in patch releases.

Deprecations will only be enforced in major releases. For example, if a behavior is deprecated in pandas 1.2.0, it will continue to work, with a warning, for all releases in the 1.x series. The behavior will change and the deprecation removed in the next major release (2.0.0).

Note: pandas will sometimes make behavior changing bug fixes, as part of minor or patch releases. Whether or not a change is a bug fix or an API-breaking change is a judgement call. We’ll do our best, and we invite you to participate in development discussion on the issue tracker or mailing list.

These policies do not apply to features marked as experimental in the documentation. pandas may change the behavior of experimental features at any time.

## 4.12.2 Python support

pandas will only drop support for specific Python versions (e.g. 3.6.x, 3.7.x) in pandas major or minor releases.

## 4.13 Roadmap

This page provides an overview of the major themes in pandas’ development. Each of these items requires a relatively large amount of effort to implement. These may be achieved more quickly with dedicated funding or interest from contributors.

An item being on the roadmap does not mean that it will necessarily happen, even with unlimited funding. During the implementation period we may discover issues preventing the adoption of the feature.

Additionally, an item not being on the roadmap does not exclude it from inclusion in pandas. The roadmap is intended for larger, fundamental changes to the project that are likely to take months or years of developer time. Smaller-scoped items will continue to be tracked on our issue tracker.

See Roadmap evolution for proposing changes to this document.

### 4.13.1 Extensibility

pandas Extension types allow for extending NumPy types with custom data types and array storage. pandas uses extension types internally, and provides an interface for 3rd-party libraries to define their own custom data types.

Many parts of pandas still unintentionally convert data to a NumPy array. These problems are especially pronounced for nested data.

We’d like to improve the handling of extension arrays throughout the library, making their behavior more consistent with the handling of NumPy arrays. We’ll do this by cleaning up pandas’ internals and adding new methods to the extension array interface.
4.13.2 String data type

Currently, pandas stores text data in an object-dtype NumPy array. The current implementation has two primary drawbacks: First, object-dtype is not specific to strings: any Python object can be stored in an object-dtype array, not just strings. Second: this is not efficient. The NumPy memory model isn’t especially well-suited to variable width text data.

To solve the first issue, we propose a new extension type for string data. This will initially be opt-in, with users explicitly requesting dtype="string". The array backing this string dtype may initially be the current implementation: an object-dtype NumPy array of Python strings.

To solve the second issue (performance), we’ll explore alternative in-memory array libraries (for example, Apache Arrow). As part of the work, we may need to implement certain operations expected by pandas users (for example the algorithm used in Series.str.upper). That work may be done outside of pandas.

4.13.3 Consistent missing value handling

Currently, pandas handles missing data differently for different data types. We use different types to indicate that a value is missing (np.nan for floating-point data, np.nan or None for object-dtype data – typically strings or booleans – with missing values, and pd.NaT for datetimelike data). Integer data cannot store missing data or are cast to float. In addition, pandas 1.0 introduced a new missing value sentinel, pd.NA, which is being used for the experimental nullable integer, boolean, and string data types.

These different missing values have different behaviors in user-facing operations. Specifically, we introduced different semantics for the nullable data types for certain operations (e.g. propagating in comparison operations instead of comparing as False).

Long term, we want to introduce consistent missing data handling for all data types. This includes consistent behavior in all operations (indexing, arithmetic operations, comparisons, etc.). There has been discussion of eventually making the new semantics the default.

This has been discussed at github #28095 (and linked issues), and described in more detail in this design doc.

4.13.4 Apache Arrow interoperability

Apache Arrow is a cross-language development platform for in-memory data. The Arrow logical types are closely aligned with typical pandas use cases.

We’d like to provide better-integrated support for Arrow memory and data types within pandas. This will let us take advantage of its I/O capabilities and provide for better interoperability with other languages and libraries using Arrow.

4.13.5 Block manager rewrite

We’d like to replace pandas current internal data structures (a collection of 1 or 2-D arrays) with a simpler collection of 1-D arrays.

pandas internal data model is quite complex. A DataFrame is made up of one or more 2-dimensional “blocks”, with one or more blocks per dtype. This collection of 2-D arrays is managed by the BlockManager.

The primary benefit of the BlockManager is improved performance on certain operations (construction from a 2D array, binary operations, reductions across the columns), especially for wide DataFrames. However, the BlockManager substantially increases the complexity and maintenance burden of pandas.

By replacing the BlockManager we hope to achieve

- Substantially simpler code
• Easier extensibility with new logical types
• Better user control over memory use and layout
• Improved micro-performance
• Option to provide a C / Cython API to pandas’ internals

See these design documents for more.

4.13.6 Decoupling of indexing and internals

The code for getting and setting values in pandas’ data structures needs refactoring. In particular, we must clearly separate code that converts keys (e.g., the argument to DataFrame.loc) to positions from code that uses these positions to get or set values. This is related to the proposed BlockManager rewrite. Currently, the BlockManager sometimes uses label-based, rather than position-based, indexing. We propose that it should only work with positional indexing, and the translation of keys to positions should be entirely done at a higher level.

Indexing is a complicated API with many subtleties. This refactor will require care and attention. More details are discussed at https://github.com/pandas-dev/pandas/wiki/(Tentative)-rules-for-restructuring-indexing-code

4.13.7 Numba-accelerated operations

Numba is a JIT compiler for Python code. We’d like to provide ways for users to apply their own Numba-jitted functions where pandas accepts user-defined functions (for example, Series.apply(), DataFrame.apply(), DataFrame.applymap(), and in groupby and window contexts). This will improve the performance of user-defined-functions in these operations by staying within compiled code.

4.13.8 Performance monitoring

pandas uses airspeed velocity to monitor for performance regressions. ASV itself is a fabulous tool, but requires some additional work to be integrated into an open source project’s workflow.

The asv-runner organization, currently made up of pandas maintainers, provides tools built on top of ASV. We have a physical machine for running a number of project’s benchmarks, and tools managing the benchmark runs and reporting on results.

We’d like to fund improvements and maintenance of these tools to

• Be more stable. Currently, they’re maintained on the nights and weekends when a maintainer has free time.
• Tune the system for benchmarks to improve stability, following https://pyperf.readthedocs.io/en/latest/system.html
• Build a GitHub bot to request ASV runs before a PR is merged. Currently, the benchmarks are only run nightly.
4.13.9 Roadmap evolution

pandas continues to evolve. The direction is primarily determined by community interest. Everyone is welcome to review existing items on the roadmap and to propose a new item.

Each item on the roadmap should be a short summary of a larger design proposal. The proposal should include

1. Short summary of the changes, which would be appropriate for inclusion in the roadmap if accepted.
2. Motivation for the changes.
3. An explanation of why the change is in scope for pandas.
4. Detailed design: Preferably with example-usage (even if not implemented yet) and API documentation
5. API Change: Any API changes that may result from the proposal.

That proposal may then be submitted as a GitHub issue, where the pandas maintainers can review and comment on the design. The pandas mailing list should be notified of the proposal.

When there’s agreement that an implementation would be welcome, the roadmap should be updated to include the summary and a link to the discussion issue.

4.13.10 Completed items

This section records now completed items from the pandas roadmap.

Documentation improvements

We improved the pandas documentation

- The pandas community worked with others to build the pydata-sphinx-theme, which is now used for https://pandas.pydata.org/docs/ (GH15556).
- Getting started contains a number of resources intended for new pandas users coming from a variety of backgrounds (GH26831).

4.14 Developer meetings

We hold regular developer meetings on the second Wednesday of each month at 18:00 UTC. These meetings and their minutes are open to the public. All are welcome to join.

4.14.1 Minutes

The minutes of past meetings are available in this Google Document.
4.14.2 Calendar

This calendar shows all the developer meetings.

You can subscribe to this calendar with the following links:

• iCal
• Google calendar

Additionally, we’ll sometimes have one-off meetings on specific topics. These will be published on the same calendar.
This is the list of changes to pandas between each release. For full details, see the commit logs. For install and upgrade instructions, see Installation.

5.1 Version 1.3

5.1.1 What's new in 1.3.1 (July 25, 2021)

These are the changes in pandas 1.3.1. See Release notes for a full changelog including other versions of pandas.

Fixed regressions

- Pandas could not be built on PyPy (GH42355)
- DataFrame constructed with an older version of pandas could not be unpickled (GH42345)
- Performance regression in constructing a DataFrame from a dictionary of dictionaries (GH42248)
- Fixed regression in DataFrame.agg() dropping values when the DataFrame had an Extension Array dtype, a duplicate index, and axis=1 (GH42380)
- Fixed regression in DataFrame.astype() changing the order of noncontiguous data (GH42396)
- Performance regression in DataFrame in reduction operations requiring casting such as DataFrame.mean() on integer data (GH38592)
- Performance regression in DataFrame.to_dict() and Series.to_dict() when orient argument one of “records”, “dict”, or “split” (GH42352)
- Fixed regression in indexing with a list subclass incorrectly raising TypeError (GH42433, GH42461)
- Fixed regression in DataFrame.isin() and Series.isin() raising TypeError with nullable data containing at least one missing value (GH42405)
- Regression in concat() between objects with bool dtype and integer dtype casting to object instead of to integer (GH42092)
- Bug in Series constructor not accepting a dask.Array (GH38645)
- Fixed regression for SettingWithCopyWarning displaying incorrect stacklevel (GH42570)
- Fixed regression for merge_asof() raising KeyError when one of the by columns is in the index (GH34488)
- Fixed regression in to_datetime() returning pd.NaT for inputs that produce duplicated values, when cache=True (GH42259)
• Fixed regression in `SeriesGroupBy.value_counts()` that resulted in an `IndexError` when called on a Series with one row (GH42618)

Bug fixes

• Fixed bug in `DataFrame.transpose()` dropping values when the DataFrame had an Extension Array dtype and a duplicate index (GH42380)
• Fixed bug in `DataFrame.to_xml()` raising `KeyError` when called with `index=False` and an offset index (GH42458)
• Fixed bug in `Styler.set_sticky()` not handling index names correctly for single index columns case (GH42537)
• Fixed bug in `DataFrame.copy()` failing to consolidate blocks in the result (GH42579)

Contributors

A total of 17 people contributed patches to this release. People with a “+” by their names contributed a patch for the first time.

5.1.2 What’s new in 1.3.0 (July 2, 2021)

These are the changes in pandas 1.3.0. See Release notes for a full changelog including other versions of pandas.

| Warning: | When reading new Excel 2007+ (.xlsx) files, the default argument engine=None to read_excel() will now result in using the openpyxl engine in all cases when the option io.excel.xlsx.reader is set to "auto". Previously, some cases would use the xld engine instead. See What’s new 1.2.0 for background on this change. |

Enhancements

Custom HTTP(s) headers when reading csv or json files

When reading from a remote URL that is not handled by fsspec (e.g. HTTP and HTTPS) the dictionary passed to storage_options will be used to create the headers included in the request. This can be used to control the User-Agent header or send other custom headers (GH36688). For example:

```
In [1]: headers = {"User-Agent": "pandas"}

In [2]: df = pd.read_csv(
      ...: "https://download.bls.gov/pub/time.series/cu/cu.item",
      ...: sep="\t",
      ...: storage_options=headers
      ...: )
```

Read and write XML documents

We added I/O support to read and render shallow versions of XML documents with read_xml() and DataFrame.to_xml(). Using lxml as parser, both XPath 1.0 and XSLT 1.0 are available. (GH27554)

```
In [1]: xml = """<?xml version='1.0' encoding='utf-8'?>
   ...: <data>
   ...:   <row>
   ...:     <shape>square</shape>
   ...:     <degrees>360</degrees>
   ...:     <sides>4.0</sides>
   ...:   </row>
   ...:   <row>
   ...:     <shape>circle</shape>
   ...:     <degrees>360</degrees>
   ...:     <sides/>
   ...:   </row>
   ...:   <row>
   ...:     <shape>triangle</shape>
   ...:     <degrees>180</degrees>
   ...:     <sides>3.0</sides>
   ...:   </row>
   ...: </data>"

In [2]: df = pd.read_xml(xml)
In [3]: df
```

(continues on next page)
Out[3]:

<table>
<thead>
<tr>
<th>shape</th>
<th>degrees</th>
<th>sides</th>
</tr>
</thead>
<tbody>
<tr>
<td>square</td>
<td>360</td>
<td>4.0</td>
</tr>
<tr>
<td>circle</td>
<td>360</td>
<td>NaN</td>
</tr>
<tr>
<td>triangle</td>
<td>180</td>
<td>3.0</td>
</tr>
</tbody>
</table>

In [4]: df.to_xml()

Out[4]:

```xml
<?xml version='1.0' encoding='utf-8'?>
<data>
  <row>
    <index>0</index>
    <shape>square</shape>
    <degrees>360</degrees>
    <sides>4.0</sides>
  </row>
  <row>
    <index>1</index>
    <shape>circle</shape>
    <degrees>360</degrees>
    <sides/>
  </row>
  <row>
    <index>2</index>
    <shape>triangle</shape>
    <degrees>180</degrees>
    <sides>3.0</sides>
  </row>
</data>
```

**Styler enhancements**

We provided some focused development on `Styler`. See also the `Styler documentation` which has been revised and improved (GH39720, GH39317, GH40493).

- The method `Styler.set_table_styles()` can now accept more natural CSS language for arguments, such as `color:red;` instead of `['color', 'red']` (GH39563)
- The methods `Styler.highlight_null()`, `Styler.highlight_min()`, and `Styler.highlight_max()` now allow custom CSS highlighting instead of the default background coloring (GH40242)
- `Styler.apply()` now accepts functions that return an `ndarray` when `axis=None`, making it now consistent with the `axis=0` and `axis=1` behavior (GH39359)
- When incorrectly formatted CSS is given via `Styler.apply()` or `Styler.applymap()`, an error is now raised upon rendering (GH39660)
- `Styler.format()` now accepts the keyword argument `escape` for optional HTML and LaTeX escaping (GH40388, GH41619)
- `Styler.background_gradient()` has gained the argument `gmap` to supply a specific gradient map for shading (GH22727)
- `Styler.clear()` now clears `Styler.hidden_index` and `Styler.hidden_columns` as well (GH40484)
• Added the method `Styler.highlight_between()` (GH39821)
• Added the method `Styler.highlight_quantile()` (GH40926)
• Added the method `Styler.text_gradient()` (GH41098)
• Added the method `Styler.set_tooltips()` to allow hover tooltips; this can be used enhance interactive displays (GH21266, GH40284)
• Added the parameter `precision` to the method `Styler.format()` to control the display of floating point numbers (GH40134)
• `Styler` rendered HTML output now follows the w3 HTML Style Guide (GH39626)
• Many features of the `Styler` class are now either partially or fully usable on a DataFrame with a non-unique indexes or columns (GH41143)
• One has greater control of the display through separate sparsification of the index or columns using the new `styler options`, which are also usable via `option_context()` (GH41142)
• Added the option `styler.render.max_elements` to avoid browser overload when styling large DataFrames (GH40712)
• Added the method `Styler.to_latex()` (GH21673, GH42320), which also allows some limited CSS conversion (GH40731)
• Added the method `Styler.to_html()` (GH13379)
• Added the method `Styler.set_sticky()` to make index and column headers permanently visible in scrolling HTML frames (GH29072)

**DataFrame constructor honors copy=False with dict**

When passing a dictionary to `DataFrame` with `copy=False`, a copy will no longer be made (GH32960).

```python
In [3]: arr = np.array([1, 2, 3])

In [4]: df = pd.DataFrame({"A": arr, "B": arr.copy()}, copy=False)

In [5]: df
Out[5]:
   A  B
  0  1  1
  1  2  2
  2  3  3

df["A"] remains a view on arr:

In [6]: arr[0] = 0

In [7]: assert df.iloc[0, 0] == 0
```

The default behavior when not passing `copy` will remain unchanged, i.e. a copy will be made.
PyArrow backed string data type

We’ve enhanced the StringDtype, an extension type dedicated to string data. (GH39908)

It is now possible to specify a storage keyword option to StringDtype. Use pandas options or specify the dtypes using dtype='string[pyarrow]' to allow the StringArray to be backed by a PyArrow array instead of a NumPy array of Python objects.

The PyArrow backed StringArray requires pyarrow 1.0.0 or greater to be installed.

Warning: string[pyarrow] is currently considered experimental. The implementation and parts of the API may change without warning.

```python
In [8]: pd.Series(['abc', None, 'def'], dtype=pd.StringDtype(storage="pyarrow"))
Out[8]:
   0   abc
   1   <NA>
   2   def
dtype: string
```

You can use the alias "string[pyarrow]" as well.

```python
In [9]: s = pd.Series(['abc', None, 'def'], dtype="string[pyarrow]"

In [10]: s
Out[10]:
   0   abc
   1   <NA>
   2   def
dtype: string
```

You can also create a PyArrow backed string array using pandas options.

```python
In [11]: with pd.option_context("string_storage", "pyarrow"):
   ....:     s = pd.Series(['abc', None, 'def'], dtype="string")
   ....:

In [12]: s
Out[12]:
   0   abc
   1   <NA>
   2   def
dtype: string
```

The usual string accessor methods work. Where appropriate, the return type of the Series or columns of a DataFrame will also have string dtype.

```python
In [13]: s.str.upper()
Out[13]:
   0   ABC
   1   <NA>
   2   DEF
dtype: string

In [14]: s.str.split('b', expand=True).dtypes
```

(continues on next page)
String accessor methods returning integers will return a value with `Int64Dtype`.

```python
In [15]: s.str.count("a")
Out[15]:
0  1
1 <NA>
2  0
dtype: Int64
```

### Centered datetime-like rolling windows

When performing rolling calculations on DataFrame and Series objects with a datetime-like index, a centered datetime-like window can now be used (GH38780). For example:

```python
In [16]: df = pd.DataFrame(
        ...:     {"A": [0, 1, 2, 3, 4]}, index=pd.date_range("2020", periods=5, freq="1D")
        ...: )
        ...

In [17]: df
Out[17]:
   A
2020-01-01  0
2020-01-02  1
2020-01-03  2
2020-01-04  3
2020-01-05  4

In [18]: df.rolling("2D", center=True).mean()
Out[18]:
   A
2020-01-01  0.5
2020-01-02  1.5
2020-01-03  2.5
2020-01-04  3.5
2020-01-05  4.0
```

### Other enhancements

- `DataFrame.rolling()`, `Series.rolling()`, `DataFrame.expanding()`, and `Series.expanding()` now support a method argument with a 'table' option that performs the windowing operation over an entire `DataFrame`. See Window Overview for performance and functional benefits (GH15095, GH38995)
- ExponentialMovingWindow now support a online method that can perform mean calculations in an online fashion. See Window Overview (GH41673)
- Added `MultiIndex.dtypes()` (GH37062)
• Added `end` and `end_day` options for the `origin` argument in `DataFrame.resample()` (GH37804)
• Improved error message when `usecols` and `names` do not match for `read_csv()` and `engine="c"` (GH29042)
• Improved consistency of error messages when passing an invalid `win_type` argument in `Window methods` (GH15969)
• `read_sql_query()` now accepts a `dtype` argument to cast the columnar data from the SQL database based on user input (GH10285)
• `read_csv()` now raising `ParserWarning` if length of header or given names does not match length of data when `usecols` is not specified (GH21768)
• Improved integer type mapping from pandas to SQLAlchemy when using `DataFrame.to_sql()` (GH35076)
• `to_numeric()` now supports downcasting of nullable `ExtensionDtype` objects (GH33013)
• Added support for dict-like names in `MultiIndex.set_names` and `MultiIndex.rename` (GH20421)
• `read_excel()` can now auto-detect .xlsb files and older .xls files (GH35416, GH41225)
• `ExcelWriter` now accepts an `if_sheet_exists` parameter to control the behavior of append mode when writing to existing sheets (GH40230)
• `Rolling.sum()`, `Expanding.sum()`, `Rolling.mean()`, `Expanding.mean()`, `ExponentialMovingWindow.mean()`, `Rolling.median()`, `Expanding.median()`, `Rolling.max()`, `Expanding.max()`, `Rolling.min()`, and `Expanding.min()` now support Numba execution with the `engine` keyword (GH38895, GH41267)
• `DataFrame.apply()` can now accept NumPy unary operators as strings, e.g. `df.apply("sqrt")`, which was already the case for `Series.apply()` (GH39116)
• `DataFrame.apply()` can now accept non-callable DataFrame properties as strings, e.g. `df.apply("size")`, which was already the case for `Series.apply()` (GH39116)
• `DataFrame.applymap()` can now accept kwargs to pass on to the user-provided `func` (GH39987)
• Passing a `DataFrame` indexer to `iloc` is now disallowed for `Series._getitem__()` and `DataFrame._getitem__()` (GH39004)
• `Series.apply()` can now accept list-like or dictionary-like arguments that aren’t lists or dictionaries, e.g. `ser.apply(np.array(["sum", "mean"]))`, which was already the case for `DataFrame.apply()` (GH39140)
• `DataFrame.plot.scatter()` can now accept a categorical column for the argument `c` (GH12380, GH31357)
• `Series.loc()` now raises a helpful error message when the Series has a `MultiIndex` and the indexer has too many dimensions (GH35349)
• `read_stata()` now supports reading data from compressed files (GH26599)
• Added support for parsing ISO 8601-like timestamps with negative signs to `Timedelta` (GH37172)
• Added support for unary operators in `FloatingArray` (GH38749)
• `RangeIndex` can now be constructed by passing a `range` object directly e.g. `pd.RangeIndex(range(3))` (GH12067)
• `Series.round()` and `DataFrame.round()` now work with nullable integer and floating dtypes (GH38844)
• `read_csv()` and `read_json()` expose the argument `encoding_errors` to control how encoding errors are handled (GH39450)

• `GroupBy.any()` and `GroupBy.all()` use Kleene logic with nullable data types (GH37506)

• `GroupBy.any()` and `GroupBy.all()` return a `BooleanDtype` for columns with nullable data types (GH33449)

• `GroupBy.any()` and `GroupBy.all()` raising with `object` data containing `pd.NA` even when `skipna=True` (GH37501)

• `GroupBy.rank()` now supports object-dtype data (GH38278)

• Constructing a `DataFrame` or `Series` with the `data` argument being a Python iterable that is not a NumPy `ndarray` consisting of NumPy scalars will now result in a dtype with a precision the maximum of the NumPy scalars; this was already the case when `data` is a NumPy `ndarray` (GH40908)

• Add keyword `sort` to `pivot_table()` to allow non-sorting of the result (GH39143)

• Add keyword `dropna` to `DataFrame.value_counts()` to allow counting rows that include `NA` values (GH41325)

• `Series.replace()` will now cast results to `PeriodDtype` where possible instead of `object` dtype (GH41526)

• Improved error message in `corr` and `cov` methods on `Rolling`, `Expanding`, and `ExponentialMovingWindow` when other is not a `DataFrame` or `Series` (GH41741)

• `Series.between()` can now accept `left` or `right` as arguments to inclusive to include only the left or right boundary (GH40245)

• `DataFrame.explode()` now supports exploding multiple columns. Its `column` argument now also accepts a list of str or tuples for exploding on multiple columns at the same time (GH39240)

• `DataFrame.sample()` now accepts the `ignore_index` argument to reset the index after sampling, similar to `DataFrame.drop_duplicates()` and `DataFrame.sort_values()` (GH38581)

Notable bug fixes

These are bug fixes that might have notable behavior changes.

Categorical.unique now always maintains same dtype as original

Previously, when calling `Categorical.unique()` with categorical data, unused categories in the new array would be removed, making the dtype of the new array different than the original (GH18291)

As an example of this, given:

```python
In [19]: dtype = pd.CategoricalDtype(['bad', 'neutral', 'good'], ordered=True)
In [20]: cat = pd.Categorical(['good', 'good', 'bad', 'bad'], dtype=dtype)
In [21]: original = pd.Series(cat)
In [22]: unique = original.unique()
```

Previous behavior:
In [1]: unique
['good', 'bad']
Categories (2, object): ['bad' < 'good']
In [2]: original.dtype == unique.dtype
False

New behavior:

In [23]: unique
Out[23]:
['good', 'bad']
Categories (3, object): ['bad' < 'neutral' < 'good']
In [24]: original.dtype == unique.dtype
Out[24]: True

Preserve dtypes in DataFrame.combine_first()

DataFrame.combine_first() will now preserve dtypes (GH7509)

In [25]: df1 = pd.DataFrame({"A": [1, 2, 3], "B": [1, 2, 3]}, index=[0, 1, 2])

In [26]: df1
Out[26]:
   A  B
0  1  1
1  2  2
2  3  3

In [27]: df2 = pd.DataFrame({"B": [4, 5, 6], "C": [1, 2, 3]}, index=[2, 3, 4])

In [28]: df2
Out[28]:
   B  C
2  4  1
3  5  2
4  6  3

In [29]: combined = df1.combine_first(df2)

Previous behavior:

In [1]: combined.dtypes
Out[2]:
A    float64
B    float64
C    float64
dtype: object

New behavior:

In [30]: combined.dtypes
Out[30]:
A    float64
B    int64
(continues on next page)
Groupby methods agg and transform no longer changes return dtype for callables
